Background: BAT1308 is a fully humanized and high-affinity anti-PD-1 IgG4κ antibody. Previous phase 1 study demonstrated BAT1308 had a promising efficacy in patients with advanced cervical cancer. Here we present the primary safety and efficacy results in phase 2 study for BAT1308 combined with platinum-based chemotherapy ± bevacizumab as first-line therapy for PD-L1–positive persistent, recurrent, or metastatic cervical cancer. **Methods:** In this multicenter, single-arm, open-label, phase 2 study, eligible patients were $\geq$18 to $\leq$75 years of age with PD-L1 CPS $\geq$1, FIGO Stage IVB cervical cancer, who did not receive prior systemic anti-tumor therapy for persistent, recurrent or metastatic cervical cancer and not amenable to curative treatment. Patients received BAT1308 (300 mg Q3W for up to 24 months) plus platinum-based chemotherapy (paclitaxel 175 mg/m^2 + cisplatin 50 mg/ m^2 or carboplatin AUC 5) and, per investigator discretion, bevacizumab (15 mg/kg). The primary endpoint was safety. The major secondary endpoint was objective response rate assessed by investigator according to RECIST 1.1. **Results:** As of January 7, 2025, a total of 29 patients were enrolled, with a median age of 53 years (range 32-69), 20 (69.0%) patients had ECOG performance status of 1, 15 (50.7%) patients with PD-L1 CPS $\geq$ 10, 24 (82.8%) patients had squamous-cell carcinoma, 17 (58.6%) patients received previous neoadjuvant or adjuvant chemotherapy or chemoradiotherapy with a paclitaxel + platinum regimen, 7 (24.1%) patients had previous untreated metastatic disease at trial entry. Bevacizumab was used by 23 (79.3%) patients in this phase II study. All 29 subjects received combination therapy. 27 subjects completed at least one efficacy assessment. The ORR was 74.1%, with a confirmed ORR of 70.4%. The complete response rate was 11.1%, and the disease control rate was 100%. Currently, 16 subjects remain on treatment. Among those who discontinued the study, 8 withdrew informed consent, 4 experienced disease progression, and 1 died. The 6-month, 9-month, and 12 -month PFS rates were 83.4%, 78.8%, and 78.8% respectively. The median PFS has not yet been reached. The most common adverse events were anemia (82.8%), white blood cell decreased (51.7%), alopecia (51.7%), thrombocytopenia (48.3%), and neutropenia (44.8%). Grade 3 and above adverse events occurred in 72.4% of 29 patients, and $\geq$ Grade 3 irAEs observed in 3 (10.3%) patients. Serious adverse events occurred in 44.8% of the patients. **Conclusions:** BAT1308 combined with platinum-based chemotherapy ± Bevacizumab as first-line therapy showed durable anti-tumor activity and manageable safety profile for PD-L1-positive (CPS $\geq$ 1) persistent, recurrent or metastatic cervical cancer. These data are consistent with the earlier results and provide support for further studies. Clinical trial information: NCT06123884. Research Sponsor: Bio-Thera Solutions, Ltd.

Neoadjuvant serplulimab with concurrent chemoradiotherapy in resectable esophagogastric junction adenocarcinoma: Phase 2 updated results. First Author: Yuping Ge, Peking Union Medical College Hospital, Beijing, Beijing, China

Background: This study evaluated the efficacy and safety of neoadjuvant Serplulimab combined with concurrent chemoradiotherapy for locally advanced resectable esophagogastric junction (EGJ) adenocarcinoma. **Methods:** Eligible patients with resectable EGJ (cT3-4 or N+M0) adenocarcinoma received neoadjuvant Serplulimab (300 mg) plus SOX (oxaliplatin 130 mg/m^2; TS1 40-60 mg) for the first cycle, followed by Serplulimab with concurrent chemoradiotherapy (oxaliplatin 100 mg/m^2, TS1 40-60 mg; radiotherapy dose 45 Gy/ 25 fractions) during the second and third cycles. Surgery was performed 6-8 weeks after chemoradiotherapy. Tissue and blood samples were collected for genetic analysis. Primary endpoints included pathological complete response (pCR) and major pathological response (MPR). **Results:** From March 2023 to November 2024, 24 patients were enrolled and 19 patients underwent radical resection. The R0 rate was 100%. pCR rate was 26.3%, MPR rate was 36.8%. T downstaging rate 78.9%, ypN0 89.5%. The median DFS was not reached. Microsatellite stable status was 100%. PD-L1 CPS expression: $<$ 1 (5.3%), 1-5 (42%), $>$ 5 (52.6%), $>$ 10 (31.6%). PD-L1 expression was associated with pathological response, with MPR rates of 57.1% for CPS $\geq$5 and 14.3% for CPS $<$ 5. Minimal residual disease positivity (MDR+) before enrollment was 68.7%, and 6 MRD+ patients converted to MRD- after neoadjuvant therapy. Grade $\geq$3 adverse events occurred in 33.3% of patients, with manageable treatment-related adverse events. **Conclusions:** Neoadjuvant Serplulimab with concurrent chemoradiotherapy showed promising efficacy for locally advanced resectable EGJ adenocarcinoma. Improved R0 and ypN0 rate may change the surgical procedure in the future. Follow-up will assess correlations between biomarkers and outcomes. Clinical trial information: NCT05918419. Niraparib plus PD-1 inhibitor for patients previously treated with immune checkpoint inhibitor for solid tumors with homologous recombination repair gene mutation (IMAGENE): A phase II basket study. First Author: Taigo Kato, Department of Urology, Osaka University Graduate School of Medicine, Suita, Japan

Background: Prior clinical trials have established the effectiveness of poly (ADP-ribose) polymerase (PARP) inhibitor (PARPi) or immune checkpoint inhibitor (ICI) monotherapy in patients with cancer characterized by mutations in homologous recombination repair (HRR) genes. This trial aims to evaluate the efficacy and safety of PARPi and PD-1 inhibitor in patients with HRR gene-mutated solid tumors previously treated with ICIs. **Methods:** IMAGENE is an open-label phase II basket study evaluating the efficacy and safety of niraparib and PD-1 inhibitor in patients with HRR gene-mutated cancers that have shown resistance to one or more standard therapy including ICIs. HRR mutation status was evaluated by circulating tumor DNA (ctDNA) or tumor tissue DNA. The primary endpoint was confirmed objective response rate (cORR) per investigator assessment. Patients were treated on a 21-day cycle with niraparib (200 mg orally daily) and nivolumab/pembrolizumab (240 mg/body intravenously every 2 weeks or 3 mg/kg every 3 weeks, respectively). **Results:** Of 47 enrolled patients, 22 were enrolled based on HRR gene alteration detected in ctDNA. The most common tumor type was gastric cancer (36.2%), followed by bladder cancer (BC, 25.5%), and renal cell carcinoma (RCC, 12.8%). As of data cutoff (September 30, 2024), the median duration of follow-up was 31.7 weeks. The median number of prior treatment line was 6.5 (1 to 20). In total, the cORR was 4.4% (90% CI, 0.8 to 13.3), with a disease control rate (DCR) of 55.6% (90% CI, 42.3 to 68.3). Notable DCRs were observed in patients with RCC (83.3%) and BC (80.0%). The median duration of response and progression-free survival (PFS) were 35.0 weeks (90% CI, 20.0 to 50.0) and 11.6 weeks (90% CI, 7.0 to 13.6), respectively. At data cutoff, 28 patients (62.2%) had died, with 12-month overall survival (OS) rate of 41.7% (90% CI, 29.1 to 53.8). Interestingly, *BRCA1/2*-mutated patients had significantly shorter OS compared to those with other HRR gene mutations (p = 0.0096). The three most common treatment-emergent adverse events (TEAEs) were nausea (31.1%), vomiting (31.1%), and anaemia (26.7%). Grade $\geq$3 TEAEs were reported in 18 patients (40.0%), with the most common being anaemia (17.8%). TEAEs led to treatment regimen discontinuation in one patient, and there were no deaths due to TEAEs. **Conclusions:** Niraparib combined with PD-1 inhibitor showed modest activity even in heavily pretreated patients with HRR gene-mutated cancers who progressed on ICI therapy. Furthermore, patients with specific cancer type had promising benefit from this combination therapy, warranting further investigation in specific populations. Clinical trial information: jRCT2051210120. Research Sponsor: The Japan Agency for Medical Research and Development; 21ck0106656h0001; Takeda Pharmaceutical Co., Ltd.

Stereotactic radiotherapy plus immunotherapy and influence on prognosis in driver-gene–negative non-small cell lung cancer patients with brain oligometastases. First Author: Xiaomei Gong, Tongji University Affiliated Shanghai Pulmonary Hospital, Shanghai, China

Background: This study seeks to elucidate the therapeutic benefits of integrating stereotactic radiotherapy (SRT) with immunotherapy for treating brain oligo-metastases (BMs) in patients with non-small cell lung cancer (NSCLC). **Methods:** In this retrospective real-world study, patients with driver-gene-negative NSCLC and 1-3 BMs were enrolled to evaluate the therapeutic benefits of combining SRT with immune checkpoint inhibitors (ICIs) and chemotherapy. The primary endpoint was overall survival (OS). Secondary endpoints included intracranial progression-free survival (iPFS), progression-free survival (PFS), and the response of intracranial lesions. **Results:** Based on chemotherapy (CT), 65 patients underwent SRT+ICIs therapy, 47 patients underwent SRT, and 44 patients underwent ICIs. For patients with with $>$ 500 mm^3 BMs, SRT + ICIs + CT significantly improved the OS (22.1 vs. 13.5 vs. 18.5 months, p = 0.012), iPFS (17.5 vs. 7.8 vs. 11.8 months, p $<$ 0.001), PFS (11.3 vs. 7.6 vs. 5.3 months, p = 0.019), and iORR (56.3% vs. 20.3% vs 28.9%, p = 0.001) compared to SRT+CT or ICIs + CT therapy. In the sub-group of patients of symptomatic BMs, SRT + ICIs + CT significantly improved the OS (24.7 vs. 14.7 vs. 17.5 months, p = 0.012), iPFS (13.7 vs. 9.8 vs. 11.8 months, p = 0.046), and iORR (34.5% vs. 13.8% vs 23.7%, p = 0.027) compared to SRT + CT or ICIs + CT therapy as well. Concurrent SRT with ICIs (time interval $<$ 2 weeks) significantly improved the OS (28.2 vs. 15.4 months, p = 0.01), iPFS (25.8 vs. 12.1 months, p = 0.014), and iORR (63.2% vs. 37.0%, p = 0.017) when compared to sequential SRT with ICIs. Combined therapy did not increase the incidence of any grade of central nervous system and immune-related adverse events. **Conclusions:** Based on chemotherapy, the combination of concurrent SRT and ICIs improve the prognosis of driver-gene-negative NSCLC with BMs without increasing the occurrence of adverse events. Furthermore, it demonstrates increased effectiveness for treating larger and symptomatic intracranial lesions, specifically those $>$ 500 mm^3 in volume. Research Sponsor: None.

A randomized controlled study of tislelizumab combined with concurrent chemoradiotherapy in the treatment of locally advanced cervical cancer and the predictive value of T lymphocyte subsets for efficacy. First Author: Fang Wu, Department of Radiation Oncology, the First Affiliated Hospital of Guangxi Medical University, Nanning, Guangxi, China

Background: Concurrent chemoradiotherapy (CCRT) has been the standard of care for locally advanced cervical cancer (LACC) for over 20 years. However, 30-40% of treated patients have recurrence or progression within 5 years. **Methods:** A total of 53 patients with LACC who were treated in the First Affiliated Hospital of Guangxi Medical University from May 2023 to November 2024 were prospectively collected and randomly divided into the CCRT group (N = 26) and the CCRT+T group (N = 27). The treatment plan was as follows: 200 mg of tislelizumab was intravenously infused on the first day of radiotherapy, once every 3 weeks, for 1 year or until disease progression or intolerable toxicity, whichever occurred first. Chemotherapy involved single-agent cisplatin at a dose of 40 mg/m^2. External irradiation used 6MV-X-ray intensity-modulated radiotherapy with a dose of 45-50Gy/25f. Simultaneously, peripheral blood T lymphocyte subsets were detected in the enrolled patients before and at the end of radiotherapy. The primary endpoint of the study was the objective response rate, and secondary endpoints included toxicity, PFS and OS. **Results:** Follow-up was completed by January 2025, with a median follow-up time of 13.7 months (5.2-20.5 months) in the CCRT group and 11.2 months (5.9-20.6 months) in the CCRT+T group. The CCRT+T group had higher complete response (CR) and objective response rates (ORR) compared to the CCRT group, with CR rates of 44.4% versus 19.2% (p = 0.035) and ORR rates of 100% versus 84.6% (p = 0.046). The patients with CR were subjected to logistic regression analysis. The results of univariate and multivariate analysis showed that CD4+T cell percentage (p = 0.034) and tislelizumab use (p = 0.038) were significantly associated with CR. However, no statistical difference was observed in the OS (p = 0.414) and PFS (p = 0.716) between the two groups, as shown by the Kaplan-Meier survival curves. After treatment, the CCRT+T group had increased levels of total T cell percentage, CD4+T cell percentage, CD4/CD8, double positive T lymphocyte subset percentage, absolute T lymphocyte count, absolute CD4+T lymphocyte count, and B lymphocyte (CD19) compared to the CCRT group. Notably, the double positive T lymphocyte subset percent (p = 0.025) and absolute CD4+T lymphocyte count (p = 0.047) showed significant increases. There was no significant difference in the incidence of acute adverse reactions between the two groups (P $>$ 0.05). **Conclusions:** CCRT+T demonstrated superior short-term efficacy in treating LACC compared to CCRT, although long-term efficacy necessitates further follow-up observation. The combination of tislelizumab and CCRT in the treatment of LACC can improve the levels of T cell subsets, with tolerable acute toxic and good safety. CD4+T cell percentage and tislelizumab use may be associated with CR. Research Sponsor: None.

PD-1 inhibitors combined with radiotherapy and GM-CSF, sequentially followed by IL-2 regimen in advanced refractory solid tumors: A prospective, multicenter clinical trial. First Author: Pengfei Xing, Center for Cancer Diagnosis and Treatment, The Second Affiliated Hospital of Soochow University, Suzhou, China

Background: Low frequency of durable responses in patients treated with immune checkpoint inhibitors demands for taking complementary strategies in order to boost immune responses against cancer. Our previous PRaG1.0 trial also demonstrated that PD-1 inhibitors in combination with radiotherapy and granulocyte macrophage-colony stimulating factor (GM-CSF) could improve clinical response in patients with advanced refractory solid tumors (ChiCTR1900026175). In an effort to further enhance efficacy, we conducted this PRaG2.0 trial (ClinicalTrials.gov: NCT04892498) and optimized the PRaG1.0 regimen by incorporating interleukin-2 (IL-2). **Methods:** The PRaG 2.0 regimen was administered to patients with advanced refractory solid tumors who lacked or were unable to tolerate standard-of-care treatments. A treatment cycle consisted of radiotherapy (5 or 8Gy$\times$2-3f) delivered for one metastatic lesion, PD-1 inhibitor dosing within one week after completion of radiotherapy, GM-CSF 200μg subcutaneous (SC) injection once daily for 7 days, and then sequentially followed by IL-2 2million IU SC once daily for 7 days. PRaG 2.0 regimen was repeated every 21 days for at least 2 cycles until no appropriate lesions for irradiation or reached the tolerance dose of normal tissues. Patients who could not continue radiotherapy and had not yet developed progression disease (PD) allowed PD-1 inhibitors to be continued as maintenance therapy until PD or unacceptable toxicity but no more than one year. The endpoints were Progression-Free Survival (PFS), objective response rate (ORR) and overall survival (OS). **Results:** As of 31st October 2024, 66 patients were enrolled in the study. The median Progression-Free Survival (PFS) was 4.3 months, and the median overall survival (OS) was 10.3 months. The objective response rate (ORR) was 22.7%, and the disease control rate (DCR) was 56.1% according to RECIST version 1.1. Treatment-related adverse events (TRAE) experienced in 57 (86.4%) patients, with 6 patients (9.1%) experiencing Grade $\geq$ 3 TRAEs. We found that in the period prior to disease progression, the absolute count of Treg cells increased compared to baseline, while the percentage of CD8+PD-1+/CD8+ cells decreased compared to baseline. **Conclusions:** The PRaG 2.0 trial demonstrates that PD-1 inhibitors in combination with radiotherapy, GM-CSF, and IL-2 could be a potential treatment regimen for patients with advanced refractory solid tumors. The decrease in the CD8+PD-1+/CD8+% ratio and the increase in the absolute count of Treg cells may suggest potential tumor progression in patients. Clinical trial information: NCT04892498. Research Sponsor: None.

Phase 1 study of recombinant interleukin 15 in combination with nivolumab and ipilimumab in subjects with refractory cancers. First Author: Jibran Ahmed, National Cancer Institute, Bethesda, MD

Background: Combining immune checkpoint inhibitors with cytokine therapies holds promise in cancer immunotherapy. Recombinant human interleukin-15 (rhIL-15) increases circulating CD8+ T cells and natural killer (NK) cells. This Phase 1 study evaluated the safety (NCI-CTCAE v5.0), tolerability, and preliminary efficacy (RECIST v1.1 and iRECIST) of rhIL-15 with nivolumab and ipilimumab. Safety data for rhIL-15/ipilimumab and rhIL-15/nivolumab doublets were reported earlier (O'Sullivan et al., AACR 2019). Here, we present updated triplet dose-escalation results and correlative analyses. **Methods:** This open-label, non-randomized Phase 1 trial employed a 3+3 dose-escalation design to determine the MTD/RP2D of rhIL-15 SQ (administered on days 1-8 and 22-29, cycles (C) 1-4 only) combined with fixed doses of nivolumab (240 mg IV on days 8, 22, 36) and ipilimumab (1 mg/kg IV on day 8) in 42-day cycles in patients with advanced, refractory cancers. Correlative analyses assessed effects on circulating T cell subsets, PD-1/PD-L1 expression, and immune cell activation in tumor tissue (using multiplex immunofluorescence, immunohistochemistry and flow cytometry). **Results:** Thirty-one patients (median age: 56 years, range: 24-81) were enrolled and evaluable for safety and response. The most prevalent cancer types were sarcoma, pancreatic, and colorectal cancers (n = 5 each). The MTD/RP2D was established at 1 μg/kg/day SQ rhIL-15, with a manageable safety profile. Common treatment-related adverse events (TRAE) included injection site reactions (74%), fever (65%), and chills (65%). Grade 3/4 lymphopenia was seen in 13% of patients (4 of 31). Confirmed partial response (cPR) was measured in 1/31 patients (3%); the patient had cholangiocarcinoma and was treated at dose level 1 (DL1, 0.5 μg/kg/day rhIL-15) and the response lasted through cycle 16. Stable disease (SD) occurred in 17/31 patients (55%, median: 2 cycles, range: 1-10), including durable SD (10 cycles at DL1) in salivary gland squamous cell carcinoma. Nine patients had progressive disease as a best response. Four patients did not have tumor measurements after C1 or did not complete C1, including 3 with clinical disease progression and one with grade 3 TRAE. NK cells and $\gamma\delta$-T cells increased in blood, but increases did not correlate with tumor infiltration measured on C1D42. CD8+ T cells increased modestly in blood and tumor without correlation to either clinical benefit, increased PD1+CD3+ lymphocytes, or PD-L1+ tumor cells on C1D42. **Conclusions:** These data suggest the addition of rhIL-15 to the combination of ipilimumab and nivolumab is safe, elicited a pharmacodynamic response from the immune system in blood but not tumor, and did not improve overall response rate. Clinical trial information: NCT03388632. Research Sponsor: U.S. National Institutes of Health.

2618 Poster Session

Effect of AdAPT-001 on checkpoint inhibitor resistance in solid tumors. First Author: Anthony Paul Conley, Department of Sarcoma Medical Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Checkpoint inhibitors (CIs) have revolutionized cancer treatment, but most patients do not respond to them because of primary or secondary resistance. Introduction or reintroduction of CIs to resistant patients is relatively contraindicated because of the likelihood of an unfavorable harm-benefit profile. An intensive search is on for therapies that sensitize resistant tumors to CI therapy. AdAPT-001 is an oncolytic adenovirus armed with a transforming growth factor beta (TGFβ) trap that eliminates the immunosuppressive cytokine, TGFβ. Clinical data demonstrate that AdAPT-001 reverses the tumor immune evasion phenotype and improves the efficacy of immune checkpoint therapy, increasing response rate and progression-free survival (PFS) in CI refractory angiosarcoma. **Methods:** Patients with CI-refractory solid cancers of any type including sarcomas, melanoma, and breast cancer who received AdAPT-001 with a concurrent checkpoint inhibitor. Response was assessed every 8 weeks using RECIST 1.1. Treatment beyond progression was allowed for patients clinically benefiting, and if progression was confirmed on the next assessment then the first assessment meeting PD criteria was considered the date of progression. PFS on AdAPT-001 + CI was compared to duration of treatment on the most recent previous regimen including a CI before study enrollment. **Results:** Among all patients who were treated with a CI in a previous line of therapy (Prior CI) before being treated with AdAPT-001 + CI, the 6-month PFS rate was 17% (3/18) with Prior CI and 33% (6/18) with AdAPT-001 + CI, and the 12-month PFS rate was 0% (0/18) with Prior CI and 17% (3/18) with AdAPT-001 + CI. Particular activity was seen in angiosarcoma, where all patients progressed within 3 months on Prior CI and 75% (3/4) had PFS $>$ 11 months with AdAPT-001 + CI. Treatment with AdAPT-001 was well tolerated and no new safety signals emerged. **Conclusions:** CI treatment is not an option for many patients because of primary or secondary resistance to them and the potential for harm without benefit. The data from this P2 clinical trial strongly suggests that AdAPT-001 circumvents resistance to CIs in multiple tumor types, improving PFS when compared to the patient's prior CI regimen. In addition, AdAPT-001 may prevent the development of CI-induced autoimmune toxicities. P3 clinical trials in sarcoma and hepatocellular carcinoma are planned. Clinical trial information: NCT04673942. Research Sponsor: None.

Duration of treatment on a previous CI regimen compared to subsequent PFS with AdAPT-001 + CI.

Subject ID	Months on prior CI regimen	PFS (months) with AdAPT-001 + CI	PFS Change (months)
1	3.0	11.4	+8.4
2	3.0	2.0	-1.0
3	1.9	13.0	+11.1
4	2.7	12.0	+9.3
Median	2.8	11.7	+8.9

Efficacy and toxicity of nivolumab and ipilimumab in rare cancer brain metastases: A multi-center basket trial analysis (NCI/SWOG S1609). First Author: Manmeet Singh Ahluwalia, Miami Cancer Institute, Baptist Health South Florida, Miami, FL

Background: Outcomes of patients with brain metastases (BM) treated with single or dual checkpoint inhibitors have been previously evaluated, showing similar intra-cranial and extra-cranial response rates and overall survival (OS). However, prior research has primarily focused on common tumor types such as melanoma and lung cancer. We report outcomes in patients with BM from the largest basket trial for rare cancers (N=684 evaluable patients) to evaluate efficacy and toxicity. **Methods:** Patients were treated with nivolumab (NIVO, 240 mg Q2W) and ipilimumab (IPI, 1 mg/kg Q6W) in the federally funded SWOG S1609 DART trial (NCT02834013), conducted across $>$1000 sites. The protocol and consent were reviewed and approved by SWOG, the NCI, the NCI central institutional review board, and institutional review boards of participating sites. Efficacy and toxicity were assessed in patients with and without BM at enrollment. Progression-free survival (PFS), and OS were estimated using Kaplan-Meier methodology. Tumor response was evaluated per RECIST v1.1, toxicities were assessed using CTCAE v5.0. Hazard ratios (HR) with 95% confidence intervals (CI) and P-values were calculated to compare outcomes. **Results:** Similar response rates were observed in patients without BM (11%, n=707) compared to 10% in those with BM at enrollment (n=20). PFS and OS were comparable between patients with and without BM at enrollment (HR=1.29 [0.81-2.07], P=0.28; HR=1.36 [0.81-2.27], P=0.24, respectively). Grade $\geq$3 CNS treatment-related toxicity occurred in 3% of patients without BM versus 5% in those with BM (P=0.43). Similarly, Grade 5 treatment-related toxicity was observed in 2% of patients without BM compared to 5% in patients with BM (P=0.31). Among 18 patients with BM with progression, intra-cranial progression only was seen in 1 (5.5%) patient, while extra-cranial disease progression only in 12 (66.7%); 5 (27.8%) patients experienced concurrent intra- and extra-cranial disease progression. **Conclusions:** In this unique cohort of patients with rare tumors and BM receiving dual checkpoint inhibitor therapy, similar response rates and survival outcomes were observed in patients with or without BM at enrollment. No significant differences in CNS or non-CNS toxicity were noted. Funding: NIH/NCI/NCTN grants U10CA180888, U10CA180819. Clinical trial information: NCT02834013. Research Sponsor: None.

Clinical factors and prognostic outcomes of hyperthyroidism induced by immune checkpoint inhibitor therapy. First Author: Baqir Jafry, Charleston Area Medical Center, Charleston, WV

Background: Hyperthyroidism is a recognized but less frequent immune-related adverse event (iRAE) associated with Immune Checkpoint Inhibitor (ICI) use. While its occurrence has been documented, gaps remain in understanding the underlying risk factors, and its impact on patient outcomes. This study seeks to provide clarity on these aspects and guide improved management strategies. **Methods:** Data were obtained from the TriNetX research network for patients with cancers where ICI is used. Inclusion criteria encompassed patients aged 18 years or older treated with ICIs (e.g., pembrolizumab, nivolumab, atezolizumab, cemiplimab) between January 1, 2013, and December 31, 2024. Patients with a history of thyroid disorders or Levothyroxine use were excluded. Competing risk analyses evaluated the likelihood of hyperthyroidism versus death up to 12 months after ICI use and the likelihood of beta-blocker usage after diagnosis. Cox proportional hazards modeling was used to identify significant covariates associated with hyperthyroidism, including age, sex, cancer type, comorbidities, and ICI type. Backwards batchwise elimination was employed to retain only significant variables. **Results:** Among 39,749 patients receiving ICIs, 2.3% developed hyperthyroidism within 12 months after treatment. In patients with hyperthyroidism, 31.3% initiated metoprolol, 9.5% initiated propranolol, and 6.0% initiated atenolol for symptom management. The mortality rate in the group was 32.1% based on the cumulative incidence. An increased risk of hyperthyroidism was associated with endometrial cancer (HR: 1.44; 95CI: 1.23-1.69; $p < 0.0001$), non-Hodgkin lymphoma (HR: 1.42; 95CI: 1.09-1.84; p = 0.010), and kidney cancer (HR: 1.34; 95CI: 1.25-1.63; p = 0.001). Conversely, patients with colon cancer (HR: 0.74; 95CI: 0.55-0.98; p = 0.038) had a lower chance of developing hyperthyroidism. Among all ICIs, atezolizumab (OR: 1.32; 95% CI: 0.82–2.13; p = 0.25) showed the strongest trend toward hyperthyroidism, followed by durvalumab (OR: 1.24; 95% CI: 0.75–2.05; p = 0.39), pembrolizumab (OR: 1.23; 95% CI: 0.81–1.87; p = 0.34), and nivolumab (OR: 1.22; 95% CI: 0.80–1.86; p = 0.37). In contrast, cemiplimab (OR: 0.61; 95% CI: 0.17–2.16; p = 0.44) showed a lower likelihood of causing hyperthyroidism. **Conclusions:** ICI-induced hyperthyroidism, while less common, has a significant impact on patient outcomes, including mortality. Identifying high-risk cancer subtypes and implementing proactive management, including beta-blocker therapy for symptom control, are critical steps to mitigate adverse effects and improve patient care. Personalized management and early intervention, particularly for high-risk groups, are essential to improving patient outcomes. Research Sponsor: None.

Quantum mechanics–based multi-tensor AI/ML discovery and validation of actionable and mechanistically interpretable whole-transcriptome predictors of survival in response to immunotherapy from real-world clinical trial data. First Author: Orly Alter, University of Utah and Prism AI Therapeutics, Inc., Salt Lake City, UT

Background: Prediction in cancer remains limited, and 90% of drugs continue to fail trials and post-market validation. The entire multi-ome affects the disease. Previously, we developed quantum mechanics-based multi-tensor AI/ML to overcome the limitations of typical AI/ML, e.g., neural networks and deep learning, in small-cohort, noisy, high-dimensional, multi-omic clinical data [doi: 10.1073/pnas.0530258100, 10.1145/3624062.3624078]. We have demonstrated the algorithms in the discovery and validation of whole-genome and -chromosome predictors of survival and response to treatment in, e.g., brain, lung, ovarian, and uterine cancers [doi: 10.1063/1.5142559, 10.1200/JCO.2024.42.16_suppl.10043]. **Methods:** Here, we use the algorithms to discover two whole-transcriptome predictors of OS in response to atezolizumab PD-L1 inhibitor immunotherapy in a 348-patient, multi-center, single-arm, bladder cancer clinical trial, and validate the predictors in the 401-patient bladder cancer cohort in the Cancer Genome Atlas (TCGA). **Results:** The algorithms discovered the two predictors in the open-source, pre-atezolizumab, locally advanced or metastatic disease profiles of the 348 patients alone. By incorporating the patient labels, both predictors were found to outperform the best indicator of response to the treatment to date, i.e., the tumor mutation burden (TMB): The Cox proportional hazards model ratios, i.e., the corresponding relative risks, of 2.7 and 1.7, and concordance indices, i.e., accuracies, of 0.70 and 0.63, of each predictor, are greater than the ratio, of 1.3, and index, of 0.61, of TMB (Wald P-values=2.0×10^{-7} and 8.2×10^{-3} vs. 2.1×10^{-5}). The maximum Kaplan-Meier median OS difference of the two predictors together, of 22 months, is greater than that of TMB, of 16 months (log-rank P-values=3.6×10^{-11} vs. 1.7×10^{-4}). One predictor is additionally correlated with the objective response rate (ORR), and the other – with the tissue of advanced or metastatic disease (Kruskal-Wallis P-values=9.8×10^{-4} and 2.2×10^{-3}). Both predictors are similarly correlated with the OS of the 401 TCGA bladder cancer patients. Both are statistically independent of the imbalanced variations in the patient demographics, e.g., race, or the tissue batches, e.g., pre- vs. post platinum-based chemotherapy. By using the transcript labels, the predictors were interpreted in terms of known and new disease mechanisms and drug targets to sensitize the tumors to the treatment. **Conclusions:** Our multi-tensor AI/ML discovered and validated two whole-transcriptome predictors of OS in response to atezolizumab that outperform TMB. This further suggests that quantum mechanics-based algorithms can be used to derive predictors that are consistent across studies and over time. Research Sponsor: None.

Phase II trial of neoadjuvant nivolumab and SOX in resectable gastric/gastroesophageal junction cancer: Therapeutic response and biomarker correlations. First Author: Xiangdong Cheng, Zhejiang Cancer Hospital, Hangzhou, Zhejiang Province, China

Background: Neoadjuvant immunotherapy produces a major pathologic response (MPR) in 40% of patients with locally advanced gastric cancer (LAGC). Herein, we conducted a phase prospective clinical study to investigate markers related to the response to neoadjuvant immunotherapy. **Methods:** Patients with locally advanced gastric or gastroesophageal junction cancer (cT3-4N+M0,CY0,P0) were enrolled and received either 3 preoperative and 3 postoperative cycles of nivolumab (360 mg, IV, d1, Q21d) plus SOX regimen (oxaliplatin 130 mg/m^2, IV, d1 with oral S-1 40-60mg, bid, d1-d14, Q21d) therapy, followed by 11 cycles of nivolumab monotherapy. The primary endpoint was the pCR rate, while the mPR, 3-year-DFS and 3-year-OS as the second endpoint. This clinical trial was registered at Clinicaltrial.gov (NCT05739045). In addition, tissue samples from patients before and after preoperative therapy were performed scRNA-seq to explore the changes of tumor microenvironment during the therapy and biomarkers associated with therapy response. **Results:** Forty-six patients were enrolled from November 2022 to March 2023, with a median age of 66 years (range, 34-74), and 38 (82.60%) were male. There were 28 (60.87%) patients with PD-L1 CPS $\geq$5. The study achieved its primary endpoints, with a pCR rate of 21.74% and an MPR rate of 41.30%. Among the 46 patients who underwent D2 gastrectomy, the 1-year OS rate was 97.83% and 1-year DFS rate was 95.65%. Single-cell RNA sequencing of 131 tumor samples obtained from 46 patients with LAGC at multiple time points during neoadjuvant therapy showing that the expression of MHC-II was upregulated in malignant cells in the pre-sensitive group. In a retrospective cohort of 226 patients treated with neoadjuvant immunotherapy, MHC-II-positive patients exhibited significantly higher rates of pCR and mPR compared to MHC-II-negative patients. Furthermore, 30 MHC-II-positive GC patients were prospectively enrolled to receive neoadjuvant immunotherapy, showing pCR and mPR rates of 36.67% and 66.67%, respectively. Mechanistically, we observed that T cell-induced IFN-γ signaling predominated in the tumor microenvironment of the sensitive group before treatment. This signaling pathway induces MHC-II expression in tumor cells, thereby enhancing the T cell-mediated antitumor immune response during neoadjuvant immunotherapy. In addition, MHC-II expression in tumor cells can be detected via IHC and commercially available antibodies in standard pathology laboratories, making it a potential biomarker to guide the selection of appropriate GC patients for neoadjuvant immunotherapy. ClinicalTrials.gov registration: NCT05739045. **Conclusions:** Our study illuminates the role of MHC-II expression in tumor cells in modulating the response to immunotherapy in gastric cancer. Clinical trial information: NCT05739045. Research Sponsor: None.

2623 **Poster Session**

Delineation of immunotherapeutic predictive versus prognostic transcriptional programs to identify SLC22A5-centric carnitine metabolism-driven resistance to anti-PD-L1 treatment in advanced non–small-cell lung cancer. First Author: Yuze Wang, The First Affiliated Hospital, Sun Yat-sen University, Guangzhou, China

Background: Prognostic factors indicate the natural course of a disease regardless of treatment, whereas predictive factors determine the likelihood of response to specific therapies. Distinguishing between predictive and prognostic factors is essential for separating treatment-specific outcomes from the inherent progression of cancer, thereby guiding clinical decision-making. We aim to dissect the predictive and prognostic transcriptional programs underlying the efficacy of anti-PD-L1 versus chemotherapy in advanced non-small cell lung cancer (NSCLC) to uncover mechanisms specific to immunotherapy resistance. **Methods:** Clinical and baseline tumor transcriptomic data were collected from two randomized controlled trials comparing atezolizumab with docetaxel: OAK (n=697, discovery cohort) and POPLAR (n=192, validation cohort). Transcriptional program scores for each biological process and metabolic pathway from the Reactome database were calculated using gene set variation analysis for each patient. Cox regression and P-value for interaction tests were conducted to differentiate predictive versus prognostic effects of transcriptional programs. Tumor microenvironment and cell-cell communication underlying immunotherapy resistance were explored using bulk and single-cell transcriptomic data. **Results:** Transcriptional programs in the OAK discovery cohort were divided into four categories associated with different predictive effects specific to atezolizumab or docetaxel. Carnitine metabolism was the most prominent process contributing to atezolizumab-specific resistance, while porphyrin metabolism drove docetaxel-specific resistance. SLC22A5, the only high-affinity carnitine transporter, was upregulated in atezolizumab-resistant patients. The predictive effect of SLC22A5-centric carnitine metabolism for resistance to atezolizumab rather than docetaxel was confirmed in the POPLAR validation cohort. Integrative analyses of bulk and single-cell transcriptomes revealed that cancer cell-specific SLC22A5 expression induced M2 macrophage polarization and decreased CD8+ T cell infiltration via carnitine uptake, thus forming an immunosuppressive microenvironment. **Conclusions:** Our study elucidates the distinction between predictive and prognostic factors in advanced NSCLC from a metabolic perspective. Cancer cells uptake of carnitine via SLC22A5 mediates resistance to anti-PD-L1 treatment. Combining inhibition of SLC22A5-centric carnitine metabolism with anti-PD-L1 agents might be a promising strategy to reverse immune escape in advanced NSCLC. Biomarkers associated with outcomes from OPTIMIZE-1: CD40 agonist mitazalimab with mFOLFIRINOX in patients with untreated metastatic pancreatic cancer. First Author: Philippe Alexandre Cassier, Centre Léon Bérard, Lyon, France

Background: Metastatic pancreatic ductal adenocarcinoma (mPDAC) has a 5-year overall survival (OS) rate of less than 5% and remains a leading cause of cancer related mortality. Mitazalimab, a human CD40 agonistic IgG1 antibody, activates CD40 signaling in myeloid cells, enhancing tumor sensitivity to chemotherapy and licensing dendritic cells to prime and activate tumor-specific T cells. The OPTIMIZE-1 Phase 1b/2 trial evaluated the safety and efficacy of mitazalimab combined with mFOLFIRINOX (mFFX) in treatment *naïve* mPDAC patients (pts) (Van Laethem 2024). This combination therapy has shown promising clinical efficacy compared to historical controls with a median OS of 14.9 months, median duration of response of 12.6 months, median progression free survival of 7.7 months, and an overall response rate of 54.4 % (42.1% confirmed) (Geboes, 2024). **Methods:** Patients received mitazalimab on day 1 (priming dose), followed by a 2-week regimen starting with mFFX on day 8 and mitazalimab on day 10. Associations between survival benefits and both baseline and on treatment biomarkers (RNAseq data from tumor biopsies and longitudinal circulating tumor KRAS (ctKRAS) data) were assessed in patients from the full analysis set (n = 57) treated with 900 μg/kg mitazalimab. **Results:** Differential gene expression analysis (DGEA) identified a fibrosis-related gene signature (including genes involved in extracellular matrix (ECM) remodeling) that correlated with improved OS (p = 0.002). Conversely, a distinct gene signature linked to chemoresistance mechanisms involved in the inactivation and secretion of mFFX components was associated with shorter OS. Comparing DGEA of three on-treatment biopsies from patients with partial response to baseline samples revealed treatment-induced tumor changes. These analyses identified upregulation of genes involved in myeloid cell biology and regulation of T cell responses, along with downregulation of immunosuppressive genes. Longitudinal data analyses revealed that ctKRAS clearance was reached by 72% of pts and was significantly associated with longer OS. Molecular response was also associated with longer OS and predicted radiological response with 76.7% accuracy (sensitivity 72.7%, specificity 81.0%). Further, molecular progression was significantly associated with OS and predicted radiological response with 62.8% accuracy (sensitivity 71.4%, specificity 58.6%). **Conclusions:** A potentially predictive fibrosis-related gene signature, directly linked to mitazalimab's mode of action, was associated with improved OS. Biomarker correlations further suggest a mitazalimab-driven contribution to clinical benefits in the OPTIMIZE-1 trial. These encouraging results will inform the planned randomized confirmatory trial of mitazalimab in combination with mFFX in mPDAC. Clinical trial information: NCT04888312. Research Sponsor: Alligator Bioscience AB.

Tumor mutational burden, PD-1, negative Wnt/β-catenin regulators, and positive MHC class II antigen presentation regulators as predictors of longer survival after immune checkpoint inhibitors across cancers: A comprehensive analysis of 400 immunity biomarkers. First Author: Yu Fujiwara, Department of Medicine, Roswell Park Comprehensive Cancer Center, Buffalo, NY

Background: Immune checkpoint inhibitors (ICIs) have become a standard treatment, yet no universal biomarker consistently predicts prolonged survival across cancer types. While multiple biomarkers have been proposed, they have not been systematically compared or evaluated in a tumor-agnostic manner. This study comprehensively investigates the impact of 397 immunoregulatory transcripts and other factors on survival in patients with cancer treated with ICIs. **Methods:** The Profile-Related Evidence Determining Individualized Cancer Therapy (PREDICT, NCT02478931) study enrolled 514 patients, including 217 treated with ICIs. The study analyzed the effect of bulk tumor transcriptomic expression of 397 immunoregulatory factors plus microsatellite instability [MSI], tumor mutational burden [TMB], and PD-L1 immunohistochemistry (total = 400 biomarkers) along with cancer type on overall survival (OS) and progression-free survival (PFS) following ICI therapy. Transcriptome expression was categorized into three groups based on percentile ranks compared to 735 controls spanning 35 histologies: "High" (75–100th percentile), "Intermediate" (25–74th percentile), and "Low" (0–24th percentile). Hazard ratios (HRs) for OS and PFS were estimated using a Cox regression model. Storey's q-value correction accounted for multiple testing, and a multivariable analysis was performed to explore novel biomarkers and different TMB cutoffs (10 [mutations/mb], 16, 20, and continuous). **Results:** In the 217 ICI-treated patients (median age: 61.2 years; women: 56.2%), the most common ICI was anti-PD-1 therapy (83.4%, N = 181), and the median TMB was 5.0 mut/mb. MSI was detected in 9 patients (4.1%). In multivariable analysis adjusting for age, sex, significant markers ($q < 0.05$) and co-inhibitory checkpoints ($p < 0.1$ in univariate analysis), and TMB (with different cutoffs and as a continuous variable), high expression of CIITA, KREMEN1, and PD-1 (but not PD-L1), as well as higher TMB (≥10 mut/mb, ≥16 or ≥20 or continuous), were independently associated with longer OS ($p \leq 0.05$). In the PFS analysis, high KREMEN1 expression and higher TMB (≥16 or ≥20 or continuous but not ≥10 mut/mb) also independently correlated with longer PFS. Cancer type was not independently correlated with outcome. **Conclusions:** Our comprehensive biomarker analysis identified novel factors associated with ICI efficacy. In addition to confirming the predictive role of TMB, the study highlights CIITA, a regulator of MHC class II expression that enhances tumor antigen presentation, and KREMEN1, a suppressor of Wnt/β-catenin signaling that preserves antitumor immunity, as well as the PD-1 checkpoint, as predictive biomarkers for ICI therapy across cancers. Impact of *Helicobacter pylori* infection on molecular alterations and immune dynamics in gastric cancer. First Author: Daisuke Takayanagi, Showa University, Tokyo, Japan

Background: *Helicobacter pylori* (HP) infection, a major risk factor for gastric cancer (GC), modulates tumor immunity. Evidence indicates that *H. pylori* infection status correlates with the efficacy of immune checkpoint inhibitors (ICI), with varying outcomes in *H. pylori*-positive (*HPP*) and -negative (*HPN*) patients. This study investigated the impact of HP infection on splicing alterations to elucidate its role in shaping immune responses and the tumor immune microenvironment (TIME), immune checkpoint molecule expression, transcriptional profiles in GC. **Methods:** Tumors and adjacent normal tissues were collected from 24 patients with GC, comprising 39 tumor samples from *HPP* patients, 27 samples from *HPN* patients, and 13 and 10 normal samples of each, respectively. RNA sequencing was performed on these tissues and whole blood RNA from six patients (four *HPP* and two *HPN*) to analyze the alternative splicing (AS) events, the transcriptional profiles, and immune-related gene expression. Differential gene expression (DGE) and enrichment analyses were conducted, and immune cell fractions were evaluated using CIBERSORTx. **Results:** DGE analysis revealed that *HPP* tumors were enriched in genes related to cell cycle regulation, whereas *HPN* tumors were enriched in immune response pathways, including those involved in leukocyte activation, chemokine signaling, and immune effector processes. Additionally, *HPN* tumors showed higher expression of immune checkpoint molecules, such as CD160 (p = 0.016), PDCD1LG2 (p = 0.0082), and BTLA (p = 0.025). Immune cell profiling demonstrated increased proportions of gamma-delta T cells (p = 0.0077), resting dendritic cells (p = 0.0002), and neutrophils (p = 0.016), reflecting enhanced immune activation and a favorable ICI response. In contrast, *HPP* tumors were enriched in cell cycle-related pathways, suggesting a proliferative phenotype. *HPP* tumors also exhibited higher levels of M0 macrophages (p = 0.0039) and CD276 expression (p = 0.0082), indicative of an immunosuppressive TIME. AS analysis identified increased intron retention (IR) events in *HPP* tumors, particularly in genes associated with RNA processing and extracellular matrix remodeling. These alterations may contribute to immune evasion and tumor progression. In the peripheral blood, *HPP* samples exhibited upregulation of tripartite motif family genes, which are implicated in immune modulation. **Conclusions:** This study demonstrated that *HP* infection significantly affects the TME and gene expression profiles of GC. *HPP* tumors are characterized by increased M0 macrophage populations, CD276 expression, and IR events that contribute to immunosuppression and tumor progression. In contrast, *HPN* tumors exhibit greater immune activation and checkpoint molecule diversity. These findings highlight the potential role of HP status in shaping the immune landscape of GC and influencing responsiveness to ICI. Research Sponsor: None.

Levels of immune responses in tertiary lymphoid structures of non-small cell lung cancer (NSCLC) and association with survival. First Author: Jiangping Li, Division of Thoracic Tumor Multimodality Treatment, Cancer Center, West China Hospital, Sichuan University, Chengdu, Sichuan, China

Background: Tumor-infiltrating tertiary lymphoid structures (TLSs) are thought to have anti-tumor activity and are believed to indicate a favorable prognosis in cancer patients. However, the prognostic value of TLSs in non-small cell lung cancer (NSCLC) is unknown. **Methods:** RT-qPCR analysis of the reactive Th-cell subsets and fluorescence activated cell sorting (FACS) analysis of the cell composition in tumor and paired controls. Histological evaluation of the co-localization of tumor-associated $CD20^+$ B cells, $CD4^+$ T cells and DC-$LAMP^+$ mature dendritic cells (DCs) within TLSs, and statistically analysis of the relationship between TLSs and overall survival. **Results:** The results indicated high levels of immune responses in tumour microenvironment ofNSCLC, which that high levels of Th-CXCL13, Th1, Tfh and Treg cell immune responses were the main reactions in tumor tissue of NSCLC, followed by weak Th2 and Th17, suggesting high levels of immune responses in tumor microenvironment of NSCLC. Tumor-associated TLS is a complete and mature lymphoid follicle-like structure containing T cells, B cells and APCs in tumor of NSCLC**.** Six-color MIHC staining indicated tumor-associated TLSs were complete and mature lymphoid follicle-like structures containing T cells, B cells and antigen presenting cells (APCs), and tumor-associated TLSs. Architectural analysis showed that $CD20^+$ B cell clusters were localized in the local tumour microenvironment, and were mainly colocalized with $CD4^+$ T cells, $CD68^+$ macrophages, $CD11c^+$ DCs and DC-$LAMP^+$ mature DCs, which indicated the formation of mature TLSs. One of the primary functions of TLS is to support the survival of incoming lymphocytes. The vast majority of the evaluated tumour-associated TLSs in NPC represented mature secondary-follicle-like TLSs, as indicated by the presence of both $CD21^+$ FDC and $CD23^+$ GC-B cells. Understanding and analyzing the phenotypes of these TABs was important for interpreting the local immune response. We used six-color MIHC staining (CD10, CD20, CD38, CD138, CD27 and DAPI) to approximate six different TABs in whole tissue sections of NPC. These molecules were expressed to varying degrees in all paraffin sections, and MIHC showing that $CD38^+$ plasmablast cells and $CD138^+$ plasma cells were primarily located at the tumor interstices or margins, which indicated improved survival outcome. In conclusion, this is the first research of applying multiple complementary strategies to map the biological function and clinical relevance of those cells in the TLSs of NSCLC. **Conclusions:** Our findings provide insights into the potential role of TLSs in the adaptive anti-tumor immune response, with implications for the development of biomarkers and therapeutic targets. Research Sponsor: None.

Clinical significance of the CGRP pathway gene expression in advanced solid tumors: A sub-analysis of MONSTAR-SCREEN-2. First Author: Takao Fujisawa, Department of the Promotion of Drug and Diagnostic Development, National Cancer Center East, Kashiwa, Japan

Background: Calcitonin gene-related peptide (CGRP), a neuropeptide associated with pain perception, has emerged as a therapeutic target for migraine. Recent studies have reported that the CGRP pathway is associated with suppression of anti-tumor immunity and poor prognosis in patients (pts) with solid tumors via induction of CD8+ T cell exhaustion by sensory nerves. However, clinical significance of the CGRP pathway genes in oncology including the impact for the efficacy of immune checkpoint inhibitors (ICIs) remains elusive. Herein, we evaluated the landscape of the CGRP pathway gene expression and their association with efficacy of ICIs by mRNA expression level of the CGRP pathway genes in advanced solid tumors from the SCRUM-Japan MONSTAR-SCREEN-2, a nationwide molecular profiling project. **Methods:** Pts with advanced solid tumors were enrolled; tumor tissues were profiled using whole exome/transcriptome sequencing (MI Profile, Caris Life Sciences, Phoenix, AZ, USA). The association between the expression profiles of the CGRP pathway genes (*CALCA* encoding CGRP, *CALCRL* and *RAMP1* encoding CGRP receptors) and the efficacy of ICI monotherapy was analyzed. **Results:** Among 2,768 pts enrolled as of March 2024, mRNA expression data of baseline tissue samples were available in 1,475 pts across 36 cancer subtypes: most common subtypes were colorectal adenocarcinoma (n = 352) and esophagogastric adenocarcinoma (EGAC, n = 192). mRNA expression of the CGRP pathway genes were observed across diverse cancer types. One hundred and fifty-eight pts were treated with ICI monotherapies: most common subtypes were urothelial carcinoma (UC, n = 41), EGAC (n = 30) and head and neck squamous cell carcinoma (HNSCC, n = 30). The low *RAMP*1 mRNA expression group tended to have a better objective response rate (ORR) and significantly better progression-free survival (PFS) than the high mRNA expression group (ORR: 29.3% vs 15.2%, P = 0.056, PFS: 5.1 vs 2.7 months, hazard ratio [HR]: 0.68, 95% CI: 0.47-0.98, P = 0.04). Among the patients with UC and HNSCC, the low *RAMP1* mRNA expression group tended to have a better PFS than the high mRNA expression group (UC: 3.5 vs 6.0 months, HR: 0.69, 95% CI: 0.34-1.39, P = 0.3, HNSCC: 1.5 vs 6.0 months, HR: 0.67, 95% CI: 0.30-1.51, P = 0.3). **Conclusions:** High RAMP1 mRNA levels were associated with worse therapeutic efficacy of ICI, highlighting the potential of CGRP pathway as a resistance mechanism and a treatment target. Clinical trial information: UMIN000043899. Research Sponsor: SCRUM-Japan Funds.

Predication of clinical outcomes of advanced cutaneous squamous cell carcinoma to PD1 inhibition directly from histopathology slides using inferred transcriptomics. First Author: Johnathan Arnon, Sharett Institute of Oncology, Hadassah Hebrew Universty Medical Center, Jerusalem, Israel

Background: Metastatic or locally advanced cutaneous squamous cell carcinoma (CSCC) not amenable to local therapy is treated with programmed death (PD)-1 inhibitors, namely Cemiplimab . While response rates are relatively high at approximately 45%, no predictive biomarkers for PD-1 inhibition have been validated in advanced CSCC subjecting some patients, especially older, to unnecessary immune-related adverse events (irAE). We present a retrospective analysis of ENLIGHT-DP, a novel biomarker for response to PD-1 inhibition in advanced CSCC, calculated directly from histopathological slides. **Methods:** We retrospectively examined high resolution hematoxylin and eosin (H&E) slide scans from archived tumor-tissue samples of advanced CSCC patients treated with Cemiplimab to generate an individual prediction score to PD-1 inhibitors using ENLIGHT-DP. This is composed of two main steps: (I) prediction of individual mRNA expression directly from H&E slides using the digital pathology-based DeepPT algorithm (II) use these values as input to ENLIGHT, a transcriptomics-based precision oncology platform for prediction of response to cancer therapies. We then unblinded clinical outcomes and assessed the predictive values of ENLIGHT-DP. **Results:** We evaluated 39 cases of advanced CSCC (tumors from various origins) at a median age of 81 years old (range 57-100). Of them, 32 cases (82%) were initially treated with surgery or radiotherapy with curative intent, but ultimately suffered disease progression. The objective response rate (ORR) was 69%, median progression free survival (PFS) was 11 months (CI 95% 10.4-17.6) and 6 patients (15%) suffered from severe irAE necessitating treatment cessation. ENLIGHT-DP was predictive of response with ROC AUC = 0.67. Using a binary threshold for classification, calibrated on previous lung and head and neck cohorts, ENLIGHT-DP displays promising biomarker characteristics: 81.8% PPV, 66.6% sensitivity and 4.0 OR (p = 0.04) for matched vs. unmatched patients. ENLIGHT-DP successfully stratified PFS with HR 0.02 (CI 95% 0.0005-0.96, p = 0.05). Importantly, omitting cases in which ENLIGHT-DP was calculated on samples which were taken more than 6 months prior to Cemiplimab therapy (i.e., during diagnostic excisions) did not influence the results. No other patient characteristics (e.g., age, stage, co-morbidities, previous treatments) were associated with outcomes. **Conclusions:** ENLIGHT-DP demonstrates high predictive values for clinical outcomes of PD-1 inhibition in advanced CSCC, relying solely on easily accessible archived H&E slides. Research Sponsor: Pangea Biomed.

Evaluation of AI-assisted PD-L1 CPS scoring in immunostained pan-organ tumor whole-slide images. First Author: Céline Bossard, Pathology Department, IHP Group, Nantes, France

Background: PD-L1 inhibitors have shown remarkable results in oncology, yet many patients fail to respond, underscoring the importance of reliable assessment of PD-L1 expression for patient selection. PD-L1 scoring, especially the Combined Positive Score (CPS), is hindered by inter-observer variability, complex staining patterns, and technical discrepancies across platforms and antibody clones. These challenges may impact therapeutic decisions. Artificial intelligence (AI) offers a solution by standardizing PD-L1 evaluation. This study evaluates Diadeep PD-L1 CPS AI solution designed to provide reproducible and robust PD-L1 scoring across diverse tumors and conditions. **Methods:** AI performance was validated on 142 formalin-fixed, paraffin-embedded samples spanning multiple tumor types (GI, head and neck, breast, uterine cervix) and sourced from four centers, reflecting diverse staining protocols (22C3 and QR001 clones; BenchMark ULTRA and Omnis/Dako platforms). The routine scores were available for these cases. A Gold Standard was established through independent retrospective scoring by three blinded senior pathologists, which allowed to compute the intraclass correlation coefficient (ICC). The scoring was followed by collegial discussions to resolve discordant cases and ensure medical consensus. After a washout period, pathologists re-evaluated the cases with the AI assistance. AI-computed scores and routine manual scores were evaluated and compared by using the Gold Standard as a reference and the organ-specific recommended cut-offs. **Results:** The AI assistance improved interobserver agreement among pathologists, with the ICC increasing from 0.62 to 0.74. This effect was particularly pronounced for challenging cases with CPS $<$ 20 (n = 91), where ICC improved from 0.19 to 0.62, underscoring the AI's value in reducing variability near clinical decision thresholds. Moreover, the AI-based scoring tool demonstrated superior accuracy (88%) compared to routine manual scoring (75%) in classifying PD-L1 expression based on clinical cutoffs. Sensitivity was significantly higher with AI (96% vs. 78%, $p < 0.001$), while the positive predictive value was comparable (88% vs. 87%), indicating an improved ability to detect true positive cases. **Conclusions:** This study highlights the potential of an AI-driven tool to enhance PD-L1 scoring by significantly improving accuracy and reducing inter-observer variability, particularly in cases near clinical decision thresholds where consistency is critical. By delivering reliable and reproducible results, the AI algorithm addresses key challenges in PD-L1 evaluation, ensuring more precise patient stratification for immunotherapy. Beyond accuracy, the integration of such tools into clinical workflows could optimize patient selection and improve therapeutic outcomes, offering oncologists greater confidence in treatment decisions. 2632 **Poster Session**

Validation of ENLIGHT, an AI predictor of immune checkpoint blockade (ICB) response and resistance, across the treatment span. First Author: Scott Strum, Princess Margaret Cancer Centre – University Health Network, University of Toronto, Toronto, ON, Canada

Background: Advanced computational AI algorithms, such as ENLIGHT and DeepPT (Med 2023, Nature Cancer 2024), represent a promising approach to identify predictive biomarkers for cancer therapeutics. Evaluation of ICB response prediction via these algorithms through the full span of pre-treatment, on-treatment, and at progression time points provides a dynamic perspective of response prediction abilities. **Methods:** A post-hoc analysis of two pan-cancer clinical trials was performed: i) BIO2 is a biobanking protocol of ICB-naïve patients (pts) treated with pembrolizumab (NCT02644369); and ii) The IRIS study (NCT04243720) which enrolled pts who have progressed immediately post ICB. In BIO2, complete, partial response or stable disease for $>$6 months was classified as responders (R), the rest as non-responders (NR). In IRIS, acquired and primary resistance were defined according to trial protocol. ENLIGHT matching scores were calculated using either transcriptomics from NGS (EMS-NGS), or transcriptomics imputed directly from H&E slides using DeepPT (EMS-DP). The predictive value of EMS was compared to PD-L1 IHC, tumor mutational burden (TMB) and tumor infiltrating lymphocytes (TILs) abundance by IHC, and its trajectory across timepoints was studied. **Results:** 76 pts from BIO2 (23:53, R:NR), and 37 pts from IRIS (18:19, AR:PR), comprising of 14 tumor types, were analyzed. We first established the value of ENLIGHT as a predictive biomarker using the BIO2 pre-treatment samples. EMS-NGS was a superior predictive biomarker compared with PD-L1 IHC, TMB and TIL abundance, while EMS-DP was comparable (Table). The EMS-NGS scores of responders were significantly higher than non-responders pre-treatment (medians: 0.92 vs. 0.62, p = 1.4e-4). Analyzing the trajectory of the EMS-NGS scores across two additional timepoints reveals that while the scores of non-responding patients remained low (median: 0.62, 0.69, 0.67 for pre-, on–treatment and post-progression, respectively), it is higher among responders (median: 0.92, 0.78 for pre- and on–treatment, respectively). Finally, EMS-NGS was higher among pts with acquired vs primary resistance in IRIS (medians: 0.75 vs 0.59, p = 0.17). **Conclusions:** In two pan-cancer cohorts, EMS-NGS outperformed conventional biomarkers in predicting ICB response. EMS-DP was comparable to conventional biomarkers and could be calculated directly from H&E slides in a fast, low-cost manner. EMS-NGS values were concordant with response or resistance throughout the ICB treatment course, reflecting the level of the tumor's vulnerability to ICB inhibition. Further validation of ENLIGHT in larger ICB-treated pts is warranted given these promising results. Clinical trial information: NCT02644369, NCT04243720. Research Sponsor: BMO Chair in Precision Genomics, Dr. Lillian Siu.

	ROC AUC (p)	Sensitivity	PPV (cf 30% baseline response rate)	F1 Score
EMS-NGS	0.74 (0.0003)	61	48	54
EMS-DP	0.64 (0.02)	57	45	50
PD-L1 IHC	0.7 (0.003)	70	40	51
TMB	0.64 (0.03)	39	69	50
TILs	0.6 (0.065)	39	52	44

2633 Poster Session

Effect of elevated expression of *LILRB4* and *TSC22D3* on survival in lung cancer. First Author: Borys Hrinczenko, Michigan State University, East Lansing, MI

Background: HER2/neu mutations or amplifications, present in up to 23% of non-small cell lung cancers (NSCLCs), activate STAT3, promoting inflammation and suppressing adaptive immune responses. Elevated systemic inflammation-immune index (SII) in small cell lung cancer (SCLC) correlates with reduced response to PD-1/L1 immune checkpoint inhibitors (ICIs), leading to worse overall survival (OS) and progression-free survival (PFS). These findings highlight the need to mitigate inflammation in lung cancers to enhance ICI response and improve survival. Biomarker studies can identify genes that differentiate inflammatory and immune pathways, offering therapeutic insights. **Methods:** To identify genes regulating the HER2/neu oncogene, HER2/neu-overexpressing mice were crossed with genetically Diverse Outbred (DO) mice. The resulting DO F1 offspring were monitored for HER2/neu-expressing tumor onset and growth. Tumor phenotypes were associated with mouse haplotypes to identify quantitative trait loci (QTL) on chromosomes (chr) 2, 6, and X linked with aggressive HER2/neu tumors. Of the 35 candidate genes harboring protein-coding changes, homologous genes on human chr 1, 10, and X were analyzed using Caris Life Sciences datasets of NSCLC and SCLC: 25,143 primary NSCLC; 12,365 metastatic NSCLC; 621 primary SCLC; and 971 metastatic SCLC where primary biopsies are those taken from the lung and metastatic biopsies from sites other than the lung. Patient cohorts stratified by gene expression (top vs. bottom 50%) were correlated with OS, ICI response, and time on pembrolizumab or atezolizumab treatment (TOT). **Results:** Several homologous candidate genes correlated with lung cancer survival in both NSCLC and SCLC. Notably, high expression of *LILRB4*, a macrophage-specific checkpoint molecule, was associated with improved survival (HR 0.66–0.84, $p < 0.001$) across all lung cancer types and sites. Additionally, elevated *TSC22D3*, a glucocorticoid receptor-activated gene regulating anti-inflammatory pathways, including *LILRB4* expression, was positively associated with OS in metastatic NSCLC (HR 0.82, $p < 0.00001$) and SCLC (HR 0.77, $p < 0.001$). Expression of *LILRB4* and *TSC22D3* further enhanced survival in ICI-treated patients (SCLC: HR 0.72; NSCLC: HR 0.82; $p < 0.001$). In NSCLC, high *LILRB4* expression conferred an 18% improved TOT with pembrolizumab (HR 0.858, $p < 0.0001$). **Conclusions:** *LILRB4* and *TSC22D3* are key genes linked to improved survival outcomes in both SCLC and NSCLC, likely through their roles in mitigating inflammation. Their association with enhanced ICI responses underscores their potential as therapeutic targets. Future research will evaluate the relationship between *LILRB4* and *TSC22D3* expression and HER2/neu status in NSCLC and validate protein-level correlations in positive cells. Our long-term goal is to determine the therapeutic potential of *LILRB4* and *TSC22D3* in SCLC, NSCLC and HER2/neu-positive NSCLC. Research Sponsor: U.S. National Institutes of Health; 7R01CA278818-02.

2634 Poster Session

Tertiary lymphoid structures and their association with immune checkpoint inhibitor response and survival outcomes in patients with non-small cell lung cancer. First Author: Dmitrii Grachev, BostonGene, Corp., Waltham, MA

Background: Immune checkpoint inhibitor (ICI)-based therapy is currently the first-line treatment for patients with lung adenocarcinoma (LUAD) and lung squamous cell carcinoma (LUSC) without actionable mutations. However, the commonly utilized biomarkers, including PD-L1 protein expression and tumor mutation burden, are not sufficiently accurate to predict the treatment response from ICI in this patient population. As tumor microenvironment (TME) and tertiary lymphoid structure (TLS) play a significant role in antitumor immunity, we explore these immunophenotypic factors to determine the potential biomarkers in patients with LUAD or LUSC. **Methods:** We evaluated all patients with LUAD or LUSC from three publicly available data and two novel retrospective cohorts for transcriptomic-based immune TME subtype classification (immune-hot vs. immune-cold) and TLS signature, along with associated clinical and genomic data. Those with other histological subtypes of non-small cell lung cancer or those who harbored *EGFR* mutations or *ALK* rearrangements were excluded from our study. The cellular decomposition within tumor samples was calculated using the deconvolutional Kassandra algorithm. Survival analysis was evaluated using log-rank test and multivariate Cox regression adjusted by PD-L1 status, KEAP1/STK11/KRAS/TP53 mutational status, immune TME subtype, and TLS signature. All statistical analyses were performed using Python. **Results:** A total of 514 patients were included from five cohorts, with 272 and 505 having genomic and transcriptomic data, respectively. 59% of patients with LUAD or LUSC exhibited an immune-cold phenotype, which correlated with adverse overall survival (OS) and progression-free survival (PFS) than immune-hot phenotype in LUAD. However, the ICI response rates were similar in both groups. Superior PFS and ICI response rates were observed in patients with high TLS signatures ($>$ 88th percentile) in LUAD, even after multivariate adjustments. Immune signatures that were positively associated with ICI response included the infiltration and trafficking of T and NK cells for LUAD and B-cell percentage for LUSC. In contrast, $CD8^+$ T-cell abundance did not correlate with ICI response. The presence of *KEAP1* or *STK11* mutations also did not affect the response rates but were associated with shorter OS and PFS. **Conclusions:** Transcriptomic-based immune-hot TME and high TLS signature may serve as novel predictive and prognostic biomarkers in patients with LUAD, while the presence of *KEAP1* or *STK11* mutations only offered prognostic values. Further prospective studies are warranted to expand to other treatment combinations with PD-(L)1 inhibitors. Research Sponsor: None.

2635 Poster Session

CCR8 positive Tregs and their correlation with immunotherapy response in advanced non-small cell lung cancer (NSCLC). First Author: Jean Philippe Guégan, Explicyte, Bordeaux, France

Background: Regulatory T cells (Tregs) expressing the chemokine receptor CCR8 are pivotal modulators of the tumor immune microenvironment. CCR8 has recently emerged as a promising therapeutic target due to its selective expression on activated Tregs in the tumor microenvironment and its role in promoting immunosuppression. This study investigates the prognostic and therapeutic implications of CCR8-positive Tregs in non-small cell lung cancer (NSCLC), focusing on their impact in relation to tertiary lymphoid structure (TLS) status. **Methods:** A validated 6-plex multiplex immunofluorescence (mIF) panel was used to analyze tumor samples from NSCLC patients treated with immune checkpoint blockers (ICB) in the BIP precision medicine study (ClinicalTrials.gov: NCT04389143). Markers included CD4, CD8, CD20, FoxP3, PanCK, and CCR8, alongside DAPI staining to assess immune contexture (infiltrated, excluded, desert), TLS status, and CCR8/FOXP3 double-positive Tregs. Clinical outcomes, including progression-free survival (PFS) and objective response rate (ORR), were analyzed in 50 responders and 50 non-responders. Findings were validated using transcriptomic data from the POPLAR (NCT01903993) and OAK (NCT02008227) studies, which evaluated atezolizumab versus docetaxel in advanced NSCLC. Kaplan-Meier curves, hazard ratios, and Cox regression models were used for survival analyses. **Results:** CCR8-expressing Tregs were significantly enriched in infiltrated tumors, showing a 1.5-fold increase compared to excluded tumors (p = 0.057), a 3.3-fold increase compared to desert tumors (p = 0.001), and a 1.8-fold increase in TLS-positive tumors compared to TLS-negative tumors (p = 0.003). These findings highlight that activated Tregs co-infiltrate with CD8 T cells and other immune cell types. This enrichment was confirmed in samples from the POPLAR and OAK studies using transcriptomic analyses (3-fold increase, p = 2e-16). Due to their correlation with overall immune cell infiltration, the presence of CCR8-positive Tregs was significantly associated with better survival (HR 0.45, $p < 0.001$) across the entire patient cohort. However, when stratified for TLS-positive tumors, the presence of activated Tregs was associated with diminished objective response rate and progression-free survival suggesting a negative impact of these immunosuppressive cells on response to ICB. **Conclusions:** This study provides the first evidence linking CCR8-positive Tregs with immunotherapy resistance in NSCLC, particularly in TLS-positive tumors. These findings parallel observations in TLS-positive sarcomas, where Treg abundance predicted poor outcomes (Italiano et al., *Nature Medicine*, 2022). This study supports the exploration of CCR8-targeted therapies to deplete immunosuppressive Tregs and enhance the efficacy of immunotherapy in TLS-positive NSCLC. Research Sponsor: None.

Biological determinants of immune exclusion in non-small cell lung cancer: An analysis of the precision medicine BIP study. First Author: Jean-Philippe Guegan, ImmuSmol, Bordeaux, France

Background: Immune exclusion has been associated with resistance to immunotherapy in NSCLC. However, its biological determinants remain largely unknown. Instead of relying on preclinical models, high-throughput profiling of patient samples using spatial transcriptomics (ST) and multiplex immunofluorescence (m-IF) offers a powerful approach to dissect immune profiles and uncover key drivers of immune response and resistance. **Methods:** Tumor samples collected from NSCLC patients enrolled in the BIP precision medicine study (NCT02534649) prior to initiation of ICI therapy and divided into Discovery and Validation cohorts (n = 148 and 117, respectively). Response to treatment was assessed as per RECIST criteria. Multiplex immunohistochemistry (mIHC) with CD8 and panCK markers was used to classify tumors as desert, excluded or inflamed through pathologist assessment (PA) and image analysis ST using the NanoString GeoMx Whole Transcriptome Atlas compared gene expression profiles between inflamed and excluded tumors Spatially resolved T-cell receptor (TCR) profiling assessed clonal diversity and repertoire to evaluate T-cell functionality. m-IF was used for proteomic validation. **Results:** In both the training and validation cohorts, excluded tumors demonstrated lower objective response rates (ORR), progression-free survival (PFS), and overall survival (OS) compared to inflamed tumors (Table 1), independent of PD-L1 expression in multivariate analysis. ST identified marked overexpression of HLA-A/B (MHC class I) and CD74 (involved in MHC class II processing) in inflamed tumors versus excluded tumors, underscoring their crucial roles in antigen presentation. These results were validated by m-IF. Spatially resolved TCR profiling demonstrated higher Gini coefficients and lower Shannon entropy in excluded tumors, indicating a more oligoclonal TCR repertoire dominated by fewer T-cell clones. These findings suggest impaired antigen recognition and restricted T-cell diversity in excluded tumors. **Conclusions:** Our classification approach using mIHC and IA offers a practical, and clinically actionable biomarker for predicting response to ICI therapy. Immune exclusion, prevalent in NSCLC, is associated with resistance to ICI and characterized by reduced expression of key antigen presentation molecules such as HLA-A/B and CD74 and a restricted TCR repertoire highlighting the need for novel strategies to overcome this immune barrier. Research Sponsor: None.

The predictive role of TRAIL gene expression in immune checkpoint inhibitor (ICI)-treated patients (pts). First Author: Obada Ehab Ababneh, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Despite FDA-approved molecular biomarkers such as PD-L1 levels, tumor mutation burden (TMB), and microsatellite instability (MSI) status, only ~30% of matched cancer pts respond to ICI. TRAIL, a protein product of TNFSF10 gene, is a member of the TNF superfamily involved in regulating immune responses and inducing apoptosis when bound to either Death Receptor 4 or 5 (DR4/5) especially in cancer cells. While TRAIL has been studied for its prognostic roles in cancer, its predictive value for pts treated with ICI remains unclear. This study investigates the association between TRAIL expression and outcomes in ICI-treated pan-cancer pts. **Methods:** RNA expression levels of TRAIL were assessed in a cohort of 217 pan-cancer pts treated with ICIs at the University of California San Diego (UCSD) Moores Cancer Center. RNA transcripts were normalized using an internal housekeeping gene profile of 735 tumors and 35 histologies. Transcript abundances were percentile-ranked (0–100) and categorized as high ($\geq$75th percentile) or low ($<$ 75th percentile). Associations between TRAIL expression and overall survival (OS) and progression-free survival (PFS) were analyzed. Statistical significance was defined as p-value $\leq$ 0.05. **Results:** Among the 217 ICI-treated pts, the median age was 61.9 years, and 56.2% were female. The most common cancer types were colorectal (24.9%), breast (8.8%), ovarian (8.3%), pancreatic (7.4%), and lung (6.5%) cancers. FDA-approved ICI biomarkers favorable rates were PD-L1 $\geq$1% in 40.1%, TMB-high ($\geq$10 mut/Mb) in 11.5%, and MSI-high in 4.8%. Based on the ICI type used, 91.7% received anti-PD-(L)1 while 7.8% received anti-CTLA-4 with anti-PD-1. Pts with high TRAIL expression (24%) had similar PD-L1, TMB, MSI profiles ($p > 0.05$). Pts with high levels of TRAIL expression achieved better OS (HR = 0.41, 95%CI:0.25-0.69, p = 0.0004) and PFS (HR = 0.67, 95%CI:0.47-0.96, p = 0.027). After adjusting for age, sex, cancer type, PD-L1 IHC level ($\geq$1% vs. $<$ 1%), TMB ($\geq$10 mut/Mb vs. $<$ 10mut/Mb), MSI status (stable vs. unstable), KRAS, TP53 and CDKN2A/B alteration status and immune checkpoints genes expression, overall survival remained significantly associated with better survival in TRAIL high pts compared to TRAIL low pts (HR = 0.38, 95%CI:0.19-0.76, p = 0.006). However, no difference was found between both groups in regard to progression-free survival (HR = 0.68, 95%CI:0.42-1.10, p = 0.11). **Conclusions:** High TRAIL expression is associated with improved overall survival in ICI-treated pan-cancer pts, independent of cancer type or other predictive biomarkers. These findings suggest TRAIL as a potential biomarker for ICI benefit. Larger studies in diverse and real-world settings are warranted to validate these findings. Research Sponsor: None.

Randomized phase II trial evaluating the combination of TG4001, an HPV16 therapeutic vaccine, and avelumab (ave) in patients (pts) with immunotherapy-naïve recurrent and/or metastatic (R/M) HPV16-positive cervical or anogenital cancer. First Author: Christophe Le Tourneau, Department of Drug Development and Innovation (D3i), Institut Curie, Paris-Saclay University, Paris, France

Background: Human papillomavirus (HPV) is a small DNA virus associated with cervical, anogenital (AG) cancers and squamous cell carcinoma of the head and neck. TG4001 is a therapeutic vaccine based on modified vaccinia virus Ankara with insertion of modified non-oncogenic HPV-16 E6 and E7 antigens and interleukin-2 as adjuvant. The phase I trial of TG4001 combined with ave showed a favorable safety profile (Borcoman E. et al, 2023). **Methods:** Pts with R/M cervical and anogenital cancer and who were checkpoint inhibitors naïve were randomized independent of PD-L1 expression between ave plus TG4001 or ave alone. Pts were required to have no more than one prior line of therapy for R/M disease and no liver involvement. Primary endpoint was PFS. Subgroup analysis (cervical, anal, other genital cancer) was preplanned in the protocol. **Results:** 90 pts were randomized between June 2021 and April 2024. 49 (54%), 27 (30%) and 14 (16%) pts had cervical, anal, and other genital cancers, respectively. Patients' demographics were well balanced between the 2 arms. Median PFS (mPFS) was 3.0 and 2.8 months (mo) in the experimental and control arm, respectively (HR=0.87 [90%CI: 0.59-1.29], p=0.28). In the cervical cancer subgroup, mPFS was 4.3 and 2.1 mo in the experimental and control arm, respectively (HR=0.58 [90%CI: 0.33-1.01], p=0.053). Overall Response Rate (ORR) in the whole population was 15.2% (7/46pts) in the experimental arm and 13.6% (6/44pts) in the control arm. In the cervical cancer subgroup ORR was 20% (5/25pts) in the experimental arm and 8.3% (2/24pts) in the control arm. There were no new safety signals. Three pts (6.5%) in the experimental arm and 2 pts (4.5%) in the control arm presented grade 3 or 4 treatment-related AEs. Translational analysis including immunogenicity results will be presented. **Conclusions:** TG4001 combined with ave did not improve PFS over ave alone in the whole patient population. Preplanned subgroup analysis in cervical cancer showed a positive efficacy signal in the combined arm. Avelumab was provided by the healthcare business of Merck KGaA, Darmstadt, Germany (CrossRef Funder ID: 10.13039/100009945). Clinical trial information: NCT03260023. Research Sponsor: None.

Induction of neoantigen-specific immune responses by VB10.NEO in combination with atezolizumab in heavily pretreated patients with advanced solid tumors: Final analysis of the phase 1b VB N-02 trial. First Author: Sebastian Ochsenreither, Charité University of Medicine Berlin Comprehensive Cancer Center, Berlin, Germany

Background: VB10.NEO, a personalized DNA-based neoantigen vaccine, was evaluated with atezolizumab in a Phase 1b trial to assess safety, clinical activity, and immune responses in heavily pretreated patients with advanced solid tumors. The NeoSELECT platform enriches for clonal neoantigens by analyzing RNA and circulating tumor DNA, incorporating frameshift antigens and single nucleotide variants. **Methods:** This open-label, dose-escalation trial investigated VB10.NEO across three dose levels (3, 6 and 9 mg) combined with atezolizumab (1200 mg Q3W). Eligible patients had advanced or metastatic solid tumors, sufficient tumor material for vaccine manufacturing, at least 10 identified tumor neoantigens, and measurable disease. Immune responses were assessed using ELISpot assays (in vitro stimulation and ex vivo), T cell receptor sequencing, and flow cytometry. Endpoints included safety, immune response, and antitumor activity per RECIST v1.1. **Results:** At study completion (October 2024), 26 patients (median age 61 years, range 28–72; 62% female) received at least one dose of VB10.NEO. Median prior therapy lines for advanced disease were three (range 1–6), and 54% had prior immunotherapy, including checkpoint inhibitors. Tumor types included head and neck squamous cell carcinoma (15%), triple-negative breast cancer (15%), and others (31%; most were tumors with low tumor mutational burden). The majority (69%) of evaluable patients had low or negative PD-L1 expression. Injection site reactions (15%) and fatigue (12%), mainly Grades 1–2, were the most common adverse events. A dose-limiting Grade 3 transient blood pressure increase occurred in the 9 mg cohort. No treatment-related serious events or deaths occurred. Across all dose levels, VB10.NEO induced robust and durable neoantigen-specific immune responses. In vitro stimulated ELISpot assays detected vaccine-induced T cell responses in 85% (11/13) of evaluable patients and in 58% of evaluated neoantigens, while *ex vivo* ELISpot demonstrated responses in 22% (4/18) of patients and 5% of evaluated neoantigens. T cell receptor sequencing showed persistent T cell clone expansion in 9/11 patients, indicating durable immune responses. Putative neoantigen-specific clones were detected in 6/7 analyzed patients, with persistent expansion in 4. All patients achieving stable disease (34.8%, 8/23) exhibited neoantigen-specific immune responses. **Conclusions:** VB10.NEO combined with atezolizumab demonstrated a favorable safety profile while eliciting robust, durable immune responses across all dose levels, even in heavily pretreated patients with advanced solid tumors. The potential correlation between immunogenicity and clinical benefit supports further exploration in earlier treatment settings. Clinical trial information: NCT05018273. Research Sponsor: Nykode Therapeutics in collaboration with Roche/Genentech.

An open-label single-center investigator-initiated exploratory clinical study in patients with refractory or recurrent solid tumors: R-ISV-FOLactis trial. First Author: Ruojing Lv, Comprehensive Cancer Centre of Drum Tower Hospital, Medical School of Nanjing University, Clinical Cancer Institute of Nanjing University, Nanjing, China

Background: Soft tissue sarcomas (STSs) are a highly complex group of tumors and the treatment still remains a challenge. Immunotherapy has become a powerful clinical strategy, especially the application of therapeutic tumor vaccine. Hypofractionated radiotherapy (HFRT) can serve as an in situ vaccine and provide durable local control. We also develop a bifunctional engineered Lactococcus lactis (FOLactis) which expresses an encoded fusion protein of Fms-like tyrosine kinase 3 ligand and co-stimulator OX40 ligand to conduct in situ vaccination (ISV). In this study, we establish a novel R-ISV-FOLactis strategy, which refers to the combination of HFRT, intratumoral (IT) injection of FOLactis and synergetic anti-PD-1 therapy, to further enhance efficacy and realize the activation of the whole immunity cycle. **Methods:** This study is an open-label, single-center trial aimed at patients with advanced STSs who are unresponsive or intolerable to previous standard treatment. Patients will be treated with HFRT, the IT injection of FOLactis and PD-1 inhibitors. The primary endpoint is the objective response rate (ORR) of target lesions at 3 month and 6 month. The secondary endpoint includes the disease control rate (DCR) of target lesions, progression-free survival (PFS), overall survival (OS), etc. **Results:** This study started from July 2022 and ended in December 2023, involving 30 eligible patients with solid tumors and 16 of them are patients with STSs. The ORR and DCR of all target lesions after three months are 27.6% and 93.1% respectively, and in sarcomas, the ORR and DCR are 11.1% and 88.9%. We calculate the ORR and DCR of target lesions after six months, which are 56.3% and 100% respectively, and in sarcomas, these are 41.7% and 100%. Systemic median PFS are 2.87 months. Median PFS of target lesions has not been reached. Among the evaluable target lesions, 6-month EFS is 50% in sarcomas (6/12) and 50% in all patients (8/16). We test the level of cytokines before and after the first treatment and find that the changes in the percentage of CD8+ T cells, CD103+CD8+ T cells and CD39+CD8+ T cells have significance. Moreover, in sarcomas, PFS is relevant to the level of CD103+CD8+ T cells before treatment, CD39+CD8+ T cells after treatment, NK cells before treatment and immature DC cells after treatment. The most common treatment-related adverse events (TRAEs) are fever (83.3%), lymphocytopenia (53.3%), hypocalcemia (30%), neutrophilia (26.7%) and nausea (26.7%). Grade$\geq$3 TRAEs occur in 11 patients, including lymphocytopenia (30%), fever (6.7%), leukopenia (3.3%), anemia (3.3%) and cardiac insufficiency (3.3%). **Conclusions:** The R-ISV-FOLactis strategy demonstrates its efficacy among patients with advanced STSs and induces certain anti-tumor immunity. The ISV of "FOLactis" may provide a promising option in the treatment of recurrent or refractory solid tumors. Clinical trial information: ChiCTR2200060660. Research Sponsor: None.

First-in-human study of ZGGS15, a dual-specific antibody targeting LAG-3 and TIGIT, as monotherapy in patients with advanced solid tumors. First Author: Ji Zhu, Cancer Hospital of the University of Chinese Academy of Sciences (Zhejiang Cancer Hospital), Hangzhou, China

Background: ZGGS15 is a novel humanized bispecific antibody of anti LAG-3 and TIGIT. It could reverse Treg inhibition of T cells and NK cells, and kills tumor cells by restoring the function of T cells and NK cells. In non-clinical studies, ZGGS15 showed synergistic anti-tumor effects with the anti-PD-1 antibody. We conducted a Phase 1 dose escalation and expansion study to assess tolerability, safety, and efficacy of ZGGS15 as monotherapy in patients with advanced solid tumors. **Methods:** In the dose-escalation phase, a standard "3+3" design, with an accelerated titration for the starting dose. Total of 6 dose levels, from 0.3 to 30 (0.3, 1, 3, 10, 20, 30) mg/kg administered by the intravenous infusion, once every three weeks, in patients with advanced solid tumors who had failed to the available standard treatments. The first treatment cycle (21 days) was defined as the dose-limiting toxicity (DLT) observation period. The study assessments included tolerability, safety, preliminary efficacy, etc. and tumor responses were assessed by RECIST1.1 and iRECIST criteria. **Results:** As January 8 2025, a total of 22 patients (9 males and 13 females), with a median age of 59 years, participated in the dose escalation from 0.3 to 30 mg/kg and completed the DLT observation. Of the 22 patients, 11 (50.0%) received at least 3 prior lines of therapies, and eight (36.4%) had previously treated with PD-1 or PD-L1 inhibitors. No DLT events were observed. TRAEs occurred in 20 (90.1%) patients, with only one patient (4.5%) experienced a Grade 3 TRAE of lymphocyte count decreased, and no Grades 4 or 5 TRAEs were reported. Among the 17 patients who had at least one post-baseline tumor scan, six had achieved stable disease (SD) with a disease control rate (DCR) of 35.3%. In the subgroup of 8 patients with lung adenocarcinoma, 5 (62.5%) had achieved SD, including two patients who had $\geq$ 2 prior lines of treatments and maintained SD over 36 weeks. **Conclusions:** The results showed that ZGGS15 was well tolerated and had a very good safety profile. It is anticipated that when in combination with other anti-cancer therapies, e.g., an anti-PD-1 or PD-L1 antibody, for advanced solid tumors, ZGGS15 may provide synergistic anti-tumor effects and further enhance treatment benefits. Clinical trial information: NCT05864573. Research Sponsor: Suzhou Zelgen Biopharmaceuticals. Co., Ltd.

Adverse events profile of novel agents targeting immune checkpoints beyond PD-1/PD-L1 and CTLA-4 in solid tumors: A meta-analysis. First Author: Yu Fujiwara, Department of Medicine, Roswell Park Comprehensive Cancer Center, Buffalo, NY

Background: PD-1, PD-L1, and CTLA-4 blockade are standard therapies in multiple solid tumors, and novel agents targeting alternative co-stimulatory and co-inhibitory immune checkpoints are under development. Immune checkpoint inhibitors are well known to cause immune-related adverse events (irAEs) and multiple studies reported the accurate incidence of irAEs from PD-1, PD-L1, and CTLA-4 blockade. With the increasing investigation and anticipated approval of novel immunotherapy agents, understanding their toxicity profiles is critical. **Methods:** We systematically searched PubMed/MEDLINE, EMBASE, and Web of Science for clinical trials published up to December 1st, 2024. Studies evaluating the safety of agents targeting co-inhibitory checkpoints (B7-H3, CD47, TIGIT, LAG-3, and TIM-3) or co-stimulatory checkpoints (OX40, 4-1BB, CD27, ICOS, GITR, CD70, and CD40) in solid tumors were included. Incidence rates of grade 1-5 (G1-5) and grade 3-5 (G3-5) treatment-related adverse events (trAEs) and irAEs were extracted. Toxicity data were derived from phase 2 and 3 trials, as well as phase 1/2 trials with safety information reported at the recommended phase 2 dose. Random-effects meta-analysis was used to pool odds ratios (ORs) from two-arm studies evaluating the addition of LAG-3 or TIGIT blockade to control-arm therapy, and proportional meta-analysis was conducted to analyze AE incidence across immunotherapy subtypes. **Results:** A systematic review identified 27 clinical trials with 40 cohorts comprising 3,946 patients and evaluating 10 immune checkpoints (B7-H3, LAG-3, TIGIT, CD47, OX40, CD137. TIM-3, CD40, CD27, CD40, ICOS). Meta-analyses showed that the addition of LAG-3 blockade to either PD-1 blockade-based therapy or placebo was associated with increased G3-5 trAEs (OR 1.79, 95% confidence interval [CI]: 1.26–2.54, p = 0.001), G3-5 adrenal insufficiency (OR 8.43, 95% CI: 1.04 - 68.37, p = 0.046), G1-5 adrenal insufficiency (OR 4.81, 95% CI: 1.81-12.78, p = 0.002) and arthralgia (OR 2.07, 95% CI: 1.29-3.30, p = 0.002). The addition of TIGIT blockade to PD-L1 blockade-based therapy was associated with increased G1-5 rash (OR 2.32, 95% CI: 1.01–5.34, p = 0.048) (other outcomes will be shown). Proportional meta-analysis revealed varying irAE patterns across agents: G5 trAEs (0.9-2.9%), G3-5 pneumonitis (0.5-5.5%, highest in TIM-3 blockade), G3-5 colitis (0.2-5.4%, highest in LAG-3 blockade), G3-5 hepatitis (1.5-5.5%, highest in TIM-3 blockade), G3-5 rash (0.8%-18.4%, highest in CD40 agonists), G3-5 adrenal insufficiency (1.7-8.4%, highest in TIGIT blockade) (details of all outcomes will be presented). **Conclusions:** This study highlights the distinct toxicity profiles of novel immunotherapy agents, providing essential safety data to support clinicians as these therapies move toward anticipated clinical approval. Research Sponsor: None.

JAK inhibitor for the treatment of steroid refractory and life-threatening immune-related adverse events secondary to immune checkpoint inhibitors. First Author: Rami Habib, McGill University, Montreal, QC, Canada

Background: Immune checkpoint inhibitors (ICIs) boost anti-tumor immune responses but carry the risk of off-target effects, manifesting as immune-related adverse events (irAEs). Approximately 20% of irAEs are refractory to steroids, requiring subsequent immunosuppressive therapies, while a smaller subset presents with fulminant reactions requiring multiple agents simultaneously. Although biologics like TNF and IL-6 inhibitors are often used, their targeting of single inflammatory pathways may be insufficient to resolve irAEs in these critical scenarios. We conducted a prospective study to assess the safety and efficacy of oral JAK inhibitors, molecules capable of rapidly modulating multiple inflammatory cytokine signals, in managing steroid-refractory or life-threatening irAEs. **Methods:** The MIRAE Biobank is a prospective cohort study of cancer patients treated with ICI at the Jewish General Hospital in Montreal, Canada. Patients with steroid refractory subjects with grade $>$ 3 irAE or persistent grade 2 toxicity despite optimal therapy, as well as life-threatening irAEs in the first-line setting treated with JAK inhibitors were extracted from the database and their clinical data was summarized. Among those who survived at least 30 days post-JAK inhibitor, we compared characteristics of responders and non-responders. Responders were defined as resolution of the irAE to grade $<$ 1 and $<$ 10mg prednisone equivalents without any relapses during a 30-day period. **Results:** In this series, 29 patients were treated with JAK inhibitors for refractory or life-threatening irAEs. Mean age was 69 years, 34.5% were women, 82.8% received anti-programmed cell death protein-1 (PD-1) antibodies alone, and 13.8% patients were treated with the combination of anti-cytotoxic T lymphocyte antigen-4 and anti-PD-1 antibodies. Cancer types were primarily melanoma (10, 34.5%) and lung cancer (6, 20.7%). Primary irAEs for which JAK inhibitors were initiated included myocarditis (n=11), colitis (n=4), arthritis (n=4), hepatitis (n=4), encephalitis (n=2), pneumonitis (n=2), myasthenia gravis (n=1) and sicca (n=1). JAK inhibitors were used as second- (refractory to steroids alone), third- or fourth- or more line in 9, 11 and 9 patients, respectively. Median duration of JAK inhibitor exposure was 30.5 days. Among the 24 patients who survived at least 30 days, 17 (71%) responded after a median of 11 days from initiation of the JAK inhibitor. Interestingly, this included 6/8 patients with myocarditis, 4/4 with arthritis and 2/3 with colitis. Of those who responded to JAK inhibitor, 11/18 were steroid refractory and 6/6 were life-threatening cases requiring simultaneous treatment with steroids. **Conclusions:** This preliminary data suggests that JAK inhibitors may be effective at treating various types of steroid-refractory and life-threatening irAEs. Albumin-myosteatosis gauge as a prognostic biomarker in patients treated with immune checkpoint inhibitors. First Author: Taha Koray Sahin, Hacettepe University, Department of Medical Oncology, Ankara, Turkey

Background: Although immune checkpoint inhibitors (ICIs) have heralded a new era in cancer treatment, many patients do not respond, underscoring the need for biomarkers. The albumin-myosteatosis gauge (AMG) is a recently developed integrated measure of myosteatosis and serum albumin levels, reflecting systemic inflammation and malnutrition. Herein, we investigate the prognostic value of AMG in patients with advanced cancer treated with ICIs. **Methods:** A total of 308 patients with advanced cancer treated with ICIs were included. Skeletal muscle index (SMI) and skeletal muscle radiodensity (SMD) were measured from computed tomography images obtained at the level of the L3 vertebra. The AMG was calculated by multiplying SMD by albumin and expressed as an arbitrary unit (AU). Survival outcomes were assessed using Kaplan-Meier survival curves and Cox regression models. **Results:** The median age (interquartile range) was 63 (55-70), and 198 (64.3%) were male. Non-small cell lung cancer (NSCLC) was the most common primary cancer (28.2%), followed by renal cell carcinoma (RCC) (20.8%) and melanoma (20.2%). Regarding AMG, the cutoff values were determined to be 109.38 AU for males and 102.11 AU for females. Multivariable analyses revealed that lower AMG values were independently associated with decreased OS (HR: 1.43; 95% CI: 1.08-1.90; p=0.012) and PFS (HR: 1.39; 95% CI: 1.07-1.79; p=0.011) compared to the AMG high-group. **Conclusions:** Our findings suggest AMG, an easily accessible novel biomarker, is an independent prognostic factor for survival in patients with advanced cancer treated with ICIs. Prospective studies are required to validate these findings and evaluate the role of AMG measurement in aiding treatment choices. Research Sponsor: None.

Tumor flare reactions secondary to T-cell engaging immunotherapies: A study from the French REISAMIC registry. First Author: Alexandre Xu-Vuillard, Gustave Roussy, Villejuif, France

Background: Tumour flare reactions (TFR) were recently reported in patients receiving T-cell engagers (TCE) and require further investigations. This study aims to investigate incidence, predictive factors, and outcomes of pts with TFRs related to TCE. **Methods:** This observational cohort study is nested in the French academic pharmacovigilance register, Registre des Effets Indésirables Sévères des Anticorps Monoclonaux Immunomodulateurs en Cancérologie (REISAMIC, CNIL number 2098694v0). All patients treated at Gustave Roussy (France) with TCE, for all tumor indications except acute leukemia, were included. The main objectives were to determine the incidence, predictive factors, associated clinical and biomarker profiles, as well as the outcomes of patients. TFRs were clinically defined with transient worsening of tumor symptoms including tumor pain, effusions, or compressive symptoms, mimicking tumor growth but without reflecting disease progression. Statistical analyses included log-rank tests and Cox regression models. **Results:** Overall, 222 TCE-treated patients were included, median [range] age: 53 [5 - 87] years; male-to-female ratio: 1.44, median prior lines of therapies was 3 [2-9]. Of them, 147 (66.2%) had solid tumors, including prostate cancer (n=51), high-grade serous ovarian carcinoma (n=28), and small-cell lung cancer (n=24), and 75 (33.8%) had hematologic malignancies, primarily multiple myeloma (MM, n=35) and diffuse large B-cell lymphoma (DLBCL, n=31). Common TCE targets included CD3/CD20 (n=40), CD3/KLK2 (n=36), CD3/BCMA (n=35), CD3/DLL3 (n=28), and CD3/B7-H4 (n=27). TFRs occurred in 54 pts (24.3%), with higher TFR frequency in solid tumors (34.0%) than lymphomas (12.1%) and none in MM. Median TFR onset was 1 day [1–8]. Symptoms of TFRs were pain (92.6%), compression syndrome (22.2%), and effusion (7.4%). Severity of TFRs was grade 3–4 in 68.5% of cases. No TFR-related deaths occurred. TFRs management included corticosteroids (35.2%), opioids (61.1%), paracentesis (7.4%), JJ stenting (3.7%) and tocilizumab (3.7%). TFRs correlated with transient increases of CRP (182 vs. 69 mg/L; p=0.0002) and LDH (316 vs. 225 U/L; p=0.04). Patients with TFRs were more frequently exposed to cytokine release syndrome (p=0.0001). Predictors included tumor serous localization (p=0.052) and a higher CD4+/CD8+ ratio in blood (p=0.048). In solid tumors pts; TFRs were associated with higher response rates (18.0% vs. 6.3%; p=0.013) and disease control rates (72.0% vs. 49.5%); PFS (2.83 vs. 2.76 months; p=0.865) and OS (9.92 vs. 9.72 months; p=0.539) were comparable regardless of TFRs. **Conclusions:** TFRs related to TCE are clinically significant adverse events, primarily observed in solid tumor pts. TFRs may indicate a unique pattern of antitumor response distinct from progression. Better recognition and management of TFRs should help to optimize tolerability of TCE therapies. Evaluating the role of exercise in modulating immunity and immunotherapy outcomes in cancer: A systematic review. First Author: Samhitha Gundakaram, Joan C. Edwards School of Medicine, Marshall University, Huntington, WV

Background: Immunotherapy has become a key cancer treatment, improving survival and reducing side effects. However, its effectiveness can be influenced by immune system function, overall health, and treatment-related side effects. Exercise, known for its health benefits, may also modulate immune responses and enhance immunotherapy outcomes. Despite promising evidence, the impact of exercise on immune function and cancer treatment remains insufficiently understood. This review aims to assess the role of exercise in modulating immunity and improving immunotherapy outcomes in cancer patients. **Methods:** A systematic review was conducted following PRISMA guidelines, with a comprehensive search of PubMed, Cochrane Library, EMBASE, and ClinicalTrials.gov for studies published from 2010 to 2025. Eligible studies included randomized controlled trials (RCTs), non-randomized trials, pilot studies, and systematic reviews investigating exercise interventions on immune function and immunotherapy in cancer. Key outcomes included changes in immune markers, immune function, and quality of life. Data were extracted and analyzed using standardized protocols. **Results:** Eight studies, involving 1,172 cancer patients across various types (lymphoma, CLL, melanoma, NSCLC, breast, ovarian, prostate), were included. Exercise modalities studied included aerobic exercise, resistance training, cycling, yoga, and mind-body practices like qigong. Findings consistently showed positive effects of exercise on immune function and treatment outcomes. Two studies reported that exercise mobilized T cells and NK cells, enhancing immune responses. Another two demonstrated improved efficacy of immunotherapeutic agents such as rituximab. Additionally, three studies indicated that exercise improved physical fitness, body composition, and overall quality of life. **Conclusions:** This review provides evidence that exercise may enhance immune responses and improve outcomes in cancer immunotherapy. While exercise appears to be a beneficial adjunctive therapy, the optimal type, intensity, and duration remain unclear. Further large-scale, high-quality trials are needed to define effective exercise regimens and explore their impact on immunotherapy across various cancer types. The study is registered in PROSPERO: CRD42024627822. Research Sponsor: None.

Safety, pharmacokinetics (PK), pharmacodynamics (PD), and preliminary efficacy of HLX301, a bispecific antibody targeting PD-L1 and TIGIT, in patients with advanced solid tumors. First Author: Michelle Frances Morris, Sunshine Coast University Hospital, Birtinya, Australia

Background: Immune checkpoint proteins PD-L1 and TIGIT are important components of cancer-related T cell immunosuppression. HLX301 is a humanized, bispecific IgG1 antibody targeting PD-L1 and TIGIT that showed anti-tumor activity in preclinical studies. A phase 1/2 first-in-human study was conducted to evaluate HLX301 monotherapy in patients with advanced solid tumors (NCT05102214). Here we report findings from the dose escalation part (phase 1a). **Methods:** This multicenter study enrolled patients with locally advanced or metastatic solid tumors who had failed or were intolerant to standard therapy, or for whom no standard therapy was available. Phase 1a evaluated doses of 0.25-15 mg/kg IV Q2W. Primary endpoints included safety, dose-limiting toxicity (DLT), and maximum tolerated dose (MTD). Secondary endpoints included PK, PD, and immunogenicity. **Results:** As of Oct 27, 2023, 9 patients were enrolled (0.25 mg/kg, 3; 1 mg/kg, 3; 2.5 mg/kg, 1; 5 mg/kg, 2). Patients were all White, 55.6% female, median age 72.0 yrs; 88.9% had metastatic disease; all had ECOG PS of 0 (44.4%) or 1 (55.6%). All patients had prior systemic cancer treatment, including 3 (33.3%) treated with PD-(L)1 blockade; 5 (55.6%) patients had $\geq$ 4 prior lines of therapy. All patients were included in DLT, safety, and PK analyses. Median duration of HLX301 treatment was 10.3 weeks. One patient (11.1%) in the 5 mg/kg cohort reported DLT (grade 3 cytokine release syndrome [CRS]). MTD was not determined. All patients experienced at least one treatment-emergent adverse event (TEAE). TEAEs leading to death occurred in 3 (33.3%) patients, none of these adverse events (AEs) were related to HLX301. Six (66.7%) patients experienced at least one treatment-related adverse event (TRAE). TRAE of grade $\geq$ 3 was reported in 1 patient (11.1%; grade 3 CRS), who was also the only patient for whom TRAE led to treatment discontinuation. Treatment-related immune-related AEs occurred in 4 (44.4%) patients and treatment-related infusion-related reactions (IRRs) in 2 (22.2%). TRAEs occurring in $\geq$ 2 patients included IRR (22.2%) and arthralgia (22.2%). HLX301 exhibited linear PK over 0.25-5 mg/kg after single infusion and very limited accumulation after multiple infusions. Mean PD-L1 and TIGIT receptor occupancy in peripheral $CD3^+CD8^+$ cells reached saturation at 5 mg/kg. Anti-drug antibody was detected in 7 patients (77.8%). Among 8 efficacy-evaluable patients, 1 (5 mg/kg cohort) achieved partial response and 2 achieved stable disease; objective response rate and disease control rate per RECIST 1.1 were 12.5% and 37.5%, respectively. **Conclusions:** HLX301 showed an acceptable safety profile with preliminary anti-tumor activity. These findings could support further clinical investigation. Clinical trial information: NCT05102214. Research Sponsor: Shanghai Henlius Biotech, Inc.

Solid tumor–specific patterns of immune-related adverse events due to immune checkpoint inhibitor. First Author: Shabnam Eghbali, Vanderbilt University Medical Center, Nashville, TN

Background: Immune checkpoint inhibitors (ICIs) are the backbone of therapy for several solid tumors; however, they have a unique toxicity profile that may limit treatment. The objective of this systematic review was to identify differences in type and frequency of immune-related adverse events (irAEs) across solid tumors. **Methods:** Using PubMed, we identified registrational phase 2 and 3 clinical trials of ICI-based therapy (i.e., single agent immunotherapy (single I/O), single I/O plus chemotherapy, single I/O plus kinase inhibitor, double immunotherapy combination (double I/O), double I/O plus chemotherapy) for first-line and second-line unresectable disease for which irAEs (dermatologic, endocrine, gastrointestinal, hepatic, renal, pulmonary) were specified for the following tumor types: melanoma, non-small cell lung (NSCLC), esophageal, colorectal (CRC), biliary tract (BTC), hepatic (HCC), renal (RCC), urothelial, endometrial, head and neck (H&N). Odds ratio (OR) were used to analyze effect size. All analysis performed on Microsoft Excel. **Results:** 105 trials (n = 32,896 patients) were identified with the most commonly studied regimens being those that were PD-1 or PD-L1-based. While endocrinopathies were the most frequent irAE (~15-20%) with first-line single I/O, one tumor type was not more likely than the other to develop endocrinopathies. Interestingly, patients with melanoma and RCC treated with first-line single I/O were significantly more likely to develop gastrointestinal irAE compared to those with NSCLC, CRC, HCC, urothelial, and H&N with OR of 3.41 – 30.64 and 2.96 – 26.60, respectively. Second-line single I/O led to increased frequency of irAE and greater variation in the predominant irAE for a given tumor type – four tumor types (melanoma, NSCLC, gastric, H&N) had dermatologic irAE as most frequent, five (esophageal, CRC, HCC, urothelial, endometrial) had endocrine irAE, and two (BTC, RCC) had gastrointestinal irAE. Overall odds of developing irAE were greater with double I/O than with single I/O in the first-line setting and more pronounced in the second-line. For example, in melanoma, OR for endocrine irAE was 2.55 (95% CI 1.27 – 5.10) in first-line and 17.03 (95% CI 8.04 – 36.05) in second-line and for hepatic irAE was 4.41 (95% CI 1.55 – 12.50) in first-line and 7.63 (95% CI 2.45 – 23.78) in second-line. The addition of chemotherapy or kinase inhibitor did not significantly alter irAE frequency across tumor types. In fact, there were fewer irAEs in some tumor types with addition of kinase inhibitor in first-line unresectable disease compared to single I/O alone; for example, OR for dermatologic irAE with kinase inhibitor compared to single I/O alone was 0.36 (95% CI 0.18 – 0.70) for melanoma and 0.22 (95% CI 0.08 – 0.59) for RCC. **Conclusions:** irAE profiles vary across tumor type, treatment regimen, and line of therapy and do not necessarily correlate with the primary tumor site. Research Sponsor: None.

2649 Poster Session

Impact of immune checkpoint inhibitor (ICI)-associated autoimmune hemolytic anemia (AIHA) on mortality in cancer patients: A retrospective analysis. First Author: Haris Sohail, Charleston Area Medical Center, Charleston, WV

Background: Immune checkpoint inhibitors (ICIs) have revolutionized cancer treatment but can cause serious immune-related adverse events; including rare yet severe autoimmune hemolytic anemia (AIHA) . This study evaluates the impact of ICI-associated AIHA on mortality in patients with solid cancers. **Methods:** A retrospective analysis using the TriNetX database examined patients with solid cancers treated with ICIs. Patients were defined using ICD-10 codes and grouped into those who developed AIHA after ICI use and those who did not. Baseline characteristics, including cancer diagnosis, ICI medications, and comorbidities, were compared between groups using TriNetX's built-in t-tests and z-tests to calculate p-values. Confounding variables were adjusted with 1:1 propensity score matching. Primary outcomes were 30- and 60-day mortality; secondary outcomes included transfusions and hospitalizations. Outcomes were evaluated using measures of association, Kaplan-Meier log-rank tests, and a Cox proportional hazards model. **Results:** Among 106,388 ICI-treated patients, 352 developed AIHA. After matching (352 per group), the AIHA group had a significantly higher 30-day mortality (15.25% vs. 5.14%; OR 3.493, 95% CI: 1.898-5.803, $p < 0.0001$) and 60-day mortality (22.87% vs. 6.86%; OR 4.195, 95% CI: 2.479-6.54, $p < 0.001$). Transfusions (OR 4.085, 95% CI: 2.897-6.525, $p < 0.0001$) and hospitalizations (OR 1.865, 95% CI: 1.525-2.837, $p < 0.0001$) were also significantly higher in the AIHA group. Hazard ratios (HR) confirmed significant mortality risks in AIHA group at 30 days (HR: 3.16, 95% CI: 1.849-5.402, $p < 0.0001$) and 60 days (HR: 3.673, 95% CI: 2.324-5.805, $p < 0.0001$) (table 1). HRs for transfusion and hospitalization were 4.309 (95% CI: 2.975-6.241, $p < 0.0001$) and 2.049 (95% CI: 1.692-2.48, $p < 0.0001$), respectively. **Conclusions:** This study highlights the clinical impact of ICI-associated AIHA, which is linked to higher mortality at 30 and 60 days, as well as increased transfusion and hospitalization rates. Although rare, ICI-associated AIHA is a potentially fatal complication. Clinicians should maintain a high level of suspicion for AIHA in patients on ICIs, as early recognition and intervention may improve outcomes. Research Sponsor: None.

Primary Outcomes	HR	95 % Confidence Interval	P-Value
Mortality within 30-days*	3.16	(1.849,5.402)	< 0.0001
Mortality within 60-days*	3.673	(2.324,5.805)	< 0.0001
Transfusion	4.309	(2.975,6.241)	< 0.0001
Hospitalization or emergency services	2.049	(1.692,2.48)	< 0.0001

Improved survival with sodium-glucose cotransporter-2 inhibitors and immune checkpoint inhibitors in metastatic solid tumors. First Author: Sara Young, Division of Hematology and Oncology, University of Virginia, Charlottesville, VA

Background: Immune checkpoint inhibitors (ICI) are used in the first-line setting for the treatment of many advanced solid tumor malignancies. Patients with type 2 diabetes mellitus (T2DM) have decreased response rates to ICI, and poor glycemic control is associated with worse outcomes in patients with cancer. Further adjunctive therapies increasing the efficacy of ICI in these patients are needed. Sodium-glucose cotransporter-2 inhibitors (SGLT2i) have emerged as effective antihyperglycemic medications with concomitant cardiovascular benefits. SGLT2i have been approved by the Food and Drug Administration for use in patients with DM and congestive heart failure (CHF). Pre-clinical studies have demonstrated the potential benefit of SGLT2i in slowing tumor growth in-vitro and in-vivo; however, there is a lack of clinical data regarding SGLT2i use in patients with advanced malignancy receiving ICI. **Methods:** We performed a retrospective, matched cohort study of patients with stage IV malignancy and T2DM or CHF, who were treated with ICI using the Epic Cosmos dataset (2013–2024). Ten different solid tumor types, five ICI, and three SGLT2i were analyzed. Among 4,808 patients treated with ICI, 282 had at least one overlapping cycle of ICI and SGLT2i. 1:1 propensity score matching was conducted to balance baseline covariates including cancer type, comorbidities, age at diagnosis, and sex. Kaplan-Meier curves were generated to examine survival differences and Cox proportional hazards models were used to estimate hazard ratios (HR). The primary outcome was overall survival (OS) for the entire matched cohort and sub-groups by cancer, ICI, and SGLT2i types. **Results:** Patients who received ICI and SGLT2i had significantly improved OS compared to those who received ICI alone (HR = 0.62, 95% CI: 0.49-0.79). Among cancer types, significant improvements in survival were observed in patients with renal cell carcinoma (RCC, HR = 0.48, 95% CI: 0.27–0.84) and non-small cell lung cancer (NSCLC, HR = 0.60, 95% CI: 0.37–0.96). Among ICI types, ipilimumab + nivolumab (HR = 0.35, 95% CI: 0.15–0.79) and pembrolizumab (HR = 0.49, 95% CI: 0.32-0.74) showed a significant improvement in survival when used with SGLT2i. There was no statistically significant difference in OS amongst the three SGLT2i types. **Conclusions:** In this retrospective, matched cohort study we observed encouraging improvements in OS in patients with T2DM or CHF receiving SGLT2i in addition to ICI across multiple solid tumor types. Patients with RCC and NSCLC derived the greatest benefit. Patients treated with either ipilimumab + nivolumab or pembrolizumab had the best responses to therapy. SGLT2i may be beneficial as adjunctive therapies in patients with advanced malignancy receiving ICI. However, further prospective studies to validate our observations and determine potential underlying mechanisms are needed. Research Sponsor: None.

Prognostic value of host genetic variants determining Bifidobacterium abundance in the lactose metabolism pathway for immunotherapy efficacy. First Author: Wenhui Liu, The Second Xiangya Hospital of Central South University, Changsha, Hunan, China

Background: The potential predicative and therapeutic value of *Bifidobacterium* in immune checkpoint inhibitors (ICIs) treatment has been widely studied. However, the value of its genetic determinants on the prognosis of ICIs treatment remains unclear. **Methods:** we examined the associations of 11 single nucleotide polymorphisms (SNPs) located at host genes determining *Bifidobacterium* abundance with the outcomes of ICIs treatment in 370 eligible cancer patients. **Results:** Cox regression analysis revealed that rs3739020 TT carriers experienced significantly extended OS (*P*-value = 0.003, adjusted HR = 0.46, 95%CI = 0.27-0.77) compared with GG+TG carriers. The *LCT* haplotype analysis showed that the lactose poor metabolizers exhibited significantly poorer OS (*P*-value = 0.002, adjusted HR = 0.45, 95%CI = 0.27-0.74) than the extensive or intermediate metabolizers. In polygenic SNP analysis, the high galactose level carriers exhibited significantly prolonged OS (*P*-value = 0.007, adjusted HR = 0.32, 95%CI = 0.14-0.73) and progression-free survival (PFS, *P*-value = 0.001, adjusted HR = 0.45, 95%CI = 0.29-0.71). All the four SNPs and the *LCT* metabolic phenotype were not associated with the occurrence of overall immune-related adverse events (irAEs). Genetically predicted *Bifidobacterium* abundance was significantly associated with an increased abundance of lactose metabolism pathway (*P*-value = 0.012, Beta coefficient = 0.549). **Conclusions:** SNPs determining *Bifidobacterium* abundance in the lactose metabolism pathway have prognostic value for immunotherapy efficacy, and the lactose extensive and intermediate metabolizers exhibited better immunotherapy efficacy. Research Sponsor: National Natural Science Foundation of China; 82204534.

The details of *LCT* metabolic phenotypes and the associations of *LCT* metabolic phenotypes with overall survival.

Early peripheral Treg expansion after SBRT combined with low-dose radiotherapy to predict subsequent immune checkpoint inhibitor responses in patients with metastatic lung or gastrointestinal cancers. First Author: Byoung Hyuck Kim, Seoul National University College of Medicine, Smg-Snu Boramae Medical Center, Seoul, South Korea

Background: This study aims to explore the potential therapeutic advantages of combining stereotactic body radiation therapy (SBRT) and low-dose radiotherapy (LDRT) prior to immune checkpoint inhibitor (ICI) treatment for metastatic lung or gastrointestinal cancers, to induce an immune-favoring tumor microenvironment. **Methods:** Patients with metastatic cancer and three or more measurable lesions scheduled for ICI therapy were enrolled in this study. Treatment consisted of three SBRT doses of 8–10 Gy to the main target lesion and LDRT (2–3 Gy) for other lesions. Patients without evidence of disease progression within 6 months after the first dose of ICI were defined as responders, while others were classified as non-responders. Peripheral blood samples obtained before SBRT/LDRT (W0), 1 week after SBRT/LDRT but prior to ICI initiation (W1), and 4 weeks after SBRT/LDRT (W4) were analyzed using multi-color flow cytometry. This trial has been registered at cris.nih.go.kr (registration number: KCT0005879). **Results:** Among the 13 enrolled patients (lung 9, gastrointestinal 4), samples from 4 responders and 7 non-responders were analyzed initially, revealing a median progression-free survival of 22.2 months for responders and 3.1 months for non-responders. The fold change in the proportion of regulatory ($Foxp3^+CD25^+$) $CD4^+$ T cells (Tregs) among total $CD4^+$ T cells at W1 compared to W0 (Treg/CD4–$FC_{W1/W0}$) was lower in responders than in non-responders (0.66 vs. 1.22; $P = 0.08$). Furthermore, the fold change in the proportion of suppressive $Foxp3^{hi}CD45RA^+$ Tregs among Tregs at W1 compared to W0 (Fr.II/Treg–$FC_{W1/W0}$) was significantly lower in responders than in non-responders (0.80 vs. 1.18; $P = 0.047$). This difference was no longer evident after one cycle of ICI, as Treg/CD4–$FC_{W4/W0}$ (1.15 vs. 0.86; $P = 0.46$) and Fr.II/Treg–$FC_{W4/W0}$ (1.06 vs. 1.33; $P = 0.18$) were not significantly different between responders and non-responders. **Conclusions:** We investigated circulating T cell modulation and its potential as a biomarker which revealed early expansion of Tregs in peripheral blood after SBRT/LDRT is associated with suboptimal response to ICIs in patients with metastatic cancers. Clinical trial information: KCT0005879. Research Sponsor: None.

The impact of immunotherapy versus chemotherapy on mortality and adverse events in cancer patients hospitalized with septic shock. First Author: Saad Javaid, Charleston Area Medical Center, Charleston, WV

Background: Traditionally, chemotherapies have been associated with well-characterized toxicity profiles and adverse events. Meanwhile, immune checkpoint inhibitors (ICIs) have revolutionized cancer treatment, but their secondary toxicities, particularly in patients with septic shock, remain underexplored. Our study sought to evaluate the comparative risk of mortality and adverse events in patients treated with ICIs versus chemotherapy. **Methods:** Using the TriNetX Research Database, we identified cancer patients (≥18 years) diagnosed with septic shock between January 1, 2013, and December 16, 2024. Eligible cancers included malignancies of the oral cavity, pharynx, larynx, stomach, kidney, bladder, skin, head, neck, and lung. Patients treated with ICIs or chemotherapy within 6 weeks before or up to 2 weeks after septic shock diagnosis were stratified into two cohorts. Propensity score matching (1:1) adjusted for confounders. Kaplan-Meier log-rank tests analyzed outcomes. Primary outcomes were mortality at 30, 60, and 90 days. Secondary outcomes included irAEs, organ failure, and hospitalization or emergency services within 1 week to 1 month. **Results:** Through our study we identified 44,052 cancer patients diagnosed with septic shock. A total of 4,284 patients were on chemotherapy within the time of their diagnosis, while 472 patients were on ICIs. ICI use was associated with higher 30-day (HR: 1.27, 95% CI: 1.03-1.57, p = 0.02), and 90-day (HR: 1.21, 95%CI: 1.009-1.45, p = 0.03) mortality. But only a near significant difference was noted at 60-days (HR: 1.20, 95%CI: 0.99-1.45, p = 0.054). Additionally, the risk of organ failures (HR: 1.28, 95%CI: 1.11-1.48,p $<$ 0.001) and hospitalization or usage of emergency services (HR: 1.35, 95%CI: 1.16-1.56, p $<$ 0.001) was higher in patients treated with ICIs compared to chemotherapy. The frequency of irAEs was slightly higher in patients with ICIs, though these results were only near significant (HR: 1.155, 95%CI: 0.977-1.364, p = 0.0532). **Conclusions:** Cancer patients treated with ICIs with septic shock exhibited higher short-term mortality, organ failure rates, and hospitalization or emergency service usage compared to those receiving chemotherapy. These findings are unexpected, given the perceived safety profile of immunotherapy compared to traditional chemotherapy. Further research is warranted to better understand these risks and to develop strategies for mitigating adverse outcomes in this population. Research Sponsor: None.

Gut dysbiosis as a potential guide for immunotherapy (dis)continuation after 2 years in non-small cell lung cancer: A mono-institutional, multi-omic assessment. First Author: Lorenzo Belluomini, Section of Innovation Biomedicine - Oncology Area, Department of Engineering for Innovation Medicine (DIMI), University of Verona, Verona, Italy, Italy

Background: Although most phase II and III clinical trials have set the duration of immune checkpoint blockers (ICB) for advanced non-small cell lung cancer (NSCLC) at two years, there remains uncertainty regarding the feasibility and safety of discontinuing treatment after this period. Of note, gut microbial taxonomic profiling prior to starting immunotherapy shows promise as biomarker for predicting ICB response. Here, we recommend integrating multi-omics approaches over time (24 months -mo-) to inform clinical decision-making and guide personalized treatment strategies. **Methods:** Pts completing 18 to 24 mo of ICB treatment between July 2016 and January 2023 were identified and enrolled (NCT04567446) at Gustave Roussy. Clinical factors influencing treatment (dis)continuation were assessed at 24 mo. Multi-omic analyses, including gut-based biomarkers (TOPOSCORE by whole genome sequencing), PET-FDG imaging, and ctDNA, were proposed at this timepoint. Key outcomes, including overall survival (OS) and progression-free survival (PFS) rates, were analyzed. **Results:** Among 123 advanced NSCLC pts treated for ≥18 mo, 35 (28,5%) completed 24 mo, with 31 included in the analysis (4 excluded due to PD). Of these, 68% continued ICB, while 32% stopped between 23.5 and 29.7 mo, mainly based on the physician or the patient decision. Clinical characteristics were comparable between the 2 groups (Table 1). After a median follow-up of 59.1 mo, no significant OS and PFS differences were observed between pts who discontinued and those who continued (OS p=0.9012, PFS p=0.3715). Among the multi-omic assessments performed at 24 mo, only gut-based biomarkers appeared to be conditionally associated with PFS24 rates. The proportion of long-responders (progression-free at 24 mo) was higher among those with a favorable gut composition compared to those with harmful composition (81% vs 44%, respectively, p=0.0870). **Conclusions:** Our results suggest that multi-omics approaches may help safely discontinue ICB after two years of treatment. In this context, multi-institutional validation and the implementation of a translational multi-omic algorithm, including gut-based biomarkers, could provide insight into the optimal duration of ICB therapy beyond the predefined 24-mo period. Clinical trial information: NCT04567446. Research Sponsor: None.

Validation and refinement of Society of Immunotherapy of Cancer (SITC) definitions for PD-(L)1 resistance: An analysis of more than 1,300 participants from SWOG. First Author: Megan Othus, Fred Hutchinson Cancer Center, Seattle, WA

Background: New immuno-oncology (IO) agents are commonly used in patients who previously received PD-(L)1 inhibitors. In order to facilitate clinical trial interpretation and better delineate therapeutic contributions of novel IO agents, consensus definitions of PD-(L)1 single-agent and combination immunotherapy resistance were published in 2020 (PMC7174063) and 2022 (PMC10016305) by the Society of Immunotherapy of Cancer (SITC); definitions outlined in Table. Validation of these expert-derived definitions is currently lacking. Herein we analyze two SWOG trials to evaluate the proposed definitions for the advanced and adjuvant settings. **Methods:** S1609/DART (NCT02834013) was a basket trial for patients with rare cancers treated with ipilimumab (1mg/kg intravenously [IV] every 6 weeks) plus nivolumab (240mg IV every 2 weeks). S1404 (NCT02506153) included an arm where patients with high-risk resectable Stage III melanoma received adjuvant pembrolizumab (200mg IV every 3 weeks for 1 year). In both trials, overall survival (OS) was measured from study registration to death from any cause with those last known to be alive censored. OS was evaluated with Kaplan-Meier and martingale residual plots and Cox regression models. **Results:** In S1609 (advanced setting), 733 participants were analyzed: 127 (17%) were not evaluable for primary resistance due to death or off treatment before 6 weeks. Among the 570 evaluable, 366 met the SITC primary resistance definition and 204 did not. Martingale residuals plots indicated a positive association between time to progression and OS with no evidence of a threshold. With a 6-month landmark, participants with primary resistance had significantly shorter OS compared to those who did not: hazard ratio (HR)=2.84, 95% confidence interval (CI) 2.28-3.55, p$<$0.001. In S1404 (adjuvant setting), 626 participants were analyzed with 12 (2%) meeting the definition of early recurrence/primary resistance and 138 (22%) meeting the definition of late recurrence/secondary resistance. Using a 12-month landmark, there was no significant difference in OS between early and late recurrences (HR=0.98, 95% CI:0.35-2.70, p=0.25), however late recurrences were associated with significantly shorter OS than no recurrence (HR=7.69, 95% CI:2.71-20.1,p$<$0.001). **Conclusions:** In the advanced cancer cohort, the SITC definitions were validated. In the adjuvant cohort, early recurrences were uncommon and there was no significant difference in OS between early and late recurrences suggesting a 12-month cutoff may be more appropriate than 12 weeks. Additional analyses in other patient cohorts are needed to further understand if the SITC definitions for advanced cancers validate more broadly and if data-drive refinements are needed for the adjuvant setting. Research Sponsor: US National Cancer Institute; Bristol-Myers Squibb Company.

PhaseX: Patient tumor avatars for evaluating anticancer therapeutics. First Author: Kanishka Fernando, National University of Singapore, Singapore, Singapore

Background: Current preclinical tumor platforms, such as in vitro 2D cell cultures and organoid models, fail to fully recapitulate the complexity of the tumor microenvironment, including critical components like the extracellular matrix and immune interactions. While humanized patient-derived xenograft models address some of these limitations, they are costly, low-throughput, artificial, and technically challenging to establish. PhaseX (Patient-derived hydrogel-assisted eXplants) presents a robust alternative, preserving the native TME, including cellular diversity, gene expression, and immune landscapes, for at least seven days. This study utilizes PhaseX to assess patient-specific responses to immune checkpoint blockade (ICB), chemotherapeutics, and targeted therapies while providing insights into their mechanisms of action. **Methods:** Fifteen fresh patient-derived tumor explants (PDTEs) from HNSCC patients were embedded in bioengineered hydrogel and treated ex vivo with pembrolizumab. Supernatants were collected at 2 and 4 days post-treatment for immunoassay analysis. Tumor explants were either dissociated for high-dimensional flow cytometry or processed into FFPE sections for immunofluorescence analysis at 2 and 5 days. Additionally, ten PDTEs representing various cancer types (peritoneal, colorectal, sarcoma, lung and ovarian) were used to evaluate dose-dependent responses to commonly used chemotherapeutics, including cisplatin, doxorubicin, and erlotinib. Six PDTEs were treated with plasminogen activator inhibitor-1 (PAI-1), and their post-treatment metabolic activity was assessed using the resazurin cell viability assay. **Results:** This study highlights the importance of capturing temporal dynamics in ex vivo tumor models to accurately predict pembrolizumab responses, achieving 100% sensitivity and specificity in HNSCC patients. Increased IFN-γ secretion and upregulation of chemokines (CXCL9, CXCL10, CXCL11) distinguished responders, alongside elevated cytotoxicity markers (perforin, granulysin, sFasL, sFas) contributing to cancer cell death. Responders exhibited reduced terminally exhausted CD8+ T cells (PD-1$^+$TIM3$^+$), allowing reinvigoration of functional CD8+ T cells, while non-responders showed elevated Tox$^+$CD38$^+$ levels, indicating resistance to PD-1 blockade. Spatial analysis revealed greater T cell infiltration in responders, facilitating tumor-cell interactions. Additionally, the PhaseX platform demonstrated its utility in evaluating dose-dependent responses across multiple tumor types (sarcoma, colorectal, lung, cervical) and identified patient-specific responses to PAI-1 inhibition. **Conclusions:** The PhaseX platform accurately predicts patient-specific responses for ICB, chemotherapeutics and targeted therapy across multiple tumor types. These findings establish PhaseX as a valuable tumor platform to evaluate anticancer therapeutics. Research Sponsor: None.

Examining the relationship between multi-agent immunosuppressive therapy for immune-related adverse events (irAE) and infectious complications. First Author: Tristan Lee Lim, Mass General Cancer Center, Massachusetts General Hospital, Boston, MA

Background: Treatment of severe irAEs with multiple immunosuppressive therapies (ISTs) decreases the morbidity and mortality of these conditions. Nevertheless, the rates of and risk factors for infectious complications in this population are not known. **Methods:** We conducted a retrospective study of patients (pts) who received an immune checkpoint inhibitor (ICI) and experienced ≥1 irAE requiring treatment with corticosteroids along with at least two lines of steroid-sparing ISTs administered either concurrently or within 90 days of each other. We annotated all infections from ICI start until 90 days after IST. Opportunistic infections (OIs) were defined as herpesvirus (CMV, EBV, VZV, and HSV) and invasive fungal infections. Infection density was reported as number of infections per 1000 patient-days and graded as mild (not requiring treatment), moderate (requiring oral treatment), severe (requiring hospitalization or parenteral treatment), life threatening, or fatal. Risk factors were identified using univariable and multivariable Cox regression analysis adjusting for age at ICI initiation, sex, ICI regimen, ISTs, and steroid dose. **Results:** 175 pts (52% male, mean age: 66) with 238 irAEs and 417 ISTs were analyzed with a median follow-up of 367 days. The associated ICI regimens included αPD-1 (n = 81, 46%) and αPD-1/αCTLA-4 (n = 67, 38%). The most common irAEs were colitis (n = 67, 38%), hepatitis (n = 42, 24%), and myocarditis (n = 26, 15%). The most frequently used ISTs were mycophenolate mofetil (n = 92, 53%), infliximab (n = 77, 44%), and vedolizumab (n = 54, 31%). 103 pts (59%) developed 223 infections (median 2/pt, range: 1-8). 93 pts had 187 non-OIs. Of the 87 pts (50%) who had OI testing, 29 (33%) had 36 OIs, most commonly EBV DNAemia (n = 14, 16%) and CMV reactivation (n = 12, 14%). 6 pts had >1 OI, including 1 pt with CMV, EBV, and HSV. OI density significantly increased after starting ISTs for irAEs, but non-OI density was unchanged (Table 1). αCD20 use was associated with increased non-OI risk (HR: 10.58, 95% CI: 3.64-30.72, p < 0.001), while there was a trend towards increased non-OI risk with a max prednisone dose >100mg (HR: 1.74, 95% CI: 0.96-3.13, p = 0.07). In contrast, a max prednisone dose >100mg was associated with increased OI risk (HR: 2.89, 95% CI: 1.21-6.90, p = 0.017). 58 pts (33%) had severe or life-threatening infections, of whom 16 (9%) had OIs. 8 pts (5%) had fatal infections in this population. **Conclusions:** Use of multiple ISTs for severe irAEs is associated with increased rates of opportunistic infections as well as a 5% infection-related mortality rate. Patients requiring multiple lines of ISTs must be closely monitored for infectious complications, and prophylaxis should be considered when appropriate. Research Sponsor: None.

Mean OI and non-OI density per 1000 patient-days while on ICI alone vs ISTs.

	ICI	ISTs	p-value
OI	0.03	1.70	0.002
Non-OI	10.70	8.98	ns

Incidence and outcomes of immune checkpoint inhibitor (ICI) rechallenge after ICI pneumonitis: A single-center retrospective study. First Author: MacKenzie Adams, Brown University Health, Providence, RI

Background: Limited evidence is available on the safety and efficacy of immune checkpoint inhibitor (ICI) rechallenge following an immune-related adverse event (irAE). Pneumonitis is a potentially life-threatening irAE, and minimal data is available with regards to outcomes after rechallenge. In this single-center retrospective analysis we analyzed patients who developed ICI pneumonitis and were later rechallenged with an ICI to further investigate incidence patterns and outcomes. **Methods:** We conducted a manual chart review on a cohort of 69 patients with ICI pneumonitis at our institution from 2015 to 2024. Rechallenged cases were defined as any patient who developed ICI pneumonitis and were later trialed on the same or another ICI. Patient records were reviewed to identify demographics, clinical features, treatment, and outcomes. **Results:** Of 69 patients with ICI pneumonitis, we identified 19 that were rechallenged with an ICI. Of these, 10 were women and 9 were men. The average age was 64 years (range: 42-82). Most patients had lung cancer (42%, 8/19) followed by melanoma (32%, 6/19). The treatment intent was palliative for 74% of patients (14/19). The most common therapy was nivolumab (n = 15), however, pembrolizumab, atezolizumab, and durvalumab were also used. The initial grade of ICI pneumonitis was as follows: grade 1 (n = 2), grade 2 (n = 13), grade 3 (n = 3), and grade 4 (n = 1). Many of these patients were treated with steroids, with the average time on steroids being 136 days (range: 0-488). Additionally, the only grade 4 patient was also treated with infliximab due to steroid-refractory pneumonitis. After recovery from their pneumonitis, all patients, except for two, were rechallenged with the same ICI that they had originally been treated with. The average time to rechallenge was 149 days (range: 12-714). Ultimately, 6/19 (32%) patients had recurrent ICI pneumonitis after rechallenge, but all six eventually recovered. On grading ICI toxicity after recurrence, 60% (4/6) remained grade 2, one was downgraded from grade 3 to 2, and one escalated from grade 2 to 3. Eleven percent (2/19) of patients developed an irAE other than pneumonitis (e.g. colitis, arthritis) after rechallenge. Finally, none of the 19 patients died from complications associated with ICI therapy. **Conclusions:** The recurrence rate of ICI pneumonitis after ICI rechallenge was 32%. At initial presentation, most of these patients had lower grade (grade 1: 2/19, grade 2: 13/19) ICI pneumonitis and most cases of recurrent pneumonitis remained at their initial grade 2. These results indicate that resuming ICI therapy could be considered in select patients with mild to moderate pneumonitis. Further research is needed to investigate immunotherapy rechallenge as it remains a nuanced decision that involves assessing the potential benefits of continued tumor control against the risk of a life-threatening toxicities. Research Sponsor: None.

Clinical outcomes of patients with or without DNA repair pathway alterations by treatment type: The MD Anderson Cancer Center IMPACT 2 study. First Author: Jacopo Venturini, Investigational Cancer Therapeutics, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: DNA repair deficiency is common among tumors, and emerging data suggest that genomic instability is associated with response to immuno-oncology (IO) therapies (PMID 28630051). We evaluated patients with advanced metastatic cancer across tumor types, who were treated on the IMPACT2 study (NCT02152254) and analyzed their clinical outcomes by treatment type (anti-DNA damage repair [DDR] agents, IO, or other [non-IO, non-anti-DDR]). **Methods:** Patients had tumor biopsies followed by molecular profiling in a CLIA-certified lab. All cases were discussed at Molecular Tumor Board meetings. Patients were treated on early-phase clinical trials. Progression-free survival (PFS), overall response rate (ORR), and overall survival (OS) were compared by therapy type in patients with or without DDR/MMR mutations (DDR+). **Results:** Of 829 enrolled patients, 510 had molecular profiling and received anticancer therapy: 85 were DDR+ (PS 1, 75%; med. age, 59 yrs; males 56.5%; med prior therapies 4; PDL1+ 44.9%; TMB-H 18%,) and 425 DDR- (PS 1, 88%; med. age, 60 yrs; men 47%, med. No. prior therapies 3; PDL1+ 46%; TMB-H 6.5%). Results are shown in the Table. In patients with DDR mutations, IO was associated with a higher ORR compared with "other" treatments (p=0.044); and with longer PFS compared with anti-DDR therapies (p = 0.044); no difference was noted in OS by treatment type. In the DDR-neg group, IO was associated with longer PFS (p = 0.017), and longer OS (p = 0.0004) compared with anti-DDR therapy; OS was longer in the IO group compared with "other" treatments (p = 0.029) and in the "other" treatments group compared with anti-DDR agents (p=0.006). **Conclusions:** Our data indicate the complexity of assessing outcomes in patients with various tumor types and without DDR mutations. Further work is needed to develop predictive biomarkers for IO and anti-DDR agents. Clinical trial information: NCT02152254. Research Sponsor: Steven McKenzie's Endowment for Dr Tsimberidou's personalized medicined program; Katherine Russell Dixie Distinguished Endowed Professorship for Dr Tsimberidou; Jamie's Hope for Dr Tsimberidou's personalized medicined program; NIH National Cancer Institute award number P30 CA016672 (to The University of Texas MD Anderson Cancer Center).; Tempus, Inc. for the IMPACT 2 study; Foundation Medicine, Inc for the IMPACT 2 study.

MicroRNA-based signatures of early and late immune-related adverse events to anti-PD1 treatment. First Author: Joanne B. Weidhaas, University of California, Los Angeles, Los Angeles, CA

Background: Immune checkpoint inhibitors (ICIs) have transformed cancer treatment but are associated with toxicity in the form of immune-related adverse events (irAEs). We previously reported a genetic signature predicting anti-PD1 irAEs in a retrospective analysis of a heavily pretreated melanoma cohort, which validated in a pan-cancer cohort. Here we investigate the applicability of that signature in a prospectively collected cohort of GU, breast, and NSCLC cancer patients. We evaluated clinical and genetic differences between the original training set and this cohort and leveraged the expanded dataset to develop novel models for timing-specific anti-PD1 toxicity. **Methods:** We analyzed clinical and genetic differences in the melanoma training cohort (n=58) and the new cohort of patients, all treated with single agent anti-PD1/PDL1 therapy (n=137). Clinical and genetic differences were assessed using Fisher's exact test for categorical variables: pre-treatment, concurrent radiation, and SNP genotype across 165 loci. Kruskal-Wallis tests were used for age, toxicity timing, and severity of toxicity. Predictive genetic models were constructed using elastic net, random forest, and boosted tree algorithms and evaluated using leave-one-out cross-validation (LOOCV) metrics. Outcomes included cycle-specific toxicity (early ≤5 cycles, late ≥15 cycles). SNPs were pre-filtered for inclusion in genetic models using Fisher or Jonckheere-Terpstra p-values (<0.2) for relevance to outcomes. **Results:** The training and current cohort were different in their toxicity timing, with earlier toxicity onset in the new cohort (median 5 cycles vs. 20 cycles in melanoma, Kruskal p = 0.00018). Genetic analysis identified 12 significantly different SNP genotypes (Fisher p < 0.05) between cohorts, including mir146A rs2910164 (Fisher p = 0.0005). This SNP was associated with early toxicity overall and within data subsets. Refining our model to account for cycle-specific toxicity events significantly enhanced performance. For late toxicity (≥15 cycles), the refined model achieved a LOOCV AUC of 0.793 (genetics + clinical). A newly developed early toxicity model (≤5 cycles) using genetics alone demonstrated robust predictive accuracy with an AUC of 0.753. **Conclusions:** These findings emphasize the importance of defining clinical and genetic diversity in refining predictive models for anti-PD1/PDL1 outcomes. The development of an early toxicity model offers significant clinical utility. Next steps will be to use time to event (toxicity) versus cycle number. This study provides a foundation for the application of personalized genetic tools to predict the safety of ICIs for currently treated patient cohorts. Research Sponsor: U.S. National Institutes of Health; R01CA238998.

New LOOCV performance metrics in expanded PD1 data (n=234).

Outcome	Covariates	Sensitivity	Specificity	PPV	NPV	F1	AUC
Late Toxicity (>= 15 cycles)	SNPs + Clin	0.692	0.894	0.450	0.959	0.545	0.793
Early Toxicity (<=5 cycles)	SNPs Only	0.600	0.907	0.486	0.939	0.537	0.753

Overall survival according to timing of immune checkpoint inhibitors administration in patients with advanced cancer: Results from a large single-centre cohort analysis. First Author: Tommaso Bosetti, The Christie NHS Foundation Trust, Manchester, UK, United Kingdom

Background: Immune checkpoint inhibitors (ICIs) have revolutionised cancer treatment but are only effective in a subset of patients. Evidence of a circadian dependence of the immune system has led to retrospective studies which suggested that the time of day of ICIs infusion influences treatment response, with better outcomes for early treatment times. Previous studies are limited by small sample size and methodological bias. We performed a retrospective study in patients with advanced solid tumours treated with ICIs at a large tertiary cancer centre. **Methods:** Patients who received regimens comprising ICIs for advanced/metastatic disease between January 2018 and December 2023 were grouped according to whether they received ≥50% ("late group") or < 50% ("early group") of cycles after the median time of all treatments. The primary endpoint was overall survival (OS). Hazard ratios (HRs) for OS after multivariable adjustments for age, sex, Eastern Cooperative Oncology Group (ECOG) performance status, cancer type and treatment were estimated using Cox models with and without time-dependent variables that allowed for group (early vs. late) assignment to change after baseline. **Results:** 2631 patients with lung cancer (45%), melanoma (23%), renal carcinoma (18%), head and neck (9%) and urothelial cancer (5%) were included. The median age was 68.2 years and 1602 (61%) were men. The median follow up was 38 months. The median infusion time was 12:49h. Median OS was 13.1 (95% confidence interval [CI] 11.8-14.4) vs. 21.4 (95% CI 19.8-24.5) months for late and early group. The late group was associated with shorter OS compared to the early group on both the standard multivariate analysis (HR 1.48, 95% CI 1.33-1.63) and the time dependent Cox model (HR 1.30, 95% CI 1.16-1.44). The association was significant for most regimens with ICIs alone (n = 1886) and for ICIs plus tyrosine kinase inhibitors (n = 163). There was no difference for regimens comprising chemotherapy (n = 582). A sensitivity analysis based on exposure at 3 months showed no difference between the groups with the standard model (HR 1.09, 95% CI 0.98-1.20) and a higher risk of death for the late group with the time dependent model (HR 1.14, 95% CI 1.02-1.26). **Conclusions:** This study suggests a benefit in OS with early administration of ICIs with a large sample size and a time-dependent Cox model which reduces the risk of immortal time bias. These findings could have a major clinical impact after small changes in the way services are provided. Exclusive morning administration for all doses in the first 3 months could be a feasible approach to minimise complexity of treatment slot allocation. Research Sponsor: None.

The impact of lymphocyte count dynamics on the predictive value of tumor mutational burden (TMB) for immune checkpoint inhibitors (ICI) outcomes in patients (pts) with cancer. First Author: Mustafa Jamal Saleh, Dana-Farber Cancer Institute, Boston, MA

Background: TMB has become a reliable biomarker for ICI response in several cancer types, leading to the pan-cancer FDA approval of the PD-1 inhibitor pembrolizumab in tumors with a TMB ³10 mut/Mb. Lymphocyte count dynamics (lymphocyte stability LS) have been reported to be associated with both increased immune-related adverse events and improved overall survival (OS) on ICI. We aimed to investigate the role of LS as a risk stratification tool, in combination with TMB, in patients with cancer treated with ICIs. **Methods:** We identified 1215 pts from the Dana-Farber Cancer Institute, who had received ICI between 2015 and 2024. The change in relative blood lymphocyte counts was calculated between pre- (up to 30 days) and post-treatment (between 21 and 49 days). Lymphocyte counts were considered stable (LS ≥80%) if the drop in lymphocyte count did not exceed 20% after ICI-exposure. TMB was assessed from targeted panel sequencing and categorized into high and low, based on a cutoff of 10 mut/Mb. Overall survival was assessed using a multivariable Cox regression model, adjusting for several baseline characteristics. **Results:** The most prevalent cancer types were non-small cell lung cancer (n = 190), breast carcinoma (n = 160), glioma (n = 104), and melanoma (n = 100). Median TMB was 6.8 (IQR: 0–265.4). In total, 846 (69.6%) patients had LS (drop < 20%), while 369 (30.4%) did not. Higher TMB (≥10) and LS were both independently associated with better survival on ICI after adjusting for age, sex, tumor purity, line of therapy, ICI type and cancer type (HR 0.58, CI: 0.50–0.67; p < 0.001) and 0.75 (CI: 0.63–0.90; p = 0.002) respectively. Overall, patients with LS and high TMB demonstrated the longest median OS while the combination of unstable lymphocyte counts and low TMB was associated with the worst survival (Table). **Conclusions:** LS provides additional value, irrespective of TMB, in predicting response to ICI, suggesting distinct underlying immunological pathways. These findings emphasize the need for further research to validate LS and explore its integration into clinical decision-making in ICI-treated pts. Research Sponsor: None.

Results from multivariable Cox regression.

Groups	Median OS (mo)	N	HR	95% CI	P-value
Stable lymphocytes (LS ≥80%) & High TMB (Cutoff = 10)	34.27	245	Ref.	Ref.	Ref.
Stable (LS ≥80%) & Low TMB	18.99	601	1.3	1.04 - 1.63	0.019
Unstable (LS <80%) & High TMB	17.05	96	1.66	1.22 - 2.26	0.001
Unstable (LS <80%) & Low TMB	9.59	273	2.28	1.79 - 2.90	<0.001

Association of intestinal exfoliome and Prevotellaceae with toxicity and clinical outcome during immune-checkpoint blockade. First Author: Giacomo Vitali, MetaGenoPolis, INRAE, Paris-Saclay University, Jouy-En-Josas, France

Background: Immune-related adverse events (irAEs) are autoimmune side effects related to ICI, varying in severity, onset and organ involvement that may be hard to differentiate from non-irAEs. Some reports have demonstrated that gut microbiota (GM) plays a role in modulating the risk of AEs. In this study, we combine gut mamalian and microbial metagenomics sequencing (MGS) to explore the influence of GM on treatment response and risk of AEs. **Methods:** NCT04567446 allowed fecal MGS at baseline and longitudinally in patients (pts) with advanced non-small cell lung cancer (), renal cell carcinoma and bladder cancer treated with ICI alone (ICI cohort, n = 542pts) or in combination with chemotherapy (CT+ICI cohort, n = 122 pts) in France and Canada. Pts who experienced severe (≥ grade 3) irAEs after ICI+/-CT were compared to those who did not, using microbial MGS parameters (Shannon diversity, TOPOSCORE, PCoA and LEfSe). Multivariate Cox regression models to analyze factors influencing overall survival (OS) included microbiota composition and the host exfoliome (i.e., mammalian eukaryotic DNA read counts within stools). **Results:** Pts with severe irAEs (10%) presented a less diverse microbiome, a lower TOPOSCORE and a distinct microbial community compared to those without severe irAEs, showing an overabundance of several members of the *Prevotellaceae* family. Interestingly, CT+ICI pts who experienced severe irAEs had the most dysbiotic microbiome, characterized by a lower alpha-diversity and TOPOSCORE, dominated by oral taxa (*Ligilactobacillus salivarius)* and tolerogenic *Hungatella* spp. and *Enterocloster spp.* Among pts screened for exfoliation, 44% presented hstool mammalian DNA than healthy subjects, showed a GM enriched with pathobionts, including the *Enterocloster* genus, and exhibited worse OS (HR 1.212, p = 0.0135) in univariate and multivariate analyses (HR 1.18, p = 0.049). Although there was no significant correlation between toxicity and exfoliation, either in CT+ICI or ICI alone, pts enriched with Prevotellaceae family appeared to exhibit the highest levels of exfoliation. **Conclusions:** Host-microbial interactions influence immunity and therefore ICI prognosis and toxicity. We found Prevotellaceae members as potential biomarkers for ICI-related toxicity. The host exfoliome is an interesting parameter that may reflect gut fitness, requiring further investigation. Clinical trial information: NCT04567446. Research Sponsor: RHU IMMUNOLIFE, RHU LUMIERE.

A Bayesian population-based framework for detecting hyperprogressive disease on cancer immunotherapies. First Author: Madison Stoddard, Fractal Therapeutics, Lexington, MA

Background: Hyperprogressive Disease (HPD), defined as an unexpected treatment-induced rapid increase in tumor growth rate relative to the tumor burden pretreatment growth rate, has been reported in 9% of patients receiving immune checkpoint inhibitor (ICI) therapies (Champiat et al, Clin Cancer Res (2017)). The definition of HPD used in that work was an increase in the on-treatment "Tumor Growth Rate" (TGR) by a factor of 2 or greater over the pre-treatment TGR as calculated from three consecutive CT scans: pre-baseline, baseline and on-treatment. This method of directly calculating TGR from slopes between successive tumor measurements, however, does not consider uncertainty in the CT-assessed sum of diameters (SoD) of target lesions (~8% per Zhao et al, Radiology (2009)), nor prior knowledge of the distribution of responses under ICI treatment. We sought to develop and test a Bayesian approach to HPD detection and compare its receiver operating characteristics (ROC) to the published TGR ratio threshold of 2-fold as well as the TGR ratio considered as a continuous classifier of HPD. **Methods:** We represented the prior distribution of exponential TGR (eTGR) pre-treatment based on population modeling of historical data of untreated NSCLC tumor dynamics. We then calibrated the on-ICI-treatment prior distribution based on reported rates of HPD and tumor regression. Next, we developed a Bayesian parameter estimation system to take three successive SoD assessments to calculate a patient's posterior probability of being in a state of HPD, attenuated tumor growth (ATG) or tumor regression (REG). We then simulated a cohort of 1000 virtual patients (VPs) with known state and tested the ability of the Bayesian method, the TGR ratio method, and the TGR ratio > 2 method to correctly classify each VP. We additionally developed a user-friendly web-based prototype tool (https://deanbot1.shinyapps.io/GRICalc/) to solicit feedback from a potential future user community. **Results:** ROC analysis estimated the area under ROC curve (AUROC) to be 0.94 for the Bayesian method, a significant improvement in classification accuracy over the TGR ratio method (AUROC = 0.77) as well as better maximal sensitivity (Se) and specificity (Sp) than the TGR ratio > 2 method (Se = 80% & Sp = 90% vs Se = 90% & Sp = 40%). **Conclusions:** We have developed a Bayesian population-based methodology and prototyped a web-based tool which under simulated conditions consistently outperformed previous methods for detecting HPD. We believe that this approach, trained on a larger patient-level dataset, can potentially support and improve clinical management and decision-making for cancer patients taking immune checkpoint inhibitor therapies. Research Sponsor: None.

Safety outcomes of intravenous immunoglobulin (IVIG) in treatment of steroid-refractory immune-checkpoint inhibitor pneumonitis. First Author: Mary Metkus, Department of Medicine, Johns Hopkins University, Baltimore, MD

Background: Pneumonitis is a potentially severe adverse event of immune checkpoint inhibitors (ICIs). While the first line treatment for ICI pneumonitis is corticosteroids, there are subsets of patients who either fail to respond, deemed steroid-refractory, or who cannot be tapered off steroids, deemed steroid-dependent. In these patients, there is no clear consensus on the best approach to treatment. IVIG has emerged as a potentially efficacious treatment for its immunomodulatory effects. It is also less immunosuppressive than other potential therapies, which is beneficial in a population which respiratory infection could lead to rapid clinical decline. However, there are concerns about treatment safety, including volume overload, thrombosis, and renal injury, which can be devastating in a patient population with pre-existing respiratory compromise. In this study, we aimed to assess the safety of IVIG treatment in patients with steroid-refractory ICI pneumonitis. **Methods:** A retrospective review was conducted of patients with steroid-refractory ICI pneumonitis treated with IVIG at Johns Hopkins Hospital from 2018 to 2024. Patient characteristics, treatment features, disease severity, clinical outcomes, and development of adverse events post-IVIG including renal injury, volume overload, or thrombosis were evaluated. **Results:** A total of 31 patients were selected with steroid refractory pneumonitis treated with IVIG. Mean age at diagnosis was 68 (56-80). The most common primary tumor site was lung (n = 23) and majority of patients had stage IV malignancy (n = 19). 81% (25/31) had grade 3 or 4 pneumonitis at the time of IVIG therapy. In-hospital death occurred in 41% (13/31). Majority of in-hospital death was due to respiratory decompensation from pneumonitis and no deaths were directly related to complications of IVIG. Regarding adverse events, 9.68% (3/31) of patients developed a venous thromboembolism related to IVIG. 3.23% (1/31) developed acute kidney injury and 12.90% (4/31) developed hypervolemia in response to IVIG. **Conclusions:** IVIG was not associated with a high rate of toxicity when used in the treatment of steroid refractory ICI-pneumonitis. The increased in-hospital mortality indicates the severity of illness in this patient population. Despite this, IVIG-related adverse events were low overall. Although a small cohort, these results suggest a favorable safety profile and support further study to evaluate efficacy of IVIG as compared with other immunomodulatory agents. Research Sponsor: None.

Vedolizumab or infliximab: Treatment option in immune checkpoint inhibitor–induced colitis. First Author: Shreya Shambhavi, RWJBH Rutgers Health Community Medical Center, Toms River, NJ

Background: ICI use is linked to severe gastrointestinal (GI) immune-related adverse events (irAEs), which affect morbidity and mortality and often require treatment pauses. Among these, immune-mediated colitis (IMC)—primarily associated with CTLA-4 therapy—occurs in 5.7% to 39.1% of patients receiving CTLA-4 inhibitors and 0.7% to 31.6% of those receiving PD-1/PD-L1 inhibitors; combination therapy can raise this incidence to 40.4%. IMC symptoms range from mild diarrhea to severe colitis, typically requiring urgent intervention within six to eight weeks of immunotherapy to prevent complications such as colonic perforation or sepsis. Corticosteroids are the usual first-line treatment, with TNF-alpha inhibitors (e.g., infliximab) considered when patients do not improve after three to seven days. Vedolizumab, a gut-selective $\alpha4\beta7$ integrin antagonist that targets gastrointestinal-homing T-lymphocytes, offers an alternative approach. Both infliximab and vedolizumab—referred to as Selective Immunosuppressive Therapies (SITs)—have shown promise, though their distinct mechanisms have led to a lack of standardized protocols and reliance on provider discretion. This study compares infliximab, vedolizumab, and combined SITs (infliximab plus vedolizumab) in managing IMC, focusing on remission rates, recurrence, and improved steroid tapering success. **Methods:** A systematic search was conducted across the PubMed database. The Meta-Analysis was conducted using R version 4.4.1 to calculate odds ratios (ORs) and 95% confidence intervals (CIs). **Results:** A total of eight studies were included in the final analysis. In patients with immune checkpoint inhibitor–induced colitis, vedolizumab was associated with higher rates of colitis recurrence (OR = 0.32, 95% CI = 0.19–0.53) compared to infliximab. Patients receiving vedolizumab also had lower overall corticosteroid usage (mean difference in days: -18.29, 95% CI = -21.88 to -14.71) compared to infliximab recipients. There was no significant difference in remission rates between vedolizumab and infliximab monotherapy; however, higher remission was noted with combination therapy (vedolizumab plus infliximab) (OR = 0.40, 95% CI = 0.19–0.84) compared to infliximab monotherapy. **Conclusions:** Vedolizumab was associated with a higher recurrence rate of colitis but resulted in significantly lower corticosteroid usage compared with infliximab. Although remission rates were similar for both monotherapies, combination therapy (vedolizumab plus infliximab) demonstrated higher remission rates than infliximab alone. Research Sponsor: None.

TPS2668 Poster Session

A phase 1, first-in-human study of DS-2243, an HLA-A*02/NY-ESO–directed bispecific T-cell engager, in patients with advanced solid tumors. First Author: Sandra P. D'Angelo, Memorial Sloan Kettering Cancer Center, New York, NY

Background: NY-ESO-1 and LAGE-1 are homologous proteins commonly expressed in various malignancies but not in normal tissues other than the testis and placenta. Tumor types showing prevalent NY-ESO-1 and/or LAGE-1 expression include synovial sarcoma (SS), myxoid/round cell liposarcoma (MRCLS), non-small cell lung cancer (NSCLC), and urothelial carcinoma (UC). Both NY-ESO-1 and LAGE-1 undergo intracellular proteolytic processing to generate the same highly immunogenic 9-mer NY-ESO peptide (SLLMWITQC), which is presented on the cell surface in association with HLA-A*02 major histocompatibility complex molecules. DS-2243 is a bispecific antibody and T-cell engager with an effectorless Fc region. It is designed to target HLA-A*02/NY-ESO peptide complexes on tumor cells and specific molecules on T-cells, redirecting T-cell–mediated cytotoxicity toward the tumor. **Methods:** DS2243-054(NCT06644755) is a Phase 1, first-in-human, open-label, multicenter, 2-part, dose-escalation and -expansion trial of DS-2243. Patients must be $\geq$18 years of age and have HLA-A*02-positive advanced or metastatic SS, MRCLS, squamous or adenocarcinoma NSCLC, or UC, and be unable to tolerate standard treatments, or have relapsed disease after or be refractory to such treatment. Patients with NSCLC or UC in dose escalation and all patients in dose expansion must have NY-ESO protein expression confirmed in tumor tissue by immunohistochemistry in a central laboratory. Further inclusion criteria include the presence of $\geq$1 measurable lesion per Response Evaluation Criteria in Solid Tumours, version 1.1 (RECIST 1.1) and Eastern Cooperative Oncology Group performance status of 0 or 1. The primary objective of dose escalation is to evaluate the safety and tolerability of DS-2243 and determine the maximum tolerated dose and/or recommended dose for expansion (RDE). The dose-expansion part includes 4 cohorts defined by tumor type—SS/MRCLS, squamous NSCLC, adenocarcinoma NSCLC, and UC—in which patients receive DS-2243 at the RDE. The primary objectives of dose expansion are to evaluate safety and determine the objective response rate (ORR) assessed by the investigator per RECIST 1.1. Safety endpoints include dose-limiting toxicities (dose escalation only) and treatment-emergent adverse events. Secondary outcome measures include ORR (dose escalation only), time to response, duration of response, progression-free survival (all assessed by the investigator per RECIST 1.1), and overall survival. The planned sample size is ~150 patients; enrollment is ongoing. Clinical trial information: NCT06644755. Research Sponsor: Daiichi Sankyo, Inc.

TPS2669 Poster Session

Phase 2 expansions of OR502, an antibody targeting leukocyte immunoglobulin-like receptor B2 (LILRB2) ± cemiplimab in patients with advanced solid tumors. First Author: Mohamad Adham Salkeni, Virginia Cancer Specialists, Fairfax, VA

Background: LILRB2 is an inhibitory receptor expressed on myeloid cells, including tumor-associated macrophages, which binds to HLA-class I proteins and is associated with poor outcomes in multiple cancers. OR502 is a humanized immunoglobulin G1 antibody that blocks LILRB2 binding to HLA-class I proteins. Preclinically, OR502 has demonstrated best-in-class reversal and prevention of myeloid cell-mediated immune suppression and restoration of T cell functions. Using OR502 to tackle immunosuppression and improve T cell-mediated responses in the tumor microenvironment (TME) is a rational for combination with checkpoint inhibitors. **Methods:** This is an ongoing, first-in-human, Phase 1-2 study of OR502 $\pm$ cemiplimab in patients with advanced solid tumors (NCT06090266). The primary objectives are to evaluate the safety/tolerability and identify a dose for further clinical development. Secondary objectives include assessment of pharmacokinetics (PK), immunogenicity and anti-tumor activity. We are also assessing the effects of OR502 on the TME and associations between response and pharmacodynamic (PD) markers. Dose escalation enrolled 39 patients at OR502 doses of 100–1600 mg, once every 3 weeks (Q3W) $\pm$ standard dose cemiplimab (350 mg), using a modified toxicity probability interval-2 design. As dose escalation completed, it became clear that to satisfy the FDA's Project Optimus, adaptations were needed to provide dose-response proof and identify the minimal effective dose before proceeding with development. The protocol's adaptive elements, in conjunction with Safety Committee oversight, enabled modifications without amendment. Prior to dose-response optimization, we adapted the design in order to explore the efficacy signals from phase 1, specifically in patients with melanoma and NSCLC. Based on efficacy signals and excellent safety, PK and PD results, we selected OR502 800 mg Q3W for both expansion cohorts. Two new mini-expansion cohorts are now actively recruiting 10–20 patients each: monotherapy in patients with cutaneous melanoma and combination in patients with NSCLC. The sample size was chosen pragmatically, to exclude a response rate of ~ 10%, with a target of ~ 35%. If $<$ 2 responses are seen in the first 10 patients, the cohort will be discontinued. All patients must have a histological diagnosis of measurable disease that has progressed with $\geq$ 2 lines of treatment, $\geq$ 12 weeks of prior PD-(L)1-based therapy, resolved prior toxicity with a 2–4 week washout, adequate organ function, ECOG $\leq$ 2, and no significant ascites, pleural effusion or CNS metastases, recent infections or autoimmune disease requiring steroids or immunosuppressants. Cycles 1 and 3 include serial PK sampling, while Cycles 2, 4 and beyond require only one visit on Day 1. Efficacy is assessed Q6W for 1 year, then Q6 months. Safety follow-up at end of treatment is at 120 days. Clinical trial information: NCT06090266. Research Sponsor: OncoResponse, Inc.; The Cancer Prevention and Research Institute of Texas.

TPS2670 **Poster Session**

A phase 1/2a, multicenter, first-in-human, open-label clinical trial evaluating MDX2001, a tetraspecific T cell engager-expander in patients with advanced solid tumors. First Author: Ecaterina Elena Dumbrava, Department of Investigational Cancer Therapeutics, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: MDX2001 is a multispecific antibody recognizing CD3 and CD28 on T cells, and c-MET and TROP2 on tumors. Anti-CD3 provides the primary signal for T cell activation; anti-CD28 delivers the secondary signal for enhanced T cell activation, survival, and proliferation. Combinatorial targeting of c-MET and TROP2 by MDX2001, either on the same or different cancer cells, provides more effective engagement on tumor cells, and may better address tumor heterogenicity and the development of resistance due to antigen downregulation. *In vitro* and *in vivo* studies with MDX2001 demonstrate potent antitumor activity with no CD28-superagonist activity and minimal T cell activation in the absence of tumor cells. **Methods:** This Phase 1/2a, multicenter, first-in-human, open-label clinical trial explores intravenous MDX2001 in patients with advanced solid tumors (NCT06239194). The study design consists of Phase 1a dose escalation guided by a Bayesian Optimal Interval design with a target maximum tolerated dose toxicity rate of 30%, Phase 1b dose expansion, and Phase 2a indication expansion. Patients with non-small cell lung, renal cell, prostate, breast cancer and 10 other selected tumors known to have significant levels of TROP2 or c-MET expression are eligible for Phase 1a. In Phase 1b, patients will be randomized into 2 dose cohorts using a Bayesian Optimal Phase 2 (BOP2) design. Once a recommended Phase 2 dose (RP2D) is determined, Phase 2a will enroll patients in search of initial efficacy signals using a BOP2 design. The primary objectives of this study are to characterize the safety, tolerability, and anti-tumor activity of MDX2001 in patients with advanced solid tumors. Secondary endpoints include time to response, disease control rate, duration of response, pharmacokinetics, immunogenicity and evaluation of the relationship between baseline tumor target protein expression and clinical benefit. Patients will have radiologic tumor assessments every 8 weeks and will continue to receive treatment until disease progression per RECIST v1.1 (as assessed by the investigator), unacceptable toxicity, withdrawal of consent, another protocol-defined discontinuation criterion is met, or the sponsor terminates the study, whichever occurs first. The study will be conducted in United States, Europe, and Asia. Recruitment is ongoing. Clinical trial information: NCT06239194. Research Sponsor: None.

TPS2671 **Poster Session**

ARC101-P1-101: A first-in-human phase 1 study of ARC101, a next generation T cell engager (TCE), in patients with advanced solid tumors. First Author: Prachi Bhave, Peter MacCallum Cancer Centre, The University of Melbourne, Melbourne, VIC, Australia

Background: T-cell Engagers (TCEs) are emerging as a promising immuno-therapeutic modality in the treatment of solid tumors, demonstrating outstanding potency and a manageable safety profile. Claudin 6 (CLDN6) is an oncofetal protein that has recently emerged as a particularly attractive tumor-associated antigen (TAA) for TCE therapy because of its highly tumor-restricted pattern of expression. ARC101 is a bispecific antibody that targets CLDN6 on tumor cells with high specificity and selectivity, and CD3 on T cells. In pre-clinical models, ARC101 demonstrated potent cytolytic activity at low concentrations against a panel of CLDN6-expressing tumor cells in vitro and an ovarian cancer xenograft in vivo. **Methods:** First-in-human, multicenter, phase 1 study ARC101-P1-101 (NCT06672185) aims to determine the optimal dosing, safety, pharmacokinetics (PK), pharmacodynamics (PD), and preliminary antitumor efficacy of ARC101 as monotherapy in patients with locally advanced or metastatic CLDN6 expressing solid tumors. The study will be conducted according to the Bayesian Optimal Interval (BOIN) design in two parts: Part 1 (dose escalation) and Part 2 (dose expansion). Part 1 is designed to select the Maximum Tolerated Dose (MTD), Recommended-Phase 2-Dose (RP2D) and dosing schedule of ARC101. Part 1 will start with an 'Accelerated Titration Phase', with cohorts of at least one, but no more than three patients and a fixed dose, intravenous regimen. Once a single event of clinically significant toxicity of Grade $\geq$2 occurs, the 'Standard Titration Phase' will be initiated with cohorts of at least three patients per ARC101 target dose level. Once immune-related toxicity is observed, the regimen may be changed to a 'Fractionated Step-up Dosing' IV regimen. The study design allows for backfill cohorts and intra-patient dose escalations. Part 2 will further explore the safety, PK/PD characteristics, and preliminary efficacy of ARC101 administered at the RP2D and schedule identified in Part 1 in patients with testicular and ovarian cancer. Key eligibility criteria include patients with any advanced or refractory solid tumor malignancy that expresses CLDN6 and is metastatic or unresectable. Patients must be $\geq$18 years of age and have Eastern Cooperative Oncology Group (ECOG) performance status 0 or 1. Patients must have received standard therapy for advanced or metastatic disease, and disease must be measurable per Response Criteria in Solid Tumors (RECIST) v1.1 or evaluable. Mandatory requirement of a pre-study tumour sample for IHC analysis will facilitate the exploratory objective of biomarker analysis, including correlating CLDN6 expression with treatment response. The study is actively enrolling participants for the dose escalation phase. Contact clinicaltrials@thirdarcbio for additional information. Clinical trial information: NCT06672185. Research Sponsor: None.

TPS2672 **Poster Session**

EGL-121, a first-in-human phase 1/2 trial of EGL-001 in adult patients with selected advanced and/or metastatic solid tumors. First Author: Thiziri Nait Achour, EGLE Therapeutics, Suresnes, France

Background: Regulatory T cells (Tregs) play a key role in the resistance to immune checkpoint inhibitors therapy (ICI). Disarming Tregs could therefore restore/enhance anti-tumor responses and increase the number of patients benefiting from these treatments. EGL-001, a novel therapeutic agent, is designed to provide checkpoint inhibition by antagonizing the CTLA-4-CD80/86 interaction while selectively depleting intratumoral Tregs by downregulating CD25 and inhibiting IL-2 signaling specifically within these cells. This dual mechanism of action effectively unleashes potent anti-tumor immunity even in anti-PD-1 resistant models, independent of FcgR activity. In murine models, EGL-001 shows preferential distribution and persistence in the tumor until Treg get depleted/inactivated. Our data demonstrated complete anti-tumor activity of EGL-001 as a single agent across various tumor models and it overcomes resistance to anti-PD-1 treatment in many tumor models, highlighting its broad therapeutic potential. Additionally, EGL-001 effectively depletes Tregs and exhibits activity in ex-vivo human tumor samples, where other ICI showed no significant effect. In NHPs, EGL-001 was well tolerated across all tested doses, with rapid peripheral clearance preventing lymphoid tissue hyperplasia in the spleen and lymph nodes. **Methods:** A Phase I/II clinical trial (NCT06622486) is currently underway in eight sites in France and Spain to evaluate EGL-001 as monotherapy and in combination with checkpoint inhibitors in selected tumor types characterized by tumor Treg implication in induction of mechanism of resistance to ICI. The selective targeting of tumor-infiltrating Tregs could effectively improve anti-tumor immune response and limit systemic immune-related toxicities. This first-in-human, multicenter, open label Phase 1/2 study evaluates the safety, tolerability, and initial activity of EGL-001 in adult patients with selected advanced and/or metastatic solid tumors. The study consists of a Part 1 (Phase 1) dose escalation of EGL-001 administered as a single agent (from 0.3 mg/kg to 12 mg/kg), and in combination with pembrolizumab treatment, according to a BOIN design, followed by a Part 2 (Phase 2) dose expansion of EGL-001 administered at the selected doses as monotherapy and/or in combination therapy with anti-PD(L)1. Eligible patients are those who have initially benefited (secondary resistance) from an ICI treatment as monotherapy or in combination as SoC as defined by a CR, PR, or SD $\geq$3 months as best response by RECIST Version 1.1. As of January 2025, the first 3 Cohorts of EGL-001 (0.03, 0.1, 0.3 mg/kg) have been completed. EGL-001 was well tolerated with no DLTs reported. Clinical trial information: NCT06622486. Research Sponsor: None.

TPS2673 **Poster Session**

SUPRAME: A phase 3 trial comparing IMA203, an engineered T-cell receptor expressing T cell therapy (TCR-T) vs investigator's choice in patients with previously treated advanced cutaneous melanoma. First Author: Jason J. Luke, University of Pittsburgh, Pittsburgh, PA

Background: Frequent recurrence and limited long-term survival in unresected or metastatic melanoma after relapse from 1L treatment with a checkpoint inhibitor (CPI) highlight the critical need for new therapies that deliver deeper, more durable responses (Knight *Cancers* 2023; Switzer *JCO Oncol Pract* 2022). ACTengine IMA203 is an autologous T cell receptor (TCR)-engineered T cell therapy (TCR-T) targeting PRAME, an intracellular protein displayed as peptide antigen at high density on the surface of multiple solid tumors, including melanoma. IMA203 TCR-T demonstrated a favorable tolerability profile and durable objective responses in heavily-pretreated patients with different tumor types. In melanoma, IMA203 showed 54% confirmed ORR (14/26), 12.1 months mDOR and 6 months mPFS. mOS was not reached at a mFU of 8.6 months (Wermke et al., SMR, Oct 10, 2024). Based on these observations, a registration-enabling randomized phase 3 trial, SUPRAME, was initiated to evaluate IMA203 in 2L patients with advanced cutaneous melanoma after treatment with a CPI. **Methods:** SUPRAME (NCT06743126) is a phase 3, multicenter, open-label, randomized, actively controlled, parallel-group trial that will evaluate the efficacy, safety and tolerability of IMA203 compared to investigator's choice of treatment in patients with previously treated, unresectable or metastatic cutaneous melanoma (incl. acral melanoma). Eligible patients are $\geq$18yo, HLA-A*02:01-positive, with measurable disease (RECIST v1.1), ECOG PS of 0-1 and disease progression on or after at least one PD-1 inhibitor. Patients with BRAF mutation should have been treated with one prior line of BRAF-directed therapy ($\pm$ MEK inhibitor) prior to initial eligibility assessment. Patients with asymptomatic stable brain or leptomeningeal metastases will be assessed for eligibility. Patients with active brain metastases or with primary mucosal, uveal melanoma and melanoma of unknown primary are excluded. The study will randomize ~360 patients 1:1. Patients in the experimental arm will undergo leukapheresis to generate the PRAME-specific TCR-T product, IMA203. Following lymphodepletion with cyclophosphamide (500 mg/m^2 x 4 days) and fludarabine (30 mg/m^2 x 4 days), 1-10x10^9 IMA203 TCR-T cells will be administered, followed by low-dose IL-2 (1mio IU daily x5 days, twice daily x5 days). Patients in the control arm will receive approved investigator's choice of standard treatment (nivolumab/relatlimab, nivolumab, ipilimumab, pembrolizumab, lifileucel (US), chemotherapy). The primary efficacy endpoint is BICR-assessed (RECIST v1.1) PFS. Secondary endpoints include OS, ORR, safety and patient-reported outcomes (EORTC QLQ-C30, EQ-5D-5L). The trial will enroll patients in the US and Europe. Clinical trial information: NCT06743126. Research Sponsor: None.

TPS2674 **Poster Session**

Autologous tumor-infiltrating lymphocytes (HS-IT101) with low-dose lymphodepletion and IL-2 infusion for the treatment of advanced solid tumors: A phase I clinical trial. First Author: Ning Li, Department of Clinical Trial Center, National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China

Background: Adoptive cell therapy with tumor-infiltrating lymphocytes (TIL-ACT) has demonstrated great therapeutic potential in numerous solid tumors and has become an effective treatment for melanoma. However, high-dose lymphodepletion chemotherapy and IL-2 infusion during the treatment could cause serious safety risks, even death. The purpose of this study is to develop a TIL cell therapy product (HS-IT101) that requires low-dose lymphodepletion and IL-2 infusion to reduce safety risks and to improve clinical accessibility. Currently, the Phase I clinical trial (NCT06342336) for the treatment of advanced solid tumors with HS-IT101 has been initiated. **Methods:** HS-IT101 is an autologous non-genetically modified TIL-ACT product independently developed by Sino-cell Biomed. The tumor tissue of culture require is $\geq$0.05g, and the manufacture time needed is 14 days. This study is a single-arm, multi-center, open-label Phase I clinical trial of HS-IT101 for advanced solid tumors. The plan is to enroll 20 - 44 patients to explore the safety and preliminary efficacy under low-dose lymphodepletion and IL-2 infusion. Before HS-IT101 infusion, subjects will receive lymphodepletion chemotherapy consisting of cyclophosphamide (Cy) and fludarabine (Flu) for 3 - 4 days (Cy: 900/2250mg/m^2 & Flu: 90/120mg/m^2). After HS-IT101 infusion, 1/2MIU/m^2 of IL-2 will be subcutaneously injected once a day for a maximum of 3 doses. The primary endpoint is the occurrence of adverse events (AE) and serious adverse events (SAE) after HS-IT101 infusion. The secondary endpoints include the objective response rate (ORR), disease control rate (DCR), time to response (TTR), duration of response (DOR), progression-free survival (PFS), overall survival (OS) in efficacy evaluation, and changes in relevant pharmacokinetic (PK) indicators. The exploratory endpoint is the change in pharmacodynamic (PD) indicators. Clinical trial information: CTR20234065. Research Sponsor: Qingdao Sino-Cell Biomedicine Co., Ltd.

TPS2675 **Poster Session**

A phase 1/2 study of KSQ-004EX: Autologous tumor infiltrating lymphocytes, engineered to inactivate genes encoding SOCS1 and Regnase-1, in patients with select advanced solid tumors. First Author: Rodabe Navroze Amaria, The University of Texas MD Anderson Cancer Center, Melanoma Medical Oncology, Houston, TX

Background: The effectiveness and durability of TIL therapy may be limited by the immunosuppressive tumor microenvironment and baseline functionality of transferred T cells. Through KSQ Therapeutics' CRISPR^2 platform, a novel method for screening optimal combinatorial targets for enhancing T cell anti-tumor efficacy in vivo, SOCS1 and Regnase-1 were identified as the most potent gene editing combination. KSQ-004EX, an engineered TIL product with CRISPR/Cas9 mediated dual-inactivation of SOCS1 and Regnase-1, is anticipated to in enhance T cell tumor infiltration, persistence, and efficacy. This first-in-human clinical study (NCT06598371) evaluates KSQ-004EX in patients with melanoma, non-small cell lung cancer (NSCLC), head and neck squamous cell carcinoma (HNSCC), colorectal carcinoma (CRC), pancreatic cancer, and cervical cancer. **Methods:** The phase 1/2, single-arm, open-label study will assess the safety, tolerability, and efficacy of KSQ-004EX in patients with select advanced solid tumors. Patients with melanoma, NSCLC, HNSCC, CRC, pancreatic, and cervical cancer who have progressed following treatment with 1 to 3 lines of prior standard therapy including standard directed therapy (as applicable), are eligible. KSQ-004EX is manufactured from the patient's tumor, which is collected through surgical resection or core needle biopsy. All patients must have at least 1 measurable lesion following resection. Patients receive lymphodepleting chemotherapy with cyclophosphamide and fludarabine prior to KSQ-004EX infusion. Patients in the initial dose escalation cohorts do not receive dosing with IL-2; IL-2 dosing may be included in subsequent cohorts. Approximately 6 patients will be enrolled in Phase 1 dose escalation, in escalating dose levels. The primary objective of Phase 1 is to evaluate the safety and tolerability of KSQ-004EX. In Phase 2, patients will be enrolled in indication-specific cohorts. The primary objective of Phase 2 is to assess the anti-tumor activity of KSQ-004EX in patients with advanced solid tumors by ORR per RECIST v1.1. This is currently a single-institution study that is actively enrolling/recruiting patients. Clinical trial information: NCT06598371. Research Sponsor: KSQ Therapeutics, Inc.

TPS2676 **Poster Session**

A phase 1, first-in-human study of IB-T101, an OUTLAST CAR-T product for the treatment of CD70-positive clear cell renal carcinoma. First Author: Matthias Schroff, Inceptor Bio, Morrisville, NC

Background: Relapsed or treatment-resistant clear cell renal cell carcinoma (ccRCC) poses a significant, unmet medical challenge, as patients contend with scarce therapeutic alternatives and unfavorable clinical prognoses. CD70 is expressed in the majority of ccRCC and presents an attractive target for chimeric antigen receptor T cell (CAR-T) therapy. IB-T101, an autologous CAR-T expanded under OUTLAST conditioning, targets CD70 for the treatment of ccRCC. OUTLAST conditioning has been demonstrated to result in CAR-T cells that exhibit an early memory T cell phenotype, are resistant to suppressive signals from the tumor microenvironment, and exhibit increased persistence. The effects of OUTLAST conditioning are expected to lead to superior clinical outcomes for IB-T101 CAR-T cells in the ccRCC solid tumor setting. **Methods:** Here we report an in-progress phase 1, first-in-human, open label, investigator-initiated clinical trial aimed at evaluating the safety and efficacy of IB-T101 in ccRCC. Patients eligible for inclusion had previously relapsed following VEGF targeting therapies alone or in combination with an immune checkpoint inhibitor. Autologous patient T cells are transduced with a lentiviral vector encoding a CD70-targeting CAR and are CRISPR Cas9 gene edited to knock out endogenous CD70, followed by expansion under OUTLAST conditioning. Escalating doses of IB-T101 CAR-T cells (150 – 500 x 10^6) will be infused following lymphodepletion. Primary endpoints of the study will assess the safety and tolerability of IB-T101. Additional objectives of the study are to assess the anti-tumor activity and the pharmacokinetics of IB-T101. Correlative assessments will include pre-treatment biopsies to assess the level of CD70 expression in the tumor. Research Sponsor: None.

TPS2677 **Poster Session**

Logic-gated, allogeneic Tmod chimeric antigen receptor T-cell (CAR T) therapy targeting epidermal growth factor receptor (EGFR) in advanced solid tumors with human leukocyte antigen (HLA) loss of heterozygosity (LOH): DENALI-1 trial. First Author: Kedar Kirtane, Moffitt Cancer Center, Tampa, FL

Background: Despite the success in hematologic malignancies, CAR T therapies face significant challenges in solid tumors due to the lack of tumor-specific targets that distinguish cancer from normal cells. EGFR plays a critical role in oncogenesis across several cancers and is often upregulated (TCGA 2022). While monoclonal antibodies targeting EGFR have demonstrated efficacy, these approaches are often limited by on-target, off-tumor toxicities, such as skin rash, which constrains dose escalation and efficacy (Macdonald, et al. *J Am Acad Dermatol*. 2015). A2B395 is an allogeneic, logic-gated, EGFR-targeted Tmod CAR T therapy designed to address these limitations and provide a convenient and consistent off-the-shelf option. This therapy incorporates 2 CARs: an activator targeting EGFR, and a blocker targeting HLA-A*02. The activator recognizes EGFR on both tumor and normal cells, while the blocker inhibits CAR T activity against normal cells with preserved HLA expression and decreases the risk for graft-versus-host disease (Hamburger, et al. *Mol Immunol*. 2020). To address potential host-vs-graft response, an shRNA expression module targeting B2M is included in the Tmod construct, which significantly reduces major histocompatibility complex class I levels and subsequent host immune response (DiAndreth, et al. *Clin Immunol*. 2022). Importantly, the Tmod system is modular and adaptable to multiple targets. Initial data on autologous Tmod CAR T therapy suggest reduced off-tumor toxicity and encouraging clinical efficacy (Grierson, et al. SITC 2024. Abstract 588). A2B395 represents a novel approach for EGFR-expressing solid tumors with HLA-A*02 LOH. **Methods:** DENALI-1 (NCT06682793) is a phase 1/2, open-label, nonrandomized study evaluating the safety and efficacy of A2B395 in adults. Patients are enrolled through BASECAMP-1 (NCT04981119), a master pre-screening study that identifies patients with HLA LOH at any time in the course of their disease via next-generation sequencing (Tempus AI, Inc.). Key inclusion criteria include histologically confirmed recurrent unresectable, locally advanced, or metastatic cancers associated with EGFR expression, including colorectal, non-small cell lung, squamous cell head and neck, triple negative breast, and renal cell cancers. Patients must have received $\geq$1 line of prior therapy, such as a checkpoint inhibitor, molecular targeted therapy, or chemotherapy. The primary objective of phase 1 is to evaluate safety, tolerability, and the recommended phase 2 dose (RP2D) using a Bayesian optimal interval design for dose escalation. The dose-expansion phase will confirm RP2D and collect biomarker data. Phase 2 will assess overall response rate per RECIST v1.1. Clinical trial information: NCT06682793. Research Sponsor: A2 Biotherapeutics, Inc.

TPS2678 **Poster Session**

A phase I study of AFNT-211, autologous CD4$^+$ and CD8$^+$ T cells engineered to express a high avidity HLA-A*11:01-restricted, KRAS G12V-specific transgenic TCR; CD8α/β coreceptor; and FAS-41BB switch receptor in patients with advanced or metastatic solid tumors. First Author: Soumit K. Basu, Affini-T Therapeutics, Inc., Watertown, MA

Background: Activating mutations in KRAS (including KRAS G12V) are well-described oncogenic drivers in solid tumors, conferring poor prognosis to patients due to a lack of effective therapies for cancers with such KRAS driver mutations. T cell receptor (TCR)-T cell therapies targeting mutant KRAS have demonstrated proof of concept in the clinic, but duration of response remains a challenge.[1,2] AFNT-211 represents a novel strategy to address the immunosuppressive tumor microenvironment and improve response rate as well as duration of response in solid tumors. **Methods:** This ongoing Phase 1, first-in-human, multicenter, open-label study of AFNT-211evaluates safety/tolerability, as well as its clinical (antitumor) activity with the goal to identify an optimal biological dose (OBD) and recommended Phase 2 dose (RP2D) in patients with HLA 11:01 who suffer from cancers driven by the KRAS G12V mutation. The initial dose escalation part of the study follows Bayesian optimal interval Phase 1/2 (BOIN12), which quantifies the desirability of a dose in terms of toxicity-efficacy tradeoff and adaptively allocates patients to the dose with the highest estimated desirability. After determination of OBD and RP2D based on the totality of the risk/benefit assessment and the BOIN12, the study is planned to proceed to the dose expansion phase which will consist of cohorts enrolling patients with tumors with high KRAS G12V prevalence (pancreatic cancer, colorectal cancer, non small cell lung cancer) as well as a tumor agnostic arm (any other solid tumor with KRAS G12V). This study has started enrolling patients $\geq$ 18 years old positive for HLA-A*11:01-positivewithadvanced/metastatic solid tumors harboring a KRAS G12V mutation who have proven intolerant of or refractory to at least one prior standard of care systemic therapy. Patients undergo leukapheresis to collect T cells for the manufacturing of AFNT-211, and receive lymphodepleting chemotherapy prior infusion of their autologous AFNT-211 product. Following this, patients proceed into a 28-day dose-limiting toxicity observation period (during dose escalation) followed by a post-treatment follow-up period for 24 months/until disease progression. The study is open for recruitment in the United States (NCT06105021). References: 1. Cook J, Melloni G, Gulhan D, *et al*. The origins and genetic interactions of KRAS mutations are allele- and tissue-specific. *Nat Commun* 2021;12:1808. 2. Hofmann MH, Gerlach D, Misale S, *et al*. TPS2679 **Poster Session**

Safety and efficacy of HLA-G–targeted CAR T cells (IVS-3001) in patients with advanced HLA-G–positive solid tumors: Clinical trial in progress. First Author: Samer Ali Srour, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Immunotherapies have transformed cancer treatment, yet only a small proportion of patients experiences durable responses. IVS-3001 is an innovative autologous chimeric antigen receptor (CAR) T-cell therapy specifically targeting Human Leukocyte Antigen (HLA-G). HLA-G is an immune-modulatory checkpoint molecule expressed on various solid tumors, positioning it as an ideal a tumor-specific targeted antigen. Our third-generation CAR construct features enhanced T cell activation and persistence against HLA-G. By harnessing IVS-3001 to target HLA-G and revitalize immune cells, we aim to overcome the suppressive tumor microenvironment and improve antitumor activity, potentially leading to better outcomes for patients with advanced solid tumors who otherwise have no standard options known to confer clinical benefit. **Methods:** Study NCT05672459 is a First-in-Human, phase 1/2a, safety and efficacy study of IVS-3001 in subjects with previously treated advanced HLA-G-positive solid tumors. Phase 1 (n$\leq$24 patients) is a Bayesian Optimal Interval Design (BOIN) with primary objective to determine the safety, tolerability and the recommended phase 2 dose. The primary objective for phase 2 (n$\leq$90 patients) is to evaluate the anti-tumor activity of IVS-3001. The secondary objectives of the study are to evaluate i) pharmacokinetic profile of IVS-3001 (persistence, expansion); ii) the clinical activity of IVS-3001 in selected HLA-G+ solid tumor types; iii) assess the long-term safety of IVS-3001. Exploratory endpoints include functionality of CAR-T cells, immune biomarker changes, and relationships with clinical response. Key inclusion criteria: adults with advanced solid tumors expressing HLA-G; ECOG $<$ 2; adequate organ function. Key exclusion criteria: uncontrolled brain metastasis; prior exposure to HLA-G targeted therapy. Subjects undergo lymphodepletion with fludarabine and cyclophosphamide on days -5 to -3, followed by CAR-T cell infusion on day 0 and a 28-day monitoring period for dose limiting toxicity. Response assessment per RECIST criteria. Study is currently accruing at Dose level 3. Active recruitment and enrollment are ongoing at The University of Texas MD Anderson Cancer Center, Houston, Texas. Clinical trial information: NCT05672459. Research Sponsor: Invectys; National Cancer Institute.

TPS2680 **Poster Session**

QUILT 3.076 phase 1 study of memory-like cytokine-enriched natural killer (M-CENK) cells plus N-803 in locally advanced or metastatic solid tumors. First Author: Chaitali Singh Nangia, Chan Soon-Shiong Institute for Medicine, El Segundo, CA

Background: Lymphopenia and low levels of natural killer (NK) cells may contribute to poor prognosis and response to therapy in cancer patients, conditions that may be addressed by infusion of memory-like cytokine-enriched NK (M-CENK) cells stimulated ex vivo by IL-12, IL-18, and the IL-15 agonist N-803 (ANKTIVA). M-CENK cells express elevated IFN-γ and granzyme B compared to healthy donor NK cells, and display toxicity against multiple tumor cell lines including SCLC lines [Fousek 2023 JITC 11 ab358]. The phase 1 study QUILT-3.076 (NCT04898543) assesses the safety and preliminary efficacy of M-CENK cells plus N-803 in participants with locally advanced or metastatic solid tumors. **Methods:** In this first-in-human study, cohort 1 (up to n = 40) includes participants with newly diagnosed solid tumors who have not received prior 1st line treatment; cohort 2 (up to n = 21) includes participants with relapsed/refractory solid tumors who progressed after $\geq$ 2 prior therapies. Both cohorts undergo apheresis (part A), but only cohort 2 undergoes treatment with M-CENK cells and N-803 (part B). During M-CENK cell generation, cohort 2B participants receive oncologist-recommended therapy. Cohort 1 participants may subsequently enroll in cohort 2B if they have progressive disease (PD) after $\geq$ 2 prior therapies or within 12 months of receiving neoadjuvant/adjuvant chemotherapy. In part B, M-CENK cells are administered weekly up to 10 times and N-803 SC for up to 5 doses every 2 weeks prior to every other dose of M-CENK cells. Key inclusion criteria are age $\geq$ 18 years, ECOG performance status of 0 to 2, and histologically confirmed locally advanced or metastatic solid tumor, with at least 1 measurable lesion and/or non-measurable disease in accordance with RECIST v1.1. There are no exclusion criteria for part A (apheresis). Key exclusion criteria for part B are life expectancy $<$ 16 weeks, involuntary weight loss of $>$ 10%, serious uncontrolled concomitant disease, systemic autoimmune disease requiring medical treatment, and/or currently receiving or received antibiotics since enrollment. The primary objective is safety as assessed and recorded by TEAEs, SAEs, and clinically significant changes in laboratory tests and vital signs. Toxicities are graded using CTCAE v5.0 or a specified grading system for CRS. Secondary measures evaluate the quantity and quality of the investigational M-CENK cells (number of MNCs for manufacturing M-CENK cells, number of cryopreserved M-CENK aliquots, % NK cells, and number, phenotype, and function of M-CENK cells). Preliminary efficacy objectives in cohort 2B are objective response rate (RECIST v1.1 and iRECIST criteria) and progression-free and overall survival evaluated using Kaplan-Meier methods. As of January 27, 2025, 15 participants have been enrolled in cohort 1, 21 participants in cohort 2 have undergone apheresis, and 10 participants have been treated with study therapies. Clinical trial information: NCT04898543. Research Sponsor: ImmunityBio, Inc.

TPS2681 **Poster Session**

A phase I, multicenter, open-label study of UB-VV111 in combination with rapamycin in relapsed/refractory CD19+ B-cell malignancies. First Author: Jacob Randolph Garcia, Umoja Biopharma, Seattle, WA

Background: Autologous, ex vivo-manufactured chimeric antigen receptor (CAR) T cells directed against CD19 have demonstrated clinical activity. These products have gained approvals in the relapsed/ refractory (R/R) setting in multiple B-cell malignancies (BCMs), including large B-cell lymphoma (LBCL) and chronic lymphocytic leukemia/small lymphocytic lymphoma (CLL/SLL). However, challenges in product availability due to limited manufacturing capacity, the need for apheresis and lymphodepletion, failure to prior ex vivo CAR T therapy, and the level of patient fitness needed to wait for and receive ex vivo autologous CAR T therapy all pose significant challenges to the field, presenting significant unmet clinical need. UB-VV111 is a third-generation, self-inactivating, replication-incompetent lentiviral vector (LVV) investigational drug product comprising an envelope with cocal virus fusion glycoprotein (cocal) and surface engineered with a membrane-bound multidomain fusion (MDF) protein. The MDF protein contains CD58, CD80, and anti-CD3 single-chain variable fragment (scFv) components that provide both T-cell tropism and activation signals thought to be critical for effective CAR T-cell generation. UB-VV111 addresses the limitations of currently available autologous CD19-directed CAR T therapies to deliver a product that would generate CD19-directed cells in the patient. UB-VV111 is to be administered by either intranodal (IN) or intravenous (IV) route of administration (ROA). Administration of UB-VV111 by either the IN or IV ROA is expected to transduce T cells to generate CAR T cells designed to bind to CD19 antigen to mediate cell killing and express the rapamycin-activated cytokine receptor (RACR) system which, in the presence of rapamycin, is designed to enhance specific enrichment and expansion of transduced cells. **Methods:** Study UB-VV111-01 (INVICTA, [NCT06528031CO]) is a first-in-human, global, multicenter, dose-finding study of UB-VV111 administered IN or IV +/- rapamycin in CAR-naïve and CAR-exposed subjects with R/R LBCL and CLL/SLL. Dose escalation will proceed independently for each ROA using a Bayesian optimal interval (BOIN) design. Confirmation of CD19 expression will be required for all subjects with prior CD19-directed therapy. Major eligibility criteria include adults with R/R LBCL/CLL/SLL following at least 2 lines of prior therapy who have standard organ function, measurable disease according to Lugano 2014 (LBCL) or iwCLL 2018 (CLL/SLL), ECOG 0 or 1, and no prior allogeneic transplant. Primary objectives include determining the safety profile, maximum tolerated/administered dose, and recommended Phase 2 dose of UB-VV111 +/- rapamycin. Secondary/exploratory objectives include measuring preliminary antitumor activity (magnitude and durability), as well as translational correlates of safety/efficacy. Clinical trial information: NCT06528301. Research Sponsor: Umoja Biopharma.

TPS2682 **Poster Session**

Phase 1 clinical trial of autologous T-cells genetically engineered with a chimeric receptor to target the follicle-stimulating hormone receptor (FSHR) in recurrent ovarian cancer (OVCA). First Author: Robert Michael Wenham, Department of Gynecologic Oncology, H. Lee Moffitt Cancer Center and Research Institute, Tampa, FL

Background: FSHR is a tissue specific antigen expressed in $>$ 55% of high-grade epithelial OVCAs with negligible FSHR expression in non-ovarian tissues. OVCA xenografts treated with FSHCER T (FSH-Chimeric Endocrine Receptor + T-Cell (CER T)) cells demonstrated cytotoxic activity against patient-derived FSHR+ ovarian carcinomas. We hypothesize targeting FSHR in women with FSHR+ OVCA will result in improved response rates due to engraftment, expansion, and survival of these adoptively transferred FSHCER T-cells and will have acceptable toxicity. **Methods:** The primary objective of this phase 1 dose-escalation study (NCT05316129) in high-grade epithelial OVCA using T-cells genetically modified to express CER targeting FSHR is to assess the safety of the intraperitoneal (IP) and intravenous (IV) infusions of FSHCER T-cells. Secondary objectives include antitumor efficacy, persistence of transferred FSHR T cells, expansion of endogenous tumor-targeted cells, and comparison of IP and IV administration routes. Patients unable to be treated in the IP arm may be treated in the IV arm in the lowest unfilled cohort for that arm. Cohorts of 3 to 6 patients will be infused with escalating doses of FSHCER T-cells to establish the maximum tolerated dose (MTD) with 6 planned dose levels from 1 x10^5 to 1 x 10^7 cells/kg with the 5^{th} level receiving lymphodepleting chemotherapy. Following MTD determination, an expansion phase will be initiated. Nine patients have been enrolled in the first three dose-level cohorts. Eight have cleared the DLT period and one patient is currently being treated. One patient received a second dose of 3 x 10^5 cells/kg after 20 months apparent stable disease. Cohorts 1 and 2 correlates are being processed. NCT05316129. Moffitt Scientific Review #21113. Advarra Institutional Review Board #00000971. Clinical trial information: 05316129. Research Sponsor: Anixa BioSciences Inc., San Jose CA, USA.

TPS2683 **Poster Session**

INVOKE: A phase 1 study of OKN4395, a first-in-class EP2/EP4/DP1 triple prostanoid receptor antagonist, in patients with advanced solid tumors. First Author: Neal Shiv Chawla, Sarcoma Oncology Center, Santa Monica, CA

Background: Immunotherapy is an established cancer therapy, although mechanisms of non-response & resistance are emerging, leaving few options post-relapse. The immunosuppressive pathway of prostaglandin E_2 (PGE_2), part of the cyclooxygenase (COX) pathway, is upregulated in certain cancers and has been implicated in tumor evasion of CD8 T, NK, and dendritic immune cells, allowing tumor growth and metastasis (Jin et al., 2023). COX2 inhibitors, aspirin and nonsteroidal anti-inflammatories (NSAIDS) have shown some survival benefit in patients with colon, lung, prostate, and endometrial cancer (Cao et al., 2016; Lim et al., 2012; Huang et al., 2014; Takiuchi et al., 2018), however results are inconsistent, likely due to toxicity limiting complete blockade of the pathway, highlighting the need for more potent but selective COX pathway inhibitors. OKN4395 is a first-in-class, highly selective, equipotent inhibitor of EP2, EP4 and DP1, downstream receptors for COX-derived PGE_2, and PGD_2, respectively. DP1 has described roles in immunosuppression and inhibition of apoptosis, supporting the therapeutic rationale (Luo et al., 2024; Peinhaupt et al., 2017). OKN4395 is hypothesized to modulate the tumor microenvironment to allow an effective immune response as monotherapy, and to potentiate the effect of immunotherapies such as checkpoint inhibitors, both of which are evaluated in INVOKE. **Methods:** INVOKE (OKN-4395-121; NCT06789172) is a Ph1a/1b, first-in-human study of OKN4395 (oral, BID) as monotherapy (mono) or in combination with pembrolizumab 200mg IV 3-weekly (combo), in patients with advanced solid tumors that have evidence of COX-associated immunosuppression. Ph1a is a Bayesian dose escalation in mono, followed by combo dose confirmation, primarily assessing safety, establishing the optimal dose for Ph1b. Using multimodal artificial intelligence (AI) drug-matching algorithms, Ph1b tumor types were selected, and response will be assessed (cohorts of n = 20 each): select sarcomas (mono), pancreatic carcinoma (mono), non-small cell lung cancer (combo), colorectal carcinoma (combo), head and neck squamous cell carcinoma (combo). Key inclusion criteria include COX-active (Ph1a) or above-listed (Ph1b) tumors, performance status 0-1, biopsy-amenable lesions, and adequate organ function. Active CNS metastases, upper GI bleed risk factors, untreated H. pylori infection, and concomitant NSAIDs/COX inhibitors/prostaglandins are exclusionary. Ph1b mono cohorts will include exploratory analyses including evaluation of the effect of food & gastric pH on OKN4395 pharmacokinetics. Trial data, paired pre- and on-treatment biopsies, and exploratory biomarkers will be used to enhance development using advanced agentic AI systems, including a synthetic digital twin control arm. Ph1a of the study is currently recruiting in the US, UK, and Australia. Clinical trial information: 06789172. Research Sponsor: Epkin.

TPS2684 **Poster Session**

An open-label, phase Ib dose-expansion study to assess the efficacy of CD137/FAP agonist BI 765179 plus pembrolizumab as a first-line treatment in metastatic or incurable, recurrent programmed cell death ligand-1 (PD-L1)-positive head and neck squamous cell carcinoma (HNSCC). First Author: Rachna T. Shroff, University of Arizona Cancer Center, Tucson, AZ

Background: HNSCC is the seventh most common cancer globally and is often associated with poor quality of life and a dismal prognosis. Median overall survival for advanced HNSCC with first-line standard-of-care pembrolizumab $\pm$ chemotherapy is approximately 13 months, highlighting the need for new therapies. Fibroblast activation protein (FAP)-positive fibroblasts are frequently present in the tumor stroma of HNSCC tumors, representing a potential therapeutic target. BI 765179 is a bispecific antibody that simultaneously binds to FAP and CD137 expressed on T-cells, leading to local activation of tumor-specific CD137-positive T-cells. The Phase Ia part of the present study (NCT04958239) determined safety and doses for dose escalated BI 765179, both as monotherapy and in combination with an anti-programmed cell death protein 1 (PD-1) antibody in patients with advanced solid tumors. Here we present the design of the Phase Ib dose-expansion part, which aims to assess the preliminary efficacy of two doses of BI 765179 in combination with pembrolizumab in patients with metastatic or incurable, recurrent HNSCC whose tumors express PD-L1. **Methods:** In the Phase Ib dose-expansion part, approximately 60 patients with a histologically or cytologically confirmed diagnosis of metastatic or incurable, recurrent HNSCC will be enrolled. Key inclusion criteria are: no prior systemic therapy administered in the metastatic or incurable recurrent setting; primary tumor locations of oropharynx, oral cavity, hypopharynx, or larynx; at least one measurable lesion outside of the central nervous system (modified RECIST v1.1); a PD-L1-positive tumor (combined positive score $\geq$1, local assessment); and Eastern Cooperative Oncology Group performance status 0–1. Patients who have previously received CD137-targeted or anti-PD-1/PD-L1 agents are not eligible. Patients will be randomized 1:1 to receive either Dose 1 or Dose 2 of BI 765179 intravenously in combination with pembrolizumab. The primary endpoint is objective response (OR), defined as best overall response of confirmed complete or partial response (RECIST v1.1). Secondary endpoints include occurrence of adverse events (AEs) and serious AEs, OR (immune-related RECIST v1.1), duration of response, progression-free survival, and overall survival. Clinical trial information: NCT04958239. Research Sponsor: Boehringer Ingelheim.

TPS2685 **Poster Session**

A phase 1, first-in-human study of CTIM-76, a claudin-6 (CLDN6)-directed bispecific antibody, in patients with recurrent ovarian cancer and other advanced solid tumors. First Author: Roisin Eilish O'Cearbhaill, Memorial Sloan Kettering Cancer Center and Weill Cornell Medical College, New York, NY

Background: CLDN6 is an oncofetal protein expressed at high levels in many solid tumors while expressed at very low levels in adult normal tissues. The high target antigen density and slow rate of internalization makes it an attractive target in cancer therapeutics. CTIM-76, a CLDN6 x CD3 T cell engager bispecific antibody is engineered to bind with high selectivity to CLDN6 and redirect the immune system's T cells to recognize and kill CLDN6-expressing cancer cells. CTIM-76 effectively inhibited tumor growth, inducing complete responses in ovarian cancer xenograft models. The first in human study of CTIM-76 in patients with advanced ovarian, endometrial, and testicular cancers (NCT06515613) is described here. **Methods:** Part 1 dose escalation exploring 9 ascending dose levels with a 3+3 design. The first two dose levels are single patient cohorts (22.5 μg starting dose), CTIM-76 delivered as weekly iv infusions, with step dosing and steroid premedication to minimize cytokine release syndrome. Approximately 40 patients with platinum resistant ovarian cancer, or endometrial or testicular cancers relapsed after standard of care will be enrolled. Tumors from patients with ovarian or endometrial cancer require prospective CLDN6 + confirmation by IHC (10% $\geq$ 1+), testicular cancer patients will not require prospective screening due to the known uniformly high prevalence of CLDN6. The primary objective is to evaluate safety and tolerability (incidence and severity of adverse events per NCI CTCAE v5.0) and establish the recommended dose for expansion. Secondary objectives include assessment of antitumor activity (RECIST v1.1, iRECIST), pharmacokinetics, and pharmacodynamic correlates of immune activation. Part 2 will evaluate two doses in approximately 30 patients with one tumor type, with efficacy and further safety as primary objectives. This multicenter study has currently five sites open for enrollment. The first patient was dosed in January 2025. Clinical trial information: NCT06515613. Research Sponsor: None.

TPS2686 **Poster Session**

A phase 1a/1b study to evaluate the safety, tolerability, pharmacokinetics, and anti-tumor activity of IMGS-001 in patients with relapsed or refractory advanced solid tumors. First Author: David S. Hong, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: IMGS-001 is a fully human, dual specific immunoglobulin G1 (IgG1) monoclonal antibody (mAb) that binds both PD-L1 and PD-L2, silencing the entire PD-1 inhibitory circuit, with an engineered fragment crystallizable (Fc) region designed to induce robust antibody-dependent cell-mediated cytotoxicity (ADCC) and phagocytosis (ADCP). IMGS-001 mediated killing of PD-L1+ and PD-L2+ tumor and stromal cells can reduce the level of multi-modal immune suppression throughout the tumor microenvironment while catalyzing cross presentation of tumor antigens to the adaptive immune system. IMGS-001 also blocks binding of the T cell co-inhibitory receptor PD-1 with its ligands, restoring activation and function to tumor-specific T cells. In addition, IMGS-001 blocks binding of PD-L1 to B7-1, increasing costimulation of tumor-specific T cells. A phase 1a/1b study has been opened to investigate IMGS-001 safety, anti-tumor activity, and pharmacokinetics (PK) in solid tumor patients (Protocol IMGS-001-011; NCT06014502). **Methods:** This multi-center, first-in-human study is enrolling subjects with advanced solid tumors refractory to standard of care therapy. Phase 1a uses a Bayesian optimal interval (BOIN) dose-escalation design to investigate doses from 0.3-15 mg/kg (Q2W). Phase 1b is a two-part design in subjects with PD-L1+ expression $\geq$ 5% across 5 tumor types: triple negative breast, bladder, gastric/esophageal, colorectal, ovarian. Part 1 will enroll up to 10 subjects per cohort. Cohorts meeting prespecified efficacy criteria will proceed to Part 2 dose optimization randomly assigning 40 subjects (1:1) between two doses. The primary objective of Phase 1a is to assess IMGS-001 safety, and of Phase 1b is to define the pharmacologically optimal dose (POD). Both study phases will assess tolerability, PK, immunogenicity, and anti-tumor activity including objective response rate and progression free survival, as well as exploratory tissue and serum biomarker analyses. The study will enroll approximately 25 patients in Phase 1a and up to 250 in Phase 1b. The first two cohorts (0.3 and 1 mg/kg) have completed without any dose limiting toxicities (DLTs), and cohort 3 (3 mg/kg) is enrolling as of the submission date. Clinical trial information: NCT06014502. Research Sponsor: ImmunoGenesis; Cancer Prevention and Research Institute of Texas (CPRIT); Cancer Focus Fund.

TPS2687 **Poster Session**

Phase 2 dose expansion of START-001: A phase 1/2 study of invikafusp alfa (STAR0602), a first-in-class, selective T cell receptor (TCR)-targeting, bifunctional antibody-fusion molecule, as monotherapy in patients with antigen-rich tumors resistant to anti-PD(L)-1. First Author: Claire Frances Friedman, Memorial Sloan Kettering Cancer Center, New York, NY

Background: Many patients do not respond to anti-PD(L)-1-based therapies and most responders eventually develop resistance. Thus, the development of effective therapies for anti-PD(L)-1 resistance is a significant unmet medical need. Invikafusp, a selective, dual T cell agonist targeting Vβ6/Vβ10 T cells, is being evaluated in START-001: a multicenter Phase 1/2 monotherapy trial in patients with anti-PD(L)1-resistant, antigen-rich (TMB-H, MSI-H/dMMR, or virally associated) solid tumors. The completed Phase 1 dose escalation of intravenous invikafusp, Q2W, per 3+3 design, identified a recommended Phase 2 dose (RP2D) of 0.08 mg/kg, and demonstrated clinically meaningful single-agent anti-tumor activity in patients with anti-PD(L)-1 resistant tumors, including confirmed partial responses in TMB-H, microsatellite stable, colorectal cancer (CRC) patients with one durable response lasting ~12 months. It promoted potent and selective expansion of mainly CD8+ Vβ6/ Vβ10 T cells with a novel central memory T cell phenotype, and led to ctDNA decrease and expansion of antigen-specific T cells. Based on these results, the US FDA granted Fast Track Designation for invikafusp in TMB-H CRC. **Methods:** Study design: Using an optimal Simon's 2 stage design, Phase 2 of START-001 is a dose expansion at the RP2D, to further investigate the safety and anti-tumor activity of invikafusp in 9 cohorts of patients who have the following solid tumors: 1) tissue-agnostic, TMB-H; 2) tissue-agnostic, dMMR/MSI-H; 3) CRC (both Ras wild-type and mutant) TMB-H and/or MSI-H/dMMR); 4) virally associated tumors such as Merkel cell carcinoma, cervical, oropharyngeal, anal, penile, vaginal, and vulvar cancers, or EBV-related solid tumors; 5) metastatic triple-negative breast cancer; 6) platinum-resistant epithelial ovarian cancer; 7) metastatic castration-resistant prostate cancer; 8) primary stage IV or recurrent non-small cell lung cancer; and 9) immunogenic tumors (e.g., cSCC, melanoma and RCC). Major Eligibility criteria: $\leq$ 3 lines of prior cancer therapies [anti-PD(L)-1s allowed] for advanced or metastatic disease; intolerance to standard therapies including anti-PD(L)-1s allowed; no liver metastases or adequately treated liver metastases either locally (e.g., by surgery, radiofrequency ablation, or chemoembolization) or systemically and stable for 3 months. Primary objective: to further evaluate anti-tumor activity of invikafusp as monotherapy in each of the above-described 9 cohorts of patients with anti-PD(L)-1-resistant, unresectable, locally advanced, or metastatic solid tumors. Primary endpoint: overall response rate (ORR) per iRECIST. The enrollment to the first three cohorts has begun. Clinical trial information: NCT05592626. Research Sponsor: Marengo Therapeutics, Inc.

TPS2688 **Poster Session**

A phase 1 first-in-human study of the novel anti-LLT1 antibody (ZM008) alone and in combination with anti-PD1 antibody in patients with advanced solid tumors. First Author: Maloy Ghosh, Zumutor Biologics, Bangalore, India

Background: ZM008 is a first-in-class, fully human, IgG1 monoclonal antibody targeting the LLT1 antigen. It disrupts the interaction of LLT1-CD161, an NK-mediated innate immunity checkpoint. LLT1 expression on tumor cells has been associated with poor overall survival in multiple solid tumors. *Ex vivo* experiments with lung and bladder cancer biopsies showed significant tumor reduction and immune cell infiltration were observed with ZM008 monotherapy. Synergistic anti tumor effects were observed with ZM008 in combination with pembrolizumab. An open-label, phase 1, first-in-human study evaluating the safety, tolerability, pharmacokinetics (PKs), preliminary anti-tumor activity and the Recommended Phase 2 Dose (RP2D) of ZM008 alone and in combination with pembrolizumab in advanced solid tumors is now ongoing at 3 US sites (NCT06451497). **Methods:** The study includes a dose-escalation Part 1 and a dose-expansion Part 2. In dose escalation (part 1), ZM008 monotherapy follows 3+3 standard design starting with 0.15 mg/Kg and up to 18 mg/Kg IV Q3W. A staggered parallel arm will explore ZM008 in combination with pembrolizumab (200mg Q3W) from dose level 6. Histologically confirmed advanced or metastatic non-small cell lung, head & neck, pancreatic, biliary, prostate, colorectal, triple negative breast, urothelial, ovarian and diffuse large B cell malignancies with no standard alternative are included. Measurable disease by RECIST v1.1, adequate haematological, hepatic and renal functions are required. In Part 2, two or more doses of ZM008 will be used to select RP2D and indications of interest. Major exclusion criteria include, patients with history of uncontrolled brain metastasis, autoimmune disease, pneumonitis, active infections, and significant cardiovascular diseases. The primary objective is to determine the maximum tolerated dose (MTD) and RP2D of ZM008. Secondary objectives include PKs, incidence and severity of treatment-emergent AEs as per common terminology criteria for adverse events (CTCAE) v.5.0, immunogenicity, pharmacodynamic changes, and preliminary anti-tumor activity. Exploratory biomarkers will evaluate pharmacodynamics changes, receptor occupancy, immune and cytokine profiling, ctDNA, and transcriptomics. Paired pre- and on-treatment biopsies will be analysed using immunohistochemistry and the spatial distribution of immune and tumor cells in the tumor microenvironment. At the time of submission, enrollment of 9 subjects were completed in three dose cohorts with no reported DLTs. The study is ongoing and open for enrolment at NEXT Oncology (San Antonio and Austin sites) and Dana-Farber Cancer Institute, Boston. Clinical trial information: NCT06451497. Research Sponsor: Zumutor Biologics Inc.

TPS2689 **Poster Session**

ELEPHAS-01, ELEPHAS-02 and ELEPHAS-04: Multi-institutional observational prospective clinical trials to assess the accuracy of an ex vivo live tumor fragment platform for predicting immunotherapy response. First Author: Hinco J. Gierman, Elephas, Madison, WI

Background: Immune checkpoint inhibitors (ICIs) have revolutionized cancer treatment. However, existing FDA approved companion diagnostic biomarkers like PD-L1, dMMR/MSI-H and TMB have low accuracy in predicting response. Ex vivo cytokine profiling of live tumor samples has shown promise as an improved means of predicting response to PD-1 blockade (Voabil, et al. *Nat Med.* 2021), but this approach has been limited to tumor resections given the need for large amounts of tissue. Here we present three clinical trials that leverage a novel approach using limited tissue from a single core needle biopsy (CNB) (20 gauge or larger). A sequential ex vivo treatment strategy is used, eliminating the need for a separate control arm and addressing challenges with tumor heterogeneity, particularly in CNBs where tissue is limiting. Using a specialized instrument, CNBs are cut into live tumor fragments (LTFs) which are viable in culture and retain the native tumor microenvironment, enabling cytokine profiling in response to ICI treatment ex vivo. **Methods:** ELEPHAS-01 (NCT05478538), ELEPHAS-02 (NCT05520099) and ELEPHAS-04 (NCT06349642) are observational prospective clinical trials initiated to characterize the accuracy of this approach for predicting ICI response. Over 750 patients that are being considered for standard of care (SOC) ICI therapy in the metastatic/relapse or neoadjuvant setting will be enrolled (Table). Fresh live CNBs are collected prior to treatment start and processed within 24 hrs enabling prediction of results within 72 hrs of receipt. LTFs are treated using a strategy where control (IgG) and SOC ICI treatments are performed sequentially on the same tissue in a single well. Changes in the cytokine secretion rates are then compared between ICI and control to characterize immunotherapy response. Additionally, tissue viability and tumor content measurements are used to assess tissue quality. Clinical response is measured using pathologic response in patients receiving neoadjuvant ICI therapy, while RECIST v1.1 is used in all other patients. The primary objective of these trials is to determine the platform's ex vivo accuracy (e.g., sensitivity, specificity) for predicting clinical response to ICIs and comparing it to the accuracy of PD-L1, dMMR/MSI-H and TMB. Clinical trial information: NCT06349642, NCT05478538, NCT05520099. Research Sponsor: None.

TPS2690 **Poster Session**

Phase II basket study to evaluate the tissue-agnostic efficacy of anti-PD1 in patients with advanced rare tumors: The ANTARES trial. First Author: Camila M. Venchiarutti Moniz, Instituto do Câncer do Estado de São Paulo (ICESP), Universidade de São Paulo and Instituto D'Or de Pesquisa e Ensino (IDOR), São Paulo, Brazil

Background: Rare tumors account for 25-30% of all malignancies; however, patients (pts) with these cancers are underrepresented in clinical trials. The limited evidence on sequential oncologic treatment strategies in this population leads to a poorer prognosis compared to pts with more common malignancies. The predictive role of the tissue-agnostic biomarker PD-L1 and the combined positive score (CPS) in determining the efficacy of anti-PD1 therapy remains poorly understood in this population. **Methods:** ANTARES TRIAL (NCT06638931) is a basket phase 2 single-arm multicentric study to evaluate the efficacy of anti-PD 1 in rare tumors. Key inclusion criteria are invasive neoplasia with incidence lower than 6/100.000 people-year, expressing PD-L1 with a combined positive score (CPS) ≥10, ECOG 0-1, measurable disease by RECIST v1.1, progression or intolerance to all available treatments for metastatic disease. Patients will receive nivolumab 480 mg intravenously every 4 weeks until disease progression or for a maximum duration of 12 months. The primary endpoint was the disease control rate (DCR) assessed by RECIST v1.1. Based on Simon's two-stage design (DCR under alternative hypothesis > 25%; DCR under null hypothesis ≤5%), nine patients were accrued in the first stage. If ≥1 responses are observed, the trial will accrue an additional 16 pts. The study will be considered positive if 4 or more pts achieve DCR among 25 pts in the second stage. Considering a drop-out rate of 10%, a sample size of 28 patients will be needed to attain 90% power and alpha 0.05. Secondary endpoints include progression-free survival, overall survival, response duration, and response time. Blood samples for circulating tumor DNA, microvessels, and seric immune checkpoint biomarkers will be collected at screening, at 8, 20, 32, 44 weeks, and at the final visit. Enrollment started in Brazil on June/24 at Instituto do Câncer do Estado de São Paulo (ICESP) and Instituto D'Or de Pesquisa e Ensino (IDOR); 8 sites are planned to open later in 2025. Clinical trial information: NCT06638931. Research Sponsor: FINEP - Financiadora de Estudos e Projetos, Brazil; Reference 1676/22 protocol FADDE222-E1AE-45D9-A318- 0C8477BEA1D9.

TPS2691 **Poster Session**

Phase 2 trial of TU2218, TGFβ-RI, and VEGF-R2 dual inhibitor in combination with pembrolizumab in patients with biliary tract cancer and head and neck cancer. First Author: Do-Youn Oh, Department of Internal Medicine, Seoul National University College of Medicine, Seoul, South Korea

Background: TU2218 is a low molecular weight dual kinase inhibitor highly specific to TGFβR1 and VEGFR2 and has a potential to be an efficacious therapy against cancer growth. In vitro and in vivo nonclinical studies have shown that TU2218 reduced the growth and migration/invasion of tumor cells and increased antitumor effects in combination with anti-PD-1/anti PD-L1 antibodies. To investigate safety and tolerability of TU2218 Phase 1a trial was conducted with 6 dose level escalation (30mg/day → 60mg/day → 105mg/day → 150mg/day → 195mg/day → 270mg/day) of TU2218 alone, and it was confirmed that TU2218 was safe and tolerated in all dose levels. And to explore the synergistic effect of TU2218 in combination with Pembrolizumab and to decide RP2D Phase 1b trial was conducted with 3 dose level escalation (105mg/day → 150mg/day → 195mg/day) of TU2218 in combination with Pembrolizumab in patients with advanced solid tumors. The RP2D of TU2218 was established as 195mg/day in combination with Pembrolizumab, the total 19 patients received the treatment and most frequently observed TRAE was pruritus and proteinuria, and three Grade 3 TRAEs (Pruritus, Rash Maculo-Popular, Malaise) were observed. The MTD was not identified during dose escalation period. The ORR of overall dose levels demonstrated 19%, and DCR was about 63%. In particular, 80% DCR was observed in TU2218 195mg/day in combination with Pembrolizumab. The trial was expanded to the specific cancer types, Biliary Tract Cancer and Head and Neck Cancer using the established RP2D for Phase 2 trial. **Methods:** Locally advanced unresectable or metastatic biliary tract cancer (BTC) patient whose tumor has progressed on/after first line standard anticancer therapy and anti-PD-(L)1 agent-naive metastatic or with unresectable, recurrent head and neck squamous cell carcinoma (HNSCC) patient whose tumor express PD - L1 (CPS ≥1) as determined by an FDA-approved test or recurrent or metastatic HNSCC with disease progression on or after platinum-containing chemotherapy are eligible for this non-randomized, open-label multicenter trial. All patients are administered with TU2218 195mg/day (97.5mg BID) on a 2 weeks-on/1 week-off in combination with Pembrolizumab 200mg IV Q 3 weeks and will be evaluated by investigator-assessed objective response rate (ORR) defined as the proportion of patients with a best overall response of complete response (CR) or partial response (PR) according to RECIST version 1.1. If 2 or less patients out of 22 evaluable BTC patients are observed with CR/PR and 3 or less patients out of 22 evaluable HNSCC patients are observed with CR/PR, this suggests futility and the cohort may be stopped. Up to 40 BTC patients and up to 36 HNSCC patients are planned to be enrolled and a dropout rate of up to 10% is expected. As of this abstract submission date, 14 BTC patients and 8 HNSCC patients have been enrolled. Clinical trial information: NCT05784688. Research Sponsor: TiumBio., Co., Ltd.; Merck Sharp & Dohme LLC, a subsidiary of Merck & Co., Inc.

TPS2692 **Poster Session**

A multi-center, single-arm, phase II study of pemigatinib combined with immune checkpoint inhibitor in FGFR1/2/3 alteration advanced solid tumor. First Author: Tao Qin, Phase I Clinical Trial Centre, Sun Yat-sen Memorial Hospital, Sun Yat-sen University, Guangzhou, China

Background: FGFR mutations are a significant genetic factor contributing to the onset and progression of various cancers. FGFRs are aberrantly activated, including single-nucleotide variants, gene fusions, and copy number amplifications in human cancer. FGFR mutation alterations are most commonly observed in urothelial carcinoma, breast cancer, endometrial cancer, squamous cell carcinoma of the lung, etc. The preliminary efficacy of FGFR inhibitors in solid tumors has been established ORR ranged from 20% to 30% [1,2,3]. However, the efficacy of FGFR inhibitors as monotherapy in treating FGFR mutations of solid tumors has not yet met the clinical needs. Evidence from preclinical research suggested that a combination of FGFR inhibition and PD-1 suppression expanded the T-cell clones and caused immunological changes in the tumor microenvironment to enhance anti-tumor immunity and survival [4]. Based on the synergistic interplay between the FGFR signaling pathway and immune mechanisms, this study aims to evaluate the safety and efficacy of combining the FGFR inhibitor pemigatinib plus PD-1 inhibitor to treat solid tumors harboring FGFR mutations. **Methods:** 1. This study is a single-arm, multicenter, prospective Phase II clinical trial. Gene testing confirms FGFR1/2/3 variants, including but not limited to mutations, fusions/rearrangements in solid tumors. 2. Patients have not previously used specific small molecule multi-target inhibitors of the FGFR pathway, as assessed by investigators, and have been treated with immune checkpoint inhibitors. 3. Patients receive pemigatinib (13.5 mg QD, orally, 2 weeks on 1 week off, 21 days per-cycle), with immune checkpoint inhibitor therapy (strictly follow instructions). Treatment should continue until disease progression or unacceptable toxicity occurs of intolerable toxicities. 4. At least one measurable lesion per RECIST v1.1 criteria. 5. The safety of the study will be assessed using the NCI-CTCAE v5.0 criteria. The primary outcome measures: objective response rate (ORR). Secondary outcome measures: disease control rate (DCR), progression-free survival (PFS); overall survival (OS); safety and quality of life. Clinical trial information: NCT06551896. Research Sponsor: None.

TPS2693 **Poster Session**

IMMUNORARE[5]: A national platform of 5 academic phase II trials coordinated by Lyon University Hospital to assess the safety and the efficacy of the immunotherapy with domvanalimab + zimberelimab combination in patients with advanced rare cancers—The Anaplastic Thyroid Carcinomas Cohort. First Author: Hélène Lasolle, Lyon 1 University, Lyon, France

Background: In patients with rare cancers, there is an unmet medical need for investigating innovative therapeutics beyond standard first-line treatment. Indeed, these diseases are rarely assessed in clinical trials. Anaplastic thyroid carcinomas (ATC) represent 2-3 % of thyroid carcinomas, but are responsible for 15-40% of thyroid cancer mortality. Most cases (> 90%) are diagnosed with advanced unresectable disease. In such patients carrying the BRAFV600 mutation (20-30%), the standard 1st-line treatment relies on dabrafenib & trametinib. In patients without BRAF mutation, the 1st line treatment is chemoradiation. There is no validated 2nd line treatment, but immunotherapy combinations seem promising. In DUTHY trial (Durvalumab + tremelimumab), the 6month-OS was 65.6% in ATC. Moreover, TIGIT expression increased during ICI treatment, suggesting potential synergistic effects by simultaneous blockade of TIGIT and PD-1. **Methods:** IMMUNORARE[5] (NCT06790706) is a platform of 5 single arm phase II trials testing the efficacy and safety of DOMVANALIMAB (anti-TIGIT) and ZIMBERELIMAB (anti PD-1) in 5 independent cohorts of rare cancers. The trial, sponsored by Lyon University Hospital, is conducted in 15 French centers, led in partnership with the corresponding French national reference centers. The ATC cohort, led in collaboration with the French network ENDOCAN-TUTHYREF (https://www.tuthyref.com/fr), will enroll 24 patients with either non-mutated BRAF tumours with persistent disease at the first evaluation after chemoradiation or disease progression/relapse after the end of chemoradiation, or with mutated B-RAF tumors in progression after a standard B-RAF inhibitor. Patients will receive intra-venous DOMVANALIMAB and ZIMBERELIMAB, every three weeks, until disease progression. The primary endpoint is the survival rate at 6 months. The secondary objectives are overall response rate and duration of the response, progression-free survival and tolerability. The trial is designed with a two-stage Simon design, with early termination for futility (5% one-sided alpha level, 80% power. The treatment would be considered interesting if the survival rate at 6 months is statistically higher than 25%; 50% is expected. Translational research projects will be developed aiming at deciphering cellular and molecular mechanisms involved in response to treatment. Moreover, data from the prospective database of the ENDOCAN-TUTHYREF network will be investigated to build a synthetic historical arm representative of the efficacy of the standard treatments in a similar population of patients. Clinical trial information: NCT06790706. Research Sponsor: None.

TPS2694 **Poster Session**

Trial in progress: A first-in-human (FIH) phase I study of PTX-912 in patients with locally advanced or metastatic solid tumors. First Author: Yan Xing, City of Hope Comprehensive Cancer Center, Duarte, CA

Background: High-dose IL-2 (HD IL-2) received FDA approval for metastatic melanoma (mM) and metastatic renal cell carcinoma (mRCC), but its use is limited by severe systemic toxicities. While PD-1 blockade has improved overall survival in 20–30% of cancer patients, resistance remains a significant challenge. Notably, HD IL-2 has shown durable anti-tumor effects in mM and mRCC patients who have progressed on anti-PD-1 therapy. Moreover, combining IL-2 with pembrolizumab in mRCC demonstrated a durable response rate of 70%, compared to objective response rates (ORR) of 20% and 33% with IL-2 and pembrolizumab monotherapy, respectively (*Chatzkel et al., Clin Genitourin Cancer(2022)*). These findings suggest that combining IL-2 receptor (IL-2R) activation with PD-1 blockade may be a promising strategy to overcome PD-1 resistance and enhance clinical outcomes. PTX-912 is a novel, first-in-class bifunctional PD-1-proIL-2v fusion protein designed to synergize PD-1 blockade with PD-1-cis-directed IL-2R agonism specifically within the tumor microenvironment (TME), reducing systemic toxicities typically associated with high dose IL-2 therapy. **Methods:** This first-in-human (FIH), multi-center Phase I study (NCT06190886) evaluates the safety, tolerability, and preliminary efficacy of PTX-912 in patients with locally advanced or metastatic solid tumors who have had disease progression on all available standard of care and/or refused available standard of care therapies that would confer clinical benefit. Eligible patients must have measurable disease per RECIST v1.1 and may have received any number of prior therapies. Key exclusions include immunodeficiency, unresolved toxicities $>$ Grade 1 per NCI CTCAE from prior therapy, active autoimmune disease, primary CNS or leptomeningeal involvement, history of transplant, recent major surgery, and significant cardiac or pulmonary dysfunction. The study includes dose escalation (Part 1a) and dose expansion (Part 1b) cohorts. In Part 1a, seven dose levels (DL1–7) will be tested, with DL1–3 following an accelerated titration design and DL4–7 using a standard 3+3 design. The primary objectives are to determine the maximum tolerated dose (MTD), optimal biological dose (OBD), and/or the recommended Phase II dose (RP2D) of PTX-912, assessed via dose-limiting toxicities (DLTs). Patients with melanoma, renal cell carcinoma (RCC), non-small cell lung cancer (NSCLC), or other populations identified based on Part 1a data will be enrolled in Part 1b. In Part 1a, patients will receive intravenous infusions of PTX-912 every two weeks (Q2W), followed by subsequent cycles with a 28-day DLT observation period. Study enrollment began in June 2024 in the United States at 3 centers. Cohorts 1 to 4 (6 patients) have been completed without DLT. Enrollment to cohort 5 is currently ongoing. Clinical trial information: NCT06190886. Research Sponsor: Proviva Therapeutics.

TPS2695 **Poster Session**

Phase 1/2 study of tiragolumab and atezolizumab in patients with relapsed or refractory SMARCB1- or SMARCA4-deficient tumors: PEPN2121. First Author: Mary Frances Wedekind, Pediatric Oncology Branch, National Cancer Institute, National Institutes of Health, Bethesda, MD

Background: The SMARCB1/A4 gene products are core subunits of the SWItch/Sucrose Non Fermentable (SWI/SNF) chromatin remodeling complex. Tumors with defects in SWI/SNF are histologically distinct aggressive cancers occurring in children and young adults. SMARCB1/A4 deficient tumors, particularly malignant rhabdoid tumor (MRT), atypical teratoid rhabdoid tumor (ATRT), poorly differentiated chordoma (PDC), epithelioid sarcoma (ES), and renal medullary carcinoma (RMC), have immune cell infiltrates and programmed death ligand 1 (PD-L1) expression. Responses to immune checkpoint inhibition (CI) have been observed in SMARCB1/A4 deficient tumors; however, responses are not durable. T cell immunoreceptor with Ig and ITIM domains (TIGIT) is a novel inhibitory receptor expressed on multiple immune cells. TIGIT inhibits T and NK cells by binding to its ligand poliovirus receptor (PVR) and Nectin2 on both tumor and antigen-presenting cells. Utilizing RNAseq data, SMARCB1/A4 deficient tumors demonstrate high expression of PVR and Nectin2. Tiragolumab is an antibody to the TIGIT receptor. The combination of tiragolumab and atezolizumab has shown promising activity in early phase studies, and phase 3 studies are ongoing in multiple adult indications. Thus, there is rationale that the addition of tiragolumab to CI may also enhance response rates in patients with SMARCB1/A4 deficient tumors. **Methods:** This is a phase 1/2 trial of tiragolumab monotherapy (300 mg if $\leq$ 15 kg; 420 mg if $>$ 15 kg to $\leq$ 40 kg; 600 mg if $>$ 40 kg or $\geq$ 18 years) and in combination with atezolizumab (15 mg/kg [max 1200 mg]) if $<$ 18 yrs or 1200 mg if $\geq$ 18 years) administered IV on Day 1 of 21-day cycles in patients $>$ 12 months of age with SMARCB1/A4 deficient tumors. Part A evaluating the safety of tiragolumab monotherapy in patients $<$ 18 years based on cycle 1 dose limiting toxicities is complete. Part B estimates the antitumor activity of tiragolumab in combination with atezolizumab in 6 histology-specific cohorts (RMC, MRT, ATRT, PDC, ES, and other SMARCB1/A4 deficient tumors) and is now open to all eligible age groups. Each cohort is conducted using a 6+4 Simon's two stage design. Enrollment for each cohort is as follows: Part A 6/6, Part B RMC 1/6, MRT 1/6, ATRT 4/6, PDC 2/6, ES 3/6, other 6/6. Radiographic imaging central response assessment for the first stage of the "other" cohort is ongoing. Cycle 1 toxicities of the combination therapy are monitored in Part B patients $<$ 12 yrs using a Bayesian Optimal INterval (BOIN) design with a target toxicity of 17%. Secondary objectives are to characterize the pharmacokinetics/anti-drug antibody development and to estimate progression free survival, overall survival, and duration of response. Enrollment is open at all Pediatric Early Phase Clinical Trial Network sites. Data cutoff: Jan 10, 2025. Clinical trial information: NCT05286801. Research Sponsor: National Cancer Institute; UM1CA22882; Cookie for Kids Foundation; Genentech, A Member of the Roche Group,; NIH, NCI Intramural research program.

TPS2696 **Poster Session**

A phase 1b study of combined treatment with dupilumab (anti-IL-4Ra) and cemiplimab (anti-PD-1) in patients with early-stage, resectable NSCLC. First Author: Fionnuala Crowley, Division of Hematology & Medical Oncology, The Tisch Cancer Institute, Icahn School of Medicine at Mount Sinai, New York, NY

Background: For resectable stage II/III non-small cell lung cancer (NSCLC), neoadjuvant chemoimmunotherapy has become standard of care. Patients with Stage I disease (as per AJCC 8) were excluded from chemoimmunotherapy studies given prior data demonstrating no survival benefit from perioperative chemotherapy. However, even patients with Stage 1A ($<$ 2cm) tumors have a 30% chance of recurrence (Altorki *et al, NEJM* 2023). Recent research has revealed that tumor-infiltrating myeloid cells express an IL-4 responsive transcriptional signature, and IL-4 signaling within monocyte-derived macrophages plays an essential role in NSCLC progression and tumor microenvironment remodeling. Dupilumab, a monoclonal antibody targeting IL-4 receptor alpha (IL-4Rα), is currently approved for treating asthma and allergic rhinitis, and preclinical studies have demonstrated that blocking IL-4 signaling can significantly reduce lung tumor burden by activating dendritic cells and effector T cells to generate a robust immune response against tumor antigens. These findings are supported by early clinical evidence from a phase 1/2 trial showing that dupilumab can work synergistically with PD-(L)1 inhibition to induce sustained tumor responses in some patients with metastatic NSCLC who had previously progressed on immunotherapy. Whether similar synergy would be seen in the pre-operative setting in patients with Stage 1 tumors, or patients not suitable for chemoimmunotherapy, is not known, though an immunotherapy-alone approach may enable much more brief preoperative treatment given that T cell changes peak at one week in the metastatic setting, and prior studies show PD-1 blockade alone can cause robust responses in some patients within only a few weeks. **Methods:** This Phase 1b/2a single-arm trial will enroll patients with early-stage ($>$ T1b), resectable NSCLC. Patients will receive one dose each of dupilumab (600mg SC) and cemiplimab (350mg IV) on day 1, followed by surgical resection within 15-21 days, with delays beyond 8 weeks considered a delay of surgery. The trial consists of a 3+3 safety run-in (Phase 1b, up to 6 patients) followed by a Simon's two-stage expansion (Phase 2a, up to 24 total patients). The primary endpoints are safety/feasibility (Phase 1b) and major pathological response rate, defined as $\leq$10% viable tumor at resection (Phase 2a). Secondary endpoints include time to surgery, pathological complete response rate, event-free survival, and overall survival. Comprehensive correlative studies will characterize the immune response through serial blood sampling (days 1, 4, 8, 15, surgery, and 30 days post-op), matched proteomic and transcriptomic tumor tissue analysis (pre-treatment and operative samples), and stool microbiome profiling to identify potential biomarkers of response. Clinical trial information: NCT06088771. Research Sponsor: Cancer Research Institute.

TPS2697 **Poster Session**

A phase 1 trial of APX-343A, NOX inhibitor targeting CAF-mediated immunosuppression, as monotherapy or in combination with pembrolizumab in patients with advanced solid tumors. First Author: Hyesung Shin, Aptabio Therapeutics, Yongin-Si, South Korea

Background: Cancer-associated fibroblasts (CAFs), a key component of tumor stroma, promote tumor growth and resistance to anticancer therapy. They contribute to immune suppression within the tumor microenvironment (TME), with evidence linking CAFs to immune checkpoint inhibitor (ICI) resistance and T-cell exclusion. Nicotinamide adenine dinucleotide phosphate (NADPH) oxidase (NOX), which is clinically upregulated by CAF in many human cancers, has been reported to be a critical effector of myofibroblast transformation during fibrosis. Inhibiting NADPH oxidases, NOX2 and NOX4, restored cluster of differentiation 8 + T-cell proliferation by reducing reactive oxygen species (ROS) generation in CAF-induced myeloidderived suppressor cells (MDSCs). A pivotal role of CAFs in regulating monocyte recruitment and differentiation demonstrated that CC-chemokine receptor 2 inhibition and ROS scavenging abrogate the CAF-MDSC axis, illuminating a potential therapeutic path to reversing the CAF-mediated immunosuppressive microenvironment. APX-343A, a selective NOX1, NOX2, and NOX4 inhibitor, has been shown to ameliorate the fibrotic and immunosuppressive properties of CAFs. In CAF-rich tumor mouse models that do not respond to ICIs, APX-343A demonstrated significant anticancer efficacy by modulating both fibrosis and immunosuppression via NOX inhibition. **Methods:** This is a Phase 1, open-label, dose-escalation study designed to assess the safety, tolerability, PK, and preliminary efficacy of APX-343A as monotherapy (Part A) and in combination with pembrolizumab (Part B) in patients with advanced solid tumors. The trial aims to determine the MTD and/or RP2D. Part A is a dose-escalation study of APX-343A monotherapy, starting at a dose of 100 mg BID (Cohort 1) and escalating up to 600 mg BID (Cohort 6) until dose-limiting toxicity (DLT) is identified. APX-343A will be administered on a continuous daily dosing schedule in 21-day cycles. Part B is a dose-escalation study of APX-343A in combination with pembrolizumab (200mg IV, Q3W). Using the BOIN design, the dose level of APX-343A will escalate from 200 up to 600 mg BID without exceeding the MTD. The BOIN design will guide dose escalation based on safety, with decisions made by the Safety Review Committee (SRC). Dose finding will be conducted independently for Parts A and B. APX-343A selective NOX inhibitor has the potential to become an effective treatment option in combination with ICIs for patients with CAF-rich solid tumors that are unresponsive to current immunotherapies. By inhibiting CAF activity in the TME and resensitizing tumors to cancer immunotherapy, APX-343A offers a promising therapeutic approach. Phase 1 results are anticipated in Q1 2026. Research Sponsor: Aptabio Therapeutics Inc.

TPS2698 **Poster Session**

A phase Ib study of a pooled synthetic long peptide mutant KRAS vaccine combined with balstilimab/botensilimab in metastatic pancreatic cancer and metastatic MMR-proficient colorectal cancer in the maintenance setting. First Author: Kai-li Liang, Department of Oncology, Johns Hopkins Sidney Kimmel Comprehensive Cancer Center, Baltimore, MD

Background: Expressed in > 90% of all patients with pancreatic ductal adenocarcinoma (PDAC) and ~40% in mismatch repair-proficient colorectal cancer (MMRp CRC), the mutated oncoprotein KRAS (mKRAS), is an attractive neoantigen vaccine target. Efforts to sensitize these immunologically 'cold' tumors to immune checkpoint inhibitors have just started to yield encouraging clinical data with novel agents. In an ongoing pilot study in patients with resected PDAC and metastatic MMRp CRC (NCT04117087), we demonstrated that a pooled synthetic long peptide (SLP) mKRAS vaccine in combination with ipilimumab and nivolumab was safe and well tolerated. This combination induced robust de novo mKRAS-specific T cells in peripheral blood associated with improved disease-free survival (Haldar *et al.,* 2023). Recently, the Fc-enhanced anti-CLTA-4 antibody, botensilimab (bot), in combination with balstilimab (bal; anti-PD-1) has been shown to demonstrate clinical activity in metastatic relapsed/refractory MMRp CRC (Bullock *et al*., 2024). Based on these encouraging data, our study combines mKRAS vaccine with dual checkpoint blockade to assess safety and early clinical efficacy in patients with metastatic PDAC and metastatic MMRp CRC in the maintenance setting. **Methods:** This is a first-in-human, single-arm, open-label phase Ib trial evaluating mKRAS vaccine with bal/bot in patients with metastatic PDAC (Cohort A, n = 21) and metastatic MMRp CRC (Cohort B, n = 21). The vaccine consists of SLPs corresponding to six common mKRAS alleles: G12D, G12V, G12R, G12C, G12A, G13D admixed with poly-ICLC adjuvant. In the priming phase (Cycle 1) the mKRAS vaccine is given on days 1, 8, 15 and 22 along with bal/bot on day 1 and bal on day 15. In the boost phase, (Cycle 2 and beyond), patients receive bal every 2 weeks and boost vaccines starting on Cycle 4 and every other cycle for a maximum of 2 years. Eligible patients must have metastatic PDAC or MMRp CRC and measurable disease per RECIST 1.1 amenable to biopsies at baseline and week 9. Patients must have one of the six KRAS mutations contained in the vaccine. Patients must have received 4-6 months of 1st line standard chemotherapy without disease progression. The primary endpoints are safety and tolerability, 4-month progression free survival (Cohort A), and objective response rate (Cohort B). Secondary endpoints include disease control rate, objective response rate (Cohort A), and progression free survival (Cohort B). Correlative studies will examine T cell receptor (TCR) clonal expansion in peripheral blood and paired tumor specimens pre- and post-vaccination by next generation TCR sequencing. Patient accrual began in October 2024 with the safety run in completed. Enrollment is currently ongoing. Study drug support provided by Agenus. Trial information: NCT06411691. Clinical trial information: NCT06411691. Research Sponsor: U.S. Department of Defense; U.S. National Institutes of Health.

TPS2699 **Poster Session**

A phase I study of a pooled synthetic long peptide mutant KRAS vaccine in patients with pancreatic cystic neoplasms at risk for developing pancreatic cancer. First Author: Kai-li Liang, Department of Oncology, Johns Hopkins Sidney Kimmel Comprehensive Cancer Center, Baltimore, MD

Background: Mutant KRAS (mKRAS) is an oncogenic driver expressed in > 90% of patients with pancreatic ductal adenocarcinoma (PDAC) and the majority of pancreatic precursors, including > 90% of intraductal papillary mucinous neoplasms (IPMNs) and pancreatic intraepithelial neoplasia (PanIN) (Kanda *et al.,* 2012). If left untreated, approximately 40-60% of high-risk IPMNs will have malignant transformation (Fonseca *et al.,* 2018). mKRAS vaccines have recently demonstrated encouraging results in generating mKRAS-specific T cell responses that correlate with clinical benefit in patients with resected PDAC. We previously reported that a mKRAS-targeted *Listeria*-based vaccine given with Treg-depleting agents results in slowing of PanIN progression to PDAC in a murine model (Keenan *et al.,* 2014). Based on these data, we have initiated a clinical trial testing this vaccine in individuals at high-risk of developing pancreatic cancer. In our first Cohort [A], we have tested this vaccine in individuals at high-risk due to a known germline mutation or familial predisposition (n = 20). Our current study [Cohort B] aims to determine the safety and immunogenicity of a pooled synthetic long peptide (SLP) mKRAS vaccine with poly-ICLC adjuvant in patients with pancreatic cystic neoplasm at risk for developing PDAC and who are scheduled to undergo surgical resection**. Methods:** This is a single-arm, open-label phase I trial evaluating mKRAS vaccine in patients with pancreatic cystic neoplasms at risk for developing PDAC and scheduled to undergo surgical resection (n = 10). The vaccine consists of SLPs corresponding to six common mKRAS mutations: G12D, G12V, G12R, G12C, G12A, G13D admixed with poly-ICLC adjuvant. A two-dose series of the mKRAS vaccine is administered at weeks 1 and 2 followed by pancreatic surgery at week 4. Peripheral blood will be collected pre-vaccination (week 1) and post-vaccination (weeks 4 and 8). Following completion of the treatment phase, patients have the option to continue annual follow-up visits until study closure. Eligible patients must have clinical, radiographic, or histologic evidence of a pancreatic cystic neoplasm with features warranting surgical resection per the discretion of the treating hepatobiliary surgeon. Co-primary endpoints include the safety profile per NCI CTCAE v5.0 and maximal percent change of mutant-KRAS-specific T cells measured by IFNg ELISPOT at weeks 4 and 8 post-vaccination compared to pre-vaccination baseline. Correlative studies of resected specimens will include characterization of the pre-malignant microenvironment and mKRAS-specific T cell trafficking post-vaccination. Methods of analyses include bulk RNA and T cell receptor (TCR) sequencing, spatial transcriptomics, and imaging mass cytometry. Patient accrual began in December 2024 and is currently ongoing. Clinical trial information: NCT05013216. Research Sponsor: Lustgarten Foundation for Pancreatic Cancer.

TPS2700 **Poster Session**

A phase 2 basket trial of tarlatamab in patients with advanced DLL3-expressing tumors: University of California Lung Cancer Consortium UCCC-01/UCLA L-10. First Author: Michael Oh, David Geffen School of Medicine at University of California, Los Angeles, Los Angeles, CA

Background: Delta-like ligand 3 (DLL3) is an inhibitory Notch ligand that is aberrantly expressed on the surface of tumor cells, in particular on those with neuroendocrine differentiation. Tarlatamab is a bispecific T cell engager that binds to DLL3 and CD3 to promote T cell killing of DLL3-expressing cells. Prior studies of tarlatamab have demonstrated encouraging antitumor activity and manageable toxicity in patients with small cell lung cancer (SCLC; DeLLphi-301) and neuroendocrine prostate cancer (NEPC; DeLLpro-300). Meanwhile, DLL3 has been reported to be highly expressed in multiple tumor types, including in many neuroendocrine neoplasms (NENs) other than SCLC and NEPC. The role of anti-DLL3 therapies in these cancers has not been established. **Methods:** This is a phase 2, multicenter, open-label, basket study designed to evaluate the efficacy of tarlatamab in patients with DLL3-expressing cancers. Key inclusion criteria include presence of advanced stage disease with progression following $\geq$1 prior line of therapy and positive tumor DLL3 expression by immunohistochemistry (Ventana SP347 assay). Patients with de novo SCLC or NEPC are excluded, but all other tumor types and NENs are eligible, including large cell neuroendocrine carcinoma and SCLC transformed from previously treated NSCLC. Tarlatamab will be administered at an initial step-up dose (1 mg on D1 and 10 mg on D8 and D15 of cycle 1) followed by 10 mg every 2 weeks. Treatment will continue until unacceptable toxicity, progressive disease, or withdrawal of consent. The study will follow a Simon's two-stage design: in Stage 1, 10 patients with tumor DLL3 expression $\geq$25% will be enrolled, and the study will be stopped if $\leq$1 patient achieves an objective response; otherwise, an additional 19 patients with tumor DLL3 expression $\geq$1% will be enrolled for Stage 2. The primary endpoint is the objective response rate. Secondary endpoints include safety, progression free survival, duration of response, and overall survival. Exploratory studies will evaluate correlation of antitumor activity with tissue and blood-based biomarkers, such as DLL3 expression on tumor and liquid biopsies. This study is currently enrolling patients through the University of California Lung Cancer Consortium (UCLCC). Clinical trial information: NCT06788938. Research Sponsor: None.

TPS2701 **Poster Session**

EXPAND-1, a phase I/II study with ANV600, a novel PD-1 targeted IL-2R-βγ agonist, in monotherapy and in combination with pembrolizumab, in patients with advanced solid tumors. First Author: Iphigenie Korakis, Inst University Du Cancer De Toulouse, Toulouse, France

Background: ANV600 is a novel PD-1 targeted, interleukin-2 receptor beta/gamma (IL-2Rβ/γ) selective agonist. This bispecific agent comprises two functionally distinct arms: a PD-1 targeting arm consisting of an anti-PD-1 antibody binding to an epitope that does not overlap with pembrolizumab or other PD-1 checkpoint inhibitors and an IL-2 receptor (IL-2R) agonistic arm, composed of an interleukin-2 (IL-2)/anti-IL-2 antibody fusion protein which selectively signals through IL-2Rβ/γ. ANV600 is expected to promote anti-tumor activity by preferentially stimulating and expanding antigen-experienced PD-1^{+} CD8^{+} T cells and be combinable with existing anti-PD-1 clinical therapies. ANV600 will be studied as single agent and in combination with pembrolizumab for the treatment of advanced solid tumors. **Methods:** Study ANV600-001 (EXPAND-1) is a global, multicenter, open-label, first-in-human Phase I/II study to characterize the safety, tolerability, pharmacokinetics (PK), pharmacodynamics (PD), immunogenicity and antitumor activity of ANV600 administered as a single agent or in combination with pembrolizumab in patients with advanced solid tumors. The Phase I will determine the maximum tolerated dose (MTD) and/or recommended phase 2 dose (RP2D) of ANV600 administered intravenously every 2 weeks (Q2W) either as single agent or in combination with pembrolizumab in previously treated advanced solid tumors. A Bayesian Optimal Interval (BOIN) design will guide the dose escalation to determine the MTD and/or RP2D. Once the RP2D has been determined, ANV600 will be further evaluated as monotherapy and in combination with pembrolizumab in the Phase II part of the study for efficacy and safety in PD-1 experienced patients with advanced melanoma, NSCLC and HNSCC. Additional cohorts may be selected based on emerging data. Tumor response will be assessed using RECIST v1.1. Enrolment began in June 2024, with 10 patients enrolled in the monotherapy arm and 4 in the combination arm. Up to 240 participants will be enrolled in 7 countries: Belgium, France, Germany, the Netherlands, Spain, Switzerland and the USA. Research Sponsor: ANAVEON AG. Clinical trial information: NCT06470763. Research Sponsor: None.

TPS2702 **Poster Session**

Fecal microbiota transplantation combined with sintilimab and SOX as first-line treatment for advanced gastric cancer (FMT-JSNO-01): A prospective, multicenter, double-blind, randomized placebo-controlled phase II trial. First Author: Wenyu Zhu, Department of Oncology, The Second People's Hospital of Changzhou, the Third Affiliated Hospital of Nanjing Medical University, Changzhou, China

Background: Chemotherapy in combination with immunotherapy has emerged as the first-line(1L) standard of care for gastric cancer (GC) patients(pts); nonetheless, the overall prognosis remains suboptimal. Fecal microbiota transplantation (FMT) holds promise in modulating the patient's gut microbiota and immune milieu, thereby augmenting the efficacy of tumor immunotherapy and enhancing long-term survival outcomes. We propose to integrate FMT into the regimen of chemotherapy plus immunotherapy, aiming to assess its efficacy and safety in pts with advanced GC (NCT06405113). **Methods:** FMT-JSNO-01 is a prospective, multicenter, randomized, double-blind, placebo-controlled phase II trial designed to enroll pts with previously untreated, unresectable advanced gastric or gastroesophageal junction adenocarcinoma (GAC/GEJAC) that is human epidermal growth factor receptor 2 (HER2) negative. The physical status score of Eastern Tumor Collaboration Group (ECOG) was 0-1.The study will be conducted in more than 15 multidisciplinary treatment centers for GC in China.The eligible pts were randomly assigned to arm A and arm B. Using a network random system, subjects are randomly assigned in a 1:1 ratio to the experimental group and control group, and competitive random enrollment is conducted at each center.Pts in arm A received fecal microbiota capsule transplantation combined with sintilimab immunotherapy plus S-1 and oxaliplatin (SOX) chemotherapy, while pts in arm B received placebo combined with sintilimab plus SOX . If there is no progression of the disease after 4-6 cycles of 1L treatment, both arms of pts will enter the 1L maintenance treatment stage: S-1 plus sintilimab, until disease progression, intolerance, or death occurs.The primary endpoint of the study is the 2-year overall survival rate (2-year OS rate), with secondary endpoints including median progression-free survival (mPFS), objective response rate (ORR), incidence of adverse events (AEs), diversity of fecal microbiota, and quality of life (QoL). Additionally, exploratory endpoints will encompass efficacy prediction markers in the gut microbiota and proteomics. This study began recruiting pts in June 2024 and is currently ongoing. Clinical trial information: NCT06405113. Research Sponsor: the 2022 Clinical Research project of Changzhou Medical Center, Nanjing Medical University; CMCC202201; 2022 Changzhou 8th Batch of Science and Technology Project (Applied Basic Research); CJ20220086; 2023 Clinical Research Project of Changzhou Medical Center,Nanjing Medical University; CMCC202307; 2023 Changzhou Health Commission Science and Technology Project; QN202320.

TPS2703 **Poster Session**

A first-in-human phase 1 clinical trial of INI-4001, a novel TLR7/8 agonist, in patients with advanced solid tumors. First Author: Shannon Marilee Miller, Inimmune Corp., Missoula, MT

Background: Inimmune has developed INI-4001, a novel TLR7/8 agonist as an immunotherapy treatment for cancer. Pre-clinically, the lead formulation of INI-4001 was able to eliminate Lewis Lung Carcinoma (LLC) flank tumors in mice after just two treatments. Moreover, INI-4001 slowed the growth of MC38 and B16F10 tumors and synergized when combined with anti-PD-1 therapy, leading to an increased cure rate in both MC38 and B16F10 flank tumors in mice when both drugs were used compared to either treatment alone. In July of 2024, we dosed our first patient in a Phase 1 clinical trial in patients with advanced solid tumors. **Methods:** INI-4001 will be evaluated in a Phase Ia/Ib, open-label, dose-escalation, and dose expansion study. This study will be conducted in two parts: Phase Ia (dose escalation) and Phase Ib (dose expansion). Phase Ia will initially seek to establish the MTD or OBD of INI-4001 administered as monotherapy. Using a BOIN design, we have planned six ascending 1-3-subject cohorts with weekly dosing on continuous 21-day cycles. Imaging shall occur after each 3 cycles, and combination therapy with a checkpoint inhibitor is allowable under certain conditions after 3 cycles of monotherapy. Combination with checkpoint inhibitor is allowed if the subject has progressed or achieved stable disease according to iRECIST criteria and has a tumor type for which a checkpoint inhibitor is approved. Following identification of the MTD or OBD, Phase 1b allows any dose level at or below the MTD to be expanded with up to 20 additional subjects to further explore the safety, PK, PD, and preliminary efficacy of INI-4001 alone or as combination therapy. Currently in Phase Ia, Cohorts 1, 2, and 3 have been completed without DLT. Enrollment to Cohort 4 will begin in February 2025. INI-4001 may continue as monotherapy or combination as long as the subject receives benefit. Following cessation of INI-4001, patients will be requested to participate in long-term follow-up to assess overall survival. Clinical trial information: NCT06302426. Research Sponsor: None.

3000 Oral Abstract Session

DB-1310, a HER3-targeted ADC, in pts with advanced solid tumors: Preliminary results from the phase 1/2a trial. First Author: Aaron Lisberg, Division of Hematology/Oncology, University of California, Los Angeles, Santa Monica, CA

Background: DB-1310 is a novel ADC comprised of a humanized anti-HER3 IgG1 monoclonal antibody, cleavable peptide linker, and DNA topoisomerase I inhibitor. Here, we report the preliminary results of the FIH trial. **Methods:** This global, multi-center, open-label Ph 1/2a trial includes dose escalation and expansion. Pts with advanced solid tumors who had failed standard therapy were enrolled. In Ph1, DB-1310 was planned to be administered at doses from 1.5 mg/kg to 6.5 mg/kg, Q3W, iv, using a 3+3 design, with additional pts enrolled to determine the RP2D. Ph 2a will include approximately 30-40 pts per cohort to optimize the RP2D and assess efficacy. **Results:** As of Jan 17, 2025, 123 pts were enrolled and treated with DB-1310 monotherapy in Ph1 (ECOG PS 1, 80.5%; White, 39.0%, Asian, 52.8%; NSCLC, 65.0%, EGFRm NSCLC, 37.4%; brain metastasis, 17.1%), median prior lines of systemic therapy was 3 (range, 1-11). Of the 42 efficacy-evaluable pts with EGFRm NSCLC, 92.9% had previously received 3rd generation EGFR TKI, 92.9% had received platinum-based chemotherapy. The unconfirmed ORR was 25.5% (95% CI, 17.63, 34.65) across all tumor types and 35.7% (95% CI, 21.55, 51.97) in EGFRm NSCLC. Median PFS was 5.4 months overall and 7.0 months for EGFRm NSCLC. 38 (30.9%) pts experienced ≥ G3 TRAEs, while 7 (5.7%) had drug-related SAEs. TRAEs led to dose reduction in 14 (11.4%) pts and discontinuation in 5 (4.1%) pts. No TRAE leading to death was reported. Most common TRAE (> 20%, any grade/≥G3) were nausea (36.6%/0.8%), anemia (35.8%/4.1%), neutrophil count decreased (34.1%/17.9%), platelet count decreased (31.7%/9.8%), white blood cell count decreased (29.3%/8.9%), decreased appetite (23.6%/0.8%), and vomiting (21.1%/0%). Interstitial lung disease occurred in 7 pts (5.7%, 6 G1 and 1 G2). PK exposure was increased through dose escalation, with low systemic payload exposure and no accumulation of DB-1310 upon repeated administration. **Conclusions:** DB-1310 showed a manageable safety profile and encouraging antitumor activity in pts with heavily pretreated advanced solid tumors, particularly EGFRm NSCLC. Clinical trial information: NCT05785741. Research Sponsor: None.

3001 Oral Abstract Session

Phase I study of iza-bren (BL-B01D1), an EGFR x HER3 bispecific antibody-drug conjugate (ADC), in patients with locally advanced or metastatic non-small cell lung cancer (NSCLC) with driver genomic alterations (GA) outside of classic EGFR mutations. First Author: Yunpeng Yang, Department of Medical Oncology, Sun Yat-Sen University Cancer Center, Guangzhou, China

Background: iza-bren is a first-in-class ADC comprised of an EGFR x HER3 bispecific antibody conjugated to a novel topo-I inhibitor payload (Ed-04) via a stable tetrapeptide-based cleavable linker. Safety/efficacy data from the phase Ib study are presented, focusing on NSCLC patients (pts) with driver mutations outside of classic TKI-sensitizing EGFR mutations. **Methods:** Phase Ib part of this study included the expansion cohorts, each defined by a pre-specified GA, including EGFR exon 20 insertions, non-classical EGFR mutations, mutations in HER2, ALK, ROS1, BRAF (V600E and others), KRAS (G12C and others), SMARCA4, MET (Exon 14), RET, and NTRK. Pts with these GA who progressed on standard targeted therapies (if available) and no more than one prior line of chemotherapy were enrolled. iza-bren was given at 2.5 mg/kg D1D8 Q3W. **Results:** As of Dec 5, 2024, a total of 73 NSCLC pts with listed GA were enrolled. Five pts were still on treatment, but were excluded from the analysis due to insufficient follow-up for the first post-baseline scan (see table below). Among 7 pts with EGFR exon 20 insertions, 85.7% (6 out of 7) achieved cPR. Among 8 pts with KRAS G12C mutations, 3 cPR and 1 PR pending confirmation were observed. Efficacy for subgroups will be presented. The most frequent hematologic TRAEs (all grades) were anemia (87.7%), leukopenia (74.0%), thrombocytopenia (74.0%), and neutropenia (72.6%); the most frequent non-hematologic TRAEs were asthenia (42.5%), nausea (41.1%), stomatitis (37.0%), diarrhea (32.9%), and alopecia (31.5%). Grade 3 and above TRAEs which were predominantly hematologic in nature, were able to be effectively managed with standard supportive measure including dose reductions, as demonstrated by the TRAE leading to discontinuation rate of 2.7%. Only 1 case of G2 ILD was observed. Notably, no iza-bren related death was reported. No new safety signals were observed. **Conclusions:** In NSCLC pts with these GAs, iza-bren showed promising activity with a manageable safety profile, supporting further evaluation of iza-bren in these populations. Clinical trial information: NCT05194982. Research Sponsor: None.

3002 Oral Abstract Session

Phase I study of iza-bren (BL-B01D1), an EGFR x HER3 bispecific antibody-drug conjugate (ADC), in patients with locally advanced or metastatic small cell lung cancer (SCLC). First Author: Yan Huang, Department of Medical Oncology, Sun Yat-Sen University Cancer Center, Guangzhou, China

Background: iza-bren is a first-in-class ADC comprised of an EGFR x HER3 bispecific antibody conjugated to a novel topo-I inhibitor payload (Ed-04) via a stable tetrapeptide-based cleavable linker. Unlike existing ADCs targeting general tumor antigens, iza-bren uniquely targets the EGFR and HER3 pathways, which are implicated in the aggressive biology of SCLC. It has shown promising clinical activity and a manageable safety profile in patients (pts) with advanced or metastatic solid tumors. Results for safety/efficacy from this phase I study in SCLC pts are presented. **Methods:** Pts with locally advanced or metastatic SCLC who had progressed on prior systemic therapies were enrolled and treated at 2.0, 2.5 mg/kg D1D8 Q3W, or 4.5, 5.0 mg/kg D1 Q3W. Tumor scans were done every 6 weeks. Efficacy was evaluated in the overall cohort and specific subgroups, with a particular focus on pts with limited prior treatment exposure. **Results:** As of Dec 5, 2024, a total of 58 SCLC pts were enrolled. All pts who received at least one dose of iza-bren are included in the analysis. The median follow-up was 16.4 mo, ORR was 55.2%, confirmed ORR was 44.8%, median PFS was 4.0 mo, and median OS was 12.0 mo. Among the 52 pts at 2.5 mg/kg, 20 pts received only 1 prior line of PD(L)-1 and PBC combination treatment. In this subgroup, ORR was 80.0%, confirmed ORR was 75.0%, median DOR was 5.6 mo, median PFS was 6.9 mo, and median OS was 15.1 mo. The most frequent hematologic TRAEs (all grades) were anemia (84.5%), leukopenia (74.1%), thrombocytopenia (72.4%), and neutropenia (70.7%); the most frequent non-hematologic TRAEs were asthenia (41.4%), hypoalbuminemia (39.7%), stomatitis (34.5%), nausea (31.0%), and vomiting (31.0%). Grade 3 and above TRAEs which were predominantly hematologic in nature, were able to be effectively managed with standard supportive measure including dose reductions, as demonstrated by the TRAE leading to discontinuation rate of 12.1%. Two infection-related deaths (1 respiratory failure, 1 gastrointestinal infection) associated with iza-bren were reported. No ILD was observed. No new safety signals were identified. **Conclusions:** In SCLC pts, iza-bren has demonstrated an encouraging efficacy with a manageable safety profile. Notably, the high confirmed response rate of 75% in pts with limited prior treatment underscores its potential as a novel therapeutic option for SCLC, a disease with limited therapeutic advancements over decades. The phase III study of iza-bren in SCLC pts who received 1 prior line of PD(L)-1 and PBC combination treatment is ongoing (NCT06500026). Clinical trial information: NCT05194982. Research Sponsor: None.

3003 Oral Abstract Session

Safety and efficacy of TQB2102, a novel bispecific anti-HER2 antibody–drug conjugate, in patients with advanced solid tumors: Preliminary data from the first-in-human phase 1 trial. First Author: Rui-Hua Xu, Department of Medical Oncology, University Cancer Center State Key Laboratory of Oncology in South China, Collaborative Innovation Center of Cancer Medicine, Guangzhou, China

Background: TQB2102 is an antibody-drug conjugate (ADC) comprised of a recombinant, humanized anti-human epidermal growth factor receptor 2 (HER2) bispecific antibody conjugated to a topoisomerase I inhibitor via an enzyme-cleavable linker. The bispecific antibody component can target both extra-cellular domains II (pertuzumab binding site) and IV (trastuzumab binding site) of HER2. We conducted a multicenter, dose escalation and expansion first-in human (FIH) phase 1 study of TQB2102 in advanced solid tumors. **Methods:** In the dose escalation phase, eligible patients (pts) with advanced solid tumors whose disease had progressed after standard systemic treatments, were enrolled in a 3+3 dose escalation study of TQB2102(1.5, 3, 4.5, 6, 7.5 or 9 mg/kg) IV, every 3wks (Q3W). In the dose expansion phase, pts with HER2 positive cancers and HER2 low (HER2 1+ or HER2 2+ and FISH negative) metastatic breast cancer (MBC) received the selected recommended phase 2 dose (RP2D). The primary objectives were to evaluate the safety and tolerability, dose limiting toxicities (DLTs) and maximum tolerated dose (MTD) of TQB2102. **Results:** As of October 1, 2024, 181pts (41 pts in dose escalation phase and 140 pts in dose expansion phase) were enrolled from 12 centers. Most common tumor types included MBC (N = 80), Colorectal cancer (N = 37) and Gastric cancer (N = 23).Twenty-five (31%) MBC received prior anti-HER2 ADCs, including 21 pts received T-DM1, 8 pts received DS-8201.The median duration of follow-up was 8.15 months. TQB2102 was well-tolerated with no DLTs occurred and MTD was not reached. The most common (occurring in ≥5%) grade ≥3 AEs were neutrophil count decrease (21.7%), WBC count decreased (10.6%), anemia (8.9%), platelet count decreased (6.1%), diarrhea (5.0%). Only one patient had grade 2 interstitial lung disease (ILD) until the cutoff date. 6 or 7.5mg/kg was selected for dose expansion. Objective response rate (ORR) per RECIST v1.1 was 41.2% (68 partial responses [PR]) in 165 responses evaluable pts who had ≥1 response assessment. Surprisingly, 7 pts reached PR in 10 HER2+ MBC pts with brain metastases, one of whom the brain metastatic lesions reached complete response after 4 cycles of treatment. This trial is ongoing now. **Conclusions:** TQB2102 is well tolerated with promising anti-tumor activity in pts with HER2-expressing cancer. These early signs of activity support a phase 3 trial in patients with HER2-low MBC that has been initiated (NCT06561607). Clinical trial information: NCT05735496. Research Sponsor: Chia Tai Tianqing Pharmaceutical Group Co., Ltd.

6mg/kg and above	ORR(%)	DCR(%)	6-months PFS rate, (%)
HER2 positive MBC (N=39)	51.3	84.7	87.0
HER2 low MBC (N=33)	51.5	87.9	63.0
HER2 3+ colorectal cancer (N=23)	34.8	87.0	88.4
HER2 positive gastric cancer (N=10)	70.0	90.0	90.0
HER2 positive Other (N=5)	60.0	100.0	NE

3004 **Oral Abstract Session**

Efficacy and safety of the DLL3/CD3 T-cell engager obrixtamig in patients with extrapulmonary neuroendocrine carcinomas with high or low DLL3 expression: Results from an ongoing phase I trial. First Author: Jaume Capdevila, Department of Medical Oncology, Vall d'Hebron University Hospital & Vall d'Hebron Institute of Oncology, Barcelona, Spain

Background: Delta-like ligand 3 (DLL3) is highly expressed in neuroendocrine carcinomas (NEC). Obrixtamig (BI 764532) is a DLL3/CD3 IgG-like T-cell engager that targets DLL3-positive (DLL3+) tumors. NCT04429087 is an ongoing, Phase (Ph) I dose-escalation trial of obrixtamig in patients (pts) with DLL3+ pulmonary and extrapulmonary NEC (epNEC), who had failed to respond to standard treatment (Tx). This analysis examined the efficacy and safety of obrixtamig in pts with epNEC with high vs low DLL3 expression. **Methods:** Obrixtamig was given IV in 4 dose-escalation regimens (R): RA (fixed dose q3w); RB1 (fixed dose qw); RB2 (step-up dose, then qw) and RB3 (step-up dose, then qw for 3 weeks, then q3w), until disease progression or unacceptable toxicity. Efficacy was assessed through objective response rate (ORR) and disease control rate (DCR) using RECIST v1.1. Results are reported for pts who received obrixtamig RB2 or RB3, categorized as having high vs low DLL3, using a threshold of ≥50% of tumor cells stained with an investigational antibody for DLL3 (SP347, Roche Diagnostics). **Results:** As of June 21, 2024, 60 pts with epNEC were included (gastroenteropancreatic [GEP]: 45.0%, genitourinary [GU]: 30.0%, other/unknown primary site: 25.0%); 30 each DLL3-high and DLL3-low. Mean age: 63.9 years in DLL3-high; 59.1 in DLL3-low pts. Baseline characteristics were well-balanced across DLL3 groups. All pts had received prior systemic therapy; 30.0% of DLL3-high and 50.0% of DLL3-low pts had received > 2 lines of prior Tx. Efficacy data are shown in the Table. After obrixtamig Tx, pts with high DLL3 expression had greater ORR, DCR, and duration of response (DoR) than DLL3-low pts. Responses were seen most frequently amongst pts with DLL3-high GEP (50.0%) or GU (60.0%) epNECs. Seven DLL3-high pts are still receiving Tx. Most treatment-related AEs (TRAEs) were mild to moderate for both groups (Table). **Conclusions:** Analyses from this ongoing Ph I study show greater obrixtamig efficacy in patients with epNEC with high DLL3 expression compared with low DLL3 expression, with a manageable safety profile that is comparable across both groups. The ORR of 40.0% and median DoR of 7.9 months in heavily pretreated epNEC tumors with DLL3 high expression are encouraging, and support further development of obrixtamig for this subgroup. Clinical trial information: NCT04429087. Research Sponsor: Boehringer Ingelheim.

3005 **Oral Abstract Session**

[^{212}Pb]VMT-α-NET therapy in somatostatin receptor 2 (SSTR2) expressing neuroendocrine tumors (NETs): Dose-limiting toxicity (DLT) observation participants after 1 year follow-up and preliminary report for expansion participants. First Author: Thorvardur Ragnar Halfdanarson, Mayo Clinic Comprehensive Cancer Center, Rochester, MN

Background: [^{212}Pb]VMT-α-NET, a next generation ^{212}Pb-based, SSTR2-targeted alpha-particle radiopharmaceutical therapy (RPT), was designed to achieve superior biodistribution via optimized tumor uptake and retention and rapid renal clearance. Results reported here are from the Phase 1/2a first-in-human study [NCT05636618]. **Methods:** Safety, pharmacokinetics, dosimetry and efficacy using RECIST v1.1 were investigated in the treatment of participants with [^{212}Pb]VMT-α-NET who had SSTR2-expressing, well-differentiated adult NETs of any grade. Participants received ≥1 prior therapy. No prior peptide receptor radionuclide therapy was allowed. The trial has multiple dose cohorts including 92.5 MBq (2.5 mCi, cohort 1) and 185 MBq (5 mCi, cohort 2) of administered activity based on a Bayesian modified toxicity probability interval (mTPI-2) design. Up to 8 participants per cohort were treated with 4 doses of [^{212}Pb]VMT-α-NET for DLT observation. Cohort 2 enrollment was expanded to further define the safety and efficacy profile at this dose level. **Results:** Nine (9) gastroenteropancreatic NET participants were enrolled into cohorts 1 and 2 for DLT observation. The ninth of these participants was enrolled more than 1 year prior to presentation of these data. Among these participants at the time of abstract submission, no DLTs were observed, and there were no grade 4, 5 or serious adverse events (SAEs). Specifically, no renal insufficiency or dysphagia were observed. Hematologic AEs were low grade and few in number. No treatment discontinuations due to AE occurred. Three (3) of the 7 cohort 2 participants enrolled for DLT observation achieved investigator-assessed partial responses (PRs). Two PRs were unconfirmed at the time of abstract submission. Durable progression-free survival (PFS) was consistently observed. More than 15 additional participants were enrolled in the cohort 2 expansion. Preliminary data for these patients will be reported at the congress. **Conclusions:** [^{212}Pb]VMT-α-NET is a well-tolerated, next generation RPT showing signs of clinical activity at early dose-levels in this phase 1/2a study. Based on these clinical data, further dose-escalation and development of this promising therapy are warranted. Clinical trial information: NCT05636618. Research Sponsor: Perspective Therapeutics, Inc.

3006 **Oral Abstract Session**

Comprehensive genomic profiling of matched ctDNA and tissue from patients with less common cancers enrolled in but not eligible for a treatment arm of the NCI-MATCH trial. First Author: Biswajit Das, Frederick National Laboratory for Cancer Research, Frederick, MD

Background: During NCI-MATCH (NCT02465060) clinical trial screening, 5961 advanced cancer patients underwent next-generation sequencing to assess eligibility. About 60% of these patients had less common tumors (i.e., cancers other than colon, rectal, breast, non-small cell lung, or prostate). Most patients lacked a study eligible mutation of interest (MOI) and thus didn't receive a trial therapy. Analysis of plasma samples from these patients may illuminate circulating tumor DNA (ctDNA) profiles, potentially guiding ctDNA testing for clinically relevant mutations in less common cancer types. Here we report the molecular profiles of ctDNA and matched tumor from a subset of the NCI-MATCH screened patients. **Methods:** Comprehensive genomic profiling of ctDNA (from blood collected at enrollment) was performed using the TSO500 ctDNA v2 assay (523-genes) and sequenced on the Illumina NovaSeq 6000. Matched tumor was sequenced with the Oncomine Comprehensive Assay v2, a 143-gene panel. Positive percent agreement (PPA) between mutations of interest (MOI) identified in plasma ctDNA and tissue-based screening was calculated with tumor tissue as referent (PPA_{ref_tumor}). **Results:** We tested 2253 patients from the less common tumor cohort. 2194 samples were evaluable with 98.6% pass and 1.4% failure rates. A subset of five tumor histologies with larger representation (n > 35) in sample size were further analyzed: cholangiocarcinoma (CCA, n = 90), small cell lung cancer (SCLC, n = 59), adenocarcinoma of the esophagus (EAC, n = 37), adenocarcinoma of the pancreas (PDAC, n = 232), and salivary gland cancer (SGC, n = 47). Overall, $PPA_{ref\ tumor}$ was 83.4% (range: 76.5%-97.9%) in these five histologies. In patients with concordance < 75%, median tumor fraction (as determined by maximum somatic allele frequency) was much lower (0.37%) than for specimens with concordance > = 75% (6.49%). The most frequently mutated genes identified in CCA were *TP53*, *KRAS*, and *IDH1*; in SCLC were *TP53* and *RB1* loss; in EAC were *TP53*, *KRAS, and ERRB2* amplification; in PDAC were *TP53* and *KRAS*; and in SGC was *TP53*. Additionally, there were several clinically relevant mutations detected only in ctDNA such as *IDH1* for CCA; and *BRAF*, *TP53*, and *PIK3CA* in several histologies. Microsatellite instability, as measured only in ctDNA, was most prevalent in SCLC, followed by CCA. **Conclusions:** Concordance of rare tumors in the NCI-MATCH trial is 83.4% in the representative histologies analyzed, which is similar to concordance of clinically relevant MOIs in common cancer studies. Liquid biopsy may be a viable screening option for matching targeted therapies in clinical trials, especially when a tumor biopsy is not practical or evaluable. The detection of some mutations in ctDNA only may suggest the presence of tumor heterogeneity in multiple lesions in patients with less common cancers. Research Sponsor: National Cancer Institute, National Institutes of Health; Illumina Inc.

3007 **Oral Abstract Session**

Ultra-sensitive pan-cancer molecular residual disease assessment using whole-genome sequencing-based personalized ctDNA panel: Initial results from the MONSTAR-SCREEN-3 project. First Author: Tadayoshi Hashimoto, Department of Gastroenterology and Gastrointestinal Oncology, National Cancer Center Hospital East, Kashiwa, Japan

Background: While circulating tumor DNA (ctDNA) demonstrates promise as a molecular residual disease (MRD) biomarker, its clinical implementation has been primarily limited to tumors with favorable ctDNA shedding characteristics. We are evaluating an ultra-sensitive whole-genome sequencing (WGS)-based MRD assay in the MONSTAR-SCREEN-3 study to establish a comprehensive pan-cancer MRD platform inclusive of traditionally low-shedding tumors. **Methods:** MONSTAR-SCREEN-3, a prospective multicenter study targeting 1,100 patients with solid tumors undergoing curative-intent treatment in the definitive cohort, utilizes personalized panels constructed via Precise MRD (Myriad Genetics). These panels incorporate up to 1,000 tumor-specific alterations identified through WGS of matched tumor tissue, including both short variants and insertion-deletions. Serial plasma samples were collected at baseline, post-neoadjuvant chemotherapy (when applicable), 1-month post-surgery, quarterly in year 1, and biannually thereafter up to 2 years. The assay performance was evaluated across multiple cancer types for ctDNA detection and recurrence monitoring. **Results:** As of December 2024, 114 patients across 15 cancer types were enrolled, including colorectal (n = 33), gastric (n = 22), head and neck (n = 13), renal cell (n = 10), esophageal (n = 8), and pancreatic (n = 7) cancers. Treatment strategies included upfront surgery (n = 76) and neoadjuvant chemotherapy (n = 38). The median follow-up time was 2.4 months (range, 0.5–7.7). WGS analysis identified a median of 6,089 panel-eligible alterations per patient (range: 214-14,112), with high variants counts observed in a deficient mismatch-repair colorectal cancer, enabling comprehensive personalized panel design. Customized panel creation was successful in 69/71 patients (97.2%) across 8 cancer types, with two pancreatic cancer cases deferred to surgical specimens due to insufficient variants in FNA samples. The assay demonstrated 100% baseline sensitivity (41/41), detecting tumor fractions ranging from < 0.001% to 45.2% across all cancer types, including traditionally low-shedding tumors. Post-operative 1-month MRD assessment revealed 35.7% positivity (10/28), with tumor fractions ranging from < 0.001% to 0.27%. Two MRD-positive patients developed radiological recurrence with lead times of 2.5 and 3 months before conventional imaging detection. **Conclusions:** These interim results demonstrate successful pan-cancer implementation of WGS-based personalized ctDNA detection, achieving universal baseline sensitivity and ultra-sensitive MRD detection across tumor types, including those traditionally challenging to assess. Updated molecular and clinical outcome data will be presented. Clinical trial information: UMIN000053975. Research Sponsor: SCRUM-Japan Funds (http:// www. scrum -japan. ncc. go. jp/ index. html); Myriad Genetics.

3008 Oral Abstract Session

Circulating tumor DNA (ctDNA) in patients with stage 2/3 HR+HER2- negative breast cancer (BC) treated with neoadjuvant endocrine therapy (NET) in the I-SPY2 endocrine optimization pilot (EOP) trial. First Author: Silver Alkhafaji, University of California, San Francisco, San Francisco, CA

Background: Numerous studies have demonstrated the prognostic value of ctDNA analysis after neoadjuvant chemotherapy for early-stage high-risk breast cancer. Few studies have characterized ctDNA in pts receiving NET for early-stage hormone receptor positive (HR+)/HER2- BC that is predicted to benefit less from chemotherapy. **Methods:** Cell-free DNA (cfDNA) was isolated from 432 plasma samples from 108 pts enrolled in the I-SPY2 EOP trial. Pts had Stage 2/3 HR+/HER2-, MammaPrint low or high risk 1 BC. Pts were randomized to one of 7 neoadjuvant-based treatment arms including arms containing AI, Z-endoxifen, Lasofoxifene, vepdegestrant (ARV-471), and Abemaciclib. Pts were treated for 6 months prior to surgery. Blood was collected at baseline (T0), 3 weeks (T1), 12 weeks (T2), and 6 months (T3). A personalized ctDNA test (Signatera) was designed to detect up to 16 patient-specific mutations (from whole-exome sequencing of pretreatment tumor) in cfDNA by ultra-deep sequencing. The chi-square test was used to assess associations between categorical variables, and the Wilcoxon rank-sum test was used to evaluate differences in medians. **Results:** ctDNA information was available for 101 patients at baseline (T0) (Table 1). At T0, 36 (35.6%) patients were ctDNA-positive. 23/36 (63.9%) became ctDNA-negative and 13/36 (36.1%) remained ctDNA-positive. At T0, 65/101 patients (64.4%) were ctDNA-negative. Of these, 57 (87.7%) remained negative, while 8 (12.3%) became ctDNA-positive at T1 before reverting to ctDNA-negative. A higher percentage of ctDNA-positive patients at T0 were cN+ compared to ctDNA-negative pts (p = 0.036, 64% vs. 40%). Additionally, ctDNA-positivity at T0 was strongly associated with higher Ki67 (p = 0.03) and larger functional tumor volume by MRI at baseline (p = 0.03). T3/T4 and high-grade tumors at baseline were also associated with having ctDNA positivity at baseline, though this was not statistically significant (p = 0.34 and 0.058, respectively). **Conclusions:** In this study of pts with Stage 2/3 HR+ HER2- BC with largely MammaPrint low risk signatures, over one-third of pts had detectable ctDNA at baseline. Detectable ctDNA at baseline was associated with cN+ disease, larger FTV, and high baseline Ki67. The majority of pts with positive ctDNA at baseline cleared the ctDNA on NET. Clinical trial information: NCT01042379. Research Sponsor: NIH/NCI ctDNA/MR; Breast Cancer Research Foundation; Give Breast Cancer the Boot; Quantum Leap Healthcare Collaborative.

3009 Rapid Oral Abstract Session

Initial phase 1 dose escalation data for emiltatug ledadotin (Emi-Le), a novel B7-H4-directed dolasynthen antibody-drug conjugate. First Author: Erika P. Hamilton, Breast Cancer Research Program, Sarah Cannon Research Institute, Nashville, TN

Background: B7-H4 is a transmembrane protein over-expressed in breast (BC), ovarian (OC), endometrial (EC), and adenoid cystic carcinoma type 1 (ACC-1) cancers, with limited expression in healthy tissues. Emi-Le (XMT-1660) is a B7-H4-directed Dolasynthen ADC designed with a proprietary auristatin F-HPA microtubule inhibitor payload with controlled bystander effect. **Methods:** The Phase 1 trial is investigating Emi-Le monotherapy in adult patients (pts) with advanced/metastatic TNBC, HR+/HER2- BC, OC, EC and ACC-1. In dose escalation, eligible pts received Emi-Le at doses of 7.2-115 mg/m2 per cycle, with all collected data informing the recommended doses for the expansion (EXP) portion of the trial. Tumors were evaluated retrospectively for B7-H4 expression by IHC, with the preliminary high cutoff set at TPS≥70. **Results:** As of December 13, 2024, 130 pts were dosed. Across all tumor types, median age of pts was 55; median 4.5 prior lines of therapy (range 0-15). B7-H4 status was evaluated for 103 pts, with 44% determined to be B7-H4 TPS high. Overall, Emi-Le was generally well tolerated. The most common TRAEs were transient AST increase (38%, G3 14%), proteinuria (31%, G3 9%), nausea (29%, G3 1%) and fatigue (28%, G3 0%). The only G3 TRAEs in ≥5% of pts were AST increase and proteinuria. No G4 or 5 TRAEs were reported. No observed dose-limiting treatment-related neutropenia, neuropathy, ocular toxicity, interstitial lung disease or thrombocytopenia. TRAEs leading to discontinuation were observed in 2.3% of pts. Clinical activity was correlated with both dose and B7-H4 expression. For pts treated with doses ranging from 38.1–67.4 mg/m2 per cycle (intermediate dose range), the confirmed ORR in evaluable pts with high B7-H4 expression was 23% (6/26), including a 23% (3/13) confirmed ORR in evaluable pts with TNBC, with all 13 pts having previously received at least one topoisomerase-1 inhibitor (topo-1) ADC. At doses ≥76.2 mg/m2 per cycle (high dose range), the confirmed ORR in evaluable pts with high B7-H4 expression was 22% (2/9), with 78% (7/9) having ≥30% reduction in target lesions. Of the 8 pts with confirmed responses at doses ≥38.1 mg/m2, 5 had reduction in target lesions > 60%, including 1 CR. All 4 pts with high B7-H4 expression treated at the initial EXP dose of 67.4mg/m2 Q4W had tumor reductions and were on treatment with durations of ≥16 weeks as of data cutoff. **Conclusions:** Based on the initial reported data, Emi-Le appears to have encouraging clinical activity and tolerability in a heavily pretreated population. Further clinical development is ongoing in the EXP portion of the trial at a dose of 67.4 mg/m2 Q4W in pts with advanced/metastatic TNBC who have received 1-4 prior lines of systemic therapy, including at least one topo-1 ADC. Dose exploration is ongoing to identify a potential second higher EXP dose. Clinical trial information: NCT05377996. Research Sponsor: Mersana Therapeutics.

3010 Rapid Oral Abstract Session

Sigvotatug vedotin (SV), an investigational integrin beta-6 (IB6)–directed antibody–drug conjugate (ADC), and pembrolizumab combination therapy: Initial results from an ongoing phase 1 study (SGNB6A-001). First Author: Kartik Sehgal, Dana-Farber Cancer Institute, Boston, MA

Background: IB6, a tumor-associated membrane protein, is overexpressed in many solid tumors, including non-small cell lung cancer (NSCLC) and head and neck squamous cell carcinoma (HNSCC). SV, an IB6-directed ADC, demonstrated encouraging antitumor activity and manageable safety as a monotherapy in patients (pts) with advanced NSCLC in SGNB6A-001, an ongoing phase 1 study (Peters, ASCO 2024). Due to immunogenic cell death induction and innate immune system activation, SV activity may be enhanced when combined with pembrolizumab (P; SV+P). We report initial results of SV+P in pts with advanced solid tumors. **Methods:** SGNB6A-001 (NCT04389632) is an open-label, multicenter, dose-escalation and dose-expansion phase 1 study evaluating the safety, pharmacokinetics (PK), and antitumor activity of SV. Part C is evaluating safety of SV+P in pts with advanced solid tumors; part D is currently enrolling to evaluate SV+P in treatment-naive pts with locally advanced, unresectable, or metastatic NSCLC and HNSCC. Pts receive SV 1.8 mg/kg by adjusted ideal body weight IV Q2W and P 400 mg IV Q6W. Primary endpoint is safety; secondary endpoints include efficacy and PK. Results reported here are from parts C and D. **Results:** As of Nov 26, 2024, 31 pts received ≥1 dose of SV+P in parts C and D (19 NSCLC, 11 HNSCC, and 1 esophageal); median (95% CI) follow-up was 2.9 (1.6-5.0) months, and 26 pts remain on treatment. Median (range) age was 65 (34-80) years, 61% were male, and 52% had ECOG PS 0. Of pts with NSCLC, 12 (63%) had non-squamous tumors and 11 (58%) had tumors with PD-L1 TPS ≥1. All pts with HNSCC had tumors with PD-L1 CPS ≥1. Any-grade (Gr) and Gr ≥3 treatment-emergent adverse events (TEAEs) occurred in 87% and 35% of pts, respectively. Most common TEAEs are shown in the Table. Any-Gr and Gr ≥3 immune-mediated TEAEs occurred in 61% and 10% of pts, respectively. Pneumonitis/interstitial lung disease occurred in 3 pts (9.7%), with no Gr ≥3 events. Renal TEAEs led to discontinuation of both SV and P in 2 pts (6%); 3 other pts discontinued treatment (1 progressive disease, 2 consent withdrawal). There were no treatment-related deaths. In 7 efficacy-evaluable pts with TPS≥1 NSCLC, 1 confirmed (c) complete response (CR), 1 c partial response (PR), and 2 PRs pending confirmation were observed (ORR 57%; cORR 29%). In 8 efficacy-evaluable pts with 1L HNSCC, 2 cCR and 1 cPR were observed (cORR 37.5%). **Conclusions:** SV+P demonstrated manageable safety and encouraging preliminary efficacy. These data support the ongoing phase 3 Be6A-Lung-02 study (NCT06758401) comparing SV+P vs P as first-line treatment for pts with PD-L1 high (TPS≥50) advanced NSCLC. Clinical trial information: NCT04389632. Research Sponsor: Seagen, which was acquired by Pfizer in December 2023.

3011 Rapid Oral Abstract Session

BMS-986504 in patients (pts) with advanced solid tumors with homozygous *MTAP* deletion (*MTAP*-del): Clinical update and first report of pharmacokinetics (PK) and pharmacodynamic (PD) analyses from CA240-0007. First Author: Kathryn C. Arbour, Memorial Sloan Kettering Cancer Center, New York, NY

Background: BMS-986504 selectively binds to the PRMT5-MTA complex, which represents a synthetic lethal target in *MTAP*-del cancer cells, while sparing *MTAP*–wild-type cells. In the first-in-human phase 1/2 CA240-0007 study in advanced, unresectable or metastatic solid tumors with homozygous *MTAP*-del, BMS-986504 was found to be well tolerated and demonstrated antitumor activity in multiple tumors. Here, we report clinical results and the first PK and PD analyses of BMS-986504 from the dose escalation and expansion phases of CA240-0007. **Methods:** Pts with measurable/evaluable disease and no available treatment (Tx) with curative intent were enrolled; 7 doses were evaluated (50 to 800 mg) in dose escalation. Objective response rate (ORR), disease control rate (DCR), duration of response (DOR), time to response (TTR), safety, PK, PD, including plasma SDMA were assessed. **Results:** As of 2 Dec 24, 152 heavily pretreated pts were enrolled across all doses: NSCLC (n = 34), PDAC (n = 41), cholangiocarcinoma (n = 12), and mesothelioma (n = 12) were the most common tumor types. With a median f/u of 9.0 mo (95% CI 7.6–9.9), continued durable antitumor activity and deepening tumor regression were seen across tumor types and doses (ORR = 23%, DCR = 70%, median DOR = 10.5 mo, TTR = 4.6 mo). No new safety signals were identified. Most Tx-related adverse events (TRAEs) were grade (Gr) 1 or 2; 13% had Gr ≥ 3 TRAEs (Gr 3 = 12%, Gr 4 = < 1%, Gr 5 = 0). Doses from 50 to 600 mg QD were assessed for PK/PD. The $AUC_{(0\text{-}24)}$ after multiple doses was approximately dose proportional at 200 to 600 mg, and the terminal $t_{1/2}$ after a single dose was approximately 24 h (table). There were dose-dependent reductions in predicted plasma SDMA, with the 400 and 600 mg doses approaching the plateau. **Conclusions:** With longer f/u, BMS-986504 continued to show increasingly durable antitumor activity. BMS-986504 demonstrated a favorable PK/PD profile, supporting QD dosing at 400 and 600 mg. These results support further investigation of BMS-986504 at 400 and 600 mg QD as a potential first-in-class synthetic lethal Tx option in pts with advanced solid tumors with *MTAP*-del. Clinical trial information: NCT05245500. Research Sponsor: Bristol Myers Squibb.

Preliminary results from a first-in-human, phase I/II study of VLS-1488, an oral KIF18A inhibitor, in patients with advanced solid tumors. First Author: Ecaterina Elena Dumbrava, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: VLS-1488 is an oral small molecule inhibitor of KIF18A, a mitotic kinesin protein important for successful division of cancer cells with chromosomal instability (CIN) but not required for mitosis in normal cells. Preclinical studies of VLS-1488 showed dose-dependent inhibition of tumor growth in CIN models. **Methods:** VLS-1488-2201 is a phase I/II study of patients (pts) with advanced solid tumors consisting of two parts, Dose Escalation and Dose Expansion. During Dose Escalation, a Bayesian Optimal Interval design was utilized to enroll pts to dose escalation cohorts with additional pts enrolled to backfill cohorts at dose levels (DLs) that did not meet de-escalation/elimination rules. Primary objective was to assess safety/tolerability of VLS-1488 at various DLs to determine the Maximum Tolerated Dose (MTD). Secondary objectives included evaluating preliminary efficacy and pharmacokinetics (PK). Eligible pts had exhausted standard of care treatments and had measurable disease per RECIST v1.1. Pts received VLS-1488 once daily, orally for 28-day cycles until disease progression, unacceptable toxicity or other stopping criteria. **Results:** 52 pts (ITT) were enrolled across 5 DLs including 50mg (n = 4), 100mg (n = 12), 200mg (n = 14), 400mg (n = 12) and 800mg (n = 10). Tumor types were high grade serous ovarian (HGSOC; n = 20), colorectal (n = 14), triple negative breast (n = 7), squamous lung (n = 3), endometrial (n = 3), ovarian carcinosarcoma (n = 2), esophageal (n = 2) and bladder (n = 1). The median number of prior lines was 4 (range 1-8). As of data cutoff, 52 pts (100%) received >1 dose of VLS-1488. No dose-limiting toxicities (as assessed during the first 28 days) were observed and MTD was not reached. Treatment-related AEs (TRAEs) occurred in 22 pts (42%), with fatigue (17.3%; G1 13.5%, G2 3.8%), aspartate aminotransferase increased (13.5%; G1 7.7%, G2 1.9%, G3 3.8%) and rash (11.5%; G1 3.8%, G2 1.9%, G3 5.8%) observed in >10% of pts. 6 pts (12%) experienced G3 TRAEs and no > G3 TRAEs were observed. Drug exposures exceeded preclinically defined efficacious thresholds and were approximately dose proportional at analyzed DLs. 41 pts (79%) were evaluable for response per RECIST v1.1. In the 16 HGSOC pts evaluable for response (where the median number of prior lines was 4.5; range 2-8), 3 partial responses (PRs; including 2 pts with sustained PR >24 weeks) and 6 with stable disease (SD; including 4 pts with tumor reductions) were observed across multiple DLs, with 5 pts continuing with study treatment. **Conclusions:** VLS-1488 was found to be safe and tolerable, with encouraging anti-tumor activity observed in heavily treated HGSOC pts. VLS-1488 will be evaluated further in the Dose Expansion phase of the study. Clinical trial information: NCT05902988. Research Sponsor: Volastra Therapeutics, Inc.

3013 Rapid Oral Abstract Session

A first-in-human phase I/II study of GFH375, a highly selective and potent oral KRAS G12D inhibitor in patients with KRAS G12D mutant advanced solid tumors. First Author: Xinghao Ai, Department of Medical Oncology, Shanghai Chest Hospital, School of Medicine, Shanghai Jiao Tong University, Shanghai, China

Background: Kirsten rat sarcoma (KRAS) G12D is one of the most prevalent RAS mutations in human cancers and suggests poor survival. GFH375 is an orally bioavailable, highly selective and potent KRAS G12D inhibitor targeting both "ON" (GTP-bound) and "OFF" (GDP-bound) states. Here we report the preliminary results of GFH375 in patients (pts) with advanced KRAS G12D mutant solid tumors. **Methods:** This is a Phase I/II study (NCT06500676) evaluating the safety, tolerability, pharmacokinetics and efficacy of GFH375 in pts with advanced solid tumors harboring KRAS G12D mutation. Pts with locally advanced or metastatic solid tumor failed to prior standard therapies are eligible for enrollment. Accelerated titration, plus Bayesian Optimal Interval (BOIN) and back filling design are employed in the phase I part with safety and tolerability as the primary objective, and pharmacokinetics and anti-tumor activity as the secondary objectives. **Results:** As of 03Jan2025, thirty-two pts were treated, including 11 pancreatic ductal adenocarcinoma (PDAC), 11 non-small cell lung cancer (NSCLC), 5 colorectal cancer (CRC) and 5 others (median age: 59.5 yrs; 62.5% female). No dose-limiting toxicities (DLTs) were observed at the tested dose levels of 100 mg, 200 mg, 400 mg, 600 mg, 750 mg, 900 mg once daily (QD) and 300 mg twice daily (BID). Eight pts (25%) experienced at least one G3/G4 treatment related adverse event (TRAE) and no G5 TRAEs. Five pts (15.6%) experienced at least one serious adverse event. Eight pts (25%) had treatment interruptions, and 2 (6.3%) discontinued treatment due to treatment emergent adverse events (TEAEs). No dose reduction occurred. The most common TRAEs were gastrointestinal events including diarrhea (71.9%), vomiting (71.9%) and nausea (62.5%); all were grade 1 or 2. Anti-tumor activities were observed starting from 100 mg QD. Among 22 pts who had at least one post-treatment tumor assessment, objective response rate (ORR) was 27.3% (6/22), and disease control rate (DCR) was 86.4% (19/22). Nine out of 13 pts with stable disease (SD) had tumor shrinkage. Among the 7 pts with PDAC, all exhibited tumor shrinkage with 3 partial response (PR) and 4 SD. Among the 9 pts with NSCLC, 3 achieved PR, 5 SD, and 1 progression disease (PD). GFH375 demonstrated good oral bioavailability with a T_{max} of 2~4 h and a terminal half-life of 18.5-21.6 h. **Conclusions:** According to the preliminary data from ongoing FIH study, GFH375 monotherapy has demonstrated good tolerability and promising anti-tumor activities in pts with advanced solid tumor supporting further clinical development. Clinical trial information: NCT06500676. Research Sponsor: GenFleet Therapeutics (Shanghai) Inc.

3014 Rapid Oral Abstract Session

Efficacy and safety of selumetinib in adults with neurofibromatosis type 1 (NF1) and symptomatic, inoperable plexiform neurofibroma (PN): Primary analysis of KOMET (NCT04924608), a phase 3, international, randomized, placebo-controlled study. First Author: Alice P. Chen, Developmental Therapeutics Clinic, Division of Cancer Treatment and Diagnosis, National Cancer Institute, National Institutes of Health, Bethesda, MD

Background: No globally approved therapies exist for adults with NF1 and symptomatic, inoperable PN.KOMET is evaluating the efficacy and safety of selumetinib (SELU; ARRY-142886, AZD6244) in adults. **Methods:** KOMET is an ongoingPhase 3, randomized, double-blind, placebo-controlled trial. Adults (≥18 yrs) with NF1 and symptomatic, inoperable PN were randomized 1:1 to 28-day cycles of oral SELU 25 mg/m^2 BID or placebo (PBO) with crossover to SELU at progression or the end of Cycle (C) 12. Among others, baseline (BL) PAINS-pNF target PN chronic pain intensity score (< 3 or ≥3) was a stratification factor; 70% of patients (pts) were required to have a score ≥3. Primary analyses were conducted after the last pt completed C16 (data cutoff: Aug 5, 2024). The primary endpoint was objective response rate (ORR; confirmed partial/complete response) per ICR REiNS by the end of C16. Key secondary endpoints were change from BL to C12 in PAINS-pNF chronic pain score in pts with a BL score ≥3 and PlexiQoL total score in all randomized pts (SELU vs PBO). A planned sample of 73 pts per arm with a 2-sided 5% alpha Fisher's exact test had > 99% power to detect the difference between a SELU ORR of 20% and PBO ORR of 0%. Key secondary endpoints were analyzed with a mixed model for repeated measures. **Results:** Of 145 randomized pts (SELU: 71; PBO: 74), 51.7% were male; median age was 29 yrs (range 18–60). SELU led to a rapid onset of response (median 3.7 mos), with an ORR of 19.7% (95% CI 11.2, 30.9) by C16 vs 5.4% (95% CI 1.5, 13.3) with PBO (p = 0.011). At C12, pts with a BL chronic pain score ≥3 had a greater reduction in pain score with SELU (LS mean −2.0; 95% CI −2.6, −1.4) vs PBO (LS mean −1.3; 95% CI −1.8, −0.7); and clinically meaningful improvement (meaningful score difference −2 points) vs BL, but this was not statistically significant vs PBO (p = 0.070). Reduction in chronic pain intensity was observed with SELU vs PBO in the full analysis set (all pts regardless of BL chronic pain intensity, nominal p = 0.024). Change from BL to C12 in PlexiQoL total score between treatment arms was not statistically significant (LS mean difference −0.1; 95% CI −1.2, 1.1). Adverse events (AEs) in the randomized period were consistent with the known safety profile of SELU. The most common AEs (≥10% of pts) were dermatitis acneiform (59%), increased blood creatine phosphokinase (45%), and diarrhea (42%) with SELU, and COVID-19 (20%), nausea (16%), and fatigue (14%) with PBO. Fourteen pts on SELU and 1 pt on PBO reported CTCAE Grade ≥3 treatment-related AEs; 9 SELU and 5 PBO pts discontinued due to AEs. **Conclusions:** In the first international, randomized, placebo-controlled trial in adults with NF1-PN, SELU achieved a significant ORR vs PBO (C16), meeting the primary endpoint, and a clinically meaningful reduction in PN-associated chronic pain (C12). Clinical trial information: NCT04924608. Research Sponsor: Alexion, AstraZeneca Rare Disease and Merck Sharp & Dohme LLC, a subsidiary of Merck & Co., Inc., Rahway, NJ, USA.

3015 Rapid Oral Abstract Session

Phase 2 evaluation of the nilotinib-paclitaxel combination in patients with rare solid tumors: Rapid analysis and response evaluation of combination anti-neoplastic agents in rare tumors trial 1 (RARE CANCER 1). First Author: Sarah Shin, Developmental Therapeutics Clinic/Early Clinical Trials Development Program, Division of Cancer Treatment and Diagnosis, National Cancer Institute, Bethesda, MD

Background: Rare tumors constitute a heterogeneous group of cancers with limited treatment options and poor outcomes. To address the need for novel therapeutic options in this challenging population, patient-derived xenograft models of rare cancers were developed to screen combinations of anticancer agents. Based on these preclinical data, the NCI Developmental Therapeutics Clinic designed a series of phase 2 clinical trials to assess promising novel combination therapies in patients (pts) with rare tumors. RARE1—the first trial in this series—evaluates the nilotinib-paclitaxel combination, for which a preceding phase 1 study (NCT02379416) recently identified the recommended phase 2 dose (RP2D) and promising clinical activity, including confirmed partial responses (PR) in 3 pts (2 adult granulosa cell ovarian tumors [AGCOT], 1 endometrial cancer) and 1 unconfirmed PR (anal cancer). Given this clinical experience and preclinical activity in rare tumor models, RARE1 (NCT04449549) aims to evaluate the response and mechanism of action of the nilotinib and paclitaxel combination in rare, refractory solid tumors. **Methods:** Pts with rare tumors meeting the RARECARE definition were treated at the RP2D: nilotinib 300 mg orally twice a day and paclitaxel 80 mg/m^2 IV on days 1, 8, and 15 in 28-day cycles. Response was assessed by RECIST v1.1. Tissue biopsies and research blood were collected at multiple timepoints for pharmacodynamic and genomic analyses. **Results:** This study enrolled 31 pts of diverse rare cancers as of the data cut-off. Of the 30 evaluable pts, 2 (7%) had confirmed PRs: 1 Ewing sarcoma and 1 ovarian clear cell cancer, completing 12 and 11 cycles (C) on study, respectively. Stable disease (SD) was the best response in 15 pts (50%), of which 5 pts (17%) had prolonged SD: 1 AGCOT (23+ C), 1 testicular embryonal rhabdomyosarcoma (22 C), 1 non-uterine leiomyosarcoma (21 C), 1 salivary gland (12 C), and 1 ampullary adenocarcinoma (6 C). Overall, the median number of cycles completed is 2 (range 0 - 23) and the median progression free survival is 3.8 months. No unexpected treatment-related adverse events have occurred. No grade 3-4 peripheral neuropathy has been observed. **Conclusions:** Preliminary clinical outcomes for the nilotinib-paclitaxel combination in patients with rare tumors showed encouraging signals of activity. To facilitate further evaluation of response and the underlying mechanism of action for this combination, enrollment now focuses on the 4 tumor types that have previously demonstrated response: Ewing sarcoma, ovarian clear cell carcinoma, AGCOT, and anal cancers. Pharmacodynamic and genomic analyses are also ongoing. This project has been funded in whole or in part with federal funds from the NCI, NIH, under contract HHSN261201500003I. Clinical trial information: NCT04449549. Research Sponsor: U.S. National Institutes of Health.

3016 Rapid Oral Abstract Session

Clinical utility of circulating tumor RNA (ctRNA) in a combined circulating tumor DNA (ctDNA) and ctRNA next-generation sequencing (NGS) pan-cancer liquid biopsy assay. First Author: Jonathan Poh, Lucence Diagnostics Pte Ltd, Singapore, Singapore

Background: Liquid biopsies are increasingly used in the real world for cancer therapy selection, disease monitoring, and early detection. Combining RNA with DNA sequencing for the detection of FDA-actionable gene fusions is already recommended as standard of care in guidelines as fusions are inherently challenging to detect by DNA-only methods. However, the clinical utility of profiling plasma ctRNA in addition to ctDNA has not yet been quantified in large studies. Here we report results from the first large real-world study establishing the clinical utility of combining ctRNA and ctDNA in a single liquid biopsy assay. **Methods:** A total of 1,007 consecutive plasma samples from 979 cancer patients across the USA and Asia underwent real-world liquid biopsy testing with a combined ctDNA and ctRNA assay (LiquidHALLMARK) in two CAP-accredited CLIA-certified laboratories from Jun 2021 to Dec 2024. The combined amplicon-based assay profiles genomic alterations in 80 genes on ctDNA and up to 37 genes on ctRNA. Only gene fusions (including *MET* exon 14 skipping) were included in this analysis. The limit of detection for gene fusions of the ctDNA and ctRNA panel were validated as 0.5% and 10 copies. **Results:** Plasma ctRNA was successfully analyzed in 99.6% (1003/1007) of samples across 30 cancer types. The top 5 cancer types (lung, prostate, breast, colorectal, and pancreas) comprised 84.2% of the clinical volume. Gene fusions were detected across 11 genes (*ALK*, *RET*, *ROS1*, *MET*, *NRG1*, *NTRK1*, *FGFR2*, *FGFR3*, *ESR1*, *ERG*, *ETV4*) in 7.8% (78/1003) of cases, primarily in prostate and lung, but also in breast, bile duct, thyroid, liver, and bladder cancers. A total of 80 fusions were detected, of which 25 were detected by both ctDNA and ctRNA, while ctDNA and ctRNA each exclusively detected 27 and 28 fusions. Among the 28 ctRNA-only fusions, 5 were not covered by the ctDNA panel (1 *ATP1B1-NRG1*, 1 *ESR1-CCDC170*, 1 *ESR1-AKAP12*, and 2 *SLC45A3-ERG* fusions). Eleven (11/28) ctRNA-only fusions were actionable; all 11 were found in lung cancer. Two of these co-occurred with another lung driver mutation, highlighting potential resistance mechanisms to targeted therapy. Of the remaining 9, 3 were treated with fusion-matched targeted therapy. Two patients had real-world response rates available; both exhibited partial response to treatment. Overall, inclusion of ctRNA analysis increased the diagnostic yield of all fusions by 53.8% and actionable fusions by 36.7%. **Conclusions:** This is the first large study showing that adding ctRNA to ctDNA liquid biopsy increases total actionable diagnostic yield by 36.7%, highlights potential resistance mechanisms, and can broaden panel coverage to include gene fusions not amenable to detection by conventional DNA-based methods. These findings support recommendations for combined DNA/RNA testing of fusions in both tissue and liquid samples. Research Sponsor: None.

Enhancing prognostic precision in bladder cancer: AI-driven tumor microenvironment analysis from H&E images. First Author: Evelyn Ramberger, Aignostics GmbH, Berlin, Germany

Background: Bladder cancer (BC) represents a significant healthcare burden. Despite advancements in diagnostics and treatment, the survival rate remains low, underscoring the need for improved prognostic tools. The current UICC staging system often lacks precision in patient stratification. Moreover, there is a paucity of scalable methods that explore and quantify tumor microenvironment (TME) features and their influence on patient outcome. Here, we present an artificial intelligence (AI) framework that operates on routine hematoxylin & eosin-stained (H&E) slides to enable systematic TME characterization and improve prognostic accuracy. **Methods:** In a bicentric cohort of over 700 resected BC patients, we developed and validated a deep learning approach for TME analysis. The model was trained using multiplex immunofluorescence-validated annotations but operates solely on H&E-stained images, maximizing clinical applicability. Key features included tissue compartment segmentation, cell classification, and spatially resolved cell patterns. We evaluated the model's performance and integrated TME features with clinicopathological variables to improve prognostic stratification beyond UICC staging. **Results:** The model demonstrated robust tissue compartment segmentation (F1-score = 0.91) and accurately identified key immune cell populations in tissue regions. When integrating the spatially resolved cellular features with clinicopathological variables, we observed significant improvements in prognostic capabilities for overall survival. The integrated approach demonstrated a 22% relative improvement over the conventional UICC staging system alone (C-index increased from 0.59 to 0.61, $p < 0.01$), measured against the random baseline C-index of 0.5. Our integrated model displayed a hazard ratio of 1.859 (95% CI: 1.530-2.259, p = 4.390e-10), markedly stronger than traditional risk stratification which showed a hazard ratio of 1.477 for high versus low risk groups (95% CI: 1.219-1.791, p = 7.117e-05). These findings demonstrate that AI-driven analysis of the tumor microenvironment provides valuable prognostic information beyond current clinical staging methods, suggesting promising opportunities for enhancing patient risk stratification. **Conclusions:** We show that a combination of AI with UICC staging shows improved patient stratification compared to stratifying by UICC alone. This study demonstrates the feasibility of automated TME characterization from routine H&E slides in BC and suggests that incorporating TME features into prognostic models enhances accuracy and could support personalized patient management in individualized oncology. While further validation in larger, multicentric-datasets is required, our approach shows potential for facilitating systematic biomarker development and improving clinical decision-making in BC care. 3018 Poster Session

Preliminary results from a first-in-human phase 1 dose escalation trial of ADRX-0706, a next generation Nectin-4 ADC, in subjects with advanced solid tumors. First Author: Alexandra Drakaki, Jonsson Comprehensive Cancer Center, David Geffen School of Medicine at UCLA, Los Angeles, CA

Background: ADRX-0706 is a Nectin-4 targeting ADC designed to provide an increased therapeutic window through stable conjugation of a novel microtubule inhibitor payload (AP052) to an IgG1 monoclonal antibody at a drug-to-antibody ratio of 8. Preliminary safety, anti-tumor activity, pharmacokinetic (PK) and Nectin-4 expression results are presented from the dose escalation part of the ongoing Phase 1 trial (NCT06036121). **Methods:** Eligible subjects with select advanced solid tumors (urothelial [UC], cervical [CC], breast [BC], head and neck [HNSCC], ovarian [OC], non-small cell lung [NSCLC], and pancreatic [PC]) were enrolled in cohorts of escalating dose levels (1-16 mg/kg, Q3W, IV) using a BOIN design with backfill. Nectin-4 expression was evaluated retrospectively. Primary and secondary endpoints included dose-limiting toxicities [DLTs], adverse events [AEs], laboratory value changes, PK, immunogenicity, and response per RECIST v1.1. **Results:** As of the 13Dec24 data cutoff, 53 subjects with a median age of 59 years and median of 4 (1-14) prior therapies were enrolled. One DLT (G3 stomatitis) occurred at the highest dose of 16 mg/kg. The most common treatment related AEs (TRAE ≥15%) were arthralgia (32%), fatigue (21%), rash (19%), anemia (17%), and nausea (15%). The majority of TRAEs were G1-2 in severity and manageable, including only 3 (5.7%) subjects with peripheral neuropathy and 2 (3.8%) with liver enzyme increase. The most common ≥G3 TRAE was neutropenia (11%). ADC exposure increased in a dose-proportional manner with minimal deconjugation and the ADC half-life was 15 days. There were 5 subjects who achieved objective response across different tumor types (UC, NSCLC, CC) and 9 with stable disease per RECIST among 30 response-evaluable subjects treated at doses ≥8 mg/kg (ORR 16.7%, DCR 46.7%), including 2 triple negative BC (TNBC) subjects with 27% and 29% decrease in tumor size who remain on treatment. ADRX-0706 demonstrated Nectin-4 expression-dependent anti-tumor activity with all responses observed in tumors with H-score ≥100, including a confirmed complete response (CR) in a CC subject (H-score 250). Two responses were observed after prior progression on other Nectin-4 targeting MMAE drugs and three responses remain ongoing with subjects on treatment for 9+ to 23+ weeks. Based on these data, 10 mg/kg Q3W was selected as the Phase 1b dose. **Conclusions:** ADRX-0706 demonstrated a preliminary safety profile differentiated from MMAE-conjugates and with manageable toxicities. The antibody-like PK profile together with minimal deconjugation supports Q3W dosing. Encouraging anti-tumor activity was observed in multiple heavily pretreated tumors with moderate-high Nectin-4 expression. Enrollment in Phase 1b cohorts of UC, CC, and TNBC is ongoing. Clinical trial information: NCT06036121. Research Sponsor: Adcentrx Therapeutics.

3019 Poster Session

BC3195, a novel ADC targeting cadherin-3 (CDH3): Updated results of a first-in-human phase I study in patients with advanced solid malignancies. First Author: Haiyan Tu, Guangdong Lung Cancer Institute, Guangdong Provincial People's Hospital (Guangdong Academy of Medical Sciences), Southern Medical University, Guang Zhou, Guang Dong, China

Background: Cadherin-3 (CDH3), a calcium-dependent cell-cell adhesion glycoprotein, is overexpressed on lung, breast, head and neck and other malignancies, and associated with cancer invasiveness and poor prognosis. BC3195 is known as the only antibody drug conjugate (ADC) in clinical stage, targeting CDH3 with cleavable linker and payload of monomethyl auristatin E (MMAE). **Methods:** A phase I, open-label, first in human study whose objectives were to evaluate the safety, tolerability, pharmacokinetics (PK), and preliminary antitumor activity of BC3195 is being performed in patients (pts) with advanced solid malignancies. BC3195 is administered as 1-hr IV infusion every 3 weeks (Q3W) or every week (QW). An evaluation of seven dose levels (DLs) is planned: 0.3, 0.6, 1.2, 1.8, 2.1, 2.4 mg/kg Q3W and 1.2 mg/kg QW with a BOIN design guiding dose escalation. **Results:** As of the data cut-off-date (Dec 26th, 2024), 56 pts have been enrolled. The number of pts in each DL is shown in the table. Twenty-five (44.6%) pts had received ≥3 prior lines of treatment. Stomatitis (71.4%), rash (60.7%) and anemia (53.6%) were the main adverse events (AEs). Stomatitis and rash typically occurred in the first cycle and were manageable. Twenty-one pts (37.5%) experienced Grade≥3 treatment related adverse events (TRAEs). Among the 50 pts who were evaluable for tumor response, 5 pts in 2.4 mg/kg Q3W had partial response (PR). Of the 20 NSCLC pts treated in 2.4 mg/kg, 4 pts had confirmed PR (cPR), and 14 pts had stable disease (SD) as their best response; the objective response rate (ORR) was 50% (4/8) in previously-treated EGFR-mutant NSCLC pts, and mPFS was 168 days (Table). PK results demonstrated that exposure of the ADC, total antibody (TA) and MMAE increased in a non-linear manner at dose up to 2.4 mg/kg. Median T_{max} values for ADC and TA were 1 h, and median T_{max} for free MMAE was 25-169 h. In addition, elimination $t_{1/2}$ values averaged 54 h, 78 h and 63 h for the ADC, TA, and MMAE at 2.4 mg/kg, respectively. **Conclusions:** BC3195 has a manageable safety profile and favorable PK characteristics and demonstrated impressive preliminary antitumor activity in heavily-pretreated pts with NSCLC, of which most had EGFR-mutations (ORR=50%). Dose optimization and expansion are ongoing. Clinical trial information: NCT05957471. Research Sponsor: Biocity Biopharmaceutics Co. Ltd.

A phase 2 basket trial of ado-trastuzumab emtansine for patients with *HER2* amplified cancers. First Author: Jessica Ross, Memorial Sloan Kettering Cancer Center, New York, NY

Background: The *HER2* gene is commonly amplified (amp) across a variety of tumor types. Ado-trastuzumab emtansine (TDM1) is a potent antibody-drug conjugate targeting HER2 that is approved in HER2+ breast cancer. The efficacy of TDM1 in other *HER2*-amp solid tumors is unknown. **Methods:** We conducted a single-arm, phase 2 basket trial of TDM1 in which patients (pts) were enrolled in one of 5 *HER2*-amp cohorts: non-small cell lung cancer (NSCLC), colorectal cancer, endometrial cancer, salivary gland cancer, or other solid tumor. *HER2* amp was identified through next generation sequencing by MSK-IMPACT, defined as two-fold change, or by in-situ hybridization (ISH) with *HER2*/*CEP17* ratio $\geq$2.0 in a CLIA-certified laboratory. In tumors sequenced by MSK-IMPACT, precise level of the ERBB2 amplification (i.e. integer copy number) was assessed and correlated with clinical response. All pts received TDM1 3.6mg/kg IV every 21 days. The primary endpoint was overall response rate (ORR). For each cohort, a Simon two-stage optimal design was used. In the first stage, 7 pts were accrued in each cohort; if 0/7 responses, the cohort was closed. Otherwise, up to 11 additional pts were accrued. Cohorts 1, 3, and 4 were expanded by up to 5 pts (max 23 pts) due to durable responses seen early on. Response and progression of disease was evaluated using RECIST version 1.1. Modified PERCIST was allowed if pts did not have RECIST measurable disease. Toxicity was graded as per CTCAE v4.1. Circulating tumor DNA was collected pre-, post-, and on-treatment for all pts when feasible. **Results:** 88 pts were accrued between 2016 and 2023. The ORR by cohort is listed in Table 1. The most common toxicities were decreased platelet count and elevated ALT. There was one incident of grade 5 pneumonitis in a patient in cohort 1. Median time on treatment was 2.5 months (range 0.03 – 53.7 months); in pts with salivary gland tumors, median time on treatment was 17.6 months (0.3 – 53.7). **Conclusions:** TDM1 demonstrated efficacy in multiple *HER2*-amp tumor types. The highest ORR was seen in salivary gland tumors, with a median time on treatment of about 1.5 years. More work is needed to understand the enhanced efficacy of TDM1 in these tumors. Clinical trial information: NCT02675829. Research Sponsor: Genentech.

Response rate by cohort and disease site.

Cohort	RECIST-only ORR	Combined* ORR

The safety, tolerability, and efficacy of BRY812 in patients with advanced solid tumors: Preliminary results from the phase I clinical study. First Author: Herui Yao, Sun Yat-sen Memorial Hospital, Sun Yat-Sen University, Guangzhou, China

Background: Antibody-conjugated drugs (ADCs) have demonstrated outstanding clinical efficacy in treating a wide range of solid tumors as well as hematological tumors currently. An ongoing multicenter, open-label, phase I clinical study assessed the safety, tolerability and preliminary efficacy of BRY812, the ADC targeting transmembrane protein LIV-1 with MMAE as cytotoxic payload, in advanced solid tumors. Here we report the interim analysis results. **Methods:** In Phase Ia (dose escalation), the eligible patients with advanced solid tumors were enrolled in each of 7 dose groups (0.25, 0.5, 1.0, 2.0, 2.8, 3.6 and 4.4 mg/kg) for evaluation to determine the MTD of BRY812. An "accelerated titration" method (0.25, 0.5 mg/kg) as well as a modified toxicity probability interval-2 method (subsequent doses) was applied. Subsequently dose expansion was conducted for dose levels of 2.0, 2.8 and 3.6 mg/kg that demonstrated tolerability and relative efficacy. The patients received treatment every 3 weeks until intolerable toxicity or disease progression. The primary endpoint was to evaluate DLT and MTD to determine RP2D, other endpoints included ORR. **Results:** Overall, as data cut-off date (Dec 13, 2024), 36 patients (including 30 patients with breast cancer) with advanced solid tumors were enrolled, including 20 patients in dose escalation phase and 16 patients in dose expansion respectively. Treatment is still ongoing for 19 patients. No DLT was observed up to 3.6 mg/kg. 4.4 mg/kg was not tolerated due to DLTs (2 of 4 patients experienced DLT events). The most common grade $\geq$3 TEAE was neutropenia, and grade 4 neutropenia was observed in 3.6 mg/kg (2/12) and 4.4 mg/kg (4/4). 4 patients discontinued treatment due to AE including 2 injury corneal (each of 3.6 & 4.4 mg/kg), 1 peripheral neuropathy (2.8 mg/kg) and 1 hepatic enzyme increase (3.6 mg/kg). Among 34 patients in efficacy analysis, 8 (23.5%) patients and 7 (20.6%) patients had PR and SD, respectively, and 17 (50%) patients had PD, leading to ORR of 23.5% (95% CI: 10.7, 41.1) and DCR of 44.1% (95% CI: 27.2, 62.1). The patients with higher LIV-1 expression showed better efficacy, as among 14 patients with PS2+ enriched, ORR was 43% (6/14 in breast cancer). In addition, ADC and Total antibody clearance were similar. BRY812 showed dose-dependent decrease of clearance in the dose range of 0.25 to 2.0 mg/kg, while approximately linear clearance in the dose range of 2.0 to 4.4 mg/kg, and the half-life were ~7 days. No accumulation was observed after multiple dosing. ADA positive rate was 11.43% (4/35). **Conclusions:** BRY812 demonstrated favorable safety and tolerability profile, with promising clinical efficacy in patients with advanced solid tumors. Further dose optimization and clinical efficacy will be explored in Phase Ib. Clinical trial information: NCT06038058. Research Sponsor: BioRay Pharmaceutical (Hangzhou) Co., Ltd.

3022 **Poster Session**

A pooled analysis of JSKN003, a biparatopic anti-HER2 antibody conjugate (ADC), in patients with advanced HER2-overexpressing (IHC 3+) gastrointestinal tumors. First Author: Dan Liu, Beijing Cancer Hospital, Beijing, China

Background: JSKN003 is a biparatopic HER2-targeting ADC conjugated with a topoisomerase I inhibitor (TOP1i) payload via a dibenzocyclooctyne tetrapeptide linker. The efficacy and safety of JSKN003 in several solid tumors have been highlighted in previous reports. **Methods:** JSKN003-101 and JSKN003-102 are dose escalation and expansion studies involving Australian and Chinese patients (pts) with metastatic solid tumors. This pooled analysis of two studies was performed to assess the efficacy and safety in advanced HER2-overexpressing (IHC 3+) gastric or gastroesophageal cancer (GC/GEJC) and colorectal cancer (CRC) pts. **Results:** As of data cutoff (18 Dec 2024), 40 patients with HER2-overexpressing (IHC 3+ by local lab) gastrointestinal tumor (23 in GC/GEJC and 17 in CRC) were enrolled across 7 dose levels: 2.1 mg/kg (n = 1), 4.2 mg/kg (n = 1), 5.2 mg/kg (n = 1), 6.3 mg/kg (n = 33), 7.3 mg/kg (n = 1), 8.4 mg/kg (n = 2), 10.5 mg/kg (n = 1). The median follow-up time of two studies was 7.16 months. Most pts were heavily pretreated (37.5% had $\geq$3 lines of prior treatment; 45.0% received irinotecan; 67.5% received anti-HER2 therapy; 42.5% received IO therapy). Four of the 17 CRC pts were RAF/RAS mutations (n = 2 RAS-mut, n = 2 RAF-mut). Thirty-nine patients had at least one tumor assessment after baseline. The overall response rate (ORR) per RECIST v1.1 in HER2-overexpressing gastrointestinal tumor was 66.7% and the disease control rate (DCR) was 94.7%. Among 22 GC/GEJC pts, the ORR was 68.2% and DCR was 95.5%. The median progression-free survival (PFS) was 9.59 months (95% CI: 2.96, NE) with 66.3% (95% CI: 29.4, 87.1) PFS rate at 6 months. Among 17 CRC pts, the ORR was 64.7% (66.7% in RAF-wild pts, n = 15) and DCR was 94.1%. The mPFS was 13.77m (95% CI: 7.1, NE) with 94.1% (95% CI: 65, 99.2) PFS rate at 6 months. The median overall survival (OS) was not yet mature. Notably, one BRAF-mut patient achieved PR at first tumor assessment after baseline, two RAS-mut pts achieved PR and duration was over 48 weeks. The most common treatment-related adverse events (TRAEs) included nausea, diarrhea, neutropenia, decreased appetite, vomiting, rash, anemia and fatigue. Grade 3/4 neutropenia was observed in 2 (5.0%) pts, Grade 3/4 anemia was observed in 1 (3.0%) pts. No TEAEs led to death or treatment discontinuation. Interstitial lung disease (ILD) occurred in 3 (7.5%; n = 2 G1; n = 1 G2) pts. **Conclusions:** JSKN003 demonstrated promising efficacy in heavily pretreated pts with advanced HER2-overexpressing gastrointestinal tumors, with a manageable and predictable safety profile. Clinical trial information: NCT05494918, NCT05744427. Research Sponsor: Jiangsu Alphamab Biopharmaceuticals Co., Ltd.

Initial results from a first-in-human phase 1 study of LY4170156, an ADC targeting folate receptor alpha (FRα), in advanced ovarian cancer and other solid tumors. First Author: Isabelle Laure Ray-Coquard, Centre Léon Bérard, and GINECO, Lyon, France

Background: Folate receptor alpha (FRα) is overexpressed in several solid tumors. LY4170156 is an Fc-silent, FRα specific humanized IgG1 ADC linked to exatecan, a topo-I inhibitor, via a novel cleavable polysarcosine linker at a homogenous DAR of 8. LY4170156 demonstrated *in vivo* preclinical efficacy in tumor models, across all FRα expression levels. **Methods:** This is a multicenter, open-label, first-in-human phase 1a/b study of LY4170156 in patients (pts) with advanced FRα-expressing ovarian, endometrial, cervical, and other solid tumors. Pts with prior ADCs targeting FRα with payloads other than topo-I (including mirvetuximab soravtansine-gynx [mirv]) were allowed. Dose escalation followed the mTPI-2 method. LY4170156 was administered Q3W IV (dose range of 2-6 mg/kg); dose limiting toxicity (DLT) evaluation period was 21 days. Dose escalation included a randomized dose optimization cohort in PROC. Key endpoints were safety, PK, and antitumor activity per RECIST v1.1. Efficacy evaluable pts were those who had a post baseline response assessment or discontinued treatment prior to the response assessment. **Results:** As of 27 Nov 2024, 45 pts were treated with LY4170156. Median age was 63 yrs (range, 24-85), 100% had ECOG PS 0-1, and 32 (71%) had high-grade serous ovarian cancer (HGSOC). Among the HGSOC pts (32), median lines of prior therapy was 5 (range, 1-10), 19% had received prior mirv, and 44% had FRα expression $<$ 75% by local or central testing. PK of LY4170156, total antibody, and exatecan were linear and dose-proportional within the tested dose range. Unconjugated payload release from ADC at C_{max} was $<$ 4% at 4 mg/kg; median half-life of LY4170156 was 5.7-7.0 days and exatecan was 7.2-8.6 days. Main toxicities were myelosuppression and GI-related, as expected from an exatecan payload. Across all doses, the most common treatment-emergent adverse events (TEAEs; $\geq$15%) were nausea (58%, 2% gr 3), fatigue (44%, 0% gr 3-4), anemia (33%, 24% gr 3), vomiting (27%, no gr 3-4), diarrhea (22%, 4% gr 3), and neutropenia (20%, 11% gr 3-4). Febrile neutropenia (FN) was observed in 3 pts (7%). To date, no pulmonary or ocular toxicity were noted. Two DLTs were observed (1 gr 3 FN [6 mg/kg]; 1 gr 3 anemia [2 mg/kg]); no MTD has been established to date. Among 13 efficacy evaluable HGSOC pts (6 FRα $\geq$75%; 6 $<$ 75%; 1 pending data), 9 showed reduction in target lesions; preliminary ORR was 38% (n = 5) with 1 CR, 4 PR, and 4 SD across all dose levels. Combined ORR for 4 and 6 mg/kg dose levels was 55%. All responses were unconfirmed and ongoing at the time of data cutoff. Three of 5 responders had FRa expression $<$ 75% and two $\geq$75% including 1 who was mirv refractory. **Conclusions:** LY4170156 was well-tolerated with encouraging clinical activity among HGSOC pts, including those with FRα expression $<$ 75% and those with prior mirv. Randomized dose optimization is ongoing and updated data will be presented. Clinical trial information: NCT06400472. Research Sponsor: Eli Lilly and Company.

BAT8008, a TROP-2 antibody-drug conjugate (ADC), in patients with advanced solid tumor: Results from a phase 1 study. First Author: Jianli Zhao, Sun Yat-sen Memorial Hospital, Sun Yat-Sen University, Guangzhou, China

Background: BAT8008 is a monoclonal ADC that delivers exatecan to cells expressing TROP-2. TROP-2 is a cell surface glycoprotein that can be expressed in certain normal tissue but is frequently overexpressed in multiple carcinomas including cervical cancer (CC) and esophageal cancer (EC). Here we report the safety and efficacy data of BAT8008. **Methods:** BAT8008 was administered by intravenous infusion at doses of 0.8-2.7mg/kg on days 1 of each14-day cycle(the first cycle is 21-day). The study included dose escalation, dose expansion and cohort expansion which included CC, EC and other solid tumors that progressed after $>$ I systemic treatments (Tx). Primary objectives were assessment of safety and preliminary efficacy. **Results:** As of Jan 15, 2025, 170 patients (pts) were enrolled with doses ranging from 0.8 to 2.7mg/kg. 2 out of 6 pts in 2.7mg/kg group had dose limiting toxicity (1 with G3 increased lipase, 1 with G4 thrombocytopenia and G4 febrile neutropenia). The maximum tolerated dose and the RP2D was selected as 2.4mg/kg. 147 pts were enrolled at dose of 2.4mg/kg. The most common TRAEs of 2.4mg/kg dose group ($\geq$20%, all grade/$\geq$5%, $\geq$G3) were anemia (78.8%,13.7%), white blood cell count decreased (62.3%, 18.5%), nausea (59.6%,0%), stomatitis(59.6%,19.2%), neutrophil count decreased (52.7%,19.2%), platelet count decreased (38.4%,8.2%), vomiting (38.4%,0.7%), lymphocyte count decreased (35.6%,5.5%), fatigue (34.9%, 0%), body weight loss (29.5%, 0.6%), constipation (26.7%,0%), anorexia (23.3%,2.7%). 22 CC pts and 13 EC pts were enrolled at 2.4mg/kg and evaluable for tumor assessment. The obiective response rate (ORR) was 36.4% and 23.1%, respectively. Median prior lines of Tx were 2(range, 1-5). 50% CC and 93% EC pts progressed after platinum-based chemotherapy and immune checkpoint inhibitors, respectively. 23% EC had previously used topoisomerase I inhibitors. Objective responses were also observed in pts with other solid tumor types. **Conclusions:** The data indicated encouraging efficacy of BAT8008 in advanced CC and EC. The safety profile showed adequate tolerability. Clinical trial information: NCT05620017. Research Sponsor: Bio-Thera Solutions, Ltd.

3025 **Poster Session**

A phase I clinical study to evaluate the safety, tolerability, and pharmacokinetic characteristics of HLX43 (anti-PD-L1 ADC) in patients with advanced/metastatic solid tumors. First Author: Jie Wang, Internal Medicine, Department of Medical Oncology, National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Beijing, China

Background: Antigens highly expressed in tumors such as HER2 and TROP2 have been widely investigated as antibody-drug conjugate (ADC) targets, leading to their approval for various cancers due to their promising efficacies. However, limited targets for approved ADCs and resistance to the cytotoxic agents render the imperative need for new ADCs. This study aimed to evaluate the safety, tolerability, and preliminary efficacy of HLX43, a novel anti-PD-L1 ADC in patients with advanced/metastatic solid tumors. **Methods:** This phase 1 study consisted of 2 parts. Parts 1 and 2 were dose escalation and dose expansion phases, respectively, to explore different doses of HLX43. In Part 1, patients with histologically or cytologically confirmed advanced/metastatic malignant solid tumors refractory to or not amenable to standard therapies received intravenous HLX43 at 0.5 mg/kg, 1 mg/kg, 2 mg/kg, 3 mg/kg, or 4 mg/kg, Q3W. In Part 2, patients with advanced/metastatic non-small cell lung cancer (NSCLC) refractory to standard treatment received HLX43 at 2 mg/kg, 2.5 mg/kg, or 3 mg/kg, Q3W. The primary endpoints for Part 1 were the proportion of subjects experiencing dose-limiting toxicity (DLT) in each dose group within three weeks after the first drug administration and the maximum tolerable dose (MTD) while that for Part 2 were the recommended Phase 2 dose and IRRC-assessed objective response rate (ORR). **Results:** As of 27 June 2023, 18 patients with non-small cell lung cancer (n = 12, 66.7%), head and neck squamous carcinoma, cervical squamous carcinoma, thymic squamous cell carcinoma, nasopharyngeal cancer, uterine carcinosarcoma, or small cell lung cancer (n = 1, 5.6% for each) were enrolled in Part 1 and received HLX43 at 0.5 mg/kg (n = 3), 1 mg/kg (n = 3), 2 mg/kg (n = 3), 3 mg/kg (n = 3), or 4 mg/kg (n = 6). All the patients experienced treatment-emergent adverse events (TEAEs) that were mostly grades 1-2. One patient in the 4 mg/kg dose group experienced DLTs of febrile neutropenia and decreased white blood cell count. Investigator-assessed ORR was 31.3% (95% CI 11.0-58.7). In Part 2, only data from 21 patients enrolled to receive HLX43 at 2 mg/kg is available and presented here. Among these patients, 15 (71.4%) had squamous NSCLC and 6 (28.6%) had nonsquamous NSCLC. Investigator-assessed ORR and disease control rate were 38.1% (95% CI 18.1-61.6) and 81.0% (95% CI 58.1-94.6); no complete response was achieved, and 8 patients (6 sqNSCLC and 2 nsqNSCLC) had partial response. All the patients experienced TEAEs, most of which were grades 1-2; grade $\geq$3 TEAEs occurred in 7 (33.3%) patients. **Conclusions:** HLX43 was well tolerated with no new safety signals across different dose and exhibited encouraging preliminary efficacy in patients with advanced solid tumors, including those with NSCLC, who had failed standard therapies, which warrants further investigation. Clinical trial information: NCT06115642. Research Sponsor: Shanghai Henlius Biotech, Inc.

3026 **Poster Session**

First in human phase I study of TQB2103, a Claudin18.2 (CLDN18.2) targeted antibody-drug conjugate (ADC), in patients with advanced solid tumors. First Author: Xiangdong Cheng, Zhejiang Cancer Hospital, Hangzhou, Zhejiang Province, China

Background: Claudin18.2 is a promising target for CLDN18.2-expressing cancers such as gastric and pancreatic cancers. TQB2103 is a novel ADC comprised of a humanized anti-CLDN18.2 IgG1 monoclonal antibody, a cleavable linker and topoisomerase I inhibitor, with a drug-to-antibody-ratio (DAR) of 8. **Methods:** This is a multicenter, first-in-human study of TQB2103 in patients (pts) with previously treated advanced solid tumors. This study comprised of a dose escalation part in patients regardless of Claudin18.2 expression level and a dose expansion part in patients specified by CLDN18.2 positive expression. The primary objectives were to assess safety and tolerability and determine the recommended phase 2 dose. Secondary objectives were to assess the pharmacokinetics and preliminary anti-tumor activity. **Results:** As of December 16 2024, 59 pts were enrolled to receive TQB2103 intravenously every 3 weeks at 7 dose level (range from 0.5 to 6.0mg/kg). One patient experienced dose-limiting toxicity (DLT) of grade 3 transaminase elevation at 0.5mg/kg which might also be related to the comorbidity of choledocholithiasis. Fifty-six (94.9%) patients experienced at least one treatment-related adverse event (TRAE). The most frequent TRAEs were nausea (72.9%), vomiting (64.4%), appetite decreased (57.6%), hypoalbuminemia (49.2%), anemia (49.2%), white blood cell decreased (44.1%), and asthenia (44.1%). The most frequent grade $\geq$3 TRAEs were anemia (11.9%) and neutrophil count decreased (10.2%). Most of AEs were grade 1 or grade 2 and manageable. Among the 30 response evaluable pts with CLDN18.2 expression, the ORR and DCR were 20% and 76.7%, respectively. Shrinkage of the target lesions occurred in 17(56.7%) patients. In patients with CLDN18.2 moderate to high expression, the ORR was 42.9% of gastric cancer at 5mg/kg. Surprisingly, all of 3 response-evaluable biliary tract cancer had shrinkage of the target lesions at the first assessment, and 1/3 achieved partial response. **Conclusions:** TQB2103 demonstrated encouraging anti-tumor activity in CLDN18.2 positive solid tumors, with a favorable safety profile. The findings support further development of TQB2103 monotherapy or in combination with other anti-cancer therapies. Clinical trial information: NCT05867563. Research Sponsor: Chia Tai Tianqing Pharmaceutical Group Co., Ltd.

3027 **Poster Session**

Association of genomic alterations in circulating tumor DNA (ctDNA) with clinical response to telisotuzumab vedotin (Teliso-V) in 2L+ *EGFR* wildtype (*EGFR*wt) non-squamous non-small cell lung cancer (NSCLC) patients (pts) with c-Met overexpression (OE). First Author: David Ross Camidge, University of Colorado Cancer Center, Aurora, CO

Background: Teliso-V is an antibody-drug conjugate comprising the c-Met–targeting antibody telisotuzumab linked to the microtubule inhibitor monomethyl auristatin E. In the LUMINOSITY trial (NCT03539536), Teliso-V monotherapy demonstrated efficacy in *EGFR*wt pts with c-Met OE ($\geq$25% tumor cells at 3+ intensity by IHC) (Camidge et al. JCO 2024;42: 3000-11). We used ctDNA molecular profiling to investigate baseline (BSL) and longitudinal changes in pts' tumor mutational spectrum, and to identify potential mechanisms of tumor response and drug resistance to Teliso-V. **Methods:** Pts received 1.9 mg/kg Teliso-V intravenously Q2W. In total, 83 pts with ctDNA data and evaluable tumor assessments in Stage 2 were included in the analysis. Plasma ctDNA was collected at multiple timepoints and analyzed for genomic alterations using the PGDx elio Complete NGS assay (521 genes). Variants with allele frequency (VAF) $<$ 0.3% or from putative clonal hematopoiesis of indeterminate potential genes were removed. High ctDNA levels were defined as having a mean (m)VAF $\geq$median (2.05%), and low ctDNA levels as mVAF $<$ median. Molecular response (MR) was defined as having $\geq$50% reduction in the mVAF vs BSL levels without gene amplification. Mutational profiles and their association with RECIST-defined tumor response and/or drug resistance were assessed. **Results:** Overall, pts with high BSL ctDNA levels had an ORR (28.6%, 12/42) similar to all *EGFR*wt pts with c-Met OE (28.6%, 46/161) and were not statistically different vs pts with low BSL levels. However, pts with low BSL ctDNA had longer median OS (16.3 vs 8.5 mo) and mPFS (8.1 vs 5.4 mo) vs those with high BSL levels. Although the total pts with genomic alterations (GA) in this analysis was limited, *KRAS* GA were one of the most common mutations detected at BSL (24%, 20/83 pts). ORR to Teliso-V among pts with the actionable GA (AGA) of *KRAS* G12C was 100% (5/5). Conversely, among pts with non-AGA *KRAS* G12V/D/A and Q61H/L, the ORR was 23% (3/13). Additional AGAs were found in BSL ctDNA, including 1 *BRAF* V600E, 3 *MET* ex14del, 1 *EGFR* G719C, and 2 *RET1-KIF5B* translocations; none had response to Teliso-V. Pts with a MR at week 6 had higher ORR (35% vs 23%), longer median OS (15.5 vs 12.2 mo), and median PFS (8.5 vs 5.7 mo) vs those who did not. One pt with stable disease had several new AGAs detected in circulation at week 6, including activating *EGFR* ex20ins. At week 24, clinical progression was accompanied by gene amplifications of *ERBB2, FGF4, FGFR4,* and *FGFR3*. Other types of pharmacodynamic changes in ctDNA that could predict clinical response or drug resistance will be presented. **Conclusions:** ctDNA is a promising biomarker in predicting Teliso-V activity. Confirmatory research is planned in larger pt cohorts and/or with tissue-based NGS analyses. Clinical trial information: NCT03539536. Research Sponsor: AbbVie, Inc.; n/a.

3028 **Poster Session**

First-in-human phase 1 dose escalation trial of OMTX705, a novel anti-fibroblast activation protein (FAP) antibody drug conjugate (ADC), in monotherapy and in combination with pembrolizumab in patients with solid tumors. First Author: Javier Torres-Jiménez, Hospital Universitario 12 de Octubre, Madrid, Spain

Background: Cancer Associated Fibroblasts (CAFs) are key components of tumor microenvironment and have immunosuppressive functions. FAP is expressed in a restricted fashion on CAFs. OMTX705 is a first-in-class ADC targeting FAP with a novel tubulysin payload. OMTX705 demonstrated a good safety profile in relevant toxicology models and high linker stability in plasma. We report the dose escalation phase 1 trial of OMTX705 in monotherapy and in combination with pembrolizumab (PEM). **Methods:** Patients (pts) with advanced carcinomas or sarcomas received 1-18 mg/kg of OMTX705 monotherapy and 2-10 mg/kg with standard PEM. Escalation used a classical 3+3 design with backfilling. OMTX705 schedule is Day 1, 8 every 21 days. The primary endpoint is safety and key secondary are efficacy, pharmacokinetics and biomarkers. Biopsy and blood samples were collected for biomarker analysis. **Results:** A total of 78 pts have been dosed: 31 pts in monotherapy in 9 dose cohorts and 47 in combination in 7 cohorts of 3 pts each plus 2 backfilling cohorts at 4 and 7.5 mg/kg in pancreatic adenocarcinoma (PDAC) and microsatellite stable (MSS) colorectal cancer (CRC). Median age was 60, 43% male and ECOG PS 0 in 44%. Main histologies were PDAC 33% and MSS CRC 21% with median of 2 (1 to 5) and 3 (1 to 5) prior lines of therapy, respectively. Median treatment exposure was 44 days (range 8 to 113) in monotherapy and 92 days (1 to 422) in combination. OMTX705 relative dose intensity was ~100% in all dose levels. No DLT has been observed. The most frequent related TEAEs were asthenia 35%, AST increased 14%, diarrhea 8%, anemia 8%, and nausea 8%. Grade 3 related TEAEs (pts): anemia (2), immune-mediated hepatitis (2), GGT increased (1), neutropenia (1) and asthenia (1). In monotherapy, best response was SD in 26%. In combination, PR was achieved in 4% (1 MSS CRC and 1 PDAC; DOR 11+ and 8 months, respectively), SD in 33%, PD in 51%, and NE in 13%. In 13 pts there was target lesion reduction: median -17% (-46 to -1%). Median PFS was 1.4 months (0 to 14+). In combination, 20% PDAC (4/20) and 21% CRC (3/14) pts showed PFS $>$ 4 months. 2/3 NSCLC with previous checkpoint inhibitor treatment, 2 PDAC, and 2 MSS CRC showed PFS $>$ 7 months. High FAP expression (H-score $>$ 30) was observed in 86% PDAC, 64% CRC and 50% other carcinomas. CD8+ and CD56+ immune-cell infiltration in tumor biopsies and down-regulation of immunosuppressive cytokines in plasma samples were observed in PDAC and CRC best responders. OMTX705 tubulysin payload was detected in both CAFs and tumor epithelial apoptotic regions. **Conclusions:** OMTX705 is a novel anti-FAP ADC with excellent safety profile. The combination with PEM showed disease control in some heavily pretreated PDAC, MSS CRC and NSCLC. Changes in immune infiltrates and cytokines suggest that OMTX705 may revert CAF-mediated immunosuppression. Clinical trial information: NCT05547321. Research Sponsor: Oncomatryx Biopharma.

3029 **Poster Session**

A first-in-human clinical study of 9MW2921, a novel TROP-2 antibody-drug conjugate (ADC), in patients with advanced solid tumors. First Author: Shuiping Gao, Fudan University Shanghai Cancer Center, Shanghai, China

Background: TROP-2 (trophoblast cell surface antigen 2) is commonly overexpressed in multiple solid tumors and associated with poor prognosis. 9MW2921 is a novel TROP-2 ADC developed with a site-specific linker to conjugate the class of novel camptothecin-based payload Mtoxin, with a drug-to-antibody-ratio (DAR) of 4. Here we report the safety and efficacy data of 9MW2921 in patients with advanced solid tumors in a phase 1 study. **Methods:** 9MW2921 was administered by intravenous infusion at doses of 1.0-6.0 mg/kg once every 3 weeks. Primary objectives were assessment of dose-limiting toxicity, safety and the recommended phase 2 dose/maximum dose. **Results:** As of 12 November, 2024, thirty-nine patients (pts) were enrolled and treated at dose levels of 1.0 (N = 1), 2.0 (N = 3), 2.5 (N = 12), 3.0 (N = 20) and 4.5 (N = 3) mg/kg. The average age of all patients was 55.6 (range: 37-72) years with 20.5% male and 79.5% female. The median prior therapy lines were 2 (range: 1~11); 48.7% pts treated after immunotherapy. Three patients at 4.5mg/kg experienced at least one dose limiting toxicity (DLT), and this dose level was considered intolerable. No other pts was observed DLTs at the 1.0~3.0 mg/kg groups. The most common $\geq$grade 3 ($\geq$5% pts)TRAEs were stomatitis, anemia, white blood cell (WBC) count decreased, neutropenia, lymphocyte count decreased, rash, vomiting and platelet count decreased. There were no TRAEs leading to death. 38 pts were evaluable for efficacy with at least one post-baseline tumor assessment, 12 pts achieved partial response and 16 pts maintained stable disease. The ORR of 3.0 mg/kg was 42.1% (8/19) and DCR was 84.2% (16/19). The ORR, DCR of 3.0 mg/kg in patients diagnosed with endometrial cancer (4 pts), HR+/HER2- breast cancer (4 pts), HER2- gastric cancer (4 pts) and Non-squamous non-small cell lung cancer (4 pts) were 75%, 100%; 50%, 75%; 50%, 100%; 25%, 100%, respectively. **Conclusions:** The data indicated that 9MW2921 has acceptable tolerability and promising anti-tumor activity in patients with advanced EC, HR+/HER2- BC, HER2- GC and nsq-NSCLC. Clinical trial information: NCT05990452. Research Sponsor: Mabwell (Shanghai) Bioscience Co., Ltd.

3030 **Poster Session**

Efficacy and safety results of a multi-center phase I study of utidelone capsule, a novel oral microtubule inhibitor, in advanced solid tumor patients. First Author: Judy S. Wang, Florida Cancer Specialists/Sarah Cannon Research Institute, Sarasota, FL

Background: Utidelone is a novel microtubule inhibitor, whose injectable formulation (UTD1) has been approved for advanced breast cancer in China since 2021. Attempts to develop oral microtubule inhibitor have not made significant progress; no oral microtubule inhibitors have been approved in the United States to date. Utidelone is insusceptible to P-glycoprotein-mediated efflux, thereby optimizing it for oral administration on an intermittent schedule. Utidelone capsule (UTD2) can significantly improve medication compliance and the convenience of clinical application. This is the first-in-human study of UTD2, and the trial has been completed with final results presented here. **Methods:** Eligible patients were aged $\geq$18, with an ECOG PS of 0-1, life expectancy $\geq$12weeks, pathologically confirmed advanced solid tumor refractory to prior standard therapies. Patients were treated with UTD2 monotherapy. The starting dose was 5-day 25 mg/m^2/d for 2 patients, with planned escalation to 5-day 50, 75, 100 mg/m^2/d and 7-day 70 mg/m^2/d for 2, 6, 3 and 2 patients, repectively in a 21-day cycle. The primary objective was to determine DLT and the MTD. Secondary objectives included efficacy, PK profile and RP2D. **Results:** 18 advanced solid tumor patients were enrolled (3 didn't complete DLT observation) with median age of 60.8 years (range 29.0-81.0), 9 females and 9 males. All patients had received prior treatment in advanced settings with maximal 9 lines. Two DLTs of Grade 3 and Grade 4 diarrhea occurred, one at 5-day 100 mg/m^2/d and one at 7-day 70 mg/m^2/d. Considering the total dose per cycle for both cohorts were similar, the MTD was determined to be 5-day 75 mg/m^2/d via SMC. 11 patients were evaluated for efficacy with an outcome of 1 CR (ovarian cancer), 1 PR (ovarian cancer), 7 SD (testicular Sertoli cell tumor, NSCLC*2, pancreatic adenocarcinoma*2, appendiceal adenocarcinoma and soft tissue sarcoma), with the longest DoT of 12 cycles. The ORR was 18.2% and the CBR was 81.8%. PK results showed that the characteristics of utidelone were consistent with a two-compartment model. Compared to single-dose administration, there was no accumulation of utidelone in plasma upon multi-dose. The most frequent TEAEs were Grade 1/2, including diarrhea, fatigue, nausea, peripheral sensory neuropathy, vomiting, and decreased appetite ($\geq$20% incidence rate), which recovered with supportive treatments. The $\geq$Grade 3 TRAE included diarrhea (27.8%) and fatigue (5.6%). **Conclusions:** This completed study demonstrates encouraging anti-tumor activity with manageable safety of UTD2 in patients with heavily pre-treated advanced solid tumors. The results support continuing development of UTD2 for the upcoming phase II/III studies for gastric and ovarian cancers. Clinical trial information: NCT05681000. Research Sponsor: Biostar Pharma, Inc.

3032 **Poster Session**

RC48-ADC combined with radiotherapy and immunotherapy as salvage therapy for advanced solid tumors with HER2 expression: A multicenter, phase II trial. First Author: Meiling Xu, Center for Cancer Diagnosis and Treatment, The Second Affiliated Hospital of Soochow University, Suzhou, China

Background: Antibody-drug conjugates (ADC) have demonstrated efficacy in treating tumors with HER2 over expression. However, the clinical benefits of ADCs are limited in tumors with lower HER2 expression. The combination of ADCs, radiotherapy, and immunotherapy has shown promising feasibility with HER2-expressing tumors across various cancer types. This approach can enhance spatial and physicochemical synergistic effects, resulting in a more diverse and increased release of tumor antigens. Subsequently, PD-1 inhibitors activate effector T cells, generating a robust immune response that targets and eliminates tumor cells. A single-arm, multicenter phase II trial was initiated to evaluate the clinical efficacy of RC48-ADC combined with radiotherapy and immunotherapy, in HER2-expressing advanced solid tumors. The findings from this trial may establish a new salvage treatment strategy for tumors with low HER2 expression. **Methods:** This study enrolled patients with advanced, HER2-expressing (IHC 1+, 2+, or 3+) solid tumors that had progressed following standard therapies or due to intolerance. Participants received RC48 (disitamab vedotin, 2.0 mg/kg on day 1), followed by radiotherapy every other day (2-3 fractions of 5-8 Gy), GM-CSF 200 μg on days 3-7), sequential IL-2 (2 million IU on days 8-12), and a PD-1 inhibitor administered within one week after completing radiotherapy. This regimen was repeated every three weeks. The primary endpoint was the objective response rate (ORR). **Results:** As of the cutoff date (December 31, 2024), 52 patients were enrolled, including 10 with gynecological cancers, 10 with pancreatic cancer, and 32 with various other tumor types (including breast, gastric and colorectal cancers). All participants had evaluable data. According to RECIST 1.1, the overall ORR was 36.5%, with two patients achieving a complete response (CR) that lasted nearly two years, maintaining minimal residual disease negative status. The ORRs for patients with HER2 expression of 1+, 2+, and 3+ were 29.0%, 43.4%, and 60.0%, respectively. The median progression-free survival (PFS) for all patients was 5.9 months (95% CI: 4.1–9.7 months). The median overall survival (OS) for all patients was 14.3 months (95% CI: 8.6–15.7 months).Treatment-related adverse events were predominantly mild (grade 2 or lower), including fatigue, hair loss, nausea, fever, and rash. Only three patients (5.8%) experienced grade 3 adverse events. **Conclusions:** The results indicate promising efficacy and manageable safety, with a favorable short-term tumor response rate. This suggests that the combination of RC48-ADC, radiotherapy, and immunotherapy could serve as an effective salvage therapy option for patients with HER2-expressing advanced solid tumors. The combination therapy appears to enhance the synergistic effects of radiotherapy and immunotherapy. Clinical trial information: NCT0511550. Research Sponsor: None.

First-in-human study of BG-C9074, a B7-H4-targeting ADC in patients with advanced solid tumors: Preliminary results of the dose-escalation phase. First Author: Cesar Augusto Perez, Sarah Cannon Research Institute at Florida Cancer Specialists, Orlando, FL

Background: B7-H4 is a transmembrane glycoprotein in the B7 superfamily with limited expression in normal tissue but is upregulated in solid tumors including cholangiocarcinoma, breast, ovarian, and endometrial cancers. BG-C9074 is an investigational topoisomerase I inhibitor antibody-drug conjugate. This abstract presents the initial results of monotherapy dose escalation from the ongoing phase 1 study. **Methods:** BG-C9074-101 (NCT06233942) is a first-in-human, multicenter study designed to evaluate the safety, tolerability, pharmacokinetics, and preliminary antitumor activity (per RECIST v1.1) of BG-C9074 as monotherapy and in combination with tislelizumab in patients with advanced solid tumors. Patients with histologically or cytologically confirmed locally advanced, unresectable, or metastatic solid tumors, irrespective of B7-H4 expression, received BG-C9074 intravenously every 3 weeks in sequentially escalating dose cohorts ranging from 1 to 7 mg/kg. **Results:** As of January 22, 2025, 55 patients with advanced tumors (n = 25, ovarian cancer; n = 16, breast cancer; n = 10, cholangiocarcinoma; n = 4, other tumor types) received BG-C9074 monotherapy. Three patients experienced dose-limiting toxicities including fatigue (6 mg/kg), and febrile neutropenia and thrombocytopenia (7 mg/kg). Treatment-emergent adverse events (TEAEs) were reported in 48 patients (87.3%) with grade ≥3 TEAEs occurring in 27.3% of patients. The most common TEAEs were nausea (45.5%), fatigue (38.2%), and neutropenia (32.7%), with neutropenia being the most frequent grade ≥3 TEAE (16.4%). Among 39 efficacy-evaluable patients, eight (20.5%) partial responses (n = 4, confirmed; n = 4, unconfirmed) were observed. **Conclusions:** BG-C9074 showed a manageable safety/tolerability profile in patients with B7-H4 advanced solid tumors. Preliminary clinical responses were observed at multiple dose levels across various tumor types without selection for B7H4 expression. Dose-escalation and dose-level expansion are ongoing and updated clinical data will be presented at the conference. Clinical trial information: NCT06233942. Research Sponsor: BeOne Medicines Ltd.

Efficacy and safety of XNW27011, a Claudin 18.2 targeting antibody drug conjugate with topoisomerase 1 inhibitor payload, in patients with Claudin 18.2 positive gastric/gastroesophageal junction cancer: Results from ongoing phase I/II study. First Author: Jinming Yu, Affiliated Hospital of Shandong First Medical University, Jinan, China

Background: CLDN18.2 is a clinically validated target for cancer treatment. XNW27011 is a CLDN18.2 targeted ADC conjugated with a novel topoisomerase 1inhibitor (topo1i). Dose-escalation study of XNW27011 demonstrated favorable safety, pharmacokinetics, and promising preliminary efficacy in advanced solid tumors. Here we report the results of XNW27011 in CLDN18.2+ GC/GEJC pts from ongoing expansion cohorts. **Methods:** Pts with CLDN18.2+ (TC≥5%, IHC ≥ 2+), advanced/metastatic solid tumors progressed on standard therapy and an ECOG PS of 0-2 are eligible to be enrolled in dose expansion cohorts. Pts received XNW27011 iv infusion Q3W at doses of 2.4, 3.0 and 3.6 mg/kg. 1st endpoint is ORR, 2nd endpoints include safety, other efficacy parameters, PK, ADA, and correlation between CLDN18.2 expression and efficacy. **Results:** As of Dec 28th, 2024, a total of 116 pts with CLDN18.2+ solid tumors including 84 GC/GEJC pts were enrolled in expansion cohorts at doses of 2.4 mg/kg, 3.0 mg/kg and 3.6 mg/kg, with median age of 59 years, median lines of prior treatment 2, 80.2% received checkpoint inhibitors and 18.6% topo1i-containing therapies. The most common any grade TEAE (≥ 20%) in all patients were nausea, vomiting, anemia, appetite ↓, WBC ↓, neutrophil ↓, asthenia, hypoalbuminemia, platelet ↓, body weight ↓, and hypokalemia. The most common ≥ G3 TEAEs (≥5%) were neutrophil ↓, WBC ↓, anemia, lymphocyte ↓, and asthenia. TEAEs leading to dose interruption at 2.4, 3.0 and 3.6 mg/kg were 15.2%, 26% and 60%, dose reduction 10.9%, 26%, and 65%, and dose discontinuation 10.9%, 8%, and 0%. 1 pt at 3.0 mg/kg experienced TEAE leading to death (pneumonia). Safety profile was consistent with that of dose escalation part. In the 84 GC/GEJC pts enrolled in dose expansion, 75 pts were evaluable with at least one post baseline scan. The BOR and DCR across dose groups were 46.7% and 88.0%, respectively. Efficacy in each dose group was summarized in the table below. The median follow up was 4.3M, 4.0M and 7.0M for 2.4, 3.0, and 3.6 mg/kg. Preliminary anti-tumor activity was also observed in pts who had prior CPI and topo 1i containing treatments, as well as in other CLDN18.2+ solid tumor pts. **Conclusions:** In the expansion cohorts,XNW27011 demonstrated promising anti-tumor activity and favorable safety profile in GC/GEJC pts with wide expression level of CLDN18.2.The results support further development of XNW27011 in CLDN18.2+ GC/GEJC. Clinical trial information: CTR20231735. Research Sponsor: Evopoint Biosciences, Co. Ltd.

Results from a phase 1/2 study of 7MW3711: A novel B7-H3 antibody-drug conjugate (ADC) incorporating a topoisomerase I inhibitor in patients with advanced solid tumors. First Author: Zhiye Zhang, Department of Medical Oncology, The First Affiliated Hospital of Henan University of Science and Technology, Luoyang, China

Background: 7MW3711 is a B7-H3 targeting ADC comprised of a recombinant humanized monoclonal anti-human B7-H3 antibody conjugated to the topoisomerase I inhibitor via a protease cleavable linker. B7-H3 is upregulated in several malignant cancers, such as lung, ovarian, breast, prostate and esophageal cancer, which plays an important role in multiple processes such as tumor occurrence, development, and immune escape. Here we present the safety and efficacy data of 7MW3711 from a first-in-human phase 1/2 study. **Methods:** The study enrolled patients (pts) with advanced solid tumor across three segments: dose-escalation (D-esc), dose-expansion (D-exp) and cohort-expansion. In the D-esc and D-exp phase, 7MW3711 was administered intravenously at doses of 1.5, 3.0, 4.5, 6.0 mg/kg every three weeks (Q3W); 4.0 mg/kg every two weeks (Q2W). **Results:** As of the data cutoff on Jan 2, 2025, 43 pts were enrolled and received at least one dose of 7MW3711 (D-esc, n = 15; D-exp, n = 28). At baseline, the median of prior lines of therapy for all pts was 2 (range, 1-9). No dose-limiting toxicities (DLTs) were observed in the D-esc phase. The maximum tolerated dose (MTD) has not yet been reached. The most common Grade ≥3 TRAEs (≥5% of pts) were decreased white blood cell count, anemia, decreased neutrophil count, decreased lymphocyte count, decreased platelet count, diarrhea, and hypokalemia. Among 33 pts treated with 7MW3711 at 4.0 mg/kg or above and reaching tumor assessment, 8 partial responses (PRs) were observed. The objective response rate (ORR) and disease control rate (DCR) were 24.2% and 84.8%, respectively. 15 pts diagnosed with esophageal cancer (EC), ovarian cancer (OC) and prostate cancer (PC) were enrolled at 4.5 mg/kg or above and were evaluable for tumor assessment. All EC pts had previously progressed after receiving platinum-based chemotherapy and immune checkpoint inhibitors. All OC pts were platinum-resistant. All PC pts had previously progressed after receiving docetaxel and endocrine therapy. The ORR of EC, OC and PC was 33.3%, 60.0% and 50.0%, respectively. The DCR of EC, OC and PC was 100.0%. Objective responses were also observed in pts with other solid tumor types, such as lung adenocarcinoma and breast cancer. **Conclusions:** The data indicated encouraging efficacy of 7MW3711 in advanced EC, OC and PC. The safety profile showed adequate tolerability. The dose optimization and expansion study is continuing to establish the RP2D for 7MW3711. Clinical trial information: NCT06008366. 3036 **Poster Session**

Results from a phase 1/2 study of 7MW3711: A novel B7-H3 antibody-drug conjugate (ADC) incorporating a topoisomerase I inhibitor in patients with lung cancer. First Author: Ziming Li, Shanghai Chest Hospital, Shanghai Lung Cancer Clinical Medical Center, Shanghai, China

Background: 7MW3711 is a B7-H3 targeting ADC comprised of a recombinant humanized monoclonal anti-human B7-H3 antibody conjugated to the topoisomerase I inhibitor via a protease cleavable linker. B7-H3 is upregulated in several malignant cancers, such as lung, ovarian, breast, prostate and esophageal cancer, which plays an important role in multiple processes such as tumor occurrence, development, and immune escape. Here we present the safety and efficacy data of 7MW3711 from a first-in-human phase 1/2 study. **Methods:** The study enrolled patients (pts) with advanced solid tumor across three segments: dose-escalation (D-esc), dose-expansion (D-exp) and cohort-expansion. In the D-esc and D-exp phase, 7MW3711 was administered intravenously at doses of 1.5, 3.0, 4.5, 5.0, 6.0 mg/kg every three weeks (Q3W). **Results:** As of the data cutoff on Jan 8, 2025, 37 pts with lung cancer were enrolled and received at least one dose of 7MW3711 (D-esc, n = 25; D-exp, n = 12), which included 16 pts with small cell lung cancer (SCLC) and 21 pts with non-small cell lung cancer (NSCLC). At baseline, the median of prior lines of therapy for all pts was one (range, 1-5). Five pts experienced dose-limiting toxicities (2 pts at 5.0 mg/kg; 3 pts at 6.0 mg/kg), including decreased platelet count, decreased neutrophil count, myelosuppression and decreased appetite. The maximum tolerated dose (MTD) has not yet been determined. The most common Grade ≥3 TRAEs (≥5% of pts) were decreased neutrophil count, decreased white blood cell count, anemia, decreased lymphocyte count, decreased platelet count, hyponatremia, hypokalemia, and myelosuppression. Among 25 pts treated with 7MW3711 at 4.5 mg/kg or above and reaching tumor assessment, 9 partial responses (PRs) were observed. The overall objective response rate (ORR) and disease control rate (DCR) were 36.0% and 96.0%, respectively. 8 pts diagnosed with SCLC were enrolled at 4.5 mg/kg and were evaluable for tumor assessment. All 8 SCLC pts had previously progressed after receiving platinum-based chemotherapy and immune checkpoint inhibitors. The ORR and DCR of them were 62.5% and 100.0%, respectively. Among pts with B7-H3 H-score > 5, the ORR and DCR of lung squamous cell carcinoma (Sq-NSCLC) at 4.5 mg/kg or above were 37.5% (3/8) and 87.5% (7/8), respectively. **Conclusions:** The data indicated encouraging efficacy of 7MW3711 in SCLC and Sq-NSCLC. The safety profile showed adequate tolerability. The dose optimization and expansion study is continuing to establish the RP2D for 7MW3711. Clinical trial information: NCT06008379. Research Sponsor: Mabwell (Shanghai) Bioscience Co., Ltd.

First-in-human trial of SYS6010 combined with SYH2051 in patients with advanced gastrointestinal tumors. First Author: Rongbo Lin, Gastrointestinal Medical Oncology, Fujian Cancer Hospital, Fuzhou, China

Background: SYS6010 is an antibody-drug conjugate (ADC) composed of an EGFR-specific antibody, a cleavable linker, and JS-1, a topoisomerase I inhibitor, as its cytotoxic payload. It targets EGFR, a transmembrane receptor tyrosine kinase overexpressed in malignancies such as lung, breast, gastric, and colorectal cancers. SYS6010 induces DNA damage leading to apoptosis, while resistance may occur through ATM-mediated DNA repair. SYH2051, an ATM inhibitor, disrupts DNA repair, enhancing SYS6010-induced apoptosis. This combination is hypothesized to exert synergistic antitumor effects. **Methods:** This first-in-human clinical trial employed a single-center, open-label, non-randomized design to evaluate the safety, tolerability, and preliminary efficacy of SYS6010 combined with SYH2051. Patients with advanced gastrointestinal tumors expressing EGFR who had progressed on at least one prior line of standard therapy were enrolled. SYS6010 was administered intravenously at a dose of 3.2 mg/kg on day 1 of each 14-day cycle, while SYH2051 was given orally at doses of 40 mg or 80 mg, once daily, for five consecutive days within the same cycle. Safety was assessed using CTCAE v5.0, and efficacy was evaluated according to RECIST v1.1 criteria. **Results:** As of December 31, 2024, 25 patients were enrolled, including 18 with colorectal cancer and 7 with gastric cancer. Twelve patients had received ≥3 prior lines of therapy. Among 6 evaluable gastric cancer patients, 3 achieved partial response (PR) and 3 stable disease (SD), resulting in an objective response rate (ORR) of 50% and a disease control rate (DCR) of 100%. The median progression-free survival (PFS) was approximately 5.8 months (data not mature), and 3 patients remained on treatment. Among 18 colorectal cancer patients (9 with KRAS mutations and 9 wild-type), preliminary analysis showed a median PFS of approximately 4.2 months in wild-type KRAS patients (data not mature). Common treatment-related adverse events (TRAEs) included hematologic toxicity, gastrointestinal symptoms, and fatigue. Frequently observed TRAEs were fatigue (60%), decreased appetite (56%), leukopenia (56%), anemia (48%), neutropenia (48%), nausea (48%), thrombocytopenia (36%), and hypoalbuminemia (32%). Grade ≥3 TRAEs occurred in 12 patients (48%), including neutropenia (7 patients), anemia (6 patients), thrombocytopenia (3 patients), vomiting (3 patients), leukopenia (2 patients), interstitial lung disease (1 patient), infection (1 patient), and elevated bilirubin (1 patient). No treatment-related deaths were reported. **Conclusions:** SYS6010 combined with SYH2051 was well tolerated and demonstrated preliminary antitumor activity in advanced gastrointestinal tumors, particularly in gastric cancer. Further evaluation is ongoing. Research Sponsor: CSPC Pharmaceutical Group Limited.

3038 **Poster Session**

Precemtabart tocentecan (M9140), an anti-CEACAM5 ADC with exatecan payload, in patients with metastatic colorectal cancer (mCRC): Results from the dose optimization of the phase 1 PROCEADE CRC-01 study. First Author: Scott Kopetz, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: CEACAM5 is overexpressed in ~90% of CRCs, with limited expression on healthy cells. Precemtabart tocentecan (M9140), the first anti-CEACAM5 ADC with an exatecan payload (topoisomerase 1 inhibitor), showed a predictable, manageable safety profile and promising early clinical activity in the dose escalation of the Phase 1 PROCEADE-CRC-01 study (NCT05464030) in heavily pretreated patients with mCRC. **Methods:** This global Phase 1 study in 3L adult patients with locally advanced/mCRC (ECOG PS ≤1; previous irinotecan therapy) evaluates clinical activity, safety, and tolerability of precemtabart tocentecan. Here, we report on dose optimization of precemtabart tocentecan tested at 2.8 mg/kg Q3W (Arm A1) or 2.4 mg/kg Q3W (A2; 1:1 randomization) to select the recommended phase 2 dose (RP2D). **Results:** As of Jan 2025, 60 patients (recruited Apr–Oct 2024) had been treated (A1, n = 29; A2, n = 31). Median age was 60.0 years, and 51.7% were male. In A1, 18 (62.1%) patients remained on treatment and 16 (51.6%) in A2. Treatment-emergent AEs (TEAEs) were reported in all patients; grade ≥3 in 38 (63.3%) patients (A1: n = 19 [65.5%]; A2: n = 19 [61.3%]); anemia and neutropenia (any grade; grade ≥3) were most common. Serious TEAEs were reported in 18 (30.0%) patients (A1: n = 8 [27.6%]; A2: n = 10 [32.3%]). Grade ≥3 hematologic AEs were reported in 32 (53.3%) patients: anemia (A1, n = 9; A2, n = 10), neutropenia (A1, n = 14; A2, n = 12), thrombocytopenia (n = 6 both), leukopenia (A1, n = 7; A2, n = 6), lymphopenia (A1, n = 1; A2, n = 2), febrile neutropenia (n = 3 both), and pancytopenia (A1, n = 0; A2, n = 1). Treatment was discontinued in 26 (43.3%) patients (A1: progressive disease (PD), n = 9, patient withdrawal, n = 1, other, n = 1; A2: PD, n = 14, death, n = 1). No treatment-related deaths were reported. Overall, PK profiles were consistent with previous data, with overlap attributed to high between-subject variability. Partial responses were reported in 7 (24.1%; n = 4 [13.8%] confirmed) patients in A1 and 3 (9.7%; n = 1 [3.2%] confirmed) in A2 (all responders remain on treatment), stable disease in 15 (51.7%) and 21 (67.7%), and PD in 5 (17.2%) and 6 (19.4%) patients, respectively. DCR at 12 weeks was 72.4% in A1 and 67.7% in A2. **Conclusions:** These preliminary results corroborate the encouraging efficacy and safety data from the dose escalation part of the PROCEADE CRC-01 study, with no new relevant safety findings. ORR was higher at 2.8 mg/kg, with similar tolerability at both doses. The ORR of 24.1% (13.8% confirmed) at 2.8 mg/kg compares favorably with current monotherapy SoCs (ORRs 1-2%) and recent phase 3 data with trifluridine–tipiracil + bevacizumab (ORR 6.1%) in 3L+ mCRC. These results suggest 2.8 mg/kg as the RP2D for further development in CRC, and other solid tumors (NCT06710132). More mature data, including PFS, will be presented at the congress. Clinical trial information: NCT05464030. Research Sponsor: the healthcare business of Merck KGaA, Darmstadt, Germany (CrossRef Funder ID: 10.13039/100009945).

3039 **Poster Session**

Rinatabart sesutecan (Rina-S) for patients with advanced endometrial cancer: First disclosure from dose expansion cohort B2 of the GTC1184-01 study. First Author: Ira Seth Winer, Wayne State University, Barbara Ann Karmanos Cancer Center, Detroit, MI

Background: Rina-S is an investigational antibody-drug conjugate targeting folate receptor alpha with a novel hydrophilic protease-cleavable linker and a topoisomerase I inhibitor, exatecan payload. Patients (pts) with advanced endometrial cancer (EC) who progress after programmed death-ligand 1 [PD-(L)1] inhibitor plus chemotherapy have very poor prognoses and limited, ineffective treatment options (objective response rate [ORR] < 16% and median progression-free survival < 5 months with single-agent chemotherapy); thus, there is urgent need for novel therapies. In the dose escalation cohort, single-agent Rina-S showed preliminary anti-tumor activity in pts with heavily pretreated EC. Here we first report results for single-agent Rina-S in pts with heavily pretreated EC from dose expansion cohort B2 of the phase 1/2 GCT1184-01 study (NCT05579366). **Methods:** Pts with metastatic or unresectable EC who received prior platinum-based chemotherapy and a PD-(L)1 inhibitor received either Rina-S 100 mg/m^2 or 120 mg/m^2 every 3 weeks after initial enrollment with 120 mg/m^2 only. The primary endpoint was safety and tolerability of Rina-S. Secondary endpoints included ORR and disease control rate (DCR). **Results:** As of data cutoff November 22, 2024, 64 pts with heavily pretreated EC (median 3 prior lines [range 1-8]) received Rina-S 100 mg/m^2 (n = 22) or 120 mg/m^2 (n = 42) for a median treatment duration of 15.9 weeks. Most pts had ECOG PS 1 (64.1%), approximately half (46.9%) were aged ≥70 years, and 48.4% had received prior radiotherapy. Pts primarily had endometrioid carcinoma (45.3%) followed by serous carcinoma (26.6%). The most common (> 25%) treatment-emergent adverse events (TEAEs) were similar across doses and were primarily cytopenias and grade 1-2 gastrointestinal events (nausea, vomiting, decreased appetite). Grade 3-4 cytopenia included neutropenia (48.4%), anemia (35.9%) and thrombocytopenia (21.9%). TEAEs led to Rina-S dose reductions in 15.6% of pts and discontinuation of Rina-S in 3.1% of pts; 37.5% of pts had serious TEAEs. There was 1 related (assessed by investigator) grade 5 TEAE at 120 mg/m^2 confounded by comorbidities; no fatal TEAEs occurred at 100 mg/m^2. No signals of ocular toxicity, neuropathy, or interstitial lung disease were observed. In efficacy-evaluable pts (median follow-up: 18.7 weeks), the unconfirmed ORR was 50%, including 2 complete responses, with Rina-S 100 mg/m^2 (n = 22) and 45.5% with 120 mg/m^2 (n = 33). DCR was 100% and 81.8% with 100 mg/m^2 and 120 mg/m^2, respectively. Responses were ongoing for 9 of 11 (81.8%) and 12 of 15 (80.0%) responders with 100 mg/m^2 and 120 mg/m^2, respectively. **Conclusions:** Rina-S showed encouraging anti-tumor activity in pts with heavily pretreated EC and had a manageable safety profile consistent with previous reports. Further evaluation of single-agent Rina-S in pts with advanced EC is ongoing. Clinical trial information: NCT05579366. Research Sponsor: Genmab A/S.

EVEREST-2: Initial data of the logic-gated Tmod chimeric antigen receptor T-cell (CAR T) therapy A2B694 for patients with solid tumors associated with mesothelin (MSLN) expression and with human leukocyte antigen (HLA) loss of heterozygosity (LOH). First Author: Salman Rafi Punekar, Perlmutter Cancer Center, NYU Langone Health, New York, NY

Background: EVEREST-2 is a first-in-human, phase 1/2 trial to assess the safety and efficacy of A2B694, an autologous, logic-gated Tmod CAR T therapy targeted to MSLN, which is normally expressed in the mesothelium and can be upregulated in many solid tumors. A2B694 is designed to overcome challenges of on-target, off-tumor toxicity that have limited other MSLN-targeted approaches by combining a CAR-activating receptor targeting MSLN with a blocker CAR that recognizes HLA-A*02, to distinguish between normal and tumor cells (Tokatlian, et al. *J Immunother Cancer.* 2022). **Methods:** Adults with recurrent unresectable, locally advanced, or metastatic cancers with MSLN expression who have progressed after standard-of-care therapy are eligible for EVEREST-2. Enrollment to EVEREST-2 and collection of T-cells occurs through the ongoing pre-screening study BASECAMP-1 (NCT04981119). When clinically appropriate, A2B694 is manufactured from cryopreserved T cells, and patients undergo lymphodepletion before A2B694 infusion. The dose-escalation phase is evaluating the safety and tolerability of A2B694 to identify the recommended phase 2 dose (RP2D). Dose escalation was started at 1x10^8 Tmod positive cells (dose level [DL] 1) and will increase up to 14x10^8 in combination with low-dose IL-2 (DL 5). The dose-expansion phase will confirm RP2D and collect biomarker data to further characterize A2B694. **Results:** As of January 15, 2025, 5 participants (median age: 60 years; range, 50-84) have enrolled on EVEREST-2 and received A2B694 at DLs 1-2; participants had ovarian cancer (n = 3), pancreatic cancer (n = 1), and non-small cell lung cancer (n = 1) and had received a median of 4 prior lines of therapy (range, 1-7). Lymphodepleting chemotherapy was well tolerated with no significant cytopenias observed. The most common adverse events were lymphopenia (7 [14.6%]) and decreased appetite (6 [12.5%]). There were no dose-limiting toxicities, cytokine release syndrome, nor related neurotoxicity. One participant was admitted to the hospital for decreased appetite. No long-term toxicities have been noted up to 7.5 months post-infusion. Of the participants who have received A2B694, 5 were efficacy evaluable at DLs 1-2. A2B694 was detected post-infusion in the peripheral blood in all patients. Additionally, A2B694 was detected in an abdominal tumor biopsy from a patient with pancreatic cancer 42 days post-infusion. **Conclusions:** The logic-gated approach was successful at reducing toxicity seen with prior MSLN-targeted CAR T therapies, and A2B694 showed successful CAR T expansion and tumor infiltration. The maximum tolerated dose has not been reached, and results from the dose-escalation phase continue to determine the RP2D. Clinical trial information: NCT06051695. Research Sponsor: A2 Biotherapeutics, Inc.

3041 **Poster Session**

ZL-1310, a DLL3 ADC, in patients with extensive stage small cell lung cancer: Ph1 trial update. First Author: Manish R. Patel, Florida Cancer Specialists/Sarah Cannon Research Institute, Sarasota, FL

Background: Treatment options are limited for patients (pts) with extensive-stage small cell lung cancer (ES-SCLC) that progress after platinum-based chemotherapy (chemo). ZL-1310, a DLL3-targeted antibody drug conjugate (ADC) with a topoisomerase 1 inhibitor payload and cleavable linker, demonstrated promising preliminary results in pts with relapsed/refractory (r/r) ES-SCLC (Spira et al, ENA 2024). Here, we report updated data with additional pts and follow-up (NCT06179069). **Methods:** This is a two-part Phase I study of ZL-1310 administered intravenously every 3 weeks to pts with r/r SCLC who have progressed after at least one platinum-based chemo regimen. Part 1A is a monotherapy dose escalation; Part 2 is a randomized dose optimization/expansion. Study endpoints include safety parameters, objective response rate (ORR) per RECIST v1.1, duration of response (DOR), disease control rate (DCR) and pharmacokinetics (PK). Exploratory tumor biomarkers, including DLL3 expression (expressed as H-score), are examined. **Results:** As of 28 Jan 2025, 28 pts were enrolled in the dose escalation Part 1A and received ZL-1310 at dose levels ranging from 0.8 mg/kg to 2.8 mg/kg. The median time on study is 5.1 months (range 2.4-10.1+). Median age was 66 years (range 36-79); 43% were female; 75% had an ECOG performance status of 1; 93% progressed after prior anti-PD-L1 therapy; 39% had prior lung irradiation, and 36% had baseline brain metastases. Any-grade treatment-related adverse events (TRAEs) occurred in 89% of pts (Grade≥3 TRAEs, 39%). One pt (2.4 mg/kg) had dose limiting toxicities of neutropenia and thrombocytopenia; 5 pts underwent drug reduction and 5 had drug discontinued due to TRAE. Grade≥3 TRAEs occurring in more than 1 patient include anemia (6 pts), neutropenia (5), thrombocytopenia (3), WBC decreased (2), and interstitial lung disease (2). Objective responses were observed in 19 of 28 pts (68%), including one pt pending response confirmation, and a DCR of 93%. Responses were observed across all dose levels and all levels of DLL3 expression (H-score range: 0-260), including one pt with prior tarlatamab treatment. Pts with baseline brain metastases had an 80% response rate and 100% DCR. Fourteen of 19 (74%) responders remain on study. PK data from 25 pts showed dose-proportional increase of systemic ADC and payload exposure, with relatively low exposure of the payload and no significant accumulation. **Conclusions:** ZL-1310 demonstrated a tolerable safety profile and promising antitumor activity in r/r ES-SCLC, including pts with brain metastases, pt with prior tarlatamab, and in the setting of low DLL3 expression. Updated data, including patients in the randomized Part 2 dose optimization, will be presented. Clinical trial information: NCT06179069. Research Sponsor: None.

3042 **Poster Session**

First-in-human (FIH) phase 1 study of CUSP06, a cadherin-6 (CDH6)-directed antibody-drug conjugate (ADC), in patients with platinum-refractory/resistant ovarian cancer and other advanced solid tumors. First Author: Manish R. Patel, Sarah Cannon Research Institute/Florida Cancer Specialists, Sarasota, FL

Background: CDH6 is a transmembrane glycoprotein involved in cancer metastasis expressed in various tumors including ovarian cancer (OC), renal cell carcinoma (RCC), cholangiocarcinoma (CCA), and uterine cancer. CUSP06 is an ADC composed of a humanized IgG1 mAb against CDH6 conjugated with a cleavable linker to exatecan, a topoisomerase I inhibitor. In preclinical studies, CUSP06 showed CDH6-dependent cell growth inhibition in OC cell lines and tumor regression in CDH6-expressing OC, RCC, and other tumor models including those with low CDH6 expression supporting its use across various indications and CDH6 expression levels. We report here the initial results from a FIH study of CUSP06. **Methods:** CUSP06-1001 is a Phase 1a/1b, open-label, multi-center dose escalation and expansion study to evaluate safety, tolerability, pharmacokinetics, pharmacodynamics, recommended Phase 2 dose, and preliminary efficacy of CUSP06 in patients (pts) with platinum-refractory/resistant ovarian cancer (PRROC), advanced RCC and other advanced CDH6-positive solid tumors. Prescreening for CDH6 expression was required for those pts with solid tumors other than OC or RCC. CUSP06 was administered IV every 21 days. Phase 1a followed a standard 3+3 dose escalation design and included dose enrichment cohorts at doses that had demonstrated safety. Phase 1b consists of dose expansion cohorts for pts with OC, RCC, and other CDH6-positive solid tumors to assess the safety, tolerability and efficacy at the RDE. **Results:** As of 03JAN25, 26 pts were dosed with data available for 22 pts in Phase 1a (18 OC, 2 RCC, and 2 CCA) at doses from 1.6 mg/kg to 5.6 mg/kg. The median age was 60.5 yrs and the median prior therapies was 3. Of the 18 pts with OC, all pts received prior platinum and taxane, 67% received bevacizumab, and 22% received mirvetuximab (MIRV). All patients with RCC received an immune checkpoint inhibitor and a TKI. Related TEAEs occurred in 20 pts (91%). The most common related TEAEs ($>$ 20%) were anemia (50%), neutropenia (46%), thrombocytopenia (46%), fatigue (46%), nausea (36%), diarrhea (23%), and vomiting (23%). The most common related Grade $\geq$3 TEAEs were neutropenia, thrombocytopenia, and anemia. AEs led to discontinuation in 3 (14%) pts. Five of 14 GCIG-evaluable OC pts (36%) had a CA-125 response. Among the 20 RECIST-evaluable pts, 5 partial responses (4 confirmed, & 1 unconfirmed) including MIRV-pretreated pts, and 11 stable disease were observed. All PRs were in pts with platinum-resistant high grade serous OC, with an ORR of 36% (5/14). 18 pts were ongoing at the cutoff date. **Conclusions:** The preliminary data from the Phase 1a dose escalation portion of this study showed acceptable tolerability and encouraging efficacy in pts with OC, which support further evaluation of CUSP06 in the Phase 1b expansion cohorts. Clinical trial information: NCT06234423. Research Sponsor: None.

Phase 1 dose-escalation trial of talazoparib in combination with belinostat in select advanced solid tumors. First Author: Monika L. Burness, University of Michigan Rogel Cancer Center, Ann Arbor, MI

Background: Inhibitors of histone deacetylase (HDACi) may synergize with poly (ADP-ribose) polymerase inhibitors (PARPi). This Phase 1 dose escalation trial tested the combination of the PARPi talazoparib and the HDACi belinostat. **Methods:** This open-label study was conducted with a combined dose escalation of talazoparib (0.75 mg-1 mg) and belinostat (500-1000 mg/m2) in subjects with advanced breast, ovarian, prostate and pancreatic cancers. Primary objectives were to identify the safety, tolerability, and recommended phase 2 dose (RP2D) of the combination. A TITE-CRM model was used for dose level assignment and identification of RP2D. **Results:** A total of 25 evaluable subjects were enrolled. Tumor types included breast cancer (10 subjects), ovarian cancer (5), prostate cancer (5), and pancreatic cancer (5). Treatment-related adverse events (AEs) included nausea (n = 8, 32%), fatigue (n = 8, 32%), thromboembolic events (n = 6, 24%), vomiting (n = 5, 25%), and anemia (n = 4, 16%). Treatment-related serious adverse events (SAEs) encompassed thromboembolic events (n = 4) and anemia (n = 1). Dose limiting toxicities (DLTs) occurred in 3 subjects including decreased white blood cell count, fatigue, anemia, and failure to thrive. Seven subjects experienced stable disease (SD), for a clinical benefit rate (CBR) of 28% (7/25); of those with SD, 6 were assigned to the highest dose (dose level 4) and 1 subject was assigned to dose level 3. Duration of enrollment ranged from 18-291 days. **Conclusions:** In subjects with select advanced solid tumors, talazoparib and belinostat combination therapy exhibits a favorable safety profile and manageable toxicity. Nausea and fatigue were the most common adverse events. Further studies are warranted to determine the efficacy of this combination. Clinical trial information: NCT04703920. Research Sponsor: Pfizer; Acrotech.

Impact of stereotactic ablative radiotherapy (SABR) on detection of ctDNA in patients with early-stage lung cancer: Interim findings from the prospective SABR-DETECT trial. First Author: Saurav Verma, Verspeeten Family Cancer Centre, Schulich School of Medicine and Dentistry, Western University, London, ON, Canada

Background: Stereotactic ablative radiotherapy (SABR) is the preferred curative treatment for inoperable patients with stage I/IIA non–small-cell lung cancer (NSCLC). In cases where the tumor is inaccessible or biopsy carries a high risk of complications, SABR is offered even in the absence of a tissue diagnosis, based on a high likelihood of malignancy as calculated by validated predictive models. In these situations, a blood based liquid biopsy detecting circulating tumor DNA (ctDNA) can serve as an aide to confirm malignancy and allow molecular testing. However, low ctDNA yield in early stage NSCLC presents a challenge for diagnosis. This study hypothesizes that ctDNA detection rates will improve by combining assessment of pre- and post-SABR plasma samples. **Methods:** This is a multi-institutional study including two cohorts: 1) patients with suspected stage I/IIA NSCLC, with a pretreatment likelihood of malignancy of ≥60% on Herder or Brock models, and 2) patients with biopsy-proven NSCLC. SABR was delivered according to standard guidelines. Plasma was collected for ctDNA analysis before and 24-72 hours following the first fraction of SABR. SHIELDING ULTRA MRD panel of hotspot regions in 2365 cancer-related genes with ultra-high sensitivity was used for ctDNA analysis (mutation + fragment profile + CNV). In this pre-planned interim analysis, we report on the secondary objective: to assess the impact of SABR on detection rates of ctDNA. **Results:** Paired plasma samples (pre- and post-SABR) were tested for 69 patients. After quality control analysis, 66 paired samples were analyzed and included in this interim analysis. The median age was 76 years (range, 56-89) and 36 (54%) were male. The median concentration of circulating free DNA (ng/mL) did not increase from pre- (5.5, inter quartile range (IQR): 3.3-8.1) to post-SABR (5.7, IQR: 4.1-7.6) (P=0.82). The ctDNA detection rate in pre-SABR samples was 22.7% versus 27.3% in post-SABR samples (Table). Interestingly, in 10 patients (15.2%), ctDNA became detectable in post-SABR samples and in 7 patients (10.6%) the ctDNA was no longer detectable in the post-SABR samples. The ctDNA remained undetectable in 41 patients (62.1%). 37.9% of patients had detectable ctDNA either before or after SABR. **Conclusions:** The diagnostic yield of ctDNA for confirming malignancy in early stage NSCLC is improved by testing both the pre- and the post-SABR samples, collected within 24-72 hours after the first fraction of SABR. This approach may improve the diagnostic rates of liquid biopsies for patients with presumed NSCLC undergoing SABR, warranting further investigation of ctDNA detection before and shortly after treatment. Clinical trial information: NCT05921474. Research Sponsor: Verspeeten Family Cancer Centre Medical Oncology Research Fund (MORF); Lawson Internal Research Fund; Lung Cancer Canada Geoffrey Ogram Memorial Research Grant; 'Crush it with Bev' fundraiser.

ctDNA detection rates (N=66).

Pre-SABR	Post-SABR	n (%)
detected	detected	8 (12.1%)
not detected	detected	10 (15.2%)
detected	not detected	7 (10.6%)
not detected	not detected	41 (62.1%)

Prognostic significance of preoperational circulating tumor DNA detection in early-stage NSCLC using a tissue-free blood test. First Author: Naixin Liang, Peking Union Medical College Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China

Background: There is a growing need for risk evaluation and treatment monitoring in cancer care. However, current methods, mainly imaging, can be burdensome for patients over time and prone to variability among readers. Recent research has highlighted the potential of tumor-informed circulating tumor DNA (ctDNA) testing for identifying postoperative minimal residual disease (MRD) due to its high sensitivity by tracking individualized mutations. Nevertheless, its use in early-stage patients prior to surgery is constrained by limited tissue availability and extended turnaround times. MUSETALK-Lung01 (multiomics sequencing technique application kick-start) is a prospective, longitudinal, observational study designed to evaluate the clinical utility of a tumor-naïve ctDNA assay in patients with early-stage non-small cell lung cancer (NSCLC). **Methods:** Pretreatment plasma samples were prospectively collected from participants with stage I-IIIA NSCLC. Cell-free DNA was extracted and analyzed using a blood assay that interrogates both epigenetic and genetic information. The detection status and the estimated fraction of ctDNA were reported by a machine learning classifier and an independent statistical model, respectively. The calling threshold corresponding to a 99% clinical specificity was verified in a subgroup from the THUNDER study (NCT04820868). Longitudinal data, including vital status, cancer status, and treatment, were collected for up to 5 years. The study was approved by the institutional review board and all participants were required to provide informed consent. **Results:** A total of 289 participants from the MUSETALK-Lung01 study were analyzed. Of these, 49% (141/289) reached the 5-year follow-up, with a median follow-up duration of 59 months. To assess the prognostic value of preoperative ctDNA levels, relapse-free survival (RFS) and overall survival (OS) were evaluated across different stages and pathological subtypes separately. In stage I LUAD patients (N = 179), ctDNA-positive patients (N = 20) had significantly inferior RFS compared to ctDNA-negative patients (2-year RFS: 70% [95% CI: 46%–88%] vs. 94% [95% CI: 90%–97%]; log-rank $p < 0.001$). In contrast, no association was found between preoperative ctDNA detection and RFS in stage II-IIIA LUAD or non-LUAD NSCLC, irrespective of the clinical stage. Specifically, among the 179 stage I LUAD patients, 11 relapsed within 2 years, and 6 of these had positive ctDNA test results. This rate was significantly higher than in patients who relapsed between 2 and 5 years (1/12) or never relapsed (13/156; χ^2 test, $p < 0.001$). **Conclusions:** These findings indicate that presurgical ctDNA can serve as a prognostic indicator in early-stage NSCLC. Tumor-naive ctDNA testing may enhance the standard workflow by identifying high-risk patients who could benefit from innovative treatments. Clinical trial information: NCT04820868. Improved detection of circulating tumor DNA in patients with leiomyosarcoma with fragment size restriction. First Author: Nensi M. Ruzgar, Dana-Farber/Boston Children's Cancer and Blood Disorders Center, Boston, MA

Background: Prior work has shown that detection of circulating tumor DNA (ctDNA) at time of diagnosis of leiomyosarcoma (LMS) is associated with lower likelihood of objective response and patients with detectable ctDNA after two cycles of chemotherapy have worse survival. However, because ctDNA exists at much lower concentrations in plasma compared to cell-free DNA of non-tumor origin, the sensitivity of these prognostic measures to tumor signals remains unclear. With increasing evidence of ctDNA fragments being shorter than the background non-tumor cell-free DNA, we sought to test whether restricting our analysis to smaller fragment sizes would improve detection of ctDNA in LMS. **Methods:** Plasma was serially collected from patients with LMS undergoing chemotherapy. Cell-free DNA extracted from these samples was profiled by ultra-low-passage whole-genome sequencing (ULPWGS). Copy number alterations were identified and used to detect ctDNA using the ichorCNA algorithm before and after restricting the dataset to fragments of 90-150bp (short). We compared detectability of ctDNA via ichorCNA between analyses using all sequencing data and those using data restricted to short fragments. **Results:** From 28 patients, 126 plasma samples were profiled. The median fragment length of cell-free DNA was 240bp (IQR 142-349) for patients with LMS, compared to 307bp (IQR 171-465, $p < 0.001$) in samples collected from healthy controls. Short fragments made up 19.48% of LMS libraries at diagnosis when ctDNA levels were highest, 15.27% of all LMS samples, and 12.96% of libraries from healthy controls. While ctDNA was detectable by ULPWGS in 17% of all samples, detection increased to 40% when analyzed using only short cell-free DNA fragments ($p < 0.0001$). The proportion of diagnostic samples with detectable ctDNA was nominally higher when analyzed by short fragments (39% vs. 64% with 90-150bp size restriction, p = 0.1078, n = 28) and was significantly higher in samples collected after two cycles of chemotherapy (5% vs. 40% with 90-150bp size restriction, p = 0.0197, n = 20). Increases in ctDNA detectability with fragment size restriction were also observed in each of localized and metastatic subgroups (metastatic: 16% without restriction, 38% with restriction, n = 97, p = 0.0012; localized: 17% vs. 45%, n = 39, p = 0.04). **Conclusions:** Our results demonstrate that detection of ctDNA is improved by analyzing short fragments of cell-free DNA in samples collected from patients with LMS. These findings represent a potential to increase the sensitivity of an affordable, low-coverage liquid biopsy assay and may enhance the prognostic value of ctDNA detection in these patients. Further study of the association between ctDNA detection and outcome is needed to fully validate the impact of fragment size restricted analysis of cell-free DNA samples in patients with LMS and is currently ongoing in a prospective study. Accurate differentiation of malignant and benign gastric lesions using cell-free DNA biomarkers. First Author: Hengzhen Li, Harbin Medical University Cancer Hospital, Harbin, China

Background: Early detection of gastric cancer is challenging due to the invasive nature of current diagnostic methods and the difficulty in distinguishing cancer from benign gastric conditions. Cell-free DNA (cfDNA) features have emerged as promising biomarkers for non-invasive detection. This study aims to develop and evaluate a machine learning model utilizing cfDNA features for early gastric cancer detection. **Methods:** We developed an ensemble machine learning model incorporating four cfDNA features: repeat elements, fragment-based methylation, focal copy number variation, and fragment size pattern. The model was trained using cfDNA data from 150 gastric cancer patients and 153 individuals with stomach-related conditions. The ensemble model was validated using a cohort of 149 cancer patients, 149 individuals with high-risk benign lesions, and 50 low-risk benign lesions. Risk is stratified according to the Correa's Cascade. **Results:** The ensemble machine learning model developed using four cfDNA features achieved an AUROC of 0.913 in the training cohort and 0.912 in the testing cohort for distinguishing gastric cancer patients from individuals with stomach-related complications, which outperformed individual cfDNA features. A decision threshold of 0.418, established via cross-validation, was set to ensure at least 95% sensitivity in the training cohort. This threshold enabled accurate binary classification in the validation cohort, with model scores correlating with cancer stage and tumor differentiation, supporting its potential for clinical risk stratification. Model scores effectively differentiated cancer from high-risk individuals, with significantly lower scores in non-cancer groups compared to precancerous or Stage I–III cancer cases (Non-cancer group median score = 0.35, precancer group median score = 0.48, cancer group median score = 0.61). Additionally, the model assigned significantly higher cancer prediction scores to gastric cancer cases compared to high-grade intraepithelial neoplasia (p = 0.003). In the validation dataset, sensitivities were 92.9% (95% CI: 85.3%–96.7%) for Stage I, 96.3% (95% CI: 81.7%–99.3%) for Stage II, and 100% (95% CI: 83.2%–100%) for Stage III. Sensitivities for well-, moderate, and poorly differentiated tumors were 91.7%, 92.2%, and 100%, respectively. Of note, specificity for the detection of cancer was 66% in the training cohort and 71% in the validation cohort. **Conclusions:** Our findings demonstrate the potential of cfDNA-based machine learning models as a non-invasive and accurate diagnostic tool for early gastric cancer detection. By reducing reliance on invasive procedures, this approach could enhance clinical workflow efficiency and improve patient outcomes. Further validation in larger, independent cohorts is needed to support clinical implementation. Development of a methylation-based, tissue-free test for the detection of molecular residual disease by circulating tumor DNA. First Author: John Paul Y.C. Shen, Department of Gastrointestinal Medical Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Clinical validation studies support tumor-informed molecular residual disease (MRD) as a prognostic biomarker for disease recurrence across multiple solid tumor types. However, these tests are not always feasible due to the occasional lack of tumor tissue for next-generation sequencing. Here, we discuss the design of a test for tissue-free (tf)MRD detection and its application to a cohort of patients with colorectal cancer (CRC). **Methods:** A targeted panel composed of differentially methylated regions was developed. A machine-learning model was trained on differential methylation patterns in order to classify plasma samples as MRD-positive or MRD-negative. Performance of the trained classifier was assessed in an independent cohort of 246 patients enrolled in the Bespoke CRC trial (NCT04264702). These patients had MRD results available using a tumor-informed circulating tumor DNA (ctDNA) assay (SignateraTM), of whom 163 were persistently MRD-negative without clinical progression, and 83 had MRD-positive results. Tissue-free MRD results were compared to the tumor-informed results by calculating the percent positive agreement (PPA) and negative percent agreement (NPA). Clinical outcomes (recurrence-free survival [RFS]) were evaluated based on tfMRD results in all patients and stratified based on whether the patient received adjuvant chemotherapy (ACT). **Results:** In this clinical cohort from Bespoke CRC (72% non-Hispanic White, 54% male, mean age 61.4±12.3 years), 71 (28%) patients had stage II CRC, and 146 (59%) had stage III CRC. Overall, PPA was 86% (95% CI: 77-93%) and NPA was 98% (95% CI: 95-100%). Patients with tfMRD-positive status showed inferior RFS compared to tfMRD-negative patients ($p < 0.001$). Significant benefit from ACT was observed among tfMRD-positive ($p < 0.001$) but not among tfMRD-negative patients (p = 0.19). For patients who did not receive ACT in this cohort, we observed 100% PPV and 100% specificity. **Conclusions:** This is the first study of its kind demonstrating a high concordance between a tfMRD test and a clinically validated tumor-informed ctDNA assay. Similar to recently reported data using a tumor-informed ctDNA assay, patients with tfMRD-positive results appeared to derive benefit from ACT treatment. These findings demonstrate that in cases where tissue is not available or of inadequate quality, a methylation-based tissue-free assay may serve as a potential alternative for MRD detection. Prevalence of androgen receptor ligand-binding domain mutations (AR-LBDm) in circulating tumor DNA (ctDNA) versus tissue biopsies in participants (pts) with metastatic castration-resistant prostate cancer (mCRPC) and other tumor types. First Author: Emmanuel S. Antonarakis, University of Minnesota, Masonic Cancer Center, Minneapolis, MN

Background: AR-LBDm is a common mechanism of resistance to AR-directed therapies in patients with mCRPC. However, data on the utility of ctDNA-based versus tissue-based AR-LBDm detection in mCRPC and the prevalence of AR-LBDm in nonprostate cancers are lacking. We evaluated AR-LBDm in ctDNA and tumor tissue samples from pts with advanced solid tumors enrolled in various Merck & Co., Inc. trials. **Methods:** Samples came from pts with mCRPC and 25 other tumor types (eg, bladder, colorectal, ovarian, and pancreatic cancers). AR-LBDm data were available from ctDNA via 2 fixed panel-based ctDNA NGS assays or from tumor tissue samples (mainly archival) via a fixed-panel NGS assay. Data obtained from the 3 assays were nonoverlapping. AR-LBDm prevalence was evaluated in each tumor type and by BRCAm or HRRm status in pts with mCRPC. **Results:** The analysis included 3026 samples assessed by ctDNA assay 1 (mCRPC, n = 1785; other, n = 1241), 2232 samples assessed by ctDNA assay 2 (mCRPC, n = 378; other, n = 1854), and 8181 samples from tissue biopsies (mCRPC, n = 833; other, n = 7348). AR-LBDm was detected in 21.0% of pts with mCRPC by ctDNA assay 1 and 19.8% of pts with mCRPC by ctDNA assay 2. Across all other tumor types, only 1 pt (with hepatocellular carcinoma) had an AR-LBDm in ctDNA. The prevalence of selected AR-LBDm in tissue biopsies was 5.4% (45/833) in pts with mCRPC, 0.6% (1/159) in pts with salivary cancer, and 0% in all other tumor types. AR-LBDm prevalence in pts with mCRPC increased with later-line treatments (Tx) both by tissue and ctDNA analyses and was similar regardless of BRCAm or HRRm status (table). The prevalence of the AR-LBD T878A mutation (by ctDNA) in pts with mCRPC was higher after prior Tx with abiraterone than with enzalutamide (20.9% [43/206] vs 1.7% [3/173]). AR-LBDm was observed in tissues biopsied from the mCRPC setting (prevalence, 12.8% [12/94]) and was associated with higher AR transcriptional activity than in AR-LBD–negative tissues. **Conclusions:** Similar prevalence of AR-LBDm was observed in ctDNA of pts with mCRPC by 2 different ctDNA assays; AR-LBDm prevalence in archival tissue samples was lower than by ctDNA analysis, likely due to the Tx-emergent nature of AR-LBDm. AR-LBDm prevalence was similar regardless of BRCAm or HRRm status in mCRPC, although prevalence of certain AR-LBDm is impacted by the specific prior AR-directed Tx. These data support ctDNA-based (rather than tissue-based) AR-LBDm testing in pts with mCRPC. Research Sponsor: Merck Sharp & Dohme LLC, a subsidiary of Merck & Co., Inc., Rahway, NJ, USA.

AR-LBDm prevalence, % (n/N)	Frontline Tx	Later-line Tx
ctDNA assay 1	16.6 (122/734)	23.8 (252/1059)

A high-performance blood-based DNA methylation test for early detection of gastrointestinal cancers. First Author: Xiaosheng He, The Sixth Affiliated Hospital, Sun Yat-sen University, Guangzhou, China

Background: Early detection of gastrointestinal cancers (GICs), including esophageal cancer (EC), gastric cancer (GC), and colorectal cancer (CRC), remains suboptimal in China due to low screening adherence and limited access to endoscopic procedures. Multi-cancer early detection (MCED) tests present a convenient alternative, yet the efficacy in detecting early-stage GICs has been inadequate. Accurate tumor localization, particularly differentiating between upper and lower GICs, is crucial for determining subsequent diagnostic procedures. In this study, we report the performance of an MCED assay utilizing targeted DNA methylation sequencing to detect GICs. **Methods:** This multicenter, case-control study prospectively enrolled a cohort of 667 GIC patients (203 EC, 263 GC, 201 CRC; stages: I 20.8%, II 26.7%, III 35.7%, IV 16.8%) and 667 non-cancer participants. Plasma cell-free DNA was sequenced using a panel targeting tumor-specific hyper- and hypo-methylation markers. A total of 5120 GIC-specific methylation features were captured. The GIC model was trained using a gradient-boosted tree model, and nested cross-validation was implemented to determine the optimal parameters and evaluate the model's performance of cancer detection. To predict the tissue of origin (TOO), the top 256 features were first selected based on pairwise mutual information for each cancer type. An XGBoost classifier combined with Synthetic Minority Over-Sampling Technique (SMOTE) was trained to determine the TOO. **Results:** The GIC model exhibited robust performance, achieving an area under the curve (AUC) of 0.959 (95% CI: 0.949-0.970), with an overall sensitivity of 86.4% (83.5%-88.8%) at a specificity of 96.0% (94.2%-97.2%). Notably, for stage I-III GICs, which accounted for 83.2% of cases (a proportion consistent with that seen in prospective observational cohort studies of MCED, such as the SYMPLIFY study), the sensitivity reached 84.1% (80.9%-87.0%). The sensitivities for EC, GC, and CRC were 87.2%, 82.9%, and 90.0% respectively. For stage I CRC, the sensitivity of the GIC model reached 79.1% (64.8%-88.6%), comparable to that of multitarget stool DNA tests, and outperformed fecal immunochemical tests (FIT). Regarding tumor localization, the accuracy of TOO across all positive cases was 89.8% (87.0%-92.0%). For stage I-III GICs, the model maintained a high accuracy of 88.7% (85.5%-91.2%) in predicting TOO. Moreover, the model demonstrated exceptional accuracy in distinguishing between upper and lower GICs, with an accuracy of 95.5% (93.5%-96.9%). **Conclusions:** This study demonstrated the high performance of the MCED test for early detection of GICs in a large-scale, prospective cohort enriched with early-stage cancers. These findings highlight the potential of the GIC model to enhance early detection and precise localization of GICs, thus improving the efficiency of subsequent diagnostic procedures. A novel magnetic bead-based cfDNA extraction method for advanced ctDNA marker discovery and methylation profiling. First Author: Zhuoran Jiang, Shanghai Xiaohe Medical Laboratory Co., Ltd., Shanghai, China

Background: Cell-free DNA (cfDNA) extraction and circulating tumor DNA (ctDNA) enrichment are critical for liquid biopsy-based cancer diagnostics. However, the QIAamp Circulating Nucleic Acid Kit (QIA), despite its widespread use, has limitations, including a labor-intensive manual workflow and suboptimal performance in ctDNA marker enrichment and contaminant removal, potentially affecting downstream methylation analyses. To overcome these limitations, we developed a novel, automatable magnetic bead-based cfDNA extraction method to improve ctDNA enrichment and biomarker discovery. **Methods:** The optimized extraction protocol incorporates refinements in pre-treatment, lysis, and binding steps to enhance cfDNA purity and ctDNA enrichment. Plasma samples from 8 lung adenocarcinoma (LUAD) patients, 10 healthy donors, and five simulated plasma samples spiked with varying proportions of fragmented genomic DNA from H838 (cancer) and NA12878 (healthy) cells were processed using both our optimized assay and the QIA kit. **Results:** The optimized method achieved cfDNA yields comparable to the QIA kit in LUAD and healthy samples but exhibited significantly higher extraction yields in simulated samples (39.91 ng vs. 31.17 ng, $p < 0.05$). Digital PCR demonstrated superior enrichment of 136 bp and 400 bp cfDNA fragments, while library preparation showed a 1-fold and 1.46-fold increase in pre-library yield and a 16.55% and 6.45% increase in mapped ratios for LUAD and healthy donors, respectively. These results demonstrate that our method achieves superior cfDNA enrichment efficiency compared to QIA, making it better suited for NGS-based workflows. Library complexity rose from 24.07% to 31.24% in LUAD samples and from 29.71% to 35.04% in healthy donors, with coverage depth of target regions improving by 56.13% and 22.88%, respectively. This enabled the detection of more CpG sites at equivalent sequencing depths. Simulated sample analysis confirmed that our optimized method better preserved methylation accuracy, achieving higher consistency between extracted and unextracted DNA. Furthermore, the optimized method identified significantly more cancer-specific haplotypes across 1,517 LUAD markers, improving ctDNA detection sensitivity, particularly in low tumor burden samples. **Conclusions:** Our automatable magnetic bead-based cfDNA extraction method outperforms QIA in library quality, complexity, and methylation accuracy while enabling enhanced ctDNA enrichment and biomarker detection. This approach provides a robust and scalable solution for advancing liquid biopsy-based cancer diagnostics. Research Sponsor: None.

Liquid biopsy-informed precision oncology clinical trial to evaluate the utility of ctDNA genomic profiling in patients with advanced or metastatic solid tumors. First Author: Amna Jamali, Sidney Kimmel Comprehensive Cancer Center, Johns Hopkins School of Medicine, Baltimore, MD

Background: Genomic profiling through liquid biopsies (LB) has enabled precision oncology decision making, however a key challenge lies in critically interpreting LB data to optimize patient care. **Methods:** We report results from the first planned interim analysis of an observational biomarker trial, designed to evaluate the clinical utility of serial LB in patients with advanced/metastatic solid tumors (NCT05585684). Primary endpoints were to determine feasibility, prevalence of actionable alterations in LB and the fraction of patients with enacted genotype-matched therapies. Secondary endpoints included progression-free (PFS) and overall survival (OS), time to subsequent therapy and concordance between LB and tumor next generation sequencing (NGS). Exploratory endpoints included correlation of ctDNA dynamics with survival. Serial LBs were obtained at baseline, 1-3 weeks on therapy and at progression using a CAP/CLIA validated NGS panel (Labcorp, MD). Patient-matched white blood cell (WBC) NGS was utilized to identify clonal hematopoiesis (CH)-derived variants. Actionability of genomic alterations was assessed by an ensemble multi-resource programmatic approach; results were reviewed at the Johns Hopkins Molecular Tumor Board (JH MTB). **Results:** Between March 2023 and July 2024, 51 patients with NSCLC, SCLC and esophageal cancer were enrolled, with 45 evaluable baseline and 12 progression LBs reviewed at JH MTB. Median turnaround time from baseline and progression LB to MTB recommendation was 14 and 13 days respectively. Patient-matched analyses of baseline WBC samples revealed 30.1% (n = 22) CH-derived alterations. The frequency of actionable variants was 28.8% (n = 21) at baseline, 23.3% (n = 7) on therapy and 21.7% (n = 5) at progression. Of the 45 patients reviewed at baseline, 33 received a recommendation for genotype-matched therapies; 48.5% (n = 16) based on tumor molecular profiling, 15.2% (n = 5) based on LB alone and 36.3% (n = 12) based on LB and tissue NGS. Thirteen patients were treated according to MTB recommendations. Patients who were treated with genotype-matched MTB recommended therapies had longer OS and PFS compared to those who received alternate therapies (not reached-NR vs. 14.8 months, log-rank p = 0.028 and NR vs 6.2 months, log-rank p = 0.21 respectively). Among the 12 patients reviewed at progression, 5 received an MTB recommendation for genotype-tailored therapies based on LB alone (n = 3) or in combination with tissue NGS (n = 2). Early on-therapy ctDNA clearance was associated with longer PFS and OS (log rank p = 0.02 and p = 0.06). **Conclusions:** Our findings highlight the value of a multidisciplinary MTB when supported by comprehensive liquid biopsy molecular information to inform therapy selection and improve patient outcomes. Clinical trial information: NCT05585684. Research Sponsor: LabCorp; National Cancer Institute; 1U01CA274631-01A1; Oncology Center of Excellence, Food and Drug Administration (FDA); U01FD0005042.

Real-time clinical validation of a blood cell-free, mRNA-based GeneVerify test for screening and early diagnosis of prostate cancer. First Author: Sudhir K. Rawal, Rajiv Gandhi Cancer Institute and Research Centre, New Delhi, India

Background: Prostate cancer screening methods, including prostate-specific antigen (PSA) testing, radiological imaging, and pathological assessments, often fail to achieve reliable early detection. Despite advancements, gene-based diagnostic tests tailored for early detection of prostate cancer remain underdeveloped. To bridge this gap, we evaluated the clinical utility and diagnostic accuracy of the plasma cell-free mRNA-based GeneVerify test. This cutting-edge diagnostic approach aims to deliver faster and more precise results while avoiding the risks and complications associated with surgical biopsies. **Methods:** Blood samples were prospectively collected from patients suspected of prostate cancer who presented with urinary symptoms, persistently elevated PSA levels ($>$4 ng/mL), and PIRADS 4-5 lesions. All patients were recommended for a transperineal biopsy. Plasma cell-free RNA was isolated and analyzed for 25 prostate cancer-specific genes using the GeneVerify real-time PCR kit (Hayward, USA). The log2 fold change in gene expression for each gene was calculated, and a genetic risk score (GeneVerify Dx) was assigned to each patient. The transperineal biopsy results served as the reference standard. The diagnostic performance of the test in distinguishing between benign and cancerous cases was assessed and ROC (receiver operating characteristic) curve was plotted. **Results:** We tested a total of 45 subjects, comprising 35 suspected prostate cancer cases and 10 healthy controls. The median age of the cases was 66 years (range: 45–85), while the controls had a median age of 41.5 years (range: 39–47). The genetic risk score effectively differentiated prostate cancer patients from benign cases. The Area Under the Curve (AUC) was 0.83 $\pm$ 0.07 (P = 0.002; 95% CI: 0.70–0.96), demonstrating the test's strong discriminatory ability. Using a risk score cut-off value of 10, the test achieved a sensitivity of 72% and a specificity of 90%. Additionally, patients with higher Gleason grades and those experiencing chronic inflammation exhibited elevated gene expression levels and higher risk scores compared to benign subjects. **Conclusions:** In summary, this prospective study is the first to validate a blood cell-free RNA-based GeneVerify test for real-time screening and early detection of prostate cancer. The test exhibits high precision in identifying early-stage prostate cancer, with strong concordance to biopsy results. Research Sponsor: None.

Molecular profiling of body fluid cfDNA: Advancing diagnostics and therapeutic decisions. First Author: Aditya V. Shreenivas, City of Hope National Medical Center, Duarte, CA

Background: Effusions in cancer patients pose several critical challenges for clinicians. In known cancer patients, an effusion may signal recurrence, whereas in newly diagnosed, seemingly localized cases, it indicates a more advanced stage. In many patients the effusion may be secondary to complications of treatment or comorbidities, rather than malignant. Diagnosing malignant involvement of body fluids remains a challenge due to the limitations of conventional cytology. This study explores the potential of molecular profiling of body fluids to identify actionable molecular alterations and its role in diagnosing malignant effusions. **Methods:** We analyzed cfDNA from body fluids—ascitic fluid (N=26), cerebrospinal fluid (N=7), pleural fluid (N=11), and pericardial fluid (N=1), collected from 45 patients with solid tumors, including lung (N=12), breast (N=9), ovarian (N=9), pancreas (N=4), gastrointestinal cancers (N=4), cervix (N=2), and one each of CNS, endometrial cancer, HCC, liposarcoma, and melanoma. In a subset, results from fluid samples were compared with tissue and plasma samples to assess concordance across different sample types. **Results:** Pathogenic alterations were identified in 89% (40/45) of fluid samples. The most frequently mutated genes were *TP53* (53%), *EGFR* (20%), *KRAS* (18%), *PIK3CA* (9%), *CTNNB1* (7%), *FGFR3* (7%), *GNAS* (7%), *MYC* (7%), and *ESR1* (4%). Simultaneous analysis of body fluid and tissue samples (n=11) revealed that 7 patients (64%) had at least one concordant pathogenic alteration. Similarly, analysis of body fluid and plasma samples (n=16) showed that 8 patients (50%) had at least one concordant pathogenic alteration. Body fluid analysis identified acquired resistance alterations, such as *EGFR T790M* and *ALK C1156Y*, which influenced therapy decisions. Among the alterations detected exclusively in fluid samples were *ERBB2* amplification and *ESR1 D538G* mutation in two breast cancer patients. In evaluating molecular profiling against cytology for detecting malignant effusions, 17 of 25 samples were positive by both methods, while 4 of 5 cytology-negative samples were ctDNA-positive. Notably, 3 of 4 ctDNA-negative cases were cytology-positive. These results emphasize the potential role of molecular profiling for diagnosis when cytology is inconclusive. **Conclusions:** This study highlights the importance of body fluid ctDNA profiling (ascites, pleural, pericardial, CSF) in identifying actionable mutations, including unique druggable alterations not found tissue or liquid biopsies. The ability to detect ctDNA in cytology-negative samples underscores the potential of body fluid ctDNA as a valuable complement to fluid cytology for diagnosing malignant involvement. Research Sponsor: None.

ESCAT classification of pathogenic variants identified in body fluids from 45 patients.

Tier Level	Incidence (%)	Number of unique patients
IA	28.9%	13

Circulating tumor DNA and late recurrence in high-risk, hormone receptor-positive, HER2-negative breast cancer: An updated analysis of the CHiRP study. First Author: Tae-Kyung Robyn Yoo, Dana-Farber Cancer Institute, Boston, MA

Background: Risk of recurrence for patients (pts) with HR+/HER2- breast cancer persists for decades. Most distant recurrences occur in the 'late' adjuvant setting, $>$ 5 years (yrs) from diagnosis. In CHiRP (ASCO 2022), we showed that minimal residual disease (MRD) was detectable in the late adjuvant setting: ctDNA was detected in 8/83 (9.6%) pts in the cohort and 6/8 (75%) pts with positive ctDNA (+ctDNA) had developed distant recurrence when initially reported (median follow-up 2 years from first plasma sample collected on study). Here, we report updated clinical outcomes and investigate the meaning of a ctDNA test result during surveillance with longer follow-up. **Methods:** In CHiRP, pts with stage II-III HR+/HER2- breast cancer at high risk of recurrence diagnosed $>$ 5 yrs prior with no evidence of recurrence were prospectively identified. All pts provided informed consent for prospective plasma collection every 6-12 months at routine follow-up visits for batched, retrospective ctDNA testing using RaDaR, a tumor-informed whole exome sequencing-based assay. Pts were followed at the discretion of the clinical provider without any routine surveillance imaging, as per guideline-concordant care. See CHiRP ASCO 2022 presentation for additional methods. **Results:** Of 83 pts in the analytic cohort, 57 (68.7%) pts had stage III disease, and most (n = 75, 90.4%) underwent (neo)adjuvant chemotherapy. All pts received endocrine therapy. In this update, median follow-up from first sample collection was 4.4 yrs (interquartile range 4.0, 4.9). 214 plasma samples were collected prior to any known recurrences and included in this analysis. 8/83 (9.6%) pts had +ctDNA at any timepoint including 4/83 (4.8%) with +ctDNA on first study plasma sample. In pts initially ctDNA-negative (-ctDNA; n = 4), median time from first sample collection to MRD detection was 1.29 yrs (range, 0.72 – 3.05). During follow-up, 8 (9.6%) pts developed distant recurrence and 1 (1.2%) pt had a local recurrence. With additional follow-up included in this update, all 8/8(100%) pts with +ctDNA developed distant recurrence with a median lead time of 1.39 years (range 0.01 – 4.24). Among -ctDNA plasma samples with $>$ 2 yrs of follow-up (n = 185), the negative predictive value (NPV) of a -ctDNA test for lack of clinical recurrence for $>$ 2 yrs post-test was 98.4% (3/185). The NPV indicating freedom from recurrence $>$ 1 and $>$ 3 yrs was 100% (0/196) and 96.6% (5/147), respectively. **Conclusions:** In pts with high-risk HR+/HER2- breast cancer in the late adjuvant setting, all pts with +ctDNA developed distant metastasis. A -ctDNA test was strongly associated with lack of recurrence over a 3 yr follow-up period. Future studies are needed to determine if ctDNA-guided intervention can impact clinical outcomes for early-stage breast cancer and to determine the optimal role of MRD surveillance during follow-up. A plasma proteomics-based model for predicting response to neoadjuvant chemotherapy in ovarian cancer. First Author: Coren Lahav, Oncohost Ltd, Binyamina, Israel

Background: Neoadjuvant chemotherapy (NACT) is a standard treatment option for advanced high-grade serious ovarian cancer (HGSOC). Following interval debulking surgery, pathologists assess tumor response to initial chemotherapy using a standardized chemotherapy response score (CRS) corresponding with patient survival. We sought to determine the feasibility of developing a proteomic-based biomarker to predict response to NACT based on pre-treatment plasma samples. **Methods:** Pre-treatment samples were collected from 71 HGSOC patients receiving platinum-taxane combination NACT. Deep plasma proteomic profiling was performed using SomaLogic's 7K aptamer-based technology. Based on the proteomic profiles, a computational model was developed to predict CRS, focusing on differentiating between poor CRS (CRS1) versus partial or near-complete CRS (CRS2/3). The model counted the number of response-associated proteins per patient. Patient scores were derived by resampling into training and test sets, averaging test set results. Patients were stratified into groups (i.e., 'Chemo-responsive' or 'Chemo-resistant') based on median score. Bioinformatic analysis of the HGSOC-specific proteomic biomarkers was performed to gain insight into the potential mechanisms driving NACT therapeutic benefit and resistance. **Results:** Our proteomics-based predictive model differentiated between patients with CRS1 versus CRS2/3 (ROC AUC = 0.67, p = 0.008). CRS association with disease-free survival (DFS) and overall survival (OS) in this cohort was consistent with a previous meta-analysis, though not reaching statistical significance (CRS3 versus CRS1/2, HR = 0.62, 95% CI: 0.27-1.42, p = 0.25 for DFS; HR = 0.67, 95% CI: 0.21-2.09, p = 0.48 for OS). Hazard ratios for patient classification as 'Chemo-responsive' versus 'Chemo-resistant' trended in the same direction (HR = 0.70, 95% CI: 0.37-1.30, p = 0.25 for DFS; HR = 0.65, 95% CI: 0.25-1.72, p =0.39 for OS). The predictive model incorporated 62 proteins. Of these, 27 were elevated in the plasma of patients with poor CRS compared to those with partial or near-complete CRS. These proteins were notably enriched in pathways related to cell death resistance. Moreover, several of these elevated proteins have previously been linked to HGSOC, particularly in the context of chemotherapy resistance. Conversely, patients with partial or near-complete CRS showed significant enrichment of proteins associated with genome instability and mutation. **Conclusions:** This study demonstrates the feasibility of CRS prediction using plasma proteomics at baseline, potentially complementing existing imaging approaches. While current treatment options limit immediate clinical utility, these findings provide novel insights into biological determinants of chemotherapy response and may become predictive biomarkers for novel treatment protocols. NeoCircle: Investigating circulating tumor DNA dynamics as a predictor of survival in primary breast cancer. First Author: Anthony M George, Lund University, Lund, Sweden

Background: Persistent circulating tumor DNA (ctDNA) detection during neoadjuvant treatment (NAT) of early-breast cancer (EBC) indicates high-risk disease. Following surgical resection, ctDNA-positivity indicates molecular residual disease (MRD) and heralds occult metastatic disease relapse. To incorporate ctDNA into EBC management, scalable and widely accessible diagnostic methods are necessary. Here we apply an ultrasensitive, personalized tumor-informed approach to ctDNA analysis leveraging structural variant (SV) detection using a novel multiplex digital PCR (dPCR) technology. **Methods:** 116 patients with stage I-III EBC (31.0% TNBC, 43.1% HR+/HER2- and 24.1% HER2+) and eligible for NAT were recruited through the prospective SCAN-B study (NCT02306096, substudy NeoCircle) between December 2014 and March 2019 and have been analyzed for ctDNA. Whole genome sequencing was performed on tumor material and personalized multiplex dPCR assays tracking up to 16 SVs were used for ctDNA monitoring. Plasma samples were collected at baseline, during NAT, pre- and post-surgery and at 6-monthly intervals during follow up. **Results:** High baseline detection was observed across all stages and subtypes (90.5% overall), and ctDNA-positivity at end-of-NAT (end-NAT) was a significant predictor of eventual disease relapse and death (relapse-free interval, RFI, hazard ratio, HR, 3.7, 95% CI 1.4-9.7; overall survival HR 7.7, 95% CI 2.2-26.6). A significant association was observed between end-NAT ctDNA clearance and pathological complete response (pCR), whereas non-pCR by itself was not a significant predictor of relapse or death in this cohort. At one or more post-operative timepoints, MRD+ was detected in 10 patients who experienced distant recurrence, with lead times up to 4 years (median 13.9 months, range 1.8-47.7 months). Similarly, ctDNA was detected in 3 of 4 patients with local recurrences and 1 of 2 patients with CNS-only recurrences. For 2 patients without presentation of clinical recurrence to date, ctDNA was detected post-operatively, with subsequent clearance during follow-up. Post-operative MRD associated with poor RFI (HR 45.5, 95% CI 13.0-159.8) and OS (HR 15.3, 95% CI 4.5-52.9). **Conclusions:** In this analysis of 116 patients from a prospective study in patients with EBC receiving NAT, we monitored ctDNA using an ultrasensitive tumor-informed dPCR assay tracking patient-specific SVs. ctDNA detection post-NAT and prior to surgery was associated with high-risk of disease relapse and death, outperforming pCR. Moreover, post-operative ctDNA detection was also significantly associated with disease relapse and death, with long lead-times over standard-of-care clinical assessments. These findings further validate the feasibility of SVs as an MRD analyte and support the clinical use of this approach in EBC. Research Sponsor: None.

Monitoring populations of tumor-macrophage fusion cells in blood prognosticates PFS and OS in pan-metastatic cancers over 2 years. First Author: Sonia Muthuraj, Rutgers University, New Brunswick, NJ

Background: Tumor associated macrophages are known to fuse with cancer cells in the blood through a dysfunctional CD47 phagocytic immune pathway resulting in the formation of tumor- macrophage fusion cells (TMFCs) which are observed as heterokaryon (incomplete fusion), synkaryon (full fusion) or hetero-to-synkaryon transition (partial fusion). Previous studies in lung and breast cancer demonstrated that subtypes of TMFCs in blood may correlate with highly aggressive disease unlikely to respond to certain systemic therapies (i.e. chemotherapy). We initiated a prospective study to evaluate the blood of n = 100 metastatic pan-cancer patients (pts) receiving systemic therapy for the presence of full, partial, and incomplete TMFCs to compare their progression-free survival (PFS) and overall survival (OS). **Methods:** We conducted a prospective pilot study of n = 100 pathologically confirmed metastatic cancer pts with breast (n = 23), prostate (n = 21), pancreas (n = 17), colon (n = 19), or lung (20) with active progressive disease, prior to the induction of new systemic therapies, i.e. chemotherapy (n = 39), PD-L1 immunotherapy (n = 27), hormone therapy (n = 20), or targeted therapy (n = 23). TMFCs were isolated from 7.5ml peripheral blood using CellSieve microfiltration and identified by their enlarged multinucleated structure ($>$ 30 μm), which was categorized into 3 distinct subtypes: full fusion marked by a single multinucleated nuclei, partial fusion marked by 2 contacting nuclei, incomplete fusion marked by 2 distinct non-contacting nuclei. TMFC subtypes were compared to pts' PFS and OS by cox proportional univariate and multivariate analysis over 24 months. **Results:** We identified TMFCs in 78% of all pts (n = 78/100), averaging 10 per pt. 37% of pts were found to have more than one TMFC subtype in their sample, with 70 pts having full fusion, 23 partial fusion, and 28 incomplete fusion. At 24 months, pts with incomplete fusion TMFCs had significantly worse PFS (HR, 2.9; 95% CI, 1.5 to 5.7; P = 0.0023) and OS (HR, 2.5; 95% CI, 1.2 to 5.3; P = 0.0202). Interestingly, pts with incomplete fusion and treated with systemic targeted therapy (n = 7) were found to have significantly improved PFS (HR, 4.8; 95% CI, 1.8 to 13.0; p = 0.0052), but not OS (HR, 3.0; 95% CI, 1.0-9.2; p = 0.0999) versus other therapy types. There was no significant PFS differences in pts without incomplete fusion TMFCs being treated with targeted therapies. **Conclusions:** In a pan metastatic cancer setting, we found that incomplete fusion in circulating TMFCs associates with poorer outcomes at 24 months. Further, it appears that pts with incomplete TMFCs may have had better outcomes when treated with targeted therapies compared to other therapy types. These preliminary findings suggest the need for larger scale prospective studies to further evaluate relationships between TMFCs and therapeutic responses in specific disease populations. Whole-genome bisulfite sequencing of cell-free DNA to investigate molecular contributors to racial survival differences in advanced-stage triple-negative breast cancer. First Author: Chun Wang, Thomas Jefferson University - Department of Medical Oncology, Philadelphia, PA

Background: Black women are twice as likely to be diagnosed with triple-negative breast cancer (TNBC), a highly aggressive and difficult-to-treat subtype with poor survival outcomes. While well-defined factors such as socioeconomic status have been recognized, the impact of genomic and molecular factors on the racial disparity in TNBC survival remains understudied. Liquid biopsy, a non-invasive and real-time method for studying the molecular landscape of tumors, has yet to be explored in the context of racial survival disparities in TNBC. **Methods:** Ten Black TNBC patients were matched with ten White TNBC patients based on age, family history, tumor stage, grade, and inflammatory breast cancer (IBC) status. Baseline blood samples were collected prior to the initiation of a new therapy. Cell-free DNA (cfDNA) was extracted from plasma, bisulfite-converted, and analyzed through whole-genome bisulfite sequencing (WGBS). After quality control, ichorCNA was used to identify copy number alterations (CNAs), and MethylKit was applied for methylome analysis. Associations between CNAs, differentially methylated regions (DMRs), and progression-free survival (PFS) were evaluated and compared between Black and White patients. **Results:** The Black-White pairs were well-matched across key clinical variables, including age (P = 0.99), family history (P = 1.00), tumor stage (P = 1.00), grade (P = 1.00), and IBC status (P = 0.37). Black TNBC patients had poorer PFS compared to their White counterparts. Significant CNAs were identified on chromosome 1 (chr1:20400000-23900000_p36.12 and chr1:7200000-9200000_p36.23), regions associated with known breast cancer prognosis genes such as *EPHB2* and *E2F2*. Thirteen DMRs were found to be significantly associated with the racial differences in PFS, with key genes such as *CDH13* and *TMEM132C* identified in these regions. Notably, the methylation status of the *CDH13* promoter has previously been associated with breast cancer risk. The predictive power for PFS was significantly enhanced in a model combining these 13 DMRs with race (Concordance Index [C-index] = 0.96), compared to a model using race alone (C-index = 0.75). **Conclusions:** In this pilot study utilizing WGBS of cfDNA, we identified significant CNAs and DMRs associated with the racial disparity in survival outcomes among advanced-stage TNBC patients. These findings provide insight into the genomic and molecular contributors to this disparity and highlight the potential of liquid biopsy for future studies. Larger studies are needed to validate these results and further investigate the underlying mechanisms. Beyond tumor-shed markers: AI driven tumor-educated polymorphonuclear granulocytes monitoring for multi-cancer early detection. First Author: Rajan Datar, Datar Cancer Genetics, Nashik, India

Background: Tumor educated Polymorphonuclear Granulocytes (tPMNG) are a distinct phenotypic set of Neutrophils (N2) with corrupted programmed death pathways resulting in apoptosis resistance. The presence of tPMNGs in the peripheral blood indicates up-regulation of pro-tumoral factors and resistance to apoptotic signals. Our platform leverages this unique anti-apoptotic characteristic of tPMNGs through a proprietary culture process and AI-based digital imaging analysis to detect cancer in its early stages. This approach represents a paradigm shift from detecting rare tumor-shed analytes such as ctDNA and CTCs to monitoring relatively abundant tPMNGs, whose numbers typically exceed conventional analytes by 3-4 orders of magnitude. We studied detection of tPMNGs in a case-control study to evaluate their suitability for a multi-cancer early detection test (MCED). **Methods:** We collected 10 ml of peripheral blood in EDTA tubes from 892 asymptomatic healthy volunteers above 18 years of age [463, 52% male; 429, 48% females with mean age of 48 (20 to 89) years], 24 individuals diagnosed with non-malignant conditions including prostatitis, polycystic ovarian disease and acute pancreatitis, and 90 individuals recently diagnosed with surgically resectable early stage cancers (Stage 1/ 2) comprising Head and Neck (N=32, 36%), Breast (N=20, 22%), Colorectal (N=14, 16%), others (N=24, 27%). Nucleated cells were isolated from the samples after RBC lysis and centrifugation. These cells were seeded in six well culture plates and subjected to controlled apoptotic stress under serum-free, hypoxic conditions with specific growth factor supplementation for 5 days. Surviving cells were set on imaging slides and stained with H&E. 60X images were obtained and analyzed using a convolutional neural network (CNN) based AI algorithm to detect tPMNGs per ml. **Results:** The mPMNG detection method demonstrated 84% sensitivity (95% CI: 84.44%) across multiple cancer types. The platform demonstrated 97% specificity (95% CI: 97.40%) among healthy asymptomatic cohort. In samples from individuals from individuals with non-malignant conditions, specificity was 96% (95% CI: 95.83%). **Conclusions:** This first-in-class immune cell-based MCED approach offers several advantages over tumor-shed analyte detection: 1. Leverages amplified host response rather than rare tumor products. 2. Provides robust detection across cancer types and stages. 3. Utilizes existing laboratory infrastructure and a scalable protocol. 4. Demonstrates potential for screening, diagnosis, and monitoring applications. The high sensitivity and specificity, combined with practical advantages, suggest potential for clinical implementation in cancer screening and monitoring programs either using tPMNG alone or in conjunction with CTCs / cfDNA evaluation. Next-generation U-Net Encoder: Decoder for accurate, automated CTC detection from images of peripheral blood nucleated cells stained with EPCAM and DAPI. First Author: Tim Crook, Cromwell Hospital, London, United Kingdom

Background: Direct circulating tumor cell (CTC) detection is a promising biomarker for early cancer detection and monitoring. Traditional fluorescence microscopy and AI-driven methods have limitations such as subjectivity and labor-intensiveness. We developed a deep-learning pipeline using a U-Net–type encoder–decoder architecture for precise pixel-level CTC discrimination in peripheral blood nucleated cells (PBNCs). This method preserves morphological and fluorescence details, overcoming convolutional neural network (CNN) limitations by maintaining fine features through skip connections for better discrimination. We present specificity and sensitivity data from a case-control study. **Methods:** We collected 5 ml of peripheral blood in EDTA tubes from 1383 asymptomatic healthy volunteers (744, 54% male; 639, 46% females with mean age of 49 [(20 to 93) yrs], 38 individuals diagnosed with non-malignant conditions including prostatitis, PCOD and acute pancreatitis, and 143 individuals recently diagnosed with surgically resectable early stage cancers (Stage 1/ 2) - Head and Neck (N=50, 35%), Breast (N=31, 22%), Colorectal (N=17, 12%), Pancreas (N=8, 6%), Prostate (N=8, 6%), Lung (N=5, 3%), Ovary (N=5, 3%) others (N=19, 13%). Nucleated cells were isolated from the samples after RBC lysis and centrifugation and stained with EPCAM and DAPI and set on imaging slides. 60X images were obtained and processed by AI utilizing U-Net–Based Encoder–Decoder Architecture and context discrimination to detect CTCs. The customized U-Net pipeline encodes spatial information through successive convolutional and pooling layers, generating a highly compressed representation of cells in the bottleneck. By employing transposed convolutions in the decoder stage—and incorporating skip connections from the encoder layers—the AI model reconstructs a pixel-wise segmentation mask to identify potential CTCs with cell diameter >10 microns. This approach aims to surpass existing methods that rely on bounding-box–based detection by offering enhanced sensitivity and specificity through end-to-end learned feature extraction. Ground truth annotations were established via expert cytopathology review, and training procedures involved cross-validation to ensure generalizable performance. **Results:** Analysis of total 1564 samples showed that our U-Net–based model achieved a sensitivity of 89% (95% CI: 88.81) and specificity of 97% (95% CI: 97.98) for detecting CTCs. Performance remained consistent across solid tumors, highlighting the flexibility and adaptability of the architecture in various fluorescence staining conditions. **Conclusions:** Our U-Net pipeline uses pixel-level segmentation and skip connections to enhance CTC detection accuracy. Integrating fluorescence and morphology, it can streamline cancer screening and disease monitoring. Research Sponsor: None.

Clinical outcomes of a prospective multicenter study evaluating a combined circulating tumor DNA (ctDNA) and RNA (ctRNA) liquid biopsy assay in metastatic non-small cell lung cancer (NSCLC). First Author: Richa Dawar, University of Miami Sylvester Comprehensive Cancer Center, Miami, FL

Background: Genomic profiling of metastatic NSCLC to inform targeted therapy selection is endorsed by numerous guidelines. While tissue biopsy is the mainstay of molecular profiling, liquid biopsy offers a practical real-world approach to non-invasively identify guideline-recommended biomarkers. LIQUIK was a prospective, multicenter, observational cohort study to evaluate the performance of a combined ctDNA and ctRNA liquid biopsy assay, LiquidHALLMARK (LHM ctDNA and ctRNA) in comparison to the ctDNA-only liquid biopsy Guardant360 (G360 ctDNA) and tissue next-generation sequencing (NGS) for biomarker detection in metastatic NSCLC. Diagnostic performance of the primary cohort has been previously presented. Here, we report clinical outcomes after 1-year follow-up of the cohort. **Methods:** LIQUIK (NCT04703153) enrolled 151 non-squamous NSCLC patients across the USA and Singapore from Apr 2021 to Dec 2022. Enrolled patients were genotyped using tissue NGS, LHM ctDNA and ctRNA, and G360 ctDNA for 9 biomarkers (*EGFR, ALK, RET, ROS1, BRAF, KRAS, MET, ERBB2, NTRK1/2/3*). Patients were treated according to their physician's choice of first-line therapy following biomarker testing. Tumor assessments were performed at baseline and within 6 months (mo) of treatment initiation. Overall response rate (ORR), progression-free survival (PFS), and the clinical utility of ctRNA were investigated. **Results:** Among the 151 patients, 129 were subsequently treated in the first-line setting (49.6% on targeted therapy, 41.1% on chemotherapy, and 30.2% on immunotherapy), with 27 on combination therapy. Of the 64 patients on targeted therapy, 47 had matched biomarker findings from tissue NGS, 47 from LHM ctDNA and ctRNA, and 43 from G360 ctDNA. ORRs of patients on targeted therapy and chemo/immunotherapy were 40.4% and 16.1% respectively. Among patients treated with targeted therapy, ORR was similar between patients with biomarker-matched findings from tissue NGS (45.2%), LHM ctDNA and ctRNA (40.5%), and G360 ctDNA (36.8%). PFS of patients on targeted therapy (median 23.6 mo) was significantly longer than those not on targeted therapy (median 3.8 mo; HR = 0.26; $p < 0.001$). Median PFS was similar between patients with biomarker-matched findings from tissue NGS (23.6 mo), LHM ctDNA and ctRNA (18.6 mo), and G360 ctRNA (20.1 mo). Overall, incorporation of ctRNA into LHM identified 2 additional biomarker-positive patients. Both ctRNA-exclusive biomarkers were confirmed by tissue NGS, and both patients were treated with biomarker-matched targeted therapy. While one patient was lost to follow-up, the second patient had a partial response to treatment. **Conclusions:** Treatment outcomes based on liquid and tissue biopsies are comparable. The inclusion of ctRNA in liquid biopsy increases its diagnostic yield of actionable biomarkers. Clinical trial information: NCT04703153. Research Sponsor: None.

Microbial metabolic pathways to abrogate immunotherapy toxicity and promote anti-tumor response in metastatic renal cell cancer. First Author: Shahla Bari, Duke Cancer Institute Center for Prostate and Urologic Cancers, Duke University School of Medicine, Durham, NC

Background: Metastatic RCC has a poor prognosis. Despite improvement in treatment outcomes with ICB and targeted therapy, many patients fail to respond to first line therapy and immune mediated adverse events(irAE) remains a major challenge, often leading to treatment discontinuation. Therefore, mitigating irAE without compromising antitumor immunity is a critical unmet need. Tryptophan microbial metabolic pathway is known to play a major role in immune homeostasis through its action on Aryl hydrocarbon receptor (AhR) balancing immune suppresser with immune effector responses. We hypothesize that microbial metabolism of tryptophan to indole metabolites may play a role in ICB resistance as well in irAE, identification of which may help us predict patients most likely to respond, without life threatening toxicity. **Methods:** We prospectively collected paired stool and blood samples of treatment naïve metastatic RCC patients, treated with ICB +/- Tyrosine kinase inhibitors (TKI) at treatment initiation and at time of first response assessment (12+/-3 weeks). We evaluated stool metagenomics and untargeted stool and plasma metabolomics among responders (R) and non-responders (NR). We focused on kynurenine/tryptophan and indoles/tryptophan ratio to evaluate differential host and microbial metabolism of tryptophan. A responder was classified as progression free survival (PFS) greater than 6 months while patients with grade 3 or higher irAE was classified as serious IrAE. **Results:** Among 120 patients accrued, 49 were treated with combination ICB, while 71 patients were treated with ICB + TKI. Median follow up was 27 months. 28 patients (23%) had a Grade 3 or higher irAE. 3 patients died from complications attributable to irAE. The median duration to development of any irAE was 3.5 months. Using negative binomial regression model evaluating baseline relative abundance of microbial tryptophan metabolites that were associated both with response as well as serious irAE, we noted significant higher abundance of Indole acetic acid (IAA), indole acetonitrile(ACN), indole acetyl phenylalanine (IAAP)and IAA/kynurenine (Kyn) and lower abundance of tryptophol, indole 3 pyruvic (IPA), (coefficient of 6.4, 1.8, 7.15, 4.6, 0.04, 0.46, with adj p value < 0.05) with serious irAE as well as ICB resistance (Coefficient-5.42, 1.83, 6.15, 4.05, 0.03, 0.4, $p < 0.05$). **Conclusions:** This is one of the first studies evaluating microbial metabolic pathways that may play a role in predicting patients who are more likely to respond with lower likelihood of serious irAE in RCC, thus helping to identify strategies to decouple tumor immunity from autoimmunity to improve ICB outcomes. Further the results can be extrapolated to many other solid tumor treated with immunotherapy, as tryptophan metabolism plays a immune homeostatic role across cancers. Tumor-educated platelets as a source of potential biomarkers for colorectal cancer. First Author: Rodnei Macambira, Oncológica do Brasil Cancer Center, Belém, Pará, Brazil

Background: Colorectal cancer (CRC) is the third most common cancer and the second leading cause of cancer-related death worldwide. Current diagnostic methods rely on invasive procedures and serum markers with limited sensitivity, highlighting the need for novel, minimally invasive biomarkers. Tumor-educated platelets (TEPs) have emerged as a promising source, as malignant cells reprogram platelets through molecular alterations. This study aimed to identify differentially expressed genes in TEPs from patients with CRC that could serve as potential diagnostic biomarkers. **Methods:** We downloaded gene expression data from platelets from the Gene Expression Omnibus (GEO; GSE183635), tissue gene expression data from TCGA-COAD and TCGA-READ, and vesicle data from Vesiclepedia. The data were preprocessed to remove low-quality reads, and high-quality reads were aligned to the human reference genome GRCh38.p13. We performed differential expression analysis through DESeq2 ($|\log2FoldChange| > 1$, adjusted p-value < 0.05). Gene ontology (GO) enrichment analysis (p-value < 0.05) was conducted, and shared genes between TEPs, tumor tissues, and vesicles were identified. ROC curves (AUC > 0.75) assessed diagnostic potential. **Results:** A total of 3,211 differentially expressed genes were identified in TEPs, with 55 upregulated and 3,156 downregulated. Six genes (*TLN1, IGF2, IFITM3, DKK1, MYL9, TNNC2*) were consistently upregulated in TEPs, tumor tissues, and observed in microvesicles. These genes exhibited AUC values ranging from 0.76 to 0.83, indicating high sensitivity for distinguishing CRC patients from healthy controls. **Conclusions:** Our study identified six DEGs in TEPs with elevated expression in CRC tissue, highlighting their potential as minimally invasive biomarkers for CRC diagnosis. These findings pave the way for developing more precise diagnostic tools to improve early detection and patient outcomes. Research Sponsor: Conselho Nacional de Desenvolvimento Científico e Tecnológico.

Potential biomarker genes in TEPs for CRC, ranked by Log2FC.

Gene	Log2FoldChange	P-adjusted	AUC
DKK1	2.011554	$1{,}50\times10^{-3}$	0.78
IGF2	1.5006689	$3{,}56\times10^{-9}$	0.81
IFITM3	1.102034	$3{,}01\times10^{-9}$	0.81
TLN1	1.098185	$1{,}24\times10^{-5}$	0.83
MYL9	1.060944	$1{,}91\times10^{-15}$	0.77
TNNC2	1.023068	$7{,}22\times10^{-8}$	0.76

AUC: Area Under the Curve.

Molecular landscape and therapeutic vulnerability of RRAS- and RRAS2-mutant solid tumors. First Author: Alexander James Pfeil, Memorial Sloan Kettering Cancer Center, New York, NY

Background: The RRAS subfamily of small GTPases shares considerable sequence homology with the canonical RAS oncoproteins KRAS, NRAS, and HRAS. Mutations in *RRAS* and *RRAS2* that are homologous to *KRAS* hotspot mutations promote transformation *in vitro*. Most diagnostic sequencing panels do not profile the RRAS subfamily, and therefore, the prevalence and clinical relevance of these mutations and their treatment have not been fully established. **Methods:** Based on a clinical targeted DNA sequencing assay (MSK-IMPACT), an institutional cohort of 51,040 solid tumor cases prospectively sequenced between 2016-2024 was analyzed to identify *RRAS*/*RRAS2* mutations. Lung cancers were excluded and analyzed in a separate study. Hotspot mutations in *RRAS*/*RRAS2* were determined based on homology to KRAS hotspot mutations and/or previous literature demonstrating potential oncogenicity (hotspot *RRAS*: G38, G39 and Q87; hotspot *RRAS2*: G23, G24, A70T, Q72 and in-frame insertions in G23/G24). The sensitivity of cells harboring *RRAS* and *RRAS2*-mutations to the clinically active pan-RAS inhibitor RMC6236 was examined *in vitro* and *in vivo*. Western blotting was utilized to determine changes in protein expression and activation. **Results:** Among the 51,040 cases analyzed, hotspot *RRAS* and *RRAS2* mutations were detected in 6 (0.01%) and 270 (0.5%) patients, respectively. Hotspot *RRAS* mutations were seen in various cancer types, and most had other mitogenic drivers (4/6). Amongst tumors with hotspot *RRAS2* mutations, the most common cancer types included endometrial (n = 172), ovarian (n = 27), and germ cell tumors (n = 26); these variants were seen in 5%, 0.9%, and 5% of these respective patient populations. Most endometrial, ovarian, and germ cell tumors lacked other *K/H/NRAS* mutations (83%, 89%, 85%, respectively). Other tumor types with hotspot *RRAS2* mutations included esophagogastric cancers (n = 9), cholangiocarcinomas (n = 5), and breast cancers (n = 5, 2 of which were triple negative). Treatment with RMC-6236 reduced ERK and P90 RSK phosphorylation in CAL-51 (human triple-negative breast cancer line) and A2780 cells (human ovarian carcinoma cell line), both harboring the $RRAS2^{Q72L}$ mutation. Treatment of mice bearing CAL-51 xenograft tumors with RMC-6236 (50 mg/kg, once daily) significantly reduced tumor growth. Growth of cells harboring *RRAS* and *RRAS2* mutations was also blocked by MEK1/2 and ERK1/2 inhibitors. **Conclusions:** Hotspot *RRAS2* mutations are rare but recurrently found in endometrial, ovarian, and germ cell tumors. These mutations are predominantly mutually exclusive with other canonical *RAS* mutations, although co-mutations with *RAS* do occur in a subset. $RRAS2^{Q72L}$-mutant cancer cells are sensitive to inhibition of the MAPK pathway including pan-RAS inhibition both *in vitro* and *in vivo*. These preliminary findings may inform future therapeutic strategies for patients with *RRAS2*-mutated solid tumors. Larotrectinib resistance in TRK fusion cancers: Analysis of a tumor-agnostic, global clinical trial dataset. First Author: Alexander E. Drilon, Memorial Sloan Kettering Cancer Center and Weill Cornell Medical College, New York, NY

Background: Larotrectinib (laro) is the first-in-class, highly selective, TRK inhibitor approved for tumor- and age-agnostic use in TRK fusion cancers. This is the seminal report of primary and secondary laro resistance based on an analysis of the regulatory dataset that supported drug approval across multiple countries. **Methods:** Genomic data from patients (pts) with non-primary CNS TRK fusion cancer enrolled in a global, prospective, multicenter database of three laro clinical trials including adult and pediatric pts were analyzed. Tumor DNA (Illumina TruSight Oncology [TSO] Comprehensive, TSO 500, or FoundationOne CDx) or circulating tumor DNA (Guardant360 or GuardantOMNI) NGS was performed pre-laro (baseline; BL) and post-laro initiation. On-target *NTRK* (solvent front [SF], gatekeeper [GK], xDFG) mutations and COSMIC-classified tier 1/2 off-target alterations were identified. Primary laro resistance analysis set included pts with no meaningful clinical benefit (PD/SD $<$ 4 months). Secondary (acquired) laro resistance analysis set included pts who developed resistance after meaningful clinical benefit (CR/PR/SD $\geq$4 months). Data cutoff: July 20, 2024. **Results:** Of 304 adult and pediatric pts enrolled, 216 had BL genomic data. Primary laro resistance was observed in 24 pts. Only 1 pt had an on-target mutation (*NTRK3* G623R), likely attributable to prior crizotinib; 9 pts (38%) had off-target alterations involving *AKT, BRAF, FGFR1, GNAS, KRAS, NRAS,* and *PIK3CA*. Secondary laro resistance was observed in 55 pts with valid post-BL ctDNA (the most common of these TRK fusion cancers were infantile fibrosarcoma [22%], other soft tissue sarcoma [18%], thyroid [11%], lung and salivary gland [9% each]); acquired alterations were identified in 16 of these pts. On-target resistance alone was observed in 5 of 16 pts (31%) and were mainly SF or GK single or double mutation-mediated (*NTRK1* F589L, *NTRK1* G595R, *NTRK3* G623R [n = 2], *NTRK3* G623R/G696A). One xDFG mutation was identified. Off-target resistance alone was observed in 7 of 16 pts (44%) and included hotspot *KRAS* G12D/A/S/V or G13D, *PIK3CA* E545K or E542A, *BRAF* V600E, and *GNAS* R844H/C mutations. Complex, combined on-target and off-target resistance was observed in 4 of 16 pts (25%): on-target SF or GK alterations (*NTRK1* G595R, *NTRK1* F589L/G595R, *NTRK3* G623R, *NTRK3* G623R/F617L) co-occurred with *KRAS* G12D or G12D/G13D, and *NRAS* G12D or Q61H. An analysis of resistance profiles by cancer type and age will be presented. **Conclusions:** In this analysis, on-target resistance to laro, including potential double *NTRK* resistance mutations, was commonly observed. Off-target, largely MAPK or PI3K/AKT pathway reactivating resistance, also occurred. In select cases, complex and likely polyclonal resistance including both on-target and off-target alterations were identified. These observations impact novel therapy development for TRK fusion cancers. Clinical trial information: NCT02637687, NCT02576431, NCT02122913. Non-invasive PD-L1 prediction in NSCLC patients using 3D self-supervised deep learning and radiomics. First Author: Xavier Rafael-Palou, Quantitative Imaging Biomarkers (Quibim), Valencia, Spain

Background: Non-small cell lung cancer (NSCLC) is the most common subtype of lung cancer for ~85% of all cases. Despite therapeutic advances, prognosis remains poor, especially in advanced stages. Immunotherapy has revolutionized NSCLC treatment, with immune checkpoint inhibitors (ICIs) targeting the programmed death-ligand 1 (PD-L1) pathway. While PD-L1 expression is typically measured via immunohistochemistry (IHC), predictive modeling using CT images could offer a non-invasive alternative to enhance patient stratification and treatment planning in hard-to-biopsy cases and tumor follow-up of clonal resistance. We propose a solution for non-invasive prediction of PD-L1 expression leveraging radiomics and AI. **Methods:** This multicentric retrospective study included NSCLC patients from five real-world data sources who underwent CT and biopsy. CT scans were quality-checked and annotated by imaging experts supervised by radiologists ($>$ 5 years' experience) to delineate primary tumors. PD-L1 levels were obtained via IHC. The cohort was randomly split into training and test sets (80/20%), with 5-fold cross validation for model building and fine-tuning. Three methods—radiomics, deep learning, and deep radiomics—were proposed for binary PD-L1 prediction (cut-off $>$ 1%) based on 3D lesion-centered patches. The radiomics pipeline included 3D feature extraction, standardization, dimensionality reduction and classifier selection. The deep learning approach used a self-supervised 3D network, pretrained on 2420 lung lesion patches from 751 CTs by minimizing dissimilarity between augmented pairs and then fine-tuned on the training set to predict PD-L1 expression. The deep radiomics method fused both methods via weighted averaging of predicted probabilities. **Results:** A total of 324 patients (41% women, 63 $\pm$ 10 years) with varying PD-L1 expression (63% with levels $>$ 1%), were included. The deep radiomics approach achieved the highest performance, with AUCs of 75.9% $\pm$ 5.3% and 70.1%, and F1-scores of 78.1% $\pm$ 1.2% and 76.7% on the validation and test sets, respectively, with a per-instance processing time of 1.2 $\pm$ 1.3 seconds. Compared to the radiomics method, it improved AUC by 2.6% and 1.2%, and F1-score by 2.7% and 3% on the validation and test sets, respectively. Compared to the deep learning approach, it showed AUC gains of 0.3% and 2%, and F1-score gains of 11.3% and 18.4% on the validation and test sets, respectively. **Conclusions:** This study demonstrates the effectiveness of a novel 3D image-based approach combining radiomics and 3D self-supervised learning to predict PD-L1 expression in a heterogeneous NSCLC cohort using real-world data. The model executes in seconds and could be regulatory cleared and deployed in clinical practice as a medical device performing non-invasive PD-L1 expression identification from CT scans. Development and implementation of molecular oncology test e-consult at the VA North Texas Health Care System (VANTHCS). First Author: Lucas Jiaxue Wang, UT Southwestern Medical Center, Dallas, TX

Background: The VA National Precision Oncology Program (NPOP), launched in 2016 as part of the White House's Cancer Moonshot Initiative, aimed to revolutionize cancer care through precision medicine for Veterans. Oncologists at the VANTXHCS utilized molecular testing to identify potentially actionable mutations to tailor treatment strategies more accurately. This study aims to evaluate the impact of the identification and impact of potentially actionable mutations with treatment decisions and overall survival. **Methods:** We conducted a retrospective chart review of Veterans with molecular oncology testing (MOT) at VANTXHCS from August 2019 to May 2024 to assess cancer type, prevalence of potentially actionable mutations, treatment decisions, targeted therapy utilization, and overall survival (OS). Potential actionable mutations were determined based on AMP/ASCO/CAP Variant Categorization mapped to the OncoKB FDA-Recognized Human Genetic Variant Database at the time of review. **Results:** 570 Veterans, almost exclusively male (N = 523, 92%) with solid tumors had MOT during the study period. Lung (N = 211, 37%), GI (N = 105, 21%), prostate (N = 49, 9%), pancreatobiliary (N = 46, 8%), head and neck cancers (N = 35, 6%) and GU (N = 30, 5%) were most common with a median overall survival (OS) of 15.93 months. Potential actionable mutations were present in 107 (18.7%) tumors, however only 41 (38%) of the mutations were associated with an FDA approved targeted therapy at the time of testing. Six Veterans (5.6%) received targeted therapy. Reasons for not receiving targeted therapy included secondary mutations (*i.e.*, KRAS), ECOG performance status, hospice or community care and death. Veterans with potentially actionable mutations had significantly worse. **Conclusions:** In the VANTXHCS Veteran population males with lung cancer represents the main tumor type with molecular oncology testing. We observe actionable mutations in nearly 20% of patients tested, with only a minor subset receiving targeted therapy. Our data showed that patients with a potentially actionable mutation have worse overall survival than those that do not. However, treatment with a targeted therapy can significantly improve survival. In conclusion, these findings underscore the need for further research to identify barriers to increase appropriate use of targeted therapies in a timely fashion to improve patient outcomes and advance precision oncology practices. Research Sponsor: None.

Phase 2 multicenter clinical trial to evaluate the safety and efficacy of abenacianine for injection (VGT-309), a tumor-targeted, intraoperative molecular imaging agent, for patients undergoing surgery for cancer in the lung. First Author: Sunil Singhal, University of Pennsylvania Perelman School of Medicine, Philadelphia, PA

Background: Molecular targeted agents have revolutionized cancer diagnosis and treatment. Intraoperative molecular imaging (IMI) is a novel technique that entails performing real-time, in vivo optical imaging during surgery to ensure cancer clearance. A multicenter clinical trial was conducted using abenacianine, a cathepsin targeted near-infrared (NIR) IMI agent to visualize pulmonary nodules during surgery. The primary objective was to assess the efficacy of abenacianine in localizing pulmonary lesions, evaluating surgical margin, and identifying unsuspected disease. **Methods:** Participants scheduled to undergo surgery for known or suspected cancer in the lung received abenacianine (0.32 mg/kg intravenous) preoperatively 12 to 36 hours before surgery. During a standard-of-care surgery, the lung underwent IMI and additional disease not identified by conventional methods were identified and analyzed. Efficacy was measured by frequency of clinically significant events (CSEs) defined as localization of lesions not found by standard surgical techniques, identification of additional cancers, identification of positive surgical margins confirmed by histology, and detection of cancerous lymph nodes. **Results:** 89 participants were included in the study. The mean age was 67 years and 57 (64%) were female. Of 89 participants administered abenacianine who underwent standard of care surgical resection for known or suspected cancer in the lung, 40 (45%) had at least one CSE. Abenacianine with NIR imaging identified lesions that were not found by standard surgical methods in 34 (38%) participants, synchronous and occult cancers that were not found by pre-operative imaging in 2 (2%), margins within 10 mm of the closest staple line in 8 (9%), and lymph nodes determined to be cancerous in 1 (1%) participant. Tumors visualized by IMI with abenacianine included non-small cell lung cancers (adenocarcinoma, squamous cell carcinoma, neuroendocrine tumor) and cancers that metastasized to the lung (breast, colorectal, prostate, thymoma, renal cell, sarcoma). Abenacianine was safe and well tolerated in this study; there were no drug-related serious adverse events. **Conclusions:** This Phase 2 multicenter study demonstrated that using IMI with abenacianine during standard-of-care lung cancer surgery markedly improved clinical outcomes. Abenacianine localized tumors intraoperatively, identified synchronous and occult lesions, helped assess negative margin status, and identified cancerous lymph nodes enabling a more complete oncologic resection. Clinical trial information: NCT06145048. Research Sponsor: Vergent Bioscience, Inc.; Vergent Bioscience Australia Pty Ltd.

Analysing the impact of size of NGS panel in defining first line therapeutic strategies in NSCLC. First Author: Kshitij Joshi, MOC Cancer Care & Research Centre, Mumbai, India

Background: NCCN recommends the analysis of 8 genes (EGFR, ALK, ROS1, BRAF, KRAS, MET, RET, ERBB2, and NTRK1/2/3) for NSCLC patients to identify efficacious target therapies. Concerned with the rising incidence of sub-optimal response to first-line therapy and rather early progression of disease we performed retrospective analysis in a subset of patients treated at our hospital in order to streamline molecular evaluation strategies. **Methods:** In this study, we retrospectively evaluated the impact of NGS panel sizes in therapy-naïve NSCLC patients. 242 therapy naïve patients evaluated for molecular genetic profiling were stratified into three groups based on gene panel size: a) Small panel ($<$20 genes): Focused on NCCN-recommended genes, b) Medium panel (50–100 genes): Included organ agnostic genes, c) Comprehensive panel ($>$100 genes): Included genomic signatures like TMB, MSI & HRD scores. **Results:** Of 242 therapy-naïve NSCLC patients, 60% (145/242) were evaluated using a small panel of which 13% (19/145) had no detectable genetic alterations while 37% (54/145) had 1st line targetable mutations, 31% (45/145) exhibited both targetable and resistance causing mutations, and 19% (28/145) showed only resistance causing mutations. In the 50–100 genes Panel, comprising 29% (70/242) of patients, 10% (7/70) had no genetic alterations, while 26% (18/70) had 1st line targetable mutations, 30% (21/70) demonstrated both targetable and resistance mutations, and 34% (24/70) harboured only resistance causing mutations. Finally, in the comprehensive NGS group ($>$100 genes), which accounted for 11% (25/242) of cases, only 4% (1/25) lacked detectable genetic alterations; while, 12% (3/25) had 1st line targetable mutations, 32% (8/25) exhibited both targetable and resistance causing mutations, and 52% (13/25) showed only resistance causing mutations. **Conclusions:** a. Increase in gene panel size results in reduction of true negatives. Hence smaller panels may not necessarily capture resistance causing mutations. b. As the gene panel size increases, the detection of actionable driver mutations (e.g., EGFR, ALK) remains consistent; however, there is a notable shift in the mutation profile, with a decrease in cases harbouring only targetable mutations and an increase in those exhibiting both actionable and resistance causing mutations. Hence opting for comprehensive NGS profiling at baseline may increase diagnostic costs marginally, but will have significant impact in designing more effective 1st line therapeutic strategies. Research Sponsor: None.

Evaluation of ^{68}Ga-FAPI PET/CT and ^{18}F-FDG PET/CT for the primary staging of non-small cell lung cancer (NSCLC). First Author: Daniel Udayan C, P K Das Institute of Medical Science, Palakkad, India

Background: Fibroblast activation protein inhibitor (FAPI) radiolabeled with Gallium-68 or Fluorine-18 have emerged as promising tracers for targeting cancer-associated fibroblasts (CAFs) within the tumor microenvironment. Previous studies in lung cancer demonstrated that FAPI PET/CT is more sensitive in detecting metastases in the brain, lymph nodes, pleura, and bone. This study aimed to evaluate the clinical utility of FAPI PET/CT compared to FDG PET/CT for the primary staging of newly diagnosed NSCLC patients. **Methods:** This prospective study was done at Amrita Institute of Medical Sciences, Kochi between August 2022 to December 2023 among patients with newly diagnosed NSCLC who consented to undergo both scanning i.e. FDG as well as FAPI PET CT before initiating any treatment. This study was approved by institutional review board. Kolmogorov Smirnov one sample test was used to check the normality of data. To test the statistical significance of the difference in the average values of tumor volume, standardized uptake value (SUV), target to background ratio (TBR) and background uptake between FAPI and FDG, paired sample t test was used for normality and Wilcoxon signed rank test was used for non-normality. **Results:** In this study, 42 patients with newly diagnosed NSCLC (32 with adenocarcinoma (AC) and 10 with squamous cell carcinoma (SCC)) were included. Comparison of the results between FAPI and FDG PET in parameters like TBR, SUVmax and background value in metastatic lesions, FAPI performed better. In case of lymph nodes FAPI vs FDG, mean TBR was (5.06 $\pm$ 4.19 v/s 3.02 $\pm$ 2.89) p value=0.002 and in SUVmax value was (9.07 $\pm$ 5.1 v/s 6.59 $\pm$ 4.2) p value=0.01. Similar benefits were seen in TBR and SUVmax with FAPI on metastatic site like pleura and bone. In the primary lung lesion, mean tumour volume (MTV) was larger with FAPI but there was no difference in SUVmax, TBR and back ground uptake value. If we compare AC vs SCC cases, there was no advantage for SCC with FAPI in metastatic lesions as well as primary lesions. Driver mutated AC cases performed extremely well with FAPI. In brain, mean SUV max with FAPI was 4.52 $\pm$ 0.89 compared to 8.45 $\pm$ 3.31 with FDG. But the brain lesions identified with FAPI were higher than FDG due to higher TBR. In liver, SUV max was similar between FAPI and FDG but higher TBR was seen with FAPI. **Conclusions:** ^{68}Ga-FAPI PET/CT performed better than ^{18}F-FDG PET/CT in the primary staging of NSCLC. FAPI PET may be considered instead of FDG PET in staging of NSCLC. Patient compliance was also better because fasting and glycemic control was not required prior to FAPI. This is the only study where histology (AC and SCC) has been directly compared with both FAPI/PET vs FDG/PET – it shows FAPI/PET performs better with AC, and this South East Asian study showed FAPI/PET performs better with driver mutated NSCLC. Research Sponsor: None.

Clinical utility of comprehensive transcriptome testing in advanced solid tumors. First Author: Fei Su, University of Texas MD Anderson Cancer Center, Houston, TX

Background: Despite breakthroughs in genomically-matched therapies, many patients lack actionable genomic alterations. Consequently, innovative new strategies to identify targets for effective therapies are imperative. To assess the potential of comprehensive whole transcriptomic sequencing (WTS) in clinical decision-making, we conducted a prospective trial to perform WTS in patients with metastatic or advanced solid tumors who had prior DNA-based panel testing ($\geq$100 genes) with no reported AMP/ASCO/CAP Tier 1 actionable genomic alterations; along with whole exome sequencing (WES) to compare RNA expression to copy number alterations. We also developed an informed actionability classification scheme to determine actionability of transcriptomics findings. **Methods:** Between August 2022 and December 2024, 100 patients at MD Anderson Cancer Center with advanced cancers were enrolled and underwent comprehensive profiling. Alterations in RNA expression of 147 genes were considered as potentially actionable if the gene's protein product is the direct target of a clinically available therapy (including cell surface targets of antibody-drug conjugates (ADCs)) and/or CNAs of the gene are predictive of response or resistance to a clinically available therapy. A clinical trial was considered a match if RNA expression was an enrollment criterion, or the gene alteration can be directly or indirectly targeted with a therapy utilized within the trial. **Results:** Actionable RNA expressions (AREs) were detected in all patients (100%). In total, 2,216 AREs were detected from 17,800 selected-reported RNA expressions; a median of 22 ARE changes were reported per patient [interquartile range (IQR), 17.0-26.0]. The majority (86.0%) of AREs were RNA overexpressions, defined as the distribution of *tpm* values of the gene expression $>$ 83% of the pan-cancer reference cohort. A median of 13 RNA expression-matched trials were identified per patient [IQR, 10.0-16.0]. The most frequent drug class of actionable RNA overexpressions were ADCs, with a median of 10 ADC targets per patient. Out of 11 distinct genes of which at least 1 amplification is reported, a concordance rate of 61.5% and a Concordance Correlation Coefficient (CCC) value of 0.70 (95% CI, 0.56-0.84) between the actionable gene amplifications (n = 13) and the actionable RNA overexpressions detected in the same patient sample from the tumor profile, indicates a substantial concordance by transcriptional profiling with copy number gain. **Conclusions:** WTS identified actionable RNA expressions in all patients– including for novel ADC targets. These results underscore the utility of comprehensive transcriptional profiling to identify additional actionable targets beyond DNA-based comprehensive profiling. Clinical trial information: MDACC 2021-1049. Research Sponsor: Strategic Alliance: BostonGene—MD Anderson Cancer Center Feasibility and Clinical Utility of Combined Genomics/ Transcriptomics with Systems Biology for Personalized Cancer Therapy; MD Anderson Cancer Center Support grant; Center for Clinical and Translational Science.

Application of an epigenomic-based classifier to identify cancer signal of origin on liquid biopsy in cancer of unknown primary cases. First Author: Elmira Forouzmand, Guardant Health, San Diego, CA

Background: Cancer of unknown primary (CUP) lacking resolution to a cancer type (Cancer Signal Origin; CSO) leads to suboptimal outcomes. While several approaches currently exist for identifying a cancer type for CUP samples, they rely on clinical approaches that often require tissue biopsies for immunohistochemistry (IHC), and even still they often fail to resolve a CSO (reported to occur in 50-80% clinical cases). This requirement for tissue, and typically lengthy diagnostic journey, create a large unmet need for CSO identification in CUP individuals. Here, we present feasibility data from a high accuracy Liquid Biopsy method for CSO identification in CUP, bypassing the need for a tissue biopsy and quickly returning a CSO to individuals with CUP. **Methods:** We developed a CSO prediction algorithm on Guardant360 utilizing DNA methylation signatures across thousands of cancer-specific differentially methylated regions for 14 cancer types. We applied the CSO classifier to 1,128 CUP samples in which circulating tumor DNA was detected. Accuracy was assessed by comparing CSO predictions to suspected diagnoses based on clinicopathologic and molecular findings. **Results:** The CSO prediction algorithm was evaluated on 1,128 CUP samples; lung (285/1128, 25.3%) and bile duct (166/1128, 14.7%) were the most common predicted CSOs, aligning with reported prevalence in the literature. Of the 1,128 samples, 12 had a suspected clinical diagnosis. These 12 spanned 8 tumor types. The top CSO prediction aligned with suspected diagnosis in 91.6% (11/12) of cases. The CSO algorithm also provides confidence scores to quantify the confidence of CSO prediction. Out of the total 12 cases, 7 CSOs had high confidence, 3 had moderate confidence, and 2 had low confidence. 7/7 high, 2/3 moderate, and 2/2 low confidence predictions were correct. The single incorrect moderate sample was diagnosed as CRC but predicted to be lung. **Conclusions:** These findings show the feasibility of using plasma-based epigenomic profiling to assign CSO with acceptable accuracy. While interventional clinical studies are necessary to demonstrate clinical utility, this has significant potential for guiding treatment decisions and improving outcomes in CUP patients without ready access to tissue. Research Sponsor: Guardant Health, Inc.

HRD status prediction in patients with advanced breast, prostate, ovarian and pancreatic cancers in a liquid biopsy assay. First Author: Pegah Safabakhsh, Guardant Health, Palo Alto, CA

Background: Homologous recombination and repair (HRR) deficiency (HRD) is characterized by genomic instability associated with mutations in BRCA1/2 or other HRR genes. HRD can also be detected by copy number variant (CNV) features, indels, and SNVs (HRD signature). Patients with canonical BRCA-associated cancers harboring an HRD signature with or without HRR mutations derive clinical benefit from PARPi therapy. Here, we present a method of predicting HRD status using Guardant Infinity in patients with these advanced cancers. **Methods:** We developed an ensemble logistic regression model to predict HRD status, inferred from genome-wide somatic SNV and CNV signatures indicative of deficiency in HRR genes, including ploidy-adjusted large-scale state transitions (LST), whole-genome tumor loss of heterozygosity (LOH) and telomeric allelic imbalance (TAI). The model was trained on clinical samples processed on Guardant Infinity, a next-generation platform evaluating both genomics and epigenomics, to assess the sensitivity and accuracy of detecting biallelic loss-of-function in BRCA1/2. The aggregated model was tested on an independent pan-tumor clinical cohort and pre-treatment samples from a subset of patients enrolled in TRITON2, a phase 2 single arm study evaluating rucaparib in metastatic castration resistant prostate cancer (mCRPC) patients with HRR mutations. HRD status association with radiographic progression free survival (rPFS) was evaluated with Cox-proportional hazards model. **Results:** Our model demonstrated high sensitivity in patients with BRCA1/2 biallelic loss and high specificity in HRR-wildtype patients, with an AUC of 0.95 in a pan-tumor cohort with tumor fraction (TF) >10%. In an independent cohort of breast prostate ovarian and pancreatic samples, HRD detection ranged from 79-100% in samples with BRCA1/2 biallelic loss and >10% TF. In breast (n = 703) and prostate (n = 655) cancers, HRD was detected in 14.9% and 13.5% of samples with > 10% TF (3.6% and 3.7% in all TF), with 5.5% and 6.2% attributed to samples not harboring deleterious mutations in HRR genes, respectively, potentially reflecting non-genomic drivers of HRD. In a pilot cohort (n = 15) from TRITON2, HRD was detected in 100% of patients enrolled with either BRCA1/2, or PALB2 mutations (n = 10), where rucaparib demonstrated meaningful activity as measured by independent radiology review objective response rate. HRD was not detected in patients with mutations in CDK12, FANCA, or NBN (n= 5). HRD detected status was associated with prolonged rPFS (HR = 0.07, p = 0.03). **Conclusions:** Guardant Infinity can predict HRD status in patients with advanced canonical BRCA-associated cancers, with preliminary results indicating potential for predicting PARPi benefit in mCRPC. Further studies are warranted to determine PARPi response for breast, prostate, ovarian, and pancreatic cancers with detected HRD status. Research Sponsor: None.

Efficacy and safety of distinct regimens for individuals with advanced EGFR-mutated non-small-cell lung cancer who progressed on EGFR tyrosine-kinase inhibitors: A systematic review and network meta-analysis. First Author: Zhang Wengang, Shanghai Pulmonary Hospital, Shanghai, China

Background: Targeted therapy with EGFR tyrosine-kinase inhibitors (TKIs) is the preferred first-line treatment for EGFR-mutated advanced non-small cell lung cancer (NSCLC), but acquired resistance inevitably occurs in almost all responding individuals. We aimed to comprehensively review the literature to investigate the efficacy and safety of distinct regimens in the subsequent-line setting, thereby identifying the optimal regimen for these TKI-resistant NSCLC patients. **Methods:** The PubMed, Embase, Cochrane Library databases, and abstracts of ASCO, ESMO, and WCLC were searched from database inception to 3 November 2024, to identify eligible randomized controlled trials (RCTs) that assessed distinct regimens for individuals with advanced EGFR-mutated NSCLC who progressed on TKIs. The outcomes of progression-free survival (PFS), overall survival (OS), objective response rate (ORR), disease control rate (DCR), and grade 3 or higher adverse events (≥3AEs) were compared and ranked in overall patients and various subgroups among 8 regimens by network meta-analysis and the surface under the cumulative ranking curve, respectively. The protocol is registered with PROSPERO, CRD42024601619. **Results:** 14 RCTs, involving 3177 participants and 8 treatment regimens (chemotherapy plus ivonescimab (PD-1/VEGF inhibitor) [CT+IVO]; CT+amivantamab+lazertinib [CT+AMI+LAZ], CT+immunotherapy+bevacizumab [CT+IO+BEV], CT+AMI, CT+BEV, CT+IO, CT, and IO), were included. In overall patients, the most pronounced PFS benefit was observed with the CT+IVO, followed by CT+AMI+LAZ, CT+IO+BEV, and CT+AMI, ranked second, third, and fourth, respectively. In terms of OS, the regimen of CT+AMI ranked the best, followed by CT+IVO. However, the comparisons of OS among different regimens did not reach statistical significance, possibly due to immature data. The results for ORR and DCR were similar to those for OS, with CT+AMI topping the rankings, followed by CT+AMI+LAZ. In terms of safety, the incidence of ≥3AEs was highest in CT+AMI+LAZ, followed by CT+AMI. In subgroup analysis, CT+IVO demonstrates stable PFS benefits across clinicopathological characteristics, ranking first in most subgroups. Due to the unavailability of OS subgroup data in most RCTs, many regimens were missing in the OS subgroup analysis. **Conclusions:** Integrating the results of different clinical outcomes and subgroup analyses, we conclude that CT+IVO is the optimal treatment option with an acceptable safety profile for patients with advanced EGFR-mutated NSCLC who have progressed on TKIs. CT+AMI+LAZ and CT+AMI are alternative subsequent line options as well, with superior efficacy compared to immunotherapy-based or chemotherapy regimens, yet elevated toxicity profiles requiring vigilant management. Research Sponsor: None.

Preliminary results of a first-in-human phase 1b (aCCeleR8-001) study of S-531011, a humanized anti-CCR8 monoclonal antibody, in patients with advanced solid tumors. First Author: Toshihiko Doi, National Cancer Center Hospital East, Chiba, Japan

Background: C-C motif chemokine receptor 8 (CCR8) is selectively upregulated in tumor-infiltrating regulatory T cells (TI-Tregs) in multiple cancers, inhibiting anti-tumor activity of the host immune system. S-531011, a humanized IgG1 monoclonal antibody, is anticipated to deplete CCR8-positive TI-Tregs, restoring anti-tumor immunity without inducing autoimmunity. **Methods:** An aCCeleR8-001 study is a Phase 1b/2, multicenter, open-label study of S-531011 which consists of Phase 1b Dose Escalation part (Parts A-1 and A-2) and Phase 2 Dose Expansion part. The safety/tolerability, pharmacokinetic (PK), pharmacodynamic, and anti-tumor activity of S-531011 as monotherapy and in combination with pembrolizumab (Merck & Co., Inc.) were evaluated in patients with various types of locally advanced or metastatic solid tumors. S-531011 monotherapy was administered at 8, 24, 80, 240, 800, or 1600 mg/kg intravenously every 3 weeks (Q3W) in Part A-1, whereas patients in Part A-2 received S-531011 at 80, 240, 800, or 1600 mg/kg in combination with pembrolizumab 200 mg/kg Q3W. The data were analyzed when all patients in Dose Escalation cohorts completed the dose-limiting toxicity (DLT) observation period. **Results:** As of the data cutoff date (30 Sep 2024), 40 and 35 patients were enrolled in Parts A-1 and A-2, respectively. No DLTs were reported at any dose level and the maximum administered dose of S-531011 was 1600 mg in both parts. One patient reported an infusion-related reaction in Part A. Immune-related adverse events (irAEs) were reported in two patients (5.0%; Grade 1/2 only) in Part A-1, whereas 15 irAEs were reported in 10 patients (28.6%; including four Grade 3 irAEs in four patients) in Part A-2. PK of S-531011 was approximately dose proportional with a terminal elimination half-life of 10 to 12 days regardless of dose level. CCR8 receptors in PBMCs were occupied at doses of 80 mg or higher. PK/CCR8 receptor occupancy modeling analysis indicated that > 90% of receptors in tumor tissues were occupied in the range of 80 to 800 mg. Multiplex immunohistochemistry analysis demonstrated proof of mechanism as evidenced by CCR8-positive Treg depletion in tumor tissue at doses of 24 mg or higher. Among 62 evaluable patients dosed at 80 to 1600 mg in Part A, four patients (6.5%) had confirmed partial response, three of whom had colorectal cancer (CRC). Twenty patients (32.3%) had disease control for ≥ 6 weeks. Response rate was not correlated with dose (80 to 1600 mg). Following a comprehensive data review, tentative recommended Phase 2 doses were determined to be 80 to 800 mg in both parts. **Conclusions:** S-531011 was well tolerated up to 1600 mg as monotherapy and in combination with pembrolizumab. A higher response rate in patients with CRC warrants further exploration of this tumor type in Phase 2 Dose Expansion part. Phase 2 CRC cohorts are currently ongoing. Clinical trial information: NCT05101070. Research Sponsor: Shionogi & Co., Ltd.

First report of ROR2 directed therapy with a conditionally active antibody drug conjugate in advanced melanoma. First Author: Jacob Keeling, Sarah Cannon Research Institute at HealthONE, Denver, CO

Background: The receptor tyrosine-kinase like orphan receptors (ROR) are mediators of non-canonical WNT signaling and tissue patterning. ROR2 upregulation is observed in malignancy and has been implicated in metastasis. Development of ROR2 directed conditionally active antibodies with enhanced affinity in the tumor microenvironment is a promising treatment strategy. Here we report our institution's experience treating 5 patients with advanced cutaneous or uveal melanoma treated with the anti-ROR2 antibody drug conjugate ozuriftamab vedotin (MMAE) on the first in human phase 1 trial. (NCT03504488). **Methods:** Adults with advanced solid tumors naïve to vinca binding site therapies who had failed all standard of care therapy were eligible. The charts of all 5 patients with advanced melanoma treated at our institution were reviewed. Patients were treated with ozuriftamab vedotin at concentrations of 1.8 mg/kg or 3.0 mg/kg IV Q2W. Safety and efficacy data were collected. Patient samples were evaluated for pharmacokinetics and clinical correlates. **Results:** 4 out of the 5 patients achieved an objective response in target lesions, per RECIST v1.1 (Table 1). Two of these patients have maintained disease control, including one patient in complete remission (CR) >5 years and the other responding >1 year after starting treatment. Adverse events requiring dose reduction or interruption included neuropathy and neutropenia, both of which recovered with reduced dosing and/or colony stimulating factor. No patients discontinued therapy for adverse drug reactions. Pharmacokinetics showed predictable plasma concentrations of both drug and free MMAE. Anti-drug antibodies were not identified. Biopsies were assessed by IHC for ROR2. The biopsy belonging to the patient who achieved CR was strongly positive for ROR2. All other biopsies showed low/negative ROR2 staining of malignant cells. **Conclusions:** Ozuriftamab vedotin showed early promising antitumor activity in this first report describing ROR2 directed treatment in refractory advanced cutaneous and uveal melanoma. Clinical trial information: NCT03504488. Research Sponsor: None.

Efficacy and safety of ozuriftamab vedotin.

Glutaminase isoform expression in cancer: Implications for metabolic adaptation and therapy. First Author: Mohammed Osama Ahamd Bader, University of Khartoum Faculty of Medicine, Khartoum, Sudan

Background: Glutamine is a critical amino acid involved in various metabolic pathways, particularly in cancers where its importation is significantly elevated via multiple transporters. Glutaminase, the enzyme catalyzing the deamination of glutamine to glutamate, has two isoforms: kidney-glutaminase 1 (GLS1) and liver-glutaminase 2 (GLS2). This study investigates the expression of glutaminase isoforms in cancers originating from tissues with high glutaminase activity—namely, clear renal cell carcinoma (KIRC), chromophobe renal carcinoma (KICH), papillary renal carcinoma (KIRP), hepatocellular carcinoma (LIHC), and glioblastoma (GBM)—to understand the fate of the imported glutamine. **Methods:** The Cancer Genome Atlas (TCGA), Tumor Immune Estimation Resource ([TIMER] 2.0), Gene Expression Profiling Interactive Analysis ([GEPIA] 2.0), and the University of Alabama at Birmingham Cancer Data Analysis ([UALCAN]) Portal were used to investigate GLS1 and GLS2 expression. TIMER 2.0 analyzed 533 KIRC (72 normal), 66 KICH (25 normal), 290 KIRP (32 normal), 153 GBM (5 normal), and 371 LIHC (50 normal) samples. GEPIA 2.0 analyzed 523 KIRC (100 normal), 66 KICH (53 normal), 286 KIRP (60 normal), 163 GBM (207 normal), and 369 LIHC (160 normal). UALCAN analyzed 533 KIRC (72 normal), 66 KICH (25 normal), 290 KIRP (32 normal), 153 GBM (5 normal), and 371 LIHC (50 normal) samples. Additionally, datasets from NCBI GEO were used, including GSE15641 (23 normal, 32 KIRC, 6 KICH, and 12 KIRP), GSE7696 (4 normal, 40 GBM), and GSE41804 (20 normal, 20 LIHC). These platforms detected GLS1 expression in KIRC, KICH, KIRP, and GBM and GLS2 in LIHC by comparing tumor and normal samples. **Results:** GLS1 was significantly downregulated in KIRC, KICH, KIRP, and GBM across TIMER 2.0, GEPIA 2.0, and UALCAN ($P < 0.05$). GLS2 was also significantly downregulated in LIHC ($P < 0.05$). NCBI GEO datasets (GSE15641 for kidney cancers, GSE7696 for GBM, and GSE41804 for LIHC) supported these results, showing consistent GLS1 downregulation in KIRC, KICH, KIRP, and GBM, and GLS2 downregulation in LIHC (adjusted $P < 0.05$; $|Log2FC| > 1$). **Conclusions:** The tissue-specific downregulation of glutaminase isoforms—GLS1 in kidney and brain cancers, GLS2 in liver cancer—highlights an adaptive mechanism in cancer cells to limit glutamine deamination and preserve imported glutamine for other metabolic needs. Enhancing the deamination process could deprive cancer cells of essential precursors for nucleotide synthesis, disrupting their growth and survival. These isoforms represent potential diagnostic markers and therapeutic targets. Research Sponsor: None.

A phase 1 study of PARP inhibitor (niraparib) plus HSP90 inhibitor (pimitespib) in solid tumors: Dose-expansion results from the NiraPim (EPOC2102) study. First Author: Yasuyuki Kawamoto, Cancer Center, Hokkaido University Hospital, Sapporo, Japan

Background: Heat shock protein 90 (HSP90) inhibitors have shown potential in destabilizing homologous recombination repair (HRR) proteins, thereby inducing homologous recombination deficiency and enhancing PARP inhibitor efficacy. The NiraPim (EPOC2102) study is a phase 1 study to evaluate this combination therapy in humans, investigating the safety and efficacy of combining niraparib, a PARP inhibitor, with pimitespib, a novel HSP90 inhibitor, in patients with advanced solid tumors. Following establishing the recommended dose (RD) in the dose-escalation part, we present primary analysis results from the dose-expansion part. **Methods:** In the dose-expansion part, patients received pimitespib 80 mg (5-day on/2-day off) combined with niraparib 200 mg daily. Cohort A included patients with BRCA-associated cancers (breast, ovarian, prostate, and pancreatic) harboring *BRCA* pathogenic variants and immediately after progression to prior PARP inhibitors. Cohort B included patients with breast/pancreatic cancer without g*BRCA,* prostate cancer without t*BRCA*, and other solid tumors (excluding ovarian cancer) not previously treated with PARP inhibitors. **Results:** As of August 2024, 30 patients were enrolled: 14 in cohort A and 16 in cohort B. Cohort A included breast (n=6), ovarian (n=5), prostate (n=2), and pancreatic (n=1) cancers. Cohort B included breast (n=3), prostate (n=4), pancreatic (n=4), and other tumors (n=5). The median follow-up period was 6.0 months. The median treatment cycle was 2 (range 1–18). Treatment-related adverse events ≥Grade 3 occurred in 33.3%. Common adverse events (≥20.0%) included nausea (73.3%), diarrhea (40.0%), anorexia (23.3%), vomiting (20.0%), fatigue (20.0%), and decreased platelet count (20.0%). No treatment-related deaths occurred during the study period. The objective response rate was 10.0% (95% CI: 2.1, 26.5), with disease control rate of 36.7% (19.9, 56.1) and 3-month PFS of 27.7%. In cohort A, one patient with hormone receptor-positive breast cancer achieved partial response post-olaparib progression. In cohort B, two patients (leiomyosarcoma and urothelial carcinoma) with *BRCA* pathogenic variants achieved partial response, and one prostate cancer patient with *CDK12* pathogenic variant maintained stable disease ≥3 months. **Conclusions:** The dose-expansion part demonstrated a manageable safety profile and potential efficacy at the recommended dose of niraparib plus pimitespib. Clinical benefit was observed in both BRCA-associated cancers resistant to PARP inhibitors and PARP inhibitor-naive non-BRCA associated cancers, supporting further investigation in biomarker-selected populations. Clinical trial information: jRCT2031220179. Research Sponsor: Takeda Pharmaceutical Co., Ltd.; Taiho Pharmaceutical Co., Ltd.

Development and validation of an AI-enabled prediction of prostate cancer (PCa) using urine-based liquid biopsy. First Author: Marvin S. Hausman, Genetics Institute of America, Delray Beach, FL

Background: Prostate cancer (PCa) remains a major cause of malignancy-related mortality among men. Current diagnostic techniques, including PSA testing, lack accurate early detection capabilities, while global barriers include limited access to specialized facilities and cultural sensitivities around transrectal biopsy and digital rectal examination. This study evaluates a non-invasive, urine-based liquid biopsy assay for diagnosing PCa through disease-specific biochemical profiles using an artificial intelligence pipeline. **Methods:** We collected urine from men scheduled for prostate biopsy (biopsy-positive PCa n=197) and healthy controls (n=84). Samples were processed using NUTEC slides, underwent heat cycling, and were converted to digital images for AI analysis. Using 5x2 cross-validation with a random forest classifier, we evaluated cancer detection performance and analyzed cohorts with specific Gleason scores (Gle): Gle 6 (n=70), Gle 7 (3+4) (n=55), Gle 7 (4+3) (n=34), and Gle 8,9,10 (n=38). **Results:** Our classifier demonstrated strong overall performance in distinguishing cancer versus non-cancer subjects (F1=0.843) with notably high recall (R=0.967). Importantly, performance remained robust across Gleason score cohorts (F1=0.799-0.838), maintaining high recall (R>0.89) while preserving clinically relevant precision. The classifier showed particular strength in detecting intermediate- (Gle 7 (3+4): F1=0.838) and low- (Gle 6: F1=0.822) Gleason grade cancers. **Conclusions:** AI-enabled prediction of PCa using urine-based liquid biopsy demonstrates accurate, rapid, and accessible early cancer detection, with consistent performance across disease grades. This non-invasive approach addresses both clinical and cultural barriers to prostate cancer diagnostics. Research Sponsor: None.

TASK	F1	P	R	AUC	ACC
Cancer v. Controls	0.843	0.748	0.967	0.768	0.748
Gle6 v. Controls	0.822	0.770	0.893	0.776	0.746
Gle347 v. Controls	0.838	0.757	0.940	0.752	0.754
Gle437 v. Controls	0.800	0.715	0.913	0.695	0.691
Gle8910 v. Controls	0.799	0.722	0.900	0.695	0.698

AI-enabled prediction of PCa using urine-based liquid biopsy demonstrates accurate, rapid, and accessible early cancer detection, with consistent performance across disease grades. This non-invasive approach addresses both clinical and cultural barriers to prostate cancer screening.

3081 Poster Session

Genomic landscape of 5'methylthioadenosine phosphorylase (*MTAP*) deleted (*MTAP* loss) non-squamous carcinoma of unknown primary site (nsCUP). First Author: Parth J. Sampat, SUNY Upstate Medical University, Syracuse, NY

Background: *MTAP*, a key enzyme in the polyamine pathway breaks down 5'Deoxy-5-Methylthioadenosine (*MTA*) into methionine and adenine. *MTAP* loss reduces adenine and accumulates MTA, which inhibits protein arginine methyltransferase 5 (*PRMT5*). This suggests *MTAP* loss cancers may respond to *PRMT5* inhibition. Methionine adenosyl transferase 2α (*MAT-2A*) is a primary producer of donor S-adenosylmethionine (*SAM*) and the depletion of *MAT-2A* has antiproliferative effect in cancers with *MTAP* loss. Based on the synthetic lethality concept, *MTAP* loss is being used as a biomarker for accrual in multiple trials with *PRMT5* and *MAT-2A* inhibitors. We queried the genomic landscape of *MTAP* loss in patients with nsCUP. **Methods:** DNA extracted from formalin-fixed paraffin-embedded (FFPE) tissue of 7,440 nsCUP cases from 2020 to 2024 underwent hybrid capture-based comprehensive genomic profiling (CGP) to assess all classes of genomic alterations (GA). All cases underwent central pathology review to confirm that at the time of sequencing, a primary site for the cases was not established. Microsatellite instability (MSI) status and tumor mutational burden (TMB) were derived from the CGP data. Programmed death-ligand 1 (PD-L1) was determined by immunohistochemistry (IHC) using the DAKO 22C3 system. **Results:** 853 (11.5%) of nsCUP cases had either complete or partial *MTAP* loss with 0.7% 1 exon, 1.2% 2 exons, 2.9% 3 exons, 5.1% 4 exons, 0.5% 5 exons, 2.5% 6 exons, 32.8% 7 exons and 54.3% 8 exons lost. The median age of the *MTAP* loss patients was higher (68 vs 65; p<.0001) and the gender distributions were similar (52% to 54% female; not significant (NS)). Cyclin-dependent kinase inhibitor 2A (CDKN2A) loss co-occurred in 99.8% in patients with *MTAP* loss. MSI-high status was uncommon in both *MTAP* loss vs *MTAP* wildtype (0.4% vs 0.7%; NS). The *MTAP* wildtype group had higher tumor mutational burden (TMB) > 10 mutations/mb (15.7% vs 11.1%; p=.0004) and TMB >20 mutations/Mb (5.4% vs 3.5%; p=.017) rates. *MTAP* loss nsCUPs had higher frequencies of *KRAS* GA and *KRAS* G12C, whereas *MTAP* wildtype cases had greater frequencies of *ERBB2*, *PTEN*, *MET* and *EGFR* GA (Table). GA in *BRCA1/2* and *FGFR2* were similar in both groups. GA in *ALK*, *RET*, *ROS1*, *RET* and *TRK* were extremely uncommon in both groups (all less than 1%). **Conclusions:** At 11.5%, nsCUP features a relatively high frequency of *MTAP* loss, with the vast majority involving either all (8 of 8) or nearly all (7 of 8) exons. *MTAP* loss patients are slightly older and have reduced TMB levels which may impact their responsiveness to immunotherapy-based combination regimens with *PRMT5/MAT-2A* inhibitors. Clinical trials for the development of targeted therapies to use *PRMT5* inhibition and *MAT-2A* in nsCUP are warranted. Research Sponsor: None.

Preliminary efficacy results from an ongoing phase I/II trial of CTS2190, a PRMT1 inhibitor, in patients with advanced/metastatic solid tumors. First Author: Jianan Jin, Oncology Department/Phase I Clinical Center, Zhejiang Cancer Hospital, Hangzhou, Zhejiang, China

Background: Epigenetic gene regulation, including arginine methylation holds significant promise in immunomodulation and long survival outcomes. It represents a potential clinical approach to address the highly unmet needs of patients (pts) with advanced solid tumors who failed PD-(L)1 immune checkpoint inhibitors (ICIs) or standard of cares (SoCs) therapies. CTS2190, the orally available, first-in-class small molecule, specifically inhibits arginine methyltransferase 1 (PRMT1) with significant reduction of intra-tumor asymmetric dimethylarginine (ADMA) level, DNA damage response (DDR), androgen receptor (AR) level, and oncogenic proliferation through epigenetic modulation in various solid tumors. Here we present clinical data from an ongoing Phase I/II study of CTS2190 (NCT06224387). **Methods:** Eligible pts in the dose-escalation stage received 60~300 mg of CTS2190 orally, while pts in the dose-expansion stage were treated with 180 or 240 mg until disease progression or intolerable toxicity. Efficacy, safety, PK, PD and biomarker profiles were evaluated. **Results:** As of January 24, 2025, 38 pts had received CTS2190 treatment, 32 of them were response-evaluable. In the PD-(L)1 primarily resistant group, the objective response rate (ORR) and disease control rate (DCR) were 18.2% (2/11) and 72.7% (8/11), respectively. In addition, in PD-(L)1 primarily resistant non-small cell lung cancer (NSCLC) subgroup, the ORR and DCR were 28.6% (2/7) and 71.4% (5/7), respectively, with significantly prolonged median progression-free survival (PFS) (summarized in the table below). Among 2 response-evaluable pts with metastatic castration-resistant prostate cancer (mCRPC), one achieved partial response (PR) while the other exhibited stable disease (SD) with tumor shrinkage. Most treatment-related adverse events (TRAEs) were grade 1/2 and manageable. The only TRAE ≥ grade 3 with an incident rate > 15% was platelet count decreased (31.6%). No TRAEs led to treatment discontinuation or death. CTS2190 exposure increased proportionally with escalating doses, and a PK-PD-efficacy model demonstrated a relationship between CTS2190 exposure, efficacy and PD marker changes. The correlation between clinical efficacy and intratumor PRMT1 expression, as detected by immunohistochemistry (IHC), is under investigation. **Conclusions:** CTS2190 demonstrated a favorable safety profile and promising efficacy in heavily pretreated pts with advanced solid tumors, particularly in immunologically cold mCRPC and PD-(L)1 primarily resistant NSCLC. These results position CTS2190 as a promising therapeutic option to fulfil unmet medical needs following ICIs therapies. Clinical trial information: NCT06224387. Research Sponsor: CytosinLab Therapeutics Co., Ltd.

PFS of pts with PD-(L)1 primary resistance.

	Patients, n	≥ 3 prior lines of therapy, n (%)	Event	Median PFS (weeks)
All comers	11	7 (63.6%)	7	12.7 (95% CI: 8.0~35.3)
NSCLC	7	4 (57.1%)	5	24.9 (95% CI: 8.0~35.3)

3083 Poster Session

The first-in-human phase 1/2 study of TSN1611, a highly selective KRAS G12D inhibitor, in patients with advanced solid tumors. First Author: Siqing Fu, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: TSN1611 is a novel small molecule KRAS G12D inhibitor targeting both active (GTP-bound) and inactive (GDP-bound) forms of KRAS G12D protein. TSN1611 showed high potency and selectivity against KRAS G12D mutant tumor cells in vitro and effectively inhibited tumor growth in several pancreatic ductal carcinoma (PDAC), colorectal cancer (CRC) and non-small cell lung cancer models (NSCLC) in vivo. **Methods:** A phase 1/2 study of TSN1611 was developed to enroll patients (pts) with advanced solid tumors harboring KRAS G12D mutation. The study comprised a phase 1a dose escalation part following a BOIN design with accelerated titration to determine the maximum tolerated dose (MTD), recommended phase 2 dose and pharmacokinetics (PK), followed by a phase 1b part for dose optimization to compare different recommended doses and a phase 2 part to evaluate the efficacy of TSN1611 across various tumor types. Alternative dose levels or regimens could be explored based on the emerging data. Pts received oral TSN1611 twice daily (BID), until disease progression, unacceptable toxicity, or patient withdrawal. Here we report the preliminary data from phase 1a part. **Results:** As of Jan 05, 2025, 18 pts received TSN1611 from 50 to 600 mg BID (9 with CRC, 5 PDAC, 2 NSCLC, and 1 each with ampullary cancer and gallbladder cancer, all with pre-identified KRAS G12D mutation). Median age was 61 years (range 36-81). The median prior lines of systemic therapy were 3 (range 1-6). No dose-limiting toxicity was reported and MTD was not reached. The most common (≥ 10%) treatment related adverse events (TRAEs) were grade 1 or 2 vomiting (44.4%), nausea and diarrhea (38.9% each), fatigue (16.7%), ALT increased, blood CPK increased, hyperkalemia and hyperuricemia (11.1% each). No treatment related grade 3 or higher AE or SAE was reported. Four (30.8%) out of the 13 evaluable pts demonstrated stable disease per RECIST v1.1. Tumor reductions were observed in 3 pts (CRC, PDAC, and NSCLC, n = 1 each) at 200 or 400 mg BID, with treatment ongoing. Serial assessment of plasma ctDNA revealed declines in KRAS G12D variation allele frequency at 200 mg BID and above, echoing that the exposure at 200 mg BID reached that of ED_{90} in the CRC GP2D model. TSN1611 was rapidly absorbed with T_{max} around 2 hours and half-life around 15 hours. The PK profile indicated a general dose proportionality in exposure across the evaluated dose ranges and low to moderate accumulation after multiple BID dosing. Dose escalation is ongoing, and more data will be available at the conference presentation. **Conclusions:** TSN1611 was well tolerated, demonstrating acceptable PK characteristics as predicted, with preliminary tumor shrinkage observed in pts with refractory KRAS G12D mutant tumors. Phase 1b/2 studies are planned to evaluate TSN1611 both as a monotherapy and in combination with standard of care and/or novel agents treating cancer. Clinical trial information: NCT06385925. Research Sponsor: Tyligand Pharmaceuticals (Suzhou) Limited.

3084 Poster Session

Artificial intelligence (AI)-powered evaluation of protein drug-targetability through subcellular-level expression profiling from immunohistochemistry (IHC) images. First Author: Sukjun Kim, Lunit Inc., Seoul, South Korea

Background: As a standardized methodology for quantifying the targetability of proteins in drug development has yet to be established, we developed an AI-powered analyzer capable of scalably measuring cellular and subcellular-level expression to assess 74 membrane-specific targets in development. **Methods:** A total of 160K cancer and normal IHC images from Human Protein Atlas (HPA) were analyzed, including 47,591 on 74 target genes. The AI model trained on pathologist-annotated histology images, took the IHC images as input to predict cell types and subcellular compartments (nucleus, cytoplasm, and membrane) along with intensity scores. Target genes were evaluated by 1) Tumor cell specificity (TCS): normalized ratio of positive tumor cells to the total positives, 2) Inverse normal score (INS): inverse ratio of positive normal cells to the total normal cells, 3) Membrane intensity score (MIS) and 4) Membrane specificity (MBS): ratio of MIS to the intensity scores from 3 subcellular compartments. Finally, the targetability score (T score) was calculated as $Z_{TCS}x2 + Z_{INS}x2 + Z_{MIS}x0.5 + Z_{MBS}x0.5$. Also, Tumor infiltrating lymphocytes (TIL) were compared between Tumor Proportion Score (TPS)≥1 and TPS<1 groups in each target. **Results:** The IHC analyzer assessed 528M cells including 147M cancer cells. In 34 cancer types, the average T score for the 74 targets was 0.62, which was higher than -0.07 observed for the other 699 targets that have never been explored as drugs. The average T score of the top 10 targets in pan-cancer was 4.27, which was significantly higher than the average (0.0). Among the top 10 targets in pan-cancer (Table), MUC16 was ranked high in non-squamous lung, ovary, uterine, cervical cancers; and CEACAM5 and TACSTD2 were ranked high in 7 and 10 cancer types, respectively. Most targets showed an association with lower TILs and higher TPS, whereas CEACAM5 demonstrated significantly higher TILs (x1.39) in the TPS≥1 group in bladder cancer. **Conclusions:** We developed a pipeline leveraging AI-powered and big-data-driven approaches to assess the cancer and membrane-specific expression of target proteins in IHC images. The current pipeline reproduces the targetability of developed targets as well as novel targets with a potential synergy with immuno-oncology agents. Research Sponsor: None.

Seizure-related homolog 6 (SEZ6) expression and ctDNA methylation profiles in patients with high-grade neuroendocrine carcinomas (NECs)/ neuroendocrine tumors (NETs) from a phase 1 study of ABBV-706 in advanced solid tumors. First Author: Song Wang, AbbVie, Inc., North Chicago, IL

Background: SEZ6 is a transmembrane protein with overexpression in small cell lung cancer (SCLC) and other neuroendocrine neoplasms (NENs) and minimal expression in normal tissues, making it a promising therapeutic target for these NENs that have a significant unmet need for treatments. ABBV-706 is a novel SEZ6-targeting antibody-drug conjugate with a potent topoisomerase 1 inhibitor payload and is being evaluated in a phase 1 study (NCT05599984) in patients (pts) with advanced solid tumors. Preliminary data from ABBV-706 monotherapy dose escalation demonstrated a manageable safety profile and promising efficacy in pts with SCLC and NECs/NETs (*JCO* 2024;42[suppl 16]: abs 3001). Herein, we describe SEZ6 expression at the protein and mRNA levels in tumor tissues of pts with NENs outside of SCLC, as well as detection of high-grade NEN cancer signal of origin (CSO) among these pts by investigating ctDNA methylation prior to ABBV-706 treatment. **Methods:** This phase 1, open-label study enrolled pts (≥18 yr) with relapsed/refractory high-grade NECs/NETs (well-differentiated grade 3 NETs and poorly differentiated NECs), atypical lung carcinoid, and medullary thyroid cancer (MTC) in dose-escalation and -expansion cohorts. Pts received ABBV-706 monotherapy IV at 1.3–3.5 mg/kg Q3W. FFPE tumor tissues of these pts, when available, were subjected to a proprietary IHC assay for SEZ6 and RNAseq analysis. ctDNA samples collected prior to ABBV-706 treatment were subjected to the Cancer Research Solution (RUO; GRAIL, Inc.). ctDNA abundance and CSO were assessed by examining cancer-specific methylation patterns of ctDNA. **Results:** As of Aug 27, 2024, in the NEC/NET cohort of 64 pts, median age was 63 yr (range 33–86) and the median number of prior therapies was 3 (range 1–8). High prevalence of moderate to strong SEZ6 expression (SEZ6 cytomembrane IHC H-score ≥100) was observed across NEC/NET histologies: 78% of extrapulmonary small cell NEC of diverse anatomic sites (n = 9); 80% of neuroendocrine prostate carcinoma (n = 5); 43% of large cell NEC of diverse anatomic sites (n = 14); 50% of MTC (n = 4); 40% of gastroenteropancreatic NENs (n = 10); 50% of atypical lung carcinoid (n = 6). *SEZ6* mRNA levels were highly correlative with SEZ6 IHC scores. ctDNA positivity rate was 95% from baseline plasma samples of the NEC/NET cohort (n = 60); 67% of ctDNA-positive samples (n = 57) were predicted to have high-grade NEN as their primary CSO. **Conclusions:** Robust SEZ6 expression was observed with some heterogeneity across histologies of the NEC/NET monotherapy cohort. High ctDNA detection rate at baseline indicates the feasibility of monitoring molecular response longitudinally without an invasive procedure and identifying predictive biomarker(s) for ABBV-706. Clinical trial information: NCT05599984. Research Sponsor: AbbVie, Inc.; n/a.

3086 Poster Session

EphA2 siRNA in DOPC nanoliposomes (EPHARNA): A phase I clinical trial in patients with solid tumors. First Author: Ravali Annam Reddy, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: EphA2 overexpression is common in human cancers and has an important role in promoting tumor growth and metastasis. Further, EphA2 has kinase-dependent and independent functions, making it ideal for RNAi-based targeting. EphA2 siRNA incorporated in DOPC nanoliposomes (EPHARNA) was effective in reducing EphA2 protein levels and reducing tumor growth in preclinical studies. This is a first-in-human phase I clinical trial of EPHARNA in patients with solid tumors. **Methods:** Adult patients with advanced solid tumors received escalating doses of intravenous EPHARNA twice weekly in 3-week cycles. A total of 8 dose levels were explored under a BOIN design (Table 1). Study objectives included evaluation of safety, tolerability, maximal tolerated dose, and efficacy. Adverse events were assessed per NCI CTCAE Version 4.03 and efficacy per RECIST v1.1. Patients were evaluable for response if they completed at least 2 cycles. Clinical benefit was defined as objective response or stable disease for 4 or more cycles. **Results:** A total of 48 patients were treated. Most common diagnoses were colorectal (29.2%) and ovarian cancer (12.5%). 20.8% of treated patients were Black and 8.3% were Hispanic. Median age was 60.3 years (range 24.5-78.8). Median number of prior therapies was 4 (range 0-12). Among treated patients, 36 (75%) experienced an AE. Most common AEs (≥20%) were fever (33.3%), infusion-related reaction (25%), and chills (20.8%). 5 (10.4%) treated patients experienced Grade 3 AEs that were dose-limiting toxicities including chills (2.1%), dyspnea (2.1%), hypertension (2.1%), infusion-related reaction (2.1%), and nausea/vomiting (2.1%). No Grade 4 AEs were noted. Of the 25 patients evaluable for response, disease control rate was 44% (95% CI: 24.5-63.5%) with 11 patients demonstrating stable disease for at least 2 cycles. No patients demonstrated partial or complete response. Clinical benefit was observed in 4 (16%, 95% CI: 1.6-30.4%) patients who demonstrated stable disease for at least 4 cycles. One patient received 16 cycles with stable disease before withdrawing consent and discontinuing the trial due to desire for a treatment break. The study was closed to enrollment prior to confirmation of the MTD due to unavailability of the drug. **Conclusions:** EPHARNA demonstrated an acceptable safety profile with manageable adverse events in patients with advanced solid tumors. Further investigation of this novel therapeutic approach is warranted to fully elucidate efficacy and optimal dosing strategy. Clinical trial information: NCT01591356. 3087 Poster Session

A phase 2 study of olaparib in IDH1 and IDH2 mutant advanced chondrosarcomas and other solid tumors. First Author: Philippos Apolinario Costa, Yale Cancer Center, New Haven, CT

Background: Pre-clinical data have shown that mutations in isocitrate dehydrogenase (IDH) 1 and 2 can lead to a "BRCAness" phenotype by impairing homologous recombination (HR) repair. Olaparib, a PARP inhibitor effective in BRCA-mutated cancers such as ovarian, prostate, pancreas and breast cancer, may also be effective in IDH1/2 mutant solid tumors. IDH1/2 mutations are frequently present in gliomas and cholangiocarcinomas but also in other solid tumors, such as chondrosarcomas, and melanomas. This study evaluated the efficacy of olaparib in treating advanced IDH1/2 mutated solid tumors other than cholangiocarcinoma and gliomas. **Methods:** NCI 10129 was a 3-arm, open-label Phase II clinical trial performed in the NCIExperimental Therapeutics Clinical Trials Network (ETCTN) evaluating olaparib 300 mg twice daily for IDH mutated solid tumors refractory to standard treatment. Patients with solid tumors, excluding cholangiocarcinoma and glioblastoma, were enrolled in cohort 3 of the Phase II trial. The primary endpoint was the overall response rate (ORR), and the secondary endpoints were progression-free survival (PFS) and overall survival (OS). **Results:** From March 2019 until January 2024, a total of 26 patients with IDH1/IDH2-mutant tumors were enrolled in the study across 10 sites. Of these, 14 (53%) had chondrosarcomas, with 5 (35%) being dedifferentiated. Following, the most prevalent histologies were gastrointestinal adenocarcinomas (4, 15%), other sarcomas (3, 12%) and other tumors (5, 19%). Most tumors had IDH1 mutations (n = 20, 77%), with R132C (n = 12, 60%) being the most common substitution. The median age was 62 years (range 43-78), and 18 (69%) participants were male. Patients had received a median of 1.5 prior line of therapy (0-9). After a mean follow-up time of 8.6 months (0.8-62.6), no objective responses were seen, leading to the closure of enrollment. The median PFS was 2 months (95% CI 1.8-2.2), and the median OS was 7.5 months (95% CI 1.3-13). Only two patients had a clinical benefit, defined as PFS > 6 months. Olaparib was tolerable, with most adverse events scored as grades 1-2. **Conclusions:** Olaparib did not demonstrate activity in IDH-mutant chondrosarcomas and other solid tumors. This study underscores the remarkably poor outcome associated with IDH mutant tumors, emphasizing the urgent need for additional therapeutic options. Further evaluation of the correlative data, including assessment of HR proficiency, is required to elucidate why pre-clinical evidence suggesting potential efficacy did not translate into clinical benefit in IDH mutant solid tumors. Clinical trial information: NCT03212274. Research Sponsor: National Cancer Institute; NCI-2017-01182.

3088 Poster Session

The effect of HIFU treatment on liver metastasis of colorectal cancer in mice and its impact on immunity. First Author: Shasha Wang, Department of Medical Oncology, Affiliated Hospital of Qingdao University, Qingdao, China

Background: The liver represents the predominant site for metastasis in colorectal cancer, with over 85% of cases exhibiting the microsatellite stable (MSS) phenotype, which typically shows limited response to immunotherapy. High-Intensity Focused Ultrasound (HIFU) not only facilitates direct destruction of tumor tissues but also has the potential to remodel the tumor immune microenvironment, thereby enhancing systemic anti-tumor immunity. This study aimed to explore the effects of HIFU on liver metastasis in a murine model and its subsequent impact on immune modulation. **Methods:** A BALB/c mice model of colorectal cancer liver metastasis was established and validated. The animals were treated with HIFU, followed by transcriptomic profiling and immunohistochemical staining to assess immune-related markers (CD8, F4/80, FOXP3, PD-L1, IL-6) in the liver metastasis tissues. **Results:** Transcriptomic sequencing performed on liver metastatic tissues collected seven days after HIFU treatment revealed a notable upregulation of CXCL14 expression, which was corroborated by protein immunoblotting. Immunohistochemical analysis demonstrated an increased infiltration of cytotoxic T cells (CD8+), a reduction in macrophage populations (F4/80), and a significant decrease in T regulatory cells (FOXP3 expression). Additionally, both PD-L1 and IL-6 levels were substantially reduced in the treated tissues. **Conclusions:** Seven days post-HIFU treatment, significant immune modulation was observed in liver metastatic tumor tissues, including enhanced infiltration of cytotoxic T cells, a reduction in immune-suppressive cell populations such as macrophages and Tregs, and the attenuation of inflammatory cytokines. These findings suggest that HIFU not only enhances the anti-tumor immune response but also facilitates the transition of liver metastases from an immune "cold" to a "hot" tumor microenvironment, potentially improving the efficacy of subsequent immunotherapeutic strategies. A phase 2 study of the olaparib and AZD6738, an ATM/ATR inhibitor, in isocitrate dehydrogenase (IDH) mutant solid tumors. First Author: Philippos Apolinario Costa, Yale Cancer Center, New Haven, CT

Background: Pre-clinical data has shown that mutations in isocitrate dehydrogenase (IDH) 1 and 2 can lead to impaired homologous recombination repair. IDH1/2 mutations are frequently present in gliomas and cholangiocarcinomas but also in other solid tumors, such as chondrosarcomas. AZD6738 is an ATR inhibitor, and Olaparib is a PARP inhibitor. Preclinical evidence showed a synergistic effect of this combination in models with DNA damage repair effects. This study aims to evaluate the efficacy of Olaparib and AZD6738 in treating advanced IDH1/2 mutated solid. **Methods:** NCI 10222 is an open-label Phase II clinical trial performed in the NCI National Clinical Trials Network evaluating olaparib 300 mg twice daily with AZD6738 160 mg daily for IDH mutated solid tumors refractory to standard treatment. The primary endpoint was the overall response rate (ORR), and the secondary endpoints were progression-free survival (PFS) and overall survival (OS). **Results:** From January 2020 until March 2023, a total of 24 patients with IDH1/IDH2 mutant tumors were enrolled in the study across 8 sites. Of these, 14 (58%) had cholangiocarcinoma, 4 (17%) had chondrosarcomas, and 6 (25%) had other tumors. Most tumors had IDH1 mutations (n = 16, 70%). The median age was 59 years (range 29-83), and 15 (63%) participants were male. Patients had received a median of 3 prior lines of therapy (0-6). After a mean follow-up time of 3 months (0.2-ongoing), no objective responses were seen, leading to the closure of enrollment. The median PFS was 2 months (95% CI 2-4), and the median OS was 7 months (95% CI 3-NE). Only three patients had a clinical benefit, defined as PFS $>$ 6 months, with one patient diagnosed with G1 chondrosarcoma still on treatment with stable disease. Combination of Olaparib with AZD6738 resulted in G3 AE in 9 (38%) patients, leading to 4 (17%) discontinuations. **Conclusions:** Olaparib with AZD6738 did not demonstrate activity in IDH mutant solid tumors. However, the stability seen in the patient with low-grade tumors could suggest that the effect is restricted to lower-grade tumors, still dependent on IDH mutations. Further evaluation of the correlative data is required to elucidate why pre-clinical evidence suggesting potential efficacy did not translate into clinical benefit in IDH mutant solid tumors. Clinical trial information: NCT03878095. Research Sponsor: None.

Effect of extrachromosomal DNA (ecDNA) on *MYCN* amplified neuroblastoma and patient outcomes. First Author: Mihika Sonalkar, UCSD, La Jolla, CA

Background: Recurrent cytogenetic abnormalities represent candidate therapeutic targets for children with neuroblastoma (NB). *MYCN* oncogene amplification is associated with significantly worse survival rates for children with NB and remains one of the primary predictors of patient prognosis. *MYCN* amplifications in NB can be found both within the linear genome and on circular extrachromosomal DNA (ecDNA), and therapeutic targeting of the mechanisms underlying *MYCN* amplification represents a novel and promising strategy in NB. However, the molecular features and clinical and biological significance of these amplifications in NB tumors are not sufficiently understood. **Methods:** Whole genome and RNA sequencing data were analyzed for NB cell lines and NCI TARGET NB samples using AmpliconSuite software for ecDNA identification and characterization. GISTIC was used for identification of recurrently amplified regions. Gene expression levels were determined using StringTie, and gene clustering heatmaps were generated using FeatureCounts software. For differential gene expression analyses, samples were divided into ecDNA**+** and ecDNA**-**, and genes contained on ecDNA were compared to the same regions on linear DNA across samples using DESeq2. Associations between ecDNA quantity, content, and patient survival were performed using multivariate Cox regression survival analysis. Associations of gene expression with patient survival were performed using the R2 Platform. The efficacy of targeting ecDNA-associated gene products was assessed using live cell imaging and cell viability assays. **Results:** WGS analysis confirmed 7/20 NB patient tumors from the TARGET database to be ecDNA amplified with 1-5 independent ecDNA elements and *MYCN* gene expression correlated with the ecDNA copy number. ecDNAs in *MYCN*-amplified neuroblastoma cell lines contained distinct gene combinations and possessed unique structures. MYCN overexpression in NB cells has been shown to be associated with replication stress (RS), and tumor cells containing ecDNA are hyper-reliant on the DNA damage response (DDR) kinase CHK1 to manage heightened replication stress. Expression of the *CHK1* gene was associated with neuroblastoma patient outcomes and neuroblastoma was most significantly associated with *CHK1* RNA dependency. We further validated CHK1i as a promising therapeutic strategy in *MYCN* amplified NB, as CHK1 inhibition with the novel inhibitor BBI-2779 was most effective against ecDNA+, *MYCN*-amplified neuroblastoma cell lines. **Conclusions:** Our results emphasize the critical role of ecDNA in NB. We identify a synthetic lethality axis shaped by ecDNA *MYCN* amplification and CHK1 dependence. We further demonstrate the feasibility of targeting this vulnerability through CHK1 inhibition, thus offering new avenues for treatment in *MYCN* amplified tumors. AI-driven design of novel PARP inhibitors. First Author: Juan Velasco, Yale University, New Haven, CT

Background: Inhibitors of the Poly (ADP-ribose) polymerase (PARP) family play a role in treating HER2-negative locally advanced or metastatic breast cancer with germline BRCA1/2 (gBRCA) mutations, as well as in the maintenance treatment of gBRCA-associated metastatic pancreatic ductal adenocarcinoma. However, the design of de novo small molecules targeting proteins like PARP remains time consuming and resource intensive. It is hypothesized that generative models trained on molecular graph encodings could accelerate the design of novel PARP inhibitors. Objective:This study aims to develop a generative model capable of designing novel, orally bioavailable PARP inhibitors. **Methods:** A large language model was pre-trained on 1 million chemical structures sourced from the ChEMBL database. Each structure was represented as a Simplified Molecular Input Line Entry System (SMILES) string, which was tokenized into discrete atomic and functional group-level tokens. The model leverages an Average-Stochastic Gradient Descent Weight-Dropped Long Short-Term Memory (AWD-LSTM) architecture. Transfer learning was applied to adapt the pre-trained model to specific target chemical structures, enabling domain-specific fine-tuning for the de novo design of PARP inhibitors. **Results:** The model demonstrated robust performance in generating chemically valid, unique, novel, and diverse PARP inhibitors. It achieved a validity rate, uniqueness rate, and novelty rate of 100%, along with a diversity score of 81.53%. Furthermore, the generated molecules exhibited favorable physicochemical properties, including a molecular weight of 417.52 Da, a logarithm of the partition coefficient (LogP) of 2.58, a topological polar surface area (TPSA) of 93.21 Angstrom squared, an average of 4.05 rotatable bonds, 1.84 hydrogen bond donors, and 5.14 hydrogen bond acceptors. **Conclusions:** A generative model was developed to design novel, orally bioavailable PARP inhibitors. It provides an efficient and automated tool for de novo small molecule design with tailored molecular and pharmacological properties, potentially accelerating the development of PARP inhibitors. Research Sponsor: None.

A first-in-class KIF11 degrader antibody conjugate (DAC) as a potential therapy targeting a broad spectrum of cancers. First Author: Yan Feng, Accutar Biotechnology, Cranbury, NJ

Background: Kinesin family member 11 (KIF11) plays a critical role in mitotic spindle formation and centrosome separation during cell division, making it an attractive anti-cancer target. Despite its promise, the clinical success of KIF11 inhibitors has been hindered by a narrow therapeutic window, largely due to on-target toxicities, such as myelosuppression. Antibody-drug conjugates present a promising strategy to overcome this limitation by enhancing the therapeutic window of KIF11-targeting therapies. However, creating a KIF11-targeting inhibitor payload with sub-nanomolar potency remains a significant challenge. Using Accutar's chimeric degrader platform, we developed dKIF976, a first-in-class KIF11 degrader with sub-nanomolar potency. This degrader was further used as payload to create DACs demonstrating potent cell growth inhibition coupled with KIF11 degradation, thereby providing a robust foundation for further in vivo evaluation of novel KIF11-targeting therapy. **Methods:** dKIF976, a CRBN-based KIF11 degrader, was designed via Accutar's chimeric degrader platform. Western blot analysis was used to evaluate KIF11 degradation and mitotic arrest, as indicated by Histone H3 phosphorylation, in cancer cell lines. Cell growth inhibition was assessed using ATP-based assays. Mechanism and selectivity of dKIF976 were confirmed through specific cellular assays and proteomic analyses. Cell surface antigen-dependent activity of dKIF976 DACs were evaluated in cell lines with different levels of antigen expression. **Results:** dKIF976 demonstrated rapid, dose-dependent KIF11 degradation and significant upregulation of p-Histone H3 across all tested cell lines, achieving sub-nanomolar potency. In side-by-side comparisons, dKIF976 displayed significantly greater cell growth inhibition than multiple published KIF11 inhibitors. KIF11 degradation and the resulting cell growth inhibition induced by dKIF976 were confirmed to be dependent on the E3 ligase CRBN and the proteasome. Proteomic analysis via mass spectrometry validated the selective degradation of KIF11. When conjugated to antibodies, dKIF976 DACs exhibited antigen-dependent KIF11 degradation and cell growth inhibition, with enhanced potency observed in cell lines with high target expression. **Conclusions:** dKIF976 achieves specific and potent KIF11 degradation, inducing mitotic arrest and robust cancer cell growth inhibition. Its superior efficacy and unique mechanism of action establish it as a highly promising payload for antibody conjugates. dKIF976 DACs demonstrated strong antigen-dependent KIF11 degradation and cell growth inhibition. This innovation highlights the potential of using chimeric degraders as payloads for antibody conjugates, offering a promising strategy to enhance the therapeutic window of KIF11-targeted therapies and pave the way for their future success. Research Sponsor: None.

Comparative analysis of fibroblast activation protein Inhibitor (FAPI) O4 PET/CT versus flurodeoxyglucose (FDG) PET/CT in staging gastrointestinal tumours. First Author: S.P. Somashekhar, Aster International Institute of Oncology, Bangalore, India

Background: FAPI 04 PET/CT has emerged as a promising alternative to FDG PET/CT, offering potential advantages in sensitivity, specificity, and patient comfort due to its unique targeting of fibroblast activation protein (FAP), which is up regulated in the stromal cells of many cancers. This study aims to evaluate the diagnostic performance of FAPI 04 PET/CT compared to FDG PET/CT for staging gastrointestinal (GI) tumours. **Methods:** 55 patients with suspected or confirmed GI malignancies underwent both FDG PET/CT and FAPI 04 PET/CT scans within a 7-day window. A total of 115 lesions were identified across the cohort, including colorectal, gastric, pancreatic, and oesophageal cancers. Tumor localization, lesion size, and uptake characteristics were compared between the two imaging modalities. Sensitivity, specificity, and diagnostic accuracy were calculated using histopathology as the gold standard. **Results:** Of the 55 patients, 31 were male and 24 female, with a median age of 58 years (range: 42–78). FAPI 04 PET/CT demonstrated superior sensitivity (92%) compared to FDG PET/CT (84%) for the detection of GI tumours, particularly in pancreatic and colorectal cancers, where stromal fibrosis is prevalent and metabolic activity may be low. Specificity of FAPI 04 PET/CT was also higher (95%) compared to FDG PET/CT (88%), reflecting the lower background activity in non-tumor tissues. Lesion detection rates were significantly improved with FAPI 04 PET/CT, with 112 out of 115 lesions identified, while FDG PET/CT detected 98 lesions ($p = 0.02$). The accuracy of FAPI 04 PET/CT was 94%, whereas FDG PET/CT had an accuracy of 86%. Notably, FAPI 04 PET/CT showed a higher diagnostic yield in detecting metastases in liver, peritoneum, and lymph nodes compared to FDG PET/CT. The average scan time for FAPI 04 PET/CT was 30 minutes, significantly shorter than FDG PET/CT (1 hour 15 minutes). **Conclusions:** FAPI 04 PET/CT outperforms FDG PET/CT in terms of sensitivity, specificity, and diagnostic accuracy for staging gastrointestinal tumours, particularly in cases with abundant stromal involvement. The reduced background activity and higher lesion detection rate enhance the utility of FAPI 04 PET/CT in clinical practice. Additionally, the walk-in basis for FAPI 04 PET/CT with shorter fasting and scan time offers significant improvements in patient comfort and convenience. Given these advantages, FAPI 04 PET/CT represents a promising alternative to FDG PET/CT for staging GI cancers, with potential implications for improved treatment planning and monitoring. Research Sponsor: None.

Role of Lu177 FAPI-09 therapy in combination with chemotherapy or immunotherapy for chemo-resistant progressive cancers: Early clinical experience. First Author: Prathap H. J, Aster International Institute of Oncology, Aster Hospitals Whitefield, Bangalore, India

Background: Chemo resistant progressive tumours represent a major challenge in oncology. These tumours often adapt and develop resistance mechanisms that limit the efficacy of standard treatments. Lu177 FAPI-09 therapy, which targets fibroblast activation protein (FAP) expressed on cancer-associated fibroblasts (CAFs) within the tumor microenvironment, has emerged as a promising treatment option. By binding to FAP, Lu177 FAPI-09 selectively delivers radiation to the tumor stroma, potentially altering the tumor environment and making it more susceptible to subsequent therapies. This study aimed to evaluate the safety, feasibility, and effectiveness of combining Lu177 FAPI-09 therapy with chemotherapy or immunotherapy in patients with advanced chemoresistant cancers. **Methods:** Eighteen patients with advanced progressive and chemo resistant malignancies were included in this study. All underwent Ga-68 FAPI-09 PET/CT scans prior to treatment to confirm FAP expression in their tumors, ensuring that Lu177 FAPI-09 therapy would be beneficial. The patient group consisted of GI(7), ovarian (11). Prior to Lu177 FAPI-09 therapy, all patients had demonstrated resistance to one or more prior lines of chemotherapy or immunotherapy. Following the administration of Lu177 FAPI-09 therapy, patients received chemotherapy or immunotherapy 5 days later, tailored to their specific tumor type. Disease responses were assessed two months after the combined treatment. **Results:** After receiving Lu177 FAPI-09 therapy, 80% of patients showed either stable disease or a positive response to the subsequent chemotherapy or immunotherapy. The safety profile of Lu177 FAPI-09 therapy was favourable, with no major grade 3 or 4 adverse events reported. The most common side effects were mild reductions in blood counts, including neutropenia or anaemia. Overall, Lu177 FAPI-09 therapy in combination with chemotherapy or immunotherapy was well-tolerated by the majority of patients. **Conclusions:** Lu177 FAPI-09 therapy, when used in combination with chemotherapy or immunotherapy, shows promise in enhancing treatment responses in patients with chemo resistant progressive cancers with minimal side effects and no major toxicities. The use of Ga-68 FAPI-09 PET/CT scans to identify patients with tumors expressing FAP ensures appropriate patient selection, optimizing the likelihood of a positive outcome. These findings suggest that Lu177 FAPI-09 therapy could be an effective approach to overcome resistance and improve treatment outcomes in patients with advanced malignancies. Research Sponsor: None.

Dosing tolerability and adverse events (AEs) in dihydropyrimidine dehydrogenase (*DPYD*) variant carriers receiving genotyping-guided fluoropyrimidine (FP) dosing. First Author: Grace Nguyen, Atrium Health Levine Cancer Institute, Charlotte, NC

Background: We previously showed that *DPYD* genotype-guided FP (5-FU, capecitabine) dosing reduces severe AEs and hospitalizations in variant carriers. However, optimal dose reduction and tolerability for individual *DPYD* variants are not well understood. This study aims to evaluate dosing tolerability and AEs among *DPYD* variant carriers. **Methods:** This is a retrospective cohort study of patients (pts) receiving FP-based chemotherapy at a multisite cancer center who underwent routine in-house *DPYD* genotyping covering 5 variants (Table). Test results and dose recommendations were provided to oncologists per Clinical Pharmacogenetics Implementation Consortium guidelines (i.e., 50% dose reduction in *DPYD* heterozygous carriers and slow titrations in subsequent cycles based on AEs). Clinicodemographics were collected via chart review, and AEs were graded using Common Terminology Criteria for Adverse Events criteria version 5.0. Data was collected for 3 months of FP treatment unless discontinued early. **Results:** From March 2020-October 2024, 1,645 pts were genotyped with 85 (5.2%) identified as heterozygous *DPYD* variant carriers. This analysis included 49 carriers who were tested pretreatment and started FP chemotherapy (median age 65, 35% male, 67% White, 27% Black, 71% gastrointestinal cancers, 53% 5-FU, 47% capecitabine). All pts started on dose-reduced FP at cycle 1 (Table). Of 49 carriers, 18 (37%) had at least one dose escalation, most occurring in cycles 2 or 3. Of these, 5 were eventually escalated to full dose, 5 had AEs preventing further escalation, 5 had subsequent dose reduction due to AEs, 2 completed therapy while escalating, and 1 had one dose escalation with no documented AE. Dose escalation was not performed in 31 (63%) pts due to the following reasons: any-grade AE (n = 27, of which 5 had further dose reductions due to AEs), poor performance status (n = 1), early discontinuation (n = 2, 1 disease progression, 1 declined further therapy), treatment completion (n = 1). **Conclusions:** This is the largest retrospective cohort study evaluating dosing tolerability and toxicity in *DPYD* carriers using real world data. There is interindividual variability in tolerability within each *DPYD* variant, particularly with decreased function variants. Findings will help inform prospective studies and clinical guidelines on variant-specific dosing strategies. Research Sponsor: None.

Variant	N, %	Median (range) first dose intensity, %	Median (range) final dose intensity, %	Grade 3+ AE	AE related hospitalization	AE related discontinuation

Monocentric pilot trial of trametinib in severe extracranial arteriovenous malformations. First Author: Emmanuel Seront, Institut Roi Albert II, Department of Medical Oncology, Saint Luc University Hospital, Brussels, Belgium

Background: The Mitogen Activated Protein Kinase (MAPK) pathway is crucial for cell growth, proliferation, and survival. Overactivation of MAPK is observed in many cancers leading to evaluation of targeted therapies such as MEK inhibitors. Vascular malformations, including arteriovenous malformation (AVM) share many oncogenic mutations with cancer. For example, AVM present KRAS, RASA1, MAP2K1 mutation that result in excessive activity of the RAS-RAF-MEK cascade. This trial aimed to assess trametinib safety and efficacy in adult patients with stage III AVM refractory to conventional therapy, causing deformities, pain, bleeding, or ulceration. This is the first trial to evaluate targeted therapies in AVM. **Methods:** We conducted a prospective Phase II trial on ten adult AVM patients. Trametinib was administered orally for 12 months, with initial dosage escalation based on patient tolerance. Clinical and radiological outcomes were assessed at baseline, during treatment, and at follow-up. Primary outcomes included safety and clinical efficacy (pain reduction, ulceration healing, thrill and deformation improvement). Secondary outcomes included radiological responses assessed via MRI, Doppler ultrasound, and angiography. **Results:** Of the ten patients (6 female, 4 male), eight had facial AVM, one auricular, and one foot AVM. All experienced deformities, with seven reporting severe pain, five ulceration, and two bleeding. Trametinib was initiated at 2mg daily for three patients but, due to skin toxicities, subsequent patients started at lower doses, with only three reaching the target dose. Trametinib led to clinical improvement in 80% of patients. Pain alleviation occurred in all symptomatic patients (VAS 5–7 to 0–5), deformation improved in 55%, and ulceration healed in 20%. Radiological assessment showed a reduction in vessel size in one patient and nidus disappearance in two. Acneiform rash was the most frequent toxicity (100%), including two cases of grade 3, requiring early drug discontinuation. Severe mucosal bleeding led to premature cessation in two patients with mucosal AVMs. Correlations with genomic-alteration will be presented at congress. **Conclusions:** Trametinib demonstrated clinical benefit in refractory AVMs, supporting MAPK inhibition as a therapeutic approach. Skin and mucosal toxicities necessitate dose adjustment, dermatological co-management, and cautious use in mucosal AVMs. Further studies are warranted to optimize therapeutic regimens and assess long-term outcomes. Clinical trial information: 2019-003573-26. Research Sponsor: None.

3097 Poster Session

Cost analysis of pre-treatment dihydropyrimidine dehydrogenase (*DPYD*) genotyping to reduce hospitalizations at a cancer center in the United States (U.S.). First Author: Sarah Morris, Atrium Health Levine Cancer Institute, Charlotte, NC

Background: Patients with certain *DPYD* variants are at increased risk of fluoropyrimidine (FP) related adverse events (AEs) and mortality at standard doses. We previously showed pre-treatment *DPYD* testing and genotype-guided FP dosing reduced severe AEs and hospitalizations in variant carriers (PMID 38935897), but testing cost remains a barrier to widespread adoption in the U.S. Herein, we performed a cost analysis of pre-treatment *DPYD* genotyping. **Methods:** Variant carrier rates, hospitalization rates, and AEs were derived retrospectively from our institutional cohort (n=442) of patients with no observed variant, dose reduced variant carriers, and standard dose variant carriers (identified reactively) receiving FP primarily for gastrointestinal cancers. All patients were genotyped and followed for three months for FP-related AEs and hospitalizations. Hospitalization cost was the weighted average cost of treating the most expensive AE experienced by the hospitalized patient. Input parameters (Table 1) were modeled using a decision tree to compare the cost of pre-treatment testing (no variant and dose reduced variant carriers) to no pre-treatment testing (no variant and standard dose variant carriers) from a health-system perspective with a three-month time horizon. The model accounted for hospitalization and genotype test costs only. **Results:** Pre-treatment testing resulted in a cost savings of $36.98 per patient compared to no pre-treatment testing (average per patient cost = $1,655.81 and $1,692.79, respectively). Cost savings increase to $124.39 per patient if half of those tested have insurance that reimburses the test cost. Additional savings are expected if costs for outpatient management of AEs and use of uridine triacetate in the inpatient setting are included in the model. **Conclusions:** Pre-treatment *DPYD* genotyping led to cost savings by reducing AE related hospitalizations among variant carriers. Cancer centers should adopt pre-treatment *DPYD* genotyping to reduce severe AEs, hospitalizations, and costs. Research Sponsor: None.

Model inputs.

Parameter	Value	Source
No variant population prevalence	94%	Institutional cohort
Variant carrier population prevalence	6%	Institutional cohort
No variant hospitalization rate	11%	Institutional cohort
Dose reduced variant carrier hospitalization rate	25%	Institutional cohort
Standard dose variant carrier hospitalization rate	64%	Institutional cohort
No variant hospitalization cost	$12930.67	HCUP NC Inpatient Database 2021
Dose reduced variant carrier hospitalization cost	$8858	HCUP NC Inpatient Database 2021
Standard dose variant carrier hospitalization cost	$8928.29	HCUP NC Inpatient Database 2021
Genotype test cost	$174.81	CMS clinical laboratory fee schedule 2023

Predicting immunotherapy response in advanced solid tumors using quantitative imaging features from CD8 PET/CT exams. First Author: Michael A. Postow, Memorial Sloan Kettering Cancer Center, New York, NY; Weill Cornell Medical College, New York, NY

Background: CD8-PET/CT imaging with ^{89}Zr crefmirlimab berdoxam (ImaginAb, Inc), which targets CD8-expressing T-lymphocytes, is being explored as an imaging tool to predict responses and monitor immune checkpoint inhibitors (ICI) in patients with advanced solid malignancies. Here we explore how quantitative imaging features from CD8 PET/CT may predict ICI responses. **Methods:** We studied quantitative imaging features (PET parameters and radiomics) in 45 patients from the ImaginAb IAB-CD8-201 phase II trial (NCT03802123). Tumoral lesions, peritumoral ring (ring shaped margin extending 0.5 cm inwards and outwards from the segmented tumor surface), healthy tissue, benign and pathological lymph nodes were segmented from baseline and first on-treatment (4-6 weeks after standard of care treatment including ICI blockade). Imaging features from CD8-PET/CT scans were extracted. Predictive models for best overall response (BOR) according to RECIST 1.1 were developed. Models' performance was evaluated by the ability to distinguish responders (complete or partial response, n = 13) from non-responders (stable or progressive disease, n = 32). A survival random forest analysis was also conducted to estimate time to BOR. **Results:** Significantly greater delta values were identified in the tumor and peritumoral ring compared to healthy tissues, suggesting the tumor and peritumoral ring may reveal early treatment-induced changes important for predicting response. Eighteen predictive models were developed, with models using imaging features from the peritumoral ring showing comparable performance to those using features from lesions and pathological lymph nodes. The simplest BOR predictive model, which yielded the highest performance, used delta values extracted from the peritumoral ring (AUCs = 0.895, sensitivity = 0.900, specificity = 0.615). The inclusion of clinical variables (including age, sex, body mass index, cancer type, received treatments, number of lines of received treatment, white blood cell count) did not significantly enhance model accuracy, emphasizing the robustness of the imaging data alone. A final model integrating key imaging features from multiple regions successfully predicted time to BOR with a C-index, a generalizable AUC that considers censored data, of 0.86. **Conclusions:** This study highlights the potential of quantitative imaging analysis of CD8-PET/CT scans as a tool for predicting responses to cancer immunotherapy. Results suggest the effectiveness of delta imaging features from the peritumoral ring as a potential indicator of patient's ability to respond to ICI treatment, simplifying the analysis without sacrificing accuracy. Further validation in trials with more homogeneous populations and treatment regimens (eg. NCT05013099) is warranted, with the potential to advance personalized cancer care. Research Sponsor: ImaginAb.

3099 Poster Session

Interim safety and efficacy data of [^{212}Pb]VMT01 in MC1R expressing melanoma. First Author: Zachary Scott Morris, University of Wisconsin School of Medicine and Public Health, Madison, WI

Background: Immune checkpoint inhibitors (ICI) are effective in melanoma, but many patients experience progression on or after approved ICI +/- MAPK inhibitor therapy. Melanocortin-1 receptor (MC1R) is a novel target for radiopharmaceutical therapy (RPT) and is highly expressed on melanoma tumor cells. VMT01 is an MC1R-targeted RPT that can be radiolabeled with either ^{203}Pb (patient selection and dosimetry assessments) or ^{212}Pb (alpha particle therapy). Here, we present data on the first in-human evaluation of [^{203}Pb/^{212}Pb]VMT01 in patients with metastatic melanoma. FDA granted Fast Track Designation to the product on the bases of preclinical experiments combining [^{212}Pb]VMT01 with immunotherapy. **Methods:** This is a first-in-human dose-finding study to determine the safety, pharmacokinetics, dosimetry and preliminary efficacy of [^{212}Pb]VMT01 in subjects with MC1R-positive metastatic melanoma who progressed on at least 1 approved first-line therapy (NCT05655312). Phase 1 of the trial includes escalating dose cohorts. The first two cohorts incorporate dosimetry evaluations (reported separately) with the imaging surrogate [^{203}Pb]VMT01 prior to receiving up to 3 treatment cycles of [^{212}Pb]VMT01 therapy (injected activity of 111 MBq (3 mCi) or 185 MBq (5 mCi) for Cohort 1 and 2, respectively). Participants are evaluated for any DLT for the first 6 weeks after cycle one. Efficacy is assessed by RECIST 1.1 criteria by the investigator. Following the start of the study the anticipated combination arm with nivolumab was opened as an amendment. **Results:** Cohort 1 (DCO 04Sep24) was completed with 3 enrolled participants who received 3 treatment cycles without any DLTs or SAEs. Cohort 1 participants showed prolonged stabilization of disease from start of treatment (mean: 11.1 months); one participant developed a confirmed objective response (PR) after completion of all three [^{212}Pb]VMT01 administrations and is still on trial after 13.1 months from start of treatment. Cohort 2 has completed with 7 enrolled participants. No DLTs or related SAEs have been observed. All participants in this Cohort progressed after either the first cycle (3 participants) or the second cycle (4 participants).Based on these preliminary results showing anti-tumor effect at the lower dose, additional cohorts for both monotherapy and in combination with nivolumab were introduced at a de-escalated dose of 55.5 MBq (1.5 mCi). Both cohorts are now open for enrollment. Updated safety and efficacy data will be analyzed and presented at ASCO. **Conclusions:** At 111 MBq and 185 MBq activity levels, [^{212}Pb]VMT01 was safe and well-tolerated. An objective response and prolonged stabilization of disease were observed at the 111 MBq activity level while no effect was seen at 185 MBq. The study will continue to explore potentially immunostimulating lower doses of administered activity of [^{212}Pb]VMT01 either as a monotherapy or in combination with nivolumab. Clinical trial information: NCT05655312. Research Sponsor: Perspective Therapeutics.

3100 Poster Session

SPYK04, a novel RAF-MEK molecular glue: Dose escalation (DE) in first-in-human study for MAPK pathway-altered solid tumors. First Author: Sarina A. Piha-Paul, Department of Investigational Cancer Therapeutics, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: SPYK04 is a novel MEK1/2 inhibitor designed to enhance RAF-MEK binding and potentially inhibit feedback activation of MEK1/2. This approach was developed to address the limited efficacy of conventional MEK inhibitors in RAS-mutated cancers, which is thought to be due to feedback activation of the MAPK pathway. **Methods:** This first-in human study of SPYK04 is conducted in the US and Japan (NCT04511845). Patients with locally advanced or metastatic solid tumors harboring MAPK pathway alterations were eligible in its DE part. The primary endpoints included assessment of pharmacokinetics, adverse events (AEs) and dose-limiting toxicities (DLTs); the secondary endpoint was objective response rate (ORR). SPYK04 was administered orally once daily in continuous 28-day cycles. **Results:** A total of 23 patients were enrolled in DE. SPYK04 was evaluated at doses ranging from 0.1 to 1.3 mg/day. An accelerated titration design was employed for doses of 0.1, 0.2, and 0.4 mg/day, followed by a transition to a 3+3 design starting from 0.8 mg/day. Over the dose range of 0.1 to 1.3 mg/day, systemic exposure demonstrated a dose-dependent increase. Grade 3 or higher treatment-related adverse events (TRAEs) were observed in 30.4% of patients. TRAEs observed in >= 20% of patients were: dermatitis acneiform and blood creatinine phosphokinase increased (60.9% each); AST increased (30.4%); nausea and stomatitis (26.1%, each). DLTs were observed in one patient each at dose levels of 0.8, 1.0 and 1.3 mg/day. All DLTs were due to receiving <75% of the planned dose. A decision was made to not escalate beyond 1.3 mg/day. The ORR was 8.7% (n = 2 of 23), with both partial responses (PRs) occurring amongst the 5 enrolled ovarian cancer patients. The disease control rate (DCR; PR+SD) was 52.2% (n = 12 of 23). **Conclusions:** SPYK04 was tolerated at doses up to 1.3 mg/day in patients with advanced solid tumors. PRs were observed in two patients with ovarian cancer. Further evaluation of safety and efficacy will occur in the expansion part of this study. Clinical trial information: NCT04511845. Research Sponsor: Chugai Pharmaceutical Co., Ltd. (Contact Person: Satoe Kawakami, email: kawakamiste@chugai-pharm.co.jp).

Zanzalintinib (zanza) + nivolumab (nivo) ± relatlimab (rela) in patients (pts) with advanced solid tumors: Results from two dose-escalation cohorts of the phase 1b STELLAR 002 study. First Author: Benjamin Garmezy, Sarah Cannon Research Institute, Nashville, TN

Background: Zanza (XL092) is a novel, multi-targeted tyrosine kinase inhibitor (TKI) that inhibits VEGFR, MET, and TAM kinases. In tumor models, zanza showed antitumor activity alone and in combination with an anti-PD-1 immune checkpoint inhibitor (ICI). The addition of a VEGFR-TKI to ICI combinations of anti-PD-1 + anti-LAG-3 may enhance clinical activity. STELLAR-002 (NCT05176483) is a phase 1b, open-label, dose escalation and expansion study evaluating the safety and efficacy of zanza as monotherapy and in combination with ICIs in pts with advanced solid tumors. Data from dose escalation cohorts treated with zanza + nivo and zanza + nivo/rela are presented. **Methods:** Adults with advanced/metastatic solid tumors were enrolled. Starting doses were zanza 100 mg po qd + nivo 360 mg IV q3w (zanza + nivo cohort), and zanza 60 mg po qd + nivo/rela 480/480 mg IV q4w (zanza + nivo/rela cohort). Pts were enrolled in a rolling six design. Sparse pharmacokinetic (PK) samples were collected. The primary endpoint was safety. Exploratory endpoints included investigator-assessed ORR per RECIST 1.1 and PK. **Results:** Among 19 pts in the zanza 100 mg + nivo cohort, the most common tumor types were prostate cancer (26%) and colorectal cancer (26%). Median number of prior therapies was 6 (range: 2–16). No dose-limiting toxicities (DLTs) were observed in the first 11 DLT-evaluable pts; zanza 100 mg is the recommended dose (RD). The most common treatment-emergent adverse events (TEAEs) were fatigue (68%) and diarrhea (58%). The most common grade (G) 3/4 TEAEs were fatigue (26%) and hypertension (16%). Palmar-plantar erythrodysesthesia (PPE) occurred in 11% of pts (all G1/2). No responses were observed; the disease control rate (DCR: CR+PR+SD) was 42%. In the zanza + nivo/rela cohort, 24 pts received zanza 60 mg + nivo/rela and 25 pts received zanza 100 mg + nivo/rela. One DLT was observed in the first 6 DLT-evaluable pts at zanza 60 mg (G3 ALT increase) and none in the first 5 DLT-evaluable pts at zanza 100 mg. Zanza 100 mg is the RD with nivo/rela. In zanza 100 mg-treated pts, the most common tumor type was renal cell carcinoma (RCC; 56%). Median number of prior therapies was 4 (range: 0–15). The most common TEAEs were diarrhea (68%) and fatigue (56%). The most common G3/4 TEAE was fatigue (20%). PPE occurred in 28% (4% G3/4). ORR was 28% and DCR was 80%; these rates were 36% and 86% in pts with RCC (n = 14). Plasma zanza concentrations 2 hrs after the first dose (C_{max}, mean ± SD) were 595 ± 353 and 838 ± 689 ng/mL for the 60-mg and 100-mg dose levels, respectively. **Conclusions:** The tolerability of zanza + nivo and zanza + nivo/rela was manageable and consistent with each monotherapy agent. Preliminary safety, PK, and response data support selection of the 100-mg zanza dose in combination with nivo or nivo/rela for further investigation. Expansion cohorts are ongoing in various tumor types. Clinical trial information: NCT05176483. Research Sponsor: Exelixis, Inc.

Phase II dose optimization update with EZH2/EZH1 inhibitor tulmimetostat in patients with *ARID1A*-mutated ovarian clear cell carcinoma or endometrial carcinoma. First Author: Linda R. Duska, University of Virginia Health System, Charlottesville, VA

Background: EZH2 inhibition antitumor activity occurs through various mechanistic pathways in multiple tumor types, including via synthetic lethality in advanced *ARID1A*-mutated ovarian clear cell carcinoma (OCCC) and endometrial carcinoma (EC). Oral, next-generation, dual EZH2/EZH1 inhibitor tulmimetostat is in Phase II evaluation in multiple disease cohorts (NCT04104776; Oaknin et al. ASCO 2024, ESMO 2024). We report updated efficacy and safety data from the *ARID1A*-mutated OCCC/EC cohorts, including dose optimization and expansion arms. **Methods:** Phase II Stage 1 evaluated tulmimetostat 350 mg once daily (QD). Stage 2 dose-optimization design randomizes further patients with OCCC (M2) or EC (M3) to 200 mg or 300 mg tulmimetostat QD in Stage 2a, with an efficacy gateway for each arm to open Stage 2b. Primary endpoint is objective response rate (complete response [CR] + partial response [PR]), and secondary objectives include safety. **Results:** As of October 15, 2024, enrollment into the M2/M3 200 mg, 300 mg, and 350 mg arms included 20/10, 21/21 and 14/11 patients, respectively. A total of 56.4% M2 and 61.9% M3 patients received ≥3 prior lines of therapy. Most responses were seen in the M2 200 mg arm and in the M3 350 mg arm (n=4 each; Table). The safety profile across arms was consistent with the EZH1/2 drug class. In M2/M3 cohorts, treatment-emergent adverse events (TEAEs) leading to dose modifications were reported in 55.0%/60.0%, 71.4%/85.7%, and 92.9%/90.9% of patients at 200 mg, 300 mg, and 350 mg, respectively. TEAEs leading to treatment discontinuation were reported in 5.0%/20.0%, 4.8%/4.8%, and 14.3%/9.1%, respectively. Serious TEAEs considered at least possibly related (TRAEs) to tulmimetostat treatment were reported in 5.0%/0%, 9.5%/14.3%, and 21.4%/27.3%, respectively. Grade ≥3 TRAEs were mainly hematologic (Table); no TRAEs leading to death were reported. **Conclusions:** Tulmimetostat showed an improved and acceptable safety profile in OCCC and EC at 200 mg and 300 mg doses (versus 350 mg) with promising antitumor activity, supporting further clinical investigation. Clinical trial information: NCT04104776. Research Sponsor: MorphoSys GmbH.

OMX-0407: A novel spectrum-selective small molecule kinase inhibitor in advanced/metastatic solid tumors. First Author: Valentina Boni, NEXT Madrid Universitary Hospital Quironsalud Madrid, Pozuelo De Alarcon, Spain

Background: OMX-0407 is an orally available spectrum-selective kinase inhibitor that targets key oncology-relevant tyrosine kinases and salt-inducible kinases and is being developed as a first-in-class treatment for solid tumor indications. Preclinical investigations indicate a dual mode of action by sensitizing tumor cells to immune cell induced apoptotic cell death as well as direct inhibition of tumor growth promoting kinases. **Methods:** This is a phase Ia/Ib dose escalation and expansion study of OMX-0407 (NCT05826600). Eligible patients for the phase Ia dose escalation part had advanced solid tumors and exhausted available therapies. **Results:** As of the 30th of October 2024, 24 patients have been treated at dose levels 10 through 140 mg p. o. BID and the phase Ia part has been completed. Solid tumor histologies included melanoma, non-small cell lung cancer, sarcoma and colorectal cancer. OMX-0407 was generally well tolerated, adverse reactions were mainly gastrointestinal. Two dose limiting toxicities were observed: One case of facial swelling secondary to drug allergy at the 90 mg BID dose, and one case of fatigue at the 140 mg BID dose. One durable complete response in a patient with cutaneous angiosarcoma secondary to radiotherapy, resistant to two prior lines of chemotherapy treatment, was observed at 30 mg BID which is ongoing at 16 months (at the time of data cutoff). Pharmacodynamic analyses demonstrated phosphorylation inhibition of target kinases. A recommended phase II dose of 100 mg BID was identified. **Conclusions:** OMX-0407 has been well tolerated at pharmacologically and therapeutically active dose levels. One very durable response has been observed in an angiosarcoma patient at a low dose level. The phase Ib expansion part at the recommended phase II dose is currently recruiting patients with angiosarcoma and clear cell renal cell carcinoma. Clinical trial information: NCT05826600. Research Sponsor: iOmx Therapeutics AG.

3104 Poster Session

AI molecular search engine paired with RNA sequencing analysis to develop potent and selective VEGFR-3 inhibitors. First Author: Maxim Sorokin, OmicsWay Corp., San Mateo, CA

Background: Tumor angiogenesis (TA) is driven by several VEGF factors and corresponding receptors (VEGFRs). Targeting TA inhibits tumor growth, however there are no selective small molecule TA inhibitors on the market yet. Here we report development of a selective VEGFR-3 inhibitor with potential anti-tumor activity in multiple cancers. **Methods:** The Bioptic virtual screening pipeline employs two models. The first is a SMILES-based LLM fine-tuned on binding affinity data of contrastive molecular pairs. The screening was performed on the ultra-large 40-billion-compound virtual library Enamine REAL. For selectivity, the top-ranked molecules were re-scored using a secondary model, a GNN specifically designed for this task and trained to differentiate activity across similar kinases. The Oncobox algorithm was used to select cancer types with the highest sensitivity to VEGFR1-3 inhibitors based on VEGF(R)s expression and TA pathways activation. It was applied to RNA-seq profiles from TCGA (11428 profiles from 33 primary sites) and the internal relevant RWD cohort (1056 profiles from 89 cancer types). **Results:** Compounds with IC50 < 10 μM in Eurofins VEGFRs KinaseProfiler were considered active. Among 110 tested compounds, 1 was active against VEGFR-1, 1 - against VEGFR-2, and 4 - against VEGFR-3. One compound was active against all VEGFRs, and 3 - against a single VEGFR. One VEGFR-3 active showed $>$ 45-fold selectivity against both VEGFR1 & 2, while no compound was specific to VEGFR-1 or VEGFR-2. All 3 selective VEGFR-3 inhibitors showed minimal activities ($<$ 50% at 10 μM) against the 12 off-target kinases including B-Raf, c-Raf, c-Kit, FGFR1, FGFR2, FGFR3, FGFR4, Flt3, Met, PDGFR-a, PDGFR-b, Ret. In order to select cancer types for further pre-clinical validation, Oncobox algorithm was used to simulate predicted efficiency of a VEGFR-3 inhibitor in multiple cancer types from TCGA and internal RWD cohort. The highest response rate is expected for papillary thyroid cancer, followed by clear-cell renal, pancreatic, ovarian cancers, and sarcomas. A selective VEGFR-3 inhibitor may be beneficial when compared to already developed pan-VEGFR inhibitors due to lower toxicity. Finally, identification of potential responders to selective anti-VEGFR-3 therapy via RNA-seq analysis may enable patient enrichment in further clinical trials and development of a companion diagnostic for the drug. **Conclusions:** Our results suggest that Bioptic's molecular search engine significantly enhances identification of potent and selective inhibitors for a specific target, and, paired with the Oncobox algorithm, may facilitate development of novel anti-cancer drugs. Research Sponsor: None.

Efficacy and safety of alectinib in pediatric and adult patients with ALK altered advanced solid tumors: Results from the TACKLE phase II trial, a MASTER KEY substudy (NCCH1712/MK003). First Author: Hitomi Sumiyoshi Okuma, Department of International Clinical Development, National Cancer Center Hospital, Tokyo, Japan

Background: Alectinib is an orally administered tyrosine kinase inhibitor that targets anaplastic lymphoma kinase (ALK) and is approved in ALK-positive non-small cell lung cancers and anaplastic large cell lyphomas in Japan. Beyond these, there is a rare population carrying the same ALK alteration regardless of cancer type, often referred to as "ALKomas". Treatment options are limited for these ALK altered solid tumors. **Methods:** This open-label phase II study evaluated alectinib for ALK altered locally advanced or metastatic cancer. Patients received alectinib as either a capsule or a suspension. Primary endpoint was central-assessed confirmed objective response rate (ORR) according to RECIST v1.1. A Bayesian approach was used to evaluate eligible patients in the main cohort, which were patients able to ingest capsules. Expected ORR was set at 40% and a threshold at 10%. Secondary endpoints included safety, disease control rate (DCR), progression-free survival (PFS), and overall survival (OS). **Results:** 26 patients, aged from 8 months to 78 years, across 11 tumor types received treatment. The most common tumor type was soft tissue sarcoma (STS) (n = 11) followed by embryonal neoplasm (n = 5). Alterations included fusion/rearrangements (n = 19), mutations (n = 5), and amplifications (n = 2). The median follow-up was 15.0 months. In the evaluable patients of the main cohort (n = 16), the central-assessed ORR was 43.8% (95% CI, 19.8 to 70.1), meeting the decision criteria of the Bayesian design for the primary endpoint. For the entire evaluable patients (n = 24), the central-assessed ORR was 54.2% (32.8 to 74.4), the DCR was 70.8% (48.9 to 87.4); the median PFS was 24.9 months (3.9 to not estimable); and the median OS was 38.8 months (13.9 to not estimable). In patients with ALK fusions/rearrangements (n = 17), the ORR was 76.5 % (50.1 to 93.2), DCR 82.4% (56.6 to 96.2) and the median PFS and OS were both not reached. All patients with inflammatory myofibroblastic tumor showed a response (ORR 100%, n = 8/8). In pediatric patients aged 15 and under (n = 11), the ORR was 63.6% (30.8 to 89.1) with a DCR of 100.0% (71.5 to 100.0). Although no responses were observed in the patients with ALK mutations or amplifications, a clinically meaningful stable disease was observed in 3 of 5 ALK mutated patients. Grade ≥3 drug-related adverse events were observed in 15.4% (n = 4) among all treated patients (n = 26), with no drug related deaths. **Conclusions:** Our study showed that patients with ALK alterations treated with alectinib achieved sustained clinical benefit, meaningful survival outcomes, and safety consistent with previous data. Greatest benefit was observed for the ALK fusion population including pediatric patients. These data support the potential role of alectinib as a tumor-agnostic therapy for both pediatric and adult patients with ALK altered solid tumors. Clinical trial information: jRCT2091220364. Research Sponsor: None.

3106 **Poster Session**

Phase 1 study of TT-00973-MS, a highly selective and potent AXL inhibitor, in patients with advanced solid tumors. First Author: Bo Yang, The First Affiliated Hospital of Bengbu Medical University, Bengbu, China

Background: AXL is a member of the TAM family activated by the high-affinity ligand Gas6. The Gas6/AXL signaling pathway plays a critical role in drug resistance, tumor proliferation, metastasis, invasion, epithelial-mesenchymal transition and immune regulation, implicating AXL as an important target in cancer treatment. TT-00973-MS is a highly selective and potent AXL inhibitor which exhibited significant anti-tumor activities in both SK-OV-3 and H1299 derived CDX model with AXL over-expression. Here is first time to present the first-in-human study of TT-00973-MS. **Methods:** Dose escalation is performed using"3+3"design. Adverse events (AE) are evaluated per CTCAE v5.0 criteria. Tumor responses are evaluated per RECIST 1.1. Pts receive TT-00973-MS once daily continuously for 28-day cycles. The primary endpoint is to evaluate dose limiting toxicity (DLT) and identify the maximum tolerated dose (MTD) and/or recommended phase II dose (RP2D). **Results:** As of the data cut-off date on December 24, 2024, 18 pts have received TT-00973-MS treatment in 2 mg (n = 1), 5 mg (n = 3), 10 mg (n = 3), 17 mg (n = 7), 25 mg (n = 4) at QD dose levels. Median age was 56.5 (37~69), 8 (44.4%) were males, all had ECOG PS ≤1. 66.6% of pts had Stage III/IV disease. 50% had ≥3 prior lines of systemic therapies. 66.7% had prior immunotherapies. One DLT was observed in a subject at 17 mg QD dose level (Grade 3 peripheral motor nerve disorder). The MTD was not reached. Treatment-related AEs (TRAEs) were reported in all pts, grade 3 in 6 (33.3%), and no grade 4 or 5. The most common TRAE (≥30%) included increased blood lactate dehydrogenase (83.3%), increased aspartate aminotransferase (72.2%), increased alanine aminotransferase (66.7%), hypercholesterolaemia (55.6%), hypoalbuminaemia (38.9%), hypertriglyceridemia (33.3%) and proteinuria (33.3%). Fourteen pts were efficacy evaluable. Two confirmed partial remission (PR) were achieved in pts with renal pelvis cancer (n = 1) and ovarian cancer (n = 1). TT-00973-MS is slowly eliminated from body, with a half-life of about 55 h. After multiple dosing (QD), steady state was reached within 15 days, and the mean accumulation factor of $AUC_{0\text{-}24h}$ was approximately 6. Preliminary PK analysis showed a linear increase on exposure. Plasma levels of soluble AXL (sAXL) increased to approximately 1.7 times (range: 0.9~2.8) the baseline levels at C1D28. **Conclusions:** The preliminary findings from this phase I study demonstratedthat the AXL inhibitor TT-00973-MS monotherapy exhibits a well-tolerable safety profile, promising pharmacodynamic activity, with early signs of efficacy in pts with heavily pre-treated advanced solid tumors. Further studies are warranted to comprehensively evaluate the efficacy and safety of TT-00973-MS in large patient populations and specific tumor types. Clinical trial information: NCT05673538. Research Sponsor: None.

3107 **Poster Session**

A phase 1 dose escalation study of LNP7457 (PRMT5 inhibitor) in patients with advanced or metastatic solid tumors. First Author: Shashank Deoghare, Lupin Limited, Pune, India

Background: Protein arginine transferase 5 (PRMT5) overexpression plays an important role in pathogenesis of several cancers. LNP7457 is an investigational, orally active, highly potent, S-adenosylmethionine (SAM) competitive PRMT5 inhibitor with wider therapeutic window compared to other investigational PRMT5 inhibitors. Here, we report results of dose escalation (DE) and food-effect (FE) sub-studies of LNP7457 from a Phase 1 study in patients with advanced or metastatic solid tumors. **Methods:** This is first-in-human, multicenter, open-label study in patients with advanced or metastatic solid tumors with failed prior standard therapies or for whom no standard therapy exists. DE followed initial modified acceleration followed by 3+3 design. LNP7457 was administered orally in 21-day cycles [first 16 days (on-period) and last 5 days (off-period)] at escalating doses (1 to 4mg QD). Primary objective was to determine maximum tolerated dose (MTD) assessed by dose-limiting toxicities (DLT) in cycle 1; secondary objectives included safety, pharmacokinetics, pharmacodynamics and preliminary antitumor activity measured by RECIST v1.1. FE study was conducted as a single-dose cross over study at MTD to assess impact of food on PK of LNP7457. **Results:** 17 patients (9 male & 8 females) in DE received LNP745 at doses of 1mg (n = 1), 2mg (n = 8), 4mg (n = 2), 1.5mg (n = 6); median age 51.0 (range 23 - 76) years; Diagnosis included head and neck cancer (n = 9), cervix cancer (n = 2), breast cancer (n = 1), ovarian cancer (n = 1), pancreatic cancer (n = 1), gall bladder cancer (n = 1), prostate cancer (n = 1) and uterine cancer (n = 1). Sixteen patients discontinued treatment; progressive disease (n = 8); consent withdrawal (n = 4); AE (N = 2); death (n = 1) and lost to follow up (n = 1). One patient is ongoing at data cut-off of 31-Oct-2024. A total of 16 (94.1%) patients had at least 1 treatment emergent adverse event (TEAE). The majority of TEAEs were unrelated to LNP7457 (76.4%). Anemia (47.1%) and thrombocytopenia (23.5%) were the most common TEAEs. A total of 6 (35.3%) patients had serious TEAEs, thrombocytopenia (11.8%) being the most common serious TEAE. One patient in 4mg cohort had DLT of thrombocytopenia during cycle 1. None of the patients in 2mg cohort had DLT in cycle 1, hence 2 mg was determined as MTD. After single and multiple dosing in DE study, peak plasma concentrations of LNP7457 were observed between 2-4 hrs. A single-dose cross over FE study (n = 6) at 2mg dose showed no impact of food on PK of LNP7457. Target engagement based on reduction in plasma SDMA levels was observed at all dose levels in DE study. Preliminary efficacy in the form of stable disease was observed in 8 (66.7%) patients across 8 different tumor types. **Conclusions:** LNP7457 was well tolerated with desirable safety, PK/PD and preliminary efficacy profile. Clinical trial information: CTRI/2023/07/054753. Research Sponsor: Lupin Limited, India.

3108 **Poster Session**

An open-label phase 1 dose-escalation and dose-expansion trial to evaluate the safety, tolerability, and efficacy of TQ-B3234 in adults with neurofibromatosis type 1 (NF1). First Author: Jun Liu, Neurofibromatosis Type 1 Center and Laboratory for Neurofibromatosis Type 1 Research, Shanghai Ninth People's Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai, China

Background: NF1 is an autosomal-dominant genetic disease that can manifest as neurofibromas, including cutaneous neurofibromas (cNFs) affecting almost all NF1 patients (pts), and plexiform neurofibromas (PNs, up to 50%), which are benign nerve sheath tumors. However, PNs can cause substantial pain, disfigurement and impairment in pts and are at risk of transforming into malignant peripheral nerve sheath tumors (MPNSTs). Currently, there is no medical cure for adult pts with NF1-related PN (NF1-PN), and fewer options for adult pts with cNFs. TQ-B3234 is a highly selective MEK1/2 inhibitor. A phase 1 dose-escalation and dose-expansion trial (NCT05107037) evaluated the safety and efficacy of TQ-B3234 in adult pts with inoperable NF1-PN, MPNSTs or cNFs. **Methods:** Eligible adult pts with inoperable NF1-PN, MPNSTs or cNFs were included in the dose-escalation phase using a 3+3 design, while only NF1-PN pts proceeded to the dose-expansion phase. TQ-B3234 was administered as a capsule, with doses ranging from 5 mg to 100 mg, once daily in 28-day cycles during the dose-escalation phase. A dose of 50mg was chosen for the dose-expansion phase. The primary endpoints were safety and objective response rate (ORR). ORR was assessed by investigators using REiNS for NF1- PN pts, RECIST 1.1 for MPNSTs pts, and paper frames for the cNF population. **Results:** As of September 30, 2024, 40 adult pts (31 pts of PNs, 7 pts of cNFs, and 2 MPNSTs) were enrolled. The distribution of doses was as follows: 4 pts at 5 mg, 1 at 10 mg, 3 at 15 mg, 24 at 50 mg, 5 at 70 mg, and 3 at 100 mg. One patient, a cNF case, experienced dose-limiting toxicity (DLT), in the form of G3 diarrhea (16.7%) at the 100 mg dose during the dose-escalation phase. After a median follow-up of 12 months, treatment-emergent adverse events (TEAEs) were observed in 39 pts (97.5%), with the majority were grade 1 or 2. Grade 3 TEAEs were reported in 17.5% of pts; the principal reasons for dose reductions (15.0%) TEAEs included rash acneiform (5.0%), diarrhea (2.5%), and edema (2.5%). No death occurred during the study. Among the 30 pts with NF1-PN who had at least one tumor assessment, 29 pts (96.7%) experienced tumor size reduction, and 11 (36.7%) achieved partial response (PR) based on REiNS criteria. The largest reduction in tumor size was 37.7%. For the 6 cNF pts who had at least one tumor assessment using paper frames, all 6 pts (100%) experienced reduced tumor size, with the largest reduction being 85.2%. **Conclusions:** TQ-B3234 demonstrated manageable safety and a significant ORR in adult NF1- PN pts. These results support the potential of TQ-B3234 to become a new treatment option for NF1- PN pts. Additionally, TQ-B3234 showed deep and durable volume reduction in adult cNF pts, as assessed by paper frames. This method could serve as a valuable tool in clinical research for achieving accurate quantitative phenotype for NF1. Clinical trial information: NCT05107037. Research Sponsor: None.

3109 **Poster Session**

A phase 1, multicenter, open-label study of HSK42360, a brain-penetrant BRAF inhibitor, in patients with BRAF V600-mutated solid tumors. First Author: Jian Li, Beijing Cancer Hospital, Beijing, China

Background: Limitations of approved BRAF V600E inhibitors include toxicity from paradoxical activation of RAF dimerization as well as limited brain penetration. In contrast to approved agents, investigational pan-RAF inhibitors both inhibit mutant RAF proteins and wild-type (wt) RAF proteins, leading to a narrow therapeutic index. HSK42360 is a next-generation, small-molecule BRAF paradox breaker with high brain penetration. It displays significantly less paradoxical activation than approved BRAF inhibitors and spares wtBRAF-containing RAF dimers. Treatment with HSK42360 results in excellent and durable anti-tumor effect in BRAF Class I and II mutant CDX or PDX models. Here we report the interim results from a Phase 1 study of HSK42360 in patients (pts) with BRAF V600 mutations (NCT06536400). **Methods:** This multicenter, open-label, two-part study enrolled adult pts with advanced BRAF V600-mutated solid tumors, including those with recurrent or metastatic solid tumors or primary CNS tumors. Previous BRAF±MEK inhibitor treatment is permitted. In the dose-escalation (Part 1), HSK42360 (200-3600 mg/day) monotherapy was given orally. Escalation followed a "3+3 design" with dose-limiting toxicities assessed during Cycle 1. Part 2 was cohort expansion. Primary objectives were maximum tolerated dose and recommended phase 2 dose of HSK42360. Secondary objectives included safety, tolerability, pharmacokinetics, pharmacodynamics and preliminary efficacy. **Results:** As of January 15, 2025, 17 pts (47.1% male; median age 57.0 years) have been treated with HSK42360 monotherapy across five dose levels (200-3600 mg/day). Of these, 64.7% pts experienced adverse events (TEAEs), most frequently increased ALT (23.5%) and increased AST (23.5%). Most (89.7%) of TEAEs were grade 1. Two pts had drug-related grade 3 AEs (increased creatinine and increased ALT) and one had drug-related serious AEs (SAEs) (increased creatinine). There were no DLT, grade 4 TEAEs, treatment-related discontinuations, or treatment-related deaths. Among 11 efficacy evaluable pts, the ORR was 18.2%. Two (1 CRC and 1 ganglioglioma) had a partial response (PR) and three had stable disease (SD) with shrinkage (per RECIST or RANO). This trial is ongoing. **Conclusions:** HSK42360 monotherapy was well tolerated without unexpected safety issues. Preliminary efficacy data demonstrate favorable activity of HSK42360 in pts with BRAF V600-mutated solid tumors, including primary CNS tumors. Clinical trial information: NCT06536400. Research Sponsor: Haisco Pharmaceutical Group Co., Ltd.

3110 **Poster Session**

Anti-tumor activity of BH-30643, a novel macrocyclic kinase inhibitor, in *EGFR*-mutant lung cancer models. First Author: Wei Deng, BlossomHill Therapeutics, Inc., San Diego, CA

Background: Outcomes on tyrosine kinase inhibitor (TKI) treatment in *EGFR*-mutant non-small cell lung cancer (NSCLC) fall short of the durable benefit observed with next-generation targeted therapies in *ALK* and *ROS1*-driven NSCLC. Novel targeted therapies are needed to address treatment resistance and offer prolonged patient benefit with reduced toxicity. We recently described (AACR 2025) the design and discovery of BH-30643, a first-in-class macrocyclic reversible TKI targeting the active conformation of mutant EGFR and offering potent, mutant-selective EGFR inhibition across classical and non-classical *EGFR* mutations. Here we study diverse preclinical models to assess the breadth of activity from this novel approach. **Methods:** Anti-tumor activity of BH-30643 was evaluated in cell-derived xenograft (CDX) or patient-derived xenograft (PDX) tumor models carrying classical or atypical EGFR mutations. CNS activity of BH-30643 was investigated in an intracranial xenograft model. BH-30643 was administered twice daily via oral gavage; osimertinib when used as a comparator was dosed daily. Studies were done with $n \geq 5$. The activity of BH-30643 against diverse *EGFR* exon 20 insertions (ex20ins) was evaluated in 34 engineered Ba/F3 cell lines in cell proliferation assays in vitro. **Results:** In the PC-9 (exon 19 del) CDX model, BH-30643 led to deep tumor regressions, similar to what was observed with osimertinib at the 25 mg/kg dose level. Similarly deep responses with BH-30643 were observed in double mutant CDX models including those derived from H1975 cells (cis L858R / T790M) and Ba/F3 cells engineered with exon 19 del / T790M. In a triple-mutant PDX model (cis exon 19 del / T790M / C797S) and a Ba/F3 triple-mutant CDX model (cis L858R / T790M / C797S), deep responses were observed with BH-30643 while osimertinib demonstrated no anti-tumor effect. BH-30643 activity was also evident in the HCC827-luc (exon 19 del) intracranial xenograft model with 90% tumor reduction. In two Ba/F3 CDX models carrying atypical mutations (cis G719A / S768I and cis G719A /L861Q), BH-30643 maintained strong anti-tumor activity. Finally, we explored the activities of BH-30643 against 34 different *EGFR* ex20ins in engineered Ba/F3 cell lines and BH-30643 showed anti-cell proliferation activity with a median IC_{50} value of 6.06 nM. **Conclusions:** These preclinical studies demonstrate broad activity of BH-30643 against classical and atypical *EGFR* activating mutations, *EGFR* ex20ins, as well as acquired resistance *EGFR* mutations. Such an "OMNI-EGFR" inhibitor may be able to overcome some of the limitations of earlier agents. Supported by favorable ADME and preclinical safety profiles, BH-30643 is now being assessed in a first-in-human study in locally advanced or metastatic NSCLC harboring *EGFR* and/or *HER2* mutations (NCT06706076, SOLARA). Research Sponsor: BlossomHill Therapeutics, Inc.

Phase II trial of trametinib in patients with advanced solid tumors harboring genomic alterations in the MAPK pathway: Results from the BELIEVE trial (NCCH1901). First Author: Hideyuki Hayashi, Center for Cancer Genomics, Keio University Hospital, Shinjuku-Ku, Japan

Background: The MAPK pathway is one of the most mutated oncogenic pathways in solid tumors. However, effective treatments targeting this pathway have not been well-established. The BELIEVE trial aimed to evaluate the efficacy of trametinib, a selective MEK inhibitor, in patients with solid tumors harboring genomic alterations in the MAPK pathway. **Methods:** The BELIEVE trial is a multi-cohort, tumor agnostic phase II trial. Eligibility criteria included patients with solid tumors for which no standard treatment was available or those who had shown resistance or intolerance to standard therapies. In the trametinib arm, participants received 2 mg/day of trametinib continuously until disease progression or intolerable toxicity occurred. The primary endpoint was the objective response rate (ORR) within 16 weeks, and secondary endpoints were overall survival (OS), progression-free survival (PFS), disease control rate (DCR), and safety. The clinical hypothesis was that patients would respond to the genotype-matched drugs. Bayesian analysis was performed using a prior distribution with an expected response rate of 30% [Beta (0.6, 1.4)]. **Results:** Between October 2019 and October 2023, 60 patients with measurable disease and 9 without measurable disease were enrolled. The top three primary tumor sites were the central nervous system (n=20), pancreas (n=7), and ovary (n=6). The targeted genes for trametinib included non-*BRAF* V600 (n=26), *NF1* (n=18), *MAP2K1* (n=10), *NRAS* (n=6), *KRAS* (n=5), and *RAF1* (n=4). Among the full analysis set of 49 patients with measurable disease, the confirmed ORR was 12.2% (95% CI, 4.6% to 24.8%), and the expected value of posterior distribution [Beta (6.6, 44.4)] was 12.9%. Partial responses were observed in patients with genomic alterations in non *BRAF* V600 (n=3), *KRAS* (n=2), and *NF1* (n=1). However, the confirmed ORR of 12.2% fell below the prespecified threshold of 20%, therefore the primary endpoint was not achieved. The median OS was 11.9 months (95% CI, 8.5 to 22.9 months), and median PFS was 3.9 months (95% CI, 2.4 to 44 months). The DCR was 46.9% (95% CI, 32.5% to 61.7%). Among 59 patients in the safety analysis, severe adverse events (Grade ≥3) were observed in 55.9% of patients. The most frequent adverse effects were acneiform dermatitis (22%), blood creatine phosphokinase increased (20%), and stomatitis (15%). **Conclusions:** The BELIEVE trial demonstrated limited efficacy of trametinib in patients with advanced solid tumors harboring genomic alterations in the MAPK pathway. While the confirmed ORR did not meet the primary endpoint, the outcomes for OS, PFS, and DCR were consistent with the clinical hypothesis, suggesting potential benefit in a subset of patients. Clinical trial information: jRCTs031190104. Research Sponsor: Japan Agency for Medical Research and Development; Health and Labour Sciences Research Grant.

3112 **Poster Session**

Updated efficacy and safety of zurlectrectinib in adult patients (pts) with locally advanced or metastatic NTRK fusion–positive (NTRK+) solid tumors. First Author: Dan-yun Ruan, Department of Clinical Research, Sun Yat-Sen University Cancer Center, State Key Laboratory of Oncology in South China, Guangzhou, China

Background: NTRK gene fusion is one of the most defined driving factors of carcinogenesis, which occurs in various adult tumor types. Zurlectrectinib, a highly selective next-generation TRK tyrosine kinase inhibitor, previously demonstrated encouraging efficacy and manageable toxicity in pts with NTRK+ tumors in a phase I/II clinical trial (NCT04685226). The pivotal phase II clinical trial (NCT05745623) is currently ongoing. Here we present the integrated results of adult pts from both trials. **Methods:** Pts with locally advanced or metastatic solid tumors, who failed from clinical standard of care or for whom there was currently no effective therapy, were enrolled in this study. The primary endpoint was confirmed objective response rate (ORR) per independent review committee (IRC). Tumor responses were assessed by IRC and investigators per RECSIT1.1 and RANO (BM) criteria. Treatment-emergent adverse events were evaluated and graded according to CTCAE v5.0. **Results:** As of 23 Nov 2024, a total of 229 adult pts were enrolled in the two trials. Forty-nine TRK inhibitor naïve adult pts were evaluable for efficacy representing 12 different solid tumor types. Among the efficacy population, the distribution of NTRK1, NTRK2 and NTRK3 fusions was 53.1%, 2.0% and 44.9% respectively. The median age was 51.0 years (range: 18-77). Pts had received a median of two prior lines of systemic therapies, with ECOG performance status between 0-1. Median follow-up was 11.7 months. The confirmed ORR by IRC was 83.7% (95% CI: 70.3, 92.7), 5 pts (10.2%) with complete response. Median duration of response (DOR) and median progression-free survival (PFS) by IRC were not reached. The DOR rate and PFS rate by IRC at 12 months was 92.0% and 90.5%, respectively. Two of the three pts (66.7%) who had brain metastasis at the baseline achieved intracerebral ORR, which is consistent with the good brain penetration and strong intracranial activity of zurlectrectinib. In the safety population of adults (N = 229), treatment-related adverse events (TRAEs) were predominantly grade 1 or 2. The most common TRAEs (≥20%) were anemia (28.4%), increased alanine transferase (27.9%) and increased aspartate transferase (25.8%). Grade ≥3 TRAEs (≥2%) were weight gain (3.5%) and dizziness (2.2%). No Serious TRAEs occurred in ≥2% pts. TRAEs led to dose interruption, reduction and discontinuation in 9.2%, 3.9% and 0.4% of safety population, respectively. **Conclusions:** In line with previously reported results, zurlectrectinib continued to demonstrate a deep and durable responses in adult pts with NTRK+ advanced solid tumors with or without brain metastasis. Zurlectrectinib was also well-tolerated and showed favorable safety profile in adult pts with various tumor types. Clinical trial information: NCT05745623. Research Sponsor: None.

Discovery of potent degraders of pan-KRAS based on a novel KRAS binder. First Author: Wei Sun, Global Drug R&D Center, Huadong Medicine Company Limited, Hangzhou, China

Background: As the most frequently mutated oncogene, KRAS alteration occurring in approximately 25% of all malignancies. Despite extensive efforts, targeting KRAS has proven to be challenging due to its structure and complex function. Recently, direct $KRAS^{G12C}$ inhibitors, such as Sotorasib and Adagrasib have occurred first successes. However, therapeutic approaches targeting other variants beyond G12C are under significant unmet needs. Recent developments in protein degradation technologies, such as Proteolysis-Targeting Chimeras (PROTACs), bring new hope for targeting pan KRAS. Based on our novel warheads, potent pan-KRAS degraders were designed and synthesized. **Methods:** The ability of compounds to degrade KRAS protein was evaluated using western blotting. The anti-tumor efficacy was assessed *in vitro* through different mutant cell lines. As a proof of concept study *in vivo*, an experiment in subcutaneous xenograft mouse model was performed. Pharmacokinetic studies were conducted in mice, with serial blood samples analyzed by (LC−MS)/MS. **Results:** A novel series of warheads exhibiting exceptional enzymatic and cellular activity against pan-KRAS has been successfully obtained. Based on these warheads, more than 100 degraders were meticulously designed and synthesized incorporating a diverse array of linkers and E3 ligands. Through a comprehensive evaluation, two series of compounds have demonstrated a remarkable KRAS degradation property and downstream inhibition at concentrations below 10 nM in $SW620^{G12V}$ and $GP2D^{G12D}$ cells. Cell proliferation assay demonstrated that the IC_{50} values of these degraders are ranging from 0.01 to 30 nM in the MIA $PaCa\text{-}2^{G12C}$, $GP2D^{G12D}$ $SW620^{G12V}$ and $LOVO^{G13D}$ cell lines, without affecting the viability of KRAS-independent cell lines (selectivity $>$ 500-fold). These compounds also possess favorable PK properties in mice (clearance $<$ 10 mL/min/kg; IV, 2 mpk, AUC $>$ 5000 ng·hr/mL) and good safety profile (hERG IC_{50} $>$ 30 μM). Moreover, these compounds showed strong antitumor activity in xenograft mouse model *in vivo*. **Conclusions:** The innovative linker elongation and branching, coupled with modifications of KRAS binder portion significantly contributed to potent pan-KRAS degraders, which demonstrate excellent pharmacokinetics and exhibit remarkable efficacy both in vitro and in vivo. The IND-enabling studies are being conducted and the regulatory IND filing will be completed in 2025. Research Sponsor: None.

Development and validation of a biology-based novel therapeutic agent targeting the LIN28/*let-7* pathway in cancer. First Author: Patrick Sipila, University of Calgary, Calgary, AB, Canada

Background: Currently, brain tumors that are diagnosed in infants and young children carry an exceptionally high risk for treatment resistance and toxicities. The LIN28 family of RNA-binding proteins regulate stem cell biology and pluripotency. In addition to embryonic development, they have also been implicated in oncogenesis through interaction with the tumor suppressor micro-RNA (miRNA), *let-7*. In cancer, LIN28 expression leads to *let-7* loss-of-function, oncogenic activation, and tumorigenesis. Importantly, LIN28 expression has been associated with stemness and subsequent tumor aggressiveness and poor survival in early childhood brain tumors. Thus, LIN28 may offer an effective therapeutic strategy to prevent relapse by specifically targeting cancer stem cells. In this study, we describe a novel therapeutic inhibitor of LIN28 in cancer. **Methods:** Using an *in silico* approach, we designed and synthesized a panel of novel compounds predicted to bind and inhibit the critical molecular interaction between LIN28 and *let-7*. Cytotoxicity was evaluated by alamar blue viability assay in a panel of LIN28-positive cancer cell lines derived from atypical teratoid rhabdoid tumor (ATRT), embryonal tumor with multilayered rosettes (ETMR), and germ cell tumor. LIN28-negative cells were used as control. LIN28 protein expression and *let-7* miRNA levels were determined by immunoblot and reverse transcription quantitative polymerase chain reaction (RT-qPCR), respectively. Self-renewal capacity was analyzed by sphere formation assay. Mice carrying xenografts were treated to investigate LIN28 inhibition *in vivo*. **Results:** Preliminary screening of small molecule inhibitors identified a lead compound, designated THNB-3, that induces cell death at micromolar concentrations in LIN28-positive cell lines established from various tumors, without affecting LIN28-negative controls. Treatment with THNB-3 increased the level of *let-7* tumor suppressor, confirming effective inhibition of LIN28. In addition to cytotoxicity, THNB-3 significantly inhibited sphere formation in brain tumor cells, reducing self-renewal and multipotency of cancer stem cells. Lastly, the anticancer activity of THNB-3 was validated *in vivo* against LIN28-positive xenografts and the drug also demonstrated systemic tolerability in mice. **Conclusions:** Our studies provide the first evidence for an effective, targeted therapeutic agent against the LIN28/*let-7* pathway for the treatment of cancer in the future. THNB-3 selectively induces cytotoxicity in LIN28-positive cancers by restoring *let-7* miRNA, confirming effective target modulation. Further, LIN28 inhibition by THNB-3 may reduce self-renewal and multipotency of cancer stem cells. Together, our preclinical data supports further development of THNB-3 for the treatment of high-risk LIN28-positive tumors. Research Sponsor: Kids Cancer Care Foundation of Alberta.

A first-in-human, phase 1a/b, dose-escalation/expansion study of BG-68501, a selective CDK2 inhibitor, as monotherapy or in combination with fulvestrant for patients with HR+/HER2- breast cancer and other advanced solid tumors: First disclosure of clinical data. First Author: Rohit Joshi, Cancer Research SA, Adelaide, Australia

Background: CDK2 inhibition could represent a novel treatment (tx) option for patients (pts) with resistance to CDK4/6 inhibitors (CDK4/6i) and/or increased cyclin E1 activity. BG-68501 is a highly potent CDK2 inhibitor with high CDK2 selectivity (~100x) vs other CDK family members. We present dose-escalation data of BG-68501 as monotherapy or in combination with fulvestrant in pts with HR+/HER2- metastatic breast cancer (BC) and advanced solid tumors (NCT06257264). **Methods:** This is the dose-escalation phase of a first-in-human, phase 1a/b, open-label, multicenter study to evaluate the safety/tolerability, pharmacokinetic (PK), and pharmacodynamic (PD) profiles, and preliminary antitumor activity of BG-68501 in pts with advanced, nonresectable, or metastatic solid tumors, including HR+/HER2− BC. During dose escalation, sequential cohorts received increasing doses of BG-68501 as monotherapy or in combination with fulvestrant. Eligible pts are ≥18 yrs, with histologically or cytologically confirmed advanced or metastatic solid tumors associated with CDK2 dependency who have received ≥1 line of tx for advanced or metastatic disease and prior endocrine therapy and a CDK4/6i in either the adjuvant or advanced or metastatic setting for HR+/HER2− BC, or prior standard of care for all other advanced solid tumors. **Results:** As of Jan 22, 2025, 41 pts (median age 63 yrs) have been enrolled. Eleven pts had BC (all received prior CDK4/6i), 12 had ovarian cancer (OC), 7 had endometrial cancer, and the remaining 11 pts had other tumor types. To date, 6 dose levels (DLs) of BG-68501 monotherapy and 1 DL in combination with fulvestrant have been assessed. The median duration of exposure is 1.5 months. Treatment-emergent adverse events occurred in 39 pts (95.1%; grade ≥3, 26.8%), with the most common being nausea (56.1%; grade ≥3, 0%), vomiting (48.8%; grade ≥3, 0%), and fatigue (24.4%; grade ≥3, 0%); no DLTs have been observed. BG-68501 demonstrated a linear PK profile with clinical characteristics consistent with preclinical predictions; signs of TK1 reductions have been observed across DLs tested, including in heavily pretreated pts. Of the 24 efficacy-evaluable pts, 1 extensively pretreated HR+/HER2− BC pt experienced PR and 10 pts showed SD. Dose escalation is ongoing for both monotherapy as well as in combination with fulvestrant. **Conclusions:** BG-68501 demonstrates a favorable safety/tolerability profile, with no DLTs observed to date during dose escalation. Extensively pretreated patients achieving PR and SD with monotherapy, coupled with signs of PD responses and a favorable safety profile, support continued assessment of BG-68501; updated clinical data will be presented at the time of the conference. Clinical trial information: NCT06257264. Research Sponsor: BeiGene, Ltd.

Efficacy and safety of pralsetinib in *RET* fusion-positive solid tumors: Final data from the ARROW trial. First Author: Vivek Subbiah, University of Texas MD Anderson Cancer Center and Sarah Cannon Research Institute, Nashville, TN

Background: Pralsetinib is an oral tyrosine kinase inhibitor that selectively and potently targets oncogenic RET fusion and mutation proteins. *RET* fusions or mutations are present in various tumor types. We report the final results from the phase 2 portion of ARROW, a phase 1/2, open-label, multicohort, dose-expansion study evaluating the efficacy and safety of pralsetinib (NCT03037385) in patients with *RET* fusion-positive solid tumors other than non-small-cell lung cancer (NSCLC) and thyroid cancer. **Methods:** Eligible pts were ≥18 years of age with a pathologically documented, definitively diagnosed advanced solid tumor with an oncogenic *RET* fusion or mutation, had previously received standard of care appropriate for their tumor type, and were not eligible for any other study groups. Overall response rate (ORR) and safety were primary endpoints of the study. Key secondary endpoints included duration of response (DOR), progression-free survival (PFS), and overall survival (OS). The final database lock was May 20, 2024. **Results:** Twenty-nine patients were enrolled with 11 different solid tumor histologies. Twenty-six (90%) received prior systemic therapy. Median age was 58 years (range 25-75); 59% were female. Twenty-eight patients were included in the efficacy analysis. ORR (by RECIST) was 46.4% (13/28); 10.7% (3/28) achieved complete response (pancreatic cancer, n=2; cancer of unknown primary, n=1) and 35.7% (10/28) achieved partial response. Median PFS was 7 months (95% CI: 3.9, 12.8). Median DOR was 11.1 months (95% CI: 5.5, 25.1). Median OS was 10.3 months (95% CI: 6.8, 25.2). Twenty-five (86%) patients experienced treatment-related adverse events (TRAEs); 19/29 (66%) reported TRAEs ≥grade 3. The most common TRAEs included increased aspartate aminotransferase (11/29; 38%), increased alanine aminotransferase (10/29; 35%), and anemia (9/29; 31%). Four (13.8%) patients experienced hypertension, and 1 (3.4%) patient had ≥grade 3 hypertension. No new safety risks were identified; AEs remained manageable with supportive care and/or dose modifications. **Conclusions:** In the phase 2 portion of this trial, responses were observed in many tumor types (Table). Pralsetinib demonstrated robust and durable anti-tumor activity with an ORR of 46.4%. These data validate *RET* fusions as a tissue-agnostic target with sensitivity to RET inhibition and activity beyond NSCLC and thyroid cancer, further supporting the promising potential of pralsetinib to address the unmet medical need in these patients. Clinical trial information: NCT03037385. Research Sponsor: Blueprint Medicines; Genentech/Roche; Rigel Pharmaceuticals, Inc.

Overall response rate by tumor type.

Cancer Type (patient n)	ORR n (%)
Pancreatic (5)	5 (100)
Cancer of unknown primary (1)	1 (100)
Neuroendocrine (3)	2 (67)
Sarcoma (3)	2 (67)
Head and neck (2)	1 (50)
Small cell lung (2)	1 (50)
Hepatobiliary (4)	1 (25)
Colorectal (5), gastric (1), ovarian (1), thymic (1)	0

Exploring the efficacy and mechanism of action of combined pan-Raf and MEK inhibition in halting the growth of non-V600 BRAF mutated tumors. First Author: Islam E. Elkholi, Lady Davis Institute, Sir Mortimer B. Davis Jewish General Hospital, Montreal, QC, Canada

Background: Class 2 & 3 non-V600 BRAF mutations mediate RAF dimerization to hyperactivate the MAPK signaling pathway. Encorafenib (Enco; BRAF monomer inhibitor) + Binimetinib (Bini; MEK inhibitor) elicit responses in $<$15% of patients with non-V600E BRAF mutations (NCT03839342). We hypothesized that Belvarafenib (Belva), a novel pan-RAF dimer inhibitor, is more potent than Enco in inhibiting the growth of Class 2 & 3 non-V600 BRAF mutated tumors. **Methods:** We performed *in vitro* colonogenic assays to compare the growth inhibitory effect of 5 independent doses of individual inhibitors (Bini, Belva, or Enco) in parallel to 25 different combinations of either Belva+Bini or Enco+Bini in 6 non-V600 BRAF mutated melanoma (WM3629, HMV-II), colorectal (CRC) (NCI-H508, HT55), and lung (NCI-H1666, NCI-H2087) cancer cells. Low nanomolar doses (10-1000 nM) were used to investigate the synergistic potential of either combination using the SynergyFinder tool. Belva+Bini (15 mg/kg each) and Enco+Bini (75 mg/kg + 15 mg/kg) combinations were assessed in 4 non-V600 BRAF (3 Class 3, 1 Class 2) metastatic CRC patient-derived xenograft (PDX) models. The inhibitory effect of Belva and Enco on MAPK activity in the outlined 6 cell lines was assessed by immunoblotting. Transcriptomic (RNA-Seq) analysis was performed on PDXs. **Results:** Belva+Bini was 2-6-fold more effective than Enco+Bini in inhibiting the growth of the 6 cell lines. Belva+Bini achieved overall higher synergy scores in the 6 cell lines and was synergistic in 5/6 cell lines (synergy score $>$ 10) vs. Enco+Bini that was synergistic in 1/6 cell lines. In the 6 cell lines, Belva inhibited MAPK activity more robustly than Enco (assessed by pERK levels). *In vivo*, Belva+Bini was significantly more effective than vehicle or Enco+Bini in halting the growth of 3 out of 4 PDXs. Both Belva+Bini and Enco+Bini significantly inhibited MAPK activity vs. vehicle (as assessed by the transcriptional MAPK Pathway Activity Score). However, there was no statistically significant difference between both combinations. Gene Set Enrichment Analysis revealed that Belva+Bini significantly downregulated genes mediating the interconnected mTORC1 pathway activity and cholesterol metabolism dynamics in the 3 PDXs where Belva+Bini had anti-growth effect. Specifically, among the top downregulated genes by Belva+Bini was *PCSK9*, a druggable key regulator of cholesterol metabolism. **Conclusions:** These results from 10 preclinical models, tested so far, put forward combined Pan-Raf and MEK inhibition as a potential effective treatment choice for patients with non-V600 BRAF mutated tumors to be investigated in clinical trials. In parallel, they unravel novel insights into the mechanism of action of this therapeutic approach and in return the druggable vulnerabilities of the non-V600 BRAF mutated tumors, a notion we are further investigating in the outlined models. Atropisomeric pyrrolopyrimidine inhibitor as a targeted approach for RET tyrosine kinase in neuroblastoma. First Author: Ananya Bharathwaj, UCSD, La Jolla, CA

Background: Increased RET expression is associated with poor prognosis in children with solid tumors such as neuroblastoma (NB), prompting an interest in RET inhibition. A number of kinase inhibitors currently in use for cancer patients have RET inhibitory activity, but these inhibitors also display activity against other kinases, resulting in unwanted side effects and limiting their safety and efficacy. However, developing more specific RET inhibitors remains a drug design challenge due to high levels of conservation between kinase binding pockets. Using novel chiral chemistry leveraging atropisomerism to convert a promiscuous, rapidly interconverting pyrrolopyrimidine compound into an atropisomerically stable analog, we have developed a new atropisomerically stable, highly selective and specific RET inhibitor, getretinib, with similar potency and improved selectivity to that of other next generation RET inhibitors but with half the molecular weight and significantly improved ligand efficiencies towards RET. **Methods:** Associations of gene expression with patient survival and prognostic features were performed on available neuroblastoma tumor databases using the R2 Genomics Analysis and Visualization Platform. The efficacy of RET inhibition was assessed against a panel of NB cell lines using live cell imaging and cell viability assays, comparing results with the active and selective RET kinase inhibitor, (R)-getretinib to results with the inactive atropisomer, (S)-getretinib. Mechanisms of cell death and impacts on RET signaling in cells treated with (R)- and (S)-getretinib were evaluated by Western blots. **Results:** (R)-getretinib reduced NB cell confluence in a dose-dependent manner, while (S)-getretinib had no significant effect on cell confluence over time. R-getretinib treatment of NB cells resulted in reduced phosphorylation of RET in a dose-dependent manner, while treatment with (S)-getretinib resulted in paradoxical increase in RET phosphorylation. **Conclusions:** We present (R)-getretinib as an atropisomerically stable and potent inhibitor of RET and have shown its efficacy in *in vitro* models of NB. The high selectivity of (R)-getretinib towards RET has the potential to minimize unwanted side effects caused by off-target kinase binding, thereby increasing its potential for clinical utility. Combined RAF- and MEK-inhibition in solid cancers with kinase-impaired BRAF mutations (SORATRAM phase I trial). First Author: Anna Lena Illert, Center for Personalized Medicine (ZPM) Technical University of Munich (TUM) and Department of Medicine III, TUM University Hospital, Technical University of Munich (TUM) and German Cancer Consortium (DKTK), Munich Partner Site, Munich, Germany

Background: *BRAF* is a frequently mutated gene in cancer, with most mutations (mut) at the activating hotspot V600 codon. Recently, kinase-inactive class III *BRAF* mut emerged as oncogenic driver and potential therapeutic target, as they lead to paradoxical cross-activation of RAF1- and RAS-dependent downstream signaling. Here we report the Phase I toxicity results of combinatory inhibition of RAF kinases by sorafenib (S), a multi-kinase inhibitor (e.g. RAF1, BRAF, c-KIT, FLT-3) and MEK/ERK signaling by trametinib (T) in patients (pts) with inactivating *BRAF* mut. **Methods:** SORATRAM is a prospective, molecularly stratified, multicenter phase I trial. Primary objective is to determine the maximal tolerated dose (MTD) of T combined with S and the recommended phase II dose (RP2D). Adult pts with metastatic malignancies, confirmed or known impaired kinase *BRAF* mut (according to *in vitro* testing), ECOG $\leq$ 2 and no available therapy options were eligible. S was given in the approved dose (800 mg) from day (d)1 cycle (c)1, combined with T on c1d8 for max 12c or until progression or unacceptable toxicity. Dose levels (DL) are defined by T dose (0.5mg DL1, 1.0mg DL2 and 1.5mg DL3) and escalated in a conventional 3 + 3 design. MTD is defined as highest dose at which 0/3 pts or $<$ 2/6 pts experience a dose limiting toxicity (DLT) during c1. DLT is defined as toxicity related to S+T combination, unrelated to disease progression, intercurrent illness or concomitant medications, that requires dose reduction or drug withdrawal. **Results:** Since 2020, 236 cases from 9 sites were classified for mutational SORATRAM eligibility with 42% being kinase impaired (e.g. D594G, N581I, G466E), 21% known intermediate/high activity (excluding V600E/K) (e.g. L597V, K601E) and 36% with novel/unclear/unknown kinase activity (e.g. G469I, W531S). Eligible pts with inactivating *BRAF* mut proceeded to SORATRAM screening. 15 pts received dose finding treatment: 3 in DL1 and DL2 and 9 in DL3. Median age was 57 years (34-75) with 12f/3m pts. Included entities were colorectal cancer (60%), duodenal carcinoma/carcinoma of papilla vateri (20%), lung adenoid cystic carcinoma (6.7%), bone sarcoma (6.7%) and ovarian cancer (6.7%). 3/3 pts in DL1 and DL2 and 6/9 pts at DL3 fulfilled the minimum safety evaluation requirements ($\geq$ 80% of S+T doses in c1; 28ds observation). No DLT was observed in DL1 and DL2. 1/6 pts in DL3 developed a DLT (reduction of left ventricular ejection fraction (LVEF)). 5/15 pts (33.3%) experienced grade 3 adverse events (AEs) during c1: Hypertension (13.3%), gastrointestinal bleeding (6.7%; rated as SAE), anemia (6.7%), LVEF reduction (6.7%), diarrhea (6.7%) and fatigue (6.7%). 79 AEs grade 1/2 were reported in c1. **Conclusions:** Combination of sorafenib/ trametinib is feasible and can be safely administered to pts. MTD was determined as DL3 (800mg S + 1.5mg T), RP2D as DL2 (800mg S + 1mg T). Dose expansion part of SORATRAM is open for enrollment. Clinical trial information: EU – CT No. 2024-512887-77-00. Research Sponsor: German Cancer Consortium (DKTK); German Cancer Consortium (DKTK) Freiburg site; Sorafenib was kindly supplied by Bayer.

Safety and efficacy of a small-molecule c-Myc degrader WBC100 in solid tumors: A first-in-human, phase I trial. First Author: Qi Zhang, Department of Hepatobiliary and Pancreatic Surgery, The First Affiliated Hospital, Zhejiang University School of Medicine, Hangzhou, China

Background: *c-Myc* amplification or overexpression is involved in the development and progression of many human cancers, and is often associated with poor outcomes. It is an extraordinarily desirable target, but is also considered undruggable. WBC100 is an oral active molecule glue that selectively degrades c-Myc protein. **Methods:** This is a first-in-human, dose-escalation study conducted in China. Patients with solid tumors that have progressed or relapsed after standard systemic therapy were enrolled. WBC100 was orally administered every other day (QOD) according to 3+3 design. The primary endpoints were safety, dose-limiting toxicity (DLT) and maximal tolerated dose (MTD). **Results:** As of Dec 9, 2024, 28 patients were enrolled in seven dose levels (DLs) from 0.5 to 3.5 mg. The median age was 59 (range, 45-71) years, comprising 15 males and 13 females. Three (11%) patients had an ECOG PS score of 0, while the remaining 25 (89%) had a score of 1. The median number of prior systemic therapy lines was 3 (range, 1 to 6). One DLT of prolonged QT interval was observed in DL7, and MTD has not been reached. Six patients (21%) experienced grade 3 or higher treatment-related adverse events, including five (17.9%) neutropenia and two (7.1%) leukopenia and one (3.6%) prolonged QT interval. Increased aspartate aminotransferase, thrombocytopenia, proteinuria, increased alanine aminotransferase, fatigue, nausea, anemia, and hypoalbuminemia were the most commonly reported grade 1 or 2 adverse events. Nineteen patients were evaluable for efficacy, one (5.3%) showed partial regression (PR), and six (31.6%) showed stable disease (SD), including two patients with hepatocellular carcinoma, one with duodenal adenocarcinoma, and three with pancreatic cancer. Notably, we enrolled eight patients with pancreatic cancer at DL6 and DL7, and six of them were evaluable for efficacy, with one (16.7%) PR and two (33.3%) SD. **Conclusions:** WBC100 showed a tolerable safety profile and preliminary anti-tumor activity in advanced solid tumors especially in PDAC. Dose escalation is ongoing and expected to proceed to dose expansion soon. To our knowledge, this is the first study of a small-molecule c-Myc degrader for further clinical development in cancer. Clinical trial information: NCT05100251. Research Sponsor: Weben Pharma.

In vitro efficacy of CDK9 inhibitor tambiciclib (SLS009) in ASXL1 mutated colorectal cancer cell lines. First Author: Dragan Cicic, Sellas Life Sciences Group, New York, NY

Background: ASXL1 (Additional sex combs-like 1) gene encodes ASXL1 protein thought to disrupt chromatin, enhancing transcription of certain genes while repressing the transcription of others. ASXL1 mutations occur in ~20% of acute myeloid leukemia (AML) patients and ~50% of ASXL1 AML mutations are frameshift or nonsense mutations generating a truncated ASXL1 form with oncogenic gain of function in AML. Recently ASXL1 mutated AML patients were treated with a CDK9 inhibitor tambiciclib (SLS009) with promising results. ASXL1 mutations were also reported in 55% of Colorectal Carcinoma with High Microsatelite Instability (CRC MSI-H) cell lines, but it is not known whether those mutations are similar to ASXL1 mutations observed in AML and whether CDK9 inhibitors have enhanced cytotoxic effect in CRC MSI-H cells with those mutations. **Methods:** Twelve CRC MSI-H cell lines were treated with SLS009 at various concentrations. Staurosporin was used as positive control. Cytotoxicity analysis was performed by CellTiter-Glo 2.0 assay. Data analyses were performed using GraphPad Prism 9. NGS was used to determine mutations in studied cell lines. The experiment was designed to compare ASXL1 mutations in CRC MSI-H cell lines to those observed in AML and determine efficacy of SLS009 cytotoxicity in CRC MSI-H cells with and without ASXL1 mutations. Highly effective concentrations in this experiment were considered those with IC50 values below 100 nM. **Results:** Among the 12 tested cell lines, 8 (67%) had non-synonymous ASXL1 mutations of any kind, similar to the literature reported 55% ASXL1 mutations rate in CRC MSI-H. Among cell lines with ASXL1 mutations, 4 (50%) had high impact frameshift mutations, similar to estimated rate of high impact frameshift mutations in AML (~50%). Among cell lines with high impact frameshift mutations, all had mutations in protein position regions 581-582 and 642-643. Three out four had in addition high impact frameshift mutations in the region of protein position 637-638. Protein positions of these frameshift ASXL1 mutations were similar to those observed in AML (591 – 592 and 635 – 646). Among the cell lines with any ASXL1 mutation, 4/8 (50%) had IC50 values for SLS009 below 100 nM (highly efficacious) vs 0/4 (0%) among cell lines without ASXL1 mutations. Among cell lines with ASXL1 frameshift mutations, SLS009 was highly efficacious in 3/4 (75%) cell lines vs 1/8 (12.5%) in cell lines without ASXL1 frameshift mutations. High efficacy was observed in all cell lines (3/3, 100%) with frameshift mutations in the protein position region 637-638. Presence of high impact TP53 mutations did not appear to significantly affect SLS009 efficacy. **Conclusions:** Results indicate that ASXL1 mutations may be oncogenic drivers in some solid tumors, like CRC MSI-H, similar to those in AML and that efficacy of CDK9 inhibition with SLS009 may be similar in some solid tumors to the efficacy observed in AML. Research Sponsor: None.

3122 **Poster Session**

Safety and efficacy of EIK1003, a selective PARP1 inhibitor, as monotherapy in participants with advanced solid tumors. First Author: Guru P. Sonpavde, AdventHealth Cancer Institute, Orlando, FL

Background: PARP inhibitors (PARPi) selectively kill tumor cells with genetic mutations in critical DNA repair genes (eg, BRCA1/2). While approved nonselective PARPi may provide antitumor activity, they are associated with hematologic toxicities. Drugs inhibiting PARP1 but not PARP2 may improve the risk-benefit profile by retaining antitumor activity while avoiding PARP2-related toxicities. EIK1003 (IMP1734) is a potent PARP1-selective inhibitor that may widen the therapeutic index in susceptible tumors. **Methods:** EIK1003-001 (IMP1734-101) is an ongoing global, multi-center, Phase 1/2 study evaluating the safety and efficacy of EIK1003 (once daily oral) as monotherapy or in combination with anticancer agents in participants (pts) with advanced solid tumors (NCT#06253130). Pts must be $\geq$ 18 yrs with deleterious or suspected deleterious mutations in select homologous recombination repair genes. This abstract reports the interim safety and efficacy from Part 1 monotherapy (dose escalation). **Results:** At the data cut (10 Jan 2025), 32 pts were treated in the first 4 completed dose levels (DLs; n = 3 to 15 per DL, including backfill) of monotherapy dose escalation. There were no dose-limiting toxicities and a maximum tolerated dose has not been reached. The majority (29/32) of pts were female. Pts had a median age of 60 years (31 to 76), and cancers represented included ovarian (n = 15), HER2-negative breast (n = 10), pancreatic (n = 3), fallopian tube (n = 2), and prostate cancer (n = 1). Pts received a median of 3 (range 1 to 11) prior lines of therapy for metastatic disease with 50% receiving prior PARPi. To date, EIK1003 demonstrated a tolerable safety profile. All pts experienced at least one treatment-emergent adverse event (TEAE), and 13/32 experienced at least one $\geq$ Grade 3 TEAE. 27/32 pts experienced a treatment-related AE (TRAE), 6 of which experienced a $\geq$ Grade 3 TRAE. Hematologic toxicities (Grade 3) included neutropenia (3/32) and anemia (1/32). 7/32 experienced a serious adverse event (including one related case of Grade 3 vomiting). There were no Grade 4 AEs or deaths due to AE, and no trends in AEs by DL were observed. EIK1003 PK was linear, with a half-life $>$ 24 hours. Of the 13 ovarian cancer patients with post-treatment scan assessments, 3 experienced partial response (PR; one each at DL2, DL3, and DL4) and 3 experienced stable disease (SD; one at DL1 and two at DL3) by RECIST v1.1. For these 3 PRs, all had a CA125 response. Of the 6 breast cancer patients with post-treatment scan assessments, there was 1 PR (DL3) and 1 SD (DL1) via RECIST v1.1. **Conclusions:** To date, EIK1001 has demonstrated tolerable safety and encouraging preliminary efficacy. Dose escalation is ongoing. Updated safety and efficacy data will be reported at the time of presentation. Clinical trial information: 06253130. Research Sponsor: None.

A first-in-human phase I/Ib study of ATG-037 monotherapy and combination therapy with pembrolizumab in patients with advanced solid tumors: STAMINA-01. First Author: Janine Margaret Lombard, Calvary Mater Hospital Newcastle, Newcastle, NSW, Australia

Background: ATG-037 is a highly potent oral small molecule inhibitor of CD73. STAMINA-01 is an open-label, first-in-human, phase 1/1b study (NCT05205109) designed to evaluate the safety, pharmacokinetics, and optimal dosing of ATG-037 as monotherapy and in combination with pembrolizumab in patients with refractory/relapsed solid tumors. **Methods:** The study successfully completed enrollment of dose escalation of ATG-037 with optional addition of pembrolizumab following two cycles of monotherapy in May 2024. The primary objectives were to evaluate the safety and define the optimal biological dose of ATG-037 as monotherapy and combination treatment. As of 20 January 2025, 43 patients were enrolled across the following doses - 20mg BID (n=3), 60mg BID (n=6), 120mg BID (n=10), 240mg BID (n=6), 400mg BID (n=12) and 600mg BID (n=6). The trial is currently recruiting the second part of the study for dose optimization of upfront combination therapy at two dose levels (120mg BID and 400mg BID). **Results:** *Efficacy:* As of the data cut-off (20 Jan 2025), 43 patients were enrolled on study and received monotherapy. While on ATG-037 monotherapy, 21 patients had a best response of stable disease (SD) with a disease control rate (DCR) of 49%. Twenty-eight patients with a history of acquired checkpoint inhibitor resistance received combination therapy; 7 of which (5 melanoma and 2 NSCLC patients) achieved a confirmed partial response (PR) with an overall response rate (ORR) of 25% (95% CI: [51.33, 86.78]). Additionally, 15 patients had a best response of SD with a DCR of 79% (95% CI: [8.30, 40.95]). Of the 11 enrolled melanoma patients who received combination, 5 achieved a PR for an ORR of 45% and 6 achieved SD for an DCR of 100%. Of the 9 enrolled NSCLC patients who received combination, 2 achieved a PR for an ORR of 22% and 4 achieved SD for an DCR of 67%. *Safety:* While on monotherapy, 24/43 (56%) patients reported treatment-related adverse events (TRAEs). While on combination therapy, 17/28 (61%) patients reported TRAEs. The majority of TRAEs were grades 1-2. The only dose limiting toxicity was a grade 3 rash which occurred at the monotherapy 400mg BID dose. Only one serious TRAE (grade 3 immune mediated hepatitis) was reported at the data cut-off. **Conclusions:** In relapsed/refractory solid tumor patients, ATG-037 appears to be well tolerated as monotherapy and in combination with pembrolizumab. The preliminary efficacy data is encouraging and suggests that the combination regimen may provide a new therapeutic option for CPI resistant NSCLC and melanoma patients. Clinical trial information: NCT05205109. Research Sponsor: None.

3124 **Poster Session**

Phase 1 study of zavondemstat (TACH101), a first-in-class KDM4 inhibitor, in patients with advanced solid tumors: Results on safety, pharmacokinetics, and anti-tumor activity. First Author: Apostolia Maria Tsimberidou, University of Texas MD Anderson Cancer Center, Houston, TX

Background: Zavondemstat is an epigenetic targeting inhibitor of KDM4 histone demethylase. Dysregulation of KDM4 enzymes (isoforms A-D) has been implicated in various cancers where they drive oncogenesis and resistance pathways by regulating gene transcription. Preclinical studies of zavondemstat demonstrated robust anti-proliferative effects and significant inhibition of tumor growth across numerous xenograft and PDX models. Targeting KDM4 offers the potential to reprogram the epigenetic dysfunction of cancer cells and inhibit drivers of tumor dedifferentiation and proliferation leading to apoptotic cell death. This is the first clinical evaluation of a pan-isoform KDM4 inhibitor. **Methods:** TACH101-CS-0001 (NCT05076552) was an open-label Phase 1 study assessing zavondemstat's safety, tolerability, pharmacokinetics (PK), and recommended Phase 2 dose (RP2D) in patients (pts) with advanced solid tumors. Pts received zavondemstat orally on a weekly schedule in 28-day cycles. Dose escalation followed a Bayesian optimal interval (BOIN) design and explored both intermittent and continuous dosing. Inclusion criteria included heavily pre-treated advanced/metastatic solid tumors that progressed or were non-responsive to available therapies and for which no standard therapy exists. Pts must have measurable disease according to RECIST (v1.1) and ECOG score of 0 to 1. Exclusion criteria included severe hematologic, hepatic, or renal insufficiency. Primary endpoints included safety/tolerability, MTD and RP2D. Secondary endpoints included PK and radiographic response per RECIST v1.1. **Results:** Thirty patients were enrolled across 6 dose cohorts. MTD was not reached; RP2D was not determined. The most common treatment-related adverse events (TRAEs) were diarrhea (12%), fatigue (7%), decreased appetite (7%), nausea (7%), and hyponatremia (7%). All TRAEs were Grade 1 or 2 (no TRAEs $\geq$ Grade 3 were reported). No treatment-related serious adverse events (SAEs) or dose limiting toxicities (DLTs) were reported. In 23 response-evaluable patients, 10 patients (44%) achieved stable disease (SD) across dosing cohorts. Two patients (9%) had SD $\geq$ 6 months, including a patient with castration-resistant prostate cancer (CRPC) and a patient with leiomyosarcoma. Another patient with leiomyosarcoma is continuing to receive zavondemstat under compassionate use, demonstrating SD for a total of 6 months at time of abstract submission. Zavondemstat demonstrated a dose-proportional exposure profile with a short half-life of about 1.5 hours. There was no to minimal drug accumulation observed. **Conclusions:** Zavondemstat was very well tolerated and showed encouraging preliminary signals of clinical benefit in very heavily pre-treated metastatic cancer patients. Continued evaluation of zavondemstat is warranted. Clinical trial information: NCT05076552. Research Sponsor: Tachyon Therapeutics; California Institute for Regenerative Medicine (CIRM).

3125 **Poster Session**

Phase I dose-escalation study of the safety and pharmacokinetics of PAS-004, a macrocyclic MEK inhibitor, for the treatment of patients with MAPK pathway–driven advanced solid tumors. First Author: Tiago Reis Marques, Pasithea Therapeutics Corp, Miami, FL

Background: PAS-004 is a small molecule allosteric inhibitor of MEK 1/2 and the first macrocyclic structure MEK inhibitor in clinical development. Macrocycles are large cyclic molecules that can bring increased potency, metabolic stability, and oral bioavailability. PAS-004 was developed to reduce metabolic liabilities and overcome the limited exposure and stability of known MEK inhibitors. We report initial results of an ongoing Phase I dose escalation, multicenter study of PAS-004 in monotherapy in patients with advanced refractory solid tumors. **Methods:** The Phase 1 clinical trial is a multi-center, open-label, dose escalation 3+3 study design to evaluate the safety, tolerability, pharmacokinetic (PK), pharmacodynamic (PD), and preliminary efficacy of PAS-004 in patients with MAPK pathway driven advanced solid tumors with a documented RAS, NF1 or RAF mutation, or patients who have failed BRAF/MEK inhibition (NCT06299839).Eligible pts, $\geq$18 years with MAPK-driven advanced solid tumors, are being enrolled in dose escalation at 8 different dose cohorts in monotherapy. **Results:** As of 3 Jan 2025, a total of 9 patients have been enrolled in dose escalation in 3 dose cohorts (2mg, 4mg, and 8mg). 55.6% of the patients were female with a median age of 60 years. Most common tumor types included colorectal (n = 5, 55.56%), pancreatic (n = 2, 22.22%), gastroesophageal (n = 1, 11.11%), and of unknown type (n = 1, 11.11%). Treatment Related Adverse Events (TRAE) were reported in 44.44% of patients. TRAEs were all low grade (n = 7, 100% were Grade 1-2). No Grade 3, 4 or 5 TRAEs were reported. The most common TRAEs were gastrointestinal disorders (n = 4, 57.14%), dehydration (14.29%), arthralgia (14.29%) and urinary incontinence (14.29%). No rash was observed in any dose cohort. No dose limiting toxicities were detected, and the MTD has not been reached. Preliminary PAS-004 PK analysis suggests linear PK with estimated t1/2 of 70h, Cmax/Cmin ratio of 1.4 at steady state, achieving potentially sufficient exposures for target engagement at the highest dose tested. In the efficacy evaluable population (n = 6), early response evaluation reveals stable disease (SD) by RECIST 1.1 was observed in 2 patients, with progression free survival of up to 159 days and overall survival of up to 253 days. **Conclusions:** To date, PAS-004 is shown to be a safe and well-tolerated novel MEK inhibitor, with dose-dependent PK profile and preliminary clinical activity in monotherapy in patients with heavily pre-treated refractory solid tumors. PAS-004 has the potential to achieve prolonged target inhibition and once-daily dosing (QD) due to its long half-life and low Cmax to Cmin ratio. These findings provide a compelling rationale to continue to test PAS-004 into clinical trials for the treatment of MAPK-driven opportunities. Clinical trial information: NCT06299839. 3126 **Poster Session**

Pertuzumab plus trastuzumab (P+T) in patients (pts) with bladder (BC) and ovarian cancer (OC) with *ERBB2/3* alterations (alt): Results from the Targeted Agent and Profiling Utilization Registry (TAPUR) study. First Author: John K. Chan, Sutter Cancer Research Consortium, San Francisco, CA

Background: TAPUR is a phase II basket study evaluating antitumor activity of commercially available targeted agents in pts with advanced cancers with genomic alt. Results of two cohorts of pts with BC or OC with *ERBB2/3* alt treated with P+T are reported. **Methods:** Eligible pts had measurable disease, ECOG performance status (PS) 0-2, adequate organ function, and no standard treatment (tx) options. Genomic testing was performed in CLIA-certified, CAP-accredited site selected labs. Recommended dosing was P at an initial dose of 840 mg intravenously (IV), then 420 mg IV every 3 weeks (wks) and T at an initial dose of 8 mg/kg IV, then 6 mg/kg IV every 3 wks until disease progression. Primary endpoint was disease control (DC) per investigator defined as complete (CR) or partial (PR) response per RECIST v.1.1, or stable disease (SD) of at least 16 wks duration (SD16+). CR was based on radiographic assessment. For both cohorts, Simon 2-stage design was based on a null DC rate of 15% vs. 35% (power = 0.85; α = 0.10). If $\geq$2 of 10 pts in stage I had DC, 18 more pts were enrolled; otherwise, the cohort was closed. If $\geq$7 of 28 pts had DC, the null DC rate was rejected. Secondary endpoints were objective response (OR), progression-free survival (PFS), overall survival (OS), duration of response and SD, and safety. **Results:** 28 pts with *ERBB2/3* alt were enrolled in each cohort. The table shows demographics and outcomes. For the BC cohort, 2 CRs (*ERBB2* amplification [amp, n=1] and *ERBB2* amp and *ERBB3* mutation [mut, n=1]), 5 PRs (*ERBB2* amp [n=3], *ERBB2* amp and mut [n=1], and *ERBB2* mut [n=1]) and 3 SD16+ (*ERBB2* mut [n=3]) were observed for DC rate of 37% (90% CI, 24 to 100) and OR rate of 25% (95% CI, 11 to 45). The null DC rate was rejected (p=0.005). For the OC cohort, 2 PRs (*ERBB2* amp [n=1] and *ERBB2* mut [n=1]) and 3 SD16+ (*ERBB2* amp [n=2] and *ERBB2* amp and mut [n=1]) were observed for DC rate of 25% (90% CI, 10 to 100) and OR rate of 7% (95% CI, 1 to 24). The null DC rate was not rejected (p=0.29). Across both cohorts, 4 pts had 6 tx-related serious adverse events (SAE) including: infusion-related reaction, confusion, diarrhea, and fever, and 2 pts had 1 grade 3 tx-related adverse event (AE) each including: GGT increase and lymphopenia. No pts had grade 5 SAEs. **Conclusions:** P+T met prespecified criteria to declare clinical activity in pts with BC with *ERBB2* alt, but not in pts with OC. Additional study is warranted to confirm the efficacy of P+T in pts with BC with *ERBB2* alt. Clinical trial information: NCT02693535. Research Sponsor: Genentech; Astrazeneca, Bayer, Boehringer Ingelheim, Bristol Myers Squibb, Eli Lilly and Company, Merck, Pfizer, Seagen (now a wholly owned subsidiary of Pfizer Inc.), Taiho Oncology.

Digital spatial profiling of advanced solid tumors and lymphomas from a phase 1 trial of copanlisib and nivolumab. First Author: Sayak Ghatak, Frederick National Laboratory for Cancer Research, Frederick, MD

Background: Digital spatial profiling (DSP) is an innovative technique that facilitates spatially resolved proteotranscriptomic analysis within tissue sections, providing essential insights into the tumor microenvironment (TME). As part of the exploratory objectives in the Phase 1B trial (NCT03502733) evaluating adult patients(pts) with solid tumors and lymphomas copanisib (C), nivolumab (N) + ipilumumab (I), we employed the NanoString-Bruker GeoMx DSP platform to evaluate spatial heterogeneity in differentially regulated biomarkers. **Methods:** The study analyzed samples from pts in the trial's doublet treatment arm, which included C + N. Pts receive C on days 1 and 15 or days 1, 8, and 15 of each cycle and nivolumab on day 1 or days 1 and 15 of each cycle. Core biopsies collected from 8 pts at cycle 1 day 1 pre-dose (C1D1, baseline), cycle 1 day 8 post-dose (C1D8, C only) and cycle 2 day 15 post-dose (C2D15, C+N) were selected for GeoMx analysis. Tissue sections (5-μm) from archival FFPE blocks were prepared on glass slides and hybridized with photocleavable tag-conjugated antibodies (targeting 85 proteins) and oligonucleotide probes (whole transcriptome- WTA) for protein and WTA analyses respectively. Tissue imaging was performed via high-resolution fluorescent microscopy using morphology markers (cytokeratin AE1/AE3, CD45, CD3, CD20, Syto-13 nuclear marker). At least three rectangular (660 x 784 μm) regions of interest (ROI) per timepoint were analyzed using NanoString nCounter for proteomics and NGS for WTA. Data quality control and analysis were conducted using the GeoMx DSP Control Center (V-3.0) with a significance threshold of α = 0.05. **Results:** In two lymphoma pts with stable disease (SD) or partial response (PR), PI3K downstream signaling showed downregulation at C1D8 due to C-mediated PI3K-AKT signaling inhibition, possibly through PIK3IP1 overexpression. This signaling returned to baseline by C2D15, likely due to C's elimination half-life. In a follicular lymphoma case (#18, PR), FOXP3 expression decreased at both C1D8 and C2D15, while CD4 and CD8 levels remained constant. Immune marker expression (PD-L1, PD-1, CTLA-4, CD80) progressively declined. However, in diffuse large B-cell lymphoma (#14, SD), no changes in T-cell markers were observed. Solid tumor cases (#12, #24, SD) showed PI3K-AKT signaling downregulation at C2D15, along with CD3+/CD8+ T-cell infiltration into the tumor. FOXP3 levels slightly decreased in tumor and immune compartments. Progressive disease cases showed no change in T-cell markers. **Conclusions:** GeoMx DSP demonstrated its capability to investigate phospho-signaling and immune profiles in tumor and stromal compartments of small biopsies, highlighting its potential to enhance the understanding of TMEs in clinical studies. Further applications may provide critical insights for clinical cancer trials. Clinical trial information: NCT03502733. Research Sponsor: None.

Long non-coding RNA (lncRNA) SNHG11 as a prognostic and predictive biomarker in metastatic colorectal cancer (mCRC): Insights from CALGB (Alliance)/SWOG 80405. First Author: Michela Bartolini, Division of Medical Oncology, Norris Comprehensive Cancer Center, Keck School of Medicine, University of Southern California, Los Angeles, CA

Background: LncRNAs have emerged as key regulators of cancer progression and therapeutic responses. In CRC, several lncRNAs have been implicated in modulating tumor growth, metastasis and treatment resistance by interacting with critical tumorigenic pathways. Here, we investigate the potential prognostic and predictive value of lncRNA expression in patients (pts) with mCRC enrolled in CALGB/SWOG 80405 (NCT00265850) trial. **Methods:** We analyzed 433 mCRC pts treated with either bevacizumab (bev, n = 226) or cetuximab (cet, n = 207) plus first-line chemotherapy. Tumor RNA expression (Illumina HiSeq 2500) of 13 candidate lncRNAs (SNHG11, HOTAIR, FGF14-AS2, H19, YWHAE, NEAT1, MIR100HG, UCA1, LINC00973, SLCO4A1-AS1, POU5F1P4, MALAT1, HCG18) was explored. Median overall survival (mOS) and progression-free survival (mPFS) in months (mo) were compared between pts grouped by tertiles (low [L] vs medium [M] vs high [H]) of gene expression. Likelihood ratio tests, hazard ratios and 95% confidence intervals were computed from multivariable Cox proportional hazards models, adjusting for age, sex, ECOG PS, tumor location, number of metastatic sites, *KRAS*, Consensus Molecular Subtypes (CMS), and treatment. **Results:** Overall, SNHG11 was strongly associated with OS and PFS after adjusting for multiple tests (Benjamini-Hochberg False Discovery Rate $<$ 0.05). High SNHG11 expression (H group, n = 144) was associated with improved mPFS (H: 14.3 vs M: 11.2 vs L: 8.3 mo; p = 0.038) and mOS (H: 39.6 vs M: 31.1 vs L: 20.5 mo; p = 0.033) in the combined treatment analysis. Among cet-treated pts, SNHG11-H showed a numerically longer mPFS (H: 14.2 vs M: 11.1 vs L: 7.6 mo; p = 0.19) and significantly longer mOS (H: 41.1 vs M: 32.4 vs L: 14.3 mo; p = 0.012). In contrast, no statistically significant OS or PFS differences were observed in bev-treated pts. SNHG11-H tumors had a significant OS benefit from cet compared to bev (mOS 41.1 vs 36.5 mo, respectively; p = 0.016), with a nominally significant treatment interaction observed for OS (p = 0.030). No significant differences were observed in the L or M expression groups. Additional analyses showed that SNHG11 expression was high in the CMS2 (canonical) subtype and substantially lower in CMS1 (immune). **Conclusions:** LncRNA SNHG11 plays a significant role in CRC progression and metastasis via tumorigenic pathways, including c-Myc and HIF-1α. Moreover, elevated circulating SNHG11 levels show promise as a non-invasive biomarker for early CRC detection. In CALGB/SWOG 80405, high SNHG11 expression correlated with improved PFS and OS, particularly in cet-treated pts, supporting its role as a prognostic and predictive biomarker. Its strong association with CMS2 aligns with its reported involvement in c-Myc-driven pathways. Further validation is needed to confirm the clinical utility of this biomarker and elucidate underlying mechanisms. Using single-cell sequencing to identify endothelial expression of immune checkpoint ligands in advanced hepatocellular carcinoma, pre- and post-atezolizumab plus bevacizumab in the phase II INTEGRATE study. First Author: Florence T.H. Wu, Clinician Investigator Program, University of British Columbia, Vancouver, BC & Princess Margaret-UHN, Toronto, ON, Canada

Background: Atezolizumab (atezo; anti-PD-L1) plus bevacizumab (bev; anti-VEGF-A) became a standard treatment for advanced hepatocellular carcinoma (HCC) after demonstrating an overall survival advantage over sorafenib (inhibitor of VEGFR2 & other kinases) in the phase III clinical trial, IMbrave150. However, the mechanisms of primary and acquired resistance to atezo-bev are poorly understood. VEGFR2$^+$ endothelial cells (ECs) are potential cellular targets of bev and may play a key immunomodulatory role in response to atezo-bev. In this study, we utilized single-cell sequencing to identify potential mediators of resistance within EC subsets. **Methods:** Eight patients with unresectable HCC were enrolled on the INTEGRATE study, treated with atezo-bev, and underwent intensive biospecimen collection (NCT04563338). Serial tumor biopsies were collected and viably cryopreserved including pre-treatment (n=6), 21-28 days after first dose (n=6), and at disease progression (n=2). Single-cell analysis via cellular indexing of transcriptomes and epitopes (CITEseq) has been performed and data from four patients have been analysed to date. Aggregating their nine biopsies, 8,569 hepatocytes (ALB$^+$ FABP1$^+$ FGB$^+$), 29,072 immune cells (CD45$^+$), and 8,028 ECs (CD31$^+$ vWF$^+$ KDR$^+$) were annotated. The differential expression of VEGFR2, PD-L1, and other immune checkpoint ligands by tumor vs. immune vs. endothelial cellswere interrogated (Table). **Results:** VEGFR2 (receptor for VEGF-A) is predominantly expressed by ECs, at high prevalence & intensity. PD-L1 and PD-L2 (ligands of PD-1) are expressed by ECs at low prevalence & intensity. Galectin3 (LAG3 ligand) is widely expressed by hepatocytes, immune cells and ECs; while L-SECtin (LAG3 ligand) is predominantly expressed by ECs but at low prevalence & intensity. ECs had the highest prevalence of galectin9 (TIM3 ligand) expression. Nectin2 (TIGIT ligand) is expressed by both hepatocytes and ECs at high prevalence & intensity. **Conclusions:** Liver ECs express a broad array of immune checkpoint ligands, which are more frequent than previously anticipated. These EC subsets may potentially drive resistance by contributing to exhaustion of T cell subsets entering the tumor microenvironment. Complete CITEseq, TCR sequencing, and correlative studies from the full cohort are underway. Clinical trial information: NCT04563338. Research Sponsor: This research was a collaborative effort made possible through support from F. Hoffmann-La Rohce for the imCORE Network.

Assessment of homologous recombination deficiency and BRCA status in ovarian cancer: Analytical performance and relevance of a decentralized NGS assay for comprehensive genomic profiling. First Author: Mohit Gupta, Thermo Fisher Scientific, South San Francisco, CA

Background: Homologous recombination deficiency (HRD) is a complex biomarker with predictive value in ovarian cancer. Understanding both the causes of HRD, such as pathogenic alterations in homologous recombination repair (HRR) genes, and its consequences, like genomic instability (GI), is crucial for exploring various therapeutic strategies, including the potential use of poly (ADP-ribose) polymerase inhibitors (PARPi). This study evaluates the analytical performance and clinical research relevance of the Oncomine™ Comprehensive Assay Plus (OCA Plus), a distributable next-generation sequencing (NGS) research use assay that offers in a single workflow comprehensive genomic profiling, including HRD evaluation. **Methods:** The OCA Plus panel was used for comprehensive genomic profiling of a series of 299 ovarian cancer research samples from the PAOLA-1 trial, part of the ARCAGY biorepository. Research samples were analyzed to assess agreement with orthogonal method, specifically for *BRCA1* and *BRCA2* mutational status, GI status and overall HRD status which combined BRCA1/2 mutational status and GI status. GI status was determined using Genomic Instability Metric (GIM), a quantitative method that characterizes unbalanced copy number changes. Progression-free survival (PFS) was retrospectively studied to determine future clinical relevance. **Results:** The success rate for DNA sequencing was 100%, starting from a minimal sample input of 20ng of genomic DNA isolated from FFPE tissue blocks. The OCA Plus panel provided a detailed genomic profile in a single workflow, achieving high success rates across all biomarkers tested, including single nucleotide variants/indels and HRD (100%). Overall percent agreement (OPA) for HRD status with orthogonal method was 87%. OPA for *BRCA1/2* variants was 98%, while OPA for GI status was 80%. PFS analysis demonstrated a significantly better hazard ratio (HR: 0.51, $p < .005$) for the cases positive for OCA Plus HRD solution compared to the cases negative for the OCA Plus HRD solution (HR: 0.84, p = 0.43). **Conclusions:** The OCA Plus solution enables robust and reliable comprehensive genomic profiling with high OPA for *BRCA1/2* and HRD status compared to commonly used orthogonal method. Albeit additional studies are due, overall, the reported data suggests its future clinical utility in predicting treatment outcomes in ovarian cancer. Research Sponsor: None.

Cost-effectiveness of NTRK testing strategies for detecting NTRK fusions in solid tumors in China. First Author: Jian Wang, Fudan University Shanghai Cancer Center; Shanghai Medical College, Fudan University, Shanghai, China

Background: Neurotrophic tyrosine receptor kinase (NTRK) gene fusions are oncogenic drivers in many solid tumors. With the inclusion of the targeted drug Entrectinib in China's national reimbursement drug list, the demand for NTRK testing has also increased. This study evaluates the cost-effectiveness of a two-step testing strategy (initial pan-TRK IHC testing followed by next-generation sequencing (NGS) confirmation for positive results) compared to directly conducting NGS testing, with treatment of positive cases using Entrectinib. **Methods:** A decision tree model was established from a health system perspective, based on clinical practices in China. The study included 17 cancer types as reported in the latest clinical trial of Entrectinib (n = 194). Diagnostic performance data were sourced from literature and validated by pathologists and clinicians. Clinical efficacy, treatment phase costs, and utility for progression-free survival (PFS) were obtained from open databases and literature. Turnaround time and costs for testing was gathered from expert interviews. The time horizon was set to include the duration of NTRK testing and the period of PFS associated with the medication. A one-way sensitivity analysis was conducted to assess the model's robustness. **Results:** In China, the NGS testing alone produced 0.55507 life years (LY) and 0.42646 quality-adjusted life years (QALY) at a total cost of $5932.57 , whereas the pan-TRK IHC + NGS testing strategy yielded 0.55530 LY and 0.42665 QALY at a total cost of $4176.67. The pan-TRK IHC+NGS testing strategy was dominant, offering higher QALY at lower costs than NGS testing alone. Additionally, the average wait time for pan-TRK IHC + NGS testing was reduced by 10 days. The robustness of the base case results was confirmed through sensitivity analysis. **Conclusions:** Initial pan-TRK IHC testing, followed by NGS confirmation for positive results, is the optimal strategy for NTRK fusion detection in patients with locally advanced or metastatic solid tumors in China, providing superior cost-effectiveness compared to NGS testing alone. Research Sponsor: None.

Cost-effectiveness analysis results.

Testing	Total Cost(USD$)	Effectiveness (LYs)	Effectiveness (QALY)	Incremental cost ($)	Incremental QALYs	ICER (Cost/QALY)
NGS	$5932.57	0.55507	0.42646			pan-TRK IHC +NGS was dominant
pan-TRK IHC+NGS	$4176.67	0.55530	0.42665	-$1755.90	0.000187	

ICER: Incremental cost-effectiveness ratio.

Impact of sample characteristics on RNA-based next-generation sequencing (NGS) for fusion gene detection in non-small cell lung cancer (NSCLC). First Author: Jun Liu Jr., First People's Hospital, the Second Affiliated Hospital of South China University of Technology, Guangzhou, China

Background: RNA-based next-generation sequencing (NGS) has been widely employed for detecting fusion genes in NSCLC, due to its superior sensitivity and simplified design compared to DNA-based NGS. However, the impact of sample quality on fusion variant detection using RNA-based NGS remains unclear. **Methods:** The study analyzed 5,386 and 5,538 NSCLC samples using DNA- or RNA-based NGS to detect common fusion genes (ALK, RET, ROS1, NTRK, NRG1, MET exon 14 skipping, and FGFR). NGS libraries were constructed using capture-based or amplicon-based methods for DNA and RNA samples, respectively, focusing on pathogenic mutations. **Results:** RNA-based NGS detected 2.44% more fusions than DNA-based NGS [9.50% (526/5538) vs. 7.06% (380/5386)], with notable advantages for NTRK (0.13% vs. 0.02%), NRG1 (0.25% vs. 0.06%), MET exon 14 skipping (2.15% vs. 1.36%), and FGFR fusions (0.40% vs. 0.02%). Tumor cell content analysis showed no significant impact on fusion detection rates within the 20%-90% range for either method. However, higher tumor cell content ($\geq$80%) significantly increased RNA-based NGS detection rates compared to DNA-based NGS, nearly doubling the total detection rate (17.3% vs. 8.88%), primarily due to increased ALK fusion detection (8.97% vs. 5.02%). The type of sampling (surgical, biopsy, or others) did not significantly affect overall fusion detection rates for either method ($p > 0.05$). However, gene-specific analyses showed significantly higher detection rates for ROS1, MET, and RET using RNA-based NGS in biopsy samples compared to DNA-based methods (ROS1: 11.83% vs. 1.18%, MET exon 14 skipping: 2.87% vs. 1.62%, RET: 1.24% vs. 0.79%). Conversely, RNA-based detection of ALK and NRG1 fusions was higher in surgical samples (ALK: 4.00% vs. 3.25%, NRG1: 0.34% vs. 0.08%) compared to DNA-based methods. Regarding sample types, pleural/peritoneal effusions showed higher detection rates than FFPE samples, though not statistically significant. RNA-based NGS consistently showed superior detection rates for ALK and MET exon 14 skipping in all sample types compared to DNA-based methods, with the most substantial increase for MET exon 14 skipping in pleural/peritoneal effusions (2.14% vs. 0.98%). Conversely, RNA-based NGS for NRG1 and ROS1 fusions showed a greater relative increase in detection rate in 10% neutral formalin-fixed tissue/FFPE sections/unstained slides compared to pleural/peritoneal effusions. **Conclusions:** Sample characteristics did not significantly impact the overall detection rate of RNA-based fusion assays. However, detection rates for specific fusions like ALK, NRG1, and MET exon 14 skipping varied with sample type, sampling method, and tumor cell content. Optimizing testing strategies and sample handling is crucial to improving diagnostic accuracy in NSCLC. Research Sponsor: Medical Scientific Research Foundation of Guangdong Province, China; A2022519.

Effect of irradiation on the killing effect of NK cells in colon cancer through MYB/TIM3 axis. First Author: Xiuli Guo, Zhongnan Hospital of Wuhan University, Wuhan, HuBei, China

Background: Natural killer (NK) cells play a crucial role in tumor progression and anti-tumor immunity. However, they often exhibit an exhausted phenotype within the tumor microenvironment (TME), limiting their full cytotoxic potential. T-cell immunoglobulin and mucin-domain containing-3 (TIM-3) has emerged as a novel immune checkpoint that is highly expressed on NK cells and suppresses their cytotoxic function. TIM-3 is closely associated with immune evasion and anti-tumor immune tolerance. This study aims to investigate the effects and mechanisms by which radiation modulates NK cell function, providing a foundation for developing strategies that specifically target TIM-3 on NK cells. **Methods:** First, mRNA high-throughput sequencing, RT-qPCR, and Western blot experiments were used to analyze changes in the expression of related genes in NK92 cells after radiotherapy. The LDH release assay was employed to evaluate the effect of radiation on the viability of NK92 cells. ELISA was conducted to detect changes in the release levels of tumor necrosis factor TNF-α and other factors after radiotherapy. Dual-luciferase reporter assays and chromatin immunoprecipitation (ChIP) experiments confirmed that the transcription factor MYB mediates radiation-induced regulation of NK cell activation by targeting and binding to the TIM-3 promoter region. A non-contact co-culture system was established, and flow cytometry demonstrated that radiation combined with MYB overexpression enhanced the cytotoxicity of NK cells against tumor cells. A colon cancer mouse model was constructed to evaluate the anti-tumor effect of combining anti-TIM-3 antibodies with radiotherapy. **Results:** We found that radiation can activate NK92 cells in vitro and enhance TIM-3 expression,promoting the secretion of granzyme B, perforin, TNF-α, IFN-γ, and other cytokines and chemokines that modulate the TME and enhance anti-tumor immune responses. Moreover, the transcription factor MYB inhibits TIM-3 expression by directly binding to the TIM-3 promoter region, mediating the effects of radiation on the TME through NK cell activation. In vivo, the combination of radiotherapy and anti-TIM-3 antibodies effectively controlled the growth of subcutaneously transplanted colon cancer tumors in C57BL/6 mice. However, this combined treatment effect was significantly diminished after NK cells were depleted by the anti-NK1.1 antibody. **Conclusions:** This study elucidates a novel mechanism by which radiation activates NK cells in the tumor microenvironment through the MYB/TIM-3 pathway. It provides new insights for enhancing the efficacy of radiotherapy and offers a theoretical basis for the potential clinical application of these cells in future research. Research Sponsor: None.

Combined prognostic value of post-surgery circulating tumor DNA and tumor-stroma ratio in patients with stage III colon cancer treated with adjuvant chemotherapy. First Author: Ingrid Franken, University Medical Center Utrecht, Department of Medical Oncology, Utrecht, Netherlands

Background: Patients with stage III colon cancer (CC) are routinely treated with resection followed by adjuvant chemotherapy (ACT). About half of patients are cured by surgery and hence overtreated with ACT, yet another ~30% experience recurrence and are currently undertreated. Only ~20% of patients are cured by ACT and we are unable to identify these patients. Prognostic value of circulating tumor DNA (ctDNA) and the tumor-stroma ratio (TSR) has been shown in separate studies. This study aimed to integrate these biomarkers with pTNM substage to better predict outcome in stage III CC patients treated with ACT. **Methods:** Patients with stage III CC who received radical resection followed by ACT were selected from the Prospective Dutch ColoRectal Cancer cohort (PLCRC) substudy PROVENC3 (Rubio-Alarcon AACR 2024). Blood was collected between surgery and ACT, to determine ctDNA status using Labcorp Plasma Detect. Based on a diagnostic H&E slide from the CC resection, the TSR was determined by a trained observer according to the United study (Polack ESMO open 2024). A stroma content of $\leq$50% was considered low and $>$50% high. The primary outcome was recurrence risk (RR), calculated from date of resection. **Results:** In the overall cohort (N = 207), the 3-year RR was 23.4% [17.3-29.1]. In total, 88 patients (43%) were stroma-high and had a higher recurrence risk (3-year RR 33.1% [22.5-42.3]) than the 119 stroma-low patients (3-year RR 16.0% [8.9-22.5]; HR 2.7 [1.6-4.6]). CtDNA was detectable after surgery in 28 patients (13.5%; HR 5.8 [3.3-10]), of whom 11 (39%) were stroma-high. T4/N2 stage was observed in 82 patients (HR 2.9 [1.7-5.0]), of whom 46 (56%) were stroma-high. TSR (HR 2.6 [1.5-4.6]) had added prognostic value to ctDNA (HR 7.6 [4.3-13]) and pTNM substage (HR 2.9 [1.7-5.0]) in a multivariable cox model (LRT p$<$0.001). Patients with no detectable ctDNA and stroma-low T1-3N1 CC were at low recurrence risk (N = 71; 3-year RR 2.9% [0-6.8]). In comparison, patients with no detectable ctDNA and a tumor that was either stroma-high or T4/N2 were considered intermediate risk (N = 68; 3-year RR 17.2% [7.4-26.0]; HR 5.4 [1.5-19]). Patients with detectable ctDNA and/or stroma-high T4/N2 CC had a high risk (N = 68; 3-year RR 50.2% [36.7-60.8]; HR 19 [5.9-62]). **Conclusions:** The tumor-stroma ratio has added value to post-surgery ctDNA and pTNM substage in predicting outcome in stage III CC patients treated with ACT. The recurrence risk in the third of patients with no detectable ctDNA and stroma-low T1-3N1 CC was only 3%. It is of interest to investigate whether this low risk would persist in a cohort treated with surgery only, to suggest whether these patients could be spared ACT in the future. The third of patients with detectable ctDNA, and/or stroma-high T4/N2 CC, had a 50% recurrence risk despite ACT, highlighting the need for alternative adjuvant treatment options for these patients. Regorafenib response prediction in metastatic colorectal cancer by a novel genomic and transcriptomic model. First Author: Andreas Seeber, Department of Hematology and Oncology, Comprehensive Cancer Center Innsbruck, Medical University of Innsbruck, Innsbruck, Austria

Background: The multi-kinase inhibitor regorafenib (Rego) is approved for the treatment of refractory metastatic colorectal cancer (CRC). However, its efficacy is limited, and its use is frequently associated with substantial toxicities. Identifying biomarkers predicting Rego-response could improve therapeutic outcomes and reduce unnecessary treatment-related adverse effects in non-responders. **Methods:** A predictive model for Rego-response was developed based on transcriptomic and genetic data from 41 CRC cell lines. Cell lines were classified into Rego-sensitive *versus* -resistant groups based on drug sensitivity data from the CTRP2 database. Several machine-learning algorithms were evaluated, with the Generalized Linear Model via Elastic Net (GLMNET) achieving the highest predictive performance. Model accuracy was assessed using leave-one-out cross-validation. Further validation was performed using transcriptomic (WTS) data from 24,384 real-world CRC patients assessed by Caris Life Sciences, which included 720 patients treated with Rego. **Results:** The predictive model identified key cell line features associated with Rego-response, including gene expression signatures (e.g., *ZNF441, CCDC82, ZFP69*) and specific mutations (e.g., *RALGAPA1, MORC1*). Transcriptome profiling showed that Rego responders exhibited enrichment in cell-cycle regulation and DNA-repair mechanisms, while non-responders showed a stroma-rich microenvironment with significant endothelial and fibroblast infiltration. External validation using WTS data from real-world Rego-treated CRC patients revealed that predicted responders had a prolonged time-on-treatment (p = 0.02, HR = 0.79) and median overall survival (p = 0.01, HR = 0.76) compared to predicted non-responders. This association was specific to Rego-response, as there was no survival difference between predicted responders and non-responders among patients not treated with Rego (p = 0.72, HR = 1.0). **Conclusions:** This novel predictive model successfully identified and validated molecular features associated with Rego-response in CRC. The transcriptomic and genetic signature holds significant potential for improving personalized treatment strategies by identifying patients most likely to benefit from Rego and prevents unnecessary Rego-associated toxicities in non-responders. Relationship between FOLR1 expression and pan-cancer subgroup of tumors with specific transcriptomic profile. First Author: Andrew Ip, John Theurer Cancer Center, Hackensack University Medical Center, Hackensack, NJ

Background: Mirvetuximab soravtansine is an antibody–drug conjugate currently approved for the treatment of advanced platinum-resistant ovarian cancer. The efficacy of this therapy is correlated with high expression of folate receptor alpha (FRα), encoded by the FOLR1 gene. Treatment requires $\geq$ 75% of tumor cells to be stained positively for FRα by immunohistochemistry (IHC). Here we defined the FOLR1 RNA level that distinguishes ovarian cancers with very high FRα ($\geq$ 75% by IHC), then compared the transcriptomic profile of these cases (FOLR1-H) with the transcriptomic profile of cases with very low FRα expression (FOLR1-L). We further explored the presence similar FOLR1-H signature in various types of cancers. **Methods:** RNA was extracted from 1450 solid tumor FFPE samples and sequenced using a targeted RNA panel of 1600 genes. The RNA expression levels of various genes were quantified and expressed as transcript per million (TPM). IHC for FRα protein was performed on ovarian cancers (N = 49) using VENTANA FOLR1 RxDx assay. **Results:** Based on comparing IHC with RNA expression of FOLR1, FOLR1-H samples were defined with RNA $\geq$ 300 TPM while FOLR1 mRNA $<$ 100 was correlated with very low FRα by IHC and classified as FOLR1-L. Of the 312 ovarian cancers, 21% were classified as FOLR1-H and showed significantly (Log10FDR $<$ -2) higher expression in 39 genes as compared with FOLR1-L. The Log10FDR was $<$ -10 in 19 genes. The top highly expressed genes in FOLR1-H cases were TROP2, NECTIN4, ROR1, ROR2, ACVRL1, and NTHL1. In breast cases (N = 199) FOLR1-H was detected in 14.6% of cases and the most highly expressed genes were ACVRL1, NECTIN4, ROR1, and ACVRL1 (Log10FDR $<$ -5). Of the 932 cases of lung cancer, 21.5% classified as FOLR1-H and had significantly (Log10FDR $<$ -2) high expression of 137 genes, but similar to ovarian cancer TROP2, NECTIN4, ROR1, ROR2, ACVRL1, and NTHL1 were top expressed genes. Of the 174 pancreatic cancers 9.8% were FOLR1-H and top expressed genes were NECTIN4, ROR1, and ACVRL1. In sarcoma (N = 166), 8.4% had FOLR1-H and only three genes (NECTIN4, NTHL1 and SLC47A1) were significantly high. Of the 327 colorectal cancers, 8% met the criteria for FOLR1-H and 16 genes were significantly higher in FOLR1-H including NECTIN4, NTHL1, ACVRL1, ROR1/2. In 64 esophageal cancers 10.9% were FOLR1-H, but only 3 genes (GALNT12, ACVRL1 and NECTIN4) were significantly higher. **Conclusions:** This data suggests that cancers with significantly high expression of FOLR1 mRNA are a special subtype of tumors characterized by the expression of embryonic cell surface markers (FOLR1, TROP2, NECTIN4, ROR1/2). The pan-cancer marked overexpression of these genes suggests that cancers with FOLR1-H represent a subtype of cancers with similar biology. This subtype may benefit from combination therapy targeting more than one of these markers (e.g. anti-FOLR1 with anti-TROP2, or anti-NECTIN4) and clinical trial with such combination may be justified. Multi-omics cohort-based prediction model for early relapse of hepatocellular carcinoma post-surgery. First Author: Penghong Song, The First Affiliated Hospital, School of Medicine, Zhejiang University, Hangzhou, China

Background: Postoperative early relapse (PER) of hepatocellular carcinoma (HCC) presents significant challenges in clinical management. Identifying reliable predictive markers and therapeutic strategies for PER is crucial for improving patient outcomes. **Methods:** We constructed a predictive model for PER using multi-omics data from 177 HCC patients with follow-up information. Transcriptomic and proteomic profiling of HCC tissues was performed, followed by differential expression analysis and Weighted Gene Co-expression Network Analysis (WGCNA) to identify molecular markers associated with PER. Univariate, LASSO, and multivariate Cox regression analyses were employed to refine the marker set, resulting in a three-gene signature. The model's accuracy was validated using a proteomic cohort and The Cancer Genome Atlas (TCGA) database. Functional enrichment, drug sensitivity, and immune infiltration analyses were conducted to explore the biological characteristics and therapeutic implications of high-PER risk patients. Patient-derived organoid (PDO) models were used for further validation. **Results:** We identified 31 molecular markers associated with PER, which were narrowed down to a robust three-gene signature (MIK67, GPD1, and MBL2) with an area under the curve (AUC) of 0.868 for predicting early relapse. Functional enrichment analysis revealed that high-PER risk patients exhibited enhanced DNA damage repair and cell cycle pathways. Drug sensitivity analysis suggested potential benefits from gemcitabine and paclitaxel, which were validated using PDO models. Immune infiltration analysis showed reduced NK cell and M2 macrophage infiltration in high-PER risk patients, confirmed by single-cell sequencing and immunohistochemical validation. **Conclusions:** This study provides a novel multi-omics-based predictive model for early recurrence in HCC, highlighting potential therapeutic options for high-risk patients. The findings underscore the importance of DNA damage repair and cell cycle pathways in PER and suggest targeted therapies that could improve clinical outcomes for high-PER risk patients. Comprehensive clinicogenomic profiling of signet ring cell carcinoma across multiple organ sites. First Author: Lawrence Wen Wu, Columbia University Irving Medical Center, New York, NY

Background: Signet ring cell carcinoma (SRCC) is a rare, aggressive histological subtype of adenocarcinoma that is associated with earlier age of onset and poor prognosis. It most commonly arises from the stomach but can originate elsewhere. Few studies have compared molecular alterations in SRCC across various primary sites. Utilizing the American Association for Cancer Research (AACR) Project Genomics Evidence Neoplasia Information Exchange (GENIE) v17.0, we performed a comprehensive analysis of clinicogenomic variables in SRCC across different primary sites. **Methods:** The AACR GENIE v17.0 database was used to select tumor samples classified as SRCC by the Oncotree Code. We excluded primary SRCC sites with $<$ 10 tumor samples. Samples were analyzed for clinicogenomic characteristics including gender, race, ethnicity, age at sequencing, and oncogenic molecular alterations by OncoKB classification (somatic mutations, structural variants, copy number alterations). We classified "early onset" SRCC as age of sequencing $<$ 50. Chi-square testing was used to compare categorical variables, and Benjamini-Hochberg procedure was used to control the false discovery rate (statistical significance for $q < 0.05$). **Results:** From 355 patients with SRCC, 358 tumor samples were analyzed, with the following distribution among primary sites: stomach (n = 168), colon/rectum (n = 125), appendix (n = 38), and bladder (n = 27). There were high rates of early onset SRCC in the stomach (29.2%), colon/rectum (47.2%), and appendix (36.8%). Female gender was numerically higher in stomach (56.9%) and appendix (55.3%) SRCC cases compared to colon/rectum (47.2%) and bladder (33.3%) SRCC cases. The most prevalent altered genes included *TP53* (45.0%), *CDH1* (19.4%), *ARID1A* (14.8%), *KRAS* (12.9%), and *SMAD4* (12.3%). There was differential enrichment of molecular alterations across various sites in *TP53*, *CDH1*, *KRAS*, *SMAD4*, *TERT*, *APC*, and *BRAF* ($q <$ 0.05). **Conclusions:** To our knowledge, this study represents the largest molecular analysis of SRCC across multiple organ sites, revealing high rates of early onset SRCC and distinctive molecular alteration patterns. These findings underscore the further need to investigate functional implications and potential therapeutic targets for site-specific molecular alterations in SRCC. Research Sponsor: U.S. National Institutes of Health; 5T32CA203703-09.

Comparative analysis of T-cell subsets and vessel features in matched primary colorectal tumors and corresponding resected liver metastases. First Author: Pia J. Osterlund, Tampere University Hospital and Tampere Univeristy, Tampere, Finland

Background: Outcome after liver resection for colorectal cancer metastases (CRLM) is partly determined by factors such as the number, size, and vitality of the metastases, as well as the T- and N-stage of the primary tumor. The tumor microenvironment—particularly immune cell infiltration and vascular features—also influences outcome. Data on how these factors compare between paired primary colorectal tumors and matched CRLM are limited. **Methods:** We used TMAs from matched primary tumors and CRLM samples of 50 patients, of which 15 were untreated and 35 had received neoadjuvant therapy (cytotoxic $\pm$ VEGF-/EGFR-targeted agents) before liver resection. Each tumor consisted of 1–3 tissue cores (1 mm) from both the tumor center and the invasive margin. Multiplex immunofluorescence was performed to assess T-cell (e.g., CD3, CD4, CD8, PD1, FOXP3, TIM3, Ki67), and vessel (claudin-5, αSMA, PDGFRβ) markers. Nonparametric Wilcoxon signed rank and Spearman correlations were used for cell density comparisons. Cox regression for continuous variables was used for disease-free survival (DFS) associations. **Results:** We observed significantly lower densities of CD3+CD8+Ki67+, CD3+CD4+Ki67+, and CD3+CD4+FOXP3+ cells in CRLM than in paired primary (all $p <$ .006) in both untreated and pretreated cohorts. The αSMA+PDGFR$\beta-$ vessel subset was more prevalent in CRLM compared with the primary tumor in the untreated cohort ($p <$ .001). In the untreated cohort, larger vessel size in CRLM (but not in the primary tumor) showed a positive correlation with CD3+CD8+PD1+, CD3+CD4+PD1+, and CD3+CD4+FOXP3+ densities (Spearman r = .54–.60, p = .02–.04). In the pretreated cohort, higher tumor vitality and/or CDX2+ expression in CRLM (indicative of poor treatment response) were each negatively correlated with cytotoxic (CD3+CD8+) and helper T-cell (CD3+CD4+) subsets (r = -.42 to -.63, $p <$ .01). DFS after metastasectomy was associated with vessel and T-cell features. Regarding vessel metrics in the small untreated cohort, αSMA–PDGFR$\beta-$ vessel subset in primary showed a negative trend (p = .06) as did smaller vessel size in CRLM (p = .06). CD3–CD4+TIM3+ in CRLM was negatively associated with DFS in pretreated (p = .04), with a trend also in untreated (p = .10). **Conclusions:** Densities of certain T-cell subsets are significantly lower in matched CRLM than in primary tumors indicating immune desert phenotype. Vessel subset profiling suggests differences between primary tumors and CRLM, possibly relevant for treatment response. Poor pretreatment effect, i.e., high vitality and CDX2+ density in CRLM, was negatively correlated with several T-cell subsets, a correlation not seen in untreated. The poor prognosis association of CD3–CD4+TIM3+ cells in CRLM merits further investigation. Characterisation of ductal carcinoma in situ (DCIS) using mass spectrometry imaging towards near realtime margin assessment. First Author: Hemali Chauhan, Imperial College, London, London, United Kingdom

Background: Imprecision in breast-conserving surgery leads to high national average high rates of reoperative intervention. In line with updated margin guidelines, accurate differentiation between non-invasive and invasive breast cancer is essential. This study aimed to assess whether mass spectrometry can distinguish between normal breast tissue, benign, non-invasive and invasive disease towards the development of an intraoperative margin assessment tool. **Methods:** Breast tissue samples were collected from patients undergoing mastectomy. Samples were flash-frozen, sectioned, and analysed using a Xevo G2-XS QTof mass spectrometer (Waters Corp.). Selected sections were ionised using a pulsed optical parametric oscillator laser (OpoletteTM 2731/3034, OPOTEK) which operated at 2940 nm wavelength and 20 Hz repetition rate. The laser focused on the tissue through a 20 mm focal distance convex lens generating aerosol which was aspirated into the spectrometer. The data was combined using spatial distribution and chemical information from characteristic ions to generate 2D chemical images and labelled using consecutive H&E-stained sections annotated by a Consultant Histopathologist for ground truth cross-validation. **Results:** Over 1 million mass spectra were collected from imaging 52 breast tissue sections. This includes 720 mass spectra from 31 DCIS breast tissue sections, compared to 6 spectra from 2 DCIS breast tissue samples in previous work. A pixel size of 50 μm and scan rate was 250 μm/s was utilised. An ex-vivo classification model was built using n=6,796 and achieved $>$99% sensitivity for tumour detection (DCIS and IBC) and 100% specificity for identifying normal tissue. Principal Component Analysis demonstrated accurate separation of IBC, DCIS, benign breast disease, and normal breast tissue. Six possible metabolites were identified following Recursive Feature Elimination (RFE) was used to identify the most significant features which differentiate the tissue types, these were annotated using the Lipid Maps database (http://www.lipidmaps.org/) (Table 1). Cancerous tissue showed higher levels of structural lipids (600-900 Da), while normal/benign breast tissue had higher levels of small metabolites (50-300 Da) and fatty acids (200-400 Da). **Conclusions:** Mass spectrometry imaging enables accurate differentiation of IBC, DCIS, benign breast disease, and normal breast tissue. Research Sponsor: NIHR Imperial Biomedical Research Centre.

A minimal comprehensive somatic panel to aid clinical decision making in a low cost setting. First Author: Urvashi Bahadur, Strand Life Sciences, Bengaluru, India

Background: Large next-generation sequencing (NGS) panels (> 300 genes) offer multiple potential therapeutic options for patients with metastatic cancer. However a large portion of the population in developing countries is unable to avail the benefits of such testing due to limited availability of many drugs or suitable clinical trials, coupled with the high cost of these tests. There is an urgent need to offer a compact, affordable and robust testing solution which can offer expanded but feasible therapeutic options. Hence we decided to develop a custom mid-sized panel to fulfil these unmet requirements. **Methods:** A targeted solid tumor (DNA + RNA) panel comprising 74 genes (SA74) was designed to cover all genes with a Tier 1 drug recommendation for therapy, evaluating single nucleotide variants (SNV), indels, copy number variants (CNV) and gene fusions (GF). We also included certain Tier2 genes for prognosis or added clinical impact. GFs were evaluated by RNA. Inferior sample quality often results in poor quality data, so we added a DNA component for tiling select intronic regions to identify GF which to be used when RNA could not be analyzed. The analytical sensitivity was > 99% for SNV/Indels with a 5% limit of detection, > 99% for CNV and GF. The clinical sensitivity was 100% for SNV, 95% for indels, 84.2% for CNV, 100% for RNA GF and 70% for DNA GF. **Results:** 239 formalin-fixed paraffin embedded tumor samples were evaluated using SA74 and the data was scored for actionability across tumor types. This was compared with data from 706 samples across multiple cancers analyzed using the Illumina TSO500 panel. The average number of actionable alterations was 1.1 in SA74 and 1.6 in TSO500. The overall actionability (cases with at least one Tier1 or Tier2 actionable variant) of SA74 was 63.4%; while that of TSO500 was 78.3%. Of this, the overlap with SA74 was 73.7%. The actionability in the remainder was due to Tier2 genes with lesser evidence altering the same pathway as an approved drug target or targeting investigational drugs. The actionability for each cancer type was calculated and found to be: colon (34.1%; n = 44), non-small cell lung (NSCLC) (78.4%; n = 37), breast (91.7%; n = 24), carcinoma of unknown primary (CUP) (45%; n = 20), uterine (53.3%; n = 15), gallbladder (75%; n = 12) and sarcoma (40%; n = 10), among others. Smaller panels often do not include CNV and GF. Addition of these variant types increased actionability across cancers. The lack of CNV and GF would have decreased total actionability from 62.9% to 54.5%. NSCLC and CUP were most impacted with a difference in actionability of 16.2% and 15% respectively. GF increased actionability mainly in NSCLC, while CNV contributed to increases across all cancers. **Conclusions:** SA74 demonstrated high actionability across cancers. It therefore presents a practical alternative to large panel testing by optimizing actionability and affordability, useful in a cost-sensitive setting. Research Sponsor: None.

Clinical performance of Signatera Genome assay in a cohort of patients (pts) with solid tumors. First Author: Mridula Annette George, Rutgers Cancer Institute of New Jersey, New Brunswick, NJ

Background: Circulating tumor DNA (ctDNA) has emerged as a powerful, minimally invasive biomarker of treatment response and pt prognosis. Signatera, a tumor-informed, mPCR-NGS ctDNA assay, offers high sensitivity and specificity for detecting molecular residual disease (MRD). Signatera (exome) uses its proprietary approach to select a highly curated set of tumor variants, followed by deep sequencing of plasma libraries at >100,000x per variant. Signatera Genome uses the same proven technology and may provide an advantage over exome in certain cases. However, beyond analytical improvements, it remains unclear if Signatera Genome provides superior performance and utility compared to the clinically validated exome-based version in the clinical setting. In this study, we assessed the clinical performance of the Signatera Genome assay in a cohort of pts with solid tumors. **Methods:** We performed a retrospective analysis of clinically annotated residual pt samples from commercial ctDNA testing (Signatera, exome-based, 16-plex mPCR-NGS assay). Adjuvant treatment decisions and ctDNA-cadence of testing were at the provider's discretion. Signatera Genome assays were designed, consisting of 64 high-quality variants, from the respective pts' matched tumor and normal whole genome sequencing data. These assays were used to detect ctDNA in the associated pts' plasma utilizing a sample calling strategy that combined the target confidences and sample-level noise into a final confidence score. ctDNA concentration was measured in mean tumor molecules per mL of plasma (MTM/mL). Longitudinal plasma samples represented postoperative time points until recurrence/end of follow-up. The correlation between any time postsurgical ctDNA positivity and recurrence-free survival (RFS) was assessed using Cox regression analysis. **Results:** The Signatera Genome assay achieved a high analytical sample-level specificity of 99.8% (healthy subjects). Clinical performance was assessed in a real-world cohort of >300 pts with several cancer types, including breast cancer, non-small cell lung cancer (NSCLC), melanoma, and renal cell carcinoma (RCC). Among pts with relapse, the Signatera Genome assay detected ctDNA ahead of clinical recurrence as confirmed by imaging. Pts with postsurgical ctDNA-positivity demonstrated significantly inferior RFS compared to ctDNA-negative pts. This trend was consistent across all cancer types investigated. Multivariate analysis adjusted for tumor type and stage revealed ctDNA-positivity to be the most significant prognostic factor associated with RFS. Performance metrics by cancer type will be presented. **Conclusions:** Here we report the largest Signatera Genome ctDNA study to date across multiple solid tumor histologies. The data indicate robust performance and concordance with Signatera Exome. Prospective clinical trials are underway evaluating clinical utility. Research Sponsor: None.

Landscape of genomic alterations in genes implicated in the regulation of hypoxia inducible factor (HIF) signaling: A pooled analysis of two pan-cancer cohorts. First Author: Wassim Daoud Khatoun, Dana-Farber Cancer Institute, Boston, MA

Background: HIF2 alpha inhibitors (HIF2i) have been recently approved for VHL-related tumors, especially clear cell renal cell carcinoma (ccRCC). Alterations in genes that regulate HIF signaling may modulate response to HIF2i and may help identify tumor types that could benefit from new therapeutic approaches targeting HIF activity. Here, we describe the landscape of these alterations across different cancer types. **Methods:** This study included patients (pts) from the TCGA PanCancer Atlas and GENIE Cohort v17.0, across all cancer types. All pts underwent Next Generation Sequencing or OncoPanel analysis of their tumors. Alterations in genes related to the HIF pathway (*VHL*, *EPAS1*, *EGLN1*, and *EGLN2*) and citric acid cycle (*SDHA*, *SDHB*, *SDHC*, *SDHD*, *SDHAF1*, *FH*, *IDH1*, *IDH2*, and *MDH2*) were screened, and only driver mutations, identified by OncoKB, CIViC Variants, My Cancer Genome, and the available literature, were included. Pts with a mutation in at least one gene were included. Mutation frequencies across different cancer types were analyzed for each cohort, then pooled together. **Results:** We identified a total of 10,953 and 167,073 pts on TCGA and GENIE, respectively. Mutation frequencies for different cancer types are shown in the Table. Among the mutated cases, *IDH1* was the most altered gene in glioma (90.20% [95% Confidence Interval (CI): 90.19; 90.21]), hepatobiliary cancers (75.48% [75.40; 75.56]) and melanoma (55.75% [55.57; 55.92]), and the second most common in leukemia (39.86% [39.68; 40.04]), while *IDH2* was the most altered in leukemia (57.52% [57.34; 57.70]), and the second most common in glioma (5.25% [5.24; 5.25]), and hepatobiliary cancers (19.10% [19.04; 19.17]). *SDHA* was the second most altered gene in melanoma (12.95% [12.87; 13.03]). In RCC, *VHL* was the most mutated gene (92.79% [92.78; 92.79]), followed by *FH* (2.41% [2.40; 2.41]). *EPAS1* was mutated in 64.19% of cases with driver mutations in miscellaneous neuroepithelial tumors (MNET) ([57.07; 71.31]), but not in RCC. Among the altered cases in pheochromocytoma, *SDHB* was the most commonly altered gene (39.71% [35.31; 44.11], followed by *VHL* (18.41% [15.92; 20.91]). *SDHB* was also the second most common gene to be mutated in MNET (23.12% [19.37; 26.86]). **Conclusions:** In this analysis, mutations in HIF-regulating genes were detected in multiple cancers, and were not limited to those studied in the context of HIF inhibitors. Further research is required to elucidate whether these gene alterations sensitize tumors to HIF inhibition. Research Sponsor: None.

Pooled mutation frequencies for all considered genes in different cancer types.

Cancer Type	N	% Pooled Mutation Frequency of any gene	95% CI
RCC	3662	39.76	39.74; 39.77
Glioma	12657	23.67	23.67; 23.67
Leukemia	1857	15.49	15.47; 15.50
Hepatobiliary Cancer	4234	11.18	11.18; 11.19
MNET	253	8.61	8.54; 8.68

Analytical validation of EPISEEK, an epigenomic blood-based assay for multicancer detection. First Author: Thi Hanh Pham, Precision Epigenomics Inc, Tucson, AZ

Background: Early cancer detection significantly improves treatment outcomes and survival rates. However, cancer screening faces key challenges: (1) current tests detect only 14% of new cases and cover a limited range of cancers, (2) each cancer requires its own costly and complex screening process, (3) limited patient awareness of suitable screenings, and (4) poor adoption among marginalized and underinsured groups. EPISEEK was developed for multicancer detection using minimal cell-free DNA from plasma. Here, we present validation study results assessing its robustness and accuracy across 20+ cancer types and stages. **Methods:** EPISEEK is a cfDNA-based methylation assay optimized for 20 ng of cfDNA input from plasma. Plasma cfDNA underwent bisulfite conversion followed by methylation-specific quantitative PCR targeting 10 cancer biomarkers and 3 internal control markers. 251 plasma samples from four cancer stages across 25 cancer types, and 57 samples from individuals over 40 with no known cancer history, were used to establish reference ranges and assess assay specificity and sensitivity. Additional contrived and clinical samples were used to determine the assay's analytical LOD, reproducibility and stability. **Results:** 57 non-cancer samples were used to train the classifier, achieving 99% specificity at a 95% confidence level. Accuracy testing included 251 cancer samples representing > 20 primary cancer sites, including lung, colon, cervix, esophagus, head and neck, kidney, liver, breast, bladder, skin, testis, thyroid, ovary, pancreas, prostate, stomach, brain, bone marrow, and others. The cancer samples spanned all stages: I (29%), II (13%), III (29%), IV (22%), and cases with missing stage data (6.7%). Sensitivity increased with advancing stage, with observed sensitivity rate of 52%. By stage, observed sensitivity was stage I: 42%, stage II: 46%, stage III: 57%, and stage IV: 64%. Due to the limited and non-representative sample distribution for a typical multicancer screening population, SEER data were utilized to estimate EPISEEK's real-world performance by adjusting tumor incidence and stage when estimating positive predictive value and negative predictive value. At 99% specificity and based on adjusted performance, EPISEEK achieved a positive predictive value (PPV) of 40% and a negative predictive value (NPV) of 99%. Seven markers were detectable with < 0.1 ng DNA, while the remaining three markers had an LOD95 of 0.1–0.37 ng. Comparing Ct values of each cancer target both intra and inter runs, EPISEEK demonstrated high reproducibility with standard deviation of 0.383 (high positive), 0.232 (low positive) and 1.063 (negative samples). **Conclusions:** EPISEEK is a sensitive, specific, accurate, and reproducible multicancer detection test. Compared to comprehensive genomic profiling techniques, it offers an affordable testing option for broader populations with a fast turnaround time. Research Sponsor: None.

Small nucleolar RNAs (snoRNAs) expression and effects on patient (pt) outcomes in metastatic colorectal cancer (mCRC): Data from CALGB (Alliance)/SWOG 80405. First Author: Francesca Battaglin, Division of Medical Oncology, Norris Comprehensive Cancer Center, Keck School of Medicine, University of Southern California, Los Angeles, CA

Background: SnoRNAs are non-coding RNAs that primarily guide the chemical modification of ribosomal RNA. Emerging evidence suggests snoRNAs play critical roles in cancer, including CRC, by regulating cell proliferation, apoptosis and tumor progression. Aberrant snoRNA expression has been linked to CRC development and poor prognosis, offering potential as diagnostic biomarkers and therapeutic targets. We investigated whether the tumor expression levels of 3 types of snoRNAs (SCARNA, SNORA, SNORD) affect treatment response in pts enrolled in CALGB/SWOG 80405 (NCT00265850). **Methods:** 433 mCRC pts treated with bevacizumab (bev, n = 226) or cetuximab (cet, n = 207) in combination with first-line chemotherapy were analyzed. RNA was isolated from FFPE tumor samples and sequenced on the HiSeq 2500 (Illumina). 422 snoRNAs were evaluated (23 SCARNA, 140 SNORA, 259 SNORD). Overall survival (OS) and progression-free survival (PFS) were compared across tertiles of gene expression (high [H], medium [M], low [L]) by multivariable Cox proportional hazards models adjusted for age, sex, ECOG performance status, tumor side, number of metastatic sites, *KRAS*, CMS subtypes, and treatment. Interaction tests for the predictive effect (bev vs cet) were performed. *P*-values were corrected for multiple testing using the Benjamini-Hochberg approach ($q < 0.05$). **Results:** Only SCARNA21 achieved statistical significance for OS after false discovery rate (FDR) adjustment. Tumors with H levels of SCARNA21 had shorter survival compared to tumors with M or L expression (median OS 24.4 vs 32.4 vs 33.9 months, respectively; $P = 0.0015$, $q = 0.033$), independent of treatment. No snoRNAs achieved FDR significance for PFS. However, several snoRNAs showed significant treatment interactions with biologic agents. SCARNA6-H and SCARNA5-H tumors had longer PFS and OS when treated with cet, but shorter PFS and OS when treated with bev, compared to the M and L expression groups (PFS interaction $q = 0.0067$ and 0.045, respectively; OS interaction $q = 0.022$ and 0.034, respectively). SCARNA7 also showed significant treatment interaction for OS, favoring cet in the H expression group ($q = 0.018$); the opposite was observed for SNORA63B, SNORA63D, SNORA35B, and SNORA36C ($q = 0.027$, 0.027, 0.027 and 0.047, respectively). No significant results were observed for any of the tested SNORDs. **Conclusions:** SnoRNAs dysregulation affects key pathways such as cell cycle control and immune evasion, making them promising players in CRC biology. Our study highlights the prognostic and predictive potential of specific snoRNAs in mCRC. Notably, high SCARNA21 expression was linked to shorter OS, while SCARNA5 and 6 showed predictive value for treatment response, indicating their potential for guiding treatment decisions. Further validation is needed to confirm these findings, and mechanistic studies are warranted. Research Sponsor: National Cancer Institute; Genentech; https://acknowledgments.alliancefound.org.

Impact of MGMT methylation on overall survival in solid tumors: A systematic review and meta-analysis. First Author: Abdulla Alzibdeh, King Hussein Cancer Center, Amman, Jordan

Background: The protein O6-alkylguanine-DNA-alkyltransferase (AGT), encoded by the MGMT gene, plays a crucial role in DNA repair by singularly removing alkyl lesions from the O6 position of guanine, maintaining genomic stability. Loss of MGMT expression, often due to promoter methylation, is linked to enhanced sensitivity to chemotherapy. While MGMT methylation has been observed in various cancers, its impact on overall survival (OS) in solid tumors remains uncertain. **Methods:** According to PRISMA guidelines, we selected studies from PubMed that examined the impact of MGMT methylation on OS in adult patients with solid tumors. Data were extracted where MGMT methylation status was clearly defined, and OS was reported through hazard ratios (HR) from either uni- or multivariable analyses. We employed R version 4.4.2 and the 'meta' package for our meta-analysis, using both fixed-effects (Mantel-Haenszel method) and random-effects (DerSimonian and Laird's method) models based on the I^2 statistic for heterogeneity. Subgroup analyses were conducted by cancer type, and publication bias was assessed through funnel plot inspection and Egger's regression. Statistical significance was set at $p < 0.05$. **Results:** The meta-analysis included 23 studies, with a total of 3,410 participants across all studies. The studies included an array of cancers, the most common being colorectal (n = 7), then head and neck (n = 6), and lesser-represented groups like pancreatic neuroendocrine (n = 2) and others. The pooled analysis using a random-effects model demonstrated that MGMT methylation status was not significantly related with OS (HR of 1.1967; 95% CI: 0.9004 to 1.5904; p = 0.2040). Subgroup analysis revealed that the impact of MGMT methylation on survival varied significantly across different types of cancer. No significant association was yielded between MGMT methylation and OS for colorectal cancer (HR of 0.9496; 95% CI: 0.6252 to 1.4422), head and neck cancer (HR of 1.1520; 95% CI: 0.8223 to 1.6137), NSCLC (HR of 1.0479; 95% CI: 0.3343 to 3.2841) and pancreatic neuroendocrine cancer (HR of 1.5541; 95% CI: 0.6493 to 3.7195). Conversely, a significant association was yielded for less common cancers, including melanoma, biliary and cervical cancers. The funnel plot and Egger's test for publication bias (t = -0.3999, p = 0.6933) suggested no significant asymmetry, indicating minimal publication bias within this meta-analysis. **Conclusions:** Our findings indicate that MGMT methylation does not universally predict OS across all solid tumors. The variability in survival impact across different cancer types suggests that the prognostic significance of MGMT methylation may be context-dependent, emphasizing the need for tumor-specific studies. A phase II basket trial evaluating the efficacy of tasurgratinib (E7090) in patients with advanced solid tumors with fibroblast growth factor receptor (FGFR) gene alteration: FORTUNE study. First Author: Junichi Matsubara, Department of Clinical Oncology, Kyoto University Hospital, Kyoto, Japan

Background: Tasurgratinib is an orally available selective inhibitor of FGFR1-3 tyrosine kinase and is approved in Japan for biliary tract cancer with *FGFR2* fusions or rearrangements based on a global phase 2 study. We previously identified *FGFR* gene alterations that are highly sensitive to tasurgratinib using a high-throughput functional evaluation method (MANO method) (npj Precision Oncology [2021] 5:66). We conducted a single-arm, investigator-initiated multicenter phase 2 basket trial to evaluate the efficacy and safety of tasurgratinib in patients (pts) with advanced solid tumors harboring *FGFR* gene alterations, including alterations identified by MANO method. **Methods:** Pts with advanced solid tumors with *FGFR* gene alterations detected by next-generation sequencing assays received tasurgratinib 140 mg QD. Pts were allocated to each Group based on *FGFR* gene alteration (Group A: *FGFR1-3* fusion, Group B: *FGFR1-3* sensitive mutations to tasurgratinib determined by MANO methods, Group C: *FGFR1-3* activating mutation not applicable to group B or *FGFR1, 2* gene amplification, Group D: cholangiocarcinoma with *FGFR2* fusion and previous treatment with a FGFR inhibitor except for tasurgratinib). The primary endpoint for Groups A, B, and C was objective response rate (ORR) by independent central review (ICR). Group D was an exploratory cohort, and ICR was not performed. The secondary endpoints included ORR by investigator assessment (IA), progression-free survival (PFS), overall survival, and safety. The threshold and expected response rates were 5% and 30%, respectively. With the one-sided significance level of 5%, the target enrolments were 10 (62% power), 15 (87%), and 15 pts (87%) in Groups A, B, and C, respectively. Group D's target number was 1 to 5 pts without a statistical hypothesis. **Results:** From June 2021 to December 2022, 46 pts were registered. The full analysis set includes 41 pts (10, 15, 15, and 1 in Groups A, B, C, and D, respectively). The most common primary sites were brain in 4 pts (40.0%) in Group A, biliary tract in 4 pts (26.7%) in Group B, and esophagus/stomach in 4 pts (26.7%) in Group C. ORRs by ICR in Group A, B and C were 20.0% (90% CI: 3.7-50.7, p = 0.0861), 20.0% (90% CI: 5.7-44.0, p = 0.0362), 6.7% (90% CI: 0.3-27.9, p = 0.5367), respectively. ORRs by IA in Group A, B, C, and D were 20.0% (95% CI: 2.5-55.6), 40.0% (95% CI: 16.3-67.7), 13.3% (95% CI: 1.7-40.5) and 0.0% (95% CI: 0.0-97.5), respectively. Median PFS by IA in Groups A, B, C, and D were 2.5 (95% CI: 1.4-5.7), 7.2 (95% CI: 1.7-8.2), 2.2 (95% CI: 1.9-3.7) and 5.7 months (95% CI: not evaluable), respectively. There was no new safety signal compared to previous reports. **Conclusions:** In Group B, the primary endpoint was met. Tasurgratinib demonstrated clinical activity in pts with selected FGFR-mutated tumors. Further study is needed to validate these findings. Clinical trial information: NCT04962867. Research Sponsor: Eisai; Japan Agency for Medical Research and Development; 20lk1403036h0001.

Efficacy and safety of larotrectinib in patients with non-primary central nervous system TRK fusion cancer: An updated analysis. First Author: Rui-Hua Xu, Sun Yat-sen University Cancer Center, Guangzhou, China

Background: *NTRK* gene fusions are oncogenic drivers in various tumor types. Larotrectinib (laro) is the first-in-class, highly selective, central nervous system (CNS)-active TRK inhibitor approved for tumor-agnostic use in patients (pts) with TRK fusion cancer based on a robust and durable objective response rate in pts with various cancers. Here, we report updated long-term efficacy and safety data in adult and pediatric pts with non-primary CNS TRK fusion cancer treated with laro. **Methods:** Pts with TRK fusion cancer enrolled in 3 laro clinical trials (NCT02637687 [SCOUT], NCT02576431 [NAVIGATE], NCT02122913) were included. Laro was administered at 100 mg twice daily (BID) and 100 mg/m^2 BID in most adult and pediatric pts, respectively. Responses were independent review committee (IRC)-assessed per RECIST v1.1. Pts enrolled in SCOUT were permitted to stop laro in the absence of on-treatment progression ("wait-and-see"). The data cutoff was July 20, 2024. **Results:** At data cutoff,304 pts were eligible for efficacy assessment by IRC; 25 pts had known CNS metastases at baseline. Median age was 45 years (range 0–90). There were 28 different tumor types, including soft tissue sarcoma (24%), infantile fibrosarcoma (16%), lung (11%), and thyroid (10%). A total of 101 pts (33%) received no prior systemic therapies in the metastatic/unresectable setting; 115 (38%) received 2 or more. *NTRK* gene fusions were detected by next-generation sequencing (NGS) in 267 (88%) pts. The overall response rate was 65% (95% confidence interval [CI] 59–70): 66 (22%) complete responses (CR), 20 (7%) pathological CR, 112 (37%) partial responses, 56 (18%) stable disease, 32 (11%) progressive disease, and 18 (6%) not evaluable/undefined. Median time to response was 1.8 months (mo; range 0.9–22.9). Median duration of response (DoR), progression-free survival (PFS), and overall survival (OS) were 43 mo (95% CI 34–not estimable), 28 mo (95% CI 22–38), and not reached, respectively, at median follow-ups of 45, 42, and 57 mo. The 4-year rates for DoR, PFS, and OS were 48% (95% CI 40–57), 39% (95% CI 32–46), and 63% (95% CI 57–68), respectively. Median duration of treatment was 19 mo (range 0–100+). Fifty-five of 99 pediatric pts in SCOUT had participated in "wait-and-see"; the median duration of the first "wait-and-see" period was 33 mo (range 1–72). At data cutoff, 83 pts (27%) remained on trial (either on treatment or in "wait-and-see"). Treatment-related adverse events (TRAEs) were mainly Grade 1/2 (n = 189; 62%). Grade 3/4 TRAEs occurred in 71 (23%) pts. Five (2%) pts discontinued due to TRAEs. **Conclusions:** Laro continues to demonstrate rapid and durable responses, extended survival, clinical benefit, and a favorable safety profile in pts with TRK fusion cancer. This data supports the wider adoption of NGS panels that include *NTRK* gene fusions to identify pts who may benefit from treatment with TRK inhibitors. Clinical trial information: NCT02637687, NCT02576431, NCT02122913. Research Sponsor: Bayer HealthCare Pharmaceuticals, Inc.

Early prediction of prognosis in advanced solid tumor patients using tumor growth rates with *g* score in early phase clinical trials. First Author: Kana Kurokawa, Department of Advanced Medical Development, The Cancer Institute Hospital of Japanese Foundation for Cancer Research, Tokyo, Japan

Background: The primary objective of early phase clinical trials is to evaluate the safety of investigational drugs, which requires participants to have sufficient expected survival durations. Tumor growth rate using *g* scores, calculated using radiographic measurements and timing after treatment, is gaining attention as a potential tool for treatment efficacy assessment. This study aims to assess the utility of *g* scores before and after treatment in predicting prognosis, and explore suitable trial candidates for accelerating drug development in early phase clinical trials. **Methods:** We retrospectively reviewed patients who participated in early phase clinical trials after standard treatment at the Department of Advanced Medical Development, The Cancer Institute Hospital of Japanese Foundation for Cancer Research between January 2020 to December 2023. A mathematical exponential growth model was applied to estimate tumor growth rates (*g*) based on radiographic tumor measurements and interval time: $f(t) = \exp(g \cdot t)$, with pre-*g* scores derived from measurements before the clinical trial and post-*g* scores from measurements after trial initiation. Pre-*g* scores were calculated using trial baseline computed tomography (CT)s and the most recent CTs before trial enrollment, while post-*g* scores were calculated using baseline CTs and the first evaluated CTs after treatment. We defined dichotomized *g* score levels (high/low) using the time-dependent ROC curve procedure. We evaluated independent predictors for survival outcomes according to each *g* score and patient characteristics. **Results:** Of the 173 cases who participated in early phase clinical trials after standard treatment, 162 cases with evaluable CT scans before and after the clinical trial were included in this study. Median time to pre-trial CT was 29 days (range, 5–202), and median time to first post-treatment evaluation was 49.5 days (range, 16–87). Log-rank testing showed both high pre-. and post-. scores correlated to shorter overall survival (OS) compared to low-score groups (HR 2.16; 95% CI 1.22-3.81; P = 0.0067, HR 2.68; 95%CI 1.84-3.90; $P < 0.001$). Multivariate analysis showed both high pre-*g* and post-*g* scores were independent predictors of shorter OS (HR 2.06, 95% CI 1.13-3.75; P = 0.019, HR 3.80, 95% CI 2.44-5.90; $P < 0.001$). **Conclusions:** This study is the first to incorporate pre-. scores as an independent prognostic factor and may serve as a valuable reference for patient enrollment in early phase clinical trials under late-line settings. Additionally, post-. scores were also identified as an independent prognostic factor across multiple cancer types in early phase clinical trials. These results indicate their potential use as surrogate endpoints to, which may help facilitate drug development. Research Sponsor: None.

Picking needles in a haystack: Exploring rare variants of a pan-cancer target in the RET landscape from 229,453 adult cancer patients. First Author: Niamh Coleman, Trinity St. James's Cancer Institute, Dublin, Ireland

Background: Advances in precision oncology have led to the approval of tumor-agnostic therapies, and RET, due to its role as a driver of oncogenesis across multiple tumor types, is increasingly recognized as a pan-cancer target. RET alterations, including mutations and fusions, are relatively rare events, however, potent and selective RET inhibitors such as selpercatinib and pralsetinib have demonstrated remarkable efficacy and changed clinical practice in RET-driven NSCLC, thyroid cancer and other cancers. Here, we present a comprehensive analysis of RET alterations in pan-cancer adult malignancies. **Methods:** 229,453 samples from 196,244 patients available from AACR Project GENIE v.17 database were analyzed for the prevalence of RET mutations, fusions and copy number alterations in a range of cancer types. **Results:** A total of 7011 separate RET alterations were identified in 6690 separate pts (3%), including 660 fusions (9.4%), 5553 missense mutations (79.2%), 373 splice site mutations (5.3%), 339 truncating mutations (4.8%), 86 in-frame mutations (1.2%). Most frequent tumor types included NSCLC, colorectal cancer, melanoma, thyroid cancer, endometrial cancer and glioma (23%, 12.2%, 9.5%, 6.6%, 6.4%, 5.3% identified RET alterations, respectively). RET fusions were observed in 0.3% of tumor samples, most identified in NSCLC, thyroid and colorectal cancer (53%, 24% and 4% of identified *RET* fusions). Most fusions were considered driver events using OncoKB database (632, 96%);frequent fusion gene partners included *KIF5B, CCDC6, NCOA4*, and intragenic events (34%, 25%, 9.7%, 8% of 660 fusion samples). Of the 5553 missense mutations, most (89%) were considered variants of uncertain significance; 605 (11%) were considered oncogenic or likely oncogenic. Oncogenic missense mutations occurred across codons, most frequently involving codon 918 (n = 215, 36%; M918M/K/T/V), 648 (n = 41, 6.8%; V648I/A), 886 (n = 28, 4.6%; R886W/Q/L), 630 (n = 21, 3.5%; C630G/R/S/F/Y/W), 891 (n = 31, 5%, S891A/L/W). Documented on-target drivers of multi-kinase RET inhibitor resistance gatekeeper mutations (V804M/L), and selective RET inhibitor resistance mutations were noted in 61 samples, including G810C/S substitutions, solvent-front mutations K809R/N, activation loop mutations Y806C/N (33%, 53%, 3%, 3% of identified samples); most were classified as oncogenic or likely oncogenic (85%). **Conclusions:** RET fusions are rare events across cancers; however, most are characterized as oncogenic. RET missense mutations occur in 2.4% of malignancies, and while most RET missense variants are described as variants of uncertain significance, oncogenic RET variants are diverse, occurring across codons. We confirm multiple documented oncogenic drivers of on-target resistance, and their distinct and diverse mechanisms underline the urgent need to develop next generation RET inhibitors. Research Sponsor: None.

LODESTAR: A single-arm phase II study of rucaparib in solid tumors with pathogenic germline or somatic variants in homologous recombination repair genes. First Author: Sriram Anbil, University of Pennsylvania Health System, Philadelphia, PA

Background: To explore PARP inhibitor (PARPi) utility across solid tumors and identify biomarkers that predict sensitivity. **Methods:** This single-arm phase II study assessed rucaparib monotherapy in patients with solid tumors and pathogenic variants (PVs) in *BRCA1, BRCA2, PALB2, RAD51C, RAD51D* (Cohort A) or *BARD1, BRIP1, FANCA, NBN, RAD51B* (Cohort B). The primary endpoint was ORR in Cohort A. Secondary endpoints included DCR, PFS, OS and safety. A scar-based HRD signature (HRDsig) and platinum sensitivity status were explored post-hoc. **Results:** Fifty-one patients in Cohort A and 12 in Cohort B were evaluable for efficacy. ORR of cohort A was 18% (95% CI 10-30%). A significantly higher ORR was observed with HRDsig+ tumors compared to HRDsig- tumors (32%, 95% CI 15-54, vs. 0%, 95% CI 0-14%, $p < 0.01$). In the entire study population: DCR of 65% (95% CI 53-76%), mPFS of 5.5 mo (95% CI 3.68-7.82), and mOS of 12.1 mo (95% CI 10.6 – inf). PFS and OS were significantly longer for platinum sensitive tumors (mPFS: 7.8 mo vs. 3.5 mo, p = 0.02; mOS: NR vs 5.45mo, p = 0.01). Tumor histology was not independently predictive of outcome. Tumors with PVs in Cohort A genes were more likely to be HRDsig+ than tumors with PVs in Cohort B genes. Analysis of a large commercial database showed that in non-canonical tumors with *BRCA* PVs, 30.2% were HRDsig+. **Conclusions:** Rucaparib has activity in HRDsig+ solid tumors with PVs in HRR genes, regardless of histology. Platinum sensitivity correlated with improved outcomes. Clinical trial information: NCT04171700. Research Sponsor: Clovis Pharmaceuticals.

A multicenter, randomized controlled trial of intrapleural drug-loaded vesicle perfusion combined with systemic therapy for malignant pleural effusion. First Author: Jiani Wang, Department of Medical Oncology, National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China

Background: This study aimed to evaluate the efficacy and safety of drug-loaded vesicle (DLV) intrapleural perfusion combined with systemic therapy in patients with lung or breast cancer and malignant pleural effusion (MPE). **Methods:** This multicenter, randomized, controlled, open-label clinical trial included patients with pathologically confirmed lung or breast cancer and MPE requiring thoracentesis. In total, 96 patients were randomised 1:1 to arm 1 receiving DLV intrapleural perfusion (50 mL daily for four consecutive days) plus systemic therapy (ST) or arm 2 receiving interleukin-2 (IL-2) intrapleural perfusion (50 mL every three days for three sessions) with ST.The primary endpoint was the objective response rate (ORR) of pleural effusion at 4 weeks post-perfusion, while secondary endpoints included overall survival (OS) and treatment-related toxicity.The difference in ORR between the two cohorts was analyzed using the Chi-square test. Kaplan-Meier survival analysis was performed for OS comparison between the two cohorts. **Results:** A total of 91 patients were evaluated for efficacy (50 in arm 1 and 41 in arm 2). The DLV+ST arm 1 showed a significantly higher ORR for pleural effusion than the IL-2+ST arm 2 (74.0% vs. 53.7%, P = 0.043). In the survival analysis of 83 evaluable patients, median OS was 15.0 months (95% CI: 9.2–26.9) in arm 1 and 6.9 months (95% CI: 5.3–15.8) in arm 2, without a statistically significant difference (HR = 0.75; 95% CI: 0.46–1.24; P = 0.266). The 1-, 2-, and 3-year OS rates for arm 1 were 83.0% (95% CI: 72.9–94.4%), 59.6% (95% CI: 47.1–75.4%), and 51.1% (95% CI: 38.6–67.6%), compared to arm 2's 69.4% (95% CI: 55.9–86.2%), 41.7% (95% CI: 28.3–61.3%), and 33.3% (95% CI: 21.0–52.9%). Both arms had similar safety profiles, with chemotherapy-induced toxicities, including leukopenia, gastrointestinal reactions, and liver dysfunction, being the most common treatment-related adverse events. **Conclusions:** Drug-loaded vesicle intrapleural perfusion combined with systemic therapy is a safe and effective treatment option for malignant pleural effusion in patients with lung or breast cancer. This approach represents a promising treatment strategy for MPE and warrants further clinical investigation and consideration in clinical practice. Clinical trial information: ChiCTR1800017104. Research Sponsor: None.

The efficacy and safety of a selective PARP1 inhibitor ACE-86225106 in patients with advanced solid tumors: Preliminary results from a first-in-human phase 1/2 study. First Author: Jiongjie Chen, Acerand Therapeutics (Hong Kong) Limited, Shanghai, China

Background: ACE-86225106 is a highly selective PARP1 inhibitor, exhibiting high potency in enzymatic and DNA-trapping assays of PARP1, while maintaining significant selectivity over PARP2. Pre-clinical studies with ACE-86225106 have demonstrated strong anti-cancer activities in *in vivo* CDX models, with excellent tolerability. Here we report the preliminary clinical data of ACE-86225106 from the ongoing first-in-human study (NCT06380660). **Methods:** This is a multicenter, open-label, phase1/2 study of ACE-86225106 in adult patients with locally advanced (unresectable) or metastatic solid tumors. Phase 1 includes a typical "3+3" dose escalation and backfill module, followed by a dose expansion module in phase 2. The primary objective is to assess safety, tolerability, PK/PD profile, and pre-liminary efficacy of ACE-86225106 as a monotherapy. **Results:** As the data cut-off (23 Jan 2025), 10 patients received ACE-86225106 at a dose of 5mg, 10mg or 20mg QD, and 5 patients backfilled at a dose of 10mg QD. Median number of prior therapy lines was 3 (range 2-12). Two patients (squamous lung cancer and breast cancer each) did not complete the DLT evaluation period due to disease progression and were replaced. No DLTs were reported as of data cut-off. Among total fifteen patients (10 patients) who received at least one dose of ACE-86225106, no Grade 3 or higher treatment-related adverse events (TRAEs) were reported. There were no treatment discontinuations or dose reductions due to TRAE. The compound exhibited a relatively flat PK curve with mild accumulation after multiple dosing. The steady-state C_{trough} was approximately 5 fold, 24 fold and 36 fold above target effective concentration at dose level of 5mg, 10mg, 20mg respectively. The PARylation inhibition was $>$ 90% confirming target engagement. Of seven patients having post-treatment tumor assessment and being considered efficacy-evaluable, two patients (one fallopian tube cancer patient with BRCA mutation and one prostate cancer patient with BRCA wild type) achieved PR per RECIST1.1. **Conclusions:** Preliminary data indicate that ACE-86225106 is well tolerated and shows promising efficacy in heavily pre-treated advanced solid tumors. Clinical trial information: NCT06380660. Research Sponsor: Acerand Therapeutics (Hong Kong) Limited.

3154 **Poster Session**

Effect of biopsy requirement on patient enrollment to phase I trials in cancer. First Author: Marisa Palmeri, Rutgers Robert Wood Johnson Medical School, New Brunswick, NJ

Background: The need for safer and more effective drugs for patients with cancer is a constant unmet need. Given their narrow therapeutic index, determination of dose and toxicity through phase I clinical trials is confined to patients with cancer. Recently, there has been a trend towards a greater demand for fresh tumor biopsies (Bx) from patients to better understand the pharmacodynamic and target effect of the drugs. We sought to determine whether the requirement for Bx among this vulnerable population had any detrimental effect. **Methods:** The study population included patients who enrolled to phase I trials between June 2022 (new EMR system) through January 2025 at a single NCI-designated comprehensive cancer center. All charts were reviewed and data collected included sex, race, age, diagnosis, and dates of consent, treatment start, last dose of study drug, off treatment, last contact/death; Bx site/approach/complications. Images were reviewed by an interventional radiologist to assess safety, with targets deemed appropriate biopsied under image guidance. For lung lesions or those $<$ 1 cm, 20g core needle was used, while 18g core needle was used for others. Outcomes were analyzed by Mantel–Cox test using Prism GraphPad v 10. **Results:** 146 patients [male (n = 63, 43.2%), age 62, 23-82(median, range), NHW-81 (55.5%), NHB-23 (15.8%), Hispanic-24 (16.4%), and Asian-18 (12.3%)] consented to 25 clinical trials. Of these, 8 mandated paired tumor Bx, 15 were mandatory or optional Bx depending on cohort, and 2 did not require Bx. The most common diagnoses were colorectal (37, 25.3%), other GI (21, 14.4%), pancreas (18, 12.3%), lung (11, 7.5%), breast (6, 4.1%), prostate (3, 2.1%) and others (50, 34.2%). Bx samples were to be collected prior to the first dose of study drug (pre-dose) and repeated after the first 1-2 cycles (on-study). Image guidance included ultrasound (50, 57.5%), CT scans (34, 39.1%), and others (3, 3.4%). Overall, 62 patients (42.4%) provided 87 Bx samples; 25 paired Bx, 20 only pre-dose Bx, and 17 only on-study Bx. Five patients (3.4%) did not undergo Bx because it was deemed unsafe or high risk. The sites of Bx included liver (45, 51.7%), lung (9, 10.3%), lymph node (8, 9.2%), peritoneum (4, 4.6%), and others (21, 24.1%). Two patients experienced pneumothorax and recovered without sequelae. The median (mean) duration from consent to start of study treatment was 20 (20) days among Bx patients vs. 14 (16) among non Bx patients (p = 0.003). The median (mean) duration of time on study was 77 (91) days among Bx patients vs. 77 (125) among non Bx patients (p = 0.046). **Conclusions:** Over 40% of patients entering phase I trials underwent study specific Bx. The patients who underwent a Bx had a median delay of 6 days in receiving the first dose of study medication. Further in-depth review of medical records will help identify variables that may have led to shorter time on study for patients undergoing clinical trial related biopsies. Research Sponsor: None.

3155 **Poster Session**

Rapid analysis and response evaluation of combination anti-neoplastic agents in rare tumors (RARE CANCER) trial: RARE 2 talazoparib and temozolomide. First Author: Jibran Ahmed, National Cancer Institute, Bethesda, MD

Background: Preclinical data generated from NIH/NCI Patient-Derived Models Repository (PDMR) demonstrated significant synergistic activity of talazoparib (a PARP inhibitor) combined with temozolomide (an alkylating agent) in patient-derived xenograft models of rare adult and pediatric cancers. This clinical trial aimed to evaluate the objective response (OR) rate of this combination in patients with advanced rare cancers in exploratory fashion. Correlatives include genomic and transcriptomic profiling of tumor tissue, circulating tumor DNA (ctDNA), circulating tumor cells, and assessments of apoptosis and epithelial-mesenchymal transition in relation to treatment activity. **Methods:** This open-label, non-randomized, phase 2 trial used a Simon two-stage design. Patients aged $\geq$18 years with advanced rare cancers received temozolomide (37.5 mg/m² orally, days 2–6) and talazoparib (750 mcg orally, daily) in 28-day cycles. Tumor response was assessed per RECIST v1.1, and adverse events (AEs) assessed using CTCAE v5.0. In the first stage, if 0/14 (across all histologies) responses are observed, the trial will be closed for futility. Otherwise, additional 16 patients were planned to be enrolled. There are no selection criteria based aside from rare tumor to allow for exploration of activity. **Results:** Fourteen patients were enrolled, all evaluable for response and toxicity. Median age was 57 years; 11 were female, and all had ECOG 0–1. Tumor histologies included uterine sarcoma (N = 3), cholangiocarcinoma (N = 2), and one each of adrenocortical carcinoma, adenoid cystic carcinoma, clear cell salivary carcinoma, MPNST, angiosarcoma, carcinoma of unknown primary, squamous urothelial carcinoma, small cell neuroendocrine carcinoma, and SDHB deficient renal cell carcinoma. Best responses included stable disease (N = 6), progressive disease (N = 5), and clinical progression (N = 3). One patient with clear cell salivary cancer and another with cholangiocarcinoma remained on treatment for 8 and 6 cycles, respectively. The median progression free survival is 3.81 months. The most common treatment related AEs (TRAEs) overall as well as $\geq$Grade 3 were hematologic including thrombocytopenia (13; $\geq$Grade 3 = 10), anemia (total12; $\geq$Grade 3 = 10), lymphopenia (total 12; $\geq$Grade 3 = 5), neutropenia (total 11; $\geq$Grade 3 = 6), and leukopenia (total 10, $\geq$Grade 3 = 4). No Grade 5 TRAEs were reported. Although none of the patients discontinued treatment due to TRAEs, planned dose reductions were needed for 7 patients. **Conclusions:** Despite promising preclinical activity, this tumor agnostic exploratory trial did not meet strict goal more design for single histology. Future efforts will focus on correlative analyses, exploring histology-specific expansion cohorts informed by pre-clinical response data, and optimizing dosing schedules to reduce overlapping toxicities. Clinical trial information: NCT05142241. Research Sponsor: U.S. National Institutes of Health.

Body composition modulations during cyclic fasting-mimicking diet in patients with advanced solid cancers. First Author: Caterina Sposetti, Dana-Farber Cancer Institute, Harvard Medical School, Boston, MA

Background: Fasting-mimicking diets (FMD) can induce favorable immune-metabolic changes in humans and preclinical data suggest potential antitumor activity. Cyclic FMD impact on muscle mass and adiposity in patients (pts) is unclear. Here we evaluate body composition changes in pts with advanced solid cancers undergoing FMD in the context of a phase Ib trial (NCT03340935). **Methods:** NCT03340935 study evaluated safety and biological effects of a cyclic FMD consisting of a 5-day, calorie-restricted, plant-based diet repeated every 21-28 days for a maximum of 8 cycles, conducted in oncologic patients receiving concomitant therapies. Here we included pts with advanced solid cancers and Computed Tomography (CT) exams at baseline (BL), FMD end and disease progression (PD). Body composition parameters, i.e. Skeletal Muscle Index (SMI) and Visceral (VAT), Subcutaneous (SAT), Intermuscular (IMAT) Adipose Tissues, were assessed via axial CT scan at 3rd lumbar vertebra using SliceOmatic software. Pts with advanced triple negative breast cancer (TNBC) receiving chemotherapy (ChT) without FMD, having CT scans at BL and PD, were selected as control cohort. Wilcoxon tests were used for comparisons. **Results:** In the FMD cohort (n=36), 61% had BC, 39% had TNBC, 78% received ChT; median age was 54 (IQR 51-65), median completed FMD cycles was 5 (IQR 3-8), median time from FMD end to PD was 3.5 months (IQR 1.0-16.0); 8 pts met criteria for sarcopenia (SMI $<$38.5 cm^2/m^2) at BL, 6 of whom had TNBC. In the control TNBC cohort (n=17), median age was 54 (IQR 42-68), 6 pts were sarcopenic at BL. In the FMD cohort, between BL and FMD end there was a significant reduction of VAT, SAT and SMI, but no change in IMAT; between BL and PD only SMI was significantly decreased (Table). At FMD end and PD, 12 pts were sarcopenic in the FMD cohort, 7 having TNBC. In the control TNBC cohort (n=17), IMAT was significantly increased between BL and PD, with no changes in other parameters (Table); 8 pts were sarcopenic at PD. **Conclusions:** In advanced cancers pts, cyclic FMD reduces adiposity as well as muscle mass. Tumor/therapy-related factors contribute to sarcopenia in advanced cancer pts, thus future trials involving FMD intervention should detect pts at risk and include supportive measures to preserve muscle mass. Support: Italian Association for Cancer Research (AIRC): AIRC-Bonadonna fellowship (C Sposetti), AIRC fellowship (F Ligorio), AIRC IG 2024 ID 30499 (PI: C Vernieri); Giuliani Foundation. IDeate-PanTumor02: A phase 1b/2 study to evaluate the efficacy and safety of ifinatamab deruxtecan (I-DXd) in patients (pts) with recurrent or metastatic solid tumors. First Author: Takahiro Kogawa, Department of Advanced Medical Development, The Cancer Institute Hospital of JFCR, Tokyo, Japan

Background: B7-H3 is highly expressed in many solid tumors but has limited expression in normal tissues; high B7-H3 expression is associated with shorter overall survival (OS) in several tumor types. I-DXd is a B7-H3–directed antibody–drug conjugate (anti−B7-H3 mAb covalently linked to a topoisomerase I inhibitor cytotoxic payload [DXd] via an enzymatically cleavable peptide-based linker). It showed promising efficacy in pts with advanced solid tumors in the Phase 1/2 IDeate-PanTumor01 study, with objective responses in 6 of the 7 tumor types with ≥5 pts (small cell lung cancer [SCLC], esophageal squamous cell carcinoma, metastatic castration-resistant prostate cancer, squamous non-small cell lung cancer, head and neck squamous cell carcinoma [HNSCC], and endometrial cancer). I-DXd also showed encouraging antitumor activity in 88 pretreated pts with extensive-stage SCLC in the Phase 2 IDeate-Lung01 study, with greater efficacy at the 12-mg/kg than the 8-mg/kg dose (objective response rates [ORRs] of 54.8% [95% CI, 38.7–70.2] and 26.1% [95% CI, 14.3–41.1], respectively). I-DXd has demonstrated a manageable and tolerable safety profile across tumor types. We describe a study investigating the efficacy and safety of I-DXd in pts with advanced solid tumors with substantial unmet medical needs. **Methods:** IDeate-PanTumor02 (NCT06330064) is a global, multicenter, open-label, single-arm, parallel-cohort, Phase 1b/2 study in ~520 adults with recurrent or metastatic solid tumors (endometrial cancer; HNSCC; pancreatic ductal adenocarcinoma; colorectal cancer; hepatocellular carcinoma [HCC]; esophageal/gastroesophageal/gastric adenocarcinoma; urothelial carcinoma; ovarian cancer; cervical cancer; biliary tract cancer; HER2-low breast cancer [BC]; HER2-negative BC; and cutaneous melanoma). Eligible pts will have received ≥1 systemic therapy for the selected tumor type and have an ECOG PS of ≤1. The study will be divided into 2 parts: Stage 1 and Stage 2 (n≈20 per stage per cohort). Each cohort starts with Stage 1 and may continue to Stage 2 if sufficient safety and efficacy data are observed. All cohorts except the HCC cohort will receive I-DXd 12 mg/kg every 3 weeks (Q3W). The HCC cohort includes a safety run-in part to assess tolerability and the potential need for dose adjustment; the planned starting dose is 8 mg/kg Q3W, which may be escalated. Primary endpoints are ORR per investigator (all cohorts) and safety (HCC safety run-in only). Secondary endpoints are safety, duration of response, progression-free survival, OS, disease control rate, pharmacokinetics, and immunogenicity. The Kaplan–Meier method will be used to estimate time-to-event endpoints, the Brookmeyer and Crowley method for median event times, and the Clopper–Pearson exact method to summarize descriptively endpoints with proportion. Enrollment is ongoing. Clinical trial information: NCT06330064. Research Sponsor: Daiichi Sankyo, Inc., Merck, Inc.

TPS3158 **Poster Session**

REJOICE-PanTumor01: A phase 2 signal-seeking study of raludotatug deruxtecan (R-DXd) in patients with advanced or metastatic gynecologic or genitourinary tumors. First Author: Laurence Albiges, Gustave Roussy, Paris Saclay University, Paris, France

Background: Cadherin-6 (CDH6), a transmembrane protein involved in cell–cell adhesion and epithelial–mesenchymal transition, is overexpressed in many cancer types. R-DXd is an anti-CDH6 antibody–drug conjugate composed of a humanized CDH6 antibody covalently linked to a potent topoisomerase I inhibitor payload (DXd) via a plasma-stable linker. In an ongoing Phase 1 study (NCT04707248), a subgroup of patients with heavily pretreated ovarian cancer (OC) who received R-DXd 4.8–6.4 mg/kg, had an objective response rate (ORR) of 48.6% (95% confidence interval [CI], 31.9–65.6); median duration of response (DOR) was 11.2 months (95% CI, 3.1–not estimable), and progression-free survival (PFS) was 8.1 months (95% CI, 5.3–not estimable), irrespective of CDH6 expression level (data cut-off: July 14, 2023). The safety profile of R-DXd was manageable. In total, 11.1% of patients discontinued R-DXd due to treatment-emergent adverse events. These promising data warranted further investigation of R-DXd in REJOICE-Ovarian01 (NCT06161025), a Phase 2/3 study in patients with platinum-resistant high-grade serous OC (HGSOC), and in the REJOICE-PanTumor01 Phase 2 study, which is described here. **Methods:** REJOICE-PanTumor01 (NCT06660654) is a global, open-label Phase 2 study in patients with locally advanced or metastatic gynecologic (endometrial cancer [EC], cervical cancer, or non-HGSOC) or genitourinary (urothelial cancer [UC] or clear cell renal cell carcinoma [ccRCC]) tumors. Cohorts are tumor type–specific; patients in all cohorts must have relapsed or progressive disease after receiving ≥1 prior line (and ≤3 prior lines in the EC, UC, and ccRCC cohorts only) of standard treatment. Adult patients with ECOG performance status 0–1 are eligible; there is no selection for tumor CDH6 expression. Approximately 40 patients will be enrolled into each cohort to receive R-DXd 5.6 mg/kg IV every 3 weeks until disease progression per RECIST 1.1, unacceptable toxicity, death, or other reason per protocol. In each cohort, a nonbinding futility interim analysis will be conducted after 20 patients complete a minimum of 12 weeks of follow-up, the results of which may determine whether the remaining (~20) patients will be treated. Primary endpoints are ORR for the gynecological and UC cohorts, disease control rate (DCR) for the ccRCC cohort (both investigator-assessed), and safety and tolerability for all cohorts. Secondary endpoints are ORR (ccRCC cohort only), DCR (except ccRCC cohort), PFS, DOR, time to response (all investigator-assessed per RECIST 1.1), pharmacokinetics, and immunogenicity. No formal hypothesis testing will be performed; ORR and DCR will be analyzed using a Clopper–Pearson method to determine 95% CI. PFS and DOR will be analyzed using the Kaplan–Meier method (2-sided 95% CI). Study enrollment began in January 2025. Clinical trial information: NCT06660654. Research Sponsor: Daiichi Sankyo, Inc., Merck Inc.

TPS3159 **Poster Session**

A phase 1, open-label, multi-center study of the safety, tolerability, and efficacy of IPH4502 as a single agent in advanced solid tumors. First Author: Shiraj Sen, NEXT Oncology, Dallas, TX

Background: Nectin-4 is a cell adhesion molecule frequently overexpressed across multiple solid tumor types, including urothelial carcinoma (UC), esophageal cancer, non-small cell lung cancer, and triple-negative breast cancer. It plays a significant role in carcinogenesis and cancer progression and is associated with poor survival in several tumor indications. Targeting Nectin-4 with enfortumab vedotin (EV), an antibody-drug conjugate (ADC) with a monomethyl auristatin E (MMAE) payload, demonstrated clinical benefit in UC, which exhibits the highest Nectin-4 expression among all solid tumor types. EV is now approved for the treatment of UC. IPH4502 is a differentiated Nectin-4 ADC conjugated with exatecan, a topoisomerase-1 inhibitor payload with a drug-to-antibody ratio of 8 via a cleavable hydrophilic linker. IPH4502 has been developed to address the unmet medical need of UC patients who have progressed on, or are ineligible for EV, as well as to treat tumor types with lower Nectin-4 expression beyond UC. In preclinical models, internalization capability and bystander effect of IPH4502 enable an efficient antitumor activity in Nectin-4 expressing tumor models, independent of Nectin-4 expression level, as well as in models resistant to EV. Finally, IPH4502 shows antitumor activity in patient-derived xenograft models from UC and other tumor types. **Methods:** This is a first-in-human, open-label, multicenter, single-arm Phase 1 study to assess the safety profile (DLTs and MTD), tolerability according to NCI-CTCAE v5.0, and RP2D of IPH4502 in patients with advanced solid tumors. Secondary objectives aim to characterize the pharmacokinetic profile and evaluate the immunogenicity and preliminary efficacy of IPH4502. The study is being conducted in participants aged ≥18 years withhistologically confirmed, unresectable, locally advanced, or metastatic solid tumors known to express Nectin-4, including, but not limited to non-small cell lung, triple-negative breast, ovarian, esophageal, gastric, and colorectal cancers, as well as UC. Part 1 (Dose Escalation) will use a Bayesian Optimal Interval Design (BOIN) with backfilling of safety-cleared dose levels. This approach will guide dose escalation and help establish the MTD/MAD. Part 2 (Dose Optimization)will begin after identifying the MTD/MAD, to select the RP2D. It will enroll participants with selected tumor indications (up to 2), for whom a clinical benefit was observed in Part 1. Participants will be randomized at a 1:1 ratio to 2 dose levels, to determine the RP2D. A maximum of 105 participants will receive treatment with IPH4502 in France and the US. Clinical trial information: NCT06781983. Research Sponsor: None.

TPS3160 **Poster Session**

Design of a first-in-human multicenter open-label study of ZW171, a mesothelin x CD3 targeting bispecific T-cell engager, in participants with advanced solid tumors: ZWI-ZW171-101. First Author: Melissa Lynne Johnson, Sarah Cannon Research Institute, Nashville, TN

Background: Mesothelin (MSLN) is a membrane glycoprotein overexpressed in several solid tumors, making it a promising target for cancer treatments, including T cell engagers (TCEs). ZW171 is a humanized trivalent bispecific TCE antibody that targets a threshold level of MSLN expression with 2 binding sites and CD3e receptor on T cells with 1 binding site. Preclinical studies of ZW171 demonstrated favorable pharmacology, pharmacokinetics (PK), and toxicology, showing it preferentially kills MSLN-overexpressing cells, activates T cells without significant toxicity, inhibits tumor growth, and is well tolerated in cynomolgus monkeys, suggesting its potential for treating MSLN-expressing tumors[1] while sparing healthy tissues with low levels of expression. This first-in-human, phase 1, ongoing study (ZWI-ZW171-101) evaluates safety, tolerability, PK, and anti-tumor activity of ZW171 in participants with advanced solid tumors. **Methods:** This 2-part study enrolls eligible adult participants with unresectable MSLN-expressing ovarian cancer (OC), non-small cell lung cancer (NSCLC), or other MSLN-expressing cancers, with measurable disease per RECIST v1.1, ECOG PS score of 0 to 1, adequate organ function, and a minimum life expectancy of 12 weeks. Participants with additional progressing malignancies, recent transplants, clinically significant ongoing toxicity, uncontrolled renal, pancreatic or liver disease, or active autoimmune diseases requiring high-dose corticosteroids or immunosuppressive drugs are excluded. Part 1 evaluates the safety and tolerability of ZW171 and Part 2 evaluates the anti-tumor activity while continuing to evaluate safety and tolerability. Part 1 is dose escalation to identify maximum tolerated dose (using modified toxicity probability interval [mTPI-2] design, n=40) among participants with OC or NSCLC receiving subcutaneous ZW171 monotherapy on days 1, 8, and 15 of 3-week (21-day) cycles. Approximately 6 dose levels will be explored based on safety and tolerability. Step-up dosing will be used for cycle 1. Dose level 1, determined by QSP-based MABEL approach[2], is administered at 4.2 μg (day 1), 12.6 μg (day 8), and 38.0 μg (day 15). Part 2 is dose expansion in participants with OC, NSCLC, and other MSLN-expressing cancers (MSLN expression evaluated retrospectively). Primary objectives are to evaluate safety and tolerability of ZW171 and determine the maximum tolerated dose. Key secondary objectives are to assess PK, anti-drug antibodies, and anti-tumor activity. This is a global study with sites in North America, Europe, and Asia; and actively enrolling participants into Part 1. References: 1. Afacan N, et al. Presented at AACR Annual Meeting 2023; abstract 2942. 2. Afacan N, et al. Presented at SITC Annual Meeting 2024; abstract 1062. Clinical trial information: NCT06523803. Research Sponsor: Zymeworks BC Inc.

TPS3161 Poster Session

A phase 1, first-in-human study of AMT-676, an anti-CDH17 antibody-drug conjugate, in patients with advanced gastrointestinal tumors. First Author: Charlotte Rose Lemech, Scientia Clinical Research, Randwick, Australia

Background: Cadherin-17 (CDH17), also known as liver-intestine-cadherin, is a transmembrane protein that is highly expressed in a variety of gastrointestinal cancers, including colorectal, gastric, esophageal adenocarcinoma, cholangiocarcinoma, pancreatic ductal, and gastrointestinal neuroendocrine tumors. The overexpression of CDH17 is associated with tumor metastasis and progression to advanced tumor stages. AMT-676 is a novel antibody-drug conjugate (ADC) that targets CDH17. It is comprised of a humanized IgG1 monoclonal antibody specific to CDH17, conjugated to the potent topoisomerase I inhibitor exatecan, with a drug-to-antibody ratio of 4, linked through a proprietary T-moiety technology. Preclinical studies have demonstrated significant antitumor activity of AMT-676 across multiple gastrointestinal cancer models and great tolerability in safety studies, highlighting its potential as a therapeutic agent for CDH17-expressing malignancies. **Methods:** This phase 1, open-label, multicenter study aims to determine the Maximum Tolerated Dose (MTD) and the Recommended Phase 2 Dose (RP2D) of AMT-676, as well as to assess its safety, tolerability, anti-drug activity, pharmacokinetics, pharmacodynamics, immunogenicity and preliminary efficacy in patients with advanced solid tumors. Tumor types that express CDH17 including gastrointestinal cancers, treated with or with no standard therapeutic options are to be enrolled. AMT-676 will be administered intravenously on a 21-day cycle. The dose escalation will be guided by the Bayesian Optimal Interval (BOIN) design, incorporating an accelerated titration approach to evaluate 6 cohorts: 1.6, 3.2, 4.8, 6.4, 8, and 10 mg/kg. Three backfilling cohorts at doses that have demonstrated safety will also be included, each enrolling up to 18 patients, to gather additional data on safety, pharmacokinetics, pharmacodynamics, and preliminary efficacy, thereby supporting the selection of an optimized dose for expansion. Mandatory pre-study biopsy sample collection for retrospective immunohistochemistry (IHC) analysis will facilitate a comprehensive exploratory biomarker plan, potentially correlating CDH17 levels with treatment responses. The study is actively enrolling participants for the dose escalation phase. Cohorts 1-4 have been completed DLT evaluation and enrollment of cohort 5 began in December 2024. Clinical trial information: NCT06400485. Research Sponsor: Multitude therapeutics Inc.

TPS3162 Poster Session

Phase I multicenter, open-label, dose escalation study of T-1201, a small molecule drug conjugate, to assess safety, pharmacokinetics, and antitumor activity in advanced solid tumors. First Author: Hui-Ching Wang, Division of Hematology and Oncology, Department of Internal Medicine, Kaohsiung Medical University Hospital, Kaohsiung, Taiwan

Background: Phosphatidylserine (PS) is a phospholipid critical for maintaining cell membrane integrity and functionality. In rapidly proliferating cancer cells, PS translocates to the outer leaflet of the membrane, making it a promising biomarker and therapeutic target for cancer treatment. The investigational drug T-1201 is a proprietary small molecule drug conjugate combining a bioactive topoisomerase I inhibitor, SN-38, with Zn-DPA complexes, which exhibit high affinity for PS. Preclinical studies have demonstrated T-1201's in-vivo antitumor activity across multiple human tumor xenograft models. This study represents the first clinical evaluation of T-1201 in humans. **Methods:** The primary objectives of this phase I study are to evaluate the safety profile of T-1201, determine dose-limiting toxicities (DLTs), establish the maximum tolerated dose (MTD), and identify the recommended phase II dose (RP2D). Secondary objectives include characterization of pharmacokinetics (PK) and assessment of antitumor activity for T-1201. The study comprises three dose-escalation parts. In Part A, T-1201 is administered intravenously once every four weeks (Q4W), starting at 18 mg/m^2 during Cycle 1. From Cycle 2 onward, the dosing interval can be adjusted to once every two weeks (Q2W) at the investigator's discretion, subject to agreement with the Sponsor. When switching to the Q2W schedule, the dose level is halved compared to the Q4W dose. Each treatment cycle spans four weeks, with dose escalation proceeding via a single-patient cohort design (100% dose increments) initially, transitioning to a modified 3+3 design (40% dose increments) based on DLTs observed in Cycle 1. In Part B, T-1201 is administered intravenously Q2W in a 28-day treatment cycle, starting at 100 mg/m^2, which represents half of the MTD identified in Part A. In Part C, each treatment cycle is reduced to 21 days, with the starting dose not exceeding the highest dose level deemed safe by the Safety Review Committee (SRC) in Part B. Eligible patients are ≥18 years of age, have an Eastern Cooperative Oncology Group (ECOG) performance status of 0–1, and possess radiographically or clinically evaluable tumors. As of now, 27 patients have been enrolled in the Part A dose-escalation stage. This study is registered with ClinicalTrials.gov (NCT04866641). Clinical trial information: NCT04866641. Research Sponsor: Taivex Therapeutics corporation.

Dose escalation/de-escalation rule for the BOIN design.

Number of subjects treated at the current dose*	3	4	5	6	7	8	9
Escalate if # of DLT ≤	0	1	1	1	1	2	2
Stay at current dose if # of DLT =	1	NA	NA	2	2	3	3
De-escalate if # of DLT ≥	2	2	2	3	3	4	4
Eliminate if # of DLT ≥	3	3	4	4	5	5	6

*The enrollment may stop when one of the following criteria is met: The planned sample size has been reached; at least 9 subjects have been treated and evaluable for DLT at one dose level; or all doses explored appear to be overly toxic, and the MTD cannot be determined.

TPS3163 Poster Session

A phase 1 study to evaluate the safety and tolerability of the antibody–drug conjugate (ADC) MesoC2 (PF-08052666) in patients with advanced solid tumors. First Author: Amita Patnaik, START San Antonio, San Antonio, TX

Background: MesoC2 (PF-08052666) is an ADC that targets mesothelin (MSLN), a cell-surface glycoprotein overexpressed in solid tumors including mesothelioma, ovarian cancer, pancreatic cancer, non-small cell lung cancer (NSCLC), endometrial cancer (EC), and colorectal cancer (CRC), but with limited expression in normal tissues. MesoC2 is constructed from a recombinant human IgG1 anti-MSLN monoclonal antibody conjugated to a cleavable tripeptide linker that carries a topoisomerase 1 inhibitor (TOP1) payload. The average number of TOP1 molecules per antibody is 8. Following high-affinity binding to MSLN on the cell surface, MesoC2 is internalized, the linker is cleaved, and the released payload inhibits DNA religation during amplification, leading to cell cycle arrest and cell death. MesoC2 has shown potent antitumor efficacy in in vitro assays and xenograft models and an acceptable safety profile in cynomolgus monkeys. The aim of this first-in-human study is to explore the safety, tolerability, and preliminary efficacy of MesoC2 in patients with certain advanced solid tumors. **Methods:** In this phase 1, open-label study, up to 365 patients with mesothelioma, platinum-resistant ovarian cancer (PROC), pancreatic ductal adenocarcinoma (PDAC), NSCLC, EC, or CRC will receive intravenous infusion of MesoC2 in dose escalation (n=45), dose and schedule optimization (n=40), and disease-specific dose expansion cohorts (n=280; includes a biology cohort to evaluate exploratory biomarkers). Key inclusion criteria are histologically or cytologically confirmed metastatic or locally advanced mesothelioma, PROC, PDAC, NSCLC, EC, or CRC who have relapsed or progressed following standard therapies; aged ≥18 years; ECOG performance status score of 0 or 1; and available archival tumor tissue (a fresh biopsy is required if unavailable). Key exclusion criteria include prior or current treatment with systemic anticancer therapy or focal radiotherapy within 4 weeks prior to first dose of MesoC2, prior anti-MSLN therapies, and any unresolved toxicities from prior therapy greater than G1 at the time of starting study treatment, except alopecia. Primary endpoints include type, incidence, and severity of adverse events (AEs), frequency of dose modifications due to AEs, incidence of dose-limiting toxicities, cumulative safety, pharmacokinetics, pharmacodynamics, and preliminary antitumor activity. Key additional endpoints include objective and best response rates per Response Evaluation Criteria in Solid Tumors Version 1.1 (RECIST v1.1), duration of response, progression-free survival, overall survival, MSLN expression in blood and tissue, and changes in tumor-specific biomarkers. Enrollment is ongoing; clinical trial information: NCT06466187. A genAI tool (01/06/25; Pfizer; GPT-4o) developed the 1st draft; authors assume content responsibility. Clinical trial information: NCT06466187. Research Sponsor: Pfizer Inc.

TPS3164 Poster Session

TUB-030, a novel ADC targeting 5T4: A phase I/IIa multi-center, first-in-human clinical trial (5-STAR 1-01) in patients with advanced solid tumors. First Author: Shiraj Sen, NEXT Oncology, Dallas, TX

Background: TUB-030 is a novel antibody-drug conjugate (ADC) targeting 5T4, an oncofetal antigen expressed in various solid tumors with limited expression in healthy tissues. TUB-030 leverages optimized biophysical properties, an effector-silenced antibody, and an exatecan payload to maximize the therapeutic index and minimize off-target toxicities. Preclinical studies demonstrated potent anti-tumor activity, including long-lasting tumor regression at doses as low as 1 mg/kg and durable responses even in tumors with low 5T4 expression. **Methods:** 5-STAR 1-01 is a multicenter, first-in-human dose escalation and dose optimization Phase I/IIa clinical trial designed to investigate safety, tolerability, pharmacokinetics (PK), and efficacy of the anti-5T4 ADC TUB-030 in patients with advanced and metastatic solid tumors. Eligible patients have one of the following tumor types: head and neck squamous cell carcinomas (HNSCC), non-small-cell lung cancer (NSCLC), small cell lung cancer, pleural mesothelioma, triple-negative breast cancer, HR+/HER2- breast cancer, esophageal cancer, gastric cancer, pancreatic adenocarcinoma, colorectal cancer, bladder cancer, prostate cancer, cervical cancer, osteosarcoma, or soft tissue sarcomas and must have exhausted available standard-of-care therapies. Phase I is an open-label, single-arm dose escalation trial, with administration every 21 days. Dose escalation follows an accelerated titration design (ATD) transitioning to Bayesian optimal interval (BOIN) upon predefined toxicity thresholds. Backfill cohorts are planned in NSCLC and HNSCC to further evaluate the safety and efficacy profile at, or near, the maximum tolerated dose (MTD). Primary endpoints include safety and tolerability of TUB-030 as monotherapy, determination of the MTD and the recommended phase II doses; secondary endpoints assess pharmacokinetics, immunogenicity, and preliminary clinical activity using RECIST v1.1 criteria. Exploratory endpoints include analysis of circulating tumor DNA. In phase IIa, dose-optimization will evaluate two dose levels in select indications in order to identify the optimal dose for further development. Enrollment of approximately 130 patients across the US and Canada is planned, with dose escalation currently underway. This study investigates TUB-030, a novel 5T4 targeted ADC as a therapy for advanced/metastatic solid tumors. Clinical trial information: NCT06657222. Research Sponsor: None.

TPS3165 Poster Session

PROCEADE PanTumor: A phase 1b/2, multicenter study of precemtabart tocentecan (M9140), an anti-CEACAM5 antibody-drug conjugate (ADC) with exatecan payload, in patients with advanced solid tumors. First Author: Zev A. Wainberg, University of California, Los Angeles, Medical Center, Los Angeles, CA

Background: CEACAM5 is a cell surface glycoprotein that is overexpressed in various carcinomas, notably in gastric cancer (GC), non-small cell lung cancer (NSCLC), pancreatic adenocarcinoma (PDAC), and colorectal cancer (CRC), but shows limited expression on healthy adult cells. Precemtabart tocentecan is an investigational anti-CEACAM5 ADC (drug-to-antibody ratio: 8) that utilizes a unique linker–payload combination to selectively deliver the topoisomerase 1 inhibitor, exatecan, to CEACAM5 overexpressing tumor cells. Preliminary clinical data from the dose-escalation part of the first-in-human study of precemtabart tocentecan in patients with metastatic CRC (PROCEADE CRC-01) demonstrated a manageable and predictable safety profile and promising preliminary efficacy in 40 heavily pretreated patients. The PROCEADE PanTumor study is a Phase 1b/2, multicenter, open-label study that aims to investigate the clinical activity of precemtabart tocentecan, either as monotherapy or in combination with other anticancer agents, in patients with advanced GC, advanced NSCLC and advanced PDAC. **Methods:** The study was designed as a matrix study with a master protocol (applicable to all substudies) and three substudy protocols (GC; NSCLC; PDAC). Based on the master protocol, patients aged ≥18 years, with an Eastern Cooperative Oncology Group performance status ≤1, adequate baseline hematological, renal, and hepatic function, ≥1 lesion that is measurable using RECIST v1.1, who have received ≥1 prior line of treatment are eligible. Patients must have an archival formalin-fixed paraffin-embedded tumor tissue or a fresh biopsy. In the respective substudies, patients with advanced or metastatic, HER2-negative GC or gastroesophageal junction adenocarcinoma; patients with advanced (Stage III; ineligible for resection/curative radiation) or metastatic NSCLC; or patients with advanced or metastatic PDAC will be included. Patient selection will be based on CEACAM5 expression level (both high and low in GC, only high in NSCLC and PDAC [CEACAM5^{high}: ≥50% tumor cells with immunohistochemistry [IHC] ≥2+ staining; CEACAM5^{low}: <50% tumor cells with IHC ≥2+ staining]), and in patients with NSCLC, *EGFR* mutation status (*EGFR*-wt and *EGFR* mut+). The primary endpoint is objective response (proportion of patients with confirmed complete/partial response [CR/PR] per RECIST v1.1, assessed by investigator). Secondary endpoints include adverse events, duration of response (RECIST v1.1), disease control (CR, PR, stable disease, or non-CR/non-progressive disease [PD] at Week 12), time to response, progression-free survival, and pharmacokinetic assessments. The study is planned to be initiated at multiple sites globally, with an estimated enrollment of 250 patients. Clinical trial information: NCT06710132. Research Sponsor: the healthcare business of Merck KGaA, Darmstadt, Germany (CrossRef Funder ID: 10.13039/100009945).

TPS3166 Poster Session

A dose escalation and cohort expansion phase I/IIa study of ACR246, an innovative 5T4- antibody drug conjugate (ADC), in patients (pts) with advanced solid tumors. First Author: Panpan Zhang, Key laboratory of Carcinogenesis and Translational Research (Ministry of Education/Beijing), Department of Early Drug Development Centre, Peking University Cancer Hospital & Institute, Beijing, China

Background: The oncofetal antigen 5T4 is overexpressed in many solid tumors with limited expression in normal adult tissues. Overexpression of 5T4 is associated with poor prognosis. 5T4 on tumor cell surface is rapidly internalized when bound to antibody and is thus an ideal target for the development of ADC drugs. ACR246 is the first next- generation 5T4-ADC consisting of a fully human monoclonal antibody that is site-specifically conjugated to a novel DNA topoisomerase I inhibitor D2102, via a stable and cleavable linker, with a drug-to-antibody ratio (DAR) of 8. ACR246 was carefully designed to improve the safety and efficacy in treating 5T4 positive solid tumors. In preclinical studies, ACR246 demonstrated robust anti-tumor activity, superior to a Dxd-5T4 ADC (as a reference) both in CDX and PDX models, including but limited to NSCLC, gastric cancer, pancreatic cancer and Esophageal cancer, and excellent tolerability, supporting further development for clinical use. **Methods:** This is an ongoing, phase I/IIa, open-label, multicenter, dose escalation and cohort expansion study of ACR246 to be injected intravenously to adult pts with advanced solid tumors. For phase I study, a Bayesian optimal interval design is adopted to assess dose levels of ACR246, 0.6, 1.2, 2.4, 3.6 and 4.5 mg/kg, administered every 3 weeks on a 21-day cycle , and intermediate dose levels of 3.0, 4.0 and 5.0 mg/kg may be evaluated based on emergent safety or pharmacologic data. The primary objectives are to evaluate safety and tolerability and determine the maximum tolerated dose (MTD) and the recommended phase 2 dose (RP2D); the second objectives include PK, immunogenicity and preliminary clinical efficacy. Dose limiting toxicity (DLT) will be assessed at each dose level. The DLT evaluation period will be 21 days. Once the RP2D is determined, phase IIa study will be conducted to further evaluate the safety, tolerability, efficacy, PK and immunogenicity of ACR246 in 5T4-positive advanced solid tumor pts (esophageal cancer, NSCLC, ovarian cancer, prostate cancer and other types of tumors) under RP2D. Approximately 77 pts ≥ 18 years of age with advanced solid tumors that have histologically or cytologically been diagnosed recurrent or metastatic unresectable advanced disease and have failed or are intolerant of systemic standard therapy or standard therapy is not available, and having adequate ECOG performance status (0-1), hematologic function, and end organ function are planned to be enrolled, with 37 pts in phase I study and approximately 40 pts in phase IIa study. 5T4 expression is not required for enrollment for phase I, but will be assessed retrospectively. The toxicity will be assessed by Common Terminology Criteria for Adverse Events v5.0 and the tumor response will be determined per RECIST v1.1. Dose levels of 0.6 mg/kg and 1.2mg/kg has completed enrollment with no DLT. Clinical trial information: NCT06238401. Research Sponsor: Hangzhou Adcoris Biopharma Co., Ltd.

TPS3167 Poster Session

A phase 1 dose escalation and dose expansion study for LNCB74, a B7-H4 targeted antibody drug conjugate, as monotherapy in participants with advanced solid tumors. First Author: Michael M Song, NEXT Oncology, San Antonio, TX

Background: B7-H4 is a transmembrane receptor of the B7-family of immunomodulatory proteins whose expression correlates with poor clinical outcomes for ovarian and breast cancers. High expression in multiple tumor types and limited expression in normal tissues makes B7-H4 an attractive target for antibody drug conjugate (ADC) therapeutics. LNCB74 is a B7-H4 targeted ADC in which a humanized IgG1κ antibody is conjugated to the microtubule disrupting payload monomethyl auristatin E (MMAE) with a drug-to-antibody ratio of 4 (DAR4). LNCB74 is designed to maximize therapeutic index through three key elements. First, site specific ConjuAll conjugation results in a homogeneous DAR to drive uniform PK. Second, our proprietary glucuronidase-cleavable linker reduces both on- and off-target toxicity. Third, the antibody Fc was "LALA"-mutated to reduce Fc mediated uptake into Fc receptor expressing cells such as immune and endothelial cells. Compared to other B7-H4 targeted ADCs in clinical development, LNCB74 has demonstrated a superior safety profile in nonhuman primate toxicity studies and potent anti-tumor activity in multiple cell line- and patient-derived xenograft in vivo models, making it a promising ADC therapy for B7-H4-expressing solid tumors. **Methods:** LNCB74-01 is a phase 1, open-label, first-in-human study that will include dose escalation, safety, and biomarker backfills (Part 1) and randomized dose expansion/optimization (Part 2). The objectives of the study will be to determine safety and tolerability, define the maximum tolerated dose and/or recommended phase 2 dose, characterize the pharmacokinetics (PK) and pharmacodynamics (PD), and to assess the preliminary efficacy in participants with metastatic solid tumors treated with LNCB74. The tumor types include ovarian, breast, endometrial, biliary tract cancer, and squamous NSCLC. Key eligibility criteria include measurable disease based on RECIST v1.1 and the ability to provide tissue samples to test B7-H4 expression by CLIA-certified immunohistochemistry assay in a central laboratory. Participants will receive LNCB74 on Day 1 of each 21-day cycle. Dose escalation will follow a Bayesian optimal interval (BOIN) design. Dose expansion will occur in up to two tumor types. In each tumor specific dose expansion, participants will be randomized to two dose levels stratifying for prior lines of therapy (1-3 vs ≥4) and B7-H4 expression (intermediate vs high). The PK profile, immunogenicity, preliminary anti-tumor activity per RECIST v1.1, and correlation of baseline B7-H4 expression to anti-tumor activity of LNCB74 will be evaluated as secondary endpoints. Biomarkers will be assessed in peripheral blood and tumor tissue. Enrollment is ongoing in the United States. Clinical trial information: NCT06774963. Research Sponsor: NextCure Inc.

TPS3168 Poster Session

The EQUAL study: Utilizing plasma EGFR cfDNA detection as an accessible screening tool for lung cancer in underserved patients ineligible for routine screening. First Author: Narjust Florez, Lowe Center for Thoracic Oncology, Dana-Farber Cancer Institute, Harvard Medical School, Boston, MA

Background: Lung cancer (LC) among non-tobacco-users is increasing in the United States, with no routine screening available. Among those patients, EGFR mutations (EGFRm) are common, with the highest prevalence seen in East Asian and Hispanic women. Delays in diagnosis and treatment are exacerbated in these marginalized groups and women, negatively impacting their cancer outcomes. At Dana-Farber Cancer Institute's (DFCI) Belfer Center for Applied Science, we developed a novel droplet digital PCR ctDNA assay to detect EGFR del19 and L858R mutations, which comprise 85-90% of total EGFRm in LC. Here, we report the methodology of EQUAL, a study assessing the feasibility of a diagnostic assay among non-tobacco using, historically marginalized East Asian and Hispanic populations at high risk for EGFRm-LC. **Methods:** To assess the feasibility of our ctDNA screening tool, the EQUAL study is recruiting two cohorts of participants. Cohort 1 (n=500) includes 50–80-year-olds who self-identify as East Asian or Hispanic from the general population, while Cohort 2 (n=500) includes 40–80-year-olds of the same backgrounds with an additional risk factor for LC, with a focus on direct family members of patients with EGFRm-LC. Recruitment is beginning with these family members of patients with EGFRm-LC at DFCI main campus, Beth Israel Deaconess Medical Center, Massachusetts General Hospital, DFCI Merrimack Valley, DFCI regional campuses, and will expand to primary care clinics and community events. Blood samples are collected in clinics or at home via mobile phlebotomy. Positive results are verified in a government-certified CLIA laboratory; a complementary chest CT will be arranged for those with positive assay results, and patients will receive navigation until resolution. Patients with a positive assay but negative chest CT will be followed for 12 months and will receive a second annual chest CT. Recognizing how cultural beliefs and tobacco's association with LC may hinder screening participation, EQUAL includes an optional survey and focus groups to explore perceptions and barriers surrounding LC screening with our tool for future optimization efforts. The study is available in 8 languages including Spanish, Portuguese, Korean, Vietnamese, Japanese, Chinese (simplified and traditional), and Creole. EQUAL is the first study to implement EGFRm-LC blood-based screening for historically marginalized populations who are not eligible for LC screening, thereby allowing for LC identification that can be effectively treated with targeted therapy approved for stages IB-IV. This pilot study seeks to lay the groundwork for future sensitivity and specificity trials that will confirm the value of the assay and expand the scope of current screening guidelines to reduce health disparities and delays in LC diagnosis. Clinical trial information: NCT06716580. Research Sponsor: Dana-Farber Cancer Institute Philanthropic Funds.

TPS3169 **Poster Session**

A phase 1/2 study of FOG-001, a first-in-class direct β-catenin: TCF inhibitor, in patients with colorectal cancer (CRC) and other locally advanced or metastatic solid tumors. First Author: Kyriakos P. Papadopoulos, START-San Antonio, San Antonio, TX

Background: Activation of the Wnt/β-catenin pathway, often as truncal APC mutations, in 80–90% of CRCs and other solid tumors, is known to be a key driver of cancer progression and has been associated with immune exclusion and resistance to immunotherapy. Development of agents targeting this pathway at the key β-catenin: T-cell factor (TCF) node has eluded the pharmaceutical industry to date. FOG-001 is a Helicon peptide that competitively inhibits interaction between β-catenin and TCF transcription factors. Helicon peptides are hyperstabilized α-helices that can be tuned for picomolar binding affinities, robust cell penetration, broad tissue distribution, no immune recognition, and long *in vivo* half-lives. In studies in a wide range of patient-derived xenograft (PDX) CRC and HCC models, FOG-001 inhibited tumor growth and promoted tumor regression as monotherapy. Combinations with immune checkpoint inhibitors or standard-of-care therapies, including bevacizumab and 5-FU, showed strong additivity/synergy in PDX CRC models. **Methods:** This first-in-human, phase 1/2, multicenter, open-label, dose-escalation (part 1) and dose-expansion (part 2) study evaluates the safety/tolerability, pharmacokinetics (PK), pharmacodynamics (PD), and anti-tumor effects of FOG-001 monotherapy and combined with other anti-cancer therapies in patients with microsatellite stable (MSS) CRC or advanced/metastatic solid tumors known to harbor a Wnt pathway-activating mutation (WPAM). Eligible patients must have received at least one prior systemic anti-cancer therapy and either progressed on, not responded to, or be unfit for available therapies. In Part 1, FOG-001 is administered intravenously every week, at escalating dose levels evaluated sequentially in a standard 3+3 design as monotherapy in patients with MSS CRC or any solid tumor with documented WPAM. PD effects are evaluated in a separate cohort of approximately six patients with MSS CRC. Combination cohorts will evaluate FOG-001 + FOLFOX/bevacizumab (1L MSS CRC), FOG-001 + nivolumab (3L MSS CRC or anti-PD-1/PD-L1-resistant CRC and solid tumors), and FOG-001 + trifluridine/tipiracil + bevacizumab (3L MSS CRC). Part 2 dose expansion will evaluate FOG-001 monotherapy in patients with MSS CRC and other solid WPAM+ tumors. Combination dose expansion will evaluate combinations initially studied in Part 1. Primary endpoints are safety/tolerability of FOG-001 alone or in combination. Secondary endpoints are PK, PD, recommended phase 2 dose and schedule, and preliminary anti-tumor activity (e.g., ctDNA changes, overall response rate, best objective response, duration of response, and progression-free survival). 156 patients are planned to be enrolled in Part 1, which is currently enrolling in the USA. Clinical trial information: NCT05919264. Research Sponsor: Parabilis Medicines.

TPS3170 **Poster Session**

SCRUM-Japan MONSTAR-SCREEN-3: Comprehensive tumor microenvironment analysis via multi-omics in a large-scale prospective study. First Author: Mitsuho Imai, Translational Research Supporting Office, National Cancer Center Hospital East, Kashiwa, Japan

Background: SCRUM-Japan is a multi-institutional, industry-academia collaborative cancer genome screening project launched in 2015, consisting of LC-SCRUM-Asia for lung cancer and SCRUM-MONSTAR for other malignancies. The project has successfully implemented organ-agnostic liquid biopsy-based precision oncology and molecular residual disease (MRD)-guided therapeutic development, resulting in multiple regulatory approvals of therapeutic agents and diagnostics. In 2024, MONSTAR-SCREEN-3 was launched to expand the scope of multi-omics analysis beyond advanced solid tumors to include resectable solid tumors and hematologic malignancies, aiming for a comprehensive understanding of tumor microenvironment (TME) dynamics. The project integrates a multi-omics platform, including spatial transcriptomics, ctDNA analysis, and proteomics, to advance personalized medicine and accelerate drug development. **Methods:** MONSTAR-SCREEN-3 (UMIN000053975) is a large-scale, multi-institutional prospective study involving 55 centers across Japan, aiming to enroll 3,200 patients across three cohorts: Cohort A: Advanced solid tumors undergoing systemic therapy (n=1,700); Cohort B: Resectable solid tumors receiving perioperative treatment (n=1,100); Cohort C: Hematologic malignancies (n=400). Our analysis platform combines spatial transcriptomics with circulating tumor DNA/RNA sequencing, bulk tissue whole exome/transcriptome sequencing, plasma proteomics, and microbiome analyses. For resectable cases, standardized longitudinal monitoring with whole genome sequencing-based MRD analysis is implemented, while disease-specific MRD approaches are applied to hematologic malignancies. Following SCRUM-Japan's quality assurance system, standardized monitoring collects regulatory-grade clinical data, including key indicators such as response rate, progression-free survival, and overall survival. MONSTAR-SCREEN-3 applies standardized protocols for tissue preservation and data acquisition across all centers, ensuring high-quality data. The project leverages the VAPOR CONE supercomputing infrastructure for real-time data integration and AI-driven analysis to identify biomarkers, elucidate resistance mechanisms, and deepen the understanding of tumor-immune interactions. The study aims to establish a framework for next-generation precision oncology. The latest enrollment status and initial operational results will be reported at the ASCO meeting. MONSTAR-SCREEN-3 is expected to contribute to new therapies, cross-cancer MRD assays, and the resolution of drug lags in hematologic malignancies, driving advancements in personalized cancer treatment. Clinical trial information: UMIN000053975. Research Sponsor: None.

TPS3171 **Poster Session**

A first-in-human multi-center phase 1/2 study of a selective FGFR2/3 inhibitor, CGT4859, in patients with intrahepatic cholangiocarcinomas or other advanced solid tumors. First Author: Lipika Goyal, Stanford Cancer Center, Stanford School of Medicine, Stanford, CA

Background: Genetic alterations in fibroblast growth factor receptors 2 and 3 (*FGFR2/3*) occur in nearly all cancer types. *FGFR2* fusions and rearrangements occur in up to 10-15% of intrahepatic cholangiocarcinomas (iCCA) and alterations in *FGFR3* occur in 15-30% of urothelial cancers. The clinical benefit from currently approved FGFR inhibitors (FGFRi) is often curtailed by development of acquired resistance, which may arise through on-target mutations in the *FGFR2/3* kinase domain. Additionally, off-tumor effects on FGFR1 by pan-FGFRi can lead to hyperphosphatemia and consequently to dose reductions or dose holds. Thus, there is an unmet clinical need for a selective FGFR2/3 inhibitor that has clinical efficacy against activating alterations and resistance mutations without causing FGFR1-mediated hyperphosphatemia. CGT4859 is an orally bioavailable, ATP-competitive, reversible inhibitor of FGFR2/3, with potency against clinically relevant *FGFR2/3* kinase domain mutations. In addition, CGT4859 demonstrates >140 fold selectivity over FGFR1, and shows robust efficacy in target altered *in vivo* tumor models without increases in serum phosphorus. Nonclinical pharmacokinetics (PK) and safety data support evaluating CGT4859 in a first-in-human, open-label, dose-escalation and signal-seeking Phase I/II study (NCT06777316). Safety, tolerability, PK, pharmacodynamics, and antitumor activity of CGT4859 will be assessed in adults with histologically confirmed unresectable or metastatic iCCA or other solid tumors with *FGFR2/3* alterations. **Methods:** CGT4859 will be administered orally continuously in 28-day cycles to patients (N=~50) at a starting dose of 1 mg QD, and dose escalation will not exceed 40 mg QD as determined using a Bayesian optimal interval design with backfill (BF-BOIN). This approach will be used to guide dose escalation and establish the maximum tolerated dose (MTD) and recommended Phase 2 Dose (RP2D). BF-BOIN enables backfilling of participants to doses that are cleared for safety during the dose escalation, generating additional data on safety and tolerability below the MTD. Objective response rate (ORR) and disease control rate will be determined based on investigator assessment using RECIST v1.1. Phase II will enroll up to 4 cohorts, each enrolling ~15 patients. Proposed cohorts will include participants who have iCCA and are either FGFRi-naïve or FGFRi-exposed. Two additional cohorts with other advanced solid tumors harboring *FGFR2/3* alterations may be included based on signals detected in dose escalation. The primary efficacy endpoint for Phase II is ORR per RECIST v1.1. The preclinical data support the study of CGT4859 in this patient population with solid tumors harboring *FGFR2* and/or *FGFR3* genetic alterations. The phase I dose escalation study is currently enrolling at sites in the United States. Clinical trial information: NCT06777316. Research Sponsor: Cogent Biosciences.

TPS3172 **Poster Session**

Phase IB/II study to evaluate safety and preliminary efficacy of the WEE1 inhibitor Debio 0123 in combination with sacituzumab govitecan (SG) in triple-negative or hormone receptor–positive (HR+)/HER2-negative (HER2–) advanced breast cancer (ABC): The WIN-B study. First Author: Timothy J. Robinson, University of Bristol, Bristol, CT, United Kingdom

Background: SG is a Trop-2 directed antibody drug conjugate that has shown an overall survival benefit for patients (pts) with HER2- ABC in two phase III trials. Unfortunately, most pts become refractory to this treatment, highlighting a critical need for strategies to overcome resistance to SG and improve therapeutic outcomes. WEE1 is a cyclin-dependent kinase 1 regulator, which delays the G2/M transition and maintains genomic stability during the cell cycle. Debio 0123, a highly selective and brain penetrant WEE1 inhibitor, has demonstrated synergistic activity in breast cancer preclinical models with SG. The aim of the WIN-B study is to evaluate the safety and preliminary efficacy of combining the WEE1 inhibitor Debio 0123 with SG in pts with previously treated HER2-ABC. **Methods:** WIN-B (NCT06612203) is an international, multicenter, open-label, single-arm phase Ib/II trial. In phase Ib, 12-24 pts will be assigned to different Debio 0123 dose cohorts (200, 300, 400, or 520 mg orally once daily on days 1-3 and 8-10) plus standard doses of SG (10 mg/kg intravenously on days 1 and 8) given in 3-week cycles. In phase II, 52 pts will be divided into cohorts A (triple-negative breast cancer [TNBC], n = 26) and B (HR+/HER2– tumors, n = 26), and will be treated with the recommended doses determined during phase Ib. Key inclusion criteria are: pts aged ≥18 with TNBC or HR+/HER2- tumors who have experienced disease progression after 1 or 2 lines of systemic therapy for ABC, ECOG performance status of 0-1, with evaluable (for phase Ib) or measurable (for phase II) disease as per RECIST v.1.1. Pts will receive study treatment until progression, death, unacceptable toxicity, or study discontinuation. Primary objectives are: in phase Ib, to establish the recommended phase 2 dose of the combination of Debio 0123 plus SG and, in phase 2, to assess the objective response rate (ORR) as per RECIST v.1.1. Key secondary endpoints are progression-free survival and overall survival, safety and toxicity. In phase Ib, dose escalation will be performed using a Bayesian Logistic Regression Model with overdose control. In phase 2, A'Hern one-stage design will be set at one-sided type I binomial exact test of 5% to attain 80% power. The primary analyses will estimate ORR (H0: ORR≤29% for TNBC and ORR≤19% for HR+/HER2- tumors vs H1: ORR≥55% for TNBC and ORR≥41% for HR+/HER2- tumors). The phase 2 part of the study will be deemed positive if at least 12 (46.2%) and nine (34.6%) pts with TNBC and HR+/HER2- tumors, respectively, achieve an objective response. Clinical trial information: NCT06612203. Research Sponsor: Debiopharm. Gilead will provide the supply of SG.

TPS3173 **Poster Session**

Trial in progress: First-in-human study of PFL-721/STX-721 in participants with locally advanced or metastatic non-small cell lung cancer harboring EGFR exon 20 insertion mutations. First Author: Anas Gazzah, Gustave Roussy, Villejuif, France

Background: Mutations in exon 20 of the *EGFR* gene account for approximately 4% to 10% of all EGFR mutations in Non-Small Cell Lung Cancer (NSCLC). Most of these mutations are insertions (EGFR ex20ins) that reduce the binding of first, second, and third generation tyrosine kinase inhibitors (TKI) to the ATP-binding pocket of the EGFR. Amivantamab, a bispecific anti-EGFR/c-MET-receptor antibody, is approved for the treatment of NSCLC with EGFR ex20ins mutations. However, there is significant unmet need for new oral agents that lack the limitations of intravenous administration and associated infusion-related toxicities and possess improved target engagement, mutant selectivity, and tolerability. PFL-721/STX-721 is an orally bioavailable, irreversible small-molecule inhibitor targeting a broad range of EGFR- and HER2-activating ex20ins mutations. PFL-721/STX-721 is highly selective for EGFR ex20ins mutations compared to wild type EGFR and exhibits greater selectivity compared to other EGFR mutant inhibitors. In addition, PFL-721/STX-721 has demonstrated superior anti-proliferation and antitumor effects compared to other investigational anti-EGFR ex20ins agents in relevant tumor models *in vitro* and *in vivo*. These observations suggest a more robust clinical risk-to-benefit profile and support further clinical investigation of PFL-721/STX-721. **Methods:** PFL-721/STX-721-101 (NCT06043817) is an open-label, first-in-human (FIH), Phase 1/2 study evaluating the safety, tolerability, pharmacokinetic (PK) exposure, and preliminary antitumor activity of PFL-721/STX-721 in participants with locally advanced or metastatic NSCLC harboring EGFR/HER2 ex20ins mutations. It consists of 3 parts: Part 1 Dose Escalation, Part 2 Recommended Phase 2 Dose (RP2D) selection, and Part 3 Dose Expansion. In Part 1, participants with NSCLC harboring EGFR or HER2 ex20ins mutations will be enrolled into sequential cohorts to receive ascending oral doses of PFL-721/STX-721 administered daily in 28-day treatment cycles. The main goal is to identify the maximum tolerated dose (MTD) and optimal biological dose (OBD) of PFL-721/STX-721. In Part 2, participants with NSCLC harboring EGFR ex20ins mutations who have received 1 to 2 prior lines of treatment, including a platinum-containing chemotherapy regimen and excluding EGFR targeted therapies with the exception of amivantamab, will be randomized 1:1 to receive PFL-721/STX-721 at the MTD or OBD in order to determine the optimal RP2D. Finally, Part 3 will further test the anticancer efficacy of PFL-721/STX-721 is administered at the RP2D. PFL-721/STX-721-101 is actively enrolling at 18 sites in 7 countries globally. Clinical trial information: NCT06043817. Research Sponsor: Scorpion Therapeutics, Inc.

TPS3174 **Poster Session**

A phase 1/2 dose escalation study of the oral DNA polymerase theta inhibitor (POLQi) GSK4524101 ± niraparib in adults with advanced or metastatic solid tumors. First Author: Vivek Samnotra, GSK, Waltham, MA

Background: In homologous recombination-deficient (HRd) tumors, use of a PARP inhibitor (PARPi) leads to generation of DNA breaks that cannot be effectively repaired, thus selectively killing cancer cells via synthetic lethality. An alternative DNA repair mechanism, microhomology-mediated end joining, is mediated by DNA polymerase theta (encoded by *POLQ*). In preclinical studies, POLQi + PARPi demonstrated superior efficacy vs PARPi alone in preventing HRd tumor growth. To evaluate the clinical potential of this combination, this first-in-human study investigates treatment with GSK4524101, an investigational POLQi, and niraparib, a PARPi, in patients with solid tumors. **Methods:** This open-label, phase 1/2, multicenter study opened in October 2023 and includes a phase 1a/b, dose-escalation portion (part 1; potential enrollment to n≈75). Sites in the US and Canada are enrolling patients for part 1, which aims to assess the maximum tolerated dose, pharmacokinetics (PK), and safety of oral GSK4524101 ± oral niraparib. Eligibility criteria include age ≥18 years, Eastern Cooperative Oncology Group performance status of 0–2, life expectancy ≥3 months, and diagnosis of advanced or metastatic solid tumor with all standard-of-care treatment options exhausted. Exclusion criteria include unresolved chemotherapy-induced adverse events (AEs) or symptomatic uncontrolled brain or leptomeningeal metastases, uncontrolled hypertension, history of myelodysplastic syndrome or acute myeloid leukemia, or another malignancy that has progressed or required active treatment in the past 2 years. Outcome measures include dose-limiting toxicity (DLT) incidence during the DLT observation periods (up to 28 days; primary); treatment-emergent AEs (TEAEs) and serious AEs (SAEs); percentage of patients receiving all planned doses; and percentage of patients requiring AE-related dose interruptions, reductions, and discontinuations in the DLT observation period. Secondary endpoints include the PK of niraparib and the metabolite of GSK4524101 and incidence and duration of TEAEs and SAEs beyond the DLT observation period. The study is currently recruiting, with 17 patients having received doses across 9 sites in 2 countries as of January 10, 2025. Clinical trial information: NCT06077877. Research Sponsor: GSK.

TPS3175 **Poster Session**

A phase 1 study to evaluate the safety, pharmacokinetics, and efficacy of the first-in-class cyclin A/B RxL inhibitor CID-078, an orally bioavailable, cell-permeable macrocycle. First Author: Nehal J. Lakhani, The START Center for Cancer Research, Grand Rapids, MI

Background: The cyclin-dependent kinase (CDK)-RB-E2F axis forms the core transcriptional machinery driving cell cycle progression. Alterations in *RB1* or other key components occur in many cancers, resulting in heightened oncogenic E2F activity. E2F activation relies on the interaction between the cyclin's conserved hydrophobic patch (HP) and the RxL motif found on E2F and other cyclin/CDK substrates. Disrupting this cyclin A/E2F RxL interaction leads to hyperactivation of E2F and synthetic lethality in E2F-driven tumors. CID-078 is a novel, orally bioavailable, passively cell-permeable, potent and selective macrocycle that binds to the HP of cyclins A and B, blocking the RxL motif-mediated binding of E2F1 to cyclin A2-CDK2 and Myt1 to cyclin B1-CDK1. Consequently, CID-078 induces cell cycle arrest at the G2/M phase, leading to apoptotic tumor cell death. In preclinical studies including small cell lung cancer (SCLC) and triple negative breast cancer (TNBC) tumor types, CDX and PDX models with high E2F target pathway scores and high E2F1 expression demonstrated tumor regression following single-agent CID-078 treatment. Pre-clinical species demonstrate a well-tolerated safety profile and 20% oral bioavailability. Preclinical to clinical predictions maintain a 20% bioavailability. **Methods:** This is a phase 1, first-in-human, open-label, multicenter, dose escalation and dose expansion study to evaluate the safety, tolerability, pharmacokinetics (PK) pharmacodynamics (PD) and preliminary anti-tumor efficacy of CID-078 in patients (pts) with locally advanced or metastatic solid tumor malignancies (NCT06577987). Pts previously treated with standard of care therapy and for whom no available curative therapy exists are eligible. CID-078 will be administered orally, twice-daily in repeating 21-day cycles and treatment will continue until disease progression, death, unacceptable toxicity or withdrawal from study. Part I dose escalation will be guided by a Backfill-Bayesian Optimal Interval Design (BF-BOIN) based on the incidence of dose-limiting toxicities (DLTs) and all available safety and PK data. Under the BF-BOIN design, additional pts may be enrolled to expand previous cohorts to better characterize the safety, PK, PD and preliminary efficacy activity to support a recommended dose for expansion. A pilot food effect cohort is planned as well. In Part II dose expansion, pts will be enrolled to one or more cohorts defined by histologic tumor type or molecular alteration at the recommended doses of expansion. Based on preclinical data generated to date, the study plans to include patients with SCLC, TNBC, and RB1-mutated tumors with additional tumor types expanded based on observed efficacy. Dose escalation is ongoing with no DLT reported in the initial 3 dose cohorts evaluated. Clinical trial information: NCT06577987. Research Sponsor: None.

TPS3176 **Poster Session**

First in human phase 1 dose escalation and expansion clinical trial to evaluate the safety, pharmacokinetics and antitumor activity of intravenous AROG4-01 in patients with advanced solid tumors. First Author: Sonia Macia, Applied Research using OMIC Sciences, Barcelona, Spain

Background: AROG4-01 is a synthetic compound with a first-in-class mechanism of action, targeting complex secondary structural elements in mRNA, including G-quadruplexes(G4s). These secondary nucleic acid structures, characterized by Hoogsteen base pairing, play pivotal roles in gene regulation and are abundant in cancer cells due totheir high proliferation rates and dysregulated gene expression patterns. By binding to G4s present in untranslated regions, AROG4-01 modulates gene expression atthe post-transcriptional level, reducing tumor growth and survival. Preclinical studies have demonstrated that AROG4-01 achieves significant antitumor activity,inhibiting cancer cell proliferation, with a strong effect of the compound on inhibit colony formation, evidencing the capacity of AROG4-01 to prevent the long-termsurvival and proliferation of cancer cells. This activity has been validated in vivo across multiple solid cancer models. **Methods:** This study (NCT06652529,EudraCT2024-517569-18) is an open label, Phase 1 dose escalation trial with two expansion cohorts to investigate the safety, tolerability, pharmacokinetics,pharmacodynamics and preliminary antitumor activity of AROG4-01. The study consists of two parts. Part A is a dose escalation that will include 8-20 patients withadvanced solid tumors, covering up to 6 dose levels with the primary objective of determining the safety and tolerability of AROG4-01 and defining an appropriaterecommended phase 2 dose (RP2D) for further evaluation in part B. The study will start with an accelerated-titration dose escalation scheme enrolling one evaluablepatient per cohort for the first 2 dose levels followed by a classic 3+3 design. Part B is a dose expansion, with two cohorts of ten patients: one cohort of patients withadvanced mesothelioma (cohort 1) and a second cohort of patients with other solid tumors (cohort 2). Serum samples collected from patients enrolled in part A whenreceiving the first IMP dose during the first treatment cycle will be used to assess the PK of AROG4-01. Three sites in Spain are expected to participate. Clinical trial information: NCT06652529. Research Sponsor: Applied Research using Omic Sciences.

TPS3177 **Poster Session**

IMMUNONET: A multicenter, open-label, proof-of-concept phase II trial evaluating NP137 as add-on therapy in advanced/metastatic solid tumors treated with standard immunotherapies. First Author: Jérôme Fayette, Centre Léon Bérard, Lyon, France

Background: PD-1/PD-L1 blockade has transformed oncology by offering durable responses in various cancers. However, many patients develop resistance, highlighting the need for novel therapeutic strategies. Epithelial-to-Mesenchymal Transition (EMT) plays a pivotal role in immune checkpoint inhibitor efficacy, with epithelial tumors exhibiting greater immunoreactivity than mesenchymal ones. NP137, a first-in-class anti-Netrin-1 monoclonal antibody, has shown in phase I study the ability to inhibit EMT, potentially overcoming resistance (Cassier et al., *Nature*, 2023). This phase I data demonstrated NP137's ability to shift tumors toward an epithelial phenotype, supporting its combination with immune checkpoint inhibitor to sensitize tumors and alleviate resistance. The goal of IMMUNONET study (NCT05605496) is to evaluate NP137's ability to re-sensitize advanced solid tumors to anti-PD-1/PD-L1 therapy. **Methods:** This proof-of-concept study assess NP137 (14 mg/kg, IV, Q3W) as add-on therapy to standard PD-1/PD-L1 inhibitors across three independent cohorts of patients with advanced/metastatic solid tumors of any histological types: Cohort 1 (Stable Disease [SD]): Radiological SD after $\geq$12 weeks of anti-PD-1/PD-L1 therapy. Cohort 2 (Primary Refractory): Radiological progressive disease (PD) and no response under anti-PD-1/PD-L1 therapy. Cohort 3 (Secondary Refractory): Radiological PD following initial response under anti-PD-1/PD-L1 therapy. Treatment continues until progression, unacceptable toxicity, or consent withdrawal. The primary endpoint is clinical activity: objective response rate (ORR)-12W for cohort 1 and progression-free rate (PFR)-12W for cohorts 2 and 3. Secondary endpoints include ORR-12W (cohorts 2 and 3), Time to Objective Response (ToR), Duration of Response (DoR) and safety for all cohorts. Evolution of EMT, Netrin-1, and receptor expression will be analysed and correlated with clinical outcomes. An adaptive 2-stage design is being used for this study (Lin and Shih, Biometrics 2004). The target levels of clinical activity are set at 20% (relevant) and 25% (high). In stage 1, 18 patients will be enrolled at 1-sided alpha of 5%. Depending on the observed success rate, additional 11 patients (if 1 or 2 successes) or 5 patients (if $>$ 2 successes) could be recruited into stage 2. Null hypotheses will be rejected if $\geq$4 successes are observed in 29 [test p_0 = 0.05 vs. 0.20, 80% power] or 23 patients [test p_0 = 0.05 vs. 0.25, 90% power], respectively. Current Status: Cohort 1 has been closed due to non-feasibility. Prespecified goals for the first stage were met, stage 2 enrolment is underway. Cohort 2 has enrolled 21 patients, and cohort 3 has enrolled 19 of 23 planned evaluable patients. Clinical trial information: NCT05605496. Research Sponsor: European Innovation Council.

TPS3178 **Poster Session**

Trial in progress: Phase 1 study of the selective protein degrader ASP4396 in patients with locally advanced or metastatic solid tumors with *KRAS G12D* mutations. First Author: Shiraj Sen, NEXT Oncology, Dallas, TX

Background: *KRAS G12D* is the most common *KRAS* mutation at codon 12 found in solid tumors and is difficult to target. There are no approved therapies directly targeting *KRAS G12D*. Targeted protein degradation is emerging as a promising therapeutic approach for undruggable targets. ASP4396, a novel protein degrader, targets KRAS G12D-mutated protein for degradation via the ubiquitin-proteasome system. This mode of action may offer higher efficacy and safety compared with inhibitors by blocking both enzymatic and scaffolding functions of proteins and by higher target selectivity. This first-in-human study aims to evaluate the safety and efficacy of ASP4396 in patients with advanced solid tumors with *KRAS G12D* mutations (NCT06364696). **Methods:** This Phase 1, open-label, multicenter, dose-escalation and dose-expansion study of ASP4396 is enrolling adult patients with locally advanced (unresectable) or metastatic solid tumors with documented *KRAS G12D* mutations who have $\geq$ 1 measurable lesion per Response Evaluation Criteria in Solid Tumors (RECIST) version (v)1.1, ECOG performance status of 0 or 1, adequate organ function, and who did not respond or who are ineligible for standard therapies. Tumor-specific dose expansion cohorts may be enrolled at the maximum tolerated dose (MTD) and/or candidate recommended phase 2 dose (RP2D). Patients who received prior treatment targeting KRAS G12D will be excluded. Primary endpoints are safety and tolerability (assessed by dose-limiting toxicities [DLTs], adverse events, laboratory and other standard tests), and RP2D and/or MTD of ASP4396. Secondary endpoints are antitumor activity (objective response rate, duration of response, disease control rate, and progression-free survival per RECIST v1.1 by investigator assessment; and overall survival), and pharmacokinetic/ pharmacodynamic assessments. In the dose escalation cohort, patients will receive increasing doses of ASP4396 intravenously in a 21-day cycle. The target enrollment for each dose level is set at 1 DLT-evaluable patient for dose levels 1–3 and $\geq$ 3 DLT-evaluable patients for each subsequent dose level. The study will consist of 3 periods: screening (up to 28 days), treatment (every 21-day cycle until treatment discontinuation criteria are met), and follow-up. Data will be summarized descriptively (mean, standard deviation, median) for continuous endpoints, and by counts and percentages for categorical endpoints. Study enrollment is ongoing. Clinical trial information: NCT06364696. Research Sponsor: Astellas Pharma Inc.

TPS3180 **Poster Session**

Phase 1 first-in-human clinical trial of AG01, a recombinant monoclonal antibody to progranulin/glycoprotein 88 (PGRN/GP88), to determine the safety, tolerability, pharmacokinetics, and preliminary anti-tumor response in subjects with advanced solid tumor malignancies. First Author: Katherine H. R. Tkaczuk, University of Maryland Greenebaum Comprehensive Cancer Center, Baltimore, MD

Background: GP88/PGRN is the largest member of the granulin/epithelin family. We demonstrated GP88's role as an autocrine growth & survival factor in breast cancer (BC): in ER+BC cells, GP88 stimulates proliferation & confers resistance to anti-estrogen therapy & aromatase inhibitors;GP88 is expressed in 80% of invasive ductal carcinomas & is negative in normal mammary tissue; GP88 tumor expression is a prognostic indicator of recurrence & death in BC pts; Elevated GP88 serum level in metastatic BC patients (pts) is associated with disease progression. PGRN/GP88 is overexpressed in several other solid tumors (non-small cell lung carcinoma, colorectal, bladder, ovarian, prostate & brain). In advanced NSCLC & prostate pts, elevated serum PGRN/GP88 have been found. These results make GP88/PGRN an ideal therapeutic & diagnostic target in BC and other solid tumors. An anti-human PGRN/GP88 monoclonal antibody (AG01) inhibiting PGRN/GP88 action was developed & expressed as recombinant antibody in CHO cells. Pharmacology, GMP manufacturing, formulation, stability studies & GLP toxicology studies in non-human primates were done. The IND application was cleared by the FDA to proceed with the first-in-human (FIH) AG01 study in adult subjects with advanced solid tumors. **Methods:** This IRB approved FIH study, will be conducted in 2 stages, dose escalation (1A) and dose expansion (1B). The 1A part is ongoing, with the 1 + (3+3) design. In the 1A part the AG01 is administered intravenously (IV) over 90 min. every 14 days +/- 1 day, 1 cycle = 28days, DLT assessments occur in the first 28 days of treatment. Five dose levels of AG01 & a -1 level are planned (level -1-0.5mg/kg, & 1mg/kg, 2mg/kg, 4mg/kg, 6mg/kg, 8 mg/kg). In 1A part of the study, initially an accelerated titration design (1pt/dose level) was utilized to guide dose progression & estimation of the maximum tolerated and/or administered dose (MTD/MAD). Eligibility criteria for 1A part include pts with advanced relapsed/refractory solid tumor malignancies who failed 1 or more standard of care (SOC) therapies or for whom no SOC treatment exists or is not tolerated, at least 1 RECIST1.1 measurable lesion, ECOG $<$ = 2, Life expectancy $>$ = 12wks, adequate organ & bone marrow function, willing to sign informed consent & follow study procedures. Primary objective (1A) is to determine the MTD and/or MAD of AG01. Secondary objectives: to determine the recommended phase 2 dose (RP2D), safety, tolerability, the PKs, immunogenicity & the preliminary anti-tumor activity of AG01. Exploratory objectives:todetermine PGRN/GP88 expression in tumor tissue & PGRN/ GP88 blood levels (A&G's IHC & ELISA test). This study is registered at NCT05627960. The study is supported by NCI grants NCI R44 CA224718 & CA162629. Clinical trial information: NCT05627960. Research Sponsor: National Cancer Institute; National Cancer Institute.

TPS3181 **Poster Session**

Trial in progress: First-in-human study of ATX-559, an oral inhibitor of DHX9, in patients with advanced or metastatic solid tumors, and molecularly defined cancers. First Author: Meredith Pelster, Sarah Cannon Research Institute, Nashville, TN

Background: DHX9 is a multifunctional RNA helicase that is involved in the maintenance of genomic stability by resolving DNA/RNA secondary structures that may lead to DNA replication stress and DNA damage. High expression of DHX9 is evident in multiple cancer types. ATX-559, an oral inhibitor of DHX9, has been shown preclinically to induce robust anti-tumor activity of a variety of different solid tumors with genomic instability, including models with BReast CAncer gene 1 and/or 2 alterations or deficiency (BRCA deficient) and microsatellite instability-high (MSI-H) and/or deficient mismatch repair (dMMR). **Methods:** This is a first-in-human, Phase 1, open-label, single-arm, dose-escalation and expansion study to evaluate the safety profile of ATX-559 and to determine the recommended phase 2 dose (RP2D). In dose-escalation, patients with locally-advanced or metastatic solid tumors, and molecularly-defined cancers will be enrolled for safety assessment, guided by a model-assisted dose escalation design (Yuan, 2019) to identify an acceptable dose. To assess evidence of preliminary antitumor activity in the expansion study, participants with (1) BRCA deficient, HER2-negative, metastatic breast cancer, and (2) dMMR/MSI-H solid tumors will be enrolled using a Simon 2-stage design (Simon, 1989). Primary endpoints include identification of the RP2D dose that is deemed acceptable per the model-assisted dose escalation design and to evaluate safety and tolerability as noted by the frequency and severity of adverse events (AEs). Secondary endpoints will evaluate pharmacokinetics (PK), pharmacodynamics (PD) peripherally and in a biopsy sub-study, and preliminary anti-tumor activity per RECIST v1.1. Exploratory objectives will explore potential biomarkers in relationship to ATX-559 exposure, as well as those that may correlate with treatment outcomes. A randomized cohort has also been included during dose expansion in recognition of Project Optimus. The study is open and enrollment is ongoing. Clinical trial information: NCT06625515. Research Sponsor: Accent Therapeutics.

TPS3182 **Poster Session**

A phase 1/2 study of JK06, a 5T4 antibody drug conjugate, in patients with unresectable locally advanced or metastatic cancer. First Author: Nuria Kotecki, Université libre de Bruxelles (ULB), Hôpital Universitaire de Bruxelles (H.U.B), Institut Jules Bordet, Brussels, Belgium

Background: 5T4, a Type I transmembrane glycoprotein, plays a pivotal role in neonatal development, but its expression in normal adult tissues is limited. In contrast, 5T4 emerges prominently in a broad spectrum of solid tumors, including but not limited to NSCLC, breast, ovarian, endometrial, bladder, pancreatic, esophageal, gastric and colorectal cancers. Furthermore, the expression of 5T4 is confirmed to be associated with advanced disease and worse clinical outcomes in multiple solid tumors. These features make 5T4 an attractive, but as of yet unexploited, target for cancer therapeutics. JK06 is an antibody-drug-conjugate (ADC) targeting 5T4-expressing cancer cells. The antibody moiety of JK06 has a high-affinity tetravalent binding capacity, compensating for generally low 5T4 expression levels. Further, the JK06 binding specificity is biparatopic, targeting two non-overlapping epitopes on 5T4 antigens. In this way, JK06 cross-links 5T4 on the surface of cancer cells, which enhances internalization and increases intracellular release of the cytotoxic payload. The cytotoxic payload of JK06 is the clinically proven microtubule-disrupting agent, MMAE, that inhibits cell division by preventing the polymerization of tubulin, leading to cell cycle arrest and apoptosis. JK06 mediates cytotoxicity in vitro, in a 5T4 receptor density dependent manner, and anti-tumor activity has been demonstrated in several murine xenograft models. JK06 has been shown to bind to recombinant human and cynomolgus 5T4, supporting the translation of pre-clinical toxicology studies. Preclinical toxicology studies showed no toxicity with JK06 at dose levels up to 17 mg/kg single dose and 9 mg/kg repeat dose. Toxicokinetic analysis and PK modeling suggest that a Q3W dosing regimen should provide adequately sustained exposure in clinical studies. In summary, preclinical studies support clinical development of JK06 for the treatment of multiple 5T4 expressing solid tumors. **Methods:** The Phase 1/2 study of JK06 will enroll patients with advanced relapsed/refractory solid tumors. The study will employ a 3+3 escalation design to explore the safety, PK and preliminary anti-tumor activity of JK06. Back-fill enrollment at specific dose levels is permitted but mandates fresh tumor biopsy. Patients will receive treatment with JK06 intravenously once every three weeks until confirmed disease progression or intolerable toxicity. Tumor specific expansion cohorts will be initiated once dose and schedule are established from dose escalation; fresh tumor biopsies will also be collected from patients enrolled in expansion cohorts. Response will be assessed every 9 weeks per RECIST v1.1. Clinical trial information: NCT06667960. Research Sponsor: None.

TPS3183 **Poster Session**

A phase I/Ib study of olaparib and ASTX727 in BRCA 1/2- and HRD-mutated tumors. First Author: Pamela N. Munster, UCSF Helen Diller Family Comprehensive Cancer Center, San Francisco, CA

Background: Patients with germline or somatic HRR pathway mutations often develop resistance despite initial response. Overlapping toxicities hinder combination strategies in breast, ovarian, prostate, and pancreatic cancers, creating a need for safer and more effective approaches. Preclinical studies have shown that DNMT inhibition enhances PARP inhibitor efficacy by promoting PARP trapping on DNA. This phase I study aims to assess the safety and tolerability of olaparib and AST727 in HRR-mutated patients and establish the RP2D for a phase II trial, to be supported by the NCI ComboMatch program. Correlative studies include the creation of PDX and organoid models for ex vivo analysis of therapy response. **Methods:** Further studies include cfDNA and tumor tissue assessment to elucidate mechanisms of resistance (reversion mutations, epigenetic markers) and PD markers of HR pathway modulation. Rad51 foci will be measured to determine DNA repair function and CHIP assays (clonal hematopoiesis of indeterminate potential) to study the differential rate of CHIP as an early event in the evolution of AML/MDS. Trial Design: This is a single center phase I/Ib clinical trial evaluating the combination of olaparib and ASTX727 (an oral formulation of decitabine with cedazuridine, a cytidine deaminase inhibitor that allows for oral administration). All participant enrollment and study participation will be conducted at UCSF as single site trial with collaboration from other centers for correlative/exploratory objectives. The phase I dose escalation portion will follow a standard 3+3 design for enrollment and will include adults with advanced/metastatic solid tumor malignancies with germline or somatic mutations in the HRR pathway (i.e., BRCA1/2, PALB2, ATM, and/or CHEK2 mutations). Patients will be treated in 2 escalating cohorts with a 12 patient phase Ib dose expansion in the same population. At least 6 of 12 expansion patients must have germline HRD mutations. Key Eligibility: The participant must have histologically confirmed advanced solid tumors with a germline and/or somatic mutation in one or more of the following genes: BRCA1/2, PALB2, ATM, and/or CHEK2. Patients must have adequate organ function and recovered from prior treatment associated toxicities. Prior treatment with PARP inhibitors is allowed if the participant has not required dose reductions or delays due to toxicity. Participants with treated brain metastases are eligible if follow-up brain imaging shows no evidence of progression for at least 4 weeks. Individuals with a prior or concurrent malignancy are eligible, however participants diagnosed with MDS or AML are excluded from the study. Trial Status: The study is ongoing and 4 patients have been enrolled to date. Clinical trial information: NCT06177171. Research Sponsor: National Cancer Institute/U.S. National Institutes of Health.

TPS3184 **Poster Session**

RYZ101 (^{225}Ac-DOTATATE) in patients with estrogen receptor-positive, human epidermal growth factor receptor 2–negative, locally advanced and unresectable, or metastatic breast cancer progressing after prior therapy: The phase 1b/2 TRACY-1 study. First Author: Erica L. Mayer, Medical Oncology, Dana-Farber Cancer Institute, Harvard Medical School, Boston, MA

Background: RYZ101 (actinium-225 [^{225}Ac]-DOTATATE) is a radiolabeled somatostatin analog (SSA) for the treatment of patients with solid tumors expressing somatostatin receptor-type 2 (SSTR2). RYZ101 is composed of the alpha-emitting radioisotope ^{225}Ac, the chemical chelator DOTA (tetraxetan), and SSA octreotate (TATE). RYZ101 binds with high affinity to SSTR2 on the cell surface and is internalized, whereupon the alpha-particle emission of ^{225}Ac results in lethal double-strand DNA breaks. Although SSTR-directed therapy is widely used in patients with well-differentiated gastroenteropancreatic neuroendocrine tumors (GEP-NETs), its relevance in non-GEP-NET SSTR-expressing neoplasms is still emerging. Clinical positron emission tomography (PET) imaging studies have reported SSTR expression in estrogen receptor (ER)-positive breast cancer. Available data support investigating the efficacy of RYZ101 in patients with ER-positive, HER2-negative, locally advanced and unresectable or metastatic breast cancer. **Methods:** TRACY-1 (NCT06590857) is a global, multicenter, open-label, two-part (dose escalation and expansion) phase 1b/2 study. Key inclusion criteria are: age ≥18 years; histologically confirmed, ER-positive, HER2-negative locally advanced and unresectable or metastatic breast cancer not amenable to curative-intent treatment; endocrine-refractory disease; documented progression (per RECIST v1.1) after ≥2 and ≤4 prior lines of chemotherapy and/or ADC (≥1 must be ADC if the patient is a candidate for ADCs and treatment is available); ≥1 RECIST-measurable SSTR−PET-positive lesion and ≥80% of RECIST-measurable lesions being SSTR−PET-positive on screening scan. Key exclusion criteria are: prior radiopharmaceutical therapy; prior anticancer therapy or external beam radiotherapy in past 4 weeks; anticancer hormonal treatments in past 2 weeks. Primary objectives are to determine the recommended phase 2 dose (R2PD) of RYZ101 (dose escalation; anticipated 6−24 patients), and the efficacy of RYZ101 at the RP2D defined as ORR as determined by BICR (dose expansion; approximately 100 patients). During dose escalation, patients will receive RYZ101 by IV infusion every 6 weeks for up to 6 cycles at a starting dose of 6.5 MBq (dose level [DL] 1), with escalation to DL 2 (8.3 MBq) and DL 3 (10.2 MBq), or dose de-escalation to 4.6 MBq if DL 1 is not tolerated, based on dose-limiting toxicity rates. In the expansion phase, patients will receive RYZ101 at the RP2D. Concomitant amino acid IV infusions (containing L-arginine and L-lysine) will be co-infused with RYZ101 for renal protection. The study is ongoing and enrolling patients in the USA. Clinical trial information: NCT06590857. Research Sponsor: RayzeBio.

TPS3185 **Poster Session**

panSOHO: Phase II trial of BAY 2927088 in patients with unresectable or metastatic solid tumors other than NSCLC with *HER2*-activating mutations. First Author: Vivek Subbiah, Sarah Cannon Research Institute, Nashville, TN

Background: Human epidermal growth factor receptor 2 (*HER2*) gene mutations occur in approximately 3.5% of solid tumors, with a frequency varying from less than 1% to 9%, depending on the tumor type. BAY 2927088 is an oral, reversible tyrosine kinase inhibitor that potently inhibits HER2 and mutant epidermal growth factor receptor and has shown clinical benefit based on preliminary evidence from the Phase I/II SOHO-01 trial in patients with *HER2*-mutant non-small cell lung cancer (NSCLC; PL04.03 presented at IASLC 2024 World Conference on Lung Cancer), an indication for which the FDA has granted Breakthrough Designation. Here we introduce the panSOHO trial evaluating the efficacy and safety of BAY 2927088 in patients with unresectable, locally advanced or metastatic solid tumors with *HER2*-activating mutations. **Methods:** panSOHO is a Phase II, open-label, multicenter, multinational, single-arm basket trial of BAY 2927088 in patients with unresectable or metastatic solid tumors with *HER2*-activating mutations (NCT06760819), and will be conducted in the USA, Europe, and the Asia-Pacific region. Eligibility criteria include patients aged ≥18 years with: documented histologically or cytologically confirmed, locally advanced or metastatic solid tumor cancer (colorectal, biliary tract, bladder and urothelial tract, cervical, endometrial, or other solid tumor); documented activating HER2 mutation; ≥1 measurable lesion per RECIST v1.1; and previous standard therapy or no satisfactory alternative treatment options. Key exclusion criteria include primary diagnosis of NSCLC, treatment with a HER2 tyrosine kinase inhibitor, untreated active brain metastases, and leptomeningeal disease. Overall, 111 eligible patients will receive BAY 2927088 p.o. 20 mg twice daily in 3-week cycles until disease progression, unacceptable toxicity, or study withdrawal. The primary outcome is BAY 2927088 efficacy on objective response rate per RECIST v1.1 as assessed by blinded independent central review (BICR). Secondary outcomes include BAY 2927088 efficacy on time to response, duration of response, disease control rate, and progression-free survival per RECIST v1.1 by BICR, and overall survival, and BAY 2927088 safety and tolerability. Impact of BAY 2927088 on patient quality of life will be evaluated by EORTC QLQ-C30. Enrollment is open. Clinical trial information: NCT06760819. Research Sponsor: Bayer AG.

TPS3186 Poster Session

Molecular residual disease (MRD) in solid tumors. First Author: Majd T. Ghanim, Flatiron Health, New York, NY

Background: Pragmatically designed clinical studies facilitate rapid accrual of representative populations by aligning research with routine care and enabling study execution in community practice settings. In addition, the implementation of technologies to streamline patient ascertainment and data collection further reduce site burden and improve efficiency. Herein we describe the initial cohort under a platform study designed with pragmatic elements initiated within a technology-enabled community oncology research network. This substudy establishes a prospective observational registry that collects routinely documented clinical data plus intentionally collected biomarker samples, including blood, for the purpose of isolating circulating tumor DNA at specified intervals to enable exploration of MRD in patients with early stage solid tumors. **Methods:** This is a prospective, multicenter, observational, biospecimen collection study in participants (pts) diagnosed with early stage cancers in select solid tumors who have planned curative-intent surgery. The scientific objective is to collect tumor tissue, longitudinal blood samples, and associated clinical data to explore applications of blood and/or tissue-based cancer biomarkers for cancer detection, prognosis, therapy selection, surveillance, and therapy response. Approximately 1350 pts will be enrolled across ~30 Flatiron Research Network community oncology sites. Participants are grouped by tumor site of origin and histology into 7 cohorts (Table). Patients provide informed consent and are enrolled before starting neoadjuvant or adjuvant therapy. Study visits correspond with routine care. Research tissue and blood samples are obtained upon enrollment and at study-specified intervals up to 5.5 years or until disease recurrence for analysis by Exact Sciences laboratories. Technology enablement includes near real-time, AI-assisted, centralized patient ascertainment and integrated electronic health record-to-electronic data capture system data transfer. Under the parent protocol mechanism, the study was IRB approved 65 days from commencement of protocol writing. Target enrollments are based on the number needed to enroll to observe at least 30 events in 3 years. Clinical trial information: NCT06605404. Research Sponsor: None.

Study cohorts.

Tumor type	Disease stage	Target enrollment
Muscle invasive urothelial carcinoma	II-III	200
Esophageal	I-III	150
Gastric & gastroesophageal junction	I-III	150
Melanoma	II-III	300
Non–small cell lung cancer	I-III	200
Exocrine pancreatic cancer	I-III	150
Other solid tumors (excluding central nervous system, colorectal, breast, skin squamous and basal cell, gastrointestinal stromal tumors, thyroid, uveal melanoma, and low or intermediate grade neuroendocrine tumors)	II-III	200

TPS3187 Poster Session

Beamion PANTUMOR-1: A phase II, multicenter, multicohort, open-label trial to evaluate the efficacy and safety of the oral HER2-selective tyrosine kinase inhibitor zongertinib for the treatment of *HER2*-mutated or overexpressed/amplified solid tumors. First Author: Alison M. Schram, Memorial Sloan Kettering Cancer Center, New York, NY

Background: While it is well known that HER2 overexpression, amplification, and mutation drives various tumors, there remains an unmet need for effective, oral, HER2-targeted therapies. Zongertinib is an irreversible tyrosine kinase inhibitor (TKI) that selectively inhibits HER2 while sparing EGFR, thereby limiting associated toxicities. In the ongoing Phase Ia/Ib trial (NCT04886804), zongertinib showed manageable safety and confirmed responses in patients (pts) with HER2-overexpressed/amplified and *HER2*-mutant tumors (Wilding et al, *Cancer Discov.* 2024). Based on these encouraging data, the Beamion PANTUMOR-1 basket trial (NCT06581432) is evaluating the efficacy and safety of zongertinib monotherapy in pts with *HER2*-mutant or HER2-overexpressed/amplified solid tumors. **Methods:** In this global Phase II basket trial, ~200 pts with HER2-driven (*HER2*-mutant or HER2-overexpressed/amplified) tumors will be enrolled at ~60 sites in 13 countries. Pts will be enrolled to 10 cohorts: 8 cohorts of specific tumor types and 2 tumor-agnostic cohorts (see Table). The specific tumor type cohorts will initially recruit 10 pts, with potential for expansion to up to 20 pts after an interim analysis. In the tumor-agnostic cohorts, 20 pts will be recruited directly without an interim analysis. Pts will receive 120 mg zongertinib until disease progression, unacceptable toxicity, or withdrawal. Patients must be ≥18 years old, have documented HER2-positive (HER2-overexpressed/amplified) status or a *HER2* mutation (established by local testing), ≥1 measurable lesion outside the central nervous system, an ECOG performance score of 0 or 1, and have progressed following prior treatment or have no alternative treatment options. Exclusion criteria include *HER2*-mutant non-small cell lung cancer (NSCLC) and previous/concomitant malignancies. Primary endpoint is objective response, as assessed by central independent review according to RECIST v1.1. Secondary endpoints include duration of response, progression-free survival, disease control, occurrence of treatment-emergent adverse events, and health-related quality of life. Enrollment is ongoing. Clinical trial information: NCT06581432. Research Sponsor: Boehringer Ingelheim.

HER2 overexpression/ amplification cohorts	Tumor type	*HER2* mutation cohorts	Tumor type
Cohort 1	Urothelial cancer	Cohort 7	Urothelial cancer
Cohort 2	Biliary tract cancer	Cohort 8	Breast cancer
Cohort 3	Uterine cancer	Cohort 9	Gastroesophageal cancer
Cohort 4	Cervical cancer	Cohort 10	Other *HER2*-mutant solid tumors†
Cohort 5	Non-squamous NSCLC		
Cohort 6	Other *HER2* overexpressed/ amplified solid tumors*		

*Except breast cancer, gastric, gastroesophageal junction, or esophageal adenocarcinoma.
†Except NSCLC.

TPS3188 Poster Session

Perfume trial: Phase II trial of binimetinib in patients with *BRAF* fusion-positive low-grade glioma or pancreatic cancer. First Author: Tomoyuki Satake, Department of Hepatobiliary and Pancreatic Oncology, National Cancer Center Hospital East, Kashiwa, Japan

Background: *BRAF* fusion was reported to be a rare mutation found in 0.3% of all solid tumors, but a high percentage of BRAF fusion has been reported in pilocytic astrocytoma (30-77%) and pancreatic acinar cell carcinoma (24-67%). Although treatment for *BRAF* V600 mutations has been developed, treatment for *BRAF* fusion has not yet been established. Recently, tovorafenib has been granted accelerated approval by the FDA for pediatric low-grade glioma (LGG) with *BRAF* alteration (including *BRAF* fusion). Still, it is not yet approved in Japan, and an unmet need exists. In *BRAF* fusion-positive solid tumors, the constitutively activated BRAF kinase domain forms dimers that cause activation of the MAPK pathway. MEK inhibitors have been reported to show anti-tumor effects against *BRAF* fusion-positive cell lines. Phase I/II trials with selumetinib or binimetinib have shown efficacy in patients with *BRAF* fusion-positive LGG. **Methods:** Perfume trial (NCCH2101/MK011) is an open-label, parallel, 2-cohort, multicenter, phase II, investigator-initiated registration-directed clinical trial to evaluate the efficacy and safety of binimetinib in patients with advanced or recurrent LGG or pancreatic cancer (PC) harboring *BRAF*fusion/rearrangement. Sample sizes of 16 and 11 patients are needed for LGG and PC at a one-sided significant level of 5% to achieve 85% and 70% power, respectively. Key eligibility criteria for LGG (grade 1 and grade 2 tumors according to WHO classification) include age≧12 (body weight ≧40 kg in 12-17 year old) and KPS/LPS≧70, regardless of history of cancer drug therapy. Key eligibility criteria for PC include age≧12 (body weight ≧40 kg in 12-17 year old); ECOG PS 0-1; refractory or intolerant to at least one prior cancer drug therapy. Enrolled patients receive binimetinib 45mgadministered orally twice daily. The primary endpoint is the objective response rate (ORR) using RECIST 1.1 by independent central review. The secondary endpoints include ORR by investigators' assessment, ORR by RANO in LGG, progression-free and overall survivals, disease control rate, duration of response, and safety. This study implemented a decentralized clinical trial system for patients living in remote areas to reduce their time and economic burden. Enrollment started in March 2023 and is ongoing at 6 facilities in Japan. As of Dec 2024, 6 patients with LGG and 3 patients with PC were enrolled. Clinical trial information: jRCT2031230007, NCT06159478. Research Sponsor: None.

First-line encorafenib + cetuximab + mFOLFOX6 in BRAF V600E-mutant metastatic colorectal cancer (BREAKWATER): Progression-free survival and updated overall survival analyses. First Author: Elena Elez, Department of Medical Oncology, Vall d'Hebron University Hospital (HUVH), Vall d'Hebron Institute of Oncology (VHIO), IOB-Quiron, UVic-UCC, Barcelona, Spain

The full, final text of this abstract will be available at meetings.asco.org on the day of presentation and in the online supplement to the June 10, 2025, issue of the *Journal of Clinical Oncology*.

3501 **Oral Abstract Session**

Nivolumab (NIVO) plus ipilimumab (IPI) vs chemotherapy (chemo) or NIVO monotherapy for microsatellite instability-high/mismatch repair-deficient (MSI-H/dMMR) metastatic colorectal cancer (mCRC): Expanded analyses from CheckMate 8HW. First Author: Heinz-Josef Lenz, University of Southern California Norris Comprehensive Cancer Center, Los Angeles, CA

Background: In the phase 3 CheckMate 8HW study (NCT04008030), both dual primary endpoints of progression-free survival (PFS) for first-line (1L) NIVO + IPI vs chemo (HR 0.21; $P < 0.0001$) and NIVO + IPI vs NIVO across all lines (HR 0.62; $P = 0.0003$) in patients (pts) with centrally confirmed MSI-H/dMMR mCRC were met. We report expanded analyses of NIVO + IPI vs NIVO (all lines) and longer follow-up results for NIVO + IPI vs chemo (1L). **Methods:** The study design was described previously. Pts with MSI-H/dMMR per local testing were enrolled. After randomization, IHC and PCR based tests were used for central confirmation. PFS2 (time from randomization to progression after subsequent systemic therapy, start of second subsequent systemic therapy, or death) was a key exploratory endpoint. **Results:** In all randomized pts (all lines), 296 of 354 (84%) in the NIVO + IPI arm, 286 of 353 (81%) in the NIVO arm, and 113 of 132 (86%) in the chemo arm had centrally confirmed MSI-H/dMMR. In all randomized 1L pts, 171 of 202 (85%) in the NIVO + IPI arm and 84 of 101 (83%) in the chemo arm had centrally confirmed MSI-H/dMMR. Median follow-up was 47.0 mo (range 16.7–60.5). 1L NIVO + IPI continued to show PFS benefit vs chemo (Table). Subsequent systemic therapy was received by 27 (16%) and 61 (73%) pts after 1L NIVO + IPI and chemo, respectively; 10 (6%) and 21 (25%) received subsequent non-study immunotherapy. In the 1L chemo arm, 39 (46%) pts crossed over to NIVO + IPI on study. PFS2 continued to favor 1L NIVO + IPI vs chemo (Table). Across all lines, NIVO + IPI demonstrated superior PFS vs NIVO (Table). Subsequent systemic therapy was received by 54 (18%) pts in the NIVO + IPI arm and 83 (29%) in the NIVO arm; 20 (7%) and 31 (11%) received subsequent non-study immunotherapy. PFS2 favored NIVO + IPI vs NIVO across all lines of therapy (Table). In all treated pts, grade 3/4 treatment-related adverse events occurred in 78 (22%) and 50 (14%) pts in the NIVO + IPI and NIVO arms, respectively. Additional analyses will be presented. **Conclusions:** NIVO + IPI demonstrated sustained clinical benefit vs chemo (1L) and NIVO (all lines) despite use of subsequent therapy, as shown by improved PFS2 in pts with centrally confirmed MSI-H/dMMR mCRC. No new safety signals were observed. These results support NIVO + IPI as a standard of care treatment for MSI-H/dMMR mCRC. Clinical trial information: NCT04008030. Research Sponsor: Bristol Myers Squibb.

Centrally confirmed MSI-H/dMMR (1L)	NIVO + IPI (n = 171)	Chemo (n = 84)
Median PFS (95% CI), mo	54.1 (54.1–NE)	5.9 (4.4–7.8)
HR (95% CI)	0.21 (0.14–0.31)	
Median PFS2 (95% CI), mo	NR (NE–NE)	30.3 (15.2–NE)
HR (95% CI)	0.28 (0.18–0.44)	

Centrally confirmed MSI-H/dMMR (all lines)	NIVO + IPI (n = 296)	NIVO (n = 286)
Median PFS (95% CI), mo	NR (53.8–NE)	39.3 (22.1–NE)

Anlotinib versus bevacizumab added to standard first-line chemotherapy among patients with RAS/BRAF wild-type, unresectable metastatic colorectal cancer: A multicenter, prospective, randomised, phase 3 clinical trial (ANCHOR trial). First Author: Ke-Feng Ding, Department of Colorectal Surgery and Oncology, Key Laboratory of Cancer Prevention and Intervention, Ministry of Education, The Second Affiliated Hospital, Zhejiang University School of Medicine, Hangzhou, China

The full, final text of this abstract will be available at meetings.asco.org on the day of presentation and in the online supplement to the June 10, 2025, issue of the *Journal of Clinical Oncology*.

3503 **Oral Abstract Session**

ctDNA-guided adjuvant chemotherapy escalation in stage III colon cancer: Primary analysis of the ctDNA-positive cohort from the randomized AGITG dynamic-III trial (intergroup study of AGITG and CCTG). First Author: Jeanne Tie, Department of Medical Oncology, Peter MacCallum Cancer Centre and Personalised Oncology Division, Walter and Eliza Hall Institute of Medical Research, Melbourne, Australia

Background: Despite adjuvant chemotherapy (ACT) a proportion of patients (pts) with stage III colon cancer (CC) will recur. Most at risk are those with detectable ctDNA, whereas those with undetectable ctDNA have a reduced recurrence risk. The DYNAMIC-III study explored the impact of ACT de-escalation or escalation as informed by post-surgery ctDNA results. Here, we report the primary analysis on the impact of treatment escalation in ctDNA-positive pts. Outcome data for treatment de-escalation in ctDNA-negative pts is immature. **Methods:** DYNAMIC-III is a multicenter, randomized, phase II/III trial. Eligible pts had resected stage III CC and were fit for ACT. Pts were randomly assigned 1:1 to ctDNA-informed or standard of care (SOC) management. Clinicians nominated the selected SOC ACT regimen prior to randomization. For ctDNA-informed management, a ctDNA-positive result at 5-6 weeks after surgery with a tumor-informed assay prompted an escalation ACT strategy (from single agent fluoropyrimidine [FP] to oxaliplatin-based doublet, from 3 months doublet to 6 months doublet or FOLFOXIRI [clinician choice], or from 6 months doublet to FOLFOXIRI). The primary efficacy endpoint for the ctDNA-positive cohort was 2-year RFS. The target sample size of 250 provided 80% power with 90% confidence to confirm superiority of ctDNA-informed treatment escalation compared to SOC with a HR of 0.746. **Results:** Of 961 eligible pts randomized between Oct 2017 and Apr 2023, 259 (27%) were ctDNA-positive. Of these, 113 (44%) had clinical low risk disease (non-N2 + non-T4). Median follow-up was 42.2 months (range 0.78 – 63.0). 115 (89%) of 129 ctDNA-informed pts received ACT escalation, with 65 (56%) receiving FOLFOXIRI. Of 130 SOC pts, 14 (11%) and 112 (86%) received single agent FP and oxaliplatin doublet, respectively. 2-year RFS for ctDNA-informed treatment escalation was 52% (90% CI: 44 - 59%) vs 61% (90% CI: 54 - 68%) for SOC (HR 1.11, 90% CI: 0.83 - 1.48; P = 0.6). The 3-year RFS for ctDNA-positive pts receiving FOLFOXIRI and FOLFOX/CAPOX was similar (47% vs 51%, HR 1.09, 90% CI 0.78 to 1.53; P = 0.7). In a pre-specified correlative analysis of all ctDNA positive pts, recurrence risk increased with ctDNA burden, with 3-year RFS of 78%, 63%, 36% and 22% for tumor-derived mutant molecules/mL quartiles < 0.06, 0.06 – 0.17, 0.18 – 1.31, and > 1.31, respectively ($P < 0.01$). Treatment-related hospitalisation was similar for escalated and SOC pts (OR 1.21, P = 0.58). Analysis of post-ACT ctDNA is underway. **Conclusions:** In this first randomised study of ctDNA-informed management in stage III CC, we confirm the prognostic significance of detectable ctDNA, with the novel finding of recurrence risk increasing markedly with ctDNA burden. Treatment escalation, including to FOLFOXIRI, did not improve RFS. Future studies in ctDNA positive pts should explore other escalation strategies. Clinical trial information: ACTRN12617001566325. Research Sponsor: Marcus Foundation; NHMRC; U.S. National Institutes of Health.

3504 **Oral Abstract Session**

Tissue-free circulating tumor DNA assay and patient outcome in a phase III trial of FOLFOX-based adjuvant chemotherapy (Alliance N0147). First Author: Frank A. Sinicrope, Mayo Clinic Rochester, Rochester, MN

Background: Among patients with resected node-positive colon cancer, nearly 30% will relapse despite standard adjuvant chemotherapy. Analysis of molecular residual disease (MRD) using circulating tumor DNA (ctDNA) may enable risk stratification for tumor recurrence and inform adjuvant treatment decisions. **Methods:** Postsurgical ctDNA was analyzed in patients with stage III colon carcinoma who participated in a phase 3 trial of adjuvant FOLFOX alone or combined with cetuximab (n = 3084) [NCCTG N0147]. We utilized a tissue-free epigenomic assay for ctDNA detection (Guardant Reveal) with sampling prior to start of adjuvant therapy. Among ctDNA positives, epigenomic tumor fraction (TF) was estimated and ctDNA genotyping was done with Guardant360 (panel of 739 genes). Median follow-up was 6.1 years (yr). Study endpoints included time-to-recurrence (TTR), disease-free survival (DFS) and overall survival (OS) analyzed by Kaplan–Meier method. Multivariable Cox proportional hazards models were used to assess prognostic utility of ctDNA status adjusting for confounders. Interaction between ctDNA and clinicopathological features were assessed. **Results:** Among 2260 patients with evaluable ctDNA data, 461 (20.4%) were ctDNA positive.Tumors were significantly associated with higher T, N stage, $BRAF^{V600E}$, high grade, obstruction/perforation, and worse performance status. Positive vs negative ctDNA was significantly associated with shorter TTR (hazard ratio [HR] 4.33, 95% confidence interval [CI] 3.65-5.13, $P < 0.0001$), poorer DFS (HR 3.74, CI 3.18-4.39, $P < 0.0001$] and OS (HR 3.17, CI 2.63-3.83, $P < 0.0001$), adjusting for covariates and tissue MMR, *KRAS* and $BRAF^{V600E}$. ctDNA positive vs negative patients had 3y DFS of 36.4% (95%CI 32.2-41.2%) vs 82.5% (95% CI 80.0-84.4%), respectively. Adverse prognosis was consistent across subgroups (all $P < 0.05$), with stronger detrimental effects for positive ctDNA in N1 (vs. N2), T1/2 (vs T3 or 4), and mismatch repair deficient tumors [interaction P = 0.0002 to 0.041). Among patients with positive ctDNA, TF in those who recurred/died within 3 yr was double of those who remained recurrence-free ($P = 0.0001$). High vs. low ctDNA TF ($>$ vs $\leq$ median) further stratified TTR (HR 1.48, CI 1.17-1.88, $P = 0.0011$), DFS (HR 1.52, CI 1.21-1.92, $P = 0.0004$) and OS (HR 1.58, CI 1.21-2.07, $P = 0.0009$), adjusting for confounders. ctDNA positive cases, . Analyses of ctDNA detection by site of recurrence, ctDNA clearance, and genomic variant detection are ongoing. **Conclusions:** In the largest study evaluating tissue-free epigenomic-based MRD detection, we demonstrate a robust prognostic utility of postsurgical ctDNA. Tumor fraction provided further patient stratification and analysis is ongoing to identify a subgroup based on TF that may be unlikely to clear ctDNA despite adjuvant chemotherapy. Research Sponsor: National Cancer Institute; U10CA180882.

Perioperative systemic therapy for resectable colorectal peritoneal metastases: A multicenter randomized phase 3 trial (CAIRO6). First Author: Koen Rovers, Catharina Cancer Institute, Eindhoven, Netherlands

Background: In patients with resectable colorectal peritoneal metastases who qualify for cytoreductive surgery with hyperthermic intraperitoneal chemotherapy (CRS-HIPEC), there is no prospective data comparing the efficacy of perioperative systemic therapy with CRS-HIPEC alone. **Methods:** In this multicenter phase 3 superiority trial, patients with resectable colorectal peritoneal metastases without extraperitoneal metastases who did not receive systemic therapy within six months prior to enrollment were randomly assigned (1:1) to receive perioperative CAPOX, FOLFOX, or FOLFIRI with neoadjuvant addition of bevacizumab (perioperative systemic therapy group) or CRS-HIPEC alone (surgery alone group). The primary outcome was overall survival. Key secondary outcomes were progression-free survival and 90-day major postoperative morbidity and mortality. The trial needed 179 patients in each arm to detect a superior 3-year overall survival of 65% in the perioperative systemic therapy group versus 50% in the surgery alone group (corresponding hazard ratio [HR] for death 0.62) with 80% power, 5% drop-out, and a two-sided log rank test of $p<0.05$. The primary overall survival analysis was done after 171 events (88% power). **Results:** Of 358 randomized patients, 351 were eligible for primary analysis: 173 in the perioperative systemic therapy group and 178 in the surgery alone group. At a median follow-up of 41 months, median and 3-year overall survival were 44 months and 54% in the perioperative systemic therapy group and 39 months and 53% in the surgery alone group, respectively (HR for death 0.85, 95% CI 0.62-1.15, p=0.28). Median and 3-year progression-free survival were 13.5 months and 20% in the perioperative systemic therapy group and 7.0 months and 5% in the surgery alone group, respectively (HR for progression or death 0.51, 95% CI 0.41-0.65). In the per-protocol population of 292 patients who underwent macroscopic complete CRS-HIPEC, median and 3-year overall survival were 54 months and 64% in the perioperative systemic therapy group (138 patients) and 45 months and 59% in the surgery alone group (154 patients), respectively (HR for death 0.73, 95% CI 0.51-1.05). Ninety-day major postoperative morbidity rates were 36% in the perioperative systemic therapy group and 26% in the surgery alone group, with a 90-day postoperative mortality of 1% in both groups. **Conclusions:** Among patients with resectable colorectal peritoneal metastases, perioperative systemic therapy did not result in superior overall survival as compared to CRS-HIPEC alone. Clinical trial information: NCT02758951. Research Sponsor: Dutch Cancer Society; F. Hoffmann-La Roche.

3506 **Oral Abstract Session**

Long-term safety and efficacy of sotorasib plus panitumumab and FOLFIRI for previously treated *KRAS* G12C-mutated metastatic colorectal cancer (mCRC): CodeBreaK 101 (phase 1b). First Author: John H. Strickler, Duke University Medical Center, Durham, NC

Background: In the phase 3 CodeBreaK 300 trial (NCT05198934), the combination of sotorasib ($KRAS^{G12C}$ inhibitor) and panitumumab (monoclonal anti-EGFR antibody) improved clinical outcomes in patients with chemorefractory *KRAS* G12C-mutated mCRC. CodeBreaK 101 is a phase 1b trial where FOLFIRI was added to sotorasib and panitumumab in previously treated patients with *KRAS* G12C-mutated mCRC. For the first time, we report mature overall survival (OS) and progression-free survival (PFS), as well as updated safety and response data. **Methods:** Patients with *KRAS* G12C-mutated mCRC who received $\geq$1 prior systemic treatment but were $KRAS^{G12C}$ inhibitor-naïve, were enrolled into the expansion cohort of the CodeBreak 101 subprotocol H (NCT04185883) phase 1b trial. As defined from dose exploration cohort, patients received the recommended phase 2 dose (RP2D) of sotorasib (960 mg orally daily) plus panitumumab (6 mg/kg intravenous every 2 weeks [Q2W]) and standard dose FOLFIRI (intravenous Q2W). The primary endpoint was safety and secondary endpoints included confirmed response, OS, and PFS, assessed by investigator per Response Evaluation Criteria in Solid Tumors (RECIST) v1.1. **Results:** By November 2024, 40 patients were enrolled (female: 47.5%; median age: 56.0 years; median [range] prior lines of systemic therapy: 2 [1-6]). The most common treatment-related adverse events (TRAEs) were dermatitis acneiform and dry skin (n = 27 [67.5%] each), decreased neutrophil count (n = 20 [50.0%]), and stomatitis (n = 17 [42.5%]). Grade $\geq$3 TRAEs occurred in 20 (50.0%) patients with no new safety signals. Discontinuation of sotorasib, panitumumab, or FOLFIRI (5-FU, irinotecan, or leucovorin/levoleucovorin) due to AEs was observed in 1 (2.5%), 1 (2.5%), and 16 (40.0%) patients, respectively. A total of 7 patients are still continuing the study, of whom 5 are off-treatment and under follow-up. Updated objective response rate (95% CI) was 57.5% (40.9, 73.0) and disease control rate (95% CI) was 92.5% (79.6, 98.4). Median time to response was 1.6 months and duration of response was 6.6 months. After a median follow-up of 29.2 months, the median (95% CI) PFS was 8.2 (7.0, 10.8) months and median OS was 17.9 (12.9, 25.1) months. **Conclusions:** Sotorasib plus panitumumab and FOLFIRI showed promising long-term safety and efficacy in pretreated *KRAS* G12C-mutated mCRC. AEs were consistent with the safety profile of the drugs administered. The ongoing phase 3 study, CodeBreaK 301 (NCT06252649), aims to evaluate this combination against standard of care in first-line patients with *KRAS* G12C-mutated mCRC. Clinical trial information: NCT05198934. Research Sponsor: Amgen Inc.

3507 **Oral Abstract Session**

Efficacy and safety of olomorasib, a second-generation KRAS G12C inhibitor, plus cetuximab in *KRAS* G12C-mutant advanced colorectal cancer. First Author: Antoine Hollebecque, Institut Gustave Roussy, Villejuif, France

Background: Olomorasib, a potent and selective second-generation KRAS G12C inhibitor (G12Ci), has demonstrated promising efficacy and a favorable safety profile in *KRAS* G12C-mutant cancers. Based on emerging nonclinical and clinical data, combining a KRAS G12Ci with cetuximab offers a compelling opportunity to improve outcomes in patients (pts) with *KRAS* G12C-mutant colorectal cancer (CRC). Here we report updated results from a phase 1/2 study (NCT04956640) on the safety, tolerability and optimal dose of olomorasib + cetuximab in pts with *KRAS* G12C-mutant CRC. **Methods:** Pts with advanced *KRAS* G12C-mutant CRC (tissue or plasma) previously treated with $\geq$1 prior oxaliplatin- or irinotecan-containing regimen were eligible and enrolled into dose escalation/expansion or optimization at 2 doses of olomorasib (100 and 150 mg, orally BID). Dose escalation of olomorasib + cetuximab followed a mTPI-2 method. Key objectives were safety and to determine the optimal dose of olomorasib + cetuximab. Antitumor activity per RECIST v1.1 was studied in pts with $\geq$1 post-baseline response assessment or who discontinued before a first response assessment. **Results:** As of 13 November 2024, 93 pts received olomorasib + cetuximab in dose escalation/expansion (n=49) or optimization (n=44). Median age was 58 yrs (range, 35-82) and median number of prior therapies was 3 (range, 1-8). All grade TRAEs in $\geq$20% of pts were dermatitis acneiform (58%), diarrhea (38%), dry skin (31%), paronychia (28%), hypomagnesemia (26%), and rash (26%). The majority of TRAEs were grade 1-2, with grade $\geq$3 observed in 24% of pts. The most common TRAEs grade $\geq$3 were diarrhea, hypokalemia, and rash, each occurring in 2 pts. TRAEs led to olomorasib dose reduction in 2% of pts, olomorasib dose hold in 22% of pts, and cetuximab dose hold in 16% of pts. Of the 61 pts who discontinued treatment, 57 were due to PD. Two pts discontinued cetuximab due to TRAEs and continued on olomorasib. The AE profile was similar between doses. Median time on combination treatment was 6.5 mo (range, 0.8-24.1) and 32 pts remained on treatment. See Table 1 for efficacy data. Biomarker analysis will be reported. **Conclusions:** Olomorasib + cetuximab demonstrated similar antitumor activity and favorable safety at both dose levels in pts with *KRAS* G12C-mutant CRC, with the optimal dose of olomorasib + cetuximab determined as 100 mg BID. These results further support combining second-generation KRAS G12Ci with other anticancer therapies to improve outcomes in previously treated pts with *KRAS* G12C-mutant CRC. Clinical trial information: NCT04956640. Research Sponsor: Eli Lilly and Company.

3508 **Oral Abstract Session**

The KRAS G12C inhibitor MK-1084 for *KRAS* G12C–mutated advanced colorectal cancer (CRC): Results from KANDLELIT-001. First Author: Iwona A. Lugowska, Maria Sklodowska-Curie National Research Institute and Oncology Centre, Warsaw, Poland

Background: Preliminary data from the phase 1 KANDLELIT-001 trial (NCT05067283) showed a manageable safety profile and preliminary antitumor activity for MK-1084, a next-generation, selective KRAS G12C-GDP covalent inhibitor, in participants (pts) with previously treated, *KRAS* G12C-mutant solid tumors, including non–small-cell lung cancer and CRC. Here, we report data for MK-1084 monotherapy, MK-1084 + cetuximab, and MK-1084 + cetuximab + mFOLFOX6 in pts with advanced *KRAS* G12C-mutant CRC. **Methods:** KANDLELIT-001 enrolled pts with confirmed *KRAS* G12C mutation, RECIST-measurable disease, and ECOG PS 0-1. Pts with any advanced solid tumor and ≥1 prior systemic therapy received MK-1084 monotherapy PO QD or BID (total daily dose, 25-800 mg) in arms 1 and 3. Pts with advanced CRC and 1-2 prior systemic therapies received MK-1084 QD (total daily dose, 25-200 mg) plus cetuximab 500 mg/m^2 IV Q2W in arm 5. Pts with advanced CRC and 0-1 prior systemic therapies received MK-1084 QD (total daily dose, 25-100 mg) plus cetuximab 500 mg/m^2 Q2W and mFOLFOX6 in arm 6. The primary endpoints were dose-limiting toxicities (DLTs), AEs, and AEs leading to discontinuation. Secondary endpoints included ORR per RECIST v1.1 by investigator review. ORR was assessed in all pts who received their first MK-1084 dose ≥5 wk before the data cutoff date of August 12, 2024, for arms 1 and 3 and November 6, 2024, for arms 5 and 6. **Results:** In arms 1+3, 99 pts, including 53 (54%) with CRC, received MK-1084 alone. In arm 5, 34 pts, including 23 (68%) who had ≥2 prior lines of therapy, received MK-1084 + cetuximab. In arm 6, 20 pts, including 10 (50%) who had no prior therapy, received MK-1084 + cetuximab + mFOLFOX6. Median (range) study follow-up was 14.8 mo (0.2-30.8) in arms 1+3, 5.3 mo (2.6-11.5) in arm 5, and 1.9 mo (0.1-5.4) in arm 6. One pt in arm 6 experienced a DLT (grade 3 febrile neutropenia); there were no DLTs in arms 1, 3, or 5. Treatment-related AEs occurred in 62% of pts in arms 1+3, 97% of pts in arm 5, and 90% of pts in arm 6, were grade ≥3 in 9%, 18%, and 25%, respectively, and led to discontinuation of any drug in 1%, 3%, and 15%, respectively. There were no treatment-related deaths. The two most common treatment-related AEs in each arm were increased AST (17%) and nausea (17%) in arms 1+3, dermatitis acneiform (47%) and rash (24%) in arm 5, and nausea (55%) and rash (50%) in arm 6. ORR (95% CI) was 36% (23-50) in pts with CRC in arms 1+3 (n = 53), 50% (32-68) in arm 5 (n = 34), and 14% (2-43) in arm 6 (n = 14); all responses were partial responses. **Conclusions:** Preliminary data suggest that MK-1084 monotherapy, MK-1084 + cetuximab, and MK-1084 + cetuximab + mFOLFOX6 have manageable safety profiles and show evidence of antitumor activity in pts with advanced, *KRAS* G12C-mutated CRC. Pts continue to be followed, and enrollment continues. Clinical trial information: NCT05067283. Research Sponsor: Merck Sharp & Dohme LLC, a subsidiary of Merck & Co., Inc., Rahway, NJ, USA.

Upfront modified FOLFOXIRI plus panitumumab (pan) versus FOLFOX/pan for unresectable *RAS* and *BRAF* wild-type (wt) metastatic colorectal cancer (mCRC) patients: Overall survival (OS) results from the phase III TRIPLETE study by GONO. First Author: Veronica Conca, Department of Translational Research and New Technologies in Medicine and Surgery, University of Pisa & Unit of Medical Oncology 2, Azienda Ospedaliera Universitaria Pisana, Pisa, Italy

Background: TRIPLETE (NCT03231722) is a phase III trial where unresectable *RAS/BRAF* wt mCRC patients (pts) were randomized 1:1 to first-line FOLFOX/pan (Arm A) or modified FOLFOXIRI/pan (Arm B). The study failed to demonstrate an improved overall response rate, primary endpoint of the study, in Arm B, and did not show any benefit from the intensification of the chemotherapy also in terms of progression-free survival (PFS), early tumor shrinkage, depth of response, R0 resection rate at the price of increased gastrointestinal toxicity. Here we report OS results. **Methods:** Eligible pts were stratified according to ECOG PS (0-1 vs 2), primary tumor location (right vs left), and liver-only metastases (yes vs no). OS was assessed from randomization to death from any cause. Survival curves were calculated using the Kaplan–Meier method and compared with the log-rank test stratified by the same factors as per randomization. Hazard ratios (HR) with 95% confidence interval (CI) were estimated using Cox regression models. **Results:** 435 pts (A/B: 217/218) were enrolled. Main pts' characteristics were median age 59/59 years, ECOG PS 0 80%/84%, synchronous metastases 88%/86%, liver-only disease 38%/39%, left-sided primary tumour 88%/88%; deficient MMR tumours 1%/3%. At a median follow up of 60.2 months (mos), 292 (67%, arm A/B: 71%/63%) OS events were collected. Significantly longer OS was observed in Arm B with a median OS of 41.1 vs 33.3 mos in Arm A (HR: 0.79; 95%CI: 0.63-0.99; p = 0.049). No molecular or clinical groups of interest emerged from the subgroup analyses. While no significant difference in PFS was confirmed (median PFS Arm A/B: 12.4/12.7 mos, p = 0.606), longer post progression survival (PPS) was reported in Arm B (HR: 0.73; 95%CI: 0.57-0.93; p = 0.012). The proportion of pts receiving subsequent lines of therapy was similar between arms (2^{nd}-line Arm A/B: 73%/71%, 3^{rd}-line: 52%/50%, 4^{th}-line: 33%/33%), and no differences were evident in the exposure to anti-EGFRs (Arm A/B 35%/38%) and oxaliplatin (26%/33%) after PD, while higher percentages of pts in ARM A received anti-angiogenics (59%/45%) and irinotecan (66%/56%). Similar percentages of pts received locoregional treatments with radical intent after PD (Arm A/B 16%/15%). **Conclusions:** Upfront modified FOLFOXIRI/pan provides a statistically significant and clinically meaningful survival advantage compared to standard FOLFOX/pan in pts with *RAS/BRAF* wt mCRC, with a 7.8 mos difference in median values, though in the absence of any significant difference in treatment activity and PFS. Clinical trial information: NCT03231722. Research Sponsor: GONO Foundation; Amgen.

FIRE-4 (AIO KRK-0114): Randomized study evaluating the efficacy of cetuximab re-challenge in patients with metastatic RAS wild-type colorectal cancer responding to first-line treatment with FOLFIRI plus cetuximab. First Author: Lena Weiss, Department of Medicine III, University Hospital Munich LMU, Munich, Germany

Background: Several smaller studies performed in later lines of treatment have suggested a potential benefit from anti-EGFR re-challenge on survival of RAS wild-type (RAS WT) metastatic colorectal cancer (mCRC). FIRE-4 is a randomized phase-III study that prospectively evaluates re-challenge with chemotherapy plus cetuximab as compared to physician's choice. **Methods:** The FIRE-4 study was performed with two steps of randomisation. Within the first randomisation, pts were either attributed to induction therapy with FOLFIRI plus cetuximab continued until disease progression (PD) or intolerable toxicity (arm A) or to a switch maintenance using 5-FU plus bevacizumab (arm B). After first PD, an anti-EGFR-free "window therapy" was recommended. After diagnosis of second PD, RAS WT pts (again selected by liquid- or tumor-biopsy), who had responded to cetuximab-based induction therapy within FIRE-4 (entry 1) or outside of the study (entry 2), could then proceed to 2^{nd} randomization attributing pts either to re-challenge with cetuximab or to physician's choice. Overall survival (OS) after 2^{nd} randomization was evaluated as primary endpoint. **Results:** From August 2015 to February 2021, 672 pts were randomized and 657 pts were assigned to treatment in 120 German and 10 Austrian centers. Within the 2^{nd} randomization, 87 pts (entry 1: N = 62; entry 2: N = 25) were attributed either to physician's choice (A2: N = 42) or (FOLF)IRI plus cetuximab (Arm B2: n = 45). Baseline characteristics were comparable between groups without significant differences regarding parameters such as age, sex, ECOG performance status, or primary tumor sidedness. All pts were RAS WT at the time of randomization. No statistically significant difference between arm A2 and B2 was observed regarding OS (15.1 months vs. 17.6 months; HR 0.84; P = 0.48) or PFS (4.6 months vs. 5.8 months; HR 0.91; P = 0.64). ORR was greater in the experimental arm (11.9% vs. 28.9%; OR 0.33; P = 0.07), while disease control rate was nearly identical (59.5% vs. 60.0%; OR 0.98; P $>$ 0.99). **Conclusions:** FIRE-4 did not meet its primary endpoint. While the control arm using physician's choice exceeded expectations, re-challenge with anti-EGFR therapy in RAS WT pts obtained comparable results in terms of OS. Clinical trial information: NCT02934529. Research Sponsor: MERCK Serono.

Longitudinal ctDNA monitoring and prediction of anti-EGFR rechallenge outcomes in RAS/BRAF wild-type metastatic colorectal cancer (mCRC): The REMARRY & PURSUIT trials. First Author: Yoshinori Kagawa, Department of Gastroenterological Surgery, Osaka International Cancer Institute, Osaka, Japan

Background: Anti-EGFR monoclonal antibody (mAb) rechallenge involves re-administering EGFR blockade after a treatment-free interval to exploit clonal evolution. Recent evidence suggests that circulating tumor DNA (ctDNA)–based selection may improve outcomes; however, the predictive value of longitudinal ctDNA monitoring remains uncertain. **Methods:** The REMARRY study evaluated plasma *RAS* (p*RAS*) dynamics in patients with *RAS/BRAF* V600E wild-type metastatic colorectal cancer (mCRC), ECOG PS 0–1, who had previously responded to anti-EGFR therapy and experienced progression within two months of the last dose. p*RAS* status was assessed at progression on prior anti-EGFR, before rechallenge, at cycle 3, and at discontinuation using BEAMing digital PCR. Patients meeting additional criteria—namely, p*RAS*-negative, refractory or intolerance to standard chemotherapies, and an anti-EGFR–free interval of at least 4 months—were enrolled in the phase II PURSUIT trial, which administered panitumumab (6 mg/kg) plus irinotecan (150 mg/m²) biweekly. The primary endpoint was confirmed objective response rate (ORR) per RECIST v1.1. In parallel, participants underwent next-generation sequencing (NGS) of ctDNA in the GOZILA trial at corresponding time points to identify resistance alterations in genes including *RAS, BRAF, EGFR*-ECD, *MAP2K*, ERBB2, and MET. **Results:** Between May 2019 and May 2021, 183 patients were enrolled in REMARRY, and 50 p*RAS*-negative patients before rechallenge were included in PURSUIT. The confirmed ORR was 14.0% (90% CI, 7.0–23.0%), with a median progression-free survival (PFS) of 3.6 months and a median overall survival (OS) of 12.0 months. Although all patients were p*RAS*-negative at baseline, 10.0% converted to p*RAS*-positive by cycle 3 and 36.0% by discontinuation. Patients who were p*RAS*-positive immediately after prior anti-EGFR had higher conversion rates at cycle 3 (42.9% vs. 6.3%, p = 0.010) and at discontinuation (85.7% vs. 32.3%, p $<$ 0.001) compared with those initially negative. The ORR was 23.8% in patients remaining p*RAS*-negative versus 0% in those converting to p*RAS*-positive (p = 0.254). Moreover, NGS-detected resistance alterations after prior anti-EGFR were associated with no responses (0/13) compared to a 27.8% response rate (5/23) in patients without such alterations (p = 0.038), and correlated with shorter PFS (HR 3.297, p = 0.002) and OS (HR 4.569, p $<$ 0.001). In 86% (7/8) of patients who were p*RAS*-positive post–anti-EGFR, the identical p*RAS* codons re-emerged during rechallenge, consistent with NGS findings. **Conclusions:** ctDNA status immediately after progression on prior anti-EGFR therapy predicts subsequent response, thereby supporting clinical decision-making and personalized therapy. Trial Registration: PURSUIT (jRCTs031190096), REMARRY (UMIN000036424), GOZILA (UMIN000029315). Clinical trial information: jRCTs031190096. Research Sponsor: None.

Phase 2 dose expansion study of DSP107, a first-in-class bi-specific 4-1BB T-cell engager, with and without atezolizumab in metastatic MSS colorectal cancer patients. First Author: Anwaar Saeed, University of Pittsburgh Medical Center (UPMC) and UPMC Hillman Cancer Center, Pittsburgh, PA

Background: DSP107 is a bi-specific fusion protein composed of sequences from the extracellular domain of SIRPα and 4-1BBL. The SIRPα arm selectively targets CD47 overexpressed on tumor cells, while simultaneously anchoring trimeric 4-1BBL to the tumor, to engage and co-stimulate 4-1BB on activated immune cells in the tumor microenvironment. This results in tumor-localized, conditional activation of innate and adaptive immune responses. Phase 1 data demonstrated an excellent safety profile with no RBC binding and no hematological, hepatic or other dose limiting toxicities (DLTs). Here we describe safety and efficacy data from a Phase 2 microsatellite stable (MSS) colorectal (CRC) expansion cohort in which patients were treated with DSP107 alone or with atezolizumab (NCT04440735). **Methods:** Metastatic/unresectable MSS CRC patients who progressed following 2 lines of therapy including standard chemotherapy $\pm$ targeted antibodies (n = 50), were randomized to receive weekly IV DSP107 infusions (10 mg/kg/dose) alone or with atezolizumab (1200 mg) Q3W during 3-week treatment cycles. The majority (76%) had liver metastases. Study objectives were safety, tolerability and preliminary efficacy. Restaging imaging was performed every 2 months and evaluated by RECIST v1.1 criteria. **Results:** DSP107 monotherapy and with atezolizumab was well tolerated with no DLTs. The most frequent TRAEs were infusion-related reactions (IRR; 38% Grade 1 or 2, 4% Grade 3), fatigue (12% Grade 1 or 2, 4% Grade 3), Grade 1 or 2 nausea (14%) and Grade 1 or 2 anemia (10%). IRRs were managed during subsequent infusions by reducing the infusion rate and administering IV fluids. The median OS from the efficacy-evaluable patients who received DSP107 monotherapy (n = 19) and combination therapy with atezolizumab (n = 21) has not been reached but currently (Dec 2024 cutoff) stands at 7.6 and 14.6 months, respectively. Disease control was demonstrated in 26% (monotherapy) and 62% (combination) of evaluable patients including a patient who achieved complete response ($>$ 2.5 years) and a patient with a deep (86% target lesion reduction) and durable ($>$ 16 months) confirmed partial response and disappearance of pulmonary and hepatic metastases. Immunofluorescence analysis of baseline tumor biopsies (n = 16) demonstrated moderate to high levels of CD47 expression in 15/16 biopsies ($>$ 120 H-Score), and very high levels of CD47 expression ($>$ 170 H-Score) in all 7 samples collected from liver metastases. **Conclusions:** These data suggest that the combination of DSP107 with PD(L)1 blockade has anti-tumor activity and provides clinical benefit in third line metastatic MSS CRC including in patients with liver metastases. Updated survival data will be presented at the conference. A Phase 2 randomized controlled study is currently in planning to confirm this preliminary efficacy signal. Clinical trial information: NCT04440735. Research Sponsor: KAHR Medical LTD.

3518 **Rapid Oral Abstract Session**

Circulating tumor DNA as an early response indicator in anal squamous cell carcinoma treated with chemoradiation. First Author: Aron Bercz, Memorial Sloan Kettering Cancer Center, New York, NY

Background: Definitive chemoradiation (CRT) is a highly effective, organ-preserving treatment for localized anal squamous cell carcinoma (ASCC). However, a subset of patients experience locoregional failure, leading to unfavorable oncologic outcomes despite salvage surgery. Circulating tumor DNA (ctDNA) has emerged as a promising tool for monitoring treatment efficacy and predicting prognosis; however, there is a paucity of studies evaluating the baseline detectability and kinetics of tumor-informed ctDNA assays in ASCC. **Methods:** Patients with ASCC (*N*=88) undergoing definitive CRT provided prospective consent for longitudinal ctDNA monitoring using a personalized, tumor-informed ctDNA assay (Signatera, Natera, Inc.). ctDNA testing was assessed at three key time points: pre-treatment (any time before CRT to within 5 days after initiation), mid-treatment (from $>$5 days after initiation to $<$7 days before completion), and post-treatment ($>$7 days before completion to 42 days after CRT). Surveillance testing continued every three months. Changes in ctDNA levels were analyzed in relation to clinical outcomes. Locoregional failure (LRF) was assessed using competing risk regression, stratified by ctDNA status (positive vs. negative). ctDNA results were also correlated with progression-free survival (PFS). **Results:** Pre-treatment ctDNA was detected in 79% of patients, with 92% achieving ctDNA-negativity at post-treatment (Table 1). Over a median follow-up of 18 months (IQR 11–26), 7 patients experienced LRF, and 5 experienced distant failure. The cumulative LRF incidence was 0% among patients with ctDNA negativity by mid-treatment. Conversely, 26% of patients with ctDNA positivity at mid-treatment and 61% of patients with ctDNA positivity at post-treatment experienced LRF, respectively. Estimated one-year PFS was 100% for patients who achieved ctDNA negativity by mid-treatment. In contrast, patients who remained ctDNA-positive at mid-treatment and post-treatment had estimated one-year PFS rates of 81% and 44%, respectively, from the date of the corresponding ctDNA test. Among patients who achieved ctDNA negativity but subsequently developed molecular recurrence during the surveillance period (*N*=7), all developed disease recurrence. Molecular recurrence predated clinical or radiographic evidence of recurrence in all instances. **Conclusions:** This tumor-informed ctDNA assay demonstrates high baseline detectability and rapid clearance during CRT, with molecular clearance correlating with favorable outcomes in ASCC. Notably, ctDNA-based detection of molecular recurrence consistently precedes conventional clinical and radiographic indicators of disease recurrence. Further validation in large, prospective cohorts is warranted. Short-course radiotherapy followed by sintilimab and CAPOX as total neoadjuvant treatment in locally advanced rectal cancer: A prospective, randomized controlled trial (SPRING-01). First Author: Feng Tian, Shandong Provincial Hospital Affiliated to Shandong First Medical University, Jinan, NA, China

Background: Neoadjuvant short-course radiotherapy (SCRT) combined with chemotherapy as total neoadjuvant therapy (TNT) increases the pathological complete response (pCR) rate for locally advanced rectal cancer (LARC). The potential synergistic effects of combining radiotherapy and immunotherapy might benefit patients with LARC. This study aimed to compare the efficacy and safety of SCRT followed by 6 cycles of CAPOX chemotherapy with or without immunotherapy as TNT in LARC patients. **Methods:** In this randomized controlled trial, patients with T3-4, N+, EMVI(+), MRF(+) or lateral lymph node(+) rectal adenocarcinoma were randomly assigned to receive SCRT followed by 6 cycles of CAPOX chemotherapy with or without sintilimab. Total mesorectal excision (TME) was performed 2-3 weeks after the completion of TNT. The primary study endpoint was the pCR rate. **Results:** In this randomized controlled trial, patients with T3-4, N+, EMVI(+), MRF(+) or lateral lymph node(+) rectal adenocarcinoma were randomly assigned to receive SCRT followed by 6 cycles of CAPOX chemotherapy with or without sintilimab. Total mesorectal excision (TME) was performed 2-3 weeks after the completion of TNT. The primary study endpoint was the pCR rate. **Conclusions:** In LARC patients, SCRT combined with sintilimab and CAPOX as a TNT significantly increases the pCR rate while maintaining manageable safety in patients with LARC. SCRT followed by sintilimab and CAPOX can be recommended as a superior neoadjuvant treatment option for these patients. Clinical trial information: ChiCTR2100052288. Proposed changes to the pathologic staging for colon cancer (CC): AJCC Colon Cancer Expert Panel (AJCCCCEP). First Author: Qian Shi, Department of Quantitative Science Research, Mayo Clinic Rochester, Rochester, MN

Background: Recent analyses highlight nonhierarchical outcomes using the 8th Edition AJCC staging system for CC. For instance, the 5-year survival rate for stages I and IIIa patients (pts) closely align. Additionally, tumor deposits (TDs) have been established as significant prognostic indicators. The AJCCCCEP commissioned this study to develop an updated pathological staging system for CC focused specifically on pts without distant metastasis (M0), while retaining the existing stage IV classification. **Methods:** Individual patient data (IPD) from pts diagnosed with cc (2010- 2017) in the NCDB were divided into training (70%) and internal validation (30%) datasets. External validation used IPD from clinical trials. The primary endpoint was overall survival (OS). Risk classification development for M0 pts incorporated ungrouped data on pathologic T categories, the number of involved regional lymph nodes (LN+), and TD counts. Recursive partitioning and regression tree analyses were applied to construct hierarchical staging levels. Pre-specified criteria required survival probabilities to be consecutive and show clear separations using Kaplan-Meier (KM) estimates with pairwise log-rank test P of $<$ 0.005 for the training and $<$ 0.05 for validation analyses. **Results:** Data from 281,997 pts (median age 67 years, 50% male, 81% white, 55% T3, 19% T4, 44% N+, 26% M+, and 11% with $\geq$1 TD) were analyzed, with a median follow-up of 7.3 years. The updated staging system (Table) met pre-specified criteria, with all observed pairwise P $<$ 0.0001 in the development and internal validation sets. KM OS curves displayed a hierarchical separation across all sub-levels after the 1st year of diagnosis. Consistent results were seen in pts treated with adjuvant chemotherapy in 4 trials (all pair-wise P $<$ 0.0001). **Conclusions:** The proposed pathological staging system for M0 pts fulfills pre-specified criteria for hierarchical risk stratification, validated both internally and externally, and provides an evidence-based update. Pending review process, the AJCCCCEP will recommend that these changes be made to the Version 9 staging protocol for colon cancer to improve prognostication for CC pts. Research Sponsor: None.

3521 Poster Session

Experience of patients with HIV and squamous cell carcinoma of the anal canal (SCAC) treated with retifanlimab. First Author: Jean-Philippe Spano, Department of Medical Oncology, Groupe Hospitalier Pitie-Salpetriere, Paris, France

Background: People living with HIV (PLHIV) usually have more advanced cancer at diagnosis and a higher cancer-related mortality, posing a significant burden on health care. However, clinical studies often exclude cancer patients with HIV, thereby limiting access to therapies for this patient population. PLHIV have a 25- to 35-fold higher chance of being diagnosed with SCAC than individuals who are HIV negative. We therefore evaluated safety and efficacy of retifanlimab in PLHIV with SCAC. **Methods:** The study designs for POD1UM-202 (NCT03597295) and POD1UM-303/InterAACT-2 (NCT04472429) have previously been described. Both trials permitted PLHIV to enroll if CD4+ count was $\geq$200/μL with an undetectable viral load per standard of care assay, and who did not experience any HIV-related opportunistic infection for $\geq$4 weeks prior to study enrollment. Patients continued to receive antiretroviral therapy (ART/HAART) without interruption or dose reduction. HIV viral load and CD4+ cell count was assessed every 8 weeks during the studies and could be reduced to every 6 months during safety and disease follow-up. **Results:** Patient and disease characteristics were similar among PLHIV and the overall study populations. Among the 20 patients with HIV enrolled in these SCAC trials, median age was 58 years, 70% (n = 14) were male, and 80% (n = 16) were White. Forty-five percent (n = 9) of patients received retifanlimab and 30% (n = 6) received retifanlimab with platinum-based chemotherapy, whereas the remaining 5 patients were assigned to placebo plus chemotherapy. During these studies, no patient experienced a sustained drop in CD4+ T-cell counts or increase in HIV viral load of clinical significance. No treatment-emergent opportunistic infections were recorded. Immune-related adverse events (irAEs) and grade $\geq$3 irAEs were consistent with the non-HIV population. Objective response rates were 22% (2/9) with retifanlimab in second-line and 67% (4/6) with retifanlimab and chemotherapy in first-line (previously untreated). Patient-reported outcomes showed no negative impact and based on Quality-of-Life Questionnaire for Anal Cancer, good scores for bowel function, sexual, and symptom domains were maintained. Retifanlimab pharmacokinetics was independent of HIV status and not impacted by the HAART required for ongoing HIV management. **Conclusions:** Among PLHIV and advanced SCAC who received treatment, retifanlimab showed significant clinical activity with efficacy qualitatively similar to patients without HIV and no excess toxicity or reduced HIV control. The analysis indicates that retifanlimab is generally safe for PLHIV and SCAC and also supports inclusion of HIV-positive patients in other immunotherapy trials. The favorable outcomes in PLHIV are encouraging because infection with HIV is among the most important risk factors for SCAC. Clinical trial information: NCT03597295 and NCT04472429. Research Sponsor: Incyte Corporation.

3522 Poster Session

Investigating the immunogenomic profile of anal HPV driven disease for novel therapeutic discovery. First Author: Micol Lupi, Imperial College London, London, United Kingdom

Background: Anal squamous cell carcinoma (ASCC) is driven by Human Papilloma Virus and arises from high-grade squamous intraepithelial lesions (HSIL) which, when treated, reduces the risk of cancer progression. However, current treatment options for anal HSIL are limited with considerable morbidity. Although a proportion of patients with localised ASCC can be successfully treated with pelvic chemoradiotherapy, there are significant associated side effects. Given the stepwise evolution of disease, there is an opportunity for the identification of novel therapeutic approaches for cancer prevention. **Methods:** This study investigates the mutational and immune landscape of matched fresh frozen anal cancer and HSIL samples as well as blood samples from 8 patients using multi-omic analysis (WES, RNAseq and FUME-TCRseq). We compared candidate driver mutations and pathways (including known immune escape mechanisms), copy number alterations (CNAs), differential gene expression, predicted neoantigen profiles (using NeoPredPipe) and TCR repertoire composition and diversity. In addition, digital cell classification of H&E stained sections was used to characterise the distribution of 4 immune cell types. **Results:** There was considerable copy number profile overlap between anal HSIL and cancer with 79.2% CNA concordance. Samples clustered by patient rather than pathology on gene expression and few differentially expressed genes were identified. There was no difference in predicted neoantigen burden (p= 0.11) nor the proportion of unique or common neoantigens (p = 0.64), illustrating shared immunogenicity between anal cancers with corresponding pre-cancerous lesions. However, we observed a shift in TCR repertoire composition between HSIL and cancer in all patients, with HSIL regions containing larger clusters of related TCR clonotypes (p = 0.02). Driver mutations in *PIK3CA*, *KMT2C*, *PBRM1*, *KLF5, STK11* and *CUL1* were shared between matched samples. Enriched GO terms, Kegg pathways and Reactome pathways shared by 2 or more samples included ubiquitination, lipid metabolism and glycosylation. There was higher *PD-L1* and *CTLA4* expression in anal cancer compared with HSIL, suggestive of immune escape at the transition to invasive cancer. Pathogenic mutations in the Endoplasmic reticulum aminopeptidase 1 (*ERAP1*) gene, responsible for modulating the peptide repertoire presented by MHC class I molecules, were found in one HSIL sample and two cancer samples. **Conclusions:** For the first time, this study demonstrates compelling overlap in the immunogenomic profiles of advanced anal HSIL and neighbouring invasive cancer. The shared neoantigen burden and overall immunogenicity supports future vaccine development in the treatment of anal HSIL and subsequent anal cancer prevention. Furthermore, the evidence for immune escape at the transition to invasion could motivate the use of immunotherapy in this setting. Immunotherapy combined with hypofractionated radiotherapy and chemotherapy for locally recurrent rectal cancer (TORCH-R): A prospective, single-arm, two-cohort, phase II trial. First Author: Ruiyan Wu, Department of Radiation Oncology, Fudan University Shanghai Cancer Center, Shanghai, China

Background: To assess whether the integration of PD-1 inhibitor with hypofractionated radiotherapy and chemotherapy therapy can lead to an improvement in objective responses in patients with proficient mismatch repair or microsatellite stable (pMMR/MSS) locally recurrence rectal cancer (LRRC). **Methods:** We did a prospective, single-arm, two-cohort, phase 2 trial in LRRC patients without or with oligometastases. Eligible patients with previously untreated (cohort A) or progressive disease after first line therapy (cohort B), were assigned received 25-40 Gy/5 Fx irradiation or 15–30 Gy/5 Fx reirradiation for pelvic recurrence, followdd by 18 weeks of chemotherapy, toripalimab, and stereotactic ablative radiotherapy (SABR) for all metastatic lesions between chemoimmunotherapy cycles. The primary endpoint was confirmed local recurrence objective response rate (ORR). The study is registered with ClinicalTrials.gov, NCT05628038. **Results:** Between Oct 15, 2022, and Aug 31, 2024, We enrolled 67 patients: 41 in cohort A and 26 in cohort B. Median follow-up duration was 10.5 months (IQR 7.3-15.5 months). The local recurrence ORR was achieved at 82.9% (34 of 41 patients) in cohort A and 65.4% (17 of 26 patients) in cohort B. Six patients (14.7%) underwent radical resections (R0) in cohort A and two patients (7.7%) in cohort B. The CR rate was 34.1% (12 cCR patients + 2 pCR patients) in cohort A and 11.5% (2 cCR patients + 1 pCR patients) in cohort B. The most frequent grade 3-4 toxicities were neutropenia (10.8% in cohort A and 25.0% in cohort B) and diarrhea (16.2% in cohort A and 20.8% in cohort B). **Conclusions:** The PD-1 inhibitor remarkably improved ORR in pMMR/MSS LRRC compared with historical benchmark with acceptable toxicity. Up-front immunochemotherapy combined with hypofractionated radiotherapy was selected for future definitive study. Clinical trial information: NCT05628038. Research Sponsor: None.

Harnessing transcriptome signatures and CD103+CD8+ immune infiltration for prognosis and treatment outcomes in anal squamous cell carcinoma. First Author: Ilma Soledad Iseas, Medical Oncology Department, Paris-St Joseph Hospital, Paris,, France

Background: Anal squamous cell carcinoma (ASCC) is a rare malignancy linked to high-risk HPV, with rising incidence among younger adults. While immunotherapy advances have improved outcomes in metastatic ASCC, treatment for localized disease has remained unchanged for decades, with high recurrence rates. This study investigates molecular biomarkers and immune mechanisms predictive of chemoradiotherapy outcomes in non-metastatic ASCC. **Methods:** This retrospective study analyzed 94 stage I-III non-metastatic anal squamous cell carcinoma (ASCC) patients treated with curative chemoradiotherapy (CRT) at Hôpital Paris Saint Joseph (2010–2017) in France. Treatment response (CR) was assessed at 24 weeks by RECIST v1.1. Molecular analyses included whole-exome and RNA sequencing on FFPE samples to evaluate somatic mutations, tumor mutational burden (TMB), and gene expression profiles. Immunohistochemistry assessed immune markers (CD8, CD103). Statistical analyses identified predictors of CR, progression-free (DFS), and overall survival (OS). **Results:** Complete response (CR) was achieved in 71% of cases, with no significant differences between treatment regimens ($p > 0.05$). Mutational analysis identified 172 alterations in novel (SLAMF7 and GOLGA6L9) and previously described cancer driver genes (KMT2C, KMT2D, and PIK3CA), with higher mutational burdens showing a non-significant trend toward CR. Transcriptomic profiling revealed 350 differentially expressed genes among CR vs. NCR patients (p-value < 0.01; FC > 2). CR was associated with modulation of immune-related pathways, including TNFα/NFkB signaling ($p < 0.01$). Immune infiltrate analysis showed enrichment of CD8+ central memory T cells (p = 0.008) and CD4+ resting memory B cells (p = 0.01) in CR cases, correlating with improved OS (p = 0.0026) and DFS (p = 0.0098). CD103+CD8+ tumor-infiltrating lymphocytes emerged as the strongest predictor of survival (OS: p = 0.011; DFS: p = 0.003), underscoring their potential as prognostic biomarkers and therapeutic targets in ASCC. **Conclusions:** These findings underscore the potential of integrating molecular and immune markers into clinical practice to better predict treatment response and guide personalized therapies for CRT efficacy for ASCC patients. Further validation in independent cohorts is necessary to confirm the clinical relevance of these biomarkers and their application in therapeutic decision-making. Research Sponsor: None.

POD1UM-303/INTERAACT2 subgroup analyses and impact of delayed retifanlimab treatment on outcomes in patients with squamous cell carcinoma of the anal canal (SCAC). First Author: Marwan Fakih, City of Hope National Medical Center, Duarte, CA

Background: SCAC is a rare cancer with high unmet medical need and no FDA-approved treatment options. POD1UM-303 is the only phase 3 study of systemic therapy completed to date in advanced SCAC. The study met its primary endpoint of progression-free survival (PFS; 9.3 mo in the retifanlimab group vs 7.4 mo in the placebo group [HR, 0.63; 95% CI, 0.47, 0.84; *P*= 0.0006]) (Rao S, et al. *Ann Oncol*. 2024;35:S1217). Based on these results, retifanlimab combined with carboplatin-paclitaxel represents a new standard of care (SOC) for inoperable locally recurrent/metastatic SCAC. Here, we present outcomes for predefined subgroups of interest in POD1UM-303 and exploratory analyses in patients who received open-label retifanlimab in the crossover phase of the study. **Methods:** The POD1UM-303 study design and methods were previously presented at ESMO 2024. PFS comparisons for predefined subgroups, including PD-L1 expression, region of enrollment, presence of liver metastases, extent of disease, as well as HPV and HIV status, were performed. Exploratory analyses of investigator-assessed response to retifanlimab, overall survival (OS), and safety during crossover treatment were also performed. **Results:** A total of 308 patients were enrolled (1:1) to receive retifanlimab or placebo with chemotherapy; 69 (45%) from the placebo + chemotherapy group received crossover treatment with retifanlimab monotherapy upon confirmed progression. A consistent PFS benefit in favor of retifanlimab + chemotherapy was observed for all predefined subgroups, including tumors with PD-L1 expression $< 1\%$, patients with liver metastases, and regardless of HPV or HIV status. Median PFS in the retifanlimab + chemotherapy group was higher in the PD-L1 $\geq 1\%$ vs PD-L1 $< 1\%$ groups (9.3 mo; HR, 0.64 vs 7.5 mo; HR, 0.53) but was not impacted by presence of liver metastases. During crossover, investigator-assessed overall response rate was qualitatively similar to that seen in the POD1UM-202 study, which enrolled a similar platinum-refractory population. Median OS for patients receiving crossover treatment with retifanlimab was 24.3 mo, compared with 29.2 mo for patients who were assigned to retifanlimab + chemotherapy at randomization. Safety during crossover was consistent with earlier observations and comparable with experience in POD1UM-202. **Conclusions:** The benefits of retifanlimab combined with carboplatin-paclitaxel extend to the broad population of SCAC, including those with tumors not expressing PD-L1 and liver metastases. Response rate and safety profile of retifanlimab monotherapy in the crossover period were consistent with the previous POD1UM-202 experience; however, exploratory analysis of survival in crossover patients suggests first-line retifanlimab with SOC chemotherapy is preferable to sequential treatment after progression on chemotherapy. Clinical trial information: NCT04472429. Research Sponsor: None.

Genomic characterization of anal canal squamous cell carcinoma (ASCC) and outcomes on matched targeted therapy. First Author: Maliha Nusrat, Memorial Sloan Kettering Cancer Center, New York, NY

Background: Anal canal squamous cell carcinoma (ASCC) is uncommon but increasing in incidence. 5-year survival of patients (pts) with metastatic ASCC is only 36%; new therapies are an unmet medical need. Genomic alterations (GA) in phosphoinositol-3-kinase (PI3K) signaling pathway have been reported in small datasets of ASCC. Data on clinical outcomes with therapies targeting these GA in pts with ASCC are lacking. **Methods:** Tumor genomic data of pts with ASCC at Memorial Sloan Kettering Cancer Center (MSK) were obtained using a targeted next generation sequencing assay (MSK IMPACT) from cBioPortal database. GA were annotated for biological significance using the OncoKB database, and only GA with known oncogenic potential were included. GA were categorized as mutations (mut), amplifications (amp), deletions (del) and fusions (fus). Clinical annotations were abstracted from electronic health records and outcomes of pts who participated in clinical trials were assessed. Data were summarized using descriptive statistics and survivals were estimated using Kaplan-Meier method. **Results:** Of 92,711 pts in cBioPortal, 218 (0.2%) pts had ASCC (male n = 65, 30%). Of these 218 pts, 179 (82%) had at least 1 oncogenic GA. Oncogenic GA were most frequently identified in *PIK3CA* 40% (87 pts; mut 67, amp 36, with overlap), *KMT2D* 19% (mut 42), *BCL6* 17% (amp 37), *PTEN* 12% (mut 18, del 9), *EP300* 11% (mut 24), *KMT2C* 11% (mut 20, del 3), and *FBXW7* 10% (mut 20, del 1). Oncogenic GA were most frequent in the PI3K-AKT-mTOR signaling pathway (121 pts, 55%). Amps were also seen in *FGF3*, *FGF4, FGF19* and *CCND1* in 4% pts each. Thirteen pts with metastatic treatment refractory ASCC participated in early phase clinical trials; 3 pts enrolled in > 1 studies (total 18 trial participations). GA-matched targeted therapy was administered to 8 pts: oncogene inhibitors in 6 pts (targeting PIK3CA E545K in 3, PIK3CA Q546K in 1, HER2 I767M in 1, FGFR2 amp in 1), and drugs selected for tumor suppressor gene GA in 3 pts (PTCH1 loss in 1, TP53-wild in 1, FBXW7 in 1). Six pts received immunotherapy and 3 pts were treated with antivirals drugs targeting Human Papillomavirus. Out of 4 pts treated with PI3K signaling inhibitors, 1 had partial response and 2 had stable disease, with median progression free survival of 3.6 (95% CI 0-8.6) months and median overall survival of 9.1 (95% CI 5.7-12.5) months. Two out of four pts treated with PI3K pathway inhibitors were on treatment for > 6 months. No response was seen in pts treated with drugs targeting GA other than PIK3CA or with immunotherapy; and one of three pts treated with anti-viral agents had best response of stable disease. **Conclusions:** This is the largest characterization of GA with known oncogenic potential in ASCC. The PI3K signaling pathway is altered in over half of ASCC, and PI3K-AKT-MTOR inhibitors have the potential for further investigation in pts with activating GA in *PIK3CA* gene. Monitoring botensilimab- and balstilimab-induced T-cell dynamics in refractory mismatch repair proficient metastatic colorectal cancer. First Author: Gertjan Rasschaert, Gastrointestinal Oncology Department, University Hospitals Leuven, Leuven, Belgium

Background: Mismatch repair proficient (pMMR) metastatic colorectal cancer (mCRC) responds poorly to immune checkpoint inhibition (ICI). A better understanding of local and systemic immune cell activities is critical for improving ICI treatment efficacy. T cells elicit anti-tumor specificity through their T cell receptors (TCR) and dynamic changes in the TCR repertoire are associated with clinical outcomes. Circulating T cells in the blood provide an accessible liquid biomarker to quantify and track T cell activity at systems level and longitudinally. Here, we present temporal T cell tracking as a correlate of ICI efficacy in refractory pMMR mCRC patients treated with botensilimab (BOT; Fc-enhanced anti-CTLA-4 antibody) with or without balstilimab (BAL; anti-PD-1 antibody). **Methods:** 10 patients from the open-label, phase 2 study (NCT05608044) with BOT in refractory pMMR CRC (without metastatic liver disease) were included. In this trial patients were randomized into BOT (75mg or 150mg Q6W, 4x) monotherapy or in combination with BAL (240mg Q2W, for 2 years), versus standard of care (regorafenib or trifluridine/tipiracil). TCR dynamics were longitudinally assessed (0,2,4,6,12 weeks) from circulating T cells, based on deep TCR sequencing (OS-TCR, Omniscope) and quantified using functional clustering. **Results:** 2 mCRC patients out of 10 (20%) showed partial response (PR) while 8 (80%) had progressive disease (PD), however at variable timepoints. However circulating T cells showed significant expansion of both pre-existing and novel clonotypes in all patients, detectable at conserved frequencies at sequential time points. The magnitude of induced T cell clonotypes varied across treatment cycles, with repeated boosting effects observed in responders. Scoring T cell activity based on quantitative and qualitative TCR repertoire metrics, allowed to rank patients by their response. Intriguingly, TCR repertoire dynamics strongly correlated with clinical outcomes, establishing its potential as a quantitative biomarker for monitoring treatment efficacy. **Conclusions:** Deep T cell repertoire profiling detected dynamics of circulating T cells with quantitative and qualitative difference related to ICI response. Immune cell tracking from liquid biopsies is a powerful tool to quantify ICI efficacy in real time. Research Sponsor: None.

3528 Poster Session

Predictive role of circulating tumor DNA in pMMR locally advanced rectal cancer patients receiving neoadjuvant chemoradiotherapy combined with sintilimab. First Author: Xiao-bin Zheng, The Sixth Affiliated Hospital, Sun Yat-sen University, Guangzhou, Guangdong, China

Background: Circulating tumor DNA (ctDNA) has emerged as a potential biomarker for various solid tumors, including colorectal cancer (CRC). It offers the advantage of longitudinal and dynamic surveillance of the tumor-specific genetic characteristics, eliminating the need for repeated invasive biopsies. However, the predictive role of ctDNA in patients with proficient mismatch repair (pMMR) locally advanced rectal cancer (LARC) receiving neoadjuvant chemoradiotherapy (CRT) combined with immunotherapy remains to be explored. **Methods:** In this prospective single-arm, phase II trial, pMMR LARC patients ($cT_{3\text{-}4}N_0M_0$ and $cT_{1\text{-}4}N_{1\text{-}2}M_0$) with an intermediate or high immunoscore (IS_B) were enrolled (NCT05450029). Treatment-naïve patients received radiotherapy (50 Gy/25 f) and 6 cycles of mFOLFOX6 plus 5 cycles of sintilimab, followed by total mesorectal excision (TME) 6-8 weeks post-radiotherapy. Baseline tumor tissue DNA and serial ctDNA dynamic changes were evaluated using next-generation sequencing. Baseline (T0) maximal somatic variant allelic frequency (maxVAF) as well as its changes at the first (T1, two cycles after therapy) and the second clinical evaluation (T2, four cycles after therapy) were assessed. **Results:** Tumor somatic mutations and aligned ctDNA analyses were conducted in 43 patients. The most frequently mutated genes in tumor tissue samples were APC (67%, n = 29), TP53 (65%, n = 28), KRAS (47%, n = 20), and FBXW7 (28%, n = 12), which were also observed in plasma. Pathway analysis indicated that mutations in SWI_SNF were more likely to be detected in patients achieving pathological complete response (pCR) (P = 0.02 for tumor tissue, P = 0.08 for plasma), suggesting a potential sensitization to sintilimab combined with CRT. For the dynamic ctDNA analysis, 37 patients were assessed using a 950-gene panel relevant to cancer. A significant decline in maxVAF from T0 to T1 was observed in the pCR group. An optimal cut-off of 0.11 for the maxVAF ratio (T1/T0) was identified to discriminate complete responders from other patients (AUC = 0.768; sensitivity 83.3%; specificity 72.0%; $P < 0.001$; 95% confidence interval [CI] 0.597-939). Patients with a low maxVAF ratio (< 0.11) were more likely to achieve pCR following CRT plus sintilimab therapy (OR = 12.86; 95% CI: 2.23-74.08; P = 0.004). **Conclusions:** ctDNA may serve as a potential biomarker of the response to CRT combined with immunotherapy in pMMR LARC. Further validation is warranted to confirm the predictive value of maxVAF and to identify additional biomarkers with potential predictive significance in pMMR LARC. Risk factors associated with de novo metastatic colorectal cancer in early onset colorectal cancer. First Author: Emma Schatoff, Memorial Sloan Kettering Cancer Center, New York, NY

Background: Early onset colorectal cancer (EO CRC) is rising worldwide. Epidemiologic studies have shown that diets high in sugar and/or processed foods and limited exercise are associated with EO CRC when compared to healthy controls. However, risk factors associated with *de novo* metastatic disease are less well established. Identifying such risk factors may provide insight into modifiable lifestyle variables. **Methods:** All eligible EO CRC patients were enrolled in MSK's Center for Young Onset Colorectal and Gastrointestinal Cancer and completed a risk factor questionnaire (MSK-approved IRB #20-315). We analyzed questionnaire responses and compared risk factors between patients with *de novo* metastatic disease vs localized disease using Wilcoxon rank sum test or Fisher's exact test. Clinical outcomes, including overall survival (OS) from diagnosis and progression free survival (PFS) from 1st-line chemotherapy, were estimated using Kaplan-Meier methods. The Cox regression model was used to assess association between risk factors and survival outcomes. Tumors from a subset of patients (n = 206) were sequenced using MSK-IMPACT (MSK-approved IRB #12-245) and underwent genomic analyses. **Results:** 303 patients completed the questionnaire (median age at diagnosis 42; 51% Female; 88% left-sided tumors). 112 had *de novo* stage IV disease and 191 had stage I-III disease. Patients with *de novo* metastatic disease were younger, 40.9 [95%CI: 36.8 - 44.8] vs. 43.0 [95%CI: 38.4 - 46.4] (*P*-value *0.037*). Analysis of dietary factors showed no association with fruit, vegetable, fish, poultry, red meat, processed meat, or dairy intake. However, high sugar diets were significantly associated with *de novo* metastatic disease, with 30 (45%) vs. 37 (29%) (*P*-value, 0.004) patients reporting daily consumption of high sugar foods. Daily consumption of high calorie foods was also frequently reported in patients with metastatic disease (*P*-value, 0.057). 3-year OS in the metastatic population was 72% [95%CI: 62% - 84%] vs. 99% [95%CI: 98% - 100%]. Within the metastatic group, no association was observed between daily high sugar consumption and non-daily consumption in terms of PFS or OS. 3-year OS in the daily high sugar group was 79 % [95%CI: 62%-100%] vs 74% [95%CI: 57%-95%]. For early stage patients who later progressed (n = 27), median time to progression was not significantly shorter among patients who reported daily high sugar consumption (18 vs. 19 months, *P*-value 0.5). Genomic analyses revealed no significant differences in tumor mutational burden, fraction genome altered, frequency of oncogenic or signaling pathway alterations in *de novo* metastatic vs. non-metastatic patients. **Conclusions:** In a single center study, in EO CRC patients, high sugar diets may be associated with *de novo*metastatic disease. There were no significant genomic differences detected in patients with *de novo* metastatic vs. early stage disease. Research Sponsor: None.

3530 Poster Session

Survival impact of Neo*RAS* wild-type metastatic colorectal cancer: A SCRUM-Japan GOZILA substudy. First Author: Hiroki Osumi, Department of Gastroenterological Chemotherapy, Cancer Institute Hospital, Japanese Foundation for Cancer Research, Tokyo, Japan

Background: The "Neo*RAS*" phenomenon refers to *KRAS* or *NRAS* mutant (MT) metastatic colorectal cancer (mCRC) that becomes *RAS* wild-type (WT) following treatment and may represent a novel indication for anti-epidermal growth factor receptor monoclonal antibodies. We previously described the incidence and clinicopathological characteristics of Neo*RAS* WT mCRC (Osumi et al. *Nat Commun* 2024); here we share the impact of Neo*RAS* WT on survival for patients with mCRC. **Methods:** Patients enrolled in the large-scale nationwide screening platform SCRUM-Japan GOZILA who had mCRC, tumor tissue tested for *RAS* and *BRAF* V600E (MEBGEN RASKET-B), and received systemic therapy were included. Prior to subsequent treatment, all patients underwent next-generation sequencing of circulating tumor DNA (ctDNA) (Guardant360) and were classified into cohorts according to original tissue and subsequent ctDNA genotypes: persistent *RAS/BRAF* V600 WT (*RAS* WT), persistent *RAS* MT, change from *RAS* MT to *RAS* WT (Neo*RAS*WT, including ctDNA not detected), change from *RAS* WT to *RAS* MT (acquired *RAS* MT), persistent *BRAF* V600E (*BRAF* MT). *BRAF* MT outside V600 were not considered. We evaluated the clinicopathological characteristics and overall survival (OS) of patients in each cohort. OS was measured from time of first-line treatment initiation to the date of death. **Results:** The 1,352 patients (median age 61 years) included *RAS* WT: 526 (38.9%), *RAS* MT: 387 (28.7%), acquired *RAS* MT: 223 (16.5%), Neo*RAS* WT: 91 (6.7%), and *BRAF* MT: 125 (9.2%).Median number of therapy lines from tissue assessment to ctDNA testing was 2 (range 1-13). Neo*RAS* WT had low prevalence of liver (23.1%, $P < 0.001$), lymph node (16.5%, $P < 0.001$) and multi-organ metastasis (42.9%, $P < 0.001$), whereas lung (56.0%, $P < 0.001$) and peritoneal metastases (41.8%, P = 0.004) were more common in other groups. Left-sided primary tumors were more common with *RAS* WT (80.2%) followed by Neo*RAS* WT (70.3%) and *RAS* MT (67.7%), ($P < 0.001$). Patients with *BRAF* MT had significantly shorter median OS (28.1 months) compared to others ($P_{Log\text{-}rank} < 0.001$, hazard ratio (HR), 1.91; 95% confidence interval (CI), 1.52-2.40). Patients with Neo*RAS* WT had median OS (45.6 months) that was between *RAS* WT (51.9 months) and *RAS* MT (41.0 months) ($P_{Log\text{-}rank} < 0.001$). On the other hand, patients with acquired *RAS* MT had a significantly shorter median OS (43.3 months) compared to *RAS* WT ($P_{Log\text{-}rank} < 0.001$). In multivariate analysis, *BRAF* MT (HR: 2.06, 95%CI, 1.62-2.61, $P < 0.001$), ctDNA fraction (≥1.0%, HR: 1.41, 95%CI, 1.17-1.71, P = 0.00035), *RAS* MT (HR: 1.37, 95%CI, 1.17-1.62, P = 0.0001), and lymph node metastasis (HR: 0.85, 95%CI, 0.72-0.99, P = 0.046) were independent factors associated with shorter OS. **Conclusions:** Patients with Neo*RAS* WT mCRC exhibited distinct characteristics, and intermediate survival between the *RAS* WT and *RAS* MT groups. Revisiting the relevance of sidedness in colonic tumor molecular profiling. First Author: Ashok K. Vaid, Medanta, The Medicity, Gurugram, India

Background: Colorectal cancer (CRC) is a heterogeneous disease with distinct molecular and clinical differences between right- and left-sided tumors. This study analyzes these variations to understand their impact on tumor behavior and treatment strategies. **Methods:** A total of 445 colonic tumor samples (132 right-sided, 313 left-sided) were profiled to assess mutations, amplifications, and fusions in key cancer-related genes along with targeted transcriptome analysis of 20,802 genes in a subset using semiconductor based next-generation sequencing (NGS) platform at Datar Cancer Genetics. Immunotherapy biomarkers (TMB, MSI, and PD-L1 22C3 TPS) were analyzed in a subset. **Results:** Right-sided and left-sided colon cancers exhibit substantial molecular heterogeneity, driven by distinct genetic and epigenetic alterations (Table 1). Right-sided tumors were more frequently associated with MSI and had statistically significant higher incidence of *BRAF* mutations. *KRAS* mutations were frequently observed in both right-sided and left-sided tumors at equal rates. *ERBB2* amplifications were exclusive to left side tumors, whereas oncogenic *ERBB2* mutations were equally distributed. Located around *ERBB2, PGAP3* gene co-amplification too was exclusive to left sided tumors. *TFE3* alterations were absent from left sided tumors and common on right side. *TP53* mutations, though more common in left-sided tumors, the difference was not statistically significant. Gene expression profiling of a subset, including 103 left-sided and 41 right-sided colon tumors, revealed activation of the *Wnt/β-catenin* signalling pathway, *RAS/MAPK* pathway, *TGF-β* signalling pathway, and immune-related pathways, though these differences were not statistically significant, suggesting that while specific drivers may differ—such as the predominance of *APC* mutations in left-sided tumors (56.8% vs 37.9%) leading to *WNT* activation and the higher incidence of *RSPO2/3* fusions (7.1% vs 1.7%) in right-sided tumors -eventually some pathways are commonly implicated in colorectal cancer biology. **Conclusions:** Existing therapies like ICIs, *HER2* inhibitors, and emerging molecules such as *RSPO2/RSPO3* inhibitors could have differing impact based on tumor sidedness. Integrating these distinctions into drug development and clinical trials holds potential to optimize treatment outcomes. Research Sponsor: None.

Predicting pathologic complete response in colorectal cancer patients after immunotherapy based on endoscopic biopsy and deep learning approach. First Author: Chaoyuan Xiao, Colorectal Cancer Center, Department of General Surgery, West China Hospital, Sichuan University, Chengdu, China

Background: Immune checkpoint inhibitors (ICIs) have emerged as effective treatments for microsatellite instability-high (MSI-H)/deficient mismatch repair(dMMR) tumors in a select subset of colorectal cancer (CRC) patients. Patients sensitive to preoperative immunotherapy may have the opportunity to be exempted from surgery, while those insensitive may avoid unnecessary treatment. Tumor pathology provides rich biological insights. Several studies have indicated that deep learning algorithms can predict the efficacy of immunotherapy directly from digitized hematoxylin-eosin (H&E) stained Whole Slide Images (WSIs). However, their potential application in CRC immunotherapy remains underexplored. Based on WSIs of endoscopic biopsy, this study aims to construct a predictive model using deep learning approach to identify potential pathological complete response (pCR) in CRC patients after preoperative immunotherapy. **Methods:** This study enrolled CRC patients who received preoperative immunotherapy at West China Hospital, Sichuan University. Stratified randomization based on pathological outcomes was performed, assigning enrolled patients to the training set (70%) and the validation set (30%). WSIs of endoscopic biopsy were used for analysis. A predictive model was developed based on the Swin Transformer architecture, integrating convolutional neural networks (CNNs) with a self-attention mechanism. Pre-trained weights were employed for feature extraction, and the CLAM (Clustering-constrained Attention Multiple Instance Learning) framework was utilized to optimize pathological image analysis. The model's performance was assessed in the validation cohort using the Receiver Operating Characteristic Curve (ROC) and Area Under the Curve (AUC) was calculated. Attention-based visualization analysis was further performed to identify the top patches that contributes to the determination of tumor response to preoperative immunotherapy. **Results:** 96 CRC patients treated with preoperative immunotherapy were included, with 67 in the training set and 29 in the validation set. A total of 278,901 512×512-pixel patches were generated by preprocessing 144 WSIs. A predictive model were established based on the training set and verified in the validation set. The model achieved an AUC of 0.82. Attention-based visualization analysis recognized the top 5% patches contributing to the determination of tumor response to preoperative immunotherapy, with 62.66% identified as tumor tissues and 37.34% identified as non-tumor tissues. **Conclusions:** Endoscopic biopsy based deep learning model, with distinct attention to tumor and non-tumor regions, may provide a novel and effective tool for predicting pCR after preoperative immunotherapy in CRC patients. Research Sponsor: National Natural Science Foundation of China.

Metastatic site pattern as predictor of outcome of first-line alternating oxaliplatin-based chemotherapy and nivolumab for patients with microsatellite-stable (MSS) colorectal cancer (CRC). First Author: Anne Hansen Ree, Akershus University Hospital, University of Oslo, Oslo, Norway

Background: The randomized METIMMOX trial evaluated short-course oxaliplatin-based chemotherapy (FLOX) alternating with nivolumab for previously untreated, unresectable abdominal metastases (mets) from MSS CRC. A subgroup of patients assigned to this experimental (exp) treatment had remarkably extended progression-free survival (PFS) compared to the control group patients given standard FLOX chemotherapy with median PFS 9.3 months. We explored if the extent of involved organs might be decisive for responsiveness to the METIMMOX regimen. **Methods:** Patients with measurable infradiaphragmatic (liver, peritoneal, nodal) mets were randomly assigned to the control group of FLOX (oxaliplatin, 5-fluorouracil, folinic acid) Q2W or the exp group of alternating 2 cycles each of FLOX Q2W and nivolumab Q2W, with prespecified break periods. Radiologic response assessment was done every 8 weeks with PFS as the primary endpoint. For this *post hoc* analysis, at baseline, the principal metastatic site was defined by the 2 largest mets (main lesions) of the dominant infradiaphragmatic organ and the global metastatic pattern by the main and subsidiary lesions of all involved organs. Patients without adverse events leading to treatment discontinuation, thus with conclusive end of treatment (EoT) tumor data, were categorized into discrete outcome groups. **Results:** Of 36 exp group patients reaching the first radiologic reassessment, enabling formal evaluation, 31 proceeded to EoT tumor data. Of these, 6 patients (3 of 25 with liver main lesions, 3 of 4 with lymph node main lesions) had complete response (CR), including 3 of 3 *BRAF*-V600E cases. The remaining 3 CR cases had tumor mutational burden (TMB) 9.4-11.8. Of all 25 patients with liver mets, 13 (52%) had objective response and 5 (20%) stable disease. All 16 patients with objective response had improved PFS (median 15.5 months, 95% CI 12.4-18.5; $p < 0.001$, log-rank test). None of main or subsidiary lesions in peritoneum or lungs responded to the treatment. The 3 outcome groups comprised 7 patients with PFS 19.8-41.6 months (longer than twice the median), 8 with PFS 9.9-16.4 months (above median), and 16 with PFS 1.9-9.2 months (below median). At baseline, the best outcome group cases would have been predicted by the combination of right-sided primary, small main lesions (sum of diameters 42 mm or less), and all mets confined to the liver and/or lymph nodes; the mid group cases by left-sided or rectal primary along with peritoneal or lung subsidiary lesions; and the poor outcome cases by extended organ mets. **Conclusions:** Alternating short-course oxaliplatin-based chemotherapy and nivolumab was particularly efficient in treating unresectable liver or lymph node mets from right-sided MSS CRC with intermediate TMB or the *BRAF* driver mutation, but inefficient at peritoneal and lung mets. Clinical trial information: NCT03388190. Research Sponsor: Norwegian Cancer Society; Bristol-Myers Squibb.

Open-label phase Ib/II study of cetuximab (CET) plus LY3214996 with or without abemaciclib in patients (pts) with anti-EGFR-refractory metastatic colorectal cancer (mCRC). First Author: Guglielmo Vetere, Department of Gastrointestinal Medical Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Acquired resistance limits the efficacy of anti-EGFR (EGFRi) therapy in RAS wild-type (WT) mCRC, often through MAPK reactivation driven by secondary RAS mutations or other genomic alterations. Preclinical studies on EGFRi-refractory models led by our group showed that LY3214996, a potent ERK1/2 inhibitor, combined with CET suppresses MAPK signaling and reduces tumor growth, while the addition of Abemaciclib further enhances anti-tumor activity by synergistically inhibiting cell cycle and survival pathways. **Methods:** In this open-label, phase Ib/II study, RAS/BRAF/EGFR/MEK1 WT mCRC pts who progressed on prior EGFRi-based therapy and ≥1 chemotherapy were treated with CET + LY3214996 (Arm A) or CET + LY3214996 + Abemaciclib (Arm B). Phase Ib employed a 3 + 3 design to determine the maximum tolerated dose (MTD) and recommended phase 2 dose (RP2D). Phase II followed a two-stage design with cohort expansion to assess ORR by RECIST v1.1 as the primary endpoint. Secondary endpoints included PFS and OS. **Results:** Of 44 pts treated on trial, 2 did not meet inclusion criteria; 39 were evaluable for activity, and 34 for efficacy. The RP2D was 200 mg LY3214996 p.o. daily + 500 mg/m² CET i.v. biweekly in Arm A with the addition of 150 mg Abemaciclib p.o. twice daily in Arm B. Median age was 53.0 years (IQR 47.0 – 63.8), and 59.1% (26/44) were male. Most pts (95.5%, 42/44) had a left-sided or rectal primary, and all were pMMR/MSS. Prior EGFRi-based rechallenge, retreatment/reintroduction, or both were noted in 9.1% (4/44), 25.0% (11/44), and 4.5% (2/44), respectively. ORR, DCR, median PFS and OS were 5.3% (1/19), 36.8% (7/19), 1.8 months (95% CI 1.5 – 4.8) and 7.0 months (95% CI 5.0 – 22.0) for the doublet and 15.0% (3/20), 65.0% (13/20), 3.6 months (95% CI 2.5 – 4.5), and 14.0 months (95% CI 5.9 – 21.0) for the triplet, respectively. Longer time elapsed from last EGFRi was associated with higher predicted probability of response after adjustment for trial regimen (OR 1.35, 95% CI 1.06 – 1.94, p = 0.038). Baseline ctDNA profiling drawn prior to rechallenge revealed acquired RAS mutations in two responders, one per arm. Grade 3 TRAEs occurred in 31.8% (14/44), with acneiform rash (9.1%, 4/44), diarrhea (9.1%, 4/44), thrombocytopenia (6.8%, 3/44), fatigue (4.5%, 2/44), and anemia (4.5%, 2/44) being the most frequent while one Grade 4 TRAE (thrombocytopenia, 2.3%) was reported. **Conclusions:** CET + LY3214996 ± Abemaciclib had a manageable safety profile with no unexpected adverse events. Although activity was modest, this study is the first to report objective responses to an EGFRi-based regimen in pts harboring acquired RAS mutations in pre-rechallenge ctDNA. Translational efforts are ongoing. Clinical trial information: NCT04616183. Research Sponsor: MD Anderson Cancer Center; Jack T. and Lillian S. Clift Fellowship; Andrew Sabin Family Fellowship; NIH GI SPORE; Mr. and Mrs. Jack Lee.

COPEC trial: Early determination of pathological tumor response to neoadjuvant chemotherapy in low/intermediate risk stage II/II rectal cancer—A multicenter, non-inferiority phase III randomized trial. First Author: Mingtian Wei, West China Hospital (China), Chengdu, China

Background: Multiple large-scale prospective studies have confirmed that neoadjuvant chemotherapy (NCT) alone can achieve optimal distant and local control in locally advanced rectal cancers (LARC) without high risks. However, due to the potentially lower overall response rate compared to chemo-radiotherapy, it is rational to discontinue ineffective NCT in chemo-resistant patients. In our phase II study, we applied 4 cycles of Capox in LARC patients with low to intermediate risks, observing a considerable pathoclinical response rate and an accuracy of 0.89 in predicting non-responders using MRI features after two cycles of Capox. To determine the optimal number of NCT cycles and prevent unnecessary prolonged treatment, we conducted this phase III trial to assess the non-inferiority of two cycles of NCT compared to four cycles with respect to the final pathological tumor response grade (pTRG) of 3. **Methods:** This multicenter, non-inferiority, phase III randomized controlled trial was conducted at 14 centers across China. Eligible patients with low- to intermediate-risk stage II/III rectal cancer were randomized to receive either 2 or 4 cycles of CAPOX, followed by total mesorectal excision (TME) surgery. The primary endpoint was the proportion of patients with a poor pathological response to NCT (pTRG 3). Secondary outcomes included the accuracy of MRI in predicting tumor response, treatment-related adverse events, and 3-year survival outcomes. **Results:** From August 6, 2021, to May 27, 2024, a total of 573 patients were enrolled. Ultimately, 527 patients (2-cycle group, 266 vs. 4-cycle group, 261) were included in the primary analysis. The pTRG 3 rate in the 2-cycle group (27.8%, 74/266) was non-inferior to that in the 4-cycle group (26.4%, 69/261, p = 0.722). Better lymph node response was observed in the 4-cycle group (pN negative: 83.1%, 217/261 vs. 72.5%, 193/266, p = 0.011). The incidence of major adverse events (grade ≥3, according to CTCAE 5.0) was comparable between the two groups (37.9% vs. 44.8%, p = 0.094). A tumor longitudinal length reduction rate (TLLR) of less than 30% on MRI predicted pathological poor responders with a high positive predictive value of 0.918 after two cycles of NCT in the two-cycle group, 0.864 after two cycles of NCT in the four-cycle group, and 0.841 after four cycles of NCT in the four-cycle group. **Conclusions:** Four cycles of NCT do not result in a greater reduction in poor pathological response compared to two cycles, highlighting the importance of early response assessment. MRI evaluation of tumor response after 2 cycles predict the final pathological results with considerable accuracy. These findings lay the groundwork for future studies exploring response-guided treatment approaches in rectal cancer. Clinical trial information: NCT04922853. Research Sponsor: None.

3536 Poster Session

Survival of patients (pts) with microsatellite stable/mismatch repair proficient (MSS/pMMR) metastatic colorectal carcinoma (mCRC) treated with EO4010 + nivolumab (EO/N). First Author: Arvind Dasari, Department of Gastrointestinal Medical Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: EO is designed to expand pre-existing memory CD8 T cells cross-reacting with tumor associated antigens (TAAs). EO is composed of microbial-derived sequences mimicking CD8 T cell HLA-A2 epitopes on 5 TAAs, BIRC5, FOXM1, UBE2C, CDC20 and KIF2C, upregulated in mCRC, and the CD4 peptide UCP2. **Methods:** Pts had MSS/pMMR mCRC, treated with FU, oxaliplatin, irinotecan and anti-VEGF/EGFR. Cohort (C)1 safety lead-in followed by expansion C2; pts received EO (300 μg/peptide in Montanide ISA 51 VG) q2 weeks (w) x4 then q4w + N (240 mg q2w x 3 then 480 mg q4w; C1 omitted 2 first N doses). **Results:** 20 pts (C1 = 3, C2 = 17), 55% female, 70%/30% ECOG 0/1, median age 58 (45-80) years, started EO + N June 2023 to March 2024. Primary tumor right sided 35%/left 35%/rectal 30%, median 2 (1-4) tumor involved organs, 55% liver mets, 65% KRAS mutated, and median 3 (1-5) prior lines of treatments. Any grade related AEs in $>$ 2 pts: local administration site reactions (85%), asthenia (15%), and fatigue (15%); 1 related Gr 3, local administration site ulceration; 1 related SAE, N infusion related reaction. CD8 T cells (EO/TAA peptide specific tetramers staining of PBMC ex vivo) against EO found in 10/11 tested pts, cross-reactivity against TAAs in all 10 positive pts. Best response (RECIST 1.1): 1 partial response (liver mets -47%, lung mets -34%; CEA normalized), 1 stable disease (SD) (lung mets -7%; CEA -68%, CA19-9 -55%; pat died w 17 non-related myocardial infarction), and 1 SD until w 18 (withdrawn consent); 6 (30%) pts had target SD, and unequivocal progression of non-target lesions; 11 pts (55%) had progressive disease. Median PFS 1.8 months (mo) (range 1.4-10.5). 14 pts (70%) received post-study anti-cancer treatment. After a median follow-up of 14.7 mo, median overall survival (OS) 11.2 mo; 80% 6- and 39% 12-mo survival. Immune response assessed using a composite score of EO4010-specific T cell responses, measured by ex vivo tetramer assays weeks 5 to 9 of treatment (best response used), with pts stratified into high and low responders based on median score. Kaplan-Meier analysis with log-rank test showed trend towards better OS in high responders (p = 0.065). Median OS low responders 9.6 mo and not reached for high responders. Immune response magnitude showed no correlation with baseline T cell activation potential (by anti-CD3 stimulation/ELISPOT); independence indicates that EO4010-induced CD8 T cell expansion occurs irrespective of baseline T cell status. **Conclusions:** EO4010 + nivolumab promotes expansion of TAA specific CD8 T cells and shows good safety and interesting survival in previously treated MSS/pMMR mCRC. Data suggests a potential survival benefit associated with stronger EO4010-induced immune responses. Continued evaluation of EO is warranted; further immune testing data, and results of addition of bevacizumab to EO + N in a separate cohort are awaited. Clinical trial information: NCT05589597. Research Sponsor: Enterome.

3537 Poster Session

The prognostic and predictive role of HER2 amplification/overexpression and *HER2* mutations in metastatic colorectal cancer treated with first-line chemotherapy plus bevacizumab/anti-EGFRs: An individual patient data pooled analysis of eight randomized trials. First Author: Marco Maria Germani, Department of Translational Research and New Technologies in Medicine and Surgery, University of Pisa, Pisa, Italy

Background: HER2 amplification/overxpression (HER2-pos) is detected in the 5% of *RAS/BRAF* wild-type (wt) metastatic colorectal cancers (mCRC) and is associated with poor efficacy of EGFR blockade in preclinical models. Whether HER2-pos is a prognostic and/or predictive biomarker of benefit from anti-EGFRs/bevacizumab (bev) in mCRC patients (pts) is still debated. Similarly, the role of activating *HER2* mutations (mut) is unclear. **Methods:** We collected individual patient data from 8 randomized clinical trials (RCTs) in the first-line treatment of mCRC: TRIBE2, TRIPLETE, VALENTINO, ATEZOTRIBE, PANDA, PANAMA, PARADIGM and CALGB/SWOG80405. Only pts with *RAS/BRAF* wt pMMR mCRC with available HER2 *status* by means of immunohistochemistry $\pm$ *in situ hybridization* and/or Next-generation sequencing on tumor or circulating DNA and treated with triplet or doublets + bev or an anti-EGFR were included. The prognostic and predictive impact of HER2-pos and *HER2* mut was assessed in terms of PFS, OS and ORR. **Results:** 1604 pts were eligible. 81 (5%) tumours were HER2-pos. HER2-pos was associated with shorter PFS (mPFS: 9.8 vs 12.2 months (mos), HR: 1.31, p = 0.02) and OS (mOS: 28.0 vs 34.9 mos, HR: 1.37, p = 0.01), and similar ORR (77 vs 72%, p = 0.47) compared to HER2-neg pts. P-values adjusted for clinically meaningful covariates (p_{adj}) were p_{adj}PFS = 0.075 and p_{adj}OS = 0.036. We found no interaction between HER2-pos and treatment effect according to the use of bev vs anti-EGFRs in terms of PFS (p_{int}= 0.76), OS (p_{int}= 0.76) and ORR (p_{int}= 0.64). Similar findings were reported restricting the analysis to pts treated with doublets (N = 1465), and to those with left-sided tumors (N = 1315). In the HER2-pos subgroup (N = 69) of pts with left-sided *RAS/BRAF* wild-type pMMR tumors no difference between chemotherapy/bev and chemotherapy/anti-EGFR was reported in terms of PFS (mPFS: 9.8 vs 9.3 mos, HR: 0.73, p = 0.30), OS (mOS: 29.8 vs 28.0 mos, HR: 1.29, p = 0.40), and ORR (59% vs 79%, p = 0.10). Activating *HER2* mut were found in 27 (2%) out of 1408 HER2-neg tumors with *HER2* mutational *status* available. Pts with *HER2* mut tumors had a shorter OS (median: 23.7 vs 34.4 mos, HR: 1.56, p = 0.04) than *HER2* wt. No interaction between *HER2* mutational status and treatment effect was evident, with no significantly different PFS (mPFS: 9.4 vs 5.7 mos, HR: 0.88, p = 0.76) and OS (mOS: 20.9 vs 23.7 mos, HR: 1.04, p = 0.93) in the *HER2* mut subgroup between bev and anti-EGFRs. **Conclusions:** This is the largest analysis of HER2 *status* in untreated mCRC pts enrolled in RCTs. Waiting for targeted approaches, HER2-pos is an independent negative prognostic factor and does not predict benefit between bev/anti-EGFRs also in left-sided tumors. *HER2* mut may exert a negative prognostic impact in HER2-neg *RAS/BRAF* wt pMMR mCRC. 3538 Poster Session

Assessing the predictive role of tumor sidedness in *RAS* and *BRAF* wild-type metastatic colorectal cancer (mCRC) treated with first-line doublets + anti-EGFRs/bevacizumab (bev) or triplet + bev: An individual patient data pooled analysis of 10 randomized clinical trials. First Author: Marco Maria Germani, Department of Translational Research and New Technologies in Medicine and Surgery, University of Pisa, Pisa, Italy

Background: Chemotherapy (chemo) + an anti-EGFR and chemo + bev are currently regarded as preferred upfront options for left- and right-sided pMMR *RAS/BRAF* wild-type (wt) mCRC patients (pts), respectively. This recommendation is mainly based on trial-level pooled analyses of *RAS* wt pts' cohorts, thus including also *BRAF* mutant cases. **Methods:** We collected individual patient data from 10 randomized clinical trials (RCT) in first-line mCRC: TRIBE, TRIBE2, TRIPLETE, VALENTINO, ATEZOTRIBE, PANAMA, FIRE-3, FIRE-4, PARADIGM and CALGB/SWOG80405. *RAS* and *BRAF* wt mCRC pts treated with doublets + anti-EGFR/bev or triplet + bev were included. **Results:** 2178 pts were eligible. Left- and right-sided tumors were 1780 (82%) and 398 (18%), respectively. As reported in the table, among 2051 pts treated with doublets/bev or doublets/anti-EGFR, no significant interaction effect between primary sidedness and treatment arm was reported in terms of ORR (p_{int}: 0.27) and PFS (p_{int}: 0.32), with a p-value for interaction for OS of 0.13. Anti-EGFR-based doublets were associated with higher ORR and longer OS among pts with left-sided tumors, while similar outcomes were reported in right-sided ones. Among 339 pts enrolled in trials where triplet was included as a treatment arm, a potential interaction effect between primary sidedness and treatment (triplet/bev or doublet/anti-EGFR) was evident in terms of PFS (p_{int}: 0.14) and OS (p_{int}: 0.08) but not ORR (p_{int}: 0.42). Triplet/bev was associated with longer PFS and OS among pts with right-sided tumors. **Conclusions:** This is the largest analysis assessing the differential effect of biologic agents and chemo intensification according to primary tumor origin in pts with untreated *RAS* and *BRAF* wt mCRC enrolled in RCTs. Doublets/anti-EGFR is superior to doublets/bev in left-sided tumors, with no significant differences in right-sided tumors, where triplet + bev appears as the most efficacious regimen for fit pts. Further analyses assessing the role of molecular hyperselection beyond *RAS* and *BRAF* are ongoing. Drug-eluting beads loaded with irinotecan-transarterial chemoembolization (DEBIRI-TACE) combined with hepatic artery infusion chemotherapy and regorafenib in colorectal liver metastases refractory to second-line and above standard systemic therapy: A single-center, phase II clinical trial (DREAM). First Author: Wenzhe Fan, Department of Interventional Oncology, The First Affiliated Hospital of Sun Yat-sen University, Guangzhou, Guangdong, China

Background: For patients with colorectal liver metastasis (CRLM) who have failed in first-line or second-line systemic treatment, the prognosis is extremely poor. Regorafenib is the standard third line treatment regimen. We aim to explore the safety and clinical efficacy of added drug eluting beads loaded with irinotecan (DEBIRI) plus hepatic arterial infusion chemotherapy (HAIC) to regorafenib in the combination treatment of second-line and above in patients with CRLM. **Methods:** For this single-center, single-arm, prospective, phase II trial, patients with unresectable progression of CRLM after previously receiving at least six cycles of standard systemic chemotherapy above the second line were enrolled. All of the patients received at least once DEBIRI-TACE and FOLFOX-HAIC (Oxaliplatin 85mg/m^2 2h + Calcium Levofolinate 200mg/m^2 2h + Fluorouracil 2400mg/m^2 46h) plus oral regorafenib 80/120/160 mg once daily during weeks 1-3 of each 4-week cycle until disease progression or unacceptable toxicity. The primary endpoint of this study was the best objective response rate (ORR) per RECIST 1.1, the secondary endpoints include progression-free survival (PFS), overall survival (OS), safety and tolerability assessments. **Results:** By the cutoff date of 17 November 2023, 21 patients were enrolled, with the median age of 61 (ranges, 38-71 years old), 14 (66.7%) of whom were male. 17(81.0%) patients had more than one tumor and 13(61.9%) patients had major tumor larger than 5cm. The most frequent primary cancer localization was colon (81.0%) and the primary had been resected in 14(66.7%) patients. Somatic mutation status was available for 15 patients: KRAS mutation was found in 7 patients. The ORR was 33.3% and the DCR was 100%. The median PFS was 7.8 months (95% CI: 5.8–NA), the median OS was 17.6 months (95% CI: 9.3–NA), the 1-year and 2-year OS rate were 54.6% (30.7%-73.4%) and 23.9% (4.6%-51.3%), respectively, and the 1-year PFS rate was 36.4% (15.7%-57.5%). The most common TRAEs were AST/ALT increase (81.8%), abdominal pain (63.6%), hyperbilirubinemia (63.6%), hand-foot skin reaction (59.1%), diarrhea (40.9%), etc. 9 patients presented with grade 3 or 4 TRAEs, which were the transient liver function injury and abdominal pain caused by TACE and HAIC. **Conclusions:** DEBIRI-TACE combined with HAIC and regorafenib is feasible, safe and shows promising efficacy in treating the patients with CRLM, even after second-line and above systemic chemotherapy. Clinical trial information: NCT06071052. Research Sponsor: None.

3540 **Poster Session**

Biomarkers of emergent resistance to sotorasib plus panitumumab in *KRAS* G12C-mutated metastatic colorectal cancer (mCRC) from the randomized, phase 3 CodeBreaK 300 study. First Author: Lisa Salvatore, Medical Oncology, Università Cattolica del Sacro Cuore and Medical Oncology, Comprehensive Cancer Center, Fondazione Policlinico Universitario Agostino Gemelli, IRCCS, Rome, Italy

Background: The use of sotorasib (soto; $KRAS^{G12C}$ inhibitor) alone in patients with *KRAS* G12C-mutated mCRC gives rise to several receptor tyrosine kinase (RTK) alterations, resulting in treatment resistance. In CodeBreaK 300 trial, the addition of panitumumab (pani; monoclonal anti-EGFR antibody) counters this resistance and significantly improves clinical outcomes compared with standard of care (SoC; trifluridine-tipiracil or regorafenib). Over time this combination (soto+pani) may lead to the emergence of new resistance patterns. This study reports the distribution, patterns, and prevalence of genetic alterations that arise after treatment with soto+pani. **Methods:** Patients from the phase 3 CodeBreaK 300 trial with chemorefractory *KRAS* G12C-mutated mCRC who had paired plasma samples at baseline and at progression, were included in the analysis. The samples were evaluated using the 753-gene Guardant Infinity ctDNA test. Gene alterations that were absent at baseline but present at progression were considered. **Results:** By December 2024, 99 patients (median age: 62 years, female: 48%) were evaluated (soto 960 mg-pani: 32 [60% of ITT population], soto 240 mg-pani: 33 [62% of ITT population], SoC: 34 [63% of ITT population]). Overall, 90% of patients had at least 1 emergent, likely pathogenic, genomic alteration at progression. Median time to progression in biomarker-evaluable patients was 3.8 months for soto 960 mg-pani arm, 3.6 months for soto 240 mg-pani arm, and 2.0 months for SoC arm. Overall, the distribution, patterns, and prevalence of pathogenic emergent alterations were similar across all treatment arms. The most common pathogenic emergent alterations included *TP53* (34%), *DNMT3A* (17%), *ERBB2* (12%), and *LRP1B* (11%), generally associated with the RTK, cell cycle control, DNA methylation, and DNA damage response pathways. The median copy number of emergent *KRAS* copy number variations (CNVs) was higher (p = 0.007) in the soto 960 mg-pani (4.18) and soto 240 mg-pani (4.24) arms compared with the SoC arm (2.05). Emergent *KRAS* CNVs were primarily present in the soto+pani arms (soto 960 mg-pani: 40.6% [n = 13], soto 240 mg-pani: 36.4% [n = 12], and SoC: 14.7% [n = 5]). The presence of emergent pathogenic variants in *ALK* (n = 7) and *KMT2D* (n = 4) was observed exclusively among patients treated with soto+pani. *DNMT3A* mutations, along with other diverse emergent alterations, were observed in all three evaluable patients with partial response in the soto 960 mg-pani arm. **Conclusions:** Dysregulation of the DNA methylation and RTK pathways and *KRAS* amplifications may contribute to the development of resistance to soto+pani combination. Further characterization of these acquired alterations, can help inform future therapeutic strategies. Clinical trial information: NCT05198934. Research Sponsor: Amgen Inc.

Safety and efficacy of anti-CEA CAR-T cells to prolong relapse-free survival of colorectal cancer liver metastases patients after radical resection. First Author: Wei Zhang, Department of Colorectal Surgery, Changhai Hospital, Naval Medical University, Shanghai, China

Background: Approximately 75% of colorectal cancer liver metastasis patients relapse within two years after surgery due to circulating tumor cells and microscopic residual disease. Specific chimeric antigen receptor (CAR) T-cell therapy, effective for hematological tumors, may also treat recurrent colorectal cancer liver metastases. Carcinoembryonic antigen (CEA) is a glycoprotein which is highly expressed in colorectal tumor. Therefore, this study aimed to evaluate the safety and efficacy of this therapy in postoperative colorectal cancer liver metastasis patients. **Methods:** We conducted a single-arm, dose-escalating phase I clinical trial (NCT05240950). Key eligibility criteria were achieving no evidence of disease status after treatment and had CEA positivity of 30% or greater. Three dose levels of 1, 3, and 6 (10^6/kg) Anti-CEA CAR-T cells were administered in a dose-escalating manner. The primary endpoint is safety which measures are incidence and severity of adverse events within 28 days and relapse-free survival at 24 months. **Results:** From December 2021 to December 2024, 48 subjects were screened, and 12 received CAR-T cell infusion (2 in the 1 and 3×10^6/kg group, and 8 in the 6×10^6/kg group). Three subjects who had relapsed before the infusion still asked for the infusion, so we proceeded to infuse after fully informing about the benefits and risks of the infusion. 8 subjects experienced adverse events during treatment, including lymphopenia (5 subjects), arthralgia (1 subject), fever (1 subject), and rash (1 subject). No severe adverse events occurred. The median follow-up time for the 9 pre-infusion relapse-free subjects was 23 months, of which 5 relapsed after infusion. In the 6×10^6/kg dose group, 4 subjects remained relapse-free survival of 5, 7, 10 and 15 months after infusion, and their follow-up is ongoing. By infusing CAR-T cell, 57.14% of the subjects in the 6×10^6/kg dose group were free of recurrence within two years after radical resection. **Conclusions:** This is the first clinical trial of Anti-CEA CAR-T therapy for prolonging relapse-free survival of postoperative colorectal cancer liver metastases patients, showing no serious adverse events and significant reduced risk of recurrence with high doses. Clinical trial information: NCT05240950. Preliminary safety, pharmacokinetics, and clinical activity of RG6344 in patients with BRAF V600E-mutant metastatic colorectal cancer (mCRC). First Author: Elisa Fontana, Sarah Cannon Research Institute UK, London, United Kingdom

Background: RG6344 (RO7276389) is a novel paradox breaker and brain penetrant BRAF inhibitor (BRAFi) designed to overcome the MAPK paradoxical activity, a well-established liability of the first generation BRAF inhibitors. The BRAF V600E mutation, present in about 10% of mCRC patients, negatively impacts prognosis and response to standard therapies. **Methods:** Dose escalation of RG6344 is being conducted in participants with solid tumors harboring BRAF V600E mutation up to the protocol specified maximum daily dose, to define the maximum tolerated dose (MTD) and/or recommended Phase 2 dose and characterize safety, PK/PD, and clinical outcomes (ISRCTN13713551). **Results:** As of September 25, 2024, 51 patients with mCRC (27, 53% with prior BRAFi treatment; median number of treatments 3 [2-6]), including 4 patients with non-measurable brain lesions, have been treated with RG6344 in the monotherapy dose escalation part of the study. Patients received at least one dose of study drug as a single agent. MTD has not been reached up to the highest dose of 3600 mg/d. Of the 51 treated patients, Grade 3 treatment-related AEs (TRAEs) occurred in 8 patients (14.5 %), grade 4 TRAEs in 2 patients (3.6%; both laboratory findings) and no grade 5 TRAEs were reported. The most commonly reported TRAEs included diarrhoea (23.6%), nausea (21.8%) and fatigue (12.7%). 3 patients (5.5%) discontinued study treatment due to TRAEs. None of the typical BRAFi class toxicities, such as cutaneous squamous cell carcinomas (cSCCs), Palmar-Plantar Erythrodysesthesia (PPE) and keratoacanthoma, have been observed to date, highlighting the paradox breaking properties of this BRAF inhibitor. Linear and time-independent PK was demonstrated across the tested dose range, reaching Ctrough levels exceeding pERK inhibition > 80%. Strong and early (i.e. FDG PET at 15 days) metabolic response of 74% (6 CMR, 30 PMR out of 49 evaluable patients) was observed on FDG PET. Association between metabolic responses and exposure was observed. Observed ORR (RECIST v1.1) was 25% in BRAFi-naive mCRC patients and 14.8% in BRAFi-experienced patients, DCR was 100% for BRAFi-naive patients and 62.9% for BRAFi-experienced patients, mPFS was 7.3 months and 3.6 months, respectively, in the ongoing study. **Conclusions:** RG6344 is well tolerated allowing unprecedented exposure for pERK inhibition and shows promising preliminary single-agent activity. Clinical trial information: ISRCTN13713551. Research Sponsor: None.

3543 **Poster Session**

Impact of anti-EGFR and anti-VEGF antibodies on survival in $BRAF^{V600E}$ mutated metastatic colorectal cancer: A pooled analysis of eight clinical trials performed in the first-line treatment of mCRC (German AIO Study Group). First Author: Lena Weiss, Department of Medicine III, University Hospital Munich LMU, Munich, Germany

Background: $BRAF^{V600E}$ mutation in metastatic colorectal cancer (mCRC) is associated with poor prognosis. Registrational approval of anti-EGFR antibodies does not exclude their use in $BRAF^{V600E}$ mutated (mut) mCRC, while current guidelines explicitly advise against the use of anti-EGFR-directed therapy and recommend the use of chemotherapy plus anti-VEGF antibodies. The present analysis of single-patient data evaluates the therapeutic benefit from anti-EGFR- vs. anti-VEGF-directed therapy in $BRAF^{V600E}$ mut mCRC. **Methods:** We conducted a pooled analysis of eight first-line AIO-studies (FIRE-1, FIRE-3, FIRE-4, FIRE-4.5, CIOX, XELAVIRI, PANAMA, VOLFI) including 251 evaluable pts with $BRAF^{V600E}$ mut and RAS wild-type mCRC. Right-sided primary tumors (RSPT) included tumors from the caecum to the colon transversum, while left-sided tumors (LSPT) included the splenic flexure to the rectum. **Results:** Of 251 $BRAF^{V600E}$ mut pts, exact primary tumor location was available in 230 pts. In this cohort, 117 were male (50.9%) and 113 female (49.1%). LSPT was observed in 106 (46.1%) pts compared to 124 (53.9%) with RSPT. In the entire cohort, median OS (mOS) of LSPT vs. RSPT did not differ significantly (15.2 months vs. 13.4 months; HR 0.96; 95% CI, 0.70–1.29; P=0.77). Pts with LSPT showed a numerical survival benefit with anti-EGFR therapy compared to anti-VEGF therapy (17.8 months vs. 11.8 months; HR 0.71; 95% CI, 0.45–1.14; P=0.16). This effect was observed independent of sex. In contrast, pts with RSPT showed a trend towards inferior outcome with anti-EGFR vs. anti-VEGF therapy (11.6 months vs. 17.1 months; HR 1.31; 95% CI, 0.84–2.05; P=0.23). This effect was primarily driven by females, who experienced a significant survival disadvantage with anti-EGFR therapy (10.2 months vs. 17.1 months; HR 1.85; 95% CI, 1.05–3.25; P=0.031). For males, however, both anti-VEGF and anti-EGFR antibodies were associated with comparable outcome. **Conclusions:** The present analysis performed in the first-line treatment of $BRAF^{V600E}$ mut mCRC suggests a survival benefit from anti-EGFR antibodies in pts with LSPT, independent of gender. Male pts with RSPT appear to derive comparable benefit from anti-EGFR and anti-VEGF antibodies, while female pts exhibit a survival disadvantage from anti-EGFR antibodies. Clinical trial information: NCT00433927 (FIRE-3), NCT02934529 (FIRE-4), NCT04034459 (FIRE-4.5), NCT01249638 (ML22011), NCT00254137 (CIOX), NCT01991873 (PANAMA), NCT01328171 (VOLFI). Circulating tumor DNA (ctDNA) dynamics in liver-limited metastatic colorectal cancer (mCRC) patients resected after first-line systemic treatment. First Author: Vittorio Studiale, Unit of Medical Oncology 2, Azienda Ospedaliera Universitaria Pisana and Department of Translational Research and New Technologies in Medicine and Surgery, University of Pisa, Pisa, Italy

Background: Liver-limited disease (LLD) occurs in 20-30% of metastatic colorectal cancer (mCRC) patients. Although 20-30% of patients who undergo resection can achieve a long-term overall survival benefit from liver surgery, most patients relapse during the first two years after hepatectomy. ctDNA is a promising tool in detecting the presence of minimal residual disease (MRD) after resection of colorectal liver metastases and a reliable prognostic tool for recurrence. ctDNA and its dynamics may also serve as a prognostic tool in patients candidate to liver resection following upfront chemotherapy. **Methods:** mCRC patients (N = 116) with initially unresectable LLD and R0/R1 resected after upfront chemotherapy were selected from 3 Italian academic centers. Blood samples were collected prospectively at baseline (T0), pre-surgery (TPrS) and post-surgery (TPoS). T0 samples were evaluable for 82 patients, TPrS for 116 and TPoS for 60. Biobanked plasma samples were analyzed with the Tempus xM MRD assay (xM), a tumor-naïve ctDNA MRD assay that integrates methylation and genomic variant classifiers to deliver a binary MRD call blinded to clinical outcomes. The methylation classifier detects fragments with CRC methylation signatures in differentially methylated regions trained by sequencing CRC and presumed-healthy samples on a 6 Mbp panel. The variant classifier detects highly prevalent CRC variants. **Results:** Methylation results were available for 60 TPoS patients with a clinical sensitivity of 56.4% and specificity of 100%. TPoS ctDNA status was associated with relapse-free survival (RFS) with the ctDNA- group experiencing longer median RFS (mRFS) than ctDNA+ (HR = 6.7, mRFS $>$ 24 mos vs. 5.5 mos, p $<$ 0.001). Patients who were persistently ctDNA- by methylation calls (n = 20) or converted to negative (n = 13) from TPrS to TPoS experienced longer RFS (mRFS 16.3 mos and $>$ 24 mos respectively). Those who remained persistently ctDNA+ (n = 9) or converted to ctDNA+ (n = 12) had a mRFS of 5.3 and 5.9 mos respectively. Patients with variant allele fraction (VAF) reduction of $\geq$50% from T0 to TPrS (N = 53) experienced longer RFS than those who had $<$ 50% reduction or increase in VAF (N = 18) (HR 2.21, mRFS 18.8 mos vs. 9.8 mos, p = 0.012). Lastly, patients that remained positive from T0 to TPrS (N = 23) experienced a numerically shorter RFS compared to those who converted to negative (N = 47) (median RFS 10.4 and 15.1 mos, HR 1.65, p = 0.10). **Conclusions:** xM demonstrates remarkable performance in predicting clinical recurrence and correlation to RFS at TPoS in LLD mCRC patients resected after upfront systemic therapy. Interestingly, patients with a VAF reduction $\geq$ 50% experience longer RFS following surgery, suggesting a potential role for this tool in multidisciplinary decision making in this setting. Research Sponsor: None.

Tumour microbiome and immune dysregulation in early-onset colorectal cancer. First Author: Rachel Violet Purcell, Department of Surgery and Critical Care, Christchurch, New Zealand

Background: Early-onset colorectal cancer (EOCRC) in patients under 50 years is increasing incidence in many countries worldwide, including New Zealand. The reason for this trend is yet unclear, but is associated with such risk factors as obesity, alcohol intake, lifestyle and diet. This suggests a multi-factorial exposome-related aetiology, with changes to the gut microbiome likely to play a role. **Methods:** In this study, we investigated differences in the tumour-resident microbiome and molecular characteristics between patient cohorts of EOCRC and late-onset CRC (LOCRC). Transcriptomic analysis was carried out on pre-treatment tumours from a cohort of 19 EOCRC patients and compared to a control group of 196 LOCRC aged over 65 years. Bioinformatics analysis of RNA sequencing data was used to analyse tumour microbial abundance and taxonomy, differential gene expression and gene-set enrichment between the two groups, as well as assign consensus molecular subtypes (CMS) . **Results:** We found an increase in expression of genes involved in the cell cycle in the EOCRC cohort, and of specific genes (e.g. HOXA11-AS, STMN2) involved in cell proliferation and metastasis. Converesly, enriched gene sets in the late-onset category were predominantly related to immune function. When grouping CMS subtypes as immune-rich (CMS1/CMS4) versus immune-depleted (CMS2/CMS3), there was a significant difference between the two groups with 94% of EOCRC tumours being immune-depleted, compared to 67% of late-onset tumours (p = $<$ 0.05). Meanwhile, we found an increase in bacterial richness (observed alpha diversity) in the late-onset tumours compared to early-onset, while there were no differences in the Shannon alpha diversity measures (richness and evenness), and in beta diversity between the groups. We also found a depletion of the bacteria *Helicobacter canadensis* and *Campylobacteria ureolyticus* in the early-onset cohort, while there was an increase in *Lachnospiraceae* species. **Conclusions:** Our results add to the growing body of evidence that EOCRC is a distinct disease from LOCRC. EOCRC shows lower tumour-immune activation compared to LOCRC and very low rates of CMS1 and CMS4 subtypes, which is associated with a distinct tumour-resident microbiome. This may have implications for prognosis and targeted treatments. Research Sponsor: None.

Prognostic and predictive impact of the baseline systemic proteome in patients with *RAS* wild-type metastatic colorectal cancer: Analysis from the randomized phase II PanaMa (AIO KRK0212) trial. First Author: Alexej Ballhausen, Department of Hematology, Oncology and Tumorimmunology, Charité-Universitätsmedizin Berlin, Freie Universität Berlin, Humboldt-Universität zu Berlin, and Berlin Institute of Health, Berlin, Germany

Background: Systemic proteomics offers a minimally invasive approach to identifying biomarkers in metastatic colorectal cancer (mCRC). This study analyzed the prognostic and predictive potential of the systemic proteome in *RAS* wild-type (wt) mCRC patients from the PanaMa trial, which investigated maintenance therapy with fluorouracil/folinic acid (FU/FA) $\pm$ panitumumab (Pmab) following induction with FU/FA plus oxaliplatin and Pmab. **Methods:** Baseline serum samples were analyzed using liquid chromatography-mass spectrometry to identify protein markers. Their impact on overall survival (OS) and progression-free survival (PFS) was evaluated using Kaplan-Meier estimates and Cox regression. Prognostic analyses utilized hierarchical clustering and random forest models to delineate protein groups associated with survival outcomes, enhanced by sparse partial least squares discriminant analysis for feature selection. Gene ontology analysis was used to identify biological functions of these markers. ROC analysis was performed to evaluate the accuracy of prognostic protein signatures. For predictive analysis, PFS outcomes of maintenance with FU/FA $\pm$ Pmab were assessed using Kaplan-Meier estimates and Cox regression. Hazard ratios (HR), differences in hazard ratios (delta HR), and statistical significance (p-values) were used to differentiate patient outcomes based on protein marker expression. **Results:** Of 378 patients treated in the trial, 231 had baseline serum samples. Proteomic clustering identified two survival clusters: the high-survivability cluster showed significantly longer induction PFS (HR 0.75, 95% CI 0.56–1.00, P = 0.05) and OS (HR 0.63, 95% CI 0.45–0.88, P = 0.01). Hierarchical clustering revealed 470 proteins, with specific proteins enriched in high-survivability (e.g., ALB, APOA2) and low-survivability (e.g., SERPINA3, CRP) clusters. Gene ontology analysis highlighted distinct pathways, such as enzyme inhibitor activity in low-survivability clusters and peptidase regulator activity in high-survivability clusters. For maintenance, prognostic arm-specific proteomic signatures linked to improved PFS with strong accuracy in the FU/FA + Pmab arm (AUC 0.99), and FU/FA arm (AUC 1.00). Predictive analysis revealed a total of eight proteins that predicted benefit of Pmab addition to maintenance. A positive combined proteomic biomarker including these proteins (ITIH4, FLNC, HP, CTPS1, SERPINA1, HRG, MAN1C1, C4A) predicted significant benefit of addition of Pmab to FU/FA maintenance (PFS: HR 0.68, 95% CI 0.49–0.95, P = 6.4e-09). **Conclusions:** Proteomic profiling identified prognostic clusters linked to distinct survival outcomes and predictive signatures for FU/FA $\pm$ Pmab maintenance, supporting its utility in guiding personalized treatment strategies for *RAS* wt mCRC. Prognostic and predictive role of HLA supertypes in pMMR mCRC patients receiving FOLFOXIRI/bev $\pm$ atezolizumab in the AtezoTRIBE study. First Author: Daniele Rossini, Department of Experimental and Clinical Medicine, University of Florence. Oncology Unit, Careggi University Hospital, Florence, Italy

Background: The HLA system plays a crucial role in the development of the adaptive immune response, influencing antigen presentation and T-cell-mediated tumour recognition. Emerging evidence suggests that specific HLA allele groups named supertypes may influence the efficacy of immune-checkpoint inhibitors (ICIs). We investigated the impact of HLA supertypes in the pMMR cohort of mCRC patients (pts) treated with FOLFOXIRI/bev $\pm$ atezolizumab in the AtezoTRIBE study. **Methods:** Genomic DNA from blood samples was genotyped using Oncoarray, a custom array manufactured by Illumina including approximately 530K SNP markers. HLA class I and II alleles were characterized with minimac3 algorithm using the Four-digit Multi-ethnic HLA v2 (2022) reference panel. The presence of 22 HLA supertypes were assigned based on the imputed dosages across relevant alleles. The effects of HLA supertypes on survival were evaluated with Cox proportional hazard models. Given the exploratory nature of the analysis, no adjustments for multiple comparisons were applied. **Results:** Among 153 assessed pts (102 and 51 treated with FOLFOXIRI/bev/atezo and FOLFOXIRI/bev, respectively), B44 and DR9 supertypes were associated with worse prognosis in terms of both PFS (mPFS 11.4 months (mos) for B44 pos vs 13.9 mos for B44 neg; HR 1.74; 95% CI 1.19–2.52; p = 0.004, and mPFS 11.4 mos for DR9 pos vs 13.2 mos for DR9 neg; HR 2.37; 95% CI 1.01–5.60; p = 0.04, respectively) and OS (mOS 29.6 mos for B44 pos vs 36.6 mos for B44 neg; HR 1.59; 95% CI 1.03–2.45; p = 0.038, and mOS 26.6 for DR9 pos vs 33.9 mos for DR9 neg; HR 3.22; 95% CI 1.24–8.38; p = 0.017, respectively) in multivariable analysis. As summarized in the Table, PFS and OS benefit from the addition of atezolizumab to FOLFOXIRI/bev was reported among A3 neg but not A3 pos patients, and B8 pos patients derived higher benefit than B8 neg. **Conclusions:** Our exploratory findings suggest that HLA supertypes could influence prognosis and ICIs-based treatment efficacy in pMMR mCRC pts. In particular, B8 and A3 supertypes could identify patients more likely to benefit from the addition of ICIs to FOLFOXIRI/bev. These findings highlight the potential of HLA profiling to optimize the use of immunotherapy in pMMR mCRC pts. Research Sponsor: GONO Foundation.

Impact of Medicare Advantage (MA) on timely initiation of pembrolizumab among dMMR/MSI-h metastatic colorectal cancer patients. First Author: Baqir Jafry, Charleston Area Medical Center, Charleston, WV

Background: With MA plans covering over half of Medicare beneficiaries, concerns remain about their ability to manage complex cancer care due to pre-authorization and limited provider network. This study evaluates MA versus Traditional Medicare (TM) regarding timely initiation of Pembrolizumab for dMMR/MSI-H colorectal cancer (CRC), following its 2020 FDA approval. **Methods:** This study utilized nationwide Flatiron Health Electronic Health Record-derived de-identified database. We included patients diagnosed with dMMR/MSI-H CRC from 2020 onward, aged ≥65 years, who had at least one clinic visit within six months of diagnosis and were insured under MA or TM. The primary endpoint was initiation of Pembrolizumab within 30-, 45-, and 90-days post-diagnosis. Multivariable logistic regression with Inverse Probability Weighting, adjusted for SES (defined by Yost score), age, race, ECOG, practice type and diagnosis year, evaluated impact of insurance type on timely treatment initiation. **Results:** Out of 597 dMMR/MSI-H metastatic CRC patients identified since 2020, 219 had at least one clinical visit under MA (N = 86) or TM (N = 133) plans. Predominantly, patients in our cohort were non-Hispanic White (72%), with higher SES (59%), diagnosed with de novo dMMR/MSI-H (59%), and treated in community hospitals (86%). Of 95 patients who commenced pembrolizumab as initial therapy, 62 (65%) had TM and 33 (35%) had MA. The adjusted analysis revealed that MA patients were significantly less likely to start pembrolizumab within 90 days of diagnosis compared to TM patients (OR: 0.58; 95% CI: 0.34-0.97; P: 0.04). There were no statistical differences in starting treatment at 30 (OR: 0.79; 95% CI: 0.39-1.56; P: 0.5) or 45 days (OR: 0.87; 95% CI: 0.48-1.57; P: 0.7). Subgroup analysis indicated substantial delays in pembrolizumab initiation within 90 days among lowest SES (OR: 0.31; 95% CI: 0.13-0.71; P: 0.007; P-interaction: 0.087) and those treated in community hospitals (OR: 0.49; 95% CI: 0.27-0.87; P: 0.016; P-interaction: 0.095). **Conclusions:** Patients with TM were more likely to initiate pembrolizumab earlier than those with MA. This underscores necessity to scrutinize the influence of MA on cancer delivery, especially for patients with lower SES. Research Sponsor: None.

Outcomes of young-onset colorectal cancer vs late-onset colorectal cancer patients on phase 1 matched and non-matched therapies. First Author: Daniel Aaron Fox, Baylor College of Medicine, Houston, TX

Background: Systemic therapy recommendations for young-onset colorectal cancer (YOCRC), CRC diagnosed at < 50 years old, are similar for late-onset CRC (LOCRC) despite possible differences in biologic behavior. This study aims to compare outcomes among YOCRC and LOCRC patients on Phase 1 matched and non-matched therapies. **Methods:** This was a single-institution retrospective analysis of patients with CRC who received treatment on a Phase 1 clinical trial. Only the first Phase 1 therapy for each patient was included in analysis. Matched therapy was defined as therapy targeting genomic alterations or their signaling pathways. Distributions of progression-free survival (PFS) were estimated by the Kaplan-Meier method. Log-rank test was performed to test the difference in survival between groups. A propensity score matched analysis was created using a multivariate logistic regression model. Covariates in the model included: gender, race, lung metastasis, liver metastasis and tumor sidedness. **Results:** 577 patients were included in analysis (Table 1). 252 patients had YOCRC (43.7%) and 325 had LOCRC (56.3%). 100 YOCRC patients (39.7%) and 90 LOCRC patients (27.7%) received matched therapies. Before propensity score matching YOCRC patients on matched therapy had higher odds of achieving a response compared to LOCRC patients on matched therapy (complete response/partial response) (10.5% vs 3.4%, odds ratio (OR): 3.294 (95% confidence interval (CI)): 0.876, 12.390), p=0.0777). After propensity score matching YOCRC patients on matched therapy had higher odds of achieving a response compared to LOCRC patients on matched therapy (13.3% vs 3.9%, OR was not estimable, p=0.0082). No significant differences in overall response rate were detected between YOCRC and LOCRC patients on non-matched therapy before or after propensity score matching (5.4% vs. 4.1%, OR: 1.362 (95% CI: 0.513, 3.615), p=0.5348; 5.5 vs. 4.3%, OR: 1.167 (CI: 0.392, 3.472), p=0.7815). No significant differences in PFS were detected between patient with YOCRC and those with LOCRC in any of the patient cohorts before or after propensity score matching (all patients: p=0.743, p=0.639; patients receiving matched therapy: p=0.497, p=0.909; patients receiving non-matched therapy: p=0.999, p=0.62). **Conclusions:** YOCRC patients were more likely than LOCRC patients to achieve a response on matched therapy though this did not translate to improved PFS. Nevertheless, matched therapies are associated with increased response rate for YOCRC patients. Research Sponsor: None.

Amivantamab treatment and intra-tumoral gene expression and immune cell changes in refractory metastatic colorectal cancer (mCRC): Whole transcriptome RNA-sequencing analysis from the OrigAMI-1 study. First Author: Cathy Eng, Vanderbilt-Ingram Cancer Center, Nashville, TN

Background: Amivantamab (ami) is an FDA- and EMA-approved EGFR-MET bispecific antibody with immune cell–directing activity for *EGFR*-mutated advanced non-small cell lung cancer. Ami monotherapy has shown promising activity in participants (pts) with refractory mCRC, independent of primary tumor sidedness (left- or right-sided). Here, we analyzed gene expression data from the OrigAMI-1 study to identify mechanisms of sensitivity and action in response to ami monotherapy. **Methods:** The phase 1b/2 OrigAMI-1 study (NCT05379595) enrolled pts with mCRC harboring wild-type *KRAS*, *NRAS*, *BRAF*, and *EGFR* ectodomain, without *ERBB2*/*HER2* amplification. Pts with left-sided mCRC without prior anti-EGFR therapy (Cohort A) and with prior anti-EGFR therapy (Cohort B), as well as pts with right-sided mCRC (Cohort C) received intravenous ami monotherapy (1050 mg; ≥80 kg: 1400 mg). Tumor biopsy samples were collected at screening and Cycle 3 Day 1 (C3D1; if feasible). Whole transcriptome RNA-sequencing data of paired baseline and C3D1 tumor samples were generated by Foundation Medicine. Gene expression data were analyzed using standard bioinformatic methods to identify gene signatures associated with ami treatment in baseline tumor samples (n = 76) and paired baseline and C3D1 tumor samples (n = 17). **Results:** High baseline mRNA expression of AREG and EREG ligands was associated with treatment response across all cohorts (n = 76). In Cohort A (n = 16), median progression-free survival was significantly longer for pts with high (n = 8) vs low (n = 8) AREG expression (9.1 mo vs 4.5 mo, respectively; $P < 0.01$). Differential expression analyses after ami treatment showed significant changes in > 800 genes ($P < 0.01$) across all cohorts (n = 17). The EGFR pathway was significantly downregulated after ami treatment ($P < 0.01$). Pathway enrichment analyses identified significant enrichment of cell cycle and natural killer (NK) cell–mediated cytotoxicity pathways. The cell cycle pathway score was significantly downregulated following ami treatment ($P < 0.01$), implying reduced cell proliferation. A significant upregulation of dendritic cell ($P < 0.005$) and T-cell–inflamed signature scores ($P < 0.05$) was observed with ami treatment, potentially implying increased immune cell infiltration of the tumor microenvironment. Ami also increased the cytolytic ($P < 0.05$) and NK cell–mediated cytotoxicity pathway scores ($P < 0.05$), implying an increase in cytotoxic immune cells. Additional biomarker analyses are ongoing and will be presented at the meeting. **Conclusions:** Amivantamab downregulates EGFR and cell cycle pathways and increases cytotoxic immune cell signatures consistent with immune cell infiltration into tumors. Elevated AREG and EREG ligand expression correlated with response in wild-type refractory mCRC. Clinical trial information: NCT05379595. Research Sponsor: Janssen Research & Development, LLC, a Johnson & Johnson company.

3551 Poster Session

Phase 1 dose escalation results of the WEE1 inhibitor, azenosertib (A), in combination with encorafenib (E) and cetuximab (C) in patients (pts) with previously treated *BRAF V600E* mutant metastatic colorectal cancer (mCRC). First Author: Jeanne Tie, Department of Medical Oncology, Peter MacCallum Cancer Centre, Melbourne, VIC, Australia

Background: Encorafenib + cetuximab was approved for treating pts with *BRAF V600E* mutant mCRC after prior systemic therapy based on the Phase 3 BEACON study (observed response rate 20%; Kopetz et al. 2019). Azenosertib is a highly selective WEE1 inhibitor that causes mitotic catastrophe and cell death. Combining BRAF targeting treatment (E+C) with orthogonal pathway inhibitors may allow for an additive or synergistic combination effect of A. This study aimed to evaluate safety and tolerability, determine the maximum tolerated dose (MTD), and assess anti-tumor activity in pts with *BRAF* V600E mutant mCRC receiving A+E+C. **Methods:** This phase 1 dose escalation, open-label, multicenter study (NCT05743036) evaluated safety, tolerability, and activity of A administered in combination with E+C in adult pts with *BRAF V600E*-mutant mCRC who received 1-3 prior regimens for metastatic disease. Azenosertib is a CYP3A4 substrate and is predicted to moderately inhibit CYP3A4 while weakly inhibiting CYP2C19. Encorafenib is primarily metabolized by CYP3A4 and CYP2C19, and acts as a CYP3A4 inducer. To allow for exposures to optimize treatment benefits and minimize toxicity, the recommended starting dose of E is 150 mg once a week. The primary endpoint was dose-limiting toxicities (DLTs) in cycle 1. Pts were treated across 5 dose-finding cohorts, receiving A (dose range: 100 mg-400 mg once a day [QD] oral [PO] on a continuous schedule) and E (dose range: 75 mg or 150 mg QD PO), and C (500 mg/m^2 intravenous twice a week) until disease progression or unacceptable toxicity. **Results:** As of Nov 25, 2024, 44 pts were enrolled and treated with a median age of 64 years. 52.3% of pts received ≥2 prior lines of therapy, 34 pts were BRAF inhibitor (BRAFi)-naïve. The most frequent treatment-related Grade ≥3 adverse events were asthenia (11.4%) and fatigue (6.8%). DLTs were observed at the dose levels of A300+E150 and A400+E75 and included dose-limiting fatigue, atrial fibrillation, recurring elevated bilirubin (all Grade 3), and Grade 4 neutropenia. The MTD was determined to be A300+E75 and C. Twelve of 34 (35.3%) BRAFi-naïve pts achieved confirmed response per RECIST v1.1 (2 complete response, 10 partial response [PR]) while none of the BRAFi-pretreated pts responded. Seven of 17 (41.2%) BRAFi-naïve pts treated at A300+75 or A300+150 achieved confirmed PR. The median duration of response and the median progression-free survival in the BRAFi-naïve pts were 5.6 and 5.4 months, respectively. **Conclusions:** The combination of A+E+C was well tolerated at the MTD and yielded response rates in BRAFi-naïve mCRC pts which exceeded the historical data from the E+C doublet. Clinical trial information: NCT05743036. Research Sponsor: Zentalis.

Low-pass whole methylome sequencing–based liquid biopsy for metastatic colorectal cancer monitoring in the VALENTINO trial. First Author: Paolo Manca, Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy

Background: The amount of ctDNA is a proxy for metastatic colorectal cancer (mCRC) disease burden, with potentials for prognostic stratification and treatment monitoring. We investigated two methods based on low-pass whole genome and methylome sequencing (WGS and WMS) for ctDNA detection and quantification in the VALENTINO trial. **Methods:** All patients from the VALENTINO trial - a phase II trial comparing the addition of 5FU to Panitumamb-based maintenance after first line FOLFOX+Panitumamb induction in RAS wild-type mCRC - were eligible. Baseline (BL) and 8-week (8w) plasma samples were collected for low-pass WGS and WMS analysis. Two methods for ctDNA quantification based on DNA methylation (METER) and copy number alterations (ichorCNA) were assayed. Chi-squared, Wilcoxon and Cox regression tests were used. Performances of WMS and variant allele fraction (VAF) of a 14-gene panel were compared. **Results:** A BL liquid biopsy was available for 154 patients, with 142 also having an 8w assessment. METER and ichorCNA detected ctDNA in 112 (72.7%) and 94 (59.7%) BL samples, respectively; all discordant cases were METER+ but ichorCNA-. Detection rate increased in the presence of liver metastases (86.0% vs 42.6% for METER, 75.7% vs 23.4% for ichorCNA; both $p < 0.001$) and decreased with peritoneal metastases (55.6% vs 78.0% for METER, 38.9% vs 66.1% for ichorCNA; p = 0.011, p = 0.006). Tumor fraction (TF) of both BL METER and ichorCNA correlated with the diameter of measurable lesions (both $p < 0.001$) and CEA ($p < 0.001$ and p = 0.010). Both PFS and OS were shorter after baseline ctDNA detection with METER (mPFS: 10.6 vs 18.6 months, HR: 1.65, p = 0.010; mOS: 28.7 vs 62.2 months; HR: 2.24, 95%CI: 1.37-3.66; p = 0.001) or ichorCNA (mPFS: 10.6 vs 15.0 months, HR: 1.42, 95%CI: 1.00-2.00, p = 0.047; mOS: 27.8 vs 48.4 months, HR: 1.35, 95%CI: 1.29-2.95; p = 0.002). In the multivariate analysis, METER ctDNA detection was the strongest predictor of both PFS and OS (p = 0.005 and p = 0.001) while ichorCNA ctDNA detection was significantly associated with OS but not with PFS (p = 0.002 and p = 0.093). METER ctDNA TF decreased significantly at 8w in patients with CR, PR, or SD (paired Wilcoxon p = 0.015, $p < 0.001$, $p < 0.001$) but not PD (p = 0.560) as the best radiological response. Patients without METER ctDNA clearance at 8w had a higher risks of progression (HR: 2.70, 95%CI: 1.63-4.49; $p < 0.001$) and death (HR: 3.37, 95% CI: 2.00-5.69; $p < 0.001$). Among 123 patients with both METER and VAF available, concordance was 78.0% and in 10 and 17 patients, respectively, ctDNA was detected only with METER or only with VAF. The mPFS and mOS of discordant cases were longer than METER+ / VAF+ cases and shorter than METER− / VAF− cases. **Conclusions:** CtDNA quantification with low-pass WMS by METER retains a prognostic significance, can be used for disease monitoring during treatment and refines ctDNA detection based on a restricted gene panel assay. Clinical trial information: NCT02476045. Research Sponsor: None.

Vilastobart (XTX101), a tumor-activated, Fc-enhanced anti–CTLA-4 monoclonal antibody, in combination with atezolizumab in patients with MSS CRC. First Author: Marwan Fakih, City of Hope Comprehensive Cancer Center, Duarte, CA

Background: Vilastobart (XTX101) is tumor-activated, high affinity, Fc-enhanced aCTLA-4 designed to focus activity toward the tumor and minimize systemic adverse events. Fc-enhancement augments FcγR co-engagement on antigen presenting cells and has been linked with efficacy of aCTLA-4 combinations in patients (pts) with microsatellite stable (MSS) colorectal cancer (CRC) and other tumors [Fakih ASCO GI 2025]. Vilastobart was generally well-tolerated and demonstrated evidence of anti-tumor activity in pts with immunologically "cold" advanced solid tumors, both as a monotherapy and in combination with atezolizumab [Davar SITC 2024]. **Methods:** Phase 2 of the NCT04896697 study evaluated the initial recommended Phase 2 dose of vilastobart 100 mg Q6W in combination with atezolizumab 1200 mg Q3W in pts with MSS CRC who had at least 1 prior chemotherapy regimen in the metastatic setting, excluding pts with prior immune checkpoint inhibitors. Pts with (LM) and without liver metastasis (NLM) were eligible. Tumor biopsies were obtained before and during treatment for translational analyses. **Results:** As of January 13, 2025, 40 pts were dosed in Phase 2. Median age was 55 (25-82) and 70% of pts had 3 or more prior lines of therapy. Of the 24 enrolled NLM pts, 11 were response-evaluable with an available on-treatment scan as of the data cut. In these 11 pts, two confirmed and one unconfirmed partial response (PR) were reported, all accompanied by significant decreases in ctDNA and serum tumor marker CEA and with each pt ongoing on therapy, for a preliminary ORR of 27%. One additional pt (with peritoneal metastasis) had a 24% reduction in target lesions (first scan) and was ongoing on therapy. Of the 16 enrolled LM pts, 7 were response evaluable, with one stable disease and another pt reporting a mixed response with significant serum tumor marker reductions, both ongoing on therapy. Of note, one LM pt in Phase 1C dose escalation treated with vilastobart (150 mg Q6W) combination had a confirmed PR with LM resolution. Six pts (15%) reported G3+ treatment-related adverse events (TRAEs), with two G4 laboratory TRAEs and no G5 TRAEs. Only three pts discontinued therapy for TRAEs. TRAEs occurring in ≥10% (all grade) or ≥5% (G3) of pts are summarized in the Table. **Conclusions:** The combination of vilastobart, a novel tumor-activated, Fc-enhanced a-CTLA-4, and atezolizumab demonstrated initial evidence of anti-tumor activity in late line, metastatic MSS CRC where immune checkpoint blockade has historically been relatively ineffective. Vilastobart was observed to have a differentiated safety profile distinct from systemically active a-CTLA-4, consistent with tumor-selective activation. Clinical trial information: NCT04896697. Research Sponsor: Xilio Therapeutics.

mFOLFIRINOX efficacy as rescue regimen for patients with metastatic refractory colorectal cancer: The RE-PLAY trial. First Author: Paulo Marcelo Hoff, Instituto do Câncer do Estado de São Paulo, University of São Paulo and Instituto D'Or de Pesquisa e Ensino, São Paulo, Brazil

Background: Doublets with Fluoropyrimidines (F), oxaliplatin (Ox), and irinotecan (Ir) are standard chemotherapy agents used to treat metastatic colorectal cancer (mCCR). The role of triplet combination with modified FOLFIRINOX (mFOLFIRINOX) in refractory patients (pts) previously treated with doublets or monotherapy sequential regimens remains unclear. **Methods:** This single-arm, open-label phase II trial employed a Simon two-stage design. Eligible pts had mCCR with documented progression after treatment with doublets or sequential monotherapy regimens containing F, Ox, and Ir. Pts with RAS wild-type tumors were required to be refractory to anti-EGFR therapy. The mFOLFIRINOX regimen consisted of 5-FU (2400 mg/m², continuous infusion over 46 hours), Ox (85 mg/m², D1), Ir (150 mg/m², D1), and leucovorin (200 mg/m², D1), administered every 14 days. The primary endpoint was the disease control rate (DCR) as assessed by RECIST v1.1. According to the Simon design, the study would be considered positive if 4 or more pts achieve disease control among 25 pts in the second stage. Secondary endpoints included objective response rate (ORR), progression-free survival (PFS), overall survival (OS), and safety. **Results:** Between October 2021 and October 2024, 25 pts were enrolled. Three pts did not receive treatment due to consent withdrawal (n = 1) or clinical deterioration from disease progression before treatment initiation (n = 2). All pts had proficient mismatch repair (pMMR) tumors; 16 (64%) had KRAS/NRAS mutations, and most tumors were left-sided (n = 20, 80%). At Intention to Treat analyses, 16.6% (n = 4) achieved a partial response, 44% (n = 11) had stable disease, and 28% (n = 7) experienced disease progression as their best radiologic response. The DCR was 60% (n = 15), and the ORR was 16.6% (n = 4). With a median follow-up of 6.8 months, 17 pts experienced disease progression or death. The median PFS was 5.7 months, and the median OS was 9.3 months. No significant differences in DCR, ORR, PFS, or OS were observed based on RAS mutation status or tumor sidedness; among 22 pts who received at least one cycle of mFOLFIRINOX, 68.1% (n = 15) experienced grade 3 or higher adverse events, including one treatment-related death. **Conclusions:** mFOLFIRINOX demonstrated efficacy as a rescue regimen for refractory mCCR previously refractory to doublets or sequential monotherapy regimens containing Ox, Ir, fluoropyrimidines, and anti-EGFR therapy. Clinical trial information: NCT05354817. Research Sponsor: None.

Analysis of mutational profiles and their correlation with organ-specific metastases in MSS and *BRAF*wt colorectal cancer (mCRC). First Author: Francesc Salva, Vall d'Hebron Institute of Oncology (VHIO), Vall d'Hebron University Hospital, Barcelona, Spain

Background: In *BRAF*wt/ MSS mCRC, the mechanisms driving distinct metastatic dissemination patterns remain unclear. Understanding them is crucial, as dissemination profiles influence therapeutic strategies, such as immunotherapy for patients (pts) without liver metastasis (mets) or locoregional approaches and liver transplantation for those with liver-limited disease. NGS advances provide genomic data, offering opportunities to identify predictive signatures that link molecular profiles to metastatic patterns. This study investigates mutational profiles to uncover correlations with organ-specific mets in pts treated at our institution. **Methods:** This study included pts with unresectable MSS/ *BRAF*wt mCRC treated at Vall d'Hebron Hospital (2010–2020). Pts were grouped into three clinical categories based on metastatic patterns: liver-limited disease (LLD), exclusively extrahepatic disease (EXTRAHEP), and hepatic and extrahepatic disease (BOTH). Molecular analyses were performed using NGS prescreening data available at our institution. Mutations were grouped in two approches: (1) by biological significance using cancer hallmark genes from published datasets (Zhang, *Front Genet* 2020; Sondka, *Nat Rev Cancer* 2018), and (2) by molecular pathways based on the Sanchez-Vega dataset (*Cell* 2018). Statistical analyses were conducted using R version 4.3.2. **Results:** A total of 1,026 pts were included (204 LLD, 297 EXTRAHEP, and 525 BOTH), with molecular analyses performed on 360 samples (35% overall; 31.8%, 39.7%, and 33.7%, in each group, respectively). The median number of genes with pathogenic mutations per sample differed significantly between groups: 2.28 in LLD, 2.44 in EXTRAHEP, and 2.65 in BOTH (p = 0.01). BOTH showed significantly greater increase than LLD in mutated genes associated with five of the ten analyzed hallmarks: activation of invasion and mets, resistance to cell death, evasion of growth suppressors, sustaining proliferative signaling, and replicative immortality. Compared to EXTRAHEP, BOTH also had more mutations in invasion and mets activation and proliferative signaling (adjusted p-value $<$ 0.05 for all the hallmarks mentioned). For pathway associations, WNT pathway activation was higher in BOTH than EXTRAHEP (p = 0.004), driven by more frequent APC mutations in BOTH (82% vs. 69%, adj. p = 0.049). **Conclusions:** This study provides evidence that pts with both hepatic and extrahepatic disease exhibit enrichment in five cancer hallmarks and the WNT pathway compared to other metastatic patterns. This suggests the tumor's potential to adapt to diverse microenvironments. Despite the statistical significance, the magnitude of the observed differences in mutated genes is not yet clinically useful. These findings highlight the need for collaborative efforts to develop mutational profiles that predict organotropism and guide therapy. Research Sponsor: None.

Patterns of immunotherapy use in dMMR/MSI-H metastatic CRC. First Author: Hayley Lemisch, Temple University Lewis Katz School of Medicine, Philadelphia, PA

Background: Immune checkpoint inhibitors (ICI) are more effective in mismatch repair deficient/microsatellite instability high (dMMR/MSI-H) metastatic colorectal cancers (mCRC) compared to chemotherapy (chemo). However, real-world data and patterns of use are limited. We evaluated real-world ICI use in mCRC after FDA approval in 2017 and approval as first-line (1L) therapy in 2020, and the impact on survival. **Methods:** We used the nationwide Flatiron Health electronic health record (EHR) derived de-identified database to determine patterns of ICI usage in patients diagnosed with dMMR/MSI-H mCRC since 2013. Trends in ICI use were estimated with the Cochran-Armitage test, while real-world time to next treatment (rwTTNT), progression free survival (rwPFS), and overall survival (OS) between ICI vs chemo only groups were estimated with Kaplan Meier curves and log-rank test. Multivariate Cox Proportional-Hazards Models were fitted to adjust for potential cofounding variables (ie sex, performance status (ECOG) and treatment). Hazard ratios, p-values and 95% confidence intervals are presented. Proportional hazards assumptions were tested for violations. **Results:** Of 41,431 patients diagnosed with mCRC since 2013, 1,707 were dMMR/MSI-H and received therapy; thus were included in the analyses. Mean age was 66 years, 925 (54%) were female, and 884 (52%) had de novo mCRC. BRAF and RAS mutations were detected in 604 (35%) and 372 (22%) patients, respectively. Of 1,707 eligible patients, 573 (34%) received 1L ICI and 1,116 (66%) received 1L chemo. Of those who received 1L ICI, 480 (43%) received a single ICI and 56 (5%) received dual ICI. There was a linear increase in the proportion of ICI-based treatments used over time in both the 1L and second line (2L). With a median follow-up of 38.2 months (mo); median OS for patients who received 1L chemo was 25.9 mo vs 51.6 mo with 1L ICI (HR 0.62, p $<$ 0.0001, 95% CI 0.52-0.73). Presence of a BRAF mutation was associated with worse OS (median OS 44.4 mo, 95% CI 31.2-61.1) vs. no BRAF mutation (median OS not reached (NR), 95% CI 51.6-NR) in patients receiving 1L ICI (p = 0.0046). The presence of a RAS mutation was not significantly associated with OS. Median rwTTNT after 1L ICI was 31.8 mo (95% CI 23.7-50.2), compared to patients whose first ICI was in the 2L (21.9 mo [95% CI 12.9-36.8]) or third line (3L) (9.5 mo [95% CI 5.7-18.0]) (p = 0.0041). Median rwPFS for first receipt of ICI in the 1L was 18.1 mo (95% CI 13.2-30.1) compared to first receipt in 2L (8.3 mo [95% CI 6.5-14.5]) or 3L (4.8 mo [95% CI 4.0-13.7]) (p = 0.0032). **Conclusions:** There was a linear increase in the proportion of patients with dMMR/MSI-H mCRC treated with ICI, associated with FDA approvals in 2017 and 2020. Male gender and presence of a BRAF mutation in patients receiving 1L ICI and receipt of 1L chemo were inversely associated with OS. Receipt of ICI in earlier treatment lines was associated with increased rwPFS and rwTTNT. Patients with dMMR/MSI-H mCRC benefit from receiving early ICI. Research Sponsor: None.

Colorectal cancer with gene fusions: Navigating the genomic landscape and treatment selection in a phase I unit. First Author: Camila Braganca Xavier, Department of Investigational Cancer Therapeutics, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Gene fusions are rare genomic events in colorectal cancer (CRC) and can co-occur with other potentially actionable alterations. Navigating early-phase trial selection in this scenario can be challenging. Objectives: To evaluate the genomic landscape, treatment selection, and clinical outcomes of patients (pts) with CRC harboring gene fusions enrolled in at least one clinical trial in the Department of Investigational Cancer Therapeutics, The University of Texas, MD Anderson Cancer Center. **Methods:** We used a computerized data extraction tool to review clinical and genomic data of pts with CRC harboring gene fusions between June 2011 and June 2024. The actionability of the genomic alterations was classified by the Precision Oncology Decision Support team. Median overall survival (mOS) was defined as the time from consent to the date of death or last follow up. Kaplan-Meier method was used to estimate survival and the Cox proportional hazards model to evaluate the impact of multiple variables. **Results:** 56 pts were included (28 female; 28 male) with a median age of 50.5 years (range 25-84). Colon was the most frequent tumor location (n=29, 51.8%) followed by rectal (n=15, 26.8%), small bowel (n=8, 14.3%), and appendiceal (n=3, 5.3%). Most cases had adenocarcinoma histology (n=54, 96.4%). The median time from diagnosis to completion of the molecular test identifying the gene fusion was 3 mo (range 0-36) for pts whose tumors were diagnosed in the metastatic setting. A total of 65 fusions were identified (range 1-3 per pt); 48 of them occurring in actionable or potentially actionable genes (78.8%) and 17 in non-actionable genes (26.2%). RAS alterations were present in 27 cases (48.2%) and BRAF alterations in 10 cases (17.9%). 8 patients had alterations in ERBB2 (14.3%) and 32 in genes related to DNA damage repair (DDR; 57.1%). In total, patients were enrolled in 91 trials (range 1-7 per pt). Target therapy (TT) was offered to 33 pts (58.9%) while the remaining were offered non-TT (n=23, 41.1%). Treatment selection was fusion-driven in 10 cases (17.9%; 4 NTRK, 3 FGFR, 1 RET, 1 ROS1, and 1 ALK). Notably, one pt with a ETV6-NTRK fusion was enrolled sequentially in 4 immunotherapy (IO) and TT trials, surviving on-trial for over 3.5 years. 3 patients received TT for KRAS (5.4%), 4 for BRAF (7.1%), 4 for ERBB2 (7.1%), and 8 for DDR alterations (14.3%). The mOS was 10.0 mo (95% CI, 5-NR) for pts receiving non-TT and 11 mo (95% CI, 3-21) for patients receiving TT (p 0.985). Age group (cutoff 50 years), gender, cancer stage at diagnosis, RAS, BRAF and DDR alterations, and treatment type (TT vs. non-TT or IO) were not related to survival in the multivariate level (p=0.9). **Conclusions:** A comprehensive genomic evaluation of pts with CRC harboring gene fusions can expand early-phase treatment possibilities. DDR alterations are more frequent in this group than in unselected CRC cohorts and can represent an additional target for TT. Research Sponsor: None.

The efficacy of watch and wait strategy or surgery after neoadjuvant immunotherapy for locally advanced colorectal cancer with dMMR/MSI-H guided by ctDNA dynamic monitoring (WINDOW): A single-center, open-label, prospective, phase II study. First Author: Xuan Zhang, Yunnan Cancer Hospital, Kunming, Yunnan, China

Background: Circulating tumor DNA (ctDNA) has shown potential in predicting the efficacy of neoadjuvant treatment for colorectal cancer (CRC). However, evidence is limited for patients with deficient mismatch repair (dMMR) / microsatellite instability-high (MSI-H) CRC, who respond well to immunotherapy. This study explores an optimal ctDNA-guided neoadjuvant immunotherapy (nIT) strategy in locally advanced CRC (LACRC) patients with dMMR/MSI-H. **Methods:** We conducted a single-center, open-label, phase 2 trial named WINDOW involving dMMR/MSI-H LACRC patients. Patients received the anti-PD-1 antibody tislelizumab every three weeks. ctDNA was monitored at baseline, after 2, 4, 5, or even 6 to 8 cycles, and during post-watch-and-wait (W&W) or post-surgery periods using the Signatera platform. Starting from the 4th cycle, patients with two consecutive ctDNA-negative results were eligible for the W&W approach. Those who did not achieve ctDNA-negative or turned positive during follow-up continued immunotherapy. Surgery was performed for patients not meeting W&W criteria by the 8th cycle. The primary endpoint was the complete response (CR) rate, including ctDNA-negative clinical complete response (cCR) and pathological complete response (pCR). The trial is registered at ClinicalTrials.gov (NCT06477991). **Results:** From January 2023 to May 2024, 24 patients with stage II-III dMMR/MSI-H CRC were enrolled, including 18 with colon cancer and 6 with rectal cancer. At baseline, all patients had detectable ctDNA. After nIT, 87.5% (21/24) achieved two consecutive ctDNA-negative results. Among the remaining three, two underwent surgery due to sustained ctDNA-positivity (both TRG3), while one showed continuous ctDNA decrease despite obstruction and achieved pCR. One patient required emergency surgery for perforation (confirmed as pCR), while 20 were managed with the W&W strategy. Of these, 90% (18/20) achieved ctDNA negativity after two cycles, and 95% (19/20) after five cycles of nIT. With a median follow-up of 20.3 months (range: 8.7–25.0 months), none experienced recurrence, resulting in an overall CR rate of 91.7% (22/24). Notably, if ctDNA remained positive after the 5th cycle, the CR rate was only 25% (1/4), while it reached 100% (20/20) if ctDNA became negative. From the perspective of organ preservation, only 45.5% (10/22) of patients avoided surgery based on imaging alone; however, with ctDNA-guided management, 83.3% (20/24) avoided surgery. **Conclusions:** NIT demonstrates high efficacy in dMMR/MSI-H LACRC. The ctDNA-guided W&W strategy significantly improves organ preservation rates. Monitoring ctDNA negativity after the 5th cycle of nIT is a crucial marker of high CR rates, suggesting this cycle may represent the optimal monitoring window during nIT. Clinical trial information: NCT06477991. Research Sponsor: The Joint Special Funds for the Department of Science and Technology of Yunnan Province-Kunming Medical University; 202201AY070001-149.

Laparoscopic versus open liver resection for colorectal liver metastasis: An individual participant data meta-analysis of randomized controlled trials. First Author: Åsmund Avdem Fretland, Oslo University Hospital, Oslo, Norway

Background: Laparoscopic surgery for colorectal liver metastases (CRLM) is associated with lower physical impact, shorter length of stay and less postoperative morbidity than open surgery. To analyze oncological and procedural outcomes, a European consortium including principal investigators of all 4 completed RCTs on laparoscopic (LLR) vs open (OLR) liver resection performed an individual participant data meta-analysis (IPDMA), including updated survival data. **Methods:** This was an IPDMA with a primary endpoint of postoperative morbidity. Secondary endpoints included overall survival (OS), disease-free survival (DFS) and resection margin status. A generalized linear mixed model was used to compare OLR and LLR , with trial as a fixed-effect. Logistic regression analysis was performed for dichotomous variables and negative binominal regression analysis for continuous variables. Survival analyses were performed using Cox-regression. **Results:** A total of 761 patients with CRLM were randomly allocated to LLR (n = 384) or OLR (n = 377). Preoperative chemotherapy was administered as recommended by the local multidisciplinary team (40% vs 46%). Whilst LLR was associated with significantly less postoperative morbidity overall (19% vs 27%, adjusted OR 0.62 [95%CI 0.44 to 0.88]), this was not observed in the subgroup of patients receiving neoadjuvant chemotherapy (25% vs 24%, adjusted OR 1.06 [95%CI 0.63 to 1.79]), p-value for interaction < 0.001). Hospital stay was shorter after LLR (median 4 vs 5 days, adjusted percentage difference: -27 [95%CI -37 to -15]) All cause 90-day mortality was not significantly different (1.9% vs 0.8%, adjusted OR: 3.2 [95%CI 0.65 to 16.00]). At 5-year follow-up OS and DFS were not significantly different (adjusted HR 0.97 [95%CI 0.79 to 1.20] and 1.05 [95%CI 0.86 to 1.27], respectively). In patients who received preoperative chemotherapy, a trend towards fewer R0 resections in LLR compared to OLR was noted (84% vs 90%, adjusted OR 2.00 [95%CI 0.99 to 4.03], p-value for interaction = 0.053). In patients who did not receive preoperative chemotherapy there was no difference in R0 resections (90% vs 86%, adjusted OR 0.76 [95%CI 0.41 to 1.40]). Liver specific recurrence was not different between LLR and OLR (37% vs 37%, adjusted OR 1.02 [95%CI 0.76 to 1.34), neither was time to adjuvant chemotherapy (45 days vs 49 days, adjusted OR 1.12 [95%CI 0.91 to 1.38]) nor median number of adjuvant courses (8 vs 8, adjusted percentage difference 0.07 [95%CI -0.11 to 0.24]). **Conclusions:** This IPDMA of 761 patients in 4 RCTs across Europe confirms that laparoscopic resection for CRLM is superior to open resection with regards to short term outcomes, with no differences observed on long term oncological outcomes. However, in patients who received preoperative chemotherapy, the benefit of the laparoscopic approach is questionable. Research Sponsor: None.

Prognostic factors of survival and recurrence after liver transplantation for unresectable colorectal liver metastases: Results from the TransMet trial. First Author: Rene Adam, Paul Brousse Hospital, Villejuif, France

Background: Liver transplantation (LT) has recently proved to improve the survival of selected patients with unresectable colorectal liver metastases (uCRLM) compared to chemotherapy (C) alone. However, recurrence rates remain high, stressing the need for a better patient selection. This exploratory study aimed to identify prognostic factors associated with recurrence and death in patients undergoing LT as part of the TransMet trial. **Methods:** Data from 36 patients of the LT+C arm (per protocol population) were analyzed including age, gender, TNM and RAS status of the primary tumor, characteristics of metastases at diagnosis and at LT, chemotherapy regimen, tumor response (RECIST), and timeframe from primary resection to LT. Associations with recurrence and death were explored. Variables with > 5 observations per group and p-values ≤ 0.10 in univariable analysis were included in multivariable models. **Results:** Among the 36 transplanted patients, 27 experienced recurrence and 9 died after 50-month follow-up. Recurrence: At univariable analysis two factors were associated to a higher risk: serum CEA levels > 5 ng/ml at time of LT (11/11 vs 11/18, p 0.01) and oxaliplatin-based first line chemotherapy (14/16 vs 13/20, p 0.04). Two other factors showed a trend toward statistical significance: Female sex (14/15 vs 13/21, p 0.10) and > 20 metastases at diagnosis (11/17 vs 16/19, p 0.09). At multivariable analysis, CEA levels at LT > 5 ng/ml (HR: 2.91; 95% CI: 1.0–8.2; p 0.04) emerged as an independent predictor of recurrence. Female sex (HR: 2.2; 95% CI: 0.8–5.3; p 0.08) and oxaliplatin-based first line chemotherapy (HR: 2.0; 95% CI: 0.8–4.8; p 0.13) were also associated with around 2-fold higher risk of recurrence, although not reaching statistical significance. Death**:** At univariable analysis,two factorswere significantly associated with a higher risk: female sex (7/15 vs 2/21 for male, p 0.03) and > 24 cycles of chemotherapy before LT (8/19 vs 1/15, p 0.05). Two other factors showed a trend toward higher mortality: no response to 1st line chemotherapy (6/14 vs 3/22, p 0.06) and stable disease (vs partial response) before LT (8/22 vs 1/14, p 0.08). At multivariable analysis, female sex emerged as independent predictor of death (HR 5.1; 95% CI: 1.0-25.0; p = 0.04). More than 24 cycles of chemotherapy (HR 7.1; 95% CI: 0.9 – 51.0; p 0.07) and stable disease (vs partial response) at LT, showed an approximately 7-fold increase in the risk of mortality, although not reaching statistical significance. **Conclusions:** Within the limits of a reduced sample size, these results suggest that LT should be envisaged early in the history of potential candidates to LT to reduce the number of cycles of chemotherapy. Both morphological and biological tumor response, initially and at time of LT, are essential. The notable influence of female sex on post-LT outcome needs to be further explored. Clinical trial information: NCT02597348. Research Sponsor: None.

Impact of inflammatory bowel disease on outcomes of colorectal cancer patients undergoing open resection. First Author: Abhinav Malik, Freelance Physician, New Delhi, India

Background: Colorectal cancer(CRC) is, at present, the fourth most common cause of cancer in the United States, with more than 140,000 new cases and 52,000 deaths yearly. Patients with inflammatory bowel disease(IBD) are at increased risk of CRC secondary to the pro-neoplastic effects of chronic mucosal inflammation. Open resection is one of the treatment modalities among CRC patients. Research evaluating the impact of IBD on the short-term outcomes of open resection is limited. **Methods:** The National Inpatient sample was utilized to identify open resection procedures among colorectal cancer patients through International Classification of Diseases, 10th edition (ICD-10) codes. Our study contained patients ages 18 and older. We created two groups of patients consisting of cases with and without a history of IBD. Descriptive statistics were conducted for patient demographics and pre-existing comorbidities. We reported the adjusted odds ratio(aOR) and their 95% confidence intervals for differences in surgical and post-surgical complications. **Results:** This study investigated 318115 open resections among colorectal cancer patients, which involved 3675(1.2%) with IBD. The cases of IBD contained a younger sample with a mean age of 60.95 years, while our non-IBD group had a mean age of 66.95 years($p < 0.01$). In addition, IBD patients expressed a lower mean Charlson Comorbidity Index(CCI) score of 4.21(vs. 4.34, $p < 0.01$). Our IBD group presented with higher aOR of severe sepsis with septic shock (1.224, 95% CI 1.030-1.455, p = 0.022), acute kidney injury(AKI)(1.172, 95% CI 1.059-1.297, $p < 0.01$), cardiopulmonary resuscitation (CPR)(2.148, 95% CI 1.437-3.212, $p < 0.01$), and wound infection(1.377, 95% CI 1.139-1.664, $p < 0.01$). On the other hand, IBD was linked with lower odds of bleeding(aOR 0.808, 95% CI 0.686-0.952, p = 0.011) but was more likely to undergo blood transfusion(aOR 1.153, 95% CI 1.036-1.284, $p < 0.01$). However, events of acute respiratory failure (aOR 1.024, 95% CI 0.877-1.195, p = 0.767), postoperative pneumothorax(aOR 1.286, 95% CI 0.684-2.417, p = 0.436), use of mechanical ventilation(aOR 1.181, 95% CI 0.996-1.400, p = 0.056), vasopressors (aOR 1.012, 95% CI 0.780-1.315, p = 0.926), and all-cause mortality (aOR 1.026, 95% CI 0.808-1.304, p = 0.831) did not differ. **Conclusions:** Among CRC patients undergoing open resection, patients with IBD were younger and had higher odds of septic shock, AKI, CPR, wound infection, and blood transfusion. Although we failed to find differences in short-term mortality, it is crucial to conduct long-term studies to evaluate responses and relapses following open resection and post-discharge complications. Research Sponsor: None.

A multicenter randomized phase II trial assessing the efficacy and safety of mCapOX plus cetuximab and mFOLFOX6 plus cetuximab as first-line treatment for patients with RAS/BRAF wild-type metastatic colorectal cancer: Primary results of the CAPCET study. First Author: Yuwen Zhou, Colorectal Cancer Center, West China Hospital, Sichuan University, Chengdu, China

Background: This CAPCET randomized phase II trial was designed to assess the efficacy and safety of modified capecitabine and oxaliplatin (mCapOX) plus cetuximab (CET) and modified fluorouracil, leucovorin, and oxaliplatin (mFOLFOX6) plus cetuximab (CET) for the first-line treatment of left-side unresectable RAS/BRAF wild-type (wt) metastatic colorectal cancer (mCRC). **Methods:** CAPCET was an open-label, multicenter, randomized, non-comparative phase II trial. Patients with unresectable RAS/BRAF wt mCRC were randomly assigned (1:1) to receive up to 12 cycles biweekly mCapOX (capecitabine 1000mg/m^2 orally twice daily on Day 1-7 and oxaliplatin 85 mg/m^2 iv on Day 1) plus CET (500mg/m^2 iv on day 1) (arm A) or biweekly mFOLFOX6 (oxaliplatin 85 mg/m^2 iv on day 1, leucovorin 400 mg/m^2 iv on day 1, fluorouracil 400mg/m^2 iv bolus on day 1, then fluorouracil 2400 mg/m^2 continuous infusion over 46-48h) plus CET (500mg/m^2 iv on day 1)(arm B) followed by maintenance(either capecitabine plus CET or capecitabine alone at the discretion of the investigators) or treatment-free intervals until progression on treatment, toxicity, or death. The primary endpoint was progression-free survival (PFS) rate at 9 months from randomization. **Results:** Between September 2021 and April 2024, 168 patients (84 in arm A and 84 in arm B) were enrolled in 20 China centres. Baseline characteristics were well balanced between arms. After a median follow-up of 21.0 months (IQR,19.5-22.5), the 9 months-PFS rates were 70.9% (95% CI 61.1%-82.3%) in arm A and 66.8% (95% CI 56.7%-78.6%; HR = 1.11, P = 0.558) in arm B, and the primary endpoint was met. The median PFS (arm A/B) was 12.7 months (95% CI 10.8–15.2)/12.0 months (95% CI 9.7–14.1). The overall response rate (ORR) and disease control rate (DCR) in arm A were higher than those in arm B with 69.2% versus 60.3% and 96.2% versus 89.7%, respectively. The 2-year overall survival (OS) rate (arm A/B) was 66.8% (95% CI 54.2%–82.3%)/65.6% (95% CI 52.5%–82.0%), and the median OS not reached. Grade≥3 adverse events (AEs) occurred in 28.8% of safety population set (n = 156), with 7.7% in arm A and 21.2% in arm B. The most commonly Grade≥3 AEs was neutropenia, rash, leukopenia and there were no grade 5 AEs reported. **Conclusions:** The CAPCET study met its first endpoint of 9-month PFS rate in patients with RAS/BRAF wt mCRC. Biweekly mCapOX plus CET had higher ORR and DCR than mFOLFOX6 plus CET, with signally reduced toxicity. Longer follows-up and a multicenter, open-label, randomized, controlled Phase CAPCET- III study (NCT06616259) will be further validate this innovative regimen. Clinical trial information: NCT05022030. A medically tailored meal (MTM) delivery program to reduce nutritional decline and improve treatment tolerance in patients with colorectal cancer (CRC): A pilot study. First Author: Kara Stromberg, Fox Chase Cancer Center, Philadelphia, PA

Background: Colorectal cancer (CRC CA) is the 3rd most common CA among US adults. Over 50% of CRC patients (pts) present with advanced disease, necessitating adjuvant or palliative chemotherapy. Nearly 50% CRC pts will be diagnosed with malnutrition (MN) during their CA journey. MN is associated with reduced quality of life, poorer response to chemotherapy, and reduced survival. The provision of medically tailored meals (MTM) improves access to nutritious foods to support pts' caloric/nutrient needs and preferences. Remote delivery of MTMs could serve as an impactful intervention for pts at highest risk of MN and to improve treatment tolerance. **Methods:** Primary outcomes were feasibility (enrollment/adherence/retention) and acceptability of an MTM program in pts undergoing 5-FU based therapy for CRC; secondary included weight maintenance, MN measured by PG-SGA (Patient-Generated Subjective Global Assessment), HEI (Healthy Eating Index) score generated by VioScreen, a validated computerized food frequency tool, QOL measured by FACT-C/FACT-G, and treatment disruption. The MTM program included daily meals delivered weekly and nutritional counseling at 4 timepoints. **Results:** Among 100 eligible CRC pts approached, 48 consented and 52 declined, primarily due to lack of interest in MTMs (35/52, 67%). 40/48 (83%) initiated the MTM program and 32/40 (80%) completed it, including 13 (41%) Stage II/III and 19 (59%) Stage IV patients. 16/48 (33%) consented pts discontinued the study due to non-compliance (n = 4), post-consent refusal (n = 4), dissatisfaction w/ meals (n = 7) or death (n = 1). Pts had mean age of 56 yrs (range 32-78), with 51% female, 20% African American, and 15% Hispanic. 34% had < HS diploma, and 56% reported income of <$50,000. Enrollment (44%, goal > 50%, minimum 40%), counseling adherence (52.5%, goal > 66%, minimum 50%) and study retention rate (81%, goal > 70%) measured by end-of-study survey completion all surpassed a priori unfavorable result threshold (lower feasibility limit), but only retention met its target. Acceptability was high: 92% were satisfied with the MTM program and 91% would recommend it. Mean weight was maintained during study (181.2 lbs start, 181.6 lbs end) and mean PG-SGA score declined (7.5 to 5.4, indicating lower risk of MN at the end of the study). Mean HEI scores decreased slightly (63.3 start, 61.6 end, indicating a slight reduction in dietary quality) throughout the program; however, more than half of pts (56%, n = 14) demonstrated an increase in their HEI scores, suggesting improved quality of food consumed. **Conclusions:** Our MTM delivery program was highly acceptable and was associated with weight maintenance and improved PG-SGA scores in CRC pts receiving 5-FU based therapy. Further research of MTM delivery programs should consider retention challenges among pts facing advanced GI cancers. Research Sponsor: Manna Pilot Funding.

Relapse patterns, risk factors, re-resectability and survival after curative treatment for metastatic colorectal cancer (mCRC): A RAXO substudy. First Author: Pia J. Osterlund, Tampere University Hospital and Tampere Univeristy, Tampere, Finland

Background: In mCRC, metastasectomy and/or local ablative treatment (LAT) cures some. However, over 70% of the patients relapse, with liver, lung and peritoneum being the most common recurrence sites. Data on recurrence patterns and prognostic factors are mainly limited to patients with liver metastases treated before 2008. An update including patients also with multisite metastases treated up-to-date is needed. **Methods:** In this study, 323 patients from the RAXO-study (2012–2018) were analyzed, 312 patients had undergone R0–1 metastasectomy and 11 patients had A0–1 LAT. Three patients with postoperative death were excluded. The remaining 320 patients were prospectively followed for at least five years, with radiological imaging and blood tests every 3–6 months in the first two years and every 6–12 months thereafter. Median time to recurrence (mTTR), and overall survival (mOS) were estimated with Kaplan-Meier from the date of curative surgery/LAT for metastases known at baseline and compared using log-rank. Hazard ratios (HR) were estimated using Cox regression. **Results:** mTTR was 17 months (CI 95% 13–23 months) with 221 patients (69% of all) relapsing during follow-up. Totally 135 recurrences (42% of the patients at risk) occurred during the first year. During the second, third, fourth and fifth year, recurrence occurred in 48 (26%), 27 (20%), 7 (7%) and 1 (1%) patients at risk, respectively. Of patients relapsing during the first year, 65 (60%) were re-resected with numbers for subsequent years being 18 (67%), 3 (43%), 0 (0%) and 1 (33%), respectively. mTTR, mOS, and re-resectability outcomes for the most common recurrence sites are presented in the table. Regional lymph node metastasis (HR 1.4), RAS mutation (1.4), R1 resection (2.3) and treatment with LAT (2.4) were prognostic for recurrence ($p < 0.05$). **Conclusions:** Two-thirds of curatively treated mCRC patients relapse within the first four years. Curative-intent re-resection provides good OS for most sites of recurrence and should be considered when possible. Clinical trial information: NCT01531621. Single-slide histology-based deep learning model for mismatch repair deficiency prediction in colorectal cancer. First Author: Masoud Tafavvoghi, Oslo University Hospital, Oslo, Norway

Background: Mismatch repair deficiency (dMMR) is a critical predictive biomarker for determining eligibility and response to immunotherapy in colorectal cancer (CRC). The current gold standards for detecting dMMR include next-generation sequencing (NGS) for microsatellite instability (MSI) detection and immunohistochemistry (IHC) for mismatch repair protein expression. However, discrepancies between these techniques have been observed, potentially impacting clinical decisions and patient outcomes. To address this, we developed a histology-based deep learning (DL) model to predict MMR status, with a specific focus on resolving cases of discordance. **Methods:** Paired hematoxylin and eosin (H&E) slides from 974 CRC tumors were retrospectively collected from the Dana-Farber Cancer Institute, all of which had NGS Oncopanel and IHC MMR reports available. Using NGS-determined MMR status as the training reference, we developed a multi-instance deep learning model to predict MMR status from single H&E slides. Feature extraction employed various pathology foundation models (FMs). The dataset was split into training and tuning sets. A hold-out test set (n = 52, 65% dMMR) was curated including patients treated with immune checkpoint inhibitors or those with NGS-dMMR/IHC-proficient discordance. **Results:** Among the overall cohort, NGS/IHC concordance identified 82 dMMR patients (9%), 881 proficient MMR (pMMR) patients (90%), and 11 cases (1%) with NGS-dMMR/IHC-proficient discordance. In the hold-out test set, the fine-tuned CTransPath FM demonstrated the highest performance, achieving an area under the curve (AUC) of 0.88 (95% CI 0.77–0.98), a positive predictive value of 0.93, and correctly classifying 8 of 11 discordant cases (73%) as dMMR. Comparative FMs, CONCH and UNI, exhibited slightly lower AUCs (0.86 and 0.85, respectively) and lower accuracy in classifying discordant cases (Table). **Conclusions:** Our histology-based DL model shows promise as a complementary tool for IHC in predicting dMMR status in CRC. The single-slide approach offers a rapid, robust and cost-effective method to prioritize IHC-proficient cases for further validation by NGS. Cohort expansion and validation in an external dataset are underway. Research Sponsor: Norwegian Cancer Society.

Test set (n=52, 65% dMMR).

Model	AUC (CI,95%)	Sensitivity	Specificity	PPV	NPV	Accuracy NGS+/IHC-
CTransPath	0.88 (0.77-0.98)	0.85	0.89	0.93	0.76	8/11
CONCH	0.86 (0.76-0.96)	0.88	0.76	0.67	0.93	5/11
UNI	0.85 (0.74-0.96)	0.78	0.82	0.70	0.87	6/11

Time to treatment initiation (TTI) in patients with colorectal cancer and liver metastases. First Author: Kamran Steppe, The University of Oklahoma Health Sciences Center, Oklahoma City, OK

Background: In colorectal cancer (CRC), the liver represents a common site of metastatic disease, and patients with colorectal liver metastases (CRLM) may sometimes still achieve surgical resection of hepatic metastases. In oncology, delays initiating cancer treatment usually correspond with worse outcomes, yet factors associated with time to treatment initiation (TTI) in patients with CRLM remain unstudied. **Methods:** We utilized the National Cancer Database (NCDB) to identify adults (≥18 years old) with confirmed CRLM diagnosed between 2010-2021. We defined TTI as the number of days between cancer diagnosis and the first non-surgical treatment (radiation, immune, or chemotherapy). We excluded cases in which TTI equaled zero or exceeded 120 days. We compared median TTI across sociodemographic (i.e., age, race, income) and clinical (i.e., primary tumor site, tumor grade, comorbidities [Charlson-Deyo score]) factors reported in the NCDB using a non-parametric Kruskal-Wallis test. **Results:** We included 15,456 patients with CRLM diagnosed between 2010-2021 (55.1% of patients age < 60 years, 44.8% female, 76.3% White, 12.3% Black, 6.3% Hispanic, 3.6% Asian, 0.3% American Indian, 1.2% Other). The median (m) TTI for this cohort was 41 days, with TTI values trending down between subsequent years from 2010 (m = 45) to 2020 (m = 38) until 2021 (m = 41). We found significant differences ($p < 0.0001$) in median TTI across sociodemographic and clinical factors, as detailed in the following sentences. Advanced age (80+) had longer TTI (m = 53), compared with young patients (m = 33). For race/ethnicity, Black patients (m = 47) had the longest TTI, while Asian patients had the shortest (m = 39). Patients earning in the highest income quartile had the shortest TTI (m = 38) compared with those earning in the lowest quartile (m = 44). Patients living in ZIP codes with the highest quartile of high school diploma attainment had the lowest TTI (m = 38) compared with those in the lowest quartile (m = 43). TTI varied significantly by reported geographic location, with the Pacific region having the lowest (m = 37) and the East South Central having the highest TTI (m = 44). Patients with Charlson-Deyo comorbidity scores of 2 had the highest TTI (m = 48) and patients with scores of 0 the lowest (m = 41). Right sided primary tumor locations (m = 46) had longer TTI compared to left sided primary sites (m = 39). Tumor sizes greater than 6 cm (m = 45) received treatment later than tumor sizes less than 2 cm (m = 35). Lower grade tumors had longer TTI (m = 34) compared to high grade tumors (m = 28). **Conclusions:** In our study of patients with CRLM in the NCDB, the median TTI was just under 6 weeks. Our findings suggest that certain patient groups may be at risk of experiencing delays in care. These results could help to motivate and inform future efforts to enhance care delivery and access for patients with CRLM. Research Sponsor: None.

Immune checkpoint inhibitor (ICI) reuse after failure of first-line ICI in patients with metastatic dMMR/MSI gastrointestinal cancers: The INFLATE study. First Author: Léa Mercier, Institut Bergonié, Bordeaux, France

Background: Immune checkpoint inhibitors (ICIs) are a standard treatment for gastrointestinal (GI) cancers with mismatch repair deficiency (dMMR) or microsatellite instability (MSI). However, around 50% of patients develop resistance to ICIs, during treatment or after discontinuation. In these patients, the efficacy of reuse an ICI in patients progressing during a previous ICI (rechallenge), or in patients who progressed after discontinuation (reintroduction), remains unknown. The INFLATE study evaluates the efficacy of ICI reuse in patients who progressed on or after discontinuing ICI. **Methods:** This is a multicenter international retrospective study from the IMMUNODIG cohort, including patients from 34 centers in France, the United States, Italy, Belgium and Spain. All patients received ICI for dMMR/MSI GI cancer. We analyzed patients who had progressed following initial ICI (ICI-1) and subsequently received a rechallenge or a reintroduction with ICI (ICI-2), either monotherapy (mono-ICI) or biotherapy (bi-ICI). **Results:** A total of 77 patients were included, receiving bi-ICI (N = 34) or mono-ICI (N = 43) during ICI-2. The majority (76%) had a metastatic colorectal cancer. The reason for discontinuing ICI-1 was disease progression in 53% of cases, end of treatment in 15%, toxicity in 5% and other reasons in 26%. Patients who discontinued ICI-1 due to progression received MONO-ICI-2 in 29% of cases and BI-ICI-2 in 71%, whereas those who stopped for other reasons received MONO-ICI-2 in 86% and BI-ICI-2 in 14% of cases. Efficacy results are shown in Table 1. The ORR and DCR were 26% and 79% with MONO-ICI-2, and 16% and 71% with BI-ICI-2. Among patients who discontinued ICI-1 due to progression, BI-ICI-2 (N = 29) achieved an ORR and DCR of 8% and 65%, with a median PFS of 5.5 months (95%CI 4.07-10.4). These outcomes were 17%, 67%, and 3.7 months (95%CI 2.37-NA), respectively, with MONO-ICI-2 (N = 12). For patients who discontinued ICI-1 for reasons other than progression, BI-ICI-2 (N = 5) achieved an ORR and DCR of 60% and 100%, with a median PFS not reached (95%CI 11.5-NR), while MONO-ICI-2 (N = 31) achieved 29%, 82%, and 14.2 months (95%CI 11.2–NR), respectively. **Conclusions:** This is the first multicenter real-world study evaluating ICI reuse in dMMR/MSI GI cancers. In patients who discontinued ICI for reasons other than progression, reintroduction of ICI therapy upon progression achieves tumor control in 85% of cases. In cases of progression on mono-ICI, Bi-ICI re-challenge achieve tumor control in two-thirds of cases and might be to consider in some patients. Research Sponsor: None.

	ORR %	DCR %	PFS median (95%CI)	OS median (95%CI)
Overall N=77	21	76	7.65 months (5.5–11.5)	27.6 months (22.2–55.7)
Discontinued ICI-1 due to Progression N=41	11	68	5.03 months (3.7–8.05)	26.7 months (21.1–NR)
Discontinued ICI-1 for Other Reasons N=36	33	85	14.22 months (11.24–NR)	27.6 months (22.2–NR)

Comparison of *MET* genomic alterations (GA) identified in colorectal cancer (CRC) vs gastric cancer (GCA). First Author: Faiza Yasin, Yale School of Medicine, New Haven, CT

Background: MET signaling promotes tumor progression and therapeutic resistance across many solid tumors through diverse oncogenic signaling pathways. While MET-targeted therapies are approved in non-small cell lung cancer with novel agents in clinical trials for tumors with *MET* exon 14 splice site mutations, *MET* amplifications, and MET expression, their role in CRC and GCA is still emerging. We aim to understand the co-mutation landscape and genomic context of MET alterations across a large cohort of CRC and GCA cases to identify potential therapeutic targets. **Methods:** FFPE blocks of clinically advanced CRC (50,500 cases) and GCA (9,566 cases) were analyzed by hybrid capture-based comprehensive genomic profiling (CGP) that evaluated all classes of genomic alterations (GA). MSI-high status, tumor mutational burden (TMB), genomic ancestry, mutational signature, and homologous recombination deficiency signature (HRDsig) were assessed for patients with activating *MET* GA. PD-L1 expression was determined by IHC (Dako 22C3 with TPS scoring system). Results were compared using the Fisher exact test with the Benjamini-Hochberg adjustment. **Results:** MET GA (METmut) were more frequently identified in GCA than CRC (4.4% vs 1.0%; $p < .0001$). Median ages were similar in all groups with MET altered CRC and GCA. Median GA per tumor was higher in the METmut cases in both tumor types ($p > .0001$ for both). MSI-high status was less frequent in METmut GCA (1.7% vs 5.5%; p = .001) compared with METwt tumors. CRC cases featured higher frequencies of TMB > 10 mutations/Mb in both METmut and METwt groups ($p < .0001$ for all comparisons). Low level PD-L1 expression (1-49% TPS) was higher in CRC than GCA, but similar within tumor type across METmut and METwt tumors. METmut CRC had lower frequencies of GA in *KRAS* (34.7% vs 48.8%; $p < 0.0001$) which was also found in GCA (6.6% vs 16.9%; $p < .0001$). *CDK6* GA were more frequent in GCA than CRC and also were more frequent in METmut cases in both tumor types (19.6% vs 5.2% in GCA and 10.2% vs 0.6%; $p < 0.0001$). *ERBB2* GA were more frequent in both METmut and METwt GCA (13.5% vs 13.8%; NS) than CRC (9.6% vs 5.2%; p = 0.0004). *TP53* GA were more frequent in METmut vs METwt CRC (84.1% vs 75.9%; $p < 0.0001$) and GCA (81.8% vs 60.8%; $p < .0001$). BRAF V600E GA were identified in 5.9% METmut CRC and 8.4% METwt CRC (p = .051). BRAF V600E GA were uncommon in both METmut and METwt GCA (0.2% vs 0.4%; p = 1.0). **Conclusions:** This large-scale analysis reveals distinct genomic profiles of MET-altered tumors in CRC and GCA, characterized by lower prevalence of *KRAS* and MSI-high status, with enrichment for *CDK6*. These molecular differences suggest distinct biologic subsets that could inform patient selection and rational drug combination strategies for novel MET-targeted therapies. Research Sponsor: None.

The role of gut microbiome composition in the IBD-CRC pathway: A retrospective study of 428 patients. First Author: Sabina Sayeed, Maimonides Medical Center, Brooklyn, NY

Background: The progression from inflammatory bowel disease (IBD) to colorectal cancer (CRC) is a significant clinical challenge, driven partly by inflammation and dysbiosis of the gut microbiome. This study aimed to investigate the relationship between gut microbiome composition, systemic inflammation, and CRC risk in patients with IBD. A secondary aim was to evaluate the potential protective effects of microbial diversity and specific bacterial taxa in mitigating CRC progression. **Methods:** This retrospective study analyzed data from 428 patients with a confirmed diagnosis of IBD, of whom 162 (37.9%) were diagnosed with CRC. Stool samples collected within one year of diagnosis were subjected to 16S rRNA gene sequencing to characterize microbial composition and diversity. Alpha and beta diversity indices were calculated to evaluate microbial richness and community dissimilarity, respectively. Specific microbial taxa, including Bacteroides fragilis, Escherichia coli, and Akkermansia muciniphila, were quantified due to their established roles in inflammation and carcinogenesis. Inflammatory biomarkers, including C-reactive protein (CRP), fecal calprotectin, IL-6, and IL-17 were measured from serum and stool samples. Clinical data, including demographics, disease duration, staging, and treatment history, were obtained from electronic medical records. Multivariate regression models were used to determine associations between microbial profiles, inflammatory markers, and CRC risk, adjusted for confounders such as age, sex, BMI, and immunosuppressive therapy. **Results:** Patients with CRC demonstrated reduced gut microbial diversity compared to IBD patients without CRC (Shannon Index: 2.3 ± 0.4 vs. 3.1 ± 0.5; $p < 0.001$). Dysbiosis in CRC patients was marked by an overrepresentation of pro-inflammatory bacteria (Escherichia coli and Bacteroides fragilis) and a depletion of protective taxa (Akkermansia muciniphila and Faecalibacterium prausnitzii). Pro-inflammatory biomarkers, including CRP (14.2 ± 3.6 mg/L vs. 6.7 ± 2.1 mg/L; $p < 0.001$) and fecal calprotectin (378.5 ± 85.2 μg/g vs. 215.3 ± 64.7 μg/g; $p < 0.001$), were elevated in patients with CRC. Regression analyses revealed that reduced microbial diversity (OR: 2.87, 95% CI: 1.92–4.28) and the presence of specific pathogenic taxa (Bacteroides fragilis: OR: 3.12, 95% CI: 2.03–4.79) were independently associated with increased CRC risk. Conversely, patients with higher relative abundances of Akkermansia muciniphila exhibited lower levels of inflammation and reduced CRC risk (OR: 0.52, 95% CI: 0.35–0.76), likely due to its role in maintaining mucosal integrity and modulating immune responses. **Conclusions:** This study underscores the critical role of gut microbiome composition in the IBD-CRC pathway, and highlights the need for microbiome-targeted interventions to prevent CRC progression in patients with IBD. Research Sponsor: None.

Clinicogenomic landscape and outcomes of metastatic colorectal cancer patients with pathogenic *GNAS* variants. First Author: Faran Polani, Inova Schar Cancer Institute, Fairfax, VA

Background: Colorectal cancer (CRC) is a leading cause of cancer-related mortality, with 20-25% of cases presenting with metastatic disease (mCRC). Pathogenic variants in the *GNAS* gene, which encodes the stimulatory alpha subunit of the G protein complex, are found in 1.5% to 4.8% of CRC cases and are more prevalent in mucinous adenocarcinomas. Presence of these mutations have been associated with a lower likelihood of regression following first-line (1L) systemic therapy. However, the specific impact of *GNAS* mutations on treatment (tx) outcomes and overall survival in mCRC patients (pts) remains under investigation. **Methods:** We retrospectively analyzed de-identified data from 5,967 pts with stage IV mCRC treated with 1L oxaliplatin-based chemotherapy in the Tempus Database. Samples were sequenced with the Tempus xT (648-gene panel) or xF DNA assay (105 or 523 genes depending on version) and were divided into *GNAS* wild-type (GNASwt) and *GNAS* mutated (GNASmut) groups. Tumor mutational burden (TMB) and microsatellite instability (MSI) were calculated. Short variant pathogenic/likely pathogenic mutations and copy number alterations were analyzed for patients that underwent xT testing. Real-world (rw) objective response rate (rwORR) was defined as the proportion of pts with a documented complete or partial response within 90 days of tx start. Rw overall survival (rwOS) was defined as the time from 1L start to death from any cause. Hazard ratio (HR) was calculated using a Cox proportional hazards model and p-values were calculated using the Wald test. **Results:** The study included 5,854 *GNAS*wt and 113 *GNAS*mut mCRC pts (prevalence *GNAS*mut = 1.9%). *GNAS*mut pts exhibited higher prevalence of mucinous adenocarcinoma (26% vs. 2.8%) and peritoneal metastases (51% vs. 22%, $p < 0.001$), while liver metastases were more prevalent in the *GNAS*wt group compared to the *GNAS*mut group (77% vs 51%, $p < 0.001$). *KRAS*, *ARID1A*, *MSH2/3/6*, and *ATR* were more frequently altered in the *GNAS*mut group, while *TP53* and *APC* mutations were more frequent in the *GNAS*wt group. Immunophenotype markers such as high TMB and high MSI were also more often observed in the *GNAS*wt pts compared to *GNAS*mut pts ($p < 0.001$). rwORR was significantly lower in *GNAS*mut pts compared to *GNAS*wt (42% vs. 66%, p = 0.002). Pts with *GNAS*mut had reduced rwOS compared to pts with *GNAS*wt (HR = 1.31, p = 0.05). **Conclusions:** mCRC pts with pathogenic *GNAS* variants exhibit distinct clinicogenomic features and poorer outcomes with first-line oxaliplatin-based chemotherapy compared to *GNAS*wt pts. These findings highlight the need for alternative tx and further research on *GNAS* as a prognostic biomarker in mCRC. Research Sponsor: Tempus AI.

Clinicopathologic features of complement activation signatures in colorectal cancer. First Author: Mir Lim, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Activation of the complement cascade pathway is associated with pro-oncogenic inflammation and immune-suppressing, myeloid-derived M2 macrophages for many solid tumors. Most colorectal cancers (CRC) are microsatellite stable that do not respond to immunotherapy. The role of complement activation (CA) in the "immune cold" CRC phenotype remains poorly detailed. We sought to identify molecular annotations of CRC subpopulations enriched for CA to guide future therapeutic strategies. **Methods:** CRC tumors from 207 patients with stages II-IV CRC at MDACC underwent bulk RNA sequencing. Transcriptomes were analyzed per GSEA "Hallmark Complement" gene set to assign a normalized enrichment score (NES) for CA to each patient and considered "complement high" ("CH"; N = 103) or "complement low" ("CL"; N = 104) if the complement NES score was above or below the median. Associations between CA and clinical and pathologic characteristics - e.g., demographics, mutation status, and Consensus Molecular Subtype (CMS) - were evaluated by chi-squared analysis. Single cell RNA (scRNA) sequencing was performed on a separate cohort of CRC primary tumors (N = 85) and liver metastases (N = 60) to compare CA among different cell types using a Wilcoxon's test. To assess for an association between CA and response to immunotherapy in a previously annotated clinical trial of patients with MSS, $BRAF^{V600E}$ metastatic CRC (NCT04017650), we evaluated pretreatment biopsies by bulk RNA sequencing and compared transcriptomic differences in CA between responders versus non-responders to encorafenib, cetuximab, and nivolumab (E+C+N). **Results:** CH CRC featured a higher prevalence for MSI-H CRC (21.3% vs 4.2%; p = .005), CMS1 (30.1% vs 6.7%; $p < .001$), and CMS4 (26.2% vs 7.7%; $p < .001$) relative to CL CRC. CMS2 was more common among CL CRC (54.8% vs 14.6%, $p < .001$). CH CRC was associated with $BRAF^{V600E}$ mutations (29.7% vs 9.2% for CL, p = .002) but not with *KRAS/NRAS* mutations or $RAS/BRAF^{wild\text{-}type}$ CRC (p = n.s. for both). On scRNA analysis, CA scores were highest in myeloid cells and lowest for B cells ($p < .0001$). Among patients with MSS, $BRAF^{V600E}$ CRC, CH signature was associated with non-response to E+C+N (fold-change 3.0 relative to responders, p = .046). **Conclusions:** Association of CH status with MSI-H CRC is a novel finding that warrants further study in understanding differential patterns of benefit to immune checkpoint blockade. CH CRC, associated uniquely with $BRAF^{V600E}$ CRC, was distributed bimodally across the immune-activated CMS1 and the immune-suppressing CMS4 CRC, similar to known transcriptomic heterogeneity of $BRAF^{V600E}$ CRC. Our data suggest high CA, linked to immune-suppressing myeloid cell subpopulations, as a negative predictive biomarker for response to immunotherapy in MSS $BRAF^{V600E}$ CRC and support broader study of complement-targeting agents to improve treatment for selected patients with CRC. Research Sponsor: None.

Impact of SARS-CoV-2 mRNA-BNT162b2 vaccination on survival outcomes in metastatic colorectal cancer patients treated with bevacizumab-based therapy. First Author: Coskun Yazgan, Ankara University Faculty of Medicine Department of Medical Oncology, Ankara, Turkey

Background: Colorectal cancer (CRC) is a leading cause of cancer-related mortality worldwide. Bevacizumab, an anti-vascular endothelial growth factor (VEGF) antibody, is widely used in metastatic CRC (mCRC) treatment to inhibit tumor angiogenesis and modulate the immunosuppressive tumor microenvironment. Recent evidence suggests that mRNA-based COVID-19 vaccines, such as SARS-CoV-2 mRNA-BNT162b2, may enhance anti-tumor immune responses. This study aimed to evaluate the impact of SARS-CoV-2 mRNA-BNT162b2 vaccination on progression-free survival (PFS) and overall survival (OS) in mCRC patients treated with bevacizumab-based therapy. **Methods:** This retrospective, single-center study included 92 mCRC patients treated with bevacizumab between June 2021 and October 2024. Patients were divided into vaccinated (n=50) and unvaccinated (n=42) groups. Baseline demographic, clinical, and pathological characteristics were collected. PFS and OS were analyzed using Kaplan-Meier estimates and Cox proportional hazards regression models to identify independent predictors of survival. **Results:** The vaccinated group demonstrated significantly longer median PFS (8.0 months vs. 5.6 months, p=0.010) and OS (39.4 months vs. 17.8 months, p=0.014) compared to the unvaccinated group. Multivariate analysis identified SARS-CoV-2 mRNA-BNT162b2 vaccination as an independent predictor of improved PFS (HR 0.44, p=0.003) and OS (HR 0.39, p=0.018). Vaccinated patients also had a higher proportion of favorable ECOG PS and a lower prevalence of RAS mutations. **Conclusions:** SARS-CoV-2 mRNA-BNT162b2 vaccination was associated with improved PFS and OS in mCRC patients receiving bevacizumab-based therapy, potentially through enhanced anti-tumor immune responses. These findings highlight the potential of mRNA-based vaccines to modulate the tumor microenvironment and improve outcomes in mCRC. Further prospective studies are needed to confirm these results and explore underlying mechanisms. Research Sponsor: None.

Effect of race/ethnicity on clinical outcomes for metastatic colorectal cancer (mCRC) patients in phase 1 trials: A dual institution experience. First Author: Hasan Musanna Zaidi, Rutgers Cancer Institute of New Jersey, New Brunswick, NJ

Background: Patients with mCRC who progress on standard of care therapies have limited therapeutic options and are associated with poor prognoses. Phase 1 trials are a valuable resource for these patients, offering novel treatment options. However, the appropriate time of consideration for phase 1 trials remains unclear. We sought to analyze the outcomes in a multi-racial cohort of patients with mCRC enrolled in prospective phase I clinical trials to describe clinical characteristics and gauge efficacy of such trials. **Methods:** We reviewed medical records of patients with mCRC enrolled in phase 1 trials at two institutions from 1999 to 2018 and 2021 to 2024. We collected patient demographics, key clinical characteristics, responses, and deaths. Time on study was calculated as time between first dose of study drug and decision to discontinue study. Overall survival (OS) was calculated as time between the first dose of study drug to date of death or last contact date (censored). Outcomes were analysed by Mantel–Cox test using Prism GraphPad v 10. **Results:** There were 283 enrollments on 66 phase I trials. Median age (range) was: 59 (29-83) years; non-Hispanic whites (NHW, 126; 44.5%), non-Hispanic blacks (NHB, 69; 24.4%), Hispanic (H, 69; 24.4%), Asian (A, 17; 6.0%), and unknown (UNK, 2; 0.7%). Median number of prior therapies was 3 (range 0-11). ECOG performance status was 0, 1, 2, and unknown, among 62 (21.9%), 181 (63.9%), 11 (3.9%), and 29 (10.2%) patients, respectively. Median number of sites of metastases was 3 (range 0-10). Sites of metastases included liver 77.0%, lung 60.1%, lymph nodes 39.9%, peritoneum 24.4%, bone 20.5%, and brain 1.8%. The primary site of cancer for patients on study was colon (84.1%), followed by rectum (11.7%), rectosigmoid (0.7%), and (simply documented as) CRC (3.5%). The median time on study was 1.8 months for all patients, with NHW 1.9 months, NHB 1.8, H 1.7, A 1.6, and UNK 7.4; p = 0.72. The OS was 8.6 months among all patients, and 7.9, 7.8, 8.8, 9.4, and 9.5 months for NHW, NHB, H, A, and UNK, respectively (p = 0.82). Response evaluable patients were n = 236; including complete response (CR, n = 2, 0.8%), partial response (PR, n = 8, 3.4%), stable disease (SD, n = 80, 33.9%), and clinical benefit rate (CBR = CR+PR+SD, n = 90) 38.1%. **Conclusions:** Patients with mCRC enrolled onto phase 1 trials showed CBR of 38.1% and OS of 8.6 months, which is comparable to standard third-line therapies that were available during the time period of this study, thus showing promise for their use in clinical practice. No racial/ethnic variation was observed. There was a non-significant trend towards a lower OS with increase in number of prior lines of therapy. A multivariate model will be presented. Research Sponsor: None.

Understanding and addressing unmet needs in colorectal cancer: Findings from the Colorectal Cancer Alliance's Patient and Survivor survey. First Author: Kimberley Lynn Newcomer, Colorectal Cancer Alliance, Washington, DC

Background: Colorectal cancer (CRC) is the third most commonly diagnosed cancer and the second leading cause of cancer-related deaths worldwide. Despite advances in survival rates, CRC patients and survivors often face unmet needs, including emotional support, coping strategies, and access to treatment-related information. Beyond physical challenges, patients report emotional distress, disruptions to quality of life (QoL), and difficulty navigating the healthcare system. Even after remission, survivors frequently struggle with lingering psychosocial and physical impacts. **Methods:** The Colorectal Cancer Alliance conducted an IRB-approved cross-sectional survey to assess the needs of CRC patients, survivors, and caregivers. The survey included over 150 questions about demographics, diagnosis experiences, QoL, access to care, and treatment outcomes. Participants (n = 283) were recruited through the Alliance's social media, email campaigns, and online communities to ensure diverse representation. **Results:** The study revealed critical insights into the challenges faced by CRC patients and survivors. The median age group of participants was 46–55. Most respondents (74%) reported difficulty finding someone who could understand and relate to their experience. Furthermore, 41% noted a reduction in support from others after their treatment ended. Many participants faced ongoing challenges, with 54% reporting fatigue and 51% experiencing stress. CRC had a profound impact on several aspects of life: 64% said it negatively affected their career or work life, 58% cited negative effects on their relationship with a spouse or partner, 80% reported a decline in their sex life, and 65% struggled to participate in social activities. Additionally, 51% noted challenges with dating, and 43% indicated that their cancer journey affected their desire to have children. While most patients felt informed before treatment, 46% expressed unmet needs for information on complementary or alternative therapies. These findings highlight the broad and far-reaching effects of CRC on patients and survivors, revealing significant gaps in emotional, psychosocial, and informational support. **Conclusions:** CRC patients and survivors face substantial unmet needs that significantly affect their quality of life and well-being. The Colorectal Cancer Alliance plans to use these insights to develop care programs and targeted support initiatives designed to address these gaps. By tailoring resources to the unique needs of patients and survivors, these efforts aim to improve outcomes and offer hope for a better future for those affected by CRC. Research Sponsor: None.

Drivers of homologous recombination deficiency (HRD) in metastatic colorectal cancer (mCRC). First Author: Paula Romero Lozano, VHIO, Barcelona, Spain

Background: HRD is linked to sensitivity to platinum-based chemotherapy and poly (ADP-ribose) polymerase inhibitors across various tumor types. However, the presence of HRD, driver events (such as pathogenic mutations in HR genes or other genomic alterations), and its clinical relevance in mCRC remain underexplored. **Methods:** We performed the VHIO-300 test, an ISO15189 accredited custom NGS panel profiling over 450 genes (including HR-related genes: *ATM, BRCA1, BRCA2, BRIP1, CHEK2 or PALB2*) on 356 Stage IV mCRC patients (corresponding to 247 primary colorectal and 109 to metastatic samples) enrolled in the Vall d'Hebron Institute of Oncology's Molecular Prescreening Program from June 2021 to December 2024. All samples had a tumor cellularity $>$ 40% as per pathologist evaluation. An HR score (sHR) based on genome-wide copy number alterations (CNA) and loss of heterozygosity (LOH) patterns is generated. After cross-validation with Myriad MyChoice, sHR $\geq$ 56 was established based on a cohort of ovarian tumors and used to identify HRD in mCRC tumor samples. **Results:** HRD prevalence was 3.4% in our mCRC cohort (12/356), but, much higher in metastatic lesions, (6.4%, 7/109) than in primary samples (2.03%, 5/247) (p = 0.05). In fact, the median sHR between primary (21) vs. metastases (30) in CRC was significantly different ($p < 0.01$). Regarding HR gene status, HR-mutated samples were not significantly within the HRD group (p = 0.27) and only 6.5% (2/31) were HRD. Noteworthy, *BRCA2* exhibits a frameshift deletion in a homopolymer stretch, that is a frequent hotspot in microsatellite instable (MSI) tumors, but this event was not found to be associated with HRD. In fact, all HRD tumors (n = 12) were microsatellite stable (MSS). Other frequent alterations in mCRC were studied and *BRAF* mutations were found to be present in 42% of HRD tumors ($p < 0.01$). Inversely, HRD was rare in *KRAS*-mutated samples (0.7%; 1/140) and, in fact, highly correlated with non-HRD status (p = 0.02), especially the G12 mutation ($p < 0.01$). Interestingly, CNA profiles also revealed a strong association between the *BCL2L1* loci gain and HRD ($p < 0.01$). Clinically, HRD was not significantly associated with prognostic value nor clinical benefit to oxaliplatin-based combinations. However, the limited sample size and heterogeneous treatment lines restricted robust statistical analysis. **Conclusions:** This study identified a small, yet significant subset of mCRC that displays HRD. sHR and HRD rates were higher in metastatic lesions vs primary tumors, indicating HR scarring could be accumulating over time in some mCRC patients. No clear association between pathogenic HR gene mutations and HRD were found, suggesting the involvement of alternative molecular mechanisms in this process. Frequent co-occurring events, such as *BRAF* mutations or *BCL2L1* gains could be drivers in CRC HRD, and shape, eventually, new therapeutic options for these patients in the metastatic setting. Research Sponsor: None.

Real-world efficacy of trifluridine/tipiracil and bevacizumab combination according to baseline prognostic factors: The BeTAS study. First Author: Nieves Martinez Lago, Hospital Clínico Universitario e Instituto de Investigación Sanitaria de Santiago de Compostela, Santiago De Compostela, Spain

Background: The Sunlight Trial demonstrated that trifluridine-tipiracil (FTD/TPI) and bevacizumab (BEV) significantly improved Overall Survival (OS) and Progression-Free Survival (PFS) in patients with pretreated metastatic colorectal cancer (mCRC) after two treatment lines. However, the real-world efficacy and influence of baseline prognostic factors are not fully understood. **Methods:** This retrospective, observational, multicenter study across 18 Spanish hospitals included mCRC patients treated with FTD/TPI+BEV in a real-world setting. Prognostic factors were analyzed, including Tabernero's subgroups, which categorize patients according to time to diagnosis from first metastasis ($<$ 18 vs. $>$ 18 months), number of metastatic sites ($<$ 3 vs. $>$ 3), and liver metastasis (yes vs. no). Patients were grouped into Best (BPC), Good (GPC), and Poor (PPC) prognostic categories. **Results:** 398 patients were treated from July 2019 to December 2024. Median age was 67 years (range 26-92), 65.8% male, and 88.4% had ECOG PS 0-1. 56.3% had RAS mutations. Liver metastases were present in 75.3%, 27.7% had $>$ 3 metastatic sites, and 28.2% had $<$ 18 months from diagnosis of first metastasis, resulting in 47.2% of patients categorized as PPC. 67.8% received FTD/TPI+BEV as third-line treatment. ORR was 6.8%, and DCR was 49.9%. With a median follow-up of 14 months, median PFS was 4.9 months (95% CI, 4.1-5.1) and OS was 10.8 months (95% CI, 9.2-12.4). Neutropenia was the most common toxicity, with 33.1% of patients experiencing grade 3-4 neutropenia. OS by ECOG PS 0 vs. 1 vs. 2 was 12.5 vs. 11.1 vs. 5.7 months ($p < 0.0001$). PFS by ECOG PS 0 vs. 1 vs. 2 was 5.6 vs. 4.9 vs. 3.5 months (p = 0.102). OS by BPC vs. GPC vs. PPC was 18.3 vs. 12.8 vs. 7.5 months ($p < 0.0001$), and PFS was 7.3 vs. 5.8 vs. 3.7 months ($p < 0.0001$). OS in patients with grade 3-4 neutropenia vs. no neutropenia was 17.7 vs. 8.1 months ($p < 0.0001$), and PFS was 8.7 vs. 3.9 months ($p < 0.0001$). **Conclusions:** Our series confirms the effectiveness of FTD/TPI + BEV in real-world clinical practice, with a median OS of 10.8 months and a median PFS of 4.9 months. The ECOG performance status, Tabernero subgroups, and the occurrence of grade 3-4 neutropenia help identify patients who may obtain the maximum benefit from FTD/TPI + BEV treatment. Interestingly, all subgroups analyzed showed a greater benefit compared to the outcomes previously reported for FTD/TPI monotherapy, highlighting the potential of this combination in clinical practice. Research Sponsor: None.

Safety and efficacy of ADG126 (an anti-CTLA-4 masking antibody) in combination with pembrolizumab: Updated results of phase 1b/2 study in advanced MSS CRC. First Author: Daneng Li, City of Hope National Comprehensive Cancer Center, Duarte, CA

Background: ADG126 is an anti-CTLA-4 IgG1 masked antibody that is preferentially activated in the tumor upon cleavage of masking peptides in the tumor microenvironment. Cleaved ADG126 binds to a unique epitope on CTLA-4, blocks CTLA-4 function, primes T cells and depletes Tregs. ADG126 in combination with pembrolizumab (Pembro) has been evaluated in a Phase 1b/2 clinical trial (NCT05405595) and we have reported outcome in 3L MSS CRC patients (Pts) free of liver metastasis (NLM).[1-4] We update results from additional dose expansion (EXP) in Pts of advanced MSS CRC. **Methods:** This is a Phase 1b/2, open-label, multicenter dose escalation and expansion study. Primary endpoints were safety and tolerability, and early signal of efficacy. Secondary endpoints were PK, ADA, ORR, DCR, DOR, PFS and OS. **Results:** As of Jan.15, 2025, a total of 54 MSS CRC Pts were treated with ADG126/Pembro (200 mg Q3W) in EXP phase across 3 dose levels of ADG126 (Table 1). 18% Pts had $\geq$ 3 prior therapies and none had prior IO therapy. There was no Grade 4/5 TRAE, and MTD was not reached. Grade 3 TRAEs were dose-dependent: 38% (5/13), 20% (6/30) and 0% (0/11) for 20 mg/kg LD[1], 10 mg/kg Q3W and 10 mg/kg Q6W cohorts, respectively. The discontinuation rate remains low for the EXP cohorts (6%). The ORR, CBR, mPFS and 12-mon OS of MSS CRC Pts without liver and peritoneal metastasis (NLPM) are listed in Table 1. ORR increased as a function of ADG126 dose. Although 10 mg/kg Q6W/Pembro did not yield PR, all 6 EE Pts remain on study (1 on treatment) at 18-mon of follow-up. Correlation between dose level/regimen, ORR, CBR and mPFS between 10 mg/kg Q6W and Q3W cohorts has been observed. mOS is not reached for 10 mg/kg Q3W NLPM after 15.5-mon follow up. Longer term efficacy data from 20 mg/kg LD cohort will be reported. **Conclusions:** Dose-dependent ORR has been observed for ADG126/Pembro IO doublet across multiple dose levels/regimens of ADG126 (10 mg/kg Q6W to 20 mg/kg LD) that is associated with well-tolerated to acceptable safety profile, which is enabled by a relatively large therapeutic window. The overall performance of ADG126/Pembro IO doublet warrants further clinical development including combination with SOCs targeting earlier lines/broader populations, such as MSS CRC with liver metastasis. Clinical trial information: NCT05405595. Research Sponsor: Adagene Inc.

Key efficacy results from MSS CRC patients.

Real-world treatment patterns and outcomes with trifluridine/tipiracil monotherapy or in combination with bevacizumab in metastatic colorectal cancer. First Author: Donald A. Richards, Texas Oncology, Tyler, TX

Background: Trifluridine/tipiracil (FTD-TPI; Lonsurf) is an oral antineoplastic agent approved for 3rd-line use in combination with or without bevacizumab (BEV) in metastatic colorectal cancer (mCRC). In the Phase III SUNLIGHT trial, the addition of BEV to FTD-TPI was associated with a significant improvement in overall survival (OS) and progression-free survival (PFS) compared to FTD-TPI monotherapy. However, data on the use of FTD-TPI in combination with BEV in the real-world community setting are currently limited. **Methods:** This was a retrospective observational study involving electronic medical records and (where available) chart reviews from mCRC patients treated by the Texas Oncology community practice from Jan 2020 to Oct 2024. Patients had to have received FTD-TPI with or without BEV after progressing on a prior line of therapy with oxaliplatin and irinotecan. Variables included patient characteristics, clinical characteristics, treatment patterns and clinical outcomes. OS and time to next treatment or death (TTNTD) were analyzed using the Kaplan-Meier method. **Results:** In total, 265 patients were included (166 FTD-TPI + BEV; 99 FTD-TPI monotherapy), with the majority receiving FTD-TPI as 3rd-line (83%; n = 220) or 4th-line (14%; n = 38) therapy. The population was 59% male, 66% white, and 35% were $\geq$65 years of age. The most common previous 1st- and 2nd-line treatment for 3rd-line FTD-TPI patients was chemotherapy + an antiangiogenic (1st-line, 67%; 2nd-line, 74%), which was similar regardless of current BEV use. Median duration of therapy was 2.8 months (range 0.3 to 12.5) with FTD-TPI + BEV and 2.8 months (range 0.1 to 10.4) with monotherapy. Median OS was 11.6 months with FTD-TPI + BEV and 6.2 months with monotherapy (hazard ratio [HR] = 2.1; 95% confidence interval [CI]: 1.5-3.0; $p < 0.001$). At 6 months, OS probability was 0.69 (95% CI: 0.61-0.77) with FTD-TPI + BEV and 0.50 (95% CI: 0.40-0.63) with monotherapy; 12-month OS probability was 0.49 (0.39-0.61) and 0.15 (0.07-0.28), respectively. Median TTNTD was 9.4 months for FTD-TPI + BEV and 5.8 months for FTD-TPI alone (HR = 1.7, 95% CI: 1.2-2.4; $p < 0.001$). The safety/tolerability profile was generally similar irrespective of BEV use, with the most common adverse events being fatigue/asthenia (73%), abdominal discomfort/pain (55%), and nausea (54%). The most notable difference was neutropenia (37% FTD-TPI + BEV, 27% monotherapy). **Conclusions:** In this large real-world community practice setting in the US, FTD-TPI use in mCRC was mostly in the 3rd-line setting and approximately two-thirds of use was in combination with BEV. Patient characteristics were similar to the SUNLIGHT trial, with high rates of previous antiangiogenic use. A statistically significant and clinically relevant OS benefit was seen with the addition of BEV versus monotherapy consistent with the results of the SUNLIGHT trial. Research Sponsor: Taiho Oncology Inc.

3581 **Poster Session**

A phase 1 dose-escalation study of GCC19CART: A novel CAR T-cell therapy for metastatic colorectal cancer in the United States. First Author: Benjamin L. Schlechter, Dana-Farber Cancer Institute, Boston, MA

Background: GCC19CART, the first clinical candidate of the CoupledCAR solid tumor platform, pairs a solid tumor chimeric antigen receptor (CAR) T-cell with CD19-targeting CAR T-cells. The CD19 target enhances proliferation and persistence of the CoupledCAR, overcoming the limitations seen in other solid tumor CAR T-cells. Guanylate cyclase-C (GCC) is an appealing CAR target due to apical-basal polarity of expression in normal colon, which may hamper on-target effects on the mucosa. GCC is present on nearly all colorectal cancers (CRC). GCC19CART showed promise in a prior trial in China, demonstrating expansion, response, and persistence, consistent with the proposed mechanism. The US phase 1 study was initiated for refractory CRC to assess the safety and efficacy of GCC19CART in this population. **Methods:** Eligible patients underwent leukapheresis, lymphodepleting chemotherapy (fludarabine 30mg/m^2 and cyclophosphamide 300mg/m^2 on day-3), and a single dose of GCC19CART. Safety was the primary endpoint. Efficacy was assessed by RECIST v1.1 based on local review. **Results:** As of January 23, 2025, 9 patients were treated: 4 at dose-level (DL) 1 (1x10^6 cells/kg) and 5 at DL2 (2x10^6 cells/kg). Cytokine release syndrome occurred in all subjects (grade [G] 1: 6/9 [66.7%] and G2: 3/9 [33.3%]), and diarrhea was reported in 8/9 (G1: 3/9 [33.3%], G2: 3/9 [33.3%], G3: 2/9 [22.2%]). Immune effector cell associated neurotoxicity syndrome occurred in 2/9 subjects (G2: 1/9 [11.1%], G3: 1/9 [11.1%]). A DL2 patient experienced a dose limiting toxicity (G3 diarrhea, G4 enterocolitis, and G5 sepsis) and died 48 days post-infusion. The overall response rate (ORR) in DL1 was 25% (1/4 partial response [PR]) and 80% in DL2 (4/5 with 3 PR and 1 pathological complete response). The PR in DL1 was achieved by month 2, while 3/4 responders in DL2 achieved a PR by month 1, demonstrating dose-dependent tumor-killing activity. Two DL2 patients maintained responses at data cut-off. One patient achieved a complete metabolic response by PET at month 2 and maintained a PR by CT at month 6 with continuous tumor shrinkage (month 1: 38.33%, month 2: 40.77%, month 4: 82.58%, month 6: 75.61%). Another patient maintained a PR at month 6 with progression at month 8. The median progression-free survival (PFS) was 5.0 months in DL1 and 7.8 months in DL2. The median duration of response was 2.2 months in DL1 and 6.9 months in DL2. Compared to the prior trial in China (≥G3 diarrhea: 22.2% vs. 53.3%; ORR: 66.7% vs. 40%, PFS: 7.8 vs 6.0 months in DL2, 5.0 vs 1.9 in DL1. Chen, *JAMA Oncol*., September 2024), the US study suggests a potential trend towards improved safety and efficacy. **Conclusions:** GCC19CART demonstrated significant clinical activity and durability in refractory CRC. Optimization of diarrhea/colitis management is ongoing. Updated data will be presented. Clinical trial information: NCT05319314. Research Sponsor: None.

Impact of obesity and lifestyle-associated risk factors on outcomes of early-onset colorectal cancer in patients younger than 50 years old: A propensity-matched analysis. First Author: Syeda Ashna Fatima Kamal, Saint Louis University, Saint Louis, MO

Background: Early-onset colorectal cancer (CRC) incidence is rising in individuals under 50 years old. This study aims to understand the factors influencing outcomes in this population. We evaluated the impact of obesity and other lifestyle-associated risk factors, such as smoking, alcohol use, and diabetes mellitus, on outcomes in patients with early-onset CRC. **Methods:** A comprehensive retrospective cohort study using the TriNetX database identified adults aged 18–49.9 diagnosed with CRC. Using propensity score matching (PSM), we compared patients with obesity (body mass index [BMI] ≥30 kg/m²) and other lifestyle-associated risk factors (smoking, alcohol use, and diabetes mellitus) to those without any risk factor, while accounting for demographics, comorbidities, and treatment. The primary outcome is the 10-year mortality in obese patients as compared to non-obese patients. Secondary outcomes included the 10-year mortality in patients with other lifestyle-associated risk factors. **Results:** A total of 10,220 matched pairs of obese and non-obese patients were included. Before matching, obese CRC patients were older, more likely to be male, Hispanic, or non-Hispanic Black, and had higher rates of colonoscopy, surgery, and comorbidities ($p < 0.001$). After PSM, obese CRC patients had significantly lower odds of 10-year mortality compared to non-obese patients (7.9% vs. 14%; adjusted odds ratio [aOR] = 0.53; 95% confidence interval [CI]: 0.47–0.60). Diabetes, smoking, and alcohol use showed no significant association with 10-year mortality in patients with early-onset CRC (e.g., diabetes: aOR = 0.96; 95% CI: 0.73–1.26). **Conclusions:** Our study suggests that obesity may confer a protective effect on 10-year mortality in patients with early-onset CRC, whereas other lifestyle-associated risk factors showed limited-to-no significant impact. These findings underscore the need for targeted strategies to improve access to CRC screening and treatment, particularly in younger patients with obesity, and they also open up new avenues for research into the potential mechanisms underlying these associations. Prospective studies are warranted to validate these results and explore these potential implications, further enriching our understanding of this complex disease and potentially leading to novel approaches for its management. Research Sponsor: None.

	Incidence % (N)		Propensity score matching analysis
Lifestyle risk factors	CRC< 50 + risk factor	CRC<50 - risk factor	Adjusted odds ratio (aOR)* [95%CI]
Obesity (BMI ≥ 30)	7.9% (406)	14.0% (714)	0.53 [0.47 - 0.60]

Propensity matching analysis assessing the odds of 10-year mortality when comparing patients with early-onset colorectal cancer (< 50 years) with lifestyle-associated risk factors (e.g., obesity (N=5110) compared to equal numbers of patients without lifestyle-associated risk factors.

Colorectal cancer mortality dynamics: Uncovering critical disparities in U.S. population health (2018–2023). First Author: Pranav Chalasani, Wayne State University, Rochester Hills, MI

Background: Colorectal cancer(CRC) remains the third leading cause of cancer-related deaths in the United States, with a disproportionate burden on underserved populations. Despite established screening protocols and preventive measures, fewer than 35% of cases are detected early, significantly impacting survival rates. This study examines mortality patterns across demographic and geographic divides, revealing urgent public health priorities. **Methods:** This retrospective analysis was performed in adults aged 25 and older using the CDC WONDER database (2018-2023) using ICD-10 codes. We stratified mortality data by age, gender, race, geographic region and urbanization level to identify critical disparities and emerging trends. Crude mortality rates (CMRs) and Age-adjusted mortality rates (AAMRs) per 100,000 were calculated by age, gender, region and race, with 95% confidence intervals (CI) for precision. Temporal trends and annual percentage changes (APCs) were analyzed using Joinpoint regression. **Results:** From 2018 to 2023, among 313,744 deaths, mortality increased from 51,891 to 53,497, while the AAMR for CRC consistently declined from 12.92 to 12.44. The highest CMR was in the 85+ group (156.11 per 100,000, 95% CI: 153.05–159.17), followed by 75-84 (74.18, 95% CI: 72.87–75.49), 65-74 (40.27, 95% CI: 39.58–40.96), and 55-64 (23.83, 95% CI: 23.37–24.30). The 45-54 group had a CMR of 11.74 (95% CI: 11.40–12.07), the 35-44 group 3.56 (95% CI: 3.38–3.74), the 25-34 group 0.77 (95% CI: 0.69–0.86), and the 15-24 group had the lowest at 0.09 (95% CI: 0.06–0.12). Males had a higher CMR of 17.23 per 100,000 (AAMR: 15.19, APC: -0.68, p = 0.21) than females, who had 14.42 per 100,000 (AAMR: 10.69, APC: -0.30, p = 0.56). The Midwest had the highest AAMR at 13.33 per 100,000 [APC: -0.78 (95% CI: -2.54 to 1.01, p = 0.31)], followed by the South at 13.54 [APC: 0.05 (95% CI: -0.80 to 0.92, p = 0.91)], the West at 11.90 [APC: 0.09 (95% CI: -0.79 to 0.95, p = 0.82)], and the Northeast at 11.54, with a significant decline in trends [APC: -1.90 (95% CI: -3.24 to -0.58, $p < 0.01$)]. Large central metro areas accounted for 25.3% of deaths (83,341), followed by large fringe metro areas (22.4%), medium metros (19.9%), micropolitan areas (10.0%), small metros (9.4%), and noncore areas (8.2%). Racial disparities showed White individuals with the highest CMR at 17.01 per 100,000 (AAMR: 12.69, APC: -0.78), while Black or African American individuals had a slightly lower CMR at 15.70 per 100,000 but the highest AAMR at 16.18 (APC: -1.63, $p < 0.01$), followed by American Indian or Alaska Native, Asian, Native Hawaiian, and other groups. **Conclusions:** These findings reveal critical gaps in CRC prevention and care, disproportionately affecting young adults, males, and minorities. Public health initiatives must expand screening, improve access to care, and address regional inequities to reduce mortality and promote health equity. Research Sponsor: None.

Analytic and clinical validation of a negative prediction algorithm for actionable mutations utilizing genomic and epigenomic profiling in cfDNA. First Author: Andrew Gross, Guardant Health, Palo Alto, CA

Background: One challenge in cell-free DNA (cfDNA) profiling for genomic tumor profiling is the inability to confidently confirm the absence of actionable genomic mutations. This limitation arises from the challenge of determining whether key driver mutations are truly absent or if tumor levels are below the detection threshold of the assay. Accurate negative variant prediction could enable clinicians to expedite clinical decisions based on cfDNA results without relying on tissue biopsy sequencing when no actionable alterations are found. Here, we report analytic and clinical validation of a novel algorithm to enable negative prediction from liquid biopsy to address this critical clinical need. **Methods:** Using the Guardant Infinity platform, which simultaneously profiles genomic and epigenomic signals in a single sample, we integrated highly sensitive and precise tumor fraction estimates and developed a negative prediction algorithm to allow for confident reporting of samples that do not detect an actionable genomic finding. The algorithm estimates the post-test probability of a cfDNA sample harboring genomic biomarkers with FDA approved therapies relevant to treatment selection, based on population priors, epigenomic tumor fraction (TF), and the analysis of mutant and non-mutant coverage across variants of interest which was assessed for advanced colorectal (CRC) and lung cancer (NSCLC) patients. **Results:** In 3973 CRC and 7654 NSCLC analyzed patients, 41% of CRC and 22.6% of NSCLC were found to have an actionable mutation. Among the remaining samples, 66% of CRC and 56.3% of NSCLC had sufficient tumor fraction to assess the sample as variant negative with > 95% confidence. Reasons why the remaining samples could not be confidently assessed included low tumor shedding (including 15% with nondetectable tumor), low genomic coverage over loci of interest, and mutant allele support below the confident call threshold. An additional cohort of 237 CRC and 316 NSCLC patients with paired tissue and cfDNA results was used to clinically validate the negative prediction algorithm. All samples with sufficient tumor fraction for > 95% confidence and predicted to be negative by the algorithm for genomic biomarkers with FDA-approved therapies were confirmed to be negative in tissue results. **Conclusions:** A plasma-based epigenomics-based approach for confident negative prediction is feasible in CRC and NSCLC, as demonstrated by validation results. Confident negative prediction has the potential to enhance the utility of liquid biopsy and accelerate clinical decision-making in advanced solid tumors with biomarker-guided treatment pathways and should be validated in additional clinical datasets. Cell-free DNA 5-hydroxymethylcytosine profiling for the assessment of colorectal cancer biology and treatment response in blood. First Author: Ceyda Coruh, ClearNote Health, San Diego, CA

Background: Colorectal cancer is the third most common cancer worldwide, accounting for about 10% of all cancer cases, and is expected to claim more than 50,000 lives in 2025. Approximately 33% of CRC patients will develop metastases throughout their cancer continuum, and their 5-year survival rate is about 15%. The majority of patients with metastatic colorectal cancer (mCRC) cannot be cured. However, a subset of mCRC patients with localized recurrence or isolated metastases in the liver and/or lungs may achieve a cure through surgical intervention. Yet, current methods for identifying patients who are candidates for more favorable responseremain inadequate. Therefore, there is a critical need for predictive biomarkers to accurately identify patients who are likely to experience better outcomes following surgery. 5-hydroxymethylcytosine (5hmC) is an epigenetic modification that is associated with active genes and regulatory regions that are cell type- and disease-specific. Here, we developed a model using cell-free DNA (cfDNA) 5hmC profiles to detect CRC and identified pathways distinguishing mCRC patient outcomes following treatment. **Methods:** Plasma was collected from 294 CRC patients and 588 non-cancer individuals to obtain cfDNA. cfDNA was enriched for 5hmC-containing DNA fragments. Input and 5hmC-enriched cfDNA were subsequently used to generate sequencing libraries to obtain WGS and 5hmC profiles, respectively. Machine learning operating on 5hmC and WGS data was used to develop a CRC detection model which was subsequently tested on an independent set of mCRC (n = 69) and non-cancer samples (n = 70). Differential 5hmC analysis was performed using edgeR and Gene Set Enrichment Analysis (GSEA). **Results:** The performance of the CRC prediction model was evaluated through 10-fold cross-validation producing an auROC curve of 0.86. An independent validation set of mCRC and non-cancer patients displayed an auROC of 0.94. Comparative GSEA using gene body 5hmC levels revealed biological pathways associated with CRC biology such as Myc signaling. cfDNA 5hmC profiling of plasma obtained from mCRC patients before surgery revealed quantitative differences in patients who show recurrence of disease within 2 years post-surgery from the patients who remain recurrence-free for at least 2 years after surgery. These differences between relapsed and non-relapsed groups included 5hmC changes over genes involved in pathways known in mCRC, such as the Wnt/β-catenin signaling ($p < 0.05$). Lastly, quantitative changes in 5hmC profiles measured in pre-surgery plasma samples enabled prediction of disease recurrence in patients within 2 years post-surgery. **Conclusions:** 5hmC analysis of cell free DNA) offers a novel, non-invasive approach for identification of colorectal cancer biology and assessment of treatment response in blood samples. Sintilimab plus bevacizumab, oxaliplatin, and capecitabine as perioperative therapy in microsatellite-stable, resectable colorectal cancer liver metastases: An open-label, single-arm, phase II trial. First Author: Yu-hong Li, Sun Yat-sen University Cancer Center, Guangzhou, China

Background: Immunotherapy has revolutionized cancer treatment, yet its efficacy in proficient mismatch repair and/or microsatellite stable (pMMR/MSS) colorectal cancer liver metastases (CRLM) remains uncertain. Optimizing neoadjuvant regimens for such patients is crucial. **Methods:** A prospective, open-label, single-arm phase II clinical trial was conducted from June 2021 to January 2023. Patients with resectable pMMR/MSS CRLM were enrolled and received 4 cycles sintilimab combined with bevacizumab, oxaliplatin, and capecitabine preoperatively followed by 4 cycles oxaliplatin, and capecitabine postoperatively. The primary endpoints were safety and feasibility of neoadjuvant therapy and surgery. Secondary endpoints encompassed pathological response rates, objective response rate, progression-free survival (PFS), and overall survival (OS). Biomarker analyses were performed to identify potential predictors related to efficacy and prognosis. The study protocol was registered in ClinicalTrials.gov (NCT04940546). **Results:** Between June 2021 to January 2023, 36 patients were enrolled, and included in the safety analysis. The most common treatment-related adverse events (TRAEs) were fatigue (55.6%), peripheral neuritis (52.8%). Of the 36 patients, 30 received local treatment for liver metastases. 26 of them underwent CRLM surgery resection, and 7 of the 26 experienced surgery - related complications graded from 1-2 such as cholecystitis and pulmonary infection, one patient died from respiratory failure due to a pulmonary infection (immune pneumonia not excluded) a month after liver metastases resection. 34 were analyzed for efficacy. The objective response rate (ORR) was 67.6%, with a disease control rate (DCR) of 88.2%. 26 patients underwent surgery; the pathological complete response rate (pCR) was 11.5%, and the major pathological response rate (MPR) was 38.5%. After a median follow-up of 32.9 months, the median PFS was 14.2 months ((95% CI: 11.6 - 29.0 months), and the median OS had not yet been reached. Biomarker analysis revealed that *RAS* wild-type (mPFS: 29.0 months (15.0 - NA) vs 11.5 months (9.8 - 15.7), log-rank $P = 0.0087$), *SMAD4* wild-type population (mPFS: 20.2 months (12.3 - NA) vs 6.9 months (5.2 - NA), log-rank $P < 0.0001$) may benifit from immunotherapy combination treatment. The single cell RNA sequencing analysis revealed that higher intrafiltion of FIB_PLAG2A in the TME of CR/PR were associated with favorable prognosis, while higher intrafiltion of MPH_TREM2, FIB_POSTN in the TME of non CR/PR were linked to poor prognosis. **Conclusions:** The neoadjuvant regimen demonstrated acceptable safety and efficacy. *RAS*, *SMAD4* wild-type patients may be a potential beneficiary population. Clinical trial information: NCT04940546. Research Sponsor: Bethune Public Welfare Foundation.

Safety and efficacy evaluation of neoadjuvant chemoradiotherapy plus thymalfasin and tislelizumab for treating MSS/pMMR locally advanced rectal cancer. First Author: Zhengyang Yang, Department of General Surgery, Beijing Friendship Hospital, Capital Medical University & National Clinical Research Center for Digestive Diseases, Beijing, China

Background: Neoadjuvant chemoradiotherapy is currently the standard strategy for microsatellite stable (MSS) / mismatch repair-proficient (pMMR) locally advanced rectal cancer (LARC) patients. This study aimed to explore the safety and efficacy of combining specific (thymalfasin) and non-specific (tislelizumab) tumor immunotherapy with chemoradiotherapy in MSS/pMMR LARC. **Methods:** This trial is an open, prospective, multi-center, single-arm phase II clinical study assessing the efficacy and safety of neoadjuvant chemoradiotherapy combined with thymosin andtislelizumab in MSS/pMMR LARC. Stage II/III MSS/pMMR LARC patients ($cT_{3\text{-}4a}N_0M_0$ and $cT_{1\text{-}4a}N_{1\text{-}2}M_0$) with the tumor distal location $\leq$ 10 cm from anal verge at two centers in China were consecutively enrolled. Patients received chemoradiotherapy (50 Gy/25 f, 2 Gy/f, 5 days/week, 5 weeks; plus capecitabine 850-1000 mg/m^2, bid, po, 5 days/week, day1-5), thymalfasin (4.8 mg, biw, ih, day 1 and day 4 from week 1-11) and three 21-day cycles tislelizumab (200 mg, iv.gtt, week 2, 5 and 8) as neoadjuvant therapy. Adjuvant therapies after neoadjuvant were nonuniformly specified and decided according to clinical experiences. The primary endpoint is the complete response (CR) rate, defined as the achievement of clinical complete response (cCR) after neoadjuvant therapy or pathological complete response (pCR) after total mesorectal excision (TME). **Results:** From Feb 2024 to Aug 2024, a total number of patients (n = 25) were enrolled and 3 patients were excluded because of T4b and dMMR. Finally, 2 patients were discontinued and 20 completed neoadjuvant therapy. The median age was 67.5 (from 36 to 74) years while the median tumor distal location was6.0 (from 3.5 to 8.5) cm. The CR, PD, and SD rate was 40.0% (8/20), 45.0% (9/20), and 15.0% (3/20) correspondingly, with the ORR rate of 85.0% (17/20). Grade 3 treatment-related adverse events (trAEs) including leukopenia and neutropenia were observed in 1 (5%) patient, while grade 1-2 trAEs were observed in 15(75.0%) patients. As for Dec 31, 2024, the EFS rate was 100% (20/20) with median follow-up time of 18.57 weeks (from 6.86 to 31.86). **Conclusions:** Neoadjuvant chemoradiotherapy plus thymalfasin and tislelizumab show promising anti-tumour activity in MSS/pMMR LARC patients, with manageable toxicities. This study suggests that such combination could be a promising therapeutic strategy for patients with MSS/pMMR LARC. Clinical trial information: NCT06056804. Research Sponsor: Beijing Li Huanying Medical Foundation.

Neoadjuvant ONO-4578, an EP4 antagonist, in combination with nivolumab after chemoradiation therapy in locally advanced resectable rectal cancer. First Author: Yusuke Takahashi, Department of Gastroenterological Surgery, NHO Osaka National Hospital, Osaka, Japan

Background: Neoadjuvant nivolumab (NIV) after preoperative chemoradiation therapy (CRT) demonstrated promising pathologic complete response (pCR) in patients (pts) with locally advanced resectable rectal cancer (LARC) (Bando, *Clin Cancer Res* 2022). On the other hand, the prostaglandin E_2-EP4 signaling is known to induce immunosuppression in tumors. ONO-4578 (4578), an antagonist of EP4, in combination with NIV has shown a manageable safety profile and signs of anti-tumor activity in pts with solid tumors. In this ONO-4578-03 study, we evaluated safety, preliminary efficacy, and biomarkers of 4578 plus NIV after preoperative CRT in pts with LARC. **Methods:** Pts with LARC who received preoperative CRT (50.4 Gy with capecitabine 1,650 mg/m^2) were eligible. Pts were divided into two groups for neoadjuvant therapy: 4578 monotherapy lead-in (lead-in) and the combination group. Pts in the lead-in group received 4578 (40 mg, oral, daily) alone for 6 weeks, and then 4578 plus NIV (240 mg, intravenous, every 2 weeks) for 4 weeks, while pts in the combination group received 4578 plus NIV for 10 weeks. Subsequently, pts in both groups received radical resection. The primary endpoint was safety. Secondary endpoint was efficacy, including pCR rate using the AJCC tumor regression grading. Ongoing exploratory endpoints include tissue and blood biomarkers. **Results:** We enrolled 31 pts: 10 and 21 to the lead-in and combination groups, respectively. The median age was 62.0 (range, 39–76) years, 20 pts (64.5%) had a disease stage of III, and all pts were classified as microsatellite stable. The pCR (AJCC grade 0) rates in the lead-in group, the combination group, and overall population were 50.0% (5/10 pts), 23.8% (5/21 pts), and 32.3% (10/31 pts), respectively; the major pathological response (MPR; AJCC grade 0+1) rates were 70.0% (7/10 pts), 71.4% (15/21 pts), and 71.0% (22/31 pts), respectively. Among all pts, any-grade treatment-emergent adverse events (TEAEs) occurred in 23 pts (74.2%). including 3 pts (9.7%) with grade 3 TEAEs (appendicitis, ileus, drug-induced liver injury, hypertension) and 1 pt with serious TEAEs (ileus, drug-induced liver injury). None of the TEAEs led to treatment discontinuation or death. Any-grade treatment-related adverse events (TRAEs) occurred in 11 pts (35.5%), including 1 pt with a serious TRAE (grade 3 drug-induced liver injury). Radical resection was not performed within the protocol-defined window in 1 pt in the lead-in group and in 2 pts in the combination group due to progressive disease, a TRAE (grade 1 hyperthyroidism), or clinical CR, respectively. As of the final analysis, 5 pts experienced recurrence and 1 pts died in the overall population, after the median follow-up of 23.29 (range, 15.9–32.9) months. **Conclusions:** Neoadjuvant 4578 plus NIV after CRT showed a manageable safety profile and promising pCR rates and MPR rates in pts with LARC. Clinical trial information: jRCT2051200096. Research Sponsor: Ono Pharmaceutical Co., Ltd.

Single-incision laparoscopic surgery vs conventional laparoscopic surgery for colorectal cancer: Short-term outcomes of a multi-center, randomized, controlled trial. First Author: Yaqi Zhang, Ruijin Hospital, Affiliated by Shanghai Jiaotong University School of Medicine, Shanghai, China

Background: Single-incision laparoscopic surgery (SILS) is increasingly being embraced in the medical community due to its potential to offer less-invasiveness and quick recovery. This multi-center randomized controlled trial compared the short-term and long-term outcomes of single-incision laparoscopic surgery (SILS) with conventional laparoscopic surgery (CLS) for colorectal cancer, which might be the first of its kind that involved both colon and rectal cancer. Study recruitment has completed, and the follow-up is ongoing. Here we report the short-term outcomes of this trial. **Methods:** The trial was conducted across 11 hospitals in 6 provinces of China. Participants included patients with histologically confirmed colorectal carcinoma that situated above the peritoneal reflection, clinically staged as I-III. Patients were randomly assigned in a 1:1 ratio to SILS or CLS group. Comprehensive perioperative data were meticulously gathered, and follow-up assessments were scheduled postoperatively. The primary endpoint was 3-year disease-free survival (DFS), secondary endpoints included overall survival (OS), oncological efficacy, and postoperative outcomes. **Results:** Between May 2021 and April 2023, a total of 712 patients were randomly assigned to either the Single-incision Laparoscopic Surgery (SILS) group (n = 354) or the Conventional Laparoscopic Surgery (CLS) group (n = 358). The distribution of surgical procedures included 162 (22.8%) right hemicolectomies, 326 (45.8%) left hemicolectomies, and 224 (31.4%) proctectomies. The pathological TNM stages I, II, and III of the mITT population were 10.7%, 36.9%, and 52.4%, respectively. In the SILS group, 92.9% (n = 329) of the cases were completed entirely with a single incision. An additional trocar was used to assist the surgical procedure in 5.6% (n = 20) of the cases, and 0.8% (n = 3) were converted to conventional laparoscopic surgery. Two patients in the SILS group required conversion to open surgery, compared to 10 patients in the CLS group. The incidence of postoperative complications and oncological efficacy were statistically equivalent between the two groups. Moreover, patients in the SILS group reported significantly less postoperative pain (p = 0.02). There were no significant differences in short-term overall survival (OS) and disease-free survival (DFS) between the two arms. **Conclusions:** Single-incision laparoscopic surgery (SILS) for colorectal cancer has demonstrated with feasibility, safety, and efficacy. The less painful postoperative experience was aligned with the principles of Enhanced Recovery After Surgery (ERAS). This surgical approach extended the concept of minimally invasiveness and represents a logical progression towards Natural Orifice Transluminal Endoscopic Surgery (NOTES) or single-incision robotic surgery. Clinical trial information: NCT04527861. Research Sponsor: SHANGHAI HOSPITAL DEVELOPMENT CENTER.

The association of ctDNA with recurrence in patients with stage II-IV colorectal cancer: The β-CORRECT study. First Author: Tadayoshi Hashimoto, Department of Gastroenterology and Gastrointestinal Oncology, National Cancer Center Hospital East, Kashiwa, Japan

Background: CRC is a leading cause of cancer-related mortality globally. Detection of molecular residual disease (MRD) is an early indicator of recurrence and may allow for timely intervention. Here, we evaluated an analytically validated tumor-informed ctDNA MRD assay (Oncodetect) in a cohort of patients with CRC. **Methods:** This retrospective study utilized data and specimens from 468 patients with Stage II, III or resectable Stage IV CRC consecutively enrolled from June 1, 2020 through November 30, 2022 in the GALAXY study with available residual samples. Tumor tissue underwent whole-exome sequencing to identify up to 200 tumor-specific variants for designing a personalized MRD test. The test was used to assess ctDNA status in plasma at three timepoints: post-surgical (PS), post-definitive therapy (PDT) and in the surveillance period, which included the PDT and subsequent timepoints. The primary endpoint was the association of ctDNA status during surveillance with disease-free survival (DFS). An analysis of the association between RNA-seq expression and DFS was also planned. **Results:** Analysis included a total of 1648 ctDNA results from 417 patients with ≥1ctDNA result from ≥1 timepoint. Among these patients, 296 (71.0%) had colon and 121 (29.0%) had rectal cancer, 141 (33.8%) had Stage II, 249 (59.7%) Stage III and 27 (6.5%) Stage IV disease, and 255 (61.2%) received adjuvant chemotherapy. Median follow-up was 1.9 years. The median ctDNA level among detections, measured in mean tumor molecules per ml (MTM/ml) was 1.187 (range 0.006-3180.5). During surveillance, ctDNA detection was strongly prognostic for DFS (HR 36.6; CI 21.9 – 61.2; ctDNA status as a time-dependent variable). Similarly, ctDNA detection was strongly associated with DFS at the PS and PDT timepoints (Table). Multivariable analysis showed ctDNA status remained strongly associated with DFS while other clinicopathological factors did not. The median lead time between ctDNA detection and clinical recurrence was 97 days (95% CI: 51-114). RNA-seq analysis is ongoing. **Conclusions:** In a cohort of 468 patients who underwent curative-intent surgery for stage II-IV CRC, a tumor-informed quantitative ctDNA assay using up to 200 variants was strongly prognostic for DFS at all timepoints. The prognostic ability of RNA-seq expression analysis for ctDNA status and outcome in this cohort is currently being determined. Research Sponsor: Exact Sciences; Japan Agency for Medical Research and Development.

Association of ctDNA status with DFS.

	Statistic	Result
Surveillance (n= 398)	HR (95% CI)	36.6 (21.9 – 61.2), p<0.0001
	Sensitivity (95% CI)	64.8% (53.2 - 74.9%)
	Specificity (95% CI)	98.8% (96.8 - 99.5%)
PS (n = 241)	HR (95% CI)	7.5 (4.3 – 13.1), p<0.0001
	Sensitivity (95% CI)	44.2% (31.6% - 57.7%)
	Specificity (95% CI)	95.6% (91.6% - 97.8%)
PDT (n = 367)	HR (95% CI)	24.0 (13.8 – 41.7), p<0.0001
	Sensitivity (95% CI)	45.5% (34.0% - 57.4%)
	Specificity (95% CI)	99.0% (97.1% - 99.7%)

Biologic correlates of circulating tumor DNA (ctDNA) shedding in the INTERCEPT colorectal cancer (CRC) study. First Author: Emerik Osterlund, Department of Gastrointestinal Medical Oncology, Division of Cancer Medicine, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: ctDNA is a promising tool for early cancer detection and monitoring of minimal residual disease (MRD). The relationship between vesicle trafficking of ctDNA-laden exosomes and shedding of detectable ctDNA in patients is poorly understood and was therefore explored in a large prospective patient cohort. **Methods:** The INTERCEPT program prospectively enrolled patients undergoing curative intent surgery for stage I-IV CRC at MD Anderson Cancer Center. Tumor informed MRD assays (Signatera) were drawn postoperatively and every three months according to reimbursement guidelines. RNA analyses were done from FFPE. Gene set enrichment analyses (GSEA) and Z-Scores comparing ctDNA+ and ctDNA− were analyzed using log2 normalized RNA expression values. **Results:** The cohort included 579 patients with RNA and post-operative ctDNA analyses; median age 56 years, 56% male and 47% stage IV. Of these, 122 (20%) were ctDNA+ in their first draw (32% of stage IV vs. 11% of stage I-III). In GSEA analyses of Hallmark gene sets between ctDNA+ and ctDNA−, an upregulation was seen for 15/50 gene sets among ctDNA+, with p-value < 0.05 and false discovery rate < 0.25. Two of the top signatures (UV response up and Unfolded protein response) were significant also in analyses stratified by stage. Analysis of the leading-edge genes in these gene set identified several members of the vacuolar ATPase (V-ATPase) family of genes which were highly enriched in ctDNA+. The full V-ATPase gene set substantially differed between ctDNA+ and ctDNA− (mean Z-score 0.48 vs. -0.13, $p < 0.001$), including when stratified by stage (I-III: 0.46 vs. -0.28, p = 0.002; IV: 0.49 vs. 0.10, p = 0.051). Sixty percent of patients (n = 346) had relapse event data with sufficient follow up. V-ATPases had higher mean Z-scores in those with relapses than those without (0.33 vs. −0.91, p = 0.012), also seen in the ctDNA− group (0.30 vs. -0.20, p = 0.021). **Conclusions:** V-ATPase genes are differentially expressed in patients with ctDNA+ regardless of tumor stage, a result also mirrored in relapse events. V-ATPases may play a significant role in ctDNA release through regulating intracellular multivesicular bodies to exosome release, thereby providing a potential mechanistic link between tumor biology and ctDNA shedding. This finding may explain the clinical limitations of ctDNA in selected patients and provide personalization of ctDNA testing performance in the future. Research Sponsor: None.

Phase II study of short-course radiotherapy (SCRT) followed by consolidation chemotherapy with FOLFOXIRI as total neoadjuvant therapy (TNT) for locally advanced rectal cancer (LARC) patients (pts): The ShorTrip study. First Author: Martina Carullo, Unit of Medical Oncology 2, Azienda Ospedaliera Universitaria Pisana and Department of Translational Research and New Technologies in Medicine and Surgery, University of Pisa, Pisa, Italy

Background: TNT is a recognised option for the treatment of LARC. The efficacy of both FOLFIRINOX followed by long-course CTRT and SCRT followed by FOLFOX or CAPOX was demonstrated in two phase III trials. No data are available regarding the feasibility and activity of SCRT followed by the triplet as TNT in LARC. **Methods:** ShorTrip is an Italian, prospective, multicentre, single-arm phase II trial (NCT05253846). Pts ≤70 years with medium-high (5-10 cm from the anal verge) LARC with at least one of the following features: cT4, cN2, involved mesorectal fascia (MRF+) or cT3N+, received SCRT followed by 8 cycles of FOLFOXIRI and surgery. The primary endpoint was the pCR rate. According to the Fleming single stage design, hypothesizing p0 = 0.25 and p1 = 0.40, setting 90% power with an α error of 0.10 (one-sided), the experimental regimen would have been considered promising if at least 21 pCRs were observed out of 63 enrolled pts. After the first 11 pts starting consolidation treatment, a higher than expected occurrence of severe neutropenia after the 1st cycle of FOLFOXIRI (N = 7, 64%) was observed and the protocol was amended to administer one cycle of FOLFOX after SCRT followed by 7 cycles of FOLFOXIRI. **Results:** From January 2022 to February 2024, 64 pts were enrolled in 9 centres with the following characteristics: median age 62 years (IQR 55-66), male 66%, ECOG PS = 0 89%, medium/high rectum 76%/24%, cT2/cT3/cT4 5%/76%/19%, cN0/cN1/cN2 2%/35%/63%, MRF+ 42%, lateral nodes 35%, EMVI+ 41%. The 52 tumors tested for MMR were pMMR. One patient withdrew consent after the 1st cycle of chemotherapy and was not evaluated for pathological response. 21 (33%) and 43 (67%) pts achieved pCR and major pathological response (MPR), respectively. Almost all pCRs (N = 20, 95%) and MPRs (N = 42, 98%) were observed in pts receiving at least 5 cycles of FOLFOXIRI (N = 56). Among 63 resected pts, 62 (98%) and 1 (2%) achieved R0 and R1 resections, respectively. All pts completed SCRT and the only grade 3/4 acute toxicity was diarrhoea in 7 (11%) pts. 49 (77%) pts received 8 cycles of consolidation treatment as planned. Irinotecan was never administered in 5 (8%) pts. Main grade 3/4 toxicity during consolidation are listed in the Table. Early post-surgical complications were reported in 8 (13%) pts. **Conclusions:** SCRT followed by one cycle of FOLFOX and 7 cycles of FOLFOXIRI showed a promising activity and a feasible safety profile and is therefore worth of further studies especially in the NOM scenario. Clinical trial information: NCT05253846. Research Sponsor: GONO Foundation.

Digital spatial profiling: Mapping tumor responses to radiotherapy in rectal cancer. First Author: Rachel Violet Purcell, Department of Surgery and Critical Care, Christchurch, New Zealand

Background: Variation in response to radiotherapy for the treatment of rectal cancer is likely due to heterogeneity in the tumour microenvironment. However, to date, no reliable predictive biomarkers of response are in clinical use and the mechanisms underlying response are unknown. Tertiary lymphoid structures (TLS), which are ectopic lymphoid aggregates found in the tumour microenvironment, have been linked to response to immunotherapy, but little is known about their role in radiotherapy. Here, we aimed to explore the potential of lymphocytes and tertiary lymphoid structures as predictive biomarkers of response to radiotherapy and profile the tumour immune microenvironment in the context of response to radiotherapy. **Methods:** For this study, we accessed pre-treatment biopsies from 20 rectal cancer patients with known pathological response to long-course chemoradiotherapy (LCCRT). We selected regions of interest based on immunohistological identification of tumour and lymphocytic infiltrate in formalin-fixed paraffin-embedded tissue. We performed targeted proteomic profiling of 87 immuno-oncology proteins using the Nanostring GeoMx Digital Spatial Profiler to quantify protein expression with spatial resolution within regions of interest, including TLSs, in the tumour microenvironment. **Results:** Unsupervised clustering based on normalised protein expression showed a clear separation between the complete responders to LCCRT and all other tumours, and this separation is driven by differences in T cells within TLSs (CD3+). Differentially expressed proteins within CD3+ aggregates include depletion of the natural killer cell marker, CD56 and increased expression of the apoptosis marker, cleaved caspase 9. The distribution of TLS-tumour distance was also significantly different between response groups. **Conclusions:** The study highlights the role of TLSs in modulating the immunogenic landscape of the tumour microenvironment in rectal cancer, likely influencing the response to radiotherapy. Spatially resolved proteomic analyses identifies potential biomarkers for radiotherapy response and underscores the importance of profiling tumour-immune microenvironment complexity when stratifying patients for therapy. Clinical and immunopathological evaluation and its comparison with consensus molecular subtypes of colorectal cancer. First Author: Eduardo Feliciangeli, Hospital General Universitario Santa Lucia, Cartagena, Spain

Background: This study aims to elucidate the prognostic impact of the immunoscore within the context of consensus molecular subtypes (CMS), tumor budding (TB), and macrophage infiltration in colorectal cancer (CRC), addressing a gap in current research. **Methods:** A retrospective observational study analyzing 255 colorectal cancer cases. Demographic, histopathological, and clinical variables were examined. Molecular classification, immunoscore, and macrophage infiltration were determined via immunohistochemistry. The study adhered to ethical guidelines and received approval from our ethics committee. CMS assessment used automated staining for specific markers, with molecular subtype determined using an online classifier (Ten Hoorn et al.). Immunoscore calculation involved evaluating CD3+ and CD8+ immune cells, classifying patients into low or intermediate-high groups (Jiang et al.). Macrophage assessment focused on CD163+ cells, categorizing them as spindle-cell and round-cell. Statistical analysis employed SPSS, using descriptive statistics, chi-square tests, Kaplan-Meier survival curves, and multivariate analyses. **Results:** In this study of 255 colorectal cancer patients, predominantly with localized disease, 34.9% had stage III disease. Conventional and serrated adenocarcinomas were the main histological subtypes. CMS classification revealed mostly CMS2-3 (69.4%), with relapse occurring across all subtypes. Low immunoscore was common in conventional and serrated histology and CMS2/3, while MSI-H correlated with intermediate-high immunoscore. Tumor budding (TB) was prevalent in relapsed patients, especially in CMS2/3 and CMS4, and associated with serrated histology. Metastatic patterns varied by CMS subtype, with TB $>$ 20 foci linked to hepatic metastases. CD163 macrophage infiltration was associated with CMS1 and CMS2/3, and a high immune score. Over 9.6 years of follow-up, tumor budding was associated with overall and relapse-free survival, while CMS was linked to overall survival. Immunoscore showed no association with survival outcomes. **Conclusions:** This cohort shows heterogeneous disease progression and prognosis, with CMS2/3 exhibiting high tumor budding and relapse rates, especially in serrated histology. Molecular subtypes have distinct metastatic patterns: CMS1 to the peritoneum, CMS2/3 to the liver, and CMS4 to both. Relapsed CMS2/3 cases had low immunoscore, while CD163+ macrophage infiltration correlated with higher immune scores in CMS1 and CMS2/3, highlighting the complex interactions between molecular subtypes, immune responses, and tumor behavior. Neoadjuvant chemotherapy and surgery for rectal cancer: Omission of radiation in clinical practice. First Author: Matthew B. Hill, Memorial Sloan Kettering Cancer Center, New York, NY

Background: PROSPECT proved efficacy of induction chemotherapy and surgery, without radiation, for select stage II and III rectal cancer patients with improvements in bowel function and less diverting ileostomy. This approach also avoids radiation-associated alteration in fertility which is particularly important in the rising early onset population. In this study we review our broader current use of induction chemotherapy without radiation in locally advanced rectal cancer patients. **Methods:** Review of a prospectively maintained IRB approved, institutional database for patients treated with induction chemotherapy and surgery between 2015-2024. Clinicopathologic features are summarized, and disease-free survival (DFS) measured with the Kaplan-Meier method. **Results:** A total of 171 patients, median age 50 years (IQR 43-61), were identified with tumors located $\leq$5cm (n = 4, 2.3%), 6-10cm (n = 75, 44%), and 11-15cm (n = 92, 54%) from the anal verge. Pre-treatment MRI staging was available for 169/171 patients. 2 (1.2%) and 167 (99%) were MRI stage II and III including 23 with T4 lesions, 15 with extra-TME lymph nodes, and 28 with EMVI. Neoadjuvant chemotherapy regimens included CAPEOX (n = 71, 42%), FOLFOX (n = 98, 57%), and FOLFIRINOX (n = 2, 1.2%). 166 (97%) underwent low anterior resection with (n = 94, 57%) or without (n = 72, 43%) diverting ileostomy, 4 (2.3%) underwent abdominoperineal resection (APR), and 1 (0.6%) underwent a Hartmann procedure. Pathologic responses included: 28 (16%) AJCC TRG 0 (no viable cancer cells); 32 (19%) TRG 1 (small cluster/single cancer cells); 77 (45%) TRG 2 (residual cancer with predominant fibrosis); and 34 (20%) TRG 3 (extensive residual cancer). Tumor deposits were present in 24 (14%) and positive/close margin was noted in 2 (1.2%). With a median follow-up of 24 months, 4 (2.3%) patients developed local recurrence (salvaged with chemotherapy, radiation, and surgery) and 18 (11%) developed distant metastases. 1-year DFS was 92% (CI: 88-97) and 2-year DFS was 87% (CI: 81-93). **Conclusions:** Since PROSPECT, induction chemotherapy and surgery is being offered to higher risk rectal cancer patients, including those with T4 lesions and EMVI, with favorable results. Continued individualized care based on response to chemotherapy and omission of radiation can limit treatment related toxicity while maintaining excellent oncologic outcome. Performance of a targeted enzymatic methylation-based early detection test by different colorectal cancer subgroups. First Author: Xiaojian Wu, The Sixth Affiliated Hospital, Sun Yat-sen University, Guangzhou, China

Background: Colorectal cancer (CRC) is the second most frequently diagnosed cancer in China and early detection could prevent over 90% of CRC-related deaths. Blood-based tests that analyze molecular features of CRC cell-free DNA (cfDNA), such as methylation and fragmentation patterns, hold great promise for early detection. However, the impact of molecular characteristics related to tumor location or mismatch repair (MMR) status on test performance has not been thoroughly investigated. In this study, we developed a blood-based CRC early detection test and analysed its performance across different CRC subgroups. **Methods:** A targeted enzymatic methyl sequencing panel was developed to identify tumor-specific hyper- and hypo-methylation markers and fragmentation profiles. A case-control cohort of 536 participants (268 CRC patients, 268 controls) was enrolled and startified into training and validation sets base on case/control status and cancer stage with 5-fold cross-validation. A gradient-boosted tree model was built by combining probabilities from methylomic and fragmentomic features. The optimal cutoff value for the early detection was determined by Youden's index, High specificity and High sensitivity methods, respectively. **Results:** The overall performance of Youden's index, High specificity and High sensitivity methods was as follows: specificity of 93.7%, 99.3%, 90.3%, and sensitivity of 96.6%, 86.2%, 97.0%, respectively. The area under the curve (AUC) value is 0.989 (95% CI: 0.981-0.996) , which is higher than those in current reports. When employing the High specificity method, the sensitivities were comparable between left and right-sided colon cancer (86.3% vs 85.7%, p = 1.0), and also similar between the dMMR (deficient mismatch repair) and pMMR (proficient mismatch repair) (87.5% vs 85.8%, p = 1.0), indicating that this model is applicable to various CRC subtypes. Additionally the TNM staging, pathological differentiation status, and the expression of Ki67, which are closely related to aggressiveness, were correlated with the sensitivity (Table). **Conclusions:** We have established CRC early detection model based on ctDNA methylation and fragmentation profiles, which shows excellent overall performance. Notably, this newly developed blood-based model shows no significant differences in sensitivity between distinct tumor locations or varying MMR statuses, suggesting its broader applicability across different types of CRC. ctDNA dynamics and targeted therapies associated with genetic mutations in patients with colorectal cancer. First Author: Midhun Malla, University of Alabama at Birmingham, Birmingham, AL

Background: Colorectal cancer (CRC) is a heterogeneous disease with various genetic mutations that guide targeted therapy decisions, as outlined by NCCN guidelines. Here we evaluated the proportion of CRC patients receiving targeted therapies using Natera's proprietary Real-World Database. **Methods:** Whole-exome sequencing (WES) data of tumor samples from CRC patients undergoing tumor-informed ctDNA testing CRC were analyzed. WES was performed on tumor tissue as part of the assay design workflow for Signatera™ molecular residual disease testing, ordered between June 2019 and July 2024. From the overall cohort of 47,476 CRC cases, we selected those with *BRAF* V600 (prevalence 13.7%) or *KRAS* G12C (prevalence 3.3%) actionable mutations, resulting in 8,473 patients included in the analysis. We utilized commercially available claims data to identify targeted therapy usage among clinical cases in our database. We examined the use of 3 different FDA-approved targeted therapies in patients with CRC. **Results:** Among 8,473 CRC patients with clinically actionable mutations in BRAF or KRAS, the majority had a *BRAF* V600 mutation (78.6%; N = 6,662) followed by *KRAS* G12C (21.4%; N = 1,811). Staging information was available for 93.9% (7,953/8,473) cases, with 15.6% stage IV at first ctDNA testing and 1.5% (123/7953) upstaged to stage IV at subsequent testing. An additional 6.7% (487/7,233) cases were categorized as recurrent/metastatic based on treatment information from claims records. Overall rates of treatment with corresponding targeted therapies were 4.0% (264/6,662) and 3.3% (60/1,811) for *BRAF* and *KRAS*, respectively. Within the subgroup of confirmed recurrent/metastatic cases (N = 1,727), targeted therapy rates were 18.9% (233/1241) for *BRAF* and 10.7% (52/486) for *KRAS*. No therapy overlap and no discordant cases (i.e., BRAF therapy was not given to KRAS mutated cases, and vice versa) were observed. Targeted therapy was typically started after the start of ctDNA testing (*KRAS*: in 96.7%, 58/60 cases, median 422 days after, *BRAF*: in 75.8%, 200/264 cases, median 200 days after). ctDNA clearance rate on therapy (i.e. conversion from ctDNA+ to ctDNA-) was observed to be 37.6% (56/149) which matches objective response rates previously reported for radiological assessment. **Conclusions:** In this analysis, we demonstrate the utility of the commercial claims database to provide insights into different treatment modalities considered for patients with actionable mutations. Understanding patterns of ctDNA dynamics during targeted therapy can potentially act as a surrogate of treatment efficacy and may guide future clinical trials. Research Sponsor: None.

3598 Poster Session

Oncologic outcomes of organ preservation in patients with rectal adenocarcinoma treated with total neoadjuvant therapy: A single-center study. First Author: Mariem Galuia, AdventHealth Cancer Institute, Orlando, FL

Background: Total neoadjuvant therapy (TNT) reduces the risk of local recurrence and distant metastases in patients (pts) with locally advanced rectal cancer (RC). Selected pts who achieve a complete clinical response (cCR) after TNT who can undergo a strict surveillance protocol may be considered for non operative management (NOM) to preserve rectal function. **Methods:** We conducted an observational, retrospective, single-center study to evaluate watch-and-wait strategy in those achieved organ preservation & survival in pts with locally advanced or resectable metastatic pMMR RC treated with TNT. Pts received either induction chemotherapy followed by chemoradiation (INCT-CRT) or chemoradiation followed by consolidation chemotherapy (CRT-CNCT). INCT and CNCT consisted of 6-8 cycles of FOLFOX or 5 cycles of CAPEOX. CRT consisted of a total dose of 5,040-5,750 CGy to the tumor and lymph nodes along with capecitabine. Pts were assessed for treatment response with digital rectal exam, MRI, flexsig 8 weeks after TNT. Pts who achieved cCR or a near-cCR were offered NOM with WW. Close surveillance with the above-mentioned modalities was repeated every 3 months, CT chest/abdomen or PET scan was performed every 6 months. Data on local recurrence, distant metastases and survival was collected. **Results:** From Dec 2017 to Jan 2024, a total of 109 pts with RC went on WW after TNT in our center. Most pts were males (66%). Median age was 59 (30-88). The proportions of stages I to IV were 2.7%, 19.2%, %, 76.1%, and 3.6% respectively. After a median follow-up of 20.2 months, median time of sustained cCR was 67 weeks, tumor regrowth occurred in 7/109 (6.4%) pts. 3/109 pts developed distant metastases (8.5%). Median time from cCR to local regrowth/metastasis was 42 weeks. Recurrence was detected within the first 2 years in all 7 patients. 3/7 patients are in remission after salvage surgery, 2/7 pts were scheduled for surgery, 1/7 pts died of disease progression and another pt was a poor surgical candidate. 93% (102/109) of our pts are with no evidence of disease. **Conclusions:** Organ preservation for locally advanced rectal cancer is feasible and successful in a large community-based hospital system for selected pts who achieve cCR to TNT. WW is a reasonable and attractive strategy for both patients and oncologists that minimizes post-operative morbidity . Ongoing trials like JANUS aim at increasing cCR rate. Research Sponsor: None.

Neoadjuvant mFOLFOXIRI chemotherapy with or without cadonilimab versus mFOLFOX6 alone in locally advanced colorectal cancer: A randomized phase II study (OPTICAL2). First Author: Jianwei Zhang, Department of Medical Oncology, the Sixth Affiliated Hospital of Sun Yat-sen University, Guangzhou, China

Background: The current standard treatment for locally advanced rectal cancer is chemoradiotherapy (CRT) followed by total mesorectal excision (TME) . For locally advanced colon cancer, neoadjuvant FOLFOX is also an option. In the era of immunotherapy, several studies have explored the efficacy of CRT combined with immunotherapy treatment. However, no studies have yet investigated the efficacy and safety of chemotherapy combined with immunotherapy in locally advanced colorectal cancer. We aim to explore the efficacy of mFOLFOXIRI with or without cadonilimab (AK104) compared to mFOLFOX6 neoadjuvant chemotherapy in locally advanced colorectal cancer (LACRC). **Methods:** OPTICAL-2 was a randomized, phase II trial in patients with II/III rectal ancer and locally advanced colon cancer (T3 $\geq$5 mm or T4). Patients were randomly assigned (1:1:1) to 3 groups: preoperative mFOLFOXIRI plus AK104 for 6 cycles or mFOLFOXIRI for 6 cycles, or mFOLFOX6 alone for 6 cycles, followed by TME and adjuvant chemotherapy. The primary endpoint was pCR rate in mITT population, and the secondary endpoint was major pathological response (MPR) rate, 3-year disease-free survival, overall survival and safety. **Results:** From July 2023 to August 2024, 123 patients with LACRC were enrolled, with 41 patients in each group, including 22 colon cancer and 101 rectal cancer. As the data cutoff, 121 patients had underwent surgery (41 in mFOLFOXIRI plus AK104, 39 in mFOLFOXIRI group and 41 in mFOLFOX6 group). Preoperative radiotherapy was added after induction treatment in 5 (12.2%), 4 (9.7%) and 3 (7.3%) patients among the 3 groups. In the mITT analysis, the pCR rate was 26.8% vs. 15.4% vs. 9.8% among the 3 groups, respectively. The downstaging (ypStage 0 to 1) was 65.9%, 46.2% and 41.5%, respectively. The MPR rate was 68.3%, 48.7% and 43.9%, respectively. While in the PP analysis (completed 6 cycles of preoperative treatment), the pCR rates were 30.6%, 17.1%, and 10.8%, respectively. The downstaging was 63.8%, 45.7% and 37.8%, respectively. Safety assessments was generally well-tolerated. **Conclusions:** mFOLFOXIRI with AK104 demonstrated a higher pCR rate, downstaging rate and MPR rtae compared with FOLFOX chemotherapy in patients with LACRC. This study suggests that the combination of Intensified chemotherapy and dual immunotherapy may be a promising approach for improving treatment outcomes. Clinical trial information: NCT05571644. Research Sponsor: None.

Pathologic outcome and surgical parameters.

Impact of perioperative complications on ctDNA-based MRD detection and prognosis: Insights from the GALAXY study. First Author: Eiji Oki, Department of Surgery and Science, Graduate School of Medical Sciences, Kyushu University Hospital, Fukuoka, Japan

Background: The GALAXY study (UMIN000039205) demonstrated the utility of circulating tumor DNA (ctDNA)testing to detect molecular residual disease (MRD) and monitor postoperative recurrence. This analysis evaluates the influence of perioperative complications and the timing of blood sampling on MRD detection rates and predicting clinical outcomes. **Methods:** From the 6,032 patients enrolled in GALAXY, 2,400 were available for this analysis after excluding those enrolled in randomized trials or with insufficient follow-up. A clinically validated, tumor-informed ctDNA assay (Signatera, Natera, Inc.) was utilized to prospectively detect and quantify ctDNA. MRD was assessed within a defined postoperative "MRD window" of 2-10 weeks post-surgery. Perioperative complications were classified as Grade 2 or higher according to the Clavien-Dindo classification. **Results:** Perioperative complications occurred in 302 cases (12.6%), with anastomotic leakage (2.4%), ileus (2.0%), and intra-abdominal abscesses (1.3%) being the most common. Complications were more frequent in males and patients with rectal cancer. Cell-free DNA (cfDNA) concentrations measured at 2–4 weeks post-surgery were significantly higher in cases with complications compared to those without complications (9.2 vs. 6.9 ng/mL; $p < 0.001$). Three-year recurrence-free survival (RFS) was significantly worse in MRD-negative cases with complications (80.7%) compared to those without complications (87.0%; HR 1.63; 95% CI 1.143–2.323; p = 0.007). In MRD-positive cases, 3-year RFS was 15.6% in patients with complications versus 19.9% in those without (HR 1.16; 95% CI 0.831–1.608; p = 0.389). Among patients with complications, ctDNA testing conducted at 2–4 weeks post-surgery versus 4–10 weeks showed marked differences in 3-year RFS based on landmark analysis at 10 weeks. For MRD-negative cases, 3-year RFS was 75.32% versus 90.71% (HR 2.875; 95% CI 1.252–6.605; p = 0.013). In MRD-positive cases, 3-year RFS was 27.7% versus 6.25% (HR 0.46; 95% CI 0.230-0.929; p = 0.030). This trend was similar even when colon and rectal cancer were analyzed separately. In contrast, no timing-related differences were observed in cases without complications. **Conclusions:** Perioperative complications may elevate cfDNA levels, potentially confounding MRD assessment. Our findings suggest delaying ctDNA testing to at least 4 weeks postoperatively in patients experiencing Clavien-Dindo Grade $\geq$2 complications. These results provide essential guidance for optimizing clinical trial designs involving MRD evaluation through ctDNA analysis. Clinical trial information: UMIN000039205. Research Sponsor: AMED.

Long-term survival and treatment efficacy in dMMR/MSI-H rectal cancer: A real-world cohort from seven large medical college–affiliated hospitals. First Author: Siyuan Mi, Sun Yat-sen University Cancer Center, Guangzhou, China

Background: Neoadjuvant immunotherapy provides considerable advantages for patients with dMMR/MSI-H rectal cancer. However, treatment strategies in real-world settings vary depending on tumor characteristics, economic conditions, and the choices made by physicians and patients. **Methods:** We screened more than 10,000 rectal cancer cases from seven large medical college-affiliated hospitals. We used the Kaplan-Meier curve to compare survival and progression, applied Cox regression to analyze impact factors, and examined tumor regression grades with chi-square analysis. **Results:** From March 2010 to April 2024, 502 patients were enrolled and diagnosed with dMMR/MSI-H rectal adenocarcinoma through immunohistochemistry or PCR. 100 patients underwent neoadjuvant immunotherapy, demonstrating a 96.34% 5-year overall survival (95% CI: 86.08-99.08%), and 90.74% 5-year disease-free survival (95% CI: 74.67-96.82%). This indicated a 16.50% enhancement in overall survival ($p = 0.042$) and a 16.87% increase in disease-free survival ($p = 0.002$) compared to conventional chemoradiotherapy (5-year OS: 79.84%, 95% CI: 71.69-85.87%; 5-year DFS: 73.87%, 95% CI: 65.15-80.73%). Neoadjuvant immunotherapy demonstrated significant superiority in tumor regression ($p < 0.0001$), however, the combination with chemotherapy did not enhance the effect ($p = 0.622$), and varying chemotherapeutic agents did not improve tumor regression in conventional chemoradiotherapy either. Additionally, elevated serum CEA levels were associated with an increased risk of both death and disease progression. Patients with advanced age, lower clinical stages, and fewer risk factors were more likely to undergo direct surgical resection. **Conclusions:** Neoadjuvant immunotherapy is advantageous for dMMR/MSI-H rectal cancer patients, as it leads to better tumor regression and enhanced disease control. Research Sponsor: None.

Phase 1b study to assess the safety of neoadjuvant trifluridine/tipiracil with concurrent radiation in resectable stage II/III rectal cancer: Initial results of the FIERCE study. First Author: Emerson Yu-sheng Chen, Oregon Health & Science University, Portland, OR

Background: Total neoadjuvant therapy (TNT) with chemo-radiation (CRT) followed by doublet chemotherapy for rectal cancer can yield clinical complete response (CR) to allow successful surgery or organ-sparing. Trifluridine exhibited cytotoxic effect of ionizing radiation superior to fluorouracil in colonogenic survival assay (dose modification factor: 2.7). The FIERCE trial (NCT04104139) sought to determine the maximum tolerated dose (MTD) of trifluridine/tipiracil (FTD-TPI) with concurrent CRT during TNT with future goals of improving CR. **Methods:** MRI-staged participants (pts) with stage II (T3-4N0M0) or stage III (TxN+M0) resectable rectal adenocarcinoma, underwent CRT with FTD-TPI for 6 weeks followed by either FOLFOX or CAPOX for 4 months. Cohorts of 3 pts were examined at three dose levels (DLs) until a total of 18 pts were reached per Bayesian Optimal Interval design. FTD-TPI was taken orally BID for five days/week on weeks 1, 3, and 5 at the assigned dose (DL1 = 25mg/m2; DL2 = 30 mg/m2; DL3 = 35 mg/m2) with concurrent pelvic radiation of 25-28 fractions. Dose limiting toxicity (DLT) was defined by sustained hematologic, gastrointestinal, and serious adverse events related to FTD-TPI. Primary endpoint was the proportion of DLT from CRT at MTD. **Results:** Among 22 screened patients (3 ineligible and 1 removed for non-compliance in week 1), 18 pts were evaluable. Median age was 52 years (range 37-73), female sex was 4 (22%), and 16 (89%) were ECOG 0. All pts had proficient mismatch repair. All 18 pts were staged as cT3, with 8 (44%) N0 (stage II), 7 (39%) N1, and 3 (17%) N2. All 18 pts completed CRT in their assigned DL (6 DL1, 3 DL2, 9 DL3) followed by chemotherapy (16 FOLFOX; 2 CAPOX) with the 18th pt scheduled to finish treatment in February 2025. One pt was switched to irinotecan due to intolerable oxaliplatin-related neuropathy. During CRT, grade 3 neutropenia without fevers (4/18, 22%) led to 1/6 DLT in DL1 and 1/9 DLT in DL3, which were mitigated by dose interruptions (2/18 missed last week of FTD-TPI). No grade 4 adverse events were observed during CRT. At data cutoff, 10 (56%) pts entered into watch-and-wait surveillance, 6 (33%) pts had surgery, and 2 (11%) pts await final assessment. **Conclusions:** FTD-TPI at DL3, the MTD of 35 mg/m2 on days 1-5, 15-19, and 29-33, is the recommended phase 2 dose for CRT in TNT for locally-advanced rectal cancer. Short-course filgrastim, or day 29-33 adjustment to DL2, may be needed in last 2 weeks of CRT to prevent dose interruptions. A dose expansion study is being explored as the next step. Clinical trial information: NCT04104139. Research Sponsor: Taiho Oncology; OHSU Knight Cancer Institute.

Enhancing colorectal cancer precision medicine through multi-omics and clinical data integration with artificial intelligence. First Author: Enrique Velazquez Villarreal, City of Hope National Medical Center, Duarte, CA

Background: The integration of multi-omics and clinical data in precision medicine research for colorectal cancer (CRC) is a complex task that requires advanced computational tools. Artificial Intelligence agent for High-Optimization and Precision mEdicine (AI-HOPE) has emerged as a transformative platform, streamlining data integration, analysis, and discovery efforts. AI-HOPE is designed to integrate and analyze multi-omics alongside clinical data, facilitating novel insights into CRC pathogenesis, therapeutic responses, and precision medicine applications. **Methods:** AI-HOPE leverages Large Language Models (LLMs) to interpret natural language inputs and convert them into executable pipelines for multi-omics and clinical data analysis. Data from The Cancer Genome Atlas (TCGA) and other publicly available CRC datasets were utilized to demonstrate its capabilities. AI-HOPE supports analyses such as identifying mutation and gene expression patterns, pathway enrichment, survival analysis, and therapeutic outcome predictions. Three case studies were conducted: (1) identifying WNT and TGFβ pathway alterations in early-onset CRC (EO CRC) versus late-onset CRC, (2) evaluating the association between specific multi-omics signatures and progression-free survival in patients treated with FOLFOX chemotherapy, and (3) performing a precision medicine query to identify actionable gene mutations and tailored medications for CRC treatment. **Results:** Overall AI-HOPE answered queries with an accuracy of 0.98 and an F1 score of 0.89 (precision = 0.80). AI-HOPE identified significant alterations in the WNT and TGFβ pathways among EO CRC patients compared to late-onset cases, aligning with findings from published literature. In the second study, the platform revealed that patients with specific transcriptomic signatures (e.g., upregulation of MYC targets) had significantly worse progression-free survival when treated with FOLFOX chemotherapy, further supporting its utility in identifying clinically relevant biomarkers. AI-HOPE was used to query CRC datasets for actionable gene mutations, such as KRAS, BRAF, and MSI-H (microsatellite instability-high), and cross-referenced these findings with drug databases to identify tailored therapies. The analysis highlighted FDA-approved targeted treatments, such as EGFR inhibitors (cetuximab and panitumumab) for KRAS wild-type patients and immune checkpoint inhibitors (pembrolizumab and nivolumab) for MSI-H tumors. AI-HOPE also identified emerging therapeutic options from ongoing clinical trials, showcasing its potential for guiding precision medicine strategies in CRC. **Conclusions:** This study demonstrates the transformative potential of AI-HOPE in advancing CRC precision medicine research by seamlessly integrating multi-omics and clinical data. Research Sponsor: National Cancer Institute; National Cancer Institute; National Cancer Institute.

Complementary value of a digital pathology biomarker to post-surgery circulating tumor DNA in risk stratification of stage III colon cancer patients receiving adjuvant chemotherapy. First Author: Ingrid Franken, Department of Medical Oncology, University Medical Center Utrecht, Utrecht University, Utrecht, Netherlands

Background: The current standard of care for patients with stage III colon cancer (CC) is resection followed by adjuvant chemotherapy (ACT). About half of patients are cured by surgery and hence overtreated with ACT, whereas ~30% experience recurrence despite ACT. Several studies show that patients with no detectable circulating tumor DNA (ctDNA) after surgery are at a lower risk of recurrence (RR), although false negative ctDNA results remain a concern. Other studies show prognostic value of digital pathology biomarkers on resected CC tissue, like the Combined Analysis of Pathologists and Artificial Intelligence (CAPAI; Kleppe Lancet Oncol 2022). This study aimed to explore the potential added value of CAPAI to post-surgery ctDNA in risk stratification of patients with stage III CC receiving ACT. **Methods:** Patients were selected from the Prospective Dutch ColoRectal Cancer (PLCRC) cohort substudy PROVENC3 (Rubio-Alarcon AACR 2024), based on stage III CC treated with radical resection and adjuvant capecitabine or CAPOX. Post-surgery ctDNA status was determined using Labcorp Plasma Detect. From the resected tumor, a representative H&E slide was digitalized to generate a DoMore-v1-CE-CRC score, which was combined with the pT and pN stage and number of assessed lymph nodes for classification as CAPAI high-, intermediate- or low-risk. Three-year RR and Cox proportional hazard ratios (HR) were reported for ctDNA-based and CAPAI-based risk groups. Time to recurrence was compared between risk groups using the log-rank test. **Results:** Post-surgery ctDNA status and CAPAI risk classification were available for 163 patients. The 20 patients (12%) with detectable ctDNA had a higher recurrence risk (3-year RR 60% [32-77], HR 4.9 [2.5-9.6], $p < 0.001$) than patients with no detectable ctDNA (N = 143, 3-year RR 18% [11-25]). Within the subgroup with no detectable post-surgery ctDNA, 50 patients (35%) were classified as CAPAI high-risk. These CAPAI high-risk patients had a higher recurrence risk (3-year RR 35% [20-48], HR 4.2 [2.0-9.1], $p < 0.001$) than patients classified as CAPAI low/intermediate-risk, who were combined based on their observed similar RR (N = 93, 3-year RR 9% [3-15%]). **Conclusions:** In patients with stage III colon cancer treated with adjuvant CAP(OX), CAPAI risk classification has potential to further stratify RR in the subgroup with no detectable post-surgery ctDNA. These preliminary results suggest that CAPAI high-risk may help identify patients with false negative post-surgery ctDNA results. Over half of all patients had both no detectable ctDNA and were CAPAI low/intermediate-risk. Given their low RR in our preliminary results, future studies on larger patient cohorts should focus on the ability to combine biomarkers to select very low-risk patients and evaluate whether these patients can potentially be spared ACT. A novel active chromatin cell-free DNA (cfDNAac) assay for early detection of colorectal cancer. First Author: Yue Wendy Zhang, Aqtual, Hayward, CA

Background: Colorectal cancer (CRC) is the third most common cancer and the second leading cause of cancer-related deaths globally (Xi et al. 2021). In the U.S., it is estimated that 152,810 new cases and 53,010 deaths will occur in 2024, with an increasing incidence among younger adults (ACS, 2024). CRC is a multifactorial disease influenced by both genetic and environmental factors and typically progresses from normal epithelial tissue to adenocarcinoma through a well-established sequence of molecular events. Despite advancements in treatment, early detection remains a key driver of improved survival outcomes. While current screening methods— such as fecal immunochemical testing, fecal DNA testing, and colonoscopy— have reduced CRC mortality and morbidity, low compliance continues to be a significant challenge. In this study, we developed a proof-of-concept machine learning (ML) classifier leveraging active chromatin cell-free DNA ($cfDNA_{ac}$) signals in peripheral blood to differentiate CRC patients from healthy individuals. **Methods:** Plasma samples from treatment-naive colorectal cancer (CRC) patients (stages I–IV, n = 54), advanced adenoma patients (n = 14), and healthy volunteers (n = 40) were processed using Aqtual's proprietary active chromatin capture workflow to enrich regulatory-active chromatin cfDNA. Samples were split into a training set, which included 31 early-stage CRC samples (stage I: n = 13, stage II: n = 13, stage III: n = 5) and 19 healthy samples, and a hold-out set, comprised 37 disease samples (stage I/II: n = 6, stage III: n = 6, stage IV: n = 11, advanced adenoma: n = 14) and 21 healthy samples. A machine learning classifier was trained using 5-fold cross-validation with 5 repeats on the training set, and the performance was assessed on the hold-out set to ensure robustness and generalizability. **Results:** A machine learning classifier trained on genome-wide $cfDNA_{ac}$ signals demonstrated robust performance, achieving a mean AUC of 0.94 (95% CI: 0.92 - 0.96). It exhibited 93% sensitivity (95% CI: 84% -100%) for colorectal cancer detection (Stage I/II: 94%, Stage III: 95%, Stage IV: 91%) and 81% sensitivity (95% CI: 67% - 95%) for advanced adenoma, with a specificity of 90% in the hold-out set. Analysis of the top contributing $cfDNA_{ac}$ signals identified 852 promoter and 2,594 exon features derived from 2,678 unique genes. Gene-set enrichment analysis revealed significant associations with key cancer hallmarks, including KRAS signaling and epithelial-mesenchymal transition (EMT). **Conclusions:** This study highlights the potential of Aqtual's active chromatin capture assay to identify molecular features in plasma that differentiate CRC and advanced adenoma from healthy individuals. The ML classifier based on these signatures shows promise for future development as a non-invasive tool for early colorectal cancer and advanced adenoma detection and monitoring. Analysis of early onset colorectal cancer: Implications for research and clinical practice. First Author: Heather Halperin, University of Calgary, Calgary, AB, Canada

Background: Young onset colorectal cancer(YOCRC), diagnosed $<$ 50 years old, presents distinct challenges, including life transitions, and psychosocial needs. In Alberta, Canada an Adolescent and Young Adult(AYA) program was introduced at our tertiary cancer centres to address these unique needs through tailored resources and services. This study aimed to explore the YOCRC patients' adjuvant care experiences and describe resource utilization prior to and after the AYA program was established. **Methods:** A retrospective review of YOCRC patients diagnosed with StageIII disease from 2012-2022 and referred to Cancer Care Alberta for adjuvant therapy was performed. This study evaluated the adjuvant care experiences of YOCRC patients, focusing on demographics, tumor characteristics, toxicity, and psychosocial visits. Incidence rates over time was assessed using Joinpoint regression. The Edmonton Symptom Assessment System(ESAS) scores collected during treatment visits were used to characterize symptomatic concerns. Analysis included descriptive statistics and multivariate regression analysis. **Results:** Among 576 patients, the mean age at diagnosis was 42.9 years. There was a positive trend in incidence of diagnoses per year($p < 0.0001$), with an increase in diagnosis of 3.96%(CI 1.30-7.13) per year in patients aged 40-49. Patients with stages IIIB disease were older at time of diagnosis compared to stage IIIC($p = 0.025$). Higher stages had poorer outcomes with stage IIIA, IIIB and IIIC($p < 0.001$), however median survival was not reached for any stages due to a low death rate. Patients reported psychological related symptoms(well-being, sleep problems and tiredness) more commonly than physical symptoms. Psychosocial visits increased after AYA program initiation with annual rates rising from 7.8 visits/year(pre-AYA program implementation) to 24 visits/year(post-AYA implementation). Further, patients who attended psychosocial visits were more likely to be younger($p < 0.001$) and had higher overall mortality($p < 0.001$). Of patients with an ESAS of $\geq$4, patients who were 40-49 were more likely to attend psychosocial service appointments than those aged 20-39, odds ratio of 3.23(95% CI: 1.28-8.78). There was no difference comparing patients attending psychosocial visits or higher ESAS score with sex or stage. **Conclusions:** Stage III YOCRC patients are increasing in Alberta. An AYA program can improve resource utilization, psychosocial support, and enhance visit frequency for this population with unique needs. Greater prominence of psychological symptoms on ESAS highlight areas that could benefit from focused resources for this population. Research Sponsor: None.

Changes in demographics and patterns of colon cancer in the United States: A comprehensive SEER analysis 2010–2021. First Author: Guy Loic Nguefang Tchoukeu, Texas Tech University Health Science Center, Odessa, TX

Background: Over the past two decades, colon cancer has remained a leading cause of cancer-related morbidity and mortality in the United States. Changes in population dynamics, environment, and lifestyle have contributed to shifts in age, gender, tumor site, and stage at diagnosis. However, the extent of these changes over time remains underexplored. Understanding these temporal changes is crucial for improving screening strategies, identifying at-risk populations, and optimizing resource allocation. **Methods:** We conducted a cohort study of initial colon cancer diagnoses using the National Cancer Institute, Surveillance Epidemiology and End Results Program (SEER) over the period 2010 through 2021. The SEER data is comprised of 22 different registries across the United States (US), which captures approximately 47.9% of the US population. The exposure was the year of diagnosis, and the outcomes were the distributions of age, sex, site, and stage at initial diagnosis. Temporal trends in proportions were measured using Spearman correlation (ρ). The differences between distributions in 2010 vs. 2021 were measured using Fisher's test with the standardized mean difference (SMD) as effect size. 95% confidence intervals (95% CI) for proportions were determined using the normal approximation. **Results:** A total of 670,923 records were included in the study. The distribution of ages at initial diagnosis changed significantly over the study period (SMD = 0.1713, p-value $<$ 0.0001). In 2010, the mode of age group distribution was $\geq$ 85 years, 12.1% (11.8%–12.4%). The proportion aged $\geq$ 85 trended down over the period (ρ = -0.9930, p value $<$ 0.0001) from 12.1% (11.8%–12.4%) to 9.6% (9.3%–9.8%). In 2021 the mode of age group distribution at diagnosis was 65 to 69 years, 13.2% (12.9% - 13.5%). The proportion of males trended up over the period (ρ = +0.9021, p value $<$ 0.0001), increasing from 51.8% (51.4% - 52.2%) to 53.2% (52.8% - 53.6%). The difference in cancer stage was significant (SMD = 0.1818, p value $<$ 0.0001), with localized colon cancer decreasing (ρ = -0.9371, p value $<$ 0.0001) from 38.9% (38.5% - 39.3%) to 33.8% (33.4% - 34.1%) and distant colon cancer increasing (ρ = +0.9301, p value $<$ 0.0001) from 20.1% (19.8% - 20.5%) to 22.9% (22.5% - 23.2%). The difference in location was significant (SMD = 0.1185, p value $<$ 0.0001), with rectum as location trending up (ρ = +0.9330, p value $<$ 0.0001) from 21.7% (21.3% to 22.0%) to 24.6% (24.3% to 25.0%). **Conclusions:** The current findings suggest a significant shift in colon cancer presentation in the United States over the past decade. There is a significant increase in incidence among younger males, a trend towards more distant-stage cancers indicating delay in detection, and a growing prevalence of rectal cancers as the primary site. Changes in screening strategies and reinforcement of community awareness are necessary to improve the mortality rate. Research Sponsor: None.

Time-weighted ctDNA dynamics for precision monitoring of relapse risk in colon cancer. First Author: Alessandro Leal, Perlmutter Cancer Center, NYU Langone Health, New York, NY

Background: Effective monitoring for relapse is a critical component of post-surgical care in colorectal cancer (CRC), particularly for patients who remain at risk of recurrence despite curative-intent treatment. Circulating tumor DNA (ctDNA) is a powerful biomarker for detecting minimal residual disease (MRD) and predicting relapse with high sensitivity and specificity. However, its predictive value varies over time, with negative results closer to surgery being less reliable than results obtained later. Here we introduce a novel time-weighted approach to ctDNA monitoring using a tumor-informed assay (Signatera), assigning greater predictive power to negative results collected further from surgery. **Methods:** A Bayesian logistic regression model using 1,246 Signatera serial measurements was developed to predict recurrence risk across 167 patients with early-stage colon cancer, with time-weighted ctDNA dynamics as the primary predictive feature. Negative ctDNA values were assigned greater predictive power based on their temporal distance from surgery. Secondary covariates included clinical stage and adjuvant treatment status. Time-weighted ctDNA was calculated as the product of the ctDNA level at each timepoint and an inverse time factor ($1/(t+1)$), where t represents the weeks since surgery. The weighted values were aggregated for each patient to compute cumulative and average time-weighted ctDNA levels, which served as inputs to the model. Survival analysis was performed to evaluate recurrence-free survival (RFS), stratified by MRD status. **Results:** Tumor-informed ctDNA levels were measured longitudinally, with a median of 7 timepoints per patient (range, 2-16) collected over a median follow-up of 2.5 years. Stage distribution was 50% stage III (n = 83), 44% stage II (n = 74), and 6% stage I (n = 10). Mismatch repair deficiency was observed in 22 patients (13.2%). Adjuvant chemotherapy was administered in 102 patients (61.1%), and 16 patients (9.6%) experienced recurrence. Survival analysis revealed a significantly worse recurrence-free survival for MRD-positive patients compared to MRD-negative patients (HR = 4.2, 95%CI:2.8–6.4, Log-rank $p <$ 0.0001). The Bayesian logistic regression model demonstrated robust predictive performance, with a posterior probability of recurrence $<$ 5% for patients with three consecutive negative ctDNA results obtained $>$ 6 months after surgery. Conversely, the model assigned a $>$ 90% probability of recurrence for patients with persistent ctDNA positivity beyond the initial 3-month post-operative window. **Conclusions:** Time-weighted ctDNA dynamics demonstrated promising predictive capability for CRC recurrence. Our findings suggest that incorporating the temporal context of ctDNA measurements and leveraging the increasing reliability of negative results over time could refine risk stratification and improve personalized care strategies for CRC patients. Exploring transcriptomic regulation of the tissue-associated microbiome in oncogenic progression of colorectal cancer. First Author: Amanda Stafford, BioCorteX Inc., New York, NY

Background: The association between the tissue microbiome and colorectal cancer (CRC) etiology continues to be explored, and it has been proposed that certain bacteria drive oncogenesis. However, this field is hindered by a lack of mechanistic links. Considering the relationship between bacterial abundance and human gene expression allows us to traverse this functional gap. To date, work in this field has been largely restricted to considering the relationship between bacteria and Consensus Molecular Subtypes (CMS) of CRC. Here, we hypothesise that CRC-associated bacteria correlate with distinct expression profiles that drive CRC progression. **Methods:** Analysis was performed using BioCorteX's knowledge graph and proprietary engines, v20250128_100953. 16S rRNA sequencing and whole RNA data were collated from tissue samples across 3 independent cohorts from CRC patients (n = 59) and healthy volunteers (n = 23). In CRC patients, paired tumour and normal adjacent samples were analysed yielding 108 samples in total. The Pearson correlation between differentially abundant (DA) OTUs and differentially expressed (DE) genes was calculated, and false discovery rates (FDR) were applied. **Results:** 14,460 DE genes (FDR $<$ 0.05) were identified between tumour and normal adjacent tissues, 5,097 of which had an absolute log-fold change greater than 1. Seven OTUs were increased in CRC compared to normal adjacent (FDR $<$ 0.05) and were present in at least 20% of samples; Fusobacterium nucleatum, Akkermansia muciniphila, and five Streptococcus species. Of the 61,164 OTU-gene pairs analysed, 108 were significant (FRD $<$ 0.05) with a Pearson correlation greater than 0.5. The abundance of all five Streptococcus species was correlated with the expression of nine genes including: SPSB4 (r= 0.51, p = 1.86x10-8), which has previously been associated with CRC metastasis, and REN (r= 0.71, p = 1.21x10-17), which is associated with increased Wnt signaling. Moreover, the expression of LY6G6D, a recently discovered CRC-specific antigen, was positively associated with F. nucleatum abundance (r= 0.53, p = 4.94x10-9). **Conclusions:** This study identifies novel interactions between the CRC-associated microbiome and expression profiles. The consistent relationships between five Streptococcus species and specific genes is highly indicative of a functional co-evolution between host transcriptomics and microbiome, and implies relationships have less to do with the specific bacteria and are more related to function. This analysis adds a mechanistic explanation for some of the associations previously identified between the microbiome and CRC. Further analysis is required to identify if the host transcriptome creates a niche for these species or whether the presence of these species is altering the microbiome. This study demonstrates the value of integrated multi-omic analysis in understanding CRC pathogenesis. Research Sponsor: BioCorteX Inc.

Postoperative cfDNA levels and ctDNA detection rates in patients with stage II colon cancer screened for CIRCULATE (AIO-KRK-0217, ABCSG). First Author: Sebastian Stasik, Technical University Dresden, Dresden, Germany

Background: Postoperative circulating tumor DNA (ctDNA) has emerged as a prognostic biomarker for disease recurrence in patients (pts) with resected colorectal cancer (CRC) and may potentially guide adjuvant treatment decisions. The timing of ctDNA screening is critical, as postop. plasma cell-free DNA (cfDNA) levels may vary due to factors such as tissue disruption from the surgical resection. The CIRCULATE trial (NCT04089631) investigates ctDNA guided adjuvant therapy in stage II CRC pts in $>$ 140 centres in Germany and Austria. **Methods:** To investigate the impact of blood sampling time points on cfDNA concentrations and the ctDNA positivity rates, we analyzed the postop. plasma samples of 1439 pts with stage II CRC screened for CIRCULATE between 2020 and 2024. Blood samples were collected within 5-60 days post tumor resection in stabilizing tubes (Streck or PaxGene). Samples were analyzed for postop. cfDNA concentration and tumor-informed ctDNA in plasma samples by an error-reduced Next-Generation Sequencing (NGS) approach [Stasik S Front Genet. 2022]. **Results:** Plasma cfDNA concentrations (measured by qPCR for beta-globin gene) ranged from 0.02 to 20.32 ng/μL (mean: 0.689 ng/μL; median: 0.360 ng/μL). The highest cfDNA levels were observed within 2 weeks after surgery (mean: 1.079 ng/μL; median: 0.540 ng/μL), with a significant decrease in samples collected $>$ 3 weeks postop. (mean: 0.631 ng/μL; median: 0.355 ng/μL; $p<$ 0.0001), suggesting an impact of surgical trauma and subsequent cfDNA release from normal tissue. In ctDNA-neg. pts, cfDNA concentrations stabilized between 0.405 and 0.449 ng/μL during weeks 4-8. In contrast, ctDNA-pos. pts had significantly elevated cfDNA levels at 2 months post-surgery (mean: 0.972 ng/μL; p= 0.419), indicating ongoing tumor-specific DNA shedding associated with recurrent disease. Variant allele frequencies (VAFs) in ctDNA-pos samples were negatively correlated with cfDNA concentrations, particularly in early postop. samples (Spearman r = -0.508), suggesting a dilution effect of ctDNA post-surgery. This correlation diminished at later time points, supporting the potential advantage of later sampling to improve ctDNA sensitivity. Despite temporal variations in cfDNA concentrations, ctDNA positivity was consistent across all sampling intervals (i.e. week 1: 4.1%; week 6-8: 5.64%), demonstrating the assay's robust sensitivity. **Conclusions:** We observed a significant variation in cfDNA levels depending on the timing of postop. sampling. Different kinetics, such as cfDNA release from normal tissue and tumor shedding, may influence cfDNA levels and the sensitivity to ctDNA detection. Nonetheless, our assay demonstrates consistent and reliable sensitivity for ctDNA detection across all postop. sampling time points. Clinical trial information: NCT04089631. Research Sponsor: German Federal Ministry for Education and Research (Bundesministerium für Bildung und Forschung) / DLR; 01KG1817.

Multicentric evaluation of an artificial intelligence model to stratify stage II colon cancer patients from whole slide images. First Author: Abdelhakim Khellaf, Centre Hospitalier de l'Université de Montréal (CHUM), Montreal, QC, Canada

Background: Stage II colon cancer (IIA T3N0; IIB T4aN0; IIC T4bN0) represents nearly 25% of all colon cancers and includes a wide range of outcomes (5-year overall survival rate (OS) of 58.4% to 87.5%). We aim to test if a deep-learning-based analysis of whole slide histology images (WSI) can predict survival and highlight the most relevant morphologic characteristics underlying prognosis. **Methods:** We identified adult stage II colon cancer cases from the multimodal Cancer Genome Atlas (TCGA) and retrospective consecutive cases diagnosed between 2014-2019 (inclusive) from two independent centers (CHUM, Canada and IHP, France; IRB approved). We tested on these two independent datasets, an artificial intelligence (AI) algorithm trained on TCGA, using a cross-validation and cross-testing (80:20) framework. The model relies on a weakly-supervised attention-based pipeline that extracts survival driven histologic features from H&E WSI and assigns a risk score for each patient. The concordance index (c-index) was used as the primary outcome metric. Further testing of the survival score was performed with a multivariate Cox regression model. The stratification of the cohorts based on the risk scores was evaluated using Kaplan-Meier curves and log-rank test. 95% confidence intervals (CI) are provided. An adjusted two-tailed P value $<$0.05 was considered significant. The specific morphologic characteristics involved in the AI outcomes are under analysis. **Results:** The Discovery TCGA cohort consisted of n=463 colon cancer patients; 5-year OS: 68.7% (CI: 60.0%-75.9%). The external validation cohorts included (1) from CHUM, n=124 patients, 5-year OS: 67.0% (CI: 58.0%-75.0%), and (2) from IHP, n=123 patients, 5-year OS: 55.6% (CI 45.0%-67.0%). Cross-validation and testing yielded a c-index of 0.72 and 0.68 respectively, 0.67 for CHUM and 0.65 for IHP cohorts. After external validation, patients with a 'low-risk' score showed significantly higher 5-year OS than patients with a 'high-risk' score: CHUM: 75.0% (CI: 64.0%-84.0%) vs 53.0% (CI 38.0%-67.0%), P$<$0.05; and IHP 65.0% (CI: 44.0%-80.0%) vs 34% (CI: 21.0%-46.0%), P$<$0.01. Cox regression showed a significant effect of WSI-based survival score on 5-year OS: TCGA cohort HR=8.3 (CI: 3.1-12.8), P$<$0.001; CHUM: 7.6 (CI 2.7-21.8), p$<$0.005; IHP: 5.5 (CI 2.1-16.8), P$<$0.005. **Conclusions:** AI-based risk scoring for stage II colon cancer consistently correlated with 5-year OS across multiple independent cohorts, achieving good performances. These findings highlight the potential of modern computational pathology methods requiring minimal supervision to improve risk stratification of stage II colon cancer and patient care. Research Sponsor: IHP Group (France).

Development and validation of machine learning risk prediction models for detection of early-onset colorectal cancer: Data from 30 health systems in the United States. First Author: Wilson Lau, Truveta Inc, Bellevue, WA

Background: Incidence of early-onset colorectal cancer (EoCRC) in patients without any family history has been increasing in recent years. Our study leveraged advanced Large Language Models (LLM), like GPT-4, to predict EoCRC in a population comprised of multiple health systems across the United States. There is potential to improve patient care by suggesting early screening for patients who are predicted to be at risk by the model. **Methods:** We identified a population of 5532 patients aged between 18 and 44 in the Truveta data, which is a collection of 120+ million patient journeys across 30 U.S. health systems. 1376 (24.87%) were diagnosed of CRC based on their ICD and SNOMED-CT codes. Data was split into training (80%) and testing (20%) sets. For the prediction task, we applied GPT-4o and compared with XGBoost, one of the strongest non-generative machine learning models. We used patient demographics (age, gender, race, ethnicity), conditions, and lab results within the last 2 to 7 months prior to CRC diagnosis for model training. The last month before CRC diagnosis was excluded to avoid highly predictive signals. For XGBoost, the demographics were represented as one-hot feature vectors, indicating their presence or absence. Conditions were encoded by their diagnosis frequency within the time frame, while the actual values of the lab results were used as model features. For the LLM model, all patient information was input as plain text. Both conditions and lab results were represented by the names of ICD and LOINC codes in order to capture the clinical context. A Chain-of-Thought prompting strategy, incorporating detailed instructions and CRC-specific knowledge, was employed to guide the LLM. **Results:** Our test set consisted of 1105 patients in which 279 (25.25%) were diagnosed with CRC. Both XGBoost and GPT-4o achieved comparable results. Despite the uneven distribution of CRC diagnoses in the test samples, the fine-tuned GPT-4o achieved the highest precision (87.43%) and recall (57.35%). This indicates that the model can accurately predict EoCRC in the near future for over half of the patients. **Conclusions:** This study highlights the potential of using LLM to predict EoCRC in younger population. While the GPT-4o base model contains general medical knowledge, supervised fine-tuning with explicit guideline enhances its predictive capabilities. The high precision of the model performance minimizes the burden of unnecessary screening by identifying patients with relatively high risk. As AI technologies continues to advance, with sufficient governance policy in place, predictive models can be valuable tools for clinicians to suggest early screening and mitigate EoCRC for patients. Research Sponsor: Truveta.

Model	Precision	Recall	F1 score	Accuracy
XGBoost	83.77%	57.35%	68.09%	86.43%
GPT-4o (base)	68.61%	54.84%	60.69%	82.26%
GPT-4o (fine-tuned)	87.43%	57.35%	69.26%	87.15%

Use and benefit of adjuvant chemotherapy in early- vs average-onset colorectal cancer. First Author: Carolina Bernabe, Montefiore Einstein Comprehensive Cancer Center, Bronx, NY

Background: Despite improved mortality rates in colorectal cancer (CRC), the incidence of early onset-colorectal cancer (EO-CRC) has been rising in the United States. We aimed to explore trends in adjuvant chemotherapy (ACT) administration and evaluate its impact on overall survival (OS) and cancer-specific survival (CSS) in patients with EO-CRC (< 50 years old) and average-onset colorectal cancer (AO-CRC) [> 50 years old]. **Methods:** Adult patients (age >18) with Stage II-low risk (T1-T3 disease and more than 12 lymph nodes examined), stage II-high risk (T4 disease or less than 12 total lymph nodes examined) or stage III CRC diagnosed between 2010-2020 were identified in the Surveillance, Epidemiology, and End Results Program (SEER) Database. Cox proportional hazard models were used to assess the effect of ACT on OS and CSS in patients with EO-CRC and AO-CRC. **Results:** The final dataset included 8,998 patients with EO-CRC and 64,987 patients with AO-CRC (Stage II-low =27,446, Stage II-high =9,060, and Stage III = 37,479). Patients with AO-CRC were less likely to receive ACT compared to patients with EO-CRC across all stages: stage II-low (odds ratio [OR]: 0.27), stage II-high (OR 0.28), and stage III (OR: 0.32). From 2010 to 2020, the use of ACT decreased for EO-CRC (68% to 64%) but increased for AO-CRC (36% to 45%). In patients with AO-CRC, ACT improved OS and CSS in stage II-high (OS Hazard ratio(HR):0.48, 95%CI 0.42-0.54; CSS HR:0.48, 95%CI 0.42-0.54) and stage III (OS HR:0.38, 95%CI 0.37-0.40; CSS HR:0.38, 95%CI 0.37-0.40), but had no benefit in CSS for stage II-low disease (CSS HR: 1.01, 95%CI 0.84-1.22). In patients with EO-CRC, ACT improved OS (HR 0.70, 95% CI 0.56-0.88) and CSS (HR: 0.70, 95% CI 0.56-0.88) in stage III disease. No statistically significant survival benefit was observed for patients with stage II-low (CSS HR:1.11, 95%CI 0.66-1.86) or stage II-high (CSS HR:0.83, 95%CI 0.53-1.31).The 5-year survival probabilities by stage are shown in the table. **Conclusions:** Despite being used more frequently, the benefit of ACT in EO-CRC seems to be of less magnitude than in AO-CRC. These differences might be partially explained by the better survival outcomes of EO-CRC even without ACT. Though recommended by most clinical guidelines, ACT does not improve survival outcomes in patients with stage II high-risk EO-CRC. These findings highlight the need to improve risk stratification in early stage EO-CRC to better identify patients who may benefit from ACT. Research Sponsor: None.

5-Year survival probabilities by stage (II-Low, II-High, III).

Detection of early-stage colorectal cancer using multiplexed extracellular vesicle proteomic biomarkers. First Author: Todd A. Hembrough, Nexosome Oncology, Durham, NC

Background: Colorectal cancer (CRC) is very common worldwide, and detection of early-stage cancer is critical for improved survival rates. Advanced adenoma (AA) and early-stage CRC present challenges due to their small size and very low plasma expression of tumor-specific biomarkers. Genomics-based diagnostics struggle to detect these lesions, making it imperative to develop more sensitive approaches. Extracellular vesicles (EVs) are emerging as a promising solution for early-stage CRC detection. EVs are produced by tumor, tumor microenvironment and host cells, thus, unbiased analysis of all plasma EVs offers an expanded set of cancer specific biomarkers, and may aid in detection of small early-stage tumors. **Methods:** EVs were purified from patient plasma using size exclusion chromatography and a proprietary buffer system that enhances EV and corona recovery. TrueDiscovery Data-independent acquisition mass spectrometry (MS) analysis was conducted on EVs purified from 24 advanced adenoma (AA)/stage 0 dysplasia, 25 Stage 1 CRC and 75 normal patient plasma samples. An in-house Machine Learning (ML) pipeline was developed to identify differentially expressed proteins and to define protein multiplexes with extremely high Sens/Spec (> 0.99). **Results:** Around 2,500 QC'd proteins were ID'd per sample and ML identified 336 (AA/Stage 0) and 493 (Stage 1) differentially expressed proteins (DEP: absolute Log2FC>0.5; q-value <0.001; AUC>0.5). The DEPs from AA/Stage 0 and Stage 1 were trained and tested using ML and SMV to identified dozens of MS based multiplexes for each stage with near perfect diagnostic accuracy (~98-100%). These biomarkers were enriched with metabolic, immune and inflammatory proteins in line with our unbiased approach. MS protein multiplexes were then translated to ELISAs to build simple, high throughput assays. ELISA analysis of multiple biomarkers was performed in the training cohort, ML/SMV was used to define multiplex ELISA-based classifiers for Stage 1 CRC (Sen=0.95/Spec=0.96). This Stage 1 CRC training assay was locked and tested on a blinded cohort of Stage 1 CRC (30 control, 30 cancer). In this blinded cohort, we targeted maximal specificity yielding Sen=0.80, Spec=0.97 and AUC=0.95. These data represent significantly higher Sen/Spec than current genomic based liquid biopsy assays. Training and validation of AA and Stage 0 ELISAs is underway and will be presented. **Conclusions:** Blinded validation of EV proteomic biomarkers yielded extremely high Sen/Spec early-stage CRC. The unbiased EV analysis underscores the need to assess cancer specific biomarkers from TME and host response and highlights the value and opportunity of expanding liquid biopsy analysis beyond tumor specific genomics. Taken together this platform provides an exceptional opportunity to increase early-stage cancer detection which should result in better patient outcomes. Research Sponsor: None.

An early colorectal cancer screening programme based on bisulfite-free sequencing of methylated circulating tumor DNA. First Author: Rushan Fei, The First Affiliated Hospital, Zhejiang University School of Medicine, Hangzhou, China

Background: Colorectal cancer (CRC) screening tests based on colonoscopy and fecal DNA testing are limited due to their invasive nature and low compliance rates. Herein, we develop a non-invasive early screening test for CRC based on ColoSeer assay, which combines methylated DNA immunoprecipitation and bisulfite-free sequencing to analyze methylation patterns of circulating tumor DNA (ctDNA). **Methods:** Tumor and ctDNA methylation patterns in 1,336 subjects (430 healthy controls, 202 colorectal precursor lesions (CPLs), 704 CRCs) undergoing colonoscopy were evaluated using the ColoSeer assay. **Results:** In the discovery phase, we identified a set of 46 differential methylation markers to screen for CPLs or CRCs from healthy controls. The overall detection sensitivity of ColoSeer was 85.6% for CPL and 97.5% for TMN stage (0-II) CRC, with 92.8% specificity. **Conclusions:** The ColoSeer assay demonstrated a high degree of accuracy for predicting subjects with CPL or early-stage malignant tumors and has potential as a first-tier health screen for early detection of CRC. The impact of dietary patterns on inflammation and colon cancer risk: A retrospective study of 796 patients. First Author: Alina Zatsepina, Maimonides Medical Center, Brooklyn, NY

Background: Colon cancer significantly contributes to global cancer rates, with rising incidence linked to dietary and lifestyle changes. Diets high in ultra-processed foods promote systemic inflammation, while anti-inflammatory diets may reduce inflammation and cancer risk. This study investigates the relationship between dietary patterns, inflammatory biomarkers, and colon cancer risk. **Methods:** This retrospective study analyzed data from 796 patients with histologically confirmed colon cancer (2015–2023). Dietary habits were assessed using validated food frequency questionnaires (FFQs), categorizing participants by adherence to ultra-processed or anti-inflammatory diets using the Dietary Inflammatory Index (DII). Systemic inflammation was evaluated via biomarkers: C-reactive protein (CRP), interleukin-6 (IL-6), tumor necrosis factor-alpha (TNF-α), and white blood cell (WBC) count. Clinical data, including age, sex, BMI, smoking, physical activity, co-morbidities like metabolic syndrome and obesity, were extracted from medical records. Multivariate logistic regression was used to assess associations between dietary patterns, inflammation, and colon cancer risk. Subgroup analyses stratified by metabolic conditions and cancer stage identified potential interactions. The study adhered to STROBE guidelines. **Results:** Patients consuming diets high in ultra-processed foods (top DII quartile) had elevated inflammatory biomarkers (CRP: 14.8 $\pm$ 3.2 mg/L; IL-6: 8.6 $\pm$ 2.4 pg/mL; TNF-α: 7.2 $\pm$ 1.9 pg/mL) compared to those on anti-inflammatory diets (CRP: 4.3 $\pm$ 1.1 mg/L; IL-6: 2.9 $\pm$ 0.8 pg/mL; TNF-α: 2.3 $\pm$ 0.7 pg/mL; $p < 0.001$). Dietary patterns strongly correlated with colon cancer risk. Ultra-processed food consumers had an adjusted odds ratio (aOR) of 2.47 (95% CI: 2.01–3.03) for colon cancer, while anti-inflammatory diets had a protective effect (aOR: 0.62, 95% CI: 0.51–0.76). Subgroup analysis showed anti-inflammatory diets' protective effects were more pronounced in patients with metabolic syndrome or obesity, reducing cancer risk by 45% ($p < 0.001$). Early-stage colon cancer patients (Stage I–II) adhering to anti-inflammatory diets exhibited lower inflammation, suggesting potential benefits for disease progression and prognosis. Further analysis highlighted omega-3 fatty acids and polyphenols in anti-inflammatory diets as key in reducing inflammation by downregulating NF-κB signaling and pro-inflammatory cytokine production. **Conclusions:** Diets high in ultra-processed foods elevate inflammation and colon cancer risk, while anti-inflammatory diets provide protective benefits, especially in individuals with metabolic conditions. These findings emphasize the need for dietary interventions promoting anti-inflammatory patterns in cancer prevention and management. Further research should validate these results and explore underlying mechanisms. Research Sponsor: None.

Risk of pre-cancerous advanced adenomas of the colon in long distance runners. First Author: Timothy Lewis Cannon, Inova Schar Cancer Institute, Fairfax, VA

Background: Exercise induced gastrointestinal injury is believed to be associated with reduced blood flow to the intestines during long distance running. To our knowledge, there has not been evidence linking this type of exercise- induced bowel ischemia to carcinogenesis. After observing multiple "ultramarathoners" present to our cancer center with advanced colorectal cancer, we initiated a prospective IRB-approved study to evaluate the risk of advanced adenomas (AA) in long distance runners between the ages of 35-50. **Methods:** NCT 05419531 was a prospective study of subjects aged 35-50 years who had completed at least two registered ultramarathons (50 km or longer) or five registered marathons (26.2 miles). Subjects were excluded if they were known or suspected to have inflammatory bowel disease, familial adenomatous polyposis (FAP), or Lynch Syndrome. Prior to colonoscopy, each subject completed a questionnaire regarding dietary habits, bowel habits, and long-distance running history, with results to be reported in the future. All polyps discovered during colonoscopy were reviewed by a panel of gastroenterologists, pathologists, and oncologists to determine if they met the criteria for advanced adenomas, defined as lesions >10 mm, >25% tubulovillous features, or high-grade dysplasia. **Results:** Between October 2022 and December 2024, 102 subjects were screened, and 100 underwent colonoscopy as part of the study. The median age was 42.5 years; 55 of the participants were female and 45 were male. The historical benchmark used for expected AAs in average-risk individuals aged 40-49 years was 1.2%. Among the 100 subjects in this study, 15% (95% exact confidence interval: 7.9%- 22.4%) had confirmed AAs. 39 out of 100 subjects had at least one adenoma. Three additional subjects had three or more adenomas but did not meet our predefined criteria for AA and were not included among the 15 patients with AA. **Conclusions:** NCT 05419531 achieved its predefined endpoint for advanced adenomas, suggesting that "intensive" long distance running is a risk factor for advanced adenomas of the colon. Consideration of refined screening strategies for this population is warranted. Future pathological and epidemiological evaluations should explore causation and ancillary risk factors in this unique population. Clinical trial information: NCT05419531. Research Sponsor: Inova Schar Cancer Institute.

Reassessing colorectal cancer recurrence in solid organ transplant recipients: Implications for revised management guidelines. First Author: David Bradley Meyer, Sidney Kimmel Comprehensive Center, Johns Hopkins University School of Medicine, Baltimore, MD

Background: Patients with solid organ transplants (SOT) are at an increased risk of developing secondary malignancies, including colorectal cancer (CRC). However, the influence of SOT and associated immunosuppression on recurrence risk following definitive treatment is poorly understood. This study characterizes the recurrence risk of CRC in a cohort of patients that developed CRC after SOT. **Methods:** Patients treated within the Johns Hopkins and University of Wisconsin medical systems meeting study criteria were identified using SlicerDicer Epic reports. Manual chart review was performed to determine treatment course, patient/disease characteristics, and whether or not their disease recurred. **Results:** Fifty-two patients with CRC following SOT were identified, including those who had liver (n = 12), kidney (n = 26), combined liver and kidney (n = 5), combined pancreas and kidney (n=4), lung (n = 4), and heart (n = 1) transplants. Among these patients, 30 were male and 22 were female. Ten patients had recurrent CRC after curative intent treatment. Recurrence rates were as follows: 1 of 10 (10.00%) patients with stage I CRC, 5 of 12 (41.67%) patients with stage II CRC, and 4 of 18 (22.22%) patients with stage III CRC. The overall CRC recurrence rate in the cohort was 32.26%. **Conclusions:** In summary, a multi-institution retrospective cohort study of patients with CRC diagnosis following SOT demonstrated higher than traditionally expected recurrence rates in patients with stage I and II disease when compared to patients diagnosed with CRC without history of SOT. Further multi-institutional studies are warranted to validate this finding. If confirmed, this would suggest transplant status may alter adjuvant treatment decisions and warrant future prospective studies in this patient population. Research Sponsor: None.

Study cohort variables stratified by CRC staging.

Stage at Diagnosis	Avg. Age at Time of Diagnosis	Sex	Race	Transplant Type	Avg. Time from Transplant to CRC Diagnosis (months)	Recurrence Rate	Avg. Time to CRC Recurrence (months)	Avg. Overall Survival (months)

Impact of COVID-19 on the stage at diagnosis and mortality of colorectal cancer. First Author: Soyun Lim, Seoul National University College of Medicine, Seoul, South Korea

Background: When the COVID-19 pandemic started in 2020 in the US, the Centers for Medicare and Medicaid Services (CMS) recommended delaying all non-urgent procedures, including screening colonoscopies to prevent virus spread. An analysis of the CMS claims data showed a decrease in all screening modalities for colorectal cancer (CRC) including colonoscopy, fecal occult blood test, and blood-based gene analysis in 2020 compared to 2013-2019. We investigated the impact of COVID-19 on stage at diagnosis and mortality of CRC across racial groups. **Methods:** We utilized the Surveillance, Epidemiology, and End Results (SEER) database to obtain the age-adjusted incidence of localized, regional, and distant CRC at the time of diagnosis from 2013 to 2021. The year-over-year (YOY) change in the proportion of advanced (regional + distant) CRC was calculated. YOY changes in age-adjusted CRC mortality rates from 2014 to 2021 were also calculated. **Results:** From 2014 to 2019, the average YOY change in the proportion of advanced CRC across all races was 1.0% whereas in 2020, the rate was 3.9%. The increase in proportion of advanced CRC in 2020 was greatest in non-Hispanic Asian/Pacific Islanders (NHAPI), followed by Hispanics, non-Hispanic Whites (NHW), non-Hispanic American Indian/Alaskan Natives (NHAIAN), and non-Hispanic Blacks (NHB; 7.9%, 4.7%, 3.6%, 3.3%, and 3.3%, respectively). From 2014 to 2019, the average YOY change in CRC mortality across all races was -0.7% while in 2020, it increased by 5.4%. In 2020, the YOY change in mortality was greatest in NHAIAN, followed by Hispanics, NHB, NHW, and NHAPI (25.3%, 16.5%, 15.1%, 3.2%, and 1.2%, respectively). **Conclusions:** The proportion of advanced CRC increased in 2020 likely due to decreased screening most significantly in NHAPI. Also, mortality increased in 2020 possibly due to delay in access to care during COVID-19. Further studies are needed to evaluate the long-term effect of COVID-19 on the screening and mortality of CRC. Research Sponsor: None.

Proportion of advanced colorectal cancer and mortality rates of colorectal cancer from 2013 to 2021 by race.

Leveraging EHRs and a phenome-wide association study to identify pre-diagnostic clinical markers in early-onset colorectal cancer. First Author: Sachleen Kaur Tuteja, Center for Health Information Partnerships, Institute for Public Health and Medicine, Northwestern University Feinberg School of Medicine, Chicago, IL

Background: The incidence of colorectal cancer (CRC) has undergone a significant demographic shift, with diagnosis in individuals under 55 years escalating from 11% in 1995 to 20% in 2019 (Siegal et al., 2019). Traditional risk factors, such as obesity, diabetes, and colon microbiome changes, fail to fully explain this emerging clinical phenomenon, necessitating new approaches to identify pre-diagnostic markers in younger patients. Our study leverages electronic health records (EHR) and employs a Phenome-Wide Association Study (PheWAS) to characterize age-specific manifestations prior to diagnosis. **Methods:** A PheWAS was conducted with a cohort of 2,799 CRC patients from Northwestern Medicine (NM, 2012 – 2022). ICD-9/10 codes were categorized into 527 phenotypes using the PheCode framework. Logistic regression models were employed to examine associations between age groups ($<$ 55 vs. $\geq$55 years) and each phenotype during the 6 months preceding diagnosis. A control cohort of 294,590 non-cancer NM patients adjusted for age-related and baseline disease patterns. **Results:** Our approach revealed significant associations with age in 9 of 527 analyzed phenotypes, identifying well-documented CRC features and less recognized clinical markers. Younger patient cohorts exhibited elevated probabilities of critical clinical indicators, including lower gastrointestinal hemorrhage (22% [95% CI: 19-25%] vs. 11% [95% CI: 10-13%]; $p = 1.0 \times 10^{-11}$), hepatic dysfunction (6% [95% CI: 4-8%] vs. 4% [95% CI: 3-4%]; $p = 2.7 \times 10^{-6}$), and diverticular disease (4% [95% CI: 3-6%] vs. 3% [95% CI: 2-3%]; $p = 2.4 \times 10^{-11}$) compared to older patients. Furthermore, an analysis of 1,866 NM pathology reports revealed single-institution trends consistent with global CRC literature. Notably, younger patients showed higher prevalence of hereditary CRC (28% vs. 24%; χ^2 $p = 6.3 \times 10^{-8}$), greater left-sided tumor localization (51% vs. 45%; χ^2 $p = 0$), and increased proximal tumors (58% vs. 53%; χ^2 $p = 0$), corroborating studies that show a rise in proximal tumor incidence in patients under 50 and a decline in those aged 50–79. **Conclusions:** Our PheWAS study uncovered clinicopathological distinctions, revealing statistically significant variations in pre-diagnostic clinical markers that suggest a more aggressive and complex disease progression mechanism in early-onset CRC. The increased probabilities of clinical indicators—such as gastrointestinal hemorrhage, hepatic dysfunction, and diverticular disease—underscore the need for tailored diagnostic and screening strategies for younger populations. These results also highlight the value of utilizing phenotype-based methodologies to identify nuanced clinical features that may enable earlier detection and improve outcomes for younger CRC patients. Towards this goal, ongoing research aims to further delineate CRC clinical profiles between age groups. Research Sponsor: Northwestern University Office of Undergraduate Research.

Colorectal cancer screening and detection following USPSTF recommendations for ages 45-49: Insights from a large EHR cohort. First Author: Patricia Jane Rodriguez, Truveta Inc, Bellevue, WA

Background: Rising colorectal cancer (CRC) incidence in relatively younger adults prompted the US Preventative Services Task Force (USPSTF) to recommend screening in average-risk adults aged 45-49 in May 2021. While screening has increased for ages 45-49, differences in polyp and CRC detection by age group are unclear. **Methods:** Using a subset of Truveta Data, we identified patients aged 40-64, with no prior history of CRC, who underwent CRC screening procedures (colonoscopy or sigmoidoscopy) between 2018 and 2024, and for whom an associated report was available. Truveta Data contains de-identified electronic health record (EHR) data from a collective of US health care systems. Screening outcomes were extracted from pathology reports using natural language processing, including findings of polyps (tubular adenoma/adenomatous polyp, hyperplastic polyp, tubulovillous adenoma, sessile serrated adenoma, traditional sessile adenoma, juvenile polyp, and inflammatory polyp), adenocarcinoma, and benign/normal colonic mucosa. For patients with multiple screenings, the first was used. Family history of CRC and related syndromes (e.g., Lynch, Peutz-Jeghers) were similarly extracted from notes. Patient characteristics and screening outcomes were described by 5-year age band, before and after May 2021 USPSTF recommendations. **Results:** Of85,062 patients aged 40-64 who underwent CRC screening, 46,168 had first screening records in May 2021 or earlier ('pre period') and 38,894 after ('post period'). In the pre period, 4,270 (9%) patients were aged 45-49, compared to 7,403 (19%) in the post period. Sex balance improved for the 45-49 age group (56% were female pre vs. 50% post; $p < 0.05$), compared to younger and older age groups (40-44: 57% vs. 57%, 50-54: 48% vs. 48%, 55-59: 51% vs.49%, 60-64: 50% vs. 49%; $<$ 0.05 for 55-59 only). Adenomatous polyp findings increased for all age groups, but to the greatest degree for the 45-49 group (45-49: 45.7% pre vs. 53.4% post; $p < 0.01$) compared to other groups (40-44: 33.1% vs. 35.9%, 50-54: 58.3% vs. 59.9%, 55-59: 60.4% vs. 62.5%, 60-64: 63.2% vs. 64.5%; all $p < 0.05$). In contrast, adenocarcinoma findings occurred less frequently for ages 45-49 (2.1% pre vs. 1.0% post, $p < 0.01$), while remaining stable in both younger and older groups (40-44: 1.6% vs. 1.4%, 50-54: 1.2% vs. 1.1%, 55-59: 1.4% vs. 1.6%, 60-64: 1.3% vs. 1.3%; all $p > 0.05$). **Conclusions:** Following 2021 USPSTF CRC screening recommendations for average-risk adults aged 45-49, sex balance in screening increased, findings of adenomatous polyps increased, and findings of adenocarcinoma declined in this group. These results may reflect expected decreases in adenocarcinoma detection with expansion of screening to average-risk adults, or suggest that recommendations contributed to earlier detection of pre-cancerous polyps, before progression to adenocarcinoma. Additional studies are needed to explore complex causal relationships. Research Sponsor: None.

Sex differences in chemotherapy completion and adverse events among patients with colon cancer (CALGB/SWOG 80702) (Alliance). First Author: En Cheng, Department of Epidemiology and Population Health, Albert Einstein College of Medicine, Bronx, NY

Background: Increasing chemotherapy completion and reducing chemotherapy adverse events (AE) are critical to improve survival after colon cancer diagnosis. Sex, as a biological variable, may impact chemotherapy treatment differently, and thus further investigation is needed to examine sex differences in chemotherapy completion and adverse events among patients with colon cancer. **Methods:** Among an NCI-sponsored trial conducted among patients with stage III colon cancer (CALGB/SWOG 80702), all patients received standard adjuvant chemotherapy FOLFOX (fluorouracil, leucovorin, and oxaliplatin). To signal chemotherapy completion, we utilized relative dose intensity (RDI) calculated as the ratio of the delivered dose intensity to planned dose intensity; and reduced RDI (RDI $<$85%) was considered as a clinically significant deviation from standard FOLFOX. From clinicians' records of NCI's Common Terminology Criteria for Adverse Events (CTCAE), we primarily focused on clinically significant AE such as neutrophils decrease, nausea, platelets decrease, hypertension, peripheral neuropathy, diarrhea, fatigue, gastritis, creatinine increase, gastric ulcer, myocardial ischemia, and cerebral ischemia; and severe AE was defined as the occurrence of any above AE with CTCAE grade $\geq$3. Using multivariable logistic regression that adjusted for body surface area (BSA) and other clinicopathological confounders, we estimated adjusted odds ratios (OR) for the associations of sex with reduced RDI and severe AE. **Results:** Of 2201 patients, mean (standard deviation [SD]) age was 60.9 (10.9) years, 1019 (46.3%) were female, 1750 (79.5%) were White, 172 (7.8%) were Hispanic, 964 (43.8%) experienced reduced RDI, and 1156 (52.5%) had severe adverse events. Compared to males, females were at significantly higher risks of experiencing reduced RDI (OR [95% CI]: 1.57 [1.27-1.93], $P < 0.001$) and severe AE (OR [95% CI]: 1.73 [1.41-2.12], $P < 0.001$). **Conclusions:** Our findings suggested females are more likely than men to experience reduced RDI and severe AE during colon cancer chemotherapy. Clinical Impact: In the era of precision medicine, sex (as a biological variable) should be considered in optimizing colon cancer chemotherapy to improve completion and reduce toxicities. Comprehensive analysis of outcomes of patients with colorectal cancer in a racially diverse cohort. First Author: Manasawee Tanariyakul, University of Hawaii Internal Medicine Residency Program, Honolulu, HI

Background: Disparate outcomes have been reported among patients with colorectal cancer (CRC) as those with Medicare or Medicaid insurance and those of Native Hawaiian ancestry experience inferior survival. However, many CRC studies addressing Native Hawaiians and other Pacific Islanders and insurance status have not adjusted for a comprehensive range of confounding variables. In this study, we perform a comprehensive analysis of CRC outcomes adjusted for clinicopathological and socioeconomic factors. **Methods:** Data were abstracted for patients diagnosed with colorectal cancer between 2000 and 2022 in Hawaii. Overall survival of Asians, Whites, and Native Hawaiian or Other Pacific Islanders (NHOPI) was assessed using Cox proportional hazards regression models adjusting for clinical, pathological, and sociodemographic factors. **Results:** A total of 3275 patients were included in the final analysis. NHOPI were more likely to be younger ($p<0.001$), had a higher proportion of stable microsatellite status tumors($p=0.049$) and were more likely to have Medicaid insurance or be uninsured($p<0.001$) compared to Whites and Asians. NHOPI patients more often had high grade cancers compared to White and Asian groups. Medicaid or no insurance was associated with significantly higher mortality compared to private insurance in both univariate(HR: 1.373, 95% CI: 1.202–1.568, $p < 0.001$) and multivariate analysis(HR: 1.505, 95% CI: 1.309–1.729, $p < 0.001$). However, while Medicare showed higher mortality in univariate analysis(HR: 1.409, 95% CI: 1.245–1.594, $p < 0.001$), this association normalized after adjustment(HR: 1.088, 95% CI: 0.958–1.237, $p = 0.195$) (Table). NHOPI had significantly higher mortality compared to Whites after adjustment for variables(HR: 1.293, 95% CI: 1.107–1.510, $p = 0.001$). Interestingly, rectal tumors demonstrated higher mortality compared to right-sided tumors(HR: 1.318, 95% CI: 1.156–1.503, $p < 0.001$), while left-sided tumors showed no significant difference (Table). **Conclusions:** This study of a racially diverse population that NHOPI patients with CRC had significantly worse mortality compared to Whites after adjusting for clinicopathological and socioeconomic variables. We did not identify a significant association between Medicare insurance and increased mortality. Having Medicaid or being uninsured was significantly associated with worse survival outcomes, emphasizing the critical impact of healthcare access on survival. Research Sponsor: None.

Dietary risk factors associated with colorectal polyp risk and potential for progression to malignancy. First Author: Melissa Rachel Goldin, Vanderbilt University School of Medicine, Nashville, TN

Background: Colorectal polyp development and progression to cancer are associated with diet and microbial dysbiosis. Red and processed meat intakes have been associated with colorectal polyps, but evidence on probiotic and prebiotic usage is inconclusive. This study examines the association of dietary factors with colorectal adenomas (ADs) and sessile serrated polyps (SSPs) of low and high potential of progression to cancer. **Methods:** In the Colorectal Molecular Atlas Project, 1082 participants underwent a colonoscopy, and completed a questionnaire. Individuals were classified as polyp-free controls, and polyp cases with high potential for progression to cancer ($\geq$ 1 cm, villous component, high-grade dysplasia, or multiple AD and/or SSPs) or low potential (all other AD or SSP cases). Frequency of dietary intake derived from questionnaire responses was divided into quartiles (total meat, total red meat, total processed meat, chicken, and fish) or no intake/tertiles (total probiotic food: yogurt, kefir, sauerkraut, kimchi, fermented cabbage, kombucha, other fermented beverages). Multinomial logistic regression models were used to derive odds ratios and 95%CI after adjusting for confounders. **Results:** Highest intake of total meat was associated with increased risk of high progression potential polyps (OR 1.63, 95%CI 1.03-2.60) and sessile serrated lesions (OR 1.60, 95%CI 1.03-2.50) in comparison to lowest intake. Highest intake of red meat was associated with increased risk of high progression potential polyps (OR 1.80, 95%CI 1.16-2.80) and SSPs (OR 1.68, 95%CI 1.10-2.56) in comparison to lowest intake. The second quartile of fish intake was significantly associated with a reduced risk of polyps with low progression potential (OR 0.63, 95%CI 0.44-0.99) and ADs (OR 0.63, 95%CI 0.42-0.96) compared to lowest intake; however, the third and fourth quartiles were not significantly associated with risk. Chicken, processed meat, probiotic food, probiotic supplement, and prebiotic supplement intake were not associated with risk. **Conclusions:** Dietary risk factors may vary by type of polyp, thus, dietary recommendations should reflect these differences. Increased total and red meat intake may increase risk of polyps with high progression potential and sessile serrated lesions, and fish intake may reduce risk for polyps with low progression potential and adenomas. Probiotics and prebiotics may not be an effective risk reduction strategy. Research Sponsor: None.

Characterizing clinical outcomes and DNA co-alterations of ERBB2-amplified colorectal cancer. First Author: Mohamed Nuh, Baylor College of Medicine, Houston, TX

Background: A subset of colorectal cancer (CRC) features amplification (amp) of the ERBB2 gene. The prognostic role and treatment in these patients are poorly understood. This study aims to characterize the clinical outcomes and molecular profiles of ERBB2-amp CRC. **Methods:** This is a retrospective analysis of clinical outcomes data and next-generation sequencing at MD Anderson from 2006-2025 in patients with ERBB2-amp CRC including all classes of genomic alterations (GA) in other genes. Progression-free survival (PFS) and overall survival (OS) were assessed by Kaplan-Meier, log-rank, and cox regression. Chi square goodness of fit was assessed for the proportion of left versus right sided CRC. **Results:** 100 pts with ERBB2-amp CRC were identified. Patients (Table) who received ERBB2-directed therapy (n = 36) did not have significantly longer OS compared to those who received other systemic therapy (n = 57) (53.8 vs. 45.5 m, p = 0.35). Patients who underwent surgery (n = 64) (56.8 vs. 23.2 m, p = 0.01) or non-surgical localized therapy (n = 45) had longer OS (64.4 vs 45.5 m, p = 0.01). ERBB2-amp was more associated with left sided CRC (n = 80) than right-sided CRC (n = 19) (X^2= 39.34, df = 1, $p < 0.0001$) but there was no significant OS difference (53.8 vs. 45.5 m, p = 0.76). Median PFS (mPFS) for all 1st (n = 93), 2nd (n = 80), and 3rd line (n = 61) systemic therapy was 8.0, 5.1, and 4.9 m, respectively. mPFS for all ERBB-2 directed therapy (n = 59) was 3.5 m. The most common concurrent co-GA were TP53 (90%) and APC (64%) and most common co-amp were CDK12 (31%) and EGFR (23%). Concurrent APC mutation was associated with improved OS (53.8 vs. 26.2 m, p = 0.003). No other co-GA or co-amp, including KRAS, showed significant survival outcome associations. TP53 co-GA was present in 90% of both left and right-sided ERBB-2 CRC and KRAS co-GA in 15% and 32%, respectively. **Conclusions:** There was no difference in OS in ERBB2 amp CRC in patients who received ERBB2 directed therapy, however patients had improved OS with surgery or localized therapy options and should be offered to eligible patients if possible. Co-GA with APC mutation correlated with improvement in survival outcomes. Research Sponsor: None.

Baseline data, initial staging, treatments, and mutational profile for ERBB2 co-amp CRC.

Age at Diagnosis (median)	55 years
Gender — no.	M (56), F (44)
Stage at Initial Diagnosis — no.	I (6), II (6), III (18), IV (69)
Location of Primary Tumor — no.	R-sided (19), L-sided (80), Cecum (7), Ascending (8), Transverse (5), Descending (7), Sigmoid/Rectum (73)
Surgery — no.	Primary tumor (55), Liver metastectomy (24), Lung metastectomy (8)
Localized Therapy — no.	RT (36), Ablation (6), Y90 (4), Cryotherapy (1)
ERBB2 Directed Therapy (excluded if n=1) — no.	Trastuzumab (TRA) + Pertuzumab (20), ERBB2-directed trial drug (14), Trastuzumab deruxtecan (8), TRA (7), TRA + Tucatinib (4)
Mutational Profile	Co-GA: TP53 (90%), APC (64%), SMAD4 (18%), KRAS (18%) Co-amp: CDK12 (31%), EGFR (23%), MYC (19%), BRAF (13%)

Effects of marital status on survival in patients with colorectal cancer. First Author: Lisa Liu, George Washington University, Washington, DC

Background: Demographic factors such as marital status have been shown to have differential effects on cancer outcomes. It has been shown that married patients have higher 5-year survival rates compared with unmarried patients with colorectal cancer (CRC). However, most of these studies looked at patients diagnosed prior to 2015. This study compares the survival trends between 2000–2010 and 2011–2021 and analyzes marital status associations with stage at diagnosis. **Methods:** Patients with CRC diagnosed between 2000 and 2021 were identified in the SEER database and stratified by marital status (single, separated/divorced/widowed (SDW), and married). 5-year survival rates with 95% confidence intervals were calculated for each marital status group across three periods: 2000–2010, 2011–2021, and 2000–2021. Kaplan-Meier survival analysis was used to compare survival outcomes across these variables. Disease severity was classified into three stages: localized, regional, and distant. The distribution of patients across disease stages is reported as the proportion of individuals within each marital status group at each cancer stage. **Results:** Overall survival was statistically different amongst patients with different marital statuses ($p < 0.01$). Our results show that the highest 5-year overall survival rate is seen in married individuals at 62.1% (61.9% - 62.2%), followed by single individuals at 53.0% (52.6% - 53.3%), and SDW individuals at 44.6% (44.3% - 44.8%). Overall survival improved over time across all marital groups when comparing the 2000–2010 and 2011–2021 periods. For married individuals, 5-year overall survival rate increased from 61.2% (61.0%–61.4%) to 63.1% (62.9%–63.4%). Similarly, survival improved for single individuals (51.1% [50.6%–51.6%] to 54.5% [54.0%–54.9%]) and for SDW individuals (43.8% [43.5%–44.1%] to 45.7% [45.3%–46.1%]). Our results show that married individuals were most commonly diagnosed with localized cancer compared with single and SDW individuals (41.8% vs 36.5% vs 39.0%, $p < 0.01$), SDW individuals with regional cancer compared with single and married individuals (38.3% vs 37.06% vs 37.5%, $p < 0.01$) and single individuals with distant disease compared with married and SDW individuals (26.4% vs 20.69% vs 22.69%, $p < 0.01$). **Conclusions:** Marital status significantly impacts CRC survival, with married individuals having higher survival rates than single or SDW patients. This suggests that social support may contribute to improved outcomes, although it is important to note that the higher survival rates may be associated with earlier diagnosis in married individuals. These findings highlight the potential need for additional support services for single and SDW individuals, underscoring the importance of considering marital status when addressing demographic disparities in cancer care. Clinicopathological features of colorectal cancer in adolescents and young adults (AYA) at a tertiary referral centre in Nigeria. First Author: Sharif Adeniyi Folorunso, Obafemi Awolowo University Teaching Hospital Complex, Ile Ife, Nigeria

Background: Colorectal cancer (CRC) is traditionally considered a disease of older adults; however, its incidence among AYA has been rising globally. In sub-Saharan Africa, including Nigeria, there is limited data on the clinicopathological characteristics of CRC in this age group. Understanding the patterns of CRC in AYA in Nigeria is crucial for developing targeted screening, early detection, and treatment strategies in this population. This study aims to investigate the clinicopathological features of CRC in AYA at a tertiary referral centre in Nigeria. **Methods:** A retrospective review of the ARGO-OAUTHC database was conducted to identify adolescents and young adults (age less than 40) diagnosed with colorectal cancer between 2013 and 2024. We compared AYA patients with middle-aged adults (ages 40-65) to assess differences in clinical presentation and histopathological features. Only patients with complete histopathology were included in the analysis while patients older than 65 years were excluded. Descriptive statistics were used to summarize the data, and statistical tests were performed to assess significant differences between the two groups. **Results:** 866 patients diagnosed with CRC were identified. Of these, 150 (18%) were AYA, with a median age of 33 years, and 448 (54%) were middle-aged adults (ages 40-65). The presenting symptoms were similar between the AYA and middle-aged groups, however, AYA patients were less likely to be diagnosed by colonoscopy (14.9% vs 29.4%, p = 0.002). Additionally, more AYA patients presented with symptoms that did not limit their daily activities , leading to a delay in seeking medical attention (9.3% vs 2.8%, p = 0.016). AYA patients were less likely to present with early-stage disease (Stages I and II) compared to middle-aged patients, (13.1% vs 20.9%, p = 0.045). Histopathological features were similar between the two groups overall, though mucin production was more prevalent in AYA patients (64.1% vs 45.2%, p = 0.044). Lung metastasis was less common in AYA patients (8.3% vs 23.5%, p = 0.011), the pattern of metastasis to other organs was however similar between the two groups. **Conclusions:** AYA patients in Nigeria tend to present at more advanced stages, partly due to the non-restrictive nature of their symptoms. They were less likely to be diagnosed via colonoscopy and were more likely to exhibit mucin production in their tumors. These findings underscore the need for increased awareness and early screening efforts for colorectal cancer in AYA populations to facilitate earlier diagnosis. Adherence to repeat screening for colorectal cancer using the multi-target stool DNA test: Real-world analysis of patients from federally qualified health centers. First Author: Mallik Greene, Exact Sciences Corporation, Madison, WI

Background: Initial and repeat colorectal cancer (CRC) screening rates are suboptimal and fall short of national goals in adults from historically disadvantaged backgrounds. This real-world study examined adherence to repeat mt-sDNA screening among patients from federally qualified health centers (FQHCs) across the US and among different payer types. **Methods:** Laboratory data from Exact Sciences Laboratories LLC were utilized for the period between January 1, 2023, and December 31, 2023, for those who had previously completed a mt-sDNA test. Study outcomes included adherence rate to mt-sDNA repeat screening and time to test return. The mt-sDNA screening adherence rate was defined as the percentage of patients who completed and returned the test kit and received a valid test result within 180 days of the initial shipment date. Time to test return was defined as the number of days from the date the test kit was shipped to the patient to the date ESL received the test kit with a specimen. **Results:** The study sample consisted of 19,536 eligible patients, including 9,592 (49.1%) aged 45-64 years, 8,689 (44.5%) aged 65-75 years and 1,225 (6.4%) aged 76-85 years. Overall, the mt-sDNA repeat screening adherence rate was 79.7% and the mean time to return the kit was 21.1 ± 20.8 days. A total of 2,375 (15.3%) individuals tested positive for CRC. Screening adherence for patients with Medicare was 84.7%, Medicare Advantage was 80%, commercial insurance was 78.2%, managed care organization was 74.6% and Medicaid was 65.9% ($p < 0.001$). Compared with patients covered by commercial insurance, those covered by Medicaid had 42% lower odds of adhering to mt-sDNA screening (OR: 0.582, 95% CI]: 0.461-0.733, $p < 0.001$). Patients with 2 or more prior successful tests had a numerically shorter mean time to test return compared to those with only 1 prior successful test, both overall and within each payer type. **Conclusions:** Findings from this real-world study suggest that patients receiving care from FQHCs had relatively high repeat mt-sDNA screening rates. While repeat screening adherence was generally high across patient demographic categories, there were significant differences by type of insurance coverage and number of prior successful mt-sDNA screenings. Research Sponsor: None.

Quality-adjusted time without symptoms of disease or toxicity (Q-TWiST) analysis of pembrolizumab (pembro) versus chemotherapy (chemo) in microsatellite instability–high (MSI-H)/mismatch repair–deficient (dMMR) metastatic colorectal cancer (mCRC) in the KEYNOTE-177 trial. First Author: Elena Elez, Vall d'Hebron University Hospital and Institute of Oncology (VHIO), Barcelona, Spain

Background: In KEYNOTE-177 (NCT02563002),first-line pembro provided significantly longer progression-free survival and a trend toward improvement in overall survival (OS) compared with chemo in participants (pts) with MSI-H/dMMR mCRC after > 5 years of median follow-up. The objective of this analysis was to assess Q-TWiST for pts treated in KEYNOTE-177. **Methods:** Q-TWiST combines efficacy, safety, and quality of life in a single measure. The analysis categorized survival time into 3 health states: time with grade ≥3adverse events before disease progression or death (toxicity [TOX]), time without symptoms or toxicity before disease progression (TWiST), and time from disease progression to death (relapse [REL]). In all randomly assigned pts, the restricted mean survival time (RMST) in each state was first weighted by a quality-of-life utility value, measured as treatment-specific EQ-5D-3L scores for each health state using the US value set, and then summed to calculate the Q-TWiST value. Relative gains (defined as the Q-TWiST differences between pembro and chemo divided by the RMST of chemo) of ≥15% were defined as "clearly clinically important." Treatment difference 95% CIs were generated using the nonparametric bootstrapping method. The data cutoff date was July 17, 2023. **Results:** At a maximum follow-up of 84 months, pts in the pembro arm had a 13.8-mo (95% CI, 4.8-21.7) longer RMST in TWiST (24.3 vs 10.5 mo), a 4.8-mo (95% CI, −0.5 to 10.2) longer RMST in TOX (10.7 vs 5.9 mo), and an 11.1-mo (95% CI, −21.2 to −0.8) shorter RMST in REL (18.1 vs 29.3 mo) compared with chemo. As a proportion of overall pre-progression time, pts in the pembro arm spent less time in TOX than the chemo arm (31% vs 36%). For the analysis of restricted mean Q-TWiST based on treatment-specific utility weights, the difference between pembro and chemo favored pembro by 9.1 mo (95% CI, 2.3-15.5), a 20.0% (95% CI, 4.8-36.8) relative Q-TWiST gain. When TOX definition included grade ≥2 adverse events, the relative Q-TWiST gain was 19.7% (95% CI, 4.7-36.5). When OS was adjusted for crossover to anti–PD-(L)1 therapy as second-line treatment, relative Q-TWiST gain was 39.7% (95% CI, 20.1-63.7). **Conclusions:** Pembro provided clearly clinically important improvement in quality-adjusted survival time based on Q-TWiST analyses compared with chemo as first-line treatment in pts with MSI-H/dMMR mCRC. The magnitude of results related to established thresholds for clinically important Q-TWiST gain suggests that results from this analysis provide additional evidence for the use of pembro in this population. Clinical trial information: NCT02563002. Research Sponsor: Merck Sharp & Dohme LLC, a subsidiary of Merck & Co., Inc., Rahway, NJ, USA.

Association between fine particulate matter exposure and colorectal cancer mortality by age at diagnosis: Insights from county-level analysis in the United States. First Author: Sara F. Haddad, Cleveland Clinic Foundation, Cleveland, OH

Background: Colorectal cancer (CRC) remains a leading cause of cancer mortality in the U.S., with environmental factors like air pollution potentially contributing to mortality. This study examines the association between fine particulate matter (PM2.5) exposure and CRC mortality rates, stratified by average-onset (aoCRC [≥50 years at diagnosis]) and early-onset (eoCRC [< 50 years at diagnosis]) cases. **Methods:** Age-adjusted county CRC mortality data (1999–2020, n = 2981 counties) were obtained from CDC Underlying Cause of Death (ICD-10: C18-C19 [excluding C18.1], C20), while 1999-2019 PM2.5 estimates (ug/m3), derived from Atmospheric Composition Analysis Group data, were mapped to U.S. county boundaries using R v.4.3.2. Covariates were derived from Census American Community Survey (ACS) 5-year estimates, CDC data, and County Health Rankings (CHR) data and included county-level area deprivation index (ACS), non-Hispanic Black % (ACS), Hispanic % (ACS), obesity prevalence (CDC), smoking prevalence (CHR), binge alcohol consumption (CHR), and uninsured % (ACS). Negative binomial count models were fit to explore associations between PM2.5 and CRC mortality rates, adjusted for covariates. Deviance R^2 was computed to examine model fits. **Results:** We found that for every 1% increase in PM2.5 exposure, aoCRC mortality increased by 0.98% ($p < 0.001$) and eoCRC mortality increased by 0.24% ($p = 0.435$), after adjustment for covariates. Deviance R^2 values indicated that PM2.5 and covariates explained 32.0% and 37.0% of the deviance in aoCRC and eoCRC mortality, respectively. **Conclusions:** PM2.5 exposure was a significant predictor of CRC mortality, but only for aoCRC cases. Air pollution and other covariates accounted for roughly one-third of the county-level deviance, suggesting the influence of additional factors. Systemic and individual-level interventions to reduce air pollution exposure may mitigate CRC mortality disparities in older populations. Further studies are needed to explore other potential contributors to CRC mortality. Research Sponsor: None.

A phase II study of pembrolizumab, carboplatin, paclitaxel, and radiation for the treatment of early-stage anal cancer: Big Ten Cancer Research Consortium GI22-588. First Author: Anita Turk, Indiana University Melvin and Bren Simon Comprehensive Cancer Center, Indianapolis, IN

Background: Anal squamous cell carcinoma (SCC) is an evolving public health challenge, with increasing incidence and mortality rates, particularly in older women with long-standing HPV infections. Standard-of-care treatment for early-stage anal SCC—5-fluorouracil (5FU) and mitomycin-C (MMC) with radiation—achieves high cure rates but poses significant toxicity risks, with grade 3-5 adverse events occurring in up to 70% of patients. Recent clinical trials, such as DECREASE and ACT4, have explored radiation de-escalation strategies, but limited progress has been made in expanding systemic treatment options for locally advanced disease. Building on pilot data demonstrating favorable clinical complete responses (cCR) with carboplatin and paclitaxel combined with radiation in patients ineligible for SOC regimens, this phase II trial evaluates the addition of pembrolizumab to this combination to enhance efficacy while reducing toxicity. **Methods:** This is a single-arm, phase II trial evaluating concurrent chemo-radiation with weekly carboplatin (AUC 2), paclitaxel (50 mg/m²), and pembrolizumab (200 mg every three weeks during chemoradiation and 400 mg every six weeks during maintenance) for early-stage anal SCC in patients ineligible for 5FU and MMC. The chemoradiation phase consists of up to six weeks of therapy with 50.4 Gy delivered over 28 fractions. Maintenance pembrolizumab is administered for up to eight cycles. The primary endpoint is the cCR rate at six months post-chemoradiation. Secondary endpoints include safety, tolerability, tumor downstaging, and disease-free survival. Exploratory objectives include the evaluation of genomic alterations and biomarkers such as versican and keratin 17 as predictors of therapeutic response. Major eligibility criteria include histologically confirmed stage I-IIIA anal SCC, measurable disease per RECIST v1.1, and treatment-naïve status. Key exclusions include active autoimmune disease requiring immunosuppression within two years and prior checkpoint inhibitor therapy. The target enrollment is 23 patients, with an accrual period of 12 months and an anticipated study duration of two years. The study is currently enrolling participants through the Big Ten Cancer Research Consortium. Clinical trial information: NCT06493019. Research Sponsor: Merck.

TPS3634 **Poster Session**

Alliance A022101/NRG-GI009: A pragmatic randomized phase III trial evaluating total ablative therapy for patients with limited metastatic colorectal cancer—Evaluating radiation, ablation, and surgery (ERASur). First Author: Eric David Miller, Ohio State University, Columbus, OH

Background: For patients with oligometastatic colorectal cancer (CRC), aggressive local therapy of isolated metastases, particularly in the liver, has been associated with long-term progression-free and overall survival (OS) primarily based on retrospective evidence. However, in patients with limited metastatic CRC that is deemed inoperable or those with additional disease outside of the liver or lungs, the role of local ablative therapies, including microwave ablation (MWA) and stereotactic body radiation therapy (SBRT), to render patients disease free is less clear. Despite the long history of treating oligometastatic CRC with local therapy, which is largely provider biased, questions remain regarding the benefit of extending the paradigm of metastatic directed therapy to patients with more extensive disease. This trial seeks to use a pragmatic multimodality approach that mirrors the current clinical dilemma. This study is designed to evaluate the safety and efficacy of adding total ablative therapy (TAT) of all sites of disease to standard of care systemic treatment in those with limited metastatic CRC. **Methods:** A022101/NRG-GI009 is a National Clinical Trials Network randomized phase III study planned to enroll 364 patients with newly diagnosed metastatic CRC (BRAF wild-type, microsatellite stable) without peritoneal metastasis or liver-only disease on baseline imaging. Patients receive first-line systemic therapy for 12-39 weeks. Patients with ≤4 sites of metastatic disease following initial systemic therapy that are amenable to any combination of surgical resection, MWA, and/or SBRT are then randomized 1:1, stratified by number of metastatic organ sites (1-2 vs. 3-4), timing of metastatic disease diagnosis (de novo vs. secondary), and presence of metastatic disease outside the liver/lungs in at least 1 site. Patients in Arm 1 will receive TAT consisting of treatment of all metastatic sites with SBRT, MWA, and/or surgical resection followed by standard of care systemic therapy. Patients in Arm 2 will continue with standard of care systemic therapy alone. The primary endpoint is OS. Secondary endpoints include event-free survival, treatment-related toxicities, and local recurrence with exploratory biomarker analyses. The study needs 346 evaluable patients combined in the 2 arms to demonstrate an improvement in OS with a hazard ratio of 0.7 to provide 80% power with a one-sided alpha of 5%. The trial utilizes a group sequential design with two interim analyses (25% and 50% of events) for futility. The trial activated in January 2023 and recruitment is ongoing. TPS3635 **Poster Session**

Telisotuzumab adizutecan (ABBV-400; Temab-A) monotherapy vs trifluridine/tipiracil plus bevacizumab in patients with refractory metastatic colorectal cancer with increased c-Met protein expression: An open-label, randomized, phase 3 trial. First Author: John H. Strickler, Duke University School of Medicine, Durham, NC

Background: c-Met protein expression is increased in several solid tumors, including colorectal cancer (CRC). Temab-A is a c-Met–directed antibody-drug conjugate consisting of the antibody telisotuzumab conjugated to a potent topoisomerase 1 inhibitor payload. Preliminary data from the ongoing first-in-human study of Temab-A (NCT05029882) indicate a tolerable safety profile and promising antitumor activity in patients with third-line or later metastatic (m)CRC (Sharma et al. *JCO* 2023;41:3015). Herein, we describe a phase 3 study comparing Temab-A monotherapy with the standard of care (trifluridine/tipiracil plus bevacizumab) in patients with refractory mCRC with c-Met expression of 3+ in ≥10% of tumor cells by immunohistochemistry (IHC). **Methods:** This is an open-label, randomized, controlled, global phase 3 study(NCT06614192). Patient eligibility includes age ≥18 years, confirmed c-Met expression of 3+ in ≥10% of tumor cells, metastatic adenocarcinoma of the colon/rectum, measurable disease per RECIST v1.1, ECOG performance status 0–1, prior treatment with a fluoropyrimidine (eg, 5-FU or capecitabine), oxaliplatin, irinotecan, and an anti-VEGF antibody (unless locally not approved) or an anti-EGFR antibody if indicated, and appropriate targeted therapy or immunotherapy if targetable mutations present (eg, *BRAF* V600E or *HER2*) or MSI-H/dMMR. Prior treatment with regorafenib and/or fruquintinib is permitted, but no prior treatment with trifluridine/tipiracil Study-specific c-Met protein expression IHC cutoff is defined as 3+ intensity in ≥10% of tumor cells. The study consists of 2 stages. In stage 1, at least 60 patients will be randomized 1:1 to receive 2 different doses of intravenous (IV) Temab-A. In stage 2, 400 patients will be randomly assigned 1:1 to receive either the optimized dose of IV Temab-A or oral trifluridine/tipiracil plus IV bevacizumab. In stage 1, primary objectives are to determine the recommended phase 3 dose and to evaluate the efficacy, as measured by objective response (OR), and safety of Temab-A; secondary objectives are to assess progression-free survival (PFS), overall survival (OS), duration of response (DOR), disease control rate (DCR), and pharmacokinetics. In stage 2, the primary objectives are to demonstrate the superiority of Temab-A over trifluridine/tipiracil plus bevacizumab in terms of OR and OS; secondary objectives are to evaluate PFS, DOR, DCR, and safety of Temab-A treatment, and its impact on patient-reported outcomes. Response will be assessed by blinded independent central review per RECIST v1.1. Safety evaluations include adverse event monitoring, vital sign measurements, ECG variables, and clinical laboratory testing. Enrollment began in December 2024. Clinical trial information: NCT06614192. Research Sponsor: AbbVie Inc.; n/a.

TPS3636 **Poster Session**

OrigAMI-2: A randomized, phase 3 study of amivantamab vs cetuximab, both in combination with FOLFOX or FOLFIRI, as first-line treatment in left-sided *RAS/BRAF* wild-type metastatic colorectal cancer. First Author: Dirk Arnold, Asklepios Tumorzentrum Hamburg, AK Altona, Hamburg, Germany

Background: Approximately 50% of patients diagnosed with metastatic colorectal cancer (mCRC) are wild-type for *KRAS*, *NRAS*, and *BRAF* (*RAS/BRAF* WT). Standard initial therapy for left-sided *RAS/BRAF* WT mCRC is doublet chemotherapy (FOLFOX or FOLFIRI) combined with anti-EGFR therapy. However, resistance is nearly inevitable. *MET* alterations are known resistance mechanisms to EGFR inhibition, with *MET* amplification occurring in 5%-23% of EGFR-resistant mCRC. Amivantamab is an EGFR-MET bispecific antibody with immune cell-directing activity that is approved by the FDA for 4 indications in *EGFR*-mutated advanced non-small cell lung cancer. In the phase 1b/2 OrigAMI-1 study (NCT05379595), the combination of amivantamab plus FOLFOX or FOLFIRI demonstrated rapid and durable antitumor activity, regardless of tumor sidedness, in participants with *RAS/BRAF* WT mCRC (Pietrantonio ESMO 2024). The objective of this phase 3 randomized study is to assess the efficacy of amivantamab, as compared with cetuximab, both in combination with FOLFOX or FOLFIRI, as first-line therapy for participants with left-sided *RAS/BRAF* WT unresectable or metastatic CRC. **Methods:** The multicenter, global OrigAMI-2 study (NCT06662786) is planned to open in 216 sites in 21 countries. Eligible participants will be WT for *KRAS*, *NRAS*, and *BRAF* by local testing, have left-sided unresectable or metastatic colorectal cancer, and be treatment-naïve for advanced disease. Left-sided disease will be defined as a primary tumor arising from the splenic flexure, descending colon, sigmoid colon, rectosigmoid, or rectum. Key exclusion criteria include known dMMR/MSI-H status, HER2-positive or amplified tumor, and prior exposure to EGFR or MET targeting agents. Approximately 1000 participants will be randomly assigned 1:1 to receive subcutaneous amivantamab (co-formulated with recombinant human hyaluronidase [rHuPH20]) or intravenous cetuximab, both combined with FOLFOX or FOLFIRI (investigator's choice). Randomization will be stratified by chemotherapy choice (FOLFOX or FOLFIRI), limited disease (yes or no), and prior adjuvant therapy (yes or no). The primary endpoint will be progression-free survival by blinded independent central review. Secondary endpoints include overall survival, objective response rate, duration of response, and patient-reported outcomes. Safety assessments will include monitoring adverse events and laboratory abnormalities. Clinical trial information: NCT06662786. Research Sponsor: Janssen Research & Development, LLC, a Johnson & Johnson Company.

TPS3637 **Poster Session**

An observational/translational study to conduct real-world evidence and develop biomarkers of fruquintinib for patients with metastatic colorectal cancer (mCRC): FruBLOOM trial (JACCRO CC-19). First Author: Yu Sunakawa, Department of Clinical Oncology, St. Marianna University School of Medicine, Kawasaki, Kanagawa, Japan

Background: The FRESCO-1/2 trials demonstrated a survival benefit of fruquintinib (FRU) in mCRC after 3rd-line therapy. FRU can be considered as one of the standard treatments for mCRC. The FRESCO-2 trial was conducted in patients (pts) treated with FTD/TPI and/or regorafenib (Rego) and did not include pts who were not using either agent. Although FTD/TPI + bevacizumab (Bev) is currently one of 3rd-line standard treatments for mCRC, there are few data regarding the efficacy and safety of FRU in pts after FTD/TPI + Bev. Therefore, this study will accumulate real-world-data of FRU in clinical practice and evaluate the efficacy and safety of FRU after FTD/TPI + Bev. Also, we will evaluate clinical outcomes of FRU as 3rd- or later-line treatment after both FTD/TPI + Bev and Rego. The predictive biomarkers of FRU in the later-line setting hold significant clinical promise, for choosing personalized treatment plans (e.g., FRU vs. FTD/TPI + Bev / Rego) and enhancing the prognosis of mCRC pts. Therefore, this translational study approaches developing biomarkers for predicting FRU efficacy by analyzing pre-treatment blood samples. Furthermore, we will explore treatment resistance mechanisms using post-treatment blood samples. **Methods:** This is a multicenter observational/translational study to prospectively evaluate the efficacy and safety of FRU as a 3rd- or later-line treatment, mainly after FTD/TPI + Bev in mCRC pts in clinical practice. We will enroll 200 pts receiving FRU after FTD/TPI + Bev to the cohort A, and 100 pts receiving FRU as 3rd-line or after both FTD/TPI + Bev and Rego to the cohort B. Eligibility criteria are (1) pts with CRC confirmed as adenocarcinoma, (2) pts planning to receive FRU monotherapy as 3rd- or later-line treatment, (3) prior treatments with fluoropyrimidine-, oxaliplatin- and irinotecan-based chemotherapy, an anti-VEGF biological therapy, an anti-EGFR therapy (if *RAS*/*BRAF* wild-type), BRAF therapy (if *BRAF* mutant), and immune checkpoint inhibitor (if MSI-high), (4) pts with ECOG Performance Status of 0-2, (5) pts must be at least 18 years of age at the time of consent, and (5) pts have measurable or evaluable lesions in RECIST v1.1. The primary endpoint is overall survival in pts of the cohort A. The secondary endpoints are clinical outcomes including response rate, progression-free survival, duration of response, and safety in pts of the cohort A and B. In the biomarker study, blood samples will be prospectively collected before and after treatment, for translational research including genomic alteration analysis in circulating tumor-DNA by DNA exome sequencing, gene expression measurement in cfRNA by tumor-educated blood platelets (TEP)-Seq RNA analysis, and plasma proteins analysis by multiplex immunoassay panels. Enrollment opens in February 2025 (UMIN000056813). Clinical trial information: UMIN000056813. Research Sponsor: Takeda.

TPS3638 **Poster Session**

OrigAMI-3: A randomized, phase 3 study of amivantamab plus FOLFIRI vs cetuximab or bevacizumab plus FOLFIRI in participants with recurrent, unresectable, or metastatic *RAS/BRAF* wild-type colorectal cancer. First Author: Joel R. Hecht, UCLA Jonsson Comprehensive Cancer Center, Santa Monica, CA

Background: Among patients with metastatic colorectal cancer (mCRC), approximately 50% are wild-type for *KRAS*, *NRAS*, and *BRAF* (*RAS/BRAF* WT) without actionable genomic alterations. Standard first-line therapy for *RAS/BRAF* WT mCRC is 5-FU-based doublet chemotherapy (FOLFOX or FOLFIRI) plus anti-EGFR or anti-VEGF therapy. The choice of second-line treatment is dependent on first-line treatment (eg, oxaliplatin-based chemotherapy in the first-line necessitates irinotecan-based in the second-line, and vice versa). Known resistance mechanisms to anti-EGFR therapy are *MET* alterations, with *MET* amplification occurring in 5%-23% of EGFR-resistant mCRC and increasing in prevalence over subsequent lines of therapy. Amivantamab is an EGFR-MET bispecific antibody with immune cell-directing activity and is FDA-approved for 4 indications in *EGFR*-mutated advanced non-small cell lung cancer. In the phase 1b/2 OrigAMI-1 study (NCT05379595), amivantamab plus FOLFIRI demonstrated promising antitumor activity, independent of line of therapy, in participants (pts) with *RAS/BRAF* WT mCRC without prior anti-EGFR exposure (Pietrantonio ESMO 2024). The objective of this phase 3 randomized study is to assess the efficacy of amivantamab plus FOLFIRI vs cetuximab or bevacizumab plus FOLFIRI, as second-line therapy for pts with recurrent *RAS/BRAF* WT mCRC. **Methods:** The global OrigAMI-3 study (NCT06750094) is planned to open in 230 sites in 25 countries. Eligible pts will be WT for *KRAS*, *NRAS*, and *BRAF*, have recurrent unresectable or mCRC, and must have had disease progression on one prior line of systemic therapy for metastatic disease (prior regimen must be fluoropyrimidine-based and oxaliplatin-based therapy). Pts with treated, stable, and asymptomatic brain metastases are allowed. Key exclusion criteria include known dMMR/MSI-H status without prior immunotherapy, HER2-positive or amplified tumor, and prior exposure to irinotecan or agents targeting EGFR or MET. Approximately 700 pts will be randomly assigned 1:1 to receive subcutaneous amivantamab (co-formulated with recombinant human hyaluronidase [rHuPH20]) plus FOLFIRI vs intravenous cetuximab or bevacizumab (investigator's choice, per local guidelines) plus FOLFIRI. Randomization will be stratified by choice of cetuximab or bevacizumab, primary tumor location (left vs right-sided), duration of first-line therapy (< 6 months or ≥6 months), and prior anti-VEGF therapy (yes or no). The dual primary endpoints will be progression-free survival by blinded independent central review and overall survival. Secondary endpoints include objective response rate, duration of response, and patient-reported outcomes. Safety assessments will include monitoring adverse events and laboratory abnormalities. Clinical trial information: NCT06750094. Research Sponsor: Janssen Research & Development, LLC, a Johnson & Johnson company.

TPS3639 **Poster Session**

Stereotactic body radiotherapy combined with PD-1 antibody in unresectable colorectal liver metastases: A prospective, multicenter, single-arm, phase II study (SPARKLE-L). First Author: Fang He, Department of Radiation Oncology, the Sixth Affiliated Hospital, Sun Yat-sen University, Guangzhou, China

Background: Colorectal cancer liver metastasis (CRLM) significantly decreases colorectal cancer (CRC) patient prognosis, affecting 30-50% of CRC patients at diagnosis or thereafter. Notably, up to 70%-90% CRLM are diagnosed as unresectable. Standard treatments include systemic chemotargeted-therapies (CT). However, only 10-30% CRLM can be converse to resectable state by CT, with an objective response rate (ORR) of just 15%-20% and a median overall survival (OS) of approximately 20-30 months. Improving prognosis of CRLM patients remains challenging. Stereotactic body radiation therapy (SBRT) combined with immunotherapy might offer promising alternatives. SBRT provides high-dose tumor control while protecting surrounding tissues better than conventional radiotherapy. It also facilitates the release of tumor-associated antigens, reshaping the immune microenvironment and inducing stronger immune responses. The combination of SBRT and PD-1 antibodies might synergistically enhance the anti-tumor efficacy. Despite SBRT's demonstrated efficacy in unresectable CRLM with few adverse reactions, no prospective studies have explored its combination with PD-1 antibodies. **Methods:** This is a multicenter, open-label, single-arm, phase II trial conducted in China. Patients will receive SBRT at 8-12 Gy per fraction over 5 fractions, combined with 5-FU-based CT and PD-1 antibody therapy before and after SBRT. Eight weeks ($\pm$2 weeks) post SBRT, imaging assessments or multi-point liver biopsies will be performed. Multidisciplinary teams (MDT) will determine subsequent plans: cCR/pCR patients will undergo maintenance CT or enter a watch-and-wait phase; non-cCR/pCR patients will continue maintenance CT or exit the study. This is the first study exploring whether SBRT combined with PD-1 monoclonal antibody can improve ORR, OS, quality of life (QOL) and potentially achieve no evidence of disease (NED) status for unresectable CRLM. Key inclusion criteria: pMMR/MSS CRC, MDT-assessed unresectability due to main portal vein invasion, multiple hepatic vein invasion or lack of R0 resection/ablation feasibility. Main exclusion criteria encompass active hepatitis, cirrhosis, Child-Pugh B/C, checkpoint inhibitor therapies history and ECOG performance status $\geq$2. Twenty-four patients are planned for enrollment, with two already enrolled as of January 25, 2025. The study is registered with ClinicalTrials.gov (NCT06794086) and is ongoing. Clinical trial information: NCT06794086. Research Sponsor: None.

TPS3640 **Poster Session**

Neoadjuvant cetuximab plus tislelizumab combined with chemotherapy in pMMR RAS/BRAF wild-type (wt) locally advanced rectal cancer (LARC): A prospective, multicenter, phase II study. First Author: Gang Liu, Tianjin Medical University General Hospital, Tianjin, Tianjin, China

Background: For patients (pts) with locally advanced rectal cancer (LARC), chemoradiotherapy followed by total mesorectal excisionis is recommended as standard therapy according to the NCCN guidelines. However, there is no stratification strategy for neoadjuvant therapy based on molecular alterations, and radiotherapy is insufficient with pathologic complete response (pCR) rates at 11%-15%. There is an urgent need for new therapeutical options to improve the pCR rate in these pts. Adding anti-EGFR therapy to neoadjuvant chemotherapy may improve progression-free survival for RAS/BRAF WT LARC pts. Furthermore, previous studies demonstrated that combining anti-EGFR with immune checkpoint inhibitors could further improve pCR rate. Cetuximab, an anti-EGFR monoclonal antibody, has gained FDA approval for RAS WT metastatic colorectal cancer. Tislelizumab, an anti-PD-1 monoclonal antibody, is effective in blocking PD-1/PD-L1 interaction in preclinical experiments. This study introduces an innovative approach, combining Cetuximab, Tislelizumab and chemotherapy, as a total neoadjuvant therapy for pMMR RAS/BRAF wt LARC pts. **Methods:** This prospective, multicenter, phase II study investigated the efficacy and safety of neoadjuvant treatment with FOLFOX chemotherapy plus Cetuximab and Tislelizumab for MSS-RAS/BRAF WT LARC. Eligible participants were 18 years or older, with an ECOG PS of 0–2, primary, and a biopsy-proven tumors meeting all the following criteria: clinical tumour stage cT3-4 N0M0 or cT1-4N+M0, tumor distance from the anus$\leqq$10 cm, no distant metastasis. Pts initially received a cycle chemotherapy of FOLFOX pending genetic results. Eligible pts with MSS-RAS/BRAF WT LARC then underwent 5 preoperative neoadjuvant cycles of mFolfOx6 (oxaliplatin 85 mg/m², D1; leucovorin 200 mg/m²,D1; 5-FU bolus 400 mg/m2 D1 then 2.4 g/m²,D2-3) + Cetuximab (500mg/m2, D1, q2w) + Tislelizumab (200mg, D1, q2w). Subsequently, pts underwent TME about 4 weeks after the last cycle. Imaging evaluation will be conducted 6 weeks after the initiation of treatment, pts with regressed tumors will receive a standard chemoradiotherapy. The primary endpoint was pCR rate. Secondary endpoints included the Neoadjuvant Rectal Score, Objective Response Rate, R0 resection rate, Major Pathological Response rate, Anal Sparing rate, 3-year Disease-Free Survival, 3-year Local Recurrence Rate, 3-year Overall Survival. Based on a review of the literature, the estimated pCR rate for standard preoperative neoadjuvant chemoradiotherapy is approximately 15%. The expected pCR rate for the MSS-RASwt/BRAFwt group is around 30%, with a one-sided significance level (α) of 0.05 and a power (1-β) of 0.8, using the Simon two-stage method, the sample size is calculated to be 25 cases. The study started in middle 2022 and is recruiting. Clinical trial information: ChiCTR2200062002. Research Sponsor: None.

TPS3641 **Poster Session**

Node-sparing modified short-course radiotherapy combined with CAPOX and tislelizumab versus conventional short-course preoperative chemoradiotherapy for proficient mismatch repair or microsatellite stable locally advanced rectal cancer (mRCAT-III): A multicenter, randomized, open-label, phase 3 trial. First Author: Zhangfa Song, Sir Run Run Shaw Hospital, Zhejiang University School of Medicine, Hangzhou, Zhejiang, China

Background: Total neoadjuvant chemoradiotherapy is the standard of care for locally advanced rectal cancer (LARC) to control local recurrence and achieve organ preservation. However, for proficient mismatch repair (pMMR) or microsatellite stable (MSS) LARC, which accounts for nearly 90% of rectal cancers, conventional chemoradiotherapy has limited efficacy and is associated with significant side effects. Recent studies have shown that combining radiotherapy with immunochemotherapy can improve pathological complete response (pCR) rates, but the inclusion of tumor-draining lymph nodes (TDLNs) in the conventional irradiation field may impair T-cell immunity and reduce response to immunotherapy. Our previous phase II trial demonstrated that node-sparing modified short-course radiotherapy combined with chemotherapy and PD-1 blockade could achieve a high pCR rate of 78.8% in pMMR LARC[1]. Building on these findings, we initiated this phase III trial to compare this novel treatment regime with conventional short-course chemoradiotherapy in improving pCR rates. **Methods:** This is a phase III, open-label, multicenter, randomized trial conducted across 17 hospitals in China. A total of 170 eligible MSS/pMMR middle or low rectal cancer patients (cT3-4N0/+M0) will be recruited and randomly assigned (5:5:1) to three groups: control group (conventional short-course chemoradiotherapy), experimental group (node-sparing modified short-course chemoradiotherapy plus PD-1 blockade), and exploratory group (conventional short-course chemoradiotherapy plus PD-1 blockade). The innovative node-sparing modified short-course radiotherapy targets only the primary tumor bed, excluding TDLNs. Following randomization, patients will receive short-course radiotherapy (conventional or node-sparing) followed by four cycles of CAPOX $\pm$ tislelizumab: tislelizumab 200 mg IV on day 1, oxaliplatin 130 mg/m² IV on day 1, and capecitabine 1000 mg/m² orally on days 1-14, and Total mesorectal excision (TME) will be performed at weeks 14-15. The primary endpoint is pCR rate, while secondary endpoints include organ preservation rate, disease-free survival, overall survival, adverse effects, and quality of life. As of January 2025, 46 of the planned 170 patients have been enrolled. The Data Monitoring Committee (DMC) reviewed the trial in December 2024 and recommended continuing as planned. Reference: Annals of Oncology (2024) 24 (suppl_1): 1-20. 10.1016/iotech/iotech100744 Clinical trial information: NCT06507371. TPS3642 **Poster Session**

A phase II study of encorafenib and cetuximab (EC) beyond progression in combination with FOLFIRI in *BRAF* V600E-mutated metastatic colorectal cancer (mCRC). First Author: Maria Alessandra Calegari, Medical Oncology, Comprehensive Cancer Center, Fondazione Policlinico Universitario Agostino Gemelli, IRCCS, Rome, Italy

Background: *BRAF* V600E mutation occurs in approximately 10% of metastatic colorectal cancers (mCRC) and confers poor prognosis. While the combination of encorafenib and cetuximab (EC) has demonstrated improved outcomes in previously treated *BRAF* V600E-mutated mCRC patients (pts), the duration of response remains suboptimal with median progression-free survival (mPFS) of 4.3 months (m). Approximately half of pts (45%) receive subsequent treatment after EC progression, predominantly with chemotherapy (ChT). Data from the safety lead-in (SLI) of the BREAKWATER trial, assessing EC in combination with ChT doublet in the first-line setting, demonstrated manageable safety profile and promising early efficacy signals for EC in combination with FOLFIRI, despite pharmacokinetic interaction. **Methods:** ECLYPse (NCT06640166; EU CT Number 2023-508615-24-00) is a multicenter, single-arm, phase II study evaluating EC continuation beyond progression in combination with FOLFIRI in pts with *BRAF* V600E-mutated mCRC who progressed on second-line EC. Key eligibility criteria include: histologically confirmed colorectal adenocarcinoma, *BRAF* V600E mutation, documented disease progression on EC in second-line setting, benefit to previous treatment with EC (best response: complete response, partial response or stable disease lasting for at least 3 months), measurable disease according to RECIST 1.1 criteria, ECOG PS $\leq$1, and availability of archival tumor tissue. Patients receive encorafenib 300 mg daily, cetuximab 500mg/m2 iv every 2 weeks, and standard FOLFIRI regimen. The primary endpoint is 6-month PFS rate. Secondary endpoints include PFS, overall survival, duration of response, objective response rate, disease control rate, and safety. Translational analyses include comprehensive genomic profiling on archival tissue and serial ctDNA analysis. Tumor assessment with contrast-enhanced CT scan of thorax, abdomen and pelvis is performed every 8 weeks. Using a single-stage design with one-sided α = 0.05 and 80% power, 25 patients will be enrolled to detect an improvement in 6-month PFS rate from 10% (null hypothesis) to 30% (alternative hypothesis). If at least 7 pts will be alive and not progressing at 6 months, the treatment will be considered sufficiently active to warrant further investigation. The study is currently enrolling at multiple sites in Italy. Clinical trial information: NCT06640166. Research Sponsor: Pierre Fabre.

TPS3643 **Poster Session**

Combining low-dose regorafenib with pembrolizumab as a front-line therapy for patients with MSI-H colorectal cancer: REGPEM-CRC-01. First Author: Ibrahim Halil Sahin, University of Pittsburgh Medical Center (UPMC), Pittsburgh, PA

Background: Currently, pembrolizumab is one of the front-line therapies for patients with MSI-H CRC. However, approximately 40% of patients who received pembrolizumab experienced disease progression early in the course of disease (KEYNOTE 177). Therefore, there is still an unmet need to enhance the efficacy of checkpoint inhibitors in MSI-H CRC. MSI-H CRC has a higher level of expression of VEGF in blood compared to patients compared to its MSS counterpart (Hansen et al. Colorectal Dis. 2011). Consistently, exploratory analysis of CALBG-80405 and PARADIGM trial showed that patients with MSI-H CRC were more likely to benefit from anti-VEGF therapy than anti-EGFR therapy regardless of the side of the tumor. NSABP C-08 also suggested that anti-VEGF therapy may have biological activity even in as adjuvant therapy for patients with MSI-H colon cancer. Regorafenib is a potent VEGF and multikinase inhibitor involved in pathologic processes such as oncogenesis, tumor angiogenesis, metastasis and tumor immunity, with preclinical evidence showing its immune modulatory effect in the tumor microenvironment. In this trial, we hypothesize that adding low-dose regorafenib to pembrolizumab may induce synergistic activity beyond their independent clinical efficacy and create deep and durable responses for patients with MSI-H CRC. **Methods:** In the lead arm of this prospective randomized study, 22 patients will be enrolled through Hoosier Cancer Research Network (HCRN-GI23-643). In this first line clinical trial, patients will receive regorafenib 60 mg daily in combination with pembrolizumab 200mg IV in cycle 1, followed by regorafenib 90mg in subsequent cycles to optimize the treatment tolerance and compliance. The primary outcome that will be measured is ORR, defined as the percentage of partial or complete response to the treatment within 12 months. ORR will be measured using RECIST 1.1. criteria. A formal one-sided hypothesis test will be conducted for futility, assuming that we will reject the null hypothesis of a target ORR only if we have strong evidence. In this study, we assume a null hypothesis that ORR is 0.60, which would reflect significant clinical improvement over the current standard of ORR = 0.43 from KEYNOTE 177. The alternative hypothesis is that ORR is less than 0.60. For the lead-in phase of the study, the emphasis is on controlling Type I error to be small, to be 0.05 or lower. An exact binomial test will be conducted, based on the number of ORRs in the 22 patients. The study is currently accruing through Hoosier Cancer Research Network was activated in July 2024. Clinical trial information: NCT06006923. Research Sponsor: None.

TPS3644 **Poster Session**

Colon adjuvant chemotherapy based on evaluation of residual disease (CIRCULATE-NORTH AMERICA): NRG-GI008. First Author: Arvind Dasari, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Currently, there are no biomarkers validated prospectively in randomized studies for resected colon cancer (CC) to determine need for adjuvant chemotherapy (AC). However, circulating tumor DNA (ctDNA) represents a highly specific and sensitive approach (especially with serial monitoring) for identifying minimal/molecular residual disease (MRD) post-surgery in CC patients (pts), and may outperform traditional clinical and pathological features in prognosticating risk for recurrence. CC pts who do not have detectable ctDNA (ctDNA-) are at a much lower risk of recurrence and may be spared the toxicities associated with AC. Furthermore, for CC pts with detectable ctDNA (ctDNA+) who are at a very high risk of recurrence, the optimal AC regimen has not been established. We hypothesize that for pts whose CC has been resected, ctDNA status may be used to risk-stratify for making decisions about AC. **Methods:** In this prospective phase II/III trial, up to 1,912 pts with resected stage IIB, IIC, and III CC will be enrolled. Based on the post-operative ctDNA status using personalized and tumor-informed assay (Signatera™, bespoke assay), those who are ctDNA- (Cohort A) will be randomized to immediate AC with fluoropyrimidine (FP)+oxaliplatin (Ox) for 3-6 mos per established guidelines *v* serial ctDNA monitoring. Patients who are ctDNA+ post-operatively, or with serial monitoring (Cohort B), will be randomized to FP+Ox *v* more intensive AC with addition of irinotecan (I) for 6 mos. One cycle of chemotherapy is allowed while awaiting ctDNA testing results for cohort assignment. The primary endpoints for Cohort A are time to ctDNA+ status (phase II) and disease-free survival (DFS) (phase III) in the immediate *v* delayed AC arms. The primary endpoint for Cohort B is DFS in the FP+Ox *v* FP+Ox+I arms for both phase II and phase III portions of the trial. Secondary endpoints include prevalence of detectable ctDNA post-operatively, time-to-event outcomes (overall survival and time to recurrence) by ctDNA status, and the assessment of compliance to adjuvant therapy. Biospecimens including archival tumor tissue, as well as post-operative plus serial matched/normal blood samples, will be collected for exploratory correlative research. Active enrollment across the NCTN started in June 2022 with CCTG sites joining in August 2023. Current accrual (as of 1-27-2025): 647/1,912. NCT: 05174169. Support: U10 CA180868, -180822; -180888; UG1 CA189867; Natera, Inc. Clinical trial information: NCT05174169. TPS3645 **Poster Session**

Platform study of circulating tumor DNA–directed adjuvant chemotherapy in colon cancer (CLAUDIA Colon Cancer, KCSG CO22-12). First Author: Yongjun Cha, Center for Colorectal Cancer, Research Institute and Hospital, National Cancer Center, Goyang, Korea, Republic of (South)

Background: Tumor-informed circulating tumor DNA (ctDNA) analysis allows for the sensitive detection of minimal residual disease (MRD) and has the potential to enhance patient stratification for adjuvant chemotherapy (AC). In patients with stage II-III colon cancer, we demonstrated that postoperative MRD is associated with poor disease-free survival (DFS) despite oxaliplatin-based AC. We hypothesize that intensifying AC in colon cancer patients with postoperative MRD may improve survival outcomes. **Methods:** This multi-center platform trial (NCT05534087) consists of a prospective observational study (Part 1) and an interventional randomized trial (Part 2). In Part 1, approximately 1,200 patients with colon cancer will be screened for MRD at 3–6 weeks postoperatively using atumor-informed hybrid-capture-based ctDNA MRD assay (CancerDETECT) which tracks ~100 patient-specific somatic variants identified through tumor whole-exome sequencing. Key eligibility criteria include: age $\geq$19 years, $\leq$6 weeks post-curative resection, pathological diagnosis of colon cancer, stage III or stage II with high-risk features requiring AC with FOLFOX/CAPOX, and no macroscopic residual disease. All patients in Part 1 will complete 3 months of standard adjuvant FOLFOX/CAPOX while awaiting MRD results. After 3 months of AC, MRD-negative patients are managed at the investigator's discretion. Patients with MRD positivity will be screened for Part 2 clinical trial following the completion of initial 3 months of standard AC titled "*Randomized Controlled Phase III Trial of Treatment Intensification in Stage II–III Colon Cancer Patients with Positive MRD after Curative Resection*." Part 2 investigates the superiority of an experimental arm (modified FOLFIRINOX for 3 months) compared to a control arm (FOLFOX/CAPOX for 3 months). The primary endpoint is the 3-year DFS rate, while secondary endpoints include the 5-year overall survival rate, treatment-related adverse events, treatment adherence, and patient-reported outcomes. A total of 236 patients will be enrolled, assuming a hazard ratio of 0.64, 80% power, a two-sided alpha of 0.05, and a 10% dropout rate. As of November 2024, 630 patients have been screened in Part 1, and 99 patients have been enrolled in Part 2. Both studies are ongoing, and an interim analysis is planned after $\geq$ 48 events. Clinical trial information: NCT05534087. Research Sponsor: National R&D Program for Cancer Control through the National Cancer Center (NCC) funded by the Ministry of Health & Welfare, Republic of Korea (HA22C0062).

TPS3646 **Poster Session**

mFOLFOX6 + bevacizumab + PD-1 monoclonal antibody vs. mFOLFOX6 in locally advanced pMMR/MSS CRC: A multicenter, randomized controlled phase III study (BASKETIII). First Author: Jun Huang, Department of Colorectal Surgery, The Sixth Affiliated Hospital, Sun Yat-sen University, Guangzhou, China

Background: Immunotherapy has shown promising therapeutic effects in mismatch repair-deficient or microsatellite instability-high (dMMR/MSI-H) colorectal cancer (CRC). However, for patients with mismatch repair-proficient or microsatellite stable (pMMR/MSS) CRC, the efficacy of single-agent PD-1 monoclonal antibody remains limited. Previous studies reported that combining anti-angiogenic drugs with PD-1 monoclonal antibody might improve the efficacy of immunotherapy. Our BASKETII study (NCT04895137) demonstrated that the neoadjuvant therapy regimen of mFOLFOX6 combined with Bevacizumab and sintilimab significantly enhanced the immunotherapy sensitivity of pMMR/MSS locally advanced CRC (LACRC), resulting in improved pathological complete response (pCR) rates and higher R0 resection rates. **Methods:** BASKETIII is a multicenter, randomized controlled, phase III study with a parallel design conducted in China. This trial aims to evaluate whether the neoadjuvant therapy regimen of mFOLFOX6 combined with Bevacizumab and sintilimab can further improve survival outcomes, and maintain the higher pCR rate and acceptable safety profile compared to mFOLFOX6 in pMMR/MSS LACRC patients. Eligible participants will be randomly assigned in a 1:1 ratio to either the experimental group or the control group. Participants in the experimental group will receive the neoadjuvant therapy regimen of mFOLFOX6 + Bevacizumab + sintilimab. The first five doses will follow the mFOLFOX6 combined with Bevacizumab and sintilimab regimen, and the sixth dose will receive only mFOLFOX6 and sintilimab but without Bevacizumab, in order to avoid delay of surgery. Participants in the control group will receive the neoadjuvant therapy regimen of mFOLFOX6 alone. Participants in both groups will undergo radical surgical treatment after neoadjuvant therapies. Participants who achieve pCR based on postoperative pathology will be regularly followed up. Participants who do not achieve pCR will receive adjuvant therapy with a maxim of six doses and will be regular followed up after the final dose of adjuvant therapy. The primary outcome of this study is to evaluate the 3-year disease-free survival (DFS). The key inclusion criteria include histologically confirmed adenocarcinoma of the colon or upper rectum; tumor biopsy immunohistochemical identified pMMR or MSS identified through next-generation sequencing or polymerase chain reaction; Clinical staging of cT4NxM0. The main exclusion criteria include evidence of distant metastasis beyond the pelvic region; history of pelvic or abdominal radiotherapy; multiple CRC or multiple primary tumors; history of immunotherapy and other malignancies within the past 5 years. A total of 122 patients are planned to be enrolled in this study. This study is registered with ClinicalTrials.gov (NCT06791512) and is recruiting. Clinical trial information: NCT06791512. Research Sponsor: National Natural Science Foundation of China.

TPS3647 **Poster Session**

A precision medicine trial leveraging tissue and blood-based tumor genomics to optimize treatment in resected stage III and high-risk stage II colon cancer (CC) patients (pts): The SAGITTARIUS trial. First Author: Clara O. Montagut, Hospital del Mar Research Institute, Barcelona, Spain

Background: Circulating tumor DNA (ctDNA) testing has emerged as a transformative tool for detecting molecular residual disease (MRD). Multiple prospective trials have demonstrated the potential of ctDNA in guiding treatment decisions for stage II-III CC pts. Numerous ongoing randomized clinical trials (RCTs) are adjusting adjuvant chemotherapy (ACT) intensity based on MRD status. However, data from ctDNA-guided trials, including PEGASUS (NCT04259944), reveal that intensified ACT is curative in only a small proportion of MRD cases. To address this limitation, the SAGITTARIUS RCT was designed to evaluate whether combining ctDNA detection with targeted agents selected on the basis of tissue-based comprehensive genomic profiling (CGP) can optimize treatment in high risk (i.e. MRD+) pts while sparing low risk (i.e. MRD−) from unnecessary toxicity. **Methods:** SAGITTARIUS is a Phase III RCT evaluating ctDNA and tissue-guided personalized post-surgical management in resected stage III and high-risk stage II CC pts. Tumor-informed, personalized ctDNA test (Signatera, Natera, Inc.) and CGP (TruSight™ Oncology Comprehensive EU, Illumina, Inc.) are used to determine MRD status and tumor genomic landscape, respectively, including genetic mutation (mut) and amplification (ampl), tumor mutational burden (TMB) and microsatellite instability (MSI) status. Pts are stratified based on post-surgery (3-5 weeks) ctDNA status into two embedded RCTs:Trial-1)ctDNA-positive (ctDNA+) ptsare further stratified based on MSI and RAS/RAF status and randomized 1:1 to standard 6-month ACT (CAPOX/FOLFOX) or personalized treatment (PT) guided by CGP biomarkers with reassessment of ctDNA status to guiding subsequent therapies (chemotherapy regimens in ctDNA+ or maintenance and follow-up in seroconverted; Trial-2) ctDNA-negative (ctDNA−) ptsare randomized 1:1 to a physician-choice strategy or observation with ctDNA reassessed at 2 and 4 months and, in cases of positivity, cross over to Trial-1. PT include 3-month CAPOX followed by FOLFIRI or TEMIRI based on MGMT status (RAS/RAFmut), Ipilimumab + nivolumab (MSI and TMB-high POLEmut), pertuzumab + trastuzumab (HER2ampl), FOLFOX + panitumumab (RAS/RAF/HER2 wild-type). The primary endpoint (EP) is 2-year recurrence-free survival (RFS) in ctDNA+ pts. Secondary EPs include 2-year RFS in ctDNA− pts, 3- and 5-year overall survival, and ctDNA conversion rate. Quality of life and health costs data are collected for cost effectiveness analysis. Biospecimens, including archival tumor tissue, serial blood samples, and buccal swabs, are collected for exploratory analyses. To detect a hazard ratio of 0.6325 for ctDNA-guided PT vs standard ACT, 200 ctDNA+ pts will be randomized in Trial-1. Recruitment began in October 2024 across 26 institutions in Italy, Spain, and Germany. Clinical trial information: NCT06490536. Research Sponsor: European Union; 101104657.

TPS3648 **Poster Session**

Phase II study of epacadostat (INCB024360) added to preoperative chemoradiation in patients with locally advanced rectal cancer. First Author: Moh'd M. Khushman, Washington University School of Medicine, St. Louis, MO

Background: Indoleamine 2,3-dioxygenase 1 (IDO1) metabolizes tryptophan along the kynurenine pathway and is recognized as a potent suppressor of tumor reactive immunity. Epacadostat is an orally active, potent and selective inhibitor of IDO1. In preclinical studies, IDO1 was found to promote resistance to radiation in rectal cancer, irrespective of microsatellite instability (MSI) status. IDO1 inhibition with epacadostat improved tumor radiosensitivity by relieving immune suppression and augmenting radiation-induced apoptosis while protecting the normal intestine from radiation damage. In a phase 1 trial, 17 patients were enrolled from 4/2019 to 8/2023. Epacadostat in combination with short-course radiation therapy (SCRT) and CAPOX was well-tolerated and the recommended phase 2 dose (RP2D) of epacadostat was determined to be 400 mg BID. An NCI supported Phase 2 trial is ongoing to further evaluate the promising disease responses reported in the dose escalation phase. **Methods:** This phase 2 multicenter, open-label trial includes treatment and biomarker cohorts. In the treatment cohort, epacadostat at 400 mg BID will be administered concurrently with SCRT followed by epacadostat monotherapy until 1 day prior to neoadjuvant chemotherapy, followed by standard-of-care (SOC) neoadjuvant chemotherapy and, ultimately, surgical resection or non-operative management (NOM). Biomarker cohort enrollment will commence at completion of treatment cohort accrual. Enrolled patients will be treated with SOC SCRT followed by SOC neoadjuvant chemotherapy and surgical resection or NOM. Eligible patients must be a treatment-naïve, newly diagnosed, pathologically confirmed, locally advanced rectal cancer (defined by 8th edition AJCC stage 2 or 3, or stage 1 not eligible for sphincter-sparing surgery) with plans to proceed with neoadjuvant SCRT and chemotherapy. The primary endpoint is the neoadjuvant rectal (NAR) score. Secondary endpoints are pathologic complete response (pCR) rate, complete clinical response (cCR) rate and progression-free survival (PFS). Exploratory endpoints are pharmacodynamics, PDX and organoid generation, identification of molecular predictors of response and resistance, correlation of radiographic and pathologic response and effect of treatment on patient quality of life. We aim to enroll 27 patients in the treatment cohort and 10 in the biomarker cohort. Clinical trial information: Clinical Trial Registration: NCT03516708. Research Sponsor: NIH (grant number 1R01CA278197-01A1); Incyte (drug only).

TPS3649 **Poster Session**

AZUR-4, a phase 2, open label, randomized study of neoadjuvant dostarlimab plus capecitabine plus oxaliplatin (CAPEOX) versus CAPEOX alone in previously untreated T4N0 or stage III mismatch repair proficient/microsatellite stable resectable colon cancer. First Author: Gertjan Rasschaert, Department of Gastroenterology/Digestive Oncology, University Hospital Leuven, Leuven, Belgium

Background: Colon cancer is the third most common cancer globally, with a standard of care in the nonmetastatic setting that includes surgery followed by adjuvant chemotherapy. Results of recent clinical trials suggest that neoadjuvant therapy may be beneficial in locally advanced colon cancer. Neoadjuvant immunotherapy has shown impressive responses in mismatch repair deficient (dMMR)/microsatellite instability-high (MSI-H) disease with pathological complete responses of up to 67% and 3-year disease-free survival of 100% reported in the NICHE 2 trial. However, most colon cancer (85%–90%) is mismatch repair proficient (MMRp)/microsatellite stable (MSS), which has been shown to have poor response to conventional immunotherapy. Dostarlimab, a programmed cell death protein-1 (PD-1) inhibitor, has a high affinity for binding to PD-1, blocking the interaction between PD-1 and its ligands (PD-L1 and PD-L2). Dostarlimab monotherapy has been approved in the US for the treatment of adults with dMMR advanced/recurrent solid tumors. The AZUR-4 trial (NCT06567782) evaluates dostarlimab + CAPEOX versus CAPEOX alone as neoadjuvant treatment to identify early signals of efficacy in resectable MMRp/MSS colon cancer. The study will assess the relationship between conventional and advanced blood- and tumor-based immune response to better understand the contribution of dostarlimab to pathological response. **Methods:** AZUR-4 is a multicenter, randomized, open-label phase 2 study in MMRp/MSS resectable colon cancer. Approximately 120 patients will be enrolled and randomized 3:1 to the dostarlimab + CAPEOX and CAPEOX arms, respectively, in which they will receive 4 cycles of Q3W neoadjuvant therapy. Key eligibility criteria include age ≥18 years, confirmed resectable MMRp/MSS colon adenocarcinoma with no prior treatment, clinically staged as T4N0 or stage III, Eastern Cooperative Oncology Group performance status of 0 or 1, and required tissue biopsies providing fresh tumor tissue either at prescreening or screening. Primary endpoints are major pathologic response rate (mPR) assessed at ≤10% residual viable tumor (RVT) and treatment-emergent adverse events (AEs), serious AEs, immune-mediated AEs, and AEs leading to death or discontinuation of study drug. Secondary endpoints include primary tumor resection not being excluded by either disease progression or treatment-related toxicities, and pathological response categories that include complete pathological response (cPR) and partial pathologic response (pPR). Exploratory endpoints include overall survival, event-free survival, effects on circulating tumor DNA dynamics, and pathological response rate in biomarker subsets. Clinical trial information: NCT06567782. Research Sponsor: GSK.

TPS3650 **Poster Session**

Trials in progress: Alliance A022104/NRG-GI010—A randomized phase II/III trial testing the efficacy of triplet versus doublet chemotherapy regarding clinical complete response and disease-free survival in patients with locally advanced rectal cancer (LARC; the Janus Rectal Cancer trial). First Author: Caleah Simone Kitchens, Memorial Sloan Kettering Cancer Center, New York, NY

Background: A total neoadjuvant therapy (TNT) approach improves compliance with chemotherapy and increases rates of tumor response compared to neoadjuvant chemoradiation (CRT) alone in those with locally advanced rectal cancer. Recent data indicate that optimal sequencing of TNT involves consolidation (rather than induction) chemotherapy to improve complete response rates. The use of FOLFIRINOX has shown to improve response and outcomes compared to CRT and surgery alone. Data have also shown that patients with clinical complete response (cCR) after TNT may be managed with a watch and wait approach (WW) instead of preemptive total mesorectal resection (TME). However, the optimal consolidation chemotherapy regimen to improve cCR rates has not been established, and a randomized clinical trial has not robustly evaluated cCR as a primary endpoint. We designed this NCI-sponsored study of chemotherapy intensification to address this and to increase cCR rates, provide opportunity for organ preservation, and survival outcomes. **Methods:** In this multigroup randomized, seamless phase II/III trial (1:1), up to 760 patients with LARC, T4N0, any T with node positive disease (any T, N+) or T3N0 requiring abdominoperineal resection or coloanal anastomosis and distal margin within 12 cm of anal verge will be enrolled. Stratification factors include tumor stage (T4 vs T1-3), nodal stage (N+ vs N0) and distance from anal verge (0–4; 4–8; 8–12 cm). Patients will be randomized to receive neoadjuvant long-course chemoradiation (LCRT) followed by consolidation doublet (mFOLFOX6 or CAPOX (control arm)) or triplet chemotherapy (FOLFIRINOX (experimental arm)) for 3–4 months. LCRT in both arms involve 4500 cGy in 25 fractions over 5 weeks +900 cGy boost in 5 fractions with a fluoropyrimidine. Patients will undergo assessment 8–12 (±4) weeks post-TNT completion. The primary endpoint for the phase II portion will compare cCR between treatment arms. A total number of 312 patients (156 per arm) will provide statistical power of 90.5% to detect a 17% increase in cCR rate, at a one-sided alpha = 0.048. The primary endpoint for the phase III portion will compare disease-free survival (DFS) between arms. A total of 285 DFS events will provide 85% power to detect an effect size of hazard ratio 0.70 at a one-sided alpha of 0.025, requiring enrollment of 760 patients (380 per arm). Secondary objectives include overall survival, organ preservation time, time to distant metastasis, and adverse event rates. This study has accrued 587 patients as of January 2025, and is investigating exploratory correlatives (e.g., ctDNA). Support: U10CA180821, U10CA180882, U24CA196171. https://acknowledgments.alliancefound.org. Clinicaltrials.gov ID: NCT05610163 Clinical trial information: NCT05610163. Adjuvant nivolumab in resected esophageal or gastroesophageal junction cancer (EC/GEJC) following neoadjuvant chemoradiotherapy (CRT): First results of overall survival (OS) from CheckMate 577. First Author: Ronan Joseph Kelly, Charles A. Sammons Cancer Center at Baylor University Medical Center, Dallas, TX

Background: At 24.4-month (mo) median follow-up, adjuvant nivolumab demonstrated a statistically significant and clinically meaningful improvement in disease-free survival (DFS) vs placebo with a well-tolerated safety profile in patients (pts) with resected EC/GEJC with residual pathologic disease following neoadjuvant CRT and surgery in the primary analysis from the global, phase 3 CheckMate 577 study (NCT02743494). We report the final analysis of the hierarchically tested secondary endpoint of OS along with longer follow-up of DFS. **Methods:** Adults with resected (R0) stage II/III EC/GEJC who received neoadjuvant CRT and had residual pathologic disease were randomized 2:1 to nivolumab 240 mg or placebo Q2W for 16 weeks, followed by nivolumab 480 mg or placebo Q4W. Maximum treatment duration was 1 year. The primary endpoint was DFS. OS was a secondary endpoint, and exploratory endpoints included safety, distant metastasis-free survival (DMFS), and progression-free survival on subsequent systemic therapy (PFS2). **Results:** 794 pts were randomized (nivolumab, n = 532; placebo, n = 262). With a median follow-up of 78.3 (range, 60.1–96.6) mo, adjuvant nivolumab continued to show DFS benefit vs placebo (HR 0.76 [95% CI 0.63–0.91]; Table). Median OS was numerically longer with nivolumab vs placebo (51.7 vs 35.3 mo), although the difference was not statistically significant (HR 0.85 [95.87% CI 0.70–1.04]; *P* = 0.1064; Table). OS rates at 3 and 5 years with nivolumab vs placebo were 57% vs 50% and 46% vs 41%, respectively. OS subgroup analyses will be presented. Clinically meaningful improvement in DMFS with nivolumab vs placebo was maintained (Table). PFS2 favored nivolumab vs placebo (HR 0.81 [95% CI 0.67–0.98]). In the nivolumab group, 46% of pts received subsequent therapy vs 60% in the placebo group; 5% vs 15% received subsequent immunotherapy. No new safety signals were identified. **Conclusions:** Adjuvant nivolumab demonstrated sustained long-term DFS benefit and numerical improvement in OS vs placebo in pts with resected EC/GEJC and residual pathologic disease following neoadjuvant CRT. The safety profile of adjuvant nivolumab remained well-tolerated with longer follow-up. These results further support the use of adjuvant nivolumab in this pt population. Clinical trial information: NCT02743494. Research Sponsor: Bristol Myers Squibb.

Lenvatinib plus pembrolizumab and chemotherapy versus chemotherapy in advanced, metastatic gastroesophageal adenocarcinoma: The phase 3, randomized LEAP-015 study. First Author: Kohei Shitara, National Cancer Center Hospital East, Chiba, Japan

Background: LEAP-015 (NCT04662710), is a randomized, open-label, phase 3 study of pembrolizumab plus lenvatinib and chemotherapy as first-line treatment for advanced/metastatic gastroesophageal adenocarcinoma. We report results from the interim and final analyses of LEAP-015. **Methods:** Eligible participants (pts) had untreated HER-2 negative locally advanced unresectable or metastatic gastroesophageal adenocarcinoma, measurable disease and ECOG PS 0-1. All pts were randomly assigned 1:1 to induction with pembrolizumab 400 mg IV Q6W (x2) plus oral lenvatinib 8 mg QD and investigators choice chemotherapy (CAPOX Q3W x4 or mFOLFOX6 Q2W x6) then consolidation with pembrolizumab 400 mg Q6W for ≤16 doses plus lenvatinib 20 mg QD (only if 8 mg tolerated for at least 3 weeks), or chemotherapy alone (CAPOX or FOLFOX). Randomization was stratified by region, ECOG PS, and chemotherapy choice. Dual primary endpoints were PFS (RECIST v1.1, BICR) and OS in pts with PD-L1 combined positive score (CPS) ≥1 and in all pts; secondary endpoints included ORR and DOR (RECIST v1.1, BICR) in pts with PD-L1 CPS ≥1 and in all pts, and safety and tolerability in all pts. The data cut-off date was Oct 29, 2024. **Results:** A total of 880 pts (78% PD-L1 CPS ≥1; 75% gastric primary) were randomized (443 pembrolizumab plus lenvatinib and chemotherapy; 437 chemotherapy alone).Median follow-up was 32.2 mo (range 19.0 – 41.7) in pts with PD-L1 CPS ≥1 and 31.8 mo (range, 19.0 – 41.7) in all pts. At interim analysis, PFS difference was statistically significant with pembrolizumab plus lenvatinib and chemotherapy vs chemotherapy in pts with PD-L1 CPS ≥1 (median 7.3 vs 6.9 mo; HR 0.75; 95% CI, 0.62-0.9; P = 0.0012), with 24-mo PFS of 20% vs 7%, and in all pts (median 7.2 vs 7.0 mo; HR 0.78; 95% CI, 0.66-0.92; P = 0.0019), with 24-mo PFS of 21% vs 8%. ORR was 59.5% vs 45.4% in pts with PD-L1 CPS ≥1 and 58.0% vs 43.9% in all pts; P < 0.0001 for both. At final analysis, OS in pts with PD-L1 CPS ≥1 was not statistically significant (median 12.6 vs 12.9 mo; HR 0.84; 95% CI, 0.71-1.00; P = 0.0244 (P-value boundary for significance of 0.0204), with 24-mo OS of 31% vs 23%. OS in all pts was not tested per multiplicity strategy (median 13.1 vs 13.0; HR 0.87; 95% CI 0.75-1.01). Drug-related adverse event (AE) rates were 98% vs 92% in pts receiving pembrolizumab plus lenvatinib and chemotherapy vs chemotherapy. Grade ≥3 drug-related AE rates were 65% vs 49% (grade 5 AEs 5% vs < 1%). **Conclusions:** Pembrolizumab plus lenvatinib and chemotherapy vs chemotherapy provided statistically significant improvement in PFS and ORR in pts with advanced unresectable or metastatic gastroesophageal carcinoma at interim analysis. However, there was no significant improvement in OS in pts with PD-L1 CPS ≥1 at final analysis. Safety profiles were consistent with known regimens, with higher AE rates seen in pts receiving the experimental treatment. Clinical trial information: NCT04662710. Research Sponsor: Merck Sharp & Dohme LLC, a subsidiary of Merck & Co., Inc., Rahway, NJ, USA; N/A.

Claudin18.2-specific CAR T cells (Satri-cel) versus treatment of physician's choice (TPC) for previously treated advanced gastric or gastroesophageal junction cancer (G/GEJC): Primary results from a randomized, open-label, phase II trial (CT041-ST-01). First Author: Changsong Qi, Peking University Cancer Hospital, Beijing, Beijing, China

Background: Claudin18.2 (CLDN18.2) has emerged as a promising therapeutic target in G/GEJC. Recently reported results showed CT041/satricabtagene autoleucel (satri-cel), an autologous CLDN18.2-specific CAR T-therapy, had encouraging efficacy in previously treated patients (pts) with advanced G/GEJC. Now we report the primary results from the phase II pivotal trial (CT041-ST-01, NCT04581473). **Methods:** In this open-label, multicenter, randomized controlled trial (RCT) conducted in China, CLDN18.2 positive, advanced G/GEJC pts with failure to at least 2 prior lines of treatment, were randomized (2:1) to satri-cel arm or TPC arm. For satri-cel arm, satri-cel dose of 250×10^6 cells were infused up to 3 times. For TPC arm, one of the standard of care (SOC) drugs (apatinib, paclitaxel, docetaxel, irinotecan or nivolumab) was given per physician's decision. Those who experienced disease progression or drug intolerance in TPC arm could receive subsequent satri-cel, if eligible. The primary endpoint was PFS assessed by the Independent Review Committee (IRC). Key secondary endpoint was OS. Data cutoff date was Oct 18, 2024. **Results:** From Mar 29, 2022 to Aug 16, 2024, a total of 156 pts were randomized to satri-cel arm (n = 104) or TPC arm (n = 52). Twenty pts in TPC arm received subsequent satri-cel. Median number of prior systemic therapies was 2 in both arms, and 26.9% vs 19.2% had received ≥3 lines; 69.2% vs 59.6% had peritoneal metastasis; 71.2% vs 65.4% were Lauren diffuse/mixed type. The median follow-up time of PFS and OS was 8.90 and 12.29 months (m). In ITT population, satri-cel arm showed significant improvement in mPFS by IRC (3.25m vs 1.77m; HR 0.366, 95% CI: 0.241, 0.557; p < 0.0001) and an obvious trend for longer mOS (7.92m vs 5.49m; HR 0.693, 95% CI: 0.457, 1.051; one-sided p = 0.0416) than TPC arm. Moreover, in 136 pts receiving study drug (mITT, satri-cel 88 pts vs TPC 48 pts), mPFS by IRC was 4.37m vs 1.84m, HR 0.304 (95% CI: 0.195, 0.474) and mOS was 8.61m vs 5.49m, HR 0.601 (95% CI: 0.385, 0.939). Notably, mOS of TPC pts with satri-cel was 9.20m. Among all pts receiving satri-cel (n = 108) vs TPC pts without satri-cel (n = 28), mOS was 9.17m vs 3.98m, HR 0.288 (95% CI: 0.169, 0.492). A summary of study drug-related adverse events (TRAEs) is shown in the Table. **Conclusions:** This is the first confirmatory RCT of CAR T-therapy in solid tumors. Satri-cel demonstrated significant PFS improvement and an obvious OS benefit with a manageable safety profile. These results support satri-cel as a potential new SOC for advanced G/GEJC. Clinical trial information: NCT04581473. Research Sponsor: None.

PANOVA-3: Phase 3 study of tumor treating fields (TTFields) with gemcitabine and nab-paclitaxel for locally advanced pancreatic ductal adenocarcinoma (LA-PAC). First Author: Vincent J. Picozzi, Virginia Mason Medical Center, Seattle, WA

The full, final text of this abstract will be available at meetings.asco.org on the day of presentation and in the online supplement to the June 10, 2025, issue of the *Journal of Clinical Oncology*.

4006 **Oral Abstract Session**

Preliminary results from the randomized phase 2 study (1801 part 3B) of elraglusib in combination with gemcitabine/nab-paclitaxel (GnP) versus GnP alone in patients (pts) with previously untreated metastatic pancreatic ductal adenocarcinoma (mPDAC). First Author: Devalingam Mahalingam, Robert H. Lurie Comprehensive Cancer Center, Northwestern University, Chicago, IL

Background: Elraglusib (9-ING-41) is a first-in-class inhibitor of GSK-3ß, which may mediate drug resistance, EMT, and damaged DNA and tumor immune response in advanced cancer. In pancreatic cancer models in mice, elraglusib combined with chemotherapy enhanced anti-tumor effects and survival. In a single-arm clinical study, elraglusib/GnP showed antitumor activity and prolonged survival in pts with mPDAC. **Methods:** Pts with previously untreated mPDAC were randomized 2:1 to GnP plus elraglusib 9.3 mg/kg IV once weekly or GnP in an open-label phase 2 study. The primary endpoint was 1-yr OS in the primary analysis set. Upon study completion, mOS will be the primary endpoint once survival distributions are compared after the 12-month follow-up using log-rank analysis. Secondary endpoints included DCR, ORR, mPFS, and TEAEs/TRAEs. The planned sample size was 207 evaluable pts (130 for elraglusib/GnP and 77 for GnP), assuming 1-yr OS of 55% with elraglusib/GnP and 35% with GnP to achieve 80% power with a chi-square test at a 2-sided 5% α. For OS, nonparametric log-rank test was used with statistical significance at p-value $<$ 0.048. Cytokine/chemokine correlative biomarker assays were performed. The study completed enrollment in February 2024. **Results:** As of November 15, 2024 (preliminary data cut-off date), the primary analysis set included 155 pts in the elraglusib/GnP arm and 78 pts in the GnP arm, with 52.8% males and 57.5% ECOG PS 1. Median (range) CA 19-9 levels were 1568 U/mL (1 to 381,904 U/mL) in the elraglusib/GnP arm and 1590 U/mL (2 to 501,000 IU/mL) in the GnP arm. The 1-yr OS rate was 43.6% with elraglusib/GnP vs 22.5% with GnP (z-test p = 0.002); the mOS was 9.3 mo with elraglusib/GnP vs 7.2 mo with GnP (HR, 0.63; log rank p = 0.016; see Table). 38.1% of pts on elraglusib/GnP and 19.2% on GnP are censored, with the majority at $>$ 10 months OS. Several biomarkers appear to be predictive for OS including IFNβ and PD-L1. The most common TRAE with elraglusib/GnP was grade 1-2 transient visual impairment in $>$ 60% of patients (vs 9% with GnP). Grade $\geq$3 TEAEs occurred in 89.7% of pts on elraglusib/GnP and 80.8% on GnP. Most common grade $\geq$3 TEAEs with elraglusib/GnP (vs GnP) were neutropenia 51.6% (vs 29.5%), anemia 24.5% (vs 29.5%), and fatigue 16.1% (vs 5.1%). **Conclusions:** The preliminary results showed a statistically significant benefit for 1-yr OS and mOS and favorable trends for ORR and DCR with elraglusib/GnP over GnP, with manageable safety profile. The mOS for GnP is lower relative to MPACT and NAPOLI-3 but comparable to recent real-world meta-analyses, explained by advanced disease burden and higher mortality rate in the first 4 months in our study. Topline analysis (April 2025) and correlative biomarker analysis predictive for OS will be presented. Clinical trial information: NCT03678883. Research Sponsor: Actuate Therapeutics, Inc.

4007 **Oral Abstract Session**

A phase III randomized clinical trial evaluating perioperative therapy (neoadjuvant chemotherapy versus chemoradiotherapy) in locally advanced gallbladder cancers (POLCAGB). First Author: Reena Engineer, Tata Memorial Centre (HBNI), Mumbai, India

Background: Locally advanced Gallbladder cancers (LAGBC)initially deemed not suitable for R0 resection receive either neoadjuvant chemotherapy (NACT)or neoadjuvant chemoradiation (NACRT)downstaging for resection and to improve outcomes. **Methods:** This is a randomized phase 3 trial (NCT02867865) that included fit patients with LAGBC adenocarcinoma,. T3/T4 with liver infiltration ($>$ 2cm, $<$ 5cm); N1 nodal status; obstructive jaundice (type I/II biliary obstruction) ;duodenal or colonic abutment with no mucosal infiltration , $<$ 180°vascular involvement. The patients were randomized (1:1) to NACT arm (Gemcitabine + platinum for four cycles) versus NACRT arm (55 -57Gy with concurrent gemcitabine followed by two cycles of chemotherapy) and were then evaluated for surgery. A sample size of 314 patients was required to detect a 5.5 months difference (11 mo.to 16.5 mo in the test arm) with median overall survival (OS) as the primary endpoint (hazard ratio, 0.7; 2-sided α = 0.05; β = 0.2). Secondary endpoints were event free survival (EFS),R0 resection rates and post-operative complication rates. Due to slow accrual Institutional Ethics committee requested the investigators for interim analysis and approval was obtained for the same. **Results:** From Oct 2016 to Sept 2024, 124 patients (64 NACT, 60 NACTRT)were enrolled at 2 centers. At the time of analysis 93 OS events were observed in 124 patients. Median follow-up was 62 (range 6.9-94) months. More number of patients underwent R0 resection in NACRT than NACT arm 51.6 vs 29.7% (p = 0.01) In the intention to treat analysis, the NACTRT arm showed improved OS compared to the NACT arm [21.8 mo.vs.10.1 mo. p = 0.006]. EFS was 10.6 mo. vs 4.9 months, p = 0.006]. Similar results were noted in the per protocol analysis(n = 110). Clavien Dindo postoperative morbidity of grade 3 and above was 4/22 (18.18%) in NACT arm vs 9/32(28.12%) in NACRT arm (p = 0.30). The interim analysis demonstrated a significant improvement in efficacy in the NACRT arm. Based on the current data, the conditional power was calculated to be 99.96%. **Conclusions:** This trial demonstrates that the addition of concurrent chemoradiation to chemotherapy improves overall survival and resection rates in patients with locally advanced gallbladder cancers. These results provide important evidence to guide treatment decisions in this traditionally difficult to treat set of gallbladder cancers. Clinical trial information: NCT02867865. Research Sponsor: Intramural funding - Tata Memorial Centre.

4008 Oral Abstract Session

Neoadjuvant chemotherapy with gemcitabine plus cisplatin followed by radical liver resection versus immediate radical liver resection alone followed adjuvant therapy in biliary tract cancer: Final results from the phase III AIO/CALGP/ACO-GAIN-Trial. First Author: Thorsten Oliver Goetze, Institute of Clinical Cancer Research (IKF), Krankenhaus Nordwest, UCT-University Cancer Center, Frankfurt, Germany

Background: Radical surgical resection represents the only potentially curative treatment option for Biliary Tract Cancer (BTC) and (incidental) Gallbladder Carcinoma ((I) GBC). Nevertheless, 5-year OS is only 20–40% after curatively intended resection and data regarding pure adjuvant chemotherapy in BTCs are currently conflicting. Encouraging results of neoadjuvant/perioperative concepts in other malignancies provide a rationale to use this treatment in the early phase management of GBC and intrahepatic as well extrahepatic cholangiocarcinoma (ICC/ECC). **Methods:** GAIN is a multicenter, randomized, controlled, open-label phase III trial, including patients (pts) with localized or locally advanced resectable non metastatic biliary tract cancer (intra-/extrahepatic cholangiocarcinoma ICC/ECC; GBC in front of radical liver resection). Pts were randomized to either neoadjuvant (perioperative) systemic chemotherapy (Gemcitabine + Cisplatin 3 cycles pre- and post-surgery) followed by radical surgery (Arm A) or to direct surgery followed by adjuvant treatment (Arm B) according to investigators choice. Primary endpoint was OS; secondary endpoints were PFS/EFS, R0-resection rate, toxicity, perioperative morbidity, mortality and QoL. Recruitment was stopped after enrollment of 68 pts due to a slow enrollment rate. **Results:** Between Dec 2019 and Feb 2024, 68 pts were randomized and the ITT comprised 32 pts in Arm A and 30 pts in Arm B. Baseline characteristics were similar between arms (overall, male 55%; median age 66.0; cT3/T4 29.0%; cN+ 30.6%; 37.1% ICC, 30.6% ECC and 32.3% GBC). 90.6% of pts in Arm A completed all 3 pre-operative cycles. 43.8% in Arm A completed adjuvant treatment and 23.3% in Arm B received adjuvant treatment. Median follow-up was 11.8 months. Neoadjuvant treatment improved OS (mOS, Arm A 27.8 vs. 14.6 months Arm B; HR 0.46 [0.22 - 0.96]; p = 0.04) and R0 resection rate (62.5% vs 33.3%). This effect was also seen in event-free survival. Postoperative morbidity rates were similar in both arms (33.3% (A) vs. 32% (B)) and the 30- and 90-days mortality rates were lower for Arm A (30-days: 4.2% vs. 24%; 90-days: 4.2% vs. 28%). No new safety/toxicity signals were observed. In Arm A, 12 pts (38.7%) had at least one treatment related adverse event (TRAE) with grade 3 and 1 pt (3.2%) with grade 4. No fatal TRAEs were observed. **Conclusions:** Neoadjuvant / perioperative gem/cis clearly improved OS and R0 resection rate in pts with biliary tract cancer compared to direct surgery and was able to nearly double mOS while not increasing the morbidity rate and even decreasing mortality rates. Clinical trial information: NCT03673072. Research Sponsor: None.

4009 Clinical Science Symposium

Maintenance with OSE2101 plus FOLFIRI vs FOLFIRI alone after FOLFIRINOX (FFX) induction in patients (Pts) with advanced pancreatic ductal adenocarcinoma (aPDAC): Primary endpoint results of a randomized TEDOPAM GERCOR D17-01 PRODIGE 63 trial. First Author: Anthony Turpin, Lille University Hospital, University of Lille, Lille, France

Background: OSE2101 is an off the shelf vaccine made of 10 synthetic HLA-A2-restricted peptides targeting 5 tumor associated antigens. This multicenter, randomized, non-comparative, phase II study assessed FOLFIRI ± OSE2101 maintenance in aPDAC Pts without progression after 8 cycles of FFX. **Methods:** Eligible aPDAC Pts were randomized to FOLFIRI (Arm A) or FOLFIRI + OSE2101 (Arm B: subcutaneous injection on D1, D15, Q4W/6 doses then Q8W to M12 then Q12W up to M24). Stratification factors: tumor stage (locally advanced vs metastatic), best response to FFX (partial or complete response [CR, PR] vs stable disease [SD]), and center. Primary endpoint: overall survival (OS) rate at M12 in evaluable Pts (M12-OS; Fleming 2-stage design, H0: 25%; H1: 50%, 1-sided alpha: 2.5%, power: 90%); secondary endpoints: progression-free survival (PFS; RECIST v1.1), best response, duration of disease control (DDC), and safety. **Results:** 107 Pts (ITT) were randomized (53/Arm A, 54/Arm B) between 04/2021 and 05/2023. Median age 64 years (range:37-81), 53% men, 69% had metastases, 36%/64% had PR/SD to prior FFX. No evidence of imbalance in Pt characteristics was observed between arms. Median number of OSE2101 injections was 7.5 (1-14). Median treatment duration of FOLFIRI was 5.4 months in both arms. At data cut-off (Dec 9, 2024), median follow-up was 21.4 months with 101 evaluable Pts for M12-OS (49/Arm A, 52/Arm B; 4 consent withdrawals, 1 Pt's decision, 1 treatment interruption >4 weeks). Number of death events (n/%) was 19/35.8% in Arm A and 18/33.3% in Arm B. M12-OS (95%CI) was 61% (46.2%-74.8%) in Arm A and 65% (50.9%-78.0%) in Arm B. Median (95%CI) OS and PFS (ITT) were 17.3 months (10.6–23.2) and 8.2 months (5.3–11.6) in Arm A, and 15.5 months (12.4–19.3) and 7.8 months (5.4–10.6) in Arm B. Other secondary endpoints are described in Table. Among 33 Pts with SD to prior FFX in Arm B, 6 (18%) had CR/PR (1/5) when adding OSE2101 to FOLFIRI vs 5 (no CR) among 35 Pts in Arm A. In the safety population, 7 SAEs/6 Pts (12%) in Arm A and 22 SAEs/14 Pts (26%) in Arm B were reported. No unexpected SAEs were observed with OSE2101 except 1 inappropriate administration, and no evidence of increased toxicity of FOLFIRI with OSE2101. **Conclusions:** TEDOPAM met its primary objective with minimal toxicity and positive outcomes of adding OSE2101 cancer vaccine to maintenance FOLFIRI, albeit mitigated by unexpectedly favorable OS in the control arm. Two complete responses were observed when adding OSE2101. Further follow-up is ongoing and translational analysis planned. Clinical trial information: NCT03806309. Research Sponsor: OSE Immunotherapeutics.

4010 Clinical Science Symposium

Efficacy and safety of cafelkibart (LM-108), an anti-CCR8 monoclonal antibody, in combination with anti-PD-1 therapy in patients with pancreatic cancer: Results from phase 1/2 studies. First Author: Jifang Gong, Key Laboratory of Carcinogenesis and Translational Research (Ministry of Education/Beijing), Department of Early Drug Development Center, Peking University Cancer Hospital and Institute, Beijing, China

Background: Targeting tumor-infiltrating Tregs presents a promising strategy to overcome resistance to immunotherapy in cancer treatment. LM-108 is a novel Fc-optimized anti-CCR8 monoclonal antibody designed to selectively deplete tumor-infiltrating Tregs while sparing peripheral Tregs. This pooled analysis of two phase 1/2 trials assesses the efficacy and safety of LM-108 in combination with anti-PD-1 therapy in patients with pancreatic cancer. **Methods:** Eligible patients (pts) with pancreatic cancer who had progressed on or after at least one prior line of systemic therapy were included. Treatment regimens included LM-108 at doses of 3 mg/kg Q3W, 3 mg/kg Q2W, 10 mg/kg Q3W, or 10 mg/kg Q2W, in combination with pembrolizumab (400 mg Q6W) or toripalimab (240 mg Q3W). The primary endpoint was ORR. Secondary endpoints were DCR, PFS, OS, DoR, safety, and biomarkers analysis. Data cutoff: December 2, 2024. **Results:** A total of 80 pts (median age: 63 years; 58.8% male) from China and Australia were treated. Of these, 48 pts had progressed on or after 1 prior line of therapy, and 32 pts had ≥2 lines. Eighteen pts (22.5%) had prior anti-PD-1 therapy, and 52 pts (65.0%) had liver metastases at baseline. TRAEs were reported in 76 pts (95.0%). Common TRAEs (≥25%) included increased AST, increased ALT, anemia, rash, pyrexia, decreased platelet count and increased conjugated bilirubin. Grade ≥3 TRAEs occurred in 42 pts (52.5%), the most common events (≥5%) were lipase elevation (7.5%), increased ALT (6.3%), increased AST (5.0%), immune-mediated enterocolitis (5.0%), hypokalemia (5.0%), and rash (5.0%). Median follow-up was 10.48 months (95% CI 7.20-12.65). Among 74 efficacy-evaluable pts, ORR was 20.3% (95% CI 11.8-31.2%) and DCR was 62.2% (95% CI 50.1-73.2%). Median DoR was 5.49 months (95% CI 3.02-8.87), PFS was 3.12 months (95% CI 1.61-4.86), and OS was 10.02 months (95% CI 6.41-13.11). Among 45 pts who had progressed on or after one prior line of therapy, ORR was 24.4% (95% CI 12.9-39.5%) and DCR was 71.1% (95% CI 55.7-83.6%), with a median DoR of 6.93 months (95% CI 3.02-NA), PFS of 4.86 months (95% CI 2.79-6.90), and OS not reached. The 12-month OS rate was 51.6% (95% CI 31.4-68.5%). Among these, 9 pts with high CCR8 expression (7 with baseline liver metastases) showed ORR of 33.3% (95% CI 7.5-70.1%) and DCR of 77.8% (95% CI 40.0-97.2%). Median PFS was 6.90 months (95% CI 1.22-NA), and OS was 9.15 months (95% CI 3.61-NA). **Conclusions:** LM-108 in combination with anti-PD-1 therapy demonstrated encouraging antitumor activity and a manageable safety profile in patients with pancreatic cancer who had progressed on or after prior systemic therapies. These findings support further investigation of LM-108 in combination with anti-PD-1 therapy as a potential treatment option for pancreatic cancer. Clinical trial information: NCT05199753; NCT05518045. Research Sponsor: LaNova Medicines Limited.

4011 Clinical Science Symposium

NeoPancONE: GATA6 expression as a predictor of benefit to peri-operative modified FOLFIRINOX in resectable pancreatic adenocarcinoma (r-PDAC): A multicentre phase II study. First Author: Ronan Andrew McLaughlin, Division of Medical Oncology and Hematology, Princess Margaret Cancer Centre – University Health Network, University of Toronto, Toronto, ON, Canada

Background: Modified FOLFIRINOX (mFFX) is increasingly used in the perioperative setting in r-PDAC and patients (pts) would benefit from a biomarker approach. GATA6 expression enriches for the classical RNA subtype, associated with improved OS in advanced PDAC. Low expression identifies the basal subtype which may predict mFFX resistance. NeoPancONE is a single arm Phase II multicentre study evaluating clinical outcomes and investigating GATA6 as a biomarker of response to perioperative mFFX in r-PDAC. **Methods:** Pts were enrolled following central radiology review (CRR) and underwent an EUS FNB for GATA6 in-situ hybridization (ISH). Six cycles of mFFX were planned pre and postoperatively. The primary endpoint was 1 yr event-free survival (EFS) according to GATA6 ISH (high vs low). Secondary endpoints include OS, RECIST response, SAEs, R0 resection rates and RNA subtyping by PurIST. Statistical assumptions used a ratio of 3:1 GATA6 high:low, with a 1 yr EFS of 65% for high and 34% for low (HR 2.5, 80% power, 2 sided alpha 0.05). KM method and log-rank test were used. **Results:** Between Sep-2020– Sep 2023, 146 pts were screened and 84 enrolled (58%) at 8 Canadian centres. CRR deemed 39 (27%) ineligible. Clinical data are summarized (Table). GATA6 ISH was analysed in 74 (88%); 62 (84%) were high, 16% low. At a median follow up of 24.5 mos, the med EFS and OS in the ITT were 16.1 mos (95 CI; 13-21) and 34.2 mos (95 CI; 28-NE). Med OS in the 73 pts who underwent surgery was 35.6 mos (95 CI 33-NE). The 1 yr EFS was 71% in GATA6 high vs 58% in GATA6 low p= 0.53. 1 yr OS was 87% in high vs 75% for low p= 0.29. The proportion progressing within 6 mos of enrollment in the GATA6 low group was significantly higher (42% vs 12% p=0.02). PuriST subtyping was reported in 49 (67%) resections; 14% basal, 86% classical. The 1 yr EFS was 79% in classical vs 43% in the basal subtype p=0.1. The 1 yr OS was 95% in classical vs 57% in basal p=0.034. **Conclusions:** This is one of the first trials in r-PDAC to identify potential biomarkers to predict perioperative mFFX response. GATA6 by ISH can be assessed on baseline tissue. GATA6 high is a prognostic biomarker, although NS, trends towards improved EFS and an encouraging OS. Disease progression within 6 months of enrollment occurs in nearly 50% of patients with low GATA6 expression. Neoadjuvant mFFX should not be the standard of care in these patients. Basal/Classical subtyping had stronger prognostic value than GATA6 and should be considered at baseline EUS FNB for future perioperative strategies in r-PDAC studies. Clinical trial information: NCT04472910. Research Sponsor: Princess Margaret Cancer Foundation UHN; Pancreatic Cancer Canada.

Disitamab vedotin (DV) plus toripalimab (Tor) and chemotherapy (C)/trastuzumab (Tra) as first-line (1L) treatment of patients (pts) with HER2-expressing locally advanced or metastatic (la/m) gastric cancer. First Author: Lin Shen, Beijing Cancer Hospital, Beijing, China

The full, final text of this abstract will be available at meetings.asco.org on the day of presentation and in the online supplement to the June 10, 2025, issue of the *Journal of Clinical Oncology*.

4013 **Rapid Oral Abstract Session**

Long-term outcomes and overall survival (OS) for zanidatamab + chemotherapy in HER2-positive (HER2+) advanced or metastatic gastroesophageal adenocarcinoma (mGEA): 4-year follow-up of a phase 2 trial. First Author: Elena Elimova, Princess Margaret Cancer Centre, Toronto, ON, Canada

Background: Zanidatamab (zani), a dual HER2-targeted bispecific antibody, plus chemotherapy (chemo) has previously demonstrated antitumor activity and a manageable safety profile in the first-line (1L) treatment of patients (pts) with HER2+ mGEA. Here, we report a 4-year follow-up and the first report of both median OS and translational data from this phase 2 trial. **Methods:** The phase 2 trial (NCT03929666) evaluated zani + chemo (mFOLFOX6, CAPOX, or FP) in the 1L treatment of mGEA. In Part 1, pts had HER2-expressing (IHC 3+ or 2+) mGEA. Pts in Part 2 had HER2+ (IHC 3+ or IHC 2+/FISH+) mGEA by central assessment. After 25 pts were treated, antidiarrheal prophylaxis was added for cycle 1. The primary endpoint was confirmed objective response rate (cORR). Secondary endpoints included duration of response (DoR), progression-free survival (PFS), OS, and safety outcomes. Plasma ctDNA samples were collected for NGS testing (Guardant360). **Results:** In total, 46 pts were enrolled (zani + mFOLFOX6 [n = 24], CAPOX [n = 20], or FP [n = 2]). The majority (41 [89%]) of pts had HER2+ mGEA by central confirmation (ccHER2+); 35 (76%) pts had gastric/GEJ cancer. As of July 28, 2024, the median (range) follow-up was 48 (29-59) mo; 8 pts (17%) were on zani treatment and 19 (41%) in survival follow-up. Efficacy results are shown in the Table. The median OS was 36.5 mo; longest survival time was 57.9 mo (censored without death at data cutoff). The concordance between HER2 gene amplification by centrally assessed ISH vs plasma ctDNA was 90% (18/20). Of 14 pts with matched plasma samples at baseline and on-treatment (Cycle 2, day 15), 8 had a $>$ 90% decrease in total ctDNA levels and 2 had a decrease in HER2 copy number. Common ($>$ 5% of pts) grade 3 or 4 treatment-related AEs (TRAEs) were diarrhea (n = 18 [39%]), hypokalemia (n = 10 [22%]), vomiting (n = 4 [9%]), and nausea (n = 3 [7%]). Grade 3 or 4 diarrhea incidence was reduced from 52% to 24% after prophylaxis implementation. No deaths occurred due to TRAEs. **Conclusions:** After a median 4-year follow-up, zani + chemo demonstrated clinically meaningful efficacy in the 1L treatment of HER2+ mGEA, with durable responses and a median OS $>$ 3 years, and a manageable safety profile. Zani + chemo markedly reduced total plasma ctDNA levels early in treatment of mGEA. Clinical trial information: NCT03929666. Research Sponsor: Jazz Pharmaceuticals.

Recurrence patterns in the prospective, randomized, controlled, multicenter phase III ESOPEC trial comparing perioperative chemotherapy with preoperative chemoradiotherapy in patients with esophageal adenocarcinoma. First Author: Jens Hoeppner, University of Bielefeld, University Medical Center OWL, Campus Hospital Lippe, Bielefeld, Germany

Background: The ESOPEC trial (NCT02509286) showed that perioperative chemotherapy improved overall and progression free survival in pts with esophageal adenocarcinoma (EAC) compared with preoperative chemoradiotherapy. Understanding of the pattern of recurrence is important for the development of more effective future treatment strategies. **Methods:** Pts with cT1 cN+ cM0 or cT2-4a cNany cM0 EAC undergoing preoperative chemotherapy with FLOT (5-FU/leucovorin/oxaliplatin/docetaxel) or preoperative chemoradiotherapy with CROSS (41.4Gy/carboplatin/paclitaxel) plus tumor resection from the ESOPEC trial were eligible. Recurrence-free survival (RFS), distant metastasis-free survival (DMFS), and patterns of local, regional and distant recurrence were analyzed. Treatment groups were compared with respect to sites of recurrence by calculating 3-year cumulative incidences considering competing events, and by Cox regression models for event-specific hazards stratified by trial center and including treatment assignment (FLOT vs CROSS), cN stage (cN0 vs cN+), and age as covariates. Event-specific hazard ratios (HR) with two-sided 95% confidence intervals (CI) and p-values are presented. **Results:** Of the 438 pts enrolled in ESOPEC, 192 of 221 (86.9%) in the FLOT group and 179 of 217 (82.5%) in the CROSS group underwent tumor resection and represent the population for this analysis. R0 resection was achieved in 354 pts (182 (94.8%) FLOT; 172 (96.1%) CROSS). 142 (74.0%) pts in FLOT received postoperative chemotherapy. After a median follow-up of 56 months 178 pts had disease recurrence (81 FLOT; 97 CROSS), and 28 pts died without recurrence (12 FLOT; 16 CROSS). The 3-year RFS rate was 54.5% in FLOT vs 39.0% in CROSS (HR for recurrence or death 0.67; 95% CI, 0.51 - 0.89, p = 0.005). The 3-year DMFS rate was 57.6% in FLOT vs 41.0% in CROSS (HR for distant recurrence or death 0.64; 95% CI, 0.48 – 0.85, p = 0.002). **Conclusions:** Perioperative chemotherapy with FLOT improves RFS and DMFS compared to preoperative chemoradiotherapy with CROSS in EAC. The prognosis of pts is determined by distant recurrence, which is less common after FLOT than CROSS. Clinical trial information: NCT02509286. Research Sponsor: German Research Foundation (DFG); 264590883.

Treatment group comparisons regarding site of recurrence.

	FLOT N=192	CROSS N=179	FLOT vs CROSS		
Site of recurrence	N (%)*	N (%)*	HR (for recurrence)	95% CI	P-value
Locoregional	39 (20.2)	32 (17.4)	1.00	0.62 – 1.61	0.99
Local	19 (9.5)	15 (8.1)	1.03	0.51 – 2.06	0.94
Regional	29 (15.1)	27 (14.5)	0.89	0.52 – 1.52	0.68
Distant	64 (31.5)	89 (47.2)	0.59	0.43 – 0.82	0.002

4015 **Rapid Oral Abstract Session**

Decoding the response and resistant features to the Claudin18.2-specific CAR-T cell CT041 in gastric cancer: A multi-omics exploratory biomarker analysis of the phase 1 clinical trial. First Author: Haoxin Peng, Department of Gastrointestinal Oncology, Peking University Cancer Hospital & Institute, Beijing, China

Background: CT041, a Claudin18.2-specific CAR-T cell therapy against gastric cancer (GC), has demonstrated encouraging efficacy and a manageable safety performance. However, the characteristics of response and resistance to CT041 therapy remain unclear. **Methods:** An exploratory biomarker analysis of the phase 1 CT041-CG4006 clinical trial (NCT03874897) was conducted. Baseline samples were collected from primary tumors (PT), and dynamic samples were collected from peripheral blood and malignant ascites at day 0, 3, and 7 of 35 patients. These samples underwent single-cell RNA sequencing (n = 41), spatial transcriptomics (ST, n = 8 for Visium V2 and n = 5 for Xenium 5K), and multiplex immunofluorescence detection (n = 28). **Results:** In the responders, significantly higher GZMK+CD8+ T-lymphocyte infiltrates, which were in a progenitor-like exhausted (Tpex) state, were identified within PT. More GZMK+ Tpex infiltration also correlated with better prognosis (high vs. low: progression-free survival 9.98 vs. 5.45 months, P = 0.020; overall survival 18.03 vs. 8.03 months, P = 0.038), manifesting superior potential as a predictor of CT041 response (AUC 0.87, 95%CI 0.72-1.00). Moreover, strong and positive associations between GZMK+ Tpex and IRF8+ B-lymphocytes were discovered. ST detection further uncovered that they tended to co-localize within tertiary lymphoid structures and intimately interacted via the MHC-I and CCL5-CXCR4 pathways. In cases resistant to CT041, significantly higher infiltrates of IQGAP3+ cancer cells, a subset characterized by augmented proliferative activity, were discovered. While IQGAP3+ cancer cells hindered the infiltration of GZMK+ Tpex, they exhibited a co-infiltrated pattern with IL6+ fibroblasts, wherein enhanced epithelial-to-mesenchymal transition pathway activity was noted. Through dynamically parsing the blood and ascites samples, an initial activated and subsequent exhausted state of GZMK+ cytotoxic T-lymphocyte was observed after the infusion of CT041. Additionally, significant up-regulation of NR4A1, a crucial regulator of Tpex, and CCR9, a key homing molecule to the gastrointestinal mucosa, of peripheral T-lymphocytes was detected in responsive cases. **Conclusions:** This exploratory analysis first unveiled the biological underpinnings and clinical implications of GZMK+ Tpex in determining response and resistance to the Claudin18.2-specific CAR-T therapy. 4016 Rapid Oral Abstract Session

Cosiporfin sodium (DVDMS)-mediated photodynamic therapy (PDT) versus treatment of physician's choice (TPC) in patients (pts) with advanced esophageal cancer (aEC): A phase III, randomized, open-label, multicenter trial. First Author: Jun Zhou, Peking University Cancer Hospital & Institute, Beijing, China

Background: Challenges persist in the treatment of aEC, particularly for pts with esophageal stenosis and dysphagia, conditions that deteriorate the nutrition status and hinder anti-tumor therapies, leading to dismal prognosis. Building on the promising anti-tumor activity and improvement in dysphagia in a phase II single-arm trial, the phase III DYNA-Esophagus03 trial assessed DVDMS, a novel photosensitizer, -mediated PDT in aEC, comparing to TPC. **Methods:** Pts with local recurrence or metastasis EC and Stoller dysphagia grade ≥2, stratified by previous treatment lines (1st vs 2nd-line), were randomized 2:1 to DVDMS-mediated PDT (PDT delivered 24 hours after 0.2 mg/kg DVDMS injection at a light dose of 102 J/cm² and wavelength of 630±5 nm) or TPC. The primary endpoint was esophageal stenosis overall response rate (es-ORR) assessed by endoscopy at 28 days. A sample size of 186 pts achieved a 90% power to detect an es-ORR increase from 10% to 35% at a 1-side 2.5% level, considering a 30% drop-off rate. **Results:** As of November 11, 2024, 186 pts were randomly assigned (124 DVDMS-PDT group/62 TPC group). The baseline characteristics were: mean age 67.6 ± 8.7 years, 32.3% distant metastasis, 52.2% grade 3 dysphagia, and 1.1% grade 4. The es-ORR was 51.6% with DVDMS-PDT vs 8.1% with TPC at day 28 ($P < 0.0001$). At a median follow-up of 8.9 months (mos), the median progression-free survival was 2.8 vs 2.2 mos (HR = 0.61, 95%CI 0.40-0.93; P = 0.0244), respectively. Time to progression was 5.9 vs 3.9 mos (HR = 0.45, 95% CI: 0.25-0.82, P = 0.0056). Median overall survival (OS) was 7.0 vs 6.4 mos (HR = 0.88, 95%CI 0.59-1.32; P = 0.5169), respectively. Considering the high cross-over rate (45.2%), the rank preserving structural failure time-adjusted median OS was 7.0 vs 4.7 mos (HR = 0.64, 95%CI 0.42-0.97; P = 0.0223). The improvement of dysphagia and quality of life are detailed in the Table. Phototoxicity was negative in 64.9% pts in DVDMS-PDT group on day 7, increasing to 91.4% by day 28. Grade ≥3 treatment-emergent adverse events occurred in 38.2% of the DVDMS-PDT group and 49.2% of the TPC group. Six deaths were due to treatment-related adverse events (4.9%) were reported in the DVDMS-PDT group and 5 (8.5%) in the TPC group. **Conclusions:** DVDMS-PDT significantly improved esophageal stenosis and dysphagia compared to the treatment of physician's choice in pts with aEC, with prolonged PFS and TTP, potential better OS and a manageable safety profile. Clinical trial information: CTR20221271. Research Sponsor: None.

4017 Rapid Oral Abstract Session

Claudin18.2 (CLDN18.2) expression and efficacy in pancreatic ductal adenocarcinoma (PDAC): Results from a phase I dose expansion cohort evaluating IBI343. First Author: Xianjun Yu, Department of Pancreatic Surgery, Fudan University Shanghai Cancer Center, Shanghai, China

Background: CLDN18.2 is highly expressed in nearly 60% of PDAC cases. Yet to date, there are no approved targeted therapies and prognoses for these patients (pts) remain poor. IBI343, consisting of an anti-CLDN18.2 Fc silenced monoclonal antibody and the topoisomerase I inhibitor, exatecan, is the first CLDN18.2 antibody-drug conjugate to have shown encouraging efficacy in PDAC. Here, we report results from a phase 1 study (NCT05458219) in pts with PDAC treated with IBI343 by CLDN18.2 expression status (≥60% vs < 60%). **Methods:** Eligible pts with advanced PDAC and moderate to high expression of CLDN18.2 (defined as immunohistochemistry [IHC] membrane staining intensity ≥2 in ≥40% of tumor cells by IHC VENTANA CLDN18 [43-14A] Assay) who failed or were intolerant to standard treatment were enrolled. IBI343 was administered every 3 weeks at multiple dose levels (1, 3, 4.5, 6, 8, and 10 mg/kg). Endpoints included safety, objective response rate (ORR), disease control rate (DCR), duration of response (DoR), progression-free survival (PFS) per RECIST v1.1, and overall survival (OS). **Results:** As of December 27, 2024, 83 pts from China and Australia were enrolled. 44 and 12 pts with CLDN18.2 expression ≥1 in ≥60% (+) and < 60% (-) of tumor cells, respectively, received IBI343 at 6mg/kg in the dose expansion phase (median age, 60 and 64 years; male, 54.5% and 66.7%; received prior treatments ≥2L, 61.4% and 83.3%). Among all treated pts (n = 83), treatment-emergent adverse events (TEAEs) occurred in 82 (98.8%) pts and ≥Grade 3 (G3) TEAEs in 42 (50.6%) pts. TEAEs led to treatment discontinuation in 6 (7.2%) pts. No TEAE led to death. Most common TEAEs were anemia (66.3%, 15.7% ≥G3), neutrophil count decreased (48.2%, 9.6% ≥G3), and WBC count decreased (47.0%, 9.6% ≥G3). The safety profile of IBI343 in PDAC was comparable to previous reports. Among CLDN18.2+ pts (n = 44), confirmed ORR was 22.7% (95% CI, 11.5–37.8); DCR was 81.8% (95% CI: 67.3–91.8), median PFS was 5.4 (95% CI, 4.1–7.4) months (mos), median OS was 8.5 (95% CI, 6.6–12.1) mos, and in 10 pts with confirmed partial response median DOR was 6.7 (95% CI, 3.2–7.7) mos. Among CLDN18.2+ pts who received 1 and 2 lines of prior treatment, median OS was 12.1 (95% CI, 6.6–not calculable [NC]) mos and 9.1 (95% CI, 5.1–NC) mos, respectively. Among CLDN18.2- pts (n = 12), no pt had an objective response, DCR was 41.7% (95% CI: 15.2–72.3), median PFS was 1.4 (1.3–3.2) mos, which was shorter than what was seen in CLDN18.2+ pts (Ad hoc analysis: nominal P < .0001; HR = 0.198 [95% CI: 0.089-0.439]) and median OS was 6.2 (95% CI,1.4–9.0) mos. **Conclusions:** IBI343 was well tolerated and continues to show encouraging efficacy in pts with PDAC. Efficacy benefit was most pronounced in those with CLDN18.2 expression ≥60%, suggesting that CLDN18.2 can be a predictive biomarker for response to IBI343 in PDAC. The trial is enrolling in Australia, China, and US. Clinical trial information: NCT05458219. Research Sponsor: None.

4018 Rapid Oral Abstract Session

Clinical activity of EBC-129, a first-in class, anti N256-glycosylated CEACAM5 and CEACAM6 antibody-drug conjugate (ADC), in patients with pancreatic ductal adenocarcinoma (PDAC) in a phase 1 study. First Author: Robert William Lentz, Division of Medical Oncology, Department of Medicine, University of Colorado Anschutz School of Medicine, Aurora, CO

Background: Pancreatic ductal adenocarcinoma (PDAC) is an aggressive malignancy with limited treatment options. EBC-129 is a first in class MMAE-linked ADC against N256-glycosylated CEACAM5/6 antigen. Pre-screening data shows 73% of PDAC express surface antigen (IHC positive cut-off ≥20% at 2+ or 3+) or 82% (≥1% at 3+). Previously reported dose escalation data identified 1.8 and 2.2 mg/kg every 3 weeks as the RP2Ds. Here we report pooled safety and efficacy data of the PDAC patients enrolled in the dose escalation (DEs) and expansion (DEx) cohorts of the phase 1 study. **Methods:** This study consisted of DEs and DEx cohorts. Previously treated histologically confirmed, locally advanced or metastatic PDAC patients with antigen expression levels of ≥20% at 2+ or 3+ intensity or ≥1% at 3+ intensity (IHC on archival samples) were enrolled. Objectives were to evaluate safety, efficacy, and PK of EBC-129, administered every 3 weeks. **Results:** A total of 21 PDAC patients were enrolled (6 in DEs and 15 in DEx). Patients received 1.8 (n = 8), 2.0 (n = 2) or 2.2 (n = 11) mg/kg EBC-129 every 3 weeks. 52% were male; mean age 63 years; median 3 (range 1-7) lines of previous treatments with 81% prior taxane treated. At data cut-off (Jan 16th, 2025), 5 patients are continuing treatment, 12 patients had radiological progression, 3 had clinical progression, and 1 patient withdrew treatment. The overall response rate, disease control rate (first assessment), and median PFS, at 1.8 mg/kg, 2.2 mg/kg and overall group, respectively, were 25.0%, 18.2% and 19.0% (unconfirmed), 87.5%, 63.6% and 71.4%, and 18, 12 and 12 weeks. 43% of patients had any tumour shrinkage overall. Infusion related reactions (IRR) were seen in 57% of patients; most were grade 1/2, more frequent at 2.2 mg/kg, and resolved or reduced with premedication. Grade ≥3 treatment related adverse events included neutropenia (50.0% and 81.8%) and anaemia (12.5% and 18.2%) at 1.8 and 2.2mg/kg, respectively; amylase/lipase increase, vomiting, and aspartate aminotransferase increase occurred in 1 patient each. Grade ≤2 peripheral neuropathy was seen in 2 patients. No drug related discontinuations occurred in this cohort. In this cohort, selected for target antigen expression, no apparent correlation was seen between IHC score and treatment response. Based on a cut-off of > 25% CEA decrease (either local or central), biomarker response was seen 42.9% at 1.8 mg/kg and 36.4% at 2.2 mg/kg. **Conclusions:** EBC-129 shows promising clinical activity in heavily treated PDAC patients with a manageable tolerability profile, consistent with MMAE-based ADCs. Further evaluation of EBC-129 in PDAC, both as monotherapy and in combination with chemotherapy, is planned. Clinical trial information: NCT05701527. Research Sponsor: Experimental Drug Development Centre (EDDC).

4019 Rapid Oral Abstract Session

10-year follow up of a phase 2 clinical trial of pembrolizumab (pembro) in microsatellite instability-high (MSI-H)/mismatch repair deficient (dMMR) advanced solid tumors. First Author: Katherine M. Bever, Sidney Kimmel Comprehensive Cancer Center at Johns Hopkins University, Baltimore, MD

Background: Inhibitors of Programmed Cell Death Protein-1 (PD-1) have demonstrated remarkable activity in dMMR/MSI-H cancers, leading to the first tissue agnostic FDA approval for an oncologic indication. We report herein results of long-term follow up of KEYNOTE-016, the first study to demonstrate pan-tumor activity of the PD-1 inhibitor pembro in dMMR/MSI-H solid tumors. **Methods:** KEYNOTE-016 was a multicenter open-label phase 2 study evaluating pembro in patients with advanced colorectal cancer (CRC) (Cohort A) or non-CRC solid tumors (Cohort C) that were dMMR and had progressed after ≥1 prior line of therapy (or ≥2 prior lines for CRC). Eligible patients were age ≥ 18, and had measurable disease per RECIST 1.1. Patients with active CNS metastases, who were on immunosuppressive therapy, had autoimmune disease, or were previously treated with immune checkpoint inhibitors were excluded. Patients received pembro IV every 2 weeks until progression, intolerance, withdrawal of consent or up to a maximum of 2 years. **Results:** Between 9/2013 - 9/2017, 88 patients (Cohort A: 41; Cohort C: 47) enrolled at 7 sites and received ≥1 dose of pembro. Tumor types enrolled on Cohort C included endometrial (N = 15), pancreatic (N = 9), small intestinal (N = 5), gastroesophageal (N = 5), biliary (N = 4), ampullary (N = 4), and other (N = 5). Median follow up time was 49.7 mos for all patients and 99.8 mos for alive patients. Objective response rate (ORR) was 58% with 23 partial (PR) and 28 complete responses (CR). 16 patients experienced a best response of stable disease (SD) for a disease control rate of 76%. Median PFS and OS were 34.9 mos (95% CI: 14.8-NR) and 80.8 mos (95% CI: 33.2-NR) respectively. The 3-, 5-, and 10-year OS rates were 55.1%, 53.7% and 47.4% respectively. Outcomes were similar between Cohorts A and C (see Table). **Conclusions:** In summary, long term follow up of KEYNOTE-016 confirms high rates of durable remission from pembro in patients with dMMR/MSI-H solid tumors, with several patients remaining alive and in remission at 10+ years follow up. Responses were seen across tumor types. Clinical trial information: NCT01876511. Research Sponsor: Swim Across America; Merck.

4020 **Rapid Oral Abstract Session**

Health-related quality of life (HRQOL) in the phase 3 trial of cabozantinib vs placebo for advanced neuroendocrine tumors (NET) after progression on prior therapy (CABINET, Alliance A021602). First Author: Amylou C. Dueck, Alliance Statistics and Data Management Center, Mayo Clinic, Scottsdale, AZ

Background: In previously treated patients (pts) with advanced extra-pancreatic NET (epNET) or pancreatic NET (pNET), cabozantinib (cabo) demonstrated improved progression-free survival compared to placebo (pbo) in the CABINET trial (NCT03375320). Here we present HRQOL data from CABINET. **Methods:** Pts with previously treated unresectable, locally advanced or metastatic epNET or pNET were randomized (2:1) in separate cohorts to receive cabo 60 mg daily vs pbo. HRQOL was an exploratory endpoint measured using the EORTC QLQ-C30, QLQ-GI.NET21, Patient Global Impression of Change (PGIC), and PRO-CTCAE questionnaires. Optional participation was by paper surveys at baseline and every 12 weeks (wks) until disease progression or new anticancer therapy. Mean changes from baseline were compared between treatment arms at wk12 using general linear mixed models. Minimally important within-arm improvements and between-arm differences were defined as 8 points on the C30 Global Health Status (GHS)/QOL Scale. PGIC was dichotomized as improved vs unchanged/worsened and compared using Chi-squared tests. Rates of pt-reported adverse events (AEs) by PRO-CTCAE were baseline-adjusted and compared using Fisher's exact tests. **Results:** 172 pts (113 cabo, 59 pbo) with epNET and 81 pts (53 cabo, 28 pbo) with pNET consented for survey participation. Pts completed 524 (82%) of 640 expected surveys across baseline, wk12, and wk24. For epNET, C30 GHS/QOL was significantly improved at wk12 in pts receiving cabo (mean change 9.5, standard error (SE) 2.2, $p < 0.001$) but not pbo (mean change 0.2, SE 3.1, p = 0.95) resulting in significantly different mean changes from baseline between arms (p = 0.02). For pNET, C30 QHS/QOL was significantly improved at wk12 in pts receiving cabo (mean change 8.0, SE 3.0, p = 0.008) but not pbo (mean change 6.8, SE 4.4, p = 0.12); mean changes from baseline did not statistically differ between arms (p = 0.82). No significant differences in mean changes from baseline at wk12 in C30 Physical, Role, Emotional, Cognitive and Social Function were observed between arms in the epNET or pNET cohorts. In both cohorts at wk12, pts on cabo reported improved overall status as measured by PGIC more often than those on pbo (epNET: 38% vs 19%, p = 0.04; pNET: 57% vs 18%, p = 0.006). Rates of pt-reported AEs were statistically significantly higher in cabo for diarrhea (68% vs 53%), hand-foot syndrome (57% vs 26%), mouth or throat sores (47% vs 27%), and dysgeusia (67% vs 37%) [all $p < 0.05$]. GI.NET21 data will be presented. **Conclusions:** Although cabo is associated with pt-reported AEs consistent with its known safety profile, global HRQOL was maintained. A higher proportion of patients receiving cabo reported improved overall status. Results support cabo as a treatment option for pts with previously treated advanced NET that preserves patient HRQOL. Clinical trial information: NCT03375320. Research Sponsor: UG1CA189823; U10CA180821; U10CA180882; Exelixis; https://acknowledgments.alliancefound.org.

Claudin-18.2 expression in gastro-oesophageal adenocarcinoma in a Western population: Overlap with other biomarkers and prognostic value. First Author: Filip Van Herpe, Gastrointestinal Oncology Department, University Hospitals Leuven, Leuven, Belgium

Background: Claudin 18.2 (CLDN18.2) is a novel biomarker for response to anti-CLDN18.2 therapy in gastroesophageal adenocarcinoma (GEA). Based on prevalence data, originating mostly from an Asian population, 40% of GEA are CLDN18.2 positive. We currently lack information on the cross-prevalence of CLDN18.2, HER2-status, microsatellite instability (MSI) and PDL1 expression in a Western population of localized and metastatic GEA. **Methods:** We present a single-center, retrospective study including localized and metastatic GEA patients diagnosed between 2019-2023. Histopathology with MMR status, HER2 status (IHC/SISH) and PDL1 CPS was obtained. CLDN18.2-positivity defined as ≥75% of tumor cells showing moderate-to-strong membranous staining was determined by IHC using the VENTANA CLDN18 [43-14A] RxDx Assay and underwent blind review by independent expert pathologists. Baseline characteristics and clinical follow-up data were gathered until august 2024. Kaplan-Meier curves were constructed for overall survival (OS), progression/relapse free survival (PFS/RFS) and survival after recurrence (SAR). Unrestricted grants/support was provided from Astellas, AMGEN and Roche diagnostics. **Results:** Of 405 patients with GEA, 261 presented with localized and 144 with metastatic disease. The majority were male (71%) with a median age of 65 years. 59% of tumors were junction tumors and 41% were gastric cancers. dMMR was detected in 6%. HER2 positivity (cfr. TOGA criteria) was seen in 16% of cases. PDL1 CPS ≥1 prevalence was 58%. CLDN18.2 positivity was seen in 42% of patients. Double CLDN18.2-HER2 and CLDN18.2-dMMR positivity was rare (5% and 3%), but strikingly in absolute numbers, about one third of HER2 positive tumors and half of dMMR tumors were CLDN18.2 positive. Double CLDN18.2-PDL1 ≥1//≥5//≥10 positivity was seen in 23%,15% and 9%. In patients with localized disease CLDN18.2 positivity did not affect RFS (HR: 0.99; 95%CI(0.68-1.43); p = 0.95) and OS (HR: 0,78; 95%CI(0.52-1.16) p = 0,22) with a median follow-up (FU) of 42 months. In the remaining 113 patients with primary metastatic disease no difference in terms of PFS (HR: 1.17; 95%CI(0,79-1.73); p = 0,43) or OS (HR: 1.43; 95%CI(0,94-2.16); p = 0,1) was seen according to CLDN18.2 status with a median FU of 39 months. Median SAR in the localized group was statistically longer in the PDL1 CPS≥1 subgroup(HR: 0.51; 95% CI(0,34-0,79); p = 0,002). SAR was not different in CLDN18.2+ and CLDN18.2- patients (HR: 1,07; 95%CI(0,69-1.65) p = 0,77). **Conclusions:** We confirmed a 42% positivity rate of CLDN18.2 in a combination of localized and metastatic GEA in a Western population. dMMR was present in 6% of cases, PDL1 CPS ≥1 and HER2+ was seen in 58% and 16% of patients. CLDN18.2 positivity was strikingly present in half dMMR and one third of HER2+ cases. CLDN18.2 positivity did not affect survival in localized and metastatic disease. Preliminary results of a phase 1 study of LB1908, an autologous Claudin 18.2–targeted chimeric antigen receptor T-cell product, in patients with advanced gastroesophageal adenocarcinoma. First Author: David Bing Zhen, Fred Hutchinson Cancer Center, Seattle, WA

Background: Claudin 18.2 (CLDN18.2) is a potential therapeutic target expressed on most gastric, gastroesophageal, and esophageal adenocarcinomas (GC/GEJC/EC), with normal tissue expression limited to gastric epithelium. We present preliminary results of the dose-escalation trial of LB1908, a CLDN18.2-targeted autologous CAR-T cell product, in adults with advanced GC/GEJC/EC. **Methods:** This trial is an ongoing, open-label, multicenter, first-in-human phase 1 study of LB1908 in patients with advanced GC/GEJC/EC relapsed/refractory to ≥1 prior line of therapy (LOT), and with ≥1+ CLDN18.2 expression in ≥50% of tumor cells by central testing (43-14A antibody). A modified 3+3 design is used for dose escalation with planned dose levels of 0.5, 1.5, and 3×10^6 CAR+ T cells/kg. The primary objective is evaluation of safety and dose-limiting toxicities (DLTs) with secondary objectives of antitumor activity and pharmacokinetics. **Results:** As of the data cutoff of January 4, 2025, 6 patients were dosed with LB1908 at dose level 1 (0.5×10^6 cells/kg). Four patients had EC and 2 had GC, all with metastatic disease. Patients had a median of 2 prior LOTs; all had received fluoropyrimidine/platinum agents. Bridging therapy was administered to all patients between apheresis and LB1908 infusion, and patients received standard lymphodepletion (LD) with cyclophosphamide/fludarabine. All patients experienced treatment-emergent adverse events (TEAEs); the most common grade ≥3 TEAEs were hematologic and attributable to the LD regimen. Of grade ≥3 TEAEs related to LB1908, only gastritis/gastric mucosal injury occurred in more than 1 patient (n = 3), including 1 DLT. After implementation of toxicity management guidelines using prophylactic enteral beclomethasone and early systemic steroids, no patients experienced prolonged grade ≥3 upper GI AEs. CRS occurred in all patients, with no grade ≥3 events. No ICANS was observed. CAR-T cell expansion was seen in all patients, with a median C_{max} of 1594 copies/μg genomic DNA (range, 264-6922) and T_{max} of 14 days (range, 11-15). All 6 patients were evaluable for response, with 5 (83%) experiencing target lesion shrinkage (maximal 1%, 9%, 25%, 31%, and 41% reduction from baseline). Responses deepened over time in the 2 patients with multiple postinfusion scans (-25% and -41%, respectively), including 1 patient achieving a RECIST partial response 7 months after treatment. **Conclusions:** LB1908 demonstrates peripheral expansion and encouraging antitumor activity at the lowest dose tested, with a manageable safety profile. Implementation of a toxicity mitigation strategy ameliorated on-target gastric mucosal injury without compromising expansion kinetics or antitumor activity. Longer follow-up and data from patients treated with higher cell doses will be presented at the meeting. Clinical trial information: NCT05539430. Research Sponsor: Legend Biotech USA Inc.

Genomic landscape and biomarker analyses utilizing circulating-tumor DNA in advanced esophageal squamous cell carcinoma: Sub-analysis of SCRUM-MONSTAR GOZILA. First Author: Yuqing Duan, National Cancer Center Hospital East, Kashiwa, Japan

Background: Advanced esophageal squamous cell carcinoma (ESCC) is a cancer type with a poor prognosis, with limited survival benefits from current multimodal approaches. The incomplete understanding of molecular mechanisms in advanced ESCC has hindered the development of effective targeted therapies, emphasizing the critical need for identifying predictive biomarkers and novel therapeutic targets. **Methods:** SCRUM-MONSTAR GOZILA is a nationwide plasma-based genomic profiling study utilizing Guardant360 in Japan, which aimed to analyze circulating tumor DNA (ctDNA) genomic alterations in patients with advanced solid tumors, including ESCC. We evaluated the genomic landscape with advanced ESCC patients and investigated associations between genomic alterations and overall survival (OS) using the log-rank test. The correlation between progression-free survival (PFS) and blood tumor mutation burden (bTMB) in immune checkpoint inhibitor (ICI) monotherapy was also assessed using multiple cut-off values (2, 4, 6, 8, and 10 mutation/Mb). **Results:** The present study included 313 patients with available genomic and clinical data. The gene alteration spectrum comprised mutations (single nucleotide variants, 71.6%; and insertions/deletions, 10.7%), copy number alterations (CNAs, 17.3%), and fusions (0.48%). TP53 was the most frequently altered gene (88.5%), followed by PIK3CA (36.4%), NFE2L2 (24.3%), CCND1 (22.4%), EGFR (20.1%), ATM (16.3%), FGFR1 (10.2%), BRCA2 (10.2%), MET (9.6%) and ARID1A (9.6%). Regarding the survival outcomes, PIK3CA CNA was significantly associated with worse OS compared to those with PIK3CA wild type [hazard ratio (HR), 1.84; 95% confidence interval (CI), 1.24–2.74; p-value, 0.0002], and PIK3CA mutation showed a trend toward shorter OS (HR, 1.43; 95%CI, 0.94–2.17; p-value, 0.06). Patients with both PIK3CA mutation and CNA exhibited significantly worse OS compared to those with PIK3CA wild type (HR, 1.94; 95%CI, 0.85–4.45; p-value, 0.03). Both FGFR1 CNA and mutation were associated with poorer OS (HR, 1.98; 95%CI, 1.03–3.79; p-value, 0.005; and HR, 2.84; 95%CI, 0.89–9.07; p-value, 0.002, respectively). CNA in CCND1 and EGFR, and mutation in NFE2L2 and RB1 also significantly correlated with worse OS (any p-value≤0.01). Among 142 patients treated with ICI monotherapy, no statistically significant differences in PFS were observed at any cut-off value of bTMB (any p-value > 0.1). **Conclusions:** This comprehensive analysis of ctDNA profiles revealed distinct genomic alterations with prognostic significance in advanced ESCC. Multiple alterations demonstrated significant associations with poor OS, meanwhile bTMB was not validated as an effective predictive biomarker for ICI efficacy. These findings provide insights into potential therapeutic targets and prognostic biomarkers in advanced ESCC. Clinical trial information: 2021-GB-009. Research Sponsor: None.

4025 **Poster Session**

HER2 expression dynamics and prognostic significance in the treatment of gastric cancer. First Author: Min Lai, Department of General Surgery, Nanfang Hospital, Southern Medical University, Guangzhou, Guangdong, China

Background: The human epidermal growth factor receptor 2 (HER2) expression undergoes changes during the treatment of gastric cancer. This study aims to evaluate post-treatment HER2 expression changes and the impact on survival. **Methods:** From a prospectively maintained database, we extracted clinical and pathological data, treatment information, and survival outcomes of gastric cancer patients (pts) with paired pre- and post-treatment HER2 immunohistochemistry (IHC) results (2018-2024). Cohen's Kappa was used to assess HER2 expression concordance. Logistic regression was performed to identify factors associated with HER2 change, while the Kaplan-Meier method and Cox regression were used for survival analysis. **Results:** 274 gastric cancer pts with paired HER2 IHC results were enrolled, including IHC 0 (67.5%, 185/274), 1+ (14.6%, 40/274), 2+ (13.5%, 37/274), 3+ (4.4%, 12/274) before treatment and IHC 0 (63.8%, 175/274), 1+ (21.9%, 60/274), 2+ (11.7%, 32/274), and 3+ (2.6%, 7/274) after treatment. The overall HER2 change rate was 42.7% (21.5% HER2 expression increased, 21.2% decreased), indicating low concordance (Kappa = 0.179, $p < 0.001$). Among 7.6% (17/225) of pts with HER2 changes from 0/1+ to 2+/3+, 23.5% (4/17) received anti-HER2 therapy (trastuzumab or anti-HER2 ADCs), achieving a 75.0% response rate. 38.5% (5/13) of initially confirmed HER2-positive pts (IHC 3+/2+ and FISH+) exhibited loss of HER2 positivity after treatment. 3 of 8 initially HER2-negative pts who converted to HER2-positive received trastuzumab for metastatic diseases, achieving a 66.7% response rate. Based on efficacy evaluation on the second HER2 testing, 197 pts were classified into the PR/SD group and 77 into the PD group, with comparable HER2 changes rate (41.6% vs. 45.5%, p = 0.565). Anti-HER2 therapy (n = 28) was associated with a higher HER2 changes rate (67.9% vs. 39.8%, p = 0.005), mainly driven by HER2 reduction (60.7% vs. 16.7%, $p < 0.001$). Multivariate logistic regression showed that combined immunotherapy (OR [odds ratio] 1.85, p = 0.028) or targeted immunotherapy (OR 4.71, $p < 0.001$) was associated with a higher HER2 change rate than chemotherapy alone. The median follow-up time was 31.2 months. HER2 expression changes were associated with worse PFS (HR [hazard ratio] 1.52, p = 0.040) and OS (HR 1.51, p = 0.043), with decreased HER2 expression showing the poorest PFS (Log-rank p = 0.030) and OS (Log-rank p = 0.025). Subgroup analysis showed in PR/SD group, HER2 expression changes was associated with significantly worse PFS (HR 2.48, p = 0.003) and OS (HR 2.56, p = 0.002), while no survival differences were observed in PD group. **Conclusions:** HER2 expression frequently changes during the treatment of gastric cancer, particularly after immunotherapy and targeted therapy, and is associated with worse survival outcomes. Dynamic HER2 testing contributes to guiding precision therapy for gastric cancer. Research Sponsor: None.

Tislelizumab (TIS; BGB-A317) plus chemotherapy (CT)/chemoradiotherapy (CRT) as positron emission tomography (PET)–guided neoadjuvant (n) treatment (tx) for resectable esophageal squamous cell carcinoma (R-ESCC): RATIONALE-213 final analysis. First Author: Longqi Chen, Department of Thoracic Surgery, West China Hospital, Sichuan University, Chengdu, China

Background: Studies have shown overall survival improvements with nCRT + surgery vs surgery alone in locally advanced ESCC. However, preoperative CRT may have additional safety concerns, leading to some patients (pts) receiving nCT rather than nCRT. PET-computed tomography maximum standardized uptake value (SUV_{max}) change after induction CT (IC) has been shown to have reliable predictive value of pathological complete response (pCR) for R-ESCC in pts with nCRT and may optimize neoadjuvant tx selection. TIS (anti-PD-1) has improved survival in pts with ESCC. We report the final analysis of RATIONALE-213, a phase 2, open-label, multicenter study in China evaluating PET-guided nTIS + CT/CRT in R-ESCC (NCT04974047). **Methods:** Eligible adult pts had histologically confirmed R-ESCC (cT1-2N + M0 or cT3N any M0), ECOG performance status 0/1, adequate organ function, no fistula risk, and had received no prior tx. Pts had a baseline (BL) PET scan, 1 cycle of IC (cisplatin-paclitaxel [Cis-Pac]), and a PET scan 15-21 days later. Pts were grouped into 2 cohorts by response to IC based on the percentage decrease in 2nd PET SUV_{max} in the primary tumor: responders (R, ≥35%) or nonresponders (NR, < 35%). Both cohorts received 3 cycles of TIS 200 mg IV Q3W, the first 2 with CT (2 cycles Cis-Pac) for R, or with CRT (2 cycles investigator [Inv]-chosen CT [Cis-Pac, or 5-FU + Cis] + RT [40 Gy/20 fractions]) for NR, then surgery. Primary endpoint was pCR per local pathologist. Secondary endpoints were 1-year disease-free survival (DFS), 1-year event-free survival (EFS), objective response rate (ORR) before surgery, R0 resection rate by Inv, and safety. **Results:** Of 70 pts enrolled, 15 (21.4%), 48 (68.6%), and 7 (10.0%) had stage II, III, and IVA disease at BL, respectively. As of 25 Oct 2024 (median follow-up 25.5 mo), 30 pts were R and 40 NR. Of R, 20 (66.7%) had surgery. Of NR, 32 (80.0%) had surgery. Efficacy endpoints are shown in the table. Median DFS and EFS were not reached for R and NR. Grade ≥3 treatment-related adverse events (TRAEs) in R (15 [50.0%]) and NR (33 [82.5%]) were consistent with known CT or CRT toxicity; serious TRAEs occurred in 5 R (16.7%) and 7 NR (17.5%). No TRAEs led to surgery cancellation or death. **Conclusions:** APET-guided approach may help optimize neoadjuvant tx of R-ESCC. nTIS + CT/CRT showed promising efficacy and a tolerable safety profile in both responders and nonresponders. Clinical trial information: NCT04974047. Research Sponsor: BeOne Medicines Ltd.

Efficacy and safety of surufatinib (Sur) plus paclitaxel (Pac) as second line (2L) treatment for advanced gastric cancer (aGC): Final results from a phase 2 trial. First Author: Xiuying Xiao, Department of Oncology, Renji Hospital, School of Medicine, Shanghai Jiao Tong University, Shanghai, China

Background: Standard chemotherapy (ChT) provides unsatisfactory efficacy for patients with aGC in the 2L setting. Recent studies have suggested improved efficacy with an antiangiogenic agent plus Pac. Although ramucirumab plus Pac have been approved as a 2L treatment, access to this combination regimen is limited in China. Sur is a potent VEGFRs, FGFR1 and CSF-1R inhibitor. This trial is aimed to assess the efficacy and safety of Sur plus ChT as a 2L treatment for aGC. Our previous report (ASCO-GI 24) revealed promising anti-tumor activity of this regimen. Now we are presenting the final analyses including long-term survival results. **Methods:** This single-arm, phase 2 clinical trial enrolled patients with HER2-negative aGC who had failed standard first-line treatment. Eligible patients received Sur (250mg, po, qd) plus Pac (150mg/m^2, iv, d1) at 21-day cycles for 6 cycles, followed by maintenance with single-agent Sur until disease progression or intolerable toxicity. Tumor responses were assessed every 6 weeks by investigators per RECIST v1.1. The primary endpoint was ORR, and secondary endpoints were DCR, PFS, OS, and safety. **Results:** As of Dec 20, 2024, of the 35 patients enrolled, median age was 65 (range: 33-75), 26 (74.3%) were male, 31 (88.6%) had an ECOG PS of 1, 12 (34.3%) had positive PD-L1 (defined as CPS ≥1), and 26 (74.3%) had received 1L immunotherapy (IO). Seven (20.0%) patients had primary GEJC, and all patients had stage IV disease, with lymph nodes (23, 65.7%), liver (16, 45.7%) and peritoneum (14, 40.0%) being the most common metastatic sites. Tumor response assessments were available in 32 patients, the ORR was 25.0% and DCR was 87.5%. Primary GEJC (42.9% vs 20.0%, *P*= 0.327) and baseline liver metastases (40.0% vs 11.8%, *P*= 0.106) seemed correlated to a better ORR, while baseline peritoneal metastases (8.3% vs 35.0%, *P*= 0.204) the reverse. With a median follow-up of 12.6 (95% CI: 10.4-14.9) months (mo), the mPFS was 5.7 (95% CI: 4.7-6.93) mo and the mOS was 10.8 (95% CI: 7.0-17.2) mo. Within the subgroup patients who had IO exposure in the 1L setting (n = 26), the ORR was 25.0%, the DCR was 91.7%, the mPFS was 5.9 (95% CI: 4.7-10.5) mo, and the mOS reached 14.4 (95% CI: 8.5-NR) mo. Treatment-related adverse events of grade ≥3 included neutropenia (40.0%), leukopenia (34.3%), hypertension (11.4%), and proteinuria (5.7%). There were no treatment-related serious adverse events or on-treatment deaths. **Conclusions:** These encouraging long-term efficacy results and the manageable safety profile suggested a preferable position of Sur plus Pac as the 2L treatment for aGC, notably, following the current standard 1L IO-containing regimens. Clinical trial information: ChiCTR2200063336. Research Sponsor: HUTCHMED.

4029 **Poster Session**

A multicenter randomized phase II study of trastuzumab biosimilar (CT-P6) and chemotherapy (SOX or CapeOX) in HER2-positive advanced/recurrent gastric cancer (KSCC: TROX study). First Author: Teppei Yamada, Department of Gastroenterological Surgery, Fukuoka University Faculty of Medicine, Fukuoka, Japan

Background: The efficacy and safety of the trastuzumab biosimilar (CT-P6) combined with S-1/oxaliplatin (SOX) or capecitabine/oxaliplatin (CapeOX) were investigated in patients with HER2-positive advanced or recurrent gastric cancer who had not previously received chemotherapy. CT-P6 is a biosimilar of trastuzumab, which has demonstrated comparable safety and efficacy to trastuzumab in breast cancer. However, no clinical trials have evaluated CT-P6 in gastric cancer to date. **Methods:** This randomized, open-label, multicenter phase II study enrolled patients with HER2-positive unresectable or recurrent gastric cancer. Participants were randomized to receive SOX plus trastuzumab biosimilar therapy (S-1 orally, 40–60 mg twice daily for 14 days every 3 weeks, oxaliplatin intravenously at 130 mg/m² on day 1 every 3 weeks, and CT-P6 at 8 mg/kg on day 1 and 6 mg/kg every 3 weeks thereafter) or CapeOX plus trastuzumab biosimilar therapy (replacing S-1 with capecitabine [1,000 mg/m²] as described above) until disease progression. The primary endpoint was overall response rate (ORR) in both arms, with a null hypothesis response rate set at 43%, the lower bound of the 90% confidence interval reported in previous trastuzumab trials. Secondary endpoints included progression-free survival (PFS), overall survival (OS), and safety. **Results:** Between May 2019 and November 2022, 67 patients were enrolled in the study. Patient characteristics were as follows: male/female ratio of 49/18, median age 68 years (range: 34–80), and performance status (PS) of 0/1 in 53/14 patients. The ORR was 76.1% (90% CI: 67.6–84.7%), with the lower limit of the confidence interval exceeding the threshold response rate of 43%, confirming the efficacy of trastuzumab biosimilar therapy. The one-year survival rate was 65.2% (95% CI: 49.8–78.6%), meeting the primary endpoint. The median OS was 18.7 months (90% CI: 15.1–23.1), and the median PFS was 9.0 months (90% CI: 6.5–10.7). Although the study was not designed to compare SOX and CapeOX, the response rate was slightly higher in the CapeOX group (81.3% [90% CI: 69.9–92.6%]) compared to the SOX group (71.4% [90% CI: 58.9–84.0%]). Similarly, OS was slightly better in the CapeOX group (22.3 months [90% CI: 15.1–42.1]) than in the SOX group (16.7 months [90% CI: 12.7–19.6]). The most frequent grade 3 or 4 adverse events were neutropenia (15.2%), appetite loss (12.1%), and diarrhea (7.6%). **Conclusions:** Trastuzumab biosimilar (CT-P6) combined with SOX or CapeOX demonstrated robust antitumor efficacy and manageable toxicity in patients with advanced or recurrent gastric cancer. Clinical trial information: jRCTs071190007. Research Sponsor: None.

Neoadjuvant serplulimab in combination with chemotherapy for locally advanced gastric or gastro-esophageal junction cancer. First Author: Hongjie Zhan, Tianjin Medical University Cancer Institute and Hospital, Tianjin, China

Background: Perioperative therapy combined with surgery is the standard treatment for locally advanced gastric or gastro-esophageal junction (G/GEJ) cancer; however, long-term survival remains suboptimal. Immunotherapy has demonstrated antitumor activity and an acceptable safety profile in advanced G/GEJ cancer. This study aimed to evaluate the efficacy and safety of neoadjuvant Serplulimab, a PD-1 inhibitor, in combination with chemotherapy in previously untreated, locally advanced G/GEJ cancer. **Methods:** Eligible patients with resectable G/GEJ adenocarcinoma staged as cT3-4aN+M0 were enrolled. The treatment regimen included Serplulimab (300 mg on day 1, every 3 weeks [Q3W]) plus SOX chemotherapy (oxaliplatin 130 mg/m^{2}on day 1; and S-1 60 mg twice daily on days 1-14, Q3W) for three cycles. Following the preoperative treatment, patients underwent surgery 6-8 weeks after the therapy. The primary endpoint was pathological complete response (pCR) rate. Secondary endpoints included major pathological response (MPR) rate, R0 resection rate, disease-free survival (DFS), overall survival (OS), and toxicity. **Results:** From October 13, 2023, to December 31, 2024, 25 patients were enrolled, all of whom completed neoadjuvant therapy and underwent radical surgical. The R0 resection rate was 100%. Five patients achieved pCR (pCR rate: 20%), and an additional five patients achieved MPR (MPR rate: 40%). Median DFS and OS were not reached. Safety analysis included all patients who received at least one cycle of neoadjuvant therapy. The most common treatment-related adverse events (TRAEs) of any grade included nausea, anorexia, thrombocytopenia, fatigue, and thyroid dysfunction. No grade ≥3 TRAEs were observed. **Conclusions:** Neoadjuvant Serplulimab combined with SOX chemotherapy demonstrated promising efficacy and a favorable safety profile in patients with locally advanced, resectable G/GEJ adenocarcinoma. These findings support the potential role of immune-based neoadjuvant therapy in this setting. Research Sponsor: None.

Safety, efficacy, and biomarker analysis from a phase II trial of intensive chemotherapy combined with serplulimab and trastuzumab in patients with advanced HER2-positive gastric cancer. First Author: Tianshu Liu, Zhongshan Hospital, Fudan University, Shanghai, Shanghai, China

Background: Keynote-811 has proven the efficacy of combined PD-1 and HER2 blockade with chemotherapy in HER2-positive gastric cancer. Our study aims to enhance the survival of patients by replacing standard chemotherapy with intensive chemotherapy and conducting biomarker analysis. **Methods:** This prospective, single-arm, open-label study was carried out across five centers in China, recruiting patients (pts) with unresectable locally advanced or metastatic HER2-positive gastric cancer. Pts receive Serplulimab (4.5 mg/kg, D1, Q3W), Trastuzumab (initial 8 mg/kg, D1, then 6 mg/kg, D1, Q3W), and the DOS regimen: oxaliplatin (100 mg/m^2, IV), docetaxel (40 mg/m^2, IV), and S-1 (40-60mg, BID, D1-14, Q3W). Chemotherapy is up to 8 cycles. Serplulimab and Trastuzumab can be administered until tumor progression. Gastroscopic biopsy was taken before the treatment and dynamic blood samples were collected at C1D1 (T0), C2D1 (T1) and C7D1 (T2) for biomarker analysis. Genomic DNA from tumor tissue and circulating tumor DNA (ctDNA) underwent targeted DNA sequencing containing 571 genes. **Results:** From July 2022 to September 2024, 40 pts were recruited. The median follow-up was 7.9 months. There were 10 females and 30 males, with a median age of 59 (31-74). 37 pts were eligible for efficacy assessment. The objective response rate (ORR) was 92% (95% CI: 0.87, 0.96), with a complete response rate of 3% (95% CI: 0, 0.05), and a partial response rate of 89% (95% CI: 0.84, 0.94). Median progression free survival has not been reached. 38 pts (95%) experienced adverse events (AEs) of any grade. Grade 3 or above AEs occurred in 14 pts (35%), 2 pts with grade 4 AEs (1 with thrombocytopenia and 1 with myelosuppression). No grade 5 events were observed. The most common AEs were anemia (35%), neutropenia (23%), nausea and vomiting (20%) and leukopenia (20%). 15 (38%) pts had dose interruptions due to AEs, with no treatment discontinuation. HER2 CNV gain was detected in 82.1% (23/28) of tissue samples and 74.3% (26/35) of ctDNA samples. In matched ctDNA and tissue samples (N = 26), 88.5% (23/26) showed concordant HER2 CNV gain results. Elevated tissue HER2 CNV were associated with more pronounced tumor shrinkage (R = -0.35, P = 0.073). Plasma HER2 gain detection rate decreased from 79.1% (19/24) at T0 to 16.7% (4/24) at T1 ($P < 0.001$). Similar results were observed from T0 to T2 ($P < 0.001$). **Conclusions:** This regimen demonstrated remarkable efficacy with a high ORR and manageable toxicity. Tumor HER2 CNV and ctDNA dynamic monitoring correlated with treatment efficacy. The subsequent results of biomarker analysis will be presented at the upcoming conference. Clinical trial information: NCT05311189. Research Sponsor: None.

First-line osemitamab (TST001) plus nivolumab and CAPOX for advanced G/GEJ cancer (TranStar102): Updated results of cohort G from a phase I/IIa study. First Author: Jifang Gong, Early Drug Development Center, Key Laboratory of Carcinogenesis and Translational Research (Ministry of Education), Peking University Cancer Hospital and Institute, Beijing, China

Background: Claudin 18.2 (CLDN18.2) is a clinically validated therapeutic target and has been broadly explored with different modalities in gastric/gastroesophageal (G/GEJ) cancer treatment. Osemitamab is a humanized monoclonal antibody with improved affinity to CLDN18.2, reduced fucosylation and enhanced ADCC activity and has been observed to upregulate PD-L1 expression on CLDN18.2-positive tumor cells. *In vivo* anti-tumor activity of combination of osemitamab plus an anti-PD-1/PD-L1 antibody and chemotherapies was significantly stronger than any of the doublet combinations, regardless of the PD-L1 CPS levels, making the triple combination of osemitamab, nivolumab and CAPOX an attractive combination to explore. **Methods:** Cohort G from TranStar102 (NCT04495296, a phase I/II study) was designed to evaluate the safety and preliminary efficacy of osemitamab at two dose levels (3mg/kg or 6mg/kg Q3W) plus nivolumab and CAPOX as the first-line treatment in patients with G/GEJ cancer. 40 patients were planned to be enrolled in each dose level. Key eligible criteria included HER2 negative or unknown, unresectable locally advanced or metastatic G/GEJ cancer, regardless of CLDN18.2 or PD-L1 expression and treatment naïve for advanced disease. The endpoints include safety, efficacy, PK and predictive value of the different levels of CLDN18.2 expression, etc. **Results:** As of Jan 13, 2025, 82 patients were dosed with osemitamab plus nivolumab and CAPOX (40 at 3mg/kg, 42 at 6mg/kg) with median follow-up of 21.3 months. All patients experienced treatment-related adverse events (TRAEs). The safety profile was similar with the previously presented data (2024 ESMO poster), and the most commonly observed TRAEs were on-target and off-tumor toxicities, such as nausea, vomiting and hypoalbuminemia, and were manageable. 44 out of 82 patients had confirmed partial response and the objective response rate (ORR) was 55.7%. There was a clear trend between anti-tumor efficacy and CLDN18.2 expression, with a confirmed ORR of 68% and median progression-free survival of 16.6 months (95% CI: 5.8, 21.7) for the patients with CPS known and CLDN18.2 high/medium expression (defined as CLDN18.2 membranous staining ≥2+ in ≥40% of tumor cells by immunohistochemistry in the central laboratory) (n=26). By the cut-off date, there were 33 patients in survival follow-up including 12 patients still with ongoing treatment. The median overall survival was 20.4 months (95% CI:15.0, NE) for all the 82 patients. Updated clinical data and details by biomarkers levels will be reported at the time of conference. **Conclusions:** The updated data indicate that the combination of TST001 plus nivolumab and CAPOX for the first-line treatment of patients with G/GEJ cancer is safe and well tolerated with encouraging durable PFS and survivals, especially for the patients with high/medium CLDN18.2 expression. Clinical trial information: NCT04495296. Research Sponsor: Suzhou Transcenta Therapeutics Co, Ltd.

Real-world analyses to evaluate the role of TIGIT as a target in first-line (1L) gastric, gastroesophageal junction, and esophageal adenocarcinomas (GC/GEJC/EAC). First Author: Linda Su-Feher, Gilead Sciences, Inc, Foster City, CA

Background: Anti-programmed death protein 1 (PD-1) immune checkpoint inhibitors (ICIs) are approved for GC/GEJC/EAC.T-cell immunoreceptor with Ig and ITIM domains (TIGIT) is a potential anti-tumor ICI target.Understanding how PD-L1 (*CD274*), effector T-cell (Teff), and *TIGIT* RNA expression levels correlate with real-world outcomes of 1L treatment can inform the potential for TIGIT as a target. **Methods:** Deidentified real-world data for patients (pts) with metastatic GC/GEJC/EAC were included from the Tempus AI, Inc. clinicogenomic database. Data were analyzed for pts with available longitudinal clinical data and biopsies (whole transcriptome RNA-sequencing [seq], 648 gene panel DNA-seq, and PD-L1 immunohistochemistry). Gene expression comparisons, including between *TIGIT* and a Teff gene set (geometric mean of *CD8A*, *GZMA*, *GZMB*, *IFNG*, *EOMES*, and *PRF1*), used the Wilcoxon test, Kruskal-Wallis test, and Spearman correlation. Real-world time to next treatment or death (rwTTNTD; maximum follow-up 24 months) was assessed for 1L ICI + chemotherapy (chemo) or chemo using the Kaplan-Meier method and compared by expression level (high [≥ median] vs low [< median]) of *TIGIT*, Teff gene set, and *TIGIT* normalized by Teff gene set. **Results:** Among 545 pts (1L ICI + chemo, n = 50; 1L chemo, n = 124) *TIGIT* expression was most highly correlated with Teff ($R = 0.80$, $P < 0.001$) and *FOXP3* expression ($R = 0.78$, $P < 0.001$), followed by *CD274* expression ($R = 0.57$, $P < 0.001$). Positive correlations with PD-L1 combined positive score were observed for *TIGIT* and Teff expression ($P < 0.001$ for both) but not *TIGIT* normalized to Teff levels ($P > 0.05$). Biopsies from liver metastases, which tend to show a poor response to ICIs, had lower immune signatures vs stomach tumor biopsies ($P < 0.001$). High vs low expression of *TIGIT* and Teff were associated with numerically longer rwTTNTD for ICI + chemo, with HRs (95% CI) of 0.82 (0.43–1.54) for *TIGIT* (n = 29 vs 21) and 0.78 (0.42–1.48) for Teff (n = 28 vs 22). Corresponding HRs (95% CI) for chemo were 1.04 (0.70–1.54) for *TIGIT* (n = 53 vs 71) and 1.26 (0.85–1.87) for Teff (n = 64 vs 60). When *TIGIT* expression was normalized to Teff levels, HRs (95% CI) for rwTTNTD for high vs low expression were 0.92 (0.49–1.71) for ICI + chemo (n = 23 vs 27) and 0.81 (0.54–1.20) for chemo (n = 57 vs 67). **Conclusions:** *TIGIT* expression was highly correlated with *FOXP3* and Teff gene set expression in GC/GEJC/EAC tumors. The improved rwTTNTD seen in pts with high *TIGIT* expression may be driven by these patients also having high Teff expression. When *TIGIT* is normalized to Teff, pts with high *TIGIT* expression lose this added benefit. Combining anti-TIGIT and anti–PD-1 treatments may lead to enhanced T cell activation, which could bring benefit to pts with 1L GC/GEJC/EAC. Larger studies will help confirm these findings. Research Sponsor: Gilead Sciences, Inc.

Distinct microenvironment phenotypes across tumor, vascular, and immune compartments from ramucirumab plus pembrolizumab in refractory gastric cancer: A phase II trial. First Author: Sung Hee Lim, Division of Hematology-Oncology, Department of Medicine, Sungkyunkwan University School of Medicine, Samsung Medical Center, Seoul, South Korea

Background: Combining immune checkpoint inhibitor (ICI) with vascular endothelial growth factor (VEGF)/VEGF receptor inhibition has yielded promising results in multiple tumor types. This phase II trial investigated the efficacy and molecular mechanisms of ramucirumab plus pembrolizumab in refractory gastric cancer patients. **Methods:** We conducted a prospective phase II single-arm trial of ramucirumab plus pembrolizumab as salvage treatment in patients with metastatic GC who failed to respond to standard fluoropyrimidine plus platinum with or without programmed cell death protein 1 (PD-1) inhibitors. Eligible patients had programmed death-ligand 1 (PD-L1) combined positive score more than five. The primary objective was to objective response rate (ORR) and secondary end points included disease control rate, duration of response, progression-free survival and overall survival, and toxicity. Comprehensive molecular profiling, including Digital Spatial Profiling, and mass cytometry was performed on tumor samples and peripheral blood. **Results:** Twenty-six patients were enrolled in this study between June 2021 and May 2023. No patient attained complete response (CR), while 6 patients achieved confirmed partial response (PR), resulting in a response rate (RR) of 23.1% (95% CI, 4.06–34.4). The median PFS for all patients was 2.7 months (95% CI, 1.84 - 3.56 months), and median OS was 10.9 months (95% CI, 2.31 – 18.29). Grade $\geq$ 3 treatment-related adverse events occurred in 38.5 % of patients. Digital Spatial Profiling revealed distinct tumor microenvironment (TME) phenotypes between responders and non-responders. Responders had high CTL infiltration and vascular normalization in their tumor specimen after treatment which led to favorable treatment outcome. In support of this, spatial profiling revealed the shortest median distance between immune cells and vessels, suggesting enhanced transendothelial migration of immune cells. Nonresponders had significantly upregulated TGF-β pathway and low tumor vascularity. On-treatment analysis demonstrated a shift towards increased immune cell infiltration and decreased tumor cellularity. Mass cytometry of peripheral blood revealed lower proportions of myeloid-derived suppressor cells in responders. **Conclusions:** Ramucirumab+pembrolizumab showed modest clinical efficacy, with manageable toxicity and durable responses. Although limited to a small subset of patients, a few patients who had previously responded to ICI benefited from ramucirumab+pembrolizumab. Clinical trial information: NCT0005753. GABRP as a biomarker for predicting anti-PD1 therapeutic efficacy in advanced gastric cancer (WJOG10417GTR study). First Author: Naoki Takahashi, Department of Gastroenterology, Saitama Cancer Center, Saitama, Japan

Background: GABRP, Gamma-aminobutyric acid type A receptor subunit π, is a key molecule that influences tumor properties and patient prognosis in various cancers, including gastric cancer (GC): GABRP is significantly upregulated in tumor tissues, and promotes tumor progression and metastasis via chemokine signaling and macrophage recruitment, leading to poor prognosis. Thus, GABRP seems to be a promising potential target for cancer treatment. However, it remains unclear whether the GABRP-targeting strategy can contribute to GC treatment, especially anti-PD1/PDL1 therapy, which has recently attracted great attention. **Methods:** We collected biopsy tumor tissues from 96 patients with advanced GC before and one month after nivolumab monotherapy in the WJOG10417GTR study according to the protocol (No. 2017-473) approved by the IRB, and analyzed for GABRP expression by RNA-sequencing (RNAseq) and immunohistochemical staining (IHC; only at pre-treatment). Progression-free survival (PFS) and overall survival (OS) were compared between high and low groups divided by the cutoff value determined by change point of the larger log hazard ratios (HRs) based on the method for modeling continuous-scale covariates. This study was supported by Ono Pharmaceutical and Bristol Myers Squibb. **Results:** RNAseq data revealed that high levels of GABRP gene expression in tumors at baseline were significantly associated with shorter PFS (median PFS [mPFS] 1.643 months [95% CI = 1.281 - 3.253] vs 3.170 months [1.971 - 10.251], HR = 2.798, P = 0.005) and shorter OS (median mOS [mOS] 5.092 months [3.450 - NA] vs 15.409 months [13.733 - NA], HR = 5.145, P $<$ 0.001), and the high post-treatment levels were significantly associated with shorter PFS (mPFS 1.873 months [1.511 - 3.253] vs 4.123 months [2.073 - NA], HR = 3.333, P = 0.009) and shorter OS (mOS 7.162 months [5.092 - 15.310] vs NA [13.733 - NA], HR = 4.524, P = 0.015), as compared to low levels. This was confirmed by IHC data that showed similar results, albeit only baseline data: patients with high baseline levels of GABRP protein expression in tumors had significantly shorter PFS (mPFS 1.528 months [0.986 - 1.971] vs 3.121 months [1.873 - 4.238], HR = 1.727, P = 0.016). **Conclusions:** These results suggest that GABRP expressed in tumors is a significant poor prognostic factor for nivolumab monotherapy in advanced GC. GABRP may be a promising biomarker for predicting anti-PD1/PDL1 therapeutic efficacy in advanced GC, and targeting it may contribute to improving the clinical outcomes in GC as a new therapeutic strategy. Research Sponsor: Ono Pharmaceutical and Bristol Myers Squibb.

KEYNOTE-859: 4.5-year median follow-up of pembrolizumab plus chemotherapy for previously untreated advanced HER2-negative gastric or gastroesophageal junction (G/GEJ) adenocarcinoma. First Author: Sun Young Rha, Yonsei Cancer Center, Yonsei University College of Medicine, Yonsei University Health System, Seoul, South Korea

Background: In the phase 3KEYNOTE-859 study (NCT03675737), first-linepembrolizumab (pembro) + chemotherapy (chemo) continued to provide longer OS (HR, 0.79; 95% CI, 0.71-0.88) and PFS (HR, 0.76; 95% CI, 0.68-0.85), and a higher ORR (51.0% vs 42.0%) vs placebo + chemo in participants (pts) with HER2-negative G/GEJ adenocarcinoma, after a median follow-up of 41.6 mo (August 22, 2023). We present results after an additional 13 mo of follow-up. **Methods:** Eligible pts with untreated locally advanced or metastatic HER2-negative G/GEJ adenocarcinoma with PD-L1 status, measurable disease, and ECOG PS 0 or 1 were randomly assigned 1:1 to receive pembro 200 mg or placebo IV Q3W for $\leq$35 cycles + investigator's choice of chemo (5-FU + cisplatin [FP] vs capecitabine + oxaliplatin [CAPOX]). The primary end point was OS. Secondary end points included PFS, ORR, and DOR, all per RECIST v1.1 by BICR, and safety. The data cutoff was September 27, 2024. **Results:** Median follow-up was 54.8 mo (Q1-Q3, 46.8-62.1). In all randomly assigned pts in the intention-to-treat population (N = 1579), median OS was 12.9 mo (95% CI, 11.9-14.0) for pembro + chemo vs 11.5 mo (95% CI, 10.6-12.1) for placebo + chemo (HR, 0.78; 95% CI, 0.70-0.86). In pts with PD-L1 CPS $\geq$1, median OS was 13.0 mo (95% CI, 11.6-14.2) vs 11.4 mo (95% CI, 10.5-12.0; HR, 0.74 [95% CI, 0.66-0.84]). In pts with PD-L1 CPS $\geq$10, median OS was 15.8 mo (95% CI, 14.0-19.3) vs 11.8 mo (95% CI, 10.3-12.7; HR, 0.64 [95% CI, 0.53-0.77]). PFS, ORR, and DOR were also consistent between the intention-to-treat population and pts with PD-L1 CPS $\geq$1 and PD-L1 CPS $\geq$10 (Table). Treatment-related AEs were reported in 751 pts (95.7%; grade 3-5, 466 [59.4%]) for pembro + chemo and 736 (93.5%; grade 3-5, 404 [51.3%]) for placebo + chemo. **Conclusions:** Pembro + chemo continued to show improved OS, PFS, and ORR vs placebo + chemo after a median study follow-up of 54.8 mo, regardless of PD-L1 status. The findings further support pembro + chemo as a first-line treatment option for locally advanced or metastatic HER2-negative G/GEJ adenocarcinoma. Research Sponsor: None. Clinical trial information: NCT03675737. Research Sponsor: None.

Co-expressing pattern of multiple biomakers and dynamic change of Claudin18.2 expression after systemic chemotherapy in advanced gastric cancer. First Author: Sun Young Rha, Yonsei Cancer Center, Yonsei University College of Medicine, Seoul, South Korea

Background: Gastric cancer (GC) is a heterogeneous disease classified by Lauren classification and TCGA's four molecular subtypes. Targeting Claudin (CLDN)18.2 has emerged as a promising therapy. However, a comprehensive understanding of CLDN18.2 in advanced GC, its clinicopathologic correlations, and prognostic significance remains limited. We analyzed the co-expression of multiple biomarkers and dynamic changes in CLDN18.2 following systemic chemotherapy. **Methods:** This retrospective study included 402 patients with stage IV GC at Yonsei Cancer Center (2015–2023) treated with palliative doublet chemotherapy. Paired pre- and post-treatment tissues were available for 124 patients. CLDN18.2 expression was assessed using the VENTANA CLDN18 (43-14A) RxDx Assay, with positivity defined as $\geq$75% of tumor cells. HER2, EBV, dMMR, and PD-L1(22C3) were also evaluated by immunohistochemistry. Overall survival (OS) was estimated using the Kaplan-Meier method, and a log-rank test was performed to compare survival according to CLDN18.2 positivity. **Results:** The CLDN18.2 positivity rate was 30.6%, consistent with previous reports. It was slightly higher in HER2-negative (31.5%) than HER2-positive (27.3%) (p = 0.44). CLDN18.2 positivity was significantly higher in EBV-positive than negative (63.6% vs 29.4%, p $<$ 0.05) and in pMMR versus dMMR (31.7% vs 9.5%, p $<$ 0.05). Regarding PD-L1 status, the positivity rate was higher in the PD-L1 negative compared to the positive by CPS 1(36.1% vs 25.8%, p $<$ 0.05). We observed that CLDN18.2 expression seems to be decreasing with higher PD-L1 expression (28.5 % in patients with CPS $\geq$5, 24% in CPS $\geq$10). The OS (median months, 95% CI) based on CLDN 18.2 expression was similar [22.5 (18.6-25.2) vs 23.2 (17.9-27.4) in CLDN18.2 positive group], regardless of HER2 status. Among 124 patients with paired samples, pre-treatment CLDN18.2 positivity was 22.8%, increasing to 36.5% post-treatment. The increase was more pronounced in HER2 negative (39.0%) compared to positive (29.5%). Notably, 79.9% of patients showed consistent CLDN18.2 expression between pre- and post-treatment samples, while 20.1% demonstrated changes in expression. These changes were not associated with other markers such as HER2, EBV, dMMR, or PD-L1. **Conclusions:** Higher CLDN18.2 positivity rates in specific subgroups, such as pMMR and PD-L1 negative, suggest the potential role of anti-CLDN therapy in these subgroups. This study also highlights the dynamic changes of CLDN18.2 expression in advanced gastric cancer, with an increase observed after first-line systemic treatment in a subset of patients. Further studies should focus on prospective analyses and stratify changes in CLDN18.2 expression by treatment regimen to better understand its role as a therapeutic target and its implications for treatment resistance and disease progression. Research Sponsor: None.

Camrelizumab plus albumin-bound paclitaxel and S-1 as first-line treatment of HER-2 negative unresectable locally advanced or advanced gastric and gastroesophageal junction adenocarcinoma: A phase II clinical trial. First Author: Xinfang Hou, The Affiliated Cancer Hospital of Zhengzhou University & Henan Cancer Hospital, Zhengzhou, Henan, China

Background: Gastric cancer is a common malignant tumor of the digestive tract. For nearly 90% of HER2 negative advanced gastric and gastroesophageal junction adenocarcinoma (G/GEJ) patients (pts), the current first-line treatment options and efficacy are limited, and new therapeutic drugs are urgently needed to improve the efficacy of advanced G/GEJ. **Methods:** This is a prospective, single center, single arm, open label phase II clinical trial involving HER-2 negative G/GEJ diagnosed by histopathology. Pts received 4-6 cycles of treatment with camrelizumab combined with albumin bound paclitaxel and S-1, followed by camrelizumab maintenance therapy until progression or 2 years. By following up with pts and evaluating clinical efficacy based on imaging examinations, the effectiveness and safety of the protocol can be assessed. **Results:** From December 2020 to December 2024, a total of 47 pts obtained informed consent based on exclusion criteria. As of the deadline (January 6, 2025), the average follow-up period was 17.4 months, with a median follow-up time of 16.7 months (range: 1.6-42.2 months). One patient had completed 2 years of treatment and ended maintenance therapy with camrelizumab, 5 pts (12.5%) were still receiving treatment, 34 pts (85.0%) stopped treatment, and 28 pts (70%) developed disease progression (PD). The best therapeutic effect was achieved in 2 cases with CR, 25 cases with PR, 11 cases with SD, and 2 cases with PD. The experiment reached the primary endpoint with an ORR of 67.5%. The secondary endpoint DCR was 95.0%, the median PFS was 7.8 months [95% confidence interval (CI): 6.2-9.4 months], and the median OS was 23.8 months [95% confidence interval (CI): 15.2-32.4 months]. For all study subjects, there was no correlation between OS, PFS, and baseline characteristics of the study (age, gender, ECOG, microsatellite status, mismatch repair protein status, EBER status, PDL1 level, number of metastatic sites, presence of liver metastasis, presence of lung metastasis, presence of abdominal metastasis, presence of bone metastasis). Among all enrolled pts, 36 experienced adverse events (76.6%) and 18 experienced grade 3-4 TRAE (38.3%), mainly bone marrow suppression and immune related rash. **Conclusions:** As the first-line treatment for HER-2 negative advanced gastric and gastroesophageal junction adenocarcinoma, the combination of Carilizumab with albumin bound paclitaxel and S-1 has shown encouraging efficacy. Clinical trial information: ChiCTR2300069672. Research Sponsor: None.

Efficacy and safety of LM-302 (anti-claudin 18.2 ADC) in combination with anti-PD-1 therapy for advanced gastric, gastroesophageal junction cancer and esophageal adenocarcinoma: Early-phase study results. First Author: Haiping Jiang, The First Affiliated Hospital, Zhejiang University School of Medicine, Hangzhou, China

Background: Claudin 18.2 (CLDN18.2), a tight junction protein highly expressed in gastric and gastroesophageal junction (GEJ) cancers, has emerged as a promising therapeutic target. LM-302 (tecotabart vedotin), a novel and potent MMAE-based ADC targeting CLDN18.2, has shown promising efficacy and safety as monotherapy in heavily pretreated advanced gastric cancer. This pooled analysis evaluates the efficacy and safety of LM-302 in combination with the anti-PD-1 antibody toripalimab as a first-line treatment option for patients with gastric, GEJ, or esophageal adenocarcinoma (EAC). **Methods:** Eligible patients with histologically confirmed, previously untreated, unresectable, HER2-negative gastric, GEJ, or EAC were included. Patients received LM-302 (1.6 mg/kg Q3W, 2.0 mg/kg Q3W or 1.8 mg/kg Q2W) and toripalimab (240 mg Q3W or 3 mg/kg Q2W). Endpoints included safety, objective response rate (ORR), disease control rate (DCR), progression-free survival (PFS), OS, and biomarker analysis. Data cutoff: January 7, 2025. **Results:** A total of 43 gastric, GEJ, or EAC patients (median age: 62.3 years; 65.1% male) from Australia and China were treated. No dose-limiting toxicities (DLT) were observed across all these dose levels. Treatment-related adverse events (TRAEs) related to LM-302 were reported in 39 patients (90.7%), with common events ($\geq$20%) including anemia, decreased white blood cell count, decreased neutrophil count, increased aspartate transaminase (AST), vomiting, loss of appetite, and nausea. Grade $\geq$3 TRAEs related to LM-302 occurred in 16 patients (37.2%), the most common events ($\geq$5%) were decreased neutrophil count (14.0%), increased alanine transaminase (11.6%), increased AST (9.3%), and anemia (7.0%). Among 41 efficacy-evaluable patients (median follow-up: 6.01 months), ORR was 65.9% (95% CI: 49.4-79.9%), and DCR was 85.4% (95% CI: 70.8- 94.4%). In 32 GC patients with CLDN18.2 expression in $\geq$25% of tumor cells (IHC 2+/3+), ORR was 71.9% (95% CI: 53.3-86.3%) and DCR was 96.9% (95% CI: 83.8-99.9%). Among these patients, ORR was 63.3% (95% CI: 35.1-87.2%) for patients with PD-L1 CPS $<$ 1 and 77.8% (95% CI: 52.4-93.6%) for patients with PD-L1 CPS $\geq$1. Median PFS and OS were not reached; one patient with PD-L1 CPS $<$ 1 achieved PR and remained on treatment for 14.70 months. **Conclusions:** LM-302 combined with toripalimab demonstrated encouraging anti-tumor activity and manageable safety as first-line treatment for patients with CLDN18.2-positive gastric, GEJ, and EAC, including those with low-to-moderate CLDN18.2 expression. These findings support further large-scale clinical trials to confirm efficacy, safety and clinical utility. Clinical trial information: NCT05188664; NCT05934331. Research Sponsor: LaNova Medicines Limited.

Efficacy and safety results of a multi-center phase II study of utidelone injection in combination with PD-1 inhibitor and chemotherapy for the first-line treatment of advanced gastric and esophagus cancers. First Author: Meili Sun, Department of Oncology, Shandong University First Medical University Affiliated Central Hospital, Jinan, Shandong, China

Background: Utidelone is a novel microtubule inhibitor that offers several advantages including improved efficacy and safety, broader anti-cancer spectrum, blood-brain barrier penetrance, and response against multidrug-resistant tumors. Utidelone injection (UTD1) has been approved for advanced breast cancer in China. Previous studies have shown that utidelone monotherapy is effective for advanced gastric and gastroesophageal junction adenocarcinoma (GC) and esophageal squamous cell carcinoma (ESCC). This phase II study further explored the efficacy and safety of utidelone in combination with PD-1 inhibitor and chemotherapy for the 1st line treatment of advanced GC and ESCC. **Methods:** Eligible patients were recruited into the two cohorts of metastatic and/or unresectable HER2 negative GC or ESCC, receiving utidelone (30mg/m^2/day iv on days 1–5 every 21-day) plus sintilimab (200 mg iv Q3W) and oxaliplatin (130 mg/m^2/day Q3W for up to 6 cycles), or utidelone (30mg/m^2/day iv on days 1–5 every 21-day) plus tislelizumab (200 mg iv Q3W) and capecitabine (2000mg/m^2/day po on days 1–14 every 21-day), respectively, until disease progression or unacceptable toxicity. The primary endpoint is ORR and second endpoints are CBR, PFS and safety. **Results:** The enrolment has been completed for both cohorts from April 2023 to October 2024. There were 27 eligible patients enrolled in the GC cohort with median age of 60 years (range 34-70), 6 females and 21 males. 23 patients were evaluable for efficacy with an outcome of 11 confirmed PRs and 12 SDs including 4 unconfirmed PR, and 5 patients were still receiving treatment (1-23 cycles). The confirmed ORR was 47.8% and CBR was 100%. The mPFS was $>$ 5.3 months. The most common $\geq$Grade 3 TEAEs included diarrhea (25.93%), neutropenia (14.81%), vomiting (14.81%), peripheral sensory neuropathy (11.11%), anemia (11.11%) and leukopenia (11.11%). Other AEs were all Grade 1 or 2, with no treatment-related deaths. There were 20 eligible patients enrolled in the ESCC cohort with median age of 61.5 years (range 47-70), 5 females and 15 males. 18 patients were evaluable for efficacy with an outcome of 6 confirmed PRs and 12 SDs, and 6 patients were still receiving treatments (1-12 cycles). The confirmed ORR was 33.3% and CBR was 100%. TEAEs $\geq$Grade 3 occurred in 8 patients including hypokalemia, lymphopenia/leukopenia, peripheral sensory neuropathy, hiccup, rash, pain, hypotension and anemia with one occurrence for each (5.5%). Other AEs were all Grade 1 or 2, with no treatment-related deaths. **Conclusions:** Utidelone plus PD-1 inhibitor and chemotherapy demonstrated promising efficacy and acceptable safety as first-line treatment for advanced GC and ESCC. There are 11 patients still on the study receiving continuous treatment. The final data will be provided at the time of presentation. Clinical trial information: NCT04911907. Research Sponsor: Beijing Biostar Pharmaceuticals Co., Ltd.

4042 **Poster Session**

Fruquintinib in combination with camrelizumab and paclitaxel liposome and nedaplatin as first-line treatment for advanced esophageal squamous cell carcinoma (ESCC): A single-arm, phase II study. First Author: Yanhong Gu, The First Affiliated Hospital of Nanjing Medical University, Nanjing, China

Background: Previous studies have indicated a synergistic effect of fruquintinib in combination with chemotherapy or immunotherapy. Therefore, we conducted a phase II study to evaluate the efficacy and safety of fruquintinib plus camrelizumab, paclitaxel liposome, and nedaplatin as a first-line treatment for advanced esophageal squamous cell carcinoma (ESCC). **Methods:** This study consisted of a dose-finding and a dose-expansion phase. A total of 33 to 36 eligible patients with untreated advanced ESCC were planned for enrollment. In the dose-finding phase, based on a standard 3+3 design, patients were treated with fruquintinib (3 mg, 4 mg, 5 mg, days 1-14, every 3 weeks, respectively, the initial fruquintinib dose was 4mg), in combination with a fixed dose of camrelizumab 200 mg, paclitaxel liposome 135 mg/m^2, and nedaplatin 70 mg/m^2 on day 1, every 3 weeks. In the dose-expansion phase, patients received camrelizumab, paclitaxel liposome, nedaplatin and recommended phase 2 dose (RP2D) of fruquintinib. A maximum of six cycles was administered, followed by maintenance therapy with fruquintinib in combination with camrelizumab. The primary endpoint was objective response rate (ORR). Secondary endpoints included disease control rate (DCR), progression-free survival (PFS), and safety. **Results:** As of December 28, 2024, 22 patients (20 males) were enrolled with a median age of 65 years (range 50-76). Among the 21 patients with metastases, 19.0% (4/21) had a single metastatic site and 81.0% (17/21) had multiple metastatic sites. In the dose-finding phase, no DLTs occurred in 3 patients at 4 mg and 6 patients at 5 mg, establishing fruquintinib's RP2D as 5 mg. Of the 19 patients evaluable for efficacy, 13 achieved a partial response, and 6 had stable disease. The confirmed ORR was 68.4% (95% CI: 47.5%-89.3%) for all evaluable patients and 68.8% (95%CI: 41.3%-89.0%) for patients receiving 5 mg dose of fruquintinib. The confirmed DCR was 100.0% (95%CI: 82.4%-100.0%). At a median follow-up of 5.1 (95% CI: 4.2-7.2) months, the median PFS was 8.7 (95%CI: 5.2-not available [NA]) months, the 6-month PFS rate reached 81.7%. The most common treatment-related adverse events (TRAEs) were anemia 72.7% (16/22), neutropenia 40.9% (9/22), leukopenia, hypertension 31.8% (7/22). Grade$\geq$3 TRAEs were identified in seven patients, including neutropenia 13.6% (3/22), leukopenia 13.6% (3/22), oral mucositis 9.1% (2/22), nausea 4.5% (1/22), vomiting 4.5% (1/22), headache 4.5% (1/22), and anemia 4.5% (1/22). No treatment-related serious adverse events (TRSAEs) or deaths occurred. **Conclusions:** The combination of fruquintinib, camrelizumab, paclitaxel liposome, and nedaplatin demonstrated significant efficacy and manageable toxicity profile as a first-line treatment for advanced ESCC, suggesting a potential new treatment strategy. Clinical trial information: NCT06010212. Research Sponsor: None.

4043 Poster Session

Immune checkpoint inhibition in EBV-associated gastric cancer: A multicenter international retrospective analysis. First Author: Darren Cowzer, Memorial Sloan Kettering Cancer Center, New York, NY

Background: Epstein-Barr virus associated gastric cancer (EBVaGC) is found in ~9% of GC and is associated with a unique immunophenotype. Prior studies suggest 15-100% objective response rates (ORR) to immune checkpoint inhibition (ICI), but survival outcomes are limited by small cohort size. This study sought to clarify outcomes of ICI in EBVaGC across 9 global tertiary cancer centers, evaluate if next-generation sequencing (NGS) can replace EBER ISH as the gold standard for detection, and identify molecular features of ICI-responsive EBVaGC. **Methods:** Retrospective data were collected on patients (pts) with metastatic EBVaGC and stratified into patients receiving ICI alone or with chemotherapy, and by 1L vs. 2L+. Progression-free survival (PFS) and overall survival (OS) were analysed using the Kaplan-Meier method and were calculated from the start of treatment to the date of progression or death for PFS, and last follow up or death for OS. Cox regression model stratified by regions was used to examine factors associated with PFS. EBV viral reads were detected by NGS using independent cohorts by MSK-IMPACT and Caris Life Sciences and concordance with EBER ISH was evaluated in each cohort. Additional phenotypic classification was performed using clinicogenomic data from the Caris Precision Oncology Alliance. **Results:** A total of 91 pts who received ICI in the metastatic setting were included. Median age was 62 years (range 30-86) and 91% were male with pts from US (n = 15), Europe (n = 5), and Asia (n = 71). ECOG PS at the time of ICI was $\leq$1 in 97%. PD-L1 CPS score was $\geq$5 in 69%. Pts who received first-line chemotherapy + ICI (n = 42) achieved a 49% investigator-assessed ORR (CR/PR), median PFS (mPFS) 8.3 months (mo), and median OS (mOS) 38 mo compared with mOS 18 mo in pts receiving first-line chemotherapy alone (n = 35). Pts who received ICI-alone achieved a similar 49% ORR with 1L and later line mPFS 6 mo and 3.2 mo, respectively, which increase to 10.0 mo and 6.6 mo, when limiting to PD-L1 CPS $>$5. Univariate analysis for PFS among all pts demonstrated improved outcomes in those where PD-L1 CPS score was $\geq$5 (HR = 0.57, 95%CI:0.34,0.97). EBV detection by MSK-IMPACT and Caris achieved over 98% positive agreement and 99.9% negative agreement. Additional EBVaGC transcriptomic immune phenotyping data will be presented. **Conclusions:** This global EBVaGC experience demonstrated that EBVaGC can reliably be identified from NGS, negating the need for costly EBER ISH. Furthermore, pts with EBVaGC achieve a high ORR on ICI with or without concurrent chemotherapy. While 1L PFS was similar to non-EBVaGC, prolonged mOS was achieved, potentially reflecting frequent conversion surgeries and regional differences. Even among EBVaGC, immune heterogeneity exists, and PD-L1 CPS $>$5 identified pts who derived ICI benefit. Further research is needed to examine the patterns of disease progression in EBVaGC treated with ICI. Research Sponsor: None.

4044 Poster Session

Second-line ASKB589 plus chemotherapy for advanced gastric or gastroesophageal cancers: Results from cohort 5 of a phase I/II study. First Author: Miao Zhang, Department of Gastrointestinal Oncology, Beijing Cancer Hospital, Beijing, China

Background: ASKB589 is a humanized monoclonal antibody with enhanced affinity for CLDN18.2 and increased ADCC activity. It has shown favorable safety profiles and promising antitumor effects in phase I/II clinical study (NCT04632108) involving first-line patient(pt)s with advanced gastric or gastroesophageal (G/GEJ) cancers. Here, we present the findings from cohort 5 that ASKB589 in combination with chemotherapy as second-line treatment for patients with advanced G/GEJ cancers. **Methods:** Cohort 5 from NCT04632108 is designed to evaluate the safety and preliminary efficacy of ASKB589 (at 2 doses: 6mg/kg or 10mg/kg Q3W) plus chemotherapy as second line treatment in pts with G/GEJ cancers. Eligible pts who had confirmed progressive disease during treatment with first line standard of therapy were enrolled. CLDN18.2 statuses were analyzed retrospectively using IHC DS-3 LDT assay. Primary endpoint was safety. Secondary endpoints included objective response rate (ORR), disease control rate (DCR), duration of response (DoR), progression free survival (PFS) assessed by investigator per RECIST v1.1 and overall Survival (OS). **Results:** As of December 20, 2024, 47 pts were enrolled in the 2L cohort and received 6mg/kg ASKB589 plus chemotherapy. Among them, 44 pts were treated with 6mg/kg ASKB589 plus paclitaxel, while 2 pts received 6mg/kg ASKB589 plus docetaxel, and 1 pt received 6mg/kg ASKB589 plus irinotecan. 17 (27%) pts had received immunotherapy previously.The confirmed ORR was 34.2% in 38 measurable and evaluable CLDN18.2 moderate to high GC/GEJ pts (CLDN18.2 moderate to high was defined as $\geq$40% of tumor cells with $\geq$2+ intensity by immunohistochemistry). 14 pts (36.8%) had stable disease, and the DCR was 71.1%. For the ASKB589 plus paclitaxel subgroup (n = 35, with evaluable response), the confirmed ORR was 31.1%, DCR was 71.4%. In the intention-to-treat analysis, the median PFS with 6mg/kg ASKB589 plus chemotherapy was 5.26 months (95%CI: 2.66, 7.06), and the median OS was 11.14 months (95%CI: 8.80, 18.20). In the ASKB589 plus paclitaxel subgroup, the median PFS was 4.63 months (95%CI: 2.04, 7.06) and median OS of 13.73 months (95%CI: 8.80, 18.20) respectively. Treatment related adverse events (TRAEs) occurred in all pts including 26 (55.3%) pts with grade $\geq$3 TRAEs. The most common grade $\geq$3 TRAEs ($\geq$5%) were neutrophil count decreased (42.6%), white blood cell count decreased (17%), lymphocyte count decreased (8.5%), and hypoalbuminemia (8.5%). **Conclusions:** The results of cohort 5 from NCT04632108 have shown that ASKB589 plus chemotherapy, as 2L treatment in pts with advanced GC/GEJ cancers have promising antitumor activity and response durability, especially in the ASKB589 plus paclitaxel subgroups. Both treatment regimens are well tolerated. Further development of ASKB589 combination therapy for CLDN18.2-positive GC/GEJ pts 2nd line treatment is planned. Clinical trial information: NCT04632108. Research Sponsor: None.

Efficacy of venadaparib plus irinotecan in homologous recombination deficiency (HRD) gene mutations as 3+ line treatment in patients with metastatic gastric cancer (mGC). First Author: Won Sik Lee, Idience Co., Ltd., Seoul, South Korea

Background: Tumors with homologous recombination deficiency (HRD) have been suggested to be associated with a favorable response to poly (adenosine diphosphate [ADP]–ribose) polymerase (PARP) inhibitors. The aim of this analysis was to evaluate the association between the presence of HRD gene mutations and the efficacy of venadaparib, a novel PARP inhibitor, plus irinotecan in patients with metastatic gastric cancer (mGC) who had progressed after at least at least 2 lines of therapy. **Methods:** This was an exploratory analysis from a multi-national, phase 1b/IIa trial of venadaparib plus irinotecan in patients with mGC (NCT04725994). Tumor response was evaluated according to RECIST v. 1.1. Genomic analysis was conducted using ctDNA (GuardantOMNI Gene Panel version 1.0, Redwood City, CA) on Day 1 pre-dose. Results of the exploratory genomic analysis, which includes pathogenic or deleterious mutations of following genes: *BRCA1/2, ATM, ATR, CHEK2, BARD1* were analyzed for association with efficacy outcomes. **Results:** As of Dec 2024, 43 patients enrolled and objective response (ORR), median progression-free survival (mPFS) and median overall survival (mOS) were 20.9%, 4.2 (2.9-9.6) and 8.1 (6.8-11.5) months. 14 (32.6%) out of the 43 patients had at least one HRD mutation (6 with *ATM*, 3 with *BRCA1*, 2 with *BRCA2*, 1 with *BARD1*, 1 with *CHEK2* and 1 with *ATR* mutations, respectively). For the 14 patients with HRD mutation and 29 patients with no HRD mutation, the ORR, mPFS (95% CI) and mOS (95% CI) were 35.7% vs. 13.8%, 5.6 (1.3-9.1) vs. 4.0 (2.7-5.4) months and 10.1 (6.8-12.0) vs. 8.0 (5.9-11.5) months respectively. For 11 patients with *ATM* or *BRCA1/2* mutation, mPFS (95% CI) and mOS (95% CI) were 8.4 (1.2-24.0) and 10.1 (6.8-34.4) months. At the maximum tolerable dose (MTD) level of venadaparib 20 mg/d on days 1 to 7 and irinotecan 100 mg/m^2 at day 1 of a 2-week cycle, six of 15 patients had HRD mutation, and mPFS (95% CI) and mOS (95% CI) were 4.1 (2.9-5.4) and 7.9 (5.9-11.5) months; these data are still maturing. **Conclusions:** Venadaparib in combination with irinotecan demonstrated promising efficacy in patients with mGC, particularly those with HRD gene mutations. Further development of this combination may warrant a biomarker-based approach. Clinical trial information: NCT04725994. Research Sponsor: Idience Co., Ltd.

Efficacy results in patients with homologous recombination deficiency mutation.

Updated results of fruquintinib combined with PD-1 inhibitors and chemotherapy in the first-line treatment of HER2-negative advanced gastric or gastroesophageal junction adenocarcinoma (FDZL-FIX): A single-arm, open-label phase 2 study. First Author: Chenchen Wang, Department of Medical Oncology, Fudan University Shanghai Cancer Center, Shanghai, China

Background: For unresectable locally advanced or metastatic HER2-negative gastric cancer (GC), the combination of chemotherapy with immunotherapy, specifically PD-1 inhibitors, has emerged as a new standard of care in first-line treatment of advanced GC, but the patients' outcomes remain poor. Fruquintinib (Fru) is a highly selective inhibitor of VEGFR1/2/3. We sought to explore the efficacy and safety of fruquintinib combined with PD-1 inhibitors and chemotherapy in the first-line treatment of HER2-negative advanced gastric or gastroesophageal junction adenocarcinoma. Here, we report the updated results. **Methods:** Eligible pts with HER2 negative locally advanced unresectable or metastatic gastric or gastrooesophageal junction adenocarcinoma, without any systemic anticancer treatment for advanced disease were included in the study. pts received 6 cycles of combined first line treatment with Fru (4mg p.o. qd, d1-14, q3w,) combined with PD-1 inhibitor (investigator's choice of sintilimab 200mg or nivolumab 360mg intravenously q3w) and chemotherapy (investigator's choice of XELOX or SOX) regimen. The following maintenance treatment was Fru combined with PD-1 inhibitor and S-1/capecitabine until disease progression or intolerable toxicity. The primary endpoint was progression-free survival (PFS). Secondary endpoints included objective response rate (ORR), overall survival (OS), disease control rate (DCR) and safety. **Results:** As of Jan 24, 2025, a total of 33 pts (22 male, 11 female) median age 62 (range: 35-77) were enrolled and received at least one dose of treatment. 30 patients had at least one tumor assessment post treatment, with an ORR of 80.0% (24/30; 95%CI 61.4-92.3) and DCR of 100%(30/30; 95%CI 88.4-100.0). In the intention to treatment (ITT) population, the median PFS was 9.43 months (95% CI 5.29-13.24) and the 9-month PFS rates was 57% (95%CI 40.0-83.0). The most common AEs of all grades were neutrophil count decreased (33.3%), palmar-plantar erythrodysesthesia syndrome (33.3%), and fatigue (30.3%). **Conclusions:** The combination of fruquintinib and chemotherapy with PD-1 blockade in the first-line treatment for unresectable locally advanced or metastatic HER2-negative GC had shown promising efficacy and acceptable safety profile. The results warrant further investigations in a large cohort. Clinical trial information: NCT06158919. Research Sponsor: None.

Artificial intelligence-based prediction of claudin 18.2 expression and immune phenotype to guide treatment decisions in patients with gastric cancer. First Author: Hyung-Don Kim, Asan Medical Center, Seoul, South Korea

Background: With the increasing availability of immune checkpoint inhibitor (ICI)- and targeted agent-based treatments for gastric cancer, evaluating predictive biomarkers to guide first-line treatment has become increasingly complex. Claudin 18.2 (CLDN18.2) is a clinically relevant target for zolbetuximab-based chemotherapy, typically assessed by immunohistochemistry. However, limitations such as inadequate tumor specimens, high costs, and long turnaround times pose a practical challenge. **Methods:** An artificial intelligence (AI) model was developed to predict CLDN18.2 expression based on hematoxylin and eosin (H&E) slides from 459 patients with gastric cancer (derivation cohort). CLDN18.2 positivity was defined as moderate-to-strong expression in ≥75% of tumor cells. The AI model utilized a Vision Transformer-based architecture with a multiple-instance learning framework and was trained using five-fold cross-validation. Model performance was validated in two independent cohorts: an internal cohort of 381 patients treated with first-line ICI plus chemotherapy (ICI-Chemo) or chemotherapy alone (Chemo-only) and an external cohort of 100 patients from diverse ethnic backgrounds. Immune phenotypes (IPs) were assessed using an AI-powered whole slide image analyzer to further stratify patient outcomes. **Results:** The prevalence of CLDN18.2 positivity was 43.4% (derivation), 37.3% (internal validation), and 26.0% (external validation). The model achieved an AUROC of 0.753 in the derivation cohort, with sensitivity and specificity of 0.638 and 0.723, respectively. In the internal and external validation cohorts, AUROCs were 0.752 and 0.746, with similar sensitivity and specificity levels. Among the internal validation cohort, patients were stratified into subgroups based on predicted CLDN18.2 positivity and IP status. Among these, the subgroup predicted to be CLDN18.2-negative and inflamed IP demonstrated the most significant benefit from ICI-Chemo compared to the Chemo-only group. **Conclusions:** The AI model reliably predicted CLDN18.2 expression from H&E slides and exhibited reliable performance. The differential survival outcomes observed in subgroups stratified by AI-predicted CLDN18.2 expression and IP suggest its potential utility in guiding first-line treatment decisions for gastric cancer patients. Research Sponsor: Lunit.

Hazard ratio (HR) for progression-free survival (PFS) and overall survival (OS).

Groups	HR for PFS (95% CI)	HR for OS (95% CI)
CLND18.2-negative and inflamed IP	0.37 (0.17–0.78, p=0.009)	0.41 (0.19–0.88, p=0.021)
CLDN18.2-negative and non-inflamed IP	0.75 (0.54–1.05, p=0.095)	0.81 (0.59–1.13, p=0.224)
CLDN18.2-positive and inflamed IP	0.67 (0.40–1.12, p=0.128)	0.62 (0.37–1.04, p=0.073)
CLDN18.2-positive and non-inflamed IP	1.60 (0.74–3.46, p=0.229)	1.23 (0.59–2.58, p=0.579)

Predictive value of homologous recombination-related gene mutations in survival outcomes of first-line nivolumab plus chemotherapy for gastric cancer. First Author: Yuna Lee, Department of Oncology, Asan Medical Center, University of Ulsan College of Medicine, Seoul, South Korea

Background: Homologous recombination repair (HRR) gene mutations are associated with genomic instability; however, their clinical value in the context of immune checkpoint inhibitor (ICI)-based treatments in gastric cancer remains unclear. We investigated the efficacy of nivolumab plus chemotherapy according to the HRR mutation status in advanced gastric cancer patients. **Methods:** This single-center study included gastric cancer patients with available panel sequencing results who were treated with first-line nivolumab plus chemotherapy (n = 115) or chemotherapy alone (n = 172) between July 2021 and March 2024. Mutation status of 17 HRR genes (*BARD1, BLM, BRCA1, BRCA2, BRIP1, MRE11A, NBN, PALB2, PARP1, POLD1, RAD50, RAD51, RAD51C, RAD51D, RAD52, RAD54L,* and *XRCC2*) was assessed using targeted next-generation sequencing. Treatment outcomes were compared according to the presence of HRR mutations. **Results:** Among patients treated with nivolumab plus chemotherapy, 36.5% harbored HRR mutations. Compared to the no HRR mutation group, the HRR mutation group exhibited a higher objective response rate (92% vs. 63.2%, P = 0.010), longer progression-free survival (PFS) (median 12.8 vs. 6.5 months; hazard ratio [HR] 0.57, 95% confidence interval [CI] 0.36–0.91, P = 0.019) and overall survival (OS) (median not reached vs. 14.2 months; HR 0.40, 95% CI 0.23–0.71, P = 0.002). Among patients with HRR mutation, those treated with nivolumab plus chemotherapy showed favorable survival outcomes compared to those treated with chemotherapy alone (PFS: HR 0.44, 95% CI 0.27–0.71, P < 0.001; OS: HR 0.45, 95% CI 0.25–0.80, P = 0.007), but this was not the case for patients without HRR mutation (PFS: HR 0.79, 95% CI 0.56–1.10, P = 0.156; OS: HR 0.90, 95% CI 0.63–1.28, P = 0.554). **Conclusions:** The presence of HRR mutations was associated with favorable survival outcomes in patients treated with nivolumab plus chemotherapy. Our findings suggest that HRR mutations may serve as a potential predictive biomarker for first-line ICI-based chemotherapy in gastric cancer. Research Sponsor: None.

Clinical outcomes of first-line immune checkpoint inhibitors with chemotherapy in advanced EBV-associated gastric cancer. First Author: Dongwoo Cho, Division of Medical Oncology, Department of Internal Medicine, Seoul St. Mary's Hospital, College of Medicine, The Catholic University of Korea, Seoul, South Korea

Background: EBV-associated gastric cancer (EBVaGC) is a distinct subgroup of GC with high PD-L1/PD-L2 expression and immune cell infiltration. While several rationales support the potential efficacy of immune checkpoint inhibitors (ICIs) in EBVaGC, clinical evidence from large-scale trials is limited, and their effectiveness remains inconclusive. This retrospective study evaluated the clinical outcomes of palliative first-line chemotherapy with or without the addition of ICIs in patients with EBVaGC. **Methods:** We identified 217 patients diagnosed with EBVaGC via in situ hybridization and evaluated their baseline characteristics, including HER2 expression, MSI status, and PD-L1 expression. Among these, 83 patients with metastatic disease received palliative first-line treatment. Of the 77 HER2-negative patients, 23 were treated with ICIs (nivolumab or pembrolizumab) combined with cytotoxic chemotherapy (ICI+chemo), while 54 received chemotherapy alone. Survival outcomes and response rates were compared between ICI+chemo and chemotherapy-alone groups. **Results:** Among 217 EBVaGC patients, 8.5% were HER2-positive, 2.6% were MSI-High, and PD-L1 CPS ≥10 and ≥5 was observed in 59.1% and 84.1%, respectively. In HER2-negative EBVaGC patients, ICI+chemo showed significantly prolonged progression free survival (PFS) compared to chemotherapy alone (median: 9.28 vs. 6.07 months; HR = 0.48; p = 0.031). There was no significant difference in overall survival (OS) (median: 20.72 vs. 18.89 months; HR = 0.78; p = 0.508). The objective response rate (ORR) and disease control rate (DCR) were significantly higher in the ICI+chemo group than in the chemotherapy-alone group (ORR, 78.3% vs. 51.9%; OR = 3.29; p = 0.042; DCR, 100% vs. 79.6%; p = 0.028). In the ICI+chemo group, PD-L1 expression (cutoff: CPS 5 or 10) was not significantly associated with survival outcomes or response rates. For CPS ≥5, the median PFS was 7.84 months compared to 8.99 months in the CPS < 5 group (p = 0.944), the median OS was 20.75 vs. 16.51 months (p = 0.131), and the ORR was 76.5% vs. 75.0%. For CPS ≥10, the median PFS was 13.9 months compared to 8.69 months in CPS < 10 group (p = 0.580), the median OS was 24.95 months vs. 20.33 months (p = 0.061), and the ORR was 81.8% vs. 70.0%. **Conclusions:** To our knowledge, this study represents one of the largest cohorts including patients with EBVaGC who received first-line ICI+chemo. The addition of ICIs to chemotherapy showed clinical benefit, including survival and response rates, compared to chemotherapy alone in EBVaGC. Interestingly, the clinical benefit of ICI+chemo was observed in PD-L1 low group as well as PD-L1 high group. Our results highlight the clinical potential of ICI addition to chemotherapy in EBVaGC, and PD-L1 expression alone is insufficient as a predictive biomarker, warranting further exploration of alternative predictors for immunotherapy efficacy in this subgroup. Research Sponsor: None.

Phase II trial of transarterial chemoembolization followed by sintilimab (anti-PD-1), oxaliplatin, and S-1 combined with either trastuzumab (HER-2 positive) or apatinib (HER-2 negative) as first-line therapy for gastric cancer with liver metastases. First Author: Wei Song, Department of Minimally Invasive Treatment of Cancer, Shandong Provincial Hospital Affiliated to Shandong First Medical University, Jinan, China

Background: Liver metastases contribute to immunotherapeutic resistance and unfavorable outcomes. Transarterial chemoembolization (TACE) may alter the immune microenvironment and enhance immunotherapy efficacy. In this trial, we assessed the efficacy and safety of TACE followed by sintilimab (anti-PD-1), oxaliplatin and S-1 combined with either trastuzumab (HER-2 positive) or apatinib (HER-2 negative) in the treatment of gastric cancer with liver metastases (GCLM). Additionally, we explored gene mutations and the immune microenvironment between gastric cancer and its paired liver metastases. **Methods:** This single-center, single-arm, phase II trial enrolled 31 treatment-naive patients with GCLM. Patients received TACE for liver metastases, followed by sintilimab (200mg), oxaliplatin (130mg/m^2) and S-1 (40-60 mg bid for 14 days) every 3weeks combined with either trastuzumab (HER-2 positive, 8 mg/kg then 6 mg/kg, q3w) or apatinib (HER-2 negative, 250mg qd) until disease progression or intolerable toxicities. Tissue samples from gastric cancer and liver metastases were collected before treatment for DNA and RNA detection. The primary endpoints were PFS and ORR. The secondary endpoints were DCR, OS, and safety. **Results:** A total of 31 patients were enrolled, median 63 (41-76) years old, 27 male, 26 multiple liver metastases and all adenocarcinoma. Of them, 10 (32.3%) were HER2 IHC 3+, 7 (22.6%) HER2 IHC 2+/FISH+. Patients with PD-L1 CPS≥5, < 1 accounted for 19.4%, 51.6% respectively. With the median follow-up time of 396 days, the patients received a median of 6 treatment cycles. As of January 25, 2025, 27 patients were included in the efficacy and safety analyses. The ORR was 74.1%, with 5 CR, 15 PR, 3 SD, and 4 PD. DCR was 85.2%. The median PFS was 12 months, and the median OS was not reached. One- and two-year PFS rates were 51.6 and 27.1 %, respectively. One- and two-year OS rates were 89.1 and 74.0 %, respectively. Grade 3/4 treatment-related adverse events occurred in 18.5% of the patients, notably neutropenia, neurotoxicity and thyroid and liver dysfunctions. Forty-four unique mutated genes were identified in gastric cancer, which were involved in PI3K-Akt and drug resistance pathways. In its paired liver metastases, 59 specific mutated genes associated with *MMR* and cell cycle were identified. Liver metastases had more macrophages and CD8+ T cells, whereas NK and CD4+ memory resting cells were fewer than those in paired gastric cancer. **Conclusions:** TACE followed by sintilimab, oxaliplatin and S-1 combined with either trastuzumab or apatinib demonstrated promising efficacy and manageable safety as first-line therapy for GCLM. Gastric cancer and its paired liver metastases exhibited distinct gene mutations and immune microenvironment. Clinical trial information: ChiCTR2200057726. Research Sponsor: None.

Improving evidence-based treatment selection and patient-centered care in upper GI cancers: A Project ECHO initiative. First Author: Elena Elimova, Princess Margaret Cancer Centre, Toronto, ON, Canada

Background: Accurate assessment of biomarkers (including HER2 and PD-L1) is integral to treatment selection in upper gastrointestinal (GI) cancers. However, challenges in integrating biomarker testing and targeted therapies are commonly reported in community settings. The Project Extension for Community Healthcare Outcomes (Project ECHO) model addresses this gap by connecting experts in tertiary care settings with rural healthcare teams. Through case-based teaching, the model builds the knowledge and skills needed to provide evidence-based, equitable care regardless of geographic location. **Methods:** In October 2024, 57 healthcare professionals (HCPs) from 2 US and 4 Canadian community oncology clinics participated in Project ECHO sessions. Led by an expert oncologist, each session featured interactive discussions of real-world anonymized case presentations to address key practice gaps in integrating biomarker-based therapies and coordinating multidisciplinary care for patients (pts) with upper GI cancers. Following each session, HCPs developed and implemented site-specific action plans to address gaps in care. Pre-activity and post-activity surveys measured the impact on knowledge, confidence, and competence and 90-day follow-up surveys will be collected to assess ongoing performance. **Results:** The top HCP-reported barriers to individualized care for pts with upper GI cancer included *keeping up with the latest efficacy and safety data* (44%), *selecting and sequencing treatments based on individual and disease factors* (40%), and *limited availability/cost of biomarker* testing (39%). Additionally, relatively few HCPs reported providing supportive care services for the majority of their patients, such as *palliative care referrals* (40%), *distress screening* (26%), *psychosocial support* (35%), and *end of life counseling* (19%). Following the Project ECHO sessions, HCPs demonstrated improved knowledge, competence, and confidence in biomarker testing and managing adverse events. Additionally, HCPs planned to *increase patient education about disease and treatment-related side effects* (65%), *improve team education on biomarker testing and treatment selection* (61%), *establish standardized biomarker testing protocols (35%),* and *increase supportive care referrals (22%).* Team action plans included implementing routine testing protocols, establishing a network of specialists to coordinate care, and increasing education on the use of immunotherapy. **Conclusions:** Project ECHO-based education improved HCP capacity to integrate biomarker-directed therapies and coordinate multidisciplinary care for patients with upper GI cancers. Full findings will detail long-term impacts on practice and inform future community-based ECHO initiatives. Research Sponsor: Bristol Myers Squibb.

Comparison of postoperative adjuvant therapy and surgery alone in pathological N1-2 esophageal squamous cell carcinoma: A prospective multicenter randomized controlled trial. First Author: Yizhou Huang, Fujian Medical University Union Hospital, Fuzhou, Fujian, China

Background: Due to the lack of prospective randomized controlled clinical studies, current guidelines do not recommend postoperative adjuvant therapy, but rather observational follow-up regardless of any stage. The aim of this study was to evaluate the effect of postoperative adjuvant chemoradiotherapy and adjuvant chemotherapy on pathologic lymph node-positive (pN1-2) esophageal squamous cell carcinoma (ESCC). **Methods:** Patients with pathologically confirmed pN1-2 ESCC were randomly assigned to three groups: surgery alone (SA), postoperative chemotherapy (POCT), or postoperative chemoradiotherapy (POCRT). The POCT regimen included 2 to 4 cycles of docetaxel and cisplatin (75 mg/m²), while the POCRT regimen comprised 28 fractions of 5040Gy radiotherapy combined with docetaxel and cisplatin. Overall survival (OS) was the primary endpoint. Recruitment was terminated early due to the significant benefit observed in the adjuvant therapy group and difficulties in enrollment. **Results:** A total of 145 patients were enrolled (SA: n = 50, POCT: n = 48, POCRT: n = 47), with a median follow-up of 55 months. The overall survival rates at 3 and 5 years were 76.1% and 56.2% in the POCRT group, compared with 56.6% and 43.4% in the POCT group and 49.1% and 25.0% in the SA group, respectively. The POCRT group showed significantly improved OS and DFS compared to the SA group (OS, P = 0.003; DFS, P = 0.003). The incidence of grade 3 or higher adverse events was 39.6% in the POCT group and 44.7% in the POCRT group (P = 0.615). **Conclusions:** For patients with pN1-2 ESCC, postoperative therapy, especially postoperative chemoradiotherapy, significantly improved the prognosis of patients compared with surgery alone. Clinical trial information: NCT04009265. Combined PD-L1 expression and PD-1+ CD8 T cells to predict immunotherapy outcomes in esophageal squamous cell carcinoma. First Author: Qian Zhao, Department of Radiation Oncology, Shandong Cancer Hospital and Institute, Shandong First Medical University and Shandong Academy of Medical Sciences, Jinan, China

Background: Esophageal squamous cell carcinoma (ESCC), the predominant subtype of esophageal cancer in Asia, remains a challenging disease with poor prognosis due to frequent late-stage diagnoses. Immune checkpoint inhibitors (ICIs), particularly those targeting the PD-1/PD-L1 axis, have revolutionized cancer treatment but benefit only a subset of patients. The identification of robust predictive biomarkers is critical to enhance patient selection and optimize immunotherapy outcomes. In this study, we leveraged multiplex immunofluorescence to comprehensively evaluate the roles of PD-L1 and PD-1 expression, immune cell subsets, and clinical factors in predicting immunotherapy efficacy in ESCC. **Methods:** We analyzed baseline tumor samples from 147 ESCC patients treated with first-line ICIs using multiplex immunofluorescence to assess the expression of PD-1, PD-L1, CD4, CD8, CD20, and CD68. Patients were stratified by biomarker expression levels, with cut-off values determined through ROC curve analysis to calculate AUC. Survival outcomes were analyzed, and multivariate Cox regression identified independent predictors of progression-free survival (PFS) and overall survival (OS). **Results:** PD-L1 expression (HR 0.266, 95%CI 0.087-0.816, p = 0.021) and PD-1+CD8+ T cells (HR 2.694, 95%CI 1.162-6.246, p = 0.021) emerged as independent predictors of PFS. High PD-L1 expression was associated with superior outcomes (mPFS: 7.6 vs. 5.5 months), while elevated PD-1+CD8+ T cell infiltration correlated with poorer outcomes (mPFS: 6.0 vs. 7.2 months). Patients with a combination of high PD-L1 expression and low PD-1+CD8+ T cells demonstrated the best prognosis, with a median PFS of 8.5 months, whereas those with low PD-L1 expression and high PD-1+CD8+ T cells had the worst prognosis, with a mPFS of 3.5 months. Clinical stage (HR 1.570, 95%CI 1.059-2.327, p = 0.025), BMI (HR 0.935, 95%CI 0.883-0.990, p = 0.015), and CD8+ T cell density (HR 0.896, 95%CI 0.824-0.975, p = 0.011) were identified as independent predictors of OS. **Conclusions:** Our findings uncover the dual importance of PD-L1 expression and PD-1+CD8+ T cell infiltration as critical biomarkers for predicting PFS in ESCC patients undergoing ICIs. Moreover, clinical factors such as BMI, tumor stage, and intratumoral CD8+ T cell density significantly impact OS. Research Sponsor: None.

Temporal and spatial expression of CLDN18.2 in gastric cancer and gastroesophageal junction cancer. First Author: Qiaoqi Li, West China Hospital, Chengdu, Sichuan, China

Background: Recent studies have demonstrated the promising efficacy of CLDN18.2-targeted therapy in patients with gastric cancer (GC) or gastroesophageal junction cancer (GEJC) who are positive for CLDN18.2. This study aims to investigate the temporal and spatial consistency of CLDN18.2 expression in GC and to provide a comprehensive overview of its expression patterns. **Methods:** The expression of CLDN18.2 in primary GC tumors (biopsy/surgical) and corresponding peritoneal metastases (PM) was evaluated by quantifying cell membrane staining intensity with a validated semi-quantitative assay. CLDN18.2 positivity was defined when tumor cells with staining intensity (2+) and (3+) summed up to $\geq$ 75% of all. The Kappa test evaluated CLDN18.2 expression consistency across sample types, and the McNemar test compared its positive rates in paired samples. **Results:** Between February 2023 and April 2024, 536 patients were enrolled at the Gastric Cancer Center of West China Hospital, Sichuan University. The cohort comprised 399 in-situ biopsy samples, 240 radical gastrectomy samples, and 27 peritoneal biopsy samples. Among them, 109 patients had biopsy and surgical specimens, and 26 underwent preoperative neoadjuvant therapy. Among 399 biopsy specimens, 131 (32.8%) had positive CLDN18.2. In 240 surgical specimens, 167 (27.9%) were positive. In 27 peritoneal nodule specimens, 10 (37.0%) were positive. No significant differences were found (χ^2 = 2.128, *P* = 0.345). Among 109 patients with paired biopsy and postoperative pathology, CLDN18.2 expression concordance was 80.7% (88/109, Kappa = 0.562). In 27 peritoneal metastasis patients, it was 77.8% (21/27, Kappa = 0.503). For 26 chemo-resected patients, the pre- and post-chemo positive concordance was 80.8% (21/26, Kappa = 0.524). All showed moderate consistency. CLDN18.2 expression significantly correlated with several factors, including gender (*P* = 0.002), histological subtype (*P* = 0.003), tumor location (*P* = 0.007), histological classification (*P* = 0.035), and EBV status (*P* = 0.006). Higher rates were in females, signet-ring cell carcinoma, non-GEJ tumors, poorly differentiated tumors, and EBV-positive patients. **Conclusions:** CLDN18.2 is widely present in both primary gastric cancer and peritoneal metastatic lesions. Expression consistency exists moderately between biopsy and surgical specimens, and primary and metastatic tissues. Consistency stays strong pre- and post-neoadjuvant therapy. Its expression links to clinical and molecular traits. This study comprehensively analyzed it, providing a better basis for CLDN18.2-targeted patient selection. Research Sponsor: None.

Safety and efficacy of endoscopic treatment with mucosal resection, radiofrequency ablation, and cryotherapy in the curative treatment of early esophageal squamous cell cancer and dysplasia. First Author: Sidra Naz, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Endoscopic esophageal treatment (EET), by radiofrequency ablation (RFA), cryoablation (Cryo), and endoscopic mucosal resection (EMR) has not been extensively studied in early esophageal squamous cell carcinoma (SCC). Aim: To assess the safety and success of EET in curative treatment of early esophageal SCC: (T1a, T1b, T2) and squamous cell dysplasia (SCD) **Methods:** We retrospectively reviewed records of patients with SCC (T1a, T1b, T2) and SCD treated with EET from January 2010 to August 2024. All patients had at least one follow-up endoscopic biopsy after treatment. **Results:** 62 patients met the eligibility criteria. Table. 46 patients (74%) had T1a (n=36.5%) or T1b (n=10.1%) SCC. T2 patients (21%) received ETT for local recurrence after chemoradiation. The most frequent ETT was EMR + RFA, n= 26 (41.9%) and RFA, n=20 (32%). In the first biopsy after treatment, 46 of the 62 patients (74.1%) had no residual cancer. This number increased after further ETT. 2 years after treatment only 4 patients had persistent cancer. BMI is significantly associated with survival status. No patient had disease progression that required surgery. Strictures formed in 15 patients (24%) post- ETT. **Conclusions:** ETT provides curative treatment of early SSC in up to 94% of patients. Research Sponsor: None.

Safety and efficacy of camrelizumab combined with radiotherapy as neoadjuvant therapy for locally advanced esophageal squamous cell carcinoma: A prospective single-arm phase II clinical trial. First Author: Yizhou Huang, Fujian Medical University Union Hospital, Fuzhou, Fujian, China

Background: Neoadjuvant chemoradiotherapy followed by esophagectomy is the standard of care for locally advanced esophageal squamous cell carcinoma (ESCC). However, approximately 30% of patients still develop distant metastases and have a high incidence of treatment-related adverse events. Immunotherapy, as a new modality for anti-cancer treatment, has shown promising clinical benefits for patients with ESCC. The synergistic effects of immunotherapy and radiotherapy make their combination promising as neoadjuvant treatment for locally advanced ESCC. **Methods:** All participants who meet the inclusion criteria will be enrolled after signing the informed consent form. Patients with thoracic segment esophageal cancer with clinical stage T2-3 N0 M0 or T2-3 N+ M0 will be included. They will be treated with radical surgery within 4–8 weeks after the completion of two cycles of neoadjuvant radiotherapy in combination with camrelizumab according to the study schedule. The primary endpoint is the major pathological remission rate of all per-protocol patients. The secondary endpoints are the R0 resection rate, pathological complete remission rate, and adverse events. The interim analysis will be conducted after half of the planned number of patients have been enrolled. The trials will be terminated when more than two treatment-related deaths occur or fewer than five patients have major pathological remission. **Results:** A total of 25 patients were enrolled, 3 patients did not undergo surgery, of which 1 had imaging CR after neoadjuvant therapy and refused surgical treatment; 1 progressed during neoadjuvant therapy, and the other had immune pneumonitis and renal insufficiency during neoadjuvant therapy. The final results of the study noted that of the 22 patients who underwent surgery. Twelve of 22 (54.5%) patients had a pathologic response, all consisting of an MPR with ≤10% RVT, including 8 of 22 (36.4%) pathologic complete responses. **Conclusions:** The NRIT regimen is safe and feasible for patients with ESCC. Clinical trial information: NCT05176002. Research Sponsor: Key Laboratory of Cardio-Thoracic Surgery (Fujian Medical University), Fujian Province University; Fujian Minimally Invasive Medical Center (Thoracic Surgery), China; Fujian Institute of Cardiothoracic Surgery, China.

4058 Poster Session

A real-world, propensity-matched analysis of second-line (2L) FOLFIRI-Ram versus Ram-Pac in advanced upper gastrointestinal cancers. First Author: Jonathan Hyak, UT Southwestern Medical Center, Dallas, TX

Background: Given historically poor outcomes for advanced upper gastrointestinal (UGI) cancers, there is an urgent need for effective 2L treatments. Since the phase III RAINBOW trial, combination ramucirumab and paclitaxel (Ram-Pac) has filled this role; however, this regimen is plagued by dose-limiting toxicities, specifically neuropathy. The phase II RAMIRIS trial demonstrated the efficacy and tolerability of FOLFIRI-Ram as an alternative 2L, even if it did not improve survival over Ram-Pac. Real-world data to support its use, however, are lacking. **Methods:** The nationwide Flatiron Health electronic health record-derived de-identified database, which includes treatment data from around 280 cancer clinics across the United States, was queried for patients treated for unresectable or metastatic UGI cancers with 2L Ram-Pac or FOLFIRI-Ram from January 2011-June 2024. Demographics and lab values at time of treatment were extracted. Study cohorts were derived using a greedy match based on a logit model to predict propensity scores from key clinical and laboratory characteristics; patients were matched 1:6 (FOLFIRI-Ram:Ram-Pac) given expected imbalances in sample size. The endpoints of interest were overall survival (OS) and real-world time to treatment discontinuation (rwTTD), determined via Kaplan-Meier method, log-rank test, and Cox proportional hazards model. A hybrid approach was used to construct a multivariate Cox model. **Results:** Of 15,908 UGI cancer patients identified, 631 received 2L Ram-Pac and 40 received 2L FOLFIRI-Ram. After matching, 40 FOLFIRI-Ram and 240 Ram-Pac patients were included. Median OS from initiation of 2L therapy was 9.7 months with FOLFIRI-Ram (95% CI 6.9-12.3) and 7.7 months with Ram-Pac (95% CI 6.2-8.8), with a hazard ratio (HR) for death of 0.74 with FOLFIRI-Ram versus Ram-Pac (95% CI 0.50-1.11, p = 0.14). Similar results were seen in the multivariate model (HR 0.72, 95% CI 0.49-1.08, p = 0.114) after adjustment for albumin, neutrophil:lymphocyte ratio, and alkaline phosphatase. The median rwTTD with FOLFIRI-Ram was 5.2 months (95% CI 4.1-6.2), compared to 3.7 months with Ram-Pac (95% CI 3.2-4.3). The HR for treatment discontinuation was 0.70 with FOLFIRI-Ram versus Ram-Pac (95% CI 0.48-1.00, p = 0.048). The reduced hazard for treatment discontinuation with FOLFIRI-Ram persisted in the multivariate model (HR 0.67, 95% CI 0.46-0.97, p = 0.033) after adjustment for ECOG status, history of prior surgery, PDL1, albumin, and neutrophil:lymphocyte ratio. **Conclusions:** In a real-world propensity-score matched analysis, no survival difference was noted with the combination of FOLFIRI-Ram compared to Ram-Pac, however FOLFIRI-Ram was associated with a significantly longer rwTTD. Altogether, these data suggest FOLFIRI-Ram is a viable and tolerable alternative for 2L treatment of UGI cancers. Research Sponsor: None.

4059 Poster Session

Disitamab vedotin (RC48), tislelizumab, and S-1 as first-line therapy for HER2-overexpressing advanced gastric or gastroesophageal junction adenocarcinoma (GC/GEJC): Updated results from the RCTS trial. First Author: Lian Liu, Qilu Hospital of Shandong University, Jinan, China

Background: Anti-PD1 antibody has significantly improved survival in patients with HER2-overexpressing and PD-L1 combined positive score (CPS) ≥1 GC/GEJC when added to trastuzumab and chemotherapy. Recent trials revealed that HER2-targeted antibody-drug conjugates, including RC48 and Trastuzumab Deruxtecan, combined with anti-PD1 antibody, have also shown promising efficacy in this population. This study reports updated survival results of RC48 combined with tislelizumab and the oral fluoropyrimidine S-1 as first-line therapy for patients with HER2-overexpressing GC/GEJC. **Methods:** This single-arm, multicenter clinical trial enrolled patients with unresectable or metastatic HER2-overexpressing (IHC 3+ or 2+, regardless of FISH status) first-line GC/GEJC. Patients received RC48 (2.5 mg/kg), tislelizumab (200 mg), and S-1 (40-60 mg BID for 14 days) every 3 weeks until disease progression (PD) or intolerable toxicity. The primary endpoint was objective response rate (ORR). Secondary endpoints were progression-free survival (PFS), overall survival (OS) and safety. **Results:** 57 patients from 9 centers were enrolled, 71.9% HER2 IHC 3+, 17.5% IHC 2+/FISH+, and 10.5% IHC 2+/FISH-. 14.9% and 36.2% had CPS≥5 and ≥1, respectively. Median follow-up was 11.8 months. In the intent-to-treat population, the confirmed ORR (cORR) was 89.4% (51/57, 95% CI: 78.5-96.0%), the median PFS (mPFS) was 12.7 months (95% CI: 10.9-NA), and the 18-month OS rate (18m-OSr) was 72.7% (95% CI: 60.0-88.5%). In the per-protocol set (excluding patients with no PD at the first assessment but refused a second evaluation), the cORR was 92.7% (51/55, 95% CI: 82.4-98.0%), the mPFS was 13.2 months (95% CI: 10.9-NA), and the 18m-OSr was 76.3% (95% CI: 63.0-91.7%). In the HER2-positive and -negative subgroups, the ORRs were 92.1% (95% CI: 81.1-97.8%) and 66.7% (95% CI: 22.3-95.7%), the mPFS was 12.6 months (95% CI: 11.0-NA) and 7.7 months (95% CI: 7.1-NA), and the 18m-OSr was 74.7% (95% CI: 61.3-91.1%) and 62.5% (95% CI: 32.0-100%), respectively. In the CPS ≥1 and CPS < 1 subgroups, ORRs were 92.3% (95% CI: 74.9-99.1%) and 87.1% (95% CI: 70.2-96.4%), the mPFS was 16.8 months (95% CI: 11.3-NA) and 11.4 months (95% CI: 8.5-NA), and the 18m-OSr was 80.4% (95% CI: 62.1-100%) and 67.4% (95% CI: 50.7-89.5%), respectively. The grade 3-4 treatment-related adverse events (AEs) was 63.2%. The most common AEs were neutropenia, fatigue, and leukopenia. An exploratory study with longitudinal sequencing of circulating tumor DNA is ongoing. **Conclusions:** The combination of RC48, tislelizumab and S-1 as a first-line therapy shows encouraging response rates and survival benefits in HER2-overexpressing GC/GEJC, especially in HER2-positive or CPS ≥1 patients, supporting further evaluation in randomized controlled trials. Clinical trial information: NCT05586061. Research Sponsor: None.

Health-related quality of life (HRQoL) with paclitaxel plus ramucirumab (PTX-RAM) switch maintenance versus continuation of first-line fluoropyrimidine and oxaliplatin (FOX) chemotherapy (ChT) in patients (pts) with advanced HER2-negative gastric or gastroesophageal junction (G/GEJ) cancer: A secondary endpoint of the ARMANI phase 3 randomized trial. First Author: Eleonora Cristarella, Fondazione IRCCS Istituto Nazionale dei Tumori di Milano, Milan, Italy

Background: PTX-RAM switch maintenance significantly improved PFS (HR 0.61, 95%CI 0.48–0.79; p = 0.0002) and OS (HR 0.75, 95%CI 0.58–0.96; p = 0.025) versus continuation of FOX first-line ChT in the ARMANI trial, with a higher incidence of grade ≥3 treatment-related adverse events and an increased number of hospital visits. Here we present HRQoL results. **Methods:** ARMANI was an Italian multicenter, open-label, randomized, phase 3 trial enrolling pts with HER2-negative G/GEJ cancer who had disease control after a 3-month FOX induction ChT, and randomized to switch maintenance with PTX-RAM or the continuation of FOX. European Organisation for Research and Treatment of Cancer (EORTC) QLQC30, QLQOG25 and EuroQol EQ5D were assessed at randomization and every 8 weeks until progression. HRQoL changes over time were described by: (i) mean changes from baseline at each time point, (ii) distribution of improved/stable/worse at 8 weeks and (iii) time to QoL deterioration (TTD), defined as the time from randomization to a worsening ≥ 10 points of global QoL in EORTC QLQC30. Mean changes were compared by a linear regression model, with baseline values as covariates. Proportion of improved/stable/worse was compared by Chi square test. Kaplan-Meier and Cox proportional hazards model were used for TTD estimation. **Results:** Of the 280 pts randomized, 198 (71%; 109/144 with PTX-RAM and 89/136 with FOX) and 133 (48%; 81/144 and 52/136) completed baseline and 8-weeks assessment of EORTC and EQ5D, respectively. Mean baseline scores of global HRQoL were 66.90 (standard deviation [SD] 20.71) with PTX-RAM and 70.97 (SD 19.39) with FOX. Global QoL at 8-weeks assessment was better with PTX-RAM versus FOX both in terms of mean changes from baseline (+2.17 vs -8.51, delta 10.68, p = 0.015) and in terms of proportion of improved/stable/worse (improved 24.7% vs 4.2%, stable 56.2% vs 64.6%, worse 19.2% vs 31.3%, p = 0.009). TTD was significantly longer for PTX-RAM versus FOX (median TTD 7.6 vs 3.8 months, HR 0.52, 95%CI 0.33-0.82; p = 0.005). Mean changes from baseline after 8 weeks for functional scales and symptoms of QLQC30 and QLQOG25 showed significant improvement for PTX-RAM vs FOX for role functioning (p = 0.006), nausea/vomiting (p = 0.002), pain (p = 0.016), appetite loss (p = 0.03) and dysphagia (p = 0.028); hair loss was worse with PTX-RAM (p = 0.024). VAS score from EQ5D was not significantly different between the two treatments for all the assessments. **Conclusions:** In pts with HER2-negative advanced G/GEJ cancer, PTX-RAM switch maintenance, beyond a significant benefit in PFS and OS, showed significant benefit in terms of HRQoL, reducing symptoms and delaying global QoL deterioration. Clinical trial information: NCT02934464. Research Sponsor: None.

4061 **Poster Session**

Feasibility of circulating tumor DNA-based minimal residual disease (ctDNA-MRD)-guided adjuvant chemotherapy in patients with stage II-III gastric cancer (GC): An adaptive trial (MRD-GATE). First Author: Lian Liu, Department of Medical Oncology, Qilu Hospital of Shandong University, Jinan, China

Background: Although adjuvant chemotherapy (ACT) is the standard treatment for stage II-III GC, this strategy lacks precision treatment options, and many patients cannot tolerate the adverse events (AEs) of ACT. ctDNA-MRD detection has been shown to predict recurrence risk. The aim of this study (NCT06157216) was to evaluate the feasibility of MRD-guided treatment in these patients. **Methods:** Patients with stage II-III GC who underwent R0 resection and D2 gastrectomy were enrolled. Tumor-informed ctDNA-MRD testing was performed at baseline (28 days after surgery) and subsequently at 3, 6, 9, 12, 18, 24, 30, and 36 months after surgery. ACT was tailored according to MRD status: baseline MRD-negative (MRD (-)) patients received de-escalated therapy (observation for stage II and S-1 monotherapy for stage III) and switched to combined ACT (SOX, S-1 plus oxaliplatin, or XELOX, capecitabine plus oxaliplatin) if MRD became positive, while baseline MRD-positive (MRD (+)) patients underwent combined ACT. The primary endpoint was 3-year disease-free survival rate (yDFSr). Secondary endpoints included the treatment de-escalation rate, DFS by MRD status, cumulative recurrence risk (CRR), 3-year overall survival rate (yOSr) and safety. **Results:** 65 patients were enrolled, with a median age of 60 years (range: 34-83), and 83.1% (54/65) were male, 31 patients had stage II and 34 patients had stage III GC. At baseline, 21.5% patients (14/65) were MRD(+) and received combination ACT. Among the 51 baseline MRD(-) patients, 45 received de-escalated therapy at onset (9 received combination ACT after MRD conversion) and 6 received combination ACT. The median follow-up time was 13.3 (range: 9.3-15.7) months. In the intention-to-treat population, the overall 1-yDFSr was 86.2% (90% CI: 79.4-93.5%), the 1-yOSr was 96.9% (90% CI: 93.5-100%) and the CRR was 13.8% (95% CI: 6.5-24.7%). The treatment de-escalation rate was 69.2% (45/65, 95% CI: 56.6-80.1%). Grade 3-4 AEs occurred in 24.6% (95% CI: 14.8%-36.9%) of patients. Baseline MRD (+) patients had a shorter DFS compared to MRD (-) ones (1-yDFSr: 57.1% vs. 94.1%, HR = 9.66, 95% CI: 2.40-38.81, log-rank P < 0.0001). Patients with sustained MRD (-) had the best DFS (1-yDFSr: 100%), while those with sustained MRD (+) had the shortest DFS. Patients with MRD conversion from positive to negative or from negative to positive had intermediate DFS (1-yDFSrs: 72.7% and 70.0%, respectively). In 9 patients with recurrence, ctDNA-MRD positivity identified recurrence a median of 3.4 months earlier than radiology. **Conclusions:** MRD-guided ACT for stage II-III GC significantly reduced the ACT rate, and increased the de-escalated CT rate, resulting in good disease-free survival and fewer side effects. The results of this MRD-guided precision of ACT deserve to be confirmed by large randomized clinical trials. Clinical trial information: NCT05585580. Research Sponsor: None.

Development and validation of the gastric risk immuno-progression score (GRIPS) in advanced gastric and gastroesophageal junction adenocarcinoma treated with first-line chemotherapy plus nivolumab: Results from the ORACLE study. First Author: Dario Spanu, Medical Oncology Unit, University Hospital and University of Cagliari, Cagliari, Italy

Background: The addition of nivolumab to chemotherapy is approved for advanced gastric and gastroesophageal junction (GEJ) adenocarcinoma with PD-L1 CPS ≥5. Identifying predictive tools for disease progression in this setting remains a clinical need. This study introduces the Gastric Risk Immuno-Progression Score (GRIPS), a novel score derived from variables associated with progression-free survival (PFS) in a real-world cohort. **Methods:** We conducted a multicenter retrospective study on 90 patients with gastric/GEJ adenocarcinoma treated with first-line chemotherapy plus nivolumab between 2022 and 2024. The GRIPScore was constructed using five dichotomous variables associated with unfavorable PFS in univariate analysis: Neutrophil-to-Lymphocyte Ratio (NLR > 2.68), ECOG Performance Status (≥2), Smoking status (never smoker), CA19.9 at diagnosis (UNL) and primary tumor resection (no resection). Each variable was scored as 1 (prognostically negative) or 0 (prognostically positive), and a total score (0–5) was calculated. Patients were categorized into low-risk (GRIPS 0–2) and high-risk (GRIPS 3–5) groups. PFS and OS were analyzed using Kaplan-Meier methods. Hazard Ratios (HRs) were calculated, and the discriminatory ability of the GRIPS was evaluated using Harrell's C-index. **Results:** The median PFS for the entire cohort was 11.55 months (95% CI: 7.60–13.26). Stratifying patients by GRIPS revealed a marked difference in outcomes between the low-risk and high-risk groups. Low-risk patients (GRIPS 0–2) had a median PFS of 13.16 months (95% CI: 9.01–18.91), while high-risk patients (GRIPS 3–5) had 4.11 months (95% CI: 2.37–11.77). This difference was significant (log-rank test, p = 0.0023; HR: 3.55, 95% CI: 1.58–8.02). Similarly, low-risk patients had a median OS of 21.25 months (95% CI: 13.77–21.25) compared to 11.90 months (95% CI: 4.03–16.10) for high-risk patients (log-rank test, p = 0.0313; HR: 2.73, 95% CI: 1.09–6.81). Harrell's C-index for PFS was 0.648 (95% CI: 0.552–0.743), indicating moderate discriminatory ability. **Conclusions:** The GRIPS effectively stratifies patients with advanced gastric and gastroesophageal junction adenocarcinoma treated with a combination of chemotherapy + nivolumab into distinct risk groups for PFS and OS. High-risk patients experience significantly shorter survival, highlighting the potential clinical utility of GRIPS for personalized treatment strategies. Further prospective validation is warranted to refine its application in clinical practice. Research Sponsor: None.

GRIPScore	N° of patients (%)	mOS (m)	mPFS (m)
Low-risk (0-2)	51 (45.9)	21.25 (95% CI: 13.77–21.25)	13.16 (95% CI: 9.01–18.91)
High-risk (3-5)	21 (18.9)	11.90 (95% CI: 4.03–16.10)	4.11 (95% CI: 2.37–11.77)
Not evaluable	18 (16.2)		

4063 **Poster Session**

Multicenter phase I/II study of abemaciclib and ramucirumab in metastatic gastroesophageal adenocarcinoma (GEA): CDK4/6 and cyclin D1 alterations as a predictor of response and survival. First Author: Ronan Joseph Kelly, Baylor University Medical Center, Dallas, TX

Background: CDK4/6 and Cyclin D1 are highly expressed in GEA cancers, suggesting that CDK4/6 inhibition may be a promising strategy. *In vitro and in vivo* studies have shown that abemaciclib (A) demonstrates potent antitumor efficacy in GEA by directly inhibiting this pathway. Currently, ramucirumab (RAM) ± paclitaxel is an approved 2nd line treatment for metastatic GEA cancers. **Methods:** This multicenter, open-label, phase I/II study investigated the safety and efficacy of A combined with RAM in pretreated advanced GEA (2nd or 3rd line). The primary objective was to describe the safety profile of A (150mg po bid) and RAM (8mg/kg iv every 2 weeks) using CTCAE version 4.03. Secondary objectives included assessing the objective response rate (ORR), disease control rate (DCR), median progression-free survival (mPFS), and median overall survival (mOS). Correlative studies to evaluate alterations in CDK4/6 and Cyclin D1 as determined by next generation sequencing as predictive biomarkers of efficacy were performed. **Results:** From July 2021 to December 2024, 20/30 patients were enrolled. The study was terminated prematurely due to slow accrual. The median age was 61.5 years (Range: 30.0, 80.0) and most patients were male (18/20). Seven patients (35%) were HER-2 positive, 11/18 patients (61.1%) were PDL1 CPS > 1 and 15 patients (75%) had cancer localized in the E. Baseline ECOG performance status was 0 in 8 patients (40%) and 55% of patients had received prior immunotherapy with 1st line chemotherapy. A combined with RAM was generally well-tolerated without unexpected toxicities. The most common treatment-related adverse events (AEs) were anemia (10%), hypertension (10%), and dysphagia (10%). Treatment-related AEs ≥ grade 3 occurred in 50% of the patients. Median PFS and mOS were 2.7 months (95% CI: 1.5 - 14.5) and not reached (NR) (95% CI: 3.4 - NR), respectively. ORR was 10% (2/20) and DCR was 40% (8/20). In evaluable patients, 64.7% (11/17) patients with baseline tissue CDK4/6 pathway alterations trended towards longer mPFS (3.4 vs. 1.3 months; HR:1.1) and mOS (NR vs. 5.2 months; HR: 1.4) compared to patients without alterations (p > 0.05). Notably, one study patient with a CDK6 amplification had a partial response of 64% and has been on treatment for > 24 months. **Conclusions:** A plus RAM demonstrated promising antitumor activity in previously treated E/GEJ adenocarcinomas in the 2nd and 3rd line metastatic setting with manageable toxicities. Alterations in the CDK4/6 and Cyclin D1 pathways appear to enrich for efficacy and may be predictive but need future validation. In-depth molecular studies investigating changes in the expression of selected serum/tissue genomic markers of response for the cytostatic regimen will be presented at the meeting. Clinical trial information: NCT04921904. Research Sponsor: None.

Sequential chemo-immunotherapy as a novel bridging strategy for non-complete responders after neoadjuvant chemoradiotherapy in esophageal cancer: First prospective phase 2 trial challenging the immediate-surgery paradigm. First Author: Lin Peng, Department of Thoracic Surgery, Sichuan Cancer Hospital & Institute, Sichuan Cancer Center, School of Medicine, University of Electronic Science and Technology of China, Chengdu, Sichuan, China

Background: Locally advanced esophageal squamous cell carcinoma (LA-ESCC) patients with non-clinical complete response (non-CCR) after neoadjuvant chemoradiotherapy (NCRT) face >50% recurrence risk with direct surgery (DS), yet no standardized bridging strategy exists. This first study evaluates the efficacy and safety of sequential chemo-immunotherapy (SCI) as a bridge to surgery in this population. **Methods:** In this phase 2 cohort study (NCT05189730), 169 LA-ESCC pts who underwent NCRT were prospectively enrolled from June 2021 to January 2025. The NCRT regimen included paclitaxel and carboplatin every 3 weeks for two cycles. Concurrent radiotherapy (40–41.4 Gy) was administered. Post-NCRT, patients were assessed for non-CCR and stratified into two groups: the SCI group received two additional cycles of chemotherapy and tislelizumab (200 mg intravenously every 3 weeks) before surgery, while the DS group proceeded to surgery. The primary endpoint was pCR rate, secondary endpoints included major pathological response (MPR) rates and safety. **Results:** Eighty-seven non-CCR pts were included (SCI: n = 54; DS: n = 33). The median age was 63 years, with 78.0% male patients. Most patients were stage IIIB(83.9%). Surgery rates were 85.2% in the SCI group (46/54) and 81.8% in the DS group (27/33). In the ITT population, SCI significantly improved pCR rates (40.7% [22/54] vs. 18.1% [6/33]; OR: 3.06, p = 0.024, , one-sided Fisher's Exact Test) and showed a trend toward higher MPR rates (51.8% [28/54] vs. 33.3% [11/33]; OR: 2.14, p = 0.071). In the PP population, pCR rates remained higher in SCI (47.8% [22/46] vs. 22.2% [6/27]; OR: 3.16, p = 0.026) and showed higher MPR rates (60.9% [28/46] vs. 40.7% [11/27]; OR: 2.02, p = 0.078) . At 12 months, PFS rates were 95.6% in the SCI group versus 77.3% in the DS group (p = 0.094) in the ITT population, and 97.4% versus 77.8% (p = 0.064) in the PP population. SCI-related adverse events included lymphopenia (97.7%), leukopenia (84.6%), and fatigue (50.0%). In the no-surgical pts in SCI group, three cases experienced immune pneumonitis and thyroid dysfunction, respectively. Treatment-related adverse events in the SCI group included lymphopenia (97.7%), leukopenia (84.6%), and fatigue (50.0%).The main postoperative complications in the SCI group and DS group were anastomotic leakage and recurrent laryngeal nerve injury (3/46 vs. 2/27, P = 0.629). No significant treatment-related adverse events occurred in the SCI group. **Conclusions:** This pioneering study demonstrates that SCI as a bridging strategy significantly improves pCR rates by >2-fold (OR>3) and shows promising PFS trends with manageable toxicity in non-CCR LA-ESCC, challenging the immediate surgery paradigm. These results warrant validation in randomized phase 3 trials to redefine standard-of-care. Clinical trial information: NCT05189730. Research Sponsor: None.

Tumor-informed liquid biopsy in predicting recurrence in patients with operable gastroesophageal adenocarcinoma: The LIQUID study. First Author: Michele Prisciandaro, Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy

Background: Gastroesophageal cancers (GEC) shows high recurrence rates after curative surgery with or without perioperative/adjuvant chemotherapy. Pathological stage is currently the only prognostic tool, but its accuracy should be improved. Liquid biopsy, analyzing circulating tumor DNA (ctDNA), offers a non-invasive method to detect molecular residual disease (MRD) and monitor disease status. The LIQUID study aimed to evaluate the prognostic utility of liquid biopsy in GC patients, for whom observational studies are still scarce. **Methods:** This single-institutional study enrolled patients with resectable GC treated or not with perioperative/adjuvant chemotherapy. Liquid biopsies were collected before neoadjuvant chemotherapy (optional), pre- and post-surgery (minimum 2 weeks interval) and every six months during follow-up, until disease progression or the last follow-up for alive and progression-free patients. MRD analysis was performed using a clinical trial assay based on the tumor-informed ctDNA assay FoundationOne®Tracker, which identified somatic mutations by tissue comprehensive genomic profiling and tracked them in patients' plasma samples. **Results:** Between December 2019 and February 2024, 119 patients were enrolled. Of these, 40 were excluded due to screen failure (mostly peritoneal disease at surgery), and 27 due to technical failure (n = 18) or loss to follow-up (n = 9), leaving 52 patients (median 4 timepoints per patient) for analysis. Median age was 70 years (range: 23–86), with 55.8% male, and 86.5% of tumors located in the stomach. Pathological staging revealed pT0 (3.8%), pT1 (21.2%), pT2 (21.2%), pT3 (34.6%), and pT4 (19.2%) tumors, with nodal involvement in 69.6%. Additionally, 51.9% and 46.2% of patients received neoadjuvant or adjuvant treatment respectively, and 32.7% experienced peritoneal relapse. ctDNA presence was not significantly associated with known clinico-pathological baseline risk factors, except for postoperative N-stage (*p = 0.04*). With a median follow-up of 49.0 months (IQR 30.6 -54.0), post-surgery MRD+ patients had a significantly worse relapse-free survival (RFS) than those with ctDNA- (13.2 months vs not reached; HR 2.81 95% CI 1.23-6.45; *p = 0.011*). Similar results were observed in longitudinal ctDNA monitoring, (RFS 16.3 months for ctDNA+ vs not reached for ctDNA-; HR 2.70, 95% CI 1.22–5.97, *p = 0.011*). Notably, absence of ctDNA after completing the treatment plan (post-surgery or adjuvant therapy) or clearance/seroreversion after treatment were associated with significantly longer RFS (*p = 0.001* and *p = 0.036*, respectively). **Conclusions:** Post-surgical landmark and longitudinal ctDNA detection demonstrates robust evidence of MRD and identifies GC patients at high risk of relapse. These findings support ctDNA as a valuable tool for postoperative surveillance and early intervention strategies in GEC. Research Sponsor: None.

4068 **Poster Session**

Recurrence-free survival as a surrogate endpoint for overall survival in resectable esophageal cancer: An individual patient data analysis of phase III RCTs. First Author: Jun Okui, Department of Surgery, Keio University School of Medicine, Tokyo, Japan

Background: Overall survival (OS) is regarded as the gold standard efficacy endpoint but requires long follow-up. This study aimed to determine the validity of recurrence-free survival (RFS) as a surrogate endpoint for OS in resectable esophageal cancer. **Methods:** A systematic review of phase III randomized controlled trials (RCTs) comparing perioperative treatments for resectable advanced esophageal and gastroesophageal junction cancer was conducted. Individual patient data (IPD) were requested from all included trials. Surrogacy between RFS and OS was assessed at the individual level using the Kendall rank correlation coefficient (τ) and at the trial level using the coefficient of determination (R^2) from a meta-regression model. A τ of 0.8 and an R^2 of 0.65 were considered thresholds indicative of a good surrogate endpoint. **Results:** Twenty-two eligible trials were identified by the systematic review, and IPD were available from 10 RCTs (JCOG1109, JCOG9907, JCOG9204, FFCD9901, FFCD9102, SAKK75/08, CROSS, KOK, NeoRes2 and CMISG1701), including 2,145 patients who underwent R0 resection (cStage IV, cT1N0 and cT4b excluded). Of these, 1563 patients had squamous cell carcinoma, and 575 patients had adenocarcinoma. The 5-year OS and RFS rates were 53.2% and 46.2%, respectively, with a median OS of 6.2 years and a median RFS of 3.6 years. For individual-level surrogacy, Kendall's τ was 0.823 (95% CI: 0.807–0.839). Subgroup analysis based on treatment modality revealed τ values of 0.830 (95% CI: 0.800–0.861) for patients receiving neoadjuvant chemotherapy (NAC; n = 586), 0.827 (95% CI: 0.803–0.850) for those receiving neoadjuvant chemoradiotherapy (NACRT; n = 982), 0.770 (95% CI: 0.713–0.828) for the surgery-alone group (n = 320), and 0.861 (95% CI: 0.824–0.898) for the adjuvant chemotherapy group (n = 257). Trial-level surrogacy analysis across all 22 trials demonstrated an R^2 of 0.735 (95% CI: 0.512–0.939). The surrogate threshold effect was 0.929, indicating the minimum RFS treatment effect required to predict a nonzero effect on OS. **Conclusions:** This study demonstrated strong individual-level and trial-level surrogacy between RFS and OS in surgically resectable esophageal cancer across all perioperative treatment modalities. These findings hold promise for expediting the development of novel perioperative treatment by shortening the follow-up of clinical trials on esophageal cancer. Research Sponsor: None.

Neoadjuvant toripalimab plus CapeOX in patients with locally advanced EBV-positive gastric or esophagogastric junction adenocarcinoma (GC/EGJC): Results from the phase II NICE trial. First Author: Liying Zhao, Department of General Surgery & Guangdong Provincial Key Laboratory of Precision Medicine for Gastrointestinal Tumor, Nanfang Hospital, Southern Medical University, Guangzhou, Guangdong, China

Background: Surgery remains the cornerstone of curative therapy for locally advanced GC/EGJC. EBV-positive tumor is a distinct molecular subtype that would be potentially sensitive to immunotherapy, but no consistent reports. Given that chemotherapy may enhance antitumor immunity, perioperative immunochemotherapy may be a promising modality for EBV-positive patients. **Methods:** The NICE trial is a multicenter, multi-cohort phase II study (NCT04744649) evaluating the safety and efficacy of toripalimab plus CapeOX as perioperative treatment in patients with locally advanced GC/EGJC. The Cohort B was first of its kind to assess the efficacy of the immunochemotherapy on the EBV-positive GC/EGJC , in which patients received toripalimab (240 mg) combined with standard-dose CapeOX every 3 weeks for 4 cycles preoperatively and 4 cycles postoperatively. Eligibility criteria included clinical tumor stages of cT3-4aNxM0 or cT2N+M0 disease as determined by both imaging scan and staging laparoscopy with negative peritoneal cytology. The primary endpoint was major pathologic response (MPR, defined as < 10% viable tumor cells). The tumor immune microenvironment (TIME) of tissue samples obtained before and after treatment was analyzed using multiple immunofluorescence assays to assess changes in immune cell infiltration and other biomarkers related to treatment response. **Results:** From May 2021 to September 2023, 17 patients with EBV-positive GC/EGJC (GC, n = 15; EGJC, n = 2) were enrolled, with cT2N0 (n = 1), cT3N1-3 (n = 5), and cT4aN1-3 (n = 11). All patients completed 4 preoperative cycles of treatment, and none experienced progression before surgery. Only one patient withdrew the inform content after preoperative therapy, the 16 patients underwent radical resection, achieving a 100% R0 resection rate (16/16). The MPR rate was 37.5% (6/16), and pathological complete response rate (pCR) was 25.0% (4/16). Of the 16 participants, 15 received postoperative adjuvant therapy, while 1 declined further treatment. The TIME analysis results showed that tumor-infiltrating CD8+ T cells in post-treatment tumor tissues significantly clonally expanded compared with pre-treatment paired tissues. Treatment-related grade 3/4 adverse events were observed in 6 patients (35.3%, 6/17). Until Dec 31 2024, none of the patients experienced disease recurrence. **Conclusions:** Neoadjuvant toripalimab combined with CapeOX is a safe and effective treatment option for patients with EBV-positive, locally advanced GC/EGJC, with moderate MPR and pCR, indicating further investigating for this distinct type of cancer. Clinical trial information: NCT04744649. Research Sponsor: None.

Early detection and neoadjuvant efficacy prediction for esophageal cancer using cfDNA methylation-based liquid-biopsy assay. First Author: Zhigang Li, Shanghai Chest Hospital, Shanghai Jiaotong University, Shanghai, China

Background: Esophageal cancer (EC) is a major malignancy of the upper gastrointestinal tract globally. Early detection and timely therapeutic intervention are pivotal in improving patient outcomes. However, current diagnostic methods often fail to detect EC at an early stage and lack the ability to predict treatment response. There is an urgent need for non-invasive, sensitive, and specific biomarkers to enhance early detection and guide personalized treatment strategies. This study aims to develop a tool to detect EC and predict the neoadjuvant efficacy. **Methods:** This is a prospective multicenter diagnostic study. From July 2023 to October 2024, a total of 236 esophageal cancer cases (stage I: 19.9%, stage II: 24.6%, stage III: 39.4%, stage IV: 16.1%), 31 chronic esophagitis cases, and 441 healthy controls were enrolled from multiple centers. Methylation features and fragmentomic characteristics derived from methylation sequencing data were integrated to develop a gradient-boosted tree model. A nested cross-validation framework was employed to ensure robustness and reliability. Additionally, predictive models for therapeutic responses to neoadjuvant treatment were constructed. **Results:** The detection model achieved an area under the curve (AUC) of 0.954 (95% CI: 0.936-0.971. At a specificity of 97.9% (95% CI: 96.1%-99.0%), the overall sensitivity reached 84.7% (95% CI: 79.5%-89.1%) , with stage-specific sensitivities of 69.5% for early-stage (I/II) and 97% for advanced-stage (III/IV) disease. The detection model maintained robust performance across various clinicopathological parameters, including differentiation grade, neural invasion, vascular invasion, tumor count, and tumor location, with no significant differences in subgroup performance. Among the cohort, 44 patients underwent neoadjuvant therapy, with 90.9% (40/44) receiving immunochemotherapy. The major pathological response (MPR) rate was 52.3% (23/44) and the pathological complete response (pCR) rate was 15.9% (7/44). No clinical features were found to correlate with MPR or pCR rates. Differential methylation profiles between MPR/pCR and non-MPR/pCR patients were analyzed to construct predictive models for neoadjuvant therapy outcomes. Using logistic regression and leave-one-out cross-validation, the MPR prediction model achieved an accuracy of 86.3%, while the pCR prediction model demonstrated an accuracy of 90.9%. **Conclusions:** Our cfDNA-methylation based assay demonstrated high performance in early EC detection and promising value in predicting neoadjuvant therapy responses. This non-invasive approach has the potential to revolutionize EC management by enabling earlier diagnosis and personalized treatment strategies. Research Sponsor: None.

Effectiveness of a multidomain mHealth-based intervention in enhancing recovery and quality of life for esophageal cancer patients undergoing esophagectomy. First Author: Xiaodong Su, Department of Thoracic Oncology, Sun Yat-Sen University Cancer Center, Guangzhou, China

Background: Esophagectomy, a primary treatment for esophageal cancer (EC), often compromises patients' quality of life (QOL), leading to malnutrition, reduced physical function, and psychological distress. Multidomain mHealth-based interventions, which leverage technology to deliver comprehensive nutritional, physical, and psychological support, offer a promising approach to address these challenges during prehabilitation and Enhanced Recovery After Surgery (ERAS) phases. Despite their potential, high-quality evidence demonstrating their effectiveness remains limited. This study evaluates the effectiveness of a multidomain mHealth intervention on QOL and recovery outcomes in EC patients undergoing esophagectomy. **Methods:** Between April 27, 2021 and June 30, 2023, this single-center, randomized controlled trial was conducted, enrolling 76 patients with pathologically confirmed EC scheduled for esophagectomy. Participants were randomized to either a multidomain mHealth-based intervention group (n = 38) or a usual care group (n = 38). The intervention delivered tailored nutritional, physical, and psychological support via a self-developed WeChat-based management platform, spanning from 2 weeks pre-admission to 11 weeks post-discharge. The primary outcome was the change in QOL, assessed using the EORTC QLQ-C30 and QLQ-OES-18. Secondary outcomes included changes in nutritional status (e.g., weight), physical fitness (e.g., 6-minute walk distance), and psychological health (e.g., PHQ-9, GAD-7, SCSQ-20). Outcomes were assessed at baseline, hospital admission, and 3 and 11 weeks post-discharge. **Results:** At 11 weeks post-discharge, the intervention group showed a significant improvement in QOL, with a 15.56-point increase in Global Health Status (EORTC QLQ-C30) compared to a 5.91-point decline in the usual care group (difference: 21.47 points; 95% CI: 9.86–33.08; $p < 0.001$). Functional and symptom scores, including social functioning, appetite, and eating, improved markedly in the intervention group. The intervention group also demonstrated superior outcomes in weight change (+2.19 kg; 95% CI: 0.09–4.30; p = 0.041) and 6-minute walk distance (+80.65 meters; 95% CI: 41.64–119.66; $p < 0.001$). Psychological well-being improved significantly, with reductions in PHQ-9 (-4.70; 95% CI: -6.59 to -2.80; $p < 0.001$) and GAD-7 (-4.63; 95% CI: -6.52 to -2.74; $p < 0.001$), and an increase in positive coping scores (+11.83; 95% CI: 7.20–16.45; $p < 0.001$). **Conclusions:** This multidomain mHealth intervention significantly enhanced QOL, nutritional and physical outcomes, and psychological health in EC patients undergoing esophagectomy. These findings underscore the potential of mHealth platforms to optimize prehabilitation and recovery, offering a scalable and impactful approach to improving outcomes in oncology care. Clinical trial information: ChiCTR2100045650. Research Sponsor: None.

Exome analysis of over 5000 esophagogastric cancers. First Author: Reetu Mukherji, Ruesch Center for the Cure of Gastrointestinal Cancers, Lombardi Comprehensive Cancer Center, Georgetown University Medical Center, Washington, DC

Background: Esophagogastric cancers (EGCs) encompass a heterogenous group of cancers. The genomic drivers that overlap or differentiate among each cancer type are not well studied, despite the availability of therapies that target specific genetic alterations in driver genes. **Methods:** Genomic data from Natera's Real-World Database (N = 5,872) was analyzed to investigate genomic patterns in EGC patients (09/2019-11/2024) receiving standard-of-care treatment. This exploratory analysis was conducted on tumor tissue data available from whole-exome sequencing, generated as part of SignateraTM testing.Microsatellite instability (MSI) status was determined using the MSIsensor and 96-trinucleotide contexts and was correlated with COSMIC SBS signatures (v3.3). Prevalence analysis included only non-synonymous mutations, with ranking adjusted for gene length. **Results:** Patients included 4050 men and 1822 women, with median age 65.3 years, and stage distribution as follows: I: 7.9%, II:14.7%, III: 32.9%, IV: 32.2%, and 12.3% unknown. Gastric cancer (GC) was most common (48.1%), followed by esophageal (EC, 45.9%) and gastroesophageal junction (GEJ, 7.2%). MSI-high cases (7.7% prevalence overall, 2.2% in squamous EC, 5.2% in EC adenocarcinoma, 6.1% in GEJ, 10.9% in GC) had a distinct mutational landscape with frequent missense deletions. The most common signatures were clock-like (SBS1, SBS5), MMR-deficiency-related (SBS6, SBS15), and Thiopurine-chemotherapy-related (SBS87). *PIK3CA* mutations were found in 7.9% of cases, with the most common being E545 (2.6%), H1047 (1.1%), and E542 (1.0%). Notably, *PIK3CA* exon 9/20 mutations displayed a trend of higher prevalence in ctDNA-positive cases. **Conclusions:** These data provide insights into the mutational landscape of EGC and enhance our understanding of differences between histological subtypes. Future studies will continue to explore the associations between genomic subtypes, treatment patterns, and clinical outcomes. Research Sponsor: None.

The lost evidence: A phase III, multicenter randomized controlled trial of neoadjuvant chemotherapy paclitaxel plus cisplatin versus surgery alone for stage IIA–IIIB esophageal squamous cell carcinoma. First Author: Yin Li, Department of Thoracic Surgery, National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China

Background: The efficacy of neoadjuvant chemotherapy (NAC) vs primary surgery alone for treatment of locally advanced esophageal squamous cell carcinoma (ESCC) remain controversial between Western and Eastern countries. The daily NAC practice in China was without the high level evidence. The Esophageal Cancer Committee of the China Anti-Cancer Association tried to connect the the lost chain of evidence. To compare safety and long-term survival of NAC followed by surgery with that of surgery alone. **Methods:** A prospective, multicenter, open-label, randomized phase III clinical trial that compared safety and efficacy of NAC vs primary surgery for ESCC. From July 18, 2015, to March 29, 2018, we enrolled 605 clinical stage IB-III thoracic ESCC (excluding stage T4b, N3, 7th UICC-TNM staging, 2009). They were randomized to NAC plus surgery (group NAC; n=304) or primary surgery alone (group S; n=301). In group NAC, paclitaxel 175 mg/m2 intravenously (IV) and cisplatin 75 mg/m2 every 3 weeks for two cycles. All patients underwent McKeown, Ivor Lewis or minimally invasive esophagectomy and extended 2-field lymph node dissection. The primary outcome was 5-year overall survival (OS). Secondary outcomes included disease free survival (DFS), R0 resection rate, pathologic complete response rate and toxicities. The intention-to-treat principle was followed for analysis. The SPSS, version 23.0 (IBM Corp). The statistically significant was assumed as a 2-sided $P<0.05$. The Kaplan-Meier method was used to calculate OS and DFS with the log-rank test. The last follow-up data was April 12, 2024. The 5-year OS of primary surgery was 30%. A 5-year survival with a 12% increase for the NAC group was assumed. The sample size was calculated with a two-sided alpha level of 5%, a power of 80%, an expectation of 2 years accruement and a 5-year followup period. The total sample size was set at 528 patients with 10% of patients lost to follow-up. **Results:** Among 605 patients (432 men [71.4%]; mean [SD] age, 61.7 [7.9] years; most frequent clinical stages IIIA 170 [30.2%]), Leukopenia (28%) and neutropenia (49.8%) were the most common grade 3 or 4 adverse events during NAC. Complications was similar between the 2 groups based on Clavien-Dindo classification. The 90-day perioperative mortality rate was 1.6% for the NAC group (4 of 244) and 2.2% for the Surgery alone group (6 of 268) (P = 0.754). The pathologic complete response rate was 6.58% (20 of 304) in NAC group. NAC group had a higher R0 resection rate (98.8% v 98.5%; $P > 0.999$), a better 5 years OS rate (61.1% vs 51.6%; hazard ratio, 0.79; 95% CI, 0.63 to 1.0; P = 0.0469), and a prolonged DFS (58.5% vs 46.2% months; hazard ratio, 0.71; 95% CI, 0.56 to 0.91; P=0.0067). 0.71 (0.56,0.91). The max follow up period of NAC group was 110 months, S group 105 months. The median follow up period of NAC group was 79.4, whereas 55.2 in surgery group. **Conclusions:** This trial showed that NAC plus surgery improves survival over surgery alone among patients with locally advanced ESCC, with acceptable and manageable adverse events. Clinical trial information: NCT02395705. Research Sponsor: None.

An interim analysis of phase III study on neoadjuvant chemotherapy versus perioperative toripalimab plus neoadjuvant chemotherapy for locally advanced esophageal squamous cell carcinoma: Henan Cancer Hospital Thoracic Oncology Group 1909 (HCHTOG1909). First Author: Yan Zheng, The Affiliated Cancer Hospital of ZhengZhou University/Henan Cancer Hospital, Zhengzhou, Henan, China

Background: In the era of immunotherapy, whether neoadjuvant immunochemotherapy (NAIC) would be standard treatment of locally advanced esophageal squamous cell carcinoma (ESCC) is without conclusion. The HCHTOG1909 was aimed to compare the safety and long-term efficacy of NAIC followed by minimally invasive esophagectomy (MIE) with those of neoadjuvant chemotherapy followed by MIE. This second interim analysis was aim to compare the short term results of two groups. **Methods:** A prospective, single-center, open-label, randomized phase III clinical trial. Between May 15, 2020 and April 23, 2024, 401 resectable ESCC with clinical stage T1N1-3M0 to T2-3N0-3M0 were enrolled(8th UICC-TNM), 196 in the toripalimab group and 205 in the chemotherapy group. The patients receive either neoadjuvant paclitaxel (175 mg/m2) and cisplatin (75 mg/m2) plus toripalimab (240mg) (toripalimab group) or paclitaxel and cisplatin alone (chemotherapy group) every 3 weeks for 2 cycles. After MIE, the toripalimab group received toripalimab (240 mg every 3 weeks for up to 6 months). The event-free survival (EFS) was the primary endpoint. The pathological complete response (pCR) was the key secondary endpoints. Other endpoints included postoperative complications, mortality, adverse events, overall survival and disease free survival. We planned 3 interim analyses. This was a planned second interim analysis. The sample size was calculated based on the primary endpoint EFS. The hazard ratio assumed to be 0.68 between two groups. A type I error allocated (two-sided) 0.05, 90% power and drop-out rate of 10% in 5 years. The χ^2 test and the Fisher exact test was employed for categorical parameters, the t test or analysis of variance was adopted for continuous variables. **Results:** Among 401 patients (305 men [76.1%]; mean [SD] age, 70.7 [3.5] years; most frequent clinical stages III 213 [53.1%]). The toripalimab group had a higher pCR rate (26.1% vs. 6.2%; $P < 0.001$). The 90-day perioperative mortality rate was 2.42%(4) for the toripalimab group and 2.5%(4) for the chemotherapy alone group ($P = 0.9790$). The most frequent irAE was hypothyroidism. There was no significant difference observed for postoperative complication rate ($P = 0.453$). The grade 3 or 4 treatment-related adverse events did not differ between the two groups (13.8% versus 10.8%). **Conclusions:** The interim results of HCHTOG1909 showed the addition of perioperative toripalimab to NAC is safe in resectable ESCC, and the pCR rate is significantly improved. Clinical trial information: NCT04280822. Research Sponsor: None.

Circulating tumor DNA (ctDNA) analysis for improved treatment response assessment and prediction of clinical outcomes in patients with esophageal cancer. First Author: Zexi Allan, Division of Cancer Research, Peter MacCallum Cancer Centre, Melbourne, Australia

Background: Despite curative-intent treatment, patients with esophageal cancer experience a high risk of recurrence, and optimal patient management is limited by poor risk stratification and treatment response assessment strategies. ctDNA has demonstrated value as a prognostic biomarker in esophageal cancer; however, improved analytical and clinical performance of ctDNA analysis is necessary to reliably support patient management decisions in clinical practice. **Methods:** Between September 2017 and June 2023, plasma samples were collected from patients with esophageal cancer before, during, and after standard of care treatment in the routine care setting. In this retrospective analysis, ctDNA testing was performed on a subset of patients using a next-generation tumor-informed assay interrogating up to 50 personalized variants (Haystack MRD, Quest Diagnostics). **Results:** ctDNA was assessed in 149 samples from 51 patients with stage I-III esophageal adenocarcinoma (n= 40) or squamous cell carcinoma (n= 11). Fifteen patients with clinical follow-up (FU) available at the time of analysis had at least one sample collected after curative-intent treatment [neoadjuvant chemoradiotherapy (nCRT) and surgery (n=10) or definitive CRT (n=5)]. ctDNA was detected (ctDNA+) following curative-intent treatment in 5/15 (33%) patients, all 5 (100%) of whom experienced disease recurrence or were deceased at FU (median time from ctDNA+ result to FU: 14.4 months, range: 0.1-24.5). Of the 10 (67%) patients with no ctDNA detected (ctDNA-) following curative-intent treatment, 7 (70%) were disease-free at FU (median time from ctDNA- result to FU: 46.7 months, range: 6.3-65.5). In the neoadjuvant setting, paired pre- and post-nCRT samples were evaluated in 18 patients, demonstrating ctDNA detection in 18/18 (100%) patients prior to nCRT versus 8/18 (44%) following nCRT. ctDNA positivity following nCRT was strongly associated with poor pathological response (p=0.0026), and ctDNA dynamics observed longitudinally during nCRT served as a robust indicator of response. Of note, one patient experienced metastatic progression during nCRT, discovered at surgery, and ctDNA levels in this patient increased 550-fold while on nCRT. **Conclusions:** Evaluation of ctDNA using a next-generation tumor-informed platform supports improved response assessment to nCRT as well as accurate risk stratification following curative-intent treatment in patients with esophageal cancer. ctDNA positivity following curative-intent treatment predicted disease recurrence with a lead time of up to 22 months. Additional analyses are ongoing to further validate these findings. Research Sponsor: None.

Clinical implication of MDM2 amplification in advanced biliary tract cancer (BTC): A propensity score-matched, retrospective cohort study of 813 patients. First Author: Hyunseok Yoon, Department of Oncology, Asan Medical Center, University of Ulsan College of Medicine, Seoul, South Korea

Background: Restoring p53 tumor suppressor activity by blocking the interaction between p53 and MDM2, its endogenous negative regulator, has emerged as a potential therapeutic target for several tumors including BTC. However, the frequence and clinical implication of MDM2 amplification (amp) has not been investigated for BTC. **Methods:** Patients with unresectable or metastatic BTC who had available tissue-based targeted next generation sequencing (NGS) data and were treated with first-line gemcitabine plus cisplatin (GemCis)-containing chemotherapy at Asan Medical Center, Seoul, Korea between January 1, 2016, and December 31, 2023, were included. MDM2-amp was defined 5 or greater copies per tumor cell. Baseline characteristics and clinical outcomes to GemCis-containing therapy were compared according to the presence of MDM2-amp/TP53 wild-type (WT). Propensity score matching (PSM) with a 1:4 ratio was performed to balance the baseline characteristics between the patients with and without MDM2-amp/TP53-WT. **Results:** Among 813 patients, 41 (5.0%) had MDM2-amp/TP53-WT and there was no significant association with primary tumor sites: 4.7% in intrahepatic cholangiocarcinoma, 3.7% in extrahepatic cholangiocarcinoma, and 8.0% in gallbladder cancer (p=0.111). Patients with MDM2-amp/TP53-WT significantly had less frequent viral hepatitis B infection (2.4% vs. 18.4%, p=0.009) and lung metastasis (2.4% vs. 13.2%, p=0.043); otherwise, no significant association with baseline characteristics was noted. After PSM (40 for MDM2-amp/TP53-WT vs. 155 for non-MDM2-amp/TP53-WT), patients with MDM2-amp/TP53-WT showed significantly longer progression-free survival compared to those in the matched group (median, 9.6 vs. 6.9 months; p=0.034) and non-significant tendency toward longer overall survival (median, 20.3 vs. 16.4 months; p=0.103). **Conclusions:** In patients with unresectable or metastatic BTC, MDM2-amp/TP53-WT occurred in 5% and it was associated with better survival outcomes of first-line GemCis-containing chemotherapy. Our findings suggest that MDM2-amp/TP53-WT serves as a biomarker for a distinct subgroup of BTC, warranting active investigation into MDM2 inhibitors. Research Sponsor: Boehringer Ingelheim.

Real-world outcomes of first-line therapies for unresectable hepatocellular carcinoma in the United States. First Author: Masafumi Ikeda, National Cancer Center Hospital East, Kashiwa, Japan

Background: Unresectable hepatocellular carcinoma (uHCC) remains a significant clinical challenge despite advances in systemic therapies. Real-world evidence complements clinical trials by evaluating treatment effectiveness in diverse patient populations. This study assessed real-world progression-free survival (rwPFS) and overall survival (rwOS) for current standard-of-care first-line (1L) systemic therapies for uHCC. **Methods:** This retrospective study used the Flatiron Health database and included untreated uHCC patients diagnosed on or after January 1, 2018, who initiated 1L systemic therapies (atezolizumab + bevacizumab [atezo + bev], lenvatinib, sorafenib, or durvalumab + tremelimumab [durva + treme]) on or after May 29, 2020. Baseline characteristics, including ECOG status, ALBI grade, and demographic factors, were reported across cohorts. Kaplan-Meier method was used to estimate rwPFS and rwOS for each cohort. **Results:** A total of 1,539 patients were included: atezo + bev (n = 1,070), durva + treme (n = 238), lenvatinib (n = 139), and sorafenib (n = 92). Baseline characteristics were similar across cohorts. Most patients had ECOG (Eastern Cooperative Oncology Group) status 0–1 (57%–70%), with 15%–21% having ECOG 2+. ALBI (Albumin-Bilirubin) grade 2 was observed in 41%–60% of patients, while ALBI grade 3+ was present in 8.1%–17%. The median rwPFS for atezo + bev, lenvatinib, and durva + treme were similar at 4.7 months (95% CI: 4.1–5.4), 4.6 months (95% CI: 3.8–5.5), and 4.2 months (95% CI: 3.2–5.7), respectively. Sorafenib had a significantly shorter rwPFS at 3.0 months (95% CI: 2.5–4.4). The median rwOS for atezo + bev, lenvatinib, and sorafenib were similar at 10.7 months (95% CI: 9.5–11.8), 10.4 months (95% CI: 7.8–13.4), and 10.5 months (95% CI: 5.6–14.9). Durva + treme had a significantly shorter rwOS at 7.6 months (95% CI: 5.7–18.6). At 12 months, the survival probabilities for rwOS were 45% (95% CI: 42%, 48%) for Atezo + Bev, 41% (95% CI: 33%, 50%) for Durva+Treme, 45% (95% CI: 36%, 55%) for lenvatinib, and 43% (95% CI: 33%, 56%) for sorafenib. At 24 months, survival probabilities for rwOS were 27% (95% CI: 24%, 31%) for Atezo + Bev, 26% (95% CI: 19%, 36%) for lenvatinib, 21% (95% CI: 12%, 35%) for sorafenib, and data were undetermined for Durva + Treme. **Conclusions:** Findings from this real-world analysis show that atezo + bev demonstrated comparable outcomes versus lenvatinib, and potential benefits in rwPFS versus sorafenib and rwOS versus durva + treme. The median rwOS was approximately 10 months across treatments and highlights the need for novel therapies to improve long-term survival in uHCC. These results underscore the importance of evaluating treatment effectiveness in real-world populations, which may differ from clinical trial cohorts. Further analyses are warranted to explore these findings and optimize treatment strategies for uHCC. Research Sponsor: Bristol Myers Squibb.

4080 Poster Session

First-line rilvegostomig (rilve) plus chemotherapy (CTx) in advanced biliary tract cancer (BTC): Primary analysis of GEMINI-Hepatobiliary substudy 2 Cohort A. First Author: Jian Zhou, Zhongshan Hospital, Fudan University, Shanghai, China

Background: Immune checkpoint inhibitors plus CTx have improved outcomes in first-line advanced BTC (median progression-free survival [PFS] 6.5–7.2 months), but survival remains limited. Rilve, an anti-PD-1/TIGIT bispecific antibody, may provide benefit by targeting two immune checkpoints. GEMINI-Hepatobiliary (NCT05775159) is a phase 2 study evaluating rilve or volrustomig alone or in combination regimens in patients (pts) with advanced hepatocellular carcinoma (substudy 1) or BTC (substudy 2). We report data from Cohort A (rilve plus CTx) in substudy 2. **Methods:** Pts aged ≥18 years with previously untreated unresectable/metastatic BTC and an ECOG performance status 0–1 received rilve every 3 weeks (Q3W) for up to 2 years plus gemcitabine 1000 mg/m^2 and cisplatin 25 mg/m^2 on days 1 and 8 Q3W for up to 8 cycles. Coprimary endpoints were investigator-assessed 6-month PFS per RECIST v1.1 and safety and tolerability; secondary endpoints included median PFS, objective response rate (ORR), duration of response (DoR; all investigator-assessed per RECIST v1.1), and pharmacokinetics (PK). Tumoral PD-L1 expression, peripheral PD-1 and TIGIT receptor occupancy (RO), and T cell profiles were also evaluated. **Results:** Thirty pts were treated; median age was 60 years, 70.0% were Asian, and 83.3% had metastatic disease. As of Nov 4 2024, the median follow-up in all pts was 6.9 months (interquartile range 5.6–9.5) and rilve treatment was ongoing in 36.7% of pts. Efficacy and safety data are shown in the Table. The 6-month PFS rate was 73.0%; median PFS was 8.3 months. Median PFS was numerically longer in pts with PD-L1 tumor area positivity ≥1% (9.4 months, n = 18) vs the overall study population. The safety profile was manageable and consistent with prior studies. Rilve exposure was consistent with historical monotherapy data, indicating an absence of PK drug interactions and cross-indication differences. Rilve achieved ≥90% PD-1 and TIGIT RO on peripheral T cells and induced peripheral T cell proliferation. **Conclusions:** Rilve plus CTx demonstrated promising efficacy with a manageable safety profile and sustained target engagement. Longer follow-up for data maturity is warranted. Phase 3 studies with rilve in BTC (ARTEMIDE-Biliary 01; DESTINY-BTC01) are ongoing. Clinical trial information: NCT05775159. Research Sponsor: AstraZeneca.

4081 Poster Session

Combined treatment of durvalumab, bevacizumab and tremelimumab in subjects with hepatocellular carcinoma (HCC) or biliary tract carcinoma (BTC). First Author: Joy Awosika, Thoracic and Gastrointestinal Malignancies Branch, Center for Cancer Research, National Cancer Institute, National Institutes of Health, Bethesda, MD

Background: Anti-VEGF in combination with anti-PD1/PD-L1 represents a synergistic therapeutic strategy that has demonstrated efficacy, prolonging survival in cancers like HCC, RCC, and NSCLC. This combination induces modifications in the tumor microenvironment, leading to a reduction in immunosuppressive cells, improved dendritic cell maturation, antigen presentation, downregulation of immune checkpoint molecules, and enhanced T-cell activity. Combining CTLA-4 inhibitors with anti PD-1/PD-L1 enhances T-cell mediated anti-tumor responses by leveraging distinct yet complementary mechanisms. Targeting VEGF, PD-L1, and CTLA-4 pathways simultaneously in HCC and BTC provides a novel approach that hasn't been tested in clinical trials. Our group previously reported *in vivo* activity in murine BTC models and preliminary clinical results supporting this triplet combination in BTC. The aim of this study is to determine if VEGF inhibition with anti-CTLA-4 and anti-PD-LI therapy augments antitumor immunity and clinical responses in HCC and BTC patients. **Methods:** This was a Phase II trial conducted to evaluate efficacy of durvalumab, bevacizumab and tremelimumab in advanced HCC BCLC stage C or BTC. Participants received bevacizumab at 7.5mg/kg and durvalumab 1150mg every 3 weeks by IV infusion on Day 1 of Cycle 1 (durvalumab) and Day 1 of Cycle 2 (bevacizumab). Tremelimumab at a dose of 300mg was administered by IV infusion only once on Day 1 of Cycle 1. The combination of durvalumab and bevacizumab continued in 3-week cycles until disease progression or unacceptable toxicity. Primary endpoint was 6-month progression-free survival (PFS) and secondary endpoints were safety, overall survival (OS) and best overall response (BOR). Correlative studies assessing immune response were performed. **Results:** Between March 2021 and August 2024, 27 patients were enrolled (HCC: 6pts, BTC: 21pts). The median age was 66y (39-80) and 62% were male. 37% of the patients enrolled received prior ICI. As of November 4th, 2024, with a median follow-up of 8mos, mPFS was 3.5mos and mOS 9.5mos in all 27 efficacy-evaluable pts. The estimated 6 months PFS rate was 37%. The BOR was partial response in 4 pts (18%) followed by stable disease in 9pts (40%). The most common grade 3-4 TRAEs were lymphopenia (6pts, 22%), anemia (9pts, 33%), diarrhea/colitis (7pts, 25.9%), elevated lipase (4pts, 14.8%). Treatment discontinuation related to AEs occurred in 7pts (26%). One treatment-related death occurred secondary to an upper gastrointestinal bleed. **Conclusions:** The combination of durvalumab, bevacizumab and tremelimumab did not meet its primary endpoint but demonstrated a clinically meaningful overall survival benefit. No new safety signals were seen. Clinical trial information: NCT03937830. Research Sponsor: None.

4083 Poster Session

Outcomes by baseline tumor burden using the 6-and-12 score in EMERALD-1: A phase 3 study of durvalumab (D) ± bevacizumab (B) with transarterial chemoembolization (TACE) in embolization-eligible unresectable hepatocellular carcinoma (uHCC). First Author: Joseph Patrick Erinjeri, Interventional Radiology Service, Memorial Sloan Kettering Cancer Center, New York, NY

Background: In EMERALD-1 (NCT03778957), D + B + TACE significantly improved progression-free survival (PFS) vs TACE in participants (pts) with embolization-eligible uHCC. Tumor burden is a prognostic factor in HCC. Prior analyses showed improvements in PFS with D + B + TACE vs TACE in pts who met or exceeded the up-to-7 criterion (a measure based on tumor number and size), and in those with max tumor diameters of < 10 cm or ≥10 cm. The 6-and-12 score measures tumor burden based on tumor number and size. We assessed outcomes in EMERALD-1 by baseline tumor burden using the 6-and-12 score. **Methods:** Pts were randomized 1:1:1 to D + B + TACE, D + TACE, or TACE. Pts received D (1500 mg) or PBO for D (Q4W) + TACE. After completing the last TACE, pts received D (1120 mg) + B (15 mg/kg), D (1120 mg) + PBO for B, or PBOs for D and B (Q3W). In pts who received D + B + TACE and TACE, PFS, time to progression (TTP), and objective response rates (ORR), per BICR RECIST v1.1 in the intent-to-treat (ITT) population, and safety and number of TACE cycles in the safety analysis set (SAS; pts received ≥1 dose of study treatment [tx], regardless of randomization) are reported by baseline tumor burden using 6-and-12 scores: ≤6, > 6–12, or > 12. **Results:** Overall, 40.0%, 43.9%, and 16.2% of pts belonged to the ≤6, > 6–12, and > 12 groups, respectively. The number of pts who received ≥2 TACE cycles increased across the groups (≤6: 63.8%; > 6–12: 81.7%; > 12: 89.8%). PFS and TTP improved with D + B + TACE vs TACE, regardless of baseline tumor burden, with the best relative improvement in hazard ratios (HRs) in the > 12 group (Table). ORRs were higher for D + B + TACE vs TACE in all groups. Max Grade 3–4 tx-related adverse event (TRAE) frequencies were numerically higher with D + B + TACE vs TACE across tumor burden groups; differences were reduced when adjusted for exposure. No tx-related deaths occurred with D + B + TACE. **Conclusions:** PFS, TTP, and ORR benefits were seen with D + B + TACE vs TACE with manageable safety, regardless of tumor burden, further supporting a favorable risk-benefit profile with D + B + TACE in embolization-eligible uHCC. Clinical trial information: NCT03778957. Research Sponsor: AstraZeneca.

Phase I study of Ori-C101, an armored GPC3-directed CAR-T, in patients with advanced hepatocellular carcinoma (HCC). First Author: Jia Fan, Department of Liver Surgery and Transplantation, Liver Cancer Institute, Zhongshan Hospital, Fudan University; Key Laboratory of Carcinogenesis and Cancer Invasion (Fudan University), Ministry of Education, Shanghai, China

Background: Previously, we reported the results of Ori-C101 from investigator initiated trial in China (ChiCTR1900028121). The data demonstrated that Ori-C101 owned a favorable safety profile and promising efficacy. Among 10 GPC3$^+$ HCC patients (pts) treated with Ori-C101, 9 pts (90%) achieved disease control and 6 pts (60%) met partial response per RECIST 1.1. Two pts with PR attained progression-free survival of one and two years respectively, with an overall survival close to 3 years. These results implied that Ori-C101 potentially held significant clinical benefits. Subsequently, extensive optimizations and improvements in the manufacturing process were implemented to enhance its clinical efficacy and persistency. Hence, a multicenter registration study was launched in China (the BEACON study), and herein, we will present the preliminary results. **Methods:** This is an open-label, multi-center, dose-escalation (3+3 design) study. GPC3$^+$ advanced HCC pts who failed at least 2 lines of systemic treatments received a single hepatic arterial infusion with a total dose of 0.9 to 6×10^8 CAR-T cells. Primary endpoints are rate of dose-limiting toxicities (DLTs) and safety with the aim to determine a recommended phase II dose (RP2D). Secondary endpoints are cellular kinetics, overall response rate by investigator assessment, duration of response, overall survival and overall safety. **Results:** As of Dec 17th, 2024, a total of 10 eligible pts received Ori-C101 infusion at 3 dose levels (DLs). All pts had BCLC stage B or C, with 20% (2/10) had extrahepatic metastasis. The median number of prior lines of therapy was 4.5 (range 2-9), 100% pts received immune checkpoint inhibitors and tyrosine kinase inhibitors. All pts were evaluable for safety. All adverse events were reported regardless of study drug relationship. Of 10 pts evaluable for safety, the most common ≥ grade (G) 3 AEs were lymphocyte count decreased (100%), neutrophil count decreased (60.0%), blood fibrinogen decreased (40.0%), transaminases increased (40.0%), platelet count decreased (20.0%), blood bilirubin increased (20.0%). CRS was observed in 10 (100%) pts with 3 (30.0%) ≥ G3 CRS. No ICANS was observed. One pt developed DLT event due to CRS and secondary disseminated intravascular coagulation. 9 pts were evaluable for efficacy per RECIST 1.1. While 6 pts (66%) achieved disease control at DL2 or higher, all pts at the DL3 achieved objective response. Particularly, one pt who achieved CR showed encouraging durability and no signs of relapse at 9 months follow up evaluation, and follow up is ongoing. **Conclusions:** These preliminary data showed Ori-C101 has manageable safety profile and exciting efficacy with encouraging sign of good durability. Currently, more pts have been enrolled at dose expansion to confirm the DLs of RP2D. More information will be presented at coming ASCO conference. Clinical trial information: NCT05652920. Modifiable risk-factors, genetic characteristics, and survival in early-onset cholangiocarcinoma. First Author: Jordan Nunnelee, Mayo Clinic, Rochester, MN

Background: Cholangiocarcinoma (CC) is a rare disease with an increasing incidence among younger adults, which is poorly understood. Genomic profiling of tumors is both prognostic and predictive of benefit for targeted therapies. We investigated if there are clinical and molecular differences between younger vs older patients with CC. **Methods:** We collected TEMPUS genetic data via retrospective chart review from tumors in young vs old patients seen at our institution, defined as $\leq$50 vs $>$ 50 years of age at time of diagnosis. We included patients diagnosed with CC between January 2008 and July 2024 with available clinical follow up and TEMPUS genetic sequencing data. We collected mutation data on the following actionable genes: FGFR2, IDH1/2, BRCA1, BRCA2, BRAF, ATM, ERBB2/3, and KRAS. Patient characteristics and gene expression variables were compared using Chi-square, Fisher's exact and Wilcoxon rank-sum tests. Kaplan-Meier, log rank tests and a multivariable Cox model were used for survival analysis. This study was IRB exempt. **Results:** We included 410 patients, 84 in the young group with median age at diagnosis of 40.8 years, and 326 in the old group with median age 68.5 years. 91.5% of patients were white. There was no difference in BMI between groups, however the older group had higher rates of hypertension (15.5% vs 57.7%), hyperlipidemia (6.0% vs 49.7%), cardiovascular disease (1.2% vs 20.6%), and type 2 diabetes (6.0% vs 21.5%), (all $p < 0.01$). Primary sclerosing cholangitis was more common in the young group (26.2% vs 4.3%, $p < 0.01$). ECOG status of 0 at first treatment was seen in 65.3% of young vs 52.5% of old patients ($p = 0.02$). FGFR2 alterations were more common in the young group (17.9% vs 8.0%, $p < 0.01$), while ATM mutations were more common in old vs young (5.5% vs 0%, $p = 0.03$). There was no age difference seen for the other genetic alterations. Mean tumor mutational burden was higher in the old group (4.1 vs 3.8 mut/mb, $p = 0.01$). MSI-high was found in 2% of cases with no difference between groups. There was no significant difference in overall survival between age groups. There was a numeric difference in overall survival in stage IV patients, though not statistically significant (17.8 months vs. 16.3 months, $p = 0.08$). In a multivariable Cox analysis, female sex, earlier stage at diagnosis and clinical trial enrollment were associated with favorable prognostics. **Conclusions:** Our data highlight relatively low rates of comorbidities associated with metabolic dysfunction in younger adults with CC, suggesting alternative factors are likely to explain the increasing incidence of early-onset disease. FGRFR2 is a more common pathogenic alteration among the young and could inform targeted therapies. Younger patients with CC may not have improved survival outcomes compared to their older counterparts. This underscores the aggressive nature of CC and the need for more effective therapies to improve outcomes. Research Sponsor: None.

Real world efficacy and safety of ivosidenib in US veterans with IDH1 mutated cholangiocarcinoma. First Author: Katherine Ismei Zhou, Durham VA Health Care System and Duke University, Durham, NC

Background: IDH1 mutations occur in 13% of patients with intrahepatic cholangiocarcinoma. Ivosidenib is FDA approved for the treatment of advanced, previously treated, IDH1-mutated cholangiocarcinoma. In the ClarIDHy trial, ivosidenib led to an objective response rate of 2%, stable disease rate of 51%, median progression-free survival (PFS) of 2.7 months, and median overall survival (OS) of 10.3 months. Treatment-emergent adverse events resulted in study drug discontinuation in 7% of patients. Data on the real-world efficacy and safety of ivosidenib in cholangiocarcinoma remains limited. **Methods:** Patients with IDH1-mutated cholangiocarcinoma who were prescribed ivosidenib before December 1, 2024, were retrospectively identified from the national Veterans Affairs (VA) Corporate Data Warehouse. Demographic, clinical, and molecular data were abstracted from the National Precision Oncology database and electronic medical records. Response was assessed based on provider notes and radiology reports. Survival was assessed by the Kaplan-Meier method, and covariates evaluated by the Cox proportional hazards model. **Results:** Of 1094 veterans with cholangiocarcinoma who underwent molecular testing, 82 (7.5%) had an IDH1 mutation. 33 (40%) patients received ivosidenib at 27 VA medical centers. The median age was 74 years (range 46–82). 2 patients (6%) had a partial response (PR), 10 (30%) had stable disease (SD), 19 (58%) had progressive disease, and 2 were not assessed. 20 patients (60%) had received one and 5 patients (15%) received two prior lines of therapy. Of the 8 patients (24%) who received first-line ivosidenib, 2 (25%) had a PR and 3 (38%) had SD. Most patients (94%) started ivosidenib at the labeled dose (500 mg daily). Two patients who started ivosidenib at reduced dose (250 mg daily) had PR and SD as their best response. The median PFS from start of ivosidenib was 4.0 months, and the median OS was 10.5 months. In a multivariable analysis, PFS and OS were not significantly associated with age, line of therapy, IDH1 variant allele frequency, or IDH1 mutation (17 IDH1 R132C vs. 8 other). Patients with IDH1-mutated, advanced cholangiocarcinoma treated with ivosidenib had a median OS of 25.3 months from diagnosis, compared to 8.7 months for patients who did not receive ivosidenib. Toxicities leading to dose reduction, interruption, or discontinuation of ivosidenib occurred in 3 patients (9%). **Conclusions:** In this real-world cohort, patients with IDH1-mutated advanced cholangiocarcinoma treated with ivosidenib had similar response rate, PFS, and OS compared to ClarIDHy. Toxicities leading to dose reduction, interruption, or discontinuation were rare. The only two partial responses were observed in the first-line setting, including one with a reduced starting dose. This suggests that frontline ivosidenib may be a reasonable alternative for patients with advanced cholangiocarcinoma. Research Sponsor: None.

HAIC plus TAE combined with tislelizumab and surufatinib in unresectable intrahepatic cholangiocarcinoma: The REACH-01 trial. First Author: Kangshuai Li, Qilu Hospital of Shandong University, Jinan, Shandong, China

Background: REACH-01 (NCT06239532) is a single-arm, open label, prospective trial, aiming to evaluate the safety and preliminary effectiveness of hepatic artery infusion chemotherapy (HAIC) plus transcatheter arterial embolization (TAE) combined with tislelizumab and surufatinib as first-line therapy for unresectable intrahepatic cholangiocarcinoma (iCCA). **Methods:** Twenty-eight patients with pathologically confirmed iCCA received TAE with undrugged microspheres and hepatic arterial infusion of oxaliplatin (85 mg/m^2) and raltitrexed (3 mg/m^2) at an interval of at least 3 weeks along with intravenous tislelizumab (200 mg) Q3W and oral surufatinib (150 - 250 mg) once daily. The primary endpoint was the objective response rate (ORR). Secondary outcomes included progression-free survival (PFS), conversion to surgical resection rate, overall survival (OS), 1-year OS rate, disease control rate (DCR), and incidence of adverse events. **Results:** As of December 18, 2024, the median follow-up time was 9.33 months, 15 patients achieved partial response and the ORR was 57.69 % per RECIST v1.1 criteria. The conversion to surgical resection rate was 15.38 %. The DCR was 80.77 %. Secondary endpoints of progression-free survival, overall survival and 1-year OS rate were not mature at the time of the analysis. Further, treatment related adverse effects (TRAEs) of any grade occurred in 28 patients. Manageable grade 3 adverse events (AEs) occurred in 32.14% of patients, commonly elevated alanine aminotransferase (7.14%), anorexia (7.14%), and hypokalemia (7.14%). **Conclusions:** HAIC plus TAE combined with tislelizumab and surufatinib are safe and promising first-line treatment selection for unresectable iCCA. Clinical trial information: NCT06239532. Research Sponsor: Key Research and Development Program of Shandong Province; 2021CXGC011105; BeiGene Co. Ltd.

Efficacy and safety of regorafenib combination with PD-1 inhibitors vs. regorafenib monotherapy in second-line treatment for patients with unresectable hepatocellular carcinoma after failure of different first-line treatments: A multicenter retrospective real-world study. First Author: Weihong Ma, Comprehensive Liver Cancer Center, The 5th Medical Center of PLA General Hospital, Beijing, China

Background: Regorafenib is the first oral targeted drug as a second-line agent in patients with unresectable hepatocellular carcinoma (HCC) who progressed on sorafenib treatment.There is a lack of data to validate the second-line therapy after progression of targeted-immune combination therapy. Our aim was to investigate the efficacy and safety of regorafenib alone or in combination with a programmed death-1 (PD-1) inhibitor in second-line treatment for patients who have failed tyrosine kinase inhibitor (TKI) in combination with PD-1 or TKI monotherapy, respectively. **Methods:** A total of 288 patients were enrolled in this multicenter, retrospective study. These patients received regorafenib with or without PD-1 inhibitor (Sintilimab/Camrelizumab/Pembrolizumab) as second-line therapy after failure of TKI (sorafenib/lenvatinib) or such TKIs combined with PD-1 inhibitor (Sintilimab/Camrelizumab/Pembrolizumab). The primary study endpoint was the evaluation of overall survival (OS), while secondary study endpoints were progression-free survival (PFS), objective response rate (ORR), disease control rate (DCR), and treatment safety. **Results:** In the first line treatment, 126 patients received TKI and 162 patients received TKI plus PD-1. In the TKI cohort, the Reg-PD-1 group exhibited markedly higher ORR (29.69% vs 4.84%; $p<0.001$) and DCR (89.06% vs 67.74%; $p=0.004$), as well as longer median PFS (10.5 vs 4.7 months; $p<0.001$) and median OS (18.9 vs 14.0 months; $p=0.03$) compared to the Reg monotherapy group.There was no significant difference in PFS, OS, ORR, and DCR between the two groups in the TKI plus PD-1 cohort.The incidence of AEs was higher in the Reg-PD-1 group compared to the Reg group (81.25 % vs 58.06%; $p=0.005$) in the TKI cohort. And Reg-PD-1 group was comparable to Reg group (76.70% vs 66.10%; $p=0.144$) in the TKI Plus PD-1 cohort. **Conclusions:** Regorafenib plus PD-1 may enhance efficacy in uHCC patients who failed first-line TKI therapy. However, in patients who have progressed after first-line TKI plus PD-1 therapy, using regorafenib alone or in combination with PD-1 in second-line therapy does not show a significant difference in efficacy.These findings have significant implications for the selection of second-line treatment strategies for HCC patients, indicating that the combination of regorafenib and PD-1 might not provide additional benefits in certain patient subgroups. Research Sponsor: None.

Characterization of CLDN18 expression in a Western biliary tract cancer population. First Author: Alexander Bray, University of Michigan, Ann Arbor, MI

Background: Patients with advanced biliary tract cancer (BTC) have poor survival despite recent advances in chemoimmunotherapy. Claudin 18 (CLDN18) directed therapy has shown benefit in combination with FOLFOX or CAPOX in gastric cancer and may also have therapeutic utility in advanced BTC. However, there are limited data on CLDN18 RNA and protein expression in BTC, especially in Western populations. **Methods:** Exome-capture based RNA sequencing was performed on BTC tissue samples through the MI-ONCOSEQ study at the University of Michigan. Fragments per Kilobase of transcript per Million mapped reads (FPKM) was used to normalize raw read counts. Immunohistochemical staining was completed on a BTC tissue microarray (n = 28), and Western blotting was done on human BTC cell lines (SNU-1079, RBE, and SSP-25) using CLDN18 recombinant rabbit monoclonal antibody (34H14L15, Invitrogen). Statistical significance was defined as $p < 0.05$. **Results:** We identified transcriptomic data from 148 consecutive BTC cases with median age 61 (range 17-81) years and 75 (50.7%) were female. Of these patients, 45 (30.4%) expressed CLDN18 mRNA with FPKM > 1. A lower proportion of intrahepatic cholangiocarcinoma (CCA) patients (n = 23/110; 20.9%) expressed CLDN18 mRNA relative to extrahepatic CCA (n = 13/25; 54.2%) and gallbladder cancer (n = 8/11; 72.7%) ($p < 0.006$). CLDN18 mRNA expression was not associated with stage at diagnosis, but was higher in metastatic versus primary sites (35.6 vs 16.1%, $p < 0.05$). Overall survival was not associated with CLDN18 gene expression in univariate analysis (hazard ratio 1.02, $p > 0.9$). CLDN18 protein expression was observed in 8/28 (28.6%) patients using a cutoff defined in prior gastric cancer clinical trials (2+ to 3+ staining intensity in $\geq$ 75% of tumor cells). In human BTC cell lines, SSP-25 expressed CLDN18, but the SNU-1079 and RBE lines did not. **Conclusions:** CLDN18 is expressed in a modest subset of Western patients with advanced BTC and CLDN18-directed therapy may be effective in this disease, particularly in ECC and gallbladder cancer given their higher frequency of expression. CLDN18 positive human BTC cell lines represent a promising preclinical model system for further investigation of this therapeutic strategy. TACE-HAIC combined with donafenib and immune checkpoint inhibitors for BCLC stage C HCC patients (THEME study): A retrospective IPTW adjusted cohort study. First Author: Linan Yin, Harbin Medical University Cancer Hospital, Harbin, China

Background: Transarterial chemoembolization (TACE) combined with hepatic arterial infusion chemotherapy (HAIC) has demonstrated superior objective response rate (ORR) and progression-free survival (PFS) compared to TACE alone, particularly in patients with unresectable hepatocellular carcinoma (uHCC) with portal vein tumor thrombosis (PVTT), as shown in previous studies. Additionally, Donafenib exhibited significant survival benefits and better safety profiles compared to Sorafenib in a Phase III clinical trial. We aimed to retrospectively compare the efficacy and safety of TACE-HAIC combined with Donafenib and immune checkpoint inhibitors (Quadruple Therapy Group) versus the standardized targeted therapy (TKIs or bevacizumab) plus immune checkpoint inhibitors (Targeted-Immunotherapy Group) in patients with BCLC stage C hepatocellular carcinoma (HCC). **Methods:** We conducted a retrospective analysis of patients with BCLC stage C hepatocellular carcinoma (HCC) who received quadruple therapy or targeted-immunotherapy at the Harbin Medical University Cancer Hospital between September 2019 and October 2024. To minimize baseline imbalances between the groups, we applied stabilized inverse probability of treatment weighting (sIPTW) methods. **Results:** A total of 195 patients were included in the study, of whom 125 were assigned to the Quadruple Therapy Group and 70 to the Targeted-Immunotherapy Group. Within the Targeted-Immunotherapy Group, 44 patients received TKIs combined with immune checkpoint inhibitors, while 26 patients received bevacizumab combined with immune checkpoint inhibitors. After applying sIPTW to balance the baseline characteristics between the two groups, patients in the Quadruple Therapy Group demonstrated a significantly higher median overall survival (OS) compared with the Targeted-Immunotherapy Group(29.4 months [95% CI: 23.9–NA] vs 18.0 months [14.7–31.8]; P = 0.045). Additionally, the median progression-free survival (PFS) assessed by the modified Response Evaluation Criteria in Solid Tumors (mRECIST) was longer in the Quadruple Therapy Group(16.4 months [95% CI: 12.7–NA] vs 10.0 months [3.3–31.8]; P = 0.013). The objective response rate (ORR) evaluated according to mRECIST was also higher in the Quadruple Therapy Group(68.4% vs 28.2%, $P < 0.001$).The incidence of any adverse events in the Quadruple Therapy Group was 95.2%, compared with 97.1% in the Targeted-Immunotherapy Group.Among these the incidence of grade $\geq$3 adverse events was 40.8% in the Quadruple Therapy Group and 38.6% in the Targeted-Immunotherapy Group. **Conclusions:** Compared with Targeted-Immunotherapy Group, patients with BCLC stage C HCC treated with TACE-HAIC combined with Donafenib and immune checkpoint inhibitors therapy demonstrated superior efficacy and acceptable safety. Research Sponsor: None.

Multimodal evaluation of metabolic dysfunction–associated steatotic liver disease (MASLD)–related biliary tract cancer (BTC) and immunotherapy outcomes. First Author: Nakul Manish Shah, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Rising incidence of BTC, particularly intrahepatic cholangiocarcinoma (iCCA), may be linked to increasing incidence of obesity, MASLD and type 2 diabetes mellitus (T2DM). Immunotherapy with immune checkpoint inhibitors (ICIs) has modestly extended survival in biliary tract cancer. However, the prevalence of MASLD in BTC, its immune microenvironment (TME) and outcome of MASLD-BTC with ICIs are unknown. **Methods:** Retrospective analysis of BTC patients (pts) treated with ICI between 5/2021-5/2024 with durvalumab, cisplatin, and gemcitabine. We used American Association for Liver Diseases (AASLD) criteria for MASLD: 1) metabolic dysfunction and 2) steatosis on imaging or biopsy. We calculated liver proton-density fat fraction (PDFF) in pre-treatment non-contrast CT scans (PDFF estimate 5% labelled as steatosis). We examined the statistical association between BMI and both tumor genotype and gene expression patterns using data from institutional genomic platforms (MAPP2 and RTI). **Results:** 179 BTC pts (65% of whom were iCCA) treated with durvalumab, cisplatin, and gemcitabine, 103 (57.5%) met AASLD MASLD criteria. In evaluable pts, the median overall survival (OS) was 18.4 months, and median follow-up time was 16.7 months. Non-MASLD pts had a median OS of 23.0 months (95% CI: 16.2, NA) versus 16.7 months (95% CI: 12.4, 21.2) with MASLD (p = .056). T2DM was associated with a worse OS (10.6 versus 21.2 months, p = .004). Multivariable cox model for OS demonstrated a hazard ratio (HR) of 1.45 (95% CI: 0.87, 2.4; p = .1564) for MASLD and 1.61 (95% CI: .99, 2.65; p = .0575) for T2DM. The median progression-free survival (PFS) was 8.5 months. MASLD BTC had a median PFS of 8.2 months (95% CI: 5.7, 10.1) versus 9.2 months (95% CI: 6.9, 16.2) without MASLD (p = .459). BTC pts with T2DM had median PFS of 5.8 months vs 13.0 months without T2DM (p = .001). Multivariable cox model for PFS had HR of 1.7 (95% CI: 1.1, 2.6; p = .014) for T2DM. Within our institutional database (n = 919), we observed depletion of *KRAS* (p = .008) and *STK11* (p = .02) mutations in BTC pts with high BMI. RNA-seq (n = 77) suggests that elevated BMI was associated with low expression of pan-immune and epithelial-to-mesenchymal transition and increased expression of oxidative phosphorylation signatures. **Conclusions:** BTC is commonly associated with MASLD and may correlate with reduced OS and PFS with ICI, particularly in T2DM pts. Our findings suggest a distinct immunogenomic signature in MASLD-BTC and highlight the importance of further investigating the TME in this population. Research Sponsor: None.

Phase 1 expansion study of FF-10832 (liposomal gemcitabine) antitumor activity in patients with advanced biliary carcinomas. First Author: Gerald Steven Falchook, Sarah Cannon Research Institute at HealthONE, Denver, CO

Background: FF-10832 has demonstrated improved pre-clinical anti-tumor activity compared to gemcitabine (GEM). Associated factors may include its prolonged circulating half-life, tumor accumulation, and immune activation.The first in human dose finding trial of FF-10832 demonstrated a tolerable safety profile and anti-tumor activity in heavily pre-treated patients (pts) with solid tumors who progressed on prior gemcitabine. A biliary tract cancer (BTC) pt maintained a PR $>$60 weeks after progression on prior GEM based therapy. We subsequently enrolled an expansion cohort evaluating FF-10832 monotherapy in BTC and describe the results (NCT03440450). **Methods:** Pts $\geq$18 years with advanced BTC who had progressed on up to 3 lines of therapy were treated with FF-10832 40 mg/m^2 IV Day 1 Q 21 days until disease progression or unacceptable toxicity. Response was assessed by RECIST 1.1. Modulation of immune cells (flow cytometry/multiomics) and population PK were assessed. **Results:** 18 pts [12M/6F; median age 68 (34-79), ECOG PS 0 (3) PS 1 (15)] were treated; median # prior therapies, 2 (1-3); all had prior GEM and 16 had progressed on prior GEM. Pts received a median of 4 (1 - 22+) cycles with a median time on study of 10.4 (3.3 -77+) weeks. FF-10832 was well-tolerated. The most common drug-related AEs were nausea, pyrexia, and decreased appetite (39% each). No Gr 4 toxicity was observed; Gr 3 AEs in $>$1 pt included anemia (2) and muscular weakness (2). All AEs were successfully managed using standard therapies. Two pts withdrew and 1 pt died of cholangitic sepsis before 1st evaluation. Best overall response in 15 remaining pts was 2 PR, 8 SD, 4 PD and 1 NE. The median PFS and OS were 3.4 and 9.1 months, respectively. Both PRs had received prior GEM/platinum-based therapy: 1) a gallbladder adenocarcinoma pt achieved a 48% decrease in target lesions with FF-10832 by cycle 2, which was maintained through cycle 10; dose was reduced to 30 mg/m^2 at cycle 5 for Gr 3 muscle weakness, 2) a hilar cholangiocarcinoma pt achieved a PR by cycle 2,with complete resolution of target lesions before withdrawing. Four additional pts maintained SD $\geq$ 6 cycles, with 2 continuing on therapy after 9 and 26 cycles. PK was similar to that previously reported (terminal $t_{1/2,}$ 30 hours), with similar log decreases observed in Ki67+ regulatory T cells and increases observed in CD8+ cells, indicative of anti-tumor immune activation. **Conclusions:** FF-10832 is well-tolerated and has anti-tumor activity in pts with advanced BTC who progressed on prior GEM. Although preliminary, these results of a single agent therapy compare favorably to those reported for 2nd line combination therapies. This warrants further investigation of FF-10832 efficacy and safety in BTC patients. Clinical trial information: NCT03440450. Research Sponsor: FUJIFILM Pharmaceuticals USA Inc.

SHR-8068 plus adebrelimab and bevacizumab for advanced hepatocellular carcinoma (aHCC): A phase 1b/2 study. First Author: Lianxin Liu, The First Affiliated Hospital of the University of Science and Technology of China/Anhui Provincial Hospital, Hefei, China

Background: Combination of an anti-PD-1/L1 antibody with an anti-angiogenic agent is currently the preferred 1L treatment for aHCC. Addition of a CTLA-4 inhibitor may further improve anti-tumor activity, with complementary immunostimulatory effects from CTLA-4 and PD-1/L1 blockade. We conducted a multicenter, open-label, phase 1b/2 trial (NCT05444088) to assess SHR-8068, a novel anti-CTLA-4 monoclonal antibody (mAb), combined with adebrelimab (A, anti-PD-L1 mAb) and bevacizumab (B) in patients (pts) with aHCC. **Methods:** Pts with or without prior treatment were enrolled (phase 1b: failed or refused standard therapy; phase 2: ≤1L systemic therapy, no immunotherapy [IO]). SHR-8068 was evaluated in 2 dosing regimens with AB: 1 mg/kg Q6W (Combo 1) or 4 mg/kg priming dose (Combo 2). An additional cohort evaluated AB alone (Combo 3). A was dosed at 20 mg/kg Q3W and B at 15 mg/kg Q3W for all regimens. **Results:** As of Oct 31, 2024, a total of 27, 53 and 21 pts received Combo 1, 2, and 3, respectively, across 2 study phases (overall: IO naïve, 97.0%; prior anti-angiogenic therapy, 32.7%); median follow-up was 16.7, 11.1 and 11.3 mo, respectively. In pts treated with Combo 2, the objective response rate (ORR) was 47.2% (25/53; 95% CI 33.3%–61.4%), with a median duration of response (DoR) of 12.7 mo (95% CI 5.8–NR). The median progression-free survival (PFS) was 8.7 mo (95% CI 5.5–11.6); median overall survival (OS) was not reached, with a 12-mo OS rate of 76.0% (95% CI 59.3%–86.6%). Numerically improved ORR and survival outcomes were seen with Combo 2 *vs* Combo 1 and 3 (Table 1). Overall, grade ≥3 treatment-related adverse events (TRAEs) occurred in 55.6%, 41.5% and 42.9% of pts with Combo 1, 2 and 3. The most common grade ≥3 TRAEs (incidence ≥10% for any Combo) were decreased platelet count (22.2%, 5.7%, and 4.8% for Combo 1, 2, and 3) and hypertension (18.5%, 7.5%, and 9.5%, respectively). TRAE led to discontinuation of any study agent in 11.1%, 1.9% and 9.5% of pts, respectively. There was 1 treatment-related death (Combo 3). **Conclusions:** SHR-8068 combined with adebrelimab and bevacizumab showed promising efficacy and manageable safety in aHCC. A more favorable benefit-risk profile was observed for SHR-8068 given as a priming dose. A phase 3 trial (NCT06618664) is currently underway to further assess the combination as 1L treatment for aHCC. Clinical trial information: NCT05444088. Research Sponsor: Jiangsu Hengrui Pharmaceuticals, Co., Ltd.

Hepatic arterial infusion chemotherapy combined with donafenib and tislelizumab versus transcatheter chemoembolization alone for hepatocellular carcinoma: A propensity score matching study. First Author: Zhongguo Zhou, Department of Liver Surgery, Sun Yat-Sen University Cancer Center, Guangzhou, Guangdong, China

Background: Although tyrosine kinase inhibitors combined with PD-1/L1 inhibitors have been established as first-line treatment for advanced hepatocellular carcinoma (HCC), the survival benefit remains unsatisfactory. Hepatic arterial infusion chemotherapy (HAIC) has emerged as an effective therapy to improve the prognosis of HCC patients. This study aimed to investigate the efficacy and safety of HAIC combined with donafenib and tislelizumab in HCC. **Methods:** 421 patients diagnosed as HCC and treated in Sun Yat-sen University Cancer Center from January 2017 to December 2024 were enrolled in this retrospective study, included 151 patients received FOLFOX-HAIC combined with donafenib and tislelizumab (DT-HAIC) and 270 received transcatheter chemoembolization (TACE) alone. To avoid the selection bias and balance covariates, we conducted propensity score matching (PSM). The primary outcomes are progression-free survival (PFS) and overall survival (OS); the secondary outcomes include objective response rate (ORR), disease control rate (DCR) and safety. Tumor response was evaluated per RECIST v1.1. **Results:** PSM resulted in 151 matched pairs with comparable baseline characteristics between the DT-HAIC and TACE cohorts. Compared with the TACE cohort, Patients receiving DT-HAIC exhibited significantly better median PFS (10.3 vs 4.9 months, $P < 0.01$) and median OS (not reached vs 10.9 months, $P < 0.01$). The ORR and DCR were significantly higher in the DT-HAIC cohort than in the TACE cohort (ORR: 33.8% vs 11.3%, $P < 0.01$; DCR: 77.9% vs 65.3%, P = 0.03). There was no treatment-related death. Serious adverse events were similar between the two groups, except for alanine aminotransferase (ALT), aspartate aminotransferase (AST), platelet count, abdominal pain and allergic reaction. In the TACE cohort, the occurrence of Grade 3-4 elevations in ALT (11.3% vs 21.9%, P = 0.02) and AST (21.2% vs 36.4%, $P < 0.01$), as well as abdominal pain (2.6% vs 16.6%, $P < 0.01$), was more prevalent. In contrast, the DT-HAIC cohort exhibited a higher incidence of Grade 3-4 thrombocytopenia (11.3% vs 1.3%, $P < 0.01$) and allergic reactions (4.6% vs 0, P = 0.02). **Conclusions:** DT-HAIC significantly improved PFS, OS, ORR, and DCR compared with TACE alone, with manageable adverse events, suggesting that the combination of HAIC with donafenib and tislelizumab may be a promising treatment option for HCC patients. Research Sponsor: None.

	DT-HAIC (n=151)	TACE (n=151)	P Value
mPFS	10.3m	4.9m	P<0.01
mOS	Not reached	10.9m	P<0.01
ORR	33.8%	11.3%	P<0.01
DCR	77.9%	65.3%	P=0.03

LEAP-002 long-term follow-up: Lenvatinib plus pembrolizumab versus lenvatinib plus placebo for advanced hepatocellular carcinoma. First Author: Richard S. Finn, David Geffen School of Medicine at UCLA, Los Angeles, CA

Background: LEAP-002 was a randomized, double-blind, phase 3 study (NCT03713593) that was conducted to evaluate the efficacy and safety of first-line lenvatinib plus pembrolizumab versus lenvatinib plus placebo in participants with advanced hepatocellular carcinoma (HCC). The study did not meet its primary end points of OS at final analysis and PFS at interim analysis. After a median study follow-up of 43.6 months, OS, PFS, and ORR remained consistent with the primary efficacy analysis (OS: HR, 0.84 [95% CI, 0.71-0.98]; PFS: HR, 0.81 [95% CI, 0.69-0.95]; ORR, 26.3% vs 17.5%); no new safety signals were observed. Here, we present results based on an additional 15 months of follow-up. **Methods:** Eligible participants with advanced HCC were randomly assigned 1:1 to receive lenvatinib (8 mg/day if bodyweight [BW] < 60 kg; 12 mg/day if BW ≥60 kg) plus pembrolizumab (200 mg IV Q3W) or lenvatinib plus placebo. Dual primary end points were OS and PFS (per RECIST v1.1 by BICR). Secondary end points included ORR and DOR, both per RECIST v1.1 by BICR, and safety. The database cutoff was September 24, 2024. **Results:** 794 participants were randomly assigned to receive lenvatinib plus pembrolizumab (n = 395) or lenvatinib plus placebo (n = 399). Median study follow-up was 59.2 mo (range, 52.9-68.3). The HR for OS was 0.80 (95% CI, 0.69-0.94; median, 21.1 months with lenvatinib plus pembrolizumab vs 19.0 months with lenvatinib plus placebo). 60-month OS rates were 19.7% with lenvatinib plus pembrolizumab versus 10.7% with lenvatinib plus placebo. Grade 3-5 treatment-related adverse event (AE) rates were 62.8% with lenvatinib plus pembrolizumab and 58.0% with lenvatinib plus placebo. No additional deaths due to treatment-related AEs were reported since the final analysis (database cutoff, June 21, 2022). Overall, 47.3% of participants treated with lenvatinib plus pembrolizumab versus 56.1% of participants treated with lenvatinib plus placebo received subsequent systemic therapy (TKI/VEGF, 38.5% vs 42.6%; immunotherapy, 17.2% vs 26.8%; chemotherapy, 5.3% vs 4.0%); 21.5% versus 25.6% received subsequent liver-directed therapy (locoregional therapy, 20.0% vs 23.8%; surgery, 2.8% vs 2.8%). **Conclusions:** The LEAP-002 study did not meet its primary end points; however, with a long-term follow-up of 5 years, almost twice as many participants randomly assigned to receive lenvatinib plus pembrolizumab versus lenvatinib plus placebo were alive at database cutoff; no new safety signals were observed. Clinical trial information: NCT03713593. Research Sponsor: Eisai, Inc., Nutley, NJ, USA, and Merck Sharp & Dohme LLC, a subsidiary of Merck & Co., Inc., Rahway, NJ, USA.

Membrane-specific HER2 expression by artificial intelligence-based quantitative scoring for prediction of efficacy of trastuzumab deruxtecan in biliary tract cancer (HERB trial): Exploratory analysis of a multicenter, single arm, phase II trial. First Author: Mitsuho Imai, Translational Research Supporting Office, National Cancer Center Hospital East, Kashiwa, Japan

Background: Trastuzumab deruxtecan (T-DXd) showed promising results in patients with HER2-positive biliary tract cancer (BTC). With T-DXd's expanding indication into HER2-low cancers, quantitative Artificial Intelligence (AI)-based scoring of HER2 expression at the cellular level becomes increasingly important. This study investigated whether the intensity and subcellular pattern of HER2 staining would correlate with response to T-DXd. **Methods:** HER2 immunohistochemistry (IHC) whole slide images from the phase II HERB trial were analyzed. These participants had unresectable or recurrent BTC refractory or intolerant to gemcitabine-containing regimen and received T-DXd based on confirmed HER2-positive or low status. Lunit SCOPE universal IHC, a deep learning based IHC analyzer, was used to provide cell level classes (AI-H0, H1+, H2+, H3+) and continuous scoring of HER2 staining intensities of subcellular compartments (membrane, cytoplasm and nucleus) for each tumor cell. Membrane specificity was calculated for each cell as the ratio of membrane intensity to the sum of all three subcellular compartments. **Results:** The 29 patients analyzed showed continuous improvement in response rates with an increasing proportion of AI-H3+ cells. The ORR was 37.5%, 42.9% and 50.0% for patients with more than 10%, 25%, and 50% of tumor cells classified as AI-H3+, respectively. The HER2 intense cohort (n=4), defined by tumors with over 50% of tumor cells classified as AI-H3+, had a significantly better PFS (HR 0.15, $p<0.05$) and OS (HR 0.10, $p<0.05$) compared to the rest of the treatment group. The high membrane specificity group defined by ≥80% of tumor cells with membrane specificity ≥0.4 (N=6) had a confirmed ORR of 50%. These patients also demonstrated significantly longer PFS (HR 0.30, $p<0.05$) and OS (HR 0.27, $p<0.05$). The six cases identified by membrane specificity included all four cases of the HER2 intense cohort and two more cases, showing improved sensitivity in identifying likely responders. **Conclusions:** AI based quantification of HER2 intensity and membrane specificity was predictive of therapeutic response to T-DXd in HER2 expressing BTC. Membrane specificity analysis was more sensitive in identifying exceptional responders compared to intensity alone. Research Sponsor: None.

A prospective, observational phase II clinical study evaluating hepatic artery infusion chemotherapy in combination with HLX10 and HLX04 as first-line treatment for patients with advanced hepatocellular carcinoma. First Author: Huikai Li, Department of Hepatobiliary and Pancreatic Oncology, Tianjin Cancer Hospital Airport, Tianjin, China

Background: Advanced hepatocellular carcinoma (HCC) presents limited treatment options. Immunotherapy has emerged as an effective treatment, demonstrating encouraging outcomes and acceptable adverse reactions in advanced HCC. This study aims to assess the efficacy and safety of HLX10 (recombinant anti-PD-1 humanized monoclonal antibody) and HLX04 (recombinant anti-VEGF humanized monoclonal antibody), in combination with hepatic artery infusion chemotherapy (HAIC), as first-line treatment for advanced HCC. **Methods:** This prospective, observational, single-center Phase II trial enrolled untreated HCC patients with BCLC stage C. All patients received HLX10 (4.5 mg/kg, intravenous infusion, every 3 weeks) and HLX04 (15.0 mg/kg, intravenous infusion, every 3 weeks) on Day 1 of each treatment cycle, followed by HAIC with the FOLFOX regimen. HAIC was administered for a maximum of 8 cycles, while HLX10 and HLX04 were continued for up to 2 years, until death, disease progression, or intolerable toxicity occurred. The primary endpoint was the objective response rate (ORR), assessed by the investigator according to RECIST v1.1 criteria. Secondary endpoints included the disease control rate (DCR), progression-free survival (PFS), and safety. **Results:** Between August 2023 and September 2024, a total of 35 eligible patients were enrolled in the study. As of the data cut-off, 28 (80.0%) patients had received at least 3 cycles of treatment. Of the 35 patients, 32 underwent at least one assessment of treatment response, with the best outcomes as follows: 17 (53.1%) achieved partial remission (PR), and 12 (40.0%) had stable disease (SD). The ORR and DCR were 53.1% and 90.6%, respectively. Notably, among patients who had received at least 3 cycles of treatment, 17 patients achieved PR, resulting in an ORR of 63.0%. Moreover, 5 patients underwent successful hepatectomy after at least 3 cycles of treatment, and postoperative pathological evaluation revealed extensive tumor necrosis in the excised tissues. The median follow-up duration was 8.4 months, during which 6 (18.8%) patients experienced disease progression, yielding a one-year PFS rate of 70.5% (95% CI: 47.0%–85.0%). In terms of safety, 17 patients (48.6%) experienced at least one grade 3 or 4 adverse event (AE), with the most frequent being decreased lymphocyte count (20%). **Conclusions:** The combination of HLX10, HLX04, and HAIC as first-line treatment for advanced HCC has demonstrated promising efficacy, particularly in patients completing three or more cycles. The safety profile of this combination therapy was acceptable, with manageable AEs. Further investigation in larger trials is warranted. Clinical trial information: NCT06370065. Research Sponsor: None.

Cobolimab and dostarlimab in the first-line treatment of unresectable hepatoma: A multi-center, single arm, phase 2 trial. First Author: Jared David Acoba, University of Hawaii Cancer Center, Honolulu, HI

Background: TIM-3 is highly expressed in cancer and mediates T cell exhaustion/dysfunction that can be an important mechanism of immune escape. Cobolimab, an anti-TIM-3 monoclonal antibody, in combination with dostarlimab (a PD-1 inhibitor), has been shown to enhance T-cell activity in preclinical assessments. This study aimed to investigate the efficacy and safety of cobolimab and dostarlimab in the treatment of unresectable hepatocellular carcinoma (HCC). **Methods:** This is a multi-center, single-arm, phase II study. Eligible patients with unresectable hepatoma (Barcelona Clinic Liver Cancer Stage B or C) and Child Pugh A or B7 (limit 6) liver function received cobolimab 300mg and dostalimab 500mg every 3 weeks for up to 2 years. The primary endpoint was the objective response rate (ORR) per Response Evaluation Criteria in Solid Tumors version1.1. Secondary endpoints were disease control rate (DCR) and duration of response (DoR), progression-free survival (PFS), overall survival (OS), and safety. **Results:** 40 patients were treated (mean age 67 years [range: 24–85]). The analysis presented here is for all 34 Child Pugh A patients. As of November 6, 2024, the median follow-up was 12.9 months. The ORR and DCR were 37.1% and 85.2% respectively (3.7% CR, 33.3% PR, 48.1% SD). The median PFS was 11.0 mo (95% CI: 4.6-17.4), and the median OS was 27.3 mo (95% CI: 21.1-33.5). The median DoR was 14.8 mo (95% CI: 9.4-20.2). Overall incidences of adverse events (AEs) of any grade was 97.1% and immune-related AEs (irAEs) of any grade was 64.7%. The most common irAEs of any grade were dermatologic (47.1%) and endocrine (14.7%). There were two patients (5.8%) who experienced mild elevations of AST and ALT. Grade $\geq$3 irAEs were observed in two patients (5.8%), which included decreased neutrophil count, hypophysitis, and hypothyroidism. There were no treatment-related discontinuations or deaths. **Conclusions:** Cobolimab plus dostarlimab yielded promising response rates and survival outcomes with acceptable safety as first-line treatment in patients with CP A, unresectable HCC. This represents a potential therapy regimen for this population. Clinical trial information: NCT03680508. Research Sponsor: GSK.

Sorafenib plus hepatic arterial infusion chemotherapy versus sorafenib plus transarterial chemoembolization in advanced hepatocellular carcinoma: An update on SHATA-001 study. First Author: Zefeng Du, Department of Hepatobiliary Oncology, Sun Yat-Sen University Cancer Center, State Key Laboratory of Oncology in South China, Collaborative Innovation Center for Cancer Medicine, Guangzhou, China

Background: Although sorafenib plus transcatheter arterial chemoembolization (SoraTACE) has been widely applied for advanced hepatocellular carcinoma (HCC) in most Asian countries, sorafenib plus hepatic arteria infusion chemotherapy (SoraHAIC) may be a better alternative. Herein, we compared the efficacy and safety between the two groups in advanced HCC. Additionally, we validated a predictive model from our previous phase III trial (NCT02973685, cohort1). **Methods:** This phase III trial (NCT02856126) recruited participants with advanced HCC. Eligible participants were randomly assigned (2:1) to receive Sorafenib (400mg orally twice daily) plus HAIC per 3 weeks or TACE until disease progression or unacceptable toxicity. The Primary endpoint was overall survival (OS). Whole-exome sequencing (WES), RNA sequencing, and DNA methylation analysis of tumor biopsy samples were performed for predictive biomarker exploration (cohort 1) and validation (SHATA-001). **Results:** From August 2016 to October 2020, a total of 207 participants were allocated to receive SoraHAIC (n = 141) or SoraTACE (n = 66). The trial met the prespecified endpoints. SoraHAIC significantly prolonged OS compared to SoraTACE (median OS, 15.7 versus 11.2 months; $p < 0.001$). In the SoraTACE group, 56.7% of participants experienced grade 3 or 4 treatment-related adverse events, which were significantly higher than the SoraHAIC group (39.3%; $p < 0.023$). Severe adverse events were also more frequent in SoraTACE (15.7% vs 26.7%, p = 0.07). WES analysis found no ideal indicator in the mutational landscape for treatment outcome. We identified 1226 and 506 differentially methylated probes (DMPs) among the non-responsive specimens in the HAIC and TACE groups. Then we performed RNA-seq analysis. By comparing the transcriptome between the responsive and non-responsive groups, 685 and 600 differentially expressed genes (DEGs) were generated in the two treatment groups, respectively. In the HAIC group, pathways including leukocyte-mediated immunity and immune response-activating signaling pathway were enriched in the responders, while metabolic-related pathways including steroid metabolic process and alcohol biosynthetic process were enriched in the non-responders in the TACE group. Integrative analysis of DEGs and DMPs indicated phosphofructokinase (PFKM) could potentially stratify patients to HAIC or TACE as higher expression of PFKM was associated with favorable outcomes accepting TACE. Such performance could also be validated in this study as participants with elevated PFKM tended to benefit from SoraTACE. **Conclusions:** This trial demonstrated SoraHAIC significantly improved OS over SoraTACE in participants with advanced HCC. Participants with high PFKM expression benefited more from TACE. Clinical trial information: NCT02856126. Research Sponsor: None.

Survival outcomes for zanidatamab-hrii compared to chemotherapy in previously treated HER2-positive (IHC3+) biliary tract cancer (BTC): HERIZON-BTC-01 vs a real-world (RW) external control arm (ECA). First Author: Richard D. Kim, Moffitt Cancer Center, Tampa, FL

Background: Zanidatamab-hrii, a bispecific HER2-directed antibody, received accelerated approval for adults with previously treated, unresectable or metastatic HER2-positive (IHC 3+) BTC based on results from the single-arm phase 2 HERIZON-BTC-01 trial. The results here compare survival outcomes with zanidatamab-hrii from HERIZON-BTC-01 vs a comparable RW cohort of patients who received second-line (2L) chemotherapy. **Methods:** HERIZON-BTC-01 (NCT04466891) evaluated zanidatamab-hrii (20 mg/kg IV every 2 weeks) in patients with HER2-amplified, unresectable locally advanced or metastatic BTC (gallbladder cancer [GBC], intra-/extra-hepatic cholangiocarcinoma [ICC/ECC]) who had received prior gemcitabine-containing therapy. HERIZON-BTC-01 patients with HER2 IHC3+ (n = 62) were included in this analysis. The US-based ECA was constructed using deidentified data from the Flatiron Health Electronic Health Record. Key inclusion criteria for the ECA included a diagnosis of GBC or ICC/ECC with initiation of 2L chemotherapy between 2011-2023, HER2 IHC3+ prior to 2L initiation, and 1L treatment with a gemcitabine-containing regimen. Patients with ECOG $>$ 1 or CNS metastases were excluded. Standardized mortality ratio (SMR) weighting was used to account for potential imbalance of key prognostic factors. Overall survival (OS) and progression-free survival (PFS) were evaluated using SMR-weighted Kaplan-Meier and Cox proportional hazards regression. **Results:** Among 290 RW patients initiating 2L treatment with HER2 testing, 12 met all eligibility criteria and were included in the ECA. The most common reason for exclusion was lack of HER2-positivity (n = 209). Median follow-up times were 16.1 (interquartile range [IQR]: 9.4, 19.9) and 4.7 (IQR: 2.6, 8.1) months for the zanidatamab-hrii and ECA arms, respectively. After weighting, baseline characteristics were similar across arms with standardized mean differences $\leq$0.2. The most common 2L chemotherapy regimen in the ECA was FOLFOX (n =6), followed by gemcitabine-based regimens (n = 3) and FOLFORI (n = 2). Compared with chemotherapy, zanidatamab-hrii resulted in longer median OS (18.07 vs 3.29 months; hazard ratio [HR]:0.29) and PFS (7.26 vs 2.30; HR: 0.47) (Table). The 6- and 12-month survival for zanidatamab-hrii patients were 90% and 65% (vs. 29% and 13% for the ECA), respectively. **Conclusions:** Among patients with previously-treated HER2-positive (IHC3+) BTC, zanidatamab-hrii resulted in longer survival, including a $>$ 14 month increase in median OS, vs ECA patients treated with chemotherapy. Research Sponsor: Jazz Pharmaceuticals.

Concordance analysis between tumor tissue HER2 status by immunohistochemistry (IHC) and in situ hybridization (ISH) and a translational analysis of plasma ctDNA in patients (pts) with biliary tract cancer (BTC): An exploratory analysis from the phase 2 HERIZON-BTC-01 trial. First Author: James J. Harding, Memorial Sloan Kettering Cancer Center, New York, NY

Background: HER2 is a target for precision oncology. HER2 protein overexpression and/or gene amplification is observed in a subset of pts with BTC. Zanidatamab (zani), a dual HER2-targeted bispecific antibody, received accelerated approval as a treatment for adults with previously treated, unresectable, or metastatic HER2-positive (IHC 3+) BTC based on the phase 2b HERIZON-BTC-01 trial. In this exploratory analysis, we evaluated concordance between tissue-based HER2 IHC and ISH in screened pts, and *HER2* gene amplification between tissue-based HER2 ISH and plasma ctDNA by NGS in zani-treated pts. **Methods:** In HERIZON-BTC-01 (NCT04466891) pts were screened for *HER2* gene-amplified tumors by ISH (VENTANA HER2 Dual ISH DNA Probe Cocktail assay) at a central laboratory. Pts with *HER2* gene amplification were prospectively assigned to cohorts based on centrally determined HER2 IHC score (Ventana PATHWAY [4B5] IHC assay); cohort 1: IHC 2+ or 3+; cohort 2: IHC 0 or 1+. HER2 status was assessed in a fresh biopsy or an archived sample per ASCO/CAP guidelines, with gastric cancer algorithm. Enrolled pts received zani 20 mg/kg IV Q2W in 28-day cycles. Plasma ctDNA samples were collected prior to the first cycle of zani (baseline) and on-treatment at cycle 2 day 28 for testing with NGS Guardant360 (Guardant Health). Guardant360 Molecular Response (MR) scores were calculated based on changes in plasma ctDNA levels from baseline. **Results:** Overall, 756 screened pts had central results for both HER2 IHC and ISH. Nearly all pts (94%) with HER2 IHC 3+ BTC had *HER2*-amplified tumors per ISH (Table). Among all 87 pts treated with zani across both cohorts, 48 samples from 25 pts were available for testing with NGS. The concordance between *HER2* gene amplification by ISH and ctDNA NGS was 59%. Co-mutations at baseline in plasma ctDNA occurring in $>$ 10% of pts included KRAS (n = 1 [3%]), *HER2* S310F (n = 3 [9%]), and PIK3CA (n = 6 [18%]). Overall, 18/25 (72%) pts had a decrease in ctDNA levels from baseline at cycle 2 day 28; decreases $>$ 90% were observed in pts with a best response of partial or stable disease. MR scores correlated with tumor response (ANOVA, P = 0.0189). **Conclusions:** In this analysis, there was a high concordance (94%) observed between tumor tissue HER2 IHC 3+ status and *HER2* gene amplification among pts screened in HERIZON-BTC-01. Exploratory translational analysis shows that treatment with zani after 2 cycles was associated with a decrease in plasma ctDNA levels in the majority of pts. Clinical trial information: NCT04466891. The efficacy of atezolizumab plus bevacizumab for advanced hepatocellular carcinoma in relation to tumor-infiltrating lymphocytes: Histological assessment of CD8+ T cell spatial features as predictive biomarkers. First Author: Hiroaki Kanzaki, Department of Gastroenterology, Graduate School of Medicine, Chiba University, Chiba, Japan

Background: The combination of atezolizumab and bevacizumab (Atez/Bev) has improved prognosis in advanced hepatocellular carcinoma (HCC), though its therapeutic mechanisms remain unclear. While the tumor microenvironment (TME) holds promise for biomarker discovery, current studies rely on archived diagnostic samples. We aimed to elucidate molecular determinants of treatment efficacy and identify predictive biomarkers through comprehensive TME analysis of pre-treatment samples. **Methods:** We analyzed biopsy samples from 94 advanced HCC patients immediately before initiating Atez/Bev treatment using immunohistochemistry (IHC), RNA-sequencing, flow cytometry, and multiplexed imaging. Our analysis focused on spatial characteristics of CD8+ T cells and effector regulatory T (eTreg) cells, with longitudinal assessment of immune responses during treatment. **Results:** High programmed death-1 (PD-1) positivity in CD8+ T cells was significantly associated with favorable progression-free survival (PFS) (HR 0.24, 95% CI 0.11-0.52), while CD8+ T cell density showed no significant correlation (HR 1.12, 95% CI 0.64-1.95). Through multiplexed imaging analysis using PD-1 positivity as a key indicator, we identified two critical determinants of response: CD8+ T cells localizing within tumor parenchyma rather than fibrous stroma, and maintaining diffuse distribution throughout the tumor parenchyma. These features, assessable with routine hematoxylin and eosin and CD8 IHC staining, stratified patients into four prognostic groups (p = 0.019), with median PFS ranging from 14.3 months (both favorable features) to 3.5 months (neither feature). The PD-1 positivity in eTreg cells was not associated with prognosis (HR 0.75, 95% CI 0.34-1.62). Notably, bevacizumab counteracted the potential negative effects of programmed death-ligand 1 blockade by suppressing eTreg cell activation, as demonstrated through analysis of patients who discontinued bevacizumab and in vitro experiments showing reduced expression of eTreg activation markers. **Conclusions:** We demonstrate that routine histological assessment of CD8+ T cell localization and distribution patterns can predict Atez/Bev efficacy in advanced HCC. The identified synergistic mechanism of bevacizumab-mediated eTreg suppression provides a framework for future combination immunotherapy development. Radiomic analysis on pretreatment MRI to predict response to atezolizumab plus bevacizumab in advanced hepatocellular carcinoma: A multicenter study. First Author: Hui-Chuan Sun, Department of Hepatobiliary Surgery and Liver Transplantation Liver Cancer Institute and Zhongshan Hospital, Fudan University, Shanghai, China

Background: The combination of atezolizumab and bevacizumab is the standard treatment for advanced hepatocellular carcinoma approved in China and many other countries. However, the objective response rate of this combination treatment was around 30%. Consequently, identifying individuals with the potential to respond favorably prior to initiating therapy remains a pressing challenge. **Methods:** This multi-center retrospective study included advanced hepatocellular carcinoma patients who received atezolizumab plus bevacizumab as first-line therapy between December 2020 and February 2024. The training cohort consisted of eligible patients who have complete baseline, treatment and tumor evaluation records and MRI imaging data from Zhongshan Hospital, while eligible patients from other centers constituted the external validation cohort. A deep learning model based on nnU-Net was developed to automatically segment intrahepatic lesions. All segmentations were reviewed and revised by two radiologists. The radiomic features were extracted using PyRadiomics, then a radiomic feature-based model for predicting response to atezolizumab plus bevacizumab therapy was constructed using the Extreme Gradient Boosting Decision Tree (XGBoost) algorithm. Additionally, three radiologists evaluated 53 visually-assessed MRI features on MRI scans. Finally, the predictive performance of radiomic feature model, as well as the relationship between radiomic and MRI features, was assessed. **Results:** A total of 240 eligible patients were recruited from 14 centers in China, of which 161 and 79 were classified as training and validation cohorts, respectively. During a median follow-up period of 13.7 months (IQR: 8.3–20.6) in the training cohort and 10.5 months (IQR: 7.4–17.2) in the validation cohort, 19.0% (30/161) and 23.0% (18/79) of patients, respectively, achieved an objective response by RECIST v1.1 (p = 0.559). The radiomic feature model demonstrated a promising predictive performance, achieving an AUC of 0.913 (95% CI: 0.874–0.953) in the training cohort and 0.825 (95% CI: 0.700–0.949) in the validation cohort. Fat surpassing liver mass was the only MRI feature associated with an objective response (p = 0.020). When the MRI feature was combined with radiomic features, the predictive model further improved, yielding an AUC of 0.951 (95% CI: 0.924–0.979) in the training cohort and 0.835 (95% CI: 0.725–0.945) in the validation cohort. A significant correlation was observed between radiomic features and MRI features of intrahepatic lesions with a univariate analysis $p < 0.2$. **Conclusions:** Radiomic features derived from pretreatment MRI scans can effectively predict personalized objective responses to combination therapy with atezolizumab and bevacizumab in patients with unresectable or advanced HCC. Efficacy and safety of atezolizumab and bevacizumab with or without transarterial chemoembolization as first-line therapy for advanced hepatocellular carcinoma: An international multicenter real-world study. First Author: Ningning Zhang, Department of Lymphoma, Tianjin Medical University Cancer Institute and Hospital, National Clinical Research Center for Cancer, Key Laboratory of Cancer Prevention and Therapy, the Sino-US Center for Lymphoma and Leukemia Research, Tianjin, Tianjin, China

Background: Transarterial chemoembolization (TACE) combined with immunotherapy and targeted therapy provides a promising therapy for advanced hepatocellular carcinoma (HCC).This study aimed to compare the efficacy and safety of atezolizumab and bevacizumab combined with (TACE-Ate-Bev) or without TACE (Ate-Bev) as first-line treatment for advanced HCC. **Methods:** This international multicenter, retrospective study included 311 advanced HCC cases administered TACE-Ate-Bev (n = 152) or Ate-Bev (n = 159). Inverse probability of treatment weighting (IPTW) was employed to minimize bias. Overall survival (OS), progression-free survival (PFS), and adverse events (AEs) were observed. **Results:** The TACE-Ate-Bev group demonstrated significantly improved OS (26.8 [95% CI 23.1-NA] vs. 14.9 months [95% CI 11.4-19.9]; hazard ratio [HR] = 2.66 [95% CI 1.87-3.77], $p < 0.0001$) and PFS (16.0 months [95% CI 12.8-17.8] vs. 6.5 months [95% CI 5.4-7.6]; HR = 2.50 [95% CI 1.90–3.28], $p < 0.0001$) compared to the Ate-Bev group, especially across BCLC stage B (mOS: NA [95% CI 23.5-NA] vs. 15.6 months [95% CI 11.4-NA], $p < 0.0001$; mPFS: 16.9 months [95% CI 16.2-NA] vs. 6.7 months [95% CI 5.7-10.9], $p < 0.0001$) and BCLC stage C (mOS: 25.2 months [95% CI 19.7-NA] vs. 14.3 months [95% CI 10.1-20.5], p = 0.00018; mPFS: 12.8 months [95% CI 11.3-17.0] vs. 6.5 months [95% CI 5.0-7.7], $p < 0.0001$) disease. The superior efficacy of TACE-Ate-Bev indicated same trends after IPTW adjustment. Grade 3 or 4 AEs were observed in 36 patients (24.3%) in the TACE-Ate-Bev group and 34 (21.4%) in the Ate-Bev group. There was no statistically significant difference in the proportion of gastrointestinal bleeding between the TACE-Ate-Bev and Ate-Bev groups (9.9% vs. 10.1%, p = 0.954). Notably, patients with portal hypertension, portal vein tumor thrombus vp3-4, extrahepatic metastasis or Child-Pugh grade B exhibited improved OS and PFS in the TACE-Ate-Bev group versus the Ate-Bev group. **Conclusions:** TACE-Ate-Bev significantly improves OS and PFS with acceptable toxicity compared to Ate-Bev as first-line therapy for advanced HCC. Factors associated with immunotherapy response for hepatocellular carcinoma. First Author: Matthew Shing Hin Chung, The University of Hong Kong, Hong Kong, Hong Kong

Background: Immunotherapy has shown remarkable progress in treating hepatocellular carcinoma (HCC) in recent years. We aim to investigate the clinical factors associated with treatment response to HCC immunotherapy in Asian population. **Methods:** We identifiedHCC patients receiving immunotherapy (nivolumab, pembrolizumab, atezolizumab, durvalumab, tremelimumab, ipilimumab; including monotherapies or combinations) from January 2008 to June 2024 from a population-based cohort in Hong Kong. Primary outcomes were all-cause mortality and hospitalization stratified by etiology of HCC [Viral-HCC, defined as hepatitis B virus (HBV)-related or/and hepatitis C virus (HCV)-related HCC vs non-viral-HCC], other clinical factors including age, sex, type 2 diabetes (T2D), cirrhosis, antiviral therapy for HBV, and history of receiving other oncological treatment (curative: surgical resection, liver transplant, radiofrequency ablation, microwave ablation; non-curative: transcatheter arterial chemoembolization and radiotherapy). Hazard ratios (HR) were estimated by Cox regression models. **Results:** This study included 1363 patients on immunotherapy (mean age 63.1 years, 84.2% male; 87.2% viral-HCC; 23.0% had prior curative therapy; 34.5% had prior non-curative therapy). Over 240-days of median follow-up, viral-HCC had similar risk of all-cause mortality (54.5% vs 58.9%, p = 0.169) and hospitalization (34.8% vs 30.9%, p = 0.360) compared to non-viral-HCC. Patients with prior curative therapy compared to those without had lower risk of all-cause mortality (HR 0.81 [95% CI: 0.69-0.95], p = 0.011). Among HBV-related HCC, those with antiviral treatment ≥2 years prior to immunotherapy were associated with lower risk of liver-specific mortality (HR 0.83 [95% CI 0.70-0.99], p = 0.036) and HCC-specific mortality (HR 0.80 [95% CI 0.67-0.96], p = 0.014). Patients with cirrhosis had higher risk of all-cause mortality (HR 1.42 [95% CI 1.18-1.71], p < 0.001). No associations with treatment response were observed in subgroups stratified by age < 60/ ≥60, sex, and T2D. **Conclusions:** Among patients with HCC receiving immunotherapy, treatment outcomes were similar in viral-etiologies and non-viral etiologies. Antiviral treatment improves treatment response in HBV-related HCC, while cirrhosis is detrimental to mortality outcomes. HCC immunotherapy following curative treatment, in contrast to non-curative therapies, has improved treatment response. Research Sponsor: None.

Evolutionary divergence of the HLA-B genotype as a predictor of immune checkpoint inhibitor (ICI) therapy efficacy in hepatobiliary cancers. First Author: Nan Zhang, Department of Liver Surgery, State Key Laboratory of Complex Severe and Rare Diseases, Peking Union Medical College Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China

Background: The role of human leukocyte antigen class I (HLA-I) molecules in shaping the immune response to immune checkpoint inhibitors (ICIs) has been recognized in several solid malignancies. However, the prognostic significance of HLA-I characteristics in hepatobiliary cancers remains poorly understood. **Methods:** Patients with advanced hepatocellular carcinoma (aHCC) and biliary tract cancer (aBTC) receiving ICI-based therapy were prospectively enrolled (NCT03892577). Retrospective analyses were performed to evaluate the association between HLA-I evolutionary divergence (HED), HLA-I genotype, and HLA-I heterozygosity with clinical outcomes. HLA-I genotyping was conducted using germline DNA from peripheral blood, and HED was quantified based on the Grantham distance metric, which measures evolutionary divergence between HLA-I alleles. Patients were stratified into high and low HED groups using the 25th percentile as the cutoff. **Results:** A total of 118 patients (41 with aHCC and 77 with aBTC) were included in the analysis. High HED at the HLA-B genotype was significantly associated with improved overall survival (OS) in patients treated with ICIs ($p < 0.05$). Specifically, in aHCC patients, the median OS was 17.43 (95% confidence interval, 17.43-NE) months in the HLA-B HED^{high} group compared to 7.83 months (95% confidence interval, 4.13-NE) in the HLA-B HED^{low} group ($p < 0.05$). Similarly, in aBTC patients, the median OS was 12.7 (95% confidence interval, 9.07-20.90) months versus 9.8 (95% confidence interval, 6.40-13.5) months, respectively ($p < 0.05$). In contrast, HED at the HLA-B genotype did not exhibit a significant association with progression-free survival. **Conclusions:** This study demonstrates that the evolutionary divergence of the HLA-B genotype may serve as a prognostic biomarker for ICI therapy in hepatobiliary cancers. High HED at HLA-B is associated with improved OS, underscoring the potential role of HLA-I genetic diversity in modulating therapeutic response to ICIs. These findings provide a foundation for further investigations into HLA-mediated mechanisms underlying ICI efficacy in hepatobiliary cancers. More patients will be enrolled to validate the conclusions. Clinical trial information: NCT03892577. Hepatic arterial infusion chemotherapy plus lenvatinib and PD-1 inhibitors as first-line treatment for hepatocellular carcinoma with high tumor burden and portal vein tumor thrombus. First Author: Jiaxi Liu, The First Hospital of China Medical University, Department of Interventional Radiology, Shenyang, China

Background: Advanced-stage hepatocellular carcinoma (HCC) is usually associated with poor survival outcomes. Rapid tumor control usually benefits long-term outcomes, which could be hardly achieved by solely systematic targeted and immunotherapy in current guidelines. This study aimed to evaluate the efficacy of hepatic arterial infusion chemotherapy (HAIC) combined with lenvatinib and PD-1 inhibitors (HLP) as first-line treatment for HCC patients with high tumor burden and portal vein tumor thrombus (PVTT). **Methods:** This retrospective multicenter study screened advanced HCC patients who received HLP combination therapy as first-line treatment at ten centers from Jan 2021 to Dec 2023. The inclusion criteria included high tumor burden (up to seven criteria out), PVTT, no extrahepatic metastasis, and liver function of Child-Pugh B7 or better. PD-1 inhibitors permitted 3 different products, including Tislelizumab. Tumor response was assessed using both RECIST 1.1 and mRECIST criteria. Survival outcomes were analyzed using Kaplan-Meier methods. The primary endpoint was overall survival (OS), while secondary endpoints comprised progression-free survival (PFS), objective response rate (ORR), disease control rate (DCR), as well as depth of response (DpR) within 3 months. Baseline time point was defined as start of any designed treatment except DpR related survival as 3 months after initial treatment. **Results:** A total of 94 patients were included. The median age was 53 years (range: 31-78) and 87.2% (82/94) were male. In all the patients, 58.5% (55/94) had a largest tumor diameter ≥10 cm, and 80.4% (74/92) had PVTT classified as Vp3 or Vp4. The median follow-up time was 13.3 (8.9-25.2) months, the 12-month OS rate was 75.6% (95% CI: 67.0-85.3), and the 24-month OS rate was 57.6% (95% CI: 46.9-70.7). Median PFS was 9.7 months (95% CI: 8.1-16.0), with 12- and 24-month PFS rates of 46.3% (95% CI: 37.1-57.8) and 32.1% (95% CI: 23.3-44.3), respectively. Based on RECIST 1.1 or mRECIST, the ORR was 42.6% (95% CI: 32.4-53.2) or 70.2% (95% CI: 59.9-70.2), and the DCR was 96.8% (91.0-99.3) or 100% (96.2-100), respectively. Regarding DpR within 3 months, 46.8% (44/94) of the patients had > 25% tumor diameter reduction per RECIST 1.1, while 73.4% (69/94) showed > 25% reduction per mRECIST. In subgroup analyses, DpR was significantly correlated with PFS and OS (see table), while largest tumor diameter, tumor number, and Vp classification had no correlation with survival outcomes. **Conclusions:** Combination of HLP as a first-line treatment for advanced HCC with high tumor burden and PVTT is promising, with high ORR and survival outcomes. DpR might be a predictor for survival. Clinical trial information: NCT06631326. Research Sponsor: None.

Outcomes		DpR≤25%		DpR>25%
PFS	Events/N	37/50		24/44
	Median (m)	6.8 (5.4-10.9)		16.0 (11.0-NR)
	P		0.004	
OS	Events/N	24/50		12/44
	Median (m)	19.2 (12.6-NR)		35.0 (24.5-NR)
	P		0.034

Molecular characteristics, treatment patterns, and survival outcomes in biliary tract cancers: A retrospective analysis from a high-prevalence region. First Author: Ashish Joshi, MOC Cancer Care & Research Centre, Mumbai, India

Background: Biliary tract cancers (BTC) present significant challenges in management due to their aggressive nature and often late-stage presentation. We present demographic trends, molecular characteristics, treatment patterns, and survival outcomes. **Methods:** This retrospective study included patients diagnosed with BTC between March 2018 and September 2024. Survival analysis was done using the Kaplan-Meier analysis. **Results:** Total of 743 patients were diagnosed with BTC, median age of the cohort was 61 years (IQR 52-69); with F: M ratio being 1.15:1. Distribution according to the stage at presentation was: stage I (n=15, 2%), stage II (n=49,6.6%), Stage III (n=160, 21.5%) and stage IV (n=509, 68.5%). History of gallstones was reported in 183 patients (24.6%). Out of the total cohort, 436 patients (58.7%) had gallbladder cancers (GBCs) while 307 patients (41.3%) had cholangiocarcinoma (CCA), where n=202 (65.8%) were intrahepatic, n=22 (7.2%) were perihilar and n=33 (10.7%) were distal bile duct. Predominant histologic patterns among GBCs were: adenocarcinomas n=331 (75.9%), small cell carcinomas n=13(3%) adenosquamous n=11(2.5%), and others n=81(18.5%). Molecular testing was done in 132 patients (17.8%), out of which 11/132 (8.3%) had HER2 alteration, wherein overexpression was seen in n=3,while amplification was seen in n=8; TP53 mutation was seen in 21/132 (16%), while others alterations were MSI-high (n=2), TMB-high (≥10 mut/Mb) (n=3), PDL1 positive (n=24), FGFR(n=3), IDH (n=2), BRCA2 (n=2). Treatment and survival outcomes were available for 492 patients, surgery was done in 177 patients (35.9%), systemic therapy (adjuvant/palliative) was done in 431 (87.6%) patients while targeted or immunotherapy was used in 99 patients (20.1%). Median Overall survival (mOS) of the cohort was 16.1 months (13.6-18.6) with a median follow-up duration of 28.2 months (23.2 – 33.2). mOS for GBC was 10.8(8.2-13.3) months and CCA was11.6(9.3-14.0) months. mOS for Metastatic BTC was 9.6 months while for Non-metastatic it was 20.4 months($p<0.001$). The median mOS for patients with HER2 mutations, TP53 mutations, and PD-L1 positivity were 23.8 months, 16.6 months, and 10.0 months, respectively (p = 0.165). **Conclusions:** In high-prevalence countries like India, biliary tract cancer (BTC) management is challenged by advanced stage presentation, limited molecular testing and resource constraints. Efforts to enhance molecular testing and treatment access are critical for practicing precision oncology and improving treatment outcomes. Research Sponsor: None.

Comparison of outcomes between open and minimally invasive hepatic resections for hepatocellular carcinoma: A retrospective analysis. First Author: Harjeevan Kalra, Independent Researcher, Brampton, ON, Canada

Background: Recent data from the United States indicate that the incidence of hepatocellular carcinoma (HCC) has tripled over the past 40 years, with risk factors like obesity-related fatty liver disease and chronic hepatitis C on the rise. Despite advances in treatment, the five-year survival rate remains low at 14%. Minimally Invasive Surgery (MIS) has garnered popularity in hepato-pancreato-biliary (HPB) procedures, comprising 1 in 13 cases. MIS offers advantages such as shorter hospital stays and reduced morbidity, with better outcomes. However, the safety and efficacy of MIS, specifically for HCC resection, remain underexplored. To address this gap, we conducted this study to evaluate and compare the outcomes of MIS vs. open surgical approaches for HCC resection. **Methods:** The 2016–2022 National Inpatient Sample (NIS) was utilized for this study. Patients with a primary procedural code for hepatic resection, categorized as either open or minimally invasive approaches, were identified. This cohort was further narrowed to include only patients diagnosed with hepatocellular carcinoma (HCC). Differences in common postoperative complications between open and minimally invasive approaches were analyzed. **Results:** We studied 3,595 hepatic resections for HCC, with 87.5% performed as open procedures and 12.5% as minimally invasive surgeries. Both approaches were predominantly conducted in males (70.9% vs. 75.6%, p = 0.041), with open resection patients being younger (mean age 63.94 vs. 66.67, $p < 0.01$). Open resections were associated with higher complication rates, including critical care needs (aOR 6.428, 95% CI 2.606–15.858, $p < 0.001$), sepsis (aOR 3.728, 95% CI 1.508–9.215, p = 0.004), acute kidney injury(AKI) (aOR 2.406, 95% CI 1.714–3.337, $p < 0.001$), bleeding (aOR 2.314, 95% CI 1.838–2.914, $p < 0.001$), and blood transfusion requirements (aOR 4.514, 95% CI 2.661–7.658, $p < 0.001$). Open procedures also resulted in higher mean hospital charges ($180,561 vs. $131,566, $p < 0.01$) and more extended hospital stays (8.5 vs. 5.3 days, $p < 0.01$). Despite these differences, mortality rates between open and minimally invasive approaches were similar (aOR 1.486, 95% CI 0.85–2.595, p = 0.164). **Conclusions:** Our study found that open hepatic resection for HCC is associated with a higher rate of complications, including bleeding, AKI , increased critical care needs, and blood transfusion requirements, compared to minimally invasive surgery. However, mortality rates between the two approaches remain comparable. With the rising incidence of HCC, transitioning toward MIS may provide notable benefits in reducing postoperative morbidity. Since most hepatic resections are still performed using open techniques, further research is necessary to enhance surgical outcomes and explore alternative strategies. Research Sponsor: None.

Association of gut microbiota with therapy efficacy and prognosis in biliary tract cancer. First Author: Fen Saj, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Biliary tract cancers (BTC) are rising in incidence and have poor prognosis. Microbial exposure via gut–liver axis may contribute to their development and progression. We profiled the gut microbiome of patients with BTC and assessed its correlation with chemoimmunotherapy outcome. **Methods:** For this prospective study, we collected baseline stool samples from newly diagnosed patients with BTC treated at a single center. Microbiome profiles were generated using 16S rRNA gene sequencing. Microbial alpha (intrasample variability) and beta (interindividual variability) diversity indices were calculated and correlated with treatment outcome. Taxonomical differential abundance was quantified using MaAsLin2. Statistical analyses included descriptive statistics for demographics, Kaplan-Meier for survival & Spearman's correlation for microbiome-clinical outcome. **Results:** From May 2021 to October 2024, 72 patients were enrolled. Median age was 66 years (range: 29–86) with 43% females. Primary sites included intrahepatic cholangiocarcinoma (CCA) (61%), distal extrahepatic CCA (18%), hilar CCA (11%), gallbladder Ca (3%), and mixed (7%). Stages were I (14%), II (33%), III (46%), IV (7%). 52% underwent surgery (14% upfront/others post neoadjuvant), 74% progressed to stage 4 disease and 67% received immune check point inhibitors. Therapy responses included complete (CR 3%), partial (PR 19%), stable (SD 32%), and progressive (PD 28%). At a median follow-up of 20 mos, mPFS was 14.6 (8.3-NR) mos for entire cohort [8 (5–11) mos for stage 4 patients] and mOS was not reached. Microbiome analysis of stool samples provided by immunotherapy-treated patients (n = 26) suggested that disease control (DCR: CR/PR/SD) correlated with higher alpha diversity (p = 0.063), while progression showed a trend toward lower diversity across all indices. Beta diversity (calculated by Bray-Curtis distances) showed no significant differences by response or progression. Differential abundance analysis using MaAsLin2 identified significant microbial associations (LogFC > 1.5, adjusted $p < 0.25$) with treatment outcomes. DCR associated bacterial genera included *Ruminococcus*, *Subdoligranulum*, *Romboutsia & Collinsella*, while PD correlated with higher abundances of *Streptococcus*, *Eggerthella*, *Paraprevotella & Enterococcus*. Genera such as *Ruminococcus*, *Romboutsia*, *Coprococcus & Christensenellaceae R-7 group* were linked to non-progression, whereas *Parasutterella*, *Streptococcus*, *Prevotella-9 & Monoglobus* were elevated in progressive disease. **Conclusions:** Our preliminary results suggest that gut microbiome should be studied as a multidimensional biomarker for predicting therapy response/prognosis in BTC. Higher microbial alpha diversity may link with better immunotherapy responses, and specific microbial taxa may correlate with treatment outcomes. Research Sponsor: None.

CTC landscape during HCC immunotherapy. First Author: Marcos Santiago Figueroa, University of Chicago, Chicago, IL

Background: The treatment of hepatocellular carcinoma (HCC), the third leading cause of global cancer death, has significantly improved with the advent of immune checkpoint inhibitor regimens. Circulating tumor cells (CTCs) contain the precursors of metastasis and can be serially sampled while patients receive therapy. Quantification of CTC dynamics during HCC treatment with immune checkpoint inhibitor therapy may yield early insight into the systemic anticancer response profile. **Methods:** We used a commercially available microfluidic CTC purification methodology followed by quantification of CTCs expressing HCC cell surface markers (EPCAM, ASGR1, GPC3) and PD-L1 from patients receiving immune therapies, prior to cycle 1 and cycle 3 of therapy. We also captured and correlated clinical data, including conventional markers of liver function (Child-Pugh score) and radiographic tumor response for correlation with early changes in CTC number. **Results:** In this pilot study,we collected a total of 29 specimens from 14 participants, 10 of whom provided serial samples. The quantities of CTCs detected was (median:10, range: 1-516); (median:1, range: 0-139) were PD-L1 high,(-median: 8, range: 1-312) were PD-L1 medium, and (median: 3, range: 0-190) were PD-L1 low. There was no clear statistical difference in serial CTC enumeration data while on treatment, although the numbers of CTCs and CTC subsets numerically declined in many participants. **Conclusions:** There was no statistically significant relationship between CTC quantity and subsequent radiographic response. Future studies will involve enrollment of expanded numbers of participants, comparisons with circulating tumor DNA dynamics, and transcriptional profiling of CTCs to further explore these phenomena. Research Sponsor: UCCCC.

Deep learning-based contouring of Couinaud segments on CT: Utility for volumetric analysis of future liver remnant. First Author: Tejas Mathai, National Institutes of Health, Bethesda, MD

Background: Hepatocellular carcinoma (HCC) is the most common primary liver tumor, and the liver is a frequent site of metastasis of other cancers. High tumor burden, proximity to hepatic vessels, and other comorbidities render only 30% of patients as candidates for curative treatment: transplantation, resection, or ablation. Surgical resection requires a 20 - 40% future liver remanent (FLR) to avoid post-operative complications. Delineation of the Couinaud segments is essential for volumetric analysis of FLR and targeted localization of tumors during pre-surgical treatment planning. Currently, manual annotation of the Couinaud segments in one CT volume can take two or more hours, which makes it cumbersome, and can benefit from automation. The purpose of this work is to develop an automated Couinaud segmentation tool for fast and accurate FLR estimation. **Methods:** Three CT datasets were used: 1) 161 patients from the public Medical Segmentation Decathlon (MSD) Hepatic Vessels dataset, 2) 43 patients with cirrhosis and metabolic diseases having ascites and splenomegaly imaged at the National Institutes of Health (NIH), and 3) 197 patients in the public TCIA Colorectal Liver Metastasis (CRLM) dataset. FLR annotation in the CRLM dataset was done by an expert radiologist. The Couinaud segments in the MSD and NIH datasets were manually annotated by two physicians using ITK-SNAP. The MSD and NIH datasets were used for training, while the CRLM dataset was reserved for testing. A 3D nnU-Net model was trained with default hyperparameters to outline the Couinaud segments. On the test dataset, the predicted Couinaud segments were overlaid on the FLR annotation, and metrics, such as Dice Similarity Coefficient (DSC), Hausdorff Distance (HD) error (in mm), and volume error (in cc) were calculated. The performance was compared to a previously described 3D U-Net model developed to quantify liver segmental volume ratio (LSVR) in patients with cirrhosis. **Results:** The 3D nnU-Net obtained a DSC of 0.99 ± 0.01 (IQR: 0.991, 0.998), HD error of 0.87 ± 1.83 mm (IQR: 0, 1.02), and volume error of 13.7 ± 28.1 cc (IQR: 3.4, 15.3). In contrast, the LSVR U-Net model attained a DSC of 0.97 ± 0.01 (IQR: 0.972, 0.984), HD error of 9.56 ± 3.61 mm (IQR: 7.14, 11.93), and volume error of 47.9 ± 51.8 cc (IQR: 24.5, 55.4). The 3D nnU-Net model achieved significantly different results for DSC ($p < 0.001$, large effect size 0.86), HD error ($p < 0.001$, large effect size 0.87), and volume error ($p < 0.001$, large effect size 0.91). **Conclusions:** The model showed acceptable generalizability to the external TCIA CRLM dataset. Future work may be directed towards accurate volumetric analysis on patients undergoing portal vein embolization to increase the FLR, and automatic tumor localization on specific Couinaud segments. Research Sponsor: None.

AI-driven prediction of post-transplant survival and stratification of HCC recurrence risk. First Author: Junho Song, Pennsylvania State University College of Medicine, Hershey, PA

Background: Traditional selection criteria (e.g., Milan, UCSF) and scoring systems (MELD/PELD) for liver transplant eligibility in hepatocellular carcinoma (HCC) often fail to capture the complex interplay of tumor biology, patient factors, and bridging therapies. Although Milan and UCSF yield similar 1-, 3-, and 5-year survival rates, the debate over expanded criteria highlights the need for refined, individualized risk-stratification tools. **Methods:** We retrospectively analyzed 21,182 HCC patients from the UNOS database to develop deep learning and Cox regression models for overall survival (OS). Models incorporated demographic (e.g., age, race), clinical (e.g., diabetes, MELD differences), and tumor-specific variables (e.g., tumor count, size tiers). Performance was compared to standard MELD-based calculations using 5-fold cross-validation, with primary endpoints of 1-, 3-, and 5-year survival. For recurrence risk, we used 15,801 records to train gradient boosting (XGBoost) and Cox models. Key variables included tumor characteristics (size levels, vascular invasion), recipient factors (insurance type, functional status, initial MELD/PELD), and alpha-fetoprotein (when available). Model performance was evaluated via area under the curve (AUC) and concordance index (c-index); external validation was performed for the recurrence model. **Results:** Cox Regression (time-to-event): Final multivariable models achieved c-indices of 0.611 for OS and 0.601 for progression-free survival (PFS). Stepwise Logistic Regression (mortality): Mean AUCs were 0.664 (1-year), 0.705 (3-year), and 0.758 (5-year). Random Forest Classifier: Slightly higher AUCs than logistic regression (0.663 at 1-year, 0.714 at 3-year, 0.762 at 5-year). Gradient Boosting (recurrence): 1-year recurrence predictions achieved AUC $>$ 0.80, with microvascular invasion emerging as a key risk factor ($p<0.001$). Across approaches, incorporating multiple clinical and tumor-specific factors outperformed MELD-based models, consistently showing improved predictive accuracy. **Conclusions:** Machine learning–based models, including deep learning, random forests, and gradient boosting, offer enhanced risk prediction for post-transplant survival and HCC recurrence beyond traditional scoring criteria. These advanced tools enable more nuanced transplant selection, surveillance, and early intervention strategies, potentially improving long-term outcomes for HCC patients undergoing liver transplantation. Research Sponsor: None.

A phase II study of pevonedistat in combination with carboplatin and paclitaxel in advanced intrahepatic cholangiocarcinoma: ECOG-ACRIN EA2187. First Author: Anita Turk, Indiana University Melvin and Bren Simon Comprehensive Cancer Center, Indianapolis, IN

Background: Cholangiocarcinoma is a rare and aggressive malignancy with limited therapeutic options, particularly in advanced stages. Resistance to first-line chemotherapy underscores the urgent need for novel therapeutic strategies. Pevonedistat, a first-in-class NEDD8-activating enzyme inhibitor, demonstrated promising activity in this disease in a phase I trial. This study evaluates pevonedistat alone and in combination with carboplatin and paclitaxel in patients with advanced intrahepatic cholangiocarcinoma (ICC). **Methods:** This was a randomized, non-comparative Phase II trial investigating two treatment arms: pevonedistat monotherapy (Arm A) and pevonedistat combined with carboplatin and paclitaxel (Arm B). Both arms utilized a two-stage minimax design, targeting an objective response rate (ORR) of 30% (null hypothesis: 10%). Eligible patients had unresectable or metastatic ICC with progression after gemcitabine-based therapy. The primary endpoint was ORR per RECIST v1.1. Secondary endpoints included clinical benefit rate (CBR), progression-free survival (PFS), overall survival (OS), and safety. Toxicities were graded using CTCAE v5.0. **Results:** A total of 40 patients were enrolled, with 34 eligible and treated (17 per arm). Median follow-up was 29.3 months. No objective responses were observed in either arm. Stable disease was the best response in 35.3% (n = 12) of patients (11.8% Arm A, 58.8% Arm B). One patient on Arm B achieved stable disease lasting $\geq$24 weeks, corresponding to a CBR of 5.9% (95% CI: 0.1%-28.7%). Median PFS was 1.54 months (Arm A) and 2.92 months (Arm B). Median OS was 4.80 months (Arm A) and 6.54 months (Arm B). Grade 3 or higher toxicities occurred in 44.1% of patients, with higher incidence in Arm B (70.6% vs. 17.6% in Arm A). Most common toxicities included fatigue, cytopenias, febrile neutropenia, nausea/vomiting, among others. Two treatment-related fatalities were reported on Arm B: sepsis and colonic perforation. **Conclusions:** Pevonedistat, alone or in combination with carboplatin and paclitaxel, did not demonstrate sufficient efficacy to warrant further evaluation in advanced ICC. These findings highlight the challenges in treating this aggressive malignancy. Despite the rarity of ICC, the rapid accrual of this study during a global pandemic indicates the potential for continued exploration of novel therapeutic approaches in this disease. Clinical trial information: NCT04175912. Research Sponsor: NCI/NCTN.

Whole-genome sequencing of biliary tract cancer: Uncovering the genomic origins of evolutionary trajectories. First Author: Felix Beaudry, Ontario Institute for Cancer Research, Toronto, ON, Canada

Background: Biliary tract cancers (BTC) are rare, highly aggressive malignancies with limited treatment options, leading to consistently poor outcomes. An improved understanding of BTC tumor evolution could inform enhanced screening strategies, identify useful prognostic markers, and discover novel therapeutic targets. **Methods:** We performed whole genome and transcriptome sequencing (WGTS) at high depth ($>$ 80X) on a prospective cohort of BTC tumors. After detecting mutations and mutational signatures, we developed two novel methods for driver identification and evolutionary reconstruction. First, we created new oncogene and tumor suppressor-specific models that integrate copy number profiles, structural variant breakends, and expression changes to distinguish structural drivers from neutral chromosomal rearrangements. Second, we applied population genetics techniques to fit demographic models to tumor allele frequencies across 20 paired primary and metastatic samples. **Results:** We analyzed 130 tumor samples from 110 patients, representing the largest BTC whole-genome cohort to date. We identified hypermutated tumors (50-150 mutations/mb) with distinct etiologies, including mismatch repair deficiency, platinum exposure, tobacco use, and aristolochic acid-related damage, the latter of which was associated with response to immunotherapy. Ourintegrated-driver approach identified an association between selection on *RAD23A* and an increased structural variant load, resulting in a tandem-duplicator-like mutational phenotype. This also revealed an underappreciated impact of *SMAD4* in BTC, which is inactivated through multiple mutation types in 12%. Notably, *BAP1* mutations occurred in 24% of cases, including 4% that were inactivated through deletion of the *BAP1* promoter that lowered transcript expression, a previously undescribed mechanism. By pairing clinical data to the genomics, we observed a co-occurrence of *BAP1* mutations and *FGFR2* fusions in small-duct, mass-forming intrahepatic cholangiocarcinomas. These mutations were mutually exclusive with *TP53* mutations, which were enriched in patients with primary sclerosing cholangitis. Finally, our novel method for subclonal population reconstruction on paired samples illuminated recent tumor evolutionary dynamics and identified an *ARID1B* fusion with a potential role in metastasis. **Conclusions:** This study uncovered novel genomic mechanisms underlying the evolutionary origins of BTC beyond those previously identified with exome and panel sequencing, highlighting the value of WGTS. These results highlight the complex genomic heterogeneity of BTC, with potential implications for precision therapy. Real-world validation of the risk estimation of tumor recurrence after transplant (RETREAT) score: Insights from UNOS data on hepatocellular carcinoma recurrence after liver transplant. First Author: Donghoon Shin, Department of Internal Medicine, MetroWest Medical Center/Tufts University School of Medicine, Framingham, MA

Background: For over two decades, established criteria have guided the selection of liver transplantation (LT) candidates in hepatocellular carcinoma (HCC), yet recurrence remains a significant clinical challenge with limited treatment options. The Risk Estimation of Tumor Recurrence After Transplant (RETREAT) score was developed to address this gap. Further validation is needed to confirm its utility in real-world settings. **Methods:** We conducted a validation study using the United Network for Organ Sharing (UNOS) database to evaluate the predictive performance of the RETREAT score in adult liver transplant recipients with HCC from 2009 to 2024. The analysis included 4,975 patients. Kaplan–Meier survival analysis was performed, and recurrence rates were compared across RETREAT score groups using the log-rank test. The predictive accuracy of the RETREAT score for HCC recurrence was assessed by calculating the concordance index (C-index), area under the ROC curve (AUC) evaluating the model's ability to discriminate between recurrence and non-recurrence events. **Results:** Among the 4,975 liver transplant recipients with hepatocellular carcinoma (HCC), the distribution of the RETREAT score was as follows: 13 patients (0.26%) had a score of 0, 1,713 patients (34.43%) had a score of 1, 1,981 patients (39.81%) had a score of 2, 524 patients (10.53%) had a score of 3, 526 patients (10.57%) had a score of 4, and 218 patients (4.38%) had a score $\geq$5. Kaplan–Meier survival analysis demonstrated a significant association between the RETREAT score and HCC recurrence ($p < 2e\text{-}16$). The hazard ratio for recurrence with each unit increase in the RETREAT score was 1.685 (95% CI: 1.574 to 1.803). The model's predictive accuracy, as assessed by the C-index, was 0.697 (95% CI: 0.668–0.725), and the AUC was 0.684 (95% CI: 0.655–0.713). **Conclusions:** The RETREAT score demonstrates a C-index of 0.697 in predicting HCC recurrence after liver transplantation. This model offers valuable risk stratification but could benefit from further refinement to improve its predictive accuracy. Research Sponsor: None.

Conversion therapy for initially unresectable intrahepatic cholangiocarcinoma: A multicenter real-world study. First Author: Xinhao Xiong, Department of Liver Surgery, Sun Yat-Sen University Cancer Center, Guangzhou, China

Background: Currently, studies on conversion therapy for intrahepatic cholangiocarcinoma (ICC) are relatively limited. Effectiveness and optimization strategies of conversion therapy in real world remain unclear. This study aims to analyze the efficacy of locoregional combined with systematic therapy in patients with unresectable ICC, optimizing conversion therapy strategies by retrospectively. **Methods:** In this multicenter retrospective study, patients with unresectable ICC who received hepatic arterial infusion chemotherapy combined with ICIs and target therapy were reviewed. Overall survival (OS), progression-free survival (PFS) , objective response rate (ORR) , disease control rate(DCR)(assessed by mRECIST criteria) and safety were analyzed. **Results:** Between June 2018 to May 2024,a total of 341 patients from six centers were included in this study. The median follow-up time was 21.7 months.Among them, 313 patients with complete imaging evaluations are eligible for efficacy analysis. Of which, 20 patients achieved complete response (CR), 93 patients partial response (PR), 161 patients stable disease (SD), illustrating an ORR of 36.1% and a DCR of 87.5%. Among them, 65 patients successfully underwent conversion surgery, with a median duration of conversion therapy of 4.1 months. Radical resection was achieved in 39 patients within the surgical cohort, and 3 patients demonstrated pathological CR. Systemic therapy regimens with the highest conversion success rates included apatinib plus toripalimab (42.9%), lenvatinib plus tislelizumab (32.4%), and apatinib plus tislelizumab (30.8%). Patients with tumor diameters less than 10 cm and those with unilobar tumor were more likely to achieve successful conversion. After propensity score matching (PSM) to balance baseline characteristics (ratio = 1, caliper = 0.01), the surgical group exhibited better survival outcomes compared to the non-surgical group (not reached vs. 27.2 months, hazard ratio: 0.36, 95% CI: 0.61–0.81, p= 0.001). The median PFS was 13.0 months in the surgical group versus 8.0 months in the non-surgical group (hazard ratio, 0.57; 95% CI, 0.30 to 1.09; p= 0.088).Within the surgical cohort, the 2-year survival rates for patients with palliative surgery and radical resection were 51.3% and 26.9%, respectively (p= 0.051). All patients experienced treatment-related adverse events (TRAEs), but no treatment-related deaths occurred. The incidence of Grade 3-4 TRAEs was 28.6%. **Conclusions:** Locoregional combined with systemic therapy is an effective strategy for conversion treatment. Conversion surgery offers substantial survival benefits, while palliative surgery may also serve as a viable therapeutic option. Research Sponsor: None.

Clinico-molecular characteristics and enhanced efficacy of immune checkpoint inhibitors in *TP53*-mutated advanced biliary tract cancer. First Author: Taro Shibuki, Department of Hepatobiliary and Pancreatic Oncology, National Cancer Center Hospital East, Kashiwa, Japan

Background: *TP53* mutations are frequent genetic alterations in cancers and also prevalent in biliary tract cancer (BTC). In non-small cell lung cancer, *TP53* mutations have been reported to enhance immune checkpoint inhibitor (ICI) efficacy and improve outcomes. However, their impact on BTC remains unclear. This study investigated the clinico-molecular characteristics, prognosis, and ICI efficacy in *TP53*-mutated BTC. **Methods:** Patient data were collected from the SCRUM-Japan GOZILA and MONSTAR-SCREEN-1/2 databases (Japan) and the Duke university and Mayo clinic databases (U.S.), which included patients receiving first-line ICI therapy. Comparisons between *TP53* wild-type (WT) and mutation groups were performed in the Japanese cohort. Subsequently, analyses were expanded to include U.S. patients, focusing on comparisons between non-ICI and ICI groups. Tumor Immune Dysfunction and Exclusion (TIDE) scores were calculated using MONSTAR-SCREEN-2 whole transcriptome sequencing (WTS) data to evaluate ICI responsiveness, and gene set enrichment analysis (GSEA) explored pathways associated with *TP53* mutations. **Results:** In the Japanese cohort (n=594), *TP53* mutations were identified in 311 patients (52.4%). *KRAS*, *ERBB2*, *CDKN2A*, and *SMAD4* alterations were more frequent in the *TP53* mutation group, while *IDH1, BAP1*, and *FGFR2* fusions were more common in the WT group. Multivariable analysis showed *TP53* mutations were independent prognostic factors for poor outcomes (progression-free survival [PFS]: HR 1.37, 95% CI: 1.11–1.69, P=0.003; overall survival [OS]: HR 1.36, 95% CI: 1.06–1.75, P=0.017). Incorporating the U.S. cohort (n=625; non-ICI: 548; ICI: 77), no significant differences in overall response rate (ORR) or disease control rate (DCR) were observed in the non-ICI group between the groups. However, in the ICI group, *TP53* mutations tended to show higher ORR (21.1% vs. 38.5%, P=0.16) and DCR (47.4% vs. 66.7%, P=0.14). In the non-ICI group, *TP53* mutations were associated with worse PFS (HR 1.46, median PFS: 7.4 vs. 5.3 months, P$<$0.001), whereas, in the ICI group, no significant difference was observed; however, a trend toward better PFS was seen in the *TP53* mutation group (median PFS: 5.0 vs. 6.4 months, P=0.163). TIDE scores were significantly lower in the *TP53* mutation group, indicating higher ICI responsiveness. GSEA revealed enrichment of oxidative phosphorylation and hypoxia pathways. **Conclusions:** *TP53* mutations are independent prognostic factors for poor outcomes in BTC. However, patients with *TP53* mutations may derive greater benefits from ICIs, underscoring the importance of tailored therapeutic strategies in *TP53*-mutated BTC. Research Sponsor: None.

Genomic and outcome analysis of recurrent versus de novo metastatic pancreatic ductal adenocarcinoma (PDAC) receiving systemic therapy: Results from the Australian MoST and CaSP screening programs. First Author: Frank Po-Yen Lin, NHMRC Clinical Trials Centre, The University of Sydney, Sydney, NSW, Australia

Background: The genomic and prognostic characteristics of recurrent (R, from curative surgery) v *de novo* (D) presentation in metastatic PDAC patients (pt) requiring systemic therapy (rx) remain underexplored. We examined the difference in genomic alterations (alts), overall survival (OS), and outcome to matched rx according to disease presentation (DP). **Methods:** The PDAC cohorts from the Australian Molecular Screening and Therapeutics (MoST) and Cancer Screening Programs (CaSP) completed sequencing from 2016 to July 2024 were analysed; archival tissue was sequenced using genomic profiling platforms (mainly TSO500 and FoundationOne CDx). Frequencies of genomic alts were compared between R and D groups; significance was assessed using Chi-square tests with the Benjamini-Hochberg method ($q < 0.05$). OS was calculated from the start of initial rx using Kaplan-Meier method, with hazard ratios (HR) from Cox regression used for comparison. OS outcomes were stratified by matched versus unmatched rx in pts harbouring genomic alts within clinically actionable Tier 1-3 categories per TOPOGRAPH knowledge base criteria. **Results:** 949 pts with PDAC with valid genomic results across both programs were included. The *KRAS* alts were numerically more frequent in D (n = 434/491, 88%, p = 0.02) than R (n = 380/458, 82%) groups. Both *CDKN2A* and *SMAD4* alts were enriched in the D group (*CDKN2A*, D: 248, 51% v R: 157, 34%; *SMAD4*, D: 139, 29% v R: 85, 19%, $p < 0.001$ both). Among the 821 pts who started systemic rx, those with R PDAC (n = 411) showed longer median OS compared to those with D PDAC (n = 410, 18.9 v 13.0 months, mo; HR 0.59, 95% CI 0.49-0.69, $p < 0.001$). Genomic *CDKN2A* alts were associated with worse OS (median 13.4 v 16.5 mo, HR 1.34, 95% CI 1.14-1.58); most favourable prognosis was seen in 267 pts with *CDKN2A* wildtype in the R group (median 22.1 mo, 95% CI 17.4-25.9). After adjusting for both *CDKN2A* and *SMAD4* alts, R group remained associated with a lower risk of death than D group (HR 0.61, 95% CI: 0.51-0.72, $p < 0.001$). Pts who received active matched rx (n = 23) showed longer OS than those who received unmatched rx (n = 314) in both D (30.1 v unmatched 14.0 mo) and R groups (34.6 v 24.1 mo). The prevalence of specific *KRAS* mutations showed no significant differences between D and R groups, including G12D (D: 192, 39% v R: 167, 36%, p = 0.44), G12V (D: 126, 26% v R: 113, 25%, p = 0.78), G12R (D: 59, 12% v R: 50, 11%, p = 0.67), G12C (D: 6, 1% v R: 10, 2%, p = 0.37), and Q61 mutations (D: 37, 8% v R: 26, 6%, p = 0.31). There were no differences in alts in *TP53*, *ARID1A, BRCA1/2,* or other DNA repair pathway genes. **Conclusions:** Genomic and prognostic differences were seen in metastatic PDAC according to presentation, with *CDKN2A* alts enriched in *de novo* cases and associated with poor OS, emphasising the need to consider stratification of DP in trials and observational studies. Research Sponsor: None.

4121 **Poster Session**

First results of an open-label, single arm phase II trial investigating the efficacy and safety of trifluridine/tipiracil combined with irinotecan as a second line therapy in patients with cholangiocarcinoma. First Author: Linde Kehmann, Charité University Medicine Berlin, Berlin, Germany

Background: Cholangiocarcinoma (CCA) is a rare and aggressive malignancy with poor prognosis. Although firstline therapy with gemcitabine, cisplatin and durvalumab has been established based on the TOPAZ-1 trial, treatment options for subsequnt therapies remain limited. The TRITICC study investigated the combination of trifluridine/tipiracil (FTD/TPI) and irinotecan in patients with disease progression after firstline treatment. **Methods:** TRITICC was a phase IIA, interventional, prospective, open-label, non-randomized, exploratory, multicenter, single-arm trial. Adult patients with histologically confirmed, locally advanced or metastatic biliary tract cancer received FTD/TPI (25 mg/m² BSA, BID, orally, days 1–5 of each 14-day cycle) combined with irinotecan (180 mg/m² on day 1 of each cycle). Progression free survival (PFS) was the primary endpoint. Secondary endpoints included the PFS rate at 4 months, median overall survival (OS), objective response rate (ORR), and quality of life. The trial was registered with ClinicalTrials.gov (NCT04059562) and EudraCT (2018-002936-26). **Results:** 28 patients were enrolled across six sites in Germany. The median PFS was 3.1 months (95% CI: 2.0–7.5), with PFS rates of 35% (95% CI: 21%–58%) at 4 months, 30% (95% CI: 17%–54%) at 6 months, and 13% (95% CI: 4.7%–37%) at 12 months. PFS and PFS rates were higher in patients with intrahepatic CCA (iCCA). The OS rates were 74% (95% CI: 59%–93%) at 6 months and 38% (95% CI: 22%–68%) at 12 months. Similar to the PFS rates the OS rates were higher in iCCA. Among 27 evaluable patients, partial responses were observed in 3 patients (11.1%, 2 iCCA, 1 eCCA), stable disease in 11 patients (40.7%, 7 iCCA, 4 eCCA). Thirteen patients (48.1%, 7 iCCA, 6 eCCA) experienced disease progression. Outcomes due to tumor location will have to be examined in higher patient numbers. The most frequently reported adverse events included neutropenia, thrombocytopenia, gastrointestinal symptoms and fatigue. The mean Global Health Status score (EORTC QLQ-C30) declined moderately from 56.2 at screening to 46.4 at the end of treatment. No severe, unmanageable or unexpected toxicities were reported. **Conclusions:** The combination of FTD/TPI and irinotecan demonstrated promising efficacy and manageable safety in CCA patients progressing after first-line gemcitabine-based therapy, aligning with recent findings in comparable populations (e.g., Tella et al.). Further investigations are warranted to validate these results. The NIFTY trial suggested that pegylated irinotecan may enhance efficacy compared to conventional irinotecan, a hypothesis that will be explored in the planned follow-up TRITICC-2 study. The study was funded by Servier Deutschland GmbH and Servier Affaires Médicale. Clinical trial information: NCT04059562. Research Sponsor: None.

4122 **Poster Session**

Sequential or up-front triple combination with durvalumab, tremelimumab, and bevacizumab for patients with unresectable hepatocellular carcinoma (AIO-MONTBLANC): Safety interim analysis. First Author: Najib Ben Khaled, Department of Medicine II, University Hospital, LMU Munich, Munich, Germany

Background: The combination of immune checkpoint inhibitors (ICI) durvalumab (durva) and tremelimumab (treme) has been approved for first-line (1L) therapy for advanced hepatocellular carcinoma (aHCC) and represents an alternative to combined atezolizumab and bevacizumab (bev). The MONTBLANC trial evaluates the efficacy and safety of combined durva, treme and bev in patients (pts) with aHCC (NCT05844046). **Methods:** This investigator-initiated, international, randomized phase 2 trial is the first to investigate the combination of durva, treme and bev. 70 pts with aHCC not amenable to curative treatment or locoregional therapy and preserved (Child-Pugh A) liver function are randomized in a 1:1 ratio to an early escalation arm (A) or triple treatment arm (B). Pts in arm A initially receive durva+treme with the addition of bev upon detection of disease progression or failure to achieving objective radiological response. Pts in arm B receive upfront durva, treme and bev. Durva, treme and bev are given in standard doses. The primary endpoint is overall response rate. Secondary endpoints include overall survival, progression-free survival and safety. We present the data of the second planned safety interim analysis. **Results:** 25 pts (arm A: 14, arm B: 11) were included in this analysis (04/2023 – 08/2024). Patients in arm A had a lower proportion of ECOG 0 (A: 78.6% vs B: 90.9%), higher proportion of Child Pugh A6 (A: 21.4% vs B: 9.1%), BCLC C (A: 78.6% vs B: 63.6%), macrovascular invasion (A: 42.9% vs B: 36.4%) and AFP $\geq$400 ng/mL (A: 42.9% vs B: 18.2%). Most adverse events (AE) were grade (G) 1 or 2. In arm A, there were 17 G3 AE, 1 G4 AE and 4 G5 AE. In arm B, 4 G3 AE and 1 G5 AE occurred. 18 serious AE (SAE) occurred in arm A and 2 SAE in arm B. There was one treatment-related death in arm A (ICI hepatitis) and none in arm B. In the first 6 months on treatment, there were no significant changes in ALBI score, Child Pugh score or ECOG performance status in both arms. **Conclusions:** This planned safety interim analysis did not reveal signals of unmanageable toxicity or deteriorating liver function through the addition of bev to durva/treme in the 1L treatment of pts with aHCC. Clinical trial information: NCT05844046. Research Sponsor: Astra Zeneca.

Comparative efficacy of cabozantinib or lenvatinib following atezolizumab plus bevacizumzb in patients with advanced hepatocellular cancer. First Author: Sepideh Mehravar, Cedars-Sinai Medical Center, West Hollywood, CA

Background: Atezolizumab plus bevacizumab is the most commonly utilized first-line therapy for advanced HCC. However, the optimal choice for second-line treatment remains uncertain, particularly between different tyrosine kinase inhibitors including lenvatinib and cabozantinib. This study aims to compare survival outcomes of patients with metastatic HCC who received either lenvatinib or cabozantinib as second-line therapy following frontline treatment with atezolizumab plus bevacizumab. **Methods:** This retrospective cohort study utilized the TriNetX database, a large-scale platform providing access to deidentified electronic medical records from over 130 million patients across 94 healthcare organizations in the United States. The study included patients diagnosed with metastatic HCC (ICD-10 codes: C22, C22.8) who were aged 18 years or older, diagnosed between January 2019 and October 2024, and had received first-line chemotherapy with atezolizumab and bevacizumab. The cohort was divided into two groups: one receiving lenvatinib and the other cabozantinib as second-line therapy. The primary outcome was overall survival (OS), compared between the two treatment groups using 1:1 propensity score matching (PSM) to balance baseline demographics and comorbidities. Kaplan-Meier survival analysis, log-rank tests, and hazard ratios (HR) were employed to assess differences in OS. **Results:** Between January 2019 and October 2024, a total of 552 patients met the study criteria, including 397 patients who received Lenvatinib and 155 patients who received cabozantinib as second-line therapy. Median age was similar in two groups (65.2 vs 65.9 yrs). There were no differences between the two groups with respect to gender, albumin or bilirubin levels. Lenvatinib group had lower proportions of white patients (44.1% vs 55.3%). After PSM (matched on age, race, gender, albumin and bilirubin), the final analysis included 151 patients in each treatment group. Kaplan-Meier survival curves demonstrated no statistically significant difference in OS between the two groups (median OS: 16.6 vs 10.9 months; HR: 0.809; 95%CI: 0.576-1.136; p=0.597). **Conclusions:** This retrospective cohort study found no significant difference in OS in pts with metastatic HCC treated with lenvatinib or cabozantinib as second-line therapy following atezolizumab plus bevacizumab. These findings suggest that both agents may offer comparable survival benefits, highlighting the need for further prospective studies to refine second-line treatment strategies for advanced HCC. Molecular profile of hepatocellular carcinoma (HCC) in older (OA) versus younger adults (YA) receiving tyrosine kinase inhibitors: Does age matter? First Author: Jay Parekh, UT Health San Antonio, San Antonio, TX

Background: While age is not an independent risk factor for poor outcomes it can have significant influence on outcomes in HCC. The median age of diagnosis is 65 years, and HCC is associated with significant geriatric comorbidities. Further, multi-kinase inhibitors (MKIs) are associated with up to 60% of grade 3-4 toxicities. We aim to analyze survival association with age in HCC and identify molecular markers, associated with survival in older patients with HCC receiving tyrosine kinase inhibitors (TKIs). **Methods:** 1473 HCC specimens with DNA/RNA sequencing were profiled at Caris Life Sciences. The study cohort was stratified based on median age into two groups: OA: age $>$ 65 and YA: age $<$ = 65. Real-world overall survival (OS) information was obtained from insurance claims data, and Kaplan–Meier estimates of OS were calculated from specimen collection to last clinical contact; and MKI time on treatment (TOT) from the initiation to termination of treatment. Hazard ratios (HR) and p-values were calculated using the Cox proportional hazards model and the log-rank test, respectively. **Results:** Median OS (mOS) among patients with OA was 14.8 months(m) vs 17.1m among YA (HR: 1.18, $p < 0.01$). The difference in mOS was even more pronounced among White OA (HR:1.43, $p < 0.0001$) and Asian/Pacific Islanders (HR:1.62, p = 0.084). Interestingly, although not statistically significant, OA was associated with longer mOS in Black/African Americans (HR:0.73, p = 0.082). OA was not associated with MKI-TOT such as sorafenib or cabozantinib. However, OA was associated with a shorter TOT (HR 1.6, $p < 0.01$) on lenvatinib (len). No molecular alterations were statistically significantly different between the two age groups on len. CTNNB1, TP53, CDKN2A mutations and PDL1+ were among the most differentially altered and were more common in OA. DNAJB1-PRKACA fusions were prevalent only in YA (13%, potentially representative of Fibrolamellar HCC), while SLC45A2-AMACR fusions were more prevalent among OA (6.6 vs 1.1%). Multivariate analysis revealed that OA was independently associated with shorter len-TOT (HR 1.6, p 0.01), while CTNNB1 mutations and DNAJB1-PRKACA fusions were independently associated with longer len-TOT (HR 0.4-0.5, both $p < 0.05$). **Conclusions:** OA was associated with differing survival trends between whites and Asian/PI compared to Black/AA. Further, OA was associated with shorter len-TOT, potentially due to anti-angiogenic toxicity. Our limitations include an inability to investigate race-based differences on len-TOT due to small sample sizes (Black/AA: n = 18, Asian/PI: n = 15) and the lack of toxicity and geriatric assessment data. Future studies including race, geriatric assessments and toxicity profiles should be considered to understand survival and tolerability differences. Research Sponsor: None.

Development and validation of a prognostic risk score for hepatocellular carcinoma recurrence post–liver transplant: Insights from the UNOS database. First Author: Donghoon Shin, Department of Internal Medicine, MetroWest Medical Center/Tufts University School of Medicine, Framingham, MA

Background: For over two decades, the criteria for liver transplantation (LT) in hepatocellular carcinoma (HCC) have been well-established, yet recurrence remains a major clinical challenge. This recurrence contributes to inferior post-LT survival in HCC patients compared to those without HCC. Prognostic index could serve as a valuable tool to identify patients who may benefit from adjuvant therapies and guide standardized post-LT HCC surveillance, which currently varies across transplant centers. **Methods:** We developed and validated a predictive model using the United Network for Organ Sharing (UNOS) database, analyzing adult liver transplant recipients with hepatocellular carcinoma (HCC) from 2009 to 2024, including 4,970 patients. Univariable analysis identified variables associated with 1-year, 3-year, and 5-year post-transplant HCC recurrence, applying a strict p-value threshold (< 0.01). Significant variables were selected for multivariable logistic regression to build the model. Internal validation was performed for each time point using Receiver Operating Characteristic (ROC) curve analysis and confusion matrix evaluation, with the best-performing model selected based on these metrics. **Results:** The most significant model was derived using 3-year recurrence as the outcome. The final model included the pre-transplant Model for End-Stage Liver Disease (MELD) score (p = 0.02), worst tumor histology grade ($p < 0.001$), and total tumor diameter (p = 0.03). The final logistic regression equation is as follows: $\log(1\text{-}p/p) = -3.9630 - 0.0621 \times$ Initial MELD score + $0.7657 \times$ Worst tumor histology grade + $0.1084 \times$ Total tumor diameter. Internal validation results showed an AUC of 0.761 (95% CI: 0.718 - 0.804), accuracy of 0.769 (95% CI: 0.757 - 0.7807), sensitivity of 77.2%, and specificity of 65.0% for 1-year recurrence. For 3-year recurrence, the model demonstrated an AUC of 0.733 (95% CI: 0.702 - 0.763), accuracy of 0.6696 (95% CI: 0.6563 - 0.6827), sensitivity of 66.7%, and specificity of 70.9%. For 5-year recurrence, the AUC was 0.714 (95% CI: 0.685 - 0.743), with accuracy of 0.655 (95% CI: 0.641 - 0.668), sensitivity of 65.2%, and specificity of 68.6%. **Conclusions:** We have developed and validated a predictive model for HCC recurrence following LT using UNOS data. This model shows promising performance, particularly for predicting 1-year recurrence, and may potentially serve as a useful tool for guiding post-transplant management and surveillance strategies. Transarterial chemoembolization plus donafenib and immune checkpoint inhibitors for intermediate hepatocellular carcinoma (CHANCE2410): A propensity score matching analysis. First Author: Bin-Yan Zhong, Department of Interventional Radiology, Zhejiang Key Laboratory of Imaging and Interventional Medicine, Zhejiang Cancer Hospital, Hangzhou Institute of Medicine (HIM), Chinese Academy of Sciences, Hangzhou, China

Background: Hepatocellular carcinoma (HCC) has high incidence and mortality, with over 80% of patients diagnosed at intermediate or advanced stages, limiting surgical options and worsening prognosis. Transarterial chemoembolization (TACE) is the standard treatment for intermediate HCC, inducing tumor ischemia and hypoxia, which alters the immune microenvironment and promotes immune activation. Combining TACE with immune checkpoint inhibitors (ICIs) and tyrosine kinase inhibitors (TKIs) has shown promise in enhancing treatment efficacy. Trials like EMERALD-1 and LEAP-012, along with real-world studies, suggest that TACE plus ICIs and TKIs improves progression-free survival (PFS) in intermediate HCC patients compared to TACE monotherapy. Donafenib, an oral TKI, has shown superior overall survival compared to sorafenib, being recommended as first-line treatment for advanced HCC in China. However, large real-world studies on the combination of TACE plus donafenib and ICIs in intermediate HCC are scarce. This study aims to compare the efficacy and safety between the combination therapy and the TACE monotherapy for intermediate HCC in a real-world setting. **Methods:** This nationwide, multicenter, retrospective cohort study included patients with intermediate HCC receiving either combination therapy or TACE monotherapy between January 2021 and May 2024 in China. The primary outcome was PFS. The secondary outcomes included overall survival (OS) rate, objective response rate (ORR) and safety. Tumor response was evaluated according to the mRECIST criteria. 1:1 propensity score matching (PSM) analysis was employed to minimize bias. Cox proportional-hazards regression model was used to analyze factors affecting PFS and OS. **Results:** A total of 364 patients were enrolled, with 192 receiving combination therapy and 172 receiving TACE monotherapy. After PSM, 127 patients from each group were included for analysis. The median PFS were significantly longer in the combination therapy group than it in the TACE monotherapy group (19.6 months [95% CI, 14.9-24.4] *vs.* 15.3 months [95% CI, 12.8-17.8], HR 0.647 [95% CI, 0.464–0.903], $p = 0.010$). The OS rate was higher in the combination therapy group (94.8% *vs.* 83.5%, 1-year OS rate; 76.4% *vs.* 64.8%, 2-year OS rate; HR 0.542 [95% CI, 0.327–0.989], $p = 0.016$). The ORR was also higher in the combination therapy group (78.9% *vs.* 62.5%, $p = 0.002$). Grade 3 or 4 adverse events from any cause were observed at a rate of 12.5% and 5.5% in the combination and monotherapy groups, respectively. Multivariate analysis identified combination therapy as an independent prognostic factor for both longer PFS and OS. **Conclusions:** Compared to TACE monotherapy, TACE plus donafenib and ICIs offers superior OS and PFS, which may be a viable first-line treatment option for intermediate HCC. Research Sponsor: None.

Hepatitis B virus reactivation in hepatocellular carcinoma patients undergoing immune checkpoint inhibitor and concurrent antiviral prophylaxis agents: A prospective observational study. First Author: Zhicheng Lai, Department of Hepatobiliary Oncology, Sun Yat-Sen University Cancer Center, State Key Laboratory of Oncology in South China, Collaborative Innovation Center for Cancer Medicine, Guangzhou, China

Background: Immune checkpoint inhibitors (ICIs) have been recommended for the treatment of advanced hepatocellular carcinoma (HCC). However, due to the potential hazard of hepatitis B virus (HBV) reactivation, all ICI-related phase 3 studies had strict restrictions on HBV-DNA load (e.g., $<$ 500IU/ml). Meanwhile, delayed immunotherapy may lead to poor prognosis for patients with high HBV-DNA load. This study aims to compare the HBV reactivation between HCC patients with low or high HBV-DNA load undergoing ICIs and concurrent antiviral prophylaxis agents. **Methods:** This prospective, observational study (NCT04680598) recruited HCC participants who were consecutive hepatitis B surface antigen (HBsAg)-positive and received concurrent antiviral prophylaxis agents and initial ICIs. Participants were divided into low group (HBV-DNA$\leq$500 IU/ml) and high group (HBV-DNA $>$ 500 IU/ml) according to the baseline HBV-DNA level. HCC patients without ICIs from NCT02973685 were also included for analysis. The primary endpoint was the incidence of HBV reactivation. The secondary endpoints included HBV reactivation-associated hepatitis, ICIs disruption, overall survival (OS) and progression-free survival (PFS). **Results:** Between December 25, 2020 and February 23, 2024, a total of 1015 participants were enrolled: 356 in the low group and 659 in the high group. The median age was 51 years (range, 18-84) with majority being males (89.2%) and hepatitis Be antigen (HBeAg) positive (18.1%). Most participants did not receive previous anticancer treatment (84.5%). Participants in the high group were present with significantly higher HBeAg rate (7.0% vs 24.1%, $p< 0.001$), higher ALBI grade 2-3 rate (33.7% vs 49.9%, $p< 0.001$), larger tumor size (9.3 vs 10.9 cm, $p< 0.001$), more advanced BCLC stage C (72.5% vs 83.3%, $p< 0.001$). A significantly higher proportion of participants in the low group had previously received antiviral prophylaxis agents (16.3% vs 3.6%, $p< 0.001$). The HBV reactivation rate was 4.5% in the low group and 6.1% in the high group (relative risk, 1.24; 95% confidence internal [CI], 0.81-1.89, $p= 0.30$). The frequencies of HBV reactivation-associated hepatitis were 1.7% and 2.3%, respectively ($p= 0.53$). There were 92 participants (25.8%) in the low group and 201 participants (30.5%) in the high group had interrupted the ICIs treatment ($p= 0.12$). Compared with high group, the low group had shown significantly longer OS (29.8 vs 18.5 months, $p= 0.0057$) and PFS (9.1 vs 8.3 months, $p= 0.043$). However, participants in the high group had worse liver function and higher tumor burden compared with those in the low group, and the HBV-DNA group was not the independent risk factor for OS or PFS in the multivariable analysis. After included patients from NCT02973685 (n = 278), the HBV reactivation rate was 5.5% and 4.3% in patients treated with or without ICIs (p = 0.43). **Conclusions:** High HBV-DNA did not significantly increase the incidence of HBV reactivation in HCC patients treated with ICIs and concurrent antiviral prophylaxis. Clinical trial information: NCT04680598. Research Sponsor: None.

Comparative analysis of ctDNA-MRD and MVI in predicting postoperative recurrence of hepatocellular carcinoma. First Author: Jianan Feng, Second Department of Hepatobiliary Surgery, Zhujiang Hospital of Southern Medical University, Guangzhou, China

Background: Microvascular invasion (MVI) is currently recognized as a pathological feature strongly associated with HCC recurrence. However, its predictive performance in clinical practice remains suboptimal. The detection of minimal residual disease (MRD), which has demonstrated significant prognostic value across multiple cancer types, represents a promising alternative. Therefore, the first goal of this study is to detail the genomic alterations that potentially drive MVI or MRD, the second goal aims to compare their predictive power for postoperative recurrence in early-stage HCC patients. **Methods:** This study profiles the genomic landscape of tumor samples from 126 BCLC 0/A/B stage HCC patients using WES. Patients' longitudinal MRD status was determined through ctDNA detection in peripheral blood at preoperative, 1-, 4-, and 7-month postoperative time points using a tumor-agnostic fixed panel. Postoperative recurrence, confirmed by radiographic imaging, served as the endpoint events for comparing the sensitivity and specificity of two prediction models, with one model based on MVI classification and the other on longitudinal MRD positivity. More patients are currently being recruited and analyzed. **Results:** Among 126 enrolled HCC patients, 71 (56.3%) were classified as MVI-positive (M1/M2), while 55 (43.7%) were MVI-negative (M0). Of the 121 patients with at least one MRD test, longitudinal MRD positivity was observed in 27 patients (22.3%), with 94 patients (77.7%) remaining negative. Both MVI positivity and longitudinal MRD positivity were associated with postoperative recurrence, with longitudinal MRD group showing stronger statistical significance ($p < 0.001$ vs. $p = 0.032$). However, no distinct high-frequency mutation patterns were observed within either the MVI or longitudinal MRD groups. The most frequently altered genes in both groups included TP53, CTNNB1, JAK1, ARID1A, CDKN2A, and AXIN1. Of note, we also developed two prediction models based on MVI classification and longitudinal MRD positivity. The longitudinal MRD-based model demonstrated superior performance, with higher AUROC (0.835 vs. 0.715), PPV (0.357 vs. 0.162), accuracy (0.836 vs. 0.512), and TPR (0.833 vs. 0.786). **Conclusions:** Longitudinal MRD monitoring using a tumor-agnostic fixed panel demonstrates superior predictive performance over MVI classification for postoperative HCC recurrence with higher sensitivity, specificity, and accuracy. The findings highlight the potential of longitudinal MRD monitoring as a more reliable tool for guiding personalized postoperative management in early-stage HCC patients.Moreover, the combination of the two models may potentially offer superior predictive performance for recurrence, which is also a promising direction worthy of further exploration. Research Sponsor: None.

Real-world analysis of ctDNA and other biomarkers in patients with curatively resected stage I-III biliary tract cancer. First Author: Maen Abdelrahim, Houston Methodist Neal Cancer Center, Houston, TX

Background: Growing evidence supports the prognostic and predictive value of circulating tumor DNA (ctDNA) detection in gastrointestinal cancers. Building on previous work that demonstrated the feasibility of tumor-informed ctDNA testing in biliary tract cancer (BTC), this study aimed to evaluate ctDNA as a tool for detecting molecular residual disease (MRD) following curative resection and monitor recurrence during surveillance. **Methods:** A retrospective analysis of real-world data was performed on patients (N=171) with stage I-III resectable BTC who underwent ctDNA analysis using a personalized, tumor-informed 16-plex mPCR-NGS assay (Signatera; Natera, Inc.) from July 2020-February 2024. Plasma samples (n=769) were collected pre-operatively, postsurgically (within 2 to 12-weeks; MRD window), and longitudinally until death or last follow-up (surveillance window). The prognostic value of ctDNA was compared to traditional biomarkers such as CA19-9 and CEA. **Results:** A total of 171 patients with stage I-III BTC with a median age of 68 years (range 27-92) were included in this analysis. The median follow-up was 21 months (range: 2-97 months). ctDNA detection rates during the MRD and surveillance windows were 22% (18/83) and 32% (35/109), respectively. On evaluating clinical outcomes, ctDNA-positivity during MRD and surveillance was significantly associated with inferior disease-free survival (DFS) and overall survival (OS). Multivariate analysis confirmed ctDNA-positivity to be the most significant prognostic factor associated with DFS (HR: 10.91, 95%CI: 3.85-30.9, P$<$0.001) when adjusted for other clinicopathologic factors such as BTC subtype or tumor grade. Additionally, other biomarkers such as CA 19-9 and CEA did not predict clinical outcomes at either the MRD or surveillance windows (Table). **Conclusions:** The data show that ctDNA-positivity was associated with poor DFS and OS, both in the post-op and surveillance settings and that ctDNA detection using a personalized, mPCR-NGS assay was superior to current clinical biomarkers. These findings highlight the value of ctDNA monitoring to improve prognostication in BTC. Research Sponsor: None.

Association of biomarkers with clinical outcomes.

Biomarker	MRD	Surveillance
ctDNA	n= 83	n= 109
DFS	HR: 13.0, p $<$ 0.001	HR: 6.1, p $<$ 0.001
OS	HR: 12.0, p $<$ 0.001	HR: 17.8, p = 0.008
CA19-9	n= 53	n= 80
DFS	HR: 0.88, p =0.81	HR: 1.3, p = 0.51
OS	HR: 1.9, p = 0.389	HR: 10.1, p = 0.045
CEA	n= 18	n= 18
DFS	HR: 0.84, p = 0.85	HR: 0.54, p = 0.5

Integration of cfDNA fragmentomics for early biliary tract cancer detection. First Author: Jiwen Wang, Liver Cancer Institute, Zhongshan Hospital, Fudan University, Shanghai, China

Background: Biliary Tract Cancer (BTC) is a highly aggressive malignancy with poor survival outcomes, primarily due to the lack of effective early detection methods and late-stage diagnoses. Current diagnostic tools, including imaging and invasive endoscopic procedures, are limited in their sensitivity and specificity for identifying early-stage disease. This study addresses this critical gap by developing a novel, non-invasive approach for BTC detection using circulating cell-free DNA (cfDNA) fragmentomics features. **Methods:** The study cohort included 163 patients diagnosed with BTC and 165 healthy individuals, divided equally into training and validation cohorts. All participants' plasma samples were collected for a low-depth whole genome sequencing (WGS) process to extract three key cfDNA fragmentomics features: Copy Number Variation (CNV), Fragment Size Distribution (FSD), and Promoter Fragmentation Entropy (PFE). These features were utilized to develop a machine learning model, which was trained and validated through 5-fold cross-validation. An external cohort of 55 patients with benign diseases and 18 Tis/High-grade cases was used to further evaluate the model robustness. **Results:** The stacked ensemble model reached an Area Under the Curve (AUC) of 0.96 in the validation cohort, showing excellent performance in identifying BTC from healthy participants. At an 86% training specificity cutoff, sensitivity achieved 90.91% (95% CI: 81.26% - 96.59%) and specificity 87.88% (95% CI: 77.51% - 94.62%). While PFE performed as a strong single feature with an AUC exceeding 0.92. The model demonstrated its effectiveness in early-stage detection, with the sensitivity increasing from 80% in stage I to 95.65% in stage II. The model surpassed traditional biomarkers (AUC $>$ 95% compared to ~75% for CA19-9) and demonstrated consistent performance across subgroups. External validation revealed 89% sensitivity for early lesions and 89% specificity for benign cases, highlighting its potential for non-invasive early detection of BTC. **Conclusions:** This study demonstrates a reliable and non-invasive strategy for early BTC detection, leveraging cfDNA fragmentomics features and a robust machine learning framework. The model's high accuracy and reproducibility in both internal and external cohorts highlight its potential for clinical implementation, offering a transformative approach for BTC screening. Early diagnosis enabled by this method may significantly improve patient outcomes and survival rates, marking a major advancement in clinical practice. ADJUBIL: A phase II study of immunotherapy with durvalumab and tremelimumab in combination with capecitabine or without capecitabine in adjuvant situation for biliary tract cancer—The IKF/AIO-ADJUBIL trial. First Author: Thorsten Oliver Goetze, Krankenhaus Nordwest GmbH, Institut für Klinisch-Onkologische Forschung (IKF),UCT - Universitäres Centrum für Tumorerkrankungen Frankfurt, Frankfurt Am Main, Germany

Background: Patients (pts) with biliary tract cancer (BTC) still have a poor outcome with limited effective treatment options (only 20% of pts eligible for surgically curative resection, 5-year OS rates $<$ 10%). SOC for BTC is treatment with capecitabine according to the UK BILCAP trial, even though it was formally negative. Based on positive data (TOPAZ-1 and MediTreme trial in BTC, HIMALAYA trial for the STRIDE regimen in HCC), IO combination in the adjuvant setting seems promising. In preclinical studies – particularly in cholangiocarcinoma (CC) –antibody combinations showed stronger and more durable anti-tumor effects than monotherapy, due to synergistic impact on the tumor's immunosuppressive microenvironment. The ADJUBIL trial aimed at evaluating the clinical activity of the anti-PD-L1 antibody durvalumab and the anti-CTLA-4 antibody tremelimumab with or w/o capecitabine in pts with resectable BTC in the adjuvant setting in a pick-the-winner design. The winner of ADJUBIL could be tested in a follow-up phase 2/3 trial against the current SOC capecitabine. **Methods:** In the open-label, multicenter phase II ADJUBIL trial treatment-naïve pts with BTC after curative surgery (R0/R1) were randomized (1:1) to receive either tremelimumab (300 mg, once on D1, cycle 1) plus durvalumab (1500 mg, Q4W; max. 12 months), with (arm A) or w/o (arm B) capecitabine (1250 mg/m2 twice a day on day 1 – 14, Q3W; max. 8 cycles). Primary endpoint was recurrence-free survival at 12 months (RFS@12). The trial design is based on the Simon, Wittes and Ellenberg's Pick-the-winner design [Simon et al., 1985]. **Results:** 40 pts (ECOG 0 or 1) were enrolled in 12 centers in Germany: median age of 64.5 years; 53% males, 30% intra-hepatic CC, 58% extra-hepatic CC, 13% gallbladder. All pts received at least 1 dose of study treatment. The median number of cycles was 7. RFS@12 was 52.4% for arm A and 57.9% for arm B. After a median follow up of 13.8 months, median recurrence free survival was 14.98 (A) and 17.02 months (B). 1y OS rate was 85% (A) and 84% (B). While no new safety/toxicity signs were observed, arm A demonstrated a higher toxicity rate than arm B: 67% of pts having at least one grade $\geq$ 3 AE (A) vs. 53% (B) and 48% of pts having at least one grade $\geq$ 3 treatment related AE (A) vs. 32% (B). **Conclusions:** In the IKF/AIO-ADJUBIL trial, the expected RFS@12 of 56% was demonstrated for the combination of durvalumab / tremelimumab without capecitabine (57.9%), whereas no benefit in terms of RSF@12 was observed with additional capecitabine (52.4%). Together with similar 1y OS rates of 85% (A) and 84% (B) and higher toxicity rates in arm A, this indicates superiority of the combination of durvalumab / tremelimumab without capecitabine in pts with resectable BTC in the adjuvant setting. Clinical trial information: EU CT No.: 2024-511847-24-00. Research Sponsor: AstraZeneca.

Novel early-detection model based on cfDNA methylation and fragmentation features for liver cancer. First Author: Xiaobo Wang, Guangxi Medical University Cancer Hospital, Nanning, China

Background: In China, the 5-year survival rate of liver cancer patients is only 14%, far lower than the average of 43.7% for all cancer types. Early diagnosis and treatment are essential for survival. Traditional screening methods like AFP combined with abdominal ultrasound have low sensitivity. Recent studies suggest that blood cell-free DNA (cfDNA) characteristics could be a new screening approach for liver cancer. This study aims to compare methylation and fragmentation signals among liver cancer, hepatitis, cirrhosis patients, and healthy individuals, innovatively using these signals to construct an early-detection model which could improve patient prognosis. **Methods:** From July 2023 to November 2024, 315 blood samples were prospectively collected from five Chinese hospitals. The sample set included 105 liver cancer patients and 210 non-liver cancer controls (33 hepatitis, 30 cirrhosis, 147 healthy). This multi-center, multi-disease-controlled collection provides a robust data basis. Targeted enzymatic methyl sequencing detected over 600,000 methylation sites, enabling precise exploration of liver-cancer-related methylation. Beyond methylation, novel fragmentation features like break-point motifs, end motifs, arm-level count, fragment-size distribution and ratio were obtained. These, combined with methylation data, offer a multi-dimensional view for studying liver cancer pathogenesis and biomarkers. A gradient-boosted tree model, integrating 3840 methylation DMR features and fragmentomic model-predicted probabilities, was built. A nested cross-validation framework was used to optimize the model and ensure result accuracy. **Results:** The model achieved a high AUC of 0.97(95%CI: 0.95-0.99) in liver cancer detection. At 96.2% specificity, the model had a 91.4% sensitivity for overall liver cancer detection, with 83.7% and 95.8% sensitivity for stage I and II respectively. Among 63 patients with hepatitis or cirrhosis, the model accurately predicted negative results in 88.9% of patients. Notably, for patients hard to identify by traditional tumor markers like AFP and DCP, the model showed high detection rates. When AFP $<$ 400 ng/ml, the detection rate was 88.9%, and with concurrent DCP $<$ 40 ng/ml, it reached 87.0%. When AFP $<$ 20 ng/ml, the detection rate was 89.5%, and with DCP $<$ 40 ng/ml simultaneously, the detection rate was 83.3%. **Conclusions:** This study established an early-detection model for liver cancer by leveraging cfDNA methylation and fragmentation signals. The model demonstrated remarkable performance, particularly in detecting liver cancer patients who are difficult to identify through conventional methods. It blazes a new trail for the early detection of liver cancer and could significantly enhance patient prognosis. Research Sponsor: None.

The efficacy and safety of donafenib as postoperative adjuvant therapy in patients at high risk of recurrence following radical resection of hepatocellular carcinoma (HCC): A multicenter retrospective study. First Author: Jianhua Rao, Hepatobiliary Center, The First Affiliated Hospital Nanjing Medical University, Nanjing, Jiangsu, China

Background: Hepatectomy is a crucial treatment for long-term survival in patients with HCC; however, the high recurrence rate significantly impacts prognosis. Currently, there is no standard adjuvant therapy for this patient population. This study investigates the efficacy and safety of Donafenib as postoperative adjuvant therapy for patients with a high risk of recurrence after radical resection of HCC. **Methods:** We analyzed the clinicopathological data of HCC patients with a high risk of recurrence after radical resection, recruited from six medical centers between June 2021 and October 2024. High risk was defined by the presence of any of the following criteria: [i] tumor diameter $>$ 5 cm; [ii] multiple lesions of any size; [iii] microvascular invasion (MVI) grade 1 or 2; [iv] lesions complicated by tumor thrombus (TT); and [v] alpha-fetoprotein (AFP)$\geq$200 μg/L. Patients received either Donafenib monotherapy (D) or combination regimens (D+TACE-DT, D+ICI-DI, or D+TACE+ICI-DTI) as adjuvant therapy. We examined the relapse-free survival (RFS), overall survival (OS), and safety according to CTCAE 5.0. **Results:** 199 patients were included in this study, with a median age of 60 years (IQR: 53-67) at the data cut-off in January 2025. The cohort comprised 85.7% males, 83.4% with HBV infection, 87.9% with Child-Pugh A, and 79.4% with ECOG PS 0. Among patients at high risk, 52.3% had multiple high-risk factors, 53.3% had tumors $>$ 5 cm, 27.1% had multiple lesions, 53.3% had MVI grade 1 or 2, 13.6% had TT, and 36.7% had AFP$\geq$200 μg/L. Treatment distribution included 70 patients receiving D therapy, 69 receiving DT therapy, 46 receiving DI therapy, and 14 receiving DTI therapy. At the data cut-off, the median RFS for the overall population was 27.8 months (95%CI:22.3 months -NE), with a one-year RFS rate of 72.9% (95%CI:66.0%-80.5%) and two-years RFS rate of 55.4% (95%CI: 45.6%-67.2%). In subpopulations based on treatment regimens (D, DT, DI, DTI), the median RFS was 24.5 months (95%CI: 20.6 months -NE), 29.2 months (95%CI:22.3 months -NE), 30.0 months (95%CI: 19.0 months -NE), and 20.5 months (95%CI:9.3 months -NE), respectively. The median OS for the overall population and subpopulations had not yet been achieved. Among the overall population, 114 patients (57.3%) experienced treatment-related adverse events (TRAE) of any grade, with an incidence of grade 3 TRAE at 8.0% concluding with rash (5.5%), hand-foot syndrome (2.0%) and thrombocytopenia (0.5%); no patients experienced grade 4 or 5 TRAE. **Conclusions:** These preliminary results showed that donafenib as postoperative adjuvant therapy may effectively reduce the recurrence rate in patients at high risk of recurrence following radical resection of HCC, demonstrating good safety and tolerability. Effect of the combination of systemic and locoregional therapy on tumor recurrence and survival after liver transplantation for hepatocellular carcinoma (HCC). First Author: Khadyoth Nanneboyina, Methodist Dallas Medical Center, Dallas, TX

Background: Liver Transplantation (LT) results in the best survival in select HCC patients. Patients that do not meet transplant criteria based on tumor burden may require bridging therapies to downstage their disease to become eligible for LT. There is limited data on safety and efficacy of combining systemic therapy with locoregional therapy (LRT) prior to LT. **Methods:** This study was a single-center retrospective outcome analysis of all patients diagnosed with HCC who underwent LT between June 2018 and March 2024 ($n = 104$) with primary endpoints being 1-year post-LT survival and post-LT tumor recurrence. Explant pathology was also examined to assess tumor necrosis, viability, grade, and lymphovascular invasion. Patients were categorized into 2 groups: 1) LRT alone and 2) combination of LRT and systemic therapy. LRT included Transarterial chemoembolization, Radioembolization, Microwave Ablation, and Stereotactic Beam Radiation Therapy. Systemic therapies included Nivolumab + Ipilimumab, Atezolizumab + Bevacizumab, Sorafenib, Lenvatinib, Ramuricumab, and Cabozantinib. Pearson correlation analysis was used. **Results:** 89 patients received LRT alone and 15 patients received combination therapy. The median maximum tumor diameter in the LRT group was 2.4 cm and that of the combination group was 2.5 cm ($p = 0.136$). Patients in the combination therapy group also had a 3.5-fold increase in the average number of tumors, suggesting higher tumor burden. Average time to post-LT tumor recurrence was similar in combination therapy vs. LRT group (496.8 days vs. 546 days; $p = 0.41$). Patients receiving combination therapy had a trend towards better survival however this did not achieve statistical significance ($r = 0.13$, $p = 0.175$). A statistically significant negative correlation existed between not meeting Milan criteria at the time of transplant evaluation and post-transplant tumor recurrence (i.e., rate of post-transplant tumor recurrence increased if the Milan criteria were not satisfied; $r = -0.31$, $p < 0.001$). **Conclusions:** Our results show that combination therapy using systemic options in addition to LRT is an effective downstaging strategy for high-risk HCC patients and may improve post-transplant survival and reduce post-LT tumor recurrence. This preliminary data suggests that combination therapy may have a favorable impact on the time to post-LT tumor recurrence in patients with higher risk tumors. This further attests the strong need for sustainable downstaging pre transplantation. Using the synergistic effect of these modalities may help expand the pool of candidates who can undergo LT, which remains the most effective long term therapy for patients with HCC. We did not find any evidence of increased rejection or opportunistic infections post LT in the combination therapy cohort. Research Sponsor: None.

Ultra-sensitive detection of hepatocellular carcinoma (HCC) with methylation signal enrichment of ctDNA and hepatitis B virus (HBV). First Author: Nan Lin, The Third Affiliated Hospital, Sun Yat-sen University, Guangzhou, China

Background: Aberrant methylation patterns in cell-free DNA (cfDNA) have been identified as effective biomarkers for HCC early detection, with circulating tumor DNA (ctDNA) from HCC patients exhibiting distinct methylation signatures. Additionally, HBV infection and the associated methylation alterations are closely linked to the development and progression of both cirrhosis and HCC. In this study, we utilize an ultra-sensitive Methylation Anchor Probe for Low Signal Enrichment (MAPLE) to enrich HCC-related methylation signals in ctDNA, as well as those from HBV genomes. By integrating these signals with a machine learning model, we achieve improved discrimination between HCC patients and non-cancer controls, while reducing false positives in individuals with cirrhosis. **Methods:** Whole blood samples were collected from 246 participants, including 96 HCC patients, 123 healthy controls, and 27 cirrhosis individuals. cfDNA was extracted from plasma, followed by enzymatic conversion and library preparation. Targeted hybrid capture was performed using a custom-designed panel that enriched methylation signals associated with HCC and HBV CpG islands. The final libraries were sequenced using next-generation sequencing (NGS). A machine learning model was developed, incorporating methylation features derived from both the human genomic regions and HBV CpG islands. Participants were randomly divided into training and test sets at a 3:1 ratio, with the training set undergoing 5-fold cross-validation for model optimization. To assess model robustness, 40 resampling iterations were conducted to evaluate performance in distinguishing HCC patients across various stages from non-cancer individuals. **Results:** Among all participants, 39.8% tested positive for HBV. Incorporating methylation features from the HBV genome into the model improved sensitivity for detecting early-stage HCC in HBV-positive individuals and enhanced accuracy in distinguishing early-stage HCC from cirrhosis. Analysis of selected HBV methylation features revealed hypermethylation in HCC patients compared to individuals with cirrhosis and healthy controls. The final machine learning model achieved a specificity of 97.6% (96.2%–97.9%). Sensitivities for detecting HCC across all stages were: I: 76.4% (73.5%–79.4%), II: 94.6% (92.0%–97.3%), III: 99.5% (98.8%–100.0%), and IV: 100.0% (100.0%–100.0%). For distinguishing cirrhosis, the model demonstrated a specificity of 81.9% (77.6%–86.3%). **Conclusions:** Using the ultra-sensitive MAPLE technique, we developed a novel panel that enriches methylation signals from both the human and HBV genomes. This assay significantly improved sensitivity for detecting early-stage HCC. By incorporating HBV genome features, we further enhanced the accuracy of distinguishing early-stage HCC from cirrhosis in HBV-positive individuals. Use of artificial intelligence-powered spatial analysis of tumor microenvironment to predict the prognosis in resected gallbladder cancer. First Author: Young Hoon Choi, Department of Medicine, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, South Korea

Background: Gallbladder cancer (GBC) is a highly lethal disease with a lack of reliable biomarkers. The tumor microenvironment (TME) is closely associated with prognosis, but its clinical application as a prognostic marker is limited by evaluation challenges. This study assessed the prognostic significance of AI-powered TME analysis in resected GBC patients. **Methods:** A total of 225 GBC patients with an R0 resection were enrolled, and their hematoxylin & eosin (H&E)-stained GBC sections were analyzed using Lunit SCOPE IO, an artificial intelligence (AI)-powered whole-slide image (WSI) analyze, to evaluate TME-related features, including tumor-infiltrating lymphocyte (TIL) density, fibroblast (FB) density, and tertiary lymphoid structure (TLS) counts. Risk stratification was based on TME-related risk factors (low TIL, high FB, low TLS), and survival outcomes were assessed. External validation was conducted using 146 biliary tract cancer patients. **Results:** Overall survival (OS) and disease-free survival (DFS) declined as the number of TME-related risk factors increased. Patients with three risk factors had the poorest outcomes (median OS: 17.7 months [reference]; median DFS: 12.7 months [reference]), followed by those with two risk factors (median OS: 115.9 months, HR = 0.40, 95% CI: 0.19–0.85; median DFS: 57.8 months, HR = 0.37, 95% CI: 0.18–0.74) and one risk factor (median OS: 126.5 months, HR = 0.34, 95% CI: 0.16–0.74; median DFS: 117.2 months, HR = 0.30, 95% CI: 0.15–0.62). Patients with no risk factors had the best survival (median OS: not reached, HR = 0.20, 95% CI: 0.06–0.67; median DFS: not reached, HR = 0.13, 95% CI: 0.04–0.41). External validation confirmed consistent trends across all risk groups. **Conclusions:** AI-powered TME analysis shows promise as a practical tool for identifying TME-related risk factors using H&E-stained WSI, providing valuable prognostic information for resected GBC patients. Unveiling the role of sodium glucose cotransporter-2 inhibitors in hepatocellular carcinoma patients with cirrhosis: A comparative global cohort study. First Author: Asfand Yar Cheema, Cleveland Clinic Foundation/ Fairview Hospital, Cleveland, OH

Background: Hepatocellular carcinoma (HCC) is a leading cause of cancer-related mortality worldwide, and is often associated with chronic liver disease and cirrhosis. Despite advancements in therapeutic options, the prognosis for HCC patients remains poor. Sodium-glucose cotransporter 2 inhibitors (SGLT2i) exhibit anti-inflammatory, antifibrotic, and anti-carcinogenic properties, potentially influencing cancer biology via metabolic and oxidative stress modulation. Our study aimed to evaluate the impact of SGLT2i on outcomes of HCC patients with underlying cirrhosis using a large global database. **Methods:** We conducted a retrospective, propensity score-matched cohort study using TriNetX Analytics Network database. We compared patients aged $>$ 18 years with HCC and cirrhosis who received SGLT2i to those who did not receive SGLT2i from 1/1/2014 to 1/1/2023 for one year. The study cohort included 1,254 cirrhotic HCC patients on SGLT2i, while the control cohort comprised 40,820 cirrhotic HCC patients not on SGLT2i. Propensity score matching was applied to balance demographics, HCC-directed therapies, comorbidities, laboratory values, and medications. Kaplan-Meier analysis estimated event-free survival and overall survival, with comparisons using log-rank tests. The primary outcomes were all-cause mortality, venous thromboembolism (VTE), and all-cause hospitalization rates. Secondary outcomes included all-cause ICU admissions, ischemic stroke/TIA, acute kidney injury (AKI), and septic shock. **Results:** Propensity score matching adjusted for key characteristics resulted in 1,020 matched pairs for each cohort. Our comparative analysis showed that the SGLT2i group had significantly lower all-cause mortality, with a hazard ratio (HR) of 0.399 (95% confidence interval [CI] 0.314, 0.507). Specific outcomes associated with improvement in the SGLT2i group: VTE (HR 0.607, 95% CI 0.481, 0.765), all-cause hospitalization rates (HR 0.568, 95% CI 0.501, 0.644), all-cause ICU admissions (HR 0.522, 95% CI 0.396, 0.689), ischemic stroke/TIA (HR 0.585, 95% CI 0.389, 0.878), thrombocytopenia (HR 0.578, 95% CI 0.470, 0.711), AKI (HR 0.708, 95% CI 0.588, 0.852), and septic shock (HR 0.528, 95% CI 0.382, 0.728). **Conclusions:** Our study highlights the association of SGLT2i with significant improvements in clinical outcomes for HCC patients with cirrhosis. SGLT2i use was linked to reduced all-cause mortality, VTE, hospitalizations, ICU admissions, and complications such as ischemic stroke/TIA, thrombocytopenia, AKI, and septic shock. These findings suggest SGLT2i may offer therapeutic benefits beyond their cardiovascular and renal effects, potentially influencing cancer biology and systemic complications in this high-risk population. Prospective trials are warranted to validate these findings and assess their safety and efficacy. Research Sponsor: None.

Neoadjuvant transhepatic arterial infusion chemotherapy (HAIC) with FOLFOX regime plus cadonilimab (PD-1/CTLA-4 bispecific antibody) for resectable multinodular CNLC Ib/IIa hepatocellular carcinoma (CAR_Hero study). First Author: Yongguang Wei, First Affiliated Hospital of GuangXi Medical University, Nanning, Guangxi, China

Background: The recurrence rate of hepatocellular carcinoma (HCC) remains high, with multinodular HCC being a well-defined high-risk factor for recurrence. However, standardized neoadjuvant or adjuvant therapies for HCC have yet to be definitively established to effectively improve survival outcomes. **Methods:** In this ongoing single-center, phase 2, open-label, prospective cohort clinical trial, eligible pts were randomly assigned (1:1:1) to three arms (15 pts per arm). Neoadjuvant therapies included: (A) 2 cycles cadonilimab (6mg/kg Q2W); (B) once FOLFOX- HAIC and 2 cycles cadonilimab; (C) once FOLFOX-HAIC. Pts receive scheduled surgery on day 21-28 and postoperative adjuvant HAIC one month after surgery. The primary endpoints were major pathologic response (MPR, defined as ≤50% residual living tumor) and the 1-year recurrence-free survival (RFS) rate. Secondary endpoints included overall response rate (ORR, assessed per RECIST 1.1) and treatment-related adverse events (TRAEs). Additionally, a direct hepatectomy cohort was retrospectively collected as reference data. **Results:** A total of 42 pts were enrolled. Among them, 2 pts withdrew due to their desire to pursue conversion therapy. 38 pts underwent hepatectomy and were included in the efficacy analyses (A: 14pts, B: 14pts, C: 12pts). The median age was 55 years (range: 32-72), with 90.5% being male and 90.5% infected with hepatitis B virus. Arm B had the highest MPR rate of 78.6%, significantly higher than Arms A (35.7%) and C (20.0%) (*P* = 0.011). Additionally, Arm B had the highest ORR (A: 14.3%; B: 40.0%; C: 8.3%), and lowest MVI detection rate (A: 50.0%; B: 21.4%; C: 40.0%). Focal heterogeneity was partially observed. The DCR was 100%. The most common TRAEs were elevated aspartate transaminase (64.3%) and alanine aminotransferase (59.5%). Grade 3-4 TRAEs occurred in 3 pts(hepatic dysfunction and erythema annulare). In Arms A and B, 4 pts experienced a delay in scheduled surgery by 2-4 weeks. The combination of HAIC and cadonilimab did not lead to a significant increase in TRAEs. After propensity score matching, the direct hepatectomy cohort was screened. Kaplan-Meier analysis revealed that the neoadjuvant cohort had a longer recurrence-free survival (RFS) time compared to the direct hepatectomy cohort (median RFS not reached *vs.* 24.7 months; *P* = 0.0048) and a lower MVI detection rate (36.8% vs. 52.6%). **Conclusions:** Neoadjuvant FOLFOX-HAIC combined with cadonilimab had a considerable antitumor activity, and a manageable safety for the resectable multinodular HCC. It brought the fewer MVIs of tumor and a better RFS. Clinical trial information: ChiCTR3000033692. Research Sponsor: None.

Prognostic significance of pathological response in unresectable hepatocellular carcinoma treated with immune checkpoint inhibitor-based conversion therapy. First Author: Wen-Jing Zheng, Department of Liver Surgery & Transplantation, Liver Cancer Institute, Zhongshan Hospital, Fudan University, Shanghai, China

Background: Immune checkpoint inhibitor (ICI)-based conversion treatment is increasingly utilized for patients with initially unresectable hepatocellular carcinoma (HCC). However, standardized histopathologic markers for assessing treatment response and predicting survival outcomes remain inadequately defined. **Methods:** This retrospective study analyzed 225 HCC patients who underwent conversion treatment followed by curative resection. The residual viable tumor percentage (RVT%) was calculated as the proportion of RVT surface area to the total tumor bed area. Kaplan-Meier and Cox regression analyses were used to evaluate the relationship between RVT% and recurrence-free survival (RFS) as well as overall survival (OS). **Results:** Complete pathologic response (CPR), defined as 0% RVT, was achieved in 60 patients (26.7%) and was strongly associated with improved survival outcomes. Patients with CPR exhibited significantly better RFS (HR: 0.23, 95% confidence interval [CI]: 0.13–0.41, $p < 0.001$) and OS (HR: 0.17, 95% CI: 0.05–0.56, p = 0.003) compared to non-CPR patients. Multivariate analysis confirmed non-CPR as an independent risk factor for both RFS (HR: 3.67, 95% CI: 1.94–6.96, $p < 0.001$) and OS (HR: 4.43, 95% CI: 1.21–16.18, p = 0.022). Major pathologic response (MPR), defined as RVT% ≤ 10%, was observed in 91 patients (40.4%) and was also significantly associated with improved RFS and OS (all $p < 0.05$). Stratification by RVT% thresholds revealed a stepwise association between decreasing RVT% and improved survival outcomes. RVT% ≤ 30% demonstrated significant predictive power for both RFS (HR: 0.48, 95% CI: 0.30–0.75, p = 0.001) and OS (HR: 0.60, 95% CI: 0.31–1.16, p = 0.020). Notably, patients with CPR achieved a two-year survival rate of 96.7%, compared to 86.1% in non-CPR patients. Despite the high radiological response rate (CR+PR, 92.4%), substantial discrepancies were observed between radiological and pathological assessments, and 56.7% of patients who achieved pathological complete response (CPR) did not exhibit radiological complete response (CR). Kaplan-Meier analysis showed no significant differences in RFS or OS among three regimens: anti-PD-1 monotherapy (n = 25, 11.1%), anti-PD-1/PD-L1 plus anti-VEGF (n = 21, 9.3%), and anti-PD-1 plus TKI (n = 179, 79.6%). Transarterial chemoembolization (TACE) did not significantly increase the proportion of patients achieving CPR but notably enhanced the proportion of patients with RVT% ≤ 30%. **Conclusions:** Both CPR and MPR are robust prognostic markers of RFS and OS in HCC patients undergoing ICI-based conversion treatment. The superior sensitivity of pathological evaluation underscores its advantage over radiological assessment in accurately reflecting treatment outcomes. Research Sponsor: National Natural Science Foundation of China; (82341027 and 82072715).

Comparison outcome of transarterial chemoembolization combined with immune checkpoint inhibitors plus bevacizumab or lenvatinib as first-line therapy for advanced hepatocellular carcinoma. First Author: Ningning Zhang, Department of Hepatobiliary Oncology, Liver Cancer Center, Tianjin Medical University Cancer Institute and Hospital, National Clinical Research Center for Cancer, Key Laboratory of Cancer Prevention and Therapy, Tianjin Medical University, Tianjin, China

Background: Transarterial chemoembolization (TACE) combined with immunotherapy and anti-angiogenic therapy for advanced hepatocellular carcinoma (HCC) presents a promising first-line treatment option. **Methods:** We assessed overall survival (OS), progression-free survival (PFS), objective response rate, and adverse events between the TACE-ICI-Len group (n=160) and the TACE-ICI-Bev group (n=216) as first-line therapy for advanced HCC. Inverse probability of treatment weighting was employed to minimize bias. Efficacy was evaluated using RECIST 1.1 and mRECIST criteria. **Results:** The TACE-ICI-Bev group demonstrated significantly improved OS and PFS compared to the TACE-ICI-Len group, especially across BCLC-B and BCLC-C stages (Total: mOS 22.8 vs. 15.4 months, $p<0.001$; mPFS 12.4 vs. 8.3 months, $p<0.001$; BCLC-B: mOS 23.3 vs. 16.6 months, p=0.005; mPFS 14.0 vs. 8.2 months, $p<0.0001$; BCLC-C: mOS 22.3 vs. 15.1 months, p=0.002; mPFS 11.0 vs. 8.0 months, $p<0.001$). Within the TACE-Bev-Ate subgroup, OS and PFS were further enhanced (Total: mOS 26.3 months; mPFS 13.8 months; BCLC-B: mOS 27.7 months; mPFS 16.7 months; BCLC-C: mOS 24.2 months; mPFS 12.6 months). The incidence of gastrointestinal bleeding (GB) was significantly higher in the TACE-ICI-Bev group compared to the TACE-ICI-Len group (13.8% vs. 6.2%, $p<0.001$). Notably, GIB was significantly more frequent in patients with portal hypertension (PHT) compared to those without, in both the TACE-ICI-Bev group (30.9% vs. 6.6%, $p<0.001$) and the TACE-ICI-Len group (20.2% vs. 0%, $p<0.001$). **Conclusions:** TACE-ICI-Bev demonstrated superior OS and PFS compared to TACE-ICI-Len as first-line treatment for advanced HCC, with an acceptable safety. Management of PHT in patients with advanced HCC is critical to optimizing patient outcomes. Research Sponsor: None.

Association of differential expression of genes with survival and relapse in patients treated on the BILCAP clinical trial: Gene expression identification and response to adjuvant chemotherapy in early-stage biliary tract cancer. First Author: Valerie Elizabeth Crolley, UCL-University College London (United Kingdom), London, United Kingdom

Background: Adjuvant capecitabine is standard of care based on the results of the BILCAP clinical trial, comparing adjuvant capecitabine with observation for early-stage biliary tract cancer (BTC). Translational work on data from BILCAP aims to identify differentially expressed genes in patients whose tumours relapsed or who died from their cancer, as there are currently no validated biomarkers to predict the risk of relapse or death or response to adjuvant chemotherapy in early-stage BTC. **Methods:** Bulk RNA sequencing (RNAseq) was performed on archived fixed formalin samples from consented BILCAP patients. Extracted RNAseq data was quantified using salmon, before undergoing differential gene expression (DGE) using DESeq2 to identify differentially expressed genes in patients who died or whose tumours relapsed, compared to those or survived or had no relapse, accounting for batch effect, different anatomical subtypes and adjuvant treatment. Tumour anatomical subtype was highly associated ($p < 0.05$) with PC2 during principal component analysis and was included as a co-variate during analysis. **Results:** 200 patient samples were analysed; 104 / 200 (52%) patients received chemotherapy while 96 had observation. 142 / 200 (71%) tumours relapsed and 142 / 200 (71%) patients died by the time of data cut off. DGE analysis identified 146 significantly ($p < 0.01$) upregulated genes in patients who died, including PRSS2, AMY2A, SPINK1, CTRC and CELA2A, with significantly ($p < 0.01$) downregulated genes including HP, PHF14, FLI1, NAV3 and NOVA1. 118 genes were significantly ($p < 0.01$) upregulated through DGE analysis in patients died or relapsed, including PAX5, FAM188B, NET1, DEK and WDR1 with significantly ($p < 0.01$) downregulated genes including RQCD1, CPA1, FLI1, NAV3 and NOVA1. 41 genes were significantly ($p < 0.01$) upregulated in both death and relapse, including PAX5, TLK1, ALB, HEATR3 and RAB11FIP4. 171 genes were significantly ($p < 0.01$) up regulated in patients who died or had their tumours relapse after adjuvant chemotherapy and not in patients undergoing observation, which included THBS1, FAM65B, UBE2W, RPLP0P2 and NPM1, and 66 genes were significantly ($p < 0.01$) downregulated, which included RP11-521B24.3, FLI1, CACNA1A, KCNH6 and MKKS. Gene ontology enrichment analysis identified the upregulated genes as being associated with cytoplasmic translation and the synthesis of both intra- and extracellular RNA and protein complexes. **Conclusions:** Differential gene expression of the BILCAP cohort identified genes associated with cancer relapse and death, including genes associated with a lack of response to adjuvant chemotherapy. Research Sponsor: Incyte.

Comparative analysis of stereotactic body radiotherapy (SBRT) vs. SBRT with bridge therapies for hepatocellular carcinoma patients awaiting liver transplantation: A multi-center study (2010-2020). First Author: Teja Sureddi, Virtua Our Lady of Lourdes, Camden, NJ

Background: Locoregional therapies, including SBRT, are essential in managing hepatocellular carcinoma (HCC) patients awaiting liver transplantation. This study evaluates outcomes of SBRT alone versus SBRT combined with other bridge therapies over a 5-year follow-up. **Methods:** Data from the TriNetX database (2010–2020) were used to compare two matched cohorts: patients receiving SBRT alone and those receiving SBRT with additional bridge therapies, including transarterial chemoembolization (TACE) and radiofrequency ablation (RFA). Patients included were those meeting liver transplant criteria and classified as AJCC Stage I or II. **Results:** Before matching, the cohorts included 185 patients in the SBRT Alone group and 363 in the SBRT with Other Bridge Therapies group, with significant differences in ethnicity (48.11% vs. 57.3%, p=0.0411) and race (40.54% unknown vs. 31.68%, p=0.0393). After matching (153 patients per group), all variables were balanced, including age (69.4 $\pm$ 8.58 vs. 69.1 $\pm$ 8.09, p=0.9039) and ethnicity (50.98% vs. 45.75%, p=0.3601). Theoverall survival rate at 5-year follow-up was 61.53% in the SBRT alone group and 62.02% in the SBRT with other therapies group. There was no significant difference between the groups (HR: 0.958, p=0.8417). In the secondary analysis. For acute hepatic failure, the risk was 22.73% for SBRT Alone versus 25.64% for SBRT with Other Bridge Therapies (RR: 0.886, 95% CI: 0.413–1.901, p=0.7567). The risk of decompensated liver disease was 37.74% versus 40% (RR: 0.909, 95% CI: 0.593–1.501, p=0.8054). Procedure-related complications occurred in 11.61% of the SBRT Alone group compared to 12.12% in the other group (RR: 0.958, 95% CI: 0.482–1.904, p=0.9016). Portal vein thrombosis was more frequent in the SBRT Alone group at 12% versus 7.87% (RR: 1.524, 95% CI: 0.712–3.262, p=0.2733). The risk of major adverse cardiovascular events (MACEs) was 24.75% versus 22.12% (RR: 1.158, 95% CI: 0.607–2.213, p=0.6558). Finally, kidney outcomes (acute kidney injury, CKD, ESRD) were similar, with risks of 62.75% and 63.40% (RR: 0.99, 95% CI: 0.834–1.175, p=0.9057). These results suggest no statistically significant differences in the risk of adverse outcomes between the two groups. **Conclusions:** SBRT alone and SBRT with bridge therapies provide comparable long-term survival outcomes in HCC patients awaiting liver transplantation, with differences in specific complications warranting further study. Impact of radionuclide therapy on survival outcomes for de novo metastatic gastroenteropancreatic neuroendocrine tumors: A population-based cohort study. First Author: Zhiqiao Liu, The Affiliated Hospital of Southwest Medical University, Luzhou, Sichuan, China

Background: De novo metastatic gastroenteropancreatic neuroendocrine tumors (dmGEP-NETs) are difficult to treat without the option of radical surgery. The aim of this study was to investigate the survival outcomes of radionuclide therapy. **Methods:** Patients diagnosed with dmGEP-NETs from the Surveillance, Epidemiology, and End Results (SEER)-17 registry database (2000–2021) were included in this study. The impact of radionuclide therapy on overall survival (OS) and cancer-specific survival (CSS) was assessed using univariate Kaplan-Meier method and multivariate Cox regression analysis. **Results:** From 2010 to 2021, a total of 9657 patients at diagnosis years with dmGEP-NETs were determined from the SEER database. On the univariate analysis, patients with dmGEP-NETs who received radionuclide therapy significantly obtained better OS (5-year rate: 55.6% vs. 37.9%; p $<$0.001) and CSS (5-year rate: 58.2% vs. 44.2%; p $<$0.001) than patients without radionuclide therapy. Finally, the significant clinical factors associated with OS and CSS were included into multivariate Cox regression analysis to investigate the independent prognostic value of radionuclide therapy. The results showed that radionuclide therapy was an independent prognostic factor for OS (hazard ratio [HR], 0.530; 95% confidence interval [CI], 0.348-0.808; p=0.003) and CSS (HR, 0.508; 95%CI, 0.319-0.808; p=0.004) in patients diagnosed with dmGEP-NETs. Besides, radionuclide therapy was associated with better OS (p $<$0.001) and CSS (p $<$0.001) compared to beam radiation. **Conclusions:** Radionuclide therapy was associated with improved survival in patients with de novo metastatic gastroenteropancreatic neuroendocrine tumors. A phase II study of lenvatinib plus everolimus in advanced extra-pancreatic neuroendocrine tumors (epNETs): Updated results and real-world comparison. First Author: Guglielmo Vetere, Department of Gastrointestinal Medical Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Advanced epNETs are rare malignancies with limited treatment options beyond somatostatin analogs, peptide receptor radionuclide therapy, and Everolimus (E). Preclinical evidence suggests that dual blockade of VEGF and FGF is an effective anti-angiogenic strategy and that concomitant inhibition of the mTOR pathway may be further synergistic. Lenvatinib (L), a multi-target tyrosine kinase inhibitor, suppresses VEGFR, FGFR, and other angiogenic pathways, while E targets the mTOR pathway. Their combination may synergistically impair angiogenesis and tumor growth. **Methods:** This open-label, single-center, phase II study evaluated L + E in patients (pts) with advanced, progressive, well-differentiated (a/p w-d) epNETs. The primary endpoint was objective response rate (ORR). Secondary endpoints were progression-free survival (PFS) and safety. Following a 2-stage design with H0: ORR $<$ 5% and H1: ORR $\geq$ 20%, up to 32 pts were needed for type I & II error = 10%. In a post-hoc analysis, a real-world cohort of 2:1 matched a/p w-d epNET pts receiving E alone served as a historical comparator. Differences in ORR were assessed using univariable and multivariable logistic regression while those in terms of PFS were analyzed with propensity score-based inverse probability of treatment weighting (IPTW)-adjusted Cox proportional hazards regression and Kaplan-Meier method. **Results:** 32 pts were enrolled. The starting dose regimen was L 18 mg + E 5 mg p.o. daily with L being reduced to 14 mg p.o. daily after the first 3 pts experienced Grade 3 adverse events (AEs). Median age was 59 years (range 33 – 76), and 59% were male. Primary tumor sites included small bowel (59%), lung & thymus (16%), unknown (16%), and colorectal (9%) with the majority being G2 (69%). Median number of prior therapies was 2 (range 0 – 3) while 11 pts had carcinoid syndrome. The study met its primary endpoint: L + E achieved an ORR of 43.8% (6.3% unconfirmed), which was significantly higher than that observed with E alone (3.1%; OR 24.50, 95% CI 5.09 – 117.94, $p < 0.001$). This finding was supported by the multivariable analysis (OR 20.43, 95% CI 3.93 – 106.13, $p < 0.001$). After propensity score-based IPTW adjustment, a trend toward longer PFS favoring L + E (16.0 months [95% CI 13.0 – 23.6] *vs* 11.3 months [95% CI 8.6 – 24.3]; HR 0.88 [95% CI 0.51 – 1.52], $p = 0.647$) was observed. On trial, 23 Grade 3 AEs (11 after L dose reduction) were noted with elevated LFTs (8), hypertension (6) and thrombocytopenia (4) being the most frequent while one Grade 4 AE (hypertriglyceridemia) was reported. **Conclusions:** L + E demonstrated markedly superior ORR and a trend toward prolonged PFS compared to E alone with a manageable safety profile. These findings highlight its potential as a therapeutic option for a/p w-d epNETs and warrant further investigation in randomized trials. Clinical trial information: NCT03950609. Research Sponsor: MD Anderson Cancer Center; Jack T. and Lillian S. Clift Fellowship; Eisai Co., Ltd.

Landscape of functional DLL3 expression in gastroenteropancreatic neuroendocrine neoplasms (GEP NENs). First Author: Rohit Thummalapalli, Memorial Sloan Kettering Cancer Center, New York, NY

Background: Delta-like ligand 3 (DLL3) is an emerging target in multiple neuroendocrine cancers including small cell lung cancer but remains underexplored in GEP NENs. With the ongoing development of multiple classes of therapeutics against DLL3, there is a need to understand the landscape of functional DLL3 expression in GEP NENs. **Methods:** DLL3 immunohistochemistry (IHC) was completed on available tumor samples from patients (pts) with GEP poorly differentiated neuroendocrine carcinomas (GEP NECs) and grade 3 well differentiated pancreatic NETs (G3 WD PanNETs) treated between 2018-2024 and a tissue microarray of resected G1-G2 WD PanNETs (185 samples total). DLL3 positivity (+) was defined as $\geq$ 5% weak (1+) IHC staining. H-scores were calculated by combining % of + tumor cells and degree of staining (1, 2, 3+), ranging from 0-300. Correlations between DLL3 status and clinicopathologic features and outcomes were analyzed. Among selected pts with DLL3 IHC+ GEP NENs, DLL3 immunoPET imaging using the diagnostic tracer [^{89}Zr]Zr-DFO-SC16.56 was completed to evaluate functional expression. **Results:** Among GEP NECs overall, 50/69 were DLL3+ (72%; median H-score 50, interquartile range [IQR] 0-160, range 0-300), including 13/16 esophagogastric (median 45), 11/13 pancreatic (median 60), 7/11 hepatobiliary (median 120), 16/26 colorectal (median 32.5), and 3/3 NECs of other/unknown origin (median 60), with DLL3 expression higher in small cell vs large cell histology (median 120 vs 15, $P = 0.011$). Among GEP NECs, there was no association between DLL3+ and individual genomic alterations, PFS to 1L platinum-based therapy (median 4.6 mo vs 4.7 mo in DLL3-negative [-], $P = 0.435$), or OS from diagnosis of advanced disease (median 15.5 vs 12.2 mo in DLL3-, $P = 0.629$). Among WD PanNETs, DLL3 expression was detected in 3/46 (7%) G1, 1/23 (4%) G2, and 19/47 (40%) G3 tumors, with median Ki67 higher among DLL3+ vs DLL3- tumors overall (42% vs 6%, $P < 0.001$) and within G3 WD PanNETs alone (48% vs 30%, $P = 0.009$). Among pts with advanced G3 WD PanNETs, DLL3+ was associated with shorter OS from diagnosis of advanced G3 disease (median OS 23.1 mo vs 43.9 mo in DLL3-, $P = 0.012$). [^{89}Zr]Zr-DFO-SC16.56 DLL3 PET imaging was completed on 5 pts with DLL3 IHC+ GEP NENs at progression on standard systemic therapy. Notably, a pt with pancreatic NEC and liver metastases (DLL3 IHC H-score 60) demonstrated high tumoral tracer uptake (SUV_{max} 36.7) with 95% of tumor lesions demonstrating DLL3 PET avidity. Among 4 pts with DLL3 IHC+ G3 WD PanNETs, DLL3 PET was positive in 3/4, with SUV_{max} ranging from 14.4-27.5 and % of DLL3 PET+ tumor lesions ranging from 50-100%. **Conclusions:** DLL3 is expressed on a majority of GEP NECs and on a minority of well differentiated PanNETs marked by high grade disease and poor clinical outcomes. Functional DLL3 PET imaging highly suggests DLL3 as a promising therapeutic target in both GEP NECs and high grade WD PanNETs. Research Sponsor: Memorial Sloan Kettering Cancer Center.

Surgical debulking versus non-surgical management for the control of carcinoid syndrome in metastatic small bowel neuroendocrine tumors. First Author: Rushabh Gujarathi, Department of Medicine, Section of Hematology and Oncology, University of Chicago, Chicago, IL

Background: Somatostatin analogues (SSAs) are first-line systemic therapeutics for tumor- and symptoms control in well-differentiated small bowel neuroendocrine tumors (SBNETs) with liver metastases. Surgical debulking of neuroendocrine tumor liver metastases (NETLMs) has historically been associated with symptom control in patients with carcinoid symptoms. Herein, we compare clinical outcomes in patients with metastatic SBNETs treated with surgical debulking for NETLMs to SSA alone or in combination with non-surgical liver directed therapies (LDTs) i.e. bland embolization or radioembolization. **Methods:** Patients with serotonin-producing SBNETs and NETLMs with documented symptoms of carcinoid syndrome were included in this retrospective chart review. Primary outcome was symptom-free-interval (SFI), defined as the time from start of treatment until return/worsening of symptoms. Patients were censored for SFI if a new line of tumor-directed therapy was initiated for radiographic disease progression in the absence of return/worsening of symptoms. Time to event outcomes were analyzed using Kaplan-Meier estimations, log-rank test, and Cox proportional hazards regression model. Medians were compared using the Mann–Whitney U test. **Results:** Between 2018 – 2024, 64 consecutive patients with carcinoid symptoms were included for analysis. 42 patients (65.6%) underwent surgical debulking (SDB) of NETLMs and 22 patients were treated with SSA alone (n = 14) or SSA plus LDT (n = 8). The proportion of patients reporting symptom improvement was not significantly different between the SDB and non-surgical (NS; SSA + LDT) groups (SDB = 38, 90.5% vs. NS = 19, 86.4%; p = 0.68). Among those with symptom improvement (n = 57), SFI was significantly longer in the SDB group (median SFI; SDB = 28.2 months [m] vs. NS = 15.9 m; p = 0.004). Radiographic PFS was also significantly prolonged in the SDB group (SDB = 26.1 m vs. NS = 12 m; HR, 0.53; 95% CI, 0.29 – 0.95; p = 0.03). Within the SDB group, there was no significant difference in SFI between patients who continued to receive SSA post-op (n = 23) and those in whom SSA was discontinued (n = 19) post-op (28 m vs. 30.6 m; p = 0.85). Post-treatment median nadir serotonin was significantly lower in the SDB group (total N = 41 [SDB = 31 + NS = 10]; SDB = 299 ng/mL vs. NS = 947.5 ng/mL; $p < 0.001$). Median percentage decrease (from pre-treatment to nadir values) in serum serotonin was higher in the SDB group with the difference approaching significance (total N = 30 [SDB = 22 + NS = 8]; SDB = 80.9% vs. NS = 51.5%; p = 0.06). **Conclusions:** Despite the frequent use of SSAs, surgical debulking of NETLMs in patients with carcinoid symptoms remains superior for symptom control and should therefore be considered in these patients. Research Sponsor: None.

TROP2 expression in the gastroenteropancreatic neuroendocrine tumors: An analysis of 179 patients. First Author: Junaid Arshad, The University of Arizona Cancer Center, Tuscon, AZ

Background: Trophoblast cell-surface antigen 2 (TROP2) is a transmembrane glycoprotein that exhibits overexpression in various gastrointestinal (GI) malignancies, including colorectal, gastric, pancreatic, and esophageal cancers. This overexpression has been correlated with increased tumor aggressiveness, enhanced proliferation, and unfavorable prognostic outcomes. TROP2 serves as a predictive and prognostic biomarker in several GI cancers, guiding targeted therapy and correlating with overall survival. However, there exists a notable absence of dedicated studies investigating TROP2 expression specifically in gastroenteropancreatic neuroendocrine tumors (GEP-NETs) highlighting an unmet need. This report presents the first and most extensive prospective study examining TROP2 overexpression in GEP-NETs. **Methods:** We utilized transcriptomic and clinical data derived from the National Cancer Institute's (NCI) GEP-NET project, which originates from a prospective study approved protocol (NCT05237934). For data analysis, we implemented the RNA-sequencing pipeline developed by the NCI Cancer Center Bioinformatics Resource (https://github.com/skchronicles/RNA-seek.git) along with STAR version 2.7.11b for aligning sequencing reads to the hg38 reference genome. To accommodate the variations introduced by different library preparation methodologies (including polyA, total RNA, FFPE, and access), we employed the "RemoveBatchEffect" function from the Limma package, while also accounting for disease-specific variations. **Results:** Our analysis included a total of 179 GEP-NET samples, comprised of 106 small bowel neuroendocrine tumors (NETs) and 73 pancreatic neuroendocrine tumors (pNETs). There were 54 females and 52 males in the small bowel cohort, and 37 females and 36 males in the pancreatic cohort. Notably, TROP2 expression was observed in 50% of pancreatic samples and 30% of small bowel NET samples. Furthermore, TROP2 expression appeared to correlate with decreased survival in pNETs (p=0.022), whereas its expression in small bowel NETs may suggest improved patient outcomes, although this latter correlation did not achieve statistical significance (p=0.37). Further analyses are pending study completion and will be presented later. **Conclusions:** This study highlights the critical role of TROP2 overexpression in GEP-NETs and its importance for patient prognosis. TROP2 overexpression correlates with decreased survival outcomes in pNETs relative to small bowel NETs. Additionally, the identification of TROP2 as a prognostic and predictive biomarker presents opportunities for future research focused on therapeutic targeting. Additional studies may be needed for further validation as we finalize the current research. Research Sponsor: None.

Development of a cfDNA-based protein-informed epigenetic signature (PEp-sig) to enable biomarker-based risk stratification for pancreatic ductal adenocarcinoma (PDA). First Author: Ashish Manne, The Ohio State University Comprehensive Cancer Center, Columbus, OH

Background: Novel blood-based biomarkers are needed for early risk stratification and personalized therapies for patients with PDA. An evidence-based 99-gene panel was developed focusing on genes whose protein products are implicated in PDA drug response. We hypothesized that methylation levels in these genes could serve as surrogates for their corresponding protein activity, enabling the prediction of treatment-related outcomes in PDA patients. Using this panel, we developed a cell-free DNA (cfDNA)-based PEp-sig for risk stratification of patients with PDA. **Methods:** Targeted enzymatic methylation sequencing was performed on plasma samples from PDA patients (01/2010–05/2022) receiving chemotherapy from the Ohio State University biorepository. Gene methylation levels were analyzed for associations with overall survival (OS) using univariate and multivariate Cox regression models. Significant genes and covariates such as first chemotherapy (FLC)- FOLFIRINOX (FFX) vs. gemcitabine (G)/nab-paclitaxel (NP) vs. other (Ot), and stage at diagnosis (StD) – early-stage (ES) that includes resectable and borderline resectable PDA vs. locally advanced (LA) and metastatic (Met)) were identified through backward selection. Risk scores from multivariate models were dichotomized at the median, stratifying patients into High (Hg) and low-risk groups (Lg), with survival differences assessed by Kaplan-Meier and log-rank tests. **Results:** The study cohort (SC) included 51 PDA patients (StD: 22 ES, 15 LA, and 14 Met). Among the ES cases, 3 progressed to Met after neoadjuvant therapy (NAT); in the LA subgroup, 2 proceeded to surgery post-chemotherapy. Ultimately, 21 patients had resection (Rs), while 30 underwent palliative therapy (PT), with FLC distribution as follows: PT group – 12 FFX, 16 G/NP, and 2 Ot; Rs group, NAT—9 FFX, 1 G/NP, and 1 Ot; adjuvant therapy after upfront surgery (UpS) —5 FFX, 2 G/NP, 3 Ot. Two 15-gene PEp-sig were developed: one for the SC and another for the PT group. A significant overlap (11/15) of genes was observed between the two PEp-sigs. These genes are linked to the response to G, NP, irinotecan, and platinums. The performance of PEp-sig models, with and without FLC and StD adjustments, is summarized below. **Conclusions:** In this proof-of-concept study, we present a cfDNA-based PEp-sig that effectively stratifies PDA patients by survival risk. Notably, it operates independently of FLC and StD within the PT group. Ongoing efforts aim to develop treatment selection algorithms based on these findings. Research Sponsor: None.

Models tested	SC			PT-group		
	Hg vs. Lg OS (in months)	Hazard Ratio (HR)	p-value	Hg vs. Lg OS (in months)	HR	p-value
PEp-sig alone	10.75 vs. 33	8.7				
PEp-sig + FLC*	10.62 vs. 33	8.1	<0.001	5.3 vs. 16.83	9.2	<0.001
PEp-sig + StD*	8.4 vs. 33	16.9			8	

FLC and StD significantly impacted OS in SC but not in PT.

Development of a comprehensive cfDNA methylation signature for prognostic, predictive, and diagnostic applications in pancreatic ductal adenocarcinoma (PDA). First Author: Deepak Sherpally, Metropolitan Hospital Center, New York, NY

Background: Blood-based biomarkers are promising for predicting outcomes in pancreatic ductal adenocarcinoma (PDA) and could pave the way for developing multi-omic prognostic tools. We previously identified a 15-gene cell-free DNA (cfDNA) methylation signature targeting treatment response (TRg). To enhance its utility, we incorporated additional genes with established prognostic (Prg) and diagnostic (Dxg) value from the literature, creating a composite panel. This study aimed to develop a comprehensive cfDNA methylation signature with predictive, prognostic, and diagnostic value. **Methods:** Enzymatic methylation sequencing was performed on plasma samples collected between January 2010 and May 2022 from PDA patients undergoing chemotherapy at The Ohio State University. A 206-gene panel (TRg + Prg + Dxg) was analyzed, with methylation levels correlated to overall survival (OS) using univariate and multivariate (MV) Cox regression models. Backward selection identified significant genes, and MV models adjusted for clinical covariates. Patients were stratified into high-risk (Hg) and low-risk (Lg) groups based on median risk scores. **Results:** Our study cohort had 51 PDA patients, with a median age of 65 (range: 34 -80), 53% females, and 86% Caucasian (12% African-American and 2% others). Stage at diagnosis (Dx-S) distribution: 15 locally advanced (LA), 14 metastatic (Mets), and 22 resectable/borderline resectable (R/BR). 12 patients in BR/R received neoadjuvant therapy (NT) while the rest had upfront surgery (UpS) followed by adjuvant therapy (AT). Ultimately, 21 had resection, and 30 got palliative therapy. First-line chemotherapy (FL) patients received is, 36 FOLFIRINOX (12 PT, 9 NT, and 5 AT), 19 gemcitabine (Gem)/nab-paclitaxel (NP) (16 PT, 1 NT, and 2 AT), and 6 Others. A 25-gene cfDNA methylation signature (15 TRg, 10 Prg, and 1 Dxg) stratified patients into Hg and Lg groups. OS was significantly longer in Lg compared to Hg across all models. **Conclusions:** The study successfully developed a comprehensive 25-gene cfDNA methylation signature combining predictive, prognostic, and diagnostic markers for PDA. This signature effectively stratifies patients into Hg and Lg, demonstrating significant differences in OS across various clinical models. The results highlight the potential utility of cfDNA methylation as a multi-omic tool to enhance personalized treatment strategies and improve patient outcomes in PDA. Further validation in larger cohorts is warranted to confirm its clinical applicability. Research Sponsor: None.

Models tested	OS* Hg vs. Lg	Hazard ratio
Signature-alone	7.58 vs. 33	13.5
Plus, FL	8.98 vs. 33	13.2
Plus, FL, Surgery (NAT vs. UpS vs. PT)	7.58 vs. 33	17.3
Plus, Dx-S	7.58 vs. 33	14.4

DNA methylation signatures as predictive biomarkers for chemotherapy (CT) resistance and survival in pancreatic ductal adenocarcinoma (PDA). First Author: Deepak Sherpally, Metropolitan Hospital Center, New York, NY

Background: Predicting innate treatment resistance to traditional CT in PDA can optimize therapeutic strategies and improve patient outcomes. This study investigates methylation changes in genes encoding proteins implicated in preclinical models (PDA cell lines or mouse models) influencing drugs commonly used to treat PDA, including 5-fluorouracil (5FU), oxaliplatin, irinotecan, gemcitabine (Gem), nanoliposomal irinotecan, and nab-paclitaxel. Using a comprehensive literature review (1970–2024), we curated a panel of relevant genes and analyzed their methylation patterns in The Cancer Genome Atlas (TCGA) database. We hypothesized that DNA methylation changes affect gene expression and protein production, contributing to chemotherapy resistance. **Methods:** PDA patient methylation data were accessed from the TCGA database. Survival analyses were performed using elastic net multivariate regression to identify significant methylation signatures, followed by Kaplan-Meier analysis. Model parameters, including alpha (α) and lambda (λ), were optimized through 100 iterations to minimize error. Our curated panel consisted of 138 genes, predominantly Gem-specific or Gem + 5FU (n = 93). **Results:** The TCGA database provided methylation data for 184 PDA patients (106 had Gem or Gem-based therapy), with 133/138 genes in our analysis. Our analysis identified 23 cytosines followed by guanine residue (CpG) methylation signatures within the panel, ranging from 1 to 23 CpG sites. The best-performing signature, containing 21 CpG sites, stratified patients into significantly different survival groups (17 months (m) vs. not evaluable, p = 0.004). The second-best signature, with 8 CpG sites, stratified survival as 17m vs. 66.94m (p = 0.03). Interestingly, signatures with the most (n = 23) and least (n = 1) CpG sites also demonstrated strong stratification, with survival differences of 15.15m vs. 30.02m (p = 0.01) and 18.67m vs. 44.38m (p = 0.01), respectively. Many signatures included multiple CpG sites from single genes. A Gem or Gem + 5FU-specific panel (n = 93) applied to patients treated with Gem-based therapy identified an 8-CpG signature distinguishing high-risk patients (20.84m vs. 49.38m, p = 0.02). **Conclusions:** This study highlights the potential of CpG methylation signatures to predict treatment outcomes in PDA. These findings may guide the identification of high-risk patients and the optimization of CT regimens for improved survival. The identification of methylation signatures associated with genes implicated in chemotherapy resistance provides valuable insights into the underlying mechanisms of innate treatment resistance in PDA. Further validation of these methylation signatures could contribute to more effective and targeted therapeutic approaches in clinical practice. Research Sponsor: None.

A phase I trial of binimetinib plus hydroxychloroquine in patients with previously treated metastatic pancreatic cancer. First Author: S. Daniel Haldar, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Combined MEK and autophagy inhibition exerts synergistic antitumor activity in preclinical models of RAS-mutant cancers. We hypothesized that blockade of autophagy with hydroxychloroquine (HCQ) can overcome therapeutic resistance to MEK inhibition with binimetinib (bini) and lead to clinical benefit in patients (pts) with previously treated, KRAS-mutant metastatic pancreatic ductal adenocarcinoma (PDAC). **Methods:** This is an investigator-led, single-arm, open-label, phase I dose escalation/expansion study of bini + HCQ in metastatic PDAC pts. Key eligibility criteria: ECOG 0-1, adequate organ function, $>$ 1 prior line of therapy for metastatic disease, and presence of KRAS mutation. Dose escalation followed a Bayesian optimal interval (BOIN) design. Dose level (DL) 1: bini 45 mg + HCQ 600 mg p.o. bid; DL -1: bini 45 mg + HCQ 400 mg p.o. bid; DL -2: bini 30 mg + HCQ 400 mg p.o. bid; DL -1.5: bini 30 mg + HCQ 600 mg p.o. bid. Primary endpoint was the maximum tolerated dose (MTD) of bini + HCQ. Secondary endpoints included objective response rate (ORR), disease control rate (DCR), progression-free survival (PFS), and overall survival (OS). **Results:** From December 2019 to August 2024, a total of 34 pts were enrolled in dose escalation (n = 17) and dose expansion (n = 17). Median age was 65 yrs (range: 45-79) with 56% females. Median prior lines of therapy was 2 (range: 1-4). The most prevalent KRAS mutation subtypes were G12D (35%), G12V (32%), and G12R (29%). Two dose-limiting toxicities (DLTs) occurred in 2 out 3 pts treated at DL 1: grade 3 CPK elevation with renal impairment (bini) and grade 3 QTc prolongation (HCQ). The most frequent non-hematologic AEs were rash (71%), diarrhea (71%), nausea (67%), elevated AST (67%), and elevated CPK (61%). Following dose de-escalation due to poor tolerance, the MTD was deemed to be bini 30 mg + HCQ 600 mg p.o. bid and used for dose expansion. Overall, out of 31 response-evaluable pts, 2 pts achieved a partial response (lasting 6.9 and 4.7 mos, both at DL -1.5) and 9 pts achieved stable disease (3 pts at DL -1, 6 pts at DL -1.5), consistent with ORR 6.5% and DCR 35.5%, respectively. At median follow-up of 19 mos, median PFS was 1.9 mos and median OS was 5.3 mos. **Conclusions:** Bini + HCQ demonstrated a challenging toxicity profile and limited clinical activity in a heavily pretreated cohort of metastatic PDAC pts. Minimal efficacy was observed in this treatment-refractory population; however, dual MEK and autophagy inhibition may warrant further study in earlier-line settings, potentially with more tolerable drug candidates and guided by biomarker selection. Clinical trial information: NCT04132505. Research Sponsor: None.

Pancreatic adenosquamous carcinoma (PASC): A comparative genomic landscape study. First Author: S. Daniel Haldar, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: PASC accounts for 1-4% of primary exocrine pancreatic malignancies and is associated with more aggressive disease biology and worse clinical outcomes compared to conventional pancreatic ductal adenocarcinoma (PDAC). Despite its aggressive nature, PASC lacks targeted treatment choices and is frequently excluded from clinical trials, underscoring a key unmet need. Here, we performed a comparative analysis of the genomic landscapes of PASC versus PDAC using the FoundationOne database to identify distinct molecular drivers and potential therapeutic targets. **Methods:** Comprehensive genomic profiling using hybrid capture-based next-generation sequencing (NGS) was performed on 244 PASC and 29,021 PDAC tumors to identify genomic alterations (GAs). All patients (pts) had clinically advanced disease, predominantly stage IV, at the time of profiling. Genomic ancestry, MSI status, tumor mutational burden (TMB), homologous recombination deficiency signature (HRDsig) and cosmic trinucleotide signature were assessed. PD-L1 expression was quantified using the tumor proportion score (TPS) via the Dako 22C3 immunohistochemistry assay. Statistical analysis was performed using Fisher's exact test, with false discovery rate (FDR) correction applied through the Benjamini-Hochberg method. **Results:** PASC harbored a median of 6 GAs per tumor (range: 1-23) with a similar genomic ancestry profile compared to PDAC. Of note, PASC featured a higher frequency of cases with MSI-high status (2.1% vs 0.5%; p = .027) and TMB $>$ 10 mutations/Mb (3.7% vs 1.3%; p = .013). Additionally, PD-L1 expression (TPS $>$ 1%) was significantly more common in PASC compared to PDAC (66.7% vs 37.0%; p $<$ .0001). The frequency of *KRAS* mutations and HRDsig positivity was similar between the two subtypes. Disease-associated GAs more frequent in PASC than PDAC included mutations in *CDKN2A* (77.0% vs 56.6%; p $<$ .0001), *KMT2D* (8.2% vs 3.2%; p $<$ .0001), *TP53* (89.3% vs 78.0%; p $<$ .0001), and *MTAP* loss (33.3% vs 23.8%; p = .002). **Conclusions:** PASC exhibits a genomic profile with molecular features that are both shared and distinct compared to PDAC. Given the similar frequency of *KRAS* mutations, PASC pts should be included in clinical trials of emerging RAS-targeted therapies. Furthermore, immunotherapy-based strategies (↑MSI-high, TMB, and PD-L1) and PRMT5/MAT2A inhibitors (↑MTAP loss) warrant consideration in this rare and understudied disease subtype. Research Sponsor: None.

	PDAC (n=29,021)	PASC (n=244)	P-value
Median GAs/tumor (range) (IQR)	5 (0-61) (3-6)	6 (1-23) (4-8)	$<$.0001
MSI-high	0.5%	2.1%	.027
TMB > 10 muts/Mb	1.3%	3.7%	.013
PD-L1 TPS > 1%	37.0%	66.7%	$<$.0001
HRDsig+	4.6%	3.1%	NS

Unveiling the differences in tumor immune microenvironment between *KRAS*-wildtype and *KRAS*-mutant pancreatic ductal adenocarcinoma. First Author: Heidi C. Ko, Labcorp, Durham, NC

Background: Pancreatic ductal adenocarcinoma (PDAC) is a highly aggressive cancer with a dismal prognosis despite advances in treatment. PDAC is characterized by a dense stromal environment with suppressed anti-tumor immunity that contributes to treatment resistance. Oncogenic *KRAS* mutations are present in $>$ 90% of PDACs and are known to play a role in modulating the tumor immune microenvironment (TME). In this study, we examined the differences in TME components between *KRAS*-mutant (m) and *KRAS*-wildtype (wt) PDACs. **Methods:** Comprehensive genomic and immune profiling (CGIP), including the RNA-seq based gene expression assessment of 395 immune-associated genes, was performed on 311 PDAC patient samples. Gene expression signatures of tumor immunogenicity (TIGS) and cell proliferation were calculated by averaging the gene expression ranks of 161 immune-associated genes and 10 proliferation genes, respectively. The normalized gene expression rank of 22 immune checkpoint genes and 17 cancer testis antigen (CTA) genes were also calculated. DNA-seq was used to identify *KRAS* mutations and to calculated tumor mutational burden (TMB). Continuous variables were compared between subgroups using the Wilcoxon Rank-Sum test and categorical variables were compared between groups using the Chi Squared test. For statistical significance, p $<$ 0.05 was required. **Results:** The cohort consisted of 311 PDAC patient samples, comprising 159 females (51.1%) and 152 males (48.9%) with a median age at testing of 69.3 years (38.7-92.6). A total of 264 specimens (84.9%) exhibited a *KRAS* mutation, with the most common being G12D and G12V while 47 (15.1%) had *KRAS*-wt tumors. No difference in TIGS, CP, or TMB was observed between *KRAS*-wt and *KRAS*-m tumors. *KRAS*-wt tumors exhibited greater expression of 12 of 17 tested CTAs than *KRAS*-m tumors, including GAGE13 (p = 0.004) NY-ESO-1 (p = 0.01), MAGEA3 (p = 0.01), and LAGE1A (p = 0.01). Analysis of the gene expression of 22 immune checkpoint genes showed no difference for most of the genes, though there was higher expression of PD-1 (p = 0.04) and CD27 (p = 0.03) seen in *KRAS*-wt compared to *KRAS*-m tumors. **Conclusions:** *KRAS*-wt PDACs exhibited greater expression of cancer testis antigen genes compared to *KRAS*-m tumors, suggesting potential therapeutic susceptibility to immunotherapy and adoptive cell therapies leveraging the expression of CTAs as targets. Assessment of *KRAS* status and immunotherapy susceptibility may support future clinical trial selections for therapies targeting the complex interplay of genomic and immune components of pancreatic cancer. Research Sponsor: None.

Functional role of GLI2 in cancer-associated fibroblasts for modulation of the fibrotic tumor microenvironment within pancreatic cancer. First Author: John Y. Kwon, Mayo Clinic Rochester, Rochester, MN

Background: The tumor microenvironment (TME) that surrounds pancreatic ductal adenocarcinoma (PDAC) is a multi-faceted and dynamic ecosystem in which stromal fibroblasts communicate with cancer cells to mediate tumor growth, metastasis, and chemotherapy resistance. It is well recognized that both cancer-associated fibroblasts (CAFs) and its non-cellular, fibrotic components within the TME can foster a protumorigenic environment for PDAC. However, we still lack a comprehensive understanding of the precise mechanisms in which this dense, fibrotic matrix can help drive malignant behaviors. Here, we reveal a novel mechanism in which the zinc-finger transcription factor GLI2 regulates type 1 collagen expression within CAFs and how the soluble variant of this collagen promotes irinotecan chemoresistance. **Methods:** We leveraged transcriptomic data from The Cancer Genome Atlas, International Cancer Genome Consortium, and Clinical Proteomic Tumor Analysis Consortium to evaluate GLI2 expression and stromal content of human PDAC tumors through bulk RNA-sequencing deconvolution. Using single-nucleus RNA sequencing of human PDAC tumors, we validated the association of GLI2 expression and stromal matrix constituents in CAFs. Chromatin immunoprecipitation assays in human CAFs confirmed GLI2 binding at the COL1A1 promoter. Through RNAi-based inactivation of GLI2, we determined how loss of GLI2 impacts regulation of type 1 collagen. Additionally, we conducted MTT assays to assess tumor viability in response to irinotecan treatment. **Results:** Transcriptomic analysis revealed that GLI2 is highly enriched in CAFs and strongly correlated with stromal fibrosis compared to other non-tumor cell constituents within the TME. We have shown that GLI2 directly binds to the promoter of COL1A1, a key component of type 1 collagen, in CAFs and regulates its transcription in a manner dependent on TGFβ1 signaling. Interestingly, PDAC tumors exposed to type 1 collagen show increased expression of pro-tumorigenic pathways involved in inflammation, EGR signaling, cytokine-receptor interactions, and irinotecan resistance. We further validate that human PDAC cells pretreated with collagen can confer chemoresistance to irinotecan with viability assays. **Conclusions:** Taken together, our study demonstrates a novel mechanism in which GLI2 regulates the secretion of collagen within CAFs, which in turn can enable PDAC to acquire resistance to standard-of-care treatments. These findings highlight not only the oncogenic functions for CAFs and their fibrotic secretome, but also open new avenues in which therapeutic targeting of the TME may provide clinical benefit for PDAC patients. Use of an ultra-sensitive sequencing platform to detect mutant *KRAS* in the whole blood of pancreatic cancer patients. First Author: Ryne Ramaker, Duke Cancer Institute, Duke University, Durham, NC

Background: Pancreatic Ductal Adenocarcinoma (PDAC) is a leading cause of cancer death and mortality is increasing. A contributor to poor outcomes is the absence of non-invasivebiomarkers for disease screening, treatment monitoring, and identification of therapeutic targets. Blood-based profiling of circulating tumor DNA (ctDNA) using Next Generation Sequencing (NGS) has addressed these needs in several cancer types, but available commercial ctDNA assays are not as effective in PDAC. To address this unmet clinical need, we developed an ultra-sensitive sequencing assay to detect mutant *KRAS* in the whole blood of PDAC patients. **Methods:** We adapted the bacterial Maximum Depth Sequencing (MDS) assay for Human whole blood MDS (hMDS) to improve upon the sensitivity of NGS by barcoding DNA fragments with unique molecular identifiers prior to performing multiple rounds of first-strand synthesis to resolve sequencing errors. Analytic sensitivity was evaluated by spiking PDAC cells at various dilutions into control blood isolated from 10 individuals and assaying the mixture by hMDS in triplicate. Clinical sensitivity was then evaluated by collecting paired blood draws from 200 advanced PDAC patients in prospective fashion, one to be tested with a commercial ctDNA test and one by hMDS. **Results:** ThehMDS assay reproducibly detected PDAC cells at dilutions as low as one cell per mL or one mutated fragment per million *KRAS* fragments. Thus, hMDS reached an analytic sensitivity 1000x higher than NGS. Clonal *KRAS*mutations were detected in 179 of the first 194 patient samples (92.2%), surpassing historical commercial detection rates of 50% by commercial ctDNA assays. Mutations were reproducibly detected in replicate analysis of forward and reverse DNA strands. Weak clonal *KRAS* activating mutations were also detected in several non-cancer, control patients. **Conclusions:** We developed an assay capable of sensitively detecting PDAC ctDNA in whole blood. Formal comparison to commercial testing is ongoing, but preliminary results suggest this assay could be a sensitive tool for non-invasive PDAC mutation profiling and disease monitoring. The presence of weak clonal *KRAS* mutations in control patients has motivated development of a multiplex platform capable of screening for mutations in multiple driver genes. Efficacy and safety of surufatinib (S) plus KN046 (K) and chemotherapy in first line (1L) advanced pancreatic cancer (PC): A single-arm, phase 1b/2 trial. First Author: Wen-Quan Wang, Department of Pancreatic Surgery, Zhongshan Hospital, Fudan University, Shanghai, China

Background: Gemcitabine (G) and nab-paclitaxel (nP) are standard 1L regimen for patients (pts) with unresectable PC, yet the efficacy remains unsatisfactory. K is a humanized bispecific antibody targeting PD-L1/CTLA-4, while S is a kinase inhibitor of VEGFR1-3, FGFR1 and CSF-1R with immune-regulatory potential. It is hypothesized the add-on of S and K to GnP chemotherapy would provide improved efficacy. **Methods:** This single-arm, phase 1b/2 trial enrolled pts with unresectable locally advanced or metastatic PC who were eligible for 1L treatment. The phase 1b part was designed in a "3+3" algorithm to determine the recommended phase 2 dose (RP2D) of S for dose expansion in phase 2 part. Pts received oral S at escalating dose starting from 200 mg qd, plus intravenous K at 5 mg/kg on day 1, and GnP chemotherapy on days 1 and 8 at 21-day cycles. The primary endpoint was dose-limiting toxicities (DLTs) within the first 28 days for phase 1b, and ORR per RECIST 1.1 for phase 2. Secondary endpoints included DCR, PFS, OS, safety, and efficacy-related biomarkers. **Results:** As of Dec 19th, 2024, 18 pts were enrolled with a median age of 54 (range: 41-74), predominantly male (16/18) and metastatic disease (15/18). Of the 16 pts with genetic testing, *KRAS* (15/16) and *TP53* (11/16) mutations were common, followed by DNA damage response (DDR) -related mutations (7/16) including *ARID1A*, *ATM*, *CHEK2*, etc., while TMB-H (1/16) is rare, and none had MSI-H or dMMR status. Within the 9 pts from phase 1b part (3 in S 200 mg cohort, 6 in S 250 mg cohort), no DLTs occurred thus the RP2D of S was determined as 250mg qd. In the 16 evaluable pts, the best overall responses were 1 CR, 10 PRs and 5 SDs. The ORR was 68.8% and the DCR was 100%. 2 pts received R0 resection after 6 cycles' treatment. With a median follow up of 7.43 months, the estimated median PFS was 8.25 (95% CI: 4.57-NR) months and the 6-month PFS rate was 72.9%. Estimated median OS was 11.14 (95% CI: 5.52-NR) months and the 6-month OS rate was 82.5%. In the exploratory analysis, DDR-related mutations seemed predictive for better ORR (85.7% vs 55.6%, *P*= 0.308), PFS (6-month PFS rate:100% vs 53.3%, log-rank *P*= 0.519), and OS (6-month OS rate:100% vs 62.5%, log-rank *P*= 0.116). Treatment-related adverse events (TRAEs) occurred in 14 (77.8%) pts, and most common TRAEs (≥20%) included leucopenia (44.4%), hypertension (38.9%), and thrombocytopenia (22.2%). TRAEs of grade ≥3 included leucopenia, neutropenia, thrombocytopenia, and hypertension (n = 2 [11.1%] for each). There were no treatment-related deaths. **Conclusions:** These preliminary results showed encouraging anti-tumor efficacy and an acceptable safety profile of S plus K and GnP chemotherapy as 1L treatment for advanced PC. Clinical trial information: NCT05832892. Research Sponsor: HUTCHMED, ALPHAMAB.

Early treatment ctDNA dynamics to predict response to chemotherapy in patients with metastatic pancreatic cancer: A prospective, observational pilot study. First Author: James Lee, Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Hempstead, NY

Background: Assessment of chemotherapy response using imaging has limitations in metastatic pancreatic cancer whereas circulating tumor DNA (ctDNA) may offer an alternate assessment of tumor burden with improved lead-time. This study evaluated temporal ctDNA testing as a potential biomarker of treatment response data compared to standard-of-care CT scans in metastatic pancreatic cancer. **Methods:** In this prospective, observational, single-center trial, patients with metastatic pancreatic ductal adenocarcinoma starting a first-line (1L) or second-line (2L) systemic treatment regimen underwent imaging and frequent blood-based treatment assessment. CT imaging was obtained prior to and after 8 weeks of treatment, with response measured by RECIST 1.1 criteria. CA 19-9, CEA, and longitudinal ctDNA profiling using Signatera were performed at baseline, after 2 weeks, 4 weeks, and 8 weeks. A threshold of 20% decrease achieved or not was used to dichotomize ctDNA response and other cut-offs were evaluated in sensitivity analysis. Progression-free survival (PFS) was measured and compared to biomarker response. The primary objective was to evaluate the association of ctDNA changes at 4 and 8 weeks with PFS. Exploratory objectives included evaluation of response at 2-weeks, and comparison of PFS with CA 19-9 and CEA. **Results:** Between June and December 2023, 19 patients were enrolled. Sufficient tissue was available to perform tumor-informed ctDNA profiling in 12 of 19 patients (63%) undergoing systemic therapy with 7 patients (58%) starting on 1L therapy and 5 (42%) on 2L therapy. Overall median PFS was 4.0 months (4.2 months 1L, 3.3 months 2L). CtDNA response at 4-weeks was prognostic of PFS with a median decrease in ctDNA of 83.4% (p = 0.0002). CtDNA response at 8-weeks was also prognostic of PFS (p = 0.01). Three patients achieved ctDNA clearance of over 95% by week 4 and had a PFS of 5.9 months. Of, note there was one patient who had a 1-log decrease in ctDNA at 4-weeks, but a 20-fold increase at 8-weeks, whereas CEA and CA 19-9 were stable at 8-weeks, and this patient had subsequent disease progression 1 month later. In an exploratory analysis, ctDNA as soon as 2 weeks was also prognostic of recurrence (p = 0.002). In contrast to ctDNA, CA 19-9 and CEA did not show significance at any timepoint (2 weeks: p = 0.2 and p = 0.8, respectively; 4 weeks: p = 0.7 and p = 0.8, respectively; 8 weeks: p = 0.8 and p = 0.5, respectively). Sensitivity analysis showed that 20% decrease was robust; association at 4-weeks with ctDNA remained significant across a wide threshold range (-70% to +60%). **Conclusions:** Circulating tumor DNA predicts PFS as early as 2-weeks following treatment. These findings suggest clinical utility in measuring ctDNA in mPDAC as early as 2 weeks following treatment initiation within the context of prospective interventional clinical trials. Research Sponsor: Conquer Cancer, the ASCO Foundation.

TQB2868 combined with anlotinib and nab-paclitaxel plus gemcitabine as first-line treatment for metastatic pancreatic cancer: A prospective, multi-center, single-arm, phase 2 study. First Author: Si Shi, Department of Pancreatic Surgery, Fudan University Shanghai Cancer Center, Shanghai, China

Background: Chemotherapy currently serves as the cornerstone for treating metastaticPancreatic Ductal Adenocarcinoma Cancer (mPDAC). Nevertheless, the survival of patients with mPDAC remains poor. Besides, the efficacy of single-agent immune checkpoint inhibitors or antiangiogenesis in the treatment of mPDAC is not satisfying. Therefore, it is important to explore combination therapy options for patients with mPDAC. TQB2868 injection is a bifunctional fusion protein that targets PD-1 and TGF-βRII. This trial was conducted to evaluate the effectiveness and safety of TQB2868 combined with anlotinib and nab-paclitaxel plus gemcitabine for mPDAC. **Methods:** This was a prospective, multicenter, single-arm phase II trial. Eligible pts were those who aged over 18 years, histologically or cytologically confirmed PDAC, have not received treatment before and radiographically showed distant metastases and measurable lesions. Patients received TQB2868 (300mg, I.V, D1,15) and Anlotinib (10mg, P.O, QD, D1-14), in addition to nab-paclitaxel (125mg/m^2, I.V,D1,8,15) and gemcitabine (1.0g/m^2, I.V, D1,8,15), administered over a 28-day treatment cycle.The primary endpoint was Progression-free Survival (PFS), Secondary end points included objective response rate (ORR) and disease control rate (DCR), overall survival (OS) and safety. The biomarker TGF-β1 was analyzed as exploratory results (NCT06767813). **Results:** 40 pts were enrolled and received TQB2868 combination regimen therapy, and the last follow-up time was January 10, 2025. 36 pts were eligible for response evaluation. With median follow-up duration of 5.9 months, the median PFS and OS have not been reached, with 6-month PFS and OS rates of 86% and 95%, respectively. The ORR was recorded at 63.9% (23/36) (95% CI, 46.2%-79.2%), with 23 pts achieving partial response. The DCR was 100% (36/36) (95% CI, 90.3%-100%). The most common TRAEs were neutropenia, thrombocytopenia, leukopenia, and anemia. Grade 3 TRAEs were reported in 52.5% pts (21/40). In exploratory analysis, the inhibition rate of TGFβ1 was over 90% in most cases after administration, with little to no rebound. **Conclusions:** TQB2868 combination regimen as first-line treatment was demonstrated to be tolerable, with promising anti-tumor activity in mPDAC. Clinical trial information: NCT06767813. Research Sponsor: None.

Phase II trial of serplulimab combined with gemcitabine plus nab-paclitaxel (GnP) and SBRT for metastatic pancreatic cancer as the first-line treatment. First Author: Ke Cheng, Division of Abdominal Tumor, Department of Medical Oncology, Cancer Center and State Key Laboratory of Biological Therapy, West China Hospital, Sichuan University, Chengdu, China

Background: The addition of anti-PD-1 monoclonal antibody (mAb) to gemcitabine and nab-paclitaxel (GnP) presented limited improvement in objective response rate (ORR) and disease control rate (DCR) for metastatic pancreatic ductal adenocarcinoma (mPDAC) in our previous study. Therefore, we conducted this phase II trial to evaluate the efficacy and safety of anti-PD-1 mAb (Serplulimab) plus GnP chemotherapy and stereotactic body radiotherapy (SBRT) in patients with mPDAC. **Methods:** Patients with mPDAC without previous treatment were enrolled to receive Serplulimab and GnP plus SBRT (SGSBRT) (intravenous infusion of Serplulimab 200 mg on day 1 every 3 weeks, gemcitabine 1000 mg/m^2 and nab-paclitaxel 125 mg/m^2 on day 1 and day 8, repeated every 3 weeks; SBRT delivered 5 fractions of 6.6 Gy to the primary tumor or 3 fractions of 8 Gy to the metastatic lesion in cycle 2) as the first-line treatment. The primary endpoint was 6-month progression-free survival (PFS) rate. Secondary endpoints included overall survival (OS), PFS, ORR, DCR, and adverse events (AEs). Moreover, the biomarkers such as circulating tumor DNA (ctDNA) and circulating hybrid cells (CHCs), PD-L1 expression, tumor tissue genetic status, cytokine levels, and immune microenvironment were also investigated. **Results:** As of January 2025, 47 patients have been enrolled and 41 patients have been followed for more than 6 months, with all 47 patients achieving efficacy according to the protocol. The 6-month PFS rate was 78.48%. The ORR was 74.47% (35/47), including 1 complete response (CR) and 34 partial responses (PR), and the DCR was 100%, with 12 stable disease (SD). The median PFS was 8.6 months, and the median OS was 15.5 months. The frequent grade 3 drug-related AEs were neutropenia (20/47, 42.55%), leukopenia (19/47, 40.43%), anorexia (18/47, 38.30%), and fatigue (11/34, 23.40%). The correlation between biomarkers and efficacy and prognosis are under-analyzed. **Conclusions:** This phase II study has met our preset primary endpoint with 78.48% in 6-month PFS rate, and SGSBRT presented promising efficacy with manageable safety profile and expected antitumor activity. This combination might be a promising option as first-line therapy for Chinese patients with mPDAC. Clinical trial information: ChiCTR2300073237. Research Sponsor: None.

First-line treatment with surufatinib, camrelizumab, nab-paclitaxel, and S-1 in locally advanced or metastatic pancreatic ductal adenocarcinoma (PDAC): A phase Ib/II randomized study. First Author: Guang-Hai Dai, Senior Department of Oncology, the Fifth Medical Center of the PLA General Hospital, Beijing, China

Background: PDAC is a highly aggressive cancer with limited treatment options. Previous reports of NCT05218889 showed promising efficacy of nab-Paclitaxel/S-1/Surufatinib/Camrelizumab (anti-PD-1 antibody) combination regimen (NASCA) in mPDAC (2023 ASCO abs# 4142; 2024 ASCO GI abs# 671). Here, we present the updated results. **Methods:** In phase Ib, a 3+3 dose escalation design was used to determine the RP2D of surufatinib. In phase II, patients were randomized 1:1 to receive the NASCA regimen or nab-paclitaxel plus gemcitabine (AG). The NASCA regimen was administered in 3-week cycles for up to 8 cycles. Patients without disease progression continued treatment with surufatinib, S-1, and camrelizumab, while the control group received AG regimen , q3w. Treatment continued until disease progression, unacceptable toxicity, withdrawal of consent, or death. The primary endpoints were DLTs and the RP2D of surufatinib in phase Ib, and the ORR in phase II. **Results:** As of Dec 16, 2024, 96 patients were enrolled in the study (6 in phase Ib, 90 in Phase II). In phase Ib, the RP2D for surufatinib was determined to be 200 mg (1 DLT out of 6 patients). In phase II, 45 patients were assigned to each group. Baseline characteristics were balanced between the groups. Most patients had metastatic disease (82.2% in NASCA vs 77.8% in AG). The NASCA group showed a confirmed ORR of 51.1% (23/45) versus 24.4% (11/45) in the AG group (OR: 3.2, 95% CI 1.3-8.2; p = 0.01). The median PFS were 7.9 and 5.4 months (HR: 0.63, 95% CI 0.40-0.99, p = 0.046), with 12-month OS rates of 55.5% (95% CI 39.4-68.9) in NASCA group and 52.7% (95% CI 36.6-66.5) in AG group. In the subgroup analysis of PFS, the NASCA group showed longer PFS in male patients (HR: 0.56, 95% CI 0.31-1.01), those with metastatic disease (HR: 0.57, 95% CI 0.35-0.94), and patients without liver metastasis (HR: 0.45, 95% CI 0.23-0.90). Furthermore, multiplex immunohistochemistry was performed on baseline tissue samples of 26 NASCA patients. The ratio of M1/M2 macrophage percentages was significantly higher in patients with PR than those with SD and PD (p = 0.04). Using the median as a cutoff, patients with higher levels of M1/M2 cells (p = 0.039), CD8$^+$ cells (p = 0.0024), and CD8$^+$PD-1$^+$ cells (p = 0.0064) in the stroma had longer PFS than those with lower levels. For Grade 3 and 4 TEAEs, the most frequently observed events in the NASCA group were decreased white blood cell count (31.1%), decreased neutrophil count (33.3%), and decreased lymphocyte count (20.0%). Similarly, these events were common in the AG group (26.7%, 28.9%, 8.9%, respectively). **Conclusions:** The NASCA regimen demonstrated promising efficacy with a manageable safety profile, showing a significantly higher ORR and longer PFS compared to AG group in patients with locally advanced or metastatic PDAC. Further studies are warranted to confirm these findings. Clinical trial information: NCT05218889. Research Sponsor: None.

First-line serplulimab and bevacizumab combined with nab-paclitaxel/gemcitabine followed by mFOLFOX in advanced pancreatic cancer: A phase II trial. First Author: Jieer Ying, Zhejiang Cancer Hospital, Hangzhou, China

Background: Patients with advanced pancreatic cancer (PC) have a poor prognosis, as this 'cold' tumor shows limited responsiveness to mono-immunotherapy. Chemotherapy may improve the efficacy of immunotherapy by reshaping the tumor immune microenvironment. We conducted a phase II trial to assess the anti-tumor activity and safety of first-line serplulimab (anti-PD-1) and HLX04 (a bevacizumab biosimilar) combined with nab-paclitaxel plus gemcitabine (nab-P/Gem), followed by modified FOLFOX (oxaliplatin, leucovorin, and 5-fluorouracil; mFOLFOX), in patients with locally advanced or metastatic PC. **Methods:** This single-arm phase II trial enrolled 37 patients with histologically or cytologically confirmed unresectable locally advanced or metastatic pancreatic ductal adenocarcinoma (NCT06393166). The study aims to increase the objective response rate (ORR) of the first-line sequential nab-P/Gem followed by mFOLFOX (nab-P/Gem-mFOLFOX) regimen from 50% to 68% with the addition of serplulimab and HLX04. The study employed Simon's minimax two-stage design, with a total of 23 patients achieving objective responses, thereby meeting the predefined primary endpoint. Secondary endpoints included progression-free survival (PFS), overall survival (OS), disease control rate (DCR), and safety. **Results:** Among the 37 patients analyzed, the average age was 62 years, and 22 patients (59.5%) were male. At baseline, patients had an adequate nutritional and performance status, with a mean BMI of 21.6 kg/m^2. Distant organ metastases were present in 34 patients (91.9%), with the liver being the most common site (n = 26, 70.3%). The confirmed ORR was 67.6% (95% CI, 49.5-82.6), including 1 patient with a complete response (CR), meeting the primary endpoint. Only 1 patient had progressive disease (PD) as the best response, yielding a DCR of 97.1% (95% CI, 84.7-99.9). As of the data cutoff in November 2024, the median follow-up was 6.1 months. The median PFS was 10.5 months (95% CI, 9.7-not reached), with a 6-month PFS rate of 80.0% (95% CI, 65.5-97.7). The median time to response (TTR) was 1.5 months, and the median duration of response (DOR) was 9.3 months. The OS remains immature. The incidence of treatment-related adverse events (TRAEs) was 83.8%, with grade ≥3 TRAEs occurring in 46.0% of patients. Hematologic toxicities were the most common treatment-emergent adverse events (TEAEs), and no fatal AE were observed. Overall, the treatment was manageable, and no new safety signals were identified. **Conclusions:** First-line serplulimab and HLX04 combined with nab-P/Gem-mFOLFOX demonstrates clinical feasibility and promising preliminary outcomes in advanced PC. Further follow-up is required to confirm the survival benefits, and following analyses are needed to explore the mechanisms underlying the efficacy of this novel regimen. Clinical trial information: NCT06393166. Research Sponsor: None.

4163 **Poster Session**

AI-based predictive tool for detection of ctDNA in pancreatic adenocarcinoma using nationwide comprehensive genomic profiling data. First Author: Hiroaki Ikushima, Department of Respiratory Medicine, Graduate School of Medicine, The University of Tokyo, Tokyo, Japan

Background: Comprehensive genomic profiling (CGP) has become a cornerstone of precision oncology, with liquid biopsy expanding its applicability. However, in some cases, circulating tumor DNA (ctDNA) is undetectable in liquid CGP, limiting the ability to assess genetic alterations. Identifying the optimal timing for liquid CGP remains a challenge. This study focuses on pancreatic adenocarcinoma, using nationwide CGP data and explainable AI methods to identify clinical factors associated with ctDNA detection. Based on these factors, we develop an easy-to-use AI tool to predict the probability of ctDNA detection in real-world settings. **Methods:** We conducted a retrospective analysis of nationwide CGP data collected from Jun 2019 to Dec 2023, covering 99.7% of CGP performed in Japan. Cohort 1 included 4,110 pancreatic adenocarcinoma cases analyzed by FoundationOne CDx, while Cohort 2 comprised 2,220 cases analyzed by FoundationOne Liquid CDx (F1L). Using clinical information available prior to CGP, we developed an eXtreme Gradient Boosting (XGBoost)-based predictive model to estimate ctDNA detection and employed SHapley Additive exPlanations (SHAP) analysis to elucidate contributing clinical factors. A smartphone application was deployed using the refined model. The app's performance was tested with Cohort 3, consisting of 629 pancreatic adenocarcinoma cases tested by F1L between Jan 2024 and Dec 2024. **Results:** In Cohort 1 (tissue), 98.5% of cases harbored mutations in either KRAS, TP53, CDKN2A, or SMAD4, confirming their role as surrogate markers for tumor-derived DNA detection. The predictive AI model for ctDNA detection, trained on Cohort 2 (liquid) data, achieved an AUROC of 0.754. SHAP analysis identified key predictors, including liver metastasis, the number of metastatic organs, performance status, response to recent therapy, interval from diagnosis to blood collection, and treatment line. Notably, patients with liver metastases exhibited a significantly higher rate of ctDNA detection ($p < 0.001$) compared to those without, whereas patients with peritoneal metastases demonstrated a lower rate of ctDNA detection ($p < 0.01$). A refined model incorporating representative predictors was deployed as a smartphone application. When tested on Cohort 3 (liquid), the application demonstrated predictive accuracy with an AUROC of 0.769 (sensitivity: 0.707, specificity: 0.769) and a Brier score of 0.194. **Conclusions:** This study identified clinical factors predictive of ctDNA detection in liquid CGP for pancreatic adenocarcinoma using explainable AI methods and nationwide CGP data. Based on these findings, a smartphone application was developed to predict the probability of ctDNA detection. By facilitating optimal timing of liquid CGP, this app has the potential to enhance patient access to effective therapies, contributing to improved clinical outcomes. Research Sponsor: None.

Using live true single-circulating tumor cell comprehensive genomics to show clonal evolution and tumor heterogeneity in pancreatic cancer management. First Author: Mandana Kamgar, Medical College of Wisconsin Cancer Center, Milwaukee, WI

Background: Traditional tissue and CtDNA biopsies have limitations in pancreatic ductal adenocarcinoma (PDAC) due to sampling bias and inability to capture tumor evolution effectively. ctDNA offers Tx decisions, longitudinal monitoring for recurrence, real-time tumor evolution, and responses. However, ctDNA success is limited by its low sensitivity often with NMDs. While single circulating tumor cell (sCTC) genomics may offer higher sensitivity, but challenged with selective capture of live sCTCs without leukocyte contamination. We address limitations by identifying both clonal and rare sub-clonal mutations in PDAC. We report CellBiopsy assay to capture and release of sCTCs, facilitated by ctDNA-integrated comprehensive genomic profiling (CGP) at a true single-cell. **Methods:** In an observational study, ten advanced PDAC patients receiving SOC were accrued with MCW IRB approved protocol (PREDICT-MCW NCT ID:NCT05802069). All patients gave consent to investigational interventions. Live sCTCs were isolated at baseline (BL) and follow-up (FL) using OncoIndx Ikon sCTC assay in 10 mL of blood. Live CTCs were captured using glass beads with anti EpCam antibody and released in 96 well plate assay. DNA from individually captured sCTCs was linearly amplified, followed by target enrichment using OncoIndx CGP assay. Sequencing libraries were prepared and sequenced on Illumina NextSeq2000 (500× depth). ctDNA underwent deeper sequencing at 10000x coverage. Data was processed using iCare software for sequence alignment and variant calling. **Results:** Prospectively, 74 live sCTCs were isolated at baseline and follow up (mean sCTC distribution 7). Post SOC treatment, 50% of the patients (5/10) exhibited a 30% reduction in sCTC count at FL. *NRAS* mutations were the most frequent alteration observed in sCTCs (40.5%), followed by *HRAS* (27%) and *TP53* (23%). Paired ctDNA predominantly revealed *KRAS G12* variants (40%). Additional divergent molecular alterations in sCTCs were accounted for in NRAS, TP53, SMAD4, and PIK3CA-MTOR-AKT pathways, providing insights into mechanisms of treatment resistance and disease aggressiveness. Samples with co-occurring *NRAS* and *TP53*, or *SMAD4*, mutations along with *ERBB2* amplification, were associated with aggressive disease. In FL sCTCs genomics revealed evolving molecular profiles enriched for activating variants in the PIK3CA-MTOR-AKT pathway compared to bulk tissue and ctDNA genomics at BL. **Conclusions:** Compared to ctDNA, sCTC CGP revealed heterogeneous molecular profile in PDAC, offering precise insights into tumor heterogeneity, clonal evolution, disease progression, and treatment outcome. Integrating paired DNA profiling of ctDNA and sCTC DNA may provide a more CGP landscape of PDAC. Ongoing analyses aim to evaluate temporal dynamics of CGP using ctDNA and sCTC DNA assay for advancing personalized management of PDAC. Clinical trial information: NCT05802069. Research Sponsor: None.

Homologous recombination deficiency (HRD) profiling in Chinese pancreatic ductal adenocarcinoma: Implications for platinum-based chemotherapy. First Author: Yanxia Wang, The First Affiliated Hospital, Sun Yat-Sen University, Guangzhou, China

Background: Pancreatic ductal adenocarcinoma (PDAC) is a highly aggressive cancer with poor prognosis. While platinum-based therapies have demonstrated some therapeutic benefits, their associated toxicity underscores the need to identify patients who are most likely to respond. Homologous recombination deficiency (HRD) has been linked to improved sensitivity to platinum-based therapies, but its role in PDAC, particularly beyond *BRCA1* and *BRCA2* (*BRCA1/2*) mutations, remains poorly understood. **Methods:** A retrospective analysis was conducted on 264 Chinese patients diagnosed with PDAC. Genomic data were obtained using a targeted next-generation sequencing (NGS) panel, which included: (1) 28 canonical homologous recombination repair (HRR) genes (*BRCA1, BRCA2, PALB2, ATM, ATR, BAP1, BARD1, BRIP1, CDK12, CHEK1, CHEK2, EMSY, FAM175A, FANCA, FANCC, FANCD2, FANCL, FANCI, MRE11, NBN, PPP2R2A, PTEN, RAD50, RAD51B, RAD51C, RAD51D, RAD54B,* and *RAD54L*), along with their bi-allelic loss-of-function (BILOF) status; (2) 8 genes associated with other DNA damage repair (DDR) pathways (*TP53, CDH1, EPCAM, MLH1, MSH2, MSH6, PMS2,* and *STK11*); and (3) an integrated HRD score, calculated as the unweighted sum of loss of heterozygosity (LOH), telomeric allelic imbalance (TAI), and large-scale transitions (LST). HRD score ≥ 38 and/or *BRCA1/2* BILOF was predefined as HRD positive. The association between HRD status and clinical outcomes in patients treated with first-line platinum-based therapies was systematically analyzed. **Results:** Among the 264 PDAC patients, 6.4% (n = 17) were classified as HRD-positive, a larger group compared to the 1.9% (n = 5) with *BRCA1/2* BILOF. Overall, 19.3% (51/264) of patients harbored mutations in HRR genes. Among these, 4.9% (n = 13) had *BRCA1/2* mutations, with 38.5% (n = 5) exhibiting BILOF. The most frequently mutated HRR genes included *ATM* (4.2%) and *BRCA2* (3.8%), followed by *CHEK2* (1.5%), *BRCA1* (1.5%), *ATR* (1.5%), and *FANCA* (1.5%). The median HRD score was notably higher in patients with HRR gene BILOF (25.5) compared to those with non-BILOF (14). In the first-line platinum chemotherapy cohort (n = 133), HRD-positive patients exhibited significantly improved progression-free survival (PFS), with a median PFS of 20.5 months, compared to 11.3 months in HRD-negative patients (HR = 0.385, 95% CI: 0.177-0.84, *P* = 0.012). Notably, patients with *BRCA1/2* BILOF derived substantial clinical benefit from first-line platinum-based therapies, with no instances of disease progression or death during the treatment period. **Conclusions:** HRD profiling, defined by an HRD score threshold of ≥38 and/or *BRCA1/2* BILOF status, is a valuable biomarker for predicting response to platinum-based chemotherapy in PDAC. This study suggests that scar-based HRD marker and gene BILOF status could serve as predictive markers for PDAC personalized therapy. Clinical trial information: [2024]138. Research Sponsor: National Natural Science Foundation of China; 82330065, 30900650, 81372501, 81572260, 81172232, 31430030.

4166 **Poster Session**

The differential effect of stromal genes on gemcitabine/nab-paclitaxel (GN) and GN/cisplatin (GCN) outcomes in advanced pancreatic adenocarcinoma (aPDAC). First Author: Himil Mahadevia, Mayo Clinic Florida, Jacksonville, FL

Background: GN is a front-line therapy for aPDAC. A Phase I/II study demonstrated that GCN has a higher overall response rate and median overall survival (mOS). Our previous study found no difference in outcomes among patients with DNA damage repair gene mutations; however, stromal gene expression correlated with mOS in patients receiving GCN. Here, we further evaluate differences in the outcomes with GCN and GN by site of biopsy. **Methods:** PDAC samples (n = 4,463) were analyzed by NGS (NextSeq/NovaSeq) or RNA (NovaSeq) (Caris Life Sciences, Phx, AZ). Expression of stromal and related genes (*ACTA2, ADIRF, HAS2, IL-6, MMP-2, MMP-9, SPARC, STAT3, TBGB1, TGFB2, TGFBR3, IDO1, HLA-DRB4, VEGFB)* from different biopsy sites [high expression (H) >50% of RNA transcripts per million] was correlated with outcomes to GCN or GN. mOS was obtained from insurance claims and calculated from first treatment to last contact. The hazard ratio (HR) was calculated by the Cox proportional hazards model, and p-values were calculated using the log-rank test. **Results:** 4325 patients [primary biopsy (PT), n = 1,878; non-liver metastatic biopsy (N-LM), n = 818; Liver biopsy (LM), n = 1,629] received GN while 138 patients (PT, n = 45; N-LM, n = 28; LM, n = 65) received GCN. GCN was associated with longer mOS than GN [Δ: 5.2 months (m), HR: 0.76, 95% CI 0.63-0.92, p = 0.01]. GCN was associated with longer mOS compared to GN in LM (Δ: 5.6 m, HR: 0.66, 95% CI 0.50-0.87, p = 0.003), but it was not significant in PT (Δ: 4.6 m, p = 0.13) and N-LM (Δ: 4.4 m, p = 0.35). Median *MMP2* (38.5 vs. 163.1 vs. 162.2), *VEGFB* (14.4 vs. 16.9 vs. 16.2) and *TGFBR3* (11.4 vs. 15 vs. 16.4) expression were lower in LM compared to PT and N-LM while *TGFB1* (41.6 vs. 34.5 vs. 39.8) and *IL6* (1.61 vs. 1.19 vs. 1.41) expression were highest in LM ($p < 0.05$). In LM, *IL6*-H (Δ: -11 m, p = 0.037) and *TGFB1*-H (Δ: -5.9 m, p = 0.10) were associated with worse post-GCN survival compared to GN (p = 0.82 and p = 0.57). Whereas, in N-LM, *TGFBR3*-H trended towards longer post-GCN survival (Δ: 12 m, p = 0.18), while *ADIRF*-H trended towards shorter post-GCN survival (Δ: -12 m, p = 0.056) compared to GN (p = 0.42 and p = 0.10). While in PT, *MMP2*-H (Δ: 11.3m, HR: 0.46, p = 0.16), *TGFB1*-H (Δ: 11.3 m, HR: 0.33, p = 0.09), *HLA-DRB4*-H (Δ: 12.9 m, HR: 0.44, p = 0.11) and *VEGFB*-H (Δ: 10.7, HR: 0.34, p = 0.09) trended towards longer post-GCN survival compared to GN (*MMP2*-H, Δ: 3.4 m, p = 0.03, *TGFB1*-H, p = 0.661, *HLA-DRB4*-H, p = 0.67, *VEGFB-H*, Δ: 1.3 m, p = 0.03). **Conclusions:** GCN is associated with improved mOS compared to GN, especially in LM.Stromal gene expression in the liver differs from that in N-LM and the pancreas. While high stromal gene expression trends towards worse post-GCN survival in LM, it is associated with improved survival in N-LM and PT. Further validation is needed to understand the impact of stromal gene expression in different tumor sites on survival outcomes and signature development. Research Sponsor: None.

CheMo4METPANC: Combination chemotherapy (gemcitabine and nab-paclitaxel), chemokine (C-X-C) motif receptor 4 inhibitor (motixafortide), and immune checkpoint blockade (cemiplimab) in metastatic treatment-naïve pancreatic adenocarcinoma—Updated clinical and translational findings. First Author: Gulam Abbas Manji, Columbia University Medical Center/ New York-Presbyterian Hospital, New York, NY

Background: Metastatic pancreatic ductal adenocarcinoma (mPDAC) is a uniformly fatal disease with an immunosuppressive tumor microenvironment (TME). In our KPC mouse model study, targeting the C-X-C motif chemokine receptor 4 (CXCR4)/C-X-C motif chemokine ligand 12 (CXCL12) axis in combination with αPD-1, and gemcitabine improved survival when compared to mice treated with gemcitabine or other combinations. The goal of this first-in-human study was to evaluate safety, radiologic response rate, and change in tumor microenvironment (TME) elicited by motixafortide (CXCR4i), cemiplimab (αPD1), gemcitabine, and nab-paclitaxel (MCGN) in treatment-naïve mPDAC. **Methods:** CheMo4METPANC is an open label, multicenter, investigator-initiated, study evaluating MCGN in mPDAC (NCT04543071). Here we report the updated results of the signal seeking phase of this study. The primary aim was to study the safety of MCGN. All patients received pre- on-treatment and optional on-progression biopsies. Single nucleus RNA sequencing (snRNAseq) and quantitative multiplex immunofluorescence (qmIF) were used to characterize the TME. **Results:** A total of 11 patients (1 over-enrolled) participated in the study at Columbia and Brown Universities (11/9/2020-3/3/2023). The median age was 58 years. As of 04/22/24 (median follow up 23 months), 7 (63%) and 3 (27%) patients experienced a partial response (PR) and stable disease, respectively. One patient experienced radiologic resolution of hepatic metastasis and underwent definitive radiation therapy to the primary tumor. A second had a sustained PR (11 months) and underwent pancreaticoduodenectomy and hepatic wedge resection which revealed a pathologic complete response within the hepatic and primary lesion. Median progression free survival (PFS) was 9.6 months. The most common adverse events experienced while on the study combination included skin hyperpigmentation (11/11), alopecia (10/11) and injection site reaction (9/11). The most common grade 3 or greater adverse events were anemia (5/11) and rash (3/11). Analysis of the TME revealed an increase in intratumoral CD8+ T-cells in all patients, and that patients achieving a PR were found to have higher proportions pre-treatment of CXCL12-producing cancer associated fibroblasts, a potential marker of response. **Conclusions:** Preliminary results from this pilot study of MCGN in mPDAC were promising, with a PR rate of 63% and disease control rate (DCR) of 91%. Based on these results, the study was amended to transition to a randomized phase 2 trial testing MCGN compared to GN (2:1; N = 108). The primary endpoint is PFS. The phase 2 study is actively enrolling patients and incorporates optional paired research tumor biopsies. Clinical trial information: NCT04543071. Research Sponsor: BioLine Rx and Regeneron Pharmaceuticals.

Phase 1/2 study of nivolumab and ipilimumab combined with gemcitabine, nab-paclitaxel, and adaptive stereotactic body radiotherapy in bordeline resectable, locally advanced or metastatic pancreatic cancer (LAPTOP). First Author: Inna Markovna Chen, Department of Oncology, Herlev Gentofte Hospital, Herlev, Copenhagen, Denmark

Background: This phase 1/2 study (NCT04247165) evaluated the safety and efficacy of combining nivolumab, ipilimumab, gemcitabine, nab-paclitaxel, and adaptive stereotactic body radiotherapy (SBRT) in patients with borderline resectable (BRPC), locally advanced (LAPC), or metastatic pancreatic cancer (mPC). **Methods:** Treatment-naïve patients with BRPC, LAPC or mPC received 28-day cycles of nivolumab (3 mg/kg), ipilimumab (1 mg/kg single dose), and gemcitabine (800 mg/m^2) with nab-paclitaxel (100 mg/m^2 on days 1, 8, and 15). Starting in cycle 3, patients underwent MRI or CT-guided adaptive SBRT (8 Gy x 3 fractions) targeting the primary pancreatic tumor. Primary endpoint: safety, defined by the incidence of treatment-related adverse events (TRAEs) leading to discontinuation, monitored via a Bayesian stopping rule for rates exceeding 30%. Secondary endpoints: OS, PFS, ORR, DCR, DOR, and resection rate. Exploratory endpoint: immunological changes. **Results:** A total of 55 patients received at least one treatment (BRPC: n=1, LAPC: n=23, mPC: n=31), with a median follow-up of 27.6 months (IQR 26.3-34.4) calculated via reverse Kaplan-Meier. Grade 3-4 TRAEs occurred in 70.8% of BRPC/LAPC and 71.0% of mPC patients. No grade 5 TRAEs were observed. Treatment discontinuation due to TRAEs occurred in 20.8% (BRPC/LAPC) and 9.7% (mPC). Median OS: 23.0 months (95% CI: 11.4–NR) for BRPC/LAPC and 11.2 months (6.8–15.8) for mPC. Median PFS: 14.9 months (8.7–24.2) for BRPC/LAPC and 6.1 months (3.8–8.4) for mPC. ORR: 33.3% (15.6–55.3) for BRPC/LAPC and 19.4% (7.5–37.4) for mPC. DCR: 75.0% (53.3–90.2) for BRPC/LAPC and 61.3% (42.2–78.2) for mPC. Median DOR: 8.9 months (4.0–12.7). Nine (37.5%) BRPC/LAPC patients and three (9.7%) mPC patients underwent resection. Preliminary analyses revealed treatment-induced T-cell activation, particularly after SBRT, with upregulation of activation and stemness markers in patients with durable clinical benefit. Conversely, an increase in senescence markers was observed in the rest of the cohort. **Conclusions:** The combination of nivolumab, ipilimumab, gemcitabine, nab-paclitaxel, and adaptive SBRT demonstrated an acceptable safety profile and efficacy supporting further investigation in BRPC, LAPC, and mPC patients. Clinical trial information: NCT04247165. Research Sponsor: None.

Clinico-genomic characterization of *PALB2*-mutated pancreatic adenocarcinoma. First Author: Jonathan W. Lee, Memorial Sloan Kettering Cancer Center, New York, NY

Background: Pancreatic adenocarcinoma (PDAC) with germline (g) or somatic (s) mutations in *BRCA1/2* and *PALB2* exhibit unique molecular characteristics and predict response to platinum-based chemotherapy and PARP inhibition. However, distinct features of *PALB2* and PDAC are not well described. Herein, we characterize distinct clinico-genomic features of patients (pts) with g/s *PALB2* and PDAC. **Methods:** Institutional databases and cBioPortal were queried to identify pts with g/s*PALB2* and PDAC. Pts with *PALB2* variants of unknown significance (VUS) were excluded (annotation from OncoKb, ClinVar). Demographic data and clinical outcomes abstracted from medical record. Detailed mutational analysis obtained from cBioPortal. Zygosity determined with FACETS. Progression-free survival (PFS) and overall survival (OS) estimated with Kaplan-Meier Method. **Results:** N = 29 pts with pathogenic/oncogenic g/s*PALB2* and PDAC identified between 2011-2024. N = 25 (86%) g*PALB2* (+/- s*PALB2*) and N = 4 (14%) s*PALB2* (no g*PALB2*); N = 13 s*PALB2* excluded as VUS. Median age (range): 57 years (38-78) g*PALB2* and 63 years (43-73) s*PALB2*. N = 23 (79%) white; N = 16 (55%) female. Stage IV at diagnosis: N = 11 (44%) g*PALB2*; N = 2 (50%) s*PALB2* cohort. In g*PALB2* cohort (N = 25), 4 (16%) had personal history of cancer (N = 2 thyroid, N = 1 uterine, N = 1 CLL) and N = 17 (68%) had family history of cancer (N = 7 breast/prostate/ovarian, N = 1 pancreas). *KRAS* and *TP53* variants co-occurred in 84% and 36% of g*PALB2* and 50% and 50% of s*PALB2* cases, respectively. N = 9 (56%) of patients with a *gPALB2* mutations showed biallelic loss of *PALB2* (N = 6 by LOH, N = 3 somatic LOH). None of four patients in s*PALB2* cohort (negative g*PALB2*) had biallelic loss. Median TMB (mt/Mb): 4.10 (0.80-9.10) g*PALB2*; 3.85 (2.00-5.80) s*PALB2*. For stage IV g*PALB2* (N = 11), median PFS 4.2 months (95% CI 2.4, NR) and median OS 12 months (95% CI 5.5, NR). N = 10 (90%) received platinum therapy, with N = 6 in the first line setting. Durable disease control on PARPi was observed for patients with g*PALB2* and s*PALB2*, including N = 1 s*PALB2* with 7 months on 4th-line olaparib and N = 1 g*PALB2* with 6 months on 6th line Olaparib. **Conclusions:** *gPALB2* and *sPALB2* mutations are seen in a small % of PDAC. *gPALB2* PDAC presents earlier and is linked to family history of cancer. g*PALB2* compared to s*PALB2* had higher biallelic loss; oncogenic s*PALB2* are uncommon. Identification of g/s*PALB2* has implication for therapeutics and screening. Loss of heterozygosity, TMB, telomeric allelic imbalance, large-scale state transitions, and implications for treatment will be presented. Research Sponsor: None.

Prognostic and predictive impact of next-generation sequencing in metastatic pancreatic ductal adenocarcinoma. First Author: Christopher Schumacher, University of Pittsburgh, School of Medicine, Pittsburgh, PA

Background: Outcomes in *de novo* metastatic pancreatic ductal adenocarcinoma (mPDAC) remain dismal, although considerable heterogeneity exists in responses to therapy and survival. With increased use of tumor-cell next-generation sequencing (NGS) in mPDAC, improved understanding of the prognostic and predictive value of genomic alterations is needed. **Methods:** Between 2019-2023, 949 PDAC patients (pts) underwent targeted NGS (Oncomine), of which 161 had *de novo* metastatic disease. Progression-free survival (PFS) after front-line therapy and overall survival (OS) were correlated with clinical parameters and genomic alterations. Long-term survival (LTS) was defined as OS in the top quartile. **Results:** In pts who underwent at least one dose of systemic therapy (80%, n=128), mPFS and mOS were 6.6 and 10.4 months. Pts who received 5-FU-based front-line therapy (97% received a triplet with oxaliplatin and irinotecan or liposomal irinotecan) had improved outcomes compared to pts who underwent gemcitabine-based therapy (89% gemcitabine/nab-paclitaxel [gem/nab-P]; mOS 13.2 vs 7.3 months, HR 0.66, 95% CI 0.45-0.97). Tumor mutational burden (TMB), pathogenic mutations in genes involved in cell-cycle regulation (CCR) and DNA damage response (DDR), and loss of *SMAD4* were not associated with broad differences in PFS/OS. As expected, in pts treated with 5-FU/platinum, mutations in DDR genes were associated with LTS (p = 0.04). *KRAS* mutational status was prognostic (Table; p = 0.02 for OS). Surprisingly, *KRAS* wild type (WT) pts had poorer PFS/OS compared to *KRAS*-mutated pts. However, 3/12 *KRAS* WT pts, all with Class II *BRAF* and *TP53* loss-of-function (LOF) mutations, were unable to tolerate any systemic therapy. In 3 *KRAS* WT pts with LTS, 2 had mutations in DDR genes and TMB $>$ 10 Mut/Mb, while 2 had mutations in CCR genes. Multivariate analysis confirmed improved LTS of pts harboring *KRAS G12R* compared to *G12D* (OR 0.22, 95% CI 0.07-0.72, p = 0.01). *TP53* was mutated in 75% of pts (18% gain-of-function [GOF]). WT *TP53* was associated with improved survival (mOS 10.7 vs 5.0 months, HR 0.60, 95% CI 0.43-0.84). Interestingly, in pts receiving gem +/- nab-P, LTS was lacking in those with *TP53* GOF mutations but not LOF mutations (p = 0.13), a trend not seen in pts receiving 5-FU/platinum. **Conclusions:** Herein we show novel prognostic and predictive significance of genomic alterations in mPDAC. Heterogeneity exists in *KRAS* WT pts with *BRAF* and *TP53* mutations conferring poorer prognosis and DDR and CCR gene mutations associated with LTS. *KRAS G12D* is associated with worse outcomes compared to *G12R* while *G12V* is intermediate. Pts with *TP53* GOF mutations may benefit from 5-FU/platinum upfront. Research Sponsor: None.

Interpretable artificial intelligence-driven selection of doublet chemotherapy regimens as second-line treatment in patients with advanced pancreatic cancer. First Author: Letizia Procaccio, Veneto Institute of Oncology IOV, IRCCS, Padua, Italy

Background: Guidelines recommend second-line (2L) doublet chemotherapy, NALIRI (liposomal irinotecan + 5-fluoruracil and leucovorin), FOLFIRI or FOLFOX, for patients (pts) with metastatic pancreatic ductal adenocarcinoma (mPDAC) after failure of gemcitabine+Nab-paclitaxel (GemNabP). A head-to-head comparison between doublets has not been performed. We aimed to apply interpretable artificial intelligence (IAI, i.e., AI systems in which the prescription logic can be understood) methods on real-world data to establish which pts should receive NALIRI *vs* other doublets to maximize the benefit in this setting. **Methods:** In this observational cohort study, we compared progression-free survival (PFS) of consecutive pts with mPDAC who received 2L doublets after GemNabP failure at 42 Italian centers between 2013 and 2023. The dataset was randomly split into a training set (70%) and a test set (30%). In the former, a counterfactual Cox proportional hazard model, including baseline characteristics to infer the 12-month PFS probability for a given patient under each regimen, was trained. An Optimal Policy Tree (OPT), a state-of-the-art IAI-based method, was used to read the complete reward matrix by training a decision tree with the counterfactual predictions, and OPT recommendations were validated in the test set. The potential gain of the new policy was evaluated by 12-month PFS net-benefit curves. **Results:** Among 571 eligible pts, 209 (36.6%), 209 (36.6%) and 153 (26.8%) received NALIRI, FOLFOX and FOLFIRI, respectively. Median PFS was similar among the three groups (3.3 months for NALIRI, 3.5 months for FOLFOX and 3.6 months for FOLFIRI), with a long-term benefit observed only in the NALIRI group (12-month PFS 12.0% *vs* 2.6% for FOLFIRI and 5.2% for FOLFOX). The OPT recommended NALIRI as the preferred regimen for pts with pancreatic head/body cancers, with ECOG PS 0 or with Ca19.9 $<$ 109 U/ml if ECOG PS $>$ 0. The net-benefit curves revealed that the OPT consistently outperformed the uniform strategies of administering either NALIRI or FOLFOX/FOLFIRI to all pts, attaining a 2.5 percentage-point net-benefit at a threshold probability of roughly 9%. **Conclusions:** Our findings show that 2L NALIRI can offer long-term PFS advantage in a subgroup of mPDAC pts compared with other doublets. The AI-derived policy provides a higher net benefit than treating all pts with NALIRI, avoiding unnecessary clinical and financial toxicity. Research Sponsor: None.

First safety analysis of an open-label, single arm phase II trial investigating the efficacy, safety and quality of life of neoadjuvant chemotherapy with liposomal irinotecan combined with oxaliplatin and 5-fluoruracil/folinic acid followed by curative surgical resection in patients with hepatic oligometastatic adenocarcinoma of the pancreas (HOLIPANC). First Author: Dirk Thomas Waldschmidt, Universitätsklinikum Köln, Cologne, Germany

Background: Aim of the prospective single arm HOLIPANC trial (NCT04617457) is to evaluate the efficacy and safety of multimodal treatment in pancreatic oligometastatic disease. **Methods:** Patients with hepatic oligometastatic pancreatic cancer receive up to 8 cycles of a combination of liposomal irinotecan (nal-IRI, 50mg/m^2) with 5-fluouracil (5-FU 2400mg/m^2)/folinic acid (FA, 400mg/m^2) and oxaliplatin (OX, 60mg/m^2) (NalIRIFOX) as neoadjuvant therapy followed by curative intended surgical resection of the primary tumor and liver metastases. Here, we present the first preplanned safety analysis with patients (pts) that were enrolled between 10/2021 and 04/2024. **Results:** A total of 56 pts were included in the analysis, of which 43 (77%) pts received at least 4 cycles and 16 (29%) pts 8 cycles of chemotherapy. Dose reductions of nal-IRI were required in 24 (43%) pts. Treatment-emergent adverse events (TEAE) were observed in 52 (93%) pts, 40 (72%) TEAEs were related to the neoadjuvant chemotherapy. Grade 3-4 TEAEs occurred in 30 (54%) pts, most common were gastrointestinal disorders, i.e. diarrhoea (n = 5), vomiting (n = 4) and nausea (n = 4). Hepatobiliary disorders (cholangitis (n = 5), cholestasis (n = 4)) and increased gammaglutamyltransferase (n = 4) were also frequent but generally not considered in relation to the chemotherapy. Grade 3 anemia and leukopenia were observed in 3 (5%) and 2 (4%) pts respectively. Serious TEAEs occurred in 23 patients (41%). Next to the above mentioned gastrointestinal and hepatobiliary disorders, dehydration (n = 3) and infections (n = 2) were the remaining recurring events. At the time of analysis, resection was performed in 20 pts (36%). Overall postoperative complications occurred in 7 pts (35%), n = 2 (10%) were classified as Dindo-Clavien grade $\geq$ 3. Clinically relevant pancreatic fistula was shown in 1 patient (5%). While there were no deaths related to chemotherapy or surgery, 2 pts died because of tumor progression during follow-up within 28 days of chemotherapy administration or surgery. **Conclusions:** This analysis shows for the first time safety data from a prospective clinical trial of multimodal treatment in oligometastatic pancreatic cancer. As we show, the concept of neoadjuvant chemotherapy followed by surgery is safe, the toxicity and overall morbidity is not elevated compared to available data from the NAPOLI-3 trial, even in combination with a following tumor resection after neoadjuvant treatment. Clinical trial information: NCT04617457. Research Sponsor: None.

Circulated T-cell exhausted subtypes to predict response in PDAC patients. First Author: Anastasia Xagara, Laboratory of Oncology, School of Health Sciences, University of Thessaly, Larissa, Greece

Background: In-depth analysis of T-cell exhausted subsets in the circulation of Pancreatic Ductal Adenocarcinoma (PDAC) patients may provide insights into novel therapeutic options and predictive biomarkers. We performed a detailed immunophenotypic analysis for both early-stage (resectable) and metastatic (unresectable) PDAC patients. Additionally, different T-cell populations were correlated with clinical outcome. **Methods:** Fifty-five treatment naive PDAC patients, twenty-five of which had resectable disease, and ten healthy donors (HD) were enrolled. Peripheral Blood Mononuclear Cells (PBMCs) were isolated and stained with fluorochrome-conjugated monoclonal antibodies. Multicolor flow cytometry was performed to determine differences between T-cell populations and their correlation with clinical outcome. **Results:** Advanced disease patients that harbored high percentages of $CD4^+PD\text{-}1^+$ T_{eff} cells had longer PFS (median: 190 vs. 100 days, p:0.030) and OS (median: 250 vs. 170 days, p:0.041) while for early-stage patients high percentages of $CD8^+PD\text{-}1^+T_{eff}$ displayed longer DFS (median: 422 vs. 200 days, p:0.044) and OS (median: Und vs. Und days, p:0.041). For early-stage patients, high percentages of both $CD4^+$ and $CD8^+$ T-cells expressing $PD\text{-}1^+TCF1^+$ (exhausted cells) were predictive for survival ($CD3^+CD4^+PD\text{-}1^+TCF1^+$: med. Und vs. 277 days, p: 0.0041) and ($CD3^+CD8^+PD\text{-}1^+TCF1^+$: med. Und vs. 390 days, p:0.042). Additionally, expression levels of PD-1 (MFI levels) were substantially elevated in the $PD\text{-}1^+TCF1^-$ subset for both early stage $CD3^+CD4^+$ (p:0.026), $CD3^+CD8^+$ (p: = 0.006) and advanced-stage, (p:0.0001 and p:0.045, respectively), implying that terminally exhausted ($PD\text{-}1^+TCF1^-$) T-cells exhibit higher PD-1 expression than primarily exhausted ($PD\text{-}1^+TCF1^+$). For advanced stage patients, high levels of $CD57^+$, a marker of terminally differentiated T-cells, in $CD3^+CD8^+$ were associated with improved PFS (118 vs. 92 days, p:0.178)and OS(271 vs. 152 days, p: 0.019), $CD3^+CD8^+PD\text{-}1^+TCF1^+$ (PFS: med. 260 vs. 60 days, p = 0.0063 ; OS: 271 vs. 90 days, p: 0.003) and $CD3^+CD8^+PD\text{-}1^+TCF1^-$ T-cells (PFS: med. 188 vs. 80 days, p = 0.0459 ; OS: 271 vs. 107 days, p = 0.0429). $CD57^+$ T-cells were not correlated with response in early-stage patients. **Conclusions:** T-cell exhaustion represents ineffective immune response and in both early and advanced-stage PDAC may predict clinical outcome offering opportunities for innovative therapeutic options for this fatal disease. Research Sponsor: None.

USP22 as promoter of Treg cell infiltration and modulator of immunotherapy efficacy through the PIAS1/P65/CCL22 pathway in pancreatic cancer. First Author: Aman Wang, First Affiliated Hospital of Dalian Medical University, Dalian, China/Liaoning, China

Background: Immune checkpoint inhibitors targeting PD-1 and CTLA-4 have shown success in various cancers; however, their efficacy in pancreatic cancer remains limited, likely due to its immunosuppressive microenvironment. Treg cells are crucial in tumor immune evasion and suppression. Targeting Treg cells is an emerging strategy in pancreatic cancer immunotherapy. Recent studies show that USP22 (Ubiquitin-Specific Protease 22) regulates immunity by deubiquitinating key proteins like PD-L1 and STAT1 in tumor cells, while in Treg cells, USP22 controls FoxP3, modulating Treg cell function. This study aims to explore how USP22 regulates the immune microenvironment in pancreatic cancer and identify potential targets to enhance immune checkpoint blockade responses. **Methods:** Bioinformatics analysis of tissue microarrays and the TCGA database was used to assess the correlation between USP22 and Treg cell infiltration in pancreatic cancer. 2. Tumorigenicity assays, immunohistochemistry, and flow cytometry were performed in C57BL/6 mice to determine the effect of USP22 on Treg cell infiltration. 3. Transcriptomic and proteomic analyses were conducted to explore the mechanisms by which USP22 regulates Treg cell infiltration. 4. In vitro experiments, including Western blot, qRT-PCR, immunofluorescence, deubiquitination assays, and chromatin immunoprecipitation, were used to identify the specific mechanisms of USP22 in regulating Treg cell infiltration. 5. The combination of PD-1 monoclonal antibody and nab-paclitaxel chemotherapy was tested to determine if targeting USP22 improves immunotherapy efficacy. **Results:** Immunohistochemistry and bioinformatics analysis revealed a significant positive correlation between USP22 expression and Treg cell infiltration in pancreatic cancer. 2. Tumorigenicity assays in C57BL/6 mice showed that USP22 promotes tumor growth and Treg cell infiltration. 3. Transcriptomic analysis found a strong association between USP22 and the TRAF1/NF-κB signaling pathway as well as CCL22 expression. 4. In vivo and in vitro experiments confirmed that USP22 activates TRAF1/NF-κB signaling and increases CCL22 release, promoting Treg cell infiltration. 5. USP22 deubiquitinates PIAS1, inhibiting its nuclear translocation and activating p65. 6. USP22 knockdown improved therapeutic responses to combined immunotherapy (PD-1 inhibitors) and chemotherapy (nab-paclitaxel). **Conclusions:** USP22 promotes Treg cell infiltration in pancreatic cancer by deubiquitinating PIAS1, inhibiting its nuclear translocation, and activating the TRAF1/NF-κB signaling pathway, which leads to CCL22 release. Targeting USP22 could inhibit cell proliferation, promote apoptosis, and remodel the immune microenvironment, enhancing the efficacy of immune checkpoint blockade therapy. Research Sponsor: None.

Biomarkers of response to immunotherapy in pancreatic ductal adenocarcinoma (PDAC) with homologous recombination deficiency (HRD). First Author: Clara J. Oh, University of Miami Sylvester Comprehensive Cancer Center, Miami, FL

Background: PDAC is associated with a paucity of immune effector cells, low antigenicity, and immunosuppressive factors in the tumor microenvironment (TME); consequently, treatment of unselected PDAC patients with immune checkpoint inhibitors (ICIs) has been ineffective. In HRD-PDAC, dual PD-1/CTLA-4 ICI therapy has a response rate of 14-42%. In this study, we investigated biomarkers of immunotherapy response in PDAC tumors with HRD. **Methods:** We generated a murine model of HRD-PDAC and performed transcriptomic analysis of mouse responders versus non-responders to ICI therapy to identify biomarkers of response. DNA and RNA sequencing was also performed for patient tumor samples submitted to Caris Life Sciences. Samples harboring pathogenic or likely pathogenic (P/LP) *BRCA1*, *BRCA2* or *PALB2* mutations were classified HRD, the remaining samples non-HRD. Microsatellite instability-high neoplasms were excluded. TMB-High (TMB-H) was defined as $\geq$10 mutations/Mb. PD-L1 positivity was determined by IHC (SP142, $\geq$2+, $\geq$5%). High genomic loss of heterozygosity (gLOH-H) was defined as LOH at $\geq$16% of segments analyzed (up to 552). Immune cell infiltration was estimated by RNA deconvolution using quanTIseq. Mann-Whitney U, Fisher's Exact, or Chi-squared tests were used to determine statistical significance (p), with multiple comparisons corrections as appropriate (q). **Results:** In murine HRD-PDAC tumors, chronic platinum exposure was a biomarker for response to ICI. Responding tumors had differential enrichment of cytosolic DNA sensing and cGAS-STING-related pathways, and secretomes significantly enriched for the T-cell attractant chemokines CXCL9 and CXCL10. Of 6396 human PDAC samples, 4.2% were HRD (2.7% *BRCA2*, 0.9% *BRCA1*, 0.6% *PALB2* P/LP), and 95.8% non-HRD. Compared to the non-HRD cohort, the HRD cohort was younger (median age: 66 vs 68 years, p = 0.0006), had lower prevalence of *TP53* (57.4% vs 79.0%, q $<$ 0.0001), *CDKN2A* (14.1% vs 24.7%, q = 0.0062), and *RNF43* (0.8% vs 5.8%, q = 0.0322) mutations, and was more frequently PD-L1+ (21.7% vs 14.0%, q = 0.0460), TMB-H (6.4% vs 1.9%, q = 0.0001), and gLOH-H (41.2% vs 9.5%, q $<$ 0.0001). Median infiltration of M1 macrophages was higher in the HRD cohort (6.2% vs 5.3%, p = 0.0028), while that of M2 macrophages was lower (2.9% vs 3.3%, p = 0.0081).TheHRD cohort demonstrated higher median expression measured in transcripts per million of *CGAS* (6.3 vs 5.4 TPM, p = 0.0002), *CXCL9* (2.19 vs 1.60 TPM, p = 0.0015), and *CXCL10* (4.65 vs 3.65 TPM, p = 0.0308), phenocopying observations in the murine model. **Conclusions:** PDAC tumors associated with canonical HRD variants (*BRCA1/2*, *PALB2*) have distinct genomic, transcriptomic, and TME features which are immune-permissive and explain the sensitivity of this subgroup of patients to ICI therapy. Understanding the underlying mechanisms could inform strategies to broaden the impact of ICI in this population. Research Sponsor: None.

Interim open-label phase 1 results of misetionamide (GP-2250): A small molecule antineoplastic targeting three major transcription factors. First Author: Anup Kasi, University of Kansas Cancer Center, Fairway, KS

Background: GP-2250 is a novel antineoplastic agent demonstrating effective activity on preclinical pancreatic cancer models alone or in combination with gemcitabine, and inhibits c-MYC, NFκB, and HIFα in cancer cells at clinically achievable concentrations. This open-label phase 1 trial (NCT03854110) evaluates the safety and tolerability of escalating doses of GP-2250 in combination with gemcitabine as a second-line treatment in adults with advanced pancreatic adenocarcinoma that experienced disease progression with 5-FU based chemotherapy. **Methods:** GP-2250 dose escalation (starting dose 250 mg escalating up to 40 g IV once weekly) followed a Bayesian Optimal Interval design which transitioned to a 3+3 design. A 1-week run-in of GP-2250 was followed by a full cycle (3 weeks on, 1 week off) of GP-2250 plus gemcitabine treatment for each of 11 dose cohorts. Single-patient cohorts with 100% escalation between cohorts were enrolled until the first DLT (or cohort 4), followed by 3 patient cohorts with 35%−45% escalation between cohorts. The DLT assessment period was 5 weeks at each dose. Patients were treated until disease progression or development of unacceptable toxicity. Primary endpoints were safety and tolerability of GP-2250 monotherapy and in combination with gemcitabine. Secondary and exploratory endpoints were preliminary efficacy, pharmacokinetics, and pharmacodynamic blood markers. **Results:** To date, 52 patients have been enrolled. Five serious adverse events were reported in 3 patients (2 CVAs, pneumonia, and abdominal and flank pain in 2 patients), none attributed to GP-2250. Three patients discontinued treatment: 1 disease hyperprogression (at 11 g GP-2250) and 2 neutropenia (at 21 g GP-2250), with only 1 event of grade 3 neutropenia "possibly" attributed to GP-2250. In summary, the addition of GP-2250 did not significantly alter the safety and tolerability expected of gemcitabine alone. Twelve patients (23%) had progression-free survival (PFS) of $\geq$16 weeks, or twice as long as historical gemcitabine treatment alone; 7 patients (13%) had PFS of 24 weeks, and 4 (8%) had PFS of 32 weeks. One patient survived $>$ 2 years while receiving treatment. Seventeen patients (33%) achieved stable disease and 6 (12%) achieved a partial response by RECIST criteria. While the blood half-life of GP-2250 is ~5 hours, mTOR and AKT biomarker data indicate that the biological half-life is longer, at 4–5 days. These data are within the concentrations and times required for cytotoxicity in all cancer cell lines tested with GP-2250. **Conclusions:** GP-2250/gemcitabine combination therapy showed encouraging safety and tolerability and favorable PFS outcomes compared to gemcitabine alone. These promising results in a historically difficult to treat pancreatic cancer population warrant progress to later-stage studies. This study is funded by Geistlich Pharma AG. Clinical trial information: NCT03854110. Research Sponsor: Geistlich Pharma AG.

4178 **Poster Session**

Concurrent mutations in DNA damage repair genes *BRCA1*, *POLE*, *ATM* and *FANCA* to predict overall and progression-free survival for patients (pts) with metastatic pancreatic ductal adenocarcinoma (mPDAC) treated with chemotherapy in combination with dual checkpoint inhibition in the CCTG randomized PA.7 trial. First Author: Daniel John Renouf, BC Cancer, Vancouver, BC, Canada

Background: CCTG PA.7 (NCT02879318) was a randomized phase II trial comparing gemcitabine (G) and nab-paclitaxel (N) with and without dual immune checkpoint inhibition with durvalumab (D) and tremelimumab (T) as 1st-line therapy in pts with mPDAC. Matched plasma and tissue-based sequencing was performed for exploratory correlative biomarker analysis. **Methods:** Pts received G+N+D+T (n = 11 run-in, 119 randomized, 2:1 randomization) or G+N (n = 61). Long-term trial analysis was performed with a median follow-up time of 81.6 months. Correlative analysis was performed for pts with baseline ctDNA sequencing using a 600-gene PredicineATLAS panel (n = 173), with a subset having matched archival tissue available for whole-genome sequencing (WGS; n = 46). Cox-based elastic net regression models were used to identify and rank combinations of mutations by their ability to predict survival hazard. **Results:** Long-term follow up analysis demonstrated no significant difference in median overall survival (mOS) between pts randomized to G+N+D+T *vs* G+N (9.8 *vs* 8.8 months; hazard ratio (HR) = 0.88; p = 0.46). Median progression-free survival (mPFS) was also not significantly different between treatment arms (5.5 *vs* 5.4 months, respectively; HR = 0.95, p = 0.77). Landmark analysis demonstrated 4-year survivorship of 5.4% in pts treated with G+N+D+T arm compared to 1.6% with G+N (p = 0.07). Two or more ctDNA-based mutations (somatic and germline considered separately) in DNA damage repair (DDR) genes *BRCA1*, *POLE*, *ATM* or *FANCA* was present in 18/173 pts (10.4%) and was associated with improved OS with G+N+D+T *vs* G+N (mOS 26.2 months vs. 7.1 months; HR = 0.22 [0.07-0.7]; p = 0.0041, p-interaction = 0.012) as well as PFS (mPFS 14.6 vs. 4.6; HR = 0.17 [0.05-0.6]; p = 0.0020, p-interaction = 0.0070). In pts treated with G+N+D+T, partial response (PR) was seen in 63.6% of pts with $\geq$2 DDR gene mutations compared to 26.9% in other pts (p = 0.033), and this effect was not observed with G+N (p = 0.18). The DDR gene biomarker was validated in 5/6 (83%) biomarker-positive samples using archival tissue WGS. **Conclusions:** The presence of $\geq$2 DDR gene mutations was strongly associated with benefit from the combination of chemotherapy with dual immune checkpoint inhibitor therapy, and pts with this signature had prolonged mOS of over 2 years. This represents the first prospective study in PDAC to define a predictive biomarker beyond mismatch repair deficiency for benefit from immune checkpoint therapy. Given the long-term survival noted in this subgroup, assessment of DDR gene mutations could be considered as part of routine standard of care testing for mPDAC pts. Clinical trial information: NCT02879318. Research Sponsor: Predicine; Astra Zeneca; Canadian Cancer Trials Group.

Clinical outcomes and molecular characteristics of patients with metastatic pancreatic ductal adenocarcinoma according to involved metastatic sites. First Author: Mahmoud M.G. Yousef, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: It is well documented that Pancreatic ductal adenocarcinoma (PDAC) metastasize to the liver had worse outcome than to the lung, but the molecular basis was less clear. We employ a large Real-World Evidence dataset to evaluate clinical and molecular features of PDAC according to involved metastatic sites. **Methods:** The Foundry software platform was used to query electronic medical records of patients with metastatic PDAC who underwent Next-Generation Sequencing (NGS) at MD Anderson. Involved metastatic sites were extracted using natural language process from imaging reports then manually verified. Overall survival (OS) was calculated from date of diagnosis. **Results:** We identified 1,095 patients with metastatic PDAC diagnosed between May 2003 and Oct 2024. Median follow up was 41.8 months and median OS was 22.8 (95%CI: 20.2-25.2) months. Most patients (52.9%) had multiple metastatic sites including liver, 28.5% had liver only metastases, while 8.7% had lung only metastases. 10% had metastases not including liver. Patients with lung only metastasis had the best outcomes (median = 57.6 months, HR = 0.37 relative to liver only, 95%CI = 0.27-0.52, p = 9.3e-9), followed by patients with metastases not involving liver (median = 41.3 months, HR = 0.65, 95%CI = 0.49-0.87, p = 0.003). Patients with liver only metastasis (median OS = 19.5 months) had similar survival to those with multiple sites including liver (median = 19.3 months, HR = 1.1, 95%CI = 0.96-1.4, p = 0.13). *TP53* was more frequently mutated in patients with liver only metastasis (84%) and multiple metastases including liver (85%) compared to patients with lung only (73%) and multiple sites not including liver (67%, p = 9.3e-5). *GNAS* showed lower frequency (5%) in patients with liver only and patients with multiple metastasis including liver (2%) compared to patients with lung only (8%) or non-liver metastases (10%, p = 0.003). In patients with liquid biopsy (n = 240), lung only metastasis showed significantly lower positivity rate for mutation detection (50% vs 65% for liver only, 62% for other or multiple not including liver and 79% for multiple including liver, p = 0.009), and lower *TP53* detection rate (23% for lung only vs 46% for liver only, p = 0.02). The frequency of *KRAS* mutation and mutant allele distribution were not significantly different in tissue NGS. However, patients with lung only metastasis showed significantly less frequent *KRAS* mutation detection by liquid biopsy (10% vs 52% in liver only metastasis, p = 9.6e-4). **Conclusions:** PDAC patients without liver metastasis have markedly improved OS relative to patients with liver metastasis, and lower rates of *TP53* mutation. Similar frequencies of *KRAS* mutation were found in different patients by tissue testing. However, patients with lung only metastasis had lower positivity rate of ctDNA, and lower detection rate of *KRAS* mutation by liquid biopsy. Research Sponsor: None.

Pancreatic cancer mortality trends (2018-2023): Exposing racial inequities in Michigan's cancer burden. First Author: Mekdes Asfaw, Wayne State University, Rochester Hills, MI

Background: Pancreatic cancer remains one of the most aggressive malignancies, with Black individuals facing significantly worse outcomes and a younger age of onset. Despite overall survival improvements in cancer care, racial disparities in pancreatic cancer continue to widen. This study analyzes Michigan's diverse population to quantify disparities and identify actionable solutions for healthcare equity. **Methods:** This observational study analyzed pancreatic cancer mortality patterns across Michigan in adults aged 25 and older were retrieved from the CDC WONDER database (2018–2023) using ICD-10 codes for malignant neoplasm of the pancreas. Crude mortality rates (CMRs) and Age-adjusted mortality rates (AAMRs) per 100,000 were calculated by age, gender and race, with 95% confidence intervals (CI) for precision to assess racial disparities in mortality outcomes. Temporal trends and annual percentage changes (APCs) were analyzed using Joinpoint regression. **Results:** From 2018–2023, Michigan reported 10,162 pancreatic cancer deaths, with Black residents (14.1% of the population) accounting for 1,289 and White residents (who make up 78.9%) for 8,664 deaths. Overall, CMR was higher for White residents (18.26 per 100,000) than Black residents (15.21 per 100,000) who experienced a sharper rise in AAMR, increasing by 8.10% [14.36 (13.55–15.16)] compared to 4.92% [12.36 (12.10–12.63)] for White residents. For Black residents, CMRs increased with age, rising from 8.14 per 100,000 (45-54 years) to 105.78 per 100,000 (85+ years), peaking at 69.46 (65-74 years) and 95.37 (75-84 years). White residents had lower CMRs overall, starting at 1.48 per 100,000 (35-44 years) and gradually increasing to 115.28 per 100,000 in the 85+ group.In Washtenaw County, Black residents had a rate of 14.01 per 100,000 and White residents 15.79 per 100,000 with similar trends in Genesee, Wayne, and Ingham counties. Treatment inequities compounded these disparities: Black patients faced 38% lower odds of surgery, 45% longer delays for chemotherapy, and 27% lower clinical trial enrollment. These findings highlight significant racial disparities in pancreatic cancer mortality, treatment access, and outcomes, underscoring the need for targeted public health interventions. **Conclusions:** Our findings reveal significant racial disparities in pancreatic cancer outcomes in Michigan, with Black residents experiencing higher mortality rates and a younger age of death than White residents. These disparities reflect systemic barriers, including delayed diagnosis, fewer surgeries, and limited access to specialized care. Addressing these inequities requires bias training, targeted screening for high-risk Black populations, and expanded oncology services, while actionable solutions such as patient navigation and community-based screening programs can help bridge this healthcare gap and promote equity. Multimodal machine learning predictions of treatment response and survival in advanced pancreatic cancer from the COMPASS trial. First Author: Wei Quan, University Health Network, Toronto, ON, Canada

Background: Pancreatic cancer is an aggressive malignancy with limited therapeutic options and a poor prognosis. Current approaches to prognostication are limited, especially in advanced disease. We explored whether machine learning integrating multimodal data could predict outcomes in advanced pancreatic cancer. **Methods:** We developed and evaluated machine learning models predicting disease control rate and one-year survival from the COMPASS trial (NCT02750657). Data modalities included clinical features, histopathology, radiology, RNAseq, and whole-genome sequencing (WGS). After pre-processing, we applied LASSO and XGBoost to each modality and early and late fusion techniques. Hyperparameter tuning and performance assessment were performed using repeated nested cross-validation. The PurIST RNAseq classifier served as a baseline. Area under the curve (AUC) was the primary metric. **Results:** The cohort included 260 patients (105 female; median age 64 [IQR 58–70]; 141 treated with FOLFIRINOX, 97 with gemcitabine and nab-paclitaxel). 170 (65%) achieved disease control and 168 (65%) survived at least one year. The performance of the machine learning models is shown in the Table. Predictions from the unimodal models had limited correlation with each other (the maximum pairwise correlation averaged across folds was between clinical and histopathology models, 0.21). The late fusion models upweighted data modalities with stronger unimodal performance. **Conclusions:** Multiple individual data modalities can predict outcomes in advanced pancreatic cancer, with PurIST serving as a strong baseline. Despite differing predictions across data modalities, multimodal integration did not improve prognostic performance in this cohort. Research Sponsor: Ontario Institute for Cancer Research; Princess Margaret Cancer Foundation; The Terry Fox Research Institute Marathon of Hope Cancer Centres Network.

AUC for the PurIST baseline, the top 2 unimodal models, and the best fusion model for each outcome.

Outcome	Data Modality	AUC (95% confidence interval)
Disease control	PurIST	0.69 (0.69, 0.70)
	Radiomics	0.75 (0.72, 0.79)
	RNAseq	0.71 (0.70, 0.72)
	Fusion (late)	0.71 (0.69, 0.73)
One-year survival	PurIST	0.63 (0.62, 0.63)
	DNA mutations	0.64 (0.61, 0.66)
	RNAseq	0.57 (0.55, 0.60)
	Fusion (early)	0.61 (0.56, 0.66)

Integrative analysis of tumor microenvironment in advanced pancreatic cancer: Unraveling genomic and immune landscape for targeted therapies. First Author: Catia Fava Gaspar, Division of Medical Oncology and Hematology, Princess Margaret Cancer Centre, University Health Network, University of Toronto, Toronto, ON, Canada

Background: An understanding of genotype and immunophenotype interactions in advanced pancreatic ductal adenocarcinoma (PDAC) is important in designing combination strategies. In addition, PDAC subtypes may harbor unique tumor immune microenvironments (TMEs) and confer differential sensitivity to *KRAS* inhibitors (KRASi). We aimed to characterize the baseline TME in advanced PDAC and its relationship with genomic, transcriptomic and clinical data. **Methods:** The COMPASS trial (NCT02750657) investigated whole genome (WGS) and transcriptome (RNA-Seq) sequencing in patients (pts) receiving first line therapy for advanced PDAC. We performed multiplex immunohistochemistry (mIHC) to identify 5 immune cell subtypes (CD8+/CD4+ T cells, Tregs, B cells and macrophages) and CIBERSORT, a deconvolution method that uses gene expression profiles. Statistical analyses were performed using STATA/R software and significance was defined as $p\text{-}value < 0.05$. Multivariate logistic regression was used and Kaplan Meier analyses evaluated impact on survival. **Results:** Of 268 pts, 62 had available tissue samples with mIHC, WGS, and RNA-Seq data (n = 21 primary biopsies, n = 41 metastases, 34/41 liver). All 62 pts had *KRAS* mutations (28 G12D, 19 G12V, 10 G12R, 5 other) and 29 had *KRAS* major or minor imbalances. 55 cases (88.7%) were classified as classical subtype and HRDetect^{hi} was seen in 10 pts, including 5 with *BRCA1/2* mutations (4 germline, 1 somatic). In the overall cohort, differences between tumor and stroma were evident with increased infiltration of CD8 and CD4 Tcells and Tregs in stroma ($p< 0.001$) and increased macrophages (p= 0.0343) in tumor. CIBERSORT in a subset of 51 pts demonstrated increased M0 (p= 0.0035) and M2 macrophages (p= 0.0067) in liver metastases compared to primary samples, suggesting a more immunosuppressive TME. A higher number of B cells were seen in lung metastases (median 207.5 vs. 43.2 vs. 3.7 vs. 1.8 cells/mm2, p= 0.011) compared to abdominal wall, peritoneum and liver, respectively. Pts with *KRAS* major imbalance (n =14, 3 basal like) were found to have higher median numbers of CD8+ (114.5 vs. 25.1 vs. 27.5 cells/mm2, p= 0.038) and CD4+ Tcells (292.1 vs 133.4 vs. 97.4 cells/mm2, p= 0.005) when compared to minor/balanced samples, respectively. Basal-like PDAC had fewer macrophages than classical subtype (median 13.2 vs. 28.2 cells/mm2, p= 0.0103). On survival analysis, pts with HRDetect^{lo} and classical subtype with higher macrophage counts had a tendency towards increased survival (median OS: 11.8 vs. 9.5 months, p= 0.066). **Conclusions:** We identified increased CD8/CD4 T cell infiltration in PDAC stroma, as well as in pts with *KRAS* major imbalance. Immune cell profiling may complement molecular profiling as potential biomarkers and warrants further study in this context. Research Sponsor: PM2C/MOHCCN.

BRCA1/2 and _PALB2_ short variants (SVs) contributed by clonal hematopoiesis (CH) in liquid biopsies (LBx) from patients with advanced pancreatic cancer (PC). First Author: Kim Anna Reiss, University of Pennsylvania, Philadelphia, PA

Background: CH results from fitness-enhancing mutations in hematopoietic stem cells. Many CH somatic variants (SVs) are in cancer-associated genes, including *ATM* and *CHEK2*, which do not have a homologous recombination deficiency (HRD) phenotype. SVs in well-established HRD-associated genes like *BRCA1/2* and *PALB2* also appear in white blood cells as CH, albeit more rarely. Herein, we report the prevalence of SVs of CH origin in these clinically relevant genes that confound results of PC liquid biopsies (LBx) and study their association with HRD in tissue biopsies from the same patients. **Methods:** This study uses a novel variant origin prediction algorithm to classify the origin of each SV detected by FoundationOneLiquid CDx as germline, tumor-somatic, or CH, using a combination of sample-specific and dataset-learned features including fragmentomics (trained and validated against white blood cell standard). 5,625 PC LBx sequenced during routine clinical care was used for broad prevalence data. A subset with matched tissue biopsies (TBx, n = 536) was used to compare SV detection and true HRD via HRDsig in TBx, a signature validated to predict response to PARP inhibitors across multiple cancer types. **Results:** Among 303 PC LBx with a *BRCA1/BRCA2/PALB2* SV, 52 (17.2%) were predicted to be of CH origin. This percentage is larger than for other *BRCA*-associated canonical cancer types: prostate (14.1%, 139/980), breast (9.7%, 87/902), ovarian (7.0%, 14/200), but less than some non-canonical cancer types (Table). In PC patients with both LBx and TBx available, 29/536 (5.4%) had an SV in *BRCA1/BRCA2/PALB2* detected in LBx: 8/29 in LBx only; 21/29 in both LBx and TBx. 19/29 were predicted germline by the algorithm, were all also detected in TBx, and 15 (79%) of these TBx were HRDsig+. 5/29 (17%) were predicted to be tumor-somatic; two of these were detected in TBx and one (20%) was HRDsig+. Predicted CH SVs were detected in another 5 LBx (4 *BRCA2*; 1 *PALB2*). None of these were detected in TBx and none of the tumors were HRDsig+. **Conclusions:** While the majority (58%) of *BRCA1/BRCA2/PALB2* SV+ PC LBx harbored a predicted germline SV, 25% harbored tumor-somatic SV and 17% had SV exclusively predicted as CH-derived. Determining the cellular origin of *BRCA1/BRCA2/PALB2* in PC is essential given the potential impact on treatment selection. Research Sponsor: Foundation Medicine.

5-FU + Naliri, gemcitabine plus nab-paclitaxel or both regimens given sequentially for first line treatment of metastatic pancreatic ductal adenocarcinoma: A randomized phase II comparative study (FUNGEMAX-PRODIGE 61). First Author: Julien Taieb, Hôpital Europeen Georges Pompidou, APHP, Université Paris-Clté, CARPEM Cancer Institute, Paris, France

Background: New chemotherapeutic approaches are still needed to improve survival and quality of life in metastatic pancreatic ductal adenocarcinoma (mPDAC). We have previously published results of two randomized phase II of first-line sequential treatment strategies of intensified FOLFIRI regimen followed by gemcitabine-based regimens (FIRGEM and FIRGEMAX-PRODIGE 37 studies) with good efficacy and tolerability results. FUNGEMAX-PRODIGE 61 evaluated 5FU + Naliri (NAPOLI) vs gemcitabine + Nab-paclitaxel (MPACT) vs both regimens sequentially. **Methods:** Chemotherapy-naive pts with proven mPDAC, bilirubin levels < 1.5 ULN and performance status (PS) 0-1 were randomized to receive either the NAPOLI regimen for 2 months, alternating with the MPACT regimen for 2 months (arm A), NAPOLI alone (arm B) or MPACT alone (arm C) until progression or limiting toxicity. Using the Schoenfeld method, the primary endpoint was the progression-free survival (PFS) rate at 6 months from (H0) 30% over (H1) 45%, requiring 96 patients per arm (assuming 5% lost to follow-up). **Results:** Between 11/2018 and 01/2024, 288 pts were enrolled in 31 French centers and 283 included in the modified intent to treat population (mITT, patients who received at least one dose of treatment). Database lock was done on the 20/12/2024. Baseline characteristics were well balanced between the arm A, B and C (mean age: 65/63/65, female: 47/43/47%, PS-0: 33/34/37%, > 1 metastatic site: 53/48/48%, mean albumin 39/40/39 g/L). With a median follow-up of 39.2 months, study treatment was discontinued in 89.5%, 96.8% and 93.7% of patients for arms A/B/C; median treatment duration were 6.3/3.3/5.3 months, respectively. In the mITT, neither treatment with MPACT/NAPOLI (HR = 0.76, 95%CI: 0.57-1.02; p = 0.07) nor NAPOLI (HR = 1.20, 95%CI: 0.90-1.60; p = 0.22) lead to a statistically significant improvement of PFS over MPACT. PFS, Overall survival (OS) and safety data are summarized in the table. **Conclusions:** The study did not show superiority of either the sequence MPACT/NAPOLI or NAPOLI over standard MPACT. However, the sequential MPACT/NAPOLI regimen is feasible, tolerable, and associated with higher rates of 12-mo PFS and 24-mo OS and less neuropathy and can be considered in patients unfit to receive FOLFIRINOX. NCT03693677. Clinical trial information: 2024-518143-38-00. Research Sponsor: None.

Machine learning and statistical prediction of overall survival (OS) from pre-dose plasma biomarkers in a randomized phase 2 trial (1801 Part 3B) of the GSK-3 inhibitor elraglusib in metastatic pancreatic ductal adenocarcinoma (mPDAC): Application toward patient enrichment. First Author: Taylor Weiskittel, Mayo Clinic, Rochester, MN

Background: Elraglusib is a first-in-class inhibitor of GSK-3ß, a well-credentialed target in cancer implicated in intrinsic oncologic processes and tumor immune response. Preliminary results of the 1801 Part 3B trial (NCT03678883) showed statistically significant benefits for elraglusib+GnP versus GnP for 1-year survival and mOS in mPDAC (companion abstract: Mahalingam et al.). We investigated plasma levels of cytokines/chemokines/soluble cell receptors/growth factors (CCSG) as potential biomarkers of favorable outcomes on elraglusib. **Methods:** Forty CCSGs were evaluated in pre-dose plasma from patients with previously untreated mPDAC enrolled in 1801 Part 3B treated with GnP (n = 78) or elraglusib+GnP (n = 155) using a Luminex immunoassay. Using Kaplan-Meier statistics and cutpoint determination, CCSGs were assessed for OS predictive ability in the elraglusib+GnP arm. Multivariate models were constructed to predict binarized survival at 12 months using machine learning (ML). Fivefold cross-validation was used in both analyses, and all methods were applied to the GnP arm to identify elraglusib+GnP specific predictors. **Results:** Data shown as of November 15, 2024. Multiple CCSGs significantly stratified elraglusib+GnP patients. The most extreme prognosticators were IFN-ß (average HR = 2.34), and PD-L1 (average HR = 0.52) (HR shown as high CCSG vs low CCSG). Screening of different ML approaches ranked logistic regression at the top, and hyperparameter grid search identified stochastic gradient solver with ridge regularization as the optimal method. The model had an accuracy of 88% (SD: 3.9%) and a balanced accuracy of 80% (SD: 8.5%). IFN-beta had the most substantial effect size (odds ratio (OR) = 72.28), followed by IL-18 (OR = 23.38) and PD-L1 (OR = 15.32). All other CCSGs had an OR between 0.03 and 6.71. When this model was applied to patients in the GnP arm, accuracy was 68.4%, and balanced accuracy was 43.1%. **Conclusions:** Many CCSG biomarkers were identified as promising predictors of survival benefit in mPDAC patients treated with elraglusib+GnP. Both univariate statistical and multivariate ML approaches show predictive significance with high interpretability. The initial ML model is specific to elraglusib treatment, not GnP alone. These results indicate that patients' initial immune state plays a role in response to elraglusib+GnP. However, single CCSGs for enrichment currently exclude too many patients ($> 75\%$), and thus, panels of biomarkers are being investigated with ML to overcome this limitation. The 1801 Part 3B clinical trial recruitment has been completed, and updated biomarker models reflective of topline OS data, available by April 2025, will be presented. Real-world predictors of adverse clinical outcomes in pancreatic cancer using a machine-learning framework. First Author: Akanksha Dua, University of California, San Francisco, San Francisco, CA

Background: Completion of chemotherapy is crucial for clinical benefit and has been linked to improved outcomes, but is often challenging given the toxicities of chemotherapy regimens. The main treatment regimen for pancreatic adenocarcinoma (PDA), FOLFIRINOX (FFX), is highly toxic, requires frequent dose-modifications, and most patients are too sick to tolerate multiple lines of therapy. Given the aggressiveness of the disease, selecting the appropriate first-line dosing is crucial as it can be associated with better patient outcomes. The current study objective is to evaluate the association between real-world dosing patterns and clinical toxicity using a machine-learning framework. **Methods:** Patients attending GI oncology clinics at University of California, San Francisco between November 2011 – December 2023 with a documented administration of FFX were included. Predictors of clinical outcomes included baseline demographic and clinical features, cycle-specific laboratory data, and dosing information for FFX sub-components. Group-based 5-fold cross-validation for logistic regression, random forest, and XGBoost models were used to identify features associated with clinical outcomes (anemia, dehydration, nausea/vomiting, neutropenia, and polyneuropathy). Model performance was evaluated using AUC. **Results:** Data for 505 patients with PDA receiving FFX across 5,041 cycles were included.The random forest models yielded the best fit for the prediction across all outcomes (Table). Key features consistently associated with outcomes included cycle number, cumulative dose of drug received, laboratory data (PT, INR, albumin), patient demographics (male sex, race, and smoking status), and clinical features, such as hypertension. **Conclusions:** Our study identifies clinical features in combination chemotherapy leading to specific toxicities, highlighting these as ideal strategies for intervention. Early prognostic indicators of adverse outcomes can guide early management for high-risk individuals through supportive measures and dose modification, before high-grade toxicities and discontinuations wherein patients can no longer benefit from therapy. Research Sponsor: UCSF Pancreas Center.

Summary of FOLFIRINOX model outputs across clinical outcomes.

Outcome\Model	Logistic Regression	Random Forest	XGBoost	Key Features
Anemia	0.61 ± 0.03	0.67 ± 0.03	0.62 ± 0.04	[1] INR [2] Irinotecan dose [3] Any polyneuropathy
Dehydration	0.64 ± 0.03	0.72 ± 0.02	0.68 ± 0.05	[1] Cumulative irinotecan [2] Cumulative oxaliplatin [3] Cumulative fluorouracil
Nausea or vomiting	0.62 ± 0.04	0.68 ± 0.03	0.66 ± 0.03	[1] Cumulative irinotecan [2] Cumulative oxaliplatin [3] Cumulative fluorouracil
Neutropenia	0.57 ± 0.04	0.61 ± 0.06	0.61 ± 0.01	[1] Male sex [2] Cumulative fluorouracil [3] Smoking status – never

A PBMC and machine learning based biomarker signature to predict second line chemotherapy success in advanced PDAC: Translational data of the PREDICT trial—A prospective, multicenter, trial of the AIO Pancreatic Cancer Group (AIO-PAK-0216). First Author: Anton Lahusen, Department of Internal Medicine I, Ulm University Hospital, Ulm, Germany

Background: The PREDICT trial, a recent phase IIIb/IV study, aimed to address the critical need for improved personalized treatment strategies in advanced pancreatic cancer. This translational investigation examined the predictive value of 1st line chemotherapy (CTX) response on the efficacy of subsequent 2nd line treatment by using liquid biomarkers combined with machine learning (ML). **Methods:** Pts. were stratified into two cohorts based on short or long 2nd line CTX time to treatment failure (S-/L-TTF2; *n* = 10 per group, 80/20% quantiles). Treatment-naïve PDAC tissue specimens underwent laser microdissection for tumor cell enrichment, followed by RNA profiling using NanoString™ PanCancer IO360. Selected differentially regulated genes from the omics results were utilized to screen peripheral blood mononuclear cells (PBMCs) from 2nd line treatment-naïve patients at protein (flow cytometry, FC) or RNA (RT-qPCR) levels. FC data was analyzed using R-based single-cell clustering (x-Shift, FlowSOM, T-REX) to generate HyperGates (HGs), with subsequent ML-based back-gating (HyperFinder algorithm) of the most differential clusters. Additionally, classical ManualGates (MGs) were generated. Feature selection employed the Weka-based WrapperSubsetEval (WSE) algorithm with eight different classifiers (NB, KLR, LR, SMO, IBk, RT, RF, J48). The classifier/subset with optimal performance was utilized for binary classification (S-TTF2 vs. L-TTF2) of training (80%, n = 66) and validation (20%, n = 16) datasets. **Results:** Transcriptome analysis of L- vs. S-TTF2 tumor tissues revealed increased inflammation (upregulated 18-gene signature), immune cell activation/infiltration (e.g. CD4/CD8 T cells), and immune exhaustion (upregulation of e.g. PDCD1, LAG3, CTLA4, TIGIT) in L-TTF tumors. Further, the favorable Bailey immunogenic subtype was enriched in the L-TTF2 group. Analysis of eight FC panels (19 candidates) revealed 1198 differential clusters with HGs and 881 classical MGs. Feature selection, combining FC data with RT-qPCR results and clinical parameters, identified a best performing signature of 5 HGs and 2 MGs for 7 protein markers (CXCR4, CD8, CD4, CD62P, CD307b, CD45, CD121b). ML using a kernel logistic regression successfully predicted S- and L-TTF2 binary groups prior to 2nd line CTX with nal-IRI/5-FU/LV (ROC-AUC $>$ 0.90 for training and validation). **Conclusions:** We identified a favorable tumor immune microenvironment in L-TTF aPDAC patients, characterized by CD8 T cell-inflamed ("hot") tumor tissues prior to 2nd line CTX. A 7-marker liquid biomarker panel, comprising 7 flow cytometry PBMC population gates, was developed for early prediction of 2nd line nal-IRI/5-FU/LV CTX success. These findings aim to advance personalized treatment strategies. Clinical trial information: NCT03468335. Research Sponsor: Servier.

Preliminary result of a phase Ib study: Efficacy and safety of FG-M108 plus gemcitabine and nab-paclitaxel in patients with Claudin18.2-positive, locally advanced, unresectable, or metastatic pancreatic cancer. First Author: Funan Liu, The First Hospital of China Medical University, Shenyang, China

Background: FG-M108, an ADCC-enhanced anti-CLDN18.2 monoclonal antibody, showed significant efficacy in first-line (1L) treatment of gastric cancer. Herein, we report the safety and efficacy results of FG-M108 in 1L treatment of pancreatic cancer (cohort C2 and D2). **Methods:** In this open-label, multicenter phase I/II study patients received FG-M108 (cohort C2: 300mg/m2 or cohort D2: 600mg/m2 Q3W) plus gemcitabine (1000mg/m2, d1, d8, Q3W) and nab-paclitaxel (125mg/m2, d1, d8, Q3W). Eligible patients were those with CLDN18.2 positive local advanced or metastatic pancreatic cancer who were previously untreated. The primary endpoint were the incidence of adverse events (AEs) and preliminary clinical efficacy (ORR, DCR, DOR, PFS, and OS). **Results:** As of November 15, 2024, 50 patients were enrolled and received FG-M108+gemcitabine/nab-paclitaxel treatment (39 patients in cohort C2, 11 patients in cohort D2). The median age was 61 (range 30-72). 47 (94%) patients were with CLDN18.2 moderate-high expression. Out of 50 patients, 44 patients had at least one tumor assessment after baseline and included in the efficacy analysis set. The median follow-up time (95%CI) for the 32 patients with CLDN18.2 moderate-high expression was 9.5 months (6.8,11.2) , with a maximum treatment duration of 13 months. In the subgroup of cohort C2 patients with CLDN18.2 moderate-high expression assessed by Independent Review Committee(IRC)—16 patients achieved confirmed PR, and one achieved unconfirmed PR. ORR was 53.1% (34.7,70.9), and DCR was 100.0% (89.1-100.0). The median DOR reached 9.9 months (7.8,NE), and the median PFS reached 9.9 months (7.0,NE) . OS data are not yet mature, with 23 patients still alive, achieving a median OS of 17.4 months (11.0,NE). Treatment-emergent adverse events (TEAE) occurred in 32 patients (100.0%), in which 15 (46.9%) were $\geq$ grade 3. The most common FG-M108 related AEs in cohort C2 & D2 were nausea (56.4% vs 36.4%), vomiting (48.7% vs 45.5%), and hypoalbuminaemia (46.2% vs 54.5%). **Conclusions:** The combined therapy of FG-M108 plus chemotherapy as 1L treatment for patients with CLDN18.2 positive pancreatic cancer was generally well tolerated with promising survival (PFS and OS) data especially in patients with CLDN18.2 moderate-high expression, pivatol phase III clinical study will start in 2025 Q2. Clinical trial information: NCT04894825. Research Sponsor: None.

Neo-adjuvant chemo-immunotherapy in pancreatic cancer: Results of the Australasian Gastrointestinal Trials Group (AGITG) NEO-IMPACT pilot trial. First Author: Lorraine A. Chantrill, University of Wollongong, Wollongong, NSW, Australia

Background: Despite curative intent surgery and peri-operative chemotherapy for resectable pancreatic ductal adenocarcinoma (PDAC), recurrence rate remains high ($>$80%). Whilst immunotherapy has not been shown to be effective in the metastatic setting, there may be a scientific rationale for mobilising the immune system before surgery for localised disease to improve outcomes. **Methods:** NEO-IMPACT is a single arm phase II study testing the feasibility and safety of delivering 12 weeks of neo-adjuvant immune checkpoint inhibitor in combination with FOLFIRINOX (3 doses of 1500mg durvalumab q28d + 6 cycles of FOLFIRINOX q14d) for resectable or borderline resectable pancreas cancer. The patients then received 3 months of adjuvant chemotherapy. The primary endpoint was the proportion of patients receiving $\geq$80% of planned neoadjuvant treatment. A sample size of 20 was calculated to allow 80% power. Secondary endpoints include the proportion of patients missing surgery due to treatment related adverse events (TRAEs); treatment tolerability; R0 resection rate; pathological complete response rate; objective response rate. **Results:** 20 patients with PDAC were enrolled between August 2022 and June 2024, 13 resectable and 7 borderline resectable disease. 17 of 20 patients (85%) completed planned neoadjuvant treatment. Grade 3-4 adverse events (AEs) occurred in 8 patients. The most common was infection (4), febrile neutropenia (1) and nausea (2). 1 patient died from 5FU toxicity due to homozygous loss of DPYD. There were 2 iAEs (colitis and maculopapular rash). 1 patient had TRAE and had to come off trial but proceeded to surgery. 3 patients (1 borderline/2 resectable) became unresectable at assessment for surgery following neoadjuvant therapy. Of the 16 patients who underwent surgery (12 head; 4 neck/tail), 2 had a complete pathological response. 13 had an R0 resection; 3 had an R1 resection. All 16 patients received post operative adjuvant therapy. At a median follow up of 15 months, 5 patients who proceeded to surgery and adjuvant therapy have recurred. **Conclusions:** Neoadjuvant chemoimmunotherapy is feasible and safe for patients with resectable and borderline resectable pancreas cancer. A 10% CPR rate and 70% R0 resection rate are encouraging, and this approach should be further explored in a larger population. Clinical trial information: ACTRN12622000378729. NeoOPTIMIZE: Phase II trial of adaptive switching of neoadjuvant FOLFIRINOX (FFX) to gemcitabine/nab-paclitaxel (GA) resectable/borderline resectable (BR)/locally advanced (LA) pancreatic adenocarcinoma (PDAC). First Author: Lyndsey Sandow, Internal Medicine, Oregon Health & Science University, Portland, OR

Background: Neoadjuvant chemotherapy (NAC) for localized PDAC may improve R0 resection. FFX and GA are used but lack of predictive biomarkers remains a barrier to optimal NAC. The angiotensin-II receptor blocker (ARB), losartan, remodels vascular perfusion to enhance NAC efficacy. We established an experimental platform for dynamic switching of NAC +/- radiation therapy for resectable/BR PDAC and an exploratory cohort of LA PDAC. **Methods:** Patients (pts) received 4 cycles of FFX (ox 85 mg/m2; LV 400 mg/m2; iri 150 mg/m2; 5-FU 2400 mg/m2), then were restaged in a multidisciplinary tumor board (Restage I). Pts without progression (CT and CA19-9 increase $<$30% from baseline) completed 4 more cycles of FFX. If there was progression (CT and/or CA19-9 increase $>$ 30%) or intolerance, pts were switched to GA (nab-P 125 mg/m2; gem 1000 mg/m2) for 2 months. After a total of 4 months NAC, pts were re-staged (Restage 2) and had surgery or chemoRT (if vascular involvement) then surgery. Losartan (50mg QD) was given throughout NAC/chemoRT. The primary endpoint was the proportion of resectable/BR with R0 resection. **Results:** Of 43 patients screened,16 were resectable, 21 BR, 5 LA and 1 ineligible. Median age was 65 years (range: 34-80), 49% male, 84% Caucasian white. Head of pancreas primary was 84%. Mean baseline CA19-9 96 ng/mL. 1 pt had progressive disease prior to Restage 1. Of the 36 pts at Restage 1, 31 continued FFX and 5 switched to GA. 18 patients on FFX had a radiographic response, 5 had CA 19-9 decrease $>$25%, and 8 had stable disease with unchanged CA 19-9. 3 pts switched to GA for radiographic progression,1 for increased CA 19-9 $>$30% and 1 for FFX intolerance. Of 34 pts evaluated at Restage 2, 2 continued NAC, 13 had pre-op chemoRT (12 BR and 1 resectable), and 19 proceeded to surgery. 24/27 (88%) pts on FFX had R0 resections; 4/4 (100%) pts switching to GA had R0 resections. Overall, 77% pts completing NAC FFX had R0 resections; 80% pts switched to GA had R0 resections. Grade $>$ 3 toxicities 7% FFX and 5% GA. **Conclusions:** Early switching to GA in pts progressing on FFX led to an equivalent R0 resection rate. Optimization of NAC made it possible to undergo curative intent surgery that would not have occurred. Secondary endpoints of DFS, OS and multiomic based studies of blood and tumor tissue via our Serial Measurements of Molecular and Architectural Responses to Therapy (SMMART) platform are underway to identify molecular markers to predict response and determine whether a switch in treatment is indicated. Clinical trial information: NCT04539808. Research Sponsor: None.

Development and prospective validation of a novel cfDNA-based diagnostic model for the early detection of pancreatic cancer. First Author: Xiuchao Wang, Tianjin Medical University Cancer Institute and Hospital, Tianjin, China

Background: Pancreatic cancer (PC) is one of the most lethal malignancies, with a 5-year survival rate below 10%, primarily due to late-stage diagnosis. Existing diagnostic markers, like CA19-9, show inadequate sensitivity and specificity for early detection. To address this critical gap in early PC detection, this study developed and prospectively validated a cfDNA-based diagnostic model integrating fragmentomics features, including copy number variations (CNVs), fragment size ratios (FSR), and orientation-aware cfDNA fragmentation (OCF). **Methods:** A multicenter study was carried out with a case-control cohort (n = 467) for model development and a prospective cohort (n = 1,926) for clinical validation. Plasma cfDNA underwent low-pass whole-genome sequencing to extract fragmentomics features like CNVs, FSR, and OCF. A stacked ensemble machine-learning model was built based on case-control data and validated in the prospective cohort of PC elevated-risk individuals with diabetes or obesity. Sensitivity, specificity, positive predictive value (PPV), and negative predictive value (NPV) were evaluated and compared with those of CA19-9. The follow-up was intended to last for 3 to 5 years, with the current follow-up period ranging from 12 to 24 months. **Results:** In the case-control cohort, the cfDNA-based model achieved AUCs of 0.9799 and 0.9622 in the training and validation sets, respectively, with both sensitivity and specificity exceeding 90%. In the prospective cohort (n = 1,926), for the 8 PC cases identified, the cfDNA model demonstrated a sensitivity of 75%, specificity of 98.1%, and PPV of 15.2% for detecting PC, significantly outperforming CA19-9 (sensitivity: 12.5%, specificity: 94.3%, PPV: 0.9%). Notably, the cfDNA model detected all 3 Stage 0 cases, 1 of 3 Stage I cases, and both Stage II cases, providing a median lead time of 227.5 days (range: 45–298 days) compared to imaging modalities. In contrast, CA19-9 detected only one Stage II case out of eight confirmed PC cases (12.5%). The model demonstrated significant potential in stratifying pancreatic cysts into high-risk and low-risk categories. While CA19-9 is ineffective in detecting either high-risk or benign cysts within the prospective cohort, the cfDNA model successfully differentiates between high-risk and low-risk pancreatic cysts (e.g., high-risk IPMN, 1/1 = 100% sensitivity; low-risk SCN, 0/1 = 0% false positive), which further underscores its clinical utility. **Conclusions:** This study is the first to validate a cfDNA-based diagnostic model for PC in a large elevated-risk population, showing superior performance and significant lead time benefits. The model detects PC earlier with much higher sensitivity and specificity than CA19-9, promising better outcomes with earlier treatment. The findings highlight cfDNA's potential for non-invasive PC screening in clinical settings. Prognostic value of postoperative circulating tumor DNA and tumor markers in resected pancreatic adenocarcinoma (PAAD): An interim analysis of a prospective observational study. First Author: Qian Zhan, Department of General Surgery, Pancreatic Disease Center, Ruijin Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai, China

Background: Despite the benefits of postoperative adjuvant chemotherapy, recurrence rates of PAAD remain as high as 60% within the first year, underscoring the need for improved strategies to optimize treatment plans. This prospective observational study aims to evaluate the potential of postoperative ctDNA-based minimal residual disease (MRD) as an early predictor of disease relapse in resected PAAD using next-generation sequencing. **Methods:** Pathologically confirmed stage I-III PAAD patients who underwent surgical resection and carried KRAS mutations were enrolled. Eligible criteria included negative surgical margins and no metastasis prior to adjuvant therapy. Patients who did not receive adjuvant therapy were excluded. Tumor tissue samples collected during surgery were analyzed using a 769-gene NGS panel, while plasma samples were obtained at landmark (4–8 weeks post-operation and pre-therapy), 12-, 24-, 36-, and 48-weeks post-operation, and 2 weeks post-adjuvant therapy. Plasma samples were assessed for MRD using MinerVa (Genecast Biotechnology). Concurrently, tumor biomarkers such as CA19-9 were measured. The primary endpoint was overall survival (OS), while the secondary endpoint was disease-free survival (DFS). The trial is designed for a total follow-up period of three years. **Results:** As of November 27, 2024, a total of 133 patients underwent MRD analysis. KRAS mutations were distributed as follows: p.G12D in 55%, p.G12V in 27%, p.G12R in 13% and other subtypes in 5%. Nine patients were excluded due to loss of follow-up, and 12 were excluded for less than six months of follow-up, leaving 112 patients for this interim analysis. MRD positivity rates were 16%, 9%, 10%, 15%, 11%, and 11% at landmark, 12, 24, 36, 48 weeks, and 2 weeks post-therapy, respectively. Landmark MRD positivity was a significant predictor of disease recurrence (HR = 2.39, 95%CI:1.14-5.01, p = 0.017). Combining landmark MRD with biomarker CA19-9 improved prognostic accuracy (HR = 2.70, 95%CI:1.4-5.5, p = 0.002). Patients with longitudinal MRD-positive (detected at any time point excluding landmark or relapse) had significant worse DFS (HR = 3.13, p = 0.001) and worse OS (HR = 0.73, p = 0.001) compared to those with negative MRD. Analysis of MRD status at landmark and week 36 revealed that patients transitioning from MRD-positive to MRD-negative (clearance) had significantly better DFS compared to those with persistent MRD positivity (p = 0.023). Notably, no patients deceased from the MRD clearance group. **Conclusions:** These findings underscore the clinical utility of integrating landmark and longitudinal MRD assessments with tumor markers for comprehensive risk stratification and prognostication in resected PAAD patients. This approach could potentially guide personalized treatment strategies and improve patient outcomes. Clinical trial information: NCT05479708. Research Sponsor: None.

Five-year outcomes of perioperative or only adjuvant gemcitabine plus nab-paclitaxel for resectable pancreatic cancer (the NEONAX trial): A randomized phase II trial of the AIO pancreatic cancer group. First Author: Thomas Jens Ettrich, Department of Internal Medicine I, Ulm University Hospital, Ulm, Germany

Background: Perioperative chemotherapy (CTX) in resectable pancreatic ductal adenocarcinoma (rPDAC) is still not considered standard of care and data are limited. NEONAX examined gemcitabine (Gem)/nab-paclitaxel (nab-P), in the perioperative or adjuvant therapy of resectable PDAC (NCCN criteria). **Methods:** NEONAX is a prospective, randomized phase II trial with two independent arms (127 patients, 22 German centers) and randomization 1:1 to perioperative (2 pre- and 4 postoperative cycles, po-arm A) or adjuvant (6 cycles, ad-arm B) of gem (1000mg/m2 BSA, d1, 8, 15) and nab-P (125mg/m2 BSA, d1, 8, 15), q4w. **Results:** As we previously reported were R0- and N0-resection rates high (po-R0 88%, ad-R0 67%, po-N0 33%, ad-N0 29%) in the ITT-population (all randomized pts.). The primary endpoint DFS rate of 55% @ 18 months in the mITT population (defined as R0/R1 resected pts. that either started perioperative (A) or adjuvant (B) CTX), was not reached in both arms (arm A: 32%, arm B 41%). Whereas 91.5% of pts. in po-arm A started and 84.7% completed neoadjuvant CTX, only 42.4% of pts. in ad-arm B started and 25% completed adj. CTX, so the CTX dose intensity was higher in the po-arm A. (Seufferlein et al., Ann Onc 2023) Here we report long-time 5-year outcomes according to PFS and OS and present a preplanned subgroup analysis of potential prognostic factors. The mOS in the ITT population (all randomized pts.) was 25.5 mo. in the po-arm and 16.8 mo. in the ad-arm. This corresponds to an mDFS of 11.4 mo. in the po-arm and 5.1 mo. in the ad-arm, respectively. The mOS in the mITT population (all randomized pts. that started po-ctx (po-arm) or started ad-ctx (ad-arm)) was 27.9 mo. in the po-arm and 26.8 mo. in the ad-arm. This corresponds to an mDFS of 14.1 mo. in the po-arm and 16.1 mo. in the ad-arm, respectively. In the preplanned analysis of subgroup factors impacting outcome, the benefit of po-treatment was independent of tumor size, N-status and baseline Ca19-9 level. This benefit was not visible in the mITT population where only patients in the ad-arm were included who had started adjuvant treatment postoperatively. **Conclusions:** These 5 year data confirm the outcome of patients receiving gem/nab in the po-setting in the ITT population. DFS and OS effect were numerically better compared to the ad-arm although the trial was not powered for direct comparison of the arms. This difference disappeared in the mITT population when patients received more CTX in the ad arm. We conclude that the difference between ITT and mITT is likely because more CTX could administered in the po-arm when the ITT population was considered and may constitute one of the major effects of neoadjuvant chemotherapy in resectable PDAC, particularly when a high rate of patients as in our multicenter trial could get neoadjuvant, but not adjuvant treatment. Clinical trial information: NCT02047513. Research Sponsor: Bristol Myers Squibb GmbH & Co. KGaA.

Perioperative pembrolizumab (pembro) plus chemotherapy (chemo) for locally advanced gastric or gastroesophageal junction (G/GEJ) cancer: Asia versus non-Asia subgroup analysis of KEYNOTE-585. First Author: Takashi Oshima, Kanagawa Cancer Center, Yokohama, Japan

Background: In the randomized phase 3 KEYNOTE-585 study (NCT03221426), pCR was significantly improved in participants (pts) with locally advanced G/GEJ cancer treated using perioperative pembro + chemo vs placebo (pbo) + chemo, although the difference in EFS did not meet the prespecified criteria for significance. We present an exploratory subgroup analysis by geographic region (Asia vs non-Asia). **Methods:** Eligible pts had untreated, locally advanced, resectable G/GEJ adenocarcinoma (including Siewert type 2 or 3 tumors). Pts enrolled in the main cohort (n = 804) received neoadjuvant pembro 200 mg IV Q3W or pbo + chemo (cisplatin + capecitabine or 5-FU) for 3 cycles (C); after surgery, pts received adjuvant pembro or pbo + chemo Q3W for 3C then adjuvant pembro or pbo Q3W for 11C. Pts in the FLOT cohort (n = 203) received neoadjuvant pembro 200 mg IV Q3W or pbo Q3W for 3C + FLOT Q2W for 4C; after surgery, pts received adjuvant pembro or pbo Q3W for 3C + FLOT Q2W for 4C, then adjuvant pembro or pbo Q3W for 11C. Primary end points were pCR (BICR), EFS (RECIST v1.1 by investigator), OS (main), and safety (FLOT). We report outcomes in the main and FLOT cohorts combined. The database cutoff date was February 16, 2024 (final analysis). **Results:** Of 1007 pts enrolled, 387 were enrolled in Asia; 620, at non-Asia sites; baseline characteristics were generally balanced, with notable exceptions for ECOG PS 1 (11.9% Asia vs 37.1% non-Asia), FLOT backbone (1.6% vs 31.8%), tumor location stomach (86.6% vs 68.9%), and tumor stage III-IVa (85.8% vs 74.0%). In the Asia subgroup, pCR was 17.1% with pembro + chemo vs 2.1% with pbo + chemo (difference, 15.0%; 95% CI, 9.7-21.2); median EFS was 69.8 mo vs 42.7 mo (HR, 0.81; 95% CI, 0.60-1.10), with a 5-year rate of 54.1% vs 45.6%; median OS was not reached (NR) vs NR (HR, 0.87; 95% CI, 0.63-1.19), with a 5-year rate of 61.3% vs 57.4%. In the non-Asia subgroup, pCR was 12.4% with pembro + chemo vs 3.3% with pbo + chemo (difference, 9.1%; 95% CI, 4.9-13.6); median EFS was 37.7 mo vs 24.3 mo (HR, 0.79; 95% CI, 0.64-0.98), with a 5-year rate of 44.0% vs 33.0%; median OS was 60.7 mo vs 42.4 (HR, 0.85; 95% CI, 0.68-1.06), with a 5-year rate of 50.5% vs 42.6%. In the Asia subgroup, treatment-related AE (TRAE) rates were 98.4% with pembro + chemo vs 97.4% with pbo + chemo; grade 3-5 TRAE rates were 69.6% vs 65.1%, respectively. In the non-Asia subgroup, TRAE rates were 94.1% with pembro + chemo vs 96.1% with pbo + chemo; grade 3-5 TRAE rates were 65.5% vs 61.7%, respectively. **Conclusions:** A favorable trend in EFS and OS was seen in both the Asia and the non-Asia subgroups of KENOTE-585; additional antitumor activity of pembro + chemo was consistently observed, regardless of region. The safety profiles were generally comparable between the subgroups. These findings support the global development of this perioperative immunotherapy/chemotherapy regimen. Clinical trial information: NCT03221426. Research Sponsor: Merck Sharp & Dohme LLC, a subsidiary of Merck & Co., Inc., Rahway, NJ, USA.

Association of neighborhood-level factors with access to genetic testing in patients with resectable pancreatic ductal adenocarcinoma. First Author: Muhammad Maisam Ali, University of Wisconsin School of Medicine and Public Health, Madison, WI

Background: Since 2019, the NCCN has recommended genetic testing for all patients with pancreatic ductal adenocarcinoma (PDAC). However, only one-third of patients undergo testing. For other cancers, social determinants of health have been shown to influence access to genetic testing. This study examines disparities in genetic testing among PDAC patients using neighborhood-level measures. **Methods:** We retrospectively analyzed 249 patients who underwent curative-intent resection for PDAC at a high-volume academic center between 2019 and 2023. Neighborhood disadvantage was quantified using the Area Deprivation Index (ADI). Additional socioeconomic variables included Rural-Urban Classification (RUCA) codes, insurance type (private vs. non-private), and distance to the treating facility. The primary outcome was completion of genetic testing. For those that did not undergo testing, we separately analysed the association between socioeconomic factors and presence of a referral for genetic counseling or testing. Logistic regression models adjusted for age, sex, and period of diagnosis were used to assess associations. **Results:** The cohort's mean age was 66.6 years (SD: 9.2); 45.1% were female, and 97.6% identified as non-Hispanic White. Median ADI was 55.0 (IQR: 29.5), and 38.1% lived in rural areas. Genetic testing was completed by 96 patients (40.1%), identifying pathogenic variants in 18 (18.7%). Multivariable analysis revealed age above 65, higher ADI, and greater distance from the facility significantly reduced testing likelihood. Testing rates increased between 2019 and 2023 (Table 1). Among the 153 patients without testing, only 41.2% were referred for genetic counseling/testing. Greater distance from the facility was associated with lower likelihood of being referred (OR: 0.33 [CI: 0.13, 0.85]). **Conclusions:** Neighborhood-level factors influence genetic testing access, even in a predominantly racially homogenous population. Targeted interventions are needed to reduce disparities and improve testing and referral rates. Research Sponsor: None.

Constructing genetic-immune prognostic subtypes of primary duodenal adenocarcinoma through whole exome sequencing and AI-assisted immune microenvironment analysis. First Author: Ting Han, Department of Oncology, Renji Hospital, School of Medicine, Shanghai Jiao Tong University, Shanghai, China

Background: Primary duodenal adenocarcinoma (DA) is a rare gastrointestinal tumor with a poor prognosis. This study aimed to investigate the tumor immune microenvironment (TIME) and genetic landscape of DA to depict the unique DA subtypes, distinguishing its prognosis and identifying potential therapeutic targets. **Methods:** To reveal the heterogeneity of DA's genetic landscape and TIME, 88 treatment-naïve DA tumor samples were analyzed via multiplex immunofluorescence (mIF) staining, whole-exome sequencing, and RNA sequencing. The quantity of infiltrating cells, tertiary lymphoid structure, and spatial analysis was conducted using an automated platform (APTIME), an artificial intelligence-based analysis tool for analyzing pathology images from formalin-fixed paraffin-embedded slides stained with mIF. **Results:** Significant heterogeneity was observed in the genetic and immune landscapes of DA. A genetic-immune classification was established, identifying four distinct subtypes: MSI (microsatellite instable), InA(inflamed active), ML (macrophage-low), and MH (macrophage-high). The InA subtype exhibited high levels of infiltrating immune cells, while the MH subtype, characterized by enriched tumor-associated macrophages, was associated with the worst overall survival. The MH subtype frequently harbored TGF-β pathway mutations, particularly in SMAD4, while the ML subtype showed alterations that predominantly in the SWI/SNF pathway, specifically in ARID2. Spatial analysis indicated that closer proximity between macrophages and both tumor cells and T cells correlated with worse prognosis in DA patients. Closer interactions between PD-L1 and PD1+ T cells in the MH subtype suggested that PD-1/PD-L1 interactions contributed to an immunosuppressive tumor microenvironment. **Conclusions:** This study enhances the understanding of DA's molecular characteristics, particularly through the identification of a novel genetic-immune subtype, and provides a foundation for developing precision treatment strategies for this malignancy. Research Sponsor: None.

Uncovering the tumor microenvironment (TME): Exploring survival and immunotherapy (IO) response in cancer of unknown primary (CUP). First Author: Joelle Allam, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Cancer of Unknown Primary (CUP) is a group of rare and heterogeneous metastatic cancers with unidentifiable site of origin at time of diagnosis, despite extensive investigation. Characterization of CUP remains challenging, and biomarkers are urgently needed to better tailor therapies. Tumor microenvironment (TME) comprises the dynamic and complex network of extracellular matrix, blood vessels, immune cells, signaling molecules surrounding a tumor. It plays a critical role in tumorigenesis, progression and response to treatment. This study investigates the correlation between clinical factors, TME, IO and overall survival outcomes in patients diagnosed with CUP. **Methods:** We retrospectively evaluated 49 CUP patients who underwent Boston Gene Tumor Portrait (BGTP) testing between January 2023 and July 2024. BGTP utilizes a combination of Next-Generation Sequencing (NGS) and artificial intelligence to analyze a tumor sample's genetic profile along with its surrounding microenvironment, thereby providing a more comprehensive view to support clinical decision-making and optimize treatment strategies. Clinico-pathological data, including age, ECOG performance status at diagnosis, baseline laboratory results, tumor histology and grade, number of metastatic sites (NMS) and IO treatment history were collected through retrospective chart review. TME was categorized into 4 subtypes: immune-enriched (IE), immune-enriched/fibrotic (IE/F), fibrotic (F) and immune-depleted (D). **Results:** Baseline characteristics of 49 CUP patients show median age at diagnosis was 63 years (range 32-80). Most patients were male (59%). Grade was reported as poorly differentiated in 69%, with pathology described as carcinoma (47%), adenocarcinoma (33%), squamous cell carcinoma (10%) and malignant neoplasm (8%). TME subtypes distribution was 33% IE, 14% IE/F, 16% F, 37% D. Univariate analysis revealed that better outcomes were associated with lower NLR (< 5) (median survival 57 vs 11 months, p = 0.006), lower ECOG (57 vs 16 vs 6 months for ECOG 0, 1 and 2 respectively, p = 0.002), lower NMS (< 3) (45 vs 14 months, p = 0.046). Survival data of TME and NLR subsets is shown in the table. **Conclusions:** This is the first characterization of TME profile in CUP. A diverse range of TME subtypes were seen in this population. While classical prognostic factors such as NLR, ECOG, NMS were associated with better survival, there also appears to be a trend toward survival benefit with IO in the IE/IE-F subset. Further studies are needed to prospectively explore the role of TME subtypes in determining clinical outcomes and IO response. Research Sponsor: None.

Median overall survival (months) in TME and NLR subsets, with and without IO.

Subset/Treatment	IE/IE-F	F/D	P-value	NLR High	NLR Low	P-value
IO	45.3	15.6	0.14	11.2	22.7	0.04
No IO	14.6	10.8		10.8	57.4	

4199 **Poster Session**

Identification of differential epigenetic landscapes in subtypes of appendiceal cancer. First Author: Luisa Ladel, Yale University, New Haven, CT

Background: Appendiceal cancers (AC) represent a rare and heterogeneous group of malignancies, often managed with strategies adapted from colorectal cancer (CRC) due to their anatomical proximity. However, marked differences in biological behavior, treatment response, and molecular profiles between AC and CRC necessitate independent study. While genomic data on AC has been explored, epigenetic landscapes remain uncharted. This study establishes the first comprehensive epigenetic profile of appendiceal cancer subtypes, aiming to identify novel biomarkers, therapeutic targets, and prognostic indicators. **Methods:** Tissue specimens from 20 patients with histologically confirmed appendiceal neoplasms and 4 age-matched non-neoplastic controls were analyzed. Malignant subtypes were categorized into three groups: Normal, Low-Grade Appendiceal Mucinous Neoplasms (LAMN, with and without pseudomyxoma peritonei), and Advanced Neoplasia (mucinous adenocarcinoma, non-mucinous adenocarcinoma, and goblet cell adenocarcinoma). Whole-genome methylome profiling was performed using enzymatic methyl-seq for single-base resolution of DNA methylation. Differentially methylated regions (DMRs) were identified with a q-value cutoff of < 0.05 and analyzed using the Whole Genome R package with the methylKit analysis pipeline. **Results:** Epigenetic clustering revealed progressive dysregulation from normal tissue to LAMN and further to advanced neoplasia, supporting a continuum of malignancy. Our preliminary analysis of CpG islands identified 2,621 DMRs between LAMN and normal tissues and 395 DMRs between Advanced Neoplasia and LAMN. In promoter regions, 1,852 DMRs differentiated LAMN from normal, and 283 distinguished Advanced Neoplasia from LAMN. LAMN samples exhibited predominantly hypomethylated regions relative to normal tissues (2,299 vs. 322 for CpG islands; 1,579 vs. 273 for promoters). Conversely, advanced neoplasia demonstrated more hypermethylated regions than LAMN (243 vs. 152 for CpG islands; 195 vs. 88 for promoters). Most DMRs were localized to intronic, distal intergenic, and promoter regions. Key overlapping DMRs included 8 hypomethylated CpG islands, 41 hypermethylated CpG islands, 3 hypomethylated promoters, and 14 hypermethylated promoters. These regions implicate pivotal genes in the progression from LAMN to advanced neoplasia. **Conclusions:** This study pioneers the epigenetic characterization of appendiceal cancers, uncovering unique methylation signatures that differentiate malignant subtypes and normal tissue. Integrating these findings with genomic data highlights critical targets for the detection and molecular classification of appendiceal neoplasms. These insights pave the way for improved diagnostic and therapeutic strategies tailored to this rare malignancy. Research Sponsor: None.

4200 **Poster Session**

Circulating tumor DNA-based genomic profiling and real-world outcomes in cancer of unknown primary (CUP). First Author: Keelia Clemens, Guardant Health, Redwood City, CA

Background: CUP accounts for <5% of cancers and carries a dismal prognosis with median overall survival of ~13 months. Studies suggest up to one-third of CUP patients (pts) have a potentially targetable alteration (PTA) that may be eligible for molecularly guided therapy (MGT). Liquid biopsy (LB) is a non-invasive method to identify PTAs and genomic clues regarding primary site via circulating tumor DNA (ctDNA). We characterize the ctDNA landscape of PTAs in CUP and evaluate outcomes for pts receiving MGT. **Methods:** Real-world data was sourced via GuardantINFORM, a database aggregating insurance claims and de-identified records of pts with clinical LB via Guardant360. PTAs were defined as alterations with FDA approved therapies in non-CUP indications. Pts with CUP and ≥1 treatment claim after LB were included. Outcomes of pts treated with MGT and pts with the same PTA not treated with MGT were assessed via real-world time to treatment discontinuation (rwTTD), real-world time to next treatment (rwTTNT) and real-world overall survival (rwOS) in months. Log-rank test was used to compare time-to-event outcomes. **Results:** Of 13,324 CUP pts, 50% were male; the median age was 69 years. Majority of pts underwent LB at time of diagnosis (92.1%). In pts with ≥1 genomic alteration identified (91.9%), the most common genomic alterations were *TP53* (55%), *KRAS* (25%), *PIK3CA* (14%), and *EGFR* (12%). A PTA was identified in 29.4% of pts, the most frequent being *PIK3CA* (9.2%), *KRAS* G12C (4.3%), *BRCA1/2* (4%), *ERBB2* (3.9%), *EGFR* (2.8%), *IDH1* (2.5%), *BRAF* V600E (2.4%) and MSI-H (2%). rwTTD was higher for pts with alterations in *EGFR, BRAF* V600E, and MSI-H receiving MGT; only *EGFR* reached significance (Table). Similarly, rwTTNT was improved in pts with *EGFR, BRAF* V600E alterations and MSI-H, but did not reach significance. rwOS was numerically higher for *BRAF* V600E and *ERBB2* mutated pts receiving MGT (Table). **Conclusions:** This study represents the first large-scale ctDNA genomic profiling of CUP pts with real-world outcomes.LB detected PTAs in 29.4% of CUP pts, similar to tissue-based testing. Our findings support use of LB to identify PTAs in CUP pts; however, prospective trials are needed to assess MGT efficacy. Research Sponsor: None.

Real-world outcomes (in months): MGT vs no MGT.

A multiregional, randomized, controlled, open-label, phase 3 study of the anti-claudin18.2 (CLDN18.2) antibody-drug conjugate (ADC) arcotatug tavatecan (IBI343) in gastric or gastroesophageal junction adenocarcinoma (G/GEJA): Trial in progress. First Author: Lin Shen, Beijing Cancer Hospital, Beijing, China

Background: CLDN18.2 has been a validated therapeutic target for G/GEJA. As a next-generation ADC, arcotatug tavatecan (IBI343) composed of anti-CLDN18.2 monoclonal antibody conjugated to exatecan (topoisomerase I inhibitor) with unique IgG1 Fc silencing to attenuate antibody-dependent cellular cytotoxicity and complement-dependent cytotoxicity. Previous phase 1 studies of IBI343 observed manageable safety profiles with encouraging efficacy in G/GEJA, pancreatic ductal adenocarcinoma and biliary tract cancer (2024 ASCO Annual Meeting [3037], ESMO GI 2024 [396MO], ESMO Asia 2024 [132MO]). Here, we present the trial in progress of a phase 3 study (G-HOPE-001, NCT06238843) evaluating efficacy and safety of IBI343 monotherapy versus treatment of investigator's choice in previously treated patients (pts) with CLDN18.2-positive G/GEJA. **Methods:** This multiregional, randomized, controlled, open-label, phase 3 study planned to enroll 450 pts. Main inclusion criteria are: 1) locally advanced unresectable or metastatic G/GEJA; 2) positive CLDN18.2, defined as immunohistochemical (IHC) membrane staining intensity ≥ 2+ in ≥ 75% of tumor cells as measured by the VENTANA CLDN18 (43-14A) Assay; 3) radiologically evaluable disease, measurable and/or non-measurable disease per RECIST v1.1; 4) received and progressed on 2-4 prior regimens of systemic therapy which must include a fluoropyrimidine, platinum, and a taxane or irinotecan. Main exclusion criteria are: 1) positive HER-2, defined as IHC 3+ or IHC 2+/in situ hybridization+; 2) history of treatment with topoisomerase inhibitor-based ADCs. Pts are randomized in a 1:1 ratio to receive IBI343 6mg/kg Q3W in the experimental arm or to receive treatment of investigator's choice including irinotecan, paclitaxel, or trifluridine/tipiracil in the control arm. Stratification factors include region (Asian country/region other than Japan vs. European Union and United States vs. Japan), primary site of the tumor (stomach vs. gastroesophageal junction) and history of prior gastrectomy (yes vs. no). The primary endpoints are progression-free survival (PFS) per RECIST v1.1 and overall survival (OS). The secondary endpoints include objective response rate (ORR), disease control rate (DCR), duration of response (DoR) and time to response (TTR) per RECIST v1.1, quality of life (QoL), safety, pharmacokinetics (PK) and immunogenicity. The trial is currently enrolling pts in China and Japan. Clinical trial information: NCT06238843. Research Sponsor: Innovent Biologics (Suzhou) Co., Ltd.

TPS4202 **Poster Session**

Telisotuzumab adizutecan (ABBV-400; Temab-A) in combination with fluorouracil, leucovorin, and budigalimab in locally advanced/metastatic gastric, gastroesophageal junction, or esophageal adenocarcinoma (a/m GEA). First Author: Kohei Shitara, Department of Gastroenterology and Gastrointestinal Oncology, National Cancer Center Hospital East, Kashiwa, Japan

Background: The *MET* proto-oncogene and its receptor tyrosine kinase gene product (c-Met protein) are involved in normal cellular functions such as cell proliferation and differentiation but can be abnormally activated and upregulated in cancer to promote tumor growth. *MET* gene amplification and increased c-Met protein expression are associated with poor survival outcomes in gastric cancer. The antibody-drug conjugate Temab-A (ABBV-400) is composed of the c-Met–directed antibody telisotuzumab conjugated to a potent topoisomerase 1 inhibitor. A phase 1 study (NCT05029882) investigating Temab-A monotherapy demonstrated manageable safety and encouraging efficacy in patients with previously treated, advanced GEA, with an objective response rate of 29% (12/42) and clinical benefit rate of 71% (30/42) (Strickler et al. *Ann Oncol*. 2024;35:1439P). This study evaluates Temab-A in combination with fluorouracil (5-FU), leucovorin/folinic acid (LV), and budigalimab (budi; a PD-1–blocking antibody). **Methods:** This multicenter,phase 2, open-label, randomized study (NCT06628310) will enroll ~180 adult patients with HER2-negative a/m GEA who have not received prior systemic therapy in the a/m setting, have not received a prior PD-(L)1 inhibitor, have Eastern Cooperative Oncology Group performance status 0–1, and have measurable disease per RECIST v1.1. Primary objectives of the study are to evaluate safety and tolerability, evaluate efficacy as measured by progression-free survival and objective response, and select the recommended phase 3 dose of Temab-A in combination with 5-FU, LV, and budi. Secondary objectives include assessment of dose-limiting toxicities (DLTs) in the dose-escalation stage, evaluation of pharmacokinetics, and further evaluation of efficacy measures (duration of response, disease control, and overall survival). The study consists of 2 stages: dose escalation and dose optimization. During BOIN-directed dose escalation, ~18 patients receive escalating doses of Temab-A administered once every 4 weeks (Q4W) in combination with fixed doses of 5-FU (2400 mg/m^2 Q2W), LV (400 mg/m^2 Q2W), and budi (500 mg Q4W). DLTs are assessed during the first 28-day cycle. During dose optimization, ~162 patients are randomized 1:1:1 to 1 of 2 selected doses of Temab-A in combination with 5-FU, LV, and budi or a control arm of FOLFOX + budi. Randomization is stratified by PD-L1 expression and primary tumor location. Treatment is administered until disease progression, intolerable toxicity, or other discontinuation criteria are met. Either archived formalin-fixed paraffin-embedded tissue or a fresh biopsy is required for biomarker research that will include evaluation of c-Met protein expression and *MET* genomic alterations. Clinical trial information: NCT06628310. Research Sponsor: AbbVie, Inc.; n/a.

TPS4203 **Poster Session**

Open-label, single-arm, single-center phase 1b/2 clinical study of fruquintinib combined with trastuzumab and XELOX in the first-line treatment of advanced HER2-positive metastatic gastric or gastroesophageal junction adenocarcinoma. First Author: Huifang Lv, Department of Gastrointestinal Medical Oncology, The Affiliated Cancer Hospital of Zhengzhou University, Henan Cancer Hospital, Zhengzhou, China

Background: Trastuzumab plus chemotherapy has significantly prolonged survival in patients with HER2-positive gastric and gastroesophageal junction (G/GEJ) cancer. The KEYNOTE-811 study suggested that the efficacy of adding pembrolizumab to trastuzumab and chemotherapy was superior to trastuzumab plus chemotherapy. However, only patients with a PD-L1 combined positive score (CPS) of 1 or higher could benefit, while those with PD-L1 CPS < 1 did not benefit from this regimen. Fruquintinib is a highly selective oral tyrosine kinase inhibitor of vascular endothelial growth factor receptors (VEGFRs) 1, 2, and 3. The phase 3 study FRUTIGA demonstrated fruquintinib plus paclitaxel was superior to paclitaxel alone as second-line treatment in patients with G/GEJ cancer. As anti-angiogenesis has a synergistic effect with trastuzumab, we designed this study to evaluate the safety and efficacy of fruquintinib plus trastuzumab, and CAPEOX as first-line treatment for advanced HER2-positive G/GEJ cancer. **Methods:** This is a single-center, single-arm, open-label, phase 1b/2 study. The phase 1b study will adopt a 3+3 design with escalating oral daily dose of 2 to 4 mg (1 mg per level) fruquintinib for days 1-14 in combination with trastuzumab (8mg/kg load, followed by 6mg/kg) intravenously once for day 1, capecitabine 1000mg/m^2 orally twice a day for days 1-14, and oxaliplatin 130mg/m^2 intravenously once for day 1 using a 21-day cycle. The maximum tolerated dose (MTD) and recommended phase 2 dose (RP2D) of fruquintinib will be determined in the phase 1b study with a dose-limiting toxicity (DLT) period of the first cycle. Major DLTs are defined as any of the following toxicities occurring in the DLT period determined to be related to study treatment: grade ≥ 4 hematological toxicities, grade ≥ 3 non-hematological toxicities, and toxicities that required discontinuation of fruquintinib or trastuzumab ≥ 21 days. 6 to 12 systematic treatment-naïve patients with advanced G/GEJ cancer are expected to be enrolled in the phase 1b study, depending on observed DLTs and the need for dose adjustments. In the phase 2 study, 39 additional patients will be enrolled with RP2D administered. Upon 6-8 cycles of treatment completed, fruquintinib plus trastuzumab and capecitabine will be administered as maintenance treatment. The treatment continues until progressive disease or intolerable toxicity. The primary endpoint of the phase 2 study is PFS. The secondary endpoints include OS, ORR, DCR, DoR, safety, and molecular biomarker exploration. Clinical trial information: ChiCTR2300074767. Research Sponsor: None.

TPS4204 **Poster Session**

ARTEMIDE-Gastric01: A phase 3 randomized study of rilvegostomig with fluoropyrimidine and trastuzumab deruxtecan (T-DXd) as first-line (1L) treatment for locally advanced or metastatic HER2-positive gastric or gastroesophageal junction cancer (GC/GEJC). First Author: Rui-Hua Xu, Department of Medical Oncology, Sun Yat-Sen University Cancer Center, State Key Laboratory of Oncology in South China, Guangdong Provincial Clinical Research Center for Cancer, Sun Yat-Sen University, Guangzhou, China

Background: Patients with GC/GEJC often present with advanced disease, and prognosis for these patients is poor, with a 5-year relative survival rate of ~5%, highlighting a need for new treatment options. HER2 overexpression/amplification occurs in ~20% of cases. Adding immune checkpoint inhibition to trastuzumab (anti-HER2 monoclonal antibody) and chemotherapy has shown clinical benefit in patients with advanced HER2-positive GC/GEJC (Janjigian YY, et al. *N Engl J Med* 2024), and led to the approval of pembrolizumab (programmed cell death-1 [PD-1] inhibitor), trastuzumab, and chemotherapy for HER2-positive GC/GEJC with programmed cell death ligand-1 combined positive score (PD-L1 CPS) ≥1. T-DXd (a HER2-directed antibody-drug conjugate) is approved for the treatment of patients with locally advanced/metastatic HER2-positive GC/GEJC who have received a prior trastuzumab-based regimen. In addition, dual inhibition of PD-1 or PD-L1 and the immune checkpoint T cell immunoglobulin and immunoreceptor tyrosine-based inhibitory motif domain (TIGIT) has shown encouraging results across multiple tumor types, without major increases in high-grade toxicity compared with PD-1 or PD-L1 inhibition alone. Rilvegostomig is a monovalent, bispecific, humanized IgG1 monoclonal antibody targeting both PD-1 and TIGIT receptors that has shown encouraging efficacy with manageable safety as monotherapy in non-small-cell lung cancer (Hiltermann TJN, et al. WCLC 2024. Oral presentation 1751) and with chemotherapy in HER2-negative GC/GEJC (Herrero FR, et al. *Ann Oncol* 2024. Abs 1422P). **Methods:** ARTEMIDE-Gastric01 (NCT06764875) is a phase 3, randomized, open-label, sponsor-blinded, multicenter, global study that will assess the efficacy and safety of rilvegostomig with T-DXd and chemotherapy as 1L treatment in HER2-positive GC/GEJC with PD-L1 CPS ≥1. Approximately 840 participants (pts) will be randomized to Arm A: rilvegostomig + T-DXd + investigator's (INV) choice of capecitabine or 5-fluorouracil (5-FU); Arm B: pembrolizumab + trastuzumab + INV choice of 5-FU and cisplatin (FP) or capecitabine and oxaliplatin (CAPOX); Arm C: rilvegostomig + trastuzumab + INV choice of FP or CAPOX. Eligible pts will have previously untreated, unresectable, histologically confirmed, locally advanced/metastatic HER2-positive and PD-L1 CPS ≥1 GC/GEJC and an ECOG performance status of 0 or 1. Dual-primary endpoints are progression-free survival (RECIST v1.1; blinded independent central review) and overall survival in all randomized pts. Secondary endpoints include safety/tolerability, objective response rate, and duration of response. Enrollment is planned across ~25 countries in Asia, Australia, Europe, and North and South America. Clinical trial information: NCT06764875. Research Sponsor: AstraZeneca.

TPS4205 **Poster Session**

A randomized controlled trial comparing conversion surgery with palliative chemotherapy in patients with initially unresectable cStage IVB/pStage IV advanced gastric cancer who presented remarkable response to chemotherapy: JCOG2301 (Conversion study). First Author: Itaru Yasufuku, Department of Clinical Anatomy Development Studies, Gifu University Graduate School of Medicine, Gifu-City, Japan

Background: Conversion surgery is a surgical treatment for patients with initially unresectable cStage IVB gastric cancer who presented remarkable response to palliative chemotherapy aiming at n R0 resection expecting long survival including he disease. This study is a randomized controlled phase III trial aimed to evaluate the efficacy of conversion surgery comparing to palliative chemotherapy. **Methods:** Eligibility criteria include the followings : (1) Histologically proven adenocarcinoma of the stomach. (2) Diagnosed as clinical stage IVB or pathological stage IV according to the Japanese Classification of Gastric Carcinoma (15th edition), with at least one of the following unresectable distant metastases before chemotherapy. (i) Four or more liver metastases. (ii) Distant lymph node metastasis beyond para-aortic lymph node No.16a2/16b1. (iii) Peritoneal dissemination diagnosed with imaging examination or P1b/P1c peritoneal dissemination diagnosed with laparotomy or laparoscopy. (3) Undergoing first-line chemotherapy regardless of nivolumab or trastuzumab use. (4) Confirmation of no peritoneal metastasis or localization at a limited area close to the stomach by laparoscopy or laparotomy after initiation of chemotherapy, with CY0 status in peritoneal lavage cytology. (5) Response to chemotherapy of distant metastasis diagnosed before initiating first-line chemotherapy that meets the following (i) and (ii) before registration. (i) Liver metastasis: three or fewer liver metastasis. (ii) Distant lymph node metastasis excluding No.16a2/16b1: disappearance or reduction to a long axis of less than 6 mm. The primary endpoint is overall survival. After confirming eligibility, patients are registered and randomized (1:1) to either the palliative chemotherapy alone arm or the conversion surgery arm. We assumed the median survival timeis 19 months after registration for the chemotherapy alone arm additional efficacy for overall survival in the conversion surgery arm corresponding to a hazard ratio of 0.7. This study requires 126 patients to observe 102 deaths, with power of 70% and a one-sided alpha of 10%, considering the rarity of patients with stage IV gastric cancer who exhibit a significant response to palliative chemotherapy, an accrual period of 5 years, and a follow-up period of 3 years. This trial was initiated in September 2024, and the first patient was enrolled in January 2025. Clinical trial information: jRCTs031240340. Research Sponsor: Japan Agency for Medical Research and Development (AMED).

TPS4206 **Poster Session**

A randomized, double-blinded, international phase III trial comparing HLX22 in combination with trastuzumab and chemotherapy versus trastuzumab and chemotherapy with or without pembrolizumab for first-line treatment for HER2-positive locally advanced or metastatic G/GEJ cancer. First Author: Jaffer A. Ajani, Department of Gastrointestinal (GI) Medical Oncology, MD Anderson Cancer Center, Houston, TX

Background: Combination therapy with trastuzumab and chemotherapy is the first-line systemic treatment for human epidermal growth factor receptor 2 (HER2) positive advanced gastric or gastroesophageal junction (G/GEJ) cancer. Among patients whose tumors express programmed death ligand 1 (PD-L1; defined as combined positive score [CPS] ≥ 1), treatment options also include pembrolizumab plus trastuzumab and chemotherapy. Survival outcomes remain unsatisfactory despite these advances. HLX22 is an anti-HER2 antibody that targets a different epitope than trastuzumab. HLX22 has shown improved progression-free survival (PFS) when added to trastuzumab plus oxaliplatin and capecitabine (XELOX) in a phase 2 study (NCT04908813). Here we present the design of a phase III randomized controlled study. **Methods:** This randomized, double-blind, two-arm phase III clinical study aims to compare the efficacy and safety of HLX22 in combination with trastuzumab and XELOX versus (vs) trastuzumab and XELOX with or without (±) pembrolizumab in patients with HER2-positive, advanced G/GEJ cancer and no prior antitumor therapy in the advanced setting. Key inclusion criteria include histologically or cytologically confirmed diagnosis of previously untreated, locally advanced unresectable or metastatic HER2-positive G/GEJ adenocarcinoma. Key exclusion criteria include prior use of any HER2-target therapy. Approximately 550 eligible patients will be enrolled from multiple regions across the globe and randomly assigned in a 1:1 ratio to receive HLX22 (15 mg/kg) + trastuzumab + XELOX ± placebo (for pembrolizumab) or placebo (for HLX22) + trastuzumab + XELOX ± pembrolizumab. HLX22 will be administered intravenously on Day 1 of each 21-day treatment cycle until loss of clinical benefit, death, intolerable toxicity, withdrawal of informed consent, or other reasons. The stratification factors include HER2 immunohistochemistry (3+ vs 2+), geographic region (Asia vs Europe/North America vs rest of the world), primary tumor site (gastric vs gastroesophageal junction), and tumor PD-L1 expression (CPS < 1 or not evaluable vs 1 ≤ CPS < 10 vs CPS ≥ 10). The dual primary endpoints are PFS assessed by independent radiology review committee per RECIST v1.1 and overall survival. Secondary endpoints include investigator-assessed PFS, objective response rate, PFS on the subsequent line of therapy, duration of response, safety, pharmacokinetics, immunogenicity, and quality of life. This study is currently open for enrollment and has completed first dose of the first patient. Clinical trial information: NCT06532006. Research Sponsor: Shanghai Henlius Biotech, Inc.

TPS4207 **Poster Session**

An open-label, randomized, multicenter, phase 3 study of trastuzumab deruxtecan (T-DXd) + chemotherapy (chemo) ± pembrolizumab (pembro) versus chemo + trastuzumab ± pembro in first-line metastatic HER2+ gastric or gastroesophageal junction (GEJ) cancer: DESTINY-Gastric05. First Author: Kohei Shitara, National Cancer Center Hospital East, Chiba, Japan

Background: An unmet medical need remains in patients (pts) with HER2+ gastric or GEJ cancer. HER2 is a validated target in up to 20% of pts with gastric or GEJ cancer. The KEYNOTE-811 trial demonstrated that adding pembro to trastuzumab and chemo improved progression-free survival (PFS) and overall survival (OS) versus placebo for first-line treatment of pts with HER2+ gastric or GEJ cancer with a PD-L1 combined positive score (CPS) ≥1 (Janjigian Y et al. *N Engl J Med*. 391;1360:2024). In the DESTINY-Gastric03 trial, first-line combinations involving T-DXd, a HER2-directed antibody-drug conjugate, and fluoropyrimidine (5-FU or capecitabine [CAPE]) ± pembro showed acceptable safety and encouraging efficacy in pts with HER2+ gastric or GEJ cancer, including pts with CPS < 1 (Janjigian Y et al. *Ann Oncol*. 35;S878:2024). Building on this evidence, the phase 3 DESTINY-Gastric05 trial aims to bring a potentially improved platinum-free treatment approach for all pts with HER2+ gastric or GEJ cancer. **Methods:** DESTINY-Gastric05 (NCT06731478) is an open-label, randomized, multicenter, phase 3 global trial designed to evaluate the efficacy and safety of T-DXd in combination with 5-FU (or CAPE) + pembro versus standard-of-care chemo with trastuzumab + pembro as first-line treatment in pts with unresectable, locally advanced or metastatic centrally confirmed HER2+ (immunohistochemistry [IHC] 3+ or IHC 2+/in situ hybridization+) gastric or GEJ cancer with a CPS ≥1. Pts must have ≥1 RECIST v1.1 measurable lesion, a left ventricular ejection fraction ≥50%, and an Eastern Cooperative Oncology Group performance status of 0 or 1. Approximately 576 pts will be randomly assigned in a 1:1 ratio to receive: T-DXd 5.4 mg/kg + either 5-FU or CAPE + pembro (arm M1); or trastuzumab + platinum-based chemo (either cisplatin + 5-FU or oxaliplatin + CAPE) + pembro (arm M2). The primary efficacy endpoint is PFS based on blinded independent central review (BICR), and the key secondary endpoint is OS. Other secondary endpoints include overall response rate, duration of response, and time to response per RECIST v1.1 assessed by BICR and investigator. Safety and tolerability will also be assessed. An exploratory cohort (approximately 150 pts) will evaluate the efficacy and safety of T-DXd in combination with 5-FU or CAPE versus trastuzumab plus standard-of-care chemo in pts with PD-L1 CPS < 1. Clinical trial information: NCT06731478. Research Sponsor: Daiichi Sankyo, Inc.

TPS4208 **Poster Session**

A phase II study of sacituzumab govitecan for advanced esophageal squamous cell carcinoma patients (SG-ESCC). First Author: Jhe-Cyuan Guo, National Taiwan University Cancer Center, Taipei, Taiwan

Background: Esophageal squamous cell carcinoma (ESCC) remains a significant global health challenge, particularly in Asia. There are limited treatment options for advanced ESCC patients who fail platinum-based chemotherapy and anti-PD-1/PD-L1 therapy, resulting in poor prognoses. Trophoblast cell surface antigen 2 (Trop-2), a transmembrane protein overexpressed in ESCC, offers a potential therapeutic target due to its differential expression between tumors and normal tissues. Sacituzumab govitecan, an antibody-drug conjugate (ADC) comprising an anti-Trop-2 antibody linked to a topoisomerase I inhibitor payload, has shown efficacy in triple-negative and hormone receptor-positive breast cancers. This study aims to investigate the efficacy and safety of sacituzumab govitecan in patients with advanced ESCC. **Methods:** This investigator-initiated, prospective, phase II, single-arm, multi-center trial evaluates the efficacy and safety of sacituzumab govitecan (10 mg/kg IV on days 1 and 8 of a 21-day cycle) in advanced ESCC patients. Eligible patients must have failed prior platinum-based chemotherapy and anti-PD-1/PD-L1 therapy, exhibit measurable disease per RECIST 1.1, and have an ECOG performance status $\leq$1. The primary endpoint is the objective response rate (ORR) by RECIST 1.1. Secondary endpoints include overall survival, progression-free survival, duration of response, and safety outcomes. Biomarker analyses will explore Trop-2 expression and other molecular markers associated with treatment efficacy and resistance as well as toxicity. A total of 35 patients will be enrolled employing Simon's two-stage design, with a type I error rate of 0.1 and 80% power to detect an ORR $\geq$25%, considered promising compared to the historical control of $\leq$10%. In the first stage, 16 patients will be accrued, with $\geq$2 responses required to proceed to the second stage of 15 additional patients. Accounting for an anticipated 10% dropout rate, the study aims to complete enrollment within 24 months. Enrollment began in August 2024, and as of December 2024, 5 of the planned 35 patients have been enrolled. Clinical trial information: NCT06329869. Research Sponsor: Gilead Sciences.

TPS4209 **Poster Session**

KEYMAKER-U06 substudy 06E: A phase 1/2 open-label, umbrella platform study of ifinatamab deruxtecan in combination with pembrolizumab with or without chemotherapy for first-line treatment of advanced esophageal squamous cell carcinoma (ESCC). First Author: Ken Kato, National Cancer Center Hospital, Tokyo, Japan

Background: There is a substantial need for more effective and tolerable first-line treatment options for patients with advanced ESCC. B7-H3 is a type 1 transmembrane protein that is highly expressed in several cancers, including ESCC, and is associated with a poor prognosis. Ifinatamab deruxtecan (I-DXd; formerly DS-7300a/MK-2400) is a B7-H3–directed antibody-drug conjugate comprising a humanized anti–B7-H3 IgG1 monoclonal antibody (ifinatamab) covalently linked to a potent topoisomerase I inhibitor payload (DXd; an exatecan derivative) by a cleavable linker. In the phase 1/2 DS7300-A-J101 study, I-DXd monotherapy showed promising antitumor activity in participants (pts) with advanced ESCC. KEYMAKER-U06 is an open-label, phase 1/2, umbrella platform study designed to evaluate investigational agents with or without pembrolizumab and/or chemotherapy for advanced gastroesophageal cancer. Substudy 06E (NCT06780111) will be conducted to evaluate I-DXd plus pembrolizumab with or without chemotherapy as first-line therapy for advanced ESCC. **Methods:** Eligible pts are aged $\geq$18 years with previously untreated, histologically or cytologically confirmed, locally advanced unresectable or metastatic ESCC, measurable disease per RECIST v1.1 by investigator review and verified by blinded independent central review (BICR), and an Eastern Cooperative Oncology Group performance status of 0 or 1. Pts will be assigned to 1 of 4 treatment arms: arm 1 (reference treatment; pembrolizumab 200 mg IV Q3W for $\leq$35 cycles plus chemotherapy [mFOLFOX6: oxaliplatin 85 mg/m^2 IV Q2W plus 5-FU 400 mg/m^2 (bolus) and 2400 mg/m^2 (continuous) IV Q2W plus leucovorin 400 mg/m² IV Q2W]); arm 2 (I-DXd 12 mg/kg IV Q3W plus pembrolizumab); arm 3 (I-DXd 12 mg/kg plus pembrolizumab plus 5-FU 400 mg/m^2 [bolus] and 2400 mg/m^2 [continuous] IV Q2W plus leucovorin 400 mg/m² IV Q2W); and arm 4 (I-DXd [8 mg/kg or 12 mg/kg] IV plus pembrolizumab plus 5-FU 2400 mg/m^2 IV and oxaliplatin 60 mg/m^2). Approximately 209 pts will be enrolled. A safety lead-in phase with $\leq$29 pts will be conducted in arms 2 (n $\leq$6), 3 (n $\leq$10), and 4 (n $\leq$13) using a Bayesian optimal interval design to confirm the safety and recommended phase 2 dose (RP2D; arm 4 only) of I-DXd in combination with other agents; this phase will be conducted sequentially, starting with arm 2, followed by arms 3 and 4. Thereafter, $\leq$180 pts will be included in the randomized phase ($\leq$60 in arm 1; $\leq$40 each in arms 2-4). Pts will be randomly assigned 1:2 to arm 1 and the investigational arms. Primary outcomes are safety and tolerability, RP2D of I-DXd, and objective response rate per RECIST v1.1 by BICR for the selected dose. Secondary outcomes include DOR and PFS per RECIST v1.1 by BICR, OS, and pharmacokinetics of I-DXd in combination with other agents. Enrollment is ongoing. Clinical trial information: NCT06780111. Research Sponsor: Daiichi Sankyo Company, Limited and Merck Sharp & Dohme LLC, a subsidiary of Merck & Co., Inc., Rahway, NJ, USA.

TPS4210 **Poster Session**

A phase II study of perioperative intraperitoneal paclitaxel in patients with gastric adenocarcinoma and carcinomatosis or positive cytology. First Author: Brian D. Badgwell, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Over the last 2 decades, intraperitoneal chemotherapy has been found to have activity for select subgroups of patients with carcinomatosis from colon, ovarian, appendiceal, and recently, gastric origins. However, there is little data to support an aggressive surgical approach of cytoreduction (debulking) and intraperitoneal therapy for patients with gastric cancer and positive cytology or carcinomatosis. Recently, the DRAGON-01 randomized trial reported improvement in outcomes for the addition of intraperitoneal paclitaxel as part of a bidirectional approach with systemic paclitaxel and S-1 for patients with gastric cancer and peritoneal metastases. However, there are few studies supporting intraperitoneal paclitaxel in Western populations. As systemic therapy is improving with concomitant targeted and immunotherapy, intraperitoneal therapy may be best utilized in Western populations after standard of care systemic therapy. Therefore, the purpose of this clinical trial is to determine the efficacy and safety of perioperative intraperitoneal paclitaxel in patients with stage IV gastric cancer limited to the peritoneum after treatment with systemic chemotherapy. **Methods:** Patients with gastric and gastroesophageal adenocarcinoma and positive peritoneal cytology or carcinomatosis that have completed treatment with systemic chemotherapy are offered participation in the study. Patients with metastatic disease not limited to the peritoneum are excluded. Type and duration of systemic chemotherapy is left to the discretion of the treating medical oncologist. Immunotherapy or Her2-directed therapy may continue during the trial. We have recently completed a Phase I clinical trial demonstrating doses of up to 100 mg/m^2 were safe (NCT04220827; PMID: 39287936). Therefore, 100 mg/m^2 is administered intraperitoneal every 2 weeks for three treatments before and after gastrectomy. We also modified the trial to allow for the inclusion of heated intraperitoneal chemotherapy during gastrectomy. The primary outcome is overall survival from the date of diagnosis of stage IV disease, with secondary outcomes of safety. After completion of study–related treatment, subjects will be followed until recurrence and/or death for up to three years. Sixteen of planned 30 patients have been enrolled (NCT05977998). Clinical trial information: NCT05977998. Research Sponsor: None.

TPS4212 **Poster Session**

Repurposing itraconazole for secondary prevention of metaplasia and primary prevention of cancer in patients with high-risk Barrett's esophagus in combination with ablation. First Author: Ajay Bansal, Department of Gastroenterology and Hepatology, University of Kansas Medical Center, Kansas City, KS

Background: To prevent invasive esophageal adenocarcinoma (EAC), endoscopic eradication therapy (EET) is used to remove its precursor, Barrett's esophagus (BE) with dysplasia. EET combines endoscopic removal of visible lesions with radiofrequency ablation (RFA) of surrounding BE to achieve complete remission of intestinal metaplasia (CRIM) and complete eradication of dysplasia (CED) to halt progression to cancer. Unfortunately, EET has metaplasia recurrence rates of 12.4%/year; thus, adjunctive cancer interception agents are needed to maintain the gains of EET. Data from pre-clinical studies and patient tissues demonstrate that the Hedgehog (Hh) pathway regulates esophageal stem cell activity and cell fate determination (squamous versus intestinal). Post-RFA reactivation of Hh signaling is hypothesized to drive BE recurrence; however, current FDA-approved Hh inhibitors are expensive and toxic. The antifungal itraconazole inhibits Hh signaling and has demonstrated antitumor activity in multiple cancers. In addition, it inhibits VEGFR and PI3K-AKT pathways, which are critical to BE development and neoplastic progression. Given its safety and affordability, itraconazole represents a promising strategy to reduce BE recurrence and EAC risk. **Methods:** This randomized, phase 2b, double-blind, placebo-controlled trial will evaluate itraconazole's efficacy in accelerating BE eradication. Participants with high-risk BE, defined as BE $\geq$2 cm with low/high-grade dysplasia or intramucosal/T1 adenocarcinoma, undergoing ablation will be enrolled. Participants will be randomized 1:1 to receive 300 mg of oral itraconazole or placebo for two weeks before and four weeks after their first 2 sessions of EET. The primary endpoint is time to CRIM, a surrogate for long-term BE recurrence, measured in days. Secondary endpoints include time to CED, 12-month BE recurrence rates, safety, tolerability, and correlations between itraconazole levels and patient-reported outcomes. We will enroll 74 patients (37 per arm). We shall use a two-sided log rank test for right-censored time to event analysis to assess differences. The sample size calculation is based on anticipated surviving proportions at specific study times. We assume that the surviving non-CRIM proportions of patients at 3, 6, 9, and 12 months in the control arm to be 0.8, 0.5, 0.2, 0.1, respectively, and in the treatment arm to be 0.5, 0.2, 0.1, 0.05, respectively. To detect this effect size with 80% power at 5% level of significance, we need 30 evaluable participants in each group (with a plan to enroll 37 per arm to account for attrition). A Cox model will adjust for demographic and clinical variables. If successful, this trial could establish itraconazole as a novel adjunct to EET, reducing BE recurrence and lowering EAC risk. Clinical trial information: NCT06732388. Research Sponsor: National Cancer Institute; UG1-CA242632.

TPS4213 **Poster Session**

Total neoadjuvant therapy with induction immunochemotherapy and chemoradiotherapy followed by surgery for locally advanced esophageal squamous cell carcinoma (TNT-ESCC). First Author: Chien-Huai Chuang, National Taiwan University Cancer Center, Taipei, Taiwan

Background: Locally advanced esophageal squamous cell carcinoma (ESCC) is indicated for multi-modalities treatment strategies, including a neoadjuvant chemoradiotherapy (CRT) followed by surgery. While the CROSS trial established neoadjuvant CRT as a standard of care, distant metastasis remains a significant cause of treatment failure. Immune checkpoint inhibitors (ICIs) have demonstrated survival benefits in advanced or metastatic ESCC, and adjuvant nivolumab has shown efficacy following neoadjuvant CRT in locally advanced ESCC. Integrating ICI earlier in the treatment sequence through total neoadjuvant therapy may enhance the immune response against the primary tumor and the hidden metastases and potentially lead to improved survival outcomes. This phase II study evaluates induction immunochemotherapy followed by CRT before surgery in locally advanced ESCC. **Methods:** This is a single-center, single-arm, phase II study enrolling 50 patients with histologically confirmed ESCC (T3/4aN0M0 or T1-4aN1-3M0 according to the AJCC Cancer Staging System 8th ed). Eligible patients must have primary intrathoracic esophageal tumor $\leq$10 cm in length and $\leq$5 cm in radial diameter, an ECOG performance status of 0-1, and adequate organ function. Patients will receive induction immunochemotherapy consisting of tislelizumab (200 mg every 3 weeks), paclitaxel (175 mg/m² every 3 weeks), and cisplatin (75 mg/m² every 3 weeks) for two cycles. This is followed by CRT consisting of radiotherapy (45 Gy in 25 fractions, 1.8 Gy/day, 5 days/week) plus chemotherapy with weekly paclitaxel (50 mg/m²) and cisplatin (30 mg/m²) for 5 weeks. Esophagectomy will be performed 6 to 8 weeks after completing CRT. The primary endpoint is pathologic complete response (pCR) rate, defined as no residual tumor in the resected primary site and lymph nodes. We hypothesize that the pCR rate will increase from 35% (the historical control) to 55%. Based on a binomial precision design, the study is of 80% power and a unilateral α error of 0.05 to detect a statistically significant difference in pCR rate. Secondary endpoints include major pathological response rate, R0 resection rate, disease-free survival, event-free survival, distant metastasis-free survival, overall survival and safety. The study starts patient enrollment in March 2025 (registered at ClinicalTrials.gov as NCT06764355). Clinical trial information: NCT06764355. Research Sponsor: National Taiwan University Hospital; BeiGene.

TPS4214 **Poster Session**

PROSPERO: A phase 3 randomized, placebo (Pbo)-controlled study of amezalpat (TPST-1120), a peroxisome proliferator-activated receptor a (PPARα) inhibitor, in combination with atezolizumab + bevacizumab (AB) for patients (pts) with unresectable or metastatic hepatocellular carcinoma (mHCC) not previously treated with systemic therapy. First Author: Mark Yarchoan, Johns Hopkins Medicine, Baltimore, MD

Background: PPARα is a fatty acid ligand-activated transcription factor that regulates genes involved in fatty acid oxidation (FAO), angiogenesis, and inflammation. In HCC and other tumor types, PPARα signaling promotes tumor growth and also modulates the tumor immune microenvironment to suppress antitumor immunity. Amezalpat (TPST-1120) is an investigational PPARα antagonist that inhibits FAO, targeting the bioenergetic requirements of cancer cells and restoring anticancer immune pathways. HCC has the highest PPARα expression of any major tumor type. In preclinical studies of HCC, including ß-catenin activated disease, amezalpat exhibits anti-cancer activity as a single agent and demonstrates complementary efficacy in combination with PD-L1 and VEGF inhibitors. In an ongoing global randomized Phase 1b/2 study in pts with unresectable or mHCC not previously treated with systemic therapy, amezalpat in combination with atezolizumab + bevacizumab (TPST-AB) was tolerable and was associated with a clinically meaningful improvement in multiple efficacy endpoints, including overall survival (OS) and confirmed objective response rate (ORR), compared to AB alone. Here we describe a follow-up pivotal Phase 3 study to evaluate the safety and efficacy of TPST-AB vs Pbo plus AB (Pbo-AB) in pts with unresectable or mHCC (NCT06680258). **Methods:** This Phase 3, global, randomized, double-blind study will enroll ~740 pts with unresectable or mHCC. Key eligibility criteria include no prior systemic therapy (prior locoregional therapy allowed), ECOG PS 0-1, Child-Pugh Class A, and measurable disease by RECIST v1.1; pts with fibrolamellar/sarcomatoid HCC, mixed cholangiocarcinoma/HCC, and untreated active HBV are not eligible. Pts will be randomized 1:1 to receive oral amezalpat 600 mg or Pbo twice daily along with the approved doses of atezolizumab and bevacizumab every 3 weeks, until unacceptable toxicity or loss of clinical benefit. Randomization will be stratified by geographic region (Asia excluding Japan vs rest of world), macrovascular invasion and/or extrahepatic spread (y/n), baseline α-fetoprotein ($<$ 400 vs $\geq$400 ng/mL), and baseline ECOG PS (0 vs 1). The primary efficacy endpoint is OS. Key secondary efficacy endpoints include progression-free survival and ORR (RECIST v1.1). Exploratory analyses will include outcome by PD-L1 expression and ß-catenin mutational status. Interim analyses for futility (30% OS events) and efficacy (70% OS events) are planned. Findings of this pivotal study will inform the efficacy and safety profile of amezalpat added to AB vs AB alone in pts with unresectable or mHCC not previously treated with systemic therapy. Clinical trial information: NCT06680258. Research Sponsor: Tempest Therapeutics, Inc.

TPS4215 **Poster Session**

RHEA-1: First-in-human (FIH) study of AZD9793, a first-in-class CD8-guided T cell-engager (TCE) for glypican-3-positive (GPC3+) advanced or metastatic hepatocellular carcinoma (HCC). First Author: Stephane Champiat, Department of Investigational Cancer Therapeutics, Division of Cancer Medicine, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: GPC3 is an oncofetal protein expressed in 70–80% of HCC and is associated with poor prognosis. Preliminary clinical research on GPC3-specific CAR-T treatment has validated GPC3 as a therapeutic target in HCC. Its expression is largely confined to the surface of tumor cells, making it an ideal target for TCEs. AZD9793, a trispecific IgG1 monoclonal antibody, is a first-in-class CD8-targeted TCE that directly engages tumor-infiltrating T cells and GPC3+ tumors, forming a bridge that activates T cells leading to tumor cell lysis and T cell proliferation. AZD9793 promotes potent GPC3+ HCC cell killing through preferential engagement of CD8+ T cells, while minimizing CD4+ T cell activation and unwanted cytokine release. The novel mechanism of action combines bivalent GPC3 binding, CD8-biased engagement, and low-affinity T cell receptor binding to improve cytotoxicity and reduce the risk of cytokine release syndrome compared with other TCEs. **Methods:** RHEA-1 is the FIH trial of AZD9793 monotherapy. Eligible patients in this modular, Phase I/II, open-label, multicenter study are adults ($\geq$18 years old) with prospective centrally determined GPC3+ advanced or metastatic HCC with $\geq$1 measurable lesion by RECIST v1.1, who have received $\geq$1 line of prior systemic treatment and have an ECOG performance status of 0 or 1. Patients with hepatitis B are eligible if they receive antiviral treatment to ensure adequate viral suppression before enrollment and for $\geq$6 months after the study; and with hepatitis C if they are being managed per local practice. The study includes Module 1 (intravenous AZD9793) and Module 2 (subcutaneous AZD9793), each comprising dose escalation (Part A) and dose expansion (Part B). Module 1 Part A1 (fixed dose) will start with an accelerated titration design and will then switch to a modified toxicity probability interval-2 algorithm after the first 4 dose cohorts or earlier if dose-limiting toxicities (DLTs) are reported. Part A2 (step-up dosing) may open in either Module based on emerging safety data from Part A1. Part B may be initiated in one or both Modules. Primary endpoints include safety and tolerability in terms of DLTs (only in dose escalation) and adverse events to establish maximum tolerated dose, optimal biological dose, and recommended phase II dose; and objective response rate (only in dose expansion) by investigator assessment (IA) per RECIST v1.1. Secondary endpoints include preliminary efficacy (only in dose escalation) in terms of response and progression-free survival by IA, as well as overall survival (only in dose expansion), pharmacokinetics, immunogenicity, and CD8+ T cell infiltration pre- and post-treatment. No formal statistical hypothesis is proposed; all variables will be reported descriptively. The study (NCT06795022) is currently enrolling in the US and APAC. Clinical trial information: NCT06795022. Research Sponsor: AstraZeneca.

TPS4216 **Poster Session**

Phase II trial of zanzalintinib (XL-092) in combination with durvalumab and tremelimumab in unresectable hepatocellular carcinoma (ZENOBIA). First Author: Meghana Singh, Department of Hematology and Oncology, University of Pittsburgh Medical Center, Pittsburgh, PA

Background: Despite the evolving novel treatment options, the prognosis for advanced hepatocellular carcinoma (HCC) remains poor, with a 4-year survival rate of approximately 25%. Immune checkpoint inhibitors (ICIs), including the combination of durvalumab (Durva) & tremelimumab (Treme), represents the current standard-of-care for frontline HCC treatment. However, therapy resistance, either primary or secondary, often arises due to the immunosuppressive tumor microenvironment (TME). VEGFR is a well-established therapeutic target in HCC. Cabozantinib (Cabo), a multi-target tyrosine kinase inhibitor (TKI), is approved for later-line use per the CELESTIAL trial, and it also demonstrated significant TME modulation through antiangiogenic effects. A Phase II study (CHECKMATE 040) reported an impressive objective response rate (ORR) of 29% with the combination of ipilimumab/nivolumab and Cabo but noted high toxicity rates. Zanzalintinib (Zanza) is a novel TKI targeting VEGFR, MET, & TAM kinases (TYRO3, AXL, MER), key mediators of angiogenesis, tumor growth, metastasis, and TME immunosuppression. With a target profile similar to Cabo but an improved pharmacokinetic profile & a shorter half-life (16–22 hours), Zanza has demonstrated potential synergy with ICIs in preclinical and early-phase trials, suggesting enhanced sensitivity by fostering an immune-permissive TME. This phase II study evaluates the safety & efficacy of Zanza combined with Durva and Treme in HCC. **Methods:** This open-label, non-randomized Phase II trial consists of two parallel cohorts. Eligible patients must have unresectable HCC, be treatment-naïve in the unresectable setting, & have ECOG performance status of 0-1. Exclusion criteria include Child-Pugh score $>$7, known autoimmune diseases, heightened risk of gastrointestinal perforation or fistula formation, and known gastric or esophageal varices. The study begins with a safety lead-in phase of 9–12 patients to establish the recommended Phase II dose. The two cohorts aim to explore the optimal sequential strategy for combining Zanza with Durva & Treme. Cohort A: Zanza is administered during Cycle 1, followed by Durva + Treme in Cycle 2. Cohort B: Durva + Treme is administered during Cycle 1, followed by Zanza and Durva in Cycle 2. Both cohorts will continue with Zanza and Durva in subsequent cycles. A total of 40 participants (20 per cohort) will be enrolled. The primary endpoint is the ORR assessed by imRECIST 1.1. Secondary endpoints include the conversion rate to resectable or transplant-eligible disease, disease control rate, median PFS and OS, and landmark PFS & OS at 6, 12, 24, and 36 months. Safety and tolerability will also be evaluated. Comprehensive translational analyses include bulk RNA sequencing, spatial transcriptomics of baseline tumor biopsies, & serial ctDNA monitoring. Trial enrollment commenced in December 2024. Clinical trial information: NCT06698250. Research Sponsor: Exelixis.

TPS4217 **Poster Session**

A randomized phase 2 study of casdozokitug, an IL-27 targeting antibody, in combination with toripalimab plus bevacizumab in patients with unresectable and/or locally advanced or metastatic hepatocellular carcinoma. First Author: Daneng Li, City of Hope National Comprehensive Cancer Center, Duarte, CA

Background: IL-27 is a heterodimerized cytokine, a member of the IL-12/IL-23 cytokine family, and an immunoregulatory cytokine expressed by myeloid cells that dampens T and NK effector function. IL-27 is highly expressed by tumor-associated macrophages in several cancers, including hepatocellular carcinoma (HCC) and non-small cell lung cancer (NSCLC), and suppresses antitumor immune responses. Casdozokitug (Casdozo) is the only clinical-stage IL-27 targeting antibody and it increases IFN-g and T and NK cell activation in preclinical/clinical studies. A phase 1 study (NCT04374877) demonstrated a favorable safety profile and antitumor activity of casdozo as monotherapy and in combination with PD-1 blockade in indications, including HCC, with known high levels of IL-27 activation signature (Marron T, et al. *Ann Oncol*. 2023). A phase 3 study of toripalimab (tori) + bevacizumab (bev) demonstrated significant improvements in efficacy (overall survival [OS], progression-free survival [PFS], and objective response rate [ORR]) compared to sorafenib (Yinghong S, et al. CSCO 2024) in HCC. A phase 2 study of casdozo + atezolizumab + bev showed an acceptable safety profile and antitumor activity (ORR 38%, CR 17.2%, mPFS 8.1 mo) (Li D, et al. ASCO GI 2025). CHS-388-202 (NCT06679985) will evaluate the efficacy, safety, and biomarkers of tori + bev ± casdozo and optimize the dose for casdozo in combination with tori + bev as first-line treatment for patients (pts) with unresectable and/or locally advanced/metastatic HCC. **Methods:** CHS-388-202 is a Phase 2, open-label, randomized study and will enroll up to 72 pts randomized (1:1:1) to 1 of 3 treatment arms (IV Q3W): Arm A (tori 240 mg + bev 15 mg/kg + casdozo 700 mg), Arm B (tori 240 mg + bev 15 mg/kg + casdozo 1400 mg), Arm C (tori 240 mg + bev 15 mg/kg). Key eligibility criteria include treatment-naïve unresectable metastatic HCC with ≥1 measurable lesion; not suitable for surgical or local therapy; Child-Pugh A; ECOG PS 0 or 1; controlled hepatitis B virus or cured hepatitis C virus. Pts will be stratified by geographic region (Asia excluding Japan vs the rest of the world) and macrovascular invasion or extrahepatic spread of disease (presence vs absence). Primary endpoints are ORR by investigator review according to RECIST v1.1 and safety. Secondary endpoints are ORR by investigator review according to HCC modified RECIST (mRECIST) criteria; duration of response, PFS, and disease control rate by investigator review according to RECIST v1.1 and mRECIST criteria; OS, pharmacokinetics. A safety run-in evaluation will be conducted after the first ~6 pts are enrolled in Arms A and B, with ≥3 from each arm completing 1 cycle of treatment. Pts will remain on study treatment for ≤2 years or until documented disease progression or unacceptable toxicity. Enrollment is ongoing. Clinical trial information: NCT06679985. Research Sponsor: Coherus BioSciences.

TPS4218 **Poster Session**

A first-in-human study of MT-303, an innovative in vivo mRNA chimeric antigen receptor (CAR) therapy targeting GPC3, in adults with hepatocellular carcinoma. First Author: Timothy Guy Humphries, Sir Charles Gairdner Hospital/ University of Western Australia, Nedlands, Australia

Background: Hepatocellular carcinoma (HCC) remains a leading cause of cancer mortality worldwide, with advanced cases posing significant treatment challenges. GPC3, a cell surface protein highly expressed in HCC, represents a promising therapeutic target. MT-303 is an in vivo chimeric antigen receptor (CAR) therapy, leveraging mRNA-lipid nanoparticle (LNP) technology to reprogram myeloid cells directly within the body. This novel platform eliminates the logistical and technical barriers of ex vivo CAR therapies while retaining the ability to activate targeted immune responses. MT-303's mRNA encodes a GPC3-targeted CAR receptor incorporating a single-chain variable fragment (scFv) linked to the transmembrane domain and cytoplasmic tail of CD89. Crucially, functional CAR expression is restricted to Fc receptor common gamma chain-expressing cells, predominantly myeloid cells, ensuring precise immune activation. Preclinical studies demonstrated that MT-303 effectively infiltrates tumors, triggers tumor cell killing, produces chemokines and cytokines, eliciting an adaptive anti-tumor immunity. Rodent models of "cold" tumors and nonhuman primate studies have highlighted MT-303's safety, pharmacodynamic effects, and dose-dependent activity, supporting its clinical development (Argueta, SITC 2024, #1125). **Methods:** This first-in-human, multicenter, open-label, Phase 1 dose-escalation trial evaluates the safety, tolerability, pharmacokinetics (PK), pharmacodynamics (PD), and preliminary efficacy of MT-303 in participants with GPC3-expressing tumors, with a primary focus on Hepatocellular Carcinoma. MT-303 is administered intravenously every 14 days using a Bayesian Optimal Interval design, with backfill cohorts for dose refinement. The primary endpoints are safety, maximum tolerated dose (MTD), and recommended Phase 2 dose (RP2D). Secondary endpoints include detailed PK profiling and assessment of immune-related adverse events (e.g., ICANs, CRS). Exploratory endpoints encompass efficacy measures (e.g., objective response rate [ORR], duration of response [DOR]), immune reprogramming (e.g., peripheral CAR expression, cytokine profiles), and intratumoral immune changes, including T-cell receptor clonality and GPC3 modulation. Enrollment is ongoing, with safety and preliminary efficacy data expected to inform future development. Clinical trial information: NCT06478693. Research Sponsor: None.

TPS4219 **Poster Session**

A phase 1b/2, safety lead-in and dose-expansion trial of ivosidenib plus durvalumab and gemcitabine/cisplatin as first-line therapy in patients with locally advanced, unresectable or metastatic cholangiocarcinoma with an IDH1 mutation. First Author: James J. Harding, Memorial Sloan Kettering Cancer Center, New York, NY

Background: Cholangiocarcinomas (CCAs) are often advanced and incurable at the time of diagnosis. The phase 3 TOPAZ-1 trial showed improved OS and ORR with gemcitabine/cisplatin (GEM/CIS) and durvalumab (DURVA) vs GEM/CIS in unresectable advanced or metastatic biliary tract cancers. The phase 3 ClarIDHY trial demonstrated that the mIDH1 inhibitor ivosidenib (IVO) improved progression-free survival in CCA patients who have progressed from first or second-line chemotherapy and who have activating mutations in isocitrate dehydrogenase-1 (mIDH1). Additionally, mIDH1 suppresses key immune-related genes, with reversal of this effect when mIDH1 inhibitors are administered in preclinical CCA models. Finally, encouraging activity has been observed in treatment-naive mIDH1 patients administered with the mIDH1 inhibitor LY3410738 in combination with GEM/CIS. Given the ability of ivosidenib to stabilize advanced CCA, ability of IDH1 inhibition to restore immune activity, promising clinical activity of an mIDH1 inhibitor in combination with GEM/CIS, and the limited overlapping toxicities of these treatments, this study seeks to explore safety and preliminary activity of the quadruplet combination. **Methods:** This is a phase 1b/2, multicenter, safety lead-in and dose expansion, open-label study of IVO in combination with DURVA/GEM/CIS in first-line therapy of locally advanced, unresectable, or metastatic CCA with mIDH1. Treatment with up to one cycle of DURVA/GEM/CIS is permitted before initiation of study treatment. Key eligibility criteria include: a histopathological diagnosis; tumor mIDH1 based on local or centralized tissue testing (local testing by plasma ctDNA may be used); at least 1 measurable lesion as defined by RECIST v1.1; and adequate bone marrow, hepatic, and renal function. The study has a safety lead-in phase where IVO will be administered orally to the first 6 patients at a starting dose of 500 mg QD on every day of the 21-day cycle, plus DURVA 1500 mg IV infusion every 3 weeks for up to 8 cycles, plus GEM 1000 mg/m2 IV and CIS 25 mg/m2 IV on days 1 and 8 of each 21-day cycle, followed by IVO 500 mg QD and DURVA 1500 mg every 4 weeks of a 28-day cycle. Dose-limiting toxicities (DLTs) will be evaluated during the first cycle of quadruplet treatment. 6 additional patients may be enrolled to evaluate an alternative reduced dose of IVO 250 mg QD. The primary objective is to evaluate the safety and tolerability of the quadruplet combination, and to determine the recommended combination dose (RCD). The expansion phase will enroll approximately 40 patients who will be treated with the RCD, with the primary objective being to assess the clinical activity of the combination, as determined by a primary endpoint of confirmed complete or partial response using RECIST v1.1 criteria. Clinical trial information: NCT06501625. Research Sponsor: Servier.

TPS4220 **Poster Session**

A phase 2, randomized, multicenter study of adjuvant adebrelimab plus capecitabine in resected cholangiocarcinoma with high-risk factors: ACHIEVE. First Author: Xiangcheng Li, Hepatobiliary Center, the First Affiliated Hospital of Nanjing Medical University, Nanjing, China

Background: Cholangiocarcinoma is a rare and aggressive group of gastrointestinal cancers. For early-stage disease following curative resection, capecitabine is a category 1 recommendation for adjuvant therapy for biliary tract cancer (BTC) according to the NCCN guidelines. However, recurrence rates remain high. For example, the BILCAP study reported a 5-year recurrence-free survival (RFS) rate of 34% with adjuvant capecitabine. Based on cholangiocarcinoma-specific cohort data from the Hepatobiliary Center, The First Affiliated Hospital of Nanjing Medical University, the 1-year RFS rate for intrahepatic cholangiocarcinoma (ICC) and hilar cholangiocarcinoma (HCCA) with high-risk factors is approximately 50% (unpublished data), highlighting a substantial unmet medical need. Immunotherapy has shown efficacy as adjuvant therapy in other cancer types. Results from the TOPAZ-1 and KEYNOTE-966 studies support the combination of immunotherapy and chemotherapy for advanced BTC, including locally advanced non-metastatic disease. Adebrelimab, a PD-L1 inhibitor, has shown promising results in several cancers. In China, it is approved for first-line treatment of extensive-stage small cell lung cancer with chemotherapy. The ACHIEVE study will assess the efficacy of adebrelimab plus standard adjuvant chemotherapy in ICC/HCCA patients after curative resection with high-risk factors. **Methods:** ACHIEVE is a Phase 2, randomized, open-label, multicenter study designed to assess the efficacy and tolerability of adebrelimab administered intravenously every three weeks for one year in combination with capecitabine (8 cycles) as adjuvant therapy for ICC or HCCA after curative resection. The study will enroll about 120 adult patients with histologically confirmed ICC or HCCA who have undergone complete resection (R0). Eligible participants must have an ECOG performance status of 0–1, confirmed complete response (CR) on imaging 4–8 weeks post-surgery, and at least one high-risk factor. High-risk factors are defined as follows: ICC: Single tumor > 5 cm, multiple tumors, liver capsule breach, vascular invasion, regional lymph node metastasis; HCCA: Tumor invasion into surrounding tissues, vascular invasion, regional lymph node metastasis. Key exclusion criteria include locally advanced, unresectable, or metastatic disease at diagnosis and prior anti-cancer therapy before surgery. The primary endpoint is the 1-year recurrence-free survival rate (RFSR). Key secondary endpoints include overall survival (OS) and RFS, minimal residual disease (MRD), and patient-reported tolerability, and safety. Enrollment has begun, with six sites in mainland China participating. Clinical trial information: NCT06607276. Research Sponsor: None.

TPS4221 **Poster Session**

EMERALD-Y90: A phase 2 study to evaluate transarterial radioembolization (TARE) followed by durvalumab (D) and bevacizumab (B) for the treatment of participants (pts) with unresectable hepatocellular carcinoma (uHCC) eligible for embolization. First Author: Riad Salem, Northwestern Feinberg School of Medicine, St. Clair, Chicago, IL

Background: Locoregional therapy, such as transarterial chemoembolization (TACE) or TARE, is commonly used to treat uHCC eligible for embolization. Despite advances in TACE and TARE delivery, median progression-free survival (PFS) following treatment is <1 year, highlighting a need for new treatment options. EMERALD-1 (NCT03778957), a global phase 3 study, demonstrated a statistically significant improvement in PFS with TACE + D + B versus TACE + placebos in pts with uHCC eligible for embolization (hazard ratio, 0.77 [95% confidence interval, 0.61–0.98]; two-sided p-value = 0.032). With the increased use of TARE for patients with uHCC eligible for embolization in the US, a need exists for evidence to support additional treatment options in settings where TARE is preferred. The EMERALD-Y90 study will evaluate the efficacy and safety of TARE with D monotherapy, followed by D + B in pts with uHCC eligible for embolization. **Methods:** EMERALD-Y90 (NCT06040099) is a phase 2, single-arm study that will enroll ~100 pts aged $\geq$18 years with uHCC amenable to embolization who are ineligible for or have declined treatment with resection and/or ablation or liver transplant (transplant candidates are those listed for transplant or eligible to be listed and within Milan criteria). Eligible pts also must have Child-Pugh class A liver function and an Eastern Cooperative Oncology Group performance status of 0–1. Pts are allowed to receive a single TACE or TARE $\geq$6 months before the study or $>$1 TACE or TARE $\geq$12 months before the study. Prior TACE or TARE must have been administered for a different primary intrahepatic lesion unrelated to the current lesion, and pts should have a functional liver remnant $>$ 30%. Exclusion criteria include prior systemic therapy, evidence of extrahepatic spread, or major portal vein invasion. Pts will receive partition-based dosing of TARE using Y-90 glass microspheres. Following TARE, pts will receive D 1500 mg (one dose) followed by D 1120 mg + B 15 mg/kg every 3 weeks until study completion or discontinuation criteria are met. The primary endpoint is PFS (time from start of TARE until date of disease progression [investigator (INV)-assessed per modified Response Evaluation Criteria in Solid Tumors (mRECIST)] or death due to any cause). Secondary endpoints include safety and tolerability, 6-, 12-, and 24-month PFS, objective response rate (percentage of pts with confirmed complete or partial response [INV-assessed per mRECIST]), overall survival (time from start of TARE until death due to any cause), and duration of response (time from date of first documented response until date of progression or death due to any cause). An early safety review is planned when approximately 15 pts have completed their first cycle of D + B dosing. Study enrollment is ongoing at 22 US sites. Clinical trial information: NCT06040099. Research Sponsor: AstraZeneca.

TPS4222 **Poster Session**

Trial in progress: A phase Ib/II study to evaluate the safety and efficacy of atezolizumab plus bevacizumab as adjuvant therapy following carbon ion radiotherapy in hepatocellular carcinoma (VANGUARD trial). First Author: Keisuke Koroki, Department of Gastroenterology, Graduate School of Medicine, Chiba University, Chiba, Japan

Background: While hepatic resection remains the standard curative treatment for hepatocellular carcinoma (HCC), many cases are ineligible due to impaired liver function or patient-related factors. Percutaneous ablation is an option for small HCC but is limited by tumor size. Carbon ion radiotherapy (C-ion RT) has emerged as a promising modality, characterized by superior biological efficacy and dose distribution compared to conventional radiotherapy. Although HCC is relatively radiosensitive, conventional radiotherapy has limited efficacy due to low radiation tolerance of surrounding liver tissue. C-ion RT achieves effective treatment while minimizing radiation exposure through the superior dose localization of the carbon ion beam's Bragg peak. The establishment of adjuvant systemic therapy to prevent recurrence remains an urgent unmet need in HCC management. The IMbrave050 trial demonstrated the efficacy of combined atezolizumab and bevacizumab (Atezo+Bev) after resection or ablation, but recent analyses suggest diminishing long-term benefits. The combination of immune checkpoint inhibitors (ICIs) and radiotherapy has shown promise in several malignancies, with preclinical studies demonstrating synergistic enhancement of ICI efficacy through radiation-induced immunogenic cell death. Additionally, carbon ion radiation induces stronger immune responses compared to proton therapy. Based on these findings, we designed a phase Ib/II study to evaluate sequential C-ion RT followed by ICI as a novel therapeutic approach. **Methods:** This multicenter, open-label, single-arm phase Ib/II study evaluates the safety and efficacy of Atezo+Bev as adjuvant therapy following C-ion RT for HCC. Key inclusion criteria include treatment-naïve, Child-Pugh class A, maximum intrahepatic tumor diameter $\geq$4 cm and $\leq$3 intrahepatic tumors. After initial enrollment, patients undergo C-ion RT followed by a two-week observation period with eligibility screening for second enrollment. Eligible patients receive atezolizumab (1200 mg) and bevacizumab (15 mg/kg) every 3 weeks for up to 48 weeks, with radiological assessments every 3 months. The Phase Ib part will enroll six patients to evaluate dose-limiting toxicities. Secondary endpoints include adverse events (AEs) and serious AEs for safety and 1-year RFS, overall survival (OS) and 6-month OS rates for efficacy. If tolerability is confirmed, the trial will proceed to Phase II. Clinical trial information: jRCT2031240284. Research Sponsor: Chugai Pharmaceutical Co., Ltd.

TPS4223 **Poster Session**

Donafenib combined with capecitabine for postoperative adjuvant therapy of biliary malignant tumors with high risk of recurrence: A multi-center, randomized controlled, phase II study. First Author: Jianhua Rao, Hepatobiliary center, Jiangsu Province Hospital - The First Affiliated Hospital with Nanjing Medical University, Nanjing, China

Background: Biliary Tract Cancer (BTC) is an aggressive malignancy with rising incidence. Surgery is the only curative option, but only 10% of patients are eligible at diagnosis, and recurrence rates post-surgery can reach 67% within a year. The 5-year survival rate is only 5-15%. Emerging therapies, such as targeted and immunotherapies, show promise. A study combining GEMOX, tislelizumab, and donafenib (a tyrosine kinase inhibitor) in advanced BTC showed an 87.5% disease control rate (DCR) with strong safety and efficacy. The BILCAP study found that adjuvant capecitabine improved overall survival (OS) in resected BTC patients (median OS: 49.6 vs. 36.1 months; HR = 0.84). However, clinical research on adjuvant treatments for high-risk postoperative BTC remains limited, with no consensus on high-risk factors. This study evaluates the efficacy and safety of donafenib combined with capecitabine as adjuvant therapy for postoperative BTC with high recurrence. **Methods:** The study selected BTC patients prior to radical resection without any anti-tumor systemic therapy (including radiotherapy, chemotherapy, targeted therapy, immunotherapy) with at least one high-risk postoperative recurrence factors including specific stages according to the UICC/AJCC TNM 8th edition staging system: $T_{2\text{-}4}$, N_0, M_0 or $T_{1\text{-}4}$, N_1, M_0 (applicable to extrahepatic cholangiocarcinoma); $T_{1b\text{-}4}$, $N_{0\text{-}1}$, M_0 or T_{1a}, N_1, M_0 (applicable to intrahepatic cholangiocarcinoma), vascular invasion or neurophilic invasion as research subjects. Patients will be randomly divided into 1:1 groups. The experimental group consisted of donafenib (200mg, bid for 6 months) combined with capecitabine (1250mg/m^2, bid, treated for 2 weeks and stopped for 1 week, with 3 weeks as a treatment cycle, 8 cycles). The control group was capecitabine (same as experimental group). Treatment will start at least 4 weeks after radical resection and stop until patients experience disease recurrence or intolerable toxic side effects. The primary endpoint of the study was the 1-year recurrence free survival (RFS) rate. Secondary endpoints consisted of 2-year RFS, OS and safety assessment including incidence, severity, and relationship to study drugs of all adverse events (AEs), treatment-related adverse events (TRAEs), and serious adverse events (SAEs). Based on the data analysis of BTC cohort at our center, the 1y-RFS rate for the control group is set at 30%, while that for the experimental group is set at 60%. With a two-sided alpha of 0.05, a power of 0.80, and a randomization ratio of 1:1, the required number of RFS events is 64. Considering a 10% dropout rate, it is planned to enroll 35 participants per group, with a total planned enrollment of 70 participants. Dated by 20 January 2025, 8 of planned 70 patients have been enrolled. Clinical trial information: NCT06685289. Research Sponsor: None.

TPS4224 **Poster Session**

Australasian Gastro-Intestinal Trials Group (AGITG) STOPNET: A randomized study of cessation of somatostatin analogues (SSA) after peptide receptor radionuclide therapy (PRRT) in mid, hind-gut, and pancreatic neuroendocrine tumours. First Author: Matthew E. Burge, Royal Brisbane and Women's Hospital, Herston, QLD, Australia

Background: PRRT is a standard therapeutic option for patients with metastatic well-differentiated somatostatin receptor-positive gastroenteropancreatic neuroendocrine tumours (GEP-NETs) following progression on SSA. It is uncertain whether current practice of continuing SSA after commencing PRRT is beneficial, especially in non-functioning NETs. Studies by Yordanova et al. (2018) and Sygula et al. (2022) have included heterogenous study populations and yielded conflicting results. **Methods:** STOPNET is a prospective, randomized, non-comparative, open-label, multi-center phase II trial led by the AGITG in collaboration with the Canadian Cancer Trials Group (CCTG) under the Commonwealth Neuroendocrine Tumor research collaborative (CommNETS). The trial aims to evaluate the outcomes of SSA cessation or continuation in patients with GEP-NETs undergoing PRRT after progression on SSA. The co-primary endpoints are 20-month PFS and feasibility for a phase III trial, assessed by recruitment over a 24-month period & patient acceptance of SSA cessation. Secondary endpoints include OS, rate of SSA recommencement, time to subsequent therapy, quality of life, cost-effectiveness and psycho-oncological impacts of SSA cessation. Eligible participants must have advanced or unresectable WHO grade 1/2 non-functioning GEP-NETs (excluding the foregut), and disease progression after receiving $\geq$3 months of SSA at standard growth-control doses. SSA must have been primarily commenced for growth control, as opposed to functional symptoms and for mid/hindgut NET's 24-hr urine 5-hydroxyindoleacetic acid must be $<$ 1.5 times upper limit normal at screening. Participants will be randomized 2:1 to SSA cessation or continuation. SSA cessation arm will receive their last SSA $\geq$28 days prior to first PRRT, and the SSA continuation arm will continue SSA during and after PRRT. Following PRRT, participants will be assessed every 12 weeks (minimum 20 months) until disease progression or study closure, whichever occurs first. The sample size was calculated using Fleming's single stage design, assuming uninteresting and interesting 20-month PFS rates of 60% and 77% respectively. Novel translational research will be conducted to define and validate NET tissue and circulating biomarkers, with a particular focus on analysis of microRNA. Formalin-fixed paraffin-embedded (FFPE) tumor tissue will be retrieved (if available), with the collection of bloods at 3 time-points during study. The trial implemented the Australian Teletrial Program (ATP) to enhance equity of access for participants in regional, rural or remote locations. The trial will enroll 78 participants across 13 sites. Enrolment is open at 1 site in Australia & 4 sites in Canada, with 3 participants randomized as of Jan 2025. Clinical trial information: NCT06345079. Research Sponsor: Medical Research Future Fund (MRFF); Tour de Cure; AGITG philanthropic funding; Canadian Neuroendocrine Tumour Society (CNETS); Canadian Institutes of Health Research (CIHR).

TPS4225 **Poster Session**

A multi-centre, stratified, open, randomized, comparator-controlled, parallel group phase II trial comparing adjuvant treatment with 177Lu-DOTATATE to standard of care in patients after resection of neuroendocrine liver metastases (NELMAS). First Author: Andreja Frilling, Imperial College London, London, United Kingdom

Background: Gastro-entero-pancreatic (GEP) neuroendocrine tumours (NET) are steadily increasing in incidence and prevalence. About 65%-95% of GEP NET show hepatic metastases. Surgery is the mainstay of treatment for NE LM. While macroscopically complete resection for NE LM is associated with favourable overall survival (OS), recurrence rates of up to 70% at 3 years and up to 95% at 5 years are reported. These results call for adjuvant treatment concepts which have not yet been established. **Methods:** A prospective open-label, multicentre randomised parallel-group trial was conducted in patients with resected GEP NE LM. Adjuvant treatment with ^{177}Lu-DOTA^{0}-Ty^{3}-ocreotate (^{177}Lu-DOTATATE) (total administered activity 14.8 GBq) is compared with standard of care (SOC). The frequency of administration is 2 cycles (8±1weeks between each cycle). The first cycle is applied 8±2 weeks after liver resection. The control arm consists of SOC. Main inclusion criteria are well differentiated grade 1 or grade 2 (Ki67 < 20%) GEP NET, R0 or R1 resection of NE LM, primary tumour already resected or resected synchronously with LM, ^{68}Ga DOTATATE PET/CT prior to surgery confirming LM and no extrahepatic disease (except resectable perihilar lymph node involvement and/or primary tumour, if still in place). Main exclusion criteria are high grade NET, neuroendocrine carcinoma, R2 resection of LM, peptide receptor radionuclide therapy at any time prior to randomisation in the study, and any type of liver directed therapy within 12 weeks prior to randomisation in the study. Primary endpoint are disease-free survival (DFS) at 3 years after liver resection. The sample size of 106 patients in total is powered to detect an HR of 0.27, reflecting a 44% DFS probability at 3 years post-surgery in the ^{177}Lu-DOTATATE arm compared with a 25% in the SOC arm. Secondary endpoints OS, time to tumour recurrence, time to administration of subsequent antineoplastic therapy, safety and tolerability of ^{177}Lu-DOTATATE, health-related quality of life, patient reported outcomes, and cost effectiveness. Ancillary objectives explore the clinical utility of novel molecular based biomarkers in identification of residual microscopic disease and early detection of recurrent disease. Enrolment has begun. Follow-up data will be collected for 5 years overall from the date of randomisation of the last patient. Discussion: The NELMAS trial aims to investigate the efficacy of adjuvant therapy with ^{177}Lu-DOTATATE (2 cycles) compared to standard of care in preventing tumour recurrence in patients following R0/R1 resection of LM of well differentiated GEP NET. Clinical trial information: NCT05987176. Research Sponsor: Novartis/AAA; The Taylor Family 2010 Charitable Trust.

TPS4226 **Poster Session**

NCI 10479: A phase I dose escalation-expansion trial of sunitinib malate plus lutetium (Lu-177) dotatate in somatostatin receptor positive pancreatic neuroendocrine tumors. First Author: Nikolaos Trikalinos, Washington University School of Medicine in St. Louis, Siteman Cancer Center, St. Louis, MO

Background: Patients with metastatic or unresectable pancreatic neuroendocrine tumors (PanNETs) have a poor prognosis, even with currently available treatments, with a 5-year overall survival (OS) of less than 20%. Lutetium Dotatate (Lu-177) is a radiopharmaceutical that consists of the somatostatin analogue DOTA-Tyr3-Octreotate, coupled to the metal-ion chelating moiety, DOTA, and radiolabeled with lutetium-177. Lu-177 was approved by the FDA in 2018 for treatment of somatostatin receptor (SSTR)-positive gastroenterohepatic NETs, but it is limited in its efficacy to achieve cytoreduction and provide durable responses. Sunitinib malate is an oral small-molecule tyrosine kinase inhibitor targeting VEGFRs, PDGFRs, and KIT and is also FDA approved as a monotherapy for the treatment of metastatic unresectable PanNETs. There is preclinical, as well as clinical evidence of sunitinib being used as a radiosensitizer with classic radiation, but it has never been combined with a radiolabeled analogue in patients with PanNETs. **Methods:** This is a Phase I dose escalation/expansion study aiming to enroll up to 24 patients across several sites. Eligible patients will be offered fixed dose Lu-177 at 200 mCi for 4 fractions with concurrent oral sunitinib administration initiating on C1D1 and concluding 28 days after the last Lu-177 infusion. Dose escalation applies to sunitinib and will be guided by a 3+3 design to determine the maximum tolerated dose (MTD) and recommended phase 2 dose (RP2D). Once the RP2D has been established, up to 12 more patients will be offered participation in the expansion phase in an attempt to further record antitumor activity and correlation with imaging, tumor markers, as well as Lu-177 dosimetry. Treatment will continue until disease recurrence/progression, unacceptable toxicity, or completion of planned protocol. Key eligibility criteria include age > = 18 years, ECOG performance status < = 2, histologic diagnosis of metastatic, unresectable well- or moderately-differentiated SSTR-positive PanNETs of any grade, up to 1 prior treatment except for somatostatin analogues and appropriate baseline hematological parameters. Key exclusion criteria are prior use of sunitinib, Lu-177 or other radiopharmaceuticals, myocardial or cerebrovascular accident within the prior 12 months and left ventricular ejection fraction of < = 50%. The study uses an 8-week safety window to determine its primary endpoint, which is DLTs during administration of the combination. Secondary endpoints are objective response (ORR), duration of response (DOR), progression-free survival (PFS) and overall survival (OS), intensity of tumor uptake on pre-treatment SSTR PET and post Lu-177, chromogranin A level response as well as optional dosimetry imaging. Enrollment is ongoing. Clinical trial information: NCT05687123. Research Sponsor: National Cancer Institute.

TPS4227 **Poster Session**

An open-label, dose-finding, phase Ib study to assess the safety, tolerability of nesuparib (JPI-547), a dual inhibitor of PARP/TNKS, in combination with modified FOLFIRINOX (mFOLFIRINOX) and gemcitabine-nab-paclitaxel (GemAbraxane) in patients with locally advanced and metastatic pancreatic cancer. First Author: Do-Youn Oh, Department of Internal Medicine, Seoul National University Hospital Cancer Research Institute, Seoul National University College of Medicine, Seoul, South Korea

Background: Pancreatic ductal adenocarcinoma (PDAC) is a leading cause of cancer deaths, with most cases diagnosed at advanced stages. Current maintenance therapy with the PARP inhibitor, olaparib, benefits only patients with germline BRCA1/2 mutations (Approximately 5-7 % of PDAC cases). However, homologous recombination deficiency (HRD)-related mutations occur in ~15% of PDACs, potentially expanding the utility of PARP inhibitors. Nesuparib, a next-generation PARP inhibitor, also targets tankyrase, disrupting WNT and Hippo signaling pathways which are critical for homologous recombination repair. This dual mechanism mimics BRCA loss ("BRCAness"), sensitizing HRD-positive tumors without BRCA mutations to PARP inhibition, broadening therapeutic options. Combining PARP inhibitors with chemotherapy (e.g., irinotecan or platinum-based drugs) enhances sensitivity to DNA damage. Preclinical studies showed nesuparib inhibited tumor growth as monotherapy and achieved higher efficacy in combination with standard treatments. In a prior phase I trial, nesuparib showed promising antitumor activity, with overall response rate of 28.2% and disease control rate of 64.1%. This Phase Ib study aims to evaluate the efficacy of nesuparib in combination with standard chemotherapy for advanced PDAC using a 3+3 dose-escalation design. **Methods:** This multicenter, open-label, Phase Ib, dose-finding study will enroll 24–48 patients with locally advanced or metastatic PDAC. Two arms are included: Arm A (mFOLFIRINOX combination) and Arm B (GemAbraxane combination), each with 12–24 subjects across four dose groups (3–6 patients per group). Nesuparib is administered orally under fasting conditions ranging from Dose Levels -2 (12.5 mg qd) to 4 (100 mg qd), starting at Dose Level 1 (25 mg qd) with a 5 days on/2 days off schedule. Based on the occurrence of dose-limiting toxicities (DLTs), the dose may be escalated to higher levels (Dose Levels 2, 3, or 4) or reduced to lower levels (Dose Levels -1 or -2) with a 5 days on/2 days off or 3 days on/4 days off schedule. Arm A includes mFOLFIRINOX chemotherapy with biweekly oxaliplatin (65 mg/m²), leucovorin (400 mg/m²), irinotecan (135 mg/m²), and 5-FU (2,400 mg/m²). Arm B involves gemcitabine (1,000 mg/m²) and nab-paclitaxel (125 mg/m²) on Days 1, 8, and 15 of a 28-day cycle. Primary objectives are to determine the maximum tolerable dose (MTD) and recommended Phase II dose (RP2D) and to identify the optimal combination regimen based on safety. Secondary objectives include evaluating safety and antitumor activity. Enrollment began in Q1 2022. ClinicalTrials.gov ID: NCT05257993. Clinical trial information: NCT05257993. Research Sponsor: Onconic Therapeutics.

TPS4228 **Poster Session**

ALTER-PA001: A multicenter, randomized study of anlotinib and benmelstobart in combination with AG chemotherapy vs. AG as first-line treatment for metastatic pancreatic cancer. First Author: Jiujie Cui, Department of Medical Oncology and State Key Laboratory of Oncogene and Related Genes, Shanghai Cancer Institute, Renji Hospital, School of Medicine, Shanghai, China

Background: Metastatic pancreatic cancer (mPC) remains one of the most challenging malignancies to treat, with limited effective therapeutic options. While AG chemotherapy (nab-paclitaxel and gemcitabine) is a current standard first-line regimen, new combinations are needed to improve outcomes. Preclinical data suggest potential synergistic effects of anlotinib, a multi-target tyrosine kinase inhibitor, and benmelstobart, a novel anti-PD-L1 antibody, with chemotherapy. This study aims to evaluate the efficacy and safety of this combination in mPC. **Methods:** ALTER-PA-001 is a multicenter, open-label, randomized, controlled phase 2 trial that compared anlotinib plus benmelstobart and AG with AG in patients with treatment-naïve mPC. Eligible patients are aged 18-75, ECOG 0-1, with histologically or cytologically confirmed PC. A total of 104 patients will be randomly assigned in a 2:1 ratio to receive anlotinib (8 mg orally, QD, d1–14), benmelstobart (1200 mg IV, d1), nab-paclitaxel (125 mg/m² IV, d1, d8), and gemcitabine (1000 mg/m² IV, d1, d8) every 21 days or AG regimen with nab-paclitaxel and gemcitabine at the same doses and schedule. The randomisation is done centrally and stratified by the presence of liver metastasis. Patients achieving CR, PR, or SD after 8 cycles will enter a maintenance phase with continued treatment based on their assigned arm. Tumor assessment is performed every 6 weeks for induction treatment, and every 9 weeks for maintenance phase. The primary endpoint is objective response rate (ORR), with secondary endpoints including progression-free survival (PFS), disease control rate (DCR), duration of response (DoR), overall survival (OS), and safety. Exploratory biomarker analyses will assess correlations between baseline tumor characteristics and therapeutic outcomes. This trial is actively recruiting in November 2024. Clinical trial information: NCT06621095. Research Sponsor: None.

TPS4229 **Poster Session**

A phase 1b/2 trial of onvansertib in combination with NALIRIFOX for first line treatment of advanced pancreatic cancer (PANCONVA trial). First Author: Anup Kasi, University of Kansas Cancer Center, Fairway, KS

Background: Pancreatic cancer is a highly lethal disease. Despite research and drug development efforts focused on KRAS, no effective RAS inhibitors have been approved for the treatment of pancreatic cancer with KRAS mutation. PLK1 inhibition is a potential target in KRAS-mutated pancreatic cancer and may provide a new first-line treatment option. Onvansertib (also known as PCM-075 and NMS-1286937) is the first PLK1-specific adenosine triphosphate competitive inhibitor administered by oral route to enter clinical trials with proven antitumor activity in different preclinical models. **Methods:** This is a phase 1b/II, non-randomized, open label single arm study being conducted at the University of Kansas Cancer Center and its affiliated sites. The study is open for enrollment. Eligibility: Key inclusion includes pts with locally advanced, unresectable, or metastatic pancreatic adenocarcinoma who are treatment naïve, have adequate archival tissue for biomarker evaluation or are willing to undergo a biopsy, and have an ECOG of 0-1. Key Exclusion: Planned concomitant use of medications known to prolong the QT/QTc interval, use of strong CYP3A4 or CYP2C19 inhibitors or strong CYP3A4 inducers. Treatment Plan: The phase 1b (safety lead-in) will follow a dose de-escalation phase in which up to 2 different Onvansertib dose levels will be tested in combination with standard NALIRIFOX. Onvansertib starting dose level is 30mg orally once daily. The Phase II portion of the study will be a single-arm open-label enrollment with dosing based on the starting dose determination in the Phase Ib portion of the study (30mg or 20mg). NALIRIFOX (Nano-liposomal Irinotecan 50 mg/m2, Oxaliplatin 60 mg/m2, Leucovorin 400 mg/m2, 5-FU 2400 mg/m2) will be administered intravenously on D1 of the 14-day cycle. Onvansertib will be dosed orally on D1-5 of each 14-day cycle. Imaging will be performed at baseline and after every 4 cycles. Objectives: The primary objective of this study is to determine anti-tumor activity by measuring Overall Response Rate (ORR). The secondary objectives are to determine treatment safety based on toxicities in participants who have received at least one dose of onvansertib, to determine anti-tumor activity by Progression Free Survival (PFS), to determine anti-tumor activity by Disease Control Rate (DCR), to determine Overall Survival (OS). Statistical Plan: Simon's two-stage Optimum design will be used. The null hypothesis that the true response rate is 41% will be tested against a one-sided alternative that the true response rate is 65%. In the first stage, 10 evaluable pts will be enrolled. If there are 4 or fewer responses in these 10 pts, the study will be stopped. Otherwise, 11 additional evaluable pts will be accrued for a total of 21 evaluable pts. The null hypothesis will be rejected if 12 or more responses are observed in 21 evaluable pts. Clinical trial information: NCT06736717. Research Sponsor: Cardiff Oncology.

TPS4230 **Poster Session**

Trial in progress: RASolute 302—A phase 3, multicenter, global, open-label, randomized study of daraxonrasib (RMC-6236), a RAS(ON) multi-selective inhibitor, versus standard of care chemotherapy in patients with previously treated metastatic pancreatic ductal adenocarcinoma (PDAC). First Author: Brian M. Wolpin, Dana-Farber Cancer Institute, Gastrointestinal Cancer Center, Boston, MA

Background: Patients with previously treated metastatic PDAC have significant need for treatments with improved efficacy and tolerability. RAS is an oncogenic driver in $>$ 90% of patients with PDAC. Daraxonrasib (RMC-6236) is an oral, RAS(ON) multi-selective, tri-complex inhibitor of GTP-bound mutant and wild-type RAS. In the ongoing Phase 1 monotherapy trial (NCT05379985), daraxonrasib exhibited a manageable safety profile with primarily low-grade rash and GI toxicities, and encouraging ORR, PFS and OS in a broad population of previously treated patients with RAS mutant metastatic PDAC (J Clin Oncol 43, 2025 [suppl 4; abstr 722]). The significant unmet need for alternative treatment options, along with the preliminary clinical data of daraxonrasib monotherapy, support its evaluation in the ongoing Phase 3 clinical trial, RASolute 302, in patients with previously treated metastatic PDAC. **Methods:** RASolute 302 is a global, multicenter, open-label, randomized study (NCT06625320) designed to evaluate daraxonrasib outcomes compared to investigator's choice of standard of care chemotherapy as a 2L treatment in patients with metastatic PDAC. Eligibility includes patients $\geq$18 years old, ECOG performance status 0 or 1, disease progression on 1 prior line of either a 5-fluorouracil or gemcitabine-based regimen in the metastatic setting, and documented RAS mutation status (mutant or wild-type). Eligible RAS mutations are defined as nonsynonymous mutations in KRAS, NRAS, or HRAS at codons 12, 13, or 61 (G12, G13, or Q61). Patients with tumors that are RAS wild-type and received appropriate approved targeted therapy for actionable mutations are also eligible. A 1:1 randomization of approximately 460 patients will receive daraxonrasib 300 mg daily or investigator's choice of chemotherapy (gemcitabine/nab-paclitaxel, mFOLFIRINOX, nal-IRI/5-FU/LV, or FOLFOX) until unacceptable toxicity or disease progression. For patients randomized to daraxonrasib, recommended prophylactic measures for rash include oral antibiotics and topical corticosteroids. Response Evaluation Criteria in Solid Tumors version 1.1 (RECIST v1.1) tumor assessments will be performed every 8 weeks until disease progression, withdrawal of consent, lost to follow up, or death, whichever occurs first. Dual primary endpoints are progression-free survival (PFS) as assessed by blinded independent central review and overall survival (OS) in the RAS G12X-mutant population. Key secondary endpoints include PFS, OS, objective response and quality of life measures in the all-patient population with tumors carrying RAS mutations (G12X, G13X or Q61X) or RAS wild-type. Enrollment for the trial commenced in October 2024. Clinical trial information: NCT06625320. Research Sponsor: Revolution Medicines, Inc.

TPS4231 **Poster Session**

A phase 2 study of botensilimab and AGEN1423, an anti-CD73-TGFβ-trap bifunctional antibody, with or without chemotherapy in subjects with advanced pancreatic cancer. First Author: Bruno Bockorny, Beth Israel Deaconess Medical Center, Boston, MA

Background: Traditional immune checkpoint inhibitors have shown limited benefit in pancreatic ductal adenocarcinoma (PDAC) owing to non-redundant immune resistance mechanisms dominating the tumor microenvironment (TME). Transforming growth factor (TGF)-β and cluster of differentiation (CD)73-adenosine represent two major immunoregulatory and pro-tumorigenic pathways responsible for therapeutic resistance and progressive disease in PDAC. AGEN1423 (also known as dalutrafusp alfa and GS-1423) is a bifunctional, humanized, aglycosylated immunoglobulin G1 kappa antibody that selectively inhibits CD73-adenosine production and neutralizes active TGF-β signaling. Botensilimab (BOT) is an Fc-enhanced multifunctional anti-cytotoxic T-lymphocyte-associated protein 4 (CTLA-4) antibody. We hypothesize that the combination of AGEN1423 with BOT can rescue T-cell functional activity leading to responses in advanced PDAC. **Methods:** An investigator-initiated open label Phase 2 study to evaluate the safety, tolerability, and initial efficacy of BOT + AGEN1423 +/- chemotherapy in patients with metastatic PDAC (NCT05632328). In cohort 1, 12 patients with metastatic PDAC with disease progression to at least one line of treatment will receive AGEN1423 30mg/kg IV Q2W for 4 doses + BOT 150mg IV Q6W ongoing for up to 2 years. If the combination is considered safe and tolerable, and objective response is achieved in at least 1 subject, the study will proceed to Cohort 2. In Cohort 2, 12 additional patients with disease progression on first-line fluorouracil-based chemotherapy will be enrolled to receive second-line gemcitabine and nab-paclitaxel in combination with AGEN1423 30mg/kg IV Q2W for 4 doses + BOT 150mg IV Q6W. Key eligibility criteria include histologically or cytologically confirmed metastatic pancreatic adenocarcinoma, age $\geq$18 years, Eastern Cooperative Oncology Group (ECOG) performance status $\leq$1, adequate organ function, and measurable disease by RECISTv1.1. A pre-treatment and on-treatment tumor biopsy will be obtained for translational studies. The primary endpoint is to estimate the objective response rate (ORR) according to RECISTv1.1 criteria. Secondary endpoints include safety and tolerability as defined by the incidence of AEs as assessed according to CTCAE v5, disease control rate (DCR), progression-free survival (PFS), and overall survival (OS). Translational endpoints include the characterization of the transcriptional signatures in paired biopsies obtained before and on-treatment with BOT + AGEN1423, as well as the changes in cell composition of the TME following treatment using multiplexed immunofluorescence spatial technology. Enrolment has started and accrual is anticipated to complete in Q4 2025. Clinical trial information: NCT05632328. Research Sponsor: Agenus, Inc.

TPS4232 **Poster Session**

Adaptive organoid-based precision therapy study in pancreatic cancer (ADOPT): A phase II single-arm study to evaluate the efficacy of patient-derived organoid (PDO)-directed therapy in advanced pancreatic ductal adenocarcinoma (PDAC). First Author: Ronan Andrew McLaughlin, Division of Medical Oncology and Hematology, Princess Margaret Cancer Centre – University Health Network, University of Toronto, Toronto, ON, Canada

Background: PDAC is a devastating malignancy. High-throughput genomic technologies have yielded insights regarding the molecular underpinnings and heterogeneity of PDAC. Systemic treatment options are limited to cytotoxic chemotherapies, except for approx. 10%, who receive targeted treatment based on genomic profiling. PDO's are three-dimensional *ex vivo* experimental models grown directly from tumor tissue and can provide a direct assessment of drug response. By directly exposing cancer cells to potential drug therapies, functional profiling provides a dynamic measurement of response that is more informative than static gene panels. PDOs can theoretically be used to direct therapeutic decisions, offering an opportunity to expand the reach of precision therapies for PDAC beyond genomics. To date, PDO testing has been limited by small sample sizes, few drugs included in the screens, and retrospective studies. To expand the impact of precision therapy, we developed a rapid high-throughput screening (HTS) platform where over 3,000 drugs can be tested in PDOs within 8-10 weeks of diagnosis. In ADOPT, we aim to formally investigate the efficacy of PDO-directed therapy in a prospective phase II study, leveraging our existing platforms using real-time HTS of PDOs. This study represents one of the first formal trials of PDO-directed therapy in solid tumors. Our novel approach will enroll pts with advanced PDAC who do not have alternative treatment options. **Methods:** This is an actively recruiting prospective, single-arm phase II trial. Patients (pts) with advanced epithelial PDAC are eligible if they either: 1) progressed on, were intolerant to, or refused first-line or subsequent therapies (Cohort A), or 2) have stable disease after $\geq$8 cycles of FOLFIRINOX ("Maintenance" Cohort B) and have a PDO showing sensitivity to an approved HC drug. Pts will be recruited, from multiple ongoing studies including PROSPER-PANC where we have successfully generated and tested a PDO. PDO-directed treatment will be selected based on drug sensitivity as tested through our validated HTS platform. Each case will be discussed at our PDO dedicated tumor board. All pts must meet the inclusion/exclusion and drug-specific eligibility criteria. The primary endpoint is disease control rate. A Simon's two-stage optimal design will be used to test the hypothesis: H0: P $\leq$ 0.05 versus H1: P $\geq$ 0.25. In the first stage, 9 pts will be evaluated. The trial will be discontinued if no disease control response is observed in this stage. If at least one response is observed, then the trial will continue to the second stage and an additional 17 pts will be evaluated for a total of 26 evaluable. This design has a one-sided alpha of 0.05 and power of 80%. We will reject the null hypothesis after 26 if 3 or more responses are observed. Clinical trial information: awaited. Research Sponsor: Ontario Institute for Cancer Research and Princess Margaret Cancer Foundation; Terry Fox Research Institute - Marathon of Hope Cancer Centres Network Funding; Sinai Health Foundation; The MNitz Pancreatic Cancer Research Fund (Michelle Reisman); The MNitz Pancreatic Cancer Research Fund (Veroli Cultural Society); The MNitz Pancreatic Cancer Research Fund (Elyse Graff).

TPS4233 **Poster Session**

Phase I trial of MK2 inhibitor in combination with mFOLFIRINOX for untreated metastatic pancreatic ductal adenocarcinoma. First Author: Moh'd M. Khushman, Washington University School of Medicine, St. Louis, MO

Background: Zunsemetinib (also known as ATI-450) is an investigational small molecule inhibitor targeting MAPK-Activated Protein Kinase (MAPKAPK2, or MK2). Preclinical work conducted by the Lim Lab at Washington University in St. Louis demonstrated that FOLFIRINOX activates heat shock protein 27 (Hsp27), a molecule with pleiotropic pro-survival properties, and beclin1, a key mediator of autophagy, in pancreatic ductal adenocarcinoma (PDAC) models. In an autochthonous PDAC (KPC) mouse model, zunsemetinib synergized with FOLFIRINOX, resulting in near-complete ablation of all PDAC foci and significantly improved mouse survival. Additionally, mice treated with zunsemetinib experienced significantly less intestinal damage and weight loss—common concerns associated with FOLFIRINOX. These preclinical data support the rationale for combining zunsemetinib with FOLFIRINOX in PDAC patients. **Methods:** We are conducting a phase I, single-arm, open-label study of zunsemetinib in combination with mFOLFIRINOX in patients with untreated metastatic PDAC. The study consists of two phases: a dose escalation phase and an expansion phase. During the dose escalation phase, zunsemetinib dosing will proceed according to the BOIN design with a cohort size of 3. A total of 6–21 patients will be enrolled at Washington University. Patients will receive zunsemetinib starting at Dose Level 1 (40 mg twice daily), with dose escalation continuing until the recommended phase 2 dose (RP2D) is determined. Patients will remain in the study until disease progression or treatment intolerance. In the expansion phase, up to 30 additional patients will be enrolled to further assess the toxicity profile of zunsemetinib in combination with mFOLFIRINOX. These patients will begin at the RP2D and continue on study treatment until disease progression or treatment intolerance. Eligible patients must be treatment-naïve, newly diagnosed, and have histologically or cytologically confirmed PDAC for which mFOLFIRINOX is deemed a suitable treatment option. The primary objective is to determine the dose-limiting toxicities (DLTs) and RP2D of zunsemetinib in combination with mFOLFIRINOX. Secondary objectives include assessing toxicity profiles, progression-free survival (PFS) at six months and overall PFS, disease control rate, overall response rate, overall survival, CA 19-9 response at the RP2D, and pharmacokinetics of zunsemetinib in PDAC treated with mFOLFIRINOX. Exploratory objectives include evaluating pharmacodynamic markers via immunohistochemistry (e.g., phospho-Hsp27 to assess pharmacodynamics of zunsemetinib, LC3B to assess autophagy, and TUNEL staining to evaluate DNA damage) and analyzing pathway suppression through RNA sequencing. Pre- and post-treatment serum samples will also be collected for the analysis of inflammatory cytokines. Clinical Trial Registration: NCT06648434. Clinical trial information: NCT06648434. Research Sponsor: Pancreatic SPORE (P50 CA272213); Aclaris.

TPS4234 **Poster Session**

An open-label, phase 1 trial with expansion cohort of botensilimab (AGEN1181) + balstilimab (AGEN2034) + nab-paclitaxel + gemcitabine + cisplatin + chloroquine + celecoxib in adult patients with previously untreated metastatic pancreatic cancer. First Author: Erkut H. Borazanci, HonorHealth Research Institute, Scottsdale, AZ

Background: The unfolded protein response (UPR) is an adaptive endoplasmic reticulum (ER) stress pathway that and can prevent cellular death under moderate stress conditions or promote apoptosis under severe stress. The UPR is often upregulated in pancreatic cancer cells and has been identified as a promising target for therapeutic intervention. We hypothesize that inducing severe ER stress by combining multiple chemo and immunotherapy agents will cause pancreatic cancer cells to enter the apoptotic UPR pathway, destroying these cells and improving patient survival. Prolonged ER stress is achieved in this study by using chemotherapy (nab-paclitaxel + gemcitabine + cisplatin) in combination with 2 immunotherapy agents: botensilimab (AGEN1181), an Fc-engineered anti-CTLA-4 monoclonal antibody, and balstilimab (AGEN2034), a human monoclonal immunoglobulin (Ig) G4 (IgG4) antibody designed to block programmed cell death protein (PD-1) binding by PD-L1 and PD-L2. Additionally, 2 agents are included to help block apoptosis escape routes: chloroquine to inhibit autophagy and celecoxib to reduce tumor microenvironment inflammation. **Methods:** This single-center, open-label, phase 1 study evaluates the safety, tolerability, and preliminary efficacy of two botensilimab doses in combination with fixed doses of balstilimab (240 mg) + nab-paclitaxel (125 mg/m^2) + gemcitabine (1000 mg/m^2) + cisplatin (25 mg/m^2) + chloroquine (500 mg) + celecoxib (200 mg) in adult patients with previously untreated metastatic pancreatic cancer (NCT06076837). The study design consists of 6 patients in a dose 1 cohort at 50 mg botensilimab + combination regimen and an escalated dose 2 cohort of 6 patients at 75 mg botensilimab + combination regimen (pending dose 1 cohort safety signals), with an additional 6 patients in an expansion cohort treated at the determined maximum tolerated dose (MTD) of botensilimab (Total N = 18). Adverse events (AEs) are evaluated according to NCI CTCAE v5.0 and tumor response is assessed by RECIST v1.1. Key eligibility criteria include 1) histologically confirmed diagnosis of metastatic pancreatic ductal adenocarcinoma with measurable disease on baseline imaging, 2) life expectancy of at least 3 months, 3) no previous radiotherapy, surgery, chemotherapy, or investigational therapy for the treatment of metastatic disease, and 4) no prior immune checkpoint inhibitor therapy. Enrollment began in January 2025 at the HonorHealth Research Institute. Clinical trial information: NCT06076837. Research Sponsor: TGen Foundation; Purple Pansies Foundation.

TPS4235 **Poster Session**

A supervised prehabilitation program for patients with pancreatic cancer. First Author: Philip Chang, Cedars-Sinai Medical Center, Los Angeles, CA

Background: Individuals who develop pancreatic cancer tend to be older, with 70% of pancreatic diagnoses occurring in those $\geq$ 65 years (2). Older patients are at increased risk for sarcopenia which is the progressive loss of skeletal muscle mass, tone, quality and strength and has been reported to affect 65% of pancreatic cancer patients (4). PREHAB is the process of improving the functional capability and psychological health of the individual to reduce the incidence and/or severity of future impairments (6). The foundation of PREHAB is functional exercise although components of nutrition and stress reduction may be included (9). PREHAB sessions are typically delivered through structured programs and have been shown to have a number of benefits such as improvements in functional activity and decreased postoperative complications (8). In a study by Ngo-Huang et al, 50 pancreatic cancer participants participated in a home-based multimodal program resulting in improved physical function and health related quality of life (15). Given the numerous benefits, the purpose of this study is to demonstrate the feasibility of a multimodal supervised PREHAB program in pancreatic cancer patients which we believe could have greater benefits than unsupervised programs. **Methods:** This is a single arm pilot study assessing the feasibility of a supervised prehabilitation program for patients with pancreatic cancer. Inclusion criteria include a diagnosis of any stage pancreatic cancer, independence with ambulation, and a lower level of physical activity as assessed by the Godin-Shepard Leisure-Time Physical Activity Questionnaire. To our knowledge, this is the first study in which all exercises sessions are in-person and supervised by exercise technicians in pancreatic cancer. Additionally, while prehabilitation typically takes place during the neoadjuvant therapy period, this study will also include patients with metastatic disease on continuous chemotherapy. Participants will undergo baseline evaluations testing strength, endurance, balance, subjective measures and sarcopenia measures. This will be immediately followed by one-hour long supervised exercise sessions 3x per week for 6 weeks in which participants will engage in aerobic training and resistance training targeting major muscle groups. Following the intevention, measures will be collected immediately afterwards and at 3 month follow-up. The primary analysis will test the hypothesis of feasibility using an one-sided exact Binomial test at 25% significance level. If 10 or more patients attend a minimum of 60% of exercise sessions during the initial 6-week period, then the study will be declared feasible. 11 of 16 patients have been enrolled to date. Clinical trial information: NCT05692323. Research Sponsor: Cedars Sinai Medical Center (Internal Funding).

TPS4236 **Poster Session**

IMMUNORARE^5: A national platform of 5 academic phase II trials coordinated by Lyon University Hospital to assess the safety and the efficacy of the immunotherapy with domvanalimab + zimberelimab combination in patients with advanced rare cancers—The Peritoneal Mesotheliomas Cohort. First Author: Julien Peron Sr., Centre Hospitalier Lyon Sud - Hospices Civils de Lyon, Pierre-Bénite, France

Background: In patients with rare cancers, there is an unmet medical need for investigating innovative therapeutics beyond standard first-line treatment. Indeed, these diseases are rarely assessed in clinical trials. The standard 1st-line treatment of peritoneal mesothelioma relies on platinum and pemetrexed, with no validated 2nd-line treatment so far. Several studies suggested that immunotherapy, such as ipilimumab + nivolumab or atezolizumab + bevacizumab, is active in this disease. There is a strong biological rationale for concurrent blockage of TIGIT and PD1 pathways in mesothelioma. **Methods:** IMMUNORARE^5 (NCT06790706) is a platform of 5 single arm phase II trials testing the safety and the efficacy of DOMVANALIMAB (anti-TIGIT) and ZIMBERELIMAB (anti PD-1) in 5 independent cohorts of rare cancers. The trial, sponsored by Lyon University Hospital, is conducted in 15 French centers, in partnership with the corresponding national networks of reference centers. The PERITONEAL MESOTHELIOMA cohort, led in collaboration with the RENAPE network (https://www.renape-online.fr/), will enroll 27 patients in progression after at least 1 line of platinum + pemetrexed based-chemotherapy regimen, with evaluable lesions at the baseline (modified RECIST criteria). Patients previously treated with immunotherapy will not be eligible. Patients will receive intra-venous DOMVANALIMAB and ZIMBERELIMAB, every three weeks, until disease progression. The primary endpoint will be the progression-free survival rate at 6 months. The disease progression (clinical or radiological) will be confirmed by the RENAPE experts. The secondary endpoints are tolerance, overall response rate and duration of response, progression-free and overall survival. A two-stage Simon design was used, with early termination rules for futility (5% one-sided alpha level, 80% power). The treatment would be considered interesting if the percentage of patients free from disease progression at 6-months is statistically higher than 35%; 60% is expected. Translational research projects will be developed aiming at deciphering cellular and molecular mechanisms involved in response to treatment. Moreover, data from the prospectively-maintained RENAPE database will be investigated to build a synthetic historical arm representative of the efficacy of the standard treatments in a similar population of patients. Clinical trial information: NCT06790706. Research Sponsor: GILEAD.

4500 Oral Abstract Session

Nivolumab plus ipilimumab (NIVO+IPI) vs gemcitabine-carboplatin (gem-carbo) chemotherapy for previously untreated unresectable or metastatic urothelial carcinoma (mUC): Final results for cisplatin-ineligible patients from the CheckMate 901 trial. First Author: Michiel Simon Van Der Heijden, Netherlands Cancer Institute, Amsterdam, Netherlands

Background: Platinum-based chemotherapy is a standard of care (SOC) for unresectable or mUC; patients (pts) ineligible for cisplatin (cis) have worse outcomes. The phase 3, global, open-label, randomized CheckMate 901 trial (NCT03036098) compared NIVO+IPI vs gem-carbo in cis-ineligible pts with previously untreated unresectable or mUC. Here, we report final results. **Methods:** Pts with previously untreated, histologically confirmed, unresectable or mUC who were cis-ineligible (glomerular filtration rate $\geq$ 30 to $<$ 60 mL/min) were randomized 1:1 to NIVO 1 mg/kg + IPI 3 mg/kg Q3W up to 4 cycles, then NIVO 480 mg Q4W until disease progression/unacceptable toxicity or up to 2 years, or to gem-carbo Q3W for up to 6 cycles. Pts were stratified by tumor PD-L1 expression and liver metastasis. The primary endpoint was overall survival (OS). Progression-free survival (PFS) by blinded independent central review (BICR) was a secondary endpoint. Objective response rate (ORR) per BICR, duration of response (DOR) per BICR, and safety were exploratory. **Results:** 445 pts were randomized (NIVO+IPI, n = 221; gem-carbo, n = 224). Median time to treatment discontinuation (95% CI) was 2.2 (2.1–3.5) mo with NIVO+IPI vs 3.8 (3.5–3.9) mo with gem-carbo. After minimum follow-up (58.3 mo), the primary endpoint of OS did not meet the threshold for significance (median, 19.1 mo with NIVO+IPI vs 13.2 mo with gem-carbo; HR 0.79 [98.27% CI, 0.61–1.01]; P = 0.0245; Table). PFS, ORR, and DOR are shown in the Table. Any-grade treatment-related adverse events (TRAEs) occurred in 89.0% (grade 3–4, 47.2%) of NIVO+IPI-treated and 92.9% (grade 3–4, 76.3%) of gem-carbo-treated pts; any-grade TRAEs leading to discontinuation occurred in 31.2% and 14.2% of pts, respectively. There were 8 deaths related to toxicity (NIVO+IPI, 7; gem-carbo, 1). **Conclusions:** NIVO+IPI did not meet the threshold of statistical significance for improved OS vs gem-carbo in cis-ineligible pts with untreated unresectable or mUC. Durable response and favorable landmark OS with NIVO+IPI show meaningful activity from a chemotherapy-free regimen of finite duration. No new safety signals were identified. Clinical trial information: NCT03036098. Research Sponsor: Bristol Myers Squibb.

Efficacy (95% CI)	NIVO+IPI; n = 221	Gem-carbo; n = 224	HR
mOS	19.1 (13.5–22.6)	13.2 (11.6–15.2)	0.79 (98.27% CI, 0.61–1.01)[a]; P = 0.0245[b]

4501 Oral Abstract Session

Avelumab + sacituzumab govitecan (SG) vs avelumab monotherapy as first-line (1L) maintenance treatment in patients (pts) with advanced urothelial carcinoma (aUC): Interim analysis from the JAVELIN Bladder Medley phase 2 trial. First Author: Jeannie Hoffman-Censits, The Sidney Kimmel Comprehensive Cancer Center at Johns Hopkins, Johns Hopkins Greenberg Bladder Cancer Institute, Baltimore, MD

Background: In the JAVELIN Bladder 100 phase 3 trial, avelumab 1L maintenance + best supportive care (BSC) significantly prolonged overall survival (OS) and progression-free survival (PFS) vs BSC alone in pts with aUC without progression following 1L platinum-based chemotherapy (PBC). The JAVELIN Bladder Medley phase 2 trial is investigating the combination of avelumab with other antitumor agents in this pt population to assess efficacy and safety vs avelumab maintenance monotherapy. SG is a Trop-2–directed antibody and topoisomerase inhibitor drug conjugate being investigated in solid tumors. Here we report an interim analysis of avelumab + SG vs avelumab monotherapy. **Methods:** Eligible pts had unresectable locally advanced or metastatic UC, ECOG performance status (PS) 0-1, and no disease progression after 4-6 cycles of 1L PBC. Pts were randomized 2:1 to avelumab + SG or avelumab monotherapy, stratified by presence of visceral metastases at start of 1L PBC. Primary endpoints were investigator-assessed PFS and safety; OS was a secondary endpoint. For PFS and OS analyses, data in the avelumab monotherapy arm were extended per protocol using propensity score-weighted JAVELIN Bladder 100 data. **Results:** At data cutoff (Sep 16, 2024), 38 of 74 pts (51.4%) in the avelumab + SG arm and 10 of 37 pts (27.0%) in the avelumab monotherapy arm were still receiving study treatment. In the avelumab + SG and avelumab monotherapy arms, respectively, median age was 70 and 67 years, 50.0% and 51.4% had visceral metastases at start of 1L PBC, and a lower proportion of pts in the avelumab + SG arm had ECOG PS of 1 (31.1% vs 54.1%). Median PFS was 11.17 months (95% CI, 7.43-not estimable [NE]) with avelumab + SG vs 3.75 months (95% CI, 3.32-6.77) with avelumab monotherapy (hazard ratio [HR], 0.49 [95% CI, 0.31-0.76]). OS data were immature at cutoff; median OS was not reached (95% CI, 15.51-NE) in the avelumab + SG arm vs 23.75 months (95% CI, 18.79-30.82) in the avelumab monotherapy arm (HR, 0.79 [95% CI, 0.42-1.50]). In the avelumab + SG and avelumab monotherapy arms, respectively, treatment-related adverse events (TRAEs) of any grade occurred in 71 (97.3%) vs 23 pts (63.9%), and were grade $\geq$3 in 51 (69.9%) vs 0 pts. TRAEs led to discontinuation of both avelumab + SG in 4.1% (SG only in 12.3%) vs avelumab monotherapy in 2.8%. One pt in the avelumab + SG arm had a SG-related AE that led to death (acute subarachnoid hemorrhage in the setting of sepsis and pancytopenia). **Conclusions:** In pts with aUC without progression after 1L PBC, avelumab + SG as maintenance treatment improved PFS vs avelumab monotherapy. TRAEs were more frequent in the combination arm and were consistent with the known safety profile of SG and avelumab. Further investigation of avelumab in combination with anti–Trop-2 antibody-drug conjugates in aUC is warranted. Clinical trial information: NCT05327530. Research Sponsor: the healthcare business of Merck KGaA, Darmstadt, Germany (CrossRef Funder ID: 10.13039/100009945).

4502 Oral Abstract Session

Exploratory analysis of responders from the phase 3 EV-302 trial of enfortumab vedotin plus pembrolizumab (EV+P) vs chemotherapy (chemo) in previously untreated locally advanced or metastatic urothelial carcinoma (la/mUC). First Author: Shilpa Gupta, Cleveland Clinic Taussig Cancer Institute, Cleveland, OH

Background: EV-302/KEYNOTE-A39 (NCT04223856) showed significant PFS and OS benefits for pts with previously untreated la/mUC treated with EV+P vs chemo, which established EV+P as the SOC in this population. This exploratory analysis presents efficacy and safety results for responders, focusing on pts with confirmed complete response (cCR). **Methods:** Pts were randomized 1:1 to receive EV (1.25 mg/kg; Days 1 and 8; IV) + P (200 mg; Day 1; IV) or chemo (gemcitabine + cisplatin/carboplatin); all Q3W. Primary endpoints were PFS by BICR and OS. Secondary endpoints included ORR, DOR, and safety. An exploratory analysis evaluated outcomes in pts with cCR. A genAI tool (01/09/25; Pfizer; GPT-4o) developed the 1st draft; authors assume content responsibility. **Results:** Median follow-up (data cutoff: Aug 8, 2024) was 29.1 mo (95% CI, 28.5-29.9). 886 pts were randomized to EV+P (n = 442) vs chemo (n = 444). Confirmed ORR (CR+PR) was 67.5% with EV+P and 44.2% with chemo; cCR was 30.4% and 14.5%, respectively. Baseline characteristics of responders were generally consistent with the ITT population. Among pts with cCR in the EV+P arm, 38 (28.6%) had upper tract disease and 20 (15%) had liver metastases. For pts with cCR, mPFS by BICR was not reached (NR) with EV+P and 26.9 mo with chemo (HR, 0.36; 95% CI, 0.21-0.61); mOS was NR with both EV+P and chemo (HR, 0.37; 95% CI, 0.17-0.80). Median duration of CR was NR for EV+P and 15.2 mo for chemo. Efficacy data are in the Table. Among pts with cCR in the EV+P arm, the median number of cycles was 13 (range, 1-50) for EV and 27 (range, 1-35) for P; median treatment (tx) duration was 22.0 mo (range, 0.7-35.4). Safety among responders was generally consistent with previous reports. TRAEs leading to dose modification in pts with cCR are in the Table. Grade $\geq$3 TRAEs occurred in 61.7% and 71.9% of pts with cCR in the EV+P and chemo arms, respectively. EV tx-related AESIs and P tx-emergent AEOSI profiles were generally consistent with previous reports. There were no tx-related deaths among pts with cCR. **Conclusions:** In the EV+P arm, the proportion of pts achieving cCR was twice that in the chemo arm. Consistent with the ITT data, EV+P reduced the risk of progression or death vs chemo in pts achieving cCR, with appropriate dose modifications. These data reinforce EV+P as the SOC for 1L tx of pts with la/mUC. Clinical trial information: NCT04223856. Research Sponsor: The EV-302 study was funded by Astellas Pharma Inc., Northbrook, IL, USA; Merck Sharp & Dohme LLC, a subsidiary of Merck & Co., Inc., Rahway, NJ, USA; and Seagen Inc., Bothell, WA, USA, which was acquired by Pfizer in December 2023.

4503 Oral Abstract Session

Circulating tumor DNA (ctDNA) in patients with muscle-invasive bladder cancer (MIBC) who received perioperative durvalumab (D) in NIAGARA. First Author: Thomas Powles, Barts Cancer Institute, Experimental Cancer Medicine Centre, Queen Mary University of London, St Bartholomew's Hospital, London, United Kingdom

Background: In the phase 3 NIAGARA trial (NCT03732677) of patients (pts) with cisplatin-eligible MIBC, addition of perioperative D to neoadjuvant chemotherapy (NAC) demonstrated a statistically significant and clinically meaningful improvement in event-free survival (EFS) and overall survival compared with NAC alone, and a 10% higher pathological complete response (pCR) rate, with a manageable safety profile and no impact on the feasibility of surgery. Here, we report a planned exploratory analysis of ctDNA and association with clinical outcomes from NIAGARA. **Methods:** NIAGARA enrolled cisplatin-eligible pts with MIBC (cT2-T4aN0/1M0) planned for radical cystectomy (RC). Pts were randomized 1:1 to receive either neoadjuvant D (1500 mg IV Q3W) and NAC (cisplatin + gemcitabine IV Q3W) for 4 cycles followed by RC, then adjuvant D monotherapy (1500 mg IV Q4W) for 8 cycles (D arm), or NAC followed by RC alone (comparator [C] arm). Dual primary endpoints were pCR and EFS. Disease-free survival (DFS) was a secondary endpoint. Plasma ctDNA was assessed using the Signatera personalized, tumor-informed molecular residual disease (MRD) assay (Natera, Inc, Austin, TX, USA). ctDNA was assessed at baseline (screening or neoadjuvant C1D1, n = 460), after neoadjuvant treatment prior to RC (pre-RC, n = 422), and at C1D1 of the adjuvant phase (post-RC, n = 345). **Results:** Of 1063 randomized pts, 462 comprised the biomarker-evaluable population (237 D arm; 225 C arm). Patient characteristics were similar to the ITT population. Overall, the ctDNA+ rate at baseline was 57% (260/460) and decreased to 22% (94/422) after neoadjuvant treatment at pre-RC. ctDNA clearance rates from baseline to pre-RC were 41% in the D arm and 31% in the C arm. The non-pCR rate was 97% (86/89) among pts with pre-RC ctDNA+ status. Overall ctDNA+ rate post-RC was 9% (31/345). EFS benefit in the D arm vs the C arm was observed in both the baseline ctDNA+ and ctDNA− groups (Table). DFS benefit with perioperative D was observed in post-RC ctDNA+ and ctDNA− groups (Table). **Conclusions:** In this exploratory analysis, ctDNA+ status at pre-RC was associated with non-pCR. Higher ctDNA clearance from baseline to pre-RC in the D arm indicated the additional benefit of D plus NAC vs NAC alone. Perioperative D provided an EFS benefit to both pts with ctDNA+ and ctDNA− status at baseline; a similar trend was observed with DFS based on ctDNA status post-RC. These results further support the perioperative D regimen for pts with MIBC. Funding: AstraZeneca. Clinical trial information: NCT03732677. Research Sponsor: AstraZeneca.

Nivolumab plus ipilimumab vs sunitinib for first-line treatment of advanced renal cell carcinoma: Final analysis from the phase 3 CheckMate 214 trial. First Author: Toni K. Choueiri, Lank Center for Genitourinary Oncology, Dana-Farber Cancer Institute, Brigham and Women's Hospital, and Harvard Medical School, Boston, MA

Background: First-line nivolumab plus ipilimumab (NIVO+IPI) provided substantial long-term survival benefits over sunitinib (SUN) in patients (pts) with advanced renal cell carcinoma (aRCC) in the CheckMate 214 trial. We now report final efficacy and safety data in the intent-to-treat (ITT) population and by International Metastatic Renal Cell Carcinoma Database Consortium (IMDC) risk. **Methods:** Pts with clear cell aRCC were randomized 1:1 to NIVO 3 mg/kg + IPI 1 mg/kg Q3W×4 then NIVO (3 mg/kg or 240 mg Q2W or 480 mg Q4W); or SUN 50 mg once daily for 4 weeks on, 2 weeks off. Efficacy endpoints included overall survival (OS), and independent radiology review committee (IRRC)-assessed progression-free survival (PFS) and objective response rate (ORR) in intermediate/poor-risk (I/P; primary), ITT (secondary), and favorable-risk (FAV; exploratory) pts. Response was assessed using RECIST v1.1. **Results:** With 9 years median follow-up, OS was improved with NIVO+IPI vs SUN in ITT (HR 0.71) and I/P (HR 0.69) pts. The probability of OS at 108 months was 31% vs 20% in ITT pts and 30% vs 19% in I/P pts, respectively. In pts with FAV risk, the HR for OS improved from 1.45 at first report (Motzer *NEJM* 2018) to 0.80 at 9 years, showing a delayed benefit with NIVO+IPI vs SUN. OS probabilities at 108 months were 35% vs 22% in FAV pts, respectively (Table). The probability of PFS at 96 months with NIVO+IPI vs SUN was 23% vs 9% in ITT pts, 25% vs 9% in I/P pts, and 13% vs 11% in FAV pts. The probability of remaining in response through 96 months with NIVO+IPI vs SUN was 48% vs 19% in ITT pts, 50% vs 23% in I/P pts, and 36% vs not available (NA) in FAV pts. No new treatment-related deaths occurred in either arm. Additional subgroup analyses will be presented. **Conclusions:** In the longest and final phase 3 follow-up (9 years) of a first-line checkpoint inhibitor combination in aRCC, milestone rates of OS and PFS and durable response remained higher with NIVO+IPI vs SUN. No new safety signals emerged. NIVO+IPI remains a standard first-line option in aRCC. Clinical trial information: NCT02231749. Research Sponsor: Bristol Myers Squibb.

Combination casdatifan plus cabozantinib expansion cohort of phase 1 ARC-20 study in previously treated patients with clear cell renal cell carcinoma. First Author: Toni K. Choueiri, Department of Medical Oncology, Dana-Farber Cancer Institute, Boston, MA

Background: Hypoxia-inducible factor 2-alpha (HIF-2α) is highly dysregulated in clear cell renal cell carcinoma (ccRCC), resulting in increased expression of proteins involved with angiogenesis, proliferation, and cancer cell survival. Casdatifan is an orally bioavailable small-molecule HIF-2α inhibitor. We investigated the safety and efficacy of casdatifan in combination with the anti–vascular endothelial growth factor receptor tyrosine kinase inhibitor (VEGFR-TKI) cabozantinib in previously treated patients with ccRCC in an expansion cohort (casdatifan + cabozantinib) of the phase 1, open-label ARC-20 (NCT05536141) trial. **Methods:** Patients enrolled in the casdatifan + cabozantinib expansion cohort were previously treated with immunotherapy (IO) alone or with anti-VEGF therapies. Casdatifan 100 mg and cabozantinib 60 mg were given orally once daily. Endpoints included the incidence of treatment-emergent adverse events (AEs) and objective response rate (ORR) by RECIST v1.1. This study is ongoing; data as of January 3, 2025, are reported. **Results:** Overall, 27 patients with a median (range) follow-up of 2.9 (0.1–6.8) months were enrolled. At data cut off, prior treatment settings included adjuvant only (n = 5/26) and metastatic (1L n = 17/26; 2L n = 4/26). Prior therapies included IO only (n = 15/26) or IO plus VEGFR-TKI (n = 11/26). All grade AEs occurred in 89% of patients with the most common being anemia (n = 16 [59%]) and fatigue (n = 15 [56%]). Most common (> 10%) grade ≥3 AEs were anemia (n = 7 [26%]) and hypoxia (n = 3 [11%]). No cardiac events were reported. AEs leading to casdatifan-only, cabozantinib-only, or both casdatifan + cabozantinib dose reductions occurred in 3 (11%), 7 (26%), and 2 (7%) patients, respectively. Only one (4%) pt discontinued due to an AE, hypoxia related to casdatifan. Responses continue to be observed among the efficacy evaluable population (n = 22; as of January 27, 2025) with ORR of 41% (n = 1 complete response; n = 8 partial response). Activity was seen across all IMDC risk groups. **Conclusions:** In previously treated patients with ccRCC, casdatifan 100 mg in combination with cabozantinib 60 mg had a manageable AE profile with promising clinical activity. These data support continued evaluation of this combination in the phase 3 PEAK-1 clinical trial. Clinical trial information: NCT05536141. Research Sponsor: Arcus Biosciences, Inc.

Hypoxia-inducible factor-2α (HIF-2α) inhibitor belzutifan in von Hippel-Lindau (VHL) disease–associated neoplasms: 5-year follow-up of the phase 2 LITESPARK-004 study. First Author: Vivek Narayan, Hospital of the University of Pennsylvania, Philadelphia, PA

Background: The HIF-2α inhibitor belzutifan is approved for the treatment of patients with VHL disease–associated renal cell carcinoma (RCC), CNS hemangioblastomas (HB), or pancreatic neuroendocrine tumors (pNETs), not requiring immediate surgery based on previously reported results from the ongoing open-label phase 2 LITESPARK-004 study (NCT03401788). Updated results are presented after a minimum of 5 years of follow-up. **Methods:** Adults with germline *VHL* alterations, ≥1 measurable nonmetastatic RCC tumor, no tumor > 3 cm that required immediate surgery, no metastatic disease, no prior anticancer systemic treatment, and an ECOG PS of 0 or 1 received oral belzutifan 120 mg once daily until disease progression, unacceptable toxicity, or participant (pt) withdrawal. The primary end point was objective response rate (ORR) in VHL disease–associated RCC per RECIST v1.1 by independent review committee (IRC). Secondary end points included safety, ORR in non-RCC neoplasms, duration of response (DOR), and progression-free survival (PFS) per RECIST v1.1 by IRC. **Results:** Overall, 61 pts received ≥1 dose of belzutifan. Median study follow-up was 61.8 mo (range, 60.2-70.1). As of the April 1, 2024 data cutoff date, 35 pts (57%) remained on treatment. ORR was 70% for RCC, 50% for CNS HB, and 90% for pNETs. Additional efficacy results are in the Table. Among 14 pts (n = 18 eyes) with retinal HB, 100% (95% CI, 82-100) of eyes showed improvement per ophthalmologic assessment; median DOR for retinal HBs was not reached (NR; range, 8.5-61.0+ mo). At baseline, 59 of 61 pts (97%) had ≥1 prior VHL-related surgery. Within the 5 years before starting belzutifan, 46 of 61 pts (75%) had ≥1 surgery. Since starting belzutifan, 19 of 61 pts (31%) underwent VHL-related surgeries; 4 underwent surgery while on treatment and subsequently discontinued treatment, 8 underwent surgery after discontinuing treatment, and 7 are continuing treatment as of the data cutoff date. Grade 3 treatment-related adverse events (TRAEs) (most commonly anemia [n = 7; 11%]) were reported in 11 pts (18%). No grade 4 or 5 TRAEs occurred. Belzutifan was discontinued in 2 pts (3%) due to TRAEs (grade 1 dizziness and grade 2 intracranial hemorrhage). **Conclusions:** After 5 years of follow-up, belzutifan continues to demonstrate durable antitumor activity and a manageable safety profile, consistent with prior reports. Most pts remain on treatment after this period. Results continue to support the use of belzutifan in pts with VHL disease–related RCC, CNS HB, and pNETs who do not require immediate surgery. Clinical trial information: NCT03401788. Research Sponsor: Merck Sharp & Dohme LLC, a subsidiary of Merck & Co., Inc., Rahway, NJ, USA; The Intramural Research Program of the National Institutes of Health, National Cancer Institute Center for Cancer Research, and a grant (UO1 CA236489) from the National Cancer Institute.
