Background: Current cancer physical activity guidelines recommend clinicians offer individualized 'physical activity prescriptions' to cancer survivors. However, there are limited data to support individualized physical activity prescriptions for breast cancer survivors in clinical settings. We aimed to develop a simulation model-based 'calculation engine' for a clinical decision tool that could generate individualized breast cancer outcomes associated with physical activity considering the individual characteristics of breast cancer survivors. **Methods:** We adapted an established and validated simulation model developed within the Cancer Intervention and Surveillance Modeling Network (CISNET) to estimate breast cancer-specific mortality, all-cause mortality, and life-years gained with post-treatment physical activity for women aged 50-75 years at diagnosis with stage I-III breast cancer. Model inputs were derived from clinical trials, cohort studies, national survey, and registry data. Breast outcomes were generated for 41,472 unique subgroups based on all possible combinations of age, hormone status, HER2 status, stage, tumor size, grade, body mass index, surgery, and treatment. External validation was conducted using an independent data source. We summarized 10-year breast cancer and all-cause mortality rates for varying combinations of weekly aerobic (e.g., 2.5-5.0 hours/week) and muscle-strengthening (e.g., ≥2 days/week) activity. **Results:** Overall, the 10-year breast cancer-specific and all-cause survival rates for stages I-III were 89.1% and 83.2%. These results varied by individual characteristics and physical activity levels. For example, in a 65-69-year-old-woman diagnosed with stage I, hormone receptor-positive, HER2-negative breast cancer, and a body mass index of ≥30kg/m2, the 10-year breast cancer-specific and all-cause survival rates for 0-0.5 hours/week of physical activity were 87.1% and 80.1%, respectively. If the woman was to increase aerobic activity to 0.5-2.5 hours/week, 10-year breast cancer survival increased to 88.5%, and all-cause survival increased to 81.1%. Meeting physical activity guidelines (i.e., 2.5-5.0 hours/week of moderate-intensity aerobic activity; and ≥2-days/week of muscle strengthening activity) was associated with increases in 10-year breast cancer and all-cause survival rates to 93.0% and 82.9%, respectively. The model closely replicated observed rates in independent data. **Conclusions:** These data provide a calculation engine for a clinical decision tool to support individualized physical activity prescriptions and discussions for breast cancer survivors. Research Sponsor: U.S. National Institutes of Health.

Dietary polyphenols and the risk of prostate cancer in the prospective Southern Community Cohort Study. First Author: Grace Xu, Vanderbilt University, Nashville, TN

Background: In the US, prostate cancer incidence is highest among underrepresented and underserved populations, including Black and low-income populations. Polyphenols, common in plant-based foods, are biologically active compounds previously associated with decreased risk of prostate cancer. **Objectives:** We examined intake of total polyphenols, classes, and subclasses with risk of prostate cancer in the Southern Community Cohort Study (SCCS), a large prospective cohort study established in 2002-2009 to study the causes of racial and income cancer disparities in 12 southern states. **Methods:** Polyphenol intakes (mg/day) derived from food frequency questionnaires were grouped into quintiles. Prostate cancer diagnosis was obtained from state cancer registries and death records. Cox proportional hazard models were used to estimate hazard ratios and 95% confidence intervals to determine associations between polyphenol intakes and prostate cancer risk. Analyses included 29,325 participants, including 1,145 incident prostate cancer cases. **Results:** Higher total polyphenol intake was associated with a modestly decreased risk of prostate cancer compared to the lowest intake except in the highest quintile. 8 subclasses of polyphenols derived primarily from tea, fruit juices, and red wine were associated with a statistically significant decreased risk of prostate cancer comparing the highest to lowest quintiles (e.g. HR 0.58; 0.47-0.72, $p_{trend} < 0.001$ for flavanols). Most associations were similar between Black and White individuals, but flavonoids (HR 0.42; 0.28-0.63, p = 0.0005) and hydroxybenzoic acids (HR 0.45; 0.30-0.67, p = 0.0001) were statistically significant only among White participants. In stratified analyses by smoking status and household income, only flavones were associated with a statistically decreased risk of prostate cancer, specifically among current smokers and participants with an income < $15000. **Conclusions:** Polyphenol intakes were associated with decreased prostate cancer risk among both Black and White participants. Further studies should evaluate whether polyphenol intake is associated with decreased risk for later stages of prostate cancers. Escalating impact of alcohol-related cancer mortality in the US: A call for action. First Author: Chinmay Jani, University of Miami Sylvester Comprehensive Cancer Center, Miami, FL

Background: Alcohol consumption is known to be a significant risk factor for cancer. This year, the US Surgeon General recommended adding cancer risk warning labels to alcoholic beverages, emphasizing the need for increased awareness. However, data on its impact on individual cancer mortality remains limited. This study aims to evaluate trends in alcohol-associated cancer mortality in the US utilizing Global Burden of Disease (GBD) database. **Methods:** We utilized data from the GBD to analyze absolute and proportional Age-Standardized Mortality Rates (ASMR) attributable to heavy alcohol use—defined as consumption exceeding the theoretical minimum risk exposure level—in the US from 1990 to 2021. We evaluated ASMR for all cancers combined, followed by specific cancers, including esophageal, liver, laryngeal, breast, colorectal, lip-oral cavity, nasopharyngeal, and other (oro/hypo) pharyngeal. Results were reported per 100,000 population and stratified by gender, state, and age groups (20–54, 55+). Estimated Annual Percentage Change (EAPC) was calculated using JoinPoint regression analysis. **Results:** Alcohol-associated cancer deaths in the U.S. doubled from 1990 (11,896) to 2021 (23,207). The 55+ age group showed a significantly higher ASMR than the 20-54 age group (Table 1). Proportional alcohol-associated ASMR increased for all cancers and individual cancers across both age groups and genders, except for liver cancer in 55+ age group. In 2021, for 55+ age, liver cancer had the highest alcohol-associated proportional ASMR in males (38.5%), followed by nasopharyngeal cancer (31.8%), while in females, nasopharyngeal (18.9%) and oro/hypopharyngeal cancers (18.4%) ranked highest. In 20-54 age, lip-oral cavity cancer had the highest alcohol-associated proportional ASMR for both genders (m:41.8%; f:26.9%). In 2021, the District of Columbia had the highest alcohol-associated all-cancer ASMR (m:10.0; f:3.6) followed by Texas (7.5) for males and New Hampshire for females (2.9). In contrast, Utah had the lowest (m:3.5; f:1.4). On evaluating trends, a constant increase was observed in alcohol-associated ASMR for 55+ age group for males (EAPC 0.5, 2008-2021) and females (EAPC 1.1, 2006-2021). **Conclusions:** Alcohol-associated cancer mortality has significantly increased in the U.S. over the past three decades, with a disproportionate burden observed in males and individuals aged 55 and older. Our findings highlight the critical need for targeted prevention efforts, public health policies, and increased awareness to address the rising impact of alcohol consumption on cancer-related mortality across different demographic groups and regions. Research Sponsor: None.

Alcohol associated-all cancer ASMR.

Age (n=Absolute, %= Proportional)	Male - 1990	Male - 2021	Female - 1990	Female -2021
Overall	5.7 (0.03%)	6.2 (0.04%)	2.6 (0.02%)	2.2 (0.02%)
20-54	2.2 (4.3%)	2.4 (6.8%)	1.8 (3.3%)	1.4 (3.6%)
55+	27.3 (2.4%)	31.7 (4.3%)	10.7 (1.5%)	10.4 (1.9%)

Association between wildfire-dominated $PM_{2.5}$ exposure and non-small cell lung cancer survival in California. First Author: Surbhi Singhal, University of California Davis Comprehensive Cancer Center, Sacramento, CA

Background: Wildfire emissions include hazardous constituents, including fine particulate matter $\leq$2.5 μm in diameter ($PM_{2.5}$). $PM_{2.5}$ exposure is associated with increased risk of lung cancer. However, the impact of wildfire-dominated $PM_{2.5}$ exposure on survival after non-small cell lung cancer (NSCLC) diagnosis is unknown. **Methods:** We identified all patients diagnosed with NSCLC in the California Cancer Registry between 2017-2020. Daily $PM_{2.5}$ was estimated over the same period by random forest regression fusing official air quality monitoring, satellite observations, meteorological modeling, predictive smoke modeling, and low-cost sensors, producing a consensus estimate of $PM_{2.5}$ over a 1-square kilometer grid across California. We quantified $PM_{2.5}$ exposure by averaging daily $PM_{2.5}$ in the 12 months after NSCLC diagnosis based on home address at time of diagnosis. Adjusted cox-proportional hazards regression was used to estimate the hazard ratio (HR) for cancer-related death associated with $PM_{2.5}$ exposure following NSCLC diagnosis overall and stratified by smoking status and stage at diagnosis. We adjusted for patient demographics, comorbidity, body mass index, rural residence, and COVID-19 time-period. **Results:** Among 18,585 patients with NSCLC, the mean age was 70.4 years (standard deviation [SD] 10.5) and the mean $PM_{2.5}$ concentration was 9.8 $\mu g/m^3$ (SD 2.0). Higher mean daily $PM_{2.5}$ in the 12 months after NSCLC diagnosis was associated with 20% increased hazard of cancer-related death (Table). There was a 55% increase in hazard of cancer-related death associated with $PM_{2.5}$ among patients with stage IV disease and no prior smoking use (Table). Notably, patients with Stage IV disease with former or current tobacco use who received immunotherapy had improved cancer-specific survival with more days of high $PM_{2.5}$ concentration (i.e., days with $PM_{2.5}$ $\geq$55 $\mu g/m^3$), HR=0.79, 95% confidence interval 0.66-0.94. **Conclusions:** In this large population-based NSCLC cohort, wildfire-dominated $PM_{2.5}$ exposure after diagnosis was independently associated with increased risk of cancer-related death. The improved survival among patients with Stage IV disease with a smoking history treated with immunotherapy warrants additional investigation. As the size and frequency of wildfires increases, our findings have important public health and clinical implications for patients with NSCLC. Research Sponsor: National Cancer Institute; 5K12CA138464; National Cancer Institute; P30CA093373; California Department of Public Health; Centers for Disease Control and Prevention's (CDC) National Program of Cancer Registries; 1NU58DP007156.

Hazard ratio (HR) for cancer-related death associated with $PM_{2.5}$ concentration after NSCLC diagnosis.

	Number of Patients	Number of Cancer-Related Deaths	Cancer-Related Death HR (95% confidence interval)
Total cohort	18,585	6,097	1.20 (1.05-1.37)
No prior tobacco use	5,059	1,565	1.36 (1.04-1.78)
Former or current tobacco use	13,526	4,532	1.17 (1.01-1.36)
Stage IV, no prior tobacco use	2,198	1,079	1.55 (1.12-2.16)
Stage IV, former or current tobacco use	3,783	2,097	1.09 (0.87-1.36)

Large-scale clinical validation of a blood-based, multi-cancer, early detection test across different sample types, platforms, and populations. First Author: Mao Mao, Research & Development, SeekIn Inc., San Diego, CA

Background: Many established cancer screening or diagnostic methods often face challenges in low- and middle-income countries due to high cost, complexity, and reliance on extensive medical infrastructure. OncoSeek, a multi-cancer early detection (MCED) test developed with a panel of protein tumor markers (PTMs), is both affordable (reagent cost ~$20) and accessible, requiring only a blood draw. We evaluated its performance of multi-cancer detection and diagnosis in large-scale clinical studies. **Methods:** 15,122 participants (3,029 cancer vs 12,093 non-cancer) were divided into one training and six validation cohorts according to the different sites in three countries (Brazil, China, and United States). One tube of blood (plasma or serum) from each participant was collected and quantified using a panel of 7 PTMs (AFP, CA125, CA15-3, CA19-9, CA72-4, CEA, and CYFRA 21-1) through four common immunoassay platforms (Roche, Abbott, Luminex, and ELISA) in both retrospective and prospective settings. OncoSeek, utilizing artificial intelligence (AI) algorithm, was developed to differentiate cancer cases from non-cancer cases based on 7 PTM concentrations and clinical information including age and sex. It also predicted the potential affected tissue of origin (TOO). Furthermore, the fifth validation cohort, comprising 1849 patients (1031 cancer vs 818 non-cancer), was leveraged to broaden OncoSeek's application for cancer diagnosis. This cohort specifically targeted symptomatic patients, requiring further confirmation through biopsy or surgery. **Results:** The conventional clinical method, using a single threshold for each PTM, lead to accumulate the false positive rate with the growing number of PTMs. However, OncoSeek, empowered by AI, significantly reduced the false positive rate, elevating specificity from 54.3% to 93.0% and achieving an overall sensitivity of 51.7% in the training cohort. Performance remained robust (58.4% sensitivity and 92.0% specificity) across all seven cohorts, with area under the curve (AUC) values ranging from 0.744 to 0.912. The overall accuracy of TOO prediction was 65.4%. In the fifth cohort with symptomatic patients, OncoSeek achieved a 0.845 AUC for cancer diagnosis at 73.1% sensitivity and 90.6% specificity. **Conclusions:** OncoSeek significantly outperforms the conventional clinical method, showcasing its robust performance across various races, sample types, and platforms. The extensive retrospective assessment of OncoSeek in a symptomatic population demonstrates the feasibility of this MECD test in aiding clinicians for decision-making. Its accuracy of TOO facilitates the diagnostic workup. Research Sponsor: None.

Multi-cancer risk prediction in asymptomatic adults using urinary glycosaminoglycan profiling. First Author: Francesco Gatto, Elypta AB, Stockholm, Sweden

Background: Current screening guidelines are based on established risk factors such as age and tobacco use. Currently, no biomarker is routinely used to predict cancer risk. We investigated urinary glycosaminoglycan profiles - aggregated in a "GAGome score" - for multi-cancer risk prediction. **Methods:** In this population-based case-cohort study, we included adults from the Lifelines Cohort Study, Netherlands presumed healthy at baseline. All cases who self-reported any-type cancer or died by the 5-year study visit were confirmed in the Dutch Cancer Registry and matched 1:5 to randomly selected controls. We developed a multivariable Cox proportional hazard regression to estimate the hazard ratio (HR) for incident cancer given the GAGome score and adjusted for established risk factors. Model improvement was assessed using the likelihood ratio test. Then, we used 5-year risk predictions to stratify subjects in four groups: "Low" ($<$0.15%), "High" ($>$2%), and "Very high" ($>$8.5%) risk, or "Intermediate" if otherwise (reference group). Using sampling weights, we estimated the 5-year observed risk in each group, as well as the potentially screen-detectable rate and false positive rate across population and cancer subsets. **Results:** We included 5436 adults (median age = 49 years, 58% females) of whom 827 were diagnosed with incident cancer within 5 years. A standard deviation increase in the GAGome score had an HR = 1.66 (95% CI: 1.62–1.70) for incident cancer – ranging 1.27 for endometrial cancer to 3.4 for cancer of unknown primary - explaining 36% of the variance ($p < 0.0001$). The observed 5-year risk for "Low", "Intermediate", "High", and "Very high GAGome risk" were 0.18%, 2.3%, 7.6%, and 32%, respectively. A "High GAGome risk" or higher prediction would detect 54% of incident cancers (including 54% of in situ carcinomas) with a 17% false positive rate. **Conclusions:** Implementing urine GAGomes as a strategy for risk-stratified targeted screening could pave the way for personalized surveillance approaches and potentially identify a broader range of adults with increased risk of cancer that are not being captured by current screening programs. Research Sponsor: Elypta AB.

The effect of metformin exposure on colorectal cancer incidence according to tumor sidedness. First Author: Yehudit Peerless, The Jusidman Cancer Center, Ramat Gan, Israel

Background: Colorectal cancer (CRC) is a leading cause of cancer-related morbidity and mortality. Tumor sidedness influences treatment decisions due to differences in tumor biology and response to therapies. Metformin, a widely used anti-diabetic medication, has been suggested to reduce CRC risk. This study aims to evaluate the relationship between metformin exposure and CRC risk based on tumor-sidedness. **Methods:** A nested case-control study was conducted using the Veterans Administration (VA) database (1999–2020). CRC cases were identified and classified by tumor sidedness. Controls were selected via incidence-density sampling and matched on age, sex, index date, and first VA encounter. Exposure of interest was cumulative metformin use prior to the index-date. Conditional logistic regression was used to estimate adjusted odds-ratios (ORs) and 95% confidence intervals (CIs), adjusted for race, BMI, smoking, aspirin, statins, and other anti-diabetic medications. **Results:** The study included 31,078 patients treated with metformin and 310,621 matched controls. Metformin exposure did not influence the incidence of right-sided CRC with an adjusted OR of 1.03 (95%CI 0.92 – 1.16) and 0.96 (95%CI 0.83 – 1.12) with metformin exposure of 1-3 years and 3-5 years, respectively. In contrast, in patients with left-sided CRC metformin use was associated with a decrease in CRC incidence, with an adjusted OR of 0.90 (95%CI 0.82 – 0.98) and 0.87 (95%CI 0.77 – 0.98) with metformin exposure of 1-3 years and 3-5 years, respectively. **Conclusions:** Metformin was associated with a decrease in the incidence of left-sided CRC incidence. These results suggest the influence of tumor sidedness, not only on treatment effect, but on prevention strategies as well. Research Sponsor: None.

Development and validation of a model to predict future breast cancer risk after ER-positive and HER2-negative breast cancer. First Author: Kelly-Anne Phillips, Department of Medical Oncology, Peter MacCallum Cancer Centre, Melbourne, VIC, Australia

Background: Request for bilateral mastectomy after a unilateral breast cancer (BC) diagnosis is increasing. In many cases the benefit of bilateral mastectomy is likely to be small and offset by substantial risks of morbidity, financial toxicity and overburdening of healthcare systems. It is difficult to accurately determine personal risk of developing a future BC. Existing risk prediction models only predict risk for contralateral BC. Australian consumers identified an unmet need for a model that estimates risk of developing BC in any residual breast tissue (ipsi- or contra-laterally); to help women diagnosed with unilateral BC make informed decisions about bilateral mastectomy. **Methods:** Data from 1,162 female BC cases participating in two Australian cohort studies were used to develop a model to predict risk of BC for women who developed a 1st invasive ER positive, HER2 negative BC after cohort entry or within 2 years prior to cohort entry. Women with a germline pathogenic variant in a BC predisposition gene, and those who received neoadjuvant systemic therapy were excluded. 187 (88 ipsilateral, 96 contralateral, 3 unknown laterality) BC events (161 invasive and 26 DCIS) occurred over a median follow-up of 13.8 years. Flexible parametric survival analysis was used, with time since diagnosis as the time scale, and death due to any cause considered as a competing event. Potential predictors of future BC risk were investigated, including age at 1st BC, age at 1st birth, parity, breastfeeding duration, menopausal hormone therapy use, BMI, number of 1st-degree relatives with BC, BC polygenic risk score (PRS-313), contralateral mammographic density, surgery (breast conservation vs unilateral mastectomy), tumor grade and size, number of positive axillary nodes, associated LCIS, and use of adjuvant chemotherapy or radiation. Retained in the final risk prediction algorithm (all $P < 0.05$) were age at diagnosis of 1st BC, surgery type, radiation therapy, family history, and PRS-313. For external validation of the model, data from 3,136 cases (eligibility criteria as per the training set) with 181 subsequent BC events participating in the international Breast Cancer Association Consortium were used. Calibration and a time-dependent area under the curve (AUC) at 10 years were assessed to determine model performance. Sensitivity analysis excluding PRS-313 was also performed (as it is usually not available in clinical practice). **Results:** Discriminatory ability at 10 years was AUC = 0.66 (95% CI 0.62-0.70) or 0.65 (95% CI 0.61-0.69) if PRS-313 was excluded. The model was well calibrated; expected (176 cases) to observed (181 cases) ratio = 0.97 (95% CI 0.84-1.13). **Conclusions:** This model provides valid estimates of 10-year BC risk after a 1st ER-positive HER2-negative BC and may be useful in collaborative decision-making between patients and their surgeons when considering bilateral mastectomy. Research Sponsor: National Breast Cancer Foundation (Australia); IIRS-20-029; National Health and Medical Research Council (Australia); 1195294.

Colonoscopy quality indicators for colorectal cancer precursors: Sessile serrated lesion and adenoma detection rates from a large clinical study of a blood-based test for CRC screening. First Author: Man Yee Wong, Freenome Inc, South San Francisco, CA

Background: Colorectal cancer (CRC) is the second leading cause of cancer-related deaths globally. Colonoscopy can reduce mortality by removing precancerous lesions or detecting cancer at an earlier, more treatable stage, with the adenoma detection rate (ADR) as the standard colonoscopy quality indicator. In 2024, the sessile serrated lesion detection rate (SSLDR) was introduced as a new multisociety colonoscopy quality indicator. Both quality indicators have associated performance targets, primarily based on benchmarking to colonoscopy registry data. Serrated lesions, which are precursors to 10-30% of CRC, are often missed due to their flat appearance, indistinct borders, and proximal locations. Published SSLDR data is limited, and to our knowledge, this is the first analysis of SSLDRs and ADRs in a large prospective, multicenter clinical study in an average-risk population. **Methods:** PREEMPT CRC, a clinical validation study of a blood-based test for CRC screening in adults aged 45-85, included 200 diverse U.S. sites. Based on thorough medical review of colonoscopy and pathology reports, SSLDRs and ADRs were calculated across 27,010 subjects that completed screening colonoscopy in the clinical validation. SSLDR and ADR were defined as the percentage of colonoscopies in which at least one SSL or adenoma was detected, respectively. Results were stratified by age and sex, and compared to established performance targets from colonoscopy quality guidelines. **Results:** The overall SSLDR in PREEMPT CRC was 7.2%, surpassing the newly recommended performance target of $\geq$ 6%. The overall ADR was 34.9%, aligning with the latest target of 35% overall (40% in males, 30% in females). The ADR increased significantly with age, from 26.9% in the 45-49 age group to 40.8% in the 75+ age group ($p < 0.001$). In contrast, the SSLDR remained consistent across age groups, with the 45-49 year age group (7.1%) similar to the overall SSLDR (7.2%) (p = 0.789). The ADR demonstrated a clear sex-dependence (41.9% in males, 29.4% in females, $p < 0.001$), while the SSLDR did not (7.4% in males, 7.1% in females, p = 0.433). **Conclusions:** The overall SSLDR and ADR in PREEMPT CRC were consistent with the updated colonoscopy quality guidelines, with the SSLDR exceeding the target, suggesting that the target could be updated from 6% to 7%. Our results underscore the age- and sex-independent risk of serrated lesions. Notably, even the SSLDR in the 45-49 year age group (7.1%, 6.2%-8.0%) exceeded the 6% performance target. Given the relatively high ADR of 26.9% observed among 45 to 49-year-olds, and the age-independence of the SSLDR, our findings highlight the importance of advocating for early CRC screening, especially in younger populations where screening adherence is generally poor. Clinical trial information: NCT04369053. Research Sponsor: None.

10526 **Poster Session**

Machine learning for cancer risk stratification: A bi-directional approach to screening. First Author: Erez Hasnis, Rambam Health Care Campus, Haifa, Israel

Background: Cancer screening programs are often limited by high costs, invasiveness, and potential false results. Machine learning (ML) applied to routine medical data could enable risk-stratified screening approaches. We developed ML models to predict 10-year cancer risk using data from routine periodic health examinations, aiming to identify both high and low-risk populations. **Methods:** We analyzed data from individuals who underwent routine health examinations at Rambam Medical Center (2002-2021), matched with the Israeli National Cancer Registry. After quality control, including removal of cases with previous tumors, we excluded cancers diagnosed less than 183 days after the visit to avoid prevalent cases. Using data from the initial visit only, we developed two XGBoost models for 10-year cancer risk: Model 1 (baseline) using only age and gender, and Model 2 incorporating 53 features including demographics, lifestyle factors (smoking, alcohol, physical activity), laboratory results (26 parameters including complete blood count, biochemistry, and lipids), medication categories (9 groups including statins, antihypertensives, antidiabetics), and medical history (7 disease categories). Models were trained on 75% of the data with cross-validation and evaluated on a 25% hold-out set. **Results:** Our cohort included 27,901 individuals (61% male, mean age 47$\pm$10 years), with 1,960 future incidents of cancer diagnosed at median follow-up of 8 years. Most common malignancies were prostate (21%), breast (19%), skin (15%), and colorectal (12%) cancers. For model development, we reduced the dataset to include only individuals with 10-year follow-up or cancer event within the 10-year window (N = 16,859, cancer cases = 1,268). Model 2 significantly outperformed Model 1 (AUC 0.799 vs 0.706, $p < 0.0001$) and demonstrated remarkable risk stratification. Against a population baseline risk of 7.3%, Model 2 identified: 1) a low-risk group (bottom 50%) with only 1.9% 10-year cancer risk; 2) an high risk group (90-99th percentile) with 25.1% risk (3.5-fold increase); and 3) a very high-risk group (top 1%) with 74.4% risk (10-fold increase). In comparison, the highest-risk group in Model 1 (top 1%) achieved only 20.0% risk. The most important predictive features were age, monocyte count, albumin, total bilirubin, and LDL cholesterol. **Conclusions:** ML analysis of routine health examination data can effectively stratify cancer risk, identifying both very low and exceptionally high-risk groups. This bi-directional stratification could enable more efficient screening strategies: reduce screening intervals or invasiveness in the large low-risk population, while intensifying screening in high-risk groups. Future studies should evaluate and validate these findings in different populations and study whether this approach can improve the efficiency and cost-effectiveness of cancer screening programs. Research Sponsor: ICRF - Israel Cancer Research Fund.

Efficacy and toxicity of low-doses versus standard-dose enzalutamide in advanced prostate cancer: A real-world study with implications for cancer prevention/interception. First Author: Martino Oliva, E.O. Ospedali Galliera, Genova, Italy

Background: Prostate cancer (PCa) is the most frequent cancer in males in the US and EU. Enzalutamide is effective in biochemically recurrent and advanced PCa but is associated with considerable adverse events (AEs) at standard doses (160 mg/day). In the ENACT trial, enzalutamide monotherapy reduced the risk of PCa progression compared to active surveillance (AS) in patients with intermediate/low-risk, but AEs were frequent (eg, 55% fatigue). Preliminary case reports suggest that low/intermediate doses ($\leq$80 mg/day) retain efficacy while reducing toxicity. This study evaluates the efficacy and safety of low/intermediate dose vs standard-dose enzalutamide in advanced PCa in a real-world Italian cohort. **Methods:** This single-center, retrospective observational study included 140 assessable metastatic PCa patients treated with enzalutamide for castration resistant (80%) or sensitive (20%) PCa between August 1, 2014 and December 31, 2023. Patients were categorized based on the total dose (actual vs predicted) taken: low (L, $\leq$50%, n = 11), intermediate (I, $>$ 50% and $\leq$80%, n = 16), and high (H, $>$ 80%, n = 113). The primary endpoint was the 12 month progression-free survival (PFS) by restricted mean survival time to account for violation of proportional hazards assumption. Secondary endpoints included PSA response (decline $\geq$50% at 3 months), overall survival (OS) at 36 months and worsening of AEs of special interest (fatigue, neurological disorders, hypertension). PFS and OS were adjusted for ECOG performance status at baseline. **Results:** The three dose groups were not different at baseline on PSA, BMI, Gleason Score, age and castration resistance. The choice of L dose treatment at baseline was due to clinical judgment in 82% of cases (PS $>$ 0 or age $>$ 80), whereas the I dose was due to toxicity reduction after initial high dose in 63%. The median follow-up time was 13.6 months [IQR, 7.2 – 23.1]. There were no significant differences in PFS at 12 months on H vs I dose (10.4 vs 11.4 mo, p = 0.09) and H vs L dose (10.4 vs 9.2 mo, p = 0.37). There was no difference among dose groups in PSA response (70% vs 75% vs 60% on H, I, L, respectively). The use of I or L doses showed no evidence of adverse effects on OS at 36 months. The rate of fatigue worsening on H vs I vs L dose was 61.1%, 63.0% and 27.3% (p = 0.03 for H vs L). Worsening of neurological disorders and hypertension was 19.5%, 18.8% and 0% and 18.6%, 18.8% and 9.1% on H vs I vs L, respectively. **Conclusions:** In our real-life observational cohort, low/intermediate doses of enzalutamide show comparable efficacy relative to high dose while improving tolerability, indicating the need for further search of the optimal dose of this expensive drug. Moreover, our findings prompt a study of low-intermediate dose enzalutamide in the prevention/interception setting in patients with low/intermediate risk prostate cancer under AS. Growing burden of cancer and high body mass index in the United States from 1990-2021: A benchmarking cross-state analysis. First Author: Adit Dharia, HCA Healthcare/USF Morsani College of Medicine, Oak Hill Hospital, Brooksville, FL

Background: Cancer (CA) remains a major public health challenge and is the second leading cause of death and disability in the United States. Among the various modifiable risk factors, a high body mass index (h-BMI) significantly contributes to the burden of non-communicable diseases, including CA. **Methods:** This study is the first to estimate deaths and disability attributable to h-BMI for 12 different CA types across the USA, disaggregated by age, sex, year, and location, using the standardized Global Burden of Disease Study 2021 methodology from 1990–2021. **Results:** From 1990-2021, the annual percentage change (APC) in age-standardized mortality rates (ASMR) due to CA attributable to h-BMI increased by 0.22%, disability-adjusted life years rates (ASDALR) by 0.19%, and years lived with disability rates (ASYLDR) by 0.78%. Among all CA, the highest increase in APC for ASMR was observed for liver CA at 3.81%, followed by pancreatic CA at 2.66%, uterine CA at 1.16%, thyroid CA at 0.84%, multiple myeloma at 0.50%, and kidney CA at 0.35%. Conversely, APC decreased for leukemia by 0.16%, ovarian CA by 0.37%, non-Hodgkin lymphoma by 0.44%, and gall bladder and biliary tract CA by 0.45%, as well as for colon and rectum CA by 0.49%, and breast CA by 0.85%. Among states, Mississippi observed the highest increase in APC for ASMR at 1.21%, followed by Oklahoma at 1.39%, West Virginia at 1.20%, and New Mexico at 1.19%. In terms of ASYLDR, the largest increases were seen in New Mexico at 1.83%, California at 1.77%, Mississippi at 1.74%, West Virginia at 1.60%, and Tennessee at 1.47%. Age-wise, individuals aged 20-54 recorded 3,833 deaths (95% uncertainty interval: 1,727-5,876), while those 55 and older recorded 43,371 deaths (16,854-71,488) in 2021. Similarly, DALYs for ages 20-54 were 173,448 (82,011-258,288), and for those 55 and older were 930,410 (366,885-1,528,824). In terms of gender, males observed higher increases in ASMR and ASDALR compared to females, with 0.58% vs 0.06% and 0.46% vs 0.05%, respectively, while females saw higher increases in ASYLDR at 1.02% compared to 0.86% from 1990-2021. **Conclusions:** Deaths due to CA attributable to h-BMI accounted for 14.95% of all CA attributable risk factors in 2021. Notably, liver, pancreatic, and uterine CA have shown the most significant rises in ASMR, highlighting an urgent need for targeted public health strategies and research to address these alarming trends. Conversely, decreases in APC for CA like leukemia, ovarian, and breast CA suggest that some progress is being made, possibly attributed to advancements in treatments and early detection programs. Age and gender analyses further illuminate the disproportionate burden of CA on older adults and males, though females exhibit a higher increase in YLDs. Research Sponsor: None.

Sex-based disparities in HPV-related cancer outcomes: Insights into social determinants of health. First Author: Xiangren Wang, University of Florida, Gainesville, FL

Background: Human papillomavirus (HPV) is the most common sexually transmitted infection and a leading cause of several cancers. Research suggests that males are more likely to be infected with HPV compared with females and, as a result, have a higher incidence of HPV-related cancers, attributable to multiple social determinants of health (SDoH) factors. This study was to examine these sex-based disparities, with a focus on SDoH. **Methods:** The US nationally representative sample of HPV related cancer adults were analyzed from the 2011-2023 National Health and Nutrition Examination Survey (NHANES). Participants who reported having diagnosis of HPV-related cancers were included in our study. Descriptive analyses were performed, and weighted logistic regression models were used to examine associations between HPV-related cancers(Oropharyngeal Cancer, Esophageal Cancer, Prostate Cancer, Cervical Cancer, Anal Cancer, and Uterine Cancer) and key SDoH variables, including HPV vaccination, mental health issue, education level, smoking, poverty level, and health insurance coverage. Analyses were stratified by sex and adjusted for survey weights. Results are reported as adjusted odds ratios (aORs) with 95% confidence intervals (CIs). **Results:** A total of 692 participants (equating to 22,115,631) with HPV-related cancer were identified from NHANSE 2011-2023, with 60.3% males and 39.7% females. Compared with females, the prevalence of HPV-related cancer was significantly higher among males (34% vs. 20%). Notably, none of the males with HPV-related cancer had received HPV vaccination. Men aged 65 years and older had more than 16 times greater odds of having HPV-related cancers compared to those under 65. In contrast, older women were only 1.5 times more likely to report HPV-related cancers, highlighting a striking disparity between older males and females. Males without a high school degree have significantly lower odds of HPV-related cancer (OR: 0.38, 95% CI: 0.27–0.56). This may be attributed to a lack of HPV awareness and knowledge among males, leading to underreporting. Furthermore, non-Hispanic Black (NHB) males (OR: 1.92, 95% CI: 1.43–2.57) had greater odds of HPV-related cancer compared to non-Hispanic White (NHW) males. In comparison, NHW females had higher odds of HPV-related cancers compared with other racial and ethnic groups. These findings highlight the distinct SDoH risk factors contributing to HPV-related cancers across males and females, resulting in disparities in HPV-related cancer outcomes. **Conclusions:** These findings underscore the disparities faced by males regarding HPV-related cancer. Addressing these inequities requires targeted interventions focusing on men who are particularly vulnerable to HPV-related cancers, including increasing vaccination rates and reducing behavioral risks for males. Research Sponsor: None.

Do health care providers offer advice to adolescents about nicotine-containing product use? First Author: Michael T. Halpern, University of Texas School of Public Health at San Antonio, San Antonio, TX

Background: Use of tobacco and other nicotine-containing products is a major preventable cause of cancer. Most individuals initiate nicotine product use during adolescence. Advice from health care providers is important to decrease nicotine product initiation and encourage cessation among individuals using these products. It is unclear how frequently providers offer this advice to adolescent patients. We analyzed national survey data to better understand provider interactions with adolescents about nicotine product use. **Methods:** We analyzed data from 16,120 U.S. middle- and high-school students (weighted to represent a population of 21,836,206) who saw a health care provider (doctor, dentist, or nurse) in the past 12 months and had non-missing data on nicotine product use, family affluence level, and receipt of provider advice regarding nicotine product use from the 2021 National Youth Tobacco Survey (NYTS), a school-based, self-administered survey. Nicotine product use was determined from responses to 13 NYTS questions on use of tobacco or nicotine-containing products; those who indicated use of any products in the past 30 days were classified as "current users". Receipt of advice was assessed from 3 questions on advice to not use cigarettes, e-cigarettes, or other nicotine-containing products during health care provider visits. Family affluence was based on 4 questions on family vacations, cars, computers, and bedrooms. Multivariable logistic regression analyses examined associations of receipt of advice with socio-demographic characteristics separately for current and non-current users, controlling for whether providers asked about nicotine product use adjusting for the complex survey design of the NYTS. **Results:** Of the sample, 1262 (weighted 7.9%) currently used nicotine products. Current users were significantly ($p < 0.05$) more likely to be older, female, and non-Hispanic White (vs. non-Hispanic Asian or Hispanic); 51.3% of current users vs. 44.0% of non-current users received health care provider advice. Among current users, older students were less likely to receive advice (odds ratio [OR] 0.85 per year of age, 95% confidence interval [CI] 0.77-0.93) while males (vs. females) were more likely to receive advice (OR 2.51, 95% CI 1.64-3.86). Among non-current users, older students were less likely to receive advice (OR 0.91, 95% CI 0.89-0.94). Males vs. females (OR 1.54, 95% CI 1.42-1.68); non-Hispanic Blacks vs. non-Hispanic Whites (OR 1.18, 95% CI 1.03-1.36); and those from highly affluent families (OR 1.20, 95% CI 1.06-1.36) were more likely to receive advice. **Conclusions:** Only half of adolescents received nicotine product use advice from health care providers. Those more likely to use nicotine products (older, female, non-Hispanic White students) were less likely to receive advice. Increased provider advice targeting at-risk populations may help decrease adolescent nicotine product use. Research Sponsor: None.

Awareness, knowledge, and attitudes toward breast cancer polygenic risk scores for precision prevention in a multiethnic cohort of high-risk women. First Author: Jincong Q. Freeman, Department of Public Health Sciences, The University of Chicago, Chicago, IL

Background: Polygenic risk scores (PRS) have been shown to improve the risk assessment of breast cancer. Though commercially available in the US, PRS testing remains controversial clinically. Recent qualitative research suggests that PRS is understood and accepted by women. However, quantitative research on PRS awareness, knowledge, and attitudes in the US population is scarce. **Methods:** Between July-September 2024, we surveyed high-risk women without breast cancer enrolled in the Chicago Multiethnic Epidemiologic Breast Cancer Cohort and Cancer Prone Registry. PRS awareness was assessed by asking whether participants had ever read/heard about PRS prior to the survey and discussed PRS with a provider. PRS knowledge was measured using an 11-item "true/false" assessment. The total score ranges from 0-11, with higher scores indicating better knowledge. Participants were also asked to what extent they agreed that PRS testing should be offered to the general population and a routine part of breast cancer risk assessment; and how likely receiving a PRS influences their behaviors toward risk management, using a 4-point Likert scale. We performed linear regression, controlling for demographic and socioeconomic factors. **Results:** Of 828 women (mean age 56.8 years), 69.5% identified as White, 20.8% as Black, and 9.7% as Other. Overall, 18.5% and 13.2% had ever read/heard about PRS and discussed it with a provider, respectively. Further, 32.9% reported having learned about PRS from a genetic counselor, followed by 23.1% from their own research/reading, 11.2% from a primary care provider, and 6.3% from an oncologist. There were no significant racial/ethnic differences in PRS awareness (Black 13.0%, Other 19.2%, White 20.7%; $p = .082$) and discussion (Black 11.8%, Other 11.3%, White 14.1%; $p = .874$). The overall mean score on PRS knowledge was 9.7 (SD 1.4). Black (β −0.47, *se* 0.14; $p = .001$) or Other (β −0.50, *se* 0.17; $p = .003$) women were less likely than White women to score higher on PRS knowledge. Higher education (p-trend $< .001$) and income (p-trend = .002) levels were highly associated with increased knowledge scores. 95.4% and 96.2% agreed or strongly agreed that PRS testing should be offered to the general population and a routine part of breast cancer risk assessment, respectively; 93.9% reported receiving a PRS likely or very likely influences their behaviors toward risk management. Attitudes toward PRS were also high across racial/ethnic and socioeconomic groups. **Conclusions:** In this diverse cohort of women, PRS awareness and discussion were low, and there were notable gaps in PRS knowledge. Our findings underscore the need to improve patient-provider communication of breast cancer risk and address gaps in PRS knowledge/health literacy when implementing genetic testing including PRS to increase the uptake of risk-stratified, personalized breast cancer screening. Evaluating the impact of long-term glucocorticoid use on cancer risk in patients with rheumatologic diseases: A retrospective cohort study. First Author: Farigol Hakem Zadeh, HCA North Florida Division, Gainesville, FL

Background: Long-term glucocorticoid (GC) therapy is widely used in the management of rheumatologic diseases, but its immunosuppressive effects have raised concerns about a potential increased risk of cancer. The association between long-term steroid use in patients with rheumatologic diseases and the development of cancer remains unclear. This study aims to evaluate cancer prevalence in patients with rheumatologic conditions who are on long-term steroids compared to those who are not. **Methods:** A retrospective cohort study was conducted involving 35,272 patients with rheumatologic diseases between 2011 and 2024. Patients with rheumatoid diseases were categorized into two groups: those receiving long-term GC therapy (≥30 days; n=5521) and those not on GC therapy (n= 29,751). Cancer prevalence was assessed in both groups as well as their subgroups based on sex, and age. Prevalence rates and odds ratios (OR) were calculated to determine the association between steroid use and cancer. **Results:** Cancer prevalence was significantly higher among GC users (34.2%) compared to non-GC users (20.8%). The odds ratio for cancer in GC users was 1.97 (95% CI: 1.95–2.02), indicating 97% increased odds of cancer for GC users. Stratified by sex, female GC users had a cancer prevalence of 32.6%, compared to 19.9% in non-GC users, with an odds ratio of 1.96 (95% CI: 1.48–2.59), suggesting a nearly two-fold increase in cancer risk. In male patients, cancer prevalence in GC users was 38.2%, compared to 23.4% in non-GC users, with an odds ratio of 2.02 (95% CI: 1.72–2.41), indicating a 102% increase in cancer risk. In those aged over 18 years, cancer prevalence in GC users was 34.5%, compared to 21.3% in non-GC users, with an odds ratio of 1.94 (95% CI: 1.75–2.14), suggesting a significantly higher cancer risk for those on long-term steroid therapy. **Conclusions:** Long-term steroid use in patients with rheumatologic diseases is associated with a higher prevalence of cancer. This association was observed across both sexes and age groups. The substantial cancer risk observed in patients without a personal history of cancer underscores the need for cautious GC prescribing and regular cancer screening. Further investigations should focus on additional factors, including race and comorbidities, to better understand the modulating factors behind this association and refine clinical decision-making. The Selfie study: Cervical precancer detection using novel human papillomavirus biomarkers. First Author: Sarah Phillips, National Cancer Institute, Rockville, MD

Background: Human papillomavirus (HPV) causes the majority of cervical cancers worldwide. Dual stain cytology can detect HPV oncogenic activity through biomarkers p16/Ki-67 in cervical samples. Dual stain is an acceptable triage strategy for HPV-positive results from clinician-collected samples, reducing the number of low-risk individuals sent for colposcopy or treatment. However, the ability of dual stain to triage self-collected vaginal specimen is poorly understood. The Selfie Study is an observational study to assess the diagnostic accuracy of different biomarkers for cervical precancer on self-collected samples. Here, we evaluated dual stain cytology in clinician and self-collected specimens for detection of cervical precancer. **Methods:** Individuals with a cervix ages 25-69 years undergoing cervical cancer screening, colposcopy, or treatment at George Washington University (GWU) and Sarasota Memorial Hospital (SMH) were included in this study (August 2020-August 2024). Participants were instructed to perform self-collection prior to clinician-collection during the clinic visit. Demographics and clinical outcomes of dual stain on paired cervicovaginal samples and presence of cervical intraepithelial neoplasia 2 or worse (CIN2+) were recorded and assessed using descriptive statistics. Differences in sensitivity and specificity of dual stain to detect CIN2+ between the two collection methods were assessed using McNemar's test. **Results:** A total of 548 participants enrolled in Selfie. Paired dual stain results were available for 411 participants (411/548, 75%), of which 24 participants were CIN2+ (24/411, 5.8%). Missing results were due to inadequate/absent staining for one or both collection methods. Dual stain was positive in 63 clinician-collected samples (63/411, 15.3%) and in 39 (39/411, 9.5%) self-collected samples. Overall percent agreement between collection methods was 89.3% (367/411). Percent positive agreement was 39.7% (29/73). Dual stain was 83.3% (20/24) sensitive to detect CIN2+ in clinician-collected samples and 45.8% (11/24) sensitive in self-collected samples (83.3% versus 45.8%, p = 0.003). **Conclusions:** Dual stain on self-collected samples had significantly lower sensitivity for detection of CIN2+ compared to clinician-collected samples. Additional research is needed to evaluate whether the performance is more comparable for CIN3+ endpoints. Our study highlights the challenges of conducting triage assays from self-collected specimens. Clinical trial information: NCT04423679. Research Sponsor: U.S. National Institutes of Health.

Analyzing trends in multimorbidity-related mortality among patients with cancer and myocardial infarction: A decadal analysis. First Author: Abdul Ahad, Northwest General Hospital and Research Centre, Peshawar, Pakistan

Background: Multimorbidity, defined as the coexistence of two or more chronic conditions, poses major challenges to healthcare systems globally. Cancer and myocardial infarction (MI) are leading causes of mortality, yet their combined impact remains underexplored. This study investigates trends in multimorbidity-related mortality among U.S. patients with cancer and MI over two decades, aiming to identify patterns and correlations to guide healthcare interventions and policies. **Methods:** Data were extracted from the Centers for Disease Control and Prevention Wide-Ranging Online Data for Epidemiologic Research (CDC WONDER) database from 1999 to 2020. Death certificates were analyzed for adults aged 25 years and older, with cancer and MI deaths identified using ICD-10 codes (I20 and C00–C97). Variables such as age, sex, race/ethnicity, geographical region, urban-rural classification, and location of death were extracted. Crude and age-adjusted mortality rates (AAMR) per 100,000 population were calculated and Join point regression analysis was employed to assess mortality trends and annual percent changes (APC). Statistical significance was defined at $p < 0.05$. **Results:** A total of 200,884 deaths were analyzed, with 59.9% occurring in medical facilities, followed by deaths at home (25.09%), nursing homes (12.85%), and hospice facilities (2.10%). The overall AAMR declined significantly from 6.83 in 1999 to 3.33 in 2020.Males consistently had higher mortality, with AAMR dropping from 10.85 to 4.79, compared to females (4.30 to 2.22). The highest mortality was observed in individuals aged 85 and above (CMR: 41.42). Mortality trends declined across all age groups until stabilization in recent years. Racial disparities persisted, with NH Black/African Americans experiencing higher mortality rates (8.91 in 1999 to 3.92 in 2020). Geographic analysis showed the highest mortality rates in the Midwest and Northeast regions. Metropolitan and non-metropolitan areas showed declining mortality trends until 2015, followed by stabilization or slight increases in recent years. **Conclusions:** A significant decline in multimorbidity-related mortality has been observed in patients with cancer and MI over the past two decades, with notable disparities across gender, age, race, and geography. Targeted healthcare strategies are essential to address the specific needs of high-risk populations and ensure equitable access to healthcare resources. Research Sponsor: None.

Can we determine the mechanism behind cancer risk reduction with glucagon-like peptide-1 receptor agonists (GLP-1RAs)? First Author: Junmin Song, Department of Medicine, Jacobi Medical Center, Albert Einstein College of Medicine, Bronx, NY

Background: Growing evidence suggests that GLP-1RAs may reduce cancer risk in patients with type 2 diabetes (T2D). Most studies have focused on obesity-related cancers (ORCs), with weight loss proposed as a key mechanism. Additional potential mechanisms include the anti-inflammatory effects of GLP-1RAs on various pathways. We evaluated the impact of GLP-1RAs on weight loss and ORC incidence, as well as their effects on lung cancer, which is considered a non-ORC. **Methods:** We utilized the TriNetX database to analyze patients with T2D prescribed a single GLP-1RA from 2010 to 2021. Patients with prior cancer diagnoses were excluded. Semaglutide, dulaglutide, and liraglutide were individually compared to exenatide due to their greater weight loss potential. Propensity score matching (1:1) was used to adjust for demographics, comorbidities, HbA1c, BMI, and medications. Patients were followed for 3 and 5 years, and Cox proportional hazards analyses assessed the risk of 13 ORCs and lung cancer. **Results:** We identified 726,846 patients prescribed GLP-1RAs and conducted multiple comparisons, which were well-matched across analyses. Among the agents, semaglutide demonstrated the greatest weight-loss effect, while exenatide had the least. However, the differences in weight loss did not translate to significant changes in the risk of ORCs. The hazard ratios for semaglutide were 1.11 (95% CI: 0.95–1.29) at 3 years and 1.08 (95% CI: 0.95–1.24) at 5 years. For liraglutide, the hazard ratios were 1.02 (95% CI: 0.88–1.19) at 3 years and 1.05 (95% CI: 0.93–1.20) at 5 years. Dulaglutide had hazard ratios of 1.03 (95% CI: 0.89–1.20) at 3 years and 1.01 (95% CI: 0.89–1.14) at 5 years. None of these differences were statistically significant compared to exenatide. Similarly, no significant differences were observed in the risk for lung cancer. For semaglutide, the hazard ratios were 0.88 (95% CI: 0.59–1.30) at 3 years and 0.88 (95% CI: 0.62–1.25) at 5 years. Liraglutide had hazard ratios of 0.91 (95% CI: 0.62–1.34) at 3 years and 0.90 (95% CI: 0.65–1.24) at 5 years, and dulaglutide had hazard ratios of 1.02 (95% CI: 0.71–1.49) at 3 years and 1.10 (95% CI: 0.81–1.49) at 5 years. These findings indicate no significant differences in cancer risks, whether for obesity-related cancers or non-ORC, lung cancer, among the four GLP-1RAs. **Conclusions:** All four GLP-1RAs demonstrated similar cancer risks for obesity-related cancers despite differences in weight loss among the agents. Similarly, no differences were observed in the risk of non-obesity-related cancer, specifically lung cancer. This suggests that weight loss does not clearly explain a link between GLP-1RAs and reduced cancer risk, as the results were consistent for both obesity-related and non-obesity-related cancers. Estimation of population attributable fractions based on integrated global cancer incidence data, 1990-2021. First Author: Yongjie Xu, Office of Cancer Screening, National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China

Background: The global cancer burden is increasing, yet emerging risk factors for cancer incidence have not been comprehensively summarized in terms of the population attributable fraction (PAF) from a global perspective. **Methods:** We first searched and screened cancer risk factors from 435,977 studies in the Embase, PubMed, and Cochrane databases. Cancer risk effect sizes, such as RR (relative risk), HR (hazard ratio), and IRR (incidence rate ratio) values, were then obtained from meta-analyses. We further estimated population attributable fractions (PAFs) for each risk factor, cancer type, gender, SDI (Socio-demographic Index), modifiability, and trends from 1990 to 2021, using 94 pre-defined risk factors and 39 cancer types. These risk factors include lifestyle factors, environmental exposures, occupational risks, metabolic factors, comorbidities, and family or cancer history. **Results:** A total of 811 cancer risk effect sizes were obtained covering 75 countries or regions, including 18,084 cancer RR/HR/IRR values. In 2021, 64.1% (56.7% - 71.4%) of global cancer incidences were attributable to the evaluated risk factors, with modifiable risk factors accounting for 57.6%. Among the evaluated cancers, the proportion of incidence cases attributed to risk factors exceeded 50% in 26 types of cancer, with the leading cancers being cervical cancer (97.1%), Kaposi's sarcoma (91.2%), vaginal cancer (87.0%), lung cancer (84.6%), and laryngeal cancer (83.2%). In terms of individual risk factors, tobacco use (17.9%), infection (16.1%), and overweight or obesity (10.2%) contributed the highest PAFs, followed by family and genetic history (6.9%), alcohol consumption (5.7%), cardiovascular diseases (5.0%). The high SDI region shows a higher PAF (68.2% [61.5%–75.0%]) compared to the non-high SDI region (59.6% [52.2%–67.0%]). From 1990 to 2021, the global cancer incidences attributable to risk factors increased from 61.8% to 64.1%. Overweight or obesity, neurological and psychological disorders, and dietary factors were the top three leading increasing risk factors. **Conclusions:** The global cancer burden is significantly influenced by a wide range of modifiable and non-modifiable risk factors, with over 64% of cancer incidence in 2021 attributable to these factors. The rising trends in overweight or obesity, neurological and psychological disorders, and diabetes factors between 1990 and 2021 highlight the urgent need for targeted interventions to address these rapidly growing risks and reduction of the cancer burden. Development and clinical validation of a cell-free DNA methylation sequencing test for multi-cancer early detection. First Author: Xiaosheng He, The Sixth Affiliated Hospital, Sun Yat-sen University, Guangzhou, China

Background: Achieving robust early-stage sensitivity in multi-cancer early detection (MCED) poses challenges, relying on large cohorts of early-stage samples and reliable prediction frameworks. Particularly for gastrointestinal cancers (GICs) with poor compliance of screening, early-stage sensitivity in MCED remains insufficient. Moreover, accurate tumor localization is crucial for choosing subsequent diagnostic procedures but remains suboptimal. We evaluate the performance of Genie-seq within the ProFuture study (NCT05874648), focusing on its capacity to detect five high-mortality cancers: lung, colorectal, liver, stomach, and esophageal cancers. **Methods:** The ProFuture study is a prospective multicenter case-control study that initially enrolled 3,515 participants. Following evaluations and a minimum of a half-year follow-up, 3,036 participants remained analyzable. Participants were divided into training (920 cancer; 629 non-cancer), validation (300 cancer; 215 non-cancer), and independent validation (605 cancer; 367 non-cancer) sets. Plasma cfDNA underwent a 1000X target enzymatic methyl sequencing assay (Genie-seq) targeting cancer-specific methylation patterns identified from 2,420 tumor and plasma samples. The assay normalizes abnormal fragment reads within blocks to minimize interference, using a maximization model to select sensitive and robust features. A gradient-boosted tree model was developed to integrate these features for cancer prediction, utilizing a one-vs-rest strategy to determine the tissue-of-origin (TOO). **Results:** Specificity remained consistently high across all phases: 99.0% (95% CI: 97.7-99.6%) in training, 99.1% (96.7-99.9%) in validation, and 99.2% (97.6-99.8%) in independent validation. Sensitivity was 68.6% (65.5-71.6%) in training, 71.0% (65.5-76.1%) in validation and 69.6% (65.8-73.2%) in independent validation. In independent validation set, stages I-III (account for 85.5% of cases) sensitivity reached 65.8% (61.5-69.9%) for all cancer types and 72.1% (66.9-76.9%) for three GICs. The TOO classifier assigned the origin in all screen-positive cases, achieving an accuracy of 87.4% (83.9-90.4%) in independent validation, including reducing misclassification from lung to esophageal cancer due to squamous similarity to 4.5%. **Conclusions:** This MCED test accurately identified signals from five tumor types especially in the early stages. Precise TOO localization minimizes the healthcare burden of subsequent diagnoses. The consistency of performance from training to clinical validation underscores the robustness of feature selection strategy, mitigating the risk of overfitting. Notably, this study demonstrated exceptional sensitive detection of early-stage GICs, indicating the potential efficacy of Genie-seq in MCED within the ongoing interventional Prosight study (NCT06790355). Clinical trial information: NCT05874648. Research Sponsor: None.

Utilizing cancer community outreach and engagement to explain impact of age, income, residence, knowledge, and survivorship on cancer fatalism in urban and rural/marginalized areas. First Author: Runcie C.W. Chidebe, Project Pink Blue- Health and Psychological Trust Centre, Abuja, FCT, Nigeria

Background: Nigeria has the highest cancer burden in sub-Saharan Africa, with 124,815 incidences and 78,899 deaths. Popular fatalistic beliefs such as *"cancer is a death sentence"* and *"cancer is not my portion"* exist in this population, which potentially affects cancer prevention, early detection and increases poor treatment outcomes. Yet, factors responsible for these fatalistic cancer beliefs remain largely unknown. This study utilized cancer community outreach and engagement (COE) to understand cancer health disparities among Nigerians. Specifically, we assessed the association of age, income, residence, cancer knowledge, screening, survivorship, and current health on cancer fatalism (i.e., the view that cancer is a death sentence) in Nigeria. **Methods:** A cross-sectional study was used to collect data from participants (n = 1457, 18-68 years old), in two COE events and two marginalized communities. Participants completed questionnaires via self-assessment. Multiple linear regression was used to analyze the data. **Results:** Our findings showed that individuals who had not previously participated in cancer COE events reported higher cancer fatalism ($\beta = 1.21$, $p < 0.001$) compared to those who had previously participated. More cancer knowledge was related to lower cancer fatalism among participants ($\beta = -0.21$, $p = 0.002$). Participants who reported lower monthly income ($\beta = 1.05$, $p = 0.002$) and those who reported mid-low monthly income ($\beta = 1.28$, $p < 0.001$) had higher cancer fatalism. Participants aged 30-49 ($\beta = 0.46$, $p = 0.049$), residing in rural communities ($\beta = 0.62$, $p = 0.006$), and those who were married ($\beta = 0.51$, $p = 0.029$) reported higher cancer fatalism. **Conclusions:** Our study showed that participating in cancer COE events may lower cancer fatalism. The global cancer control communities, donor agencies, and Nigeria's National Institute on Cancer Research and Treatment need to encourage more COE events as a crucial strategy for early detection and closing the cancer disparity gaps. There is a need for more cancer awareness and policy advocacy on cancer in this population. Research Sponsor: None.

Machine learning–informed navigation of patients in persistent poverty zip codes to improve colorectal cancer screening: A prospective controlled study. First Author: Ravi Bharat Parikh, Emory University, Atlanta, GA

Background: Colorectal cancer (CRC) screening remains suboptimal, particularly in racially diverse and low-income populations. Machine learning (ML) algorithms trained on routine electronic health record (EHR) data may accurately predict CRC risk. Further, patient navigation programs can address screening barriers such as lack of transportation access and low health literacy around colonoscopy preparation. We tested the impact of an intervention combining ML-based risk stratification and an evidence-based CRC screening navigation program on CRC screening rates and outcomes. **Methods:** This prospective nonrandomized controlled study (NCT05383976) was conducted at a large academic health system, enrolling adults over 50 years of age and at average-risk of CRC. All adults resided in Persistent Poverty zip codes (defined by the US Census Bureau) in the Philadelphia metro area, were attributed to a primary care physician (PCP), and had a colonoscopy order that had not been completed within the past 6 months. We adapted a validated ML algorithm that was previously trained on 22 variables – including age, sex, and longitudinal complete blood counts – to predict CRC risk. Patients enrolled in the intervention arm were prioritized by the ML algorithm for a structured navigation program, including risk-targeted phone-based education, appointment facilitation, transportation support, and mailed FIT tests. A concurrent control cohort received navigation but was not prioritized by the ML algorithm. Adjusted logistic regression models assessed the intervention's impact on the co-primary outcomes of (1) CRC screening completion (colonoscopy or FIT), and (2) positive screening result, defined as precancerous adenoma (sessile serrated, inflammatory, villous, malignant) and/or positive FIT. **Results:** 382 patients were enrolled (199 intervention, 183 control). Among intervention patients, 71.4% were reached via phone and 66.4% scheduled screening, with 26.2% and 17.6% completing colonoscopy and FIT, respectively (see Table). Screening completion was similar for intervention vs. control (46.2% vs. 43.2%; adjusted OR 1.02, 95% CI 0.67-1.56, p=0.93). For intervention vs. control, precancerous adenoma detection was 8.5% vs. 5.2% (aOR 2.43, 95% CI 0.48–12.3, p=0.57) and tubular adenoma detection was 35.6% vs. 25.0%. **Conclusions:** ML-informed navigation was feasible, did not increase screening engagement, and marginally increased rates of precancerous and tubular adenoma detection. Refinements in ML risk stratification and enhanced navigator outreach may maximize impact. Clinical trial information: NCT05383976. Research Sponsor: National Cancer Institute.

Clinical and radiological characteristics of intermediate and high-risk cases in the Brazilian early lung cancer screening trial (BRELT3): Insights into Lung-RADS categories 3 and 4 and biopsy decision-making factors. First Author: Audrey Cabral Ferreira de Oliveira, Postgraduate Program in Clinical and Translational Research (PgPCT), Gonçalo Moniz Institute (IGM), Fiocruz Bahia, Salvador, Brazil

Background: Lung cancer is the leading cause of cancer death worldwide, and low-dose computed tomography (LDCT) effectively reduces mortality through early detection. BRELT1 and BRELT2, from the Propulmão initiative, highlighted the feasibility of lung cancer screening (LCS) programs in Brazil. This report examines demographic and radiological characteristics of patients with Lung-RADS (LR) 3 and 4 nodules in BRELT3, a mobile LDCT-based LCS initiative, and factors influencing biopsy indication. **Methods:** This prospective cohort study included current or former smokers (cessation ≤15 years), with a smoking history of ≥20 pack-years, aged 50–80 years. Those with LDCT classified as LR 3 or 4 were analyzed, and clinical and tomographic data were collected. The Brock malignancy probability model (PMB, 10% threshold) was applied retrospectively to assess its association with biopsy indication. Statistical methods included logistic regression, t-test, Mann-Whitney, chi-square, and Fisher's exact test. Ethical Committee approval was obtained (SENAI-CIMATEC / Santa Izabel Hospital; n° 67431523.6.0000.9287 / 67431523.6.3001.5520). **Results:** Among 2018 screened patients, 223 (11.1%) had findings for lung cancer risk, Of these, 44.4% classified as LR3 and 55.6% as LR4. Median age was 64 years, with 87.4% self-identified as Black, 63.2% as current smokers, and 75.8% reported no family history of lung cancer. Nodules were predominantly single (82.5%) and solid (77.1%), with a mean size of 13.12 mm. LR3 nodules were smaller (9.53 mm) and exhibited lower PMB (7.43%) compared to LR 4 (15.99 mm; PMB: 18.93%). Biopsy was indicated for 45 participants (98% LR4). Nodules requiring biopsy were larger (22.97 vs 10.63 mm) and had higher PMB (26.44 vs 10.64%). Predictors for biopsy included irregular or spiculated contours (OR 5.83; $p < 0.05$), LR4B/4X vs.4A classification (OR 5.00; $p < 0.05$), PMB > 10% (OR 5.36; $p < 0.05$) and nodule size (OR 1.10; $p < 0.05$). Of the 45 nodules indicated for biopsy, 24 underwent the procedure, and 5 progressed to surgery. **Conclusions:** Mobile LDCT-based screening programs showed potential in identifying high-risk nodules among underserved populations. Factors influencing biopsy decisions included nodule size, irregular or spiculated contours, LR 4B/4X classification, and PMB > 10%. Integrating PMB into LCS may improve diagnostic accuracy and biopsy decision-making, enhancing early lung cancer detection. Research Sponsor: Bristol-Myers Squibb Foundation; Boehringer Ingelheim Brazil; Diagnósticos da América S.A. (DASA); AstraZeneca Brazil; Lung Ambition Alliance; Ethicon Brazil; Panther Brazil.

Association between nodules' characteristics and biopsy indication.

Characteristic (n = 45)	OR (CI 95%; p-value)*
Irregular or spiculated contours	5.83 (2.86 - 11.88; $p < 0.05$)
Lung-RADS 4B/4X vs.4A	5.00 (1.61 - 15.54; $p < 0.05$)
PMB - %	1.05 (1.03 - 1.07; $p < 0.05$)
Nodule size - mm	1.10 (1.06 - 1.13; $p < 0.05$)

Cost-effectiveness analysis of population-based screening for 6-gene panel testing for hereditary breast and ovarian cancer. First Author: Giovanni Galvis Rojas, Department of Health, Medicine and Caring Sciences (HMV), Linköping University, Linköping, Sweden

Background: Genetic testing for hereditary breast and ovarian cancer (HBOC) has relied on clinical and family history criteria. This approach, has been shown to overlook a significant number of mutation carriers who could benefit from preventative measures. Increasing evidence supports genetic testing in an unselected population, which facilitates the identification of more carriers and allows for the implementation of risk reduction strategies. The aim of this study is to evaluate the cost-effectiveness of utilising an expanded gene-panel in an unselected female population. **Methods:** A Microsoft Excel-based simulation model of a hypothetical cohort of unselected and previously untested 30 years old women was devised to assess three strategies. Strategy 1: genetic testing of unselected women for mutations of a 6-gene panel *BRCA1*, *BRCA2*, *PALB2*, *ATM*, *CHEK2* and *TP53*, Strategy 2: screening to individuals fulfilling family history (FH) criteria for HBOC testing and Strategy 3: no genetic screening. New Generation sequencing (NGS) using TrueSight hereditary cancer panel from Illumina was used as testing platform. The analysis includes quality adjusted life year (QALY) as a health outcome. The incremental cost-effectives ratio (ICER) is calculated using health-care costs and QALYs per treatment strategy, illustrating the additional cost in relation to the additional health benefit (QALYs) associated with the 6 gene-panel strategy compared to the FH-based strategy. One-way sensitivity analyses expressed as ICER, evaluates the uncertainty and the impact of specific parameters on the results. **Results:** A cohort of100 000 unselected women was simulated through the model over 80 cycles as well as women meeting criteria for HBOC investigation. The mutation carriers detected were 1307 and 191 for the unselected population group and FH respectively. As direct effect, 339 risk reducing surgeries (mastectomy or/and salpingo-oophorectomy) were performed in the strategy 1 compared with 50 in the strategy 2. The probabilistic analysis shows that if the willingness to pay is €100.000 per QALY, the unselected population-based testing has 75% probability of being cost-effective. **Conclusions:** Population-based screening with a six-gene panel has 75% probability to be cost-effective if the willingness to pay is over €100 000. This strategy reduces the number of (HBOC) cases and cancer specific mortality which strengthens the benefits of this screening strategy in cancer prevention. Research Sponsor: None.

The potential of multi-cancer early detection screening in reducing cancer incidence and mortality in high-risk groups: A modeling study. First Author: Jagpreet Chhatwal, Massachusetts General Hospital Institute for Technology Assessment, Harvard Medical School, Boston, MA

Background: Emerging liquid biopsy multi-cancer early detection (MCED) tests have the potential to revolutionize early cancer detection. Using a simulation model, we estimated their impact on cancer incidence and mortality in high-risk groups. **Methods:** We developed Simulation Model for MCED(SiMCED), a microsimulation model of 14 solid tumor cancer types. MCED test sensitivities were derived from the ASCEND-2 case-control study. Using a 10-year horizon, we simulated the life course of 100,000 adults aged 50-84 years, representing the US general population. In addition, we simulated screening in three high-risk groups: smokers (former and current), heavy alcohol users, and individuals with a family history of cancer in ≥1 first-degree relatives (FDRs). Cancer diagnosis could arise from usual care or annual MCED screening. After a cancer diagnosis, individuals followed SEER survival curves to determine the time and cause of death (cancer- or non-cancer-related). **Results:** The table presents overall 10-year reductions in stage IV cancer incidence and mortality per 100,000. Among smokers, MCED screening had the greatest impact (in absolute reduction terms) on lung cancer, which accounted for more than 50% of late-stage incidence. Compared to usual care only, MCED screening reduced stage IV lung cancer incidence by 43% (2,028 vs 1,146) and cancer mortality by 16% (2,589 vs 2,247). Among heavy alcohol users, MCED screening had the greatest impact on lung, colorectal, and head and neck cancer. The stage IV incidence reduction in these three cancer types were, respectively, 44% (805 vs 454), 57% (286 vs 122), and 33% (398 vs 265). The cancer mortality reduction in these three cancer types were, respectively, 14% (1,014 vs 876), 33% (371 vs 248), and 16% (265 vs 223). In the familial cancer cohort, MCED screening had the greatest impact on lung, colorectal, and pancreatic cancer. The stage IV incidence reduction in these three cancer types were, respectively, 44% (821 vs 461), 57% (257 vs 111), and 58% (233 vs 98). The cancer mortality reduction in these three cancer types were, respectively, 14% (1,030 vs 888), 33% (328 vs 220), and 14% (326 vs 279). **Conclusions:** MCED screening demonstrates potential to reduce late-stage cancer incidence and mortality in both the general population and high-risk groups. These findings highlight the value of MCED tests in advancing early detection and improving cancer outcomes. Research Sponsor: Exact Sciences Corporation.

Cohort	Usual care: Stage IV cancer incidence	Usual care + MCED: Stage IV cancer incidence	Reduction: Stage IV cancer incidence	Usual care: Cancer mortality	Usual care + MCED: Cancer mortality	Reduction: Cancer mortality

One-year impact of a large-scale pilot multimodal personalized early cancer detection and prevention program for individuals at high risk of cancers. First Author: Tarek Ben Ahmed, Department of Cancer Medicine, Gustave Roussy, Villejuif, France

Background: The Interception program (IP) is a unique initiative aiming to assess the value of a dedicated personalized care pathway for individuals at high risk (HR) of different cancers. IP includes identification of HR individuals in primary care, a One-Day-Clinic (ODC) (including individual care and workshops aimed at information, education, awareness; informed prevention decisions on an evidence-based shared personalized early detection and prevention plan), implementing and monitoring this plan with community professionals and MyIntercception digital follow-up. **Methods:** This prospective, cohort study analysed data from participants who entered IP between Jan 2021 and May 2023. Eligible participants were adults at high risk of breast (> 2.5% at 5 yrs), lung (> 1.6% at 5 yrs), prostate, pancreatic cancer, or Lynch syndrome. Data cut-off was June 2024. Primary endpoint was the 1-yr adherence rate to planned screening and risk-reduction measures (RRM), (the latter defined by full smoking cessation for smokers, or >1 point improvement of WCRF score for others (or stable if was >5 out of 7). Secondary endpoints were awareness of risk, screening and prevention measures, and cancer incidence. We assessed factors associated with 1-yr adherence to screening and RRM. **Results:** 719 participants were eligible for the present assessment, median age 50 (range 21-81), 80% female. 83% tertiary education, 38% active smokers, at HR of breast (360), lung (281), other (78) cancers. Median baseline WCRF score was 4 (range 0.5-7), 65% had a score < 5. At 1 yr, global adherence to both screening and RMM was 57%. Adherence to screening measures was between 82 and 100% overall. The 1-yr median WCRF score (N = 290) was 4.5 (range 1.25–7) (p = < 7.8e-07 vs baseline), 41% had improved (> = 1 point) their score while 7.4% had remained stable >5. However, only 18% smokers succeeded in fully quitting smoking. The crude incidence of new cancer cases was 1.5%. We found major improvements in perceived knowledge and in the accuracy of self-estimated cancer risk scores 8 days after the ODC (p = < 2.2 e-16). In the multivariable logistic regression analysis, increasing age was associated with higher odds of global adherence (OR = 1.02 per year, 95% CI [1.001, 1.046], p = 0.03). Male sex was associated with a trend toward increased adherence (OR = 1.7, 95% CI [0.97, 3.15], p = 0.06). Smokers had significantly lower odds of adherence compared to other risk categories (OR = 0.17, 95% CI [0.09, 0.3], $p < 0.0001$). Among smokers, male sex was significantly associated with higher odds of adherence compared to female sex (OR = 2, 95% CI [1.1, 3.6], p = 0.01). **Conclusions:** IP demonstrated promising results in promoting cancer risk reduction and achieving satisfactory adherence to screening among HR individuals. However, challenges remain, particularly in enhancing adherence to RRM and reaching less educated populations. Clinical impact of integrating polygenic risk scores with breast cancer risk assessment models: Results from the prospective multisite GENRE-2 clinical trial. First Author: Siddhartha Yadav, Mayo Clinic, Rochester, MN

Background: Incorporation of Polygenic Risk Scores (PRS) can refine traditional breast cancer risk assessment models to provide precise estimates of breast cancer risk. However, the impact of such an integrated model on clinical decision-making related to breast cancer surveillance and preventive strategies is not fully understood. **Methods:** The GENRE-2 is a prospective single-arm multisite clinical trial (NCT04474834) incorporating PRS into standard breast cancer risk assessment models to determine the impact of PRS on clinical decisions on breast cancer prevention and surveillance. Women at high risk of breast cancer due to NCI-BCRAT 5-year risk of $\geq$ 3%, or IBIS (Tyrer-Cuzik) 10-year breast cancer risk of $\geq$5%, biopsy-proven high-risk breast lesion, or a pathogenic variant (PV) in *ATM*, *BRCA1, BRCA2, CHEK2* or *PALB2*, were enrolled from five sites in the United States. All women were invited to complete surveys on their breast surveillance and cancer prevention decisions based on pre-PRS standard risk models and post-PRS risk estimation, and further annual surveys are planned for 10 years. **Results:** Among 902 women enrolled in the study, 605 (median age: 52 years) received PRS results and completed a survey to date. Of those who received PRS results,195 (32.2%) were PV carriers. Among non-carriers, the median 10-year and lifetime pre-PRS IBIS-based risk was 10.0% and 28.7%, respectively. Among PV carriers, the CanRisk-based 10-year and lifetime pre-PRS risk estimates were 6.3% and 25.2% for *ATM*, 22.3% and 77.6% for *BRCA1*, 18.5% and 77.7% for *BRCA2*, 7.1% and 25.7% for *CHEK2*, and 16.8% and 38.0% for *PALB2* PV carriers, respectively. After the incorporation of PRS, the lifetime risk of breast cancer increased by at least 10% in 31% of non-carriers and 7.7% of PV carriers and decreased by at least 10% in 10.7% of non-carriers and 7.7% of PV carriers. The proportion of non-carriers with lifetime risk $<$ 20% or $>$ 40% changed from 17.3% and 22.0%, respectively, in the pre-PRS evaluation to 24.4% and 32.9%, in the post-PRS evaluation. A higher lifetime post-PRS score was associated with intent to take preventive action (surgery or endocrine agents). In non-carriers, the proportion of women with a lifetime risk $<$ 20% with intent to take preventive action was 11%, compared to 36.8% of those with a lifetime risk $>$ 40% ($p < 0.001$). Similarly, in PV carriers, the proportion of women with lifetime risk $<$ 20% with intent to take preventive action was 20.8% compared to 41.1% of those with lifetime risk $>$ 40% ($p = 0.015$). **Conclusions:** The GENRE-2 trial demonstrates that the incorporation of PRS into breast cancer risk assessment models in high-risk women is feasible and leads to clinically meaningful changes in breast cancer risk estimates and decision-making regarding preventive strategies. Evaluation of the implementation of breast cancer risk management strategies in study participants is ongoing and will be reported. Clinical trial information: NCT04474834. Research Sponsor: J. Christopher and Anne N. Reyes Foundation.

Genetic predictors of 16,000 multi-omic traits and associations with breast cancer survival outcomes in the Pathways Study. First Author: Arya Mariam Roy, The Ohio State University, Columbus, OH

Background: Polygenic scores (PGS) enable the computation of a genetic predictor for any trait where a well-developed algorithm is available. This is appealing when such trait is not directly measured in the study population for association testing. Based on a large prospective breast cancer cohort, we calculated and investigated the prognostic value of $>$16,000 PGS of multi-omic traits, including plasma proteomics, plasma metabolomics, and whole-blood transcriptomics. **Methods:** The Pathways Study is a prospective cohort study of women with breast cancer who were enrolled soon after diagnosis in 2006-2013 at Kaiser Permanente Northern California, with ongoing follow-up. Using genome-wide genotypes from 3,995 study participants, we calculated 16,020 multi-omic PGS from the INTERVAL study (https://www.omicspred.org/). We analyzed three outcomes: overall survival (OS), breast cancer specific survival (BCSS), and disease-free survival (DFS), with a median (range) follow-up time of 10.5 (0.2-14.2) years. We derived hazard ratios (HRs) and 95% confidence intervals (CIs) for one standard deviation (sd) increment in PGS from multivariable hazards models in the total study population, among those self-reported as non-Hispanic White (NHW), and by tumor estrogen receptor (ER) status in NHW women, with multiple testing corrected by a false discovery rate (FDR) of $q<0.10$. **Results:** The median age at diagnosis was 60 (23.6-94.8) years, with the majority of the study population (68%) self-identifying as NHW. Most women had ER+ tumors (83.4%), diagnosis at stages I and II (89%), and 13.3% had HER2+ tumors. The majority (60%) had lumpectomy and adjuvant therapy (44.3% radiotherapy, 47.0% chemotherapy, 74.6% hormonal therapy). Four PGS-survival outcome tests reached statistical significance with an FDR $q<0.10$, notably all between gene expression PGS and OS, including OPGS013029 for *TINCR* in NHW patients, and OPGS011920 for *TTLL7*, OPGS009036 for *RNF4*, and OPGS011365 for *GGT7* in NHW ER- patients (Table). None of the PGS for proteomic or metabolomic traits reached this level of significance after controlling for multi-testing. **Conclusions:** By leveraging a large catalog of PGS of multi-omic molecular traits, we identified PGS for whole-blood RNA expression for four genes in significant associations with overall survival. Pending on validation in future studies, these genes may have prognostic value for breast cancer. Research Sponsor: None.

PGS of multi-omics traits and associations with OS in the pathways study.

Study population (race, ER status)	PGS	Outcome	Multi-omic trait	HR (95%CI) per sd increment of PGS	p	FDR q

Impact of 2021 United States cancer screening guideline changes on racial and ethnic differences in patient-reported adherence to age-appropriate colorectal cancer screening. First Author: Nishwant Swami, Hospital of the University of Pennsylvania, Philadelphia, PA

Background: In 2021, the US Preventive Services Task Force and the US Multi-Society Task Force on Colorectal Cancer updated screening guidelines to recommend that average-risk colorectal cancer (CRC) screening should begin at age 45. We used nationally representative survey data to assess CRC screening among patients across racial/ethnic groups ages 45-49 and 50+ before and after the 2021 guideline changes. **Methods:** 2019-2023 biannual data from the National Health Interview Survey (NHIS) was used to select individuals aged $\geq$45 years old who responded regarding receipt of appropriate CRC screening. Patients with prior history of CRC or missing data were excluded. Survey-adjusted percentages were used to characterize differences in CRC screening adherence by racial/ethnic group. Multivariable logistic regression models adjusting for age, gender, year, marital status, and geography generated adjusted odds ratios (aORs) with 95% CI to examine associations of race/ethnicity and CRC screening adherence. **Results:** 188,620 patients met inclusion criteria. Overall, patients aged $\geq$50 had similar CRC screening prevalence before and after guideline changes (58% vs. 61% pre- and post-change) while patients aged 45-49 years had a 10% increase in appropriate screening (21% vs 31% pre- and post-change); largest screening increase was in Non-Hispanic Black (13.92% increase) and Non-Hispanic Asian patients (12.76%) while smallest increase was noted in Hispanic patients (7.05% increase). Prior to guideline changes, among patients 45-49 years old, Asian patients (aOR: 0.45 95%CI: 0.24-0.86) were less likely to report cancer screening compared to non-Hispanic White patients. After guideline changes, among patients 45-49 years old, patients identifying as Asian (aOR: 0.56 95% CI 0.34-0.92) and Hispanic (aOR: 0.62 95% CI 0.41-0.94) were less likely to report age-appropriate cancer screening compared to non-Hispanic White patients, while there was no difference for non-Hispanic Black patients (aOR: 1.31 95% CI 0.91-1.89). Year-age interaction was significant ($p <$ 0.001), while year-race interaction was not significant. **Conclusions:** Our study highlights that while patient-reported adherence to CRC screening increased among patients 45-49 years old after updated screening guidelines, screening disparities were observed among Asian and Hispanic patients. Guidelines had a distinct impact on pts aged 45-49 in relation to pts $\geq$50 who were not impacted by the changes. The time-race interaction was not significant, suggesting no evidence of improvement in the degree of disparity. Patient reported CRC screening rates after guideline changes among pts 45-49 is lagging compared to pts $\geq$50; further work is needed to implement the updated guideline recommendations and improve screening adherence. Bariatric surgery and risk of gastrointestinal and hormone-sensitive cancers in patients with metabolic-associated steatotic liver disease and obesity: A multicenter matched cohort study. First Author: Diptasree Mukherjee, Apex Institute of Medical Science, Kolkata, India

Background: Metabolic-associated steatotic liver disease (MASLD) is strongly associated with an increased risk of hormone-sensitive and gastrointestinal (GI) malignancies due to obesity-related pro-inflammatory states and altered hormone metabolism. Bariatric surgery (BS) has shown promise in ameliorating MASLD and obesity-related comorbidities; however, data on its potential to reduce cancer risk in this population remain scarce. Hence, we aimed to assess the impact of BS on the risk of hormone-sensitive and GI cancers in patients with MASLD and obesity using a multicenter, matched cohort design. **Methods:** We conducted a retrospective cohort study utilizing the TriNetX. Patients who underwent BS (including Roux-en-Y Gastric Bypass and Sleeve Gastrectomy) were included in the BS cohort and matched controls who are standard of care without a history of BS. We performed 1:1 propensity score matching (PSM) to reduce confounder factors, including demographics, comorbidities, BMI, nicotine dependence, and family history of malignancy. A 1-year lag time was applied to minimize protopathic bias. Cox proportional hazard analysis was performed to calculate hazard ratios (HR) for overall cancer risk, hormone-sensitive cancers (endometrial, breast, prostate, kidney, and ovarian), and GI cancers (colon, rectal, pancreatic, biliary, and hepatocellular). **Results:** A total of 9848 patients with MASLD underwent BS, while 183837 MASLD patients had no history of BS. After PSM, 9791 patients were included in each cohort. The mean follow-up was 4.8 years for BS and 5.1 years for controls. BS was associated with a significantly lower overall cancer risk (HR: 0.72 (0.65-0.80)). Among hormone-sensitive cancers, BS patients demonstrated reduced risks of endometrial (HR 0.50) and breast cancer (HR 0.62), with no significant differences for prostate, ovarian, lung, or thyroid cancer. A lower risk of kidney cancer was noted (HR 0.91). For GI malignancies, BS patients had a reduced risk of HCC (HR 0.32), malignant neoplasms of the cholangiocarcinoma (HR 0.29), pancreatic cancer (HR 0.18), and colon cancer (HR 0.53). No differences were observed for esophageal or gastric cancers. **Conclusions:** In this large multicenter analysis, BS was associated with a significantly lower risk of hormone-sensitive and GI cancers in patients with MASLD and obesity. These findings suggest that weight loss and improved metabolic profiles following surgery may mitigate the pro-inflammatory and pro-neoplastic effects of obesity and MASLD. Further research is needed to explore BS's underlying mechanisms and long-term cancer prevention benefits. Research Sponsor: None.

Escalating burden and trend of cancer attributable to smoking in Southeast Asia, east Asia and Oceania from 1990-2021: A benchmarking systematic analysis. First Author: Abdullah Jamal, Baptist Hospitals of Southeast Texas, Beaumont, TX

Background: Cancer (CA) is a leading cause of death and disability in Southeast Asia (SEA), East Asia (EA), and Oceania. Among the various risk factors, smoking is notably the most preventable. Its strong association with various CA types underscores the urgent need for effective tobacco control measures as a cornerstone of CA prevention strategies. **Methods:** This study utilized the standardized methodology of the Global Burden of Disease Study 2021 to estimate deaths, disability-adjusted life years (DALYs), and years lived with disability (YLDs) attributable to smoking for 16 types of CA in SEA, EA and Oceania, stratified by age, sex, year, and location from 1990-2021. The results are presented in absolute counts and age-standardized rate. **Results:** The annual percentage change (APC) in the total number of deaths due to CA attributable to smoking increased by +2.64%, DALYs by +2.16%, and YLDs by +3.57% from 1990-2021. Regionally, the highest increase in APC was observed in EA, with deaths at +2.67% and DALYs at +2.14%. For age-standardized mortality rates (ASMR), highest increases in APC were observed in Indonesia (+0.81%), Kiribati (+0.02%), Marshall Islands (+0.56%), and Niue (+0.16%), while declines were observed in most other regions. By cancer type, the highest increases in APC in deaths were observed due to kidney CA (+4.43%), pancreatic CA (+3.54%), tracheal, bronchus, and lung CA (+3.45%), lip and oral cavity CA (+3.29%), and prostate CA (+3.23%). Moderate increases were observed due to colon and rectum CA (+2.87%), leukemia (+2.76%), bladder CA (+2.13%), liver CA (+1.81%), breast CA (+1.76%), larynx CA (+1.59%), esophageal CA (+1.50%), other pharynx CA (+1.35%), stomach CA (+0.83%), and cervical CA (+0.62%). Nasopharynx CA was the only type to show a slight decline (-0.03%). By age, an APC of +0.90% was observed in deaths among individuals aged 20-54 years and +2.97% among those aged 55+ years. By gender, APC for deaths were +2.69% in males and +2.18% in females, DALYs were +2.19% in males and +1.80% in females, and YLDs were +3.63% in males and +3.04% in females. **Conclusions:** Deaths due to CA attributable to Smoking accounted for 60.31% of all attributable risk factors in 2021. The observed increases in the APC in deaths, DALYs, and YLDs due to smoking-attributable cancers highlight a significant and growing public health burden, particularly in EA and among males and older age groups. These trends emphasize the need for strengthened tobacco control policies, early CA detection programs, and targeted public health interventions to address regional and demographic disparities. For clinicians, these findings underscore the importance of prioritizing smoking cessation counseling, routine CA screenings, and personalized treatment strategies to mitigate the impact of smoking-related CA. Global burden and trend of pancreatic cancer in high-income countries: A 30-year analysis of disease dynamics. First Author: Anmol Singh, Internal Medicine, John H Stroger Hospital of Cook County, Chicago, IL

Background: Pancreatic cancer (PC) has a disproportionately high impact in high-income countries (HIC), where it ranks as the 3rd leading cause of cancer-related deaths, compared to 6th globally. **Methods:** This study is the first ever systematic analysis estimating the incidence, prevalence, mortality, disability, and associated risk factors of PC across the HIC and its territories from 1990-2021. Using a standardized approach, this analysis examines data by age, sex, year, and location, using insights from the Global Burden of Disease Study 2021. The results are presented in absolute count and age-standardized rate (per 100,000). **Results:** From 1990-2021, the total prevalence counts increased from 89,475 (95% UI: 85,159–92,609) to 214,254 (95% UI: 192,172–227,351), while deaths rose from 105,828 (95% UI: 99,853–109,660) to 216,444 (95% UI: 193,299–230,784). Concurrently, disability-adjusted life years (DALYs) increased from 2.3 million (95% UI: 2.2–2.3) to 4.1 million (95% UI: 3.8–4.3). Western Europe exhibited the highest regional burden throughout the study period. Nationally, Denmark demonstrated the highest annual percentage change (APC) in the age-standardized incidence rate (ASIR) at 1.34%, followed by France (1.18%), Switzerland (0.85%), Germany (0.82%), and the United States (0.33%). Similarly, the highest APC in the age-standardized mortality rate (ASMR) was observed in Denmark (1.25%), followed by Switzerland (0.78%), France (0.73%), and the United States (0.20%). In 2021, the age group 70–74 years recorded the highest incidence (36,968; 95% UI: 34,001–38,744), mortality (34,990; 95% UI: 32,218–36,771), and DALYs (703,300; 95% UI: 646,488–738,141). Gender-specific analyses revealed that females exhibited a greater burden increase, with APCs of 0.52% in ASIR and 0.30% in ASMR, compared to 0.28% and 0.10%, respectively, in males. Notably, the age-standardized DALY rate (ASDALR) increased by 0.20% in females but decreased by 0.05% in males. **Conclusions:** Deaths due to PC accounted for 7.77% of all cancer related casualties in 2021 in HIC. The concentration of disease burden in older populations (70–74 years) and the greater increase observed in females compared to males highlight critical demographic and gender-specific disparities. Furthermore, the increase in DALYs, even in regions with stabilizing or declining mortality, calls for enhanced strategies to address long-term disability and improve quality of life. Research Sponsor: None.

Annual percentage of change in pancreatic cancer from 1990-2021 in high income region, age-standardized rate (per 100,000).

High Income Region	AAPC (%), 1990-2021, ASIR	AAPC (%), 1990-2021, ASMR	AAPC (%), 1990-2021, ASDALR
Australasia	0.38	0.15	0.01
High-income Asia Pacific	0.42	0.22	-0.01
High-income North America	0.29	0.14	0.04

Evaluation of a plasma cell-free DNA methylation-based multi-cancer detection test. First Author: Yupeng He, Guardant Health, Palo Alto, CA

Background: Blood-based multi-cancer detection (MCD) tests hold promise for early cancer detection. MCD tests should demonstrate high specificity, clinically meaningful sensitivity, and provide information to guide clinical diagnostic evaluation. **Methods:** We developed an MCD test that leverages a next-generation sequencing epigenomics hybrid capture assay (Shield) to measure DNA methylation in regions differentially methylated across solid tumor cancers. We then implemented a two-step classification algorithm. First, a regression model (multi-cancer classifier) was trained to distinguish cancer from non-cancer samples at 98% target specificity. Next, a cancer signal of origin (CSO) model was trained to categorize 10 solid tumors (Table 1) in samples predicted to be cancer. The test was evaluated in a blinded case-control cohort of plasma samples (3mL; Streck) from adults with treatment naïve cancer, or who were self-reported cancer free with 1 year of follow-up (NCT05334069). **Results:** Final evaluable dataset was 962 participants (excludes 31 (3.1%) that failed quality control). Median age was 62 years (range: 40-78). 55% were female. Self-reported race was 81% White. Observed specificity was 98.6% (436/442). Sensitivity for the 10 cancer types included in the CSO model was 59.7% (224/375) and was 55.7% (263/472) overall when incorporating 4 solid tumor types not included in the CSO model. Primary or secondary CSO prediction was 92% accurate for the cancer types included (Table 1). **Conclusions:** In this cohort, this MCD test shows 59.7% sensitivity, 98.6% specificity, and 92% primary or secondary CSO accuracy for the cancer types included. Integrating an MCD test with an FDA approved blood-based CRC screening test may increase the MCD clinical value in the intended use population, which should be studied further. A version of this MCD test is being studied in a prospective, interventional study evaluating MCD testing feasibility. Research Sponsor: None.

Incidence of viral and non-viral etiologies of hepatocellular carcinoma (HCC) in the US over time by race and ethnicity. First Author: Mona Cai, AbbVie, Inc., North Chicago, IL

Background: HCC has an incidence of 5–6 cases per person-yr in the US, with varying rates among different racial and ethnic groups. While viral HCC accounts for ~50% of all HCC cases in North America, recently, a shift from viral to non-viral HCC was observed in the US. Here, we investigate the incidence of viral and non-viral HCC over time across different racial and ethnic groups in the US. **Methods:** This is a cross-sectional study using data from the TARGET-HCC registry, a longitudinal observational cohort study enrolling adult patients (pts) with newly diagnosed HCC across 43 academic and community centers in the US. Pts were enrolled from 1 Jan 2017 to 30 Sep 2023, and consented to share medical records 36 mo retrospectively and prospectively for up to 60 mo. **Results:** Among 2,924 enrolled pts, etiology was available for 2,139 (73%). Median (IQR) age was 64 (59, 68) yr and 77% were male. At HCC diagnosis, 66% of pts had BCLC stage 0/A, 16% BCLC B, 13% BCLC C, and 6% BCLC D; 69% of pts had Child-Pugh class A, 26% class B, and 5% class C. 1,727 (81%) pts had underlying cirrhosis. 1,484 (72%) pts were White, 414 (20%) Black/African American (Black/AA), 86 (4%) Asian/Native Hawaiian or Pacific Islander (Asian/NH/PI), and 68 (3%) American Indian/Alaskan Native. 1,786 (87%) pts were of non-Hispanic ethnicity and 257 (13%) of Hispanic ethnicity. The incidence of viral and non-viral HCC over time by race and ethnicity is shown in the Table. In the overall population, although the incidence of viral HCC decreased over time, it remained higher than that of non-viral HCC across all periods. The proportion of pts diagnosed with viral vs non-viral HCC was 75% vs 59% in 2014–2016, 69% vs 55% in 2017–2019, and 65% vs 57% in 2020–2023. **Conclusions:** Despite variations in the number of pts enrolled in each period, there is an overall trend of decreasing incidence of viral HCC over time across all racial groups. The incidence of viral HCC has declined among non-Hispanics but increased among Hispanics. Nevertheless, non-viral liver disease remains the most common cause of HCC in Hispanics. Research Sponsor: AbbVie Inc.; n/a.

Early-onset (EO) cancer trends in Brazil: A comprehensive analysis of hospital-based cancer registry data (2000–2019). First Author: Wesley Rocha Grippa Sr., Universidade Federal do Espírito Santo, Vitoria, Brazil

Background: The rising incidence of early-onset (EO) cancers (< 45 years) since the 1990s presents a global public health challenge. In Brazil, Hospital-Based Cancer Registries (HCR) provide essential data for understanding cancer epidemiology, encompassing diagnosis, treatment, and outcomes. This study analyzes temporal trends in EO cancer incidence rates (IR) and clinical data in Brazil from 2000 to 2019. **Methods:** A retrospective cohort study was conducted using data from the Brazilian HCR system (SIS-RHC). Individuals aged 19–44 years, diagnosed with malignant neoplasms (ICD-10) and treated within Brazil's oncology network, were included. Temporal trends in cancer incidence (2000–2019) were evaluated using the Mann-Kendall test, and bivariate analyses explored associations between demographic and clinical variables. **Results:** A total of 701,115 individuals were included (mean age: 35 years, SD: 6.62); the cohort was predominantly female (71.9%), non-white (54%), with basic education (49%), and residing in the southeast region (44%). Family history of cancer was reported by 47%, alcohol use by 28%, and smoking by 29%. The Unified Health System (SUS) referred to 79% of cases. Breast (21%) and cervical (21%) cancers were the most prevalent malignancies, followed by non-melanoma skin cancers (8.8%) and thyroid cancer (7.3%). Colon cancer ranked seventh (2.8%). Most cases were diagnosed at localized stages (51.7%), with 28.3% regional and 19.8% metastatic. Localized diagnoses increased significantly over time. Sex differences were observed across age groups and cancer stages ($p < 0.001$). Annual cancer cases rose significantly from 93,714 cases (2000 to 2004) to 222,301 cases (2015 to 2019) ($p < 0.001$). Incidence rates (IR) increased with age and over time, rising from 5.65 (ages 19–24) and 46.80 (ages 40–44) in 2000 to 12.28 and 77.11 in 2019. Peaks in IR were observed in 2014 and 2016, reaching 17.41 (ages 19–24) and 111.42 (ages 40–44). Overall, reported cases increased by 219% during the study period. **Conclusions:** The incidence of EO cancers in Brazil rose by 219% between 2000 and 2019, with breast cancer as the leading malignancy. These findings emphasize the growing cancer burden among younger populations and the need for enhanced cancer registries to guide targeted EO interventions. Future population-based studies are critical to validate and expand upon these results. Research Sponsor: Fundação de Amparo à Pesquisa e Inovação do Espírito Santo (FAPES); 155/2021.

Evaluation of a polygenic risk score for breast cancer in Chinese women: A three-stage case-control study of 13,715 subjects. First Author: Yuxiang Lin, Fujian Medical University Union Hospital, Fuzhou, Fujian, China

Background: Polygenic risk score (PRS) is a valuable tool for predicting the risk of breast cancer (BC). However, limited studies have been conducted in Chinese women. This study aimed to develop and validate a PRS which could be used to identify individuals with high risk of breast cancer. The associations between the PRS and patients' clinicopathological characteristics or survival outcomes were also evaluated. **Methods:** The PRS was developed based on findings from genome-wide association studies (GWAS) and validated in four independent cohorts with a three-stage design. A total of 7,056 patients and 6,659 controls were enrolled from Fujian Medical University Union Hospital (FJMUUH) and Shanghai Breast Cancer Genetics Study (SBCGS). Five approaches were utilized to calculate the PRS, including repeated logistic regression (RLR), logistic ridge regression (LRR), artificial neural network (ANN), random forest (RF) and support vector machine (SVM). Logistic regression analyses were performed to assess the association between established PRS and clinicopathological characteristics. The correlation between PRS and patients' survival outcomes was evaluated by cox regression models. **Results:** The LRR-based PRS was indicated to have the best predictive accuracy among five approaches (AUC = 0.601, OR per 1 SD increase = 1.39, Table 1). Women in the top 5% and 80-95% percentiles of PRS had a 1.43-fold and a 1.34-fold elevated risk of developing breast cancer compared with those at average risk (PRS in 40-60th percentiles). The predictive performance of PRS for patients with HER-2 positive tumors was demonstrated to be higher than that of HER-2 negative tumors (AUC = 0.612 vs 0.585, OR = 1.47 vs 1.35). It was also identified that the PRS was not correlated with age at diagnosis nor tumor characteristics. In survival analyses, an increase in PRS was associated with unfavorable disease-free survival (DFS) for ER negative patients (HR = 1.48, 95% CI = 1.08-2.03, p= 0.016). However, this association diminished after adjusting for clinicopathological characteristics. Regarding overall survival (OS), we observed significant correlations between increased PRS and overall survival (adjusted HR = 1.35, 95% CI = 1.05-1.75, p= 0.021), especially among ER negative patients (adjusted HR = 1.57, 95% CI = 1.07-2.30, p= 0.021) in the multivariate model. **Conclusions:** The PRS could provide additional information for Chinese women at high risk of breast cancer and holds significant value for BC screening. An increase in PRS also indicates an unfavorable prognosis and could play a crucial role in the clinical management of breast cancer patients at the time of diagnosis. Research Sponsor: None.

Trends in cancer incidence in Singapore over the last two decades. First Author: Hui Miao, National University of Singapore, Singapore, Singapore

Background: Singapore has witnessed a significant rise in cancer incidence over recent decades. The most rapid increase in age-specific incidence of cancer was observed among younger age group in recent years. Gaining insight into the factors driving this trend is essential for developing prevention strategies. **Methods:** This population-based study analysed 268,189 cancer cases diagnosed between 2000 and 2021 from the Singapore Cancer Registry via the TRUST platform (https://trustplatform.sg/). Cases diagnosed in 2020 and 2021 were subsequently excluded from the trend analysis due to potential COVID-19 effects. We first examined the temporal trend of age-standardized incidence rate and estimated average annual percentage changes (AAPC) using Joinpoint regression analysis. Decomposition analysis was performed to assess the increase in cancer cases attributable to changes in population age structure, population size, and cancer risk due to epidemiological factors. We conducted an Age-Period-Cohort analysis to estimate the net drift, local drift, and the cohort- and period-specific incidence rate ratio (IRR). These analyses were repeated for the four most common cancers in Singapore: breast, colorectal, lung and prostate cancer. **Results:** Over the 22-year period, the number of cancer cases nearly doubled for both men and women. The age-standardized incidence rate rose from 200.77 per 100,000 to 246.43 per 100,000 for women and remained stable at 235.30 per 100,000 for men. The AAPC was 0.92% (0.73%-1.15%) for women and 0.13% (-0.01%-0.30%) for men, and was the largest for female breast and prostate cancer. Decomposition analysis showed that aging population was the primary driver for an overall increase in cancer cases, whereas change in cancer risk had the highest impact for breast cancer, prostate cancer and lung cancer in men. The Age-Period-Cohort analysis revealed significant period and birth cohort effects with a net drift of 1.17% (0.90% - 1.43%) for women and 0.78% (0.54% - 1.05%) for men. For breast cancer, both birth cohort and period effects showed an increasing trend [IRRcohort1990vs1950 = 1.47 (0.98-2.22), IRRperiod2015vs2000 = 1.24 (1.17-1.31)]. A similar trend was observed for prostate cancer [IRRcohort1970vs1935 = 3.42(1.83-6.38), IRRperiod2015vs2000 = 1.74(1.59-1.92)]. In contrast, a decreasing trend was noted for lung cancer in men [IRRcohort1970vs1945= 0.65(0.48-0.87), IRRperiod2015vs2000 = 0.76 (0.70-0.82)]. **Conclusions:** The rising cancer incidence in Singapore is multifactorial, with demographic factors, particularly an ageing population, playing a significant role. Our analysis revealed important temporal patterns and a notable rise in cancer risk for breast and prostate cancers, likely influenced by shifts in environmental and lifestyle factors, and cancer screening. These insights should be used to inform and guide future public health policies aimed at addressing modifiable risk factors. Research Sponsor: Singapore Translational Cancer Consortium.

Racial differences in the association between agent orange exposure and the progression of monoclonal gammopathy of undetermined significance to multiple myeloma in US Veterans. First Author: Lawrence W. Liu, St. Louis Veterans Affairs Medical Center, St. Louis, MO

Background: Agent Orange (AO), an herbicide used during the Vietnam War Era (1/9/1962-5/7/1975), is implicated in myelomagenesis due to 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD). TCDD has a long half-life (3.2 years) and many occupations (e.g. pest control, agricultural, etc) are exposed. Work from our group (Liu L, et al., *JHO* 2024) demonstrated that AO exposure during the high TCDD period of 1/9/1962-11/30/1965 was associated with increased risk of monoclonal gammopathy of undetermined significance (MGUS) to myeloma (MM) progression. Given the higher incidence of MM in Black patients, we assessed whether there are racial differences in this association. **Methods:** We identified patients diagnosed with MGUS from 10/1/1999-12/31/2021 in the Veterans Health Administration. a published natural language processing-based algorithm was used to confirm diagnoses of MGUS and MM. We excluded: progression<1y, non-IgG/IgA subtype, race other than Black or White due to low numbers, no service during 1/9/1962-5/7/1975, and birth years outside of 1924-1953 so that the groups with and without exposures both have the same birth year range. Patients were stratified by race (Black or White). AO exposure was stratified by three TCDD levels: high (1/9/1962–11/30/1965), medium (12/1/1965–12/31/1970), or low (1/1/1971–5/7/1975). The association between AO exposure levels and progression were estimated using multivariable Fine-Gray subdistribution hazard model with death as a competing event and presented by multivariable-adjusted hazard ratio (aHR). The covariates included age, sex, body mass index (BMI), monoclonal protein (M-protein) level, MGUS subtype, and Charlson Comorbidity Index (CCI). **Results:** We identified 3,960 Black patients (AO exposed: n=865 [21.8%]) and 6,887 White patients (AO exposed: n=1,986 [28.8%]) with MGUS. Compared to no exposure: Black patients had aHR 1.03 (95% CI 0.51-2.06) for high, aHR 0.88 (95% CI 0.65-1.17) for medium, and aHR 0.3 (0.08-1.18) for low exposure, and White patients had aHR 1.80 (95% CI 1.14-2.83) for high, aHR 1.18 (95% CI 0.95-1.46) for medium, and aHR 1.17 (95% CI 0.66-2.05) for low exposure. **Conclusions:** White patients had an 80% increased risk of progression with AO exposure during the high TCDD period. No association was observed in Black patients. Research Sponsor: National Cancer Institute; R01 CA253475; National Cancer Institute; CA265735.

Multivariable analysis of the association between AO exposure and risk of progression to MM by race.

Lung cancer combined with interstitial lung disease: Controversial role of preexisting hypertension and emphysema observed in a fully followed 20-year patient cohort. First Author: Zhichao Wang, Affiliated Hospital of Nanjing University of Chinese Medicine, Nanjing, China

Background: The coexistence of interstitial lung diseases (ILD) and lung cancer (LC) presents a clinical challenge. ILD, including idiopathic pulmonary fibrosis (IPF) and non-IPF entities, is associated with an elevated risk of LC. However, the clinical features, treatment patterns, and survival outcomes of ILD-LC, especially IPF-LC, remain underexplored. We aimed to comprehensively evaluate survival outcomes and risk factors for mortality of ILD-LC patients based on a real-world long-term clinical cohort. **Methods:** A total of 1,341 eligible patients for this study were drawn from the Epidemiology and Genetics of Lung Cancer research program database (Mayo Clinic) including 96 IPF-LC, 111 Non-IPF ILD-LC, 99 ILD-only, and 1,035 propensity-matched LC-only patients (Controls). Data were collected on demographics, comorbidities, tumor features, treatment, and patient outcomes. Survival analyses used Kaplan-Meier methods; risk factors were assessed via Cox Proportional Hazards models. All comparisons reported below were statistically significant with p-values≤0.001 unless specified. **Results:** Among the 20,470 primary LC patients who were diagnosed from 1997 through 2016 and followed to 2021, 207 (1.0%) had ILD-LC, of which 96 (46.4%) had IPF. Comparing to Controls, ILD-LC patients were 4 years older at the time of LC diagnosis, 63.8% (vs. 52.8%) male, had a higher rate of former smokers (60.4% vs. 47.3%), a lower proportion of adenocarcinoma (37.7% vs. 57.5%), and a higher proportion of squamous cell (28.0% vs. 20.3%) and small cell carcinoma (13.5% vs. 8.4%). Although no significant differences in either LC stage or grade, ILD-LC patients had a significantly higher mortality rate (90.3% vs. 78.8%), particularly among IPF-LC patients (97.9% vs. 83.8%). ILD-LC patients were less likely to undergo surgery or receiving pharmacological treatments (73.9% vs. 93.5%). The median 5-year overall survival rate (OS, months) were 49.5 for Controls, 35.2 for Non-IPF ILD-LC patients, and 15.9 for IPF-LC patients. Analysis of six most common comorbidities revealed that pulmonary hypertension was associated with worse OS in ILD-LC patients compared to those without it (11.9% vs. 20.1%, $P < 0.05$); however unexpectedly, hypertension in ILD-LC patients was associated with better OS (21.3% vs. 14.4%) and emphysema in IPF-LC patients with better OS (7.9% vs. 3.4%, $P < 0.05$) when compared to those without the two comorbidities, respectively. **Conclusions:** This study highlights the poorer survival outcomes in ILD-LC patients, particularly IPF-LC patients, emphasizing the need for further investigation into optimized therapies and comorbidity management. Our findings also call for attention to two unexpected associations of hypertension and emphysema, warranting in-depth research on the possible biological and physiological mechanisms. GLP-1 receptor agonists and breast cancer risk in type 2 diabetes. First Author: Guo Cheng, Greater Baltimore Medical Center, Baltimore, MD

Background: Type 2 diabetes mellitus (T2DM) is associated with an increased risk of breast cancer. Glucagon-like peptide 1 receptor agonists (GLP-1RAs), which improve glucose metabolism and promote weight loss, are widely used to treat T2DM. However, the trophic activity of GLP-1RAs is concerning. In diabetic patients, GLP-1 receptors are highly expressed in breast cancer tissues and their activation can lead to breast cancer cell proliferation. Combining GLP-1RAs and dipeptidyl-peptidase IV inhibitors (DPP4i), which also enhance GLP-1 pathway, was associated with more cases of breast cancer in the FDA Adverse Event Reporting system. We investigated the relationship of GLP-1RAs with breast cancer in T2DM patients using Epic Cosmos, a HIPPA law-compliant dataset with longitudinal records of 289 million de-identified patients. **Methods:** A retrospective cohort study was performed on patients with T2DM but without breast cancer. Patients treated with GLP1-1RAs between 1/1/2010 and 12/31/2020 were compared to those treated with metformin, sodium-glucose cotransporter-2 inhibitor (SGLT2i), sulfonylurea (SU), DPP4i, thiazolidinediones (TZD) or insulin. The incidence of breast cancer was tracked from 1/1/2021 to 12/12/2024. Subgroup analysis was conducted on White patients, African American patients, and five subgroups with different BMI ranges. Risk ratio (RR) and 95% confidence interval (CI) were calculated via RStudio (version 2024.09.1). **Results:** Patients with T2DM and treated with GLP-1RAs had a higher incidence of breast cancer compared to patients treated with each of the other antidiabetics (Table). Results of subgroup analysis were consistent with the overall effect; except that in the obese subgroups, GLP-1RA exposure was not associated with breast cancer compared with DPP4i. Weight and age were not significantly different between each pair of cohorts. **Conclusions:** GLP-1RAs was associated with an increased incidence of breast cancer compared to other antidiabetic regimens in patients with T2DM in a long-term observation. Acting on identical pathway, GLP-1RAs may show a blunt effect versus DPP4i in obese patients. The study is empowered by an enormous sample size in Epic Cosmos. Future improvements include stratifying exposure levels and stringently matching confounders. Research Sponsor: None.

Unmasking the link between sleep apnea and lung cancer risk: A retrospective propensity-matched cohort study. First Author: Mohammed Al-Nusair, MedStar Washington Hospital Center, Washington, DC

Background: Obstructive sleep apnea (OSA) is a prevalent disorder characterized by intermittent hypoxia, systemic inflammation, hypercapnia, and oxidative stress. These factors pose a risk for carcinogenesis and potential tumor formation. The association between OSA and lung cancer remains unclear. This study evaluates the impact of OSA on lung cancer incidence using a large-scale retrospective cohort analysis. **Methods:** A comparative outcomes analysis was conducted using the TriNetX database. Data were extracted from the Johns Hopkins Medicine healthcare organization. Two cohorts were defined: patients with OSA (Cohort 1, n = 124,100) and those without OSA (Cohort 2, n = 2,330,110). Propensity score matching (PSM) was employed to balance baseline characteristics, including age, gender, race, and comorbid conditions, resulting in 62,750 in each cohort. The primary outcome was lung cancer incidence (ICD-10: C34), with risk difference (RD), risk ratio (RR), and odds ratio (OR) calculated to compare the cohorts. Statistical significance was set at $p < 0.05$. **Results:** Before propensity score matching, the OSA cohort had a higher mean age (60.8 $\pm$ 16.6 vs. 51.8 $\pm$ 20.3 years) and a higher prevalence of comorbid conditions such as obesity, hypertension, and diabetes compared to the non-OSA cohort (all $p < 0.001$). After PSM, demographic and clinical characteristics were well-balanced between cohorts. In the matched analysis, the incidence of lung cancer was slightly higher in the OSA cohort at 0.8% (n = 530) compared to 0.7% (n = 440) in the non-OSA cohort. The RD was 0.1% (95% CI: 0.0%-0.2%, p = 0.004 via T-Test), and the RR was 1.205 (95% CI: 1.062-1.366). The OR for lung cancer in OSA patients relative to non-OSA patients was 1.206 (95% CI: 1.063-1.369). Kaplan-Meier survival analysis showed a modestly reduced time to lung cancer diagnosis in the OSA cohort, although the difference was not clinically significant. **Conclusions:** This study reveals a statistically significant association between OSA and lung cancer risk. Subsequent studies are needed to investigate the degree of clinical significance between OSA and lung cancer. OSA patients may benefit from screening and/or early intervention strategies. Additionally, further research is needed to elucidate the potential mechanism and pathogenesis of lung cancer formation in OSA patients. Research Sponsor: None.

Exposure to Di-2-ethylhexyl phthalate and hormone receptor-positive breast cancer incidence. First Author: Lijuan Tang, Department of Head and Neck Surgery, Sichuan Clinical Research Center for Cancer, Sichuan Cancer Hospital & Institute, Sichuan Cancer Center, School of Medicine, University of Electronic Science and Technology of China, Chengdu,China, China

Background: Phthalates are ubiquitous environmental endocrine disruptors. As the predominant phthalate, di-2-ethylhexyl phthalate (DEHP) has been considered possibly carcinogenic to humans but large-scale longitudinal evidence is needed to further clarify its carcinogenicity. Up to date, no study have examined the in-situ DEHP exposure in breast cancer, in comparison with normal breast tissue or benign breast tumor.The present study aims to examine the association between DEHP exposure and incidence of hormone receptor-positive breast cancer (HR+BC) , both in a large cohort and in a group of patients whose in-situ DEHP exposure was analyzed. **Methods:** In 116,885 women of UK Biobank cohort, diagnosis of HR+BC was ascertained using general practitioner prescription records and information from National Health Service Cancer Registry and National Death Index. Baseline and yearly-average level of external DEHP exposure via water were estimated for each individual by linking chemical monitoring record of European Environment Agency with home address of the participants by Kriging interpolation model. We used Cox proportional hazards regression to estimate the association between DEHP exposure by water and risk of breast cancer. Furthermore, in-situ internal exposure level of DEHP in tumor tissue and normal breast tissue in 67 Chinese women with HR+BC or benign tumors was quantified using high performance liquid chromatography-tandem mass spectrometry (HPLC-MS/MS), then binary Logistic regression was used to explore whether the in-situ DEHP level was higher in HR+BC compared to benign tumor or normal breast tissues. **Results:** In the UKB cohort women, during a median of 13.5 years follow up, the fourth quartile of baseline DEHP was associated with 1.20 fold risk of HR+BC (95% CI, 1.1 to1.4, $P < 0.001$). As for yearly-average exposure, each quartile of DEHP was positively associated with higher risk of HR+BC (HR, 1.12; 95% CI, 1.1 to 1.17, $P_{trend} < 0.001$). The fourth quartile of yearly-average DEHP was associated with 1.52 fold risk of HR+BC (95% CI, 1.31 to 1.78, $P < 0.001$). No significant association was found between DEHP exposure and hormone receptor-negative breast cancer (P = 0.294). In the Chinese women, the overall detection rate of DEHP (detected in any tissue type) in HR+BC women was significantly higher than in women with benign tumors (96.2% V.S. 7.1%, $P < 0.001$), and the detection rate of DEHP in breast cancer tissues was higher than in benign tumor tissue (55.7% V.S. 4.5%, $P < 0.001$). Logistic regression showed that breast cancer tissue was associated with a higher risk of DEHP contamination compared with benign tumor tissue (OR,11.77; 95% CI, 1.20 to 115.25, P = 0.034). **Conclusions:** Real-world level of DEHP exposure was associated with higher risk of HR+BC. The results may be crucial for effective and precise prevention of breast cancer. Research Sponsor: Chongqing Science and Technology Commission; 2024NSCQ-KJFZMSX0314; Daping hospital; ZXAIYB014.

Burden and trend of breast cancer attributable to high red meat consumption in the United States from 1990-2021: An insight from the Global Burden of Disease study 2021. First Author: Shivani Modi, Albert Einstein Healthcare Network, Philadelphia, PA

Background: Breast Cancer (BC) 4th most common cause of cancer in the United States (USA). In the USA, dietary factors, particularly high red meat consumption, have been implicated in the increased risk of breast cancer among women. Studies suggest that red meat intake is associated with a higher incidence of breast cancer, possibly due to carcinogens formed during cooking at high temperatures. **Methods:** We estimated incidence, deaths and disability-adjusted life years (DALYs), Years lived with disability (YLDs) due to BC attributable to diet high in red meat by age, year, location across the USA from 1990-2021 using global burden of disease study 2021. **Results:** The total percentage change (TPC) in deaths increased by 9% (range: -59% to 54%), while DALYs rose by 1% (range: -47% to 51%) from 1990 to 2021. At the sub-national level, the highest TPC in deaths was observed in Nevada, with a 148% increase, followed by Utah (80%), Alaska (69%), and Arizona (68%) over the same period. In contrast, the District of Columbia experienced the largest decrease, with a 39% reduction in deaths. Age-wise, the highest number of deaths in 2021 occurred in the 70–74-year age group, with 968 cases, while the 60–64-year age group recorded the highest number of DALYs at 26,627. Among individuals aged 55 years and older, there were 6,253 deaths (range: -2,860 to 13,435), while those aged 20–54 years recorded 1,056 deaths (range: 400 to 2,267). Regarding DALYs, the 20–54-year age group accounted for 52,503 (range: -19,790 to 114,305), and the 55+ age group contributed 142,073 (range: -70,770 to 303,577) in 2021. **Conclusions:** The results underscore the importance of widespread education campaigns promoting healthier dietary patterns, policy interventions to encourage reduced red meat consumption, and targeted prevention strategies for at-risk populations. Clinically, these findings emphasize the critical role of healthcare providers in integrating dietary risk assessments and personalized nutritional counseling into routine care. By addressing this modifiable risk factor, both public health initiatives and clinical practices can work synergistically to reduce the burden of BC, improve patient outcomes, and advance preventive care strategies. Recent trends in cancer distribution and survival outcomes among adolescent and young adult patients: A national data analysis. First Author: Fatma Nihan Akkoc Mustafayev, Miami Cancer Institute, Baptist Health South Florida, Miami, FL

Background: Cancer distribution varies significantly among adolescents and young adults (AYAs) aged 15 to 39. Understanding these trends is essential for developing strategies to enhance early detection and improve survival outcomes. This study analyzes national data to assess time-bound changes in new cases and survival outcomes within the AYA population. **Methods:** A retrospective cohort study was performed using the National Cancer Database to analyze AYA patients diagnosed with the 20 most common cancer types by mortality from 2004 to 2021. Patients with confirmed malignant neoplasms, ≥6 months of follow-up, and known survival status were included. Descriptive statistical methods were used to evaluate demographic characteristics, while survival outcomes were analyzed using Kaplan-Meier estimates and multivariable Cox proportional hazard models. Linear regression models were used to analyze changes in new cases over time for each cancer group. **Results:** A total of 637,460 AYA cancer patients were included in the analysis. The median age was 33 years (IQR: 27-37). Most were female (61.5%) and White (79.6%). Breast cancer was the most common malignancy (21.3%), followed by central nervous system (CNS) tumors (11.6%), melanoma (9.3%), testicular cancer (8.5%) and colorectal cancer (CRC, 6.9%). Between 2004 and 2021, CRC, leukemia, liver, pancreatic, renal, stomach, and uterine cancers showed significant increases in new cases ($P < 0.001$), with CRC having the highest increase (annual rate change [β]:1.7, $P < 0.001$). Bladder, Hodgkin lymphoma (HL), melanoma, cervical and lung cancer significantly decreased ($P < 0.001$), with melanoma showing the largest decline (β: -1.83, $P < 0.001$). Breast, CNS, and ovarian cancers showed no significant trends. Among AYA cancer patients, the survival rate at 3 and 6 years were 89.2% and 83.9%, respectively. The overall survival rate at 12 years was 78.1%, with the highest survival rates observed in testicular cancer (93.1%), HL (91.4%) and melanoma (90.8%), and the lowest in liver (38.6%) and stomach cancer (41.3%). AYA cancer patients aged 35–39 (HR: 1.28, 95% CI:1.25-1.30, $P < 0.001$), Black (HR: 1.47, 95% CI: 1.45-1.5, $P < 0.001$), and Hispanic individuals (HR: 1.03, 95% CI: 1.01-1.05, P= 0.003) had worse survival outcomes. **Conclusions:** Our findings indicate that the proportion of AYAs diagnosed with certain cancers, such as colorectal, liver, renal and stomach cancers, has significantly increased over the past two decades. Prioritizing early detection and tailored treatment strategies are crucial to addressing this growing challenge. Further research is needed to understand the underlying factors contributing to these trends. Research Sponsor: None.

Epidemiology of *MET* gene mRNA expression in metastatic colorectal cancer: Analyses of a real-world clinicogenomic database. First Author: Gregory Sampang Calip, University of Southern California, Los Angeles, CA

Background: The *MET* proto-oncogene encodes the c-Met protein and is associated with promotion of tumor growth, angiogenesis, metastasis, and drug resistance. Our objective was to describe the prevalence of increased corresponding to c-Met protein expression and its associations with demographic and clinical characteristics among patients with metastatic colorectal cancer (mCRC) in a US-based clinicogenomic database. **Methods:** We conducted a retrospective cohort study of patients diagnosed with mCRC between 2014 and 2023 using the ConcertAI Patient360 electronic health record database with linkage to Caris Life Sciences genomic data. Patients were followed from first-line therapy (index time) until death or end of study follow up (Jan 2024). A 5-fold cross-validated and cross-cohort tested machine learning classifier trained on c-Met protein immunohistochemistry (IHC) labels (defined as 3+, ≥10% staining) was applied to derive prevalence of increased MET gene mRNA expression from whole transcriptome sequencing. Prevalence rate ratios (RR) with 95% confidence intervals (CI) were calculated using modified Poisson regression. **Results:** From an overall cohort of 1,020 patients with mCRC with a median age of 63 at metastatic diagnosis, 46% were female and 70% were non-Hispanic White, 20% non-Hispanic Black, 1% non-Hispanic Asian, and 5% Hispanic. At mCRC diagnosis, 81% had an ECOG performance status of 0-1 and 71% were diagnosed with de novo metastatic disease. The overall prevalence of increased MET gene mRNA expression corresponding to 3+, ≥10% c-Met IHC staining in the cohort was 35% (95% CI 32-38) and most samples (84%) were collected prior to treatment initiation. Patients with and without increased expression at this cutoff were broadly similar with respect to demographic and clinical characteristics. However, trends suggested that patients with increased expression had greater representation of individuals that were ages ≥75 years, non-Hispanic Black, had body mass index (BMI) <18.5 kg/m2, ECOG of ≥2, colon as primary tumor site and were microsatellite stable. **Conclusions:** Increased MET gene mRNA expression was observed among 35% of patients with mCRC in our cohort and was correlated with older age, low BMI at metastatic diagnosis, non-Hispanic Black race/ethnicity, poor performance status, colon as primary site, and microsatellite stable tumors. Research Sponsor: AbbVie.

Decoding tumour bacterial ecosystems: Topological data analysis of bacterial association with immunogenicity. First Author: Eva Lymberopoulos, BioCorteX Inc., New York, NY

Background: The tumour microbiome is increasingly recognised as a key contributor to cancer progression and clinical outcomes, as highlighted in recent iterations of the Hallmarks of Cancer. Translating microbial signatures into actionable insights is hampered by a reliance on dimensionality reduction and a limited capacity to dissect non-linear relationships, leading to incomplete and inconsistent findings. Topological Data Analysis (TDA) is an unsupervised machine learning method that overcomes these limitations by preserving the complexity of high-dimensional data. Here, we applied TDA to characterise tumoural bacterial ecosystems across cancer types. **Methods:** Analysis was conducted using BioCorteX's knowledge graph and proprietary engines v20250124_015926. The dataset constituted of 551 sequenced primary tumour microbiome samples from six cancer types, as well as associated host age and gender. TDA Mapper was used to generate network graphs of the bacterial data, combined with an enrichment algorithm to analyse host metadata. Clusters in the TDA network represent samples with overlapping microbiome features. **Results:** The resultant network graph shows clear clustering of tumour bacteria along cancer types, suggesting distinct signatures of tumoural bacteria for each cancer. Notably, TNCB and melanoma cluster in the same area, while ovarian, colorectal, and glioblastoma cluster together in a different area of the graph. NSCLC clusters separately to both of the other two major clusters. Host age and gender do not significantly interact with the bacterial signatures or the cancer types. **Conclusions:** This strengthens the notion of highly cancer-specific tumoural bacteria, while also highlighting the similarities observed across cancer types. Notably, the 2 main clusters could suggest a bacterial association with immunogenicity: TNBC and melanoma tumours are both immune-responsive, while ovarian, colorectal, and glioblastoma tumours are generally not. Previous studies have suggested a major role of tumoural bacteria in immune responses, and this study suggests that tumoural bacteria can distinguish cancer immunogenicity. Further, it demonstrates the potential of TDA to extract novel insights from large, high-dimensional datasets, surpassing traditional approaches. Capturing non-linear associations is crucial for understanding complex host-bacteria interactions, paving the way for more precise characterisation of cancer-specific microbial signatures, with implications for oncology and therapeutic development. Research Sponsor: BioCorteX Inc.

Environmental PFAS exposure as an understudied social determinant of health for endometrial cancer disparities: A geospatial study in Florida. First Author: Ming Sheng Lee, University of Miami Sylvester Comprehensive Cancer Center, Miami, FL

Background: Endometrial cancer (EC) is the most common gynecological malignancy in the U.S. Although overall survival rate for EC in the US is 81%, non-Hispanic Black (NHB) women die from EC at higher rates than non-Hispanic White (NHW) women. Currently, population-based research on social determinants of health associated with EC disparities is limited. PFAS exposure has been linked to increased risk for EC, but the potential impacts of environmental PFAS exposure on EC disparities are largely understudied. This research examined how EC incidence rates and mortality odds by census tracts vary with respect to proximity to industrial PFAS facilities as well as drinking water PFAS contamination in Florida. **Methods:** Florida cancer registry data from 2011 to 2020 was used to calculate age-adjusted incidence rates and mortality odds (number of mortalities divided by number of cases diagnosed) of both Type I and Type II EC by race/ethnicity for all census tracts in Florida. Data on the locations of industrial facilities handling PFAS as well as ZIP codes with public drinking water tested positive for PFAS were obtained from US EPA. A geographic information system was used to calculate indicators of proximity to PFAS facilities within 5 km of a census tract. Statistical tests including two-way ANOVA and two-sample t-test were used to compare mean incidence rates and mortality odds for three levels of PFAS proximity and drinking water PFAS status. **Results:** A total of 11,796 cases (8,931 in NHW, 1,821 in Hispanics, and 1,044 in NHB) of Type I EC and 9,715 cases (6,088 in NHWs, 1,450 in Hispanics, and 2,177 in NHB) of Type II EC were diagnosed and geocoded to 3,095 census tracts in Florida from 2011 to 2020. ANOVA showed that higher proximity to PFAS facilities is associated with higher rates of poverty as well as higher likelihood of drinking water PFAS contamination. Census tracts with higher proximity to PFAS show higher age-adjusted incidence and mortality odds for both Types I and II EC in NHW. NHB living in areas with higher PFAS proximity show higher mortality odds, while no statistically significant associations were found for Hispanic. T-tests showed that positive drinking water PFAS status is associated with higher aged-adjusted incidence and mortality odds for Type I EC in NHW as well as higher type II EC mortality odds in NHB and Hispanic. **Conclusions:** Results of this study demonstrate environmental PFAS exposure as a critical yet underexplored social determinant of health for EC epidemiology. Further research is needed to unearth the effect mechanism and to firmly establish PFAS exposure as a risk factor for EC disparities in the population. Such efforts can help develop public health policies to protect vulnerable populations from PFAS exposure and subsequent EC development as well as to accelerate the regulation process for environmental PFAS contamination. Nationwide analysis and trend of liver cancer mortality attributable to drug use in United States from 1991 to 2021. First Author: Adit Patel, Saint Vincent Hospital, L.L.C., Worcester, MA

Background: Liver cancer attributable to drug use represents an escalating public health concern in the United States (US). This study analyzes mortality, and related metrics for liver cancer attributed to drug use from 1991 to 2021, focusing on national and state-level trends and examining gender disparities and geographic variations with projections of Age-standardized mortality rates (ASMR) extending to 2040. **Methods:** The Global Burden of Disease (GBD) 2021 database was used to extract age-standardized mortality rate (ASMR) and disability-adjusted life years (DALY) for liver cancer mortality attributable to drug use in the United States from 1991 to 2021. Mortality data were stratified by gender, year, and region. Joinpoint regression analysis was performed to further evaluate trends and Annual Percent Change (APC) was calculated. Time series regression was used to calculate projected ASMR in 2040. **Results:** From 1991 - 2021, the ASMR for liver cancer attributable to drug use in the U.S. increased nearly threefold, from 0.54 per 100,000 (95% CI: 0.44–0.65) to 1.60 per 100,000 (APC:6.51%, 95% CI: 1.35–1.84). The DALY rate rose significantly from 15.22 per 100,000 to 39.36 per 100,000, highlighting the growing burden. Gender analysis revealed higher ASMRs in males, increasing from 0.74 to 2.12 per 100,000, compared to 0.38 to 1.14 per 100,000 in females, with APC of 6.25% and 6.55%, respectively. A state-level analysis of ASMR in 2021 showed the highest ASMR in California (2.27), followed by the District of Columbia (2.11), and Michigan (1.93). Meanwhile, Nebraska (0.73) had the lowest ASMR in 2021, followed by Iowa (0.91) and New York (1.15). The highest annual percent change (APC) was 11.47% in Nebraska, while the lowest was 3.58% in the District of Columbia. The Joinpoint regression analysis identifies five distinct periods of varying Annual Percent Changes (APC) in liver cancer mortality attributable to drug use. From 1991 to 2001, there was a sharp increase in mortality (APC = 5.75%), followed by slow growth between 2001-2007 (APC = 2.86%). However, from 2007-2010, there was a reacceleration (APC = 4.63%). Between 2010 - 2016, the growth rate decreased further (APC = 2.67%), after which 2016 - 2021, mortality rates stabilized (APC = 0.58%). The forecasted national ASMR for 2040 is estimated to be approximately 2.38 per 100,000. **Conclusions:** This study underscores a substantial rise in liver cancer mortality attributable to drug use in the United States from 1991 to 2021, with notable gender and geographic disparities. Projected increases in ASMR, coupled with observed trend shifts, emphasize the urgent need for targeted prevention and intervention strategies to mitigate the growing burden of drug use-related liver cancer. Germline pathogenic variants in *BRCA1-, BRCA2-*, and *PALB2*- genes among Ethiopian young women and men diagnosed with breast cancer. First Author: Tove Ekdahl Hjelm, Department of Molecular Medicine and Surgery, Karolinska Institute, Stockholm, Sweden

Background: Breast cancer incidence is rapidly increasing in low-and-middle-income countries (LMICs), where access to care is limited and survival outcome is poor. Young women and men are overrepresented among breast cancer (BC) patients diagnosed in LMICs in Sub-Saharan Africa (SSA), for reasons not yet fully understood. As hereditary cancer is more common in young women and men with BC, genetic factors may play a significant role. Even though carriers of germline pathogenic variants (PV) in the genes *BRCA1*, *BRCA2*, and *PALB2* have a very high risk of BC, studies of PV in these genes are very limited in SSA. In order to increase knowledge, this study investigated the prevalence of PV in high-risk BC susceptibility genes in young women and men diagnosed with BC in Ethiopia. **Methods:** This is a descriptive cross-sectional study. One-hundred young women (age 18-39) and men (all ages) diagnosed with invasive BC were included from Departments of Oncology and Surgery at Tikur Anbessa Specialized Hospital, Addis Ababa, Ethiopia. Potential participants were given oral and written information by a trained physician, and those consenting were included in the study. Basic patient- and tumor characteristic as well as information about family history was collected. DNA was extracted from blood samples, before shipment to BRCAlab, Lund University, Sweden for genetic analysis of genes *BRCA1*, *BRCA2* and *PALB2*, using a gene panel and next generation sequencing on an Illumina platform. **Results:** Genetic analysis results were available for 89 study patients. There was a high proportion (21.3%) of PV in tested genes. In total, 19 PV were found in *BRCA1* (n = 7), *BRCA2* (n = 8) and *PALB2* (n = 4). One of the PV was in a male. There were five individuals with an identical PV in *BRCA1* (c.4524G $>$ A, NM_007294.3), three individuals with identical PV in *BRCA2* (c.5159C $>$ A, NM_000059.3), and two individuals with identical PV in *PALB2* (c.1216delG, NM_024675.4). Two novel PV not previously reported in literature were found, *BRCA1* c.5278-864_5332+621del, NM_007294.3 and *PALB2* c.1169_1170del, NM_024675.4. **Conclusions:** This study demonstrates that germline PV in *BRCA1*, *BRCA2* and *PALB2* are common among young women and men diagnosed with BC in Ethiopia, with over 1 out of 5 patients carrying a PV. Genetic predisposition appears to play an important role in the tumor genesis in the studied group. Multiple patients carried identical PV, which could indicate that the detected PV are founder variants. Since the majority of the patients in Ethiopia are young, and male BC seem more prevalent compared to in western countries, efforts directed to these groups and development of services for genetic testing and follow-up programs for carriers of PV should be further emphasized. This approach has the potential to reduce BC incidence, morbidity and mortality through increased awareness, risk-reducing procedures and earlier cancer detection. Discrepancies between germline and somatic laboratories in the reporting of germline cancer predisposition variants. First Author: Brittany Cooper, Rutgers University, Department of Genetics, Piscataway, NJ

Background: Individuals with a cancer diagnosis may not qualify for germline testing to identify cancer predisposition variants due to restrictive testing guidelines. However, many have somatic Next Generation Sequencing (NGS) to guide treatment. Somatic NGS may offer a less restrictive approach to identify germline variant carriers. However, the rate of germline variant reporting via somatic NGS is unclear. We investigated what percentage of known germline variants were reported by matched somatic testing laboratories. **Methods:** Cancer patients seen at Rutgers Cancer Institute who had a positive germline report between 1/1/18 and 1/31/23 and at least one matched somatic NGS report on file were eligible for the study. We compared each germline-somatic report pair to analyze if the pathogenic/ likely pathogenic (P/ LP) germline variant was reported by the somatic NGS laboratory. We also assessed factors impacting germline variant reporting. **Results:** A total of 65 cases were included. Of matched somatic reports, 52.9% reported the corresponding germline variant, while 47.1% of germline variants were not reported by the matched somatic laboratory. The most frequent reasons germline variants were not reported included: (1) the gene was not included on the somatic NGS panel (60%), (2) the germline variant was filtered out of reporting by the somatic NGS laboratory as a suspected incidental germline finding of limited treatment relevance (10%), (3) the variant was intronic (7.5%), and (4) the variant was a copy number variant (7.5%). Less common reasons germline variants were not reported included differences in variant interpretation, limited coverage in the region containing the variant, and suspected mosaicism and/or clonal hematopoiesis. **Conclusions:** Almost 50% of germline variants in this cohort were not reported by the corresponding somatic laboratory. So, our findings suggest that clinical providers cannot rely on somatic NGS for germline variant reporting. We also expanded on reasons certain germline variants were not reported by somatic laboratories beyond reasons previously reported. In our cohort, the second most common reason germline variants were not reported was because the variant was detected and then intentionally filtered out of reporting. In these cases, the somatic lab interpreted the variant as an incidental finding of probable germline origin with limited treatment relevance. This highlights the different goals of germline vs somatic testing labs and how these varying goals impact what is reported to ordering clinicians. We hope our findings will contribute to the growing literature surrounding the overlap between germline and somatic testing methodologies and assist clinicians in their interpretation of genomic results. Implementation of pan-cancer universal germline testing in an ethnically diverse and rural community oncology practice. First Author: Sarah Nielsen Young, Labcorp (formerly Invitae Corp.), San Francisco, CA

Background: Universal germline genetic testing (GGT) is increasingly utilized in precision cancer care. There is limited data on this approach in patients (pts) from historically underrepresented and underserved populations receiving care at community practices. Herein, we present an interim analysis of ~500 unselected pts who underwent standard of care GGT at a rural community oncology practice. **Methods:** The UNITY (UNIversal germline Testing in the communitY) trial (NCT05416710) is a prospective, observational study of pts with newly or previously diagnosed cancer from July 1, 2022-August 1, 2024 (censor date). GGT was performed largely via an 80+ gene panel and insurance-billed. Patient demographic and clinical features were collected by clinicians. NCCN criteria for the pt's primary cancer at the time of GGT determined if the pt was in-criteria (IC) or out-of-criteria (OOC). Differences among groups were determined by two-tailed Fisher's exact, one-way ANOVA and Tukey's HSD tests with significance set at $p < 0.05$. **Results:** 462 pts had complete data: 73% were female; most common cancers: breast (54%), colorectal (14.5%), lung (9%), head & neck (6%), prostate (4%); mean age at diagnosis and testing: 63.2 and 67.6; 21% stage IV/metastatic; 66% Non-Hispanic white, 30% Black/African-American; 17% > 1 cancer diagnosis; 77% family history of cancer; 48% met NCCN criteria; 61% commercial insurance; 27% annual income < $25,000. 47 pathogenic germline variants (PGV) were identified in 41 pts (8.9%). 12 pts (3%) carried a single PGV in a gene associated with autosomal recessive cancer risk (e.g. *MUTYH*) and were excluded from further analyses, resulting in 6.3% (29/462) pts with a PGV. There was no significant difference in the rate of PGVs in IC vs. OOC pts (5.9% vs. 6.7%, p = 0.85). 16/29 (55%) pts with PGVs were OOC, with *CHEK2, ATM, BRCA2* being the most frequently mutated genes. Additionally, the majority of PGVs were potentially clinically actionable (25/29, 86%) and most (14/25, 56%) were OOC. 190 (41%) pts had a variant of uncertain significance (VUS) in the absence of a PGV, with Black/African-American pts having significantly higher rates of VUS-only findings compared to non-Hispanic White pts (50% vs. 36%, p = 0.04). Conversely, PGV rate showed the opposite pattern (0.7% Black/African-American; 8.5% non-Hispanic White, p = 0.01). **Conclusions:** Universal GGT in this diverse cohort identified PGVs in nearly 1 in 15 pts, most of which were potentially clinically actionable, but > 50% would have been missed by NCCN criteria. As Black pts had significantly lower odds of carrying a PGV and higher odds of a VUS result, broader GGT testing criteria would help mitigate racial disparities by increasing the number of (diverse) individuals tested resulting in better representation of genetic variation. Clinical trial information: NCT05416710. Research Sponsor: Labcorp Genetics (formerly Invitae Corp.).

Preventative intervention uptake among women with breast cancer and pathogenic germline variants. First Author: Sarah Nielsen Young, Labcorp (formerly Invitae Corp.), San Francisco, CA

Background: Risk-reducing (RR) interventions in patients (pts) with pathogenic germline variants (PGV) in breast cancer (BC) risk genes include RR mastectomy (RRM), RR salpingo-oophorectomy (RRSO) and pancreatic cancer surveillance (endoscopic ultrasound [EUS] and/or MR cholangiopancreatography [MRCP]). Gene-specific intervention uptake was stratified by family history (FHx) of cancer in 1903 BC pts with PGV in high/moderate BC risk genes (*ATM, BARD1, BRCA1/2, CDH1, CHEK2, NF1, PALB2, PTEN, RAD51C/D, SK11, TP53*). **Methods:** Germline genetic testing (GGT) and insurance claims data were analyzed female DCIS/BC pts diagnosed 2015-24, GGT <120 days after diagnosis and ≥1 year of claims pre/post-GGT (uptake measured within 1 year of GGT). Inclusion/exclusion criteria followed prior work (PMID 32027353). Following NCCN (Genetic/Familial High-Risk Assessment: Breast, Ovarian, Pancreatic and Prostate v2.2025) guidelines, PGV were in genes in the following categories: 1) gene-specific criteria (GSC): eligible for intervention +/- FHx; 2) gene and FHx-specific criteria (GFHxSC): consider (RRM, RSSO) or eligible (EUS/MRCP) for intervention if pt has relevant FHx or 3) Other: no specific intervention eligibility. Multivariable logistic regression models compared odds of intervention uptake for pts stratified by the categories above and by relevant cancer FHx (RRM: breast, RRSO: ovarian, EUS/MRCP: pancreatic). **Results:** 1903 pts with BC had ≥ 1 PGV. Clinico-demographics included were: 70% White, 74% BC FHx, 16% ovarian FHx, 35% pancreatic FHx, and mean (range) age at GGT, 50 (21-90). RRM had the highest uptake (56% overall, 75% in those with GSC PGV). RRSO uptake: 23% overall, 37% in pts with GSC PGV. EUS/MRCP uptake was 9% in pts with GSC PGV or GFHxSC PGV (+) FHx. Pts with GSC PGV (+) FHx had 5x higher odds of RRM vs. pts with GFHxSC PGV (-) FHx. Compared to pts with Other PGV (-) FHx, pts with GSC PGV (+) FHx had 18x higher odds of RRSO and 6x higher odds of MRCP/EUS (Table). **Conclusions:** In this retrospective analysis, intervention uptake generally followed NCCN guidelines, with uptake consistently higher in pts with PGV in GSC genes and positive FHx. Other factors in the shared decision-making process should be studied to identify gaps in quality of care. Research Sponsor: None.

Better together: Synergy of germline and somatic testing in HRR pathway-driven cancers. First Author: Michelle Green, Labcorp, Durham, NC

Background: Germline and somatic pathogenic variants inform eligibility for poly (ADP-ribose) polymerase inhibitors (PARPi) in breast, ovarian, prostate and pancreatic (BOPP) cancers. The role of BRCA1/BRCA2 in BOPP cancers is well-established, but the significance of other homologous recombination repair (HRR) genes is evolving. Integrating germline and somatic data provides a comprehensive understanding of oncogenesis and informs therapeutic decisions and risk assessment. For example, patients with "two hits" (germline and somatic alteration in the same HRR gene) often exhibit exceptional responses to PARPi. **Methods:** Patients with BOPP cancers receiving standard of care germline genetic testing (GGT) (Labcorp Genetics, formerly Invitae) and comprehensive genomic profiling (CGP) (Omniseq Insight, Labcorp) between 2021-2024 were analyzed. CGP data was queried to determine if the germline pathogenic variant (PGV) 1) was detected in the tumor, 2) had suggestive loss-of-heterozygosity (LOH) with a variant allele fraction (VAF) of ≥ 0.6, 3) had a second hit in the same gene, or 4) had somatic mutation(s) in other HRR gene(s). These were compared between BRCA1/BRCA2 and other HRR PGVs using Fisher's exact test with significance set at <0.05. **Results:** 607 patients with BOPP cancers underwent GGT and CGP; 57 (9.4%) had ≥ 1 PGV in an HRR gene. The PGV+ cohort was 51% White; mean age at GGT was 62 years (26-88). Breast cancer was the most common cancer (27), followed by ovarian (15), pancreatic (12) and prostate (4); 20 (35%) patients had a BRCA1/BRCA2 PGV and 37 (65%) patients had other HRR PGV, primarily CHEK2, ATM, PALB2 (Table). Most (88%) PGV were detected by CGP, with 100% of BRCA2 PGV identified. However, 8 (12%) of PGV+ patients would have been missed by CGP testing alone. VAF ≥ 0.6 and/or 2nd hits in the same gene were significantly more likely in those with BRCA1/2 PGV vs. other HRR. Rates of additional mutations in other HRR genes were not significantly different (p>0.05) between the groups (Table). **Conclusions:** BRCA1/2 PGV were frequently identified as suspected drivers of BOPP cancers compared to other HRR genes. However, one-third of patients with other HRR variants exhibited features suggestive of driving cancer pathogenesis. These findings may qualify indicated patients for targeted therapies or trials and highlight the synergistic value of combined germline and somatic testing. Research Sponsor: None.

Polygenic risk score for breast cancer in the Thai population: Addressing genetic disparities in underrepresented populations. First Author: Phuwanat Sakornsakolpat, Division of Medical Oncology, Department of Medicine, Faculty of Medicine Siriraj Hospital, Mahidol University, Bangkok, Thailand

Background: Effective breast cancer prevention and management require accurate risk prediction tools. Polygenic risk scores (PRS) have shown promise but are often less effective in non-European populations due to differences in genetic architecture. This study evaluates PRS performance and adaptation for breast cancer in the Thai population, addressing disparities in underrepresented groups. **Methods:** We retrospectively analyzed breast cancer cases from the Genomics Thailand project at Siriraj Hospital and general population controls from the National Health Examination Survey (NHES) in Thailand. Whole-genome sequencing was performed for cases, and genotyping with imputation was done for controls using the TOPMed r2 reference panel. Clinical data were extracted from electronic medical records. PRS were constructed using SBayesRC, incorporating variants from publicly available genome-wide association study (GWAS) summary statistics and variant functional annotations. Logistic regression and area under the receiver operating characteristic curve (AUC) analyses were conducted using R. **Results:** The discovery cohort included 975 cases and 1,502 controls, with 230 cases and 265 controls in the validation cohort. Of the 330 previously reported GWAS loci, only 231 lead variants were identified in our dataset. We further analyzed variants near these lead variants within the 330 loci, identifying nominal associations with breast cancer for 329 loci ($p<0.05$). Four PRS models were tested: (1) 231 variants, (2) ~7 million functional variants based on European (EUR) data, (3) East Asian (EAS) models, and (4) combined EUR and EAS models. The EUR-based model (AUC 0.66) outperformed the 231-variant model (AUC 0.59) and the population-specific EAS model (AUC 0.58) at $p<0.05$. The combined EUR and EAS models showed no significant improvement over the EUR model alone (AUC 0.66 for both, p=0.69). Individuals in the highest PRS risk group (above the 90th percentile) had an odds ratio (OR) of 3.34 for breast cancer compared to the rest of the population (95% confidence interval: 2.54–4.42, $p<0.05$). Among 249 patients with pathology data, PRS was not associated with tumor size, estrogen receptor status, or nodal metastasis. **Conclusions:** In the Thai population, PRS derived from large-scale European GWAS provided the highest prediction accuracy for breast cancer risk. The limited transferability of a top-variant PRS (e.g., 330-variant model) underscores the challenge posed by variant availability in this population. Validation in prospective studies is essential to optimize PRS utility and address disparities in genetic risk prediction. Research Sponsor: None.

Histopathologic and demographic features of non-small cell lung cancer in patients with *BRCA* pathogenic germline variants. First Author: Benjamin Aaron Bleiberg, University of Pennsylvania, Philadelphia, PA

Background: Patients with pathogenic germline variants (PGVs) in *BRCA1* and *BRCA2* (*BRCA1/2*) have a known increased risk of breast, pancreatic, and prostate cancers. Limited data also suggest a potential increase in lung cancer risk. It is not known if the features of non-small cell lung cancer (NSCLC) in individuals with *BRCA1/2* PGVs differ from those in PGV negative patients. **Methods:** Patients with *BRCA1/2* PGVs were identified using a single-institution registry of PGV patients. Using electronic health records, NSCLC cases were identified via ICD codes. Demographic and histopathologic data were manually abstracted. A PGV negative cohort was derived from NSCLC patient cases detailed in the Penn Medicine Cancer Registry. Categorical variables were compared between the *BRCA1/2* PGV and PGV negative groups using Pearson's chi-squared test. Continuous variables were compared using the Wilcoxon rank-sum test. **Results:** 25 NSCLC patients with PGVs (10 *BRCA1* and 15 *BRCA2*), and 623 PGV negative NSCLC patients were identified. Median age at diagnosis was similar (68, IQR=14 vs 67, IQR=13 years for *BRCA1/2* PGV and PGV negative patients, respectively); sex (64% vs 51% female) and race (80% vs 74% White) were also similar between groups. Never smokers comprised a significantly larger proportion of the *BRCA1/2* PGV cohort (44%) than the PGV negative cohort (16%; $p<0.01$). Stage at diagnosis was similar between groups, with the majority diagnosed with stage I or II disease (56% in *BRCA1/2* PGV vs 66% in PGV negative patients). Histologic findings were also similar, with the most common being adenocarcinoma and squamous cell (68% and 20% in *BRCA1/2* PGV vs 71% and 19% in PGV negative patients, respectively). All 14 BRCA1/2 PGV patients with stage I-II disease received curative intent local therapy; there were 3 recurrences within 5 years. Among 11 *BRCA1/2* PGV patients with advanced stage III-IV disease, 6 had actionable genetic alterations, most commonly in EGFR (3/11). PD-L1 status in these patients was evenly distributed, 3 $<$1%, 5 1-49%, and 3 $>$50% expression. **Conclusions:** The histopathologic and demographic features of NSCLC including age and stage at diagnosis and distribution of histology were largely similar for *BRCA1/2* PGV patients and PGV negative patients. However, never smokers represented a significantly larger proportion of the *BRCA1/2* PGV cohort. The presence of actionable genetic alterations and PD-L1 expression in BRCA1/2 PGV patients with NSCLC was comparable to those reported in the general NSCLC population. Research Sponsor: None.

Features of NSCLC in patients with *BRCA1/2* PGVs compared to PGV negative patient.

	BRCA1/2 PGV (N=25)	PGV Negative (N=623)	*p*-value
Median age of onset, years, ± IQR	68±14	67±13	0.68
Female Sex	16 (64%)	319 (51%)	0.21
Never Smoker	11 (44%)	99 (16%)	<0.01
Stage I or II at diagnosis	14 (56%)	370/561 (66%)	0.20
Histology			
Adenocarcinoma	17 (68%)	445 (71%)	0.71
Squamous cell	5 (20%)	120 (19%)	0.92

Profiling DNA damage response in ATM/BRCA2 carriers to inform hereditary cancer risk. First Author: Demitrios Dedousis, Fox Chase Cancer Center/Temple University Hospitals, Philadelphia, PA

Background: Approximately 10% of cancers stem from inherited germline pathogenic variants (gPV), predominantly in DNA repair genes including *ATM* and *BRCA1* or *BRCA2*. Identification of a gPV in high-risk families can guide management, however the clinical implications of variants of uncertain significance (VUS) identified by genetic testing remain unclear. Our aim is to develop a DNA damage response (DDR) activity profile of high-risk populations with/without cancer with *ATM or BRCA2* gPV to assist in determining the relevance of *ATM or BRCA2* gPV/VUS. **Methods:** We profiled several key proteins that play a role in DDR using a Luminex-based Multianalyte immunoassay (hereafter referred to as DDR xMAP) in peripheral blood monocytes (PBMCs) derived from whole blood. The standardized DDR xMAP assay was first applied to PBMC specimens from sporadic colorectal cancer (CRC, n = 95) patients and cancer-free age-matched controls (n = 47) at baseline. The DDR xMAP was used to profile seven DDR proteins, phosphorylated $Chk1^{S345}$, $Chk2^{T68}$, $\gamma H2AX^{S139}$, $p53^{S15}$ and total ATR, MDM2, p21. Univariate classification and regression tree analysis was used to identify statistically significant cut points in DDR analyte levels. We then measured the DDR analyte levels in individuals with *BRCA2* gPVs with (n = 11) and without a diagnosis of cancer (n = 11) as well as in cancer-free non-carrier controls (n = 15) at baseline. We compared these values using the two-sided Mann-Whitney test and the Benjamini-Hochberg false discovery rate method to account for multiple markers. **Results:** Using the initial set of CRC cases and healthy controls, we identified statistically significant cut points in multiple DDR analyte levels including total ATR ($>$ 81.8), $Chk1^{S345}$ ($>$ 28.0) and $\gamma H2AX^{S139}$ ($>$ 51.3) that can individually distinguish between CRC cases and cancer-free controls ($P < 0.001$). Next, in preliminary analysis of patients with *BRCA2* gPV with and without cancer had increased levels of all DDR analytes ($P < 0.05$) compared to non-carrier cancer-free controls, except for $\gamma H2AX^{S139}$. Levels of proteins involved in replication stress response, ATR and downstream $Chk1^{S345}$, were elevated. Total MDM2 levels, negative regulator of p53, were highly elevated in *BRCA2* gPV carriers. There was not a significant difference between DDR analytes for those with *BRCA2* gPV with and without cancer. **Conclusions:** Profiling key DDR markers can significantly distinguish between CRC patients and cancer-free controls. DDR analytes are significantly increased in PBMC specimens from individuals with *BRCA2* gPV (with or without a diagnosis of cancer) compared to non-carrier cancer-free controls. Ongoing research in high-risk groups will establish cut points for this assay, improving our understanding of DDR activity in individuals with *ATM/BRCA2* gPV and clarifying the clinical significance of gPV/VUS. Age-related germline landscape of endometrial cancer: Focus on early-onset cases. First Author: Judy J. Wang, Weill Cornell Medical Center, New York, NY

Background: Endometrial cancer (EC) has traditionally been associated with older age; however, recent trends indicate more cases in younger women. There is also a growing appreciation for germline drivers of EC, and these may be enriched in younger patients (pts). Given this, we sought to define germline pathogenic variants (gPV) in pts with EC by age. **Methods:** Pts with EC treated at our institution who underwent clinical tumor-normal sequencing from 12/2024-6/2021, inclusive of germline analysis of ≥76 genes, were identified. Clinical variables including age at diagnosis were collected. Logistic regression models evaluated associations between age at EC diagnosis and presence of gPV, biallelic loss, and Lynch syndrome (LS). Age categories were defined as early-onset (EC$<$50 years) and later-onset (EC ≥70 years) and were compared to those diagnosed ages 50-69 years. Appropriate statistical analysis had been performed. **Results:** Among 1625 pts with EC, median age at diagnosis was 63 (range 24-96) years. We observed differences in gPV rate across age groups, with 28/170 (16%) in early-onset EC, 152/1066 (14%) in EC diagnosed 50-69 years, and 36/389 (9%) in later-onset EC (p=0.016). Biallelic loss also exhibited differences by age groups with enrichment in early-onset EC (8.2% vs. 4.5% vs. 2.1% respectively, p=0.004). LS was enriched in early-onset EC, with 6.5% of patients diagnosed age $<$50 years having LS. Age was associated with gPV in univariate and multivariable (MV) logistic models, even after adjusting for ancestry and molecular subtype. Compared to those with EC diagnosed 50-69 years, early-onset EC was more likely to be exhibit biallelic loss (OR 3.34 95% CI 1.44-7.35) and be associated with LS (HR 3.49 95% CI 1.63-7.01) in MV models. In contrast, later-onset EC was less likely to be associated with gPV (OR 0.56 95% CI 0.37-0.83) and biallelic loss (OR 0.37 95% CI 0.15-0.82) in MV models. Among early-onset EC, 14/28 (50%) gPV were high penetrance and 14/28 (50%) exhibited biallelic loss. For late-onset EC, only 5/36 (14%) gPV had high penetrance with 8/36 (22%) showing biallelic loss. While the most common high-penetrant gPVs were *MSH2* (n=5), *MSH6* (n=3), and *MLH1(n*=3) for the early-onset cohort, the later-onset cohort had gPV in *BRCA2* (n=3), *BRCA1* (n=1), and *PALB2* (n=1). Among the 39 pts with LS and EC, the youngest pt (*MLH1* gPV) was diagnosed at 31 years, and the oldest pt (*PMS2* gPV) was diagnosed at 69 years. Heterogeneity was observed in the early-onset EC cohort. Rates of gPV were 8.9% and 19%, biallelic loss was 0% and 11%, and LS was 2.2% and 8% in those diagnosed $<$40 years and 40-49 years respectively, suggesting potentially different drivers of very early-onset EC. **Conclusions:** Rates of gPV, biallelic loss and LS differ across age groups for EC, with higher rates of highly penetrant genes that drive tumorigenesis enriched in younger pts. However, very early-onset EC may have different drivers and necessitates more research. Research Sponsor: National Cancer Institute/U.S. National Institutes of Health; P30 CA008748.

Leveraging high variant allele frequencies (VAF) of DNA damage repair (DDR) mutations (muts) in liquid biopsy (LBx) as a surrogate for germline testing: Implications for precision medicine. First Author: Sagal Pannu, Stephenson Cancer Center at The University of Oklahoma Health Sciences Center, Oklahoma City, OK

Background: LBx based next-generation sequencing (NGS) provides a minimally invasive means to detect true DDR muts as well as DDR muts that represent clonal hematopoiesis of indeterminate potential (CHIP), and in certain cases identifying high VAF DDR muts of suspected germline origin. Herein, we aim to address the knowledge gap in interpreting these findings to guide germline testing. **Methods:** We retrospectively collected data on patients (pts) with cancer who underwent LBx with FoundationOneLiquid CDx (311 gene panel) from 2022-2024 and tissue biopsy (TBx) based NGS using either Caris Life Sciences or FoundationOne CDx. A panel of 22 muts directly involved in the DDR pathway were designated as DDR muts. Findings from LBx and TBx were reported using descriptive statistics. Best objective clinical responses were evaluated using RECIST v1.1. **Results:** The study cohort consisted of 637 pts tested using LBx, with the majority being male (62.6%; n=399) and white (81%; n=517). On LBx, 203 pts (31.8%; n=203/637) were identified to have one or more DDR muts. Paired testing with LBx and Tbx was available for 221 pts of which 28 pts (12.6%) had 'true CHIP' (identified on LBx but not on TBx), all contributed by ATM and CHEK2 (50% each; n=14/28). Of pts who had paired LBx and TBx (n=221), 24 pts (10.8%) had the same DDR mut on both, suggesting likely somatic origin (True DDRs), the most common being ATM (25%; n=6/24), PALB2 (12.5%; n=3/24) and CDK12 (12.5%; n=3/24). Using a linear mixed-effects model to account for patient- and gene-level variability in VAF, true DDRs had a significantly ($p < 0.001$) higher VAF (median: 46.8, IQR: 49.6, n = 26) compared to true CHIP DDRs (median: 0.24, IQR: 0.29, n = 31). LBx revealed potential germline implications based on high VAF in 7.9% pts (n=50/637) of which 45 pts had DDR muts. Genetic referrals were initiated in 48% (n=24/50) with subsequent confirmatory germline testing done for 66.6% (n=16/24), all confirming germline muts (table 1). Notably, for the 52% (n=26/50) without genetic referrals, 73% (n=19/26) lacked documentation of a referral discussion. Out of the 50 pts with muts likely of germline origin, 19 were enrolled in phase-1 clinical trials, with 6 receiving matched therapies targeting DDR muts (PARP and ATR inhibitors). Of these, 1 had a partial response (CHEK2) and 3 had stable disease (1-MUTYH, 2-PALB2). **Conclusions:** LBx can be used as a potential surrogate indicator of likely germline muts as evidenced by high VAFs. Our findings underscore the need for improved interpretation of LBx reports to guide timely genetic referrals and confirmatory germline testing. Research Sponsor: None.

Gene	Median VAF (IQR)
BAP1 (n=1)	52.4% (52.4-52.4)
MUTYH (n=2)	51.3% (50.7–51.9)
CHEK2 (n=2)	51.0% (50–52)
ATM (n=2)	50.2% (49.8–50.6)
BRCA2 (n=4)	50.0% (48.5–52.2)
PALB2 (n=2)	48.4% (46.7–50.2)
MSH6 (n=1)	46.6% (46.6-46.6)

Estimated prevalence of pathogenic variants in patients with breast, colon, and/or endometrial cancer who do not meet guidelines for genetic testing. First Author: Ryan Bernhisel, Myriad Genetics, Inc., Salt Lake City, UT

Background: Patients with cancer who carry pathogenic variants (PVs) in hereditary cancer genes often have improved outcomes when their treatment is guided by their germline genetics. Identifying germline PVs also allows cascade testing of family members to pursue cancer prevention interventions. Guidelines recommend genetic testing for patients with female breast (BC), colorectal (CRC), or endometrial cancer (EC) who meet specific criteria, including early age at diagnosis and/or family history (FH). However, many patients with cancer who do not meet these guidelines may unknowingly carry PVs and may, therefore, receive suboptimal care. **Methods:** Multivariable logistic regression models were constructed to analyze trends in the prevalence of PVs based on age and FH in a consecutive cohort of patients referred for hereditary cancer testing (MyRisk, Myriad Genetics). We report model-based prevalence estimates for patients without FH diagnosed with BC, CRC, or EC at various ages. Prevalence is summarized overall for 25-48 hereditary cancer genes and for genes most frequently implicated in each cancer type. **Results:** Estimates of prevalence of PVs among patients with BC and CRC decreased substantially with age of diagnosis (Table 1). For patients with BC/CRC (respectively) without FH, overall prevalence estimates were 13.0%/11.8% among those diagnosed at age 30, 6.9%/7.1% at age 50 and 2.5%/3.2% at age 80. Among BC patients, PVs were most frequently identified in the *BRCA1, BRCA2, CHEK2, ATM,* and *PALB2* genes. Among CRC patients, PVs were most prevalent in the Lynch syndrome genes *MLH1, MSH2, MSH6, PMS2*. Prevalence was not significantly associated with age at EC diagnosis. Women with no FH had overall prevalence estimates of 7.5% if diagnosed with EC at age 30, 7.3% at age 50 and 7.1% at age 80 (Table 1). PVs were most common in the aforementioned Lynch syndrome genes. **Conclusions:** These results support existing literature that a substantial fraction of patients who do not meet guidelines for genetic testing may carry PVs, including a high prevalence of PVs among EC patients without FH, regardless of age at diagnosis. Elimination of age-based restrictions on genetic testing could improve the survival of cancer patients and their family members. Research Sponsor: Myriad Genetics.

Estimated prevalence (%) according to age of diagnosis among patients with no family history of cancer.

Age at dx	30	40	50	60	70	80
BC	13.0%	9.5%	6.9%	5.0%	3.5%	2.5%
CRC	11.8%	9.2%	7.1%	5.5%	4.2%	3.2%
EC	7.5%	7.4%	7.3%	7.2%	7.2%	7.1%
BC[a]	12.3%	8.3%	5.6%	3.7%	2.4%	1.6%
CRC[b]	7.3%	5.1%	3.5%	2.4%	1.7%	1.1%
EC[b]	4.4%	4.3%	4.3%	4.2%	4.1%	4.1%

BC=breast cancer; CRC=colorectal cancer; dx=diagnosis; EC=endometrial cancer.

Performance of previously described polygenic risk scores for prostate cancer in a population with mixed ancestry. First Author: Vinícius Marques Rocha, Faculdade de Medicina da Universidade de São Paulo, São Paulo, Brazil

Background: It is unclear whether polygenic risk scores (PRS) for prostate cancer (PrCa), developed using data from European populations, are applicable to individuals of mixed ancestry, such as the Brazilian population. We are conducting a case-control study to evaluate the performance of existing PrCa PRSs in Brazilian people. **Methods:** We prospectively included unselected PrCa patients (pt). The control group consisted of 347 elderly community men from Sao Paulo city (SABE cohort) included from 2000 to 2010, with whole genome sequencing (WGS 30x depth) data previously reported in the ABRAOM study. Men who developed cancer in the follow-up were excluded. The mean age at admission to the study was 72 years. DNA was extracted from blood samples for performing WGS at 15x depth (PrCa pt), using Illumina technology. VCF quality filtering and pre-processing were performed according to best practices of GATK, BCFtools and Plink. Ancestry composition was calculated using ancestry-informative markers derived from global populations. AUCs were calculated using the results from the total PRS value obtained with PGSCalc for cases and controls, without filters. We calculated PRS scores for 11 different PRSs for PrCa, described in 7 studies, derived from people with different ancestries and available in The Polygenic Score (PGS) Catalog or the literature (BARCODE1). **Results:** A total of 588 PrCa patients were included. The median age at diagnosis was 64.6 years. Most patients were diagnosed with clinical stages II (32.8%) and III (43.1%), and ISUP grades 2 (40.2%) and 3 (22.9%). Twenty PrCa pt, who were carriers of pathogenic or likely pathogenic germline variants on high and moderate penetrance prostate cancer predisposition genes, were excluded. The mean ancestry genetic composition for PrCa pt was 61.4% European and 24.6% African. We calculated the AUC for the Brazilian cohort (BZL) for 11 PRSs available in PGS Catalog. 1) PGS000030 - Schumacher et al. 2018; 147 SNPs - AUC BZL: 0.666; 2) PGS000751 - Du et al. 2019; 178 SNPs - AUC BZL: 0.694; 3) PGS000662 - Conti et al. 2021, 269 SNPs - AUC BZL: 0.705; 4) PGS002796, PGS002797, PGS002798, PGS002799 - Shi Z, et al. 2022; 232, 67, 128, 138 SNPs - AUC BZL, respectively: 0.684; 0.663; 0.670; 0.627; 5) PGS002240, PGS002241 - Mars et al. 2022; 1,092,093 (AUC BZL: -) and 6,497,734 SNP (AUC BZL: -) PRS for risk prediction of common diseases. 6) PGS003460 - Chen F et al. 2023; 278 SNPs - AUC BZL: 0.702; 7) Barcode1 - 130 SNPs - AUC BZL:0.674. **Conclusions:** We used WGS 15x to improve SNP capture associated with population genetic differences. PRS 269 (Conti et al., 2021) and PRS 278 (Chen F et al. 2023) yielded the best results, suggesting that a multiancestry-derived PRS may be applicable to the admixed Brazilian population. We continue including participants to confirm these results. Research Sponsor: None.

Frequency and spectrum of BRCA pathogenic/likely pathogenic variants in the Hispanic population of south Florida: A retrospective analysis. First Author: Srika Amin, Miami Cancer Institute, Baptist Health South Florida, Miami, FL

Background: The genetic landscape of hereditary breast and ovarian cancer in diverse populations remains underexplored, particularly within Hispanic/Latino communities. While *BRCA1* and *BRCA2* pathogenic and likely pathogenic (P/LP) variants are well-studied in some ethnic groups, data on Hispanic populations with varied ancestries is limited. South Florida's unique demographic, characterized by a large Hispanic population with ancestries from the Caribbean, Central, and South America, provides an opportunity to examine the prevalence and spectrum of *BRCA1* and *BRCA2* variants in this group. **Methods:** Data was extracted from Progeny and Cerner PowerChart and de-identified in MS Excel. The cohort consists of individuals who underwent germline genetic testing (ranging from single site to multigene panels) at Miami Cancer Institute's Clinical Genetics clinic from 01/01/2017 to 07/08/2022 with a personal/family history of breast and/or ovarian cancer. The sample was categorized by self-reported race, ethnicity, and ancestry, with a focus on White, Black, and Hispanic/Latino categories. We compared *BRCA1* and *BRCA2* P/LP variants across race/ethnicity. **Results:** A total of 3,784 cases were reviewed, predominantly female (97.6%), with 73.6% (n = 2786) affected by breast cancer. The median age was 54 years (range: 20-92). Most of the population identified as Hispanic/Latino (65%, n = 2,460), with Cuban ancestry reported most frequently on both maternal (38.4%) and paternal (37.3%) sides. The prevalence of *BRCA1* and *BRCA2* P/LP variants in Hispanic/Latino individuals was 5.1% (126 of 2460), with the majority having a BRCA2 variant (n = 86; 68.2%). Variants of uncertain significance were observed in 3.4% of the Hispanic population. The most frequent P/LP variants in *BRCA1* included c.211A > G (n = 5, 12.5%) and c.3331_3334delCAAG (n = 3, 7.5%). In *BRCA2*, common P/LP variants were c.771_775del (n = 8, 9.3%), c.2808_2811del (n = 6, 7%), c.5799_5802del and c.9235delG (each n = 5, 5.8%), and c.5073dupA (n = 4; 4.6%). **Conclusions:** This cohort revealed a variety of unique P/LP variants in *BRCA1* (n = 31) and *BRCA2* (n = 56), reflecting the genetic diversity in this population. Other cancer susceptibility gene P/LP variants were noted but were not the focus of the study. Notably, *BRCA2* c.771_775del (n = 8), an established Icelandic founder variant not reported to be recurrent in Hispanics, was only observed in those of Cuban/Spaniard ancestry in this cohort. Other variants, such as c.9235delG and c.5073dupA in *BRCA2*, were identified in Nicaraguan and Cuban populations for the first time. The study also highlighted common founder and recurrent variants in European, Caribbean, Central, and South American populations. South Florida's Hispanic population, including individuals from underrepresented regions, offers a rich and unique dataset of *BRCA1* and *BRCA2* P/LP variants. Research Sponsor: None.

Mainstreaming the diagnosis of Lynch syndrome (LS) in colorectal cancer (CRC) patients: The ItaLynch study. First Author: Alberto Puccini, Humanitas University, Pieve Emanuele, IRCCS Humanitas Research Hospital, Humanitas Cancer Center, Pieve Emanuele, Milano, Italy

Background: International guidelines recommend universal screening for LS through somatic DNA mismatch repair deficiency (dMMR) testing in CRC. However, LS remains largely underdiagnosed, often due to inconsistent referrals from oncologists to genetic counseling and germline testing. We report preliminary results of the ItaLynch study, proposing a mainstream, oncologist-led diagnostic pathway for LS. **Methods:** ItaLynch is a prospective, observational, multicenter, multidisciplinary Italian study on pts with dMMR CRC. It started in May 2021, and is ongoing in 23 high-volume centers. The ItaLynch diagnostic pathway is based on three key steps. The first step is universal screening through dMMR testing by immunohistochemistry (IHC) in all CRC pts. The second step consists of reflex testing and a Lynch alert: MLH1-deficient (dMLH1) pts undergo reflex testing for $BRAF^{V600E}$ and, if wild-type, for MLH1 promoter methylation. A Lynch alert is added to the pathology report of all dMMR CRC pts. The alert is positive for pts with a high risk of LS as per reflex testing results or loss of non-MLH1 proteins; it is negative for pts not likely to have a hereditary predisposition (i.e. $BRAF^{V600E}$ mut or *MLH1* promoter hypermethylated dMLH1). The third and most innovative step is the oncologist-led mainstreaming germline testing for pts with a positive Lynch alert. Carriers of a germline pathogenic variant (PV) as well as those who have non-informative test results but are clinically suspicious are then referred to post-test genetic counselling. **Results:** Up to Dec. 19 2024, we enrolled 1,146 pts with dMMR CRC. Among the 937 pts eligible for the current analysis, 714 (76%) were dMLH1, and 223 (24%) displayed loss of non-MLH1 proteins. Reflex testing was carried out in 653 (91%) of the dMLH1 pts and 271 (41%) were *BRAF* wt. Of these, 219 (80%) subsequently underwent *MLH1* promoter methylation testing, and 98 (45%) were not hypermethylated. Of these, 60 (61%) underwent oncologist-led germline genetic testing, and 11 (18%) were carriers of an LS-associated PV. Among the 223 cases with loss of non-MLH1 proteins, 157 (70%) underwent genetic testing, and 86 (55%) were diagnosed with LS. At the time of writing, the overall proportion of LS cases is 10% (97/937 pts with data available for the current analysis). These 97 LS cases represent 45% of the 217 pts who were flagged with a positive Lynch alert and underwent oncologist-led genetic testing (60 of which with dMLH1 and 157 with non-MLH1 loss). **Conclusions:** Overall, our large cohort is representative of the population of pts with dMMR CRC. Our novel diagnostic algorithm, through the implementation of the Lynch Alert flagging system that identifies dMMR CRC pts with a high likelihood of LS and of an oncologist-led germline genetic testing, obtained a high diagnostic yield. Further analyses are ongoing on the entire cohort to evaluate the feasibility of the proposed diagnostic pathway. Research Sponsor: None.

10581 Poster Session

Identification of germline hereditary cancer syndrome variants and associated cancers in a healthcare biobank population. First Author: Juliann Savatt, Department of Genomic Health, Geisinger, Danville, PA

Background: Identification of pathogenic/likely pathogenic variants (P/LPV) in hereditary cancer syndrome (HCS) genes enables surveillance and prevention. Population genomic screening can complement traditional ascertainment of at-risk individuals based on personal or family history. But lack of data on cancer risks in unselected individuals with a HCS P/LPV challenges clinical decision making in these cohorts. We summarize a biobank's population screening for HCS variants and a case-control assessment of reported relevant cancers. **Methods:** MyCode is a health system biobank with >357,000 patients consented to research leveraging exome and electronic health record (EHR) data and to the receipt of medically relevant P/LPV. Available exomes were evaluated for P/LPV in 27 HCS genes based on predicted molecular consequence and ClinVar status. Clinically confirmed P/LPV were disclosed to eligible patients (cases). Patients' prior knowledge of their result was determined using EHR data and patient report. Relevant cancer diagnoses were extracted from the EHR using validated methods in cases and variant-negative controls (n=169,099) with available EHR data. Associations between P/LPV and relevant cancers were assessed using a Firth logistic regression in 9 genes with >30 cases. Ages of diagnoses were compared using Wilcoxon rank sum test. **Results:** 183,822 patients' exomes have been evaluated; 2,035 P/LPV in 27 HCS have been disclosed to 2,027 patients. 80% (n=1,625) of patients were previously unaware of their result. Increased odds and earlier ages of diagnosis for a subset of relevant cancers were observed in patients with P/LPV (Table). **Conclusions:** HCS P/LPV were disclosed to 1.1% of biobank patients, most of whom were unaware of their result. P/LPV were associated with a higher odds and earlier age of diagnosis of some relevant cancers compared to controls, indicating that genomic screening facilitates ascertainment of at-risk individuals. To guide clinical recommendations, research on cumulative cancer risks in broader populations will be needed. Research Sponsor: Geisinger; Goldsmith Foundation; Regeneron Genetics Center.

Clinical characteristics of young-onset breast cancer and the role of germline pathogenic variants. First Author: Nara Tashjian, Mayo Clinic, Rochester, MN

Background: Breast cancer is the most common cancer in young women, with an increasing incidence over the past two decades. This study aims to evaluate the characteristics of young-onset breast cancers among patients aged ≤50 and compare tumor characteristics by germline mutation carrier status. **Methods:** Patients with breast cancer diagnosis ≤50 years old and evaluated across the Mayo Clinic enterprise between 2000 and 2024 were identified through the prospective Mayo Clinic Breast Cancer Study and the institutional tumor registry. Demographics, tumor characteristics, and clinical outcomes were obtained and described using summary statistics. Germline pathogenic or likely pathogenic variant (PV) carrier status for 5 established breast cancer predisposition genes (BRCA1, BRCA2, ATM, CHEK2 and PALB2) was available in a subset of unselected patients who consented to participation in sequencing studies at Mayo Clinic. Clinical characteristics were compared between PV carriers in each gene and non-carriers utilizing Chi-square test. All tests were two-sided and p-value less than 0.05 was considered statistically significant. **Results:** Among 8,462 patients (8435 women, 27 men) with breast cancer diagnosis at age ≤50 in the study, the median age of diagnosis of breast cancer was 44 years (range 18 – 49). At diagnosis, 84% had invasive disease, 43% of the tumors were high-grade, 15.8% had triple-negative breast cancer (TNBC), more than two-thirds (67.5%) presented with stage I or II breast cancer, and 3.7% had bilateral breast cancer. Among the 2,527 patients who consented to germline sequencing, 10.1% were found to be carriers of PVs; these included BRCA1 (3.3%), BRCA2 (2.7%), CHEK2 (2.3%), ATM (1.3%), and PALB2 (0.6%). Compared to non-carriers, a significant enrichment ($p<0.05$) of invasive breast cancer (92.6% vs. 83.3%) and high grade tumors (61.7% vs. 31.4%) were noted in BRCA1 PV carriers, and of bilateral breast cancer (13.4% vs. 3.8%) and high grade tumors (46.4% vs. 31.4%) in BRCA2 PV carriers. After exclusion of in-situ disease, proportion of TNBC was observed to be significantly higher in BRCA1 (61.3%), BRCA2 (15.5%) and PALB2 (30.7%) PV carriers compared to non-carriers (11.2%), whereas >90% of ATM or CHEK2 PV carriers had ER+ breast cancer and none had TNBC. A significant difference in stage at presentation was not observed by germline PV carrier status. **Conclusions:** The high frequency (>10%) of PVs in young-onset breast cancer underscores the importance for genetic testing in this population. The observed differences in breast cancer phenotypes based on germline PV carrier status among young-women may have significant implications for clinical outcomes and needs to be further explored. Research Sponsor: None.

NuGenA (Nurse Led Genetic Counselling and Awareness): A proof-of-concept to implementation of genetic counseling for HBOC in LMICs. First Author: Asima Mukhopadhyay, Kolkata Gynecological Oncology Trials and Translational Research Group, Kolkata, West Bengal, India

Background: Poor access to genetic testing and counselling represents a major gap in cancer care in resource-restricted-settings. Our pilot work in Eastern India (2017-2019) demonstrated improved uptake of BRCA genetic testing (89% vs.55%) in ovarian cancer (OC) after training one nurse specialist in genetic counselling. We introduced NuGenA program in 2020 to scale-up this effort as proof-of-concept. **Methods:** Ethical approvals were obtained (KolGo/CTRI/2021/06/034308/HMSC). A nurse-led structured training program combining lectures/modules/live-demonstration-workshops/role-playing using offline and virtual learning methods were administered to sensitize/train all tiers of nurses including train-the-trainers in genetic counselling. A comprehensive NuGenA questionnaire including demographic, family history, CAM, pre/post-test counselling satisfaction-regret scale, QOL and willingness-to-pay (WTP) for genetic testing was administered by trained nurses. Physician and nursing interviews were conducted at 1 year to assess barriers/challenges/success of program. KolGoTrg EASE (Ethical/Acceptable/Affordable/Sustainable/Scalable/Effective/Early-diagnosis-and-treatment of barriers) matrix was used to measure key performance indicators and impact of implementation. **Results:** Through 40 sessions/workshops, 126 nurses were trained across India (8 centres, 34 nurses), Nepal (10 centres,30 nurses), Bangladesh (2 centres,60 nurses) and Africa (2 centres,2 nurses) with significant improvement in post training KAP scores. 7 genetic clinic/set-ups were created. 270 OC patients and 458 family members were counselled by nurses. 159 OC patients had BRCA testing, 48 (30%) being positive. Until now, out of 235 at-risk family members identified, 90 were counselled and 12 tested for BRCA (6 positive);2 opted for risk-reducing surgery. Unique barriers/challenges were identified including cost of BRCA test, provider hesitancy, social stigma, requiring customised solutions. WTP for genetic testing using CoPay model was accepted by 99/158 (62%). Another 100 community-nurses were sensitized through NuGenA camps/sessions approved by government/health authorities resulting in conduct of >150 COBRA (cervix/oral/ovary/breast-cancer awareness) sessions and patient-public-engagement initiatives. NuGenA modules are being included in national/international nursing curriculums. A World Ovarian Cancer Coalition charter-champion award and adoption by IGCS training sites exemplify global recognition/outreach. **Conclusions:** Nurse-led model proved scalable and impactful in resource-restricted settings, facilitating transformative changes in provider/patient-public engagement, attitude and practice towards genetic testing. Concordance of somatic whole exome sequencing and germline genotyping of DPYD to screen for DPD deficiency. First Author: Aditya Sharma, Dartmouth Cancer Center, Lebanon, NH

Background: Fluoropyrimidines are amongst the most commonly used chemotherapeutic agents in the treatment of gastrointestinal and breast malignancies. Fluoropyrimidines carry a risk of severe adverse events in the 2-3 % of the population with DPD deficiency caused by decreased function variants of DPYD. As a result, pre-treatment testing to identify patients with decreased function variants including DPYD genotyping is critical. However, pre-treatment DPYD genotyping is not yet broadly used in the United States. We hypothesized that our in-house somatic exome DHCancerSeq assay could serve as an effective tool to screen for DPD deficiency. **Methods:** We identified patients in our health system with somatic whole exome sequencing who had clinical DPYD genotyping using either a limited real time PCR assay (including the *2A, *13, and c.2846A > T alleles) or a dedicated NGS-based PGx panel covering all known clinically relevant mutations in DPYD. HapB3 screening on the somatic whole exome was performed using only the coding sequence variant (c.1236G > A), not the causative deep intronic variant (c.1129-5923C > G), given the known high linkage disequilibrium amongst these variants. We then evaluated concordance of somatic whole exome sequencing and targeted germline genotyping. **Results:** A total of 115 patients had DPYD genotyping results from both somatic and germline testing and were eligible for evaluation of concordance (48 germline PCR tests and 67 NGS based). There was complete (100%) concordance of genotypes across germline and somatic assays, with genotypes of DPYD *1/*1 (106/106 samples), *1/*2A (3/3), *1/*13 (2/2) and *1/HapB3 (4/4). **Conclusions:** There was 100% concordance of somatic whole exome sequencing with traditional germline testing for DPYD deficiency. While germline testing remains the standard of care given the nuances of somatic copy number changes, our results suggest that somatic whole exome sequencing is a viable and efficient screening tool for DPD deficiency. Clinical features and occurrence of other cancers in patients with chronic lymphocytic leukemia and their families with *POT1* tumor predisposition syndrome. First Author: Jennifer Croden, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: *Protection of telomere 1 (POT1)* tumor predisposition syndrome (POT1-TPD) is a hereditary leukemia predisposition syndrome that is identified in up to 5% of patients with chronic lymphocytic leukemia (CLL) and is characterized by a predisposition to other cancers such as gliomas, melanomas, angiosarcomas, and cardiac myxomas. Herein, we report clinical features and cancer diagnoses of the largest cohort of patients with CLL and members of families with POT1-TPD published to date. **Methods:** Patients and family members with pathogenic or likely pathogenic germline *POT1* variants evaluated in the Hereditary Hematologic Malignancy Clinic (HHMC) at MD Anderson Cancer Center were included. Individuals with a variant of uncertain significance (VUS) in the *POT1* gene were also included if found to have telomeres $>90^{th}$ percentile of age predicted length. **Results:** A total of 24 individuals in 17 families were identified. At the time of referral, 11 (46%) had a diagnosis of CLL, and 1 (4%) had monoclonal B-cell lymphocytosis (MBL). The remaining 12 individuals had no history CLL or MBL and were referred based on family history; however, 4 were found to have MBL at the time of referral (4/12, 17%). Among the 24 individuals, additional malignancies included: 6 melanoma, 3 hematologic cancers (1 CML, 2 NHL), and 1 papillary thyroid cancer. Among the 17 families, we documented a high reported prevalence of melanoma (8/17, 47%), CLL (6/17, 25%), glioblastoma (3/17, 18%) and sarcoma (2/17, 12%). Details of the *POT1* variants were available for 16 families. Variants were classified as pathogenic in 7 (44%), likely pathogenic in 7 (44%), and as VUS in 2 (19%). Additional pathogenic germline variants in *CHEK2*,*BRCA2*, and *MITF* were observed in 3 (19%) families, respectively. Five families had telomere length testing performed (31%), and lymphocyte telomere lengths were above the 99^{th} percentile in 60% and above the 90^{th}percentile in 100%. The patients with CLL (n=11) had a median age at diagnosis of 55 years (range 29-68). 82% of patients had diploid karyotype, 64% had del13q by FISH, and 60% had mutated IGHV. Of the 7 patients with NGS testing performed, additional somatic mutations were present in 6 (86%) and *NOTCH1* was the most common (43%). Five patients (45%) have received treatment for CLL with a median time to treatment of 4.5 years from diagnosis (95% CI 4.3, 4.6). Median overall survival of all patients was 13.8 years (95% CI 9.4, 18.3). **Conclusions:** This analysis provides insights into familial patterns of malignancy and the natural history of CLL in individuals with POT1-TPD. Patients with germline POT1 variants appear to develop CLL and MBL at an early age. Evaluation from a genetic counselor and augmented cancer screening due to the high risk of solid tumors and other hematological malignancies is paramount. Research Sponsor: None.

Incidence of concurrent pathogenic variants in *BRCA1* breast cancer patients. First Author: Angel Lok Yiu Lee, Lenox Hill Hospital/Northwell Health, New York, NY

Background: Over the years, advancements in genetic testing have led to an expansion in the number of detectable mutations. This progress has enabled the identification of patients with pathogenic genetic variants, allowing for the implementation of tailored cancer screening strategies. For patients with breast cancer or high risk of breast cancer, there are advocates for comprehensive expanded genetic testing panels while others prefer to only perform selective testing for genes associated with breast cancer. The goal of this study was to determine how often patients with *BRCA1* pathogenic variants have additional mutations picked up on panel tests and whether they are clinically significant. **Methods:** We used the Myriad Collaborative Research Registry to access de-identified information on breast cancer patients with *BRCA1* variants. We looked at the data collected from individuals that were tested for mutations in 26 or more genes. We identified the most commonly mutated genes that are found in patients with *BRCA1* mutations. For this study, the term deleterious is equivalent to pathogenic/likely pathogenic. **Results:** Among breast cancer patients who underwent expanded panel testing for at least 26 genes, 10,250 individuals were identified to carry deleterious mutations. Of these, 400 patients had deleterious mutations in two or more genes. Within this subgroup, 184 individuals had deleterious *BRCA1* mutations along with at least one additional pathogenic mutation. Table 1 lists the most frequently mutated additional genes in patients with *BRCA1* mutations in our dataset. The most common pathogenic mutations that co-occur with *BRCA1* mutations were found in *MUTYH* (31.5%), *CHEK2* (12.5%), *BRCA2* (12.5%), and *ATM* (11.4%). One patient had deleterious mutations in *BRCA1* and two additional genes (*MUTYH* and *BRIP1*). **Conclusions:** Our data underscores the importance of evaluating patients for additional gene mutations. Extensive evidence demonstrates that certain pathogenic genes increase the risk of specific cancers. Restricting genetic testing to a targeted panel of breast cancer-associated genes may overlook other pathogenic genes that could predispose these individuals to additional malignancies. For instance, identifying pathogenic mutations in *PMS2*, in addition to *BRCA1*, could lead to meaningful alterations in clinical management. Further research is essential to investigate the clinical significance of co-occurring genetic variants, particularly those involving *BRCA1* and other high-risk genes. Research Sponsor: None.

Most commonly identified concurrent pathogenic genes in *BRCA1* breast cancer.

Concurrent pathogenic gene	Count
MUTYH	58 (31.5%)
CHEK2	23 (12.5%)
BRCA2	23 (12.5%)
ATM	21 (11.4%)
BRIP1	16 (8.7%)
PALB2	8 (4.3%)
PMS2	8 (4.3%)
NTHL1	6 (3.3%)
BARD1	4 (2.2%)

Genes in bold are known to be associated with breast cancer.

Exploring the prevalence of germline mutations in young-onset biliary tract cancer (BTC). First Author: Osama M. MoSalem, Mayo Clinic Florida, Jacksonville, FL

Background: The American Society of Clinical Oncology (ASCO) and NCCN recommend germline testing for patients (pts) with biliary tract cancers (BTC), particularly those diagnosed at a young age. Prior studies estimate that approximately 15% of pts with BTC harbor pathogenic germline alterations. Germline testing can identify hereditary cancer syndromes, guide targeted therapy, and inform family counseling. This study aimed to further characterize and describe the prevalence of pathogenic germline variants (PGVs) in patients with young-onset BTC (YO-BTC). **Methods:** We conducted a retrospective review of medical records for pts diagnosed with YO-BTC (ages 18–55) across all Mayo Clinic tri-sites from January 2014 to October 2024. Data collected included results from germline DNA sequencing, tumor genetic testing, demographics, history of other malignancies, and family history of cancer. The primary outcome was the identification of pathogenic germline mutations associated with cancer predisposition. **Results:** Among 239 pts with YO-BTC, the median age at diagnosis was 43 years (range 19–55), with 62% female and 65.2% identifying as white. Clinical germline testing (e.g., Invitae, Ambry, Myriad) was performed in 123 pts (51.5%), revealing PGVs in 15 pts (12.1%), variants of uncertain significance (VUS) in 30 pts (24.3%), and likely benign variants in 4 pts (3.2%). Among those with PGVs, DNA repair mutations were the most common findings (10/15), including ATM (4), CHEK2 (2), BRCA2 (2), BAP1 (1), and PALB2 (1). One pt had a Lynch syndrome-associated mutation (MSH6), and four had mutations in other cancer-related genes (MUTYH, HOXB13, RMRP, and PIK3CA). Tumor genomic profiling (via CARIS, TEMPUS, or FoundationOne) was performed in 9 pts with PGVs, detecting the variant in 4 (44%), while liquid biopsy (Guardant) identified the PGV in 4 of 6 cases (66.6%).The majority of PGV carriers had advanced BTC (14/15), with intrahepatic cholangiocarcinoma being the most prevalent (11/15), while 4 had extrahepatic cholangiocarcinoma. Additionally, most PGV carriers had a first- or second-degree relative with a prior history of malignancy (14/15), and 3 pts had a second malignancy. Of the 15 pts with PGVs, 4 had BTC associated with primary sclerosing cholangitis. **Conclusions:** In this large institutional series of YO-BTC, PGVs were identified in 12.1% of pts, demonstrating a significant yield from germline testing in this population. Notably, tissue and liquid biopsies demonstrated different detection rates for PGVs, underscoring the variability in PGVs reporting across platforms. Germline testing through CLIA-approved methods should remain the standard of care. DNA repair pathway mutations, particularly ATM, CHEK2, and BRCA2, were the most frequently identified PGVs, highlighting their role in the pathogenesis of YO-BTC and their potential to guide treatment decisions. Research Sponsor: None.

Limited versus expanded multigene germline genetic testing among adolescents and young adults (AYA) with breast cancer. First Author: Baha' Sharaf, King Hussein Cancer Center, Amman, Jordan

Background: In low- and middle-income countries, like ours, breast cancer is diagnosed mostly in younger women. With a median age of 50-52 years, breast cancer is diagnosed at least 10 years younger than in Western societies. Though most breast cancer cases are sporadic, 5-10% of cases are hereditary and mostly related to *BRCA1* or *BRCA2* variants. However, the widespread use of genetic testing, mutations other than BRCA1/2 are currently detected, the clinical importance of which is questionable. In this paper, we aim to study the prevalence and pattern of pathogenic/likely pathogenic (P/LP) variants among adolescents and young adults (AYA). **Methods:** Blood samples of patients with breast cancer diagnosed at age 39 years or younger were obtained for DNA extraction and sequencing. Mutations were classified as benign/likely benign (non-carrier), P/LP (carrier), and variant of uncertain significance (VUS). At the initial phases of testing, patients were tested for only *BRCA1* and *BRCA2* (n = 415), then *PALB2* was added (n = 145). With availability and affordability of germline genetic testing, 267 patients were tested utilizing an 84-gene panel before we settled on a 21-gene panel (n = 897). Testing was done at reference referral labs. All patients were counselled by a genetic counsellor before and after testing. **Results:** During the study period, a total of 1,724 patients with breast cancer diagnosed at age 18-39 had germline genetic testing and were included in the analysis. Majority (n = 1,530, 88.8%) were Jordanian, while the rest were non-Jordanian Arab. Median (range) age was 35 (15-39) years, and except for 6 patients, all were female. Among the whole group, 262 (15.2%) had pathogenic or likely pathogenic (P/LP) variants and were mostly *BRCA2* (n = 121, 46.2%) and *BRCA1* (n = 76, 29.0%). Other variants include *TP53* (n = 15, 5.7%), *ATM* (n = 12, 4.6%), *CHEK2* (n = 11, 4.2 %) and *PALB2* (n = 8, 3.1%). Rate of P/LP variants was significantly higher among patients younger than 30 years (23.6%) compared to a rate of 13.8% among older ones aged 30-39 years, p = 0.0001. Rates of P/LP variants were higher in patients tested with the 84-multigene panel (17.9%) compared to those who were tested with the 21-MGP (15.5%) or BRCA1/2 with or without *PALB2* (13.6%). VUS rates were significantly higher with expanded gene testing; 54.7% with 84-gene, 22.5% with 21-gene and less than 10% with limited gene testing, $p < 0.0001$. Limiting testing to *BRCA1, BRCA2, PALB2, CHEK2, TP53* and *ATM* would include 92.7% (n = 243) of all P/L variants. The remaining 19 (7.3%) are variants of low penetrance. **Conclusions:** The rate of P/LP variants in AYA patients, particularly those under 30 years, with breast cancer is higher than what has been previously observed in older patients. Expanding genetic testing beyond *BRCA1, BRCA2, PALB2, CHEK2, ATM*, and *TP53* in this age group leads to a lower yield and a significantly higher proportion of VUS. Research Sponsor: None.

Sequential EHR interventions to increase genetic testing for breast and ovarian cancer predisposition across diverse patient populations in gynecology practices at Penn Medicine. First Author: Heather Heather Symecko, Basser Center for BRCA, Philadelphia, PA

Background: Genetic testing (GT) identifies individuals who may benefit from increased surveillance and risk reduction strategies. GT is under-utilized, especially in those without a personal history of cancer and in minority populations. **Methods:** We identified a patient cohort meeting NCCN criteria for genetic testing utilizing electronic health record (EHR) phenotyping in 2 diverse gynecological practices. NCCN criteria included individuals with a personal history of ovarian cancer, early-onset (<50) breast cancer diagnosed before 2021, or a family history (FH) of ovarian cancer or male breast cancer. Participants with prior genetics visits were excluded. Patient nudges and provider messaging strategies were introduced to boost genetic counseling consultation. Nudges included patient portal messaging (PP) followed by texts using the Way To Health platform (WH) in those that did not respond to PP. For non-responders to patient directed nudges, genetic counseling consult orders were placed using Epic's Pend & Send tool and sent to their gynecologist. Endpoints included the open rate for PP, response rate for the WH text, and the number of genetic counseling appointments completed. Differences between the clinics were calculated by Chi Square. **Results:** Of 1055 patients identified and who received a PP message regarding genetic counseling, 81% had a FH of ovarian cancer. Characteristics of the patient populations differed across clinics: Clinic D (n=505): 71.3% Black, 18% White and 67% < 45 years. Clinic R (n=550):10% Black, 83.5% White and 63% > 60 years.79% opened PP and 22.1% replied to PP, more in Clinic R (26.7% vs 17.0%, p<0.001). Patient engagement by PP or WH was 59.8% (631/1055), more in Clinic R (67.1% vs 51.9%, p<0.001). Of those that connected by patient nudges, 62.8% (396/631) declined additional follow-up (more in Clinic R, 41.5% then Clinic D, 33.3%, p=0.014), either due to incorrect family history in EHR, prior genetic testing, or, in the majority of cases, because they were not interested (296/631) (46.9%). Provider nudges added little to patient nudges with regard to GT uptake. 25% (266/1055) scheduled and 14.9% (157/1055) of the cohort completed GT appointments with no difference between the two (Clinic D 13.9% vs Clinic R 15.8%, p=NS). **Conclusions:** Patient directed nudges led to engagement of nearly 60% of patients in two diverse gynecology practices. 25% of individuals scheduled and 14.9% completed appointments, with continued follow-up. Although engagement in PP and WH differed between the two clinics, the number of visits did not. An EHR-based approach to identifying patients and encouraging genetic testing is a relatively low effort, scalable strategy to increase reach and encourage engagement in genetic counseling. However, a majority of patients either did not respond or did not wish to be tested. Clinical trial information: NCT05721326. Research Sponsor: National Cancer Institute; P50 CA244690; Basser Center for BRCA.

10590 **Poster Session**

Clinical utility of germline genetic testing in diverse cancer types. First Author: Diane Renee Koeller, Dana-Farber Cancer Institute, Boston, MA

Background: Germline genetic testing (GGT) is often recommended for cancer patients with an estimated ≥10% risk of carrying a clinically actionable pathogenic germline variant (PGV). Clinical utility of GGT is understudied for many cancer types, making assessing risk challenging. Herein we describe interim results from a GGT study of diverse cancer types. **Methods:** The PROACTIVE (Profile And Cancer gene Testing for IndiVidual Evaluation) Study is an ongoing institute-wide study at Dana-Farber Cancer Institute through which participants may opt-in to blood- or saliva-based clinical GGT of 133-156 genes, with results returned. Participants were identified by their clinical program, mainly consisting of those who did not meet clinical criteria for GGT based on having cancers that are considered low-risk for hereditary cancer predisposition syndromes. Clinically actionable PGV were defined as those that conferred potential eligibility for clinical management guidelines, targeted therapies and/or clinical trials. **Results:** Between 03/15/2019 and 11/30/2024, 1569 participants completed GGT. PGV were identified in 437/1569 (27.9%) participants, however 285 (18.2%) had PGV associated only with autosomal recessive cancer risk or low penetrance. Clinically actionable PGV were identified in 152/1569 (9.7%) participants and made up one-third (152/437) of PGV results. Clinically actionable PGV were identified most frequently in *ATM*, *CHEK2*, *APC*, *BRCA2*, and *TP53*, with the highest rates in gastric, central nervous system (CNS), and thyroid cancer (Table). High risk PGV were identified in 67/1569 (4.3%) participants, and were most frequent in the gastric, thyroid, and CNS cohorts (Table). Only 47/1569 (3.0%) participants had a PGV that was concordant with their cancer type. **Conclusions:** GGT identified clinically actionable findings in nearly 1 in 10 participants, most of whom were considered low-risk for hereditary cancer predisposition based on their personal cancer types. Most clinically actionable results were secondary findings unrelated to the presenting cancer type, but still impact cascade testing and screening for second primary cancers. This demonstrates the clinical utility of offering universal pan-cancer GGT to a broader range of cancer patients. Research Sponsor: None.

Clinical significance of germline CFTR mutations in pancreatic cancer. First Author: Nicholas Liguori, Cedars Sinai Medical Center, Los Angeles, CA

Background: Pancreatic ductal adenocarcinoma (PDAC) remains a malignancy with high cancer-related mortality. The majority of PDAC is sporadic, but approximately 10% are implicated by germline mutations. We recently reported that CFTR was one of the most mutated germline genes occurring in 11.9% of 1203 patients with PDAC. However, the clinical implications of germline CFTR mutations remain unknown. This study sought to evaluate the differences in clinical outcomes in PDAC patients with and without germline CFTR mutations. **Methods:** Eligible patients were ≥18 years who consented for BioBank specimen collection and Invitae genetic testing (n = 66). Patients were separated into two groups: patients with a known CFTR mutation (pathogenic variant or variant of uncertain significance (VUS)) (n = 35), and an age- and stage-matched cohort with no known CFTR mutation (n = 31). Subgroups were further stratified by stage at diagnosis: Stage I-III (early stage) vs Stage IV. Survival analysis was performed using Kaplan-Meier method and log-rank testing. A P-value < 0.05 was considered significant. Multiple linear regression was performed to investigate any associations between clinical variables (age at diagnosis, pathogenic variant vs VUS, history of smoking, alcohol use, pancreatitis) and survival. **Results:** A total of 35 patients with germline CFTR mutations and 31 age- and stage-matched patients were analyzed. Across all stages, the CFTR group had a median OS of 868 days vs 462 days (95% CI 1.014-3.48, P = 0.0390) in the non-mutated group. There was no difference in median OS between CFTR-mutant and non-mutant groups when stratified by early stage (I-III) disease: 929 days vs 765 days (95% CI 0.5950-2.478, P = 0.8543), respectively. Notably, CFTR mutated patients with stage IV disease derived greater OS benefit compared to the non-mutated group (572 days vs 182 days, 95% CI 1.025-9.639, P = 0.0140). Within the pathogenic (n = 25) and VUS (n = 10) subgroups of the germline CFTR mutant group, there was no difference in survival between those with pathogenic variants vs VUS (868 days vs 535 days, 95% CI 0.5233-5.031, P = 0.3573). Within the CFTR group, there was no difference in outcomes when analyzing for exposure to risk factors including smokers and non-smokers (868 days vs 572 days, 95% CI 0.2290-1.897, P = 0.5137), history of pancreatitis and no pancreatitis (929 vs 868 days (95% CI 0.3719-3.080, P = 0.5877), and alcohol use (chronic and social) and no alcohol use (939 days vs 622 days, 95% CI 0.5245-4.345, P = 0.0612). Multiple linear regression did not show any significant associations between pre-specified clinical variables and survival. **Conclusions:** This study suggests there is an association between germline CFTR mutation and improved survival in patients with advanced PDAC. CFTR may be a potential prognostic biomarker, which underscores the need for further studies focusing on the implications of CFTR mutations and PDAC. Research Sponsor: None.

Germline genetic testing for hereditary cancer syndromes among newly diagnosed patients with solid tumors: A report of 10,000 patients from the Jordanian Exploratory Cancer Genetics study. First Author: Hikmat Abdel-Razeq, King Hussein Cancer Center, Amman, Jordan

Background: Hereditary factors play a key role in the risk of developing several cancers. Identification of germline cancer predisposing genes can have important implications for cancer screening, risk-reduction, risk-reducing interventions, and treatment decisions. **Methods:** In this study, patients with various cancers diagnosed and treated at King Hussein Cancer Center (KHCC) between January 2014 and December 2024 who had germline genetic testing (GGT) were retrospectively reviewed. Most patients were tested as per the National Comprehensive Cancer Network (NCCN) guidelines for GGT, while 3,319 patients were tested as part of a study for universal testing of all newly diagnosed cancer patients. Genetic testing was performed at reference commercial laboratories, or at academic centers. **Results:** The study involved 9,872 patients, the mean age at diagnosis was 49.7 (range: 18-90) years. Breast cancer was the most prevalent cancer type, comprising 67.3% of all cases, followed by colorectal cancer at 11.5%. Pathogenic/likely pathogenic (P/LP) variants were detected in 1,007 (10.2%) of the patients, while variants of uncertain significance (VUS) accounted for 33.6% of all genetic test results, highlighting the challenges of expanded panel testing. The most frequently identified pathogenic genes were BRCA1 and BRCA2, with 197 (2.0%) and 333 (3.4%) P/LP variants detected, respectively. Other notable genes included CHEK2 (n=28), PALB2 (n=38) and TP53 (n=47). Breast and colorectal cancers showed the highest number of pathogenic variant detections, with breast cancer accounting for 66.3% of all P/LP cases. Among less common cancers, ovarian cancer demonstrated a relatively high pathogenic variant rate (21.9%) despite its lower overall prevalence. Testing eligibility played a significant role in outcomes, with the majority of patients undergoing guideline-based testing (60%) and 26% undergoing universal testing. Expanded testing panels increased the detection of VUS significantly but did not improve pathogenic variant detection rates compared to guideline-based testing (p<0.001). There was also a significant association between cancer type and genetic testing results (p<0.001), underscoring the importance of cancer-specific testing strategies. **Conclusions:** These findings highlight the high prevalence of pathogenic variants in breast and colorectal cancers, the clinical relevance of BRCA1/2 and other high-risk genes, and the trade-offs of expanded genetic testing panels in balancing broader detection capabilities with interpretive challenges due to increased VUS rates. This emphasizes the need for targeted genetic counseling and strategic use of comprehensive testing panels for optimal clinical impact. Research Sponsor: None.

Results of a program addressing multi-level barriers to completion of hereditary cancer genetic testing (GT) among underserved and minority individuals in Texas. First Author: Darya Aleksandrovna Kizub, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: 5-10% of breast and colorectal cancers are hereditary, but uptake of GT among eligible individuals remains low. Our previous study showed that only 10 % of the 150 underserved and minority women deemed eligible for GT based on our validated Cancer Genetic Risk Assessment (CGRA) completed GT. Based on lessons learned, we implemented a multi-level program including: 1) genetic services education; 2) one-stop CGRA screening, scoring, and GT, 3) financial navigation, 4) telegenetics, and evaluated its impact. **Methods:** This prospective 12-months two-part program was implemented in Harris County, Texas, in 2023-2024. The primary outcome was GT completion. Both participants and providers received education about hereditary cancers. In the first part of the program, women who presented for mammography screening at clinics in underserved communities filled out the CGRA. In the second part, participants who identified as Black filled out the CGRA during events organized by trusted community organizations. The CGRA was scored and, if warranted, a saliva-based GT kit was offered during the visit or mailed later. Our study coordinator assisted with all financial paperwork. When a pathogenic variant (PV) or variant of uncertain significance (VUS) was found, participants received telegenetic counseling; others were notified of negative results. Sociodemographic characteristics and genetic services participation were analyzed via descriptive statistics and standard tests of association. Program implementation was assessed via in-depth interviews with a purposeful sample of participants and providers, which were audio-recorded, transcribed, double-coded, and analyzed via thematic analysis. **Results:** In the first part of the program, out of 870 women who presented for mammography screening and were approached, 590 (87%) agreed to be screened via CGRA (median age 52), including 537 (91.0%) who identified as Hispanic, 427 (72.4%) with preferred language Spanish. Median annual salary was 19,200. 99 (16.8%) were eligible for GT and 54 (54.5%) completed it, with 35 (64.8%) negative, 14 (25.9%) VUS, 5 (9.2%) PV in MUTYH , NF1, CHEK2, MSH3. In the second part of the program, out of 4,192 people who attended 20 community events, 390 (9.3%) individuals were screened via the CGRA (median age 54); all identified as Black. Median annual salary was 65,000. 187 (47.9%) were eligible for GT and 97 (51.8%) completed it, with 74.2% (72) testing negative, 22.7% (22) VUS, 3.09% (3) PV in RAD51C, CHEK2, BRCA1. GT completion was not associated with race, ethnicity, or salary ($p > 0.05$). Based on interviews with 56 participants and 16 providers, main GT facilitators included program convenience, while main barriers included cost and fear of results. **Conclusions:** Our program was successful in improving GT completion among underserved and minority participants. Clinical trial information: NCT05649072, NCT05694559. Research Sponsor: Susan G. Komen; CH22GCT001; The Community Outreach and Engagement Fund for Underserved Texans (COEFUT) sponsored by the Quasi Endowment Committee (QEC); RCTS number: 2022-00060886-Y1.

Germline genetic testing among patients with pancreatic cancer (PC): A Pancreatic Cancer Action Network (PanCAN) patient survey. First Author: Udhayvir Singh Grewal, University of Iowa Hospitals and Clinics, Iowa City, IA

Background: Universal germline genetic testing for PC is endorsed by multiple professional organizations like the National Comprehensive Cancer Network (NCCN), yet implementation remains limited. We sought to investigate practices related to germline testing in PC and identify potential causes of under-testing through a large patient survey. **Methods:** We used the PanCAN patient registry to administer this HIPAA-compliant survey electronically to patients and caregivers. Logistic regression was used to determine the association between patient-reported demographic and clinical characteristics and the odds of undergoing germline genetic testing. A multivariate model was built to include all characteristics that were significant on univariate analysis. The association between receipt of genetic counseling and cascade germline genetic testing among first degree relatives (FDR) of patients with germline mutations was assessed via a chi-square test. **Results:** A total of 1,046 patients with PC were included, of which, 724 (69.2%) reported undergoing germline genetic testing. On multivariate analysis, race ($p = 0.01$), insurance type ($p < 0.01$), stage ($p < 0.01$), and treatment facility type ($p < 0.01$) were significantly associated with the odds of undergoing germline genetic testing after PC diagnosis. Black patients (compared to White) [OR = 0.42 (95% CI 0.23-0.78)], uninsured patients (compared to Medicare) [OR = 0.11 (95% CI 0.03-0.44)], patients insured through Veterans Health Administration (compared to Medicare) [OR = 0.26 (95% CI 0.08-0.92)] and patients receiving care at large [OR = 0.62 (95% CI 0.46-0.84)] and small community practices (compared to academic/teaching hospitals) [OR = 0.51 (95% CI 0.29-0.88)] were at significantly decreased odds of undergoing germline genetic testing. Patients with stage IV (compared to stage I) [OR = 2.23 (95% CI 1.46-3.40), stage II/III PC (compared to stage I) [OR = 1.58 (95% CI 1.11-2.23)] and those with private insurance (compared to Medicare) [OR = 1.51 (95% CI 1.11-2.05)] were at significantly increased odds of undergoing germline genetic testing. Of 724, 167 (23.2%) patients reported testing positive for germline mutations. Only 103 of 167 (61.7%) of these patients reported cascade testing among FDR. Patients undergoing genetic counselling had higher rates of cascade germline genetic testing among FDR (67.7% v 38.2%, $p < 0.01$). **Conclusions:** This is one of the largest patient-reported surveys from recent times suggesting sub-optimal implementation of guideline-based germline genetic testing in PC. This study highlights key inequities in testing based on race, insurance and practice setting. Our findings also underscore the critical role of genetic counselling in facilitating cascade testing among FDR of patients with PC and germline genetic mutations. Research Sponsor: None.

Concordance of parent-of-origin predictions for hereditary cancer variants using proband-only analysis. First Author: Lilian Cordova, Department of Medical Genetics, University of British Columbia, Vancouver, BC, Canada

Background: Determining the parental origin of germline variants is a critical gap in clinical genetics, essential for risk management, variant classification, and cascade genetic testing. Traditional methods rely on testing family members, which can be time-consuming and impractical when relatives are unavailable, deceased, or unwilling to participate. Parent-of-Origin-Aware Genomic Analysis (POAga) offers a transformative solution by enabling accurate assignment of any autosomal variant to either parent with 99% accuracy using only a blood sample from the proband. This method integrates methylation and sequence data from Oxford Nanopore long-read sequencing with chromosome-length haplotypes generated from Strand-seq, leveraging the accurate phasing of imprinted differentially methylated regions (iDMRs) that occur on each autosome to infer the parent of origin (PofO) of variants across the genome. This study aims to validate POAga across multiple hereditary cancer syndromes, including high-penetrance conditions such as hereditary breast and ovarian cancer (HBOC) and Lynch syndrome, as well as rarer syndromes with PofO effects and other genes associated with breast and gastrointestinal malignancies. **Methods:** Blood samples from carriers of pathogenic variants in *ATM*, *BRCA1*, *BRCA2*, *CDH1*, *MLH1*, *MSH2*, *MSH6*, *PMS2*, *EPCAM*, *PALB2*, *SDHD*, *SDHAF2* and *TP53* with known parental segregation, are currently being ascertained and undergoing whole-genome analysis to determine the analytic validity of POAga. These samples span diverse demographics, including variations in age, sex, ethnicity, and cancer status. PofO predictions are made according to previously described methods (Akbari V, Hanlon VCT, *et al*. Cell Genom. 2022 Dec 21;3(1):100233) under an REB-approved protocol. **Results:** To date, 188 individuals carrying 189 pathogenic variants with known parental segregation have been analyzed. The distribution of variants includes *BRCA2* (n=31), *MLH1* (n=23), *MSH2* (n=22), *BRCA1* (n=22), *SDHD* (n=21), *MSH6* (n=20), *PALB2* (n=14), *PMS2* (n=13), *ATM* (n=9), *CDH1* (n=9), *SDHAF2* (n=2), *EPCAM* (n=2) and *TP53* (n=1). PofO assignment was successful for 172 of 189 (91%) variants. Only one sample with an *MLH1* variant was misassigned, while all other cases demonstrated concordance between the predicted and known parental origin (188 of 189, 99.5% accuracy). **Conclusions:** These results support the ability of POAga to accurately infer the parental origin of pathogenic variants in diverse hereditary cancer syndromes using only blood sample from the proband. Ongoing validation will further assess its feasibility in real-world clinical settings and refine its clinical translation. POAga represents a powerful advancement in hereditary cancer genetics, with the potential transform how we conduct genetic cancer risk assessments for patients and families. Clinical decision support system based on artificial intelligence and the patient's subjective intention treatment model: A randomized controlled clinical trial. First Author: Lu Wang, Department of Oncology, Tongji Hospital of Tongji Medical College, Huazhong University of Science & Technology, Wuhan, China

Background: To achieve intelligent diagnosis and treatment of tumors through the application of artificial intelligence and to meet the needs of areas lacking medical resources, a new treatment model based on the patient's subjective intention (PSI) was proposed, and a clinical decision support system (CDSS) called Doctors In Hands (DIH) was designed. Here, we report the DIH trial with the PSI treatment model to evaluate its efficiency. **Methods:** In this randomized controlled open-label trial (ChiCTR2400094469), patients from the departments of oncology, internal medicine, and surgery signed informed consent forms and were randomly divided into the clinician group, the CDSS plus clinician group and the CDSS group. The PSI treatment model was applied in the CDSS group. The primary endpoint was the sensitivity of alternative diagnoses and treatment options. The secondary endpoints were patient satisfaction and the specificity of alternative diagnoses and treatment options in different departments and groups. A multimodal large model based on the novel PSI treatment model was used as the intelligent platform for diagnosis and treatment data analysis and human–computer interaction. **Results:** A total of 120 patients and 9 doctors were enrolled and randomly divided into three groups. In the clinician group, the sensitivity and specificity of diagnosis were 0.82 and 0.76, the Youden index was 0.58. In the CDSS group, the sensitivity and specificity were 0.85 and 0.80, the Youden index was 0.65. For the CDSS plus clinician group, the sensitivity and specificity were 0.90 and 0.87, the Youden index was 0.77. Subgroup analysis of patients according to treatment strategy revealed that the satisfaction of patients in the PSI-based CDSS group was significantly greater than that of patients in the clinician group (92% vs. 86%, $P < 0.01$), but there was no significant difference between the CDSS group and the CDSS plus clinician group (92% vs. 93%, $P = 0.37$). Subgroup analysis of the PSI-based CDSS group according to diagnostic strategy revealed that the diagnostic accuracy for patients from the department of oncology was significantly greater than that for patients from the department of internal medicine (0.88 vs. 0.81, $P < 0.05$) but was not significantly different from that for patients from the department of surgery (0.88 vs. 0.87, $P = 0.14$). **Conclusions:** DIH has good performance in the diagnosis of tumors and development of treatment plans. In the PSI model, patients can make independent choices regarding disease treatment plans according to the objective clinical or basic research evidence provided by DIH to reduce the duration of consultation and save medical resources. The clinical significance of this trial is that the CDSS can promote the sharing of medical resources and improve the efficiency and quality of clinical work in areas lacking medical institutions. Clinical trial information: ChiCTR2400094469. Research Sponsor: None.

Impact of incretin mimetic therapy on weight change in patients with cancer: A pan-cancer analysis from a single institutional cohort. First Author: Yan Leyfman, Icahn School of Medicine at Mount Sinai South Nassau, Oceanside, NY

Background: An elevated body mass index (BMI) is a frequent comorbidity in patients with cancer. Chemotherapy can exacerbate metabolic dysfunction and weight gain, further complicating cancer management. Glucagon-like peptide-1 receptor agonists (GLP-1RA) are indicated for the treatment of diabetes (DM) and obesity, promoting weight loss through mechanisms such as insulin secretion, delayed gastric emptying, and reduced appetite. However, their effect after a cancer diagnosis, particularly during chemotherapy, remains underexplored. **Methods:** This was a single-institution retrospective study evaluating cancer patients prescribed GLP-1 receptor agonists (GLP-1RA). Patient demographics, cancer type (solid vs. hematologic), and treatment details were extracted from the medical records. The overlap between GLP-1RA therapy and chemotherapy administration was recorded. Changes in BMI were analyzed using descriptive statistics, including percentiles and median values. A one-sample t-test assessed the overall significance of BMI changes, while subgroup analyses using Welch two-sample t-tests evaluated the impact of chemotherapy, sex, and cancer type on BMI reduction. R software was used to perform statistical analyses. **Results:** Between 2015 and 2024, 339 cancer patients were treated with GLP-1RAs, mainly semaglutide (48%) and liraglutide (28%). DM was the primary indication in 92% patients (Table 1). The median age at initiation was 60.8 years (range: 19.0–88.2), for a median duration of 11.8 months (range: 2.6–94.1). Median BMI decreased from 32.5 kg/m² (range: 18.9–58.9) pre-treatment to 31.5 kg/m² (range: 16.6–60.2) on/post-treatment, with a median change of -1.0 kg/m² (95%CI: -1.64, -1.01) and a median percentage reduction of -3.71% (95%CI: -4.59%, -2.83%). Subgroup analyses showed significant BMI reductions in patients receiving chemotherapy (median: -4.18%, 95%CI: -6.38%, -2.82%) and those not receiving chemotherapy (median: -2.32%, 95%CI: -4.32%, -2.31%), with no significant difference between the groups (95%CI: -0.22, 1.28). Additionally, BMI reductions were consistent across sex (95%CI: -0.91, 0.36) and cancer type (solid vs. hematologic, 95%CI: -0.77, 0.64). **Conclusions:** GLP-1RA use resulted in weight loss in cancer patients independent of chemotherapy exposure, sex, or cancer type. Although the degree of weight loss was modest, findings were consistent with GLP1-RA treatment dosed for a diabetes indication. These findings support the need for clinical trials evaluating incretin mimetics for weight management and their potential impact on cancer-specific outcomes. Research Sponsor: None.

Patient demographics.

Assessing the association between cycles of fertility treatments with gonadotropins and cancer risk. First Author: Amichay Meirovitz, Soroka - Clalit and Ben Gurion University Medical Center, Be'er Sheva, Israel

Background: Fertility treatments such as in vitro fertilization (IVF) and controlled ovarian hyperstimulation relies on exogenous hormones known as gonadotropins that directly stimulate ovarian activity. Concerns have arisen regarding the increased risk of hormone-sensitive cancer development due to repeated hormonal stimulation. The literature regarding this risk is ambiguous. We aimed to assess the association between the number of fertility treatments with gonadotropins (FT-GT) cycles and cancer risk in a large national HMO database. **Methods:** The Clalit Health Services database was analyzed between 2003-2013 to identify females who underwent FT-GT along with matched controls by age, ethnicity and socioeconomic status. FT-GT cycles were identified through the use of gonadotropins. Controls were matched 4:1 with untreated females. Patients were grouped based on number of FT-GT cycles being 1–4, 5–7, or $\geq$8. Cancer risk analysis focused on breast, colon, thyroid, stomach and pancreas, as well as any detectable cancer. We performed a separate sub-analysis of women who received $\geq$10 FT-GT cycles. **Results:** A total of 178, 637 patients were analyzed- 39,068 received FT-GT; 24,716 underwent 1–4 cycles; 7,774 underwent 5–7 cycles; and 6,578 received $\geq$8 cycles. For the separate sub-analysis, 3,949 women received $\geq$ 10 cycles. The median follow-up was 12.6 years. The risk of breast cancer increased with the number of FT-GT cycles, with the highest risk observed in patients receiving $\geq$8 cycles (HR = 1.67, 95% CI: 1.22-2.27), followed by 5-7 cycles (HR = 1.42, 95% CI: 1.07-1.89), and 1-4 cycles (HR = 1.34, 95% CI: 1.15-1.56), when adjusting for hypothyroidism. When analyzing the $\geq$ 10 cycle sub-group, the hazard ratio for breast cancer reaches 1.79 (95% CI: 1.19-2.70). There was no correlation between FT-GT cycle number and colon, stomach or pancreatic cancer, or any other detected cancer. **Conclusions:** It appears that females receiving FT-GT are at a higher risk for breast cancer from the first cycle. The risk of breast cancer increases with the number of FT-GT cycles. None of the other cancers analyzed showed any significant cancer risk associated with FT-GT. Research Sponsor: None.

Decoding oncology terminology: Using large language models for patient education. First Author: Yuqing Wang, Montefiore Medical Center - Albert Einstein College of Medicine, Bronx, NY

Background: Large language models (LLMs), such as OpenAI's ChatGPT-4, are designed to process natural language and generate responses to text-based prompts. While these models have shown promise in addressing clinical and patient-related inquiries, they lack integration with dedicated medical knowledge databases, leading to potential inaccuracies. Meanwhile, healthcare professionals and models explicitly trained in medical texts frequently rely on specialized terminology, which can create significant barriers to clear and patient-friendly communication. This study aims to utilize LLMs to translate complex medical terminology into easy-to-understand explanations, focusing on hematology and oncology fields where communicating medical concepts to the public is particularly challenging. Our objective is to develop a solution that ensures explanations are both accurate and accessible, bridging the gap between technical medical knowledge and patient comprehension. **Methods:** We curated a dataset of cancer-related terms and their explanations from two sources: the National Cancer Institute (NCI) Dictionary, which provides detailed medical definitions, and simplified explanations based on National Comprehensive Cancer Network (NCCN) guidelines for patients. Using Meta's LLaMA 7 B-based chat model, we implemented retrieval-augmented generation (RAG) to enable the model to access the NCI Dictionary as needed. To fine-tune the model to generate patient-friendly explanations, we applied LoRA-based supervised fine-tuning (SFT). The model was evaluated on a holdout set of terms. Readability was measured using the Flesch Reading Ease Score (FRES) and Dale-Chall Readability Formula (DCRF). Improvements in accessibility were quantified through a two-sample t-test, comparing the mean readability scores of the model's outputs against the baseline. **Results:** The fine-tuned model demonstrated significant improvements in both accessibility and readability, achieving a 5% and 4% increase in the FRES (baseline: 69.25; output: 72.60, $P < 0.01$) and DCRF (baseline: 9.50; output: 9.15, $P < 0.01$), respectively. Preliminary results also indicate the model's capability to translate entire paragraphs of dense medical text into patient-friendly explanations. Expert validation on a larger scale is currently underway, further solidifying the model's potential to revolutionize patient communication in oncology. This innovative approach sets a new standard for leveraging advanced language models in healthcare education. **Conclusions:** We successfully trained a LLM specifically designed to simplify complex oncology medical terms into patient-friendly language. By serving as a reliable tool for delivering precise and accessible medical information, it holds the potential to reduce the workload of healthcare providers and enhance patient understanding in clinical settings. Research Sponsor: None.

Recruitment strategies and enrollment for a virtually supervised exercise intervention for Hispanic/Latinx breast cancer survivors. First Author: Christina Marie Dieli-Conwright, Dana-Farber Cancer Institute, Boston, MA

Background: Hispanic and/or Latinx cancer survivors remain underrepresented in clinical trials, particularly in exercise oncology and energy balance research, with less than 1% of exercise oncology trials focused on this population. The purpose of this analysis was to describe recruitment strategies and enrollment rates among Hispanic and/or Latinx breast cancer survivors screened for and enrolled in an exercise intervention. **Methods:** The ROSA Trial was a culturally tailored, virtually supervised exercise intervention designed to mitigate metabolic dysregulation in sedentary, overweight/obese Hispanic and/or Latinx breast cancer survivors. Trial recruitment strategies at the Dana-Farber Cancer Institute (DFCI) involved screening pre-determined electronic medical records of breast cancer patient lists for the DFCI Boston location, direct referral from the DFCI Merrimack Valley satellite which is comprised of $>$ 70% Hispanic patient population, recruitment letter mail outs the Massachusetts Department of Public Health (MDPH) cancer registry, American Cancer Society (ACS) Making Strides for Breast Cancer Boston events (2022-23), and media outlets. Descriptive statistics were used to determine frequency of recruitment strategies used and screening variables. **Results:** Trial recruitment occurred from September 2021-August 2024. The majority of women screened were identified at the DFCI Boston location (70%) followed by the MDPH (23%), DFCI Merrimack Valley (5%), and ACS events (2%). Out of 710 women screened, 396 were ineligible. Main reasons for ineligibility included did not identify as Hispanic/Latinx (n = 78; 19.7%), not sedentary (n = 60; 15.2%), and lived out of country/state (n = 56; 14.1%). Of the 314 women deemed eligible, 240 declined participation, with primary reasons including no communication response (i.e., never responded to voicemails or emails; n = 84; 35%), not interested (n = 46; 19.2%), and no time/scheduling issues (n = 42; 17.5%). There were 74 women who consented for the trial from the 314 deemed eligible, resulting in a 23.6% success rate. A total of 64 women were successfully randomized with 10 women unable to proceed to randomization due to no time (n = 4) or did not provide a specific reason/stopped responding to study staff (n = 6). Randomized participants were 55.47 $\pm$ 9.5 years old, overweight or obese (BMI = 30.33$\pm$ 5.6), postmenopausal (71%), diagnosed primarily with stage I (37.1%) or stage II (37.1%) breast cancer. **Conclusions:** Multiple recruitment strategies with specific attention to consistent points of contact are necessary to recruit Hispanic and/or Latinx breast cancer survivors in the Greater Boston area. Unique situations such as residency out of the country is important to consider in the planning of future trials among said population. Clinical trial information: NCT04717050. Research Sponsor: American Cancer Society.

Women's breast cancer mortality trends: The impact of lifestyle factors from the 2021 Global Burden of Disease (GBD) study. First Author: Samantha El Warrak, University of Miami, Miami, FL

Background: Breast cancer (BC) remains a leading cause of death among women globally. Understanding the role of modifiable risk factors is critical for designing targeted prevention strategies. The 2021 GBD study offers a comprehensive analysis of global health, quantifying the impact of diseases and risk factors on morbidity and mortality worldwide. This study provides an updated risk factor analysis in relation to women's BC mortality over the past three decades. **Methods:** Data from the study were used to examine trends in BC mortality in the United States from 1990 to 2021, stratified by age group representing younger pre-menopausal (ages 20-54) and older post-menopausal women (ages ≥55), associated with five key risk factors: tobacco use, red meat consumption, alcohol consumption, high body mass index (BMI), and high fasting plasma glucose (FPG). Age-standardized mortality rates (ASMR) were calculated for each factor, and differences between age groups were analyzed. All rates were reported per 100,000 population. Joinpoint regression analysis was conducted to evaluate trends. **Results:** In 2021, a high red meat diet (consuming >70 g/day of red meat), was the leading risk factor for BC-ASMR overall (2.3), both in older (11.4) and younger (1.4) women, contributing 14% to ASMR across all age groups. Older women had significantly higher ASMR for all risk factors (Table 1). From 1990 to 2021, tobacco-associated BC-ASMR exhibited the greatest decline, with a global reduction of 55.06%, more pronounced in younger (58.39%) than older (46.58%) women. Alcohol-related mortality also decreased significantly, more evident in younger (37.69%) than older (13.09%) women. While the absolute increase in risk factor-associated ASMR was observed with high FPG (+4.4%), a proportional ASMR increase was observed for all three metabolism-related risk factors, including high FPG (+75%), high BMI (+32%), and alcohol use (+14%). High FPG was associated with increased BC-ASMR in both age groups, while younger women experienced a significant rise due to high BMI (+689%). **Conclusions:** These findings highlight the impact of modifiable risk factors on BC mortality. There is a notable reduction in tobacco and alcohol-related deaths, particularly among younger women, likely due to public health campaigns and smoking cessation programs. Moreover, the rising prevalence of alcohol intake in older women, the growing impact of metabolic-related morbidity in younger women, and the hormonal changes amplifying BMI-related risks in post-menopausal women, stress the need for targeted health interventions that could markedly reduce the burden of BC mortality globally. Research Sponsor: None.

Risk factors	Overall trend (1990-2021)	Ages 20-54	Ages ≥55
Tobacco	1.4→0.6	1.1→0.5	5.2→2.8
Alcohol use	1.4→1	1.3→0.8	4.6→4
High FPG	1.1→1.1	0.36→0.39	5.7→6.2
High BMI	2→1.6	0.02→0.1	12.5→10.4
Diet high in red meat	3.9→2.3	2.3→1.4	17.4→1.5

Are indulgent lifestyle practices the driving determinants behind the rising cancer rates in young adult men? First Author: Nathan Tran, California Pacific Medical Center Research Institute, San Francisco, CA

Background: This study aims to determine trends and incidences of cancers associated with social behaviors including tobacco use, excess body fat, alcohol consumption, insufficient physical activity, and human papillomavirus infection among male adults in the U.S. over a 20 year study period. **Methods:** Cancer incidence was extracted from the United States Cancer Statistics Public Use Database (USCS). Tobacco associated cancers were defined as: oropharyngeal, esophageal, stomach, colorectal, liver, pancreas, larynx, lung, kidney, bladder, and acute myeloid leukemia cancers. Obesity associated cancers were defined as: colorectal, liver, kidney, and thyroid cancers. Alcohol associated cancers were defined as: oropharyngeal, esophageal, colorectal, liver, and larynx cancers. Physical-inactivity associated cancers were defined as colorectal cancers. HPV associated cancers were defined as: oropharyngeal, penile, and anorectal cancers. SEER*Stat 8.4.1.2 and Joinpoint regression program 5.0.2 were employed to calculate estimated and actual incidence rates per 100,000 women. **Results:** Based on USCS data, the 2021 incidence of tobacco, obesity, alcohol, physical-inactivity, and HPV associated cancers for males was 217.4, 111.9, 80.9, 27.2, and 9.5 per 100,000, respectively. Moreover, besides HPV associated cancers which had an average annual percent change (AAPC) from 2001-2021 of 0.9% ($p<0.001$) among males, physical-inactivity, alcohol, tobacco and obesity associated cancers decreased at -2.63% ($p<0.001$), -1.29% ($p<0.001$), -1.28% ($p<0.001$), and -0.41% ($p<0.001$), respectively. Evaluating cancer trends among young adult males, physical-inactivity, obesity, alcohol, and tobacco associated cancers have been increasing for males aged 20-49, each with the sharpest rise among those aged 20-24 at 4.15% (p=0.037), 3.43% ($p<0.001$), 2.09% ($p<0.001$), and 1.22% ($p<0.001$), respectively. In contrast, incidence for these cancers has been decreasing among all older age groups of men (≥50). Among 20-24 year old males in 2021, the incidence of tobacco, obesity, alcohol, and physical-inactivity associated cancers was 6.46, 4.8, 2.13, and 1.16 per 100,000 men, respectively. Lastly, HPV associated cancers decreased among all males younger than 55 and increased for older male age groups (≥55) - particularly for the 65-69 age group (AAPC: 2.17%, $p<0.001$). **Conclusions:** Of cancer-related sociobehavioral lifestyle risk factors, young men were most impacted by cancers associated with tobacco use. However, younger males observed the highest annual increases in cancer incidence for these modifiable risk factors, particularly in physical-inactivity in obesity and physical-inactivity associated and obesity associated cancers. Further research is warranted to investigate whether diet, physical inactivity, alcohol, tobacco, or HPV among younger adults play a larger role in these trends. Research Sponsor: None.

Skewed offspring distribution of *TP53* pathogenic variants in Israeli Li-Fraumeni syndrome families. First Author: Naama Halpern, The Jusidman Cancer Center, Ramat Gan, Israel

Background: Li-Fraumeni Syndrome (LFS) [OMIM #151623] is an autosomal dominant cancer predisposition syndrome caused primarily by germline pathogenic (PV) or likely pathogenic variants (LPV) in the TP53 gene. Classical autosomal dominant (AD) inheritance predicts a 50% risk of inheritance for offspring of TP53 PV/LPV carriers. However, clinical observations in Israeli LFS families suggest a higher-than-expected prevalence of TP53 PV/LPV carriers among offspring. This study aims to further investigate this phenomenon. **Methods:** Relevant clinical data from 36 LFS families followed at Sheba Medical Center's high-risk clinic (2015–2024) were reviewed under an IRB-approved protocol. Twenty families met inclusion criteria after excluding those with incomplete clinical data or carriers without offspring. Detailed pedigree analyses were conducted to determine the carrier status of all offspring of confirmed and obligate TP53 mutation carriers. Probable carriers were defined as individuals who fulfilled two criteria: (1) a diagnosis of an LFS-associated malignancy, and (2) being a first-degree relative of a confirmed carrier. Deceased parents with LFS-associated malignancies, whose partners had normal TP53 sequencing and whose offspring tested positive for TP53 PV/LPV, were also considered obligate carriers. A t-test was used to compare the observed proportion of TP53 PV/LPV carriers among offspring with the expected 50% inheritance rate for AD conditions. **Results:** A total of 174 individuals met the study criteria and were either genotyped for the family-specific TP53 PV/LPV or assigned obligatory or probable carrier status. Of these, 115 (66.1%) were identified as TP53 PV/LPV carriers, either through genotyping (n= 87), obligatory (n= 13) or probable carrier designation (n= 15). This observed proportion was significantly higher than the expected 50% based on AD inheritance ($p<0.0001$). Out of the TP53 PV/LPV carriers, 67 (58.3%) individuals were healthy at the time of genotyping, and 62 (53.9%) were male. **Conclusions:** Our findings reveal a significant skewing of TP53 variant inheritance in Israeli LFS families, with a higher-than-expected prevalence of carriers among offspring. To our knowledge, this phenomenon has not been previously reported in LFS. A potential mechanism for this skewing may involve TP53's role in cell cycle regulation and apoptosis. Reduced TP53 protein levels could confer a selective advantage during early embryonic development by enhancing cell proliferation, potentially improving embryonic survival and implantation success. If corroborated in larger and ethnically diverse LFS cohorts, this finding could have implications for genetic counseling, particularly in reproductive decision-making for LFS families. Further research is needed to validate these findings and explore the underlying biological mechanisms driving this skewing. Research Sponsor: None.

Long-term safety of belzutifan in von Hippel-Lindau syndrome: A single-center experience. First Author: Paulo Siqueira do Amaral, Vandebilt University Medical Center, Nashville, TN

Background: Belzutifan has improved control in Von Hippel-Lindau (VHL) syndrome, reducing the need for interventions. However, its long-term safety and side effect burden remain incompletely understood. This study evaluates long-term safety, tolerability and the impact of dose modifications in VHL patients (pts) treated with belzutifan. **Methods:** A single-center retrospective study of VHL pts ≥ 18 years treated with belzutifan at Vanderbilt (Nov 2018 - Dec 2024). Demographic and clinical data were collected. The primary endpoint was treatment discontinuation. Secondary endpoints included incidence of adverse events (AEs) (any-grade and grade ≥ 3 per CTCAE 5.0), dose reductions, time to dose reduction, treatment interruptions, subsequent procedures, and treatment failure (defined as radiological progression per RECIST 1.1 or physician assessment) while on treatment. Follow-up duration was defined as the time from the belzutifan initiation to last follow-up or discontinuation. **Results:** Twenty-five pts were identified, with a median age of 42 years, 64% female and 88% white, with a baseline hemoglobin of 13.7 (range: 11.0 – 19.0). As of January 2025, the median follow-up was 32.5 months (mo) (range: 2.5 – 75). Most common VHL-associated neoplasms included CNS hemangioblastomas (88%), renal cell carcinoma (72%), and pNET (32%). All pts started belzutifan at 120 mg. AEs occurred in 92% of pts (detailed in Table 1). Anemia was observed in 64% of pts (no grade ≥ 3), with a median onset of 3.4 mo (range: 1.1 – 17.7). Treatment interruptions were required by 68% of pts. At the last follow-up, 32% remained on 120 mg, 52% were on 80 mg, and 16% discontinued. The median time to discontinuation was 33 mo (range: 24.5 – 34); due to symptomatic anemia (1 pt), grade 3 hypoxia (1pt), disease progression (1pt) and a non-related death (1pt). Dose reductions were needed by 60% of pts, primarily due to anemia, with a median time to dose reduction of 6.8 mo (range: 1 – 17). Among the 15 pts with dose reductions, none experienced treatment failure during a median follow-up of 21.3 mo (range: 1 – 31), although one pt had persistent grade 3 hypoxia. No pts required transfusions and 8% received erythropoietin stimulating agents. Before belzutifan, 92% of pts had undergone procedures related to VHL manifestations. Following treatment initiation, 8% required additional procedures. **Conclusions:** These findings provide long-term safety data on belzutifan in VHL. While AE were common, dose reductions were effective in maintaining tolerability without compromising disease control. Research Sponsor: None.

Adverse events in at least 5% of the safety population (25 pts).

Breast cancer post-ovarian cancer in germline non-BRCA homologous recombination (HR) gene pathogenic variant carriers. First Author: Ariadna Roque-Lloveras, Hereditary Cancer Program, Genetic Counseling Unit, Catalan Institute of Oncology (ICO), IDIBGI, Girona, Spain

Background: Ovarian cancer (OC) is characterized by deficiencies in homologous recombination (HR). Although germline and somatic *BRCA1/2* pathogenic variants (PVs) play a critical role in HR and OC, germline PVs in other genes associated with HR, such as *RAD51C, RAD51D, BRIP1*, and *PALB2*, have also been linked to an increased risk of OC development. Most of these genes are also associated with increased risk of certain types of breast cancer (BC). However, little is known about risks of secondary BC after OC in this germline non-BRCA HR population. **Methods:** We identified patients with OC treated at a single institution undergoing tumor-normal sequencing (MSK-IMPACT) from 07/01/2015 to 12/31/2020. Germline assessment of ≥76 genes was performed, including HR genes *ATM*, *BARD1*, *BRIP1*, *FANCA*, *FANCC*, *NBN*, *PALB2*, *RAD50*, *RAD51B*, *RAD51C*, and *RAD51D*. Biallelic inactivation was assessed within tumors at the germline variant locus using the FACETS (fraction and allele-specific copy number estimates from tumor sequencing) algorithm. In this study, genes with high rates of biallelic inactivation (≥60%) were included based on role in OC tumorigenesis. Thus, we focused on patients with *BRIP1*, *PALB2*, and *RAD51B/C/D* PVs and further extracted clinical data including secondary BC screening patterns and rates. **Results:** Of the 882 patients with OC and germline assessment, 56 (6%) had germline PV in non-BRCA HR genes, and 35 (4%) patients had germline PV in *BRIP1* (n = 13), *PALB2* (n = 4), *RAD51B* (n = 4), *RAD51C* (n = 4), or *RAD51D* (n = 10). With a median follow-up after OC diagnosis of 55.82 months, no metachronous BC diagnosis occurred in these 35 patients. Among this cohort, 23 (66%) patients received PARP inhibitor therapy for OC, and 17 (49%) patients died from OC. Three patients (9%) were diagnosed with BC before OC diagnosis (germline *PALB2*, *RAD51B,* and *RAD51D* PV carriers). All 3 patients were BC disease-free at the time of data cutoff, and 2 died of their OC. Twenty-five patients (71%) underwent BC screening during OC treatment/follow-up with annual mammography, and 4 (16%) underwent additional annual magnetic resonance imaging. Only two patients were more intensively followed due to abnormal breast findings that were resolved during the follow-up. No patients underwent risk-reducing breast surgery. Interestingly, 30 patients (86%) had a family history of cancer: 12 (40%) with breast cancer, 6 (20%) with ovarian cancer, 8 (27%) with both breast and ovarian cancer, and 4 (13 %) with other cancers. **Conclusions:** BC incidence after OC diagnosis and treatment in non-BRCA HR germline PV carriers remains low, probably due to the poor prognosis of OC and the potential preventive effects of PARP inhibitor treatments on BC development. Further prospective studies are needed to address this question. Research Sponsor: MSK Cancer Center Support Grant by the NIH/NCI (P30 CA008748); International Mobility Grants IDIBGI 2023; SEOM Visiting Fellowship for short-term visits to reference centers 2024.

Codon 167 missense mutations in von Hippel-Lindau syndrome: Genotype-phenotype correlations in a population-based study. First Author: Jianhui Qiu, Department of Urology, Peking University First Hospital, Beijing, China

Background: Von Hippel-Lindau (VHL) disease is caused by germline mutations of the *VHL* gene, resulting in multi-centric and multiorgan tumors. Codon 167 is most commonly affected by pathogenic missense mutations (MMs). The objective of this study is to elucidate the clinical features of individuals with germline pathogenic MMs at codon 167 of *VHL*. **Methods:** 674 patients from 282 unrelated families were enrolled. Their clinical features and prognosis were reviewed. **Results:** 86 patients from 41 unrelated families were identified with codon 167 MMs, indicating codon 167 MMs account for the largest number of patients and families. Codon 167 MMs were associated with a significantly higher risk of pheochromocytoma (HR=7.384, 95%CI 4.496-12.126, P<0.001), lower risks of central nervous system hemangioblastoma/CHB (HR=0.568, 95%CI 0.412-0.781, P=0.001) and renal cell carcinoma/RCC (HR=0.693, 95%CI 0.483-0.993, P=0.046). And codon 167 MMs correlated with better overall survival (HR=0.408, 95%CI 0.210-0.790, P=0.008) and CHB-specific survival (HR=0.201, 95%CI 0.062-0.645, P=0.007) compared with other mutations. The most dominant types of codon 167 MMs are c.499C>T p.Arg167Trp (45.3%) and c.500G>A p.Arg167Gln (48.8%). Multivariate Cox regression analyses discover that the mutation type was not an independent factor for VHL-associated tumors. **Conclusions:** In the VHL disease population, codon 167 MMs account for more than 10% of patients and unrelated families. Individuals with codon 167 MMs had unique clinical features and should be described as a separate subtype of VHL syndrome. The results of this study were important for genetic counseling and clinical decision-making. Research Sponsor: Peking University First Hospital; 2023SF40.

Clinical characteristics and cancer spectrum among breast cancer patients with TP53 germline mutation from a single institution. First Author: Ashley Woodson, University of Texas MD Anderson Cancer Center, Houston, TX

Background: Li-Fraumeni syndrome (LFS), due to germline TP53 mutations, is associated with elevated risks of multiple cancers including early onset breast cancer (BC). Due to multi-disciplinary cancer screening and treatment access, The UT MD Anderson Cancer Center (MDACC) follows a large cohort of individuals diagnosed with LFS. We aimed to describe women with BC diagnosed with LFS and the spectrum of their additional cancer history before and after BC. **Methods:** Patients with BC and LFS were identified from a prospective BC database between 2001-2024. Patients with a pathogenic variant in TP53, and in two cases a variant of uncertain significance with special clinical consideration for LFS-management, were included for review. We evaluated the cancer histories and described the breast cancer characteristics of these women. We identified the incidence of secondary cancers post radiation therapy and secondary leukemia in patients who received alkylating agents given known secondary malignancy risks with such exposures. Summary statistics were generated for the population along with statistical methods for associations between factors of interest including, Chi-squared test and Fisher's exact test. **Results:** Ninety-six women were identified with a history of BC and clinically followed for a diagnosis of LFS. A total of 127 breast tumors diagnosed among 96 women with mean age 35.8 (range 20-69 years). Of these, 68 patients had one primary BC, 26 had two BCs, one had three BCs, and one had four BCs. Individuals ranged from having a diagnosis of 1 to 7 individual cancers; 54 individuals had BC as well as at least one other type of cancer besides BC. Among individuals with more than one cancer, excluding individuals with only BCs, BC was the first cancer diagnosis in 67% (36/54). Other than BC, the other most common cancers were 40 sarcomas, 14 leukemia/other hematologic malignancy, 9 thyroid cancers, 7 brain cancers, and 29 other cancers. Fifty-six percent (54/96) of women received radiation treatment with 14 (26%) individuals developing a subsequent radiation-induced malignancy (RIM). Fourteen percent developed a hematologic malignancy following anthracycline exposure (8/56). **Conclusions:** This study describes the LFS population followed in a high-risk, multi-disciplinary clinic to further understand the spectrum of cancers among women with BC. Our study found that 29% of patients have at least a second BC. More than half of the patients also had a non-BC primary and, in the majority, BC was their first cancer. We also found a high rate of RIM as well as high rate of hematologic malignancies. Understanding multiple cancer histories in LFS could lead to better screening for other cancers. Summarizing the natural history of cancer frequency helps clinicians better predict when genetic testing may be warranted and aim to increase early detection of subsequent cancers. Research Sponsor: None.

Characterization of hereditary tumor risk in individuals with SDHA germline variants. First Author: Kelsey Ellis, Huntsman Cancer Institute at the University of Utah, Salt Lake City, UT

Background: Paragangliomas (PGLs) are rare neuroendocrine tumors with a high degree of heritability; up to 30% of individuals diagnosed with a PGL are estimated to have a germline pathogenic variant (GPV) related to hereditary PGL risk. GPVs in the *SDHA* gene have been associated with a PGL and gastrointestinal stromal tumor (GIST) risk lower than that of other hereditary PGL predisposition genes (van der Tuin *et al.* 2018). However, data about penetrance, tumor characteristics, and other aspects of *SDHA* carriers is limited. Further characterization of *SDHA* GPV is important to better understand tumor risks and develop *SDHA*-specific screening recommendations. **Methods:** Participants were identified from the Family Cancer Assessment Clinic at the University of Utah Huntsman Cancer Institute and had an *SDHA* pathogenic/likely pathogenic variant. Cancer diagnoses and diagnostic modalities were confirmed by medical records. **Results:** Out of 93 identified *SDHA*+ individuals, 14 (15%) had a personal history of an *SDHA*-associated tumor (10 PGL and 4 GIST). None of these individuals also had a known family history of an *SDHA*-associated tumor. Average age at diagnosis was 37 (range = 17-69) with two diagnoses under age 18. There were no cases of multiple PGL/GIST in a single individual. Head and neck PGLs were the most common *SDHA*-associated tumor (7/14, 50%). They appeared to have lower malignancy risk (0/7, 0%) compared to extra-adrenal PGL (3/3, 100%) and GIST diagnoses (3/4, 75%). Secreting PGLs were rare (1/10, 10%). SDHB immunohistochemistry staining was completed for 8/14 PGL/GIST and was deficient in 5/8 (63%). Fifty-four (58%) *SDHA*+ individuals were seen by HCI's hereditary paraganglioma clinic and 39 (42%) had undergone some type of high-risk PGL screening as of January 2025. The most common reasons for not undergoing screening or being seen by the clinic included age $<$10 years old or $>$70 (8/93), deceased status (4/93), and current active cancer treatment (16/93). Fifty-eight of 93 (63%) *SDHA* variants were an incidental finding or a known familial variant without a family history of PGL/GIST. Zero (0/79) asymptomatic individuals have had a documented PGL/GIST diagnosis after *SDHA*+ genetic testing. **Conclusions:** As work continues to develop gene-specific hereditary PGL screening recommendations, our analysis adds to the body of research affirming lower penetrance of *SDHA* variants compared to other hereditary PGL genes. Additionally, the lack of individuals with a personal and family history of *SDHA*-associated tumors or with multiple tumors indicates that a more nuanced approach to screening recommendations in this patient population is likely warranted. However, the younger age of onset and increased malignancy risk seen in the affected individuals in our study compared to sporadic PGL indicates that in certain contexts, such as in an individual diagnosed with a PGL/GIST, an *SDHA* GPV could impact surgical and treatment decisions. Famitinib for familial adenomatous polyposis-associated aggressive desmoid tumors: 32-month follow-up from a single-center exploratory study. First Author: Sai Ge, Department of Gastrointestinal Oncology, Key laboratory of Carcinogenesis and Translational Research (Ministry of Education), Peking University Cancer Hospital & Institute, Beijing, China

Background: Desmoid tumors (DTs) associated with familial adenomatous polyposis (FAP) are rare, locally aggressive soft-tissue tumors with high recurrence rates and poor prognosis. Famitinib, an orally administered multi-targeted tyrosine kinase inhibitor targeting VEGFR-2, PDGFR, c-KIT, and FGFR, has shown promising efficacy in a prospective, single-arm study for these patients (pts). This report presents updated efficacy and safety data from a 32-month follow-up. **Methods:** Pts with FAP carrying germline APC mutations and pathologically confirmed DTs that progressed within 6 months according to RECIST v1.1 criteria were enrolled. Famitinib was administered at 20 mg once daily in 3-week cycles. The primary endpoint was the objective response rate (ORR). Secondary endpoints included disease control rate (DCR), progression-free survival (PFS), overall survival (OS), and safety. **Results:** Between November 2021 and March 2023, 12 eligible pts were enrolled, with a median age of 35.5 years (range: 25-53). Of these, 41.7% (5/12) were male. Intra-abdominal (IA) DTs were present in 83.3% (10/12) of pts, while 2 pts had extra-abdominal (EA) DTs. Eight pts presented with stage III-IV DTs characterized by rapid progression and severe symptoms. As of January 20, 2025, the median follow-up duration was 32.2 months (21.8-37.9). Seven pts achieved partial response (PR), and five achieved stable disease (SD), with a median time to response of 7.1 months (4.1-11.7). The confirmed ORR was 50%, with a DCR of 100%. Among pts with IA DTs, the confirmed ORR was 60.0% (6/10). One patient who achieved PR withdrew from the study after being diagnosed with duodenal cancer. The 6-month and 1-year PFS rates were 100% and 91.7%, respectively, while the 1-year OS rate was 100%. At 2 years, the PFS and OS rates were 54.5% and 72.7%, respectively. The median PFS and OS were not reached. Treatment-emergent adverse events (TEAEs) occurred in all pts (100%). The most common TEAEs (all grades) included COVID-19 (91.7%), leukopenia (83.3%), hypertension (83.3%), neutropenia (83.3%), proteinuria (66.7%), and elevated bilirubin levels (50%). Grade 3 TEAEs occurred in six pts, including neutropenia (41.7%), leukopenia (25%), hypertension (16.7%), hand-foot syndrome (8.3%), intestinal obstruction (8.3%), and abdominal hemorrhage (8.3%). One patient experienced a grade 4 adverse event (intestinal perforation), declined surgical intervention, and passed away three months later. All male pts tolerated the 20 mg dose, while 5 female pts (71.4%) reduced to 15 mg. **Conclusions:** Famitinib demonstrated sustained clinical efficacy and meaningful survival benefits in pts with FAP-associated aggressive DTs after a median follow-up of 32 months. Given the unique characteristics, careful monitoring for intestinal perforation and the risk of second primary tumors is crucial during treatment. Clinical trial information: ChiCTR2100051307. Research Sponsor: None.

A phase 2 study of lanreotide as a therapy for pheochromocytomas (PCs) and paragangliomas (PGs). First Author: Bahar Laderian, Montefiore Einstein Comprehensive Cancer Center, Bronx, NY

Background: PCs arise from adrenomedullary chromaffin cells, while PGs are derived from extra-adrenal chromaffin cells of the sympathetic paravertebral ganglia of the thorax, abdomen, and pelvis, or the parasympathetic ganglia located along the glossopharyngeal and vagal nerves in the neck and base of skull. Although considered neuroendocrine tumors [NETs] by many, their rarity and often difficult management has meant they're never included in clinical trials of NETs. And while they express somatostatin receptors [SSTRs] comparable to other NETs haven't been managed with SSTR-antagonists. **Methods:** Conducted clinical trial to assess efficacy/toxicity of Somatuline Depot / Lanreotide Autogel every 4 weeks in patients with advanced/metastatic PC/PG. Evidence of recent disease progression while either not receiving any therapy or receiving a therapy deemed ineffective was required. Treatment planned for 52 weeks with option to continue for additional 52 weeks. Endpoints included OS, PFS and response according to RECIST. Additionally given rarity of these cancers, estimates of tumor growth rates were planned to allow comparisons to data in NETs enrolled in CLARINET. **Results:** Eighteen patients median age 42 years enrolled including 11 females and 7 males of whom 13 were white, 2 black, 3 other. 14/18 had an SDHx mutation. Prior therapies included surgery, RT, chemotherapy, and PRRT. Lanreotide was well tolerated with 68%G1, 26%G2, 6.5%G3 and $<$ 1% G4 adverse events (AEs) and no unexpected toxicities. No patient discontinued treatment for AEs. Blood pressure control uneventful. Ten patients completed two years of lanreotide, three ongoing, two discontinued at one year due to burden of traveling for participation and three had PD. RECIST response at one year was 15 SD, and 3 PD. One additional patient had PD at the two-year assessment. Serum chromogranin was elevated in only 4/18 and was not helpful in assessing response. With a median follow up of 40 months, median PFS exceeds 2 years with only three deaths to date 14, 18 and 52 months after enrollment. Rates of tumor growth and regression could be assessed in 16/18 patients. Growth was not detected in 5/16 but estimable in 11/16 with a median growth rate of 0.00067/day [tumor doubling time, 1034 days] compared to rate of 0.00046 for 83 patients treated with lanreotide in CLARINET. **Conclusions:** These data demonstrate efficacy for lanreotide in the treatment of PC/PG comparable to that previously found in NETs with prolonged disease stability the primary outcome. Given emerging data with PC and PG reports limited efficacy for Lutathera with meaningful toxicity, these data with lanreotide achieving a longer median PFS support a management strategy for PC/PG similar to that employed with NETs. Begin with a SSTR antagonist, extract its benefit and delay Lutathera administration until meaningful, consistent disease progression is documented. Clinical trial information: NCT03946527. Research Sponsor: Ipsen Biopharmaceuticals.

Genetics and family history in a diverse cohort of females with early-onset breast cancer. First Author: Tanaya Shroff, Yale New Haven Health - Smilow Cancer Hospital, New Haven, CT

Background: Genetic testing for breast cancer susceptibility genes is a crucial component of clinical care for patients with early-onset breast cancer (EOBC) diagnosed $<$ age 50 with implications for treatment and surgical decision-making, future surveillance, and cascade genetic testing for family. Limited data exist regarding prevalence of pathogenic/likely pathogenic variants (P/LPV) and patterns of family history (FH) of cancer across diverse patient populations and merit further research given the rise in EOBC rates. This study examines a cohort of EOBC patients from a cancer genetics program at a comprehensive cancer center to derive insights into the genetic and FH spectrum for a diverse cohort of patients with EOBC in hopes of informing clinical care and public awareness strategies. **Methods:** A retrospective analysis of women seen in the Smilow Cancer Genetics and Prevention program at Yale-New Haven Hospital from 2015-2023 was conducted. Women diagnosed with EOBC who underwent germline genetic testing were included. Data on demographics, age at diagnosis, genetic test results, and FH of breast, ovarian, pancreatic, and prostate cancer in 1st/2nd/3rd degree relatives was obtained from the electronic medical record and Progeny family history software using manual and automated querying and natural language processing. The dataset was assessed for frequency of P/LPVs in cancer predisposition genes, variants of uncertain significance (VUS), and FH of cancer. Fisher's exact test was used to assess the association between categorical variables, and ANOVA to assess the difference in continuous variables among groups. **Results:** 1676 women with available race and ethnicity data were analyzed. Patients identified as White (83.3%), Black (11.5%), Asian (5.3%). 5% of all patients identified as Latinx. Mean age at diagnosis was 42.4 years (SD 5.48 years). P/LPVs were identified in 15.1% and VUS in 22.6%. The most common genes with P/LPVs were *ATM* (4.8%), *BRCA2* (4.1%), *CHEK2* (4.1%), and *BRCA1* (3.0%). Rates of Ashkenazi Jewish ancestry were higher for Whites (7.5%) compared to Blacks (1.0%) and Asians (1.0%) ($p<0.001$). Family history of breast cancer was higher among Black (80.2%) and White patients (80.9%) than Asians (53.4%) ($p<0.001$), as was history of prostate cancer (Black, 29.7%; White, 29%; Asian, 11.4%, p=0.017). P/LPV rates were highest among Whites (15.8%), followed by Blacks (11.5%) and Asians (10.2%) while VUS rates were highest for Asians (34.1%) and Blacks (28.6%) than Whites (21.0%) ($p<0.001$). **Conclusions:** Our results from a diverse EOBC population underscore the higher rates of P/LPVs among White patients while non-White populations have higher rates of VUS. Given the rise in EOBC rates, greater genetic insights as well as additional factors impacting EOBC risk need to be identified and studied particularly across diverse racial/ethnic populations. Post-mastectomy surveillance: A patient-reported survey of 110 women with Li-Fraumeni syndrome. First Author: Renata Lazari Sandoval, Dana-Farber Cancer Institute, Boston, MA

Background: Li-Fraumeni syndrome (LFS) is a highly penetrant autosomal dominant hereditary disorder associated with young onset breast cancer (BC). Therapeutic mastectomy is preferred to enable avoidance of radiation at BC diagnosis (dx), and bilateral mastectomy (BM) for risk reduction as a preventive strategy. After a BM, current guidelines do not recommend post-mastectomy breast screening beyond clinical breast examination (CBE) for LFS carriers. During a patient-focused discussion at the 6th Li-Fraumeni Syndrome Association (LFSA) Symposium in 2022, women expressed concern about not being offered imaging after the surgery. We therefore conducted a survey study to investigate BC screening practices and new breast events following BM in women with LFS. **Methods:** Recruitment was performed through electronic invitation sent to members of the LFSA. Respondents 18 years or older who self-identified as having an LFS dx and a personal history of BM, were invited to answer a survey about their cancer history, breast screening, breast surgery and breast events after mastectomy. Post-BM BC event was defined as the first BC event after BM. Questionnaires were administered from August 13th to September 3rd, 2024. Bivariate associations between BC history and clinical characteristics were assessed using Fisher's exact test for nominal categorical variables and two-sample Wilcoxon tests for continuous variables. **Results:** Among 148 respondents, 110 were eligible; 30 (27.3%) had BM for risk reduction and 80 (72.7%) for BC treatment (60 unilateral BC and 20 for bilateral BC). Median age at first mastectomy was 35.5 years (IQR 28.2,43.0). Most patients (n=82; 74.5%) underwent breast reconstruction with implants only. Periodic CBE performed by a health provider was reported by 70 respondents (63.6%). Patients with BC prior to mastectomies received more clinical surveillance (71.2% vs 43.3%, $p<0.01$). Follow-up imaging with any modality in regular intervals was reported by 52 respondents (47.3%), and there were no differences between groups regarding BC history and imaging modalities used for surveillance. At a median follow-up of 6 years (IQR 3.0-9.8), a total of 10 post-BM BC events (10/110, 9%) were reported, 50% were identified due to symptoms. Among patients who were receiving imaging surveillance (n=52), only 1 BC event was identified through breast MRI screening. was not significantly associated with a new BC event after BM (p=0.28). All BC events in patients with a BC prior to mastectomies were in the ipsilateral breast of the first BC. Patients with a prior BC had a longer follow-up (7.0 vs 3.0 years, p=0.003). **Conclusions:** Breast cancer events after mastectomies in this cohort were identified by symptoms rather than surveillance. Further studies are needed to distinguish these subsequent BC events as recurrences or new primaries, and to confirm the clinical value of breast imaging in this setting. Research Sponsor: None.

Clinicopathologic and allele-specific analysis of germline *ATM* alterations in a pan-cancer cohort. First Author: Matteo Repetto, Memorial Sloan Kettering Cancer Center, New York, NY

Background: *ATM* is a tumor suppressor gene involved in DNA repair and telomere maintenance. *ATM* biallelic pathogenic or likely pathogenic germline variants (gPV) are associated with ataxia-telangiectasia syndrome. Monoallelic ATM gPV are associated with increased cancer risk; however, their contribution to carcinogenesis has not been elucidated. We sought to characterize the genomic landscape of gPV *ATM*-associated cancers in a pan-cancer cohort. **Methods:** *ATM* alterations (germline and somatic) were identified in patients (Pts) with a solid tumor diagnosis sequenced with MSK-IMPACT, an FDA-approved, tumor-normal paired targeted NGS. Genetic-imputed ancestry clinicopathologic characteristics and FACETS estimated allele-specific copy number profiles were evaluated. Samples with purity <0.2 or with undetermined copy number profiles were excluded. HRD score was evaluated using FACETS profiles. Both somatic and germline sequencing data were analyzed within protocol NCT01775072. **Results:** Among 40,136 Pts with cancer who underwent germline testing, 1.1% (n=442) harbored an *ATM* gPV, inclusive of 2 Pts with biallelic *ATM* gPVs. The most frequent mutations were: R2547_S2549del (n=17), K2756* (n=14) and V1268* (n=11). Among these, R2547_S2549del and K2756* were identified exclusively in Pts with European ancestry, while E343Ifs*2 (n= 9/10) and c.1065+1G>T (n= 6/7) were most prevalent in Pts with Ashkenazi Jewish (AJ) ancestry. Concomitant gPVs in other genes were observed in 10% (n=47), with the most frequent ones being *APC* (I1307K), *MUTYH*, *BRCA2, CHEK2*, and *BRCA1*. 63,270 out of 86,039 tumor samples had usable FACETS profiles. *ATM* somatic allele-specific information was available for 67% (297/442) of Pts. 62% (197/317) of tumor samples from Pts with monoallelic *ATM* gPVs exhibited somatic biallelic (Bi) *ATM* inactivation, while 38% (120/317) retained monoallelic (Mono) ATM status. The underlying mechanism of Bi-ATM inactivation was loss of heterozygosity in 75% (149/197) and additional somatic *ATM* mutations in 25% (48/197). Samples from Pts with tumors known to be associated with ATM gPVs (Breast, Pancreatic and Prostate cancers) had significant enrichment in Bi-ATM inactivation compared to tumors without strong association with ATM gPVs (88% Vs 58%; $p<0.01$). Although samples with Bi-*ATM* had higher overall HRD-scores compared to Mono-*ATM* (median = 34 Vs 20; $p<0.01$), no significant enrichment in HRD-High phenotype was seen in Bi-*ATM* (23 Vs 18; p=0.49). **Conclusions:** Evaluation of a pan-cancer Pt population with *ATM* gPVs demonstrated a high prevalence of biallelic somatic inactivation. Most Pts with *ATM* gPVs who had malignancies implicated in *ATM*-associated cancer risk, had biallelic somatic inactivation in their tumors suggestive of their contribution to tumorigenesis. While biallelic ATM inactivation is associated with higher genomic instability, no enrichment in HRD phenotype was observed. Cancer genetics evaluation among individuals at risk for Lynch syndrome across all qualifying indications. First Author: Vinit Singh, Roswell Park Comprehensive Cancer Center, Buffalo, NY

Background: < 20% of individuals suspicious for Lynch syndrome (LS) and other inherited cancer syndromes undergo genetic testing in the US. Undiagnosed individuals will not benefit from enhanced screening and prophylactic interventions. Thus, to dramatically increase the identification of at-risk individuals and respective indications, we set up the At-Risk Cancer Genetic Syndrome Identification Registry (ACAGEN-ID). **Methods:** NCCN/ACMG criteria for genetic testing were translated into three distinct rule-based conditional logic statements in the EHR. A total of 218 rules that serially evaluate each aspect of individual criteria and roll into a logic statement of "at-risk" for inherited cancer syndromes. The rules assess personal history (PH) and/or family history (FH) of cancers, determine age at onset, and categorize family relationships. Patient's genetic evaluation status, sociodemographic, and clinical data were extracted. Descriptive statistics used for summary. Pearson chi-square used for comparison of categorical variables. **Results:** Out of 1.34 million individuals in Yale New Haven Health System, ARCAGEN-ID identified 5,190 at risk individuals for LS. Of those, 3,581 (69%) had not been previously evaluated. Accuracy was assessed through a manual review of 130 randomly selected individuals among the identified, which showed appropriate identification in 129 cases. Among the already evaluated, 509/1609 (31.6%) had a pathogenic variant (PV): 124 (24.6%) MSH2, 112 (22.2%) MSH6, 55 (10.9%) MLH1, 118 (23.4%) PMS2, 3 (0.6%) EPCAM, 141(28%) other PV. Newly identified individuals through ARCAGEN-ID more often had only a PH of cancer (39.99% vs 21.01%) or only FH of cancer (41.02% vs 38.41%), and less often both, PH and FH (18.99% vs 40.58%) ($p<0.01$). The great majority of individuals with only qualifying FH or PH had not been identified before (80.90% and 70.39% respectively), while half (51.01%) with both, PH and FH, had already been identified. Having an early onset (EO) LS-associated cancer was the most common reason for prior identification (22.30%), though EO endometrial cancer (EC) (107/1135, 9.42%) was much less recognized than EO Colorectal Cancer (CRC) (284/775, 36.64%, $p < 0.01$). The highest missed identification before ARCAGEN-ID implementation was individuals with ≥2 LS-related cancers: 69.85% (190/272); FH of EO-CRC: 66.67% (298/449); ≥3 FH of CRC. Even 29.73% (121/407) of individuals with FH of diagnosed LS had been missed. 263/385 (68.31%) Patients with Non-EC/CRC related LS cancers were not evaluated. **Conclusions:** Current practice misses most individuals at-risk for LS across all qualifying indications.A system that can leverage currently existing information in the EHR can dramatically improve the identification without any other added resources. An automated outreach pilot project is underway to assess feasibility and outcomes. Research Sponsor: None.

Familial lung cancer: A thirteen-year prospective analysis of participants with germline EGFR T790M pathologic variant. First Author: Elizabeth R. Francis, Thoracic and Gastrointestinal Malignancies Branch, Center for Cancer Research, Division of Cancer Prevention, Division of Cancer Epidemiology and Genetics, National Cancer Institute, National Institutes of Health, Bethesda, MD

Background: Lung cancer in never-smokers is the eighth leading cause of cancer-related mortality in the United States. Familial lung cancer, a rare syndrome associated with germline *EGFR* pathologic variants (PV) such as T790M (accounting for 0.3-0.9% of lung adenocarcinomas), is a recently identified cause of non-tobacco-related lung cancer. Data on this population is limited. We describe a 13-year prospective analysis, the longest thus far to study the natural history. **Methods:** From2011 to 2024, 19 participants enrolled in a National Cancer Institute study of *EGFR* germline PV (NCT01306045).Eligibility included: (1) lung cancer diagnosis (invasive or pre-invasive) with two affected family members, (2) first-degree relative of someone with a germline *EGFR* PV, (3) T790M detected in lung cancer tumor before tyrosine kinase inhibitor, (4) significant family history of lung cancer, or (5) *EGFR* germline PV detected externally. Participants with germline *EGFR* PV were followed prospectively. Germline *EGFR* PV carriers completed risk-based screening computed tomography. Germline *EGFR* PV participants with lung cancer were followed while completing guideline-directed treatment and surveillance. Lung nodules were examined using standard radiologic assessment. **Results:** Of 19 enrolled participants, seven (37%) had germline *EGFR* T790M. Demographics of *EGFR* germline T790M versus not include mean age at enrollment (46, 56), gender (female 4, 9), white/African American/Asian race (6/1/0, 10/0/2), and current/former/never smoker (0/6/1, 0/4/7). Of the seven participants with *EGFR* T790M, three (43%) had lung adenocarcinoma diagnosed on average at age 63 (range, 53-80), two as stage I and one as stage IV. The other four (57%) did not have lung cancer during the study period. At diagnosis with germline *EGFR* T790M (average age 31, range 26-36), all four participants without cancer had multiple bilateral pulmonary nodules and/ or ground glass opacities (GGO) which, over 6-10 years, remained stable to slightly larger, with increased numbers. One germline *EGFR* T790M participant developed multiple primary lung adenocarcinomas (invasive, minimally invasive, in situ) over 26 months and metastasis 14 months later. One primary started with ground glass components and became solid and larger over 26 months. The two participants with stage IV lung adenocarcinoma survived 15 and 67 months. **Conclusions:** Our study confirms that germline *EGFR* T790M carriers present as early as the third decade of life with multiple bilateral GGOs that can remain dormant for years before exhibiting malignant behavior. Long-term surveillance imaging is necessary, and volumetric changes can potentially be automatically quantified using artificial tools. However, further studies are needed to define a risk-based schedule and examine the role of prophylactic therapy, such as osimertinib. Clinical trial information: NCT01306045. Mammography results in male *BRCA* carriers. First Author: Maliha Tayeb, University of Pennsylvania, Philadelphia, PA

Background: Patients assigned male at birth (AMAB) with pathogenic germline variants (PGVs) in *BRCA1* or *BRCA2* (*BRCA+*) have a 1-10% lifetime risk of developing breast cancer (BC). NCCN guidelines currently recommend that male *BRCA1/2* carriers consider annual mammograms. However, there is minimal data on the mammography among male *BRCA1/2* carriers. **Methods:** We identified a cohort of 489 *BRCA+* male patients with male gender identity from the electronic health record (EHR) at Penn Medicine who had no prior BC diagnosis. Charts were reviewed to determine indication for and results of mammography episodes between 2008-2024. A mammography episode was defined as all breast imaging studies obtained for a specific reason, i.e. asymptomatic screening or for symptoms within six months. An independent cohort of 1808 *BRCA* negative AMAB patients with male gender identity and no prior BC diagnosis from the Penn Medicine EHR was analyzed for the true positive rate of BI-RADS 4/5 findings. **Results:** Of 489 *BRCA+* individuals, 85 (17%) patients completed at least one mammography episode and 46 (9%) had at least one subsequent mammography episode during the study period. Of 85 *BRCA+* patients, 71% had *BRCA2* PGVs. Of 404 patients who did not complete a mammogram, 270 were at least 50 years old at the time of data abstraction. Of these 270 patients, 50% had no discussion of mammograms in their charts, 8% of patients had a physician ordered mammogram that was not completed by the patient, and 42% had a shared decision-making discussion between the physician and patient indicating a decision against mammography. The first observed and subsequent mammography episodes were ordered for asymptomatic screening in 65% and 83% of 85 *BRCA+* individuals, respectively. In *BRCA*neg individuals, 92% of mammography episodes were for symptoms. Nine (11%) and one (2%) *BRCA+* individuals were diagnosed with BC after the first observed or subsequent mammography episode, respectively. No breast cancers were identified on mammography episodes among asymptomatic patients. Combining all mammography data, the true positive rate of BI-RADS 4 mammograms was significantly higher in *BRCA+* vs *BRCA*neg individuals (71% vs 11%, p=0.0007); whereas the true positive rate of BI-RADS 5 mammograms was similar in *BRCA+* vs *BRCA*-neg individuals (100% vs 82%, p=0.54). Hormone receptor status and clinical stage of identified BC were similar between *BRCA+* and *BRCA*neg individuals. **Conclusions:** The majority of male *BRCA1/2* carriers in our cohort did not complete mammography. All BC diagnosed in *BRCA+* individuals were identified on mammography episodes obtained for symptoms. The true positive rate of a BI-RADS 4 mammogram was significantly higher in *BRCA+* compared to *BRCA*neg individuals. Additional data is needed regarding whether mammography identifies asymptomatic BC in male *BRCA1/2* carriers and whether mammograms improve clinical outcomes. Research Sponsor: None.

The evolution of breast cancer genetic testing: Comparative outcomes of NCCN, ASCO, and universal guidelines in 6,000+ patients. First Author: Hikmat Abdel-Razeq, King Hussein Cancer Center, Amman, Jordan

Background: Germline genetic testing for breast cancer has significantly advanced over the past decade. At King Hussein Cancer Center, 6,336 breast cancer patients underwent genetic testing between 2012 and 2024, transitioning from limited BRCA1/2/PALB2 panels to comprehensive 20-gene and 84-gene panels. Eligibility criteria evolved from strict criteria for testing to broader NCCN and ASCO guidelines by 2024. Universal genetic testing was implemented for all breast cancer cases between April 2021 and September 2022. ASCO guidelines have simpler eligibility criteria, whereas NCCN guidelines are more complex and regularly updated. **Methods:** This study analyzed genetic testing trends, categorized results by panel type, and compared detection rates of pathogenic/likely pathogenic (P/LP) variants and variants of uncertain significance (VUS). Detection rates were assessed using Chi-square tests, and linear regression calculated annual changes in positive rates. Outcomes were compared between guideline-based (ASCO/NCCN) and universal testing. **Results:** Of 6,336 patients, 1,731 (27.3%) underwent testing with the 84-gene panel, 3,759 (59.3%) with the 20-gene panel, and 846 (13.4%) with limited testing. Testing volumes increased from 248 cases between 2012-2017 to ~1,000 annually after 2021. Overall, 686 (10.8%) patients had P/LP variants, with higher rates in patients under 30 years (24.4%) and triple-negative breast cancer (20.6%). Among 5490 patients tested with multigene panels, P/LP detection rates were similar: 10.5% (306/2917) for NCCN, 9.4% (87/924) for ASCO, and 9.1% (150/1649) for Universal; p-value was 0.276. No significant difference in P/LP rates was observed between the 84-gene panel 9.2% (160/1,731), and the 20-gene panel 10.2% (383/3,759, p=0.297), but the VUS rate was significantly higher in the 84-gene panel (66.2% vs. 26.2%; p<0.001). **Conclusions:** Expanded panels (84-gene) did not improve detection of P/LP but significantly increased VUS rates. Universal testing did not lower P/LP detection rates compared to guideline-based testing, and no significant difference was observed between ASCO and NCCN guidelines. ASCO guidelines, offering simpler eligibility criteria, or even universal testing, may be more practical compared to the periodically updated NCCN guidelines and should improve compliance and referral rates. Research Sponsor: None.

Rurality and screening colonoscopy participation in patients with Lynch syndrome. First Author: Isabel Thomas, University of Vermont Larner College of Medicine, Burlington, VT

Background: Lynch Syndrome (LS) is a hereditary condition that increases risk for colorectal and other primary cancers. LS arises from pathogenic variants (PVs) in *MLH1*, *MSH2*, *MSH6*, and *PMS2*. Gene-specific prevention and surveillance strategies exist, and screening colonoscopy reduces overall mortality. Several barriers to screening colonoscopy are known, however the impact of rurality is not well characterized. **Methods:** We enumerated a cohort of LS patients residing in Vermont or upstate New York who were seen by the Cancer Genetics Program at the University of Vermont, and for whom regular screening colonoscopies were recommended based on current PV- and age-based NCCN guidelines. We reviewed electronic medical records and abstracted patient characteristics and colonoscopy procedures performed between 2021-2024, capturing most recent practices while avoiding the impact of COVID-19 restrictions. We defined screening compliance as having >1 colonoscopy in the 3-year period, concordant with the minimum expected number of procedures over this time period for all PV groups. We assigned rurality status (metropolitan/micropolitan vs. small town/rural) based on residential ZIP code using Rural-Urban Commuting Area codes. We fit log-binomial and proportional odds regression models to estimate the impact of rurality and recency of a genetics focused clinic visits on colonoscopy adherence and on the number of colonoscopies received, adjusting for age, sex, and PVs. **Results:** We enrolled 201 LS patients for whom annual, bi- or triennial colonoscopies were recommended. Median age at baseline was 60 years (range: 28-98), 131 (65%) were female, and 58 (29%) resided in a small town/rural setting. Compared with metropolitan/micropolitan, small town/rural residence was associated with a lower probability of having ≥1 screening colonoscopy in the 3-year follow-up period (43% vs. 64%; RR=0.67, 95% CI: 0.49, 0.92). This association did not change substantially upon adjustment for age, sex, and pathogenic variants. Small town/rural residence was also associated with undergoing fewer colonoscopies in the 3-year period (cumulative OR=0.46, 95% CI: 0.25, 0.84). Furthermore, recency of Cancer Genetics Program clinic visit was associated with a higher probability of receiving at least one colonoscopy, independent of rurality (*e.g.*, RR for last visit ≤3 years ago, compared with last visit >10 years ago = 1.8, 95% CI: 1.1, 2.8). **Conclusions:** In a cohort of patients with LS, residing in a rural area was associated with a reduced probability of compliance with screening colonoscopy. Resources should be invested in studies aimed at understanding and ameliorating the mechanisms underlying this association. Shorter time since last clinic visit in the genetics program was associated with a higher likelihood of having a screening colonoscopy, suggesting the importance of genetics longitudinal follow-up for hereditary cancer patients. Research Sponsor: None.

Retrospective review of hereditary leiomyomatosis and renal cell cancer at a single institution. First Author: Michael N. Trinh, Massachusetts General Hospital, Boston, MA

Background: Hereditary Leiomyomatosis and Renal Cell Carcinoma (HLRCC) is an autosomal dominant syndrome caused by loss-of-function mutations in the Fumarate Hydratase (*FH*) gene. HLRCC poses an elevated risk for skin leiomyomas, uterine fibroids, pheochromocytomas, paragangliomas, and renal cell cancer (RCC), particularly FH-deficient RCC and potentially clear cell RCC. It is recommended that patients with personal and/or family history of a single skin leiomyoma, multiple FH-deficient (by immunohistochemistry (IHC)) uterine fibroids, pheochromocytoma, paraganglioma, or FH-deficient RCC be tested for, among other genes, germline *FH* mutations, with yearly surveillance with abdominal imaging being the recommendation if positive. To better describe this patient population, we present our experience with high-volume referrals for HLRCC testing at a single institution. **Methods:** We performed retrospective chart review (2017-present) of all patients referred for HLRCC testing at the Hereditary Renal Cell Carcinoma & VHL Disease Clinic and the Hemangioblastoma Center at the Massachusetts General Cancer Center. The study was approved by the Massachusetts General Brigham IRB. **Results:** We herein describe the largest, to our knowledge, series of HLRCC patients (67) at a single institution. While the majority (30, 45%) of cases were referred due to an incidental genetic finding either on prenatal screening or through a comprehensive multi-cancer gene panel sent for hereditary cancer screening, 31% (21) of patients were referred after being found to have an HLRCC-related lesion. Of this subset, the most common first HLRCC-related lesion was a uterine fibroid that was FH-deficient by IHC (13), followed by an equal number of skin leiomyomas (4) and RCCs (4). Importantly, we calculate the rate of patients later confirmed to have an HLRCC diagnosis (pathogenic variant by genetic sequencing) based on referral reason: patients referred for uterine fibroids deficient in FH by IHC, 59.1% (13 of 21); patients referred for RCC either with loss of FH by IHC or papillary RCC, 80% (4 of 5); patients referred with cutaneous leiomyomas deficient in FH by IHC, 66.7% (4 of 6); and patients with family members with known diagnosis of HLRCC, 83.3% (15 of 18). Mutations in positive HLRCC cases either caused premature termination by nonsense or frameshift (18, 26.9%), point mutations by missense (22, 32.8%), or had an AAA duplication at c.1431_1433, causing a lysine duplication at amino acid residue 477 of the fumarate hydratase protein (20, 22.9%), the last of which has ongoing discussion of true association with HLRCC. One patient was indeed seen to have papillary RCC with this mutation, supporting the association of c.1431_1433dupAAA with HLRCC. **Conclusions:** In sum, we describe populations characteristics, common reasons for referral, and likelihood of genetic testing confirmation for patients with concern for HLRCC. Research Sponsor: None.

Characteristics and outcome of breast cancers diagnosed in patients with germline ATM mutations. First Author: Amanda Lanier, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: The purpose of this study is to investigate clinicopathologic characteristics of invasive breast cancers diagnosed in individuals carrying germline mutations in ATM. Individuals with germline pathogenic variants (PV) in ATM have an elevated lifetime risk of breast cancer (17-52%). Clinical characteristics and outcomes of breast cancer amongst patients with ATM PV are not well described. Our aim was to describe a cohort and clinical outcome of patients with breast cancer and ATM PVs. **Methods:** Patients receiving care at MD Anderson Cancer Center with at least one invasive breast cancer diagnosis and who underwent germline testing and were found to have a germline ATM PV were included in the study. Individuals with co-occurring germline mutations in BRCA2 and CHEK2 were excluded. Germline positive and tested negative patients were identified using our prospective Breast Cancer and Clinical Cancer Genetics research database. **Results:** 86 patients with ATM PV were identified. Overall ER positivity was 94.19%. 72.09% were ER+/HER2- and 22.09% were ER+/HER2+. HER2+/ER- and TNBC occurred at lower rates in this cohort (2.33% each). When compared to ATM PV negative, patients with ATM PVs were more likely to have ER+ tumors (HR 1.26). Most individuals with ATM PVs were diagnosed with Stage I (40.7%) or II (34.9%) disease. However, they were more likely to be diagnosed at Stage IV than the control cohort (10.47% vs 1.99%, HR 5.25). Amongst patients receiving neoadjuvant chemotherapy, the pathologic Complete Response (pCR) rate in the ATM positive cohort was 15.63% (5/32), compared to 46.09% in the control group. Locoregional recurrence rates were similar in the ATM and control cohorts (8.14% and 5.85%), but those with germline ATM PVs were more likely to have distant recurrence (23.26% vs 10.96%, HR 2.12).Individuals with germline ATM PVs were also more likely to be diagnosed with a second or third invasive breast cancer than those in the control group (9.3% vs 2.79%, HR 3.33). Overall survival was not significantly different between the two cohorts. In addition to invasive breast cancers, we collected data on secondary malignancies and found that in the ATM PV cohort, 34.88% were diagnosed with at least one additional invasive cancer, including breast, gynecologic, colorectal, pancreatic, melanoma, and other tumor types. **Conclusions:** Patients with hereditary ATM PVs diagnosed with breast cancer have distinct characteristics and outcomes. In our cohort patients with ATM PVs had a higher risk of distant metastasis suggesting a more aggressive disease course that may require tailored treatment strategies. In addition, they also have an increased risk of developing second and third primary breast cancers, therefore risk reducing mastectomy should be considered. Finally, because of increased risk of non-breast malignancies, screening for potential new malignancies is warranted in this patient population. Research Sponsor: None.

A process evaluation trial of a telehealth service intervention to support uptake of breast cancer prevention medications. First Author: Kelly-Anne Phillips, Department of Medical Oncology, Peter MacCallum Cancer Centre, Melbourne, VIC, Australia

Background: Breast cancer prevention medications (BCPrevMeds), such as tamoxifen and anastrozole, halve breast cancer (BC) risk. Our prior research has shown that only 2% of Australian women who know they are at increased risk of BC have ever used BCPrevMeds, and that this evidence-implementation gap is driven by lack of awareness of BCPrevMeds by patients and their primary care physicians (PCPs). In addition, few PCPs report feeling confident to discuss BCPrevMeds, most would not initiate prescribing, but 98% would provide ongoing prescriptions if initiated by a specialist. The Preventing Cancer with Medications (PCMed) Specialist Telehealth Service intervention was developed, based on the Knowledge to Action Implementation Framework, to respond to these findings. The PCMed intervention delivers personalised information to patients to facilitate their informed decision-making, initiates BCPrevMeds prescriptions, and supports PCPs to manage patients during their treatment course. **Methods:** A mixed methods process evaluation trial is evaluating the effectiveness, adoption, acceptability, feasibility, fidelity, and cost of the PCMed intervention. Women aged 20-70 years with no history of invasive BC or DCIS are eligible if they have a remaining lifetime BC risk $>$ 20% or 10-year risk of $>$ 5%. The intervention includes 1 to 2 telehealth sessions with a medical oncologist or nurse practitioner in which patients receive tailored education about the BCPrevMeds relevant to them, a personalised discussion of the absolute risk reduction they could achieve with BCPrevMeds and tailored discussion of other benefits and side-effects of BCPrevMeds applicable to them. Those who desire BCPrevMeds receive a prescription and are reviewed in 8 to 10 weeks to manage any side-effects. Care is then transferred to the PCP who receives educational information and detailed instructions to continue management. A telephone hotline is available for clinicians and patients to address any concerns relating to side effects during the treatment course. Effectiveness of the PCMed Service intervention will be determined by comparing uptake of BCPrevMeds before and after the intervention, using a chi-square, Fisher's exact test, and/or mixed effects regression (as appropriate based on the number of uptake events). Secondary outcomes include adoption of the intervention (the proportion of eligible women who attend the PCMed Service), acceptability for patients and referring clinicians (survey and semi-structured interviews based on the Theoretical Framework of Acceptability), feasibility and fidelity (adherence to the planned intervention processes), and cost (using a micro-costing approach). Currently 33 of a planned 63 participants have been recruited - sample size is based on 80% power to detect a change in uptake from 2% to 20%. Clinical Trial Information: ISRCTN 15718519. Clinical trial information: 15718519. Research Sponsor: Tour de Cure; RSP-307-2024; National Health and Medical Research Council (Australia); 1195294.

A phase II biomarker RCT in women at high risk for breast cancer: Low dose tamoxifen and lifestyle changes for breast cancer prevention (TOLERANT study). First Author: Sara Gandini, IEO, European Institute of Oncology IRCCS, Milan, Italy

Background: Breast cancer (BC) prevention in high-risk women is crucial. Tamoxifen, despite its efficacy, has limited use due to its side effects. Low-dose tamoxifen (LDT) has shown much better balance between BC risk reduction and adverse effects. Additionally, lifestyle interventions (LI) like intermittent caloric restriction (ICR) and physical activity may further reduce BC risk by modulating factors such as mammographic density (MD) and sex hormone-binding globulin (SHBG) levels, which we showed is correlated with reduced breast cancer risk. This study evaluates whether LDT increases circulating SHBG more effectively than LI with or without ICR after six months. **Methods:** The TOLERANT study is a randomized, four-arm, phase II trial involving 200 high-risk women recruited from four Italian hospitals. Participants will be randomly assigned to one of four intervention arms: (1) LDT, (2) LDT + ICR, (3) LI with step counter, (4) LI with step counter + ICR. Interventions will last six months, and participants' adherence will be monitored through visits, telephone calls and diaries. Eligible women are aged 18-70 with a high risk for BC due to genetic predisposition or a history of intraepithelial neoplasia. Key exclusion criteria include history of invasive BC, BMI $<$18.5, and certain medical conditions. LDT involves 10 mg tamoxifen every other day. ICR follows a "5:2 diet" model, with five days of normal intake and two days at 25% of regular caloric intake. LI includes personalized advice and step counters targeting 10,000 steps per day. Primary outcome is the change in SHBG levels. Secondary outcomes include changes in metabolic and inflammatory markers, QoL, body composition, microbiome diversity, and MD. Blood and stool samples will be collected at baseline (B), three (3M), and six months (6M) to analyze biomarkers. Body composition will be assessed using bioelectrical impedance analysis, at B, 3M and 6M and MD will be measured in a subset of participants using digital mammography. As of January 20, 2025, a total of 43 participants have been enrolled, including 18 with DCIS and 25 high-risk women. The study, which has received approval from relevant ethics committees, will provide insights into the effectiveness of LDT and LI in reducing BC risk among high-risk women. The results could inform personalized prevention strategies, balancing efficacy with QoL. Trial registration: EuCT number:2023-503994-39-00; Clinical trials.gov NCT06033092 Funding: This work is funded by European Union – Next Generation EU – PNRR M6C2 – Investimento 2.1 Valorizzazione e potenziamento della ricerca biomedica del SSN – Project Code: PNRR-MAD-2022-12376567 - PI Bernardo Bonanni. The Hercules study: A prospective real-world evaluation of screening whole-body MRI (sWB-MRI) for multi-cancer detection and general preventive healthcare. First Author: Yosef Chodakiewitz, Prenuvo, Vancouver, BC, Canada

Background: Cancer remains a leading cause of mortality, with major gaps in early detection contributing to later-stage diagnoses and poorer outcomes. While single cancer screening methods are effective for specific populations, they leave most cancers undiagnosed such that only 14% of cancers are detected through screening. Multi-cancer detection technologies, such as screening whole-body MRI (sWB-MRI), address this gap by enabling simultaneous systemic cancer risk stratification. Advances in sWB-MRI protocols, including whole-body diffusion-weighted imaging, improve tumor detection without the use of ionizing radiation or contrast agents. This positions sWB-MRI as a non-invasive, radiation-free tool for preventive care suitable for longitudinal monitoring. The need for prospective studies using standardized image acquisition and reporting frameworks, larger cohorts, and long-term follow-up data motivated this study. **Methods:** The Hercules Project is a prospective real-world data study evaluating the predictive accuracy and utility of sWB-MRI for detecting cancer and other clinically significant diagnoses (CSD). Radiological scoring frameworks used include: ONCO-RADS: A validated 5-point scale stratifying cancer risk, from no oncological relevance (ONCO-1) to highly suspicious (ONCO-5). CSD Framework: A novel 5-point scale categorizing pathologies (not limited to cancer) from no clinical relevance (CSD-1) to findings requiring expedited follow-up (CSD-5). Radiologists assign ONCO-RADS and CSD scores during scan interpretation, applied to structured reports by body region and organ system. These frameworks support sensitivity, specificity, PPV and NPV analyses by type of diagnosis. Follow-up at 12–18 months compares findings with diagnostic confirmation and clinical outcomes, enabling analysis of diagnostic pathways and long-term patient impact. Participants are enrolled via one of two arms: Pragmatic: Self-funded participants paying participation-fees reflecting typical U.S. out-of-pocket costs for sWB-MRI. Health Equity: Subsidized access (10–50% of cohort) reduces financial barriers for underserved populations, with sliding-scale subsidies (50–100%) based on socioeconomic factors. Endpoints: Primary endpoints include diagnostic accuracy (sensitivity, specificity, ROC AUC, PPV, NPV), time-to-diagnosis, stage at detection, healthcare utilization (e.g. TCOC), and cost-effectiveness (e.g., QALY). Exploratory endpoints assess the impact of socioeconomic and biological factors on disparities, and the utility of sWB-MRI enabled multi-dimensional diagnostics structured by ONCO-RADS and CSD frameworks. Trial Info: The study is active at a research-dedicated MRI center in Boston, with IRB approval for multi-center expansion to 20 locations. Clinical trial information: NCT06212479. Research Sponsor: None.

HERA-TEST: A novel precision oncology tool using breast milk for early detection of postpartum breast cancer. First Author: Alejandra Díaz, Instituto Maimónides de Investigación Biomédica de Cordoba (IMIBIC)-Hospital Universitario Reina Sofia, Universidad de Cordoba, Córdoba, Spain

Background: The incidence of breast cancer (BC) in women under the age of 45 has risen in recent decades, partly due to delayed childbearing. More specifically, postpartum breast cancer (PPBC), defined as BC diagnosed within 10 years of childbirth, accounts for 5 to 7% of these cases and it is recognized as a distinct clinical and molecular entity. PPBC is associated with increased aggressiveness, a higher risk of metastasis, and worse survival outcomes. Previous research has identified observed distinct signature gene expression associated with DNA repair and cell proliferation pathways, as well as T-cell immunity. However, the key molecular drivers of PPBC remain unclear. Currently, invasive procedures such as breast biopsy or ductal lavage are the primary methods to access tumour biomarkers. In this regard, breast milk represents a promising, unique and accessible source of biomarkers —including exfoliated epithelial cells and miRNAs— that directly reflects the breast microenvironment and could provide valuable insights into early molecular changes associated with cancer development. Ultimately, it holds significant potential for identify biomarkers in breast milk for early identification of women at high risk of developing PPBC. **Methods:** This study aims to recruit 2,000 lactating women, requiring a large-scale awareness campaign and collaboration with eight Andalusian hospitals to facilitate donor recruitment and sample collection. To date, breast milk samples (10–30 mL from each breast) have been collected from 3,000 women, exceeding initial recruitment goals. Samples are preserved in two formats: whole milk stored at -80°C and fractionated components (cells, serum, and lipids). This initiative has led to the establishment of the world's largest breast milk biobank. Simultaneously, dried breast milk samples are being collected parallel to the fresh milk. Additionally, comprehensive clinical, gynaecological and lactation-related data are collected via participant questionnaire, including family history of BC, breastfeeding duration, number of births, weaning patterns, prior breast conditions, and medication history. A multi-omics analysis—including genomic, epigenomic, proteomic, and viromic profiling—will be conducted to identify molecular differences between women who develop PPBC and those who do not. Integrating these findings with clinical and epidemiological data to enhance the understanding of PPBC pathogenesis and improve early detection strategies. Upon identification of robust predictive biomarkers, efforts will focus on adapting the test for use with dried milk samples, facilitating large-scale implementation. This approach aims to address critical gaps in current screening methods for young women, with the ultimate goals of enhancing clinical outcomes, reducing healthcare costs, and advancing precision medicine. Research Sponsor: Instituto de Salud Carlos III; Sociedad Andaluza de Oncología Médica (SAOM).

Acolbifene vs tamoxifen for breast cancer prevention in premenopausal women at high risk for breast cancer. First Author: Carol J. Fabian, Department of Medicine Medical Oncology and Precision Prevention, University of Kansas Medical Center, Westwood, KS

Background: The TAM01 trial of low dose (5 mg) tamoxifen (LDTAM) vs placebo was associated with significant improvement in risk for breast cancer in postmenopausal women with a hazard ratio of 0.30 along with a favorable side effect profile. Risk reduction in premenopausal women was less clear, with a non-significant hazard ratio of 0.73. Tamoxifen in premenopausal women can induce substantial increases in systemic estradiol and in preclinical studies upregulate endocrine resistance gene *AGR2*. Both phenomena may impact LDTAM efficacy in premenopausal women. A pilot study (NCT00853996) of 20 mg/d of the SERM acolbifene in premenopausal women was associated with reduction in mammographic density, benign breast tissue Ki-67, and estrogen response gene expression (Fabian et al; Cancer Prev Res 2015) with no increase in *AGR2* or vasomotor symptoms. Further studies of LDTAM and acolbifene in premenopausal women are warranted assessing change in imaging and benign breast tissue risk biomarkers with change in systemic hormones, ovarian reserve, and drug metabolites. **Methods:** NCT05941520 is a randomized, double-blind Phase II trial performed as part of the University of Michigan Early Phase Clinical Cancer Prevention (ClinCaP) Consortium part of the Cancer Prevention Clinical Trials Network (CP-CTNet) comparing 6 months of tamoxifen 5 mg and acolbifene 20 mg. Eligible participants are premenopausal women $\geq$35 without prior invasive breast cancer, but with $\geq$ 2-fold increased risk for the disease. The primary endpoint is difference in change in levels of *AGR2* mRNA between the two arms. Secondary endpoints are within-arm change in an endocrine response gene index (ERGI), mammographic density, and MENQOL. Exploratory endpoints include within-arm change in benign breast Ki-67, ER, PR and AGR2 protein, association of baseline Anti-Mullerian Hormone (a measure of ovarian reserve) with 6-month serum estradiol and change in tissue estrogen responsive gene expression and *AGR2*. Based on the preliminary data, mean log base2 (fold change, FC) of *AGR2* in the acolbifene arm is assumed to be -1, which is tantamount to a 50% reduction. The estimated SD of the log2(FC) is 2.25. Assuming a log2(FC) of +0.6 in the low dose tamoxifen arm (50% increase), and the same SD as in the acolbifene arm, 36 evaluable subjects per arm are required to detect, with 80% power at an alpha = 0.03 (two-sided), a difference in FC of this magnitude between the two arms. Secondary endpoints are assessed via paired samples t-test or Wilcoxon signed-rank test. Target enrollment in this 4-site trial is 80 over 2.5 years. The protocol opened for accrual at the University of Kansas Medical Center in October 2024 and as of January 2025 is pending activation at the other sites. Clinical trial information: NCT05941520. Research Sponsor: National Cancer Institute.

11000 Oral Abstract Session

Psychosocial digital application for caregivers of patients undergoing hematopoietic stem cell transplantation (HSCT): A randomized controlled trial. First Author: Jamie M. Jacobs, Department of Psychiatry, Mass General Brigham, Harvard Medical School, Boston, MA

Background: Caregivers (i.e., relatives and friends) of patients undergoing HSCT struggle with considerable quality of life (QOL) impairments and psychological strain before, during, and after HSCT. However, few interventions address the supportive care needs of these caregivers while prioritizing accessibility and scalability. We assessed the efficacy of a self-guided digital application, called BMT-CARE App, for improving HSCT caregivers' QOL, burden, mood symptoms, coping skills, and self-efficacy. **Methods:** We conducted a single-center randomized trial of the BMT-CARE App for HSCT caregivers, compared with usual care (UC). Eligible individuals were adults caring for patients with hematologic malignancies undergoing autologous or allogeneic HSCT at a tertiary care center and were randomly assigned 1:1 to the BMT-CARE App or UC, stratified by transplant type. Intervention participants engaged with the app before transplant and up to 60 days post-HSCT. The app comprises five modules integrating psychoeducation, evidence-based behavior change, and stress management, delivered through interactive features, educational games, and videos. Participants completed self-report measures at baseline and day 60 post-HSCT. The primary endpoint was QOL at day 60 post-HSCT assessed by the CareGiver Oncology QOL (CarGOQOL) questionnaire. We also assessed caregiving burden (Caregiver Reaction Assessment [CRA]), anxiety and depression symptoms (Hospital Anxiety and Depression Scale [HADS]), posttraumatic stress disorder (PTSD) symptoms (PTSD Checklist [PCL-5]), coping skills (Measure of Current Status-A [MOCS-A]), and self-efficacy (Cancer Self-Efficacy Scale-transplant [CASE-t]). We used analysis of covariance controlling for baseline criterion values to assess the effect of the intervention on study outcomes. **Results:** From 2/2023 - 7/2024, we enrolled 125 of 174 approached (71.8%) caregivers (BMT-CARE App n = 62, UC n = 63; median age = 58.7 years [range, 27.8-78.6]). Most participants were spouses (71.2% [89/125]). Participants assigned to BMT-CARE App used the app for a mean of 133.2 minutes (SD = 101.9). At 60 days post-HSCT, intervention participants reported better QOL compared to those assigned to UC (76.2 vs 69.9, p = 0.006]), exceeding the 5-point clinically meaningful difference on the CarGOQOL. BMT-CARE App participants also reported lower caregiving burden (11.2 vs 12.3, p = 0.024), depression (3.8 vs 5.6, p = 0.002), and PTSD symptoms (26.0 vs 31.3, p = 0.011), and better coping skills (33.9 vs 28.2, p = 0.003). The two groups did not differ significantly in anxiety symptoms or self-efficacy at day 60 post-HSCT. **Conclusions:** The BMT-CARE App, a psychosocial digital health intervention, led to substantial improvements in QOL, caregiving burden, depression and PTSD symptoms, and coping skills in caregivers of HSCT recipients. Clinical trial information: NCT05709912. Research Sponsor: Leukemia and Lymphoma Society.

11001 Oral Abstract Session

Outcomes of an electronic patient-reported outcomes (ePRO)—based symptom management program (eSyM): A cluster randomized trial. First Author: Michael J. Hassett, Dana-Farber Cancer Institute, Boston, MA

Background: Although ePROs have been shown to reduce resource utilization and improve outcomes among people with cancer, they have not been widely adopted. We conducted a pragmatic type II hybrid effectiveness-implementation cluster randomized stepped-wedge trial of an ePRO-based, EHR-integrated symptom management program (eSyM) across 6 health systems. Here, we report the primary effectiveness outcome comparing patients treated before (control/not exposed) versus after (intervention/exposed) eSyM deployment. **Methods:** Eligible patients were adults who started chemotherapy (CHEMO) or were discharged after surgery (SURG) for a suspected or confirmed GI, GYN, or thoracic cancer. The intervention included ePRO questionnaires based on PRO-CTCAE items, severe symptom alerts, self-management tip sheets, and communication support. Outcomes included having an emergency department (ED) visit or inpatient admission (INPT) within 30 and 90-days. Logistic regression models accounted for socio-demographic, clinical, calendar time, health system, and other factors. Secondary analyses stratified results by treatment and health system to assess for effect modification. **Results:** From Jan. 2018 to Feb. 2023, the control and intervention conditions accrued 21,112 and 18,830 patients, respectively (median age 62 vs. 65; female 68% vs. 63%). Patient enrollment by health system ranged from 3,961 to 14,560. In the intervention cohort, 51% of patients used eSyM to report symptoms. Crude 30-day event rates for the control and intervention cohorts were 5.4% vs. 6.2% for ED, and 8.5% vs. 9.1% for INPT. Accounting for other factors, there were no significant differences in ED or INPT at 30 (Table) or 90 days. Among SURG patients, there was significantly greater odds of ED, but not INPT, for the intervention vs. control cohort. Results varied by health system, with evidence of higher, similar, and lower odds for the intervention vs. control cohort. **Conclusions:** eSyM deployment did not significantly reduce ED or INPT events. Only half of exposed patients used eSyM to report symptoms. Since prior analyses found lower odds of acute care utilization among patients who reported symptoms via eSyM, implementation and engagement barriers may have substantially impacted effectiveness outcomes. Heterogeneity of effect by health system and treatment suggest that healthcare structures, processes, and baseline performance may influence the uptake and impact of ePRO-based symptom management systems. Clinical trial information: NCT03850912. Research Sponsor: National Cancer Instiute; 1UM1CA233080-01.

Events at 30 days		OR for ED	95%CI	OR for INPT	95% CI

11002 Oral Abstract Session

Improving care of older adults with cancer: A randomized trial. First Author: Manali I. Patel, Division of Oncology, Veterans Affairs Palo Alto Health Care System, Palo Alto, CA

Background: Undertreated symptoms are common among older adults with cancer. Previously, a lay health worker (LHW)-led proactive symptom assessment intervention was associated with reduced symptoms in one community clinic. Yet, the effect on acute care use, total costs, and end-of-life (EOL) care at scale remains unknown. **Methods:** Adults ages 75 years or older who were Medicare Advantage beneficiaries with newly diagnosed cancer were eligible to participate in this randomized trial across 43 clinics in Southern California and Arizona. Participants were randomized 1:1 into a control group (usual care alone) or an intervention group (usual care and LHW-led proactive, telephone-based weekly symptom assessments for 12 months using the validated Edmonton Symptom Assessment System) with a planned enrollment of at least 200 in both groups. The LHW reviewed assessments with a physician assistant who conducted follow-up for symptoms that changed by 2 points from a prior assessment or were rated 4 or greater. We used generalized regression models to compare acute care use and total costs (obtained from payer claims data) for 12-months follow-up or death, whichever was first, offset for length of follow-up, and, among those who died, compared EOL acute care use, costs, and acute care facility deaths. **Results:** 416 patients participated (216 control; 200 intervention) with median age of 82 years (range 75-99); 205 (49.28%) were Hispanic or Latino, 10 (2.4%) African American or Black, 12 (2.88%) Asian, 2 (0.48%) Native Hawaiian, 1 (0.24%) Pacific Islander, 180 (43.3%) Non-Hispanic White, 6 (1%) other; 219 (52.6%) were male; 118 (28.3%) had gastrointestinal, 92 (22%) had genitourinary, 62 (14.9%) had breast, and 48 (11.5%) had thoracic cancer; 171 (41%) had stage 4 disease. The intervention group had 53% lower odds of emergency department use (OR: 0.47, 95% CI 0.37-0.62) and 68% lower odds of hospital use (OR: 0.32, 95% CI 0.20-0.51) than the control group. Among deceased participants (71 (32.9%) control; 71 (35.5%) intervention), the intervention group had 68% lower odds of acute care (OR: 0.32, 95% CI 0.12-0.88), lower total costs of care by $12,000 USD per participant (p = 0.01), and 75% lower odds of an acute care facility death (OR 0.25; 95% CI 0.08-0.77). **Conclusions:** This proactive symptom assessment intervention may be one sustainable, scalable, efficient, and effective approach to improve care for older adults with cancer. Clinical trial information: NCT04463992. Research Sponsor: None.

11003 Oral Abstract Session

Randomized trial of a supportive oncology care at home intervention for patients with cancer receiving curative treatment. First Author: Ryan David Nipp, The University of Oklahoma, Oklahoma City, OK

Background: Patients with cancer receiving curative treatment often endure substantial symptoms and utilize significant healthcare resources. Symptom monitoring interventions and hospital at home care models represent a promising approach for improving these patients' outcomes. **Methods:** We conducted a randomized trial of a Supportive Oncology Care at Home intervention versus usual care in adult patients receiving treatment with curative intent (chemotherapy and/or chemoradiation) for pancreatic, rectal, gastroesophageal, and head and neck (H&N) cancer, as well as non-Hodgkin lymphoma, who resided in-state, within 50 miles of our hospital. Patients were randomized to receive the Supportive Oncology Care at Home intervention or usual care within two weeks of initiating therapy and remained on trial for up to 6 months. The intervention entailed: 1) remote monitoring of daily patient-reported symptoms, vital signs, and body weight; 2) a hospital at home care model for symptom assessment and management; and 3) structured communication with the oncology team. The primary outcome was the proportion of patients requiring inpatient hospital admission or emergency department (ED) visits during the study period. Secondary outcomes included urgent visits to the clinic, treatment delays, and longitudinal changes in monthly assessments of quality of life (QOL; Functional Assessment of Cancer Therapy-General), symptoms (Edmonton Symptom Assessment System [ESAS] and Hospital Anxiety and Depression Scale [HADS]), and activities of daily living (ADLs). **Results:** We enrolled 50.8% (199/392) of potentially eligible patients. One patient withdrew consent and 2 became ineligible following consent, resulting in 196 participants (median age=65.8 [range: 21.1-92.0], 39.8% female, cancer types: 34.2% pancreatic, 27.0% H&N, 16.3% lymphoma, 12.8% rectal, 9.7% gastroesophageal). The proportion of patients requiring hospital admission or ED visit did not differ significantly between the intervention and usual care groups (37.1% v 35.7%, p=.87). Intervention participants were less likely to require an urgent visit (7.2% v 24.5%, $p<.01$), but there were no differences in rates of treatment delays >7 days (29.9% v 33.0%, p=.62). Compared to baseline assessments, intervention participants had greater improvement in ESAS symptoms ($p<.01$) and ADLs (p=.04) over time. QOL and HADS depression/anxiety symptoms did not differ longitudinally between groups. **Conclusions:** Although this Supportive Oncology Care at Home intervention did not have a significant impact on rates of hospital admissions or ED visits, we found encouraging results for reducing urgent visits to the clinic and substantial improvement in symptom burden and ADLs, underscoring the potential utility of this novel care model for enhancing care delivery and outcomes for patients with cancer receiving curative treatment. Clinical trial information: NCT04544046. Research Sponsor: The Medically Home Group.

Empowering young-onset colorectal cancer patients with an accessible, self-navigable online platform for universal germline testing. First Author: Julie B. Moskowitz, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Since 2022, the National Comprehensive Cancer Network (NCCN) has recommended universal germline testing (UGT) for all individuals diagnosed with colorectal cancer (CRC) under age 50. Up to 20% harbor a germline cancer predisposition, and identifying this high-risk cohort is critical for personalized care. Realizing UGT has been hampered by access to and delivery of cancer genetics care, highlighting the need for novel strategies. We report the impact of an accessible, self-navigable online platform for UGT. **Methods:** Consecutive YOCRC patients were offered a standardized care pathway including UGT. A prospective quality improvement trial aimed at UGT launched an interactive online platform designed to enable self-eligibility screening, self-navigation to video-based pretest education and counseling, consent submission, and blood or saliva collection arrangements. Patients could self-opt for genetic counseling (GC, in-person or virtual) at any time, and those who did not engage with the online platform after 3 invitations were reflexively referred to GC. The trial was designed with a 3-month run-in pilot followed by a 12-month study period. The primary outcome was UGT completion rate; secondary outcomes were process feasibility and GC resource preserved. **Results:** Among 377 YOCRC patients, 158 had GT prior to referral, 7 were international, 3 declined all contact, and 209 patients were invited to the online UGT platform. Another 49 reported prior GT, leaving 160 patients of interest. Active platform engagement was observed in the majority (100 of 160 patients, 63%), where 89 (89%) completed UGT, including 79 (96%) of the 82 who self-navigated the entire online platform and 10 (71%) of the 14 who had opted for GC. Lack of platform engagement led to reflex GC referral for 60 patients, and 19 (32%) have completed GT to date. Taken together, among 160 patients of interest, pre-test GC workforce involvement was spared in 79 (49%) patients through the online platform. **Conclusions:** The rising incidence of YOCRC, increasing patient demand and limited GC resources are barriers to executing UGT. We successfully implemented an online platform achieving 96% GT completion rate among those who self-navigated the entire process, and eliminating the need for pre-test GC resource utilization in nearly half of the cases. Our experience supports online care delivery platforms that highlight accessibility and autonomy. Research Sponsor: None.

11005 **Oral Abstract Session**

Real-world social determinants of health (SDOH) and outcomes of early-onset colorectal cancer (EO-CRC): An analysis of a large, nationally representative US community oncology network. First Author: Lisa Herms, Ontada, Boston, MA

Background: The rise of EO-CRC in individuals under the age of 50 presents a major public health challenge, as these patients may encounter unique barriers to both screening and treatment. Understanding the drivers and implications of EO-CRC is crucial, and real-world data (RWD) can serve as a valuable tool by offering insights into evolving diagnostic, utilization, and practice landscapes, with robust information on social determinants of disease burden. Building on existing disparity concerns, this study leveraged RWD from a large, nationally diverse network of US community oncology practices to describe the SDOH and outcomes of patients with EO-CRC. **Methods:** This retrospective observational cohort study examined adult CRC patients within The US Oncology Network and non-Network practices, encompassing over 2,500 community-based providers treating more than 1.4 million patients annually. All patients diagnosed with CRC between 2000 and 2024 were included; patients were categorized as EO-CRC if they were $<$ 50 years at first diagnosis and average-onset (AO)-CRC otherwise. Patient characteristics were sourced from iKnowMed, an oncology-specific electronic health record system, and descriptively summarized. Overall survival (OS) was assessed from diagnosis using Kaplan-Meier methods. **Results:** A total of 104,281 patients were identified, including 14,611 (14%; median age: 44 years) with EO-CRC and 89,670 (86%; median age: 67 years) with AO-CRC. Patients in the EO-CRC cohort were more likely to be Black (11% vs. 8%), American Indian or Alaska Native race (1.3% vs. 0.9%), of a documented race other than White (20% vs. 15%), and of Hispanic/Latino ethnicity (11% vs. 8%) versus the AO-CRC cohort. Few of EO-CRC (11%) and AO-CRC (10%) patients were current smokers at time of diagnosis. More than one-third of EO-CRC group was obese (36%), slightly higher than in AO-CRC (31%). EO patients were more commonly located in urban areas (69% vs. 63% of AO patients). Among 2,810 patients with Distress Thermometer data, EO-CRC patients were more likely to report high or moderate distress (29% vs. 22%) and less likely to report low distress (71% vs. 78%). 5-year OS probability was 72% (95% CI: 71-73) for EO-CRC and 64% (95% CI: 63-64) for AO-CRC. **Conclusions:** In one of the largest cohorts of patients with EO-CRC to date, this study confirmed that EO-CRC is an emerging concern within the US community oncology setting, particularly regarding heightened disparities in race, ethnicity, and lifestyle factors. EO patients may face unique burdens related to timely screening and diagnosis, necessitating tailored and cross-disciplinary approaches to their care, and warranting additional investigation into social and clinical drivers of survival outcomes to improve long-term prognosis. Association of Medicaid expansion with five-year survival after cancer diagnosis. First Author: Elizabeth Schafer, American Cancer Society, Atlanta, GA

Background: Medicaid expansion is associated with improvements in early detection, access to treatment, and increased 2-year cancer survival. However, the association between Medicaid expansion and longer-term survival outcomes in newly diagnosed cancer patients remains understudied. **Methods:** Patients aged 18-59 years newly diagnosed with first primary cancers in 2007-2008 and 2014-2015 living in 25 states (AZ, AR, CA, CO, CT, DE, HI, IL, IA, KY, MD, MI, MN, NV, NH, NJ, NM, NY, ND, OH, OR, RI, WA, WV) that expanded Medicaid in 2014 and 12 states (AL, FL, GA, MS, MO, NC, OK, SC, TN, TX, WI, WY) that had not expanded Medicaid by the end of 2020 were obtained from the Cancer Incidence in North America (CiNA) Survival dataset compiled by the North American Association of Central Cancer Registries. Cases were stratified by cancer type, race and ethnicity, census-tract poverty level, and rurality. Difference-in-differences analysis was used to examine the association of Medicaid expansion with changes in 5-year observed overall and cause-specific survival (CSS) based on multivariable flexible parametric survival models adjusted for age group, sex, race and ethnicity, census tract–level poverty, rurality, state, and year of diagnosis. **Results:** A total of 1,256,349 individuals were diagnosed with cancer in Medicaid expansion (N = 698,870) and non-expansion states (N = 557,479) during the study period. The 5-year overall survival increased from 65.0% to 73.4% in expansion states and from 61.0% to 70.0 in non-expansion states, leading to a non-significant net increase of 0.21 percentage points (95%CI: -0.11,0.53) in expansion states after adjusting for sociodemographic factors. Increases in observed and cause-specific survival were greatest in expansion states for cancers of the pancreas (observed: 1.86ppt, 95%CI: 0.33ppt – 3.39ppt; CSS: 2.33ppt, 95%CI: 0.51ppt – 4.14ppt), colon and rectum (observed: 1.55ppt, 95%CI: 0.45ppt – 2.65ppt; CSS: 1.64ppt, 95%CI: 0.53ppt – 2.76 ppt), and lung (observed: 1.19ppt, 95%CI: 0.32ppt – 2.07ppt; CSS: 1.16ppt, 95%CI: 0.09ppt – 2.24ppt). The net increase associated with Medicaid expansion was also prominent among non-Hispanic Black patients (observed: 1.25ppt, 95%CI: 0.30ppt – 2.19ppt; CSS:0.80ppt, 95%CI: -0.10ppt – 1.70ppt), people living in the most deprived area (observed: 1.21ppt, 95%CI: -0.14ppt – 2.56ppt; CSS:1.45ppt, 95%CI: 0.16ppt – 2.75ppt), and rural communities (observed: 2.30ppt, 95% CI: -0.30ppt – 4.88ppt; CSS:2.40ppt, 95%CI: -0.03ppt – 4.83ppt). **Conclusions:** Medicaid expansion was associated with greater increases in 5-year observed and cause-specific survival for Non-Hispanic Black individuals, individuals living in the most deprived area, and rural communities. These findings reinforce the importance of Medicaid expansion in reducing disparities in cancer survival outcomes. Research Sponsor: None.

11008 **Oral Abstract Session**

A randomized controlled trial comparing pragmatic interventions to improve mammogram uptake in a non-compliant population. First Author: Sasidharan Swarnalatha Lucky, Cancer Science Institute, Singapore, National University of Singapore, Singapore, Singapore

Background: Despite over 20 years of a national breast cancer screening program, mammogram uptake in Singapore, a highly developed Asian country, remains under 40%. Limited large-scale prospective data exist on effective pragmatic interventions to boost screening participation. **Methods:** 9000 Singaporean women aged 50-69, eligible for free biennial screening, non-compliant (at least 1 prior mammogram but overdue by $>$ 2 years from last screen), with no breast cancer history and registered on hospital's mobile health app, were randomly selected from a tertiary hospital's electronic medical records and allocated to one of the 5 arms in a 2:1:1:1:1 ratio. Arm 1 (control; n = 3000) received physical mailer reminders (MR). Four intervention arms (n = 1500 each) received MR plus- Arm 2: US$7.4 voucher on screening completion, Arm 3: US$3700 lottery chance, Arm 4: video health message, and Arm 5: health concierge for appointment scheduling. Arms 1–5 also received the reminders via 3 push notifications (PN), spaced 3 weeks apart, through the app. A non-interventional (NI) cohort (n = 3000) fulfilling similar criteria served as comparison. Primary outcome was mammogram uptake rate within 4 months of reminder in Arm 1 vs Arms 2-5. Secondary outcomes included participation rate in Arm 1 vs NI group. Exploratory analysis included cost-effectiveness of intervention and app utility in shaping health behaviour. **Results:** 74% of the 12000 participants were Chinese, followed by Malay (13%) and Indian (7%), reflecting Singapore's demographics. Median age was 62 years (67% aged 60-69). 89% lived in public and 11% in private housing. 99% lived within 5 km of a mammogram facility. Median interval from last mammogram was 5.2 years (range: 2.0–21.5); longer in women aged 60-69 vs 50-59 (6.1 vs 3.9 years, $p < 0.0001$). Mammogram uptake in the NI group was 3.3% and increased to 11.2% with MR alone (Arm 1; RR 3.28, 95% CI 2.60–3.96, $p < 0.01$). Uptake in Arm 5 was slightly higher than in Arm 1 (13.8% vs 11.2%, RR 1.23, 95% CI 1.07-1.38, p = 0.01), but not significant after adjusting for multiple comparisons (p-adj = 0.11). Arms 2-4 (12.1%, 11.3%, 10.8%) showed no difference vs Arm 1. Intervention cost per compliant subject was US$7 in Arm 1, increasing to $13, $28, $32 and $40 in Arms 2-5 respectively. Only 4.1% (3.1–4.6%) in the 5 intervention arms accessed the webpage via PN and $<$ 1% clicked the self-help booking link. **Conclusions:** A physical MR significantly improved mammogram participation in a non-compliant population, but additional monetary incentives or health message offered no further benefit. A concierge service slightly improved uptake but at a 6-fold higher cost. PNs had limited utility in this older population. A low-cost MR program is scalable and piloting concierge services for targeted groups may enhance cost-effectiveness. Further research should explore barriers to digital intervention engagement in this age group. Clinical trial information: NCT06733155. Research Sponsor: National University Cancer Institute, Singapore (NCIS).

11009 Rapid Oral Abstract Session

Association between environmental burden and cancer incidence rates across population subgroups in the United States (US). First Author: Azar Mohammad Abadi Kamarei, University of Alabama at Birmingham, Birmingham, AL

Background: With more than 2 million projected new cancer diagnoses in 2025 in the US alone, many studies have linked environmental pollutants to carcinogenesis. However, they often examine exposures in isolation, overlooking the complexity of real-world multi-exposure conditions. In this study, we investigate the impact of multiple simultaneous environmental exposures on cancer incidence rates at the county level. **Methods:** Data on environmental burden (for e.g. air and water pollution, toxic sites, built environment), measured using the Environmental Burden Module (EBM), were obtained from the CDC Environmental Justice Index. County-level cancer incidence rates for breast, pancreas, prostate, lung, colon, and all cancers combined were obtained from the CDC State Cancer Profiles. Multivariable linear regression models estimated the effects of EBM quartiles (Q1 as the reference, representing the lowest burden, and Q4 noting highest) on cancer incidence rates for the total population and stratified by urbanicity, sex, and age. Interaction terms between EBM quartiles and demographic variables (sex and age) were significant ($p < 0.05$). All results are presented as cases per 100,000 population. **Results:** Higher environmental burden was associated with increasing incidence rates for all cancers in Q3 (15.61 [9.45, 21.78]) and Q4 (7.87 [1.59, 14.15]) across all US counties. Breast (4.45; 95% CI [2.10, 6.80]) and prostate cancer (2.57 [1.00, 4.78]) noted strongest association in Q4. Similarly, rural counties too showed increased rates of all cancers with increasing environmental burden (Q3: 18.22 [10.56, 25.88]); Q4: 21.15 [7.41, 34.89]). In urban counties, prostate cancer incidence was higher in Q4 (4.65; [0.08, 9.22]). Among males, lung cancer incidence increased significantly in the most environmentally burdened counties (Q4: 0.45 [0.21, 0.89]). For colon cancer, while incidence rate for males decreased significantly (Q4: -0.45 [-0.91, -0.01]), it increased among females in the most environmentally burdened counties (Q4: 21.15 [14.21, 28.18]). For older individuals ($>$ 65y), Higher rates of all cancers combined were found in Q3 (125.70 [76.95, 174.44]) and Q4 (117.15 [68.04, 166.26]). Lung cancer incidence was especially sensitive to environmental burden – higher rates were observed in Q2 (3.99 [0.12, 7.87]), Q3 (4.88 [1.49, 8.28]), and Q4 (4.73 [1.56, 7.91]). **Conclusions:** Greater environmental burden was associated with increased cancer incidence rates across several cancer types with sociodemographic variation. These results indicate the need for regulatory policy and infrastructural investment aimed at mitigating these risks in targeted communities. Further research with higher-resolution data is needed to elucidate these associations and underlying etiologic mechanisms. Research Sponsor: None.

11010 Rapid Oral Abstract Session

Complex interplay between housing insecurity and forgone care among U.S. cancer survivors. First Author: Shreya Kondle, Texas Health Presbyterian Hospital Dallas, Dallas, TX

Background: One-sixth of U.S. cancer survivors experience housing insecurity, and one-fifth report delaying or forgoing care due to costs. The role of social determinants of health (SDoH) among cancer survivors is complex and poorly understood. We sought to examine the prevalence of housing insecurity and forgone care, and their effects in conjunction with SDoH among cancer survivors. **Methods:** The Medication Expenditure Panel Survey (MEPS) is an annual survey representative of the civilian, non-institutionalized United States population. The 2022 MEPS survey included a Preventative Care Self-Administered Questionnaire measuring late rent/mortgage payments indicative of housing insecurity in the past year. We considered adult cancer survivors (excluding non-melanoma skin cancer) who reported an inability to afford or had to delay any medical/dental care or prescription medications, as forgoing care. We extracted sociodemographic and clinical characteristics. Survey-adjusted Wilcoxon rank-sum tests and chi-square tests assessed differences in continuous and categorical variables, respectively, for individuals with and without housing insecurity, cancer, and forgone care. A multivariate regression analysis adjusting for age, sex, race, and poverty status identified predictors of forgoing medical care. We conducted weighted analyses to account for the complex survey design and considered $p < 0.05$ as statistically significant. **Results:** A total of 1,776 cancer survivors (weighted (w): 21,088,176) and 20,655 individuals with no cancer (w: 311,965,067) were identified. Among cancer survivors, 13% (w: 1,315,879) reported housing insecurity while 19% (w: 4,063,946) were forgoing care. Housing insecurity was reported in 8% of female survivors compared to 4% of male survivors, while 22% of women forwent care compared to 16% of men. Black Americans were less likely to report forgone care (13%) compared to White (19%) and Hispanic cancer survivors (25%), while housing insecurity was higher among all minorities (~10%) compared to White survivors (5%). Younger cancer survivors aged 18-45 years reported four-fold rates of housing insecurity and 1.5 times the rate of forgone care compared to survivors over 65. Multivariate logistic regression revealed forgoing medical care was more prevalent in individuals aged 45–64 (aOR = 1.6), women (aOR = 1.5), the near poor (aOR = 2.9), and those experiencing housing insecurity (aOR = 4.1), but less prevalent in Black Americans (aOR = 0.5) (all $p < 0.05$). **Conclusions:** This is the first nationally representative study to report the complex interplay between housing insecurity and forgone care among cancer survivors. The interactions highlight some unexpected high-risk groups like women, near-poor individuals, and middle-aged individuals, who are more likely to forgo care when forced to choose or prioritize care. Future policies need to target these high-risk groups. Research Sponsor: None.

11011 Rapid Oral Abstract Session

Beyond the clinic: Comprehensive assessment of time burdens in cancer care. First Author: Rachel I. Vogel, University of Minnesota, Minneapolis, MN

Background: Managing cancer care can be highly demanding, consuming time and energy. Measuring this time has been limited to date. We sought to comprehensively measure the time spent on cancer-related care by leveraging a mobile application, Daynamica, which collects spatiotemporal sensing data in real-time while limiting intrusiveness to capture both objective and subjective dimensions of time use. **Methods:** As a proof-of-concept, we recruited individuals with metastatic breast or advanced stage ovarian cancer receiving treatment at the University of Minnesota and University of Alabama-Birmingham. Participants utilized the Daynamica app for 28 days, reporting healthcare encounters (location and type), along with completing end-of-day (EOD) surveys regarding at-home cancer-care related activities. We summarized the number and type of healthcare encounters and quantified time spent traveling to/from, waiting for, and receiving care. Utilizing the EOD survey data, we also quantified time spent on cancer-care related tasks at home. **Results:** A total of 58 individuals provided data for this analysis: 31 (53%) with metastatic breast cancer and 27 (47%) with advanced stage ovarian cancer; 29% were $<$ 50 years old, 72% non-Hispanic (NH) White and 17% NH Black. Participants reported a median of 6 out-of-home healthcare episodes during the study, representing a median of 108 min/week. These episodes were most frequently labeled as including treatment (33%), clinic visit (27%) and/or labs (28%); imaging (12%), pharmacy (11%) and research (3%) were less frequent. Participants reported varying wait times during their healthcare episodes, with most involving $<$ 15 min wait (37%), though both no wait (19%) and $>$ 60 min of waiting (19%) were frequent. We observed variation in time individuals spent traveling to/from their healthcare visit, with a median travel time per episode of 31 min (5th-95th percentile range 4-125). The proportion of time spent receiving care relative to wait and travel time was often less than 50% of the total time, particularly when the time spent receiving direct care was $<$ 60 min. Participants reported spending a significant amount of time on telehealth visits, taking medications, scheduling appointments, and managing insurance and medical bills (median 120 min/week); of these 4 tasks, taking medicines or injections was the most frequently reported and time-consuming category. This estimate jumped to 325 min/week when also including time spent on symptom management, arranging help/transportation, and seeking information about cancer. **Conclusions:** The time spent on cancer related-care is vastly underestimated when capturing healthcare encounters only. Comprehensive measurement of time spent on cancer related tasks is an important first step towards developing and testing interventions to improve healthcare efficiencies and reduce patient burden. 11012 Rapid Oral Abstract Session

Association of medical debt with cancer incidence rates in the US. First Author: Jiazhang Xing, Sinai Hospital of Baltimore, Baltimore, MD

Background: Medical debt is a growing challenge for U.S. patients and has been associated with higher cancer mortality. However, whether medical debt is associated with advanced-stage cancer diagnoses – a strong predictor of worse prognosis – remains unclear. This study investigated the association between medical debt in collections and overall and advanced stage cancer incidence rates in the U.S. **Methods:** We conducted an ecological study using 2019 county-level medical debt in collections data from the Urban Institute Debt in America project and age-adjusted cancer incidence rates (2017-2021) from the CDC State Cancer Profiles dataset. Outcomes were age-adjusted cancer incidence and age-adjusted late-stage (i.e., regional or distant) incidence rates for ten common cancers with screening tests or early signs. We used generalized linear mixed models, adjusting for urban-rural status, county-level Social Vulnerability Index, county population size, primary care physician density, median population age and state. **Results:** We included data from all 3,143 counties. The county-level percentage of medical debt in collections ranged from 0.0% to 23.5%. One percentage increase in medical debt was associated with a 74.80 (95% CI=43.45-106.19) increase in overall cancer incidence rate per 100,000 person-years. Regarding late-stage cancer incidence, one percentage increase in medical debt was associated with a 5.16 (95% CI=1.05-9.28) increase in late-stage incidence rate for colorectal, a 2.11 increase (95% CI=1.04-3.18) for bladder, a 2.73 (95% CI=1.08-4.39) increase for kidney and renal pelvis, a 28.69 (95% CI=22.22-35.17) for lung and bronchus, and a 0.14 (95% CI=0.01-0.26) increase for oral cavity and pharynx cancers, and a 2.99 (95% CI=1.53-4.44) increase for melanoma of the skin. No significant association was noticed in other cancer types. **Conclusions:** Medical debt in collections is associated with higher overall incidence and late-stage rates for multiple cancer types, suggesting financial barriers may impede both cancer screening and timely symptom evaluation. Research Sponsor: None.

Adjusted association of percent of population with medical debt in collections with cancer incidence rate at the county level (per 100,000).

	Incidence	Late stage incidence
All cancers	74.80 (43.45-106.19)	-
Colorectal	9.48 (3.68-15.28)	5.16 (1.05-9.28)
Kidney and renal pelvis	9.84 (6.48-13.22)	2.73 (1.08-4.39)
Lung and bronchus	41.02 (32.46-49.58)	28.69 (22.22-35.17)
Cervix	0.64(0.40-0.88)	0.17(0.00-0.34)
Melanoma	-5.73(-11.52-0.05)	2.99 (1.53-4.44)
Bladder	-0.73(-4.01-2.51)	2.11 (1.04-3.18)
Prostate	-13.70(-29.67-2.29)	-5.28(-11.10-0.42)
Breast	-1.43(-13.83-10.89)	4.57(-1.71-10.88)
Oral Cavity and Pharynx	0.16(0.01-0.31)	0.14(0.01-0.26)

Data for late-stage incidence of all cancer sites combined not available from CDC.

11013 Rapid Oral Abstract Session

Treatment preferences between survival and quality of life and their association with clinical outcomes in older adults with advanced cancer. First Author: Daniel R. Richardson, UNC Lineberger Comprehensive Cancer Center, Chapel Hill, NC

Background: Preference-concordant care improves quality of life (QoL) and reduces healthcare utilization. However, limited research exists on how preferences impact clinical outcomes in older adults with advanced cancer. Our study explores differences in outcomes between patients (pts) prioritizing extending survival versus maintaining QoL. We hypothesized that patients prioritizing survival would live longer, while those prioritizing QoL would have fewer treatment-related toxicities and hospitalizations. **Methods:** We analyzed data from pts aged $\geq$ 70 with incurable solid tumors or lymphoma and $\geq$ 1 impaired geriatric assessment domain starting a new systemic cancer treatment within NCI's Community Oncology Research Program as part of a cluster randomized trial (NCT02054741, PI: Mohile). Pts reported their preference for prioritizing extending survival versus maintaining QoL at baseline: agree, neutral, disagree. We used generalized linear mixed models and generalized estimating equations to assess the association of treatment preference with hospitalization and treatment-related toxicities, and Cox shared frailty models for survival. Analyses were adjusted for study arm, age, sex, race, education, and practice. **Results:** We included 706 pts. Mean age was 77.2 years (SD 5.4, range 70-96); 43% were female; and 89% were non-Hispanic white. Gastrointestinal (34.6%), lung (24.8%), and genitourinary (15.4%) cancers were most common. Fewer pts preferred to prioritize extending survival (n = 59, 8.4%) versus maintaining QoL (n = 506, 71.7%) versus no preference/neutral (n = 141, 20.0%). Choice of initial therapy (single agent, multiple agent, or combined chemotherapy plus another agent) did not differ by preference. Most pts (61.7%) had grade 3-5 treatment-related toxicity; 25.2% were hospitalized in the first 3 months; 26.3% died within 6 months; 47.3% died within one year. No significant associations were found between preference for prioritizing survival v. QoL and grade 3-5 toxicity (Risk ratio [RR] 0.90, 95% Confidence Interval [CI] 0.70–1.16), hospitalization (RR 0.81, 95% CI 0.48–1.36), nor survival (Hazard ratio 0.75, 95% CI 0.42–1.33 at 6 months; 1.18, 95% CI 0.82–1.71 at 1 year). **Conclusions:** Over two-thirds of older adults with advanced cancer prioritize maintaining QoL over extending survival. Prioritizing QoL was not associated with shorter survival. However, it was also not associated with reductions in hospitalization nor treatment-related toxicities. While these findings may suggest a lack of responsiveness of the healthcare system to patient preferences, additional studies are necessary to better evaluate this relationship. More research is needed to develop treatment modifications and interventions so that older adults with advanced cancer achieve those outcomes that matter most to them. Funding: UG1CA189961, R01CA177592. Research Sponsor: None.

11014 Rapid Oral Abstract Session

Utilization and timing of first tumor next-generation sequencing testing (NGS) in patients (pts) with five most common cancers in the USA. First Author: Chadi Hage Chehade, Huntsman Cancer Institute at the University of Utah, Salt Lake City, UT

Background: In the USA, the 5 most common advanced/metastatic solid tumors are advanced non-small cell lung cancer (aNSCLC), metastatic breast cancer (mBC), metastatic prostate cancer (mPC), advanced colorectal cancer (aCRC), metastatic pancreatic cancer (mPanC). Life-prolonging targeted therapies are approved for pts with tumor-susceptible alterations, and guidelines recommend NGS to identify these alterations. Herein, we assessed the overall utilization of NGS and the timing of NGS in relation to the time of death in real-world pts with these cancers. **Methods:** This retrospective study utilized the nationwide Flatiron Health electronic health record (EHR) derived de-identified database. Eligibility: diagnosis of aNSCLC, mBC, mPC, aCRC, mPanC with information on receipt of NGS (blood/tissue) and recorded date of death. The time between each pt's first NGS result and date of death was measured and pts were categorized into 3 groups: NGS results delivered $>$ 3 months (mo) before death, within 3 mo of death, and delivered/reported after death. Frequencies and percentages of the 3 categories were reported, also by the year of death and practice type. **Results:** Of 86,536 pts with aNSCLC, 31,375 received NGS (36.3%), of whom 19,958 had a date of death recorded. Of 36,000 pts with mBC, 11,550 were tested (32.1%), of whom 5,689 had a date of death recorded. Of 24,105 pts with mPC, 7,439 were tested (30.9%), of whom 3,397 had a date of death recorded. Of 35,702 pts with aCRC, 14,642 were tested (41%), of whom 8,553 had a recorded date of death. Of 14,964 pts with mPanC, 5,298 were tested (35.4%), of whom 3,957 had a recorded date of death. The timing of NGS relative to the time of death by cancer type is shown in Table. Across all cancers, the rate of pts receiving NGS results $>$ 3 mo before death increased over time, while the rate of those receiving results within 3 mo of death or after death decreased. Baseline characteristics (race-ethnicity, insurance plan, practice type) and NGS rates by year of death in the 3 categories will be presented in the meeting. **Conclusions:** Despite the availability of life-prolonging targeted therapies based on NGS results, a sizeable number of pts either do not undergo NGS or have their first NGS very late in the course of disease (i.e. within 3 mo of death). These results warrant better utilization of tumor NGS in a timely fashion in pts with cancer to optimize survival outcomes. Research Sponsor: None.

Rates of first NGS relative to the time of death (in pts who underwent NGS and had a date of death recorded).

Timing of first NGS results	aNSCLC N = 19,958	mBC N = 5,689	mPC N = 3,397	aCRC N = 8,553	mPanC N = 3,957
> 3 mo before death, n (%)	14,431 (72.3%)	4,643 (81.6%)	2,901 (85.4%)	7,271 (85%)	2,815 (71.1%)
Within 3 mo of death, n (%)	5,109 (25.6%)	959 (16.9%)	457 (13.5%)	1,173 (13.7%)	1,047 (26.5%)
After death (NGS result reported after death), n (%)	418 (2.1%)	87 (1.5%)	39 (1.1%)	109 (1.3%)	95 (2.4%)

11015 Rapid Oral Abstract Session

Overall survival and quality of life superiority in modern phase III oncology trials. First Author: Alexander Dean Sherry, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: The use of alternative endpoints, such as progression-free survival, has increased over time in phase III randomized clinical trials (RCTs). However, PFS and other alternative endpoints are often not valid surrogates for overall survival (OS) and quality of life (QOL), and may be less relevant to patients. We sought to determine the proportion of phase III oncology RCTs with OS or QOL superiority. A secondary goal was to evaluate the approach of QOL analyses, since "change-from-baseline" approaches may bias results (Bland and Altman. *Trials.* 2011;12:264). **Methods:** We performed a meta-epidemiological study of two-arm, superiority-design, interventional phase III oncology RCTs screened from ClinicalTrials.gov. RCT publications were reviewed for alternative endpoint, OS, and QOL results by at least two investigators. Alternative endpoint and OS superiority were defined for the experimental arm vs control arm according to the pre-specified statistical criteria for each RCT. QOL superiority was defined by either statistically significant or minimal clinically important differences (MCID). QOL was sub-classified as global QOL, defined by the composite summary measure obtained using the patient-reported outcome instrument, or domain QOL, referring to measures obtained from instrument subscales. **Results:** We included 791 RCTs published between 2002 and 2024, representing 555,580 enrolled patients. Primary RCT results were published between 2002 and 2024. Alternative primary endpoints were most common (n = 495, 63%). The primary endpoint was met in 53% of the RCTs (n = 420). Alternative endpoint superiority was shown in 55% of the RCTs (n = 434). OS was reported by 705 RCTs (89%), and OS superiority was shown in 28% of the RCTs (n = 221). Patient-reported outcomes were collected in 61% of the RCTs (n = 482), and 34% of the RCTs published global QOL results (n = 271). Most global QOL analyses were change-from-baseline (55%, n = 148). Global QOL superiority was shown in 11% of the RCTs (n = 84). In a sensitivity analysis of QOL subscale outcomes, 80 trials (10%) showed superiority in at least one QOL domain. Collectively, in 32% of the RCTs (n = 257), superiority of either OS or global QOL was demonstrated. In 6% of all RCTs (n = 48), both OS and global QOL superiority was shown. **Conclusions:** Phase III, superiority design oncology RCTs are commonly interpreted as "positive." However, this is usually based on improvements in unvalidated alternative endpoints. Gains in either OS or QOL are uncommon, and exceedingly rare in combination. QOL appears both under-evaluated and under-reported. Furthermore, the majority of phase III QOL analyses, which are based on change-from-baseline comparisons, may be misleading. To increase the meaningfulness of late-phase research, future trial designs and regulatory processes should be re-focused towards OS and methodologically rigorous QOL improvements. 11016 Rapid Oral Abstract Session

SWOG S2302, PRAGMATICA-LUNG: A pragmatic trial designed to increase participant representation. First Author: Karen L. Reckamp, Department of Medicine, Cedars Sinai Cancer Center, Los Angeles, CA

Background: Effective therapy following frontline immune checkpoint inhibitor (ICI)-based treatment for advanced non-small cell lung cancer (NSCLC) is needed as limited options are available. Lung-MAP S1800A was a Phase II randomized study of ramucirumab plus pembrolizumab versus standard of care (SOC) for patients with NSCLC previously treated with immunotherapy that demonstrated benefit in overall survival (OS) with an improved toxicity profile over SOC. S2302 Pragmatica-Lung trial was pragmatically designed to evaluate the impact on OS while reducing barriers to participation and decreasing clinical trial staff burden. We assessed reduction in barriers to participation and clinical staff burden in S2302 in relationship to S1800A. **Methods:** S2302 (NCT05633602) is a registration-intent randomized phase III trial for patients with advanced NSCLC who previously received PD-(L)1 inhibitor therapy for at least 84 days and platinum-based therapy, stratified by immediate prior line of therapy including PD-(L)1 inhibition (yes/no) and PS (0/1 v. 2). The pragmatic design has limited eligibility criteria, which are focused on stage, prior therapy and safety to enroll patients as would occur in real world practice. Laboratory assessment and imaging with RECIST reads are not required due to the OS endpoint. Data collection was developed to minimize the burden with fewer time points for data submitted, number of forms and number of data elements. Concomitant medications are not collected. Given the known safety profile of both study drugs, only related and unexpected grade 3/4 and all grade 5 adverse events are collected. **Results:** Accrual to S2302 was robust with 838 patients enrolled from March 2023 to December 2024 (21 months), averaging $>$ 50 patients/month in the final 6 months. The trial enrolled 77% White and 13% Black patients. versus 87% and 8%, respectively on S1800A. Over 65% were $\geq$ 65 years of age. Reduced data collection on S2302 relative to S1800A results in an estimated decrease in the number of forms and data elements submitted within the first year on study by 45% and 66%, respectively. **Conclusions:** Incorporating pragmatic elements into S2302 resulted in robust accrual, increased participant representativeness and access for patients. The reduced burden on staff due to decreased data forms and elements is substantial. Pragmatic design elements should be considered as we develop trials to generalize to a broad and representative population. Clinical trial information: NCT05633602. Benefit of adding Cureety remote patient monitoring (RPM) to usual care during injectable anticancer treatment: The OPTIMACURE multicentric French prospective randomized study. First Author: Audrey Faveyrial, Centre François Baclesse, Medical Oncology Department, Caen, France

Background: In routine care, assessing whether a patient can safely be administered an injectable anticancer treatment requires the review of blood tests, risk factors and relevant adverse events (AEs). Thus, some French centers use coordinated phone calls and blood tests to improve chemotherapy prescription accuracy and reduce wait times for patients. For example, as part of usual care, the François Baclesse center uses the OPTIMA program. Digital RPM could further streamline this process by efficiently collecting and evaluating patient data without needing systematic phone calls. The OPTIMACURE study aimed to assess whether integrating Cureety RPM into usual care (with OPTIMA or equivalent) can increase the quality of care and decrease the hospital staff workload. **Methods:** The prospective, randomized, multicenter, open-label OPTIMACURE study was designed to assess whether adding Cureety RPM to usual care would reduce the number of phone calls during the first two months after randomization. Outpatients with solid tumor initiating injectable anticancer treatment were randomly assigned (2:1) to either usual care with Cureety RPM or usual care alone (with OPTIMA or equivalent). The numbers of phone calls were compared between arms using an analysis of covariance (ANCOVA) model adjusted for study arm, treatment type, infusion frequency, performance status, and center. **Results:** From April to August 2024, 192 patients (127 in RPM arm, 65 in control arm) were enrolled in 3 centers: women (73%), mean age 61 $\pm$ 13 yrs. The cancers were breast in 40%, non-small cell lung in 14%, colorectal in 9.5%, and prostate in 7.4%. The infusion frequency was once every 1-2 weeks in 37% and $\geq$3 weeks in 63%. Nine patients were excluded due to protocol deviations. Calls, for any reasons, were significantly reduced in the RPM arm (3.80 versus 2.61, relative change of -1.20, 95% CI [-1.89 to -0.53], $p < 0.001$, ANCOVA model). Those results were further analyzed by differentiating outgoing calls to prepare the outpatient visits and those to follow-up on toxicity reports. Preparation calls were less frequent for patients in the RPM arm than those in the control arm (no preparation call for 73.2% of patients vs 12.3%; $\geq$3 calls for 3.2% of patients vs 69.2%), corresponding to a higher reduction of preparation calls (-2.7 [-3.12;-2.3], $p < 0.001$, ANCOVA model). As for calls for toxicity follow-up, they were more frequent in the digital RPM arm (1.6 [1.14;2.05], $p < 0.01$), associated with earlier report of grade 3-4 non hematological AEs (Hazard ratio for first report of severe AE: 4.06, $p < 0.001$) and better care management for patients in the RPM arm compared to the control arm. **Conclusions:** Adding digital RPM to routine cancer care was beneficial, with a significant gain in time to prepare cancer treatment in day unit and with improved detection and management of toxicities. Clinical trial information: NCT06371911. Research Sponsor: Cureety.

Improving clinical trial interpretability and efficiency: A Bayesian re-analysis of individual patient outcomes from 230 phase III oncology trials. First Author: Alexander Dean Sherry, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: The conventional interpretation of superiority oncology trials relies on statistical significance defined by *P* values, which are frequently misinterpreted and oversimplified. On the other hand, Bayesian analysis, which incorporates prior knowledge, directly estimates the probability of a hypothesis, with greater flexibility to examine clinically relevant effect sizes. Here, we studied the effects of Bayesian models on phase III trial interpretation. We further hypothesized that Bayesian approaches, using differential priors for efficacy and futility, would improve trial efficiency. **Methods:** Phase III superiority-design, two-arm oncology trials were screened from ClinicalTrials.gov for this meta-epidemiological study. Individual patient-level data were manually reconstructed from the Kaplan-Meir curves of the primary endpoint. First, Bayesian Cox regressions of reconstructed data applied skeptical *N* (0, 0.355), enthusiastic *N* (-0.41, 0.4), and neutral priors N (0, 10^6), where *N* (mean, standard deviation) denotes a normal distribution, to estimate posterior probabilities of the primary endpoint effects with Markov chain Monte Carlo sampling. Minimum clinically important differences (MCID) in the experimental arm were defined by HR < 0.8 per ASCO criteria (Ellis et al, *J Clin Oncol* 2014). Second, a single event or enrollment-driven interim analysis with Bayesian stopping rules was simulated 100 times for each trial using *in silico* models of randomly varying accrual kinetics with published patient outcomes. Interim efficacy and futility were defined per simulation by probabilities $\geq$ 85% for achieving effect sizes larger than the MCID/3 using a skeptical or enthusiastic prior, respectively. Early trial closure was recommended if $\geq$ 75% of simulations met efficacy or futility criteria. **Results:** After screening,194,129 patient outcomes from 230 trials were reconstructed. Overall survival was the primary endpoint in 90 trials (39%). All trials interpreted as positive had $>$ 90% probabilities of marginal benefits (HR < 1). However, 38% of trials interpreted as positive had $\leq$ 90% probabilities of achieving the MCID (HR < 0.8), even under an enthusiastic prior. Conversely, 24% of trials interpreted as negative had $>$ 90% probability of achieving marginal benefits, even under a skeptical prior. In the interim analysis simulations, early closure was recommended for 82 trials (36%). Bayesian interim analysis was associated with $>$99% probability of reducing enrollment sizes. The trial and its simulated interim analysis remained concordant (Bayesian Cohen's κ, 0.95). **Conclusions:** Bayesian models add unique interpretative value for clinically relevant effects, and may improve trial efficiency without compromising trial interpretation. Bayesian models should be increasingly incorporated in phase III trials. Research Sponsor: National Cancer Institute; P30CA016672; Andrew Sabin Family Foundation.

Adherence of published randomized phase 3 cancer trials to principles proposed by common-sense oncology. First Author: Omar Abdihamid, Garissa County Hospital, Garissa Cancer Center, Garissa, Kenya

Background: Randomized clinical trials (RCTs) remain the gold standard for evaluating the efficacy and safety of novel cancer therapies. Some RCTs are well-designed and show meaningful improvements in patient outcomes while others are confounded by various types of bias, or do not reflect outcomes that matter to patients. Published RCTs should be designed, analyzed and reported to provide optimal, unbiased information for clinicians to enhance treatment decision-making Common-Sense Oncology (CSO) is an initiative of clinicians, patient advocates, researchers, and policymakers with the mission of ensuring that cancer care and research are focused on outcomes that matter to patients. CSO has published a checklist for the design, analysis and reporting of RCTs evaluating systemic treatments for cancer. In the present study, we have applied the checklists to a cohort of cancer drug trials to assess the extent to which CSO principles were incorporated in reports of RCTs published in 2023 in high-impact journals. **Methods:** We reviewed retrospectively phase 3 RCTs evaluating systemic therapies for adult solid tumors published in 2023 in *The New England Journal of Medicine, Lancet, Lancet Oncology, JAMA, JAMA Oncology, Journal of Clinical Oncology,* and *Annals of Oncology*. These journals were selected based on their high impact. For each trial we evaluated the trial design in the methodology, how the results were reported and the discussion section using the CSO RCT Checklist. **Results:** 50 RCTs evaluating systemic therapies for solid tumors were published in 2023. The most common tumor types were lung, liver, and prostate cancer. Progression-free survival and overall survival were the primary endpoints in 44% (22) and 42% (21) of trials, respectively. Only 36/50 trials justified the control arm, 25/50 justified the primary endpoint, and 18 included Quality-of-Life as a secondary endpoint. Only two trials addressed strategies to limit censoring and dropout; numbers of censored patients (with numbers at risk) were shown under Kaplan-Meier curves in only 21/50 trials, and sensitivity analysis to determine the potential effects of censoring was done in only 5 trials. Chronic toxicities were reported in only one trial, only 7 trials included patient-reported outcomes and only 3/50 trials mentioned cost of the drug. **Conclusions:** Our findings underscore the need for standardized methodologies, comprehensive design, and reporting in oncology RCTs. By identifying gaps in RCT design and reporting, CSO aims to improve the quality and consistency of future trials. Research Sponsor: None.

Kaleido registry: A multi-center registry platform with site staff and automation to enable accelerated clinical research and drug development at scale in community practices. First Author: Luis T. Campos, Oncology Consultants, Medical Center, Houston, TX

Background: The number of candidate drugs and clinical trials in oncology is rapidly increasing, necessitating innovative approaches to streamline patient identification, enrollment, and trial execution. However, data collection for patient eligibility assessments remains highly manual, placing significant burden on clinical teams. Technology solutions leveraging Electronic Health Records (EHR) data are emerging, but missing or inaccurate data often impede high-fidelity and low-latency prescreening. In 2022, the Kaleido registry was initiated to address these challenges by implementing on-site staff, abstraction prior to each visit, and draft notes for medical oncologists in the registry. **Methods:** The Kaleido registry enrolls patients with oncological/hematological diagnoses at four community practice sites. Real-time data abstraction is performed in all patients prior to each visit in an expanding set of indications (NSCLC, CRC, prostate cancer, and myeloproliferative neoplasms) to provide systematic and unbiased trial prescreening. An automated prescreening tool has been developed and validated in 394 pts to identify potential trial candidates. Standardized note drafts free up staff time. A questionnaire addressing social determinants of health (SDOH) and self-reported performance status was introduced to further reduce missing data in the EHR. **Results:** To date, over 10,000 patients (61% female, 39% male) have been enrolled. 6% of approached patients declined to consent. The most common diagnoses include breast, prostate, lung, and colorectal cancer. The automated prescreening tool was validated with 90% sensitivity and 97% specificity. The patient questionnaire has a completeness rate of 99%. Real-time abstraction was demonstrated to be feasible, with completeness above 90% for key variables. Among patients with metastatic NSCLC, the genomic testing rates exceeded 80% supporting the sites' suitability for clinical trials. **Conclusions:** With high consent rates, data completeness, and a validated automation tool, the Kaleido registry offers a scalable model for systematic, unbiased patient recruitment and comprehensive data collection across oncology/hematology. This approach has the potential to accelerate clinical research and drug development in oncology and hematology, ultimately enhancing trial efficiency and improving patient outcomes. Are patients satisfied with the information in an informed consent form? Questionnaire-based study examining patients' viewpoints. First Author: Bhagyashree Pathak, Tata Memorial Hospital, Mumbai, India

Background: Ensuring that patients understand the information in an Informed Consent Form (ICF) is key to shared decision-making and ethical conduct of a trial. Data regarding patients' views on the ICF are limited. **Methods:** Descriptive questionnaire-based survey study conducted in patients with malignancy aged 18 years and over who had earlier been enrolled in an interventional clinical trial at the Tata Memorial Center (Mumbai, India) and had filled an ICF for that trial. Patients were asked to provide their basic demographic information and fill in a 14-item questionnaire regarding their views/suggestions about the information in the ICF. Primary end point was patients' satisfaction with the information provided in the ICF. Satisfaction was scored on a Visual Analog Scale of 0-10; 0 indicated "least satisfied" and 10 meant "most satisfied". Level of satisfaction was categorized as low (0 – 4), moderate (5 – 7), and high (8 – 10). The study was approved by the ethics committee and registered with CTRI. **Results:** Between Jan 2023 – Jun 2024, we recruited 426 patients. Median age was 47 (IQR, 39-56) years; 234 (54.9%) were male, and 43 (10%) were illiterate. Malignancies included head and neck (202 [47.4%]), breast (108 [25.4%]), gastrointestinal (45 [10.6%]), thoracic (44 [10.3%]), and hematolymphoid (27 [6.3%]). Intent of therapy was curative in 375 (88%). There were 31 (7.3%) patients who did not know that they had participated in a clinical trial. The ICF was not completely read by 68 (16%) patients, due to the following reasons: excessive technical terms (38 [8.9%]), lengthy ICF (18 [4.2%]) and insufficient time provided (17 [4%]). Fifty-two (12.2%) patients did not understand the language of the ICF. Majority of patients (360 [84.5%]) suggested that ICF length be limited to 1-4 pages. Over half the patients wanted the ICF to include more information on standard treatments (230, 54%), side-effects (223, 52.3%), reason for study participation (214, 50%), and risks and benefits (249, 58.5%). Twenty-two (8%) patients felt over-burdened with the information provided in the ICF. Median satisfaction score was 8 (IQR 6 – 10); but only 56.6% patients were highly satisfied with the information in the ICF. Low satisfaction was reported by 167 (39.2%) patients with the information in the reimbursement/compensation section and 164 (38.%) with the alternative treatment options section. Age, sex, education, type of cancer, intent of cancer-directed therapy, and socioeconomic status did not significantly impact the level of satisfaction with the information in the ICF. **Conclusions:** The information in the ICF for interventional clinical trials needs to be concise, and in simple language. Addressing patient preferences and providing clear information in each section would enhance patient understanding and satisfaction, fostering a more effective and ethical informed consent process. Clinical trial information: CTRI/2023/01/048999. Research Sponsor: None.

Why the duration of cancer treatment requires a closer look: An empirical analysis of recent FDA approvals. First Author: Jeremy Birkmire, Baylor College of Medicine, Houston, TX

Background: The duration of cancer treatment directly impacts its efficacy, toxicity, and cost. Yet, its systematic evaluation is missing in most clinical trials. In July 2024, the FDA critiqued trial designs for failing to assess the contribution of perioperative (adjuvant and/or neoadjuvant) components but did not address the broader question of optimal treatment duration. **Methods:** We conducted a comprehensive, retrospective review of FDA anti-tumor drug approvals issued between January 2019, and August 2024. Landmark publications supporting each approval were identified through Google Scholar, PubMed, and DailyMed. Each trial's duration of treatment design was classified as either indefinite or fixed, with subgroups of fixed perioperative, fixed non-perioperative, and single-dose. We also recorded the planned duration (PDOT) and median duration of treatment patients received (MeDOT). After excluding n=48 trials with altered initial approvals, 216 remained for overall analysis; 35 lacked MeDOT data and were excluded from MeDOT-specific analyses, leaving 169 for those analyses. We performed non-parametric comparisons and LASSO-selected multivariable regression of duration variables to explore predictors such as trial phase, treatment intent, drug class, and cancer type. As this research used publicly available, aggregate data, our protocol was reviewed by a senior team and did not require IRB submission per 45 CFR §46.102(f). **Results:** 70% of the included trials requiring >1 dose were indefinite. Among fixed, the PDOT – MeDOT difference gap was significantly larger in non-perioperative (median 16.3 months) than in perioperative (0.8 months). The MeDOT distributions for non-perioperative and indefinite trials were right-skewed with medians of 6.4 and 7.6 months respectively. In regression analyses, non-perioperative trials had significantly shorter MeDOTs, often treated hematologic malignancies, used checkpoint inhibitors, or involved front-line palliative intent. Indefinite trials were more frequent for small-molecule and tyrosine kinase inhibitors (TKIs), and fixed TKI trials had notably longer PDOTs (17.6 months). Importantly, none of the 216 approvals were based on trials comparing different treatment durations. **Conclusions:** While our findings suggest current oncology likely errs toward overtreatment, it is clear that researchers and regulators are not adequately assessing optimal treatment duration. Indefinite duration dominates current trial designs, while non-perioperative shows wide PDOT–MeDOT discrepancies, reflecting uncertainty about when therapeutic benefits plateau and harms increase. Future trials and regulatory directives should prioritize randomized duration comparisons to reduce toxicity and costs while optimizing patient outcomes. Research Sponsor: None.

Publication and data sharing of completed NCI cooperative group trials. First Author: Lauren N. Cueto, Yale School of Public Health, New Haven, CT

Background: Concerns about timely publication of NIH trial results, as well as sharing of clinical trial data, have led to important initiatives. The NCI developed an online archive of individual patient data (IPD) for cooperative group trials published after 2014, and ClinicalTrials.gov has required data sharing plans for all trials that began enrollment after 2018. We examined the dissemination of NCI cooperative group trial results via published manuscripts as well as availability of IPD from completed trials. **Methods:** We queried the Access to Aggregate Content of ClinicalTrials.gov database for phase II or III interventional trials for which NCI cooperative groups were listed as the sponsor, responsible party, or principal investigator. We included trials that were initiated between 2011 and 2022 and reached actual primary completion status (i.e. completion of data collection to fulfill the primary outcome measurement) by 2022. Primary manuscripts that reported the study primary outcome data were identified by searching NCT ID numbers on ClinicalTrials.gov, PubMed, and Google Scholar through a dual review. We restricted our 2 and 5-year assessments of study publication status to studies that had reached their primary completion date before 2022 and 2019, respectively. Individual patient data (IPD) sharing was assessed by reviewing the data-sharing statements on ClinicalTrials.gov for trials that began enrollment after the ClinicalTrials.gov mandate in January 2019. Next, we searched the NCT trial number in the NCTN/NCORP data archive to look for the availability of IPD among trials that published their primary outcome after January 2015. We also conducted a subgroup analysis of phase III trials. **Results:** Of 232 eligible studies, 159 (68.5%) were phase II, 11 (4.7%) were phase II/III, and 62 (26.7%) were phase III. NRG Oncology (n=58), Eastern Cooperative Oncology Group (n=47), and Alliance for Clinical Trials in Oncology (n=42) were the most represented cooperative groups. Overall, 33 (14.2% of the total) trials published their primary outcome results within one year of their primary completion, compared to 67 (31.6%) within 2 years, and 69 (63.3%) in 5 years. Among phase III trials, 26 (44.8%) had published their primary outcome findings within 2 years of study completion, and 22 (78.6%) published within 5 years. Among the 138 trials that published their primary outcome since January 2015, 36 (26.1%) had their IPD stored in the NCI online archive (76.1% of the 46 phase III trials). Among the 9 trials initiated since January 2019, 3 indicated on ClinicalTrials.gov that they had a plan to share their IPD. **Conclusions:** A substantial proportion of NCI cooperative group trials have not published manuscripts reporting their primary results in a peer-reviewed journal within 5 years of study completion. Approximately three quarters of phase III group trials completed during the study period had their IPD available within the NCI archive. Research Sponsor: None.

11024 **Poster Session**

Predictors of withdrawal for FDA accelerated approvals of anticancer drugs, 1992-2022. First Author: Alejandra Romano, Oncology Department, Hospital De La Santa Creu I Sant Pau, Institut d'Investigació Biomèdica Sant Pau. Departament of Medicine, Universitat Autònoma De Barcelona, Barcelona, Spain

Background: The US Food and Drug Administration's (FDA) accelerated approval pathway facilitates timely access to novel therapies based on surrogate measures that are supposed to be reasonably likely to predict clinical benefit. Post-approval, confirmatory studies are required to verify safety and efficacy, with approved indications subject to withdrawal from the labeling if these studies fail. While this pathway has been useful in some cases, concerns about delayed and an increasing number of withdrawals of anticancer indications highlight its associated risks to patients. This study identifies factors at the time of initial accelerated approval associated with subsequent withdrawal. **Methods:** In this retrospective cohort study, we analyzed FDA-approved drugs for solid and hematologic cancers receiving AA from 1992 to 2022. The analysis focused on key factors present at the time of accelerated approval, including the indication and pivotal trial characteristics, mechanisms of action and clinical outcomes. Clinical benefit was assessed using the European Society of Medical Oncology-Magnitude of Clinical Benefit Scale (ESMO-MCBS), categorizing benefits as high (A-B/4-5) or low (C/$\leq$2). Multivariable logistic regression was used to identify associations between these factors and indication withdrawal. **Results:** Among 167 accelerated approvals for 113 anticancer drugs, by August 2024, 102 (61%) had been converted to regular approval, 31 (19%) were withdrawn, and 34 (20%) were still in the accelerated approval phase. Of the 133 indications either converted or withdrawn, 52 (39%) were approvals for hematologic cancer drugs, and 41 (31%) supported genome-targeted drug approvals. Among 83 eligible indications, 46 (55%) were granted Breakthrough Therapy designation. Of 133 indications analyzed, 106 (80%) were based on single-arm pivotal trials, and 112 (84%) used response rate as the primary endpoint. Most trials (66%) showed low clinical benefit (86/130) per the ESMO-MCBS framework. In multivariable analysis, indications associated with lower withdrawal risk were more likely to have Breakthrough Therapy designation (OR 0.26; 95% CI, 0.10-0.75; p = 0.01) and be genome-targeted (OR 0.26; 95% CI, 0.08-0.80; p = 0.02). Low ESMO-MCBS scores conversely increased the likelihood of withdrawal (OR, 4.63; 95% CI, 1.50-14.33; p = 0.008). **Conclusions:** Accelerated approvals based on pivotal trials demonstrating low clinical benefit have been at higher risk of subsequent withdrawal, whereas indications with Breakthrough Therapy designation or supporting genome-targeted therapies were more likely to achieve full approval. Patients and health care providers should consider these factors when evaluating therapies newly granted accelerated approval. Disparities in NIH and federal cancer research funding across different cancer types. First Author: Suneel Deepak Kamath, Cleveland Clinic Cancer Center, Cleveland, OH

Background: National Institutes of Health (NIH) and other federal funding resources are critical for research and advocacy, but may not be equitably allocated across cancers. **Methods:** This study evaluated funding from the NIH and Congressionally Directed Medical Research Programs (CDMRP) supporting lung, breast, colorectal, pancreatic, hepatobiliary, ovarian, cervical, endometrial and prostate cancers, leukemia, lymphoma and melanoma, from 2013-2022. The primary objectives were to assess for funding disparities across different cancers compared to their incidence and mortality and across racial groups. We also determined if underfunding correlates with fewer clinical trials. Correlations between funding for each cancer and its incidence, mortality and number of clinical trials were analyzed using descriptive statistics and Pearson correlation coefficients (PCCs). **Results:** Diseases with the largest combined NIH and CDMRP funding from 2013 - 2022 were breast ($8.36 billion), lung ($3.83 billion) and prostate ($3.61 billion) cancers. Those with the least funding were uterine ($435 million), cervical ($1.12 billion) and hepatobiliary ($1.13 billion) cancers. Cancer-specific NIH and CDMRP funding correlated well with incidence (PCC: 0.85) but was poorly aligned with mortality (PCC: 0.36). Cervical, ovarian, breast, leukemia and lymphoma were consistently well funded compared to their incidence and mortality rates while lung, colorectal, liver and uterine cancers were consistently underfunded. These data are summarized in the Table. Cancers with higher incidence among Black people were disproportionately underfunded. The amount of combined NIH and CDMRP funding for a particular cancer correlated well with the number of clinical trials in that disease (PCC: 0.76). **Conclusions:** Federal cancer research funding aligns well with incidence but significantly underfunds cancers with higher mortality rates. Underfunding strongly correlates with fewer clinical trials, which impedes future advances in underfunded cancers that already have worse outcomes. Research Sponsor: None.

Communication of uncertainties about recent cancer drugs in large language models. First Author: Avi Cherla, Harvard Medical School, Boston, MA

Background: Increasingly more people use large language models (LLMs) to find information about medical treatments. However, there are notable concerns about the accuracy and completeness of information generated by these models. We assessed whether LLMs accurately summarized uncertainties about the benefits and harms of new cancer drugs. **Methods:** We identified the 10 cancer drugs approved by the US Food and Drug Administration (FDA) between 2019 and 2022 with the highest Medicare spending in 2022 (5 in Part B and 5 in Part D). We then searched FDA review documents to extract information about the uncertainties with each drug's clinical trial evidence that were identified by FDA reviewers at the time of approval. Uncertainties with clinical trial evidence were assigned to mutually exclusive categories. We evaluated the extent to which 4 state-of-the-art LLMs (OpenAI's ChatGPT-4, Google's Gemini 1.5 Pro, Meta's Llama 3.1, and Anthropic's Claude 3.5 Sonnet) provided information about FDA-identified uncertainties when queried for information about the drugs using two prompts: (1) *how well does [drug] work for [condition]?*; (2) *is there anything uncertain about how well [drug] works for [condition]?*. **Results:** For the 10 recently approved cancer drugs with the highest Medicare spending in 2022, FDA reviewers identified a total of 38 uncertainties with the clinical trial evidence. For 9 of 10 drugs, FDA reviewers identified uncertainties related to the generalizability of the evidence. Other common uncertainties included bias related to the measurement of the outcome and the use of single arm trial designs. When the LLMs were prompted about how well these 10 cancer drugs worked, the models rarely provided information about the uncertainties identified by FDA reviewers: GPT-4 (4/38, 11%), Gemini 1.5 Pro (3/38, 8%), Llama 3.1 (3/38, 8%), and Claude Sonnet (2/38, 5%). The proportion of FDA-identified uncertainties reported by the models improved marginally when specifically prompted for uncertainties about the drugs. Qualitative assessment of the information generated by the LLMs showed that most of the models tended to report similar, non-specific uncertainties for every drug with little variation. **Conclusions:** LLMs do not provide adequate information about uncertainties related to the benefits and harms of recently approved cancer drugs, despite the availability of this information in the public domain. There is a need to improve LLMs to accurately report such information, so that patients can make informed decisions about cancer treatments. Research Sponsor: None.

Performance of LLMs compared to uncertainties identified by the FDA.

Prompt	GPT-4	Gemini 1.5 Pro	Llama 3.1	Claude 3.5 Sonnet	Average
How well does [drug] work for [condition]?	4/38 (11%)	3/38 (8%)	3/38 (8%)	2/38 (5%)	3/38 (8%)

Achieving equity in genomic testing for breast cancer through partner-led strategies and policies. First Author: Mary Umahi Obasi, Stanford University School of Medicine, Division of Oncology, Stanford, CA

Background: Genomic testing is recommended for individuals with estrogen/progesterone receptor-positive, HER2-negative early-stage breast cancer to determine the need for chemotherapy alongside endocrine therapy. However, access disparities persist by race, ethnicity, and income. This study aims to identify modifiable barriers and co-design policy recommendations for equitable genomic testing for low-income, and racial and ethnic minoritized people with breast cancer in Northern California. **Methods:** Using community-based participatory research and expert panel methods, we collaborated with an 18-member expert panel of patients, caregivers, oncology clinicians, community organizations, advocates, and policymakers to identify modifiable barriers and propose solutions. Phase 1 involved an 85-question survey and semi-structured interviews with patients, caregivers, clinicians, navigators, policymakers, and payers, administered by bilingual community health workers in Spanish, Tagalog, and Chinese, to assess genomic testing barriers and solutions. Phase 2 used Delphi consensus methods with the expert panel to finalize policy recommendations. **Results:** Of 912 invited, 831 participated in surveys (90% response rate), and all 30 purposively sampled individuals participated in interviews (100% response rate). Survey participants included 514 patients, 101 caregivers, 94 clinicians, 74 navigators, 25 policymakers, and 23 payers. Among patients, 102 (19.8%) were Asian, 132 (25.7%) Black, 138 (26.9%) Hispanic White, 28 (5.5%) Non-Hispanic White, and the remainder preferred not to answer. Racial and ethnic minoritized patients had significantly lower odds of genomic testing compared to Non-Hispanic Whites: Black patients 86% lower (OR: 0.15; 95% CI: 0.07-0.31), Asian patients 71% lower (OR: 0.29; 95% CI: 0.14-0.59), and Hispanic White patients 79% lower (OR: 0.21; 95% CI: 0.11-0.43). Four themes emerged from interviews: 1) limited awareness/resources, 2) inequitable care, 3) financial/cultural barriers, and 4) insufficient social support. The expert panel reached consensus on policy recommendations, including mandating reflexive, fully reimbursed genomic testing (mean rating $\pm$ SD: 8.3 $\pm$ 0.9), eliminating prior authorization (8.2 $\pm$ 0.8), removing co-pays/out-of-pocket costs (8.1 $\pm$ 0.8), and providing educational materials in preferred languages with lay terminology (7.9 $\pm$ 1.2). **Conclusions:** Disparities in genomic testing persist, highlighting the need for targeted interventions. Policy recommendations co-designed with communities and other interested groups can be implemented to improve equitable care. Research Sponsor: California Breast Cancer Research Program.

Pain in cancer survivors in the US after federal and state opioid prescribing guidelines and laws. First Author: Justin Michael Barnes, Washington University School of Medicine in St. Louis, St. Louis, MO

Background: Cancer-associated pain is common among survivors and may require opioid medications for effective management. In 2016, the Centers for Disease Control and Prevention (CDC) published guidelines to limit opioid prescribing, leading to a subsequent decline in prescriptions in the US. Many states also enacted opioid prescribing laws after 2016. Cancer-associated pain is explicitly exempted by the CDC and from some state opioid laws. As state laws and exemptions are heterogeneous and sometimes unclear, this study was designed to assess whether cancer survivors were impacted by post-2016 opioid prescribing patterns and legislation. **Methods:** The 2011-2023 Behavioral Risk Factor Surveillance System (BRFSS), an annual, national survey, was queried for cancer survivors. Quality of life (QoL)-limiting pain (included in 2011-17) was defined as having $\geq$1 days where pain made it hard to participate in usual activities. A sensitivity analysis utilized a $\geq$7 day cutoff. Cancer-associated pain (included in 2016-23) was defined as currently having pain caused by cancer or cancer treatment. Linear probability models examined whether there were nationwide changes in QoL-limiting pain after the 2016 CDC guidelines. State-level difference-in-differences (DiD) analyses compared changes in cancer-associated pain over time between states with and without opioid prescribing laws. State opioid laws included (A) any opioid prescribing legislation and (B) explicit cancer-associated pain exemptions. States that enacted opioid policies prior to the 2nd quarter of 2016 were excluded due to lack of cancer-associated pain data before 2016. Analyses accounted for the complex survey design and BRFSS weights and utilized robust SEs, and models were adjusted for sociodemographic, Medicaid expansion, and cancer site factors. DiD analyses also accounted for state and year-quarter fixed effects. **Results:** 2,725 cancer survivors were included in the 2011-17 QoL-limiting pain analyses and 31,955 in the 2016-23 cancer-associated pain analyses. QoL-limiting pain was present for 40.3% ($\geq$1 days affected) and 27.0% ($\geq$7 days affected) and cancer-associated pain was present in 11.9%. There was no significant change in QoL-limiting pain after 2016 in our primary (-9.6 percentage points [95% CI -30.9, 11.7]) or sensitivity analysis ($\geq$7 day affected, 4.32 [-14.24, 22.89]). In adjusted DiD analyses, there were no significant associations between cancer-associated pain and state opioid laws (-2.17 [-6.32, 1.98]) or explicit cancer exemptions in state opioid laws (4.16 [-1.75, 10.07]). **Conclusions:** Among this nationally representative sample of cancer survivors, cancer-associated pain affected $>$1 in 10 survivors and $>$1 in 4 had QoL-limiting pain. However, federal and state opioid prescribing guidelines and laws had minimal impact on the prevalence of pain among cancer survivors, perhaps due to effective exemptions for cancer. Industry promotion of oncology drugs with accelerated approval that failed confirmatory trials. First Author: Maryam Mooghali, Yale School of Medicine, New Haven, CT

Background: Oncology drugs are commonly granted accelerated approval by FDA based on pivotal trials using surrogate markers as primary endpoints, while requiring sponsors to complete postapproval studies that confirm clinical benefit. Industry payments to physicians may influence treatment recommendations, which is particularly concerning for accelerated approval drugs, where clinical benefit remains uncertain. We investigated industry payments to physicians before and after results of confirmatory studies for oncology drugs with accelerated approval whose confirmatory studies failed to confirm clinical benefit. **Methods:** In this cross-sectional study, using Drugs@FDA database, we identified oncology drugs granted FDA's accelerated approval, their required postapproval confirmatory studies, and FDA status changes (withdrawn or converted to traditional approval). We searched ClinicalTrials.gov, publications, and company press releases to identify drugs with confirmatory studies failing to confirm clinical benefit. We searched OpenPayments database to record industry payments made to physicians associated with these drugs. **Results:** From 2009-2021, of 73 drugs granted accelerated approval by U.S. FDA, 7 (9.6%) had indications for which all confirmatory studies were negative. Among these, 6 were voluntarily withdrawn following FDA's recommendation, while for Pepaxto (melphalan flufenamide), the sponsor appealed FDA's proposed withdrawal; it was ultimately withdrawn by FDA. Pepaxto was excluded from our analysis as it had no reported payments on OpenPayments. The results of postapproval confirmatory trials for the remaining 6 indications were announced after a median time of 4.2 (2.2-6.6) years. All 6 drugs were withdrawn from the market, with a median duration of 4.9 (IQR, 2.7-6.9) years from approval to withdrawal. Following announcement of negative postapproval confirmatory study results, average monthly payments received by all physicians increased for Marqibo (vinCRIStine sulfate) from $138 in the year preceding announcement to $164 during the period between announcement of negative results and market withdrawal, but decreased for Farydak (panobinostat) ($12,317 to $4,916), Blenrep (belantamab mafodotin) ($152,417 to $119,394), and Ukoniq (umbralisib) ($23,139 to $14,130). Lartruvo (olaratumab) and Aliqopa (copanlisib) had almost no payments after announcement of negative confirmatory study results. **Conclusions:** Industry payments for oncology drugs with accelerated approvals mostly decreased after announcement of negative confirmatory trial results; however, there was evidence of continued promotion for certain drugs until a request for voluntary withdrawal was made by FDA. This suggests that regulatory oversight and enforcement might be necessary to mitigate ongoing promotion of such drugs after confirmatory trials fail to confirm clinical benefits. Unpacking the relationship between cancer survival and political environment in the United States (US). First Author: John E. Dobbs, Johns Hopkins Hospital, Baltimore, MD

Background: Several studies have reported on how health outcomes may differ by the political majority of a county. It is unclear the extent to which this discrepancy is due to a broader political landscape compared to underlying sociodemographic and structural determinants. Using county level presidential voting patterns and a national cancer registry, we present a rigorous analytic approach to assessing survival trends. **Methods:** We linked SEER-Medicare's (100% sample) database on the 4 most common cancers (lung, breast, prostate and colorectal) from 2007-2019 to county-level data on US presidential elections over the same period. Using the total number of votes in each party, county political environment was classified as either Democratic or Republican for the four years following a presidential election. Cox proportional hazards estimated changes in survival over time according to political party. Models were sequentially fit adjusting for age, sex, diagnosis year (Model 1), race/ethnicity (M2), rural/urban continuum code (RUCC) (M3), cancer type (M4), Medicaid/Medicare Advantage enrollment and original reason for entitlement (M5), and primary care doctors and oncologists per 100,000 people (M6). Analyses were performed separately by cancer type and for the entire cohort. **Results:** Of the 1,899,334 individuals, 1,222,228 (64%) resided in Democratic counties and 677,106 (36%) in Republican counties. Democratic counties were majority urban (90% vs 55% for Republican). Adjusting for factors generally associated with worse survival (older age, male gender, earlier diagnosis year), Republican counties had worse survival (HR 1.14, 95% CI [1.14, 1.15], $p < 0.001$) compared to Democratic counties. However, following sequential adjustment of aforementioned variables (M1-M6), this difference disappeared (HR 1.00, 95% CI [1.00, 1.01], p = 0.56, Table). In stratified analyses, similar results were noted for colorectal, lung, breast, and prostate cancer. Among all cancer types, Republican counties had 2% higher risk of diagnosis of later stage cancer, but no difference in overall survival. Finally, limiting our dataset to rural counties only, a 12% higher risk of death in Republican counties reduced to no difference following adjustment. **Conclusions:** Survival differences between counties by presidential voting status disappeared following adjustment of sociodemographic and structural determinants. In a charged political climate, our study cautions against oversimplified claims and underscores the importance of careful methodological approaches in identifying key confounders in aggregate-level studies when identifying meaningful trends. Progression-free survival in control arms of clinical trials: Analysis of FDA cancer drug approvals between 2014 and 2023. First Author: Angela Viggiano, Department of Clinical Medicine and Surgery, University of Naples Federico II, Naples, Italy

Background: FDA regularly approves new cancer drugs based on the results of surrogate endpoints, often using expedited programs. When assessing the efficacy of new anticancer treatments, the choice of the control arm plays a crucial role. Herein, we evaluated the progression-free survival (PFS) performance of control arms in trials that led to FDA approvals for oncology treatments. **Methods:** We investigated FDA drug approvals issued between January 2014 and December 2023 for the treatment of advanced cancers, available on the FDA.gov website. We analysed publications of phase III or double-arm phase II trials that prompted approvals. For each clinical trial, we collected: i) The assumed median PFS (amPFS) value of the control arm, generally indicated in the study protocol for the sample size calculation; ii) The control arm's recorded median PFS (rmPFS) and its confidence interval (CI). Control arms of each trial were considered under- or out-performing if amPFS exceeded the highest CI of rmPFS or was inferior than the lowest CI of rmPFS, respectively. All other cases were defined as "within the range". **Results:** We found 72 trials leading to new cancer drug approvals. Immune checkpoint inhibitors (ICIs) and small molecules were investigated in the majority of cases, in 27 (37.5%) and 19 (26.4%) trials, respectively. Control arms under- or out-performed in 24/72 (33.3%) and 8/72 (11.1%) cases, respectively. In the remaining 40/72 (55.5%) trials, control arms performances were "within the range". Interestingly, in 12/27 (44.4%) trials leading to ICIs approval, control arms underperformed. We found that in 6/14 (42.9%), 5/16 (31.3%) and 5/16 (31.3%) trials leading to new approvals in lung, breast and genitourinary cancers, respectively, the control arms underperformed. In 18/24 (75.0%) underperforming control arms, the discrepancy between amPFS and rmPFS was larger than 20%. Among the 19 trials with underperforming control arm and leading to expedited approval, in 7 (36.8%) cases a final overall survival (OS) advantage was not observed. **Conclusions:** The PFS benefit observed in several trials leading to FDA approval of new anticancer drugs may have been influenced by shorter-than-expected PFS in the control arms. Accurate analysis of control arms outcomes in clinical trials is essential for a comprehensive assessment of the efficacy of experimental drugs. Research Sponsor: None.

Early signals of Inflation Reduction Act impact on small-molecule versus biologic post-approval oncology trials. First Author: Hanke Zheng, National Pharmaceutical Council, Washington, DC

Background: The Inflation Reduction Act's Drug Price Negotiation Program (DPNP) has shifted the financial incentives for post-approval clinical development, which is particularly relevant to oncology given the role of subsequent indications in expanding treatment options in cancer patients. The law may disproportionately disincentivize post-approval development in small molecules, which faces a shorter timeline towards DPNP eligibility than biologic (7 vs. 11 years post first approval). We aimed to explore the impact of IRA's passage on industry-sponsored small-molecule versus biologic post-approval clinical trials in oncology. **Methods:** Using the Citeline's TrialTrove database, we identified industry-funded Phase I-III trials initiated between 7/2014 and 8/2024 for approved oncology drugs, excluding vaccines and COVID-19-related trials. Trials were categorized into subgroups based on whether they primarily tested small molecules or biologic, excluding trials testing both (e.g., combination therapies) from the subgroup analysis. We used Wilcoxon rank-sum tests to compare the monthly average of trials pre- and post-IRA for all post-approval oncology trials and in the subgroups. The pre/post-IRA comparison was conducted (1) across the full period (7/2014-7/2022 vs. 8/2022-8/2024), and (2) between the year before IRA's passage and the most recent available year (shorter-time: 8/2021-7/2022 vs. 9/2023-8/2024). We performed a difference-in-difference (DiD) analysis to assess the marginal impact ("dosage effect") of IRA on small molecule trials, using biologic trials as the counterfactual. The assumption was that trials would have followed a similar trajectory in both groups in the absence of IRA's differential DPNP eligibility timelines. **Results:** Across the full period, monthly average of post-approval oncology trials decreased by 38.4% ($p<0.01$) following the IRA' passage, and small molecule and biologic trials dropped by 48.6% ($p < 0.01$) and 27.4% ($p < 0.01$) post-IRA, respectively. In the shorter-time comparison, there was a 29.6% ($p<0.01$) reduction overall, and the monthly average of small molecule trials decreased by 43.9% ($p < 0.01$), with no statistically significant change in biologic trials (p = 0.48). Across the full period, the DiD model suggested that the IRA was associated with 7.7 fewer trials per month for oncology small molecule drugs, compared to the biologic drugs (-7.7, 95% C.I.: -9.9 to -5.5, $p < 0.01$). **Conclusions:** The IRA's passage was associated with fewer industry-funded post-approval oncology trials and larger reductions for small molecule trials than biologic trials. These findings support concerns about IRA's disincentivizing effect on post-approval development in oncology, particularly for small molecule drugs, which are subject to a shorter DPNP eligibility timeline. Cost-effective cancer care: The role of oncology biosimilars in generating cost savings. First Author: James W. Gilmore, American Oncology Network, Fort Myers, FL

Background: Biosimilar versions of biologic drugs (reference drugs) present a promising opportunity to reduce healthcare costs. Although not labeled as directly interchangeable, biosimilars are considered reasonable alternatives to their reference drugs by experts. We evaluated the adoption, costs, and savings of key biosimilars used primarily in oncology practice. **Methods:** We used publicly available, specialty agnostic, HCPCS level utilization and cost data from the Medicare Part B Spending by Drug dataset published by the Centers for Medicare and Medicaid Services to study the use of biosimilars for five reference drugs (Bevacizumab, Trastuzumab, Rituximab, Peg-filgrastim, Filgrastim) between 2015 and 2022. We then modeled two spending scenarios for 2022: one where only the reference drugs were used, and one where the lowest cost option (reference or biosimilar) was used for eligible indications. We calculated the savings and incremental savings opportunity to Medicare by comparing these scenarios to the actual 2022 spending. **Results:** Over the 8-year evaluation period, each reference drug received multiple biosimilar approvals, and biosimilar use increased from 0% to 56.4%. Lower biosimilar use of Bevacizumab may have been due to the lack of approval for ophthalmic use. The introduction of biosimilars caused price reductions for the reference drugs and the biosimilars. Biosimilar prices in 2022 were lower than their reference drugs for all except Peg-filgrastim, whose price fell below that of its biosimilars. In 2022, biosimilar adoption resulted in a 23% spending reduction for Medicare, with an additional 14% savings opportunity. Table 1 shows biosimilar adoption rates by reference drug and savings vs savings opportunity. **Conclusions:** The adoption of Oncology biosimilars has resulted in significant cost savings for Medicare, but there are still opportunities for further savings. The complex relationship between biosimilar prices and their utilization warrants additional evaluation. Additionally, the effects of biosimilar payment policies, such as those introduced by the Inflation Reduction Act, and the impact of payer specific product mandates on overall biosimilar adoption need to be explored further. Research Sponsor: None.

Access to cancer care for undocumented immigrants in the United States. First Author: Patricia Mae Garcia Santos, Division of Health Services, Outcomes, and Policy, Department of Radiation Oncology, Winship Cancer Institute, Emory University, Atlanta, GA

Background: Undocumented immigrants represent a disproportionate share of uninsured individuals in the United States, owing to federal restrictions on Medicaid eligibility. Emergency Medicaid (EM) and other state programs offer avenues for healthcare coverage, but their impact on access to cancer care remains poorly understood. **Methods:** Between January-July 2024, information on the availability and breadth of cancer coverage for undocumented immigrants under EM and other insurance mechanisms were reviewed for all 50 states and the District of Columbia (D.C.). For each state, ≥4 authors reviewed publicly available data compiled from multiple, independent sources including Medicaid policy handbooks, provider manuals, legislative documents, and other state government website resources. Abstracted data included state-specific information on extent of coverage, specifically as it pertains to cancer diagnosis, treatment, and follow-up care. Discrepancies in policy findings were discussed during consensus meetings to ensure accurate interpretation. In cases where policies remained unclear, state Medicaid agencies were directly contacted for further clarification. **Results:** Undocumented immigrants receive cancer care coverage via (1) expansions to EM (*n*=3), (2) Medicaid-equivalent programs (*n*=7), or (3) other non-Medicaid mechanisms (*n*=5; Table). Of the 6 states and D.C. with Medicaid-equivalent plans, 4 states and D.C. cover all adults, while 2 states only cover some adults (IL: limited to adults age ≥42; NY: limited to adults age ≥65, but adults age <65 can receive cancer coverage via EM). Of the 5 states with non-Medicaid mechanisms, 2 states (CO, WA) allow purchase of commercial plans on the ACA Marketplace or Marketplace-like platform; other strategies include Iowa's Breast and Cervical Cancer Treatment Program (BCCTP), Massachusetts' Health Safety Net program, or New Mexico's high-risk insurance pool. The remaining 35 states had no documented cancer coverage mechanism. **Conclusions:** In this national analysis of EM and other policies supporting healthcare coverage for undocumented immigrants, access to cancer care remains fragmented, intermittent, and largely limited to the emergency setting. Although Medicaid-equivalent plans and Marketplace-based offer promising avenues for comprehensive coverage, budgetary constraints and political challenges pose threats to viability. Absent federal support, sustainable policy solutions are needed to ensure continued progress towards a more equitable model of care. Research Sponsor: None.

Likelihood of unplanned readmission among oncology patients with a completed post-discharge follow-up encounter. First Author: Emma Hannan, Sidney Kimmel Comprehensive Cancer Center, Jefferson Health, Philadelphia, PA

Background: Literature suggests that oncology patients are more likely to be admitted from the emergency department to the hospital than patients without a cancer diagnosis[1]. Avoiding unplanned readmissions (UR) becomes a joint responsibility of the patient and the oncology care team. The premise of one ASCO Certified standard is that patients who receive post-discharge follow-up (PDFU) may avoid a readmission if their needs are addressed promptly in the outpatient setting. We evaluated the impact of completion of a PDFU after an index admission on URs. **Methods:** We performed a retrospective analysis of patients with an index admission to a system hospital between January and November 2024. Included were patients with a discharge (d/c) to home and an encounter with an oncology provider within the past year. We compared the overall proportion of patients with any UR in the measurement period between those patients who did and did not complete a PDFU, as well as that of patients who completed an early PDFU (within 3 days of d/c) and a later PDFU (between 4-7 days of d/c). PDFUs are defined as a telemedicine or clinic encounter within 7 days of the d/c date. Chi Squared analysis was utilized to evaluate if PDFU reduced UR. **Results:** 2,533 d/cs occurred within the measurement period. 542 (21%) of encounters resulted in a UR. 1,057 (42%) encounters had a PDFU. Of the 1,057 encounters where a PDFU was completed, 240 (23%) resulted in a UR. Of the 1,476 encounters where a PDFU was not completed, 302 (20%) resulted in a UR. The findings were not clinically significant. Chi-squared p-value: .17 **Conclusions:** Completion of a PDFU is not a factor in predicting an oncology patient's potential unplanned readmission. In addition, excluding some high risk patients such as those with hematologic malignancies did not change the overall analysis. We found no difference in rate of UR among patients who completed a PDFU within 3 days or 4-7 days. Further investigation is needed to better understand if modifiable factors contributed to UR in this cohort. Other factors need to be considered, such as patient risk for unplanned re-admission, in evaluating the impact of PDFU on UR, as expected in the ASCO Certified standard. [1] Waters TM; Kaplan CM, Graetz I, et al. (2019) Patient-Centered Medical Homes in Community Oncology Practices: Changes in Spending and Care Quality Associated with the COME HOME Experience. Journal of Oncology Practice, 15(1), e56-e64. Research Sponsor: None.

Molecular testing and targeted therapy use in lung cancer across state Medicaid programs. First Author: Thomas J. Roberts, Massachusetts General Hospital, Harvard Medical School, Boston, MA

Background: Comprehensive molecular testing is the standard of care for patients with metastatic non-small cell lung cancer (NSCLC) and is essential to identify patients with tumors harboring *EGFR*, *ALK* alterations that can be treated with efficacious targeted therapies. Prior work has shown that use of targeted therapies for NSCLC is lower than expected among Medicaid beneficiaries and rates of use may vary across state Medicaid programs. We used Medicaid claims and encounter data to estimate the rates of molecular testing and targeted therapy use across state Medicaid programs. **Methods:** Using Transformed Medicaid Statistical Information System Analytic Files (TAF) data from 2017 and 2018, we identified beneficiaries with new diagnoses of metastatic NSCLC who were continuously enrolled in Medicaid during the period of analysis. Among these patients, we identified claims for molecular tests that could identify *EGFR* or *ALK* alterations and claims for FDA-approved targeted therapies during a 120-day window around the first claim for antineoplastic therapy. We tabulated rates of molecular testing and targeted therapy use by state. We ran logistic regressions for molecular testing and targeted therapy use with patient characteristics, and then we used the regression coefficients to estimate adjusted rates of molecular testing and targeted therapy use for each state. **Results:** We included 41 states with complete TAF data in the study years. In these states there were 5,432 beneficiaries who initiated antineoplastic therapy for new diagnoses of metastatic NSCLC. The number of incident cases within each state Medicaid program ranged from 11 in Utah to 824 in California. In logistic regression, the characteristics associated with lower rates of molecular testing were male sex, high Charlson comorbidity indices, and lower income. The characteristics associated with low rates of targeted therapy use were older age, male sex, and lower education levels. The adjusted rate of molecular testing among patients with incident metastatic NSCLC across all state Medicaid programs was 55.9% with rates ranging from 39.2% in Texas to 69.3% in Washington state. The mean adjusted rate of targeted therapy use across state Medicaid programs was 8.6% with rates ranging from 3.4% in Michigan to 24.8% in New York. **Conclusions:** After adjusting for patient characteristics, there was substantial state-by-state variation in the rate of molecular testing and targeted therapy use among Medicaid beneficiaries with NSCLC. More work is needed to understand whether specific Medicaid policies such as prior authorizations or restrictions on access to diagnostic testing may contribute to the observed disparities. Research Sponsor: None.

Comprehensive analysis on reactive cutaneous capillary endothelial proliferation following camrelizumab-based therapy in patients with solid tumors: A large-scale pooled analysis of nine phase 2 or phase 3 registration trials. First Author: Shukui Qin, Nanjing Tianyinshan Hospital of China Pharmaceutical University, Nanjing, China

Background: Previous studies demonstrated the positive association between cutaneous immune-related adverse events and long-term survival in advanced cancer patients treated with immunotherapy. As a unique adverse event related to camrelizumab, the association of reactive cutaneous capillary endothelial proliferation (RCCEP) with patient prognosis may also exist. Here we comprehensively analyzed the characteristics of RCCEP and this association. **Methods:** This was a pooled analysis based on individual patient-level data derived from seven phase 3 and two phase 2 registration trials for new drug application in China. Patients with advanced non-small cell lung cancer, hepatocellular carcinoma, esophageal squamous cell carcinoma, nasopharyngeal carcinoma, and gastric cancer treated with camrelizumab monotherapy (Camre), camrelizumab plus apatinib (Camre-Apa), or camrelizumab plus chemotherapy (Camre-Chemo) were included. Landmark analyses taking the median time to the first RCCEP onset as cutoff reference were performed for survival. **Results:** RCCEP occurred in 74.5% (251/337) of patients with Camre, 30.6% (120/392) with Camre-Apa, and 73.2% (737/1007) with Camre-Chemo. The severity was grade 1 or 2 in almost all patients with RCCEP (97.9%; 1085/1108), and the median frequency of RCCEP events was 1 (IQR, 1-2). Median time to the first RCCEP onset was 1.0 months [IQR, 0.7-1.2] with Camre, 4.7 months (IQR, 2.8-7.8) with Camre-Apa, and 1.5 months (IQR, 1.0-2.6) with Camre-Chemo; 1-month, 5-month, and 2-month landmark analyses of survival were performed for the three treatment groups, respectively. Patients with RCCEP showed better clinical outcomes than those without (objective response rate: 22.7% vs 2.3% with Camre, 42.5% vs 18.0% with Camre-Apa, and 73.7% vs 45.9% with Camre-Chemo; median progression-free survival [landmark analysis]: 3.0 vs 1.9 months [HR = 0.51, 95% CI, 0.38-0.69], 13.8 vs 12.6 months [HR = 0.88, 95% CI, 0.61-1.26], and 9.7 vs 6.9 months [HR = 0.58, 95% CI, 0.47-0.71]; median overall survival [landmark analysis]: 11.8 vs 3.9 months [HR = 0.44, 95% CI, 0.33-0.59], 35.2 vs 23.7 months [HR = 0.66, 95% CI, 0.49-0.90], and 23.4 vs 12.0 months [HR = 0.45, 95% CI, 0.37-0.54]). Discontinuation of camrelizumab treatment due to RCCEP barely occurred (0.3%; 5/1736). **Conclusions:** Although RCCEP occurred commonly, most events were mild without impact on camrelizumab treatment. RCCEP occurred early with 1-2 events mainly in each patient. The occurrence of RCCEP was positively associated with both short-term response and long-term survival, regardless of camrelizumab monotherapy or combination therapy. These findings can enhance patient confidence in continuing camrelizumab treatment. Research Sponsor: Jiangsu Hengrui Pharmaceuticals Co., Ltd.

Demographic and clinical factors associated with young-onset rectal cancer: Is the Latinx population at higher risk? First Author: Antoine Jeri-Yabar, Icahn School of Medicine at Mount Sinai Morningside/West, New York, NY

Background: The incidence of colorectal cancer is rising among younger adults, with some studies indicating a disproportionate increase in the Hispanic population. As one of the fastest-growing demographics in the United States, Hispanic individuals face unique barriers to cancer prevention and care. However, data specifically addressing disparities in rectal cancer within this group remain limited. The aim of our study is to elucidate demographic and clinical factors associated with young-onset rectal cancer (YO-RC) and evaluate if the Latinx population is at higher risk compared to other races. **Methods:** We evaluated patients ≥18 years of age with rectal cancer from the Surveillance, Epidemiology, and End Results (SEER) database, with a study period from 2018 to 2021. The study population included adult patients diagnosed with RC as first primary, histologically confirmed diagnoses, complete data on race, MSI status, stage, and known cause of death. A retrospective cohort study was done. Individuals were divided into two groups: young onset (diagnosed <50 years old) and average-onset (diagnosed at ≥50 years old). Univariate and multivariate logistic regression was done, adjusted logistic regression to race, sex, area of living, MSI status and stage. **Results:** A total of 13,768 individuals were analyzed, with 2,661 (19.33%) classified as YO-RC and 11,107 (80.67%) as AO-RC. In the YO-RC group, 60.28% were Non-Hispanic White (NHW), 21.20% Hispanic (H), 7.22% Non-Hispanic Black (NHB), 10.54% Non-Hispanic Asian or Pacific Islander (NHAPI), and 0.76% Non-Hispanic American Indian (NHAI). Most were male (58.51%) and diagnosed at advanced stages (43.03% stage III and 27.58% stage IV), with 93.24% having MSI-stable tumors. In the AO-RC group, NHW accounted for 68.46%, followed by H (12.52%), NHB (7.70%), NHAPI (10.46%), and NHAI (0.86%). Stage III (32.86%) and stage I (24.45%) were the most common stages, and 94.97% had MSI-stable tumors. H individuals were nearly twice as likely to have YO-RC compared to NHW (aOR 1.87, 95% CI 1.67–2.10, p<0.001). Females had a higher likelihood of YO-RC than males (aOR 1.14, 95% CI 1.04–1.24, p=0.002). MSI-high tumors were associated with YO-RC (aOR 1.57, 95% CI 1.27–1.94, p<0.001). Patients diagnosed at later stages were also more likely to have YO-RC (stage III aOR 1.99, 95% CI 1.76–2.25, p<0.001; stage IV aOR 1.98, 95% CI 1.73–2.26, p<0.001). **Conclusions:** Hispanic individuals are more likely to have YO-RC, which suggests the critical need for targeted outreach and earlier screening efforts within the young Latinx population. Female patients and those with MSI-high tumors were also more likely to have YO-RC suggesting possible biological and genetic influences, including Lynch syndrome. The strong correlation of advanced-stage diagnoses and YO-RC demonstrates the need to improve early detection efforts. Research Sponsor: None.

Pharmacotherapy as an adjunct to behavioral weight loss treatment in survivors of breast cancer. First Author: Jennifer Y. Sheng, Johns Hopkins University, Baltimore, MD

Background: Approximately half of breast cancer (BC) survivors attain 5% weight loss with 6 months of behavioral intervention alone. We conducted a single-arm, phase II study evaluating the addition of FDA-approved anti-obesity pharmacotherapy Contrave (Naltrexone +Buproprion) to a behavioral weight loss (BWL) intervention in BC survivors who did not attain 5% weight loss after 8 weeks. **Methods:** Women with stage 0-III BC and BMI > 27 kg/m^2 who completed local therapy and chemotherapy were enrolled in a 6-month, remotely-delivered BWL program. Patients completed demographic and psychosocial surveys, lab draws (Hba1c and lipid panel) and were weighed in clinic at baseline, 2 and 6 months. An adaptive design utilizing weight loss at 2 months identified those with greater likelihood of weight loss at 6 months with BWL alone. Patients with and without ≥5% weight loss at 2 months were stratified as FAST-BWL and SLOW-BWL, respectively. FAST-BWL continued BWL alone for 4 months, while SLOW-BWL received Contrave plus BWL. Within the SLOW-BWL arm, the trial continued with a Simon two-stage minimax design with the proportion of SLOW-BWL attaining ≥5% weight loss at 6-months as the primary endpoint. The planned sample size of 30 had 80% power at a type I error rate of 5% if the true rate of attaining the primary endpoint by 6 months was 29%, compared to 10.9% under the null. Secondary endpoints included measures of physical function, endocrine function, pain, fatigue, depression, anxiety, sleep disturbance, and sexual problems. **Results:** Of 53 enrolled patients, 15 (28%) were FAST-BWL and 38 (72%) were SLOW-BWL responders. Compared to FAST-BWL, SLOW-BWL included more participants who were Black (32% v 7%), premenopausal (21% v 7%), and had an ECOG 1 (26% v 13%). At 6-months, mean % weight change was -5.1±2.9 and -10.8±3.5 for SLOW-BWL and FAST-BWL, respectively. In the intent-to-treat population of SLOW-BWL (n = 38), 42% had 5% weight loss by 6-months. SLOW-BWL had significant improvement in Hba1c between 2 and 6 months. Among SLOW-BWL patients, every two pounds over the two-month average change, patients were one third as likely to be successful at 6 months, OR = 0.3 (95% CI: 0.1, 0.88), p = 0.03. Of 21 in SLOW-BWL with PROs evaluable for minimally important differences at 6-months, 29% had less anxiety, 24% had improved physical function, and 19% had less pain, fatigue, sleep disturbance, and sexual dysfunction. Regardless of arm, physical function and pain improved in those with >5% weight loss (p = 0.03 and p = 0.02, respectively). The change in pain was primarily in those with > 5% weight loss in SLOW-BWL. **Conclusions:** Contrave can enhance weight loss outcomes in BC survivors who do not attain significant weight loss with diet and exercise modification alone. Further research is needed to understand individuals who benefit most from pharmacotherapy. Clinical trial information: NCT04499950. Association between frailty and clinical outcomes in older adults with early breast cancer: Results from the Hurria Older Patients (HOPE) study. First Author: Yuliya Zektser, UCLA Medical Center, Los Angeles, CA

Background: Older adults with early breast cancer are a heterogenous population with varying physiologic and functional age. Pretreatment frailty may help better characterize this heterogenous population compared to chronological age. We investigated the association between pretreatment frailty and clinical outcomes in older adults with early breast cancer treated with chemo. **Methods:** We leveraged a prospective cohort of 499 adults age ≥65 with stage I-III breast cancer undergoing treatment with neo/adjuvant chemo (R01AG037037). Pretreatment frailty status was determined using a Deficit Accumulation Index, which categorized patients as robust vs. prefrail/frail. Clinical outcomes included grade 3+ toxicity, dose reduction, treatment delay, early chemo discontinuation, hospitalization, and survival (overall, breast cancer related, and non-breast cancer related). We conducted a multivariable analysis evaluating the association between baseline frailty status (robust vs. prefrail/frail) and these outcomes, adjusting for age, race/ethnicity, stage, and regimen. **Results:** The median (range) age was 70 (65-86) years, 65% had stage II/III disease, and 38% received anthracycline. At baseline, 21% were prefrail/frail and 79% were robust. In total, 46% had a grade 3+ toxicity, 24% had a dose reduction, 26% had a treatment delay, 22% had early chemo discontinuation, and 23% were hospitalized. After multivariable analysis, prefrail/frail participants had greater odds of having grade 3+ toxicity (odds ratio [OR]=2.70, 95% CI, 1.66-4.40), dose reduction (OR=1.87, 95% CI 1.12-3.15), treatment delay (OR=1.85, 95% CI 1.10-3.13), and early chemo discontinuation (OR=1.76, 95% CI 1.05-2.95) compared to robust participants. Prefrail/frail participants had a higher likelihood of non-breast cancer related death (hazard ratio=2.56, 95% CI 1.08-6.05) compared to robust participants. There were no associations between frailty and hospitalizations, overall survival, and breast cancer related mortality. **Conclusions:** In this cohort of older adults with early breast cancer, participants who were prefrail/frail pretreatment had an increased risk of grade 3+ toxicity, dose reduction, treatment delay, early chemo discontinuation, and non-breast cancer related death. Pretreatment frailty assessments may improve risk stratification of older adults with early breast cancer and guide treatment decision-making. Clinical trial information: NCT01472094. Research Sponsor: U.S. National Institutes of Health; R01AG037037.

The impact of iron deficiency anemia on long-term cardiovascular outcomes in breast cancer patients hospitalized with heart failure preserved ejection fraction: A propensity score–matched retrospective cohort study. First Author: Colton Jones, Jefferson Einstein Hospital, Philadelphia, PA

Background: Breast cancer (BC) patients are at risk for iron deficiency anemia (IDA) due to the effects of chemotherapy on the bone marrow and because of potential malignant infiltration of the bone marrow. Additionally, BC patients are at increased risk for heart failure either from the effects of chemoradiation on the myocardium or because of direct tumor invasion of the heart. Studies have shown that IDA is associated with worse functional outcomes, hospitalization, and mortality in heart failure preserved ejection fraction (HFpEF). There is limited data on the impact of IDA on long-term cardiovascular outcomes in BC patients with HFpEF, and our study aims to assess these outcomes. **Methods:** We utilized data from the Global Collaborative Network-TriNetX. Patients aged 18 to 85 were divided into two cohorts: those with BC, HFpEF, and IDA, and those with BC, HFpEF but without IDA. Using ICD-10 codes, we evaluated the following outcomes: risk of myocardial infarction (MI), arrhythmia, cardiogenic shock, mortality, and hospitalization. Generalized linear models were used to measure the association, and estimates were presented as risk ratios and 95% confidence intervals. **Results:** After propensity score matching, each cohort consisted of 9,204 patients. The IDA cohort had a mean age of 74.4 $\pm$ 8.6 years and 94% were female. Caucasians accounted for 65% of patients and blacks 21%. Our study found that over a 5-year period (Table 1), BC patients with HFpEF and concomitant IDA had a statistically significant higher risk of MI (RR: 1.576, 95% CI 1.408-1.765), arrhythmia (RR: 1.589, 95% CI 1.300-1.942), cardiogenic shock (RR: 1.660, 95% CI 1.347-2.045), and mortality (RR: 1.052, 95% CI 1.002-1.104). There was an increased risk of hospitalization (RR: 1.256, 95% CI 0.871-1.813) but the results were statistically insignificant. **Conclusions:** Our study demonstrated that IDA is associated with long-term adverse cardiovascular outcomes in BC patients with HFpEF. More prospective studies are needed to assess the impact of iron therapy on cardiovascular outcomes, specifically in the BC population with HFpEF. Research Sponsor: None.

Sex-based differences in clinical outcomes for solid tumours: A pooled IPD meta-analysis of contemporary anticancer drug trials. First Author: Rakchha Chhetri, Flinders University, College of Medicine and Public Health, Bedford Park, Australia

Background: Sex-based differences in outcomes with contemporary oncology treatments remain underexplored, creating a gap in the evidence required for personalised care. To address this, our objective was to systematically evaluate whether sex differences exist in survival and adverse event outcomes with modern anticancer therapies. **Methods:** Individual patient data (IPD) was accessed via the Vivli platform from 60 clinical trials supporting US Food and Drug Administration approvals of anticancer medicines for the treatment of solid tumours from 2012 to 2022. Of these, 39 trials were included in analysing sex-based differences in clinical outcomes (i.e. breast, prostate, and ovarian cancer were excluded) Two-stage IPD meta-analysis approaches were employed. First, Cox proportional hazards models were applied to estimate hazard ratios (HRs) with confidence intervals for overall survival (OS), progression-free survival (PFS), and grade $\geq$3 adverse events (AEs) outcomes by sex within each clinical trial. Complete case analyses were conducted, with adjustments for covariates including age, race, ECOG performance status, and weight, as well as study-level factors, such as randomisation arm stratification. The results for each clinical trial were then pooled using random-effects meta-analysis. Subgroup analyses were performed to evaluate findings by cancer and treatment types. **Results:** Data from 39 trials for solid tumours (n=20,806; females=8,367) were analysed, including non-small cell lung (n=19), melanoma (n=6), colorectal (n=3), urothelial (n=2), gastric (n=2), and other (n=7) cancers. Treatment regimens evaluated included immunotherapies (n=9 trials), chemotherapies (n=18), and targeted therapies (n=32). In adjusted analyses, females demonstrated favourable OS (HR 0.78, 95% CI: 0.72–0.84; I^2 = 60%, p <0.001) and PFS (HR 0.84, 95% CI: 0.80–0.89; I^2 = 47%, p <0.001) compared to males. However, females had a higher risk of grade $\geq$3 AEs (HR 1.12, 95% CI: 1.05–1.18; I^2 = 40%, p <0.001). Subgroup analyses by cancer type and treatment regimen showed consistent trends in survival and AE outcomes according to sex. **Conclusions:** This meta-analysis, highlights consistency in females experiencing improved survival but higher toxicity compared to males with contemporary oncology treatments. These findings underscore the need to incorporate and prioritise sex as a key biological variable in trial design, dose optimisation, outcome analysis, and clinical decision-making within the oncology setting. 11043 Poster Session

Race/ethnicity reporting and representation in clinical trials presented at the American Society of Clinical Oncology (ASCO) presidential plenaries from 2014 to 2024. First Author: Bingtao Xiang, University of Illinois Chicago, Chicago, IL

Background: The lack of appropriate racial and ethnic representation in life saving innovative trials has been linked to poor outcomes. To address this, ASCO published an Equity, Diversity, and Inclusion Action Plan in 2021 which aimed to improve clinical trial diversity. This study evaluates the frequency of race reporting and proportional race representation in trials presented at ASCO plenary sessions. **Methods:** We reviewed ASCO plenary sessions from 2014 through 2024 to identify clinical trial presentations. These clinical trials were then identified using the National Institutes of Health trials registry (ClinicalTrials.gov). Trial characteristics and race reporting were abstracted from primary report publications or ClinicalTrials.gov if race reporting was not included in the primary report. When an ASCO plenary session involved multiple trials, each trial was included in the analysis. US population-based cancer estimates were calculated using data from National Cancer Institute-Surveillance, Epidemiology, and End Results and US Census databases. Age-standardized incidence and mortality rates adjusted to the year 2000 standard US population by race were used to calculate estimated 5-year average incidence and mortality rates from 2017 to 2021. **Results:** Between 2014-2024, 46 clinical trials with a total 67496 participants were presented at ASCO plenary sessions. Race was reported in 31 (67%) trials and both race and ethnicity were reported in 15 (33%) trials. Between 2014 and 2019 vs 2021 and 2024, the proportion of trials reporting race or both race and ethnicity increased 57% to 83% and 25% to 44%, respectively. Overall, White, Asian, Black, and Hispanic patients represented 78.8%, 8.3%, 6.8%, and 6.3% of the trial participants, respectively. Between 2014 and 2019 vs 2021 and 2024, Black (19.7% vs. 18.1% of expected) and Hispanic (40.3% vs. 46.6% of expected) patients remained underrepresented compared to White (113.8% vs 76.3% of expected) and Asian (209.7% vs. 719.1% of expected) patients. **Conclusions:** Since the ASCO 2021 Equity Action Plan, there has been an increase in reporting race and ethnicity of clinical trial participants with no significant effect on Black and Hispanic patients enrolled on trials. This study shows a need for policy revision and meaningful intervention to address underrepresented population enrollment in trials to ensure equitable access and consistent outcomes for all patients. Research Sponsor: None.

Prognostic value of time-varying patient-reported symptoms and quality of life in cancer patients receiving chemotherapy. First Author: Roshan Paudel, Dana-Farber Cancer Institute, Boston, MA

Background: Prior research has demonstrated that pre-treatment patient-reported outcomes (PROs) predict post-treatment survival. Symptom burden, physical function and overall wellbeing are time-varying concepts, so making survival predictions using pre-treatment data may have limited clinical actionability. The prognostic value of time-varying patient-reported symptom burden, physical function (PF) and wellbeing (WB) are not well characterized. **Methods:** Six US-based cancer centers collaborated to develop and deploy an EHR-integrated ePRO monitoring system to facilitate active symptom management. Patients receiving chemotherapy for a gastrointestinal (GI), gynecologic (GYN), or thoracic cancer were asked to report on 12 common symptoms using PRO-CTCAE items and 2 quality of life items twice weekly for up to 180 days after starting chemotherapy. Herein, we employed Cox regression to model 180-day survival using time-varying overall symptom burden, calculated as the sum of 12 symptom scores, PF and WB. Multivariable models also included demographics, clinical variables, treatment goal, and comorbidities. **Results:** The cohort included 3,999 patients (45% GI, 23% GYN, 32% thoracic) who submitted 42,254 symptom reports and had 481 deaths within 180 days. Median age was 66 (IQR 15), 59% female, 86% White, 42% Medicare, 5% Medicaid, 50% retired, 10% disabled. The mean symptom burden score was 7.57 (SD 4.66, min 0, max 34); severe deficit in PF and WB were reported in 13.2% and 7.8% of questionnaires, respectively. In bivariate analyses, greater symptom burden, more deficits in PF and WB, increasing age, female sex, and palliative treatment goal predicted inferior survival. After adjusting for other covariates, symptom burden, moderate and severe PF deficits, and severe WB deficits predicted inferior 180-day survival (Table). **Conclusions:** There is a significant inverse linear relationship between time-varying symptom burden and survival for patients receiving chemotherapy. Among chemotherapy patients, assessments that elicit symptom burden as well as PF and WB may augment the prognostic value and usefulness of ePRO tracking systems. Clinical trial information: NCT03850912. Research Sponsor: National Cancer Instiute; 1UM1CA233080-01.

Treatment patterns and out-of-pocket cost after CAR-T cell therapy in commercially insured patients with hematologic malignancies: A real-world US study. First Author: Mohammed Zuber, Clinical and Administrative Pharmacy, College of Pharmacy, University of Georgia, Athens, GA

Background: Chimeric Antigen Receptor T (CAR-T) cell therapy has improved outcomes in hematologic malignancies since its FDA approval in 2017. However, real-world data on treatment patterns and out-of-pocket (OOP) costs after CAR-T failure or cancer relapse remain limited. This study evaluated subsequent treatment risk, patterns, and OOP costs post-CAR-T therapy. **Methods:** A retrospective cohort study was conducted using the Merative MarketScan database (2017–2022). Commercially insured patients receiving CAR-T for acute lymphoblastic leukemia (ALL), diffuse large B-cell lymphoma (DLBCL), follicular lymphoma (FL), mantle cell lymphoma (MCL), or primary mediastinal large B-cell lymphoma (PMBCL) were included. Patients had ≥6 months of continuous insurance enrollment before the index date (CAR-T administration date) and were followed until disenrollment or the end of 2022. Initiation of additional therapy >14 days post-index (chemotherapy, immunotherapy, stem cell transplant, or radiotherapy) served as a proxy for CAR-T failure or relapse, with cumulative risk estimated using Kaplan-Meier methods. OOP costs (outpatient, inpatient, and prescription claims) were calculated for patients with ≥6 months of post-index enrollment and adjusted to 2022 USD. **Results:** Of the 246 patients, 22 had ALL, 185 DLBCL, 15 FL, 23 MCL, and 1 PMBCL. The mean age was 53.2 years (SD: 10.7), and 69.9% of patients were male. Overall, 98 patients (39.8%) initiated subsequent therapy. The cumulative risk of CAR-T failure was 21.3% (95% CI: 16.8%-25.8%) at 3 months, 37.0% (95% CI: 30.1%-43.9%) at 6 months, and 51.5% (95% CI: 43.5%-59.4%) at 12 months. After CAR-T failure, the most common first-line therapies were lenalidomide (n=12), ibrutinib (n=7), and pembrolizumab (n=5) for DLBCL, and blinatumomab (n=3) and ruxolitinib (n=2) for ALL. Total OOP costs incurred over six months were $310,246.2, with outpatient services accounting for 66.0%. The mean per-patient OOP cost for six months was $2,248.2. While the median OOP costs were similar between groups, mean per-patient OOP costs were higher for patients who required subsequent therapy ($2,881.0 vs $1,910.7), with some patients facing costs as high as $38,889.2. **Conclusions:** This study highlights a substantial risk of CAR-T failure, with targeted therapies and immunotherapies commonly used post-CAR-T. OOP costs were significant, particularly for patients requiring additional therapy, with considerable variability. These findings emphasize the need for strategies to improve outcomes and reduce financial toxicity in this population. Research Sponsor: None.

Receiving a cancer diagnosis during hospitalization and associations with care outcomes. First Author: Saurav Kadatane, The University of Oklahoma Health Sciences Center, Oklahoma City, OK

Background: Patients often receive their cancer diagnoses during a hospitalization, but little is known about patients who are diagnosed inpatient versus outpatient. We sought to describe associations between patients diagnosed with cancer in the hospital and their clinical outcomes. **Methods:** We conducted a retrospective cohort study of adults with cancer admitted from 1/2017-12/2022 to the University of Oklahoma Medical Center. Using the electronic health record, we extracted patient demographics (age, sex, race, area deprivation index [ADI; categorized into quartiles Q1-Q4; Q4=areas of highest deprivation]) and clinical characteristics (cancer type, Charlson Comorbidity Index [CCI]), including those who received their cancer diagnosis during their respective hospital admission. We used regression models to explore associations of inpatient cancer diagnosis with patients' demographics, clinical characteristics, and clinical outcomes (hospital length of stay [hazard ratio {HR} for time to discharge], time to readmission, and overall survival). **Results:** Among 20,683 hospitalized patients with cancer (mean age 62.2; 51.5% female, 80.0% White, most common cancer types: gastrointestinal [GI; 19.3%], genitourinary [GU; 13.8%], and gynecologic [GYN; 13.7%]), 36.8% of patients received their cancer diagnosis during hospital admission. We found that Black patients (OR=.81, p<.001) and female patients (OR=.91, p=.007) were less likely to receive an inpatient cancer diagnosis. Compared to those with GU cancers, patients with neuroendocrine (OR=1.72, p<.001), thoracic (OR=1.68, p<.001), hematologic (OR=1.38, p<.001), CNS (OR=1.34, p<.001), and GI (OR=1.23, p=.018) cancers were more likely to receive an inpatient diagnosis whereas patients with breast (OR=.48, p<.001), GYN (OR=.67, p<.001), and head/neck (OR=.84, p=.009) cancers were less likely. Patients residing in higher ADI areas (Q2: OR= 1.18, p=.002; Q3: OR=1.55, p<.001; Q4: OR= 1.55, p<.001) were more likely to receive an inpatient cancer diagnosis compared to Q1. Patients with more comorbidities (CCI 1-2: OR=1.41, p<.001; CCI 3+: OR=1.69, p<.001) were more likely to receive an inpatient cancer diagnosis. For clinical outcomes, those who received an inpatient cancer diagnosis had a longer hospital length of stay (HR=.71, p<.001), higher risk of readmission (HR=1.12, p<.001), and worse overall survival (HR=1.28, p<.001) than patients who were not diagnosed in the respective hospitalization. **Conclusions:** In this large cohort of hospitalized patients with cancer, we identified factors associated with receiving an inpatient cancer diagnosis and demonstrated that diagnosis during hospitalization correlated with worse clinical outcomes. These findings highlight the importance of developing targeted interventions to enhance care delivery and outcomes for individuals who receive their cancer diagnosis during a hospital admission. Research Sponsor: U.S. National Institutes of Health; U54GM104938.

11047 Poster Session

Impact of angiotensin-converting enzyme inhibitors (ACEis) or angiotensin II receptor blockers (ARBs) on mortality and kidney function in cancer patients receiving cisplatin. First Author: Saad Javaid, Charleston Area Medical Center, Charleston, WV

Background: Cisplatin is a cornerstone of cancer treatment, but its nephrotoxicity often requires dose reduction or withdrawal, compromising antitumor efficacy. This study aimed to determine if concomitant use of cisplatin with angiotensin-converting enzyme inhibitors (ACEis) or Angiotensin II receptor blockers (ARBs) increases the risk of acute kidney injury (AKI) and impacts mortality. **Methods:** A retrospective analysis using the TriNetX Research Network identified cancer patients ≥18 treated with cisplatin from January 1, 2010, to November 27, 2024. Eligible cancers included head and neck, lung, esophageal, biliary tract, pancreatic, or testicular cancer. Patients were stratified by ACEi/ARB use within 1 week of cisplatin treatment. Groups were compared using 1:1 propensity matching, adjusting for age, type 2 diabetes, hyperlipidemia, CAD, CHF, and hypertensive heart disease. Primary outcomes were AKI risk and overall mortality; secondary outcomes included renal replacement therapy (RRT), hospitalization within 3 months, and proteinuria or hematuria. Outcomes were assessed using risk analysis and Kaplan-Meier log-rank tests. **Results:** A total of 36,779 cancer patients taking cisplatin were identified. Of these, 2,585 patients were taking an ACEi/ARB within 1-week of cisplatin treatment, while 36,194 were not. Patients taking ACEis/ARBs had a significantly increased risk of AKI within 30 days of cisplatin use based on the measures of association (risk difference [RD]: 1.713%, p = 0.0152) and the Kaplan-Meier test (hazard ratio [HR]: 1.372, p = 0.01). Similarly, overall mortality was higher in patients with concomitant use of ACEis/ARBs and cisplatin based on both the risk assessment (RD: 5.228%, p = 0.0002) and the Kaplan-Meier (HR: 1.196, p< 0.0001). Patients on ACEis/ARBs also had higher rates of hospitalization 3-months after treatment with cisplatin (RD: 9.24%, p < 0.0001 and HR: 1.53, p < 0.0001). However no significant difference was noted in the need for RRT or the diagnosis of proteinuria or hematuria up to 3-months after treatment. **Conclusions:** Our study suggests that the use of Cisplatin in patients taking ACEi/ARBs increased the risk of early AKI, mortality, and hospitalizations. Careful consideration should be taken when using Cisplatin in these patient groups, focusing on alternative hypertensive regimens. Research Sponsor: None.

Sociodemographic differences in lung cancer mortality trends across the United States (US) rural-urban divide. First Author: Dena Rhinehart, The Sidney Kimmel Comprehensive Cancer Center, Johns Hopkins University School of Medicine, Baltimore, MD

Background: It is known that rural populations face higher lung cancer mortality than urban populations, but it is unknown how trends vary across demographic groups. We investigated rural-urban disparities in age-adjusted mortality rates (AAMRs) from lung cancer across demographic groups over 20 years. **Methods:** We analyzed lung cancer mortality (ICD codes C34.0 - 34.3, 34.8, 34.9) from 1999-2019 using the CDC WONDER database. Populations were classified as urban or rural based on 2013 US census definitions. AAMRs were calculated as deaths per 100,000 using the US Standard Population and stratified by sociodemographic categories. Annual percentage change (APC) and 95% CIs were estimated using linear regression with the log-scale AAMRs as the dependent variable and year as a continuous covariate. **Results:** There were 3,244,056 deaths attributable to lung cancer (79.7% urban, 20.3% rural) with overall AAMR reduction from 86.9 to 53 deaths per 100,000 from 1999-2019. Rural populations had slower mortality improvements compared to urban populations (APC -2.6 [-2.9, -2.4] vs -1.6 [-1.9, -1.3]; p <0.001), with greatest rural-urban differences seen in younger and female populations (Table). Younger adults (<65)in rural areas had nearly 2-fold slower improvement than urban areas (APC -2.1 [-2.3, -1.9] vs -3.7 [-3.9, -3.5]; p<0.001). Females in rural areas had 3-fold slower improvement than females in urban areas (APC -0.6 [-0.9, -0.3] vs -2.0 [-2.3, -1.7], p<0.001). Slower mortality improvements were also seen for non-Hispanic patients in rural than in urban areas. While AAMR remained slightly higher for Hispanic patients in rural than urban areas, it noted faster improvement in rural areas (APC -3.3 [-3.7, -3.9] vs -2.4 [-2.7, -2.2]). **Conclusions:** Patients in rural areas had higher AAMR than urban counterparts across all demographic groups analyzed with slower improvements in almost all subgroups. This study highlights populations in greatest need of health services initiatives such as tobacco cessation efforts, lung cancer screening, and guideline concordant treatment receipt to close the rural-urban gap. Research Sponsor: None.

	Overall	Urban	Rural	P
Overall	-2.5 (-2.7, -2.2)	-2.6 (-2.9, -2.4)	-1.6 (-1.9, -1.3)	<0.001
Age 25-65	-3.4 (-3.6, -3.2)	-3.7 (-3.9, -3.5)	-2.1 (-2.3, -1.9)	<0.001
Age >65	-2.1 (-2.5, -1.8)	-2.3 (-2.6, -2.0)	-1.4 (-1.8, -1.1)	0.006
Female	-1.7 (-2.1, -1.4)	-2.0 (-2.3, -1.7)	-0.6 (-0.9, -0.3)	<0.001
Male	-3.2 (-3.4, -2.9)	-3.3 (-3.6, -3.1)	-2.5 (-2.8, -2.2)	0.002
Hispanic	-2.5 (-2.8, -2.3)	-2.4 (-2.7, -2.2)	-3.3 (-3.7, -2.9)	0.025

Cost-effectiveness of ribociclib plus endocrine therapy in HR-positive, HER2-negative early breast cancer in the United States. First Author: Kunal C. Potnis, Yale School of Medicine, New Haven, CT

Background: Cyclin-dependent kinase 4 and 6 (CDK4/6) inhibitors are an efficacious treatment for HR-positive (HR+), HER2-negative (HER2-) early breast cancer. The phase 3 NATALEE trial demonstrated that ribociclib ($12,000 monthly) plus a nonsteroidal aromatase inhibitor (endocrine therapy) significantly improved invasive disease-free survival. We performed the first cost-effectiveness analysis of ribociclib plus endocrine therapy in patients with HR+, HER2- early breast cancer in the United States (US). **Methods:** We constructed a partitioned survival model based upon clinical data from the NATALEE trial, employing a health system perspective across all accepted willingness-to-pay (WTP) thresholds in the US. Patients with a median age of 51 years entered the model to receive (1) ribociclib plus endocrine therapy versus (2) endocrine therapy alone. Standard extrapolation techniques were utilized to extend overall and invasive disease-free survival curves to a 10-year time horizon. Costs were informed by the US Centers for Medicare & Medicaid Services. Effectiveness was informed by age-, sex-, and breast cancer-specific utility values and was measured in both quality-adjusted life years (QALYs) and equal value life years (evLYs). The primary outcome was the incremental cost-effectiveness ratio (ICER) in USD per evLY. We concluded with deterministic sensitivity analyses and threshold and probabilistic analyses, with all input parameters informed by relevant probability distributions. **Results:** In the base-case, ribociclib plus endocrine therapy and endocrine therapy alone accrued discounted costs of $442,000 and $186,000, with discounted QALYs/evLYs of 7.76/7.79 and 7.57/7.57, respectively. This resulted in an ICER of $1.2 million/evLY (and $1.3 million/QALY) for the addition of ribociclib (Table 1). Deterministic sensitivity analysis revealed our model was only sensitive to the price of ribociclib: no other parameter changed the conclusion. Threshold analysis demonstrated that a 90% reduction in the price of ribociclib would be necessary for ribociclib plus endocrine therapy to be cost-effective even at the highest WTP threshold. Endocrine therapy alone was favored in 100% of 10,000 Monte Carlo simulations across the entire range of accepted WTP thresholds in the US. **Conclusions:** At current pricing, ribociclib with endocrine therapy is not expected to be a cost-effective strategy compared to endocrine therapy alone for patients with HR+, HER2- early breast cancer in the US. These results align with prior studies in other countries assessing the cost-effectiveness of CDK4/6 inhibitors in HR+, HER2- early breast cancer. Research Sponsor: None.

Base-case analysis results.

Strategy	Cost (USD)	QALY	evLY	ICER (USD/evLY) [95% credible interval]
Endocrine therapy alone	186,000	7.57	7.57	–
Ribociclib with endocrine therapy	442,000	7.76	7.79	1,200,000 [800,000 to 1,700,000]

Cancer-related mortality of incarcerated populations in the United States. First Author: Owen Tolbert, University of Rochester, Rochester, NY

Background: The United States has the largest incarcerated population of any country in the world with 1.2 million prisoners as of 2022, but little research has fully characterized the disease burden in these incarcerated populations. Due to the increasing size and age of the prison population, it is paramount to better understand causes of mortality in inmate populations. **Methods:** Mortality data was collected from 41 states via UCLA's Behind Bars Data Project. 40,922 deaths were were recorded between 1999 and 2021, however, only 16,477 deaths had a specific cause of death. To account for individuals with unknown cause of death, analysis was conducted only on the cohort with a known cause of death. From this cohort, one Medical Student and two General Surgery Residents reviewed the death records and assigned each individual into one of 25 mechanisms of death. Protocol for this manual sorting of data was reviewed by the Surgical Health Outcomes and Reaching for Equity group (SHORE). This multidisciplinary group consists of statisticians, public health researchers, Surgery residents, and attending surgeons. **Results:** Of the 25 mechanisms of death, cancer was the leading cause accounting for 4,351 deaths. Approximately 26 different types of cancer were identified with the incarcerated population. The most common types of malignancies within this population were Lung, Hepatic/Biliary, Colorectal, and Esophageal cancers. The rates of Lung, Hepatic/Biliary, and Esophageal Cancer were significantly higher in the incarcerated population compared to the general population. Both the mean and median age of death in the incarcerated population was 61 years old (IQR 54-68), 37.6% were White, 21.3% were Black, 7.1% were Hispanic, and 35.8% unknown. In contrast, cancer related deaths accounted for a smaller proportion of deaths in the general population at 17.5% and 18.5% in 2021 and 2022 respectively. **Conclusions:** This analysis is the first of its kind to stratify mortality by cancer type within the prison population. Previous research that indicates prisoners have a high incidence of Hepatitis B due to the prevalence of IV drug use which is a major risk factor for Hepatic/Biliary cancer. Furthermore, incarcerated populations have higher rates of tobacco use compared to the general population which may account for some of the difference in Lung cancer rates. Delayed access to care in the prison environment may contribute to later diagnosis and correspondingly higher mortality rates among incarcerated individuals. Our results highlight the importance of access to care for effective cancer treatment, and the importance of understanding risk factors for cancer. Research Sponsor: None.

Type of Cancer	Deaths in Prison	% in Prison	Estimated Deaths in General Population	% in General Population	Difference
Lung	1041	23.9%	125,070	20.4%	3.5%
Hepatic/ Biliary	600	13.8%	29,840	4.9%	8.9%
Colorectal	363	8.3%	53,010	8.7%	-0.4%
Esophageal	325	7.5%	32,240	5.3%	2.2%

Age acceleration among adolescent and young adult patients with Ewing sarcoma and osteosarcoma. First Author: Michael J. Robinson, Vanderbilt University Medical Center, Nashville, TN

Background: Ewing sarcoma (ES) and osteosarcoma (OS) are two common bone malignancies affecting adolescent and young adult (AYA) patients, often requiring intensive and multi-modal therapy. Cancer and its associated treatments may accelerate the aging process, as reflected in phenotypic age acceleration (PAA), leading to increased risk for developing chronic health conditions typically ascribed in older individuals.We conducted a pilot study to evaluate the impact of treatment completion for ES and OS on age acceleration among an AYA cohort using the validated phenotypic age (PheAge) instrument. **Methods:** This pilot study included participants who completed treatment at Vanderbilt University Medical Center from 2012-present for either ES or OS between age 20 and 39 years. Phenotypic age at diagnosis and end of treatment was derived using a modified PheAge equation, which was validated for patients age $\geq$20 years and based on chronological age and eight clinical biochemistry measurements, including albumin, creatinine, glucose, lymphocyte percent, mean cell volume, red cell distribution width, alkaline phosphatase, and white blood cell count. PAA was then calculated as the difference between PheAge and chronologic age. A positive PAA indicates an individual's phenotypic age is older than their chronological age, signifying accelerated aging. A descriptive analysis of PAA across patient demographics and disease strata was then conducted. **Results:** Among 30 AYA participants included in our study, 15 participants were diagnosed with ES and 15 with OS. The mean age at diagnosis was 23.8 (Q1 21.8, Q3 27.5). There was an overall male predominance of 19 participants (63.3%). Among participants with ES, the median PAA was 16.1 years (13.8, 18.1) at diagnosis and 18.4 years (13.6, 25.8) at end of therapy. Among participants with OS, the median PAA was 16.0 years (12.9, 20.7) at diagnosis and 15.9 years (13.9, 19.7) at end of therapy. **Conclusions:** This pilot study suggests that AYA patients with ES and OS had accelerated aging at diagnosis and ES patients may endure further age acceleration following treatment, while patients with OS had shown a nearly unchanged PAA. These results highlight the need for a larger and more comprehensive investigation into the contributing factors of PAA, including an evaluation of genetics, environmental exposures, cancer characteristics, treatment modalities, as well as acute and chronic toxicities of therapy. Such knowledge will contribute to understanding the etiology and cumulative and long-term impact of these common bone malignancies among AYAs. Research Sponsor: National Institutes of Health (NIH)/National Cancer Institute (NCI); Vanderbilt Training Program in Molecular and Genetic Epidemiology of Cancer (MAGEC).

Evaluating the effectiveness of immersive virtual reality in reducing distress in patients with cancer receiving chemotherapy: A prospective randomized trial. First Author: Maria Herran, Department of Hematology and Oncology, Maroone Cancer Center, Cleveland Clinic Florida, Weston, FL

Background: Patients diagnosed with cancer commonly face high levels of distress, anxiety, and depressive symptoms along with discomfort or pain, that can be exacerbated during chemotherapy treatment. Immersive Virtual Reality (VR) has not been evaluated in patients with cancer as an intervention to relieve psychological and physical symptoms. In this randomized trial, we sought to assess the effect of a unique immersive type of VR on reducing distress compared to standard of care (SOC). **Methods:** This is a two-arm, prospective controlled randomized trial. Eligibility criteria included patients diagnosed with any type of cancer at any stage, with an NCCN Distress Thermometer Score $\geq$ 5, and actively receiving chemotherapy. Participants were randomized in a 1:1 ratio to receive either the intervention (VR) or the control group (SOC). Questionnaires, available in English and Spanish, were administered to both groups before and after the intervention. The primary outcome was to evaluate the effectiveness of VR in reducing distress levels while receiving chemotherapy infusion (NCCN Distress Thermometer) compared to SOC. Secondary outcomes included evaluating the effectiveness in reducing anxiety levels (GAD-7); pain (Universal Pain Assessment Tool) and improving overall wellbeing (Cleveland Clinic 4 Visual Analog Scale - CCVAS). Changes in questionnaire scores were assessed using a two-sample t-test for both arms. All data analyses were conducted using SAS version 9.4. **Results:** A total of N=70 participants meeting the eligibility criteria are expected to be enrolled in this study. To date, N=41 participants have been enrolled and were included in this preliminary analysis, with n=19 assigned to the intervention group (VR) and n=22 assigned to the control group (SOC). A significant difference was observed for the primary outcome, where the intervention group (VR) demonstrated a mean score reduction in NCCN distress thermometer of 3.9 points (SD$\pm$ 3.3) compared to 1.0 points (SD$\pm$ 2.0) for the control group (p = 0.0017). In addition, the VR group showed an improvement in overall wellbeing symptoms measured by decreased CCVAS of 1.7 (SD$\pm$2.2) vs. 0.2 (SD$\pm$1.4) points in the control group (p=0.0160). No significant difference was observed for anxiety and pain. **Conclusions:** VR is an innovative immersive experience with the potential to relieve distress and improve wellbeing during chemotherapy sessions in patients diagnosed with cancer.The study is currently ongoing, and final results will be reported upon completion. Research Sponsor: VeloSano.

Comparison of test changes between pre- and post-intervention.

	Virtual Reality (n=19)	SOC (n=22)	p-value

How cancer impacts adolescents' and young adults' (AYAs) scholastic experiences: Insight on supportive survivorship care needs from AYAs, parents, and clinicians. First Author: Carla L. Fisher, University of Florida, Gainesville, FL

Background: Cancer disrupts AYAs' educational and vocational trajectories given treatment demands and acute or late effects of treatment on cognitive functioning. This occurs during a developmental phase when scholastic experiences are central to AYAs' socio-emotional and cognitive growth. Despite education being a critical determinant of health-related quality of life, typically families do not receive support for scholastic issues. According to clinical guidelines, key stakeholders in cancer care must have a shared understanding of these concerns to effectively address them. We aimed to identify how cancer impacts scholastic experiences when diagnosed at age 15-29 through the perspectives of diagnosed AYAs, parents caring for AYAs, and AYA oncology clinicians. **Methods:** Drawn from studies funded by The Leukemia & Lymphoma Society and an NCI-Designated Cancer Center, a secondary thematic analysis was conducted on three interview datasets: AYAs (n=10); parents (n=15); clinicians (e.g., oncologists, APPs, LCSWs) (n=7). Analyses were separated by stakeholder group and triangulated to identify shared perspectives. **Results:** AYAs, parents, and clinicians all describe cancer contributing to four challenging scholastic-related impacts: 1) having to advocate for academic accommodations (e.g., virtual option, reduced workload, disability assistance); 2) disrupting school/vocational trajectories (e.g., relocating/changing schools for treatment, stopping school/career pursuits, limitations in performance); 3) losing extracurriculars (e.g., sports, school activities); and 4) losing peer social connection (e.g., feeling isolated/disconnected). They collectively described the impacts as distressful, as a parent expressed: "He was managing all this mental and emotional pain [with cancer], and then [the school] caused so much other stress and pain in our life." One positive impact was identified by AYAs and parents: changing mindsets about school/career (e.g., using school/work as motivator or way to take control, being inspired to change passion/paths). **Conclusions:** Findings illustrate distressful scholastic issues parents and AYAs need support with during cancer care. AYAs and parents described having to advocate on their own with no support. While clinicians recognized the same concerns as patients/caregivers, AYAs and parents described needing to initiate discussions with clinicians, further demonstrating a need to streamline scholastic performance into the standard of care. AYAs and parents recognized cancer could also impact AYAs' mindset about school/work in a positive manner, thus, addressing scholastic concerns may help empower and engage AYAs. Findings can inform resources and support the importance of developing a patient-centered metric that addresses scholastic performance in AYA survivors. Demographic and genomic landscape of early mortality in patients with stage IV non–small-cell lung cancer. First Author: Osama Mustafa Younis, The University of Jordan, Amman, Jordan

Background: Early mortality presents an ongoing challenge to oncologists all over the world. Specifically, one-third of patients that present with late-stage lung cancer progress rapidly, succumbing to their disease before treatment is initiated. That is why stratification of high-risk patients is imperative. In this study, we describe the epidemiologic and genomic landscape of early mortality in Stage IV non-small cell lung cancer (NSCLC). **Methods:** We retrospectively analyzed clinical and genetic data from the AACR Genie NSCLC v2.0 cohort via cBioPortal. Patients with Stage IV NSCLC who died within 3 months of their sequencing sample collection were classified as early mortality and compared to patients who survived more than 3 months. The chi-squared test was used to assess statistical association between variables. A p value or a q value of < 0.05 was considered significant. **Results:** A total of 871 patients were retrieved; 66 patients died within the first 3 months of diagnosis. Patients in the early mortality group were older (68.1 vs 64.1, $p < 0.05$). No significant difference in sex, stage, and histology was present. Patients who died earlier had more brain, adrenal, and subcutaneous metastasis ($P < 0.05$). Notably, patients in the early mortality group had a higher prevalence of current smokers as compared to a higher prevalence of never smokers in the other group, with a statistically significant difference in overall smoking rates between both groups ($p < 0.05$). A total of 18/66 (27.3%) patients received any form of treatment in the early mortality group, 3 of whom received PD-1 or CTLA4 ICI's. In terms of genomic alterations, patients who died early had a higher frequency of KRAS (56.1% vs. 27.0%, $q < 0.05$) and STK11 (38.6% vs 11.2%, $q < 0.05$). On the other hand, those who did not die early had a higher frequency of EGFR mutations (32.3% vs 6.10%, $q < 0.05$). KEAP1 alteration was higher in the early mortality group but did not achieve statistical significance (31.8% vs 11.5%, q = 0.095). **Conclusions:** Patients who are older, current smokers, and possess KRAS or STK11 mutations were more likely to die within 3 months of diagnosis. These results are in line with the literature and are known to be strong predictors of mortality in NSCLC patients and should be incorporated in the initial evaluation of Lung cancer patients. Development of second primary malignancies (SPMs) in head and neck cancer survivors stratified by receipt of radiation therapy (RT) and chemotherapy (CT). First Author: Kriti Ahuja, University at Buffalo/Roswell Park Comprehensive Cancer Institute, Buffalo, NY

Background: Head and neck cancers (HNC) often require multimodality management for curative intent with surgery, radiation therapy (RT) with or without chemotherapy (CT), resulting in significant impairment of nutrition, speech and quality of life. Survivors are also at risk for future cancers from field cancerization. We aim to study the incidence and characteristics of SPMs in HNC survivors. **Methods:** We performed a retrospective analysis of the Surveillance, Epidemiology and End Results (SEER) 17 registries database to identify the cases diagnosed with cancer of the oral cavity, pharynx or larynx as primary malignancy between the years 2000 to 2021. The data was stratified by receipt of RT and CT. Standardized incidence ratios (SIR) for the development of SPMs were calculated using the SEER Stat software. **Results:** A total of 206144 HNC survivors were identified, of which 78055 received CT + RT (CRT group) while 57898 patients received RT with no/unknown CT (RT group). The CRT group had a lower risk than the RT group for several local SPMs with SIRs ($p<0.05$): lip (5.13, 5.71), salivary gland (4.11, 5.21), floor of mouth (18.47, 19.7), gum/other mouth (20.18, 25.04), tonsil (4.54, 5.47) and larynx (5.18, 6.79). However, the CRT group had higher SIRs ($p<0.05$) than the RT group for tongue SPMs (15.91, 13.03) and all pharyngeal SPMs: nasopharynx (9.65, 8.51), oropharynx (13.21, 12.11), hypopharynx (20.47, 16.44), other oral cavity/pharynx (31.08, 24.69). The CRT group had higher SIRs ($p<0.05$) than RT recipients for most gastrointestinal SPMs: esophagus (6.44, 4.53), stomach (1.49, 1.27), colorectal (1.34, 1.23). The RT group had higher SIRs ($p<0.05$) than CRT recipients for hepatobiliary SPMs (1.48, 1.29) and anus/anal canal /anorectum SPMs (1.87, 1.73). CRT group had higher risk than RT group for nose/nasal cavity/middle ear, lung/ bronchus, bone/joint, soft tissue and kidney SPMs but lower risk for trachea, eye/orbit non - melanoma, and thyroid SPMs (Table). CRT group had a lower risk for nodal Hodgkin Lymphoma (SIR 0.3) and myeloma (SIR 0.76) than the general population ($p<0.05$). Both groups had lower risk for Chronic Lymphocytic Leukemia SPMs, with SIRs: RT 0.71, CRT 0.59 ($p<0.05$). Understandably, CRT recipients had a higher risk for Acute Myeloid Leukemia (SIR 2.24, $p<0.05$). **Conclusions:** HNC survivors demonstrate varying risks for SPMs in RT and CRT recipients. This necessitates close monitoring during survivorship care, with a comprehensive approach to screening and preventive measures to improve long-term outcomes and quality of life. Research Sponsor: None.

SPMs in HNC survivors.

SPM	RT SIR (p<0.05)	CRT SIR (p<0.05)
Nose, nasal cavity, middle ear	6.25	8.33
Lung, bronchus	4.01	4.69
Trachea	55.08	38.19
Bones, joints	4.62	6.15
Soft tissue including heart	1.67	2.21
Urinary bladder	1.27	1.24
Kidney	1.29	1.42
Eye, orbit – Non-melanoma	6.18	5.19
Thyroid	2.93	2.77

A digital intervention to enhance engagement with oral oncolytic treatments and assess patient experiences with novel therapies. First Author: David Michael Waterhouse, OHC (Oncology Hematology Care)/US Oncology Network, Cincinnati, OH

Background: Adherence to oral oncolytic therapy influences treatment efficacy and outcomes. Effectively managing adherence requires a clear understanding of how treatments impact the patient. By directly monitoring adherence through precise dose administration data and electronic patient-reported outcomes (ePROs) using ReX, clinicians can improve outcomes while enhancing overall care quality and experience. We aimed to assess the impact of ReX on oral therapy adherence, dose reductions, and treatment discontinuations in real-world practice. **Methods:** Patients at 1 large community practice and 4 academic health systems were included in this retrospective cohort analysis. Participants all had either: chronic lymphocytic leukemia, and initiated treatment with acalabrutinib on or after September 12, 2023, or hormone receptor-positive, HER2-negative metastatic breast cancer who initiated ribociclib on or after May 22, 2024. Control data was abstracted from charts within the practices from those who did not receive the ReX device. Medication was dispensed as standard of care in ReX (Dosentrx Inc), an FDA approved handheld pocket-sized device. At a programmable time, patients take their medication from ReX and are asked ePROs about side effects via a touch screen on the device. Pill intake data and ePROs were available on the ReX Therapy Manager, a cloud-based platform. **Results:** A total of 35,760 pills were taken and 16,885 ePROs answered; resulting in 95% dosing adherence and 97% ePRO engagement (total questions answered/questions presented) in those using ReX. Ribociclib control (median age 56, all female), ribociclib ReX (median age 53, all female), acalabrutinib control (median age 73, 60 males and 33 females), and acalabrutinib ReX (median age 70, 49 males and 32 females). Patients using ReX had fewer dose reductions and discontinuations compared to the control group (Table 1). **Conclusions:** This data suggests that ReX leads to high adherence and ePRO engagement rates, resulting in fewer dose reductions and significantly greater persistence of both acalabrutinib and ribociclib use in community and University settings. Future studies with a greater sample size will be needed to confirm these endpoints and assess the impact of lower discontinuation rates on health outcomes. Research Sponsor: None.

Endpoint objectives.

	Control Group	ReX	p-value*

From chemotherapy allergy to tolerance: Desensitization as a safe alternative in oncology. First Author: Magda Arredondo, Hospital Universitario "Dr. José Eleuterio González", Monterrey, NL, Mexico

Background: Hypersensitivity reactions (HSRs) are a significant challenge in oncology, often leading to treatment modifications or interruptions. Rapid Drug Desensitization (RDD) is a method to reintroduce chemotherapeutic agents and monoclonal antibodies in patients with previous HSRs. This study focuses on safety, comparing the severity of initial HSRs with breakthrough reactions (BTRs) during desensitization. **Methods:** An observational, ambispective study was conducted from August 2020 to August 2024 at the University Hospital in Mexico. Patients with HSRs underwent RDD using a 12-step, 3-bag protocol. HSR severity was classified using Brown's scale. The primary endpoint was BTR severity compared to initial reactions, with secondary endpoints assessing BTR frequency and RDD completion rates. Data were sourced from electronic medical records under a protocol reviewed and approved by the hospital's research ethics committee. Inclusion required documentation of HSRs, the need to continue treatment with the implicated drug, and completion of the RDD protocol. Missing severity data were inferred from clinical notes or excluded. Chi-square tests compared severity grades (mild, moderate, severe) between initial reactions and BTRs, including cases without reactions for comprehensive analysis. Proportional frequencies were applied to address the difference in sample size. **Results:** A total of 927 RDD procedures were performed in 219 patients, with 84% female and a median age of 43 years. The severity of initial reactions was classified as mild in 12.1%, moderate in 43.3%, and severe in 44.6%. During the 927 desensitizations, breakthrough reactions occurred in only 8.6% of cases, distributed as mild (4.5%), moderate (1.8%), and severe (2.3%). Chi-square analysis confirmed a statistically significant difference in severity distribution between initial HSRs and BTRs ($\chi^2 = 834.72$, $p < 0.0001$). This demonstrated a substantial reduction in severity for BTRs compared to initial reactions. Despite the occurrence of BTRs, all patients completed the RDD protocol, received the full therapeutic dose, and no fatalities were reported. **Conclusions:** The comparison between initial HSRs and breakthrough reactions during RDD highlights the distinct nature of these events: initial HSRs represent baseline sensitivity, whereas BTRs occur as controlled outcomes during desensitization. The analysis confirms that desensitization is a safe and effective tool in oncology, significantly reducing both the frequency and severity of breakthrough reactions compared to initial reactions, ensuring treatment continuity and minimizing risks for patients. Research Sponsor: None.

Severity distribution of initial HSRs and BTRs.

Severity	Mild (%)	Moderate (%)	Severe (%)	Total (%)	Reference Population
Initial HSRs	27 (12.3)	95 (43.3)	97 (44.2)	219 (100)	219 patients
BTRs	42 (4.5)	17 (1.8)	21 (2.3)	80 (8.6)	927 desensitizations

Exploring two decades of cancer trends in adolescents and young adults: Insights from a resource-restricted country. First Author: Sarah Abdel-Razeq, King Hussein Cancer Center, Amman, Jordan

Background: Over 40% of the Jordan population are adolescents and young adults (AYA), aged 15-39 years. Cancer diagnoses in this age group have distinct clinical characteristics and patients face unique needs and psychosocial challenges. We present data on local trends in cancer diagnoses among AYA, and their treatment outcomes. **Methods:** We utilized reports from the Jordan Cancer Registry (JCR) and the King Hussein Cancer (KHCC) registry to obtain treatment outcomes. **Results:** During 2022 a total of 8,754 new cancer cases were reported by the JCR; 4,736 (54.1%) were females and the median age at diagnosis was 57 years. Only 312 (3.6%) of the cases were diagnosed in childhood age group (<15 years), while 1,167 (13.3%) cases were diagnosed among AYA (15-39 years) and most of these cases (36.8%) were among the older AYA subgroup (35-39 years). Over the past 22 years, the total number of reported cancer cases among AYA has almost doubled from 654 in 2000 to 1,167 cases in 2022. Hodgkin's lymphoma (13.6%), testicular cancer (12.2%), non-Hodgkin's lymphoma (NHL) (10.9%), colorectal cancer (10.0%) and acute leukemia (9.8%) were the most encountered tumors in males, while breast cancer (31.5%), thyroid cancer (15.4%), Hodgkin's lymphoma (7.2%), colorectal cancer (6.2%) and ovarian cancer (5.5%) were the most common cancers in females in the AYA group. In the childhood age group, acute leukemia (24.4%) and brain tumors (20.2%) were the two most common cancers, accounting for almost half of all tumors in this group. The age-standardized incidence rate (ASIR) was higher among females compared to males across all age subgroups within the AYA. Such difference is more evident within the "older" group (30-34) years (64.3 versus 35.0) and in the (35-39) years age group (116.1 versus 52.3). These differences may be attributed to breast, and to a lesser extent thyroid cancer. Additionally, the ASIR increases with increasing age within the AYA age group; rates increased from 17.3 (15-19 years) up to 84.4 in the (35-39 years) group. Survival data on 7,202 AYA cancer patients treated and followed-up at KHCC were obtained from its hospital-based cancer registry. The 5-year overall survival was 73.0% (95% CI, 71.8-74.1), better than 57.1% (95% CI, 56.4-57.8) among 26,604 older adults (>39 years old), and lower than 75.2% (95% CI, 73.6%-76.9%) among 3,031 pediatric patients (<15 years) treated during the same period, p<0.0001. **Conclusions:** Over 40% of the Jordanian population is within the AYA age group. Though the cancer incidence is lower, and overall survival is better in this age group compared to older adults, a comprehensive plan that values the special physical and psychosocial needs of this group of patients should be addressed. Establishing a specialized AYA program with specialized ancillary services addressing these issues, especially those related to late treatment effects, is a national health care priority. Treatment patterns, use of healthcare resources, and clinical characteristics of patients with castration-resistant prostate cancer (mCRPC) in Colombia: Preliminary analysis from ProColombia RC study. First Author: Ray Manneh, Sociedad de Oncología y Hematología del Cesar, Valledupar, Colombia

Background: The clinical characteristics of metastatic castration-resistant prostate cancer (mCRPC) patients in Colombia remain poorly understood, particularly regarding their clinical profiles, stage at diagnosis, treatment options, and healthcare resource utilization (HRU). This study aims to describe real-world treatment patterns and HRU in mCRPC patients. **Methods:** This is a non-interventional, multicentre, retrospective study in mCRPC patients treated at reference centers across Colombia from Jan/2017 to Jun/2023. Data on demographic and clinical characteristics, treatment history, and (HRU) were extracted from electronic medical records. Progression-free survival (PFS) and overall survival (OS) were analyzed using the Kaplan-Meier method. **Results:** We present the Interim findings from the first 130 of the 380 patients we plan to enroll. The median follow-up was 70.0 months (IQR 46.8–136.1). The median age was 68y (IQR 61–73), with 86.2% residing in urban areas. Comorbidities were hypertension (64.6%) and type 2 diabetes (22.3%); 10.8% reported a family history of PC. Upon diagnosis, 54.6% had a Gleason grade of 4 or 5, and 82.7% passed through a metastatic hormone-sensitive prostate cancer (mHSPC) scenario and 47.7% of those mHSPC patients had high-volume disease. In the mCRPC setting, 14.6% had visceral metastases, while 78.4% had bone-predominant disease. In the first-line treatment, 73.8% received androgen receptor pathway inhibitors (ARPI) and 25.4% underwent taxane-based chemotherapy. Among the 81 patients (62.3%) who received second-line therapy, 27.1% received ARPI, 59.3% received taxane-based chemotherapy, 9.9% were treated with Radium-223, and 3.7% received PSMA-Lutetium. The median PFS in the first-line setting was 16.8 months (95%CI: 13.0–20.7), with a median OS of 39.2 months (95%CI:32.6–45.9). Only 31% of patients were tested for HRR and MSI, with median OS from mCRPC diagnosis being 59.2 months (95%CI:34.6–83.7) for those tested versus 39.5 months (95%CI:32.8–46.1) for those not tested, a statistically significant difference (p=0.016). In terms of healthcare utilization, 60.0% required palliative radiation therapy, and 52.3% consulted with a palliative care specialist; 20.8% required at least one emergency consultation due to cancer-related issues. **Conclusions:** This study represents the first comprehensive report on the demographic, clinical, treatment patterns, and HRU of mCRPC patients in Colombia. The significant survival differences based on biomarker testing highlight quality of care that patients received. Standardized PC management protocols, developed collaboratively by multidisciplinary teams and multiple institutions in Colombia, could enhance patient outcomes and healthcare efficiency across the country. Differential and cumulative impact of metabolic syndrome traits on cardiovascular, renal, and mortality outcomes in cancer patients. First Author: Arunkumar Krishnan, Department of Supportive Oncology, Atrium Health Levine Cancer, Charlotte, NC

Background: Metabolic syndrome (MetS) is a known risk factor for developing at least 13 cancer types and adverse outcomes. However, the effects of MetS on their differential and cumulative impact on cardiovascular, renal, and mortality outcomes in cancer patients remains uncertain. We aimed to determine whether MetS components increase cancer patients' risk of adverse cardiorenal and all-cause mortality. **Methods:** This large retrospective cohort study used the TriNetX database between 2013 to 2024. Adults (>18 years) with new cancer diagnoses and ≥1 MetS trait (obesity, insulin resistance(IR), hypertension (HT), or dyslipidemia (DLD)) were compared with matched controls without MetS. We performed 1:1 propensity score matching to adjust for confounding factors (demographics, comorbidities, cancer type, and medications). The primary outcomes were new adverse cardiovascular events like heart failure (HF), major adverse cardiovascular events (MACE), and cerebrovascular events (CVE). The secondary outcomes were end-stage renal diseases (ESRD), the need for dialysis, and all-cause mortality. We conducted sensitivity analyses to assess the robustness of the findings. Hazard ratios(HR) were calculated using Cox regression models stratified by MetS traits. **Results:** In total, 204,297 patients were identified (median age 54 years) with a median follow-up of 7.8 years. Patients with ≥1 MetS trait had significantly increased risks of adverse cardiorenal events. HR for HF was 1.76; this risk increased to 2.54 with ≥3 MetS traits. The risk of MACE was HR of 2.34 in those with ≥1 trait and HR of 2.47 in those with 4 traits. CVE had an HR of 1.56, increasing to 2.38 with ≥3 traits. For secondary outcomes, the risk of ESRD was HR of 1.76 in patients with ≥1 MetS trait, rising to HR of 2.29 in those with ≥3 traits. The need for dialysis was significantly elevated (HR 1.86), and all-cause mortality was HR of 2.15 in patients with ≥1 trait, increasing to 3.10 with 4 traits. Stratified analyses revealed obesity increased HF risk (HR 1.58) and mortality (HR 1.75). IR was linked to higher risks of MACE (HR 1.88) and ESRD (HR 2.59). HT increased the risk of CVE (HR 2.16) and dialysis (HR 2.11). DLD moderately elevated the risk of IHD (HR 1.47) and mortality (HR 1.59). Sensitivity analyses confirmed these findings across cancer types and treatments. A cumulative relationship was observed, with the number of MetS traits correlating to higher risks of outcomes. **Conclusions:** Our study showed a differential effect of MetS components on cardiovascular, renal, and all-cause mortality outcomes in cancer patients, with a cumulative impact of multiple MetS on overall risk. Early intervention targeting MetS traits may reduce these risks and improve outcomes. Comprehensive metabolic management should be integrated into oncology care to mitigate these risks and improve patient outcomes. Research Sponsor: None.

11061 Poster Session

Transfusion-related cost and time burden offsets in patients with myelofibrosis treated with pacritinib compared to best available therapy based on PERSIST-2 trial. First Author: Abiola Oladapo, Sobi Inc., Waltham, MA

Background: Anemia in patients (pts) with myelofibrosis (MF) is associated with a significant disease burden, especially in pts who require red blood cell (RBC) transfusions, as it negatively impacts quality of life and disease prognosis. In the PERSIST-2 trial, treatment with pacritinib (PAC), a JAK1 sparing inhibitor of JAK2/IRAK1/ACVR1, was associated with anemia benefit. A significant proportion of non-transfusion independent (non-TI) pts at baseline on PAC compared to best available treatment (BAT) achieved transfusion independence (TI) (37% vs 7%) in any 12 weeks over a 24-week interval and significantly more had a $\geq$50% reduction in transfusion burden (49% vs 9%) (Oh ST, et al. 2023) with lower RBC transfusion rates (Mean [2.45 vs 3.54/30-day]) (Data on file). This study aimed at estimating the projected differences in transfusion-related cost and time burden with PAC vs BAT. **Methods:** An economic evaluation based on transfusion-related data in pts treated with PAC or BAT (including ruxolitinib [RUX] and erythroid support [ES]) from the PERSIST-2 trial (NCT02055781). Transfusion status (TI and non-TI) at baseline and over any 12-week interval within the 24-week study period was defined based on the Gale criteria (i.e. presence or absence of RBC transfusions). RBC transfusion rates over 30-day periods, including all reported transfusions within the initial 24-week study period, were annualized and used as proxy for transfusion-related visits. Annual transfusion-related cost estimates by transfusion status were based on a previous MF burden of illness study which utilized IBM MarketScan data (Gerds AT, et al. 2022) and was adjusted to 2024 US dollars using the medical component of the Consumer Price Index. Transfusion-related time burden estimates were based on previously reported RBC transfusion visits in transfusion dependent pts with β-thalassemia (Knoth RL, et al. 2022). **Results:** Annual transfusion-related cost with PAC was projected to be 19.5% lower, with a cost saving of ~$61K compared to BAT (~$252K vs ~$313K). Annual transfusion-related time burden with PAC vs BAT was lower by 25.3% with a time saving of ~172 hrs (~508 vs ~680 hrs). Among pts who were non-TI at baseline, projected annual cost and time savings for PAC vs BAT were ~$73K and ~204 hrs, respectively. Results remained robust regardless of type of BAT (i.e. RUX or ES therapies). **Conclusions:** The reduction in transfusion rates associated with PAC treatment relative to BAT is projected to result in decreased transfusion-related medical cost and time burden for pts with MF and anemia. Research Sponsor: None.

11062 Poster Session

Trends and disparities in sepsis-related mortality among patients with malignancies: A 25-year nationwide analysis. First Author: Malik WZ Khan, Khyber Medical University, Peshawar, Pakistan

Background: Sepsis is a leading cause of mortality worldwide, with cancer patients at higher risk due to immune suppression from the disease and its treatments. Despite advancements in sepsis care, their impact on sepsis-related mortality among cancer patients remains unclear. Understanding these trends is crucial for developing targeted interventions to improve sepsis outcomes in patients with malignancies. **Methods:** We conducted a retrospective cohort analysis using the CDC WONDER database from 1999 to 2023, focusing on adults aged >25 years with malignancies. Deaths were identified using international classification of disease 10 (ICD-10) codes for instances where both sepsis and malignant neoplasms were listed as causes of death. Age-adjusted mortality rates (AAMR) per 100,000 population were extracted, and temporal trends were analyzed using Joinpoint regression to calculate the annual percentage change (APC) and its weighted average, the average annual percentage change (AAPC). Results were stratified to evaluate temporal, gender-based, racial, and geographic disparities in mortality. **Results:** From 1999 to 2023, a total of 684,930 sepsis-related deaths were recorded among adults with malignancies. Over this period, the AAMR increased significantly from 12.06 to 14.21, with an AAPC of 0.86 (95% CI: 0.74 to 1.06). Males had a higher overall AAMR (15.09) compared to females (9.91), but females experienced a sharper increase over time (23.77% vs. 9.56%). Non-Hispanic (NH) Black or African Americans had the highest AAMR (18.98), followed by NH American Indian or Alaska Natives (11.59) and NH Whites (11.35), while NH Asians/Pacific Islanders exhibited the lowest rate (10.24). Geographic disparities were significant, with state-specific AAMRs ranging from 24.62 in the District of Columbia to 7.50 in Montana. States in the top 90th percentile included Mississippi, Rhode Island, West Virginia, New Jersey, and the District of Columbia, while those in the bottom 10th percentile included Montana, Oregon, Idaho, and Wisconsin. Regionally, the Northeast had the highest AAMR (12.65), followed by the South (12.49) and West (11.69), with the Midwest exhibiting the lowest rate (11.08). **Conclusions:** This nationwide analysis highlights a concerning rise in sepsis-related mortality among patients with malignancies over the past 25 years, with females, NH Blacks and residents of the Northeastern region emerging as the most vulnerable populations. These findings underscore the need for prompt implementation of targeted strategies designed to overcome these disparities. Research Sponsor: None.

Impact of a novel oral medication delivery device on patient engagement and discontinuation in individuals receiving oral oncolytic medications. First Author: Melissa Taylor, Yale New Haven Hospital, New Haven, CT

Background: Patient-reported outcomes (PROs) are essential for monitoring patient status and improving outcomes. ReX by Dosentrx physically administers oral medications and collects PROs at the time of dosing, allowing healthcare teams to track patient adherence, medication tolerance, and side effects. ReX aims to identify early toxicities between clinic visits, reduce acute care utilization, and improve adherence and overall outcomes. This study evaluates the impact of ReX on treatment adjustments and discontinuations in individuals taking either ribociclib or acalabrutinib. **Methods:** The study focused on a cohort of individuals prescribed either ribociclib or acalabrutinib. Patients using ReX were tracked for at least 6 months. The primary objective was to evaluate discontinuation rates at 3, 6, and 12 months. Secondary objectives included evaluating dose reductions and reasons for discontinuation. Outcomes from individuals using the ReX device were compared to a historical control group drawn from the same clinics prior to ReX implementation. **Results:** In the ribociclib group, 69 patients were in the historical control cohort and 63 in the ReX cohort, with median ages of 56 and 53, respectively. For acalabrutinib, the historical control had 94 patients and the ReX cohort 81, both with a median age of 70. Table 1 presents the discontinuation at 3, 6, and 12 months, along with the clinical reasons for discontinuation. Dose reductions were lower in the ReX group, with 11% for ribociclib at 10 months and 1% for acalabrutinib at 15 months, compared to 29% and 6% in the control group. **Conclusions:** ReX demonstrated a lower percentage of medication discontinuation at 3, 6, and 12 months for patients taking ribociclib or acalabrutinib, with fewer adverse event-related discontinuations and dose reductions compared to a historical control group. Additional studies investigating the impact of this novel medication delivery device on longer term medication adherence and clinical outcomes is currently underway. Research Sponsor: None.

Discontinuation at 3, 6, and 12 months and reason for discontinuation.

Discontinuation						
	3-months		6-months		12-months	
	Control	ReX	Control	ReX	Control	ReX
Ribociclib	17.8%	6%	24.9%	11%	31.8%	11%
Acalabrutinib	10.6%	2.5%	15%	8.6%	24.5%	13.5%
Clinical Discontinuation Reason						
	Disease Progression		Adverse Events		Medication Change	
	Control	ReX	Control	ReX	Control	ReX
Ribociclib	55%	0%	27%	0%	18%	100%
Acalabrutinib	55%	50%	27%	25%	18%	25%

Impact of protein-energy malnutrition on inpatient mortality, healthcare cost and clinical outcomes among patients with head and neck cancer. First Author: Vaishali Deenadayalan, Roswell Park Comprehensive Cancer Institute, Buffalo, NY

Background: Protein-energy malnutrition (PEM) is a critical issue among patients diagnosed with head and neck cancers (HNC), primarily due to the tumor's anatomical location, and treatment-related side effects. Here, we examine the impact of PEM on the clinical outcomes and healthcare costs among hospitalized patients with HNC. **Methods:** This retrospective cohort study was conducted using data from the National Inpatient Sample database. Data of adult patients admitted with a diagnosis of HNC from 2016 to 2020 were analyzed and stratified based on the presence of PEM. The primary outcome was inpatient mortality rate, secondary outcomes included length of hospitalization, total hospital charges and other medical outcomes. **Results:** A total of 729,095 patients with HNC were identified, of whom 174,000 (23.8%) had PEM, with a mean age of 65.5 years and whites (77%) being the predominant race. Among the 32,075 patients who died, 11,715 (4.4%) had PEM. PEM was associated with a higher risk of mortality (6.74% vs 3.67%; OR:1.84, 95%CI 1.73-1.95; $P < 0.001$). Patients with PEM had an increased length of hospitalization (8.9 vs 5.2 days; adjusted difference of 3.3 days; 95% CI 3.21-3.45; $P < 0.001$), and higher total hospital charges ($98,959 vs $71,449; adjusted difference of $27,715, 95% CI $23,864-27,565; $P < 0.001$). Additionally, the presence of PEM was associated with increased risk of several secondary outcomes including septic shock, intubation, acute kidney injury, pneumonia, blood transfusion, neutropenia and urinary tract infections compared to the non-PEM cohort. **Conclusions:** This study demonstrated a two-fold increased risk of mortality and a prolonged length of stay, with approximately $27,000 more total charges in malnourished patients with HNC compared to those without PEM. Prospective trials evaluating strategies to improve PEM, and provide adequate nutritional support are essential to enhance clinical outcomes, reduce mortality and decrease healthcare costs. Research Sponsor: None.

Effect of PEM on clinical and healthcare outcomes among hospitalized patients with HNC.

Outcomes	HNC with PEM	HNC without PEM	Adjusted Odds Ratio	95% Confidence Interval	P value
Mortality	6.74%	3.67%	1.84	1.73-1.95	<0.001
Length of stay	8.9	5.2	3.33	3.21-3.45	<0.001
Total hospital charge	98,959	71,449	25,715	23,864-27,565	<0.001

Efficacy of immune checkpoint inhibitors in smokers vs non-smokers: A large real-world retrospective cohort analysis. First Author: Nanda Siva, West Virginia University, School of Medicine, Morgantown, WV

Background: Immune checkpoint inhibitors (ICIs) play a critical role in strengthening the immune response against tumors. Prior literature has shown higher objective response rates of ICIs in lung cancer patients who are smokers vs. non-smokers, thought to be due to increased expression of PD-1/PD-L1 in smokers. This study aims to assess the clinical impact of smoking on the efficacy of ICIs across multiple cancer types. **Methods:** This multicenter retrospective study utilized the TriNetX Network, a database containing over 130 million deidentified patient records to identify patients diagnosed with lung, breast, melanoma, colorectal, head and neck, bladder, hepatocellular, and renal cell carcinomas, who underwent subsequent treatment with ICIs (PD-1, PD-L1, and CTLA-4 inhibitors). Kaplan-Meier survival analysis was performed to assess three-year survivability. Propensity-score matching (PSM) was performed based on demographics, lab work, and pertinent comorbidities between smokers and non-smokers in each cancer type. The analysis included patients who had documented smoking status (ICD 10: Z72.0) prior to ICI therapy. **Results:** A total of 95,178 cancer patients receiving ICI met the inclusion criteria, of whom 15.5% were tobacco users. After PSM, 12,203 patients were in the smoking group and 12,203 were in the non-smoker group. For lung cancer patients, there was statistically significant superior survivability in the smoker group compared to the nonsmoker group, (HR: 0.894, 95% CI [0.854, 0.935]). A similar trend was identified in the colon, hepatocellular, and breast cancer groups, however, this was not statistically significant. There was no significant difference in mortality seen in the smoker versus non-smoker groups in melanoma, bladder, head and neck, and renal cell cancers. **Conclusions:** Our findings reaffirm previous studies demonstrating superior efficacy of ICIs in smokers with lung cancer. Additionally, this study highlights other cancer types, such as colon, hepatocellular, and breast cancers, that may exhibit improved outcomes in smokers, while also identifying cancers such as melanoma, bladder, head and neck, and renal cell carcinomas where smoking status appears to have no apparent effect on survivability. To our knowledge, this is the largest retrospective cohort study examining the impact of smoking status on ICI therapy outcomes across multiple cancer types. Research Sponsor: None.

Survivability in smokers compared to non-smokers treated with ICIs.

Cancer type (ICD 10)	N (smoker)	N (non-smoker)	3-year HR	95% CI
Colon (C18)	292	292	0.808	(0.622,1.048)
Liver (C22.0)	559	559	0.884	(0.748,1.045)
Lung (C34)	8130	8130	0.894	(0.854,0.935)
Breast (C50)	540	540	0.934	(0.756,1.154)
Bladder (C67)	713	713	1.001	(0.856,1.169)
Renal cell (C64)	706	706	1.016	(0.859,1.202)
Head & neck (C76.0)	583	583	1.042	(0.888,1.224)
Melanoma (C43)	680	680	1.087	(0.889,1.328)

Identifying multi-level social determinants for disparities in survival and patient-reported outcomes in national head and neck cancer trials. First Author: Jinbing Bai, Emory University Winship Cancer Institute, Atlanta, GA

Background: This study aimed to determine to what extent area-level social determinants of health (SDOH) interact with individual, institutional, and biological factors to predict outcomes in head and neck cancer (HNC) trials. **Methods:** Five NRG Oncology HNC trials (2635 patients receiving chemoradiation) were analyzed. Area-level SDOH coded by patient ZIP codes included rurality (rural-urban commuting area code), neighborhood socioeconomic deprivation (Area Deprivation Index [ADI] categorized as upper vs. lower quartile), and travel burden (distance and time to treatment site). Individual (demographic, cancer and treatment-related factors), institutional (accrual volume), biological (HPV+/-) factors, and outcomes (overall survival [OS], progression free survival [PFS], quality of life [QOL], and symptoms) were analyzed. Multivariable Cox proportional hazards regression and mediation analysis using logistic regression assessed associations using hazard ratio (HR) or odds ratios (OR) and 95% confidence intervals (CI). **Results:** Most patients were White (88%), non-Hispanic (92.7%), of mean age of 57 years, HPV+ (64.6%), and received intensity-modulated radiotherapy (95.9%) and cisplatin (94.2%). ADI and rurality were not associated with OS and PFS. OS and PFS were higher in patients with travel time $<$1 hour (HR=0.85, 95% CI [0.75, 0.98]; HR=0.85, 95% CI [0.73, 0.98]) and travel distance $<$50 miles (HR=0.84, 95% CI [0.72, 0.96]; HR=0.85, 95% CI [0.73, 0.98]). ADI, travel time, and travel distance were not associated with QOL decline. Patients treated at institutions with high rural accrual volume had worse QOL decline from baseline (OR=0.36, 95% CI [0.15, 0.85]). The impact of travel distance but not time varied by race to influence QOL decline (OR=0.38, 95% CI [0.16, 0.93]). ADI was not associated with symptoms, but patients from institutions with high rural accrual volume had worse symptoms (OR=7.83, 95% CI [1.98, 31.01]). HPV status had a significant indirect effect on the relationship between travel distance and survival at 1 year (estimate [β]=0.03, 95% CI [0.01, 0.05]) and 5 years (β=0.03, 95% CI [0.004, 0.05]), as well as a direct and total mediation effect of travel distance on QOL decline at 1 year (direct β=-0.08, 95% CI [-0.16, -0.004]; total β=-0.89, 95% CI [-0.17, -0.01]). **Conclusions:** This study showed the impact of area-level SDOH and their interactions with race and institutional accrual volume, which are associated with survival, QOL, and symptom changes. HPV status potentially mediated the effects of travel distance on outcomes. Our findings provide novel approaches to identify patients at risk for poor outcomes, such as those with travel burden at institutions with high rural accrual, to design community-based interventions to improve cancer outcomes. Impact of protein energy malnutrition on hospitalized patients with breast cancer: A United States population-based cohort study. First Author: Arshi Syal, Jefferson Einstein Philadelphia Hospital, Philadelphia, PA

Background: Advances in chemotherapeutics and surgical options have improved survival in patients with breast cancer. With prolonged survival, these patients are often predisposed to comorbidities affecting their quality of life. Patients with breast cancer suffer from varying degrees of protein-energy malnutrition (PEM) due to multiple factors, including cachexia, sarcopenia, and adverse effects of chemotherapeutics. However, the impact of PEM on outcomes among patients with breast cancer needs further exploration. **Methods:** We utilized the 2020 National Inpatient Sample (NIS) Database in conducting this retrospective cohort study. We identified patients with breast cancer and PEM using appropriate ICD-10 diagnostic codes. We stratified patients with breast cancer based on the presence or absence of PEM. A survey multivariable logistic and linear regression analysis was used to calculate adjusted odds ratios (ORs) for the primary and secondary outcomes. A p value of $<$0.05 was considered statistically significant. The aim of this study was to investigate the impact of PEM on in-hospital mortality, hospital length of stay (LOS), and total hospitalization charge among hospitalized patients with breast cancer. **Results:** We identified a total of 24770 hospitalized patients with breast cancer, of which 6.17% (1530/24770) had comorbid PEM. The overall in-hospital mortality among patients with breast cancer was 3.37% (835/24770). Among those with concomitant PEM, the mortality rate was significantly higher at 12.74% (195/1530, p$<$0.001). Utilizing a stepwise survey multivariable logistic regression model that adjusted for patient and hospital level confounders, PEM was found to be an independent predictor of increased in-hospital mortality (adjusted OR 2.74; 95% (confidence interval [CI] 1.74-4.30; p$<$0.001), longer LOS (coefficient 3.56 days; CI 2.67-4.45; p$<$0.001), but not higher total hospitalization charge ($4400; CI -$9818-$18620; p=0.544) or increased need for mechanical ventilation (adjusted OR 2.26; CI 0.89-5.69; p=0.084). **Conclusions:** Our analysis demonstrated that PEM was widely prevalent in hospitalized patients with breast cancer and was associated with significantly worsened in-hospital mortality and longer LOS. Efforts should be made to promote nutritional assessment and screening mechanisms to include early nutritional support as indicated. Further prospective studies with larger sample sizes are warranted to understand these associations better. Research Sponsor: None.

Incidence and outcomes of rejection in solid organ transplant recipients treated with immune checkpoint inhibitors: A systematic review and meta-analysis. First Author: Muhammad Awidi, Roswell Park Comprehensive Cancer Center, Buffalo, NY

Background: Immune checkpoint inhibitors (ICIs) are a cornerstone in the treatment of many solid tumors; however, their use in cancer patients with solid organ transplants (SOTs) poses unique challenges due to the risk of allograft rejection. We conducted a systematic review and meta-analysis of retrospective studies to determine the incidence of rejection and associated outcomes in SOT patients treated with ICIs. **Methods:** We searched PubMed, Embase, and Scopus to identify retrospective studies examining ICI therapy in SOT patients with cancer. Primary endpoints were the incidence of rejection and its clinical outcomes. Statistical analyses were performed using the "meta" package in R. **Results:** Seventeen studies encompassing 587 patients were included. The most frequent malignancies were hepatocellular carcinoma (HCC), melanoma, and cutaneous squamous cell carcinoma (cSCC). The overall rejection incidence was 16% (95% CI: 9%-24%), with variation across cancer types: multiple cancers (18%, 95% CI: 5%-36%), HCC (22%, 95% CI: 15%-29%), and cSCC (4%, 95% CI: 0%-21%). Rejection incidence was higher among liver transplant recipients (18%, 95% CI: 10%-26%) compared to kidney recipients (16%, 95% CI: 5%-32%). Geographic differences were observed, with rejection rates of 15% (95% CI: 1%-37%) in U.S.-based studies, 25% (95% CI: 18%-33%) in China, and 9% (95% CI: 0%-25%) in Korea. Pre-transplant ICI exposure was associated with a higher rejection rate (18%, 95% CI: 9%-28%) compared to post-transplant exposure (15%, 95% CI: 7%-26%). Outcomes of rejection varied, with 44% (95% CI: 24%-65%) achieving stabilization or resolution. Liver transplant recipients demonstrated higher resolution rates (67%, 95% CI: 46%-85%) compared to kidney recipients (27%, 95% CI: 7%-52%). Regional differences in resolution were notable, with higher rates reported in China (65%, 95% CI: 45%-83%) compared to the U.S. (26%, 95% CI: 13%-42%). **Conclusions:** This meta-analysis reveals a 16% overall rejection rate in SOT recipients treated with ICIs, higher in liver allografts and HCC, with regional disparities. Nearly half of patients who experienced rejection improved or stabilized, especially liver recipients. These findings underscore the need for personalized approaches to balance oncologic efficacy and graft survival in this complex population. Research Sponsor: None.

Category	Rate (% [95% CI])
Overall Rejection Rate	16 [9-24]
Rejection by Cancer Type	Multiple: 18 [5-36], HCC: 22 [15-29], cSCC: 4 [0-21]
Rejection by Transplant Type	Liver: 18 [10-26], Kidney: 16 [5-32]
Rejection by Geography	USA: 15 [1-37], China: 25 [18-33], Korea: 9 [0-25]
Rejection by Timing	Pre-Transplant: 18 [9-28], Post-Transplant: 15 [7-26]
Overall Reversibility	44 [24-65]
Reversibility by Transplant Type	Liver: 67 [46-85], Kidney: 27 [7-52]
Reversibility by Geography	China: 65 [45-83], USA: 26 [13-42]

Evaluating the impact of Medicaid expansion on outcomes for patients with gastric cancer in Louisiana. First Author: Donnell White III, School of Medicine, Louisiana State University Health Sciences Center, New Orleans, LA

Background: Prior to June 2016, Louisiana's Medicaid program did not extend coverage to adults, regardless of income. With the expansion, up to 138% of the Federal Poverty Level (FPL) became eligible for enrollment, allowing 784,310 adults to enroll in the state's Medicaid program as of June 2023. Medicaid expansion (ME) effects on gastric cancer treatments and outcomes have not been fully understood. This study seeks to investigate the impact of Medicaid expansion (ME) on gastric cancer outcomes, such as changes in presentation, treatment patterns, time-to-treatment, and survival in Louisiana patients. **Methods:** Patients with primary invasive gastric cancer were identified using the Louisiana Tumor Registry. Patients diagnosed with gastric cancer were stratified into pre-expansion (2012–2015) and post-expansion (2017–2020) periods. Patients under 18 years old, unknown gastrectomy status, and those with unknown insurance or socioeconomic data were excluded from the study. **Results:** A total of 2,554 patients diagnosed with primary invasive gastric cancer were analyzed, predominantly male (63.7%) and urban residents (85.3%). Post-ME, the uninsured rate decreased significantly from 5.5% to 2.2% ($p<0.001$), with the largest reductions observed in younger adults (12.4% to 4.1%; $p<0.001$), Black patients (7.2% to 1.7%; $p<0.001$), rural residents (5.7% to 2.3%; $p<0.001$), and individuals from high-poverty neighborhoods (3rd quartile: 5.6% to 2.6%; p=0.028; 4th quartile: 6.1% to 2.6%; p=0.004). For treatment patterns, chemotherapy use increased for local/regional disease (50.4% post-expansion vs. 47.6% pre-expansion; p=0.038), while gastrectomy rates remained stable (60.3% vs. 56.4%; p=0.119). The median time to treatment increased significantly for local/regional disease (38 days post-expansion vs. 29 days pre-expansion; p=0.031) and metastatic disease (33 days post-expansion vs. 30 days pre-expansion; p=0.184). Survival outcomes showed significant improvement for local/regional disease post-expansion, with 12-month survival increasing from 67.2% to 76.2% ($p<0.001$) and 24-month survival improving from 52.8% to 59.7% (p=0.008). For metastatic disease, 12-month survival improved modestly (30.5% vs. 25.9%; p=0.111), while 24-month survival remained unchanged (12.6% vs. 12.7%; p=0.968). **Conclusions:** Overall, Medicaid expansion reduced uninsured rates and improved access to chemotherapy and survival for local/regional gastric cancer. However, it had a limited impact on late-stage presentation and survival disparities across racial groups. Addressing systemic barriers and optimizing healthcare delivery remains critical to achieving equitable outcomes for gastric cancer patients. Research Sponsor: None.

Racial disparities in major adverse cardiovascular and cerebrovascular events outcomes among gastric cancer patients. First Author: Amanda Lussier, New York Medical College/Landmark Medical Center, Woonsocket, RI

Background: Racial disparities in healthcare outcomes represent a critical challenge in achieving equity in gastric cancer care. Gastric cancer, often associated with high morbidity and mortality, also places patients at risk for major adverse cardiovascular and cerebrovascular events (MACCE). This study explores racial disparities in MACCE outcomes among gastric cancer patients using data from the National Inpatient Sample (2016–2021), focusing on differences in mortality, myocardial infarction (MI), arrhythmias, and healthcare resource utilization. **Methods:** A retrospective cohort analysis of the NIS database from 2016 to 2021, identifying adult gastric cancer patients using ICD-10 codes. Demographic and clinical variables, including race/ethnicity, age, sex, income, and hospital characteristics, were analyzed. MACCE outcomes, including mortality, myocardial infarction (MI), atrial fibrillation (A-fib), arrhythmias, and other cardiovascular events, were compared across racial groups. Multivariable logistic regression adjusted for confounders to evaluate the odds of MACCE outcomes and healthcare utilization disparities. **Results:** Among 243,544 gastric cancer patients, the racial distribution included White (53.2%), Black (16.5%), Hispanic (17.3%), Asian or Pacific Islander (7.8%), Native American (0.7%), and Other (4.1%). Significant disparities were noted in MACCE outcomes: Black patients had higher odds of mortality (OR 1.196, $p < 0.001$) and sudden cardiac arrest (OR 2.206, $p < 0.001$) compared to Whites. Hispanic and Asian patients had significantly lower odds of myocardial infarction (OR 0.768, p = 0.011; OR 0.998, p = 0.991, respectively). Atrial fibrillation was significantly less frequent among Black (OR 0.486, $p < 0.001$), Hispanic (OR 0.4, $p < 0.001$), Asian (OR 0.466, $p < 0.001$), and Native American (OR 0.568, p = 0.009) populations compared to Whites. Notably, Hispanic and Asian or Pacific Islander patients had significantly higher total charges (TOTCHG) compared to Whites ($7,945.6 and $13,467.1 higher, respectively, $p < 0.001$). Length of stay (LOS) was significantly longer for Black patients (0.707 days, $p < 0.001$) compared to Whites. **Conclusions:** This study highlights significant racial disparities in MACCE outcomes, mortality, and healthcare resource utilization among gastric cancer patients. Black and Other racial groups demonstrated higher odds of mortality and sudden cardiac arrest, while Hispanic and Asian patients showed a protective effect against myocardial infarction and atrial fibrillation. Disparities in healthcare charges and LOS further emphasize systemic inequities. Addressing these disparities requires targeted interventions to reduce cardiovascular risks and improve healthcare access and equity for minority populations with gastric cancer. Research Sponsor: None.

Patient-reported communication and satisfaction in breast cancer: Does doctor-patient identity concordance matter? First Author: Kamaria L. Lee, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Effective communication is a key element in patient engagement, adherence, and satisfaction. Prior research has shown that doctor-patient race and/or gender concordance may improve both health outcomes and patient satisfaction, however the effects of identity concordance in oncology and specifically within breast cancer are less studied. **Methods:** Between 7/2023-8/2023, cancer survivors were recruited from Breastcancer.org and consented to participate in an anonymous online survey in English or Spanish. Eligibility included: US resident, age $\geq$18, and diagnosed within the past 10 years. Survey assessed patient-reported aspects of communication as well as patient-identified provider race/ethnicity and gender. Chi-square and Fisher's exact tests tested associations between patient and/or provider identity and patient-reported satisfaction with communication. **Results:** Of 997 who completed the survey, 759 reported provider race/ethnicity and gender and were included in this analysis. Patients were median age 63 (range, 32-97), mostly White race (91%) and non-Hispanic (99%); almost all were women (98%). Patients were a median of 3.3 years (1.4-10) post diagnosis. Overall, 60% had concordant gender with their provider. 64% had concordant race; White patients had higher racial concordance 68% (n=470/690) than Black (14%, n=5/35) or Asian/Pacific Islander patients (50%, n=9/18) ($p<0.0001$). 0% of Hispanic patients (n=0/11) had ethnic concordance with their provider. Patients reported high levels (94-97% "usually" or "always") of being treated with courtesy/respect, with no significant differences by identity concordance (either racial, ethnic, or gender concordance). Similarly, they reported their doctors listened carefully (89-98% usually/always) and explained things in a way they could understand (89-98% usually/always), with no differences by concordance. Most patients reported no one talked to them about possible clinical trial options (75% White, 51% Black, 56% Asian patients, p=0.003 comparison), but there were no differences by concordance. There were no significant differences by patient-reported race for questions regarding courtesy/respect, listening, explanations, or discussing clinical trials. Similarly, there were no significant differences by patient-reported provider race or gender. **Conclusions:** In this study of breast cancer survivors, patient-provider identity concordance did not have effects on patient-reported communication. There were no identified differences in communication by race, ethnicity, or gender of patient or provider, although overall satisfaction was very high with limited sample diversity which may stymie capacity for identifying differences. Very few Black and zero Hispanic patients had racial or ethnic concordance with their provider, reflecting known gaps in the oncology workforce. Patient-reported health experiences among US immigrant patients with cancer. First Author: Anh B. Lam, The University of Oklahoma Health Sciences Center, Oklahoma City, OK

Background: Patients often experience complex, multifaceted challenges while navigating cancer care, including many interactions with the health system and care teams. For immigrant patients, language barriers may further complicate their cancer care experience. **Methods:** We used the Medical Expenditure Panel Survey database from 2019-2022 to study patient-reported differences in cancer care experiences based upon immigrant status and speaking another language at home. We extracted data about patient factors (age, sex, race, marital status, poverty levels from reported income, immigrant status [born in the US or not], speaking another non-English language at home) and cancer type for all adults > 18 years with self-reported history of cancer. We compared health experiences (i.e., if provider asks about treatments/medications from other providers, if provider explains all treatment options, includes patient in medical decision-making, delays in medical care) by immigrant status and speaking another language at home using Rao-Scott Chi-square test with person-level survey weight. **Results:** We identified 7,771 patients with cancer (63.4% age 65+, 59.4% female, 82.5% White, 50.6% married). Most common cancers were breast (21.6%) and prostate (15.3%). Overall, 10.3% were immigrants and 11.4% reported speaking another language at home; these patients were more commonly younger, female, Hispanic, less educated, living below the poverty line, and had non-private insurance (table). Immigrant patients were less likely to report a provider asked about other treatments (58.5% v 64.6%, p = .022), explained all treatment options (71.6% v 78.2%, p = .032), and included patient in making medical decisions (38.8% v 45.7%, p = .007). Immigrant patients were less likely to report delays in medical care due to cost (6.1% v 6.9%, p = .022) than patients born in the US. Patients who reported speaking another language at home were less likely to report a provider asked about other treatments (58.6% v 64.6%, p = .015), explained all treatment options (71.7% v 78.2%, p = .017), and included patient in making medical decisions (36.5% v 46.0%, $p < .001$). We found no differences in reporting delays in medical care due to cost (6.6% v 6.9%, p = .059). **Conclusions:** In this national survey study, we found patient-reported health experiences (i.e., discussions about treatment and shared decision-making) differed for immigrants and those speaking another language at home. Findings should inform future work to enhance the cancer care experience in culturally and language appropriate ways for all patients. Research Sponsor: None.

Factors associated with readmission to index vs. non-index hospitals after major cancer surgery: Does centralization play a role? First Author: Avanish Madhavaram, University of Pittsburgh School of Medicine, Pittsburgh, PA

Background: While centralization of complex cancer surgery at regional referral centers improves perioperative outcomes, many vulnerable patients face barriers in accessing these hospitals. When these patients do manage to undergo surgery at referral centers, it remains unclear where they are readmitted to receive postoperative care when unplanned complications arise. Patients with cancer surgery who are readmitted to the hospital where the surgery was performed (index readmission) often have improved outcomes compared with those readmitted to a different hospital (non-index readmission). This study examined whether factors associated with readmission to index versus non-index hospitals differ for patients undergoing surgery at referral versus non-referral centers. **Methods:** We used data from the Pennsylvania Cancer Registry linked to all-payer statewide inpatient discharge records to identify patients who had surgery for bladder, brain, esophageal, liver, lung and pancreatic cancers between 2013-2019 and were subsequently readmitted within 90 days. We fit a multivariable logistic regression model to identify factors associated with 90-day readmission to an index versus non-index hospital. We included an interaction term between referral center status and cancer type in this model. We defined referral centers as National Cancer Institute-designated cancer centers or American College of Surgeons Commission on Cancer-accredited academic comprehensive cancer programs. **Results:** Of the 28,951 patients with major cancer surgery, 28% (N=8215) were readmitted within 90 days of cancer surgery. Of all patients readmitted, 57% (N=4671) were originally treated at referral centers and 78% (N=6388) were readmitted to the index hospital. On multivariable analysis, factors associated with lower odds of index versus non-index readmission included older age ($\geq$70 years: odds ratio (OR)=0.61; 95% confidence interval (CI), 0.49-0.77, relative to $<$55 years), high Elixhauser comorbidity scores ($>$16: OR=0.74; 95% CI, 0.63-0.88; relative to $<$8), longer travel times ($>$60 minutes: OR=0.12; 95% CI, 0.10-0.15; relative to $<$15 minutes), and Medicaid insurance (OR=0.68; 95% CI, 0.54-0.86; relative to commercial insurance). There was no significant difference in odds of index readmission when patients were treated at referral versus non-referral centers (OR=0.77; 95% CI, 0.50-1.20). When assessing interactions, patients with lung cancer had lower odds of index readmission when treated at referral versus non-referral centers, relative to other cancers (OR=0.59; 95% CI, 0.40-0.89). **Conclusions:** Ongoing centralization may be significantly increasing care fragmentation for patients with lung cancer surgery. Future interventions to improve care coordination after surgery should target patients with higher clinical complexity and greater travel burdens. Research Sponsor: National Cancer Institute; R37CA262366.

The association between profitability, clinical benefit, and physicians' selection of cancer drugs. First Author: Aaron Philip Mitchell, Department of Epidemiology and Biostatistics, Memorial Sloan Kettering Cancer Center, New York, NY

Background: Compensation for provider-administered cancer drugs (such as intravenous chemotherapy and immunotherapy) is volume-based and proportional to drug price. Providers receive greater compensation for more expensive drugs. If providers respond to this incentive by selecting more-profitable but clinically less-beneficial treatments, cancer care spending may be increased unnecessarily and care quality may be impacted. The goal of this study was to estimate the association between the billing (profit) margin of cancer treatments and use by oncologists. **Methods:** This was a population-based cohort study using fee-for-service Medicare claims. We included beneficiaries with an incident cancer diagnosis (a new occurrence of a cancer diagnosis code after a >= 1 year washout period) from 2014-2020. The primary outcome was which cancer treatment, among available options, each patient received. The treatment-level characteristics of interest were provider billing margin (using Medicare reimbursement rates) and clinical benefit (using the National Comprehensive Cancer Network Evidence Blocks scores), both measured coincident with each patient's diagnosis date. We included cancer treatment "indications" (e.g., metastatic melanoma, adjuvant therapy for stage III colon) that had variation in both the clinical benefit and billing margin of available treatment options. We modeled the association between treatment received, billing margin, and clinical benefit, including inverse probability-of-treatment weights to control for patient (age, comorbidity, frailty, low income subsidy, regional income and poverty prevalence, rurality) and provider (years in practice, academic setting, patient volume) characteristics. Models were estimated within individual cancer indications, and results were then aggregated via meta-analysis. **Results:** We included 12 cancer indications comprising 19,397 individual patients. Across all treatments for the 12 cancer indications, provider billing margin ranged from $0-$12,692 per course of treatment. There was no association between a $100 increase in provider billing margin and likelihood of treatment use (OR 0.97, 95%CI: 0.91-1.03). Higher clinical benefit was associated with greater treatment use (OR 1.62, 95%CI: 1.15-2.29). These findings were unchanged in sensitivity analyses applying different methods for billing margin calculation, measurement of clinical benefit, and weighting. **Conclusions:** In this observational study of Medicare beneficiaries, selection of cancer treatments was associated with treatment clinical benefit but not billing margin. Restated, oncologists preferred more beneficial treatments but not more profitable ones. These results suggest that changes in the billing margin of cancer treatments may be unlikely to shift utilization patterns. Use of low-value cancer treatments in Medicare Advantage versus traditional Medicare. First Author: Aaron Philip Mitchell, Department of Epidemiology and Biostatistics, Memorial Sloan Kettering Cancer Center, New York, NY

Background: Medicare Advantage (MA) has steadily grown during the past decade, covering over half of Medicare beneficiaries in 2024. Because MA plans receive capitated payments for Medicare beneficiaries, they have the financial incentives to reduce service utilization and costs. MA plans may discourage enrollees from using low-value services, such as medically unnecessary care and expensive treatments for which low-cost alternatives are available. No prior study examining the use of low-value services between MA and TM has evaluated the use of low-value cancer treatments specifically. We compared use of low-value cancer treatments between MA and TM. **Methods:** Using national Medicare data, we performed retrospective analyses of beneficiaries who had a new cancer diagnosis between 2016 and 2021, and who were at risk of receiving one of the following low-value treatments: growth factors (GCSF) for patients receiving low-risk chemotherapy; denosumab for castration sensitive prostate cancer (CSPC); nab-paclitaxel instead of paclitaxel for breast or lung cancers; adding bevacizumab to carboplatin + paclitaxel for ovarian cancer; and branded drugs or biologics for which generic or biosimilar versions existed. We estimated linear regression models for each cohort/outcome separately. The key explanatory variable was MA enrollment (vs. TM). We used inverse probability of treatment weights to balance characteristics between MA and TM: patient age, sex, race, Medicare and Medicaid dual-eligibility status, cancer metastasis, a frailty index, and summary health-risk scores, area-level socio-economic and health care environment variables. We included year indicators to adjust for temporal trends and oncology practice indicators to control for practice-specific prescribing patterns. **Results:** Receipt of any low-value cancer treatment was 1.7 percentage points lower in MA than in TM (34.2% versus 35.9%; $p<0.001$). MA enrollees had lower utilization than TM for GCSF (7.3% versus 8.9%; $p<0.001$), denosumab (26.4% versus 33.1%; $p<0.001$), nab-paclitaxel (7.9% versus 8.7%; $p<0.05$), addition of bevacizumab for ovarian cancer (8.3% versus 10.5%, p=0.001), and biologics with biosimilar alternatives (66.8% vs. 68.5%; $p<0.001$). Receipt of branded drugs did not significantly differ between MA and TM. **Conclusions:** For Medicare beneficiaries at risk of receiving a low-value cancer treatment, MA enrollees were less likely to receive low-value cancer treatments than TM beneficiaries. These reductions in low value services may prevent avoidable toxicity and lower treatment cost to the patient and health care system. Increased efforts are needed to identify approaches that MA plans use to reduce low-value cancer treatments, and explore ways to promote those approaches in both MA and TM. Longitudinal changes in credit status for newly diagnosed metastatic colorectal cancer patients (SWOG S1417). First Author: C. Natasha Kwendakwema, Fred Hutchinson Cancer Center, Seattle, WA

Background: We previously reported that 71% of insured patients with newly diagnosed metastatic colorectal cancer (mCRC) self-reported major financial hardship (MFH), defined as one or more of increased debt, new loans from family and/or friends, selling or refinancing a home, or 20% or more income decline, within 12 months of diagnosis. In this secondary analysis using credit data, we examined if enrolled patients experienced changes in credit status over time. **Methods:** Depersonalized credit data were obtained from TransUnion, one of the largest credit agencies in the United States, at enrollment, 6, and 12 months. Patients with a baseline and at least one follow-up credit record were analyzed. Demographic data were obtained from questionnaires at enrollment. We determined the mean number or proportion of patients with adverse credit events (defined as past due or delinquent credit cards or mortgage payments, third-party collections, tax liens, charge-offs, bankruptcies, foreclosures, or repossessions) and the mean past due credit card amount, if applicable, at baseline and follow-up. We used paired t-tests to compare credit characteristics between baseline and follow-up in the entire cohort and in subgroups with and without MFH. Multivariate logistic regression was used to identify factors associated with adverse credit events. **Results:** 318 patients were analyzed (median age 59.1, 41% female, 80% white, 59% married, 42% with private health insurance). Approximately 3.4% of patients experienced a new adverse credit event during the study period, 143 (45.0%) patients at baseline and 154 (48.4%) at follow-up (p=0.07). Overall, new adverse credit events were uncommon and only third-party collections significantly worsened over time (mean 3.20 (SD 3.17) at baseline and mean 4.11 (SD 3.85) at follow-up; $p < 0.001$). Charge-offs numerically increased over time, but the value did not reach significance. On average, past due amounts on open credit cards increased over time ($100.60 at baseline and $291.33 at follow-up), with the increase largely seen among patients self-reporting MFH. Adverse credit events were more likely to worsen in patients who were younger (OR 2.51, CI 1.08-5.84), had lower household income (OR 3.09, CI 1.07-8.92), lower educational status (OR 2.07, CI 1.10-3.88), and fewer assets, defined as less than $100,000 (OR 4.15, CI 1.58-10.91). **Conclusions:** Despite high levels of self-reported MFH in this cohort, credit data showed no significant increase in adverse credit events between baseline and follow-up, except for increased third-party collections and total past due credit card balances. This may be due to credit reports capturing only more severe financial impacts or because the impacts of financial hardship take longer to be reflected in credit reports. A future study will examine how patients leverage credit, such as applying for new credit cards or reaching credit limits. Association of county-level medical debt and timely treatment initiation among individuals newly diagnosed with cancer. First Author: Jingxuan Zhao, American Cancer Society, Atlanta, GA

Background: Medical debt is associated with adverse cancer outcomes, including poor survival. However, it is unknown if living in a county with high medical debt is associated with treatment initiation. We examined the association of county-level medical debt and timely treatment initiation among individuals newly diagnosed with cancer. **Methods:** We identified adults aged ≥19 newly diagnosed with cancer from the 2012-2021 Colorado Central Cancer Registry linked to the Colorado All-Payer Claims Database, which were combined with data on county-level share of adults with medical debt in collections. We used Cox proportional hazard models to examine the associations of county-level medical debt and receipt of any treatment within 90 days after cancer diagnosis overall and by selected cancer sites (acute leukemias, lymphomas, breast, colorectal, and lung cancers) and health insurance coverage, adjusting for individual sociodemographic characteristics. P-trend was calculated using medical debt quartile as a continuous variable in the models to examine dose-response associations. **Results:** Among 35,789 individuals newly diagnosed with cancer, individuals living in counties with the highest share of adults with medical debt in collections (Quartile 4 (Q4)) had lower likelihood of initiating treatment within 90 days after diagnosis compared to those living in counties with the lowest share of adults with medical debt (Q1), adjusting for covariates (HR: Q4 vs Q1: 0.93, 95% confidence interval: 0.90-0.97, P-trend < 0.001). When stratified by cancer site, higher county-level medical debt was associated with lower likelihood of timely treatment initiation among individuals diagnosed with lymphoma (HR: Q4 vs Q1: 0.82 (0.69-0.98), P-trend = 0.022) and female breast cancer (HR: Q4 vs Q1: 0.90 (0.85-0.94), P-trend < 0.001). When stratified by insurance, higher county-level medical debt was associated with lower likelihood of timely treatment initiation among individuals aged 19-64 years with private fee-for-service (FFS) plans (HR: Q4 vs Q1: 0.88 (0.78-0.98), P-trend = 0.011) and individuals aged ≥65 years with Medicare FFS plans (HR: Q4 vs Q1: 0.90 (0.82-0.98), P-trend = 0.007). **Conclusions:** County-level medical debt in collections was associated with delays in treatment initiation among individuals newly diagnosed with cancer. Policies aimed at preventing and alleviating medical debt could be effective strategies for improving access to timely cancer treatment. Research Sponsor: Leukemia and Lymphoma Society; HSR9027-24.

Association between cost and insurance on receipt of guideline-concordant mammography. First Author: Nicole E. Caston, The University of North Carolina at Chapel Hill, Chapel Hill, NC

Background: Many organizations offer mammography guidelines with slight differences, which can serve as a barrier to receiving a mammogram. Furthermore, it is unknown how both cost and insurance serve as a barrier to receiving a mammogram. Therefore, our study explored the associations between cost and insurance on guideline-concordant mammography. **Methods:** This cross-sectional study used 2023 National Health Interview Survey data. Inclusion criteria included women eligible for a mammogram. The outcome was receipt of guideline-concordant mammography and was based on women following 2016 US Preventive Services Task Force or current American Cancer Society guidelines for age and frequency requirements. The exposures of interest included report of at least one healthcare-related cost issue (yes, no) and insurance status (uninsured, insured). Questions for healthcare-related cost issue included: in the past 12 months did you, 1) have problems paying or were unable to pay medical bills, 2) delayed medical care due to cost, & 3) did not get necessary medical care due to cost. We estimated odds ratios (OR) and 95% confidence intervals (CI) using logistic regression to assess the interaction between cost issues and insurance status on receipt of guideline-concordant mammography. The model controlled for age at survey completion, race and ethnicity, Rural-Urban Classification Scheme, income to poverty ratio, and personal & family history of breast cancer. **Results:** A total of 13,529 women were included. Mean age was 55 years, 63% were non-Hispanic White, 10% were in poverty. About 1 in 4 had not received guideline concordant mammography. When compared to those who had received a guideline-concordant mammogram, individuals who did not have a mammogram were younger (p-value: <.0001), uninsured (<.0001), and had reported at least one cost issue (<.0001). In our adjusted analysis, we found that the uninsured, regardless of cost issue, had lower odds of receipt of guideline-concordant mammography (Table). Among insured individuals, those who did vs did not report a cost issue had 0.68 (95% CI 0.59-0.77) times the odds of receipt of a guideline-concordant mammogram. **Conclusions:** By interacting cost issues and insurance status, we found that individuals with health insurance and issues paying for care had low prevalence of guideline-concordant mammography. This is important when determining how best we can provide screening for those in need. We recommend that screening services that offer free or low-cost mammograms include women who have health insurance and report healthcare-related cost issues. Research Sponsor: None.

Shifts in Medicare spending for patients with cancer undergoing chemotherapy following implementation of the Maryland Global Budget Revenue program. First Author: Yu-Li Lin, University of Texas MD Anderson Cancer Center, Houston, TX

Background: In January 2014, the statewide Maryland Global Budget Revenue (GBR) model was implemented to control the growth in total hospital spending and improve the quality of care. Specific impacts of GBR on cancer-related spending are not fully understood. This study aimed to 1) quantify the impact of GBR on Medicare spending for beneficiaries undergoing chemotherapy for cancer and 2) investigate any shift in such spending during GBR to non-hospital settings. **Methods:** Using 2011-2018 Medicare claims from Maryland and a control set of 11 comparable states, we constructed 6-month chemotherapy episodes. Propensity matching was used to identify appropriate comparison episodes based on treatment year, patient demographic, clinical, and area-level characteristics. Using a difference-in-differences (DiD) approach, we evaluated the impact of GBR on standardized total Medicare payments and non-hospital professional payments during the episode, after confirming the parallel trends assumption during GBR's pre-period (2011-2013). **Results:** Among 42,206 and 708,486 chemotherapy episodes in Maryland and control states, respectively, we studied 42,199 episodes in Maryland matched to 42,199 episodes in control states. Our analysis showed that GBR's implementation led to smaller increases in total episode payments over time relative to control states and larger increases in non-hospital professional payments (Table); these impacts notably varied with time. **Conclusions:** Our finding of smaller increases in total Medicare payment for a 6-month chemotherapy episode in Maryland versus control states indicates that GBR's intended reductions on the spending growth in the context of cancer patients undergoing chemotherapy were actualized. Importantly, larger increases in non-hospital professional payments suggest these savings may have been attained via shifts in sites-of-care following GBR's implementation. Further studies evaluating the effects of these shifts on cancer care quality are warranted. Research Sponsor: U.S. National Institutes of Health.

Adjusted mean standardized payments in 2018 dollars during 6-month chemotherapy episodes and DiD estimates versus 2013.

	Total payments			Non-hospital professional payments		
Year	Adjusted Mean, Maryland	Adjusted Mean, Control states	DiD	Adjusted Mean, Maryland	Adjusted Mean, Control states	DiD
2013	$54,213	$52,659	Ref	$22,876	$14,844	Ref
2014	$54,522	$53,476	-$759	$21,261	$14,327	$828
2015	$55,355	$55,426	-$2,001	$22,249	$14,186	$1,433*
2016	$58,599	$59,331	-$2,940*	$24,314	$14,922	$1,286
2017	$61,141	$60,462	-$1,561	$27,954	$15,330	$3,612*
2018	$62,329	$64,756	-$4,853*	$27,969	$15,356	$2,753*

*p<0.05. The adjustment methodology accounted for patient demographic, clinical and area-level characteristics, and time-varying Hospital Service Area (HSA) level variables. For the DiD analysis, HSA fixed effects were also included.

Insurance coverage of germline genetic testing for ovarian, pancreatic, and early-onset colorectal, endometrial, and breast cancers, stratified by self-reported race and ethnicity. First Author: Erica M. Vaccari, Labcorp, San Francisco, CA

Background: Universal germline genetic testing (GGT) for patients with ovarian (OV), pancreatic (PANC), and early-onset colorectal, endometrial cancer, and breast cancer (CRC <50, ENDO <50, and BR ≤50) is the medically necessary standard of care per clinical guidelines and many payer medical policies. Individuals with multiple cancers, diagnosed at any age (MULTI), also commonly meet these guidelines for GGT. We report a single national laboratory experience with GGT coverage for these indications. **Methods:** Patients with GGT between 6/1-12/31/2023 from a commercial laboratory were stratified by cancer type (using ICD-10s), age at testing, and self-reported race and ethnicity. We assessed differences in coverage rates, frequency and types of denial codes (technical and clinical denials), and appeal success across cancer types. Reported p-values are from G-Tests of independence, only groups containing at least 100 individuals were retained in statistical tests. **Results:** We reviewed 12,304 patients with cancer, 19% with OV, 29% with PANC, 13% with CRC <50, 2% with ENDO <50, 26% with BR ≤50, and 9% with MULTI. Of all patients, GGT was not covered for 31%, including 29% of OV, 27% of PANC, 35% of CRC <50, 39% of ENDO <50, 35% of BR ≤50, and 27% of MULTI. Of all cases with no coverage for clinically indicated GGT, 30% had clinical denial codes (e.g. medical necessity, non-covered services, experimental), 68% had only technical denial codes, and 2% had no denial codes. Overall, appeals were successful in 32% of cases, including 27% of OV, 25% of PANC, 44% of CRC <50, 39% of ENDO <50, 33% of BR <50, and 22% of MULTI. The proportion of cases with coverage differed significantly by self-reported race and ethnicity (58%-81%, p <0.00001), with Black and Hispanic individuals being less likely to be covered in comparison to Ashkenazi Jewish, Asian, and White individuals. Whereas the proportion of those receiving denial codes differed between self-reported race and ethnicity groups (p <0.00001), the percentages of technical vs. clinical denial codes received did not (p = 0.56). **Conclusions:** Despite clinical guidelines and payer medical policy affirming the medical necessity of universal GGT in these cancer types, these data demonstrate that 30% of patients did not receive coverage for standard of care GGT, and was lower in traditionally under-represented groups. Denials overturned on appeal suggest those cases should not have been denied initially. These data suggest that coverage denials are a substantial obstacle to medically necessary GGT for patients with cancer despite clinical practice guidelines. Research Sponsor: None.

11081 **Poster Session**

Longitudinal risk of physical functional impairment and health care utilization in cancer survivors within 3 years of diagnosis. First Author: Ann Marie Flores, Northwestern University Feinberg School of Medicine, Chicago, IL

Background: Despite known physical functional (PF) impairment in cancer survivors, patterns of its development and relationships to healthcare utilization remain poorly characterized. We examined PF impairment trajectories among outpatient cancer survivors in a large Midwestern academic health care system during the first three years after a new cancer diagnosis. We hypothesized that PF impairment would be common, vary by extent of disease, cancer care phase, with differing patterns of rehabilitation services (RS) referral, emergency department (ED) and cancer center urgent care (CCUC) visits. **Methods:** We included 2,254 adults with a cancer diagnosis, treated in medical oncology clinics, and completed 2 or more Patient Reported Outcome Measurement Information System – Physical Function (PROMIS-PF) surveys within a 3-year period. A PROMIS-PF T-score $<$ 40 represents moderate – severe impairment. We used group-based trajectory modeling (GBTM) to identify patterns of impairment likelihood (0.7 threshold for accurate fit) in the 3 years after cancer diagnosis. Trajectory models identified the demographic profile, cancer type, stage, and treatment intent (intent to cure, non-intent to cure, other) most associated with each trajectory. We assessed trajectory associations with rates of RS referrals, and visits to ED and CCUC during the study period with multiple logistic regression ($p<.05$). **Results:** On average, participants were newly diagnosed within 11 months (s.d. 10.92) before enrollment in the study. We determined 4 PF impairment trajectory patterns during the first 3 years after a cancer diagnosis: (1) low probability of impairment which remained steady over time ("Low Steady", 64% participants); (2) decreasing probability ("Decreasing", 13%); (3) increasing probability ("Increasing", 9%); (4) high probability of PF impairment that remained high ("High Steady", 14%). Patients in trajectories 2, 3, and 4 were significantly more likely to have ED and/or CCUC visits and receive RS referrals than those in trajectory 1, although differences by cancer type, stage, and Beacon module between groups 2 – 4 were mixed. **Conclusions:** Over one-third of cancer survivors experienced substantial impairment and 14% had persistent, severe impairment with higher rates of RS referrals, ED and CCUC visits. These patterns had few variations by tumor type and cancer care phase. Our data suggest that patients in Trajectories 2 – 4 should be targeted for early and frequent monitoring with PROMIS-PF and referral for rehabilitation services to address impairments –ideally within the first six months after cancer diagnosis. PROMIS-PF effectively identified impairment variation across patients and time. Future studies will explore whether screening and triaging for appropriate cancer rehabilitation referral and intervention improve impairment trajectories. Research Sponsor: National Cancer Institute/U.S. National Institutes of Health; UM1CA233035; National Cancer Institute/U.S. National Institutes of Health; 3UM1CA233035-01S1.

Addressing disparities by implementing a supportive care program in oncology. First Author: Emily Meichun Ko, Division of Gynecologic Oncology, University of Pennsylvania, Philadelphia, PA

Background: Financial toxicity, transportation needs, and emotional strain are known barriers to receipt of cancer care and cause for disparities in cancer outcomes. We sought to evaluate the implementation of a supportive care program (SCP) on the delivery of cancer care, its associated health care utilization outcomes and cost. **Methods:** From May 2022-Nov 2024, SCP included a standardized social determinant of health (SDOH) screening tool, financial navigation, transportation ridesharing, and peer-support program in the 5 gynecologic oncology practices within a NCI Comprehensive Cancer Center. Patients were referred through the SDOH screener or usual clinical care referrals. We report descriptive statistics on the mechanism for referral for SCP, associated health care utilization, and costs. We assessed differences in SCP financial and transportation sub-groups with bivariable non-parametric testing (p-value$<$ .05 considered statistically significant). **Results:** Of 7159 patients encompassing 22041 encounters, 259 received SCP (41 financial navigation, 177 transportation, 3 transportation + financial navigation, 18 peer-support program). Only 73 (28.7%) were referred through the SDOH screening tool, and the rest through usual clinical care. Most SCP recipients (60.6%) were Black/Asian/Other, in contrast to our general clinical population (63% White). Only 65 (25.6%) of SCP patients were employed, and 72.8% had Medicare or Medicaid. Nearly all SCP patients resided in the MidAtlantic tristate area. Patients receiving financial navigation were younger ($p<0.001$), more likely to be privately insured ($p<0.001$), and less likely to reside in the metropolitan area (43.9% v. 63.8%, p=0.05) compared to those receiving transportation. A total of 1770 rides were completed, costing $51885.20 which included the ride and administrative scheduling fee. A total of 14 SCP participants were clinical trial participants; of these, 78.6% utilized transportation assistance. Following receipt of SCP, the total scheduled visits for SCP patients included 7768 visits. Patients receiving transportation assistance had higher rates of unplanned admission (43.5% v. 22.0%, p=0.011), and no-show rates (4.6% vs 1.2%, $p<0.001$) compared to those receiving financial navigation. **Conclusions:** Our SCP served primarily racial-minority and publicly insured patients. Only 25% were employed during active cancer treatment. Transportation was the most frequently used SCP service, including by our clinical trial participants. Patients with transportation needs had higher rates of unplanned admissions and no-shows than those receiving financial navigation. Financial toxicity affected younger patients including those privately insured. SCP facilitates cancer care delivery, but requires infrastructural development, substantial investment in resources, and further analyses of health care utilization, outcomes and cost. Evaluating a patient ambassador program to improve clinical trial knowledge and intent to discuss gynecologic oncology trials. First Author: Emily Meichun Ko, Division of Gynecologic Oncology, University of Pennsylvania, Philadelphia, PA

Background: To evaluate the implementation of a pilot patient-ambassador program to provide peer-to-peer clinical trial education aimed at increasing awareness, knowledge, and intent to discuss gyn oncology (GYO) trials in trial-naïve patients. **Methods:** We conducted a mixed-methods interventional behavioral study at an urban-metropolitan NCI comprehensive cancer center to evaluate the implementation of a program for initiating "chats" about GYO clinical trials. From Feb-Oct 2024, we recruited patients as "ambassadors" who previously participated in a GYO clinical trial. Ambassadors underwent training via an educational curriculum and then were paired with 5-7 "mentees," who were trial-naïve patients with high-risk or advanced gyn cancer. Outcomes assessments included post-chat quantitative surveys using the acceptability and feasibility of intervention measures (AIM & FIM), net promoter score (NPS), and change in clinical trials knowledge score. Qualitative analyses of open-ended survey responses, dyad "chat" recordings, and feedback from ambassadors at training, mid-program and exit interviews were completed by two coders using a modified content analysis approach. Chi-square test and t-tests were applied with $p<0.05$ considered significant. IRB exemption obtained (IRB #: 854317). **Results:** 3 ambassadors and 20 mentees completed the program, resulting in 20 "chats" from a pool of 266 eligible mentees. On the pre-chat survey, 90% of mentees reported they had previously heard of clinical trials and 75% of mentees reported they perceived trials as somewhat/very positive. Post chat, 90% of mentees reported their perception of trials as somewhat/very positive, 85% felt the chat changed their view of trials, and 95% felt confident to ask their oncology provider about trials. Participants reported high acceptability, feasibility, and program promotion, but no increase in knowledge (table). Qualitative themes of barriers to trial participation included misconceptions of trial types and inability to withdraw, and fear of side effects, and cost. Facilitators included desire to help humanity and hope for new treatments. Implementation concerns included emotional strain on ambassadors, mismatched ambassador-mentee expectations, and ambassadors' variability in discussing recruitment of diverse populations. **Conclusions:** This pilot patient-ambassador program is a feasible, acceptable, and highly promoted intervention to increase patients' confidence in discussing and intent to ask oncology providers about clinical trials. Research Sponsor: Robert A. Winn Diversity in Clinical Trials Award Program; National Cancer Institute; P50CA228991.

The state of the oncologist workforce in America in areas prone to natural disasters. First Author: M. Kelsey Kirkwood, ASCO, Alexandria, VA

Background: Natural disasters are increasingly common in the U.S., causing significant localized disruptions to cancer care. The American Society of Clinical Oncology (ASCO) examines the supply of and demand for cancer services in areas prone to natural disasters to support emergency preparedness planning, response, and recovery. **Methods:** We tabulated the number of U.S. hematologists and medical oncologists by county from Medicare Care Compare (March 2024 data). Demand for cancer services was approximated using 2017-2021 average annual counts of new cancer cases by county from State Cancer Profiles. We extracted US Climate Vulnerability Index county rankings for extreme flooding, storm, and wildfire events, as well as for community resilience (derived from health, social, economic, infrastructure, and environmental measures). We defined "high-risk" counties as those with the highest decile rankings for extreme flooding, storm, and/or wildfire events across all U.S. counties and determined the share of U.S. oncologists and people with incident cancer in those areas. We also identified oncologists and patient populations in counties adjacent to high-risk counties who might be affected. Among high-risk and adjacent counties, we further isolated those ranked in the highest quartile for baseline vulnerability (i.e., low community resiliency). **Results:** Of 1.7M people with newly diagnosed cancer in the U.S., a majority (65%, 1.1M) lived in proximity to counties at high-risk for extreme flooding, storms, and wildfires (642K people from 886 counties designated high-risk and 479K from 716 adjacent counties). Similarly, most oncologists (65%, 9,471 of 14,547) practiced in proximity to high-risk counties (5,501 oncologists in top ranked counties, 3,970 in adjacent counties). When factoring in community resilience, 325 counties at or adjacent to high-risk for extreme weather events also ranked highest for baseline vulnerability: 14% of oncologists (n=2,036) worked in these counties, where 13% of people with incident cancer lived (226K). **Conclusions:** ASCO has recommended that health systems create geographically appropriate plans for natural disasters. Our analysis indicates that most oncologists and most patients in the U.S. are in or adjacent to areas prone to natural disasters, and that many people at risk reside in counties with low community resilience. Practice-level emergency preparedness for response and recovery from natural disasters, including patient referrals and minimization of treatment disruptions, informed by community-specific needs, should be pursued on a broad scale. Additional planning is needed at all levels of the health care system and government to meet this substantial and potentially growing need for crises planning in cancer care. Future research could focus on other types of disasters and on global impacts. Research Sponsor: None.

Influenza and COVID-19 vaccination uptake among cancer survivors in the US. First Author: Ted Akhiwu, MedStar Health Georgetown University, Baltimore, MD

Background: Cancer survivors are at increased risk of comorbidity and mortality from respiratory viral infections including influenza (flu) and COVID-19 and therefore, vaccinations against these viruses are important for their health. Little is known about the receipt of these vaccines among cancer survivors in the post-COVID era. This study sought to evaluate the uptake of flu and COVID-19 vaccinations between cancer survivors and the general population in the US. **Methods:** We analyzed cross-sectional data from the 2023 National Health Interview Survey that used multistage probability sampling to interview US adults. Adults with a history of cancer were defined as cancer survivors, and those without a history of cancer were the general population. Flu vaccination receipt was defined as having had a flu shot in the past 12 months. COVID-19 vaccination receipt was defined as having received ≥2 doses of the COVID-19 vaccine. Weighted proportions were compared using Rao-Scott Chi-squared tests. Weighted logistic regression was conducted, adjusting for demographic and socioeconomic factors. Adjusted odds ratio (AOR) and 95% CIs were calculated. All analyses accounted for complex survey design and weights. **Results:** The total sample size was 29,522, representing a weighted sample of 258,237,552 adults in the US. The mean age was 48 years; 61.9% were White, followed by 17.5% Hispanic, 11.8% Black, and 8.8% Asian or Other; and 9.7% were cancer survivors. Overall, 73.7% (95% CI: 72.9-74.5%) received ≥2 doses of COVID-19 vaccinations, and 48.0% (95% CI: 47.1-48.8%) had a flu shot in the past 12 months. Compared to the general population, higher proportions of cancer survivors received COVID-19 vaccinations (84.8% [95% CI: 83.5-86.3%] vs 72.5% [95% CI: 71.6-73.4%], $P<0.001$) and a flu shot (67.3% [95% CI: 65.5-69.1%] vs 45.8% [95% CI: 45.0-46.7%], $P<0.001$). After covariate adjustment, cancer survivors had greater odds of having received COVID-19 vaccinations than the general population (AOR 1.38, 95% CI: 1.22-1.56). Cancer survivors also had greater odds of having had a flu shot than the general population (AOR 1.35, 95% CI: 1.23-1.49). Additionally, we found that male sex, lack of insurance or public insurance, and rural residence were associated with lower odds of having received either vaccine. **Conclusions:** In this US national adult sample, COVID-19 and flu vaccination uptakes were higher among cancer survivors than in the general population. Although this is encouraging, vaccination rates, particularly with the flu vaccine, remain below the 70% Healthy People 2030 goal. To achieve this goal, tailored interventions and policies are necessary to improve vaccine uptake and socioeconomic disparities across cancer survivors and the general population.Future research can explore how the receipt of the vaccines impact the quality of life and health outcomes of the growing population of cancer survivors. The implications of using truncated Medicare definitions of avoidable hospital visits. First Author: Pranathi Pilla, UT Southwestern Medical Center, Dallas, TX

Background: As part of the Outpatient Quality Reporting program, Medicare reports on potentially avoidable, acute hospital visits after chemotherapy, using only fee-for-service (FFS) claims. This measure aggregates emergency department visits, observations, and inpatient admissions for 10 avoidable conditions (e.g. pain, vomiting), within 30 days of a chemotherapy infusion and is known as the OP-35 measure. The literature largely applies the diagnosis codes without reference to chemotherapy: it can be impractical to apply clinic-level changes only to Medicare FFS enrollees, and large, nationally-representative, hospital visit datasets do not contain chemotherapy infusion dates. There has been little scrutiny of the implications of using such truncations of this policy tool. **Methods:** We used a population-based cohort of incident cancers (2015-2023) from two sites: an academic medical center and safety-net health system, identifiably linking patients to their comprehensive hospital use from a regional health information exchange (all non-federal hospitals within a 150-mile radius of Dallas, TX). We tracked the changes in avoidable hospital visits for each measure specification: using diagnosis codes alone; narrowing to within 30 days of chemotherapy; counting only the first visit in a 30-day span; narrowing to Medicare FFS. We used mixed-effects (clustered to patient) multivariate logit to model avoidable visits occurring within or outside of a chemotherapy 30-day window; and avoidable vs. non-avoidable hospital visits across payors, adjusting for clinical and demographic variables. **Results:** We linked 31,305 incident cancer diagnoses (mean age 64; 50.6% female; 57.7% Black or Hispanic; 23.6% advanced stage cancer; 19.2% gastrointestinal cancer, 12.2% breast, 9.2% lung) to 190,967 visits across 76 hospitals. Although 28.0% (n= 54,233) had an avoidable diagnosis coded, only 24.3% (n=13,179) of them were within 30 days of chemotherapy. After excluding multiple visits in the 30-day span, 9.1% (4,917 of the 54,233 avoidable conditions visits) remained, with 14.0% (n=689, or 1.3% of 54,233) under Medicare FFS (1.6% Medicare Advantage, 30.2% commercial, and 54.4% uninsured/Medicaid). In adjusted analyses, avoidable conditions were significantly more likely to occur within 30 days of chemotherapy than outside of it (aOR 1.34, 95% CI: 1.27-1.40, $p < 0.001$); and compared to Medicare FFS, commercially-insured encounters had higher odds of avoidable hospital visit (aOR 1.31, 95% CI: 1.12–1.50, $p < 0.001$). **Conclusions:** Three-quarters of hospital visits for avoidable conditions occurred outside of a 30-day span after chemotherapy, though in adjusted analysis, avoidable visits were more likely to occur after chemotherapy. As little as 1.3% of visits for avoidable conditions were captured by the Medicare definition. Further investigation of the best uses of this measure is warranted. United States treatment pattern response to carboplatin and cisplatin shortages. First Author: John Kent Lin, Department of Health Services Research, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: In response to cisplatin (2/10/23) and carboplatin (4/28/23) shortages, national guidelines recommended prioritizing cisplatin and carboplatin for their most important indications to preserve availability while maximizing survival outcomes. We examined the real-world response to recent platinum shortages in lung cancers (LC), for which guidelines recommended preserving platinum chemotherapies when non-metastatic versus allowing substitution to immunotherapy monotherapy when metastatic. **Methods:** Using IQVIA PharMetrics data (9/1/22-10/31/23), we developed claims algorithms to identify intravenous anticancer therapy infusion claims for patients with incident non-metastatic vs. metastatic LC, which we validated against SEER-Medicare. Our outcomes were the fraction of infusions containing either (1) cisplatin, (2) carboplatin, or (3) immunotherapy (IO) without platinum. We performed an interrupted time series (ITS) analysis, using a linear probability model with three time-periods: pre-platinum shortage (9/1/22-1/31/23), post-cisplatin shortage (2/1/23-4/30/23), and post-carboplatin shortage (5/1/23-10/31/23), adjusting for age, gender, region, and comorbidities. **Results:** There were 11,983 infusions (2,411 patients) and 1,650 infusions (428 patients) for incident non-metastatic and metastatic LC, respectively. For non-metastatic LC, between 2/2023 (cisplatin shortage) and 04/2023 (carboplatin shortage), cisplatin use declined by 1.7 percentage point (pp) per month (p=0.03) and a non-significant 1.6 pp monthly increase in carboplatin usage (p=0.24). After carboplatin shortage, there was an immediate 4.5 pp drop in use of carboplatin (p=0.04), as well as an immediate 5.8 pp increase in use of cisplatin ($p<0.0001$). Overall platinum use (receipt of either cisplatin or carboplatin) throughout this entire period did not have any significant change. For metastatic LC, cisplatin was rarely used, so results after the cisplatin shortage were not assessed. After carboplatin shortage, there was a 15.7 pp immediate decline in use of carboplatin (p=0.002), with a concomitant 18.4 pp immediate increase in use of IO without platinum ($p<0.001$). **Conclusions:** The real-world response to platinum shortages in LC appeared to follow guidelines. For non-metastatic LC, for which platinum chemotherapy increases cure rates, declines during either the cisplatin or carboplatin shortages were equally balanced with increases in the other platinum chemotherapy, such that overall platinum chemotherapy usage remain stable. For metastatic LC, declines in carboplatin were balanced with increases in immunotherapy monotherapy. Research Sponsor: None.

Medicare plan switching, hospice enrollment, and place of hospice services at the end-of-life among decedent patients diagnosed with distant stage cancers in 2010-2019. First Author: Xin Hu, Emory University School of Medicine, Atlanta, GA

Background: Prior studies showed higher hospice utilization among Medicare Advantages (MA) than among Traditional Medicare (TM) beneficiaries. With more beneficiaries enrolling in MA and switching between TM and MA in recent years, this study examines hospice utilization patterns and associated factors among patients with advanced cancers enrolled in continuous TM, continuous MA, or switching between these plans. **Methods:** We identified Medicare beneficiaries aged ≥66 years diagnosed with distant-stage breast, colorectal, lung, pancreatic, or prostate cancers in 2010-2019 and followed through 2020 from SEER-Medicare data. Patients surviving ≥3 months post-diagnosis were categorized by plan-switching patterns: continuous TM, continuous MA, switching from TM-to-MA, and from MA-to-TM. Outcomes included hospice enrollment in the last year of life, within 14 days of death, and site of last hospice service (e.g., home, nursing home, hospice facility, inpatient facility, or other). Multivariable regression models estimated associations of plan-switching patterns and patient characteristics with study outcomes. **Results:** Among a total of 196,568 patients with advanced cancers, plan switching was relatively infrequent, with 1.5% switching from TM-to-MA and 1.8% from MA-to-TM. Beneficiaries who switched plans were more likely to be racial or ethnic minorities and dual-eligible than those with continuous coverage. Hospice enrollment in the last year of life was highest for continuous MA (74.8%), followed by TM-to-MA (69.0%), continuous TM (68.5%), and MA-to-TM (66.4%). Enrollment within 14 days of death was similar across groups. The last hospice service was received at home by 49% of beneficiaries, followed by 7.6% at hospice facilities, 6.7% at nursing homes, and 5.3% at inpatient facility. Compared to continuous TM, continuous MA and TM-to-MA switching beneficiaries had higher likelihoods of receiving last hospice service at home (6.2 ppts and 3.0 ppts respectively, p-values$<.01$), while MA-to-TM beneficiaries had higher likelihoods of receiving last hospice service at nursing homes (1.7 ppts, $p<.001$). Beneficiaries who gained dual eligibility had increased likelihood of receiving last hospice service at nursing homes (25.8 ppts, $p<.001$) and decreased likelihood of receiving last hospice service at home (-23.5 ppts, $p<.001$) than non-dual-eligible beneficiaries. **Conclusions:** Continuous MA coverage was associated with greater likelihood of hospice utilization, particularly at home. In contrast, switching from MA-to-TM and gaining dual eligibility were associated with greater reliance on nursing homes for hospice care. Future research examining patient-centered outcomes across plan-switching patterns and addressing care coordination gaps to ensure equitable hospice care are warranted. Research Sponsor: None.

Disparate recovery of cancer screenings by demographic in traditional Medicare post-pandemic. First Author: T. Anders Olsen, Beth Israel Deaconess Medical Center, Boston, MA

Background: Cancer screenings are a pillar of public health and early diagnosis of cancer (doi.org/10.1016/j.soncn.2017.02.002) The COVID 19 pandemic impacted access to outpatient services, such as cancer screenings (doi:10.1001/jamaoncol.2022.5481) Our study aims to assess how this impact and the recovery following the 2020 pandemic differed by race and ethnicity in Traditional or Fee-For-Service Medicare (TM). **Methods:** Claims data on a 5% sample of TM included 1.3 million beneficiaries eligible for colorectal (CRC) cancer screenings and 736,000 females eligible for breast cancer (BC) screenings. This sample was followed for a multi-year cross sectional analysis using Medicare Beneficiary Summary Files from 2017 to 2023. Claims were linked to Current Procedural Terminology (CPT) and Healthcare Common Procedure Coding System (HCPCS) codes to monitor annual utilization rates of screenings by demographic for BC and CRC. Utilization proportions were estimated based on the eligible population categorized by race/ethnicity and sex for BC. **Results:** Overall, screenings decreased in 2020 during the first year of the pandemic. BC screenings recovered quickly to pre-pandemic levels, comparing the 2019 pre-pandemic (35%) to 2021 post-pandemic (35%) rates overall in our TM sample. This was mirrored for women of non-Hispanic white (pre/post 36%), African American (pre: 33% post: 33%) and Asian/Pacific Islander (API; pre/post: 27%) groups in TM. These demographics nearly returned to 2019 rates by the 2nd year of the pandemic in 2021. American Indian/Alaska Natives (AIAN; pre: 22% post: 21%) and Hispanic women (pre: 27% post: 25%), however, did not return to pre-pandemic rates until 2022 and 2023 respectively. AIAN and Hispanic women also had the lowest utilization of BC screenings throughout our study period. CRC screenings had a slower recovery below 2019 levels (13%) in 2021 (12%), but recovering by 2023 (13%). This was mirrored across most racial demographics with the slowest recovery amongst AIAN (pre: 8%, post: 7%) and Hispanic (pre: 13%, post: 11%) beneficiaries. AIAN and African American beneficiaries displayed the lowest rates of CRC screenings throughout our study. **Conclusions:** Past research displayed decreased cancer screenings at the outset of the pandemic in 2020.[2,3] While services generally rebounded by 2021, the rate of recovery differed not only by screening type but also by demographic. BC screenings returned overall to 2019 rates by 2021. Hispanic and AIAN women lagged in recovery and utilized the lowest rates of BC screenings annually relative to the average TM beneficiary. CRC screening utilization saw a slower recovery, narrowly meeting 2019 levels by 2023. The lowest rates of CRC screenings were noted amongst African American and AIAN beneficiaries, who also struggled to recover to pre-pandemic (2019) levels by 2023. Our data highlights the disparate effects of the pandemic, especially for CRC screenings and certain racial demographics. Research Sponsor: Department of Health and Human Services.

Workforce, economic, and infrastructural barriers to global oncology clinical trial participation: Focus on sub-Saharan Africa. First Author: Oyepeju Folashade Abioye, Allegheny Health Network, Pittsburgh, PA

Background: Despite Sub-Saharan Africa's (SSA) growing cancer burden, the region remains grossly underrepresented in global oncology clinical trials. With only 109 open trials identified continent-wide in 2019 compared to 7,557 in the United States, this disparity highlights systemic barriers. As well, the unique genetic variations in the African pan-genome makes a strong case for urgent population-specific research. **Methods:** Using the Pan African Clinical Trial Registry, we identified 151 oncology trials across 255 continent-wide recruitment sites. A review of published literature was carried out to assess oncologist distribution and SDI index within highlighted countries hosting clinical trials in SSA. **Results:** Of the 1,759 clinical oncologists identified in SSA, Egypt accounts for 85.2% (n=1,500) and hosts 46.36% of all oncology trials (n=70). Kenya, with only 0.34% oncologists (n=6), contributes 17.88% of clinical trials (n=27). Nigeria, with 3.63% oncologists (n=64), hosts 11.26% of trials (n=17). Ethiopia and Tanzania each house 0.34% oncologists (n=6), yet Ethiopia conducts 7.95% (n=12) and Tanzania 3.97% (n=6) of trials. South Africa, with 2.27% oncologists (n=40), hosts 3.97% of trials (n=6). Other countries, including Ghana and Morocco, collectively contribute to 8.61% of trials (n=13) with varying oncologist representation. The few available trials are mostly concentrated in Egypt, Kenya, and Nigeria. In addition, most trials disproportionately focus on breast and cervical cancer, with the added challenge of limited oncologist distribution. Infrastructure deficits, financial constraints, and cultural barriers further impede trial initiation and participation. **Conclusions:** Access to clinical trials remains a pillar of high-quality cancer care. Oncology research in SSA is hindered by multifaceted barriers, limiting the development of effective, region-specific therapies. Strategies to address these barriers include investing in the training of healthcare professionals, providing adequate infrastructure, increasing funding through public-private partnerships, and enhancing community engagement to build trust and improve trial participation. Research Sponsor: None.

Financial toxicity for cancer patients: Out-of-pocket costs by cancer diagnosis in traditional Medicare. First Author: T. Anders Olsen, Beth Israel Deaconess Medical Center, Boston, MA

Background: Financial toxicity is defined as the fiscal issues that can arise in a patient's life related to the costs of medical care (DOI: 10.1093/tbm/ibab091). These can include financial distress, resource rationing and even medical debt. A patient's spending obligation is measured through out-of-pocket costs (OOP) which are comprised of copayments, co-insurance and/or deductibles (DOI: 10.18553/jmcp.2022.21270). Cancer patients face especially high costs and potentially greater risk of financial distress compared to other illnesses (DOI: 10.1093/tbm/ibab091). An American Cancer Society survey of 1,218 cancer patients/survivors found that over half (51%) of respondents reported medical debt resulting from cancer treatment despite nearly all (98%) having active insurance (https://www.fightcancer.org/policy-resources/costs-cancer-survivorship-2022). Our study aims to qualify and quantify the cancers with the highest out-of-pocket costs for beneficiaries in Traditional, or Fee-for-service, Medicare (TM) to determine cancers that expose patients to the highest financial risk. **Methods:** A 5% sample of TM beneficiaries in 2023 was collected, which included 1.3 million individuals and 261,099 unique beneficiaries with some form of cancer. Beneficiary claims were categorized by International Classification of Disease (ICD-10) coded cancer diagnoses. Patient OOP costs were aggregated across inpatient, outpatient and prescription drug settings using Medicare Beneficiary Summary File (MBSF) and Prescription Drug Event (PDE) claims data across Parts A, B and D Medicare, respectively. Costs per beneficiary were sorted by highest average out-of-pocket cost per beneficiary organized by cancer diagnosis. Comparison groups in our sample included a cohort of TM beneficiaries with any type of cancer and beneficiaries without cancer. **Results:** The 5 cancers with the highest average out-of-pocket costs annually in 2023 were multiple myeloma ($14,400), acute leukemia ($10,498), biliary cancers ($9,725), hepatocellular carcinoma ($9,469) and pulmonary (small and non-small-cell) cancers ($8,572). This is relative to TM beneficiaries with any cancer who spent an average of $4,800 annually OOP in 2023 and $2,364 for beneficiaries without cancer in TM. Prescription drugs are a substantial component of OOP cost for certain cancers. For multiple myeloma and acute leukemia, 19.8% and 21.5% of OOP costs were attributable to prescriptions compared to 8.6%, 8.1% and 10.2% for biliary, hepatocellular and lung cancer, respectively. **Conclusions:** Cancer is expensive for Medicare patients in the United States. These OOP costs can pose severe affordability issues for TM beneficiaries, who had an average income of $36,000 annually in 2023 (https://www.kff.org/medicare/issue-brief/income-and-assets-of-medicare-beneficiaries-in-2023/). Within TM, patients with multiple myeloma, acute leukemia, biliary, hepatocellular and lung cancers experience especially high costs and have an elevated risk of financial toxicity. Multiple myeloma and acute leukemia notably have significantly higher prescription cost-sharing through Part D compared to high-cost solid tumors. Research Sponsor: Department of Health and Human Services.

11093 Poster Session

Climate change and cancer: An ecological evaluation of climate risks for cancer survivors. First Author: Joseph M. Unger, Fred Hutchinson Cancer Center, Seattle, WA

Background: Changes in climate patterns will influence the frequency and severity of extreme weather events, leading to increased disasters (e.g., floods, fires), air pollution levels, and climate-related costs. Cancer survivors may suffer disproportionate effects of climate change-related events on mental health, care disruptions, morbidity, and mortality, yet evaluations of area-level climate risks and cancer survivorship are lacking. We examined future climate change risks faced by communities with high levels of cancer mortality. **Methods:** Data were from the Climate Vulnerability Index, a county-level measure of future climate change risks (45 variables) alongside a baseline vulnerability index (BVI) including health, socioeconomic, and environmental factors (139 variables). Variables ranging from 0 (least vulnerable) to 100 (most vulnerable) were split into high (rank $\geq$50) vs. low (rank $<$50) categories and linked to county-level cancer mortality data from the NCI's SEER registry. We compared the top quartile of the U.S. population living in counties with the highest cancer mortality rates (54.7% of counties) to other areas. Data were randomly split using a 2:1 training/validation ratio. We identified candidate variables in bivariate analyses between climate risk factors (RFs) and area-level cancer mortality. Best-subset selection with logistic regression and K-fold cross-validation was used to derive a parsimonious model of adverse RFs. These were summed, creating a score, and split at the median to test in the validation set. All analyses were adjusted for the BVI. **Results:** Overall, N=3,139 counties were examined. In the training set (n=2,094), a model with 6 RFs was identified including weather-related events (increased hurricane, tornado, and precipitation exposure), air pollution factors (increased ozone/CO2 levels), increased climate-related costs, and future economic/productivity losses. Compared to low cancer mortality counties, high cancer mortality counties were more than threefold more likely to have high exposure to the 6 climate RFs (69.6% vs. 30.4% with 3-5 factors; OR=3.07, 95% CI, 2.52-3.74, p$<$.0001). In the test set (n=1,045), results were similar, validating the model. Overall, the BVI-adjusted model C-statistic was 0.80 (unadjusted, 0.73). The association of high cancer mortality areas and high exposure to climate RFs was evident for both high (OR=3.87, p$<$.0001) and low (OR=2.75, p$<$.0001) BVI counties. **Conclusions:** In this first-of-its-kind ecologic association study, we found that living in counties with high cancer mortality was associated with future climate change risks including extreme weather events, air pollution, climate-related costs, and economic factors. Future work is needed to identify potential mechanisms between climate events and worse cancer outcomes such as decreased treatment tolerability, treatment quality, or treatment access. Research Sponsor: None.

11094 Poster Session

Preliminary efficacy of VOICE, a decision support tool for older adults with advanced cancer: A pilot randomized trial. First Author: Amy C. Cole, The University of North Carolina at Chapel Hill, Chapel Hill, NC

Background: Quality shared decision-making (SDM) requires integrating patient values into treatment decisions. Many older patients (pts) with cancer report that clinicians do not elicit their values when making treatment decisions. We developed a decision support tool for older adults with advanced cancer (called VOICE) with values elicitation, real-time feedback to patients, and tailored question prompt lists. Prior research suggests that variation in clinician behavior may impact the efficacy of SDM tools. **Methods:** We evaluated the preliminary efficacy of VOICE to improve SDM quality in a pilot double-blinded randomized trial. We enrolled pts $\geq$ 60 years with advanced solid cancers. Pts were randomized to receive VOICE or an American Cancer Society (ACS) educational document with general cancer-related question prompts. Pts completed 2 simulated consultations where they made a treatment decision for a fictional secondary cancer diagnosis: one values-based (VB), where clinicians initiated values elicitation, and one non-values-based (NVB), where clinicians did not. Logistic regression, Fisher's exact and Mann-Whitney tests evaluated the relationship of trial arm and clinician behavior to pt reports of SDM quality (CollaboRATE) and perceived usefulness of intervention (PrepDM). Five medical students, trained in VB and NVB consultations, functioned as clinicians during consultations. All consultations were recorded and analyzed for fidelity. **Results:** Forty-four pts (ages 60-88; 50% female; 86% Caucasian, 7% Black, 7% other) with advanced cancer (34% prostate, 23% breast, 18% lung, 11% melanoma, 14% other) were randomized and completed 88 consultations. Pts were more likely to report quality SDM for VB over NVB consultations (Odds ratio [OR] 2.57, 95% Confidence Interval [CI] 1.09-6.25, p=0.03). Pts reported VOICE was more useful to inform SDM than ACS document (mean PrepDM score 65.1 v. 17.4, p$<$0.001). Pts in the VOICE arm were more likely to report quality SDM (OR 1.70, 95% CI 0.73-4.04) but this did not reach statistical significance (p=0.22). The difference in the percentage of patients reporting high-quality SDM between arms was larger for NVB (43% VOICE v. 22% ACS) than for VB consultations (57% VOICE v. 52% ACS) though not statistically significant. **Conclusions:** This study demonstrates the value of using simulated encounters for "early-phase" testing of SDM tools. In this pilot randomized trial using simulated clinical encounters, clinician initiation of a discussion of patient values resulted in the highest quality of SDM regardless of study arm. VOICE improved preparation for SDM and showed encouraging preliminary data for its potential to improve the quality of SDM for older adults with advanced cancer especially when clinicians did not engage in values elicitation. Further research is needed to improve values elicitation as part of treatment decision-making. Research Sponsor: National Cancer Institute/U.S. National Institutes of Health; 1K08CA273684.

The studies industry neglects: Characteristics of cancer clinical trials conducted by federal versus industry sponsors. First Author: Joseph M. Unger, SWOG Statistics and Data Management Center, Fred Hutchinson Cancer Center, Seattle, WA

Background: A defining feature of federally sponsored cancer clinical trials is their mandate to examine clinical research questions not routinely addressed by industry, which is financially incentivized to conduct trials that support new drug applications to the FDA. Yet no evaluation has quantified the types of trials federal versus industry sponsors conduct. These data are vital for policymakers given the need to prioritize federally sponsored trials in a clinical research landscape increasingly dominated by industry sponsorship. **Methods:** We analyzed registry data from ClinicalTrials.gov between 2008-2022. U.S.-based interventional trials for patients with cancer were included. Studies were categorized by lead sponsor (federal versus industry) and by purpose, phase, intervention, de-escalation, rare cancer, and age. Odds ratios were calculated. Chi-square tests were used. **Results:** Overall, N=9,626 federal (n=1498, 15.6%) and industry (n=8128, 84.4%) sponsored studies were examined. Most studies were conducted for treatment (federal, 92.8%; industry, 97.5%). Federally sponsored studies were more commonly prevention (5.3% vs 1.2%, OR=4.69, p$<$.001), screening (1.0% vs 0.4%, OR=2.73, p=.003), and early phase (91.6% vs 81.6%, OR=1.77, p$<$.001) studies (Table). Federally sponsored studies were more commonly multi-modality studies combining drug and biologic agents (24.3% vs. 7.4%, OR=3.28, p$<$.001) or systemic therapy with radiation or surgery. Federally sponsored studies also more commonly tested dose de-escalation strategies (1.5% vs 0.6%, OR=2.68, p$<$.001) and were more often conducted in rare cancers and in children. **Conclusions:** Nontreatment interventions, early phase, multi-modality, dose de-escalation, rare cancer, and child-focused studies were much more likely to be conducted by federally sponsored research groups than by industry. These findings highlight the unique role of federally funded studies in cancer clinical research. Research Sponsor: The Hope Foundation.

Early examination of national changes in potentially avoidable hospital visits after chemotherapy, 2018–2022. First Author: Pranathi Pilla, UT Southwestern Medical Center, Dallas, TX

Background: Medicare tallies potentially avoidable hospital visits after chemotherapy and has been publicly reporting this quality measure since 2018. The measure reports absolute visit rates for emergency department (ED) and inpatient admission (ADM), and generates relative comparisons to national rates ("better than", "no different than", "worse than"). We sought to identify changes in avoidable hospital visit rates through 2022. **Methods:** Retrospective analysis of avoidable hospital visit rates from 2018 – 2022, from a longitudinal cohort of hospitals in the Medicare Outpatient Quality Reporting Program. We performed descriptive and trend analysis for absolute visit rates and for relative performance. We stratified hospitals into quartiles of absolute performance in 2018, then applied multivariate generalized linear regression to model change in visit rates by 2022. We estimated the contribution of regression to the mean. **Results:** We analyzed 1,179 hospitals (23% teaching). National avoidable ED visit rates were 6.0% in 2018, 5.4% in 2022; ADM rates were 12.5% in 2018, 10.3% in 2022. Nearly all hospitals were deemed to have performed "no different" than the national rate each year for ED ($\geq$ 95.3%) and ADM ($\geq$ 91.1%). In adjusted analyses, visit rates for hospitals in the lowest 2018 visit rate quartiles declined the least by 2022 (ED: -0.44% 95% CI: -0.58 to -2.94; ADM: -0.91%, 95% CI: -1.14 to -0.69), but declined the most for hospitals in the highest 2018 quartiles (ED: -1.72%, 95% CI: -1.85 to -7.73; ADM: -3.03%, 95% CI: - 3.27 to -2.81). We estimated that regression to the mean accounted for a small proportion of the decline among the highest 2018 quartile of hospitals (ED: 10.6% of rate change, 95% CI: 9.8 to 11.5; ADM: 9.0%, 95% CI: 8.2 to 9.8). **Conclusions:** It appeared that nationally, and within quartiles of hospital performance, hospitals had improved their performance on this outpatient chemotherapy quality measure. Regression to the mean accounted for only a small proportion of this change, but the decline may reflect overall lower hospital visits post-COVID19 pandemic. Research Sponsor: U.S. National Institutes of Health; CA282242.

Impact of social determinants of health on mortality in diffuse large B-cell lymphoma (DLBCL) using real-world data. First Author: Maureen Canavan, Yale School of Medicine, New Haven, CT

Background: Treatment advances in DLBCL have led to remarkable improvements in patient outcomes. Social determinants of health (SDOH) can contribute to inequities in outcomes in multiple cancer types, and there is a paucity of studies evaluating their impact in DLBCL. **Methods:** We used the nationwide Flatiron Health electronic health record derived de-identified database and included adults with a confirmed diagnosis of DLBCL from 2011-2024 to evaluate the association between SDOH and real-world overall survival (from time of initial treatment). Area-level SDOH variables were derived from the Census Bureau's American Community Survey and the 2019 AHRQ's SDOH database. These census tract level measures were grouped into US population-weighted quartiles and evaluated across the following domains: economic, social (including racial segregation), neighborhood & physical environment, and healthcare. We estimated adjusted hazard ratios (aHR) for the highest social deprivation quartile (least resourced areas) compared to the lowest quartile using Cox proportional hazard models, adjusting for age, sex, race/ethnicity, LDH, ECOG, presence of extranodal disease, stage, and cell of origin. **Results:** We included 6,855 patients in the analysis. After adjustment, residence in areas with the highest social deprivation was consistently associated with increased mortality across all SDOH domains compared with the lowest deprivation areas. A higher risk of death ($>$ 20%) was found for patients residing in predominantly Black vs. White neighborhoods, those residing in medically underserved areas, and areas with the lowest levels of private insurance. Similarly, residence in areas with the least access to the internet, computing devices, and cellular data plans was associated with increased mortality risk. **Conclusions:** Higher SDOH deprivation was significantly associated with increased mortality among patients with DLBCL, despite controlling for demographic and clinical factors. The SDOH influencing mortality ranged from socioeconomic and technological inequities to limited healthcare access and racial segregation. These factors may aid improved prognostication of DLBCL, and future studies should focus on developing interventions to mitigate SDOH-linked inequities in DLBCL. Research Sponsor: None.

	aHR	95% CI	Domain

Integration of a virtual personalized medicine review board integration into a major community oncology phase 1 unit. First Author: Marilyn Elaine Hammer, Sarah Cannon Research Institute, Nashville, TN

Background: Inclusion criteria for participating in oncology clinical trials have grown more complex, often challenging the enrollment process. Our objective was to improve the process of identifying and enrolling patients by incorporating personalized medicine assistance into the initial patient intake and trial selection procedure at a major community-based phase 1 oncology unit. **Methods:** A virtual personalized medicine review board (vPMRB) comprised of two PhD scientists reviewed patients for suitable trial options based on molecular sequencing results and scientific rationale during the intake and screening processes at a phase I oncology clinic. vPMRB reviews leveraged a propriety clinical trial identification software, Genospace, to generate patient-trial matches based on general inclusion/exclusion criteria including disease, histology, staging, and biomarker criteria. Trial options were returned via email and added to patients' charts in the electronic health record for reference by their clinical care team. Trial candidates were screened for trial options and consented for treatment on trial by the enrollment nursing (ERN) team. Data pertaining to vPMRB review, trial screening, trial consent, and trial enrollment were collected by the vPMRB and ERN teams and combined to determine consent and enrollment rates. **Results:** Between 1/1/2024 and 12/31/2024, 953 patient reviews for 815 unique patients were completed by the vPMRB with an average turnaround time of 4 $\pm$ 5 business hours. 900 (94%) of these reviews included potential trial options for the patient. Of 790 reviewed patients with sufficient information for comparison with enrollment team data, 473 (60%) were screened for trial options by the ERN team in 2024. Of these, 343 (73%) consented to a trial and 270 (57%) started trial treatment in 2024. Comparatively, of the 744 patients reviewed for trial options by the ERN team, but not the vPMRB, 431 (58%) were consented to a trial and 313 (42%) started trial treatment in 2024. 167 (35%) patients consented to a trial and 130 (28%) patients started a trial recommended by the vPMRB for that patient in 2024. **Conclusions:** vPMRB review was associated with increased trial enrollment compared to patients without vPMRB review. Upcoming research will explore the effects of further personalized medicine integration techniques, including the involvement of team members in therapeutic strategy meetings held by clinical care teams, along with the use and effectiveness of clinical trial matching software in a phase 1 unit. Research Sponsor: None.

Trial consenting and screening rates in 2024 for patients with and without vPMRB review.

	vPMRB Review	No vPMRB Review
Patients screened for trial by enrollment team	473	744
Consented on Trial	343 (73%)	431 (58%)
Started Trial	270 (57%)	313 (42%)
Consented on trial surfaced in vPMB review	167 (35%)	N/A
Started on trial surfaced in vPMB review	130 (28%)	N/A

Temporal trends in opioid prescription fills following cancer-directed surgery. First Author: Andrea Catherine Enzinger, Dana-Farber Cancer Institute, Boston, MA

Background: Postoperative pain is a common complication of cancer surgery. Opioid prescribing has declined dramatically since the early 2010's; however, little is known about trends in opioid prescribing following cancer-directed surgeries. **Methods:** Using administrative data for 100% Medicare fee-for-service beneficiaries enrolled in parts A, B, and D, we identified initial episodes of cancer-directed surgeries from 2012-2021 among adults who survived $>$ 30d after surgery and were discharged home. We used Part D claims to identify early postop opioid fills, defined as prescriptions filled in the 30d after surgery for outpatient surgeries, and in the 30d following hospital discharge for inpatient surgeries. We described opioid fills, median dose, pill counts, and the proportion with subsequent fills overall and annually. **Results:** We identified 981,702 episodes of cancer directed surgeries, most often for breast (38%), colorectal (15%), prostate (13%), and lung (10%) cancers. Patients' mean age was 73(SD,8), 36% were male, 83% White, 8% Black, 4% Hispanic, and 2% Asian. Overall, 66.6% of patient episodes had $\geq$1 postoperative opioid fill, declining from 70.7% in 2012 to 59.3% in 2021. Among episodes with $\geq$1 opioid fill, the median dose of the first opioid fill declined from 225 (IQR:150,300) morphine milligram equivalents (MMEs) to 100 (IQR:75,150) MMEs between 2012-2021, and the total dose of all fills in 30d fell from 250 (IQR: 150,450) MMEs to 112.5 (IQR:75,210) MMEs. Median pill counts for the first short-acting opioid fill declined from 30(IQR:30,40) to 18(IQR:10,25) over the study. Among episodes with $\geq$1 short-acting opioid fill, the proportion with subsequent short-acting opioid fills declined from 30.7% to 17.8%. **Conclusions:** Medicare beneficiaries undergoing cancer-directed surgeries have experienced steep declines in prescription opioid medication fills in the postoperative period. Future work is needed to understand potential impacts of declining postoperative opioid prescribing on outcomes such as uncontrolled pain, pain-related emergency department visits, persistent opioid use, and development of opioid use disorders. Support: R01CA279414. Research Sponsor: None.

Integrative oncology interest in persons with a cancer diagnosis. First Author: Julia Witkowski, Thomas Jefferson University, Philadelphia, PA

Background: Integrative oncology (IO) is an evidence-informed field of cancer care that utilizes mind-body practices, natural products, and lifestyle medicine from different traditions alongside conventional therapies. With growing evidence of benefit and inclusion in guideline recommendations, the Sidney Kimmel Comprehensive Cancer Center (SKCCC) at Thomas Jefferson University's integrative oncology program assessed patients' understanding of integrative health, their utilization of integrative medicine approaches, and interest in formal IO consultations. **Methods:** Persons with a history of cancer who presented for care at a SKCCC clinical site received an electronic record invitation to complete a brief survey with binary and free-response questions regarding current knowledge, experiences, and interest in IO. At the end of the survey, patients also had the option to express their interest in IO consultations at SKCCC. **Results:** Demographics for the 1681 responders were: 1116 (67.1%) were female; 1285 (76.4%) were between 45-75 years of age; 313 identified as Black or African American (19.0%) and 1276 as White (77.5%). Breast cancer (494, 29.37%) and hematologic cancers (289, 17.18%) were the most reported malignancies. Overall, 446 (27.4%) and 153 (9.3%) had previously utilized in-person IO services and virtual IO services, respectively. 1,133 (67.36%) reported that IO was never discussed during their care. 1201 (73.9%) expressed interest in an IO consultation. Black or African American participants had 117% higher odds of expressing an interest in IO consultation (OR: 2.17, 95% CI: 1.52 – 3.09, $p<0.001$) compared to all other participants. **Conclusions:** In contrast to the prevalence of IO approaches in literature, only one third of patients who completed the survey had previously used an IO modality. However, nearly 70% expressed interest in a formal IO consultation. Due to the overwhelming interest, an IO information session hosted by a Board-Certified Medical Oncologist and Integrative Oncologist is being offered. 250 (14.9%) participants have requested appointments so far. With the increasing evidence of benefit for IO care and the inclusion of these recommendations in clinical guidelines, expansion of IO services, especially those which focus on Black or African American participants who are usually not reached by these interventions, is indicated. IO consultations can address knowledge gaps, enhance implementation of guideline-based care, and, perhaps, improve clinical outcomes. Research Sponsor: None.

Utilization and timeliness of next-generation sequencing testing for patients with resected or metastatic non-small cell lung cancer: A real-world analysis. First Author: Raheem Bell, Northwestern University Feinberg School of Medicine, Chicago, IL

Background: Comprehensive next-generation sequencing (NGS) is an evidence-based molecular testing modality used to identify actionable oncogenic drivers in tumor tissue, guiding therapy selection and improving survival in early-stage and metastatic non-small cell lung cancer (NSCLC). However, uptake of NGS in oncology practices varies. This study aimed to identify hospital-level variation in NGS testing adoption within a statewide quality improvement collaborative. **Methods:** We conducted a cross-sectional analysis of patients with clinical Stage IB-IIIA NSCLC who underwent surgical resection and clinical Stage IV NSCLC sampled in 2023 across 10 academic, community, and integrated network hospitals in a statewide cancer quality improvement collaborative. Rates of NGS testing and turnaround times between biopsy date, NGS order date, NGS result date, and first treatment time were analyzed. Subsets of patients treated at facilities with in-house molecular labs or reflex molecular testing protocols were described. Multivariable logistic regression identified demographic and clinical predictors of NGS use. In a subset of patients with EGFR or ALK mutations, we evaluated tyrosine kinase inhibitor (TKI) use across hospital sites. **Results:** Among 318 patients, 34.9% had clinical Stage IB-IIIA and 65.1% had clinical Stage IV lung adenocarcinoma. NGS testing was performed in 65.1% of patients, with rates ranging from 13.5% to 97.8% across sites. Facilities with in-house NGS capabilities had higher NGS rates (87.8%) compared to facilities relying on send-out testing (50.8%). Similarly, facilities with reflex molecular testing protocols demonstrated higher NGS rates (75.4%) compared to those without reflex protocols (50.4%). Among patients with EGFR or ALK mutations, 77.8% received TKI therapy, with rates ranging from 0% to 100%. Of 113 early-stage patients, 32 (28.3%) had NGS performed pre-resection, 36 (34.0%) post-resection, and 40 (37.7%) did not have NGS performed. Across all sites, the median time from biopsy to NGS order was 29 days (IQR 20–49), from order to results was 13 days (IQR 11–18), and from biopsy to treatment initiation was 42 days (IQR 31–58). Smoking status was an independent predictor of NGS use with OR 0.28 (0.13-0.61, p=0.002). **Conclusions:** Significant variation exists in NGS adoption across hospital sites in a statewide quality improvement collaborative. However, turnaround times were consistent across sites. These benchmarking data, combined with qualitative insights, can inform quality improvement interventions for underperforming sites. Research Sponsor: AstraZeneca Pharmaceuticals LP.

Health-related quality of life and financial toxicity among patients with gynecological cancers in southern Nigeria: A multicenter cross-sectional study. First Author: Chibuzor Franklin Ogamba, Nuffield Department of Population Health, University of Oxford, Oxford, United Kingdom

Background: Gynecological cancer-related morbidity and the financial burden of care impact the quality of life of patients. However, the health-related quality of life (HRQoL) and experience of financial toxicity (FT) of affected women in sub-Saharan Africa have not been sufficiently explored. This study assessed predictors of HRQoL and FT, and the effect of FT on HRQoL among women with gynecological cancers in Nigeria. **Methods:** This hospital-based cross-sectional study investigated consenting women with gynecological cancers receiving care at various stages at five academic hospital centers in southern Nigeria, between June 2022 and September 2024. The main outcomes were HRQoL and FT evaluated using the FACT-G and FACIT-COST tools, respectively. Patients' sociodemographic and clinical characteristics were additionally retrieved using a structured questionnaire. Multivariable linear regression models estimated the associations of patient and disease characteristics with HRQoL and FT, and the effect of FT on HRQoL, adjusting for potential confounders. Ethical approval was obtained from all centers. **Results:** Overall, 574 women were recruited with a mean FACT-G score of 58 (SD $\pm$ 15) and a median FACIT-COST score of 16. Of these, 92.8% experienced FT, with 42.6% having moderate-to-severe FT. After multivariable adjustments, HRQoL was significantly poorer among unemployed women (β = -2.4; 95%CI: -4.8, -0.02; p= .048), women with ovarian (β = -3.4; 95%CI: -6.4, -0.4; p= .028) and uterine cancers (β = -3.8; 95%CI: -7.0, -0.6; p= .021) and choriocarcinoma (β = -7.8; 95%CI: -15, -0.2; p= .045), and women with stages II (β = -4.6; 95%CI: -7.7, -1.6; p =.003), III (β = -5.5, 95%CI: -8.9, -2.2; p= .001), and IV disease (β = -4.6; 95%CI: -8.7, -0.4; p= .031). Conversely, patients in remission had significantly better HRQoL (β = 9.3; 95%CI: 5.0, 14; $p<$ .001). FT was worse with stages III (β = -2.2; 95%CI: -4.0, -0.4; p =.016) and IV disease (β = -5.4; 95%CI: -7.6, -3.2; $p<$.001), and in women on active treatment (β = -2.9; 95%CI: -4.4, -1.3; $p<$ .001). However, older women (β per 10-year increase in age = 0.6; 95%CI: 0.1, 1.1; p= .029), those with health insurance (β = 3.4; 95%CI: 1.4, 5.5; $p<$.001), higher income (β per 1000 Naira = 0.02; 95%CI: 0.01, 0.03; p= .004), ovarian cancer (β = 1.9; 95%CI: 0.3, 3.6; p= .021) and choriocarcinoma (β = 6.7; 95%CI: 2.6, 11; p= .001) had lower FT. FT scores varied linearly with HRQoL after adjustments, with better HRQoL per unit lower FT (β = 0.46; 95% CI: 0.3, 0.6; $p<$ .001). This effect was more pronounced in women with a first tumor (β = 0.53; 95% CI: 0.4, 0.7; $p<$.001), those in pre-treatment (β = 0.69; 95% CI: 0.4, 1.02; $p<$.001) and those in remission (β = 0.69; 95% CI: 0.04, 1.3; p =.037). **Conclusions:** Our findings identify possible predictors of HRQoL and FT, and suggest potential benefits of reducing FT on the HRQoL of women with gynecological cancers in Nigeria. Research Sponsor: None.

Patient preference for first-line treatments of ALK-positive metastatic non-small cell lung cancer: A discrete choice experiment. First Author: Baohui Han, Department of Respiratory and Critical Care Medicine, Chest Hospital Affiliated to Shanghai Jiao Tong University, Shanghai, China

Background: For patients with ALK-positive metastatic NSCLC, targeted therapy with ALK inhibitors is a recommended first-line treatment. The development and approval of ALK-TKIs have resulted in longer survival benefits for patients with ALK-positive mNSCLC. Three generations of ALK-TKIs are now available, varying in efficacy and side effects. Therefore, it is important to identify patients' priorities and the benefit-risk trade-offs patients are willing to make among potential treatment options. This study quantified the preferences of patients for attributes of ALK-positive mNSCLC first-line treatment. **Methods:** An online discrete choice experiment was conducted to elicit the preferences of Patients with ALK-positive mNSCLC and their family members (both decision-makers for the treatment). Respondents completed multiple hypothetical treatment profiles characterized by 7 attributes, including progression-free survival (PFS), reduced risk of brain metastasis, intracranial complete response (iCR), degree of cognitive side effects, risk of liver damage, risk of severe hyperlipidemia and the dose reduction rate. Data were analyzed using a conditional logit model and mixed logit model. **Results:** Respondents (N=115) placed most value on PFS (RI=58.13%), followed by reduced risk of brain metastasis (RI=13.04%). Attributes related to side effects were considered less critical in respondents' decision-making. Respondents exhibited a willingness to accept an increased risk of treatment for improved clinical outcomes. When the degree of side effects was altered from mild to moderate, respondents require a minimum increase of 5.34 months in PFS as compensation to maintain the same utility. Scenario analysis estimated 97.06% of respondents would endorse the new treatment option if the PFS was improved from 36 months to 60 months. Subgroup analysis revealed that the preference patterns of patients and their families are similar. However, respondents' preferences exhibit heterogeneity for patients with different brain metastasis status, age, and annually household income. **Conclusions:** This is currently the first patient preference study for First-Line Treatments of ALK-positive mNSCLC. The results revealed that patients' decision makers place the highest priority on PFS, with comparatively less emphasis on side effects, and they are willing to accept a higher risk of side effects in exchange for prolonged survival. Understanding these preferences can enhance shared decision-making between patients and clinicians, fostering personalized prophylactic treatment plans that may optimize adherence and improve clinical outcomes. Characterizing unmet supportive care needs in diverse adolescent and young adult cancer survivors. First Author: Akina Natori, University of Miami, Miami, FL

Background: Research addressing the supportive care needs of diverse adolescent and young adult (AYA) cancer survivors remains underdeveloped relative to younger and older cancer survivor populations. Given their distinct developmental, psychosocial, and healthcare challenges, it is critical to characterize the unmet supportive care needs (USCN) specific to AYAs. This study aimed to compare self-reported USCN between AYA and older (>39 years old) cancer survivors to identify age-specific gaps in care and opportunities to improve outcomes. **Methods:** Between October 2019 and October 2024, 20,520 cancer survivors (n=1,287 AYA and n=19,233 non-AYA) at Sylvester Comprehensive Cancer Center completed the *My Wellness Check* (MWC) questionnaire. *MWC* is fully integrated and scored in real-time in the electronic health record, and evaluates 16 domains of supportive care needs (e.g., stress management, financial concerns, informational resources, transportation) alongside patient-reported outcomes (PROs; PROMIS measures of pain interference, fatigue, physical function, anxiety, and depression) and health-related quality of life (HRQOL; FACT-G7). Sociodemographic and clinical characteristics and the prevalence of USCNs were compared between AYA and other cancer survivors using chi-square and t-tests. **Results:** The AYA group had a higher proportion of females (64% vs. 51%), non-White (20% vs. 14%), Hispanic (56% vs. 44%), uninsured (4% vs. 3%), and unpartnered individuals (59% vs. 34%) compared to non-AYAs (all $ps < 0.01$). Across both groups, the most frequently reported USCNs were general cancer education (11%), coping with a cancer diagnosis (11%), and financial concerns (9%). AYAs were more likely to report at least one USCN compared to non-AYA survivors (33% vs. 28%). AYAs were also more likely to endorse needs related to coping with a cancer diagnosis (14% vs. 11%), financial concerns (12% vs. 9%), work-related issues (6% vs. 3%), oncofertility (10% vs. 1%), and childcare (3% vs. 0.5%) (all $ps <$ 0.001). No significant differences were observed for other USCN, including transportation, housing, family problems, sexual health, spiritual concerns, access to medicines, and advance directives. **Conclusions:** While both AYA and non-AYA cancer survivors face substantial unmet supportive care needs, AYAs exhibit additional challenges, particularly in areas such as financial concerns, work-related issues, fertility preservation, and childcare. These findings align with prior research while uniquely emphasizing the unmet needs of a more ethnically diverse population. This study underscores the urgent need for targeted assessments and interventions to address the unique supportive care needs of AYA cancer survivors, ensuring equitable and age-appropriate survivorship care. Understanding psychosocial wellbeing and concern for death and dying: Insights from a psycho-oncology clinic. First Author: Shahrzad A. Zamani, Moffitt Cancer Center, Tampa, FL

Background: Patients with cancer face burden of mental health symptoms and an ongoing concern for death and dying. The psycho-oncology clinic aims to address these concerns by integrating mental health services into cancer care. This study evaluates key domains of psychosocial health and their relationship with mortality salience. **Methods:** Data from 60 patients treated at a psycho-oncology clinic were analyzed. Demographics, cancer site, disease stage (localized vs. metastatic), treatment status, and psychiatric diagnoses were collected. Outcomes were assessed using the Patient-Reported Outcomes Measurement Information System (PROMIS) Short Forms, including measures of Emotional Distress (Anxiety, Depression, Social Isolation), Meaning and Purpose, Psychosocial Illness Impact (Negative and Positive), and Concern for Death and Dying. Descriptive and univariate regression analyses explored cohort trends. **Results:** Among the 60 patients, the mean age was 63 years (SD=14.8), with 52.2% identifying as female, 45.5% as male, and 2.3% as non-binary. The most common primary cancer sites were lung (20.5%), breast (18.2%), and multiple myeloma (9.1%). Of the patients, 61.4% had localized disease, while 38.6% had metastatic disease. A significant proportion (79.6%) were undergoing active treatment. Calculated t-scores demonstrate that concern for death and dying was more than two standard deviations above the population mean while meaning and purpose was lower. Metastatic disease, higher levels of anxiety, depression, negative psychosocial illness impact, and a lower sense of meaning and purpose were all associated with greater concern for death and dying. **Conclusions:** This study highlights the high prevalence of concern for death and dying in patients who are referred to a psychosocial oncology clinic and its association with key psychological variables for which there are standard treatments. PROMIS measures offer valuable insights, underscoring the importance of comprehensive psychosocial assessments. Tailored interventions targeting emotional distress, meaning, and end-of-life concerns may improve patient outcomes. Research Sponsor: None.

Variables	Mean (SD)	Calculated t-score* [SE]	Regression	
Death & Dying Concern	25.2 (8.5)	71 [3.5]	95% CI	p-value
Age	63 (14.8)	-	(-0.1-0.22)	.48

Self-reported adherence to cancer therapy: Development and validation of a cancer-specific DOSE-Nonadherence measure. First Author: Yashasvini Sampathkumar, Memorial Sloan Kettering Cancer Center, New York, NY

Background: Patients with cancer take different types of medication (e.g., enteral, parenteral), with varying treatment schedules, in various settings. They are also sometimes instructed to stop medication in response to toxicity. To measure medication nonadherence in this heterogenous population, we modified and pilot-tested a self-report measure originally developed to assess nonadherence to daily oral medication, the Domains of Subjective Extent of Nonadherence (DOSE-Nonadherence), in adults with cancer. **Methods:** Participants were ≥21 years, on active cancer treatment at Memorial Sloan Kettering, and spoke English and/or Spanish. A branching logic was added to allow participants to select the setting where they take cancer medication: 1) only at home, 2) only in clinic, or 3) partly at home/partly in clinic. Based on administration setting, participants reported nonadherence to medications their clinician expected them to take over a given reference period (1 week for home and 1 month for clinic medications). Participants then reported on setting-relevant reasons for nonadherence. Survey instructions/items were refined in an iterative process using feedback from a patient investigator committee and participant cognitive interviews. During interviews, we asked participants about the interpretation of instructions/items, recall period, and comprehensiveness of reasons for nonadherence, regardless of their own adherence. After initial testing in English, a Spanish version was developed through transcreation. Adherence was dichotomized for analysis (complete adherence vs. any nonadherence). For all participants who received clinic medications, concordance between chart abstracted and self-reported adherence was evaluated. **Results:** Of 55 participants who completed the surveys and interviews (67% in English; 33% in Spanish), 87% were female and 44% identified as Latino. The majority (73%) had breast cancer; 60% had metastatic disease. 12 of 45 who received medication in clinic reported nonadherence as did 8 of 35 who took medication at home. Participants felt able to respond accurately to both recall periods. All reasons for nonadherence were perceived as relevant to themselves or other patients. There was 89% concordance between self-reported and chart abstracted adherence for clinic-administered medication. To improve concordance, changes were made to the formatting and instructions. Of 12 participants who completed the final version of the survey for clinic-administered medication, there was 100% concordance between self-reported and chart abstracted nonadherence. **Conclusions:** Our results support the reliability and validity of modified DOSE-Nonadherence for cancer patients. This instrument can be used to better identify nonadherence to cancer medications in a population of adult patients with cancer receiving various treatment regimens. Employer-sponsored insurance, paid sick leave, and financial toxicity among cancer survivors. First Author: Michael T. Halpern, University of Texas School of Public Health at San Antonio, San Antonio, TX

Background: Financial toxicity (FT), the adverse economic effects resulting from cancer, its treatment, and associated long-term effects, may affect the majority of cancer survivors. FT is associated with multiple factors including employment disruptions; however, the role of workplace policies in mitigating FT is poorly understood. We examined how employer-sponsored health insurance and paid sick leave influence FT among employed U.S. cancer survivors. **Methods:** We analyzed data from 1,122 employed cancer survivors aged 18-64 with non-missing insurance status and a self-reported history of cancer (diagnosed age 18 or older), representing a weighted total of almost 5 million survivors from the 2021/2022 National Health Interview Survey (NHIS), a nationally representative household survey of the civilian noninstitutionalized U.S. population. Multivariable logistic regression analyses examining associations of employer-sponsored health insurance and paid sick leave (separately) with FT items, controlling for sociodemographic characteristics and cancer type, were conducted using PROC SURVEYLOGISITC in SAS 9.4 adjusting for the complex survey design of the NHIS. **Results:** Compared with cancer survivors who had employer-sponsored health insurance (n = 842, weighted 76.6%), those without employer-sponsored insurance were significantly ($p < 0.05$) more likely to experience FT, including worrying about paying medical bills (odds ratio [OR] 1.7, 95% confidence interval [CI] 1.2-2.4), skipping/delaying medical care due to costs (OR 2.4, 95% CI 1.5-3.9), and delaying counseling/therapy due to costs (OR 2.5, 95% CI 1.3-4.6). These associations persisted when restricting the sample to survivors with private insurance only. Similarly, compared to survivors with paid sick leave (n = 807, weighted 72.0%), those without paid sick leave were significantly more likely to worry about paying medical bills (OR 1.4, 95% CI 1.1-1.9) and skip/delay medical care due to costs (OR 2.2, 95% CI 1.4-3.4), with consistent findings in the private insurance only subgroup. Having employer-sponsored insurance and paid sick leave were also associated with decreased food insecurity. **Conclusions:** Workplace policies can mitigate FT and food insecurity among cancer survivors. Employers should consider offering benefits that support health and economic outcomes for employees with cancer and other medical conditions and enhance their ability to contribute to positive workplace environments. Ethnic disparities in unmet supportive care needs and outcomes among older ambulatory cancer patients. First Author: Frank J. Penedo, University of Miami Sylvester Comprehensive Cancer Center, Miami, FL

Background: Older cancer patients often face unmet supportive care needs (USCNs), leading to adverse clinical outcomes. Existing research largely focuses on non-Hispanic White populations, leaving a gap in understanding the unique determinants and consequences of USCNs in underrepresented groups. This study aimed to identify factors associated with USCNs and evaluate their impact on clinical outcomes, including emergency room (ER) visits and hospitalizations, among ambulatory cancer patients aged 65 and over. **Methods:** A retrospective analysis was performed for older ambulatory cancer patients (aged ≥65) via *My Wellness Check*, an electronic health record (EHR)-based supportive care needs and patient-reported outcomes (PROs) screening and referral program. Patient demographics and clinical characteristics and outcomes were extracted from the EHR. PROs (i.e., PROMIS computerized adaptive tests for anxiety, depression, and physical function), health-related quality of life (HRQOL) using the FACT-G7, and supportive care needs (e.g., stress management, financial concerns, transportation) were also collected. Logistic regression models examined predictors of USCNs. The cumulative incidence of ER visits and hospitalization was assessed using Cox proportional hazards regression models adjusting for covariates. **Results:** A total of 8,996 older cancer patients were analyzed (mean age: 74±6.3 years, 44% female). Among participants, 3,297 (37%) were Hispanics, 4,901 (55%) were non-Hispanic White, and 561 (6%) were non-Hispanic Black. Most patients were partnered (64%) and insured (98%). Hispanics were more likely to experience USCNs (adjusted odds ratio [aOR]=1.79). Other factors associated with USCNs included non-White race (aOR=2.42), being unpartnered (aOR=1.24), uninsured status (aOR=1.80), shorter time since diagnosis (aOR=0.94), anxiety (aOR=1.03), depression (aOR=1.02), lower physical function (aOR=0.99), and poorer HRQOL (aOR=0.95). Hispanic ethnicity was independently associated with an increased risk of ER visits (adjusted hazard ratio [aHR]=1.76). USCNs were independently associated with an increased risk of ER visits (aHR=1.25) and hospitalizations (aHR=1.29) (all p's<0.05). **Conclusions:** Older Hispanic cancer patients are disproportionately burdened by USCNs, leading to higher risk of ER visits compared to their non-Hispanic counterparts. Underrepresented groups, patients lacking social support, and those experiencing greater emotional or physical distress are more likely to report USCNs. Addressing these needs is critical, as USCNs significantly contribute to increased healthcare utilization, including ER visits and hospitalizations. Tailored interventions to meet supportive care needs in historically vulnerable populations are imperative to improving outcomes and reducing healthcare disparities among older cancer patients. Research Sponsor: None.

Treatment preferences of patients, caregivers, and physicians in follicular lymphoma (FL): A global discrete-choice experiment (DCE) study. First Author: Mitchell Reed Smith, The Follicular Lymphoma Foundation, Washington, DC

Background: While recent FL therapy advances offer various treatment options, data are limited on FL treatment preferences in the shared decision-making process. A comprehensive survey with a DCE design was conducted to assess preferences of patients, caregivers, and physicians for different attributes that impact treatment choice. **Methods:** A web-based DCE survey available in English and Spanish was administered in Oct-Nov 2024 to patients with FL, caregivers, and physicians recruited in the US, the UK, Spain, Australia, and Canada through the Follicular Lymphoma Foundation (FLF). FL treatment attributes were selected based on targeted literature review, clinical inputs, and review with FLF patient and caregiver advisors. Attributes included efficacy (progression-free survival [PFS]), safety (impact of adverse events [AEs], including fatigue, cytokine release syndrome [CRS], and neurologic events [NE], on quality of life [QOL]), and convenience (mode of administration, treatment duration and frequency of visits, time needed to travel to treatment center). Survey responses were analyzed by patient, caregiver, and physician groups. Preference weights were generated from conditional logistic regression models and used to calculate the relative importance of attributes and willingness to trade off. **Results:** A total of 337 patients, 37 caregivers, and 29 physicians (median age: 59, 45, and 51 y, respectively) from 25 countries (>75% from US, UK, and Spain) responded to the DCE survey. The majority (93.7%) of patients reported having experienced ≥1 AE from previous treatment. Patients preferred treatments with longer PFS; mild or no impact of fatigue, CRS, and NEs on QOL during treatment; oral tablets vs infusions; a 3-mo duration with twice-weekly visits vs continuous duration with visits once every 3 mo; and <30 min of travel time vs >2 h (all P<.05). PFS was ranked as the most important attribute across patients, caregivers, and physicians. Following efficacy, treatment convenience attributes were ranked higher by patients and caregivers while safety attributes were more important to physicians. On average, patients were willing to accept reductions of 1 y of PFS for treatment requiring <30 min of travel vs >2 h, 0.7-1 y to receive treatments with less impact of AEs on QOL, 0.6 y for oral tablets vs blood collection and intravenous infusion, and 0.5 y for 3-mo treatment vs continuous duration. **Conclusions:** Efficacy is the most important attribute in treatment choice for patients, caregivers, and physicians. Following efficacy, patients and caregivers prioritize convenience and reduced impact of AEs, while physicians prioritize safety over convenience. Insights on differences between preferences highlight the importance of informed discussion and a balanced, individualized approach to treatment selection. Research Sponsor: BeOne Medicines Ltd.

Patient-reported pain and emergency department utilization in patients with newly diagnosed ovarian cancer: A retrospective cohort study. First Author: Esin Christine Namoglu, Memorial Sloan Kettering Cancer Center, New York, NY

Background: Pain is one of the most common reasons for emergency department (ED) visits among patients with cancer. While patient-reported pain is increasingly captured in routine clinical care, its role in predicting ED utilization remains unclear. This study aimed to evaluate whether baseline patient-reported pain after ovarian cancer diagnosis is associated with subsequent ED visits. **Methods:** We conducted a retrospective cohort study of patients aged 18 years or older treated for ovarian cancer at an urban academic institution between 2019 and 2024. Inclusion criteria required (1) completion of a pain survey within 6 months of diagnosis, (2) all or part of first line treatment at our institution, and (3) at least six months of follow-up after pain survey submission. Patients rated their average pain over the past week on a 0–10 scale as part of routine intake, with mild defined as a score of 1 to 3 and moderate to severe as 4 or higher. The outcome was the occurrence of at least one ED visit within 6 months of the pain survey submission. Multivariable logistic regression was used to assess the relationship between patient-reported pain and ED utilization, adjusting for sociodemographic and clinical variables. **Results:** Among 894 patients who met inclusion criteria, the mean age at diagnosis was 59.7 years, 74.4% (n=665) were white, 7.3% (n=65) Hispanic or Latino, 69.0% (n=617) had advanced stage (III or IV) disease, 83.9% (n=750) received chemotherapy and 66.7% (n=596) had surgery within 6 months of diagnosis. Among the cohort, 331 (37.0%) reported mild pain, 345 (38.6%) reported moderate to severe pain, and 239 (26.7%) experienced at least one ED visit in the 6 months following the survey. A higher proportion of patients with moderate to severe pain had an ED visit compared to 26.0% of those with mild pain and 15.1% of those with no pain (34.8% vs. 26.0% vs. 15.1%, $p<0.001$). After adjusting for covariates, both mild (aOR 1.77, 95% CI 1.09-2.93, p=0.02) and moderate to severe (aOR 2.28, 95% CI 1.42 - 3.73, p=0.001) pain at baseline were associated with higher odds of an ED visit compared to patients without pain. In addition, younger age, non-white race, receipt of chemotherapy or surgery, and advanced stage disease were all significantly ($p<0.05$) associated with higher adjusted odds of an ED visit. **Conclusions:** Three out of four people with newly diagnosed ovarian cancer experience pain, with higher pain levels associated with increased odds of an ED visit. Our findings suggest that routinely collected pain scores could potentially be leveraged to identify at risk population, improve pain management and reduce ED visits for people diagnosed with ovarian cancer. Patient experiences of diagnosis and treatment of invasive lobular carcinoma: A qualitative study from a prospective registry. First Author: Astrid Quirarte, University of California, San Francisco, San Francisco, CA

Background: Invasive lobular carcinoma (ILC) is the second most common subtype of breast cancer and comprises 10-15% of all cases. ILC is characterized by a diffuse tumor growth pattern due to the absence of E-cadherin, resulting in diagnostic and management challenges including delays in diagnosis. The impact of these unique features on patients with ILC is unknown. To better understand the patient experience, we conducted a qualitative study using thematic analysis. **Methods:** 92 patients diagnosed with ILC and treated at a single institution were recruited to a prospective ILC registry from 2023-2025. We collected data primarily through structured patient interviews regarding screening and surveillance methods, locoregional treatment, systemic therapy, and recurrence. Participants were also asked two open-ended questions regarding how they were diagnosed and about their overall experience. The interviews were conducted through 30 to 60-minute phone calls and transcribed verbatim. Inductive coding was used to develop themes. **Results:** Unique themes were identified corresponding to stages in the diagnosis, treatment, and surveillance of ILC. Participants commonly reported a delay in their diagnosis due to mammographically occult disease and perceived poor sensitivity of breast imaging modalities. This was more pronounced among patients who reported a physical finding related to their breast cancer prior to diagnosis. Additional themes included experiencing a dismissal of symptoms by providers, underestimation of ILC tumor size on preoperative imaging, and concerns over the impact of dense breasts on imaging sensitivity. At the treatment stage of their patient journey, participants reported that providers did not recognize ILC as a distinct tumor subtype and often recommended mastectomy as the initial surgical approach. After treatment of ILC, participants frequently recounted concerns about how they would identify a recurrence and a desire for improved surveillance methods. Reflecting on their journey, many shared that they wished they had been better informed about breast cancer symptoms and breast self-awareness before their diagnosis. **Conclusions:** This study highlights the unique challenges and concerns experienced by patients with ILC, emphasizing the need for more tailored imaging strategies, improved awareness among healthcare providers, and enhanced patient education. Research Sponsor: None.

Selected themes in the patient journey.

Patient Journey Stage	Unique themes
Diagnosis	Mammographically occult disease
	Poor sensitivity of imaging modalities
	Dismissal of symptoms
	Underestimation of ILC tumor size
	Concerns over breast density on imaging sensitivity
Treatment	Providers not recognizing ILC as a distinct tumor-type
	Recommending mastectomy
Surveillance	Concerns about identifying recurrence
	Desire for improved surveillance methods

Disparities in glioblastoma care: Insights from a nationwide survey. First Author: Jacob Ellen, Harvard Medical School, Boston, MA

Background: Glioblastoma (GBM) care requires specialized, multidisciplinary management, often creating barriers to healthcare delivery and disparities in care. To identify disparities in how GBM is treated across the United States, we conducted a nationwide survey evaluating healthcare quality and accessibility for GBM patients. **Methods:** OurBrainBank, a patient-led GBM nonprofit, designed and distributed a 36-item HIPAA-compliant survey covering patient experience, quality of life, and demographic data in collaboration with a professional market research company. The survey, available from February to September 2024, targeted current GBM patients, current caregivers, or caregivers who have lost someone within the last year. Recruitment involved newsletters, social media, and communication partnerships with brain cancer organizations. We hypothesized that financial and educational disparities would influence GBM care experiences, assessed through logistic and linear regression using R (version 4.0.5). Only patients with non-missing data were included for each regression analysis. **Results:** Of 525 participants overall (77% caregivers; 23% patients), the median age at diagnosis was 59, with 58% being male, 55% with a college degree, 66% with private insurance and 94% living in urban areas. Education and financial difficulties were associated with disparate GBM care experiences, controlling for age, race, gender, geography (rural, small town, urban), and insurance type (private, public). Participants with no college education (21%) were significantly less likely to be informed about tissue storage (OR = 0.40, 95% CI [0.21, 0.75], p = .004), to undergo MGMT and IDH testing (OR = 0.28, 95% CI [0.11, 0.68], p = .005), to be offered a clinical trial (OR = 0.50, 95% CI [0.29, 0.86], p = .013), and to discuss a second opinion with their doctor (OR = 0.44, 95% CI [0.26, 0.73], p = .002) compared to those with a college degree (55%). They also reported lower satisfaction with care on a 1-10 scale (β = -0.70; 95% CI [-1.26, -0.13], p = .016). These disparities were not observed in participants with some college experience (24%) compared to those with college degrees. Participants reporting financial difficulty in the past year (29%) were also less satisfied with their care (β = -0.58, 95% CI [-1.06, -0.10], p = .018). Financial struggles, however, did not significantly impact mutational testing (OR = 0.57, 95% CI [0.28, 1.18], p = .12), clinical trial offers (OR = 1.25, 95% CI [0.81, 1.92], p = .31), or second opinion discussions (OR = 0.94, 95% CI [0.62, 1.44], p = .79). **Conclusions:** This survey highlights disparities in GBM care, with lower educational attainment linked to reduced access to mutational testing, second opinion discussions and clinical trials, and both lower education and financial difficulties associated with lower care satisfaction. Addressing these disparities is critical to improving GBM care nationwide. Research Sponsor: None.

A prospective observational study to compare speech and swallowing outcomes in different types of oral tongue defects and reconstructions in patients undergoing treatment for oral tongue squamous cell carcinoma. First Author: Shivakumar Thiagarajan, Tata Memorial Centre, Mumbai, India

Background: The tongue is an important organ for speech and swallowing functions. Oral tongue squamous cell carcinoma (OTSCC) can per se affect these functions. Surgery followed by adjuvant treatment may further influence these functions. **Methods:** In this prospective study (CTRI/2020/01/023080) we aimed to assess the speech and swallowing outcomes of 100 treatment-naive OTSCC patients receiving the standard care at our center and compare these outcomes with the type of reconstruction done. Speech was assessed using the London speech evaluation scale (LSES), Performance Status Scale for Head & neck (PSSHN) Speech, and Speech Handicap Index (SHI). Swallowing was assessed with Functional Oral Intake Scale (FOIS), Water swallow test (WST), PSSHN diet, videofluoroscopy (VFS) and New Zealand Index for Multidisciplinary Evaluation of Swallowing (NZIMES). These assessments were done at baseline, 1 month, at 6 months and 1 year after surgery. **Results:** Between November 2021 and December 2024, 100 eligible patients were enrolled in the study. The median age of the patients was 45 years. With predominantly male patients. There were 40 T1 & T2 and 60 T3 & T4 OTSCC. Fifty percent of the patients were clinico-radiologically N+ disease. All patients underwent surgery with appropriate reconstruction and adjuvant treatment (n=77,77%). We utilised the tongue defect classification proposed by Bhattacarya S et al, of which 18 patients had type 1 defect, 32 patients had type 2 defect, 9 patients type 3 defect and 41 had type 4 defect. Primary closure was done in 23 patients, Local flaps in 19 patients, free flaps in 28 patients and pectoralis major myocutaneous/myofascial flap (PMMC/PMMF). There were no difference in the baseline functional outcomes except for the restriction in the range of tongue movements in cT3 & cT4 OTSCC. In patients with cT1 & cT2 and cT3 & cT4 OTSCC there was no difference in most of the functional assessment parameters throughout the follow up period with respect to the type of reconstruction done. There was a difference in the SHI from baseline to 1st follow up (p=0.039) and 3rd follow-up (p=0.041) in patients with class 1 & 2 defect. There was a similar difference in patients with class 3 & 4 defects at 1st (p=0.016) and 3rd follow up visit (0.041) compared to baseline. There was no major swallowing differences observed on VFS (NZIMES) in patients with class 1 & 2 defect. However, there was a significant difference in patients with class 3 & 4 defect. **Conclusions:** In this study, we have witnessed no major differences in the functional outcomes with the kind of flap used for various defects. The functional issue seem to be more associated with the defects (reflecting on the extent of resection) more rather than the type of reconstruction done. Clinical trial information: CTRI/2020/01/023080. Research Sponsor: TMC Research Adminstrative Council (TRAC); ICON.

Association between alcohol intake and health-related quality of life in breast cancer survivors. First Author: Sanjna Rajput, Mayo Clinic Hospital, Rochester, MN

Background: Advances in early detection and treatment of breast cancer (BC) have significantly improved survival outcomes. In this growing survivor population, addressing modifiable lifestyle factors such as alcohol intake (AI), a known risk factor for BC and BC recurrence, is critical to improving prognosis and health-related quality of life (HRQoL). This study examines AI patterns and their associations with mental and physical HRQoL in early BC survivorship. **Methods:** Adult patients newly diagnosed (≤1 year) with stage I–III BC at Mayo Clinic Rochester were invited to enroll in the Mayo Clinic Breast Disease Registry. Of the 3252 patients who consented, 1997 completed surveys approximately one-year post-diagnosis, capturing weekly AI, demographic factors, and PROMIS-10 scores. PROMIS-10 (a 10-item measure of health, well-being, and distress) physical and mental health T-scores (mean = 50, SD = 10) are standardized to the U.S. population. Weekly AI was categorized as minimal/none (<1 drink), mild (1–4 drinks), moderate (5–14 drinks), or high (≥15 drinks). Univariate analyses were performed with Monte Carlo-based Fisher exact tests. Multivariate multinomial logistic regression models using a glogit link function assessed AI as the outcome and PROMIS-10 scores as independent variables, adjusting for financial status, smoking, chemotherapy, and moderate exercise because those were associated with AI at year 1 in prior analyses. **Results:** Univariate analyses revealed statistically significant associations between AI and PROMIS-10 scores (Table 1). Adjusted multivariate analyses identified that patients with better physical health were more likely to drink 1–4 or 5–14 drinks/week and less likely to abstain (<1 drink/week) than those with poorer physical health (p=0.027). There was no statistically significant association between AI and mental health QoL after adjustment for covariates. **Conclusions:** Better physical HRQoL during early survivorship was associated with higher AI, suggesting that patients who are feeling physically unwell may be less likely to drink alcohol. Additional public health messaging about the relationship between AI and breast cancer risk and recurrence may be needed, especially for those who are feeling well enough to consume alcohol. Research Sponsor: National Cancer Institute; P30 CA015083.

Caregiver distress: Caring for those who care for our patients. First Author: Abigail Smith Zamorano, UTHealth Houston, Houston, TX

Background: Gynecologic cancers cause high physical and psychosocial strain, worsened by unmet social determinants of health (SDOH) in cancer care. Caregivers help patients access and complete treatment, and increased caregiver distress, especially in vulnerable populations, is linked to worse patient outcomes in chronic illnesses. This study aimed to assess caregiver distress and SDOH in a diverse gynecologic cancer population, understand the relationship between caregiver and patient distress, explore how caregiver distress evolves during chemotherapy, and examine its effect on short-term patient outcomes. **Methods:** A prospective pilot study was conducted of patients starting chemotherapy for gynecologic cancer and their self-identified caregivers at a single academic site after IRB approval. Patient distress was measured with the NCCN Distress Thermometer. Caregivers completed the Modified Caregiver Strain Index (MCSI) and SDOH questionnaires at enrollment (T0) and three months after chemotherapy initiation (T3). Descriptive statistics, χ^2 analyses, and linear regression analyzed differences between high- and low-distress caregivers and changes between time points. **Results:** Between 12/2023 and 06/2024, 60 patients and 38 caregivers enrolled. Patients' mean age was 62, with 27% identifying as Black and 37% as Hispanic. Most (72%) were starting chemotherapy for initial treatment of uterine (47%), ovarian (32%), cervical (20%), and vulvar (1.6%) cancer, and 73% had stage III/IV disease. Caregivers were 63% male, 40% Hispanic, 24% Black, and 26% over age 65. Almost 40% of caregivers did not live with their patient, and 27% cared for others, including 80% for children. Nearly 40% had incomes under $50,000; only 13.2% had paid job-related support. At T0, 77% of patients reported high distress, decreasing to 70% at T3. Caregivers of high-distress patients were younger, working full-time, and had lower incomes. At T0, 42% of caregivers reported high distress, increasing to 66% at T3. MCSI scores rose significantly from 5.84 at T0 to 9.84 at T3 (p<0.001). At T0, 63% of caregivers screened positive for ≥1SDOH domain, rising to 80% by T3. Caregivers with ≥1 SDOH domain at T3 were more likely to experience increased distress (p=0.037). Linear regression showed caregivers with one SDOH domain had MCSI scores 3.69 points higher (p=0.111); those with ≥2 domains scored 5.60 points higher (p=0.024). No differences were found in patient outcomes based on caregiver MCSI scores. **Conclusions:** Caregiver distress and SDOH needs increase significantly during the first months of chemotherapy for gynecologic cancer. Distress is also more pronounced in caregivers with greater SDOH needs. Long-term studies are needed to evaluate caregiver distress and its impact on patient survival. This study highlights the importance of monitoring caregiver well-being and addressing SDOH through targeted interventions. Factors associated with patient-reported outcomes in hospitalized patients with cancer. First Author: Noha Soror, The University of Oklahoma Health Sciences Center, Oklahoma City, OK

Background: Utilization of patient reported outcomes (PROs) in the ambulatory setting can help to improve symptom control and clinical outcomes among individuals with cancer. However, little is known about PROs among hospitalized patients with cancer. **Methods:** We conducted a prospective study to examine PROs among hospitalized patients with cancer at the University of Oklahoma Medical Center from 8/2023 to 9/2024. Within 2-5 days of admission, we asked patients to complete surveys assessing physical symptoms (MD Anderson Symptom Inventory [MDASI]; scored 0-10, higher scores = higher severity/interference), psychological symptoms (PHQ-4; scored 0-12, higher scores = higher distress), coping (Brief COPE; scored 2-8 for each of 14 coping domains), and resilience (Brief Resilience Scale [BRS] scored 1-5, higher scores = higher resiliency). We obtained demographic data and clinical characteristics from the electronic health record, including the Charlson Comorbidity Index (CCI). We used regression models to identify factors associated with PROs. **Results:** We enrolled 300 of 441 (68.0%) eligible patients (median age = 64.8 years, 43.0% female, 78.0% White, 73.3% with incurable cancer). The most common cancers were hematologic (29.6%), gastrointestinal (20.0%), and gynecologic (17.0%). The mean MDASI severity and MDASI interference scores were 4.20 and 4.77. Symptoms with the highest mean MDASI severity scores were fatigue (6.56), pain (5.87), disturbed sleep (5.77), and drowsiness (5.27). The mean MDASI interference score was highest for normal work (6.45) and general activity (6.45). The mean PHQ-4 score was 4.41, and the mean BRS score was 2.98. Coping measures with the highest mean Brief COPE scores were use of emotional support (6.66), acceptance (6.55), and religion (6.04) coping. Older age at enrollment was associated with lower MDASI severity (B = -0.02, P < .01), venting (B = -0.02, P = .03), and humor coping scores (B = -.02, P < .01), yet higher use of emotional support (B = 0.02, P = .03) and religion coping scores (B = 0.03, P = .01). Female sex was associated with higher MDASI severity (B = 0.65, P < .01), self-distraction coping (B = 0.63, P < .01), and positive reframing coping (B = 0.77, P < .01). Higher CCI was associated with higher substance use coping (B = 0.11, P < .01) and behavioral disengagement (B = 0.10, P = .03). Patients with hematologic malignancy had higher use of self-distraction coping (B = 0.55, P = .02). We found no differences in PROs for curable versus incurable cancer. **Conclusions:** Hospitalized patients with cancer report high physical and psychological symptoms, with significant associations of PROs with increasing age, female sex, comorbidities, and diagnosis of hematologic malignancy. Our findings highlight the importance of addressing symptom concerns and coping mechanisms in hospitalized patients with cancer, which could inform targeted interventions to enhance PROs and clinical outcomes. Perception of postoperative functional status in gastrointestinal and hepatobiliary cancer patients over 80. First Author: Sarah Remer, Loyola University Medical Center, Maywood, IL

Background: Advanced age independently predicts poor surgical outcomes in cancer patients, making octogenarians a particularly high-risk surgical population. Improvement in the delivery of care to these vulnerable patients is critical to improve not only morbidity and mortality outcomes, but also patient-centered outcomes such as functional status. Postoperative functional outcomes can be evaluated by subjective perception and quantified performance. The aims of this study were to 1) identify risks associated with 30-day postoperative perceptions of functional decline in octogenarians undergoing operations for gastrointestinal or hepatobiliary cancers and 2) explore whether these perceptions correlate with quantitative decline measured as a function of decreased ability to perform activities of daily living (ADLs). **Methods:** American College of Surgeons National Surgical Quality Improvement Program Geriatric Surgery data (2015-2017) was used. All postoperative diagnoses related to gastrointestinal or hepatobiliary cancers were included for patients ≥80 years old. Multivariable logistic regression models identified risks associated with perceiving worsened physical function 30-days postoperatively. Chi-square tests were used to examine concordance between 30-day outcomes of perceptions of physical function with measured performance of ADLs. **Results:** 369 patients from 14 hospitals were included. Mean age was 85.4 (SD 4.1 years). The most common diagnosis was "malignant neoplasm of ascending colon" (16%). Preoperatively 62% of patients were living supported at home, 37% were using a mobility aid, and 17% had ≥1 fall in the past year. Overall, 80% did not have a quantified decline in function as measured by ADLs; however, 17% of these reported perceived functional decline (K= 0.47). Significant risk factors for perceived functional decline were major postoperative morbidity (OR 5.5; 95% CI 2.3-13), disseminated cancer (2.2; 1.1-4.4), new postoperative mobility aid use (2.2; 1.1-4.6), and cognitive impairment (4.7; 1.7-12.9). **Conclusions:** There are inconsistencies between patient experience and clinician view of functional outcomes for octogenarians undergoing surgical intervention for gastrointestinal and hepatobiliary cancers. Ability to perform ADLs is frequently used to evaluate patient functional status. This discrepancy in patient perception and quantified measure highlights the need for the development and utilization of patient-centered and patient-reported outcome (PRO) measures to evaluate this vulnerable patient population. PROs may enhance surgeon understanding of the patient experience and allow for more nuanced goals of care discussions and targeted interventions to improve delivery of care to these patients. Prospective assessment of health-related quality of life in early phase clinical trials. First Author: Udit Nindra, Liverpool Hospital, Liverpool, Australia

Background: Early phase clinical trials (EP-CTs) provide patients with access to novel therapeutics once standard of care options are exhausted or not available. Health related quality of life (HRQoL) is not routine in all EP-CTs where key focus may lie on dose limited toxicities and safety analyses. However for clinicians, understanding the impact of such trials on HRQoL is fundamental to consent patients, especially when the benefits on tumour response may be unknown. **Methods:** The PEARLER (Patient Experience in eARLy phasE cancer clinical tRials) study was conducted with a key aim of focusing on assessing HRQoL in participants undergoing EP-CTs using a multi-centre prospective cohort setting. All participants completed a baseline demographic survey on cycle 1 day 1 with EORTC-QLQ-C30 on day 1 of cycles 1 through 6 or end of trial (EoT). Multilevel models were used to analyse trend over time for Global Health Status (GHS), and Physical Function Score (PFS). **Results:** A total of 122 participants were recruited. Median age was 62 years (25 – 83 years) with 63 (52%) participants identifying as female. Of the total participants, 47 (39%) were enrolled in immuno-oncology EP-CTs whilst the remainder participated in EP-CTs focused on targeted therapies. The median number of EP-CT cycles completed by participants was 3. Median GHS) Score was 67 at baseline and remained steady across all participants throughout their EP-CT (p=0.188). GHS deterioration, defined by a 10-point decrease from baseline to EoT, occurred in 29/122 (24%) whilst GHS improvement occurred in 16/122 (13%). Median Physical Function Score (PFS) was 87 at baseline and remained steady across all participants throughout their EP-CT (p=0.104). PFS deterioration, defined by a 10-point decrease from baseline to EoT, occurred in 30/122 (25%) whilst GHS improvement occurred in 6/122 (5%). There was no statistically difference in change in GHS or PFS in younger versus older patients (less than or equal to 60 years versus over 60 years), tumour type, EP-CT type, gender or those from lower versus higher socioeconomic backgrounds. **Conclusions:** PEARLER is the first prospective cohort study investigating change in GHS and PFS over time in patients undergoing EP-CTs. Although almost three-quarters of participants who undertake EP-CTs either sustain or improve their GHS or PFS, one quarter do not. Patients need to be educated not only on the potential response rate of the EP-CT they are enrolling into but also the possibility of reduced HRQoL whilst participating in studies. Further research is needed to identify predictive and protective factors of HRQoL in patients undergoing EP-CTs. Research Sponsor: None.

Financial, social and time toxicity in early-phase cancer clinical trials: The PEARLER study. First Author: Udit Nindra, Liverpool Hospital, Liverpool, Australia

Background: Early phase clinical trials (EP-CTs) provide patients with access to novel therapeutics once standard of care options are exhausted or not available. In addition to the drug related potential benefits and risks with participating in such studies, patients are also exposed to hidden toxicities which often go unnoticed. Hidden toxicities have been classed into a number of major categories which include but are not limited to time, financial, and social. Currently there are no prospective studies assessing these hidden toxicities in the EP-CT space. **Methods:** The PEARLER (Patient Experience in eARLy phasE cancer clinical tRials) study was conducted with a key aim of focusing on assessing time toxicity, financial toxicity and social toxicity in a multi-centre prospective cohort setting. All participants completed a baseline demographic survey on cycle 1 day 1 along a time toxicity survey and the EORTC-QLQ-C30 on day 1 of cycles 1 through 6. Multilevel models were used to analyse trend over time for financial toxicity and social toxicity. **Results:** A total of 122 participants were recruited. Median age was 62 years (25 – 83 years) with 63 (52%) participants identifying as female. A total of 47 (39%) participants were enrolled in immuno-oncology EP-CTs whilst the remainder participated in targeted-therapy focused EP-CTs. The median time toxicity was 26%. Of 122 participants, 20 (16%) reported subjective time toxicity with 17 (85%) reporting this occurring at either cycle 1 or 2. Under half (54/122, 44%) reported any degree of financial toxicity whilst participating in their EP-CT; with 9 of this 54 (17%) reporting the maximum score of '4'. Financial toxicity remained largely stable throughout EP-CT participation (p=0.136), with 6/122 (5%) participants reporting higher financial burdens at the end of their clinical trial compared with baseline. Most participants (87/122, 71%) reported any degree of reduced social function, whilst participating in their EP-CT. However, 26/122 (21%) participants reported lower social functional scores at conclusion of their EP-CT compared with baseline whilst 24/122 (20%) reported higher social functional scores. **Conclusions:** PEARLER is the first prospective cohort study investigating financial, social and time toxicity in EP-CTs. Although time toxicity remains a concern of EP-CTs, the majority of subjects did not subjectively note this to be a concern. Financial and social toxicity remained stable during EP-CT participation thereby suggesting that EP-CTs may not negatively affect the majority of participants. However almost half of patients experienced financial toxicity and more than half experienced social toxicity due to cancer related treatment and greater efforts to identify and support patients financially and socially is needed. Final patient-reported outcomes (PROs) in unselected men receiving talazoparib (TALA) + enzalutamide (ENZA) vs placebo (PBO) + ENZA as initial treatment for metastatic castration-resistant prostate cancer (mCRPC): Results from the phase 3 TALAPRO-2 study. First Author: Nobuaki Matsubara, National Cancer Center Hospital East, Kashiwa, Japan

Background: TALAPRO-2 demonstrated statistically significant improvement with TALA + ENZA vs PBO + ENZA in radiographic progression-free survival (primary endpoint; HR=0.63; 95% CI, 0.51–0.78; $P<0.0001$) in unselected men with mCRPC. Prior PRO analyses (data cutoff: Aug 16, 2022) reported no clinically meaningful between-arm differences in any functioning scales and a longer time to definitive deterioration (TTDD) in global health status (GHS)/quality of life (QoL) for TALA + ENZA (median 30.8 mo) vs PBO + ENZA (25.0 mo; HR=0.780; 95% CI, 0.62–0.99; $P=0.038$). Here we report updated (data cutoff: Sep 3, 2024) final PROs for the unselected cohort. **Methods:** PROs were assessed at day 1 (baseline) and scheduled visits (every 4 weeks until week 53, and then every 8 weeks) until radiographic progression using the EORTC QLQ-C30 and its prostate cancer module, QLQ-PR25, and worst pain by BPI-SF item 3. Prespecified PRO analyses included overall mean change from baseline (per longitudinal repeated measures mixed-effects model), time to deterioration (TTD), and TTDD. The clinically meaningful threshold was ≥10 points for EORTC scales and ≥2 points for BPI-SF. Between-arm comparisons of TTD/TTDD were made using a stratified log-rank test and a Cox proportional hazards model. **Results:** Of the 805 men randomized to treatment, 793 (TALA + ENZA, n=395; PBO + ENZA, n=398) had 1 baseline + ≥1 follow-up PRO score. With extended follow-up, median TTDD for GHS/QoL in the TALA + ENZA arm was 41.5 mo vs 34.1 mo in the PBO + ENZA arm (HR=0.878; 95% CI, 0.704–1.096; $P=0.2487$). Median TTDD for urinary symptoms in the TALA + ENZA arm was 59.8 mo vs 58.0 mo in the PBO + ENZA arm (HR=0.861; 95% CI, 0.622–1.191; $P=0.3655$). No clinically meaningful between-arm differences in QLQ-C30 functioning and symptoms scales were observed (Table). No between-arm difference in TTD for worst pain by BPI-SF was observed. **Conclusions:** With extended follow-up, QoL was maintained with TALA + ENZA. These data confirm that QoL is not compromised when TALA is added to ENZA, for initial treatment of unselected men with mCRPC. Clinical trial information: NCT03395197. Research Sponsor: Pfizer Inc.; Astellas Pharma Inc. provided enzalutamide.

QLQ-C30 Scale		Estimated Mean Difference, TALA + ENZA – PBO + ENZA (95% CI)	*P* Value
Functioning	GHS/QoL	-2.2 (-4.3, -0.1)	0.0382
	Physical	-1.6 (-3.9, 0.7)	0.1663
	Role	-1.7 (-4.2, 0.9)	0.2009
	Emotional	-0.9 (-2.7, 1.0)	0.3620
	Cognitive	-0.9 (-3.0, 1.1)	0.3791
	Social	-0.9 (-2.9, 1.2)	0.4088
Symptoms	Fatigue	2.4 (0.1, 4.7)	0.0437
	Nausea + Vomiting	0.8 (-0.1, 1.6)	0.0723
	Pain	-0.8 (-3.3, 1.7)	0.5270

Positive values favor TALA + ENZA for GHS/QoL and functioning scales; negative values favor TALA + ENZA for symptoms scales.

11121 **Poster Session**

Final patient-reported outcomes (PROs) in men with metastatic castration-resistant prostate cancer (mCRPC) and homologous recombination repair (HRR) gene alterations receiving initial treatment with talazoparib (TALA) + enzalutamide (ENZA) vs placebo (PBO) + ENZA in the TALAPRO-2 study. First Author: Andre P. Fay, PUCRS School of Medicine, Porto Alegre, Brazil

Background: The phase 3 TALAPRO-2 study showed a statistically significant improvement in radiographic progression-free survival for TALA + ENZA vs PBO + ENZA (HR=0.45; 95% CI, 0.33–0.61; $P<0.0001$) in men with HRR-deficient mCRPC. Prior PRO analyses (data cutoff: Oct 3, 2022) reported no clinically meaningful between-arm differences in any functioning scales and a longer time to definitive deterioration (TTDD) in global health status (GHS)/quality of life (QoL) for TALA + ENZA (median 27.1 mo) vs PBO + ENZA (median 19.3 mo; HR=0.69; 95% CI, 0.49–0.97; $P=0.032$). Here we report updated (data cutoff: Sep 3, 2024) final PROs for the HRR-deficient cohort. **Methods:** PROs were assessed at day 1 (baseline) and every 4 wks until wk 53, then every 8 wks until radiographic progression using the EORTC QLQ-C30 and its prostate cancer module, QLQ-PR25, and worst pain by BPI-SF item 3. Prespecified PRO endpoints included overall mean change from baseline (per longitudinal repeated measures mixed-effects model), time to deterioration (TTD), and TTDD. The clinically meaningful threshold was ≥10 points for EORTC scales, ≥2 points for BPI-SF. Between-arm comparisons of TTD/TTDD were made via stratified log-rank test and Cox proportional hazards models. **Results:** At extended follow-up, 394/399 patients in the HRR-deficient cohort (n=197, both arms) had completed baseline + ≥1 follow-up PRO score. TALA + ENZA resulted in a numerically longer TTDD in GHS/QoL vs PBO + ENZA (HR=0.766; 95% CI, 0.555–1.057; $P=0.1063$; median, 34.2 vs 22.1 mo, respectively). HR for TTDD in disease-specific urinary symptoms was 0.684; 95% CI, 0.421–1.113; $P=0.1247$) for TALA + ENZA vs PBO + ENZA. TTD in worst pain by BPI-SF favored TALA + ENZA vs PBO + ENZA (HR=0.552; 95% CI, 0.325–0.937; $P=0.0255$). Differences in physical, role, emotional, cognitive functioning scores and pain favored TALA + ENZA vs PBO + ENZA, but did not meet the clinically meaningful threshold (Table). **Conclusions:** With extended follow-up, treatment differences favoring TALA + ENZA vs PBO + ENZA were observed in some functioning and symptoms scales. Consistent with prior analyses, overall QoL was maintained in patients with HRR-deficient mCRPC receiving initial treatment with TALA + ENZA in TALAPRO-2. Clinical trial information: NCT03395197. Research Sponsor: Pfizer Inc.; Astellas Pharma Inc.

QLQ-C30 Scale		Estimated Mean Difference, TALA + ENZA – PBO + ENZA (95% CI)	*P* Value
Functioning	GHS/QoL	2.7 (-0.8, 6.2)	0.1294
	Physical	5.3 (1.9, 8.7)	0.0022
	Role	4.3 (0.0, 8.6)	0.0524
	Emotional	4.9 (1.6, 8.2)	0.0038
	Cognitive	5.5 (2.0, 9.1)	0.0024
	Social	1.9 (-1.7, 5.4)	0.3005
Symptoms	Fatigue	-1.5 (-5.2, 2.3)	0.4448
	Nausea + Vomiting	0.1 (-1.4, 1.6)	0.8936
	Pain	-8.5 (-12.3, -4.7)	<0.0001

Positive values favor TALA + ENZA for GHS/QoL and functioning scales; negative values favor TALA + ENZA for symptoms scales.

Beyond survival: Prospective longitudinal insights into quality of life after hepatectomy for colorectal liver metastases. First Author: Ankur P. Choubey, Department of Surgery, Memorial Sloan Kettering Cancer Center, New York, NY

Background: The long-term health related quality of life (QoL) after curative intent hepatectomy for high-risk colorectal liver metastases (CRLM) is not well described. **Methods:** This prospective single-center study enrolled patients with resectable CRLM with Clinical Risk Score ≥3. European Organization for Research and Treatment of Cancer QLQ-C30, LMC21, and EuroQol EQ-5D-5L were administered at preoperative and postoperative visits, and at 6, 12, 18, 24, and 36 months from hepatectomy. Patient characteristics at baseline along with colorectal cancer disease state were collected at each timepoint on a scale from no evidence of disease (NED) to progressive disease on best supportive care. Linear mixed models were used to examine the trajectory of QoL scores with disease state modeled as a time-varying variable. **Results:** From 297 consented, 146 were evaluable by completing preoperative and postoperative surveys. Median age was 52 years (IQR: 45, 63), 42% (n=61) were female, 84% (n=122) were Non-Hispanic White, 70% (n=102) had synchronous CRLM, and 80% (n=117) received hepatic artery infusion chemotherapy (HAIC). Overall, QLQ-C30 demonstrated decrease in global health from baseline at post-operative survey ($p<0.05$) with subsequent improvements until returning to pre-operative levels at 12 months. Similarly, self-assessed health state on EQ-VAS— a visual analog scale from 0 to 100 that corresponds to worst and best health possible, respectively— decreased post-operatively ($p<0.05$) with recovery to baseline by 6 months. Among NED patients, QLQ-C30 QoL scores recovered to pre-operative levels 6 months after hepatectomy, whereas those with recurrent cancer reported scores below baseline at every follow-up assessment (all $p<0.05$). On EQ-VAS, NED patients were comparable to baseline at 6 months and reported higher scores than baseline at 24 months (p=0.029). Patients with recurrence had similar EQ-VAS scores as baseline at 12 months but remained lower than NED patients at each timepoint (all $p<0.05$). HAIC did not impact QoL assessed by QLQ-C30 (p=0.725) or EQ-VAS (p=0.559) during follow-up. **Conclusions:** Health related QoL suffers in the immediate post-operative period before returning to pre-operative levels and exceeding it among patients without recurrence. While cancer recurrence significantly influenced patient experience, HAIC did not sway QoL. Research Sponsor: None.

Comparison of self-assessed EQ-VAS scores stratified by cancer recurrence status, where 0 and 100 correspond to worst and best health possible, respectively.

Time Point	No Recurrence, QoL Estimate	Cancer Recurrence, QoL Estimate	P-value
Pre-op		75.28	
Post-op		66.45	
6m	75.37	68.10	<0.05
12m	80.78	70.15	<0.05
18m	80.28	70.48	<0.05
24m	83.38	74.21	<0.05
36m	78.32	57.44	<0.05

Quality of life in a phase III study of prospective radiation therapy (IMRT) +/- cetuximab for locally advanced resected head and neck cancer: NRG/RTOG 0920. First Author: Clement K. Gwede, H. Lee Moffitt Cancer Center and Research Institute, Tampa, FL

Background: We tested the primary question whether the addition of cetuximab to postoperative radiotherapy (IMRT) results in poorer patient reported outcomes (PROs) at 12 months compared to IMRT alone. We also examined changes in PROs over time. **Methods:** Randomized and eligible patients who consented to quality of life (QOL) assessment completed PROs measured by 5 instruments, prior to treatment (baseline) and at 3, 12, and 24 months after IMRT. Instruments included: 1) *Functional Assessment of Cancer Therapy-Head & Neck (FACT-HN),* a multidimensional QOL instrument for use with head and neck cancer patients; 2) *University of Michigan Xerostomia-Related Quality of Life Scale (XeQOLS)* covering mouth/throat dryness and its impact on oral health-related QOL; 3) *Dermatology Life Quality Index (DLQI)* for skin-related changes; 4) *EuroQol (EQ-5D-3L)* covering usual activities and perceived current health state; 5) *Performance Status Scale for Head and Neck Cancer (PSS-HN)* assessing normalcy of diet, public eating, and understandability of speech. Higher scores on XeQOLS and DLQI indicate worse QOL; otherwise higher scores indicate better QOL for other measures. For FACT-HN, XeQOLS, DLQI, and EQ-5D-3L, changes from baseline were compared by Van Elteren test, and for PSS-HN, the % ≤ 50 was compared by Z test. 158 patients per arm provided 80% power to test the difference between IMRT + cetuximab and IMRT alone. Changes in PROs over time were evaluated using mixed models. Two-sided tests were used with α=0.05. **Results:** 499 of 577 eligible patients (86%) consented to QOL. There were no significant differences between treatment arms (IMRT vs. IMRT + cetuximab) for all PRO measures in change from baseline to 3 or 12 months post-IMRT (see table). At 24 months, the change from baseline was significantly different for DLQI (p=0.02), but the difference was not clinically meaningful; other PROs were not significantly different. There were no significant differences between treatment arms for PSS-HN diet, eating, or speech at any time point (see table). Regarding treatment effect over time, in both treatment groups, all PRO measures showed greatest decline at 3 months followed by improvement towards baseline by 24 months. **Conclusions:** Treatment with IMRT + cetuximab was not associated with worse PROs compared to IMRT alone. Furthermore, findings demonstrate important recovery trends in QOL with return to baseline for most measures in both study arms. Clinical trial information: NCT00956007. Research Sponsor: National Cancer Institute; UG1CA189867; National Cancer Institute; U10CA180868; National Cancer Institute and Eli Lily; U10CA180822; National Cancer Institute and Eli Lily; U24CA196067; National Cancer Institute and Eli Lily; U24CA180803.

Cancer misinformation and trust in doctors and scientists among cancer survivors. First Author: Brandon M. Godinich, Texas Tech Health Science Center El Paso, El Paso, TX

Background: Health misinformation is a significant public health concern and has acutely worsened in the past decade. Cancer survivors must navigate a complex health system after a critical diagnosis and may be particularly susceptible to the adverse effects of misinformation. This study explores information perception and trust between survivors and those without (w/o) a cancer history. **Methods:** Data from the nationally representative Health Information National Trends Survey (HINTS) from 2017-2022 was used to compare questions regarding cancer and health information and trust (grouped Strongly/Somewhat Agree and Disagree) between those with a prior cancer diagnosis (survivors) and those w/o cancer. Demographic data included: age, gender, race/ethnicity, sexual orientation, education, employment, and household income. Analysis was done in STATA with Chi-squared and T-tests testing between survivors and those w/o cancer; multivariate analysis (MVA) focused on survivors. **Results:** 21,753 people were included, 3,479 (16.0%) were cancer survivors. Survivors were demographically different than those w/o cancer including being older (median 68 vs 56), less likely employed (22.5 vs 40.5%), more commonly White (80.2 vs 69.3%) and less often Black race (12.7 vs 18.4%) ($p<001$ for all). More people w/o cancer had used the internet in the past year to look for medical information (73.6% vs 70.4% in survivors), however when searching for cancer information specifically, less survivors (49.8% vs 55.7% w/o cancer) were concerned about the quality of the information (p=0.001 both). More survivors trusted information about cancer from a doctor (77.6% survivors vs 72.3% w/o cancer, p=0.02). But less people overall trusted scientists about cancer information (52.1% survivors, 57.2% w/o cancer, p=NS) with 1 in 20 people trusting scientists "not at all" (5.1% survivors, 5.2% w/o cancer, p=NS). More than half felt that health recommendations from experts seemed to conflict/contradict one another (58.1% survivors, 56.3% w/o cancer, p=NS). In an MVA of survivors, only age was associated with being concerned about the quality of cancer information online with younger survivors being less concerned [OR 0.98, 95%CI 0.96-0.99, $p<0.001$]. **Conclusions:** In this national study, researching health information online was common and roughly half were concerned about the quality of cancer information they found. Compared to those w/o a cancer history, cancer survivors were less concerned about their ability to find high quality cancer information with younger survivors feeling the most confident. While most people trusted doctors, more than half said that experts seemed to contradict each other and 1 in 20 had no trust in scientists to provide cancer information. Future interventions should focus on health information literacy and improving communication on evidence-based cancer information. Research Sponsor: None.

Circulating tumor DNA (ctDNA) analysis guiding adjuvant therapy in patients (pts) with colorectal cancer (CRC): Impact on fear of cancer recurrence (FCR). First Author: Sue-Anne McLachlan, St. Vincent's Hospital, Melbourne, Australia

Background: ctDNA detection following curative intent treatment is highly prognostic, with potential to impact patient fear of cancer recurrence (FCR). In 3 separate randomized trials (DYNAMIC II, III, rectal), pts with early-stage CRC were randomly assigned to treatment decision guided by ctDNA results (adjuvant chemotherapy escalation if ctDNA positive, de-escalation or no treatment if ctDNA negative), or according to standard clinicopathological features. The relationship between being informed of a high recurrence risk, or treatment de-escalation, and FCR is unclear. This study aims to explore the relationship between biomarker-informed adjuvant chemotherapy (ACT) decision making and FCR, including changes over time. **Methods:** A subset of pts from the 3 DYNAMIC studies completed validated self-report questionnaires measuring FCR, anxiety, depression and quality of life. Data were collected at three time points: after surgery (T1), at the time of the ACT decision (T2), and 9-12 months later (T3). Pts randomized to the ctDNA-guided group received a ctDNA test result (positive or negative) at T2, while those in the standard of care (SOC) group did not. The primary endpoint was the FCR Inventory Short Form score (FCRI-SF). FCR patterns over time were analyzed using a mixed model 2 (Randomization) x 3 (Time) ANCOVA. A 2 (Randomization) x 2 (Chemotherapy Status) ANCOVA was used to assess ACT's impact on FCR at follow-up. Gender, age, and cancer stage were included as covariates. **Results:** 317 pts from 35 Australian sites participated in the FCR substudy (74% response rate for all timepoints). Two-thirds were male, and the mean age was 60 years. Of the ctDNA-guided group (n=176), 73% had a negative ctDNA result. At baseline, 63% of patients exhibited clinically significant levels of FCR (FCRI-SF >13). Younger age, female gender, anxiety, and higher cancer stage all predicted higher baseline FCR. FCR significantly decreased over time for all pts ($F(2,176) = 3.64$, $p = .03$). This reduction was more pronounced in the ctDNA-guided group compared to the SOC group ($F(2, 176) = 3.83$; $p = .02$), although the effect size was small (Cohen's d =0.24). In the ctDNA-guided group, no differences in FCR were found between pts based on ctDNA result (positive vs. negative). High baseline anxiety was the only independent predictor of FCR at 12 months. Chemotherapy receipt, cancer stage, depression, and quality of life scores were not predictive of FCR over time. **Conclusions:** In pts with early-stage CRC, neither a positive nor negative ctDNA result impacted FCR. ctDNA-guided approach to determining ACT was associated with a greater reduction in FCR over time compared to SOC. This biomarker-guided treatment approach has potential to improve ACT selection as well as psychosocial outcomes. Temporal reduction in FCR is likely driven by increased prognostic certainty over time. Clinical trial information: 12615000381583. Research Sponsor: St Vincents Hospital Research Endowment Fund.

Electronic patient-reported outcomes (ePRO) in patients with advanced melanoma receiving immune checkpoint inhibitors: Insights from the Canopy ePRO system. First Author: Benjamin Avi Derman, University of Chicago, Chicago, IL

Background: Health-related quality of life (HRQoL) outcomes are prognostic in melanoma. There is little data comparing HRQoL during nivolumab (nivo) and pembrolizumab (pembro) exposure in patients with melanoma. Electronic patient-reported outcomes (ePROs) provide valuable insights into HRQoL; this study reports on ePRO data from community oncology practices using the Canopy Remote Therapeutic Monitoring (Canopy RTM) platform to explore ePROs in patients with melanoma treated with nivo, pembro, or nivo/ipi. **Methods:** The Canopy RTM system is a proprietary, cloud-based platform that directly integrates with electronic medical records systems to enable RTM. Patients using Canopy RTM could submit symptom reports using smart devices or a phone system. This study retrospectively analyzed ePRO data of patients with melanoma treated with nivo, pembro, or nivo/ipi, excluding those who received chemotherapy during index treatment. Symptom and broad symptom category reporting during each treatment was assessed using descriptive statistics. Sensitivity analyses were performed, including limiting time at risk of symptom reports to 60 days following index and excluding patients with record of exposure to ipilimumab prior to index. **Results:** 386 patient treatments were included: 140 receiving nivo; 169, pembro; and 57, nivo/ipi. Median age was 66, 69, 61 years across the nivo, pembro, and nivo/ipi groups, respectively. Median time on therapy was 285, 269, 49 days for nivo, pembro, and nivo/ipi, respectively. Compared to pembro, nivo treatment was associated with higher incidence of infection symptoms, difficulty with activities of daily living, gastrointestinal symptoms, and pain (Table 1). Despite significantly shorter time on therapy, more patients reported infection and rash during nivo/ipi treatment than during nivo treatment. Sensitivity analysis limiting time at risk of symptoms to 60 days following index revealed similar findings, albeit with greater proportions of patients treated with nivo/ipi reporting symptoms across most symptoms. **Conclusions:** Pembro monotherapy may be associated with a lower incidence of some symptoms compared to nivo (+/- ipi), while nivo monotherapy has fewer symptoms than nivo/ipi treatment. Further research is warranted to confirm these findings. Research Sponsor: Canopy Care.

Select symptoms and symptom categories (composites) reported during treatment.

Symptom or composite	Pembrolizumab	Nivolumab	Nivo/Ipi
Infection (composite)	57 (34%)	67 (48%)	31 (54%)
Cough	25 (15%)	30 (21%)	14 (25%)
Fever under 100.4F	6 (3.6%)	10 (7.1%)	7 (12%)
Difficulty breathing	27 (16%)	26 (19%)	13 (23%)
Gastrointestinal (composite)	69 (41%)	67 (48%)	30 (53%)
Indigestion	13 (7.7%)	16 (11%)	5 (8.8%)
Diarrhea	36 (21%)	31 (22%)	14 (25%)

Evaluating acceptance of scalp cooling in patients receiving chemotherapy for primary gynecologic cancers: Lessons from a randomized controlled trial. First Author: Ka Yu Tse, Department of Obstetrics and Gynaecology, Queen Mary Hospital, The University of Hong Kong, Hong Kong, Hong Kong

Background: Scalp cooling is effective in preventing chemotherapy-induced alopecia (CIA) in cancer patients. However, its effect and acceptance are not certain in gynecologic cancer patients particularly in Asia. **Methods:** The CHARM study was a single-center randomized study. Women with proven gynecologic cancer planning for 3-weekly carboplatin and paclitaxel were randomised to receive usual care (control group) or scalp cooling using the Paxman Orbis II system (Paxman Coolers Limited, Huddersfield, United Kingdom) (intervention group). The primary endpoint was the incidence of psychological distress, i.e., Patient Health Questionnaire Anxiety and Depression Scale (PHQ-ADS) score $\geq$10. The study was approved by the Institutional Review Board of the University of Hong Kong/Hospital Authority Hong Kong West Cluster (UWB 19-514). **Results:** Between November 2019 to November 2021,142 women were invited to join the study. 56 women (39.4%) declined to participate, and the most common reason was worries about coldness (Table 1). 44 women were randomized to the intervention group and 42 to the control group. Fewer women in the intervention had psychological distress compared to the control group after cycle 2 of chemotherapy (27.8% vs 62.2%, p=0.003). The incidence of Grade $\geq$ 3 adverse events were similar between both groups (7.5% vs 5.1%, p=1.0). However, 12 out of 40 (30.0%) in the intervention group did not comply with scalp cooling, among which nine (75%) were due to feeling cold despite measures like using blankets and hot water. **Conclusions:** Scalp cooling was associated less-psychological distress in Asian women using chemotherapy for gynecologic cancer. Nevertheless, the high refusal rate to join the study and high drop-out rate limited its use in these women. This might be partially due to some misbelief that associated head coldness with poor general health in Traditional Chinese Medicine. More strategies are needed to improve the acceptance of scalp cooling. Clinical trial information: NCT04168242. Research Sponsor: WKK Medical Equipment Company Limited.

Reasons for refusal to join the study.

Reasons	Number of women (%)
Worries of coldness	34 (60.7%)
Worries of musculoskeletal pain/headache	2 (3.6%)
Psychiatric stress	2 (3.6%)
Personal image	4 (7.1%)
Logistic issue	3 (5.4%)

Preliminary findings from the ALVA ePRO Platform pilot study: A novel approach to collecting quality of dying and death data among informal caregivers in palliative care. First Author: Javier Retamales, Grupo Oncologico Cooperativo Chileno de Investigacion - GOCCHI, Santiago, Chile

Background: Quality of Dying and Death (QODD) is a pivotal outcome in end-of-life care, yet traditional data collection methods, such as phone calls, often suffer from low compliance and significant caregiver burden. The ALVA ePRO platform, a novel tool developed for collecting Patient-Reported Outcomes (PRO) via text messaging apps, aims to overcome these challenges by improving data collection efficiency and caregiver experience. This study evaluates the feasibility, compliance, and acceptability of ALVA ePRO among informal caregivers of terminal cancer patients in a Latin American palliative care setting. **Methods:** We conducted a pilot, single-arm study with 21 informal caregivers of terminal cancer patients. Participants received the QODD questionnaire through their preferred text messaging app. Caregivers who preferred traditional phone calls were allowed to use that method. Compliance was measured by the completion rate of the questionnaires, while acceptability was assessed through semi-structured interviews. Descriptive statistics were used for quantitative outcomes. **Results:** A total of 38 caregivers were invited to participate, and 21 caregivers signed the informed consent. Of the 21 participants, 20 completed the questionnaire, while 1 did not due to difficulty understanding the questions. Completion times ranged from 5 minutes to 23 hours and 34 minutes, highlighting considerable variability. Reasons for non-participation included technical issues, scheduling conflicts, and caregiver reluctance to attend the hospital. Preliminary interview data revealed that caregivers found the platform user-friendly and appreciated the flexibility it offered, though a few faced emotional challenges when recalling sensitive experiences. **Conclusions:** The ALVA ePRO platform demonstrates high acceptability and a strong completion rate, with significantly improved compliance compared to historical phone-based methods. It also significantly improved adherence and completion compared to our previous phone call approach using the same questionnaire. Interest in participation increased from 67.0% to 81.6%, and the completion rate from 92% to 95%. These findings suggest that text message-based data collection is an effective approach for collecting QODD data in palliative care, particularly in settings with logistical or emotional barriers to traditional methods. Future work will focus on refining the platform and exploring its scalability for larger cohorts and other palliative care contexts. Research Sponsor: The Hope Foundation for Cancer Research; 2024.

Summary of key measures and completion time for the ALVA ePRO Platform pilot study.

Measure	Preliminary Result
Enrollment (target: 20)	21 signed consent
Completion rate	95% of enrolled participants
Average Completion Time	174 minutes
Median Completion Time	16 minutes
Messaging app used	Whatsapp (100%)

11129 Poster Session

A patient-reported outcome measure (PROM) to capture patients' experiences with immuno-oncology therapy (IO)-induced cytokine release syndrome (CRS): The IO-induced CRS patient diary. First Author: Joyce R. Talavera, Sanofi, Cambridge, MA

Background: IO-inducedCRS has various signs and symptoms that impact different aspects of patients' lives. While the frequency and severity of IO-induced CRS events underscore the benefit–risk profile and tolerability of IO therapies, patients' perceptions are critical for measuring the impact of these events on their lives. In this qualitative research study, we developed a novel PROM to track the onset, resolution, and impact of IO-induced CRS events in clinical trials. **Methods:** Clinician insights and patient interviews were used to identify common IO-induced CRS signs, symptoms, and impacts. Patient-reportable symptoms and impacts were prioritized to form the basis of the IO-induced CRS Patient Diary. The PROM was tested in cognitive debriefing (CD) interviews with 3 clinicians and 3 waves of CD interviews with patients on IO (5 per wave; N = 15). Changes were made to the PROM between each wave to ensure relevance and improve interpretation and usability. **Results:** After a literature review, qualitative research with 9 clinical experts, and concept-elicitation interviews with 14 patients on IO (3 on CAR-T, 11 on non-CAR-T therapy), 37 patient-reportable signs and symptoms and 7 clinical signs (non–patient reportable) associated with IO-induced CRS were listed. Patients' concept descriptions and clinicians' concept priorities were examined, and 12 symptoms and 4 impacts across 5 domains (emotional, physical, social, activities of daily living, and financial) were included in the final diary. The IO-induced CRS Patient Diary—an electronic PROM—has three versions for use at different points in a clinical trial. The "baseline" version is completed before initial IO administration; patients report the incidence and severity of 12 symptoms and their impact on overall health (recall period: the past week). The "day of treatment" version, completed the evening of the treatment day, asks the same questions, plus about symptom manageability (recall period: since receiving the study medication on that day). The "subsequent days" version is the same as the "day of treatment" version, but also asks about impact on regular daily activities, need to rest, and amount of worry caused by CRS (recall period: past 24 hours). It may be completed daily depending on the study design or set of outcomes. **Conclusions:** The IO-induced CRS Patient Diary, the first of its kind, was developed in line with best practices and is content-valid for the intended use: to capture patients' experiences with IO-induced CRS events in clinical trials. Understanding these impacts will inform the benefit–risk profile and tolerability of IO therapies. This PROM may also have value in clinical practice, for which additional validation would be needed. Future work will aim to assess its psychometric performance in clinical trials. Research Sponsor: None.

Electronic patient-reported outcomes (ePRO)-based alerts deployed in clinical practice to inform treatment burden and care management in pancreatic cancer. First Author: Emelly Rusli, Carevive by Health Catalyst, Boston, MA

Background: Pancreatic ductal adenocarcinoma (PDAC) is characterized by aggressive growth and late-stage diagnosis. About 20% of patients are eligible for surgery at diagnosis and are usually accompanied by adjuvant/neoadjuvant chemotherapy and/or radiation, with high recurrence rates. The use of ePROs to inform patient symptom (SX) experience and guide clinical care is increasing. Objectives for this study were to assess treatment burden and management of PDAC and explore care team engagement in the clinical practice using ePRO-based alerts data. **Methods:** PDAC patients were enrolled in an ePRO platform called PROmpt from 9/2020 to 11/2024. Patients received weekly surveys to report PRO-CTCAE-derived SX experienced during treatment. When a SX was reported as moderate or severe, an algorithm-based system would generate an "alert" notification per SX to the care team who reviewed the alert, interacted with the patient, and recorded the response on the platform. Treatment burden was measured by the symptom prevalence and number of alerts per week. Results were explored by stage (I-II or III-IV), frailty status (fit vs. frail), and age (<65 vs. 65+). Time to alert resolution and clinical actions were described. **Results:** A total of 67 patients were included, of which 58 (86.6%) reported a moderate/severe SX at least once. Median age was 67 (range: 40-87), 56.7% male, 62.7% late stage, and 50.7% frail. Most patients (64.2%) received FOLFOX and 35.8% were on Gemcitabine-based regimen. No baseline difference in patients who reported an alert versus not. Patients reported, on average, 2.8 symptoms per week with median follow up of 9.3 weeks. Of 513 total alerts generated, 54.6% occurred in the first 8 weeks of treatment. The top SX triggering an alert were pain (24.4%), nausea/vomiting (15%), and decreased appetite (14%). Average number of alerts per patient per week was 1.7 (SD=1.2, Median=1). No significant difference was observed by frailty status or age, but patients in the late-stage group generated higher alert/week than early stage (1.8 vs. 1.6). Average time to alert resolution was 2.2 days with a median of 1 day. Most alerts (72.3%) were addressed in less than 2 days. The most common clinical action taken to resolve the alerts was monitoring (86%), which included contacting oncologist support as needed, increased patient education, or follow-up at next scheduled visit. **Conclusions:** The treatment burden in PDAC was high with patients experiencing about 3 symptoms per week, of which nearly 2 of them were moderate/severe. Care team engagement was high as evidenced by prompt SX mitigation. Data collected from an ePRO-based alerts system can be used to characterize treatment burden and care team response in PDAC. Future study should include broader sample size and assess the impact of alerts on health resource utilization in PDAC. Research Sponsor: None.

Evaluation of sleep quality and quality of life among patients newly diagnosed with head and neck cancer. First Author: Eric Adjei Boakye, Henry Ford Health System, Detroit, MI

Background: Patients diagnosed with head and neck cancer (HNC) often suffer from distress attributed to their cancer diagnosis which may disturb their sleep, in turn impacting their quality of life (QoL). However, there is lack of research about the association between poor sleep quality and QoL among patients newly diagnosed with HNC. We assessed the association between in poor sleep quality and QoL among patients with HNC before starting treatment. **Methods:** This is a retrospective cohort study of patients with HNC between January 2019 and September 2022. All patients with HNC treated at this tertiary care health system are evaluated prior to starting treatment by psych-oncology, using a semi-structured assessment and validated measures including the FACT-HN and Insomnia Severity Index (ISI). The FACT-HN is a 27-item validated instrument that consists of five subscales: that assesses the patient's quality of life in the physical, social/family, emotional, functional domains, and HNC-specific domains. Sleep quality was assessed via ISI, a 7-item self-report questionnaire assessing the nature, severity, and impact of sleep difficulties (defined as absence, subthreshold, moderate, or severe). We used five beta regression models to examine the association between sleep quality via the ISI and QoL via the FACT-HN (one for each subscale: emotional, social, physical, functional, and hand and neck). These models are adjusted with a variety of demographic covariates and social factors along with clinical factors. To estimate confidence intervals, bootstrap methods with bias correction were employed. **Results:** The analysis included 312 patients, 5.4% reported severe and 15.1% moderate sleep difficulties. After adjusting for other covariates, sleep difficulties were significantly associated with all FACT-HN subscales. Compared to patients with no sleep difficulties, patients with severe difficulties had a decrease in emotional (β=-1.33, 95% CI, -1.67, -0.93), social (β=-0.90, 95% CI, -1.66, -0.37), physical (β=-2.27, 95% CI, -2.67, -1.74), functional (β=-1.64, 95% CI, -2.10, -0.87), and head and neck (β=-1.11, 95% CI, -1.58, -0.65) QoL. Similarly, compared to patients with no sleep difficulties, those with severe difficulties had a decrease in emotional (β=-1.34, 95% CI, -1.66, -0.98), social (β=-0.61, 95% CI, -0.99, -0.17), physical (β=-1.85, 95% CI, -2.18, -1.49), functional (β=-1.37, 95% CI, -1.71, -0.89), and head and neck (β=-1.04, 95% CI, -1.34, -0.69) QoL. **Conclusions:** We found that patients with moderate or severe sleep difficulties had poor QoL. Early evaluation and tailored intervention to improve sleep quality are necessary to prepare these patients for HNC treatment and its consequences. Future studies are needed on sleep quality among patients during and after treatment. Research Sponsor: None.

11132 **Poster Session**

Financial burden and financial toxicity in cancer patients: A sub-analysis from a Brazilian prospective cohort. First Author: Mariana Ribeiro Monteiro, Instituto Americas, São Paulo, Brazil

Background: Financial toxicity during cancer treatment can impact patients' quality of life (QoL), adherence, and survival. Identifying subgroups with financial vulnerability among cancer patients is important to reduce disparities and develop equity-certified policies. Our study assesses financial burden (FB) and financial toxicity (FT) across different cancer types from the patient's perspective. **Methods:** This is an unplanned sub-analysis of four prospective, observational studies about real-world QoL in patients with breast (BC), prostate (PC), colorectal (CRC), and lung cancer (LC) treated at two private healthcare facilities in Brazil. We analyzed responses to Question 28 of the EORTC QLQ-C30 questionnaire. Patients reporting financial difficulties at baseline and six months were categorized as experiencing FB. Those with worsening or newly reported issues were classified as FT. FB and FT were analyzed as binary variables (any grade vs. none). Associations with clinical and epidemiological variables were assessed using univariate and multivariate logistic regression models, with a 5% statistical significance. Analyses were conducted using R software, version 4.4.1. **Results:** Between March 2015 and May 2024, 1,343 patients met the inclusion criteria: 56 with CRC, 387 with BC, 638 with PC, and 262 with LC. Most patients were male (60%) and white (77%), with a median age of 62.2 years. Only 15% had metastatic disease. At baseline, 23% reported FB, rising to 25% at six months, with 16% developing FT during treatment. Greater financial difficulties were found in women with breast cancer (FB 33%, FT 20%), while the lowest was seen in men with prostate cancer (FB 20%, FT 13%). Univariate analysis identified mixed-race ethnicity (OR 1.42; p=0,024), younger age (OR 0.96; p<0,001), and female gender (OR 0.55; p=<0,001) as FB risk factors, but only age remained significant in the multivariate model (OR 0.97; p = 0,003). Univariate analysis also linked age (OR 0.97; p<0,001), gender (OR 0.63; p=0,002), and comorbidities (OR 0.71; p=0,034) to FT, but only age remained significant in the multivariable model, with a 2% reduction in FT for each additional year (OR 0.98; p = 0.016). This study is ongoing and the impact of FB and FT on survival outcomes will be analyzed and reported in future work. **Conclusions:** This study highlights the impact of FT on cancer patients in Brazil treated in private health centers. Younger age emerged as an independent risk factor for both FT and FB after six months of treatment. Further research is needed to better understand FT within the Brazilian population, particularly in the public health system, and to develop strategies to mitigate its effects and improve patient outcomes. Research Sponsor: None.

The impact of a second primary cancer diagnosis on health-related quality of life in African American cancer survivors. First Author: Jennifer Lynn Beebe-Dimmer, Karmanos Cancer Institute, Wayne State University, Detroit, MI

Background: Survival for the most common cancers has improved dramatically over the past several decades due to advances in treatment and screening for early detection. An unintended consequence of this is that survivors now face a greater possibility of developing one or more new primary cancers in their lifetime. It has been estimated that up to 22% of cancer survivors will be diagnosed with multiple primary cancers (MPCs). Understanding the impact of these diagnoses on outcomes along the survivorship continuum is important in developing tools to mitigate risks. **Methods:** The Detroit Research on Cancer Survivors (ROCS) cohort has enrolled more than 5,000 Black cancer survivors to understand the multiplex causes of poor outcomes in this high-risk population. Detroit ROCS participants are surveyed annually following enrollment to update medical history and mental health outcomes including health-related quality of life (HRQOL) measured using the Functional Assessment of Cancer Therapy (FACT-G) survey. In addition, regular linkages with the Metropolitan Detroit Cancer Surveillance System (MDCSS) registry are used to identify second primary cancer diagnosis, confirm self-reports, and gather relevant clinical data. The ROCS cohort is in its 9th year of potential follow-up. In 2024, the Detroit Genetic Epidemiology of Multiple primary cancers (GEMS) study was funded to examine susceptibility to MPCs leveraging Detroit ROCS to identify first primary breast, prostate and colorectal cancer survivors diagnosed with a second primary cancer. Analyses included comparisons of HRQOL and other characteristics 1) between MPCs and a frequency-matched (3:1) subset of single primary cancer (SPC) cancer cases; and 2) among MPCs, using survey data collected before and after their second diagnosis. **Results:** To date, Detroit GEMS includes 371 Black MPCs confirmed in MDCSS. The most common second primary cancer diagnosed among survivors was breast, followed by colorectal, lung and hematologic cancers. No significant differences were observed between MPCs and SPCs in the total FACT-G score, however when evaluating FACT-G subscales MPCs reported a significantly lower mean functional well-being score (16.9 and 18.0, respectively; p=0.022). Similar findings were observed in a subset of 104 MPCs with functional well-being scores reported before and after their second diagnosis (18.0 and 16.1, respectively; p=0.004). **Conclusions:** Cancer survivors diagnosed with a MPC report similar HRQOL compared with survivors with a SPC, suggesting resiliency in Black cancer survivors which is encouraging. However, understanding factors that contribute to declining functional well-being will be important in early interventions to improve overall quality of life. The impact of breast cancer treatment on young women's body image and sexual health. First Author: Shari Beth Goldfarb, Memorial Sloan Kettering Cancer Center, New York, NY

Background: In 2023 MSKCC launched the Young Women with Breast Cancer Program (YWBCP) to provide comprehensive care, education, and research studies for young women with cancer. This program explored how breast cancer treatment impacts body image, sexual health, self-esteem, and personal priorities. **Methods:** MSKCC's YWBCP conducted online surveys of women aged 45 and younger at diagnosis (intake) (n=964) and six months into treatment (n=328). Surveys assessed psychological wellbeing, sexual health, body image, and referral requests. This abstract analyzes data from both surveys. **Results:** Intake data (n=964) revealed 57% (n=544) had children before diagnosis. 25%(n=236) sought information on fertility preservation, while 16% (n=156) were interested, but not ready for it. 18% (n=169) underwent fertility preservation. 26% (n=251) had a desire to protect fertility, but had not yet. Paired analysis (n=328) from intake and follow up showed 46% (n=147) felt less positive about their bodies, 42% (n=134) had no change, and 13% (n=41) improved. Half (50%; n=161) reported decreased appreciation of their body's uniqueness and 37% (n=118) no change. In response to the statement, "I act as though I like my body," 36% (n=115) declined, 24% (n=76) improved, and 40% (n=128) were consistent. Interest in sexual activity decreased (34%; n=107) more than increased (24%; n=75). Sexual satisfaction also declined in 55% (n=169), but improved in 16% (n=49) and remained the same in 29% (n=91). Concern about cancer or treatment affecting sexual ability decreased in 31% (n=98), increased in 27% (n=86) and was unchanged in 41% (n=129). At baseline women's top three concerns were cancer's impact on friends and family (27%; n=480), discussing cancer with loved ones (16%; n=282) and financial issues (15%; n=272). Social work requests prioritized individual therapy (23%; n=326), support groups (21%; n=301), family support (19%; 265), educational programs (13%; n=189), mental health resources (12%; n=170) and peer-to-peer programs (12%; n=176). Concerns were prioritized differently at 6 months, with financial issues (21%; n=113) first, followed by cancer's impact on friends and family (19%; n=102), then relationships (16%; n=83). Social work preferences changed slightly: individual therapy (28%; n=86), support groups (19%; n=59, educational programs (14%; n=45), mental health resources (14%; n=45); peer-to-peer programs (13%; n=41) and family support (11%; n=35). **Conclusions:** YWBCP data show the importance of onco-fertility and social work counseling throughout treatment. Young breast cancer patients experience significant declines in body image, sexual satisfaction, and sexual desire, highlighting the need for targeted sexual health interventions. Financial toxicity worsens over time, warranting referrals to financial services to mitigate concerns. Additional intervention studies are being performed to improve patient QoL. Research Sponsor: None.

Outpatient infusion sepsis protocol and outcomes for patients with cancer. First Author: Ashley Miles, Thomas Jefferson University, Philadelphia, PA

Background: Sepsis, a life-threatening organ dysfunction caused by infection, is a common oncologic emergency in adult cancer patients. Early sepsis detection and timely antibiotic administration can improve outcomes and reduce mortality. As more oncology treatments move to outpatient infusion centers, implementing sepsis screening in these settings can improve early detection and opportunity for intervention. As a result, we implemented a best practice alert (BPA) and protocol for the initial evaluation and managements of sepsis in an outpatient oncology infusion center. **Methods:** We performed a retrospective study from June 2022 – December 2024 comparing outcomes of patients who presented to the outpatient oncology infusion center at our institution pre- and post-implementation of our sepsis workflow. We collected the following data: BPA alerts that were activated, time to antibiotics, initial lactate drawn, repeat lactate draw, cultures collected prior to antibiotic administration, appropriate IV fluid (IVF) resuscitation, number of patients transferred to the emergency department (ED) vs. Direct Admission (DA), length of stay, and number of Intensive Care Unit (ICU) transfers. **Results:** Pre-implementation (June – December 2022), 102 oncology patients were admitted with sepsis from the infusion center. Average time to antibiotics was 6 hours (SD=6.95), 90% had blood cultures drawn prior to antibiotic administration, 85% had lactate drawn, 80% second lactate was drawn when initial lactate was $>$2, and 46% had appropriate IVF. Twenty-two percent were DA. Average LOS was 11 days (SD=9.18) and 14 patients required ICU stay. Post-implementation (June 2023 – June 2024), 118 patients were evaluated and treated for possible sepsis. Average time to antibiotics was 1.5 hours, 100% had blood cultures prior to antibiotics, 95% had initial lactate, 91% had second lactate drawn if initial was $>$2, 46% appropriate IVF. Thirty four percent of evaluated patients were managed as an outpatient. Of those admitted, 78% were DA. The average LOS was 6 days (SD=4.6), and 4 patients required ICU stay. **Conclusions:** The outpatient sepsis protocol improved early management and treatment of patients with suspected sepsis, also improving clinical outcomes. As a result of the new workflow, more patients were directly admitted to the hospital avoiding unnecessary ED utilization. Early management helped reduce severity of sepsis resulting in fewer ICU admissions and shorter length of stay in the hospital. These improvements demonstrate the protocol's effectiveness and potential for broader application in oncology settings. Additional evaluation is needed to determine the generalizability of the protocol as it is scaled across the health system. Research Sponsor: None.

The association of cancer history with markers of cognitive decline in a large US national survey registry. First Author: Emmanuel Kampanga, CCU School of Medicine, Columbus, OH

Background: Cancer is known to cause health complications, including heart and kidney disease, but its long-term impact on cognition is less understood. Cognitive impairments, such as memory and attention problems, are common in survivors, particularly those treated with chemotherapy, known as cancer-related cognitive impairment. While physical activity may help, survivors often face higher disability rates. Clarifying cancer's long-term cognitive effects is essential for improving survivors' quality of life. **Methods:** An extensive, de-identified, publicly available database from the CDC, the Behavioral Risk Factor Surveillance System. Data collected in 2021 was analyzed using a multivariable logistic regression model to assess the association between demographics, cancer diagnosis, medical diagnoses, and various markers of cognitive decline. The final analysis had over 100,000 responses. **Results:** The logistic regression model, considering various demographic and medical parameters (Table 1), revealed that a history of cancer in both males and females was associated with markers of cognitive decline. This included depression in males (OR=1.235, 95% CI 1.180-1.293, p$<$0.001); and in females (OR=1.177, 95% CI 1.137-1.218, p$<$0.001), difficulty remembering or concentrating in males (OR=1.172, 95% CI 1.110-1.238, p$<$0.001); and in females (OR=1.155, 95% CI 1.103-1.210, p$<$0.001), and difficulty running errands in males (OR=1.174, 95% CI 1.101-1.251, p$<$0.001) and in females (OR=1.194, 95% CI 1.138-1.251, p$<$0.001). Interestingly, exercise in the last 30 days was associated with a protective effect on all markers of cognitive decline. **Conclusions:** Our analysis demonstrated a significant negative association between cancer diagnosis and markers of cognitive decline in both males and females. At the same time, exercise in the last 30 days was associated with less cognitive decline. Research Sponsor: None.

Improving genetic counseling uptake for breast, pancreatic, and prostate cancers at a safety net hospital. First Author: Jenny Jing Xiang, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Despite guideline recommendations, genetic counseling (GC) for BRCA associated cancers among underserved populations remain low. We conducted a QI project to increase GC uptake for patients with breast, pancreatic, and prostate (BPP) cancers seen in a safety net oncology clinic at Harris Health. **Methods:** Analysis of electronic medical record (EMR) data along with surveys and interviews of clinicians and staff identified: 1) a complex GC referral process with 30% unscheduled referrals in 2023, 2) lower frequency of GC appointments (appts) among established patients, and 3) clinician knowledge deficits regarding GC guidelines. Our interventions consisted of 1) developing an automated referral scheduling workflow, 2) creating an EMR report of potentially eligible patients with upcoming appts and sending monthly reminders to clinicians, and a 3) GC guidelines lecture by a genetic counselor. **Results:** There were 720 patients in the preintervention period (1/2020-5/2024) and 93 patients in the postintervention period (6-12/2024). In total, 50.5% of patients were Hispanic, 24.8% were Black, 53.7% spoke Spanish, and 67.4% received financial assistance. Amongst all patients, GC appts increased from 55.4% preintervention to 67.7% postintervention (p = 0.02), with increases across breast (54.6% to 67.1%), pancreatic (55.4% to 71.4%), and prostate (59.1% to 65%) cancers. Among patients meeting select NCCN GC criteria identifiable through discrete EMR data (triple negative, stage IV HER2 negative, or diagnosed age $<$50 breast; all pancreatic; stage IV prostate), GC appts increased from 74.0% to 82.6% (p = 0.20), with increases for breast (79.4% to 86.5%) and pancreatic (55.4% to 71.4%) cancers and a decrease for prostate cancer (71.9% to 60%). All GC referrals postintervention were scheduled, with time from GC referral to GC appts improving from a mean of 170.2 days (SD 636.1) to 27.4 days (SD 19.5) (p$<$0.01). Time from first oncology appt to GC appt improved from a mean of 124.2 days (SD 199.9) to 33.3 days (SD 30.5) (p$<$0.01). 87.5% of patients with GC appts consented to testing in 2023 and 86% consented postintervention. **Conclusions:** Multilevel interventions targeting both EMR capabilities as well as clinician education and awareness of eligible patients streamlined the GC referral workflow and increased GC appts among a safety net patient population with BRCA associated cancers. Research Sponsor: None.

OncoPRO: A US national initiative supporting implementation of remote symptom monitoring with electronic patient-reported outcomes (ePROs) in oncology practices. First Author: Ethan Basch, The University of North Carolina at Chapel Hill, Chapel Hill, NC

Background: Remote symptom monitoring using electronic patient-reported outcomes (ePROs) results in improved symptom management, communication, quality of life, and in some cases survival. Furthermore, value-based cancer care models such as the CMS Enhancing Oncology Model are increasingly supporting or requiring remote symptom monitoring. However, implementation at scale in real-world settings remains challenging for practices. **Methods:** OncoPRO is a national initiative in the United States that supports oncology practices and health systems in the implementation and sustainability of remote symptom monitoring programs using ePROs, integrated with electronic health record systems. OncoPRO is funded by the Patent-Centered Outcomes Research Institute (PCORI), and is led by operational groups at the University of North Carolina and the University of Alabama, in partnership with the American Society of Clinical Oncology (ASCO), the American Cancer Society (ACS), and the PROTEUS Consortium, with observers from federal agencies. **Results:** OncoPRO was initiated in March 2024, with 15 large U.S. practices/health systems participating, as well as two national practice networks, four EHR software companies, four ePRO software companies, and observers from the U.S. Centers for Medicare and Medicaid Services and the Food and Drug Administration. The central activities of OncoPRO encompass co-learning collaborative monthly meetings where leaders from each practice in clinical care, information systems, and value-based care convene to review progress, barriers and strategies for implementation, billing tactics, and other guidance. Practices share data dashboards on implementation, discuss challenges they face, and exchange success stories under the facilitation of ASCO coaches. Support materials and standard operating processes are shared by the operational team, ACS, and software vendors. Additional practices are joining the initiative both within the US and internationally. A goal is to demonstrate that implementation of remote symptom monitoring with ePROs is feasible on a wide basis and leads to improved operational and clinical outcomes. **Conclusions:** The OncoPRO initiative is supporting practices, including both community and academic, in implementing remote symptom monitoring using ePROs through a learning collaborative that is anticipated to be of interest to others considering ePRO implementation. Transforming genomic testing in prostate cancer: A comprehensive system-wide initiative. First Author: Chinmay Jani, University of Miami Sylvester Comprehensive Cancer Center, Miami, FL

Background: Timely detection of pathogenic variants enables personalized treatment and improved outcomes in prostate cancer (PC). In 2020, NCCN guidelines recommended genomic testing for mPC, but by 2022, only 30.8% of mPC patients in Florida had undergone appropriate testing. In our current study, we evaluate the impact of system-wide quality improvements at SCCC on genomic testing rates for mPC patients. **Methods:** In alignment with NCCN guidelines, several initiatives were launched in 2023 to enhance adherence to genomic testing practices. In May 2024, SCCC partnered with Florida Society of Clinical Oncology (FLASCO) and Pfizer on a state-wide initiative to address barriers to germline testing. A survey was conducted to assess the genomic testing process and identify gaps in adherence. System improvement projects were initiated, accompanied by efforts to raise awareness. A retrospective analysis utilizing EPIC Electronic medical record (EMR) data evaluated genomic testing rates among patients with newly identified mPC at SCCC from 2022 to 2024, stratified by ethnicity. **Results:** In 2022, baseline genomic testing rates for mPC at SCCC were 57%. Starting in 2023, high-risk cancer screening programs and EMR-focused initiatives, including the Genomics Module and Invitae integration, centralized molecular results and established registry to track alterations. In 2024, the survey revealed that 50% of physicians received unstructured genomic testing results via EMR, while 83.3% faced challenges accessing results for decision-making. Drawing from the successful breast cancer screening program, multidisciplinary teams were formed to address gaps and enhance testing adherence, focusing on awareness and enhancing EMR integration, reporting, and health prompts. That year, genomic results integration into the data portal also began. Using Slicer Dicer and Epic reporting, we evaluated testing rates, which improved to 68.6% in 2023 and 74% in 2024, with Hispanic patients achieving 76.5% and 80%, respectively. **Conclusions:** Institutional initiatives at SCCC, including expanding the Genetics program and enhancements to EMR functionality, have successfully increased genomic testing rates for mPC patients across all ethnicities. Building on this progress, approved steps for 2025 include expanding the integration of molecular testing with additional testing vendors, creating a dedicated Molecular tab with discrete fields in the EMR, and expanding education and training programs to further streamline genomic testing practices. Enhancing lung cancer surgical quality: Insights from a national quality improvement collaborative. First Author: Kelley Chan, American College of Surgeons, Chicago, IL

Background: Sampling of at least 3 mediastinal and at least 1 hilar lymph node stations during lung cancer resection was adopted by the American College of Surgeons (ACS) Commission on Cancer (CoC) as Operative Standard 5.8 to ensure appropriate staging, guide adjuvant systemic therapy, and improve overall survival. Early assessments suggested difficulty with reaching goal hospital-level compliance rates of ≥80%. The objectives of this study were to compare compliance with Standard 5.8 before and after participation in the Lung NODES national quality improvement (QI) collaborative and to identify facilitators to achieving compliance. **Methods:** Lung NODES enrolled 354 CoC-accredited hospitals in January 2024. Over 12 months, all hospitals actively participated in guided root cause analyses, educational webinars, peer-to-peer learning, and the development and implementation of hospital-level strategies. Baseline and post-participation surveys collected data on Standard 5.8 compliance and differences in hospital-level compliance were assessed using Wilcoxon signed-rank tests. The post-participation survey queried hospitals on facilitators to achieving compliance. **Results:** The number of hospitals achieving ≥80% compliance with Standard 5.8 increased from 144 (40.7%) to 238 (67.2%) from baseline to post-participation, respectively. Hospital-level median compliance increased from 67.8% (IQR 42.9-90) to 90.5% (IQR 70-100), $p<0.001$. All hospital types had an increase in mean absolute difference in compliance, with the largest increase seen for community hospitals (25.4%, STD 43.5) (Table). For the 114 programs that newly achieved compliance, facilitators included surgeon buy-in (83.3%), proactive specimen labeling (76.3%), and multidisciplinary communication (73.7%). **Conclusions:** Participation in Lung NODES was associated with higher compliance with Standard 5.8 irrespective of hospital type, suggesting that national QI collaboratives may represent an effective large-scale approach to address gaps in cancer care delivery. Research Sponsor: None.

Operative standard 5.8 compliance by hospital type at baseline and after participation in Lung NODES.

Systematic communication model to facilitate conversations about metastatic breast cancer. First Author: Fernanda Mesa-Chavez, Breast Cancer Center, Hospital Zambrano Hellion TecSalud, Tecnologico de Monterrey, Monterrey, Mexico

Background: For patients with metastatic breast cancer (mBC) understanding their stage and treatment goals is essential to engage in shared decision-making. However, patient-physician communication challenges often hinder discussions about this information. This study evaluated a systematic communication model designed to guide conversations on mBC and to ease oncologists' experience when conveying this delicate information. **Methods:** Patents starting 1st-line mBC treatment were included at 7 referral centers in Mexico. During the consultation in which mBC was disclosed, their oncologists followed a 9-step communication model that facilitated and promoted conversations about mBC stage, treatment, and prognosis, considering each patient's information preferences. After 3-10 days, patients completed a survey assessing understanding of their mBC stage and treatment, and satisfaction. Oncologists also completed a survey exploring their experience providing the information. This study was funded by Pfizer. **Results:** 50 patients were included by 10 oncologists. Patients' median age was 55 yrs (IQR 15); most had ≤high school education (55%) and had recurrent mBC (63%). After receiving information through the communication model, 78% of patients were aware that their BC was metastatic, 56% that mBC is not curable, 76% that their treatment's main objective was to improve their lifespan and quality of life, and 70% that their treatment had no established end date. Patients reported having discussed their prognosis with their oncologist in 54% of cases, most of which considered this information was very useful for: making treatment decisions (94%), preparing for the future (92%), and keeping hope (92%). Overall, most (78%) were satisfied with the way in which they received information about their mBC. As for oncologists' experience, they considered the communication model was very helpful to better convey the incurability of mBC (76%), treatment objectives (82%), and prognosis (42%). With all patients, oncologists were very satisfied (46%) or satisfied (54%) after implementing the model. They felt anxious in 2% of cases, stressed in 2%, confident in 90%, and calm in 90%; their distress thermometer score was ≥4/10 in 26% of consultations. Of note, oncologists reported not completing ≥1 step of the model in 44% of consultations, mostly due to limited time (46%) and forgetfulness (29%). Compared to their usual practice, they considered that the model did not affect (42%) or moderately increased (50%) the duration of the consultation. **Conclusions:** Both patients and oncologists were highly satisfied with the way in which mBC information was disclosed through the communication model. Oncologists particularly recognized the model as a valuable aid for these conversations. Yet, prognosis was discussed with a limited proportion of patients, underscoring the need for further efforts to ease approaching this topic. Research Sponsor: Pfizer.

Epidemiologic patterns and mortality outcomes in young lung cancer non-smokers: A National Inpatient Sample analysis (2016–2021). First Author: Simo Du, Jacobi Medical Center - Albert Einstein College of Medicine, Bronx, NY

Background: While the incidence and mortality of smoking-related lung cancer have declined, cases among individuals who have never smoked (LCINS) are increasing, particularly among women and younger populations. LCINS often presents with distinct pathology features, unique genetic mutations, and a higher prevalence of early-onset disease. Despite these distinctions, limited evidence exists regarding the epidemiology and mortality outcomes of LCINS. This study aims to compare sociodemographic differences and mortality outcomes among early- and late-onset lung cancer, stratified by smoking status. **Methods:** We performed a pooled cross-sectional analysis using the National Inpatient Sample (NIS) from 2016 to 2021. Lung cancer patients, identified by ICD-10 codes (C34.x), were stratified by age ($\leq$50 years and $>$ 50 years) and smoking status (current, former, and non-smokers). Comorbidities were assessed using the Elixhauser Comorbidity Index. Descriptive statistics and multivariable logistic regression analyses were used to compare mortality outcomes, with statistical significance defined as $p < 0.05$. Analyses were performed using STATA MP 18. **Results:** A total of 199,798 lung cancer hospitalizations were identified, representing 998,990 weighted discharges across the U.S. Of these, 1.47% were young non-smokers ($\leq$50 years), 1.33% young smokers, 26.63% older non-smokers ($>$ 50 years), and 25.8% older smokers. Young non-smokers were more likely to be female (60.8% vs 50.4% of the general population) and non-white (49.2% vs 23%), with a notably higher prevalence of Asian (11.4% vs 3.3%) and Hispanic (15.1% vs 4.8%) individuals. Young non-smokers had fewer health conditions compared to the general population, with a lower mean Elixhauser Comorbidity Index (19.38 vs 20.63) and lower prevalence of chronic pulmonary disease (16.5% vs 51.3%). However, they had a higher prevalence of metastatic disease (55.8% vs 40.8%). Inpatient mortality was higher in young non-smokers (7.2%) compared to young smokers (5.2%), and higher in older non-smokers (9.1%) than older smokers (5.0%). Multivariable logistic regression showed a statistically significantly increased mortality for young non-smokers compared to young current smokers (OR 1.58, 95% CI 1.26–1.99, $p < 0.01$), and similarly for older non-smokers (OR 1.72, 95% CI 1.42–2.08, $p < 0.01$), after adjusting for age, sex, race and other confounders. **Conclusions:** LCINS, particularly in early onset cases, represents a distinct subgroup with unique sociodemographic and clinical characteristics, including a higher prevalence of non-white individuals, fewer comorbidities, and an increased mortality rate. The higher mortality may reflect the advanced stage at presentation and poorer prognosis of LCINS, suggesting potential differences in disease mechanisms compared to smoking-related lung cancer. These findings highlight the need for tailored screening strategies and personalized treatment approaches for the LCINS population. Research Sponsor: None.

Real-world assessment of breast cancer risk following hormonal therapy in endometriosis: A Global Collaborative Network propensity score matched analysis. First Author: Caterina Gianni, IRCCS Istituto Romagnolo per lo Studio dei Tumori (IRST) "Dino Amadori", Meldola, Italy

Background: Research suggests endometriosis, an estrogen-dependent condition, may be a potential risk factor for breast cancer (BC) development. While oral contraceptives are the standard treatment, their efficacy is limited in symptom control. This study examines the relationship between hormonal therapy (HT) prescribed for endometriosis management and BC risk. **Methods:** Using TriNetX Global Collaborative Network, we compared 41 029 endometriosis patients receiving HT against 111 429 control patients without HT. We excluded patients with prior contraceptive use or neoplasm diagnosis. Through propensity score matching, we created 38 311 balanced pairs, accounting for demographics (age, race), medical history (pelvic disease, family cancer history, hypertension, diabetes), and clinical factors (pregnancies, body mass index). Additional analyses were conducted by type of HT: progestins (36 156 matched pairs) and LHRH analogues (7 700 matched pairs). BC incidence was measured using hazard ratios, starting 6 months post-endometriosis diagnosis. We evaluated the rate of pregnancies and we also conducted an analysis to assess the risk of major cardiovascular events according to HT treatment for endometriosis, including stroke, cardiac ischemia, thrombosis, and pulmonary embolism. **Results:** The matched cohorts had a mean age of 34 years (standard deviation 9.3). The study population was predominantly white (60%), with lower representation of Black American (10%) and Asian (3%) patients, while race was unknown for 19% of participants. Among patients with endometriosis treated with HT, 262 of them developed BC compared to 239 cases in the control group with a hazard ratio (HR) of 1.18 (95% CI 1.0-1.4, p = 0.064), showing no significant age-related differences. LHRHa treatment was associated with higher BC incidence (66 versus 36 cases, HR 1.7, 95% CI 1.14-2.6, p = 0.009). Age-stratified analysis of LHRHa patients showed no differences for those under 30 and 40 years, while patients under 50 showed a non-significant increase (25 versus 19 cases, HR 1.28, 95% CI 0.70-2.32, p = 0.42). Progestin treatment showed marginally increased BC risk (243 versus 216 cases, HR 1.2, 95% CI 1.0-1.4, p = 0.05) without age-related differences. Patients in the control group not receiving HT presented a lower chance to get pregnant (HR 1.32, 95% CI 1.3-1.4). No significant differences were observed in terms of major cardiovascular events. **Conclusions:** While overall HT showed no clear link to BC risk, both progestins and LHRHa were associated with increased risk. These findings warrant further investigation, particularly since these medications are typically prescribed to endometriosis patients with severe symptoms who share common reproductive and hormonal risk factors with BC. Comprehensive genomic profiling in AYA cancer patients. First Author: Naomi Hayashi, The Cancer Institute Hospital, Japanese Foundation for Cancer Research, Tokyo, Japan

Background: Cancer types in Adolescents and Young Adults (AYA) vary by age. Since many AYA cancers are classified as rare, patients continue to face limited therapeutic options. This study evaluates the utility of comprehensive genomic profiling (CGP) and genome-matched therapies for AYA cancer patients, considering age-specific variations using a nationwide database. **Methods:** We analyzed data from 2,325 AYA patients (aged 15–39) who underwent CGP between 2019 and 2023. The genomic landscape and treatment status were assessed. Patients were classified into two groups: those with cancer types that are more common in those under 30 years of age and those categorized as other. Parameters were compared between the two groups. **Results:** The median age was 33 years, with *TP53* being the most frequently altered gene. Overall, 275 patients (12%) were administrated for treatment based on CGP. Cytotoxic agents were suggested when no actionable molecular targets were identified. However, there was no significant difference in overall survival (OS) between patients who received the recommended therapies and those who did not (40 vs. 33 months, $p = 0.07$). A generational comparison of cancer incidence identified 6 cancer types that were more prevalent in patients under 30 years of age: bone, peripheral nervous system, central nervous system, germ cells, adrenal gland, and soft tissue (collectively referred to as 6 specific cancer types). Among patients with the 6 specific cancer types (N = 824), *TP53* and *STK11* were the most frequently altered genes, whereas *TP53* and *KRAS* predominated in patients with other cancers (N = 1501). Treatment administrations, including cytotoxic agents, based on CGP were made for 50 patients (6.1%) and 225 patients (15%), respectively ($p < 0.01$). Among these, 28 patients (56%) with the 6 specific cancer types and 54 patients (24%) with other cancers did not receive genome-matched therapies ($p < 0.01$). Regarding OS, patients with other cancers who received the recommended therapies had significantly longer OS than those who did not (41 vs. 30 months, $p < 0.01$). However, in patients with the 6 specific cancer types, there was no significant difference in OS between those who received the recommended therapies and those who did not (38 vs 44 months, $p = 0.33$). **Conclusions:** The prognostic benefit of CGP may be limited for rare cancers that are prevalent among the younger generation, as fewer opportunities for receiving genome-matched therapies. Research Sponsor: AYA Oncology Alliance (AYAKEN).

Hospice utilization in Veterans with newly diagnosed metastatic prostate cancer. First Author: Jennifer Mei Lee, University of Michigan Medical School, Ann Arbor, MI

Background: Treating men with metastatic castration-sensitive prostate cancer (mCSPC) using androgen deprivation therapy (ADT), with or without treatment intensification, is highly palliative and leads to survival measured in years. In contrast, hospice provides end-of-life support when estimated life expectancy is $\leq$6 months, which rarely applies to men with newly diagnosed mCSPC. Although traditionally, patients transition to hospice when cancer treatments have been exhausted, the VA allows hospice enrollment during cancer treatment. This study investigates factors associated with hospice enrollment for Veterans within the first six months after diagnosis of mCSPC. **Methods:** We conducted a retrospective cohort study utilizing the VA Corporate Data Warehouse, an extensive database of medical records from 130 VA facilities, linked to Medicare data. Patients newly diagnosed with mCSPC between January 1, 2023, and June 17, 2024, were identified using a validated natural language processing tool. Veterans with prior orchiectomy, receipt of ADT the prior year, or without primary care visits the two years prior to diagnosis were excluded. Our primary outcome was hospice enrollment within six months of metastatic diagnosis. Multivariate logistic regression was used to estimate adjusted odds ratios (aOR) and 95% confidence intervals (CI), adjusting for clinical and socioeconomic variables, including neighborhood disadvantage as measured by area deprivation index (ADI). **Results:** We identified 3429 Veterans with mCSPC, with a mean age of 76 years, 30% of whom were Black. Overall, 11% (n = 391) of Veterans were referred to hospice within the first six months following mCSPC diagnosis. Older age and higher level of frailty were associated with greater odds of hospice enrollment within 6 months (aOR 1.84, 95% CI 1.59-2.14 per 10 years; aOR 4.79, 95% CI 3.74-6.13 for those with moderate/severe frailty versus not frail or mild frailty, respectively). Single Veterans (aOR 1.41, 95% CI 1.11-1.80) and those without additional healthcare insurance (aOR 2.22, 95% CI 1.74-2.85) also had greater odds of hospice referral. Neighborhood-level disadvantage was significantly associated with hospice enrollment: Veterans living in the most deprived neighborhoods (ADI 80–100) had higher odds of hospice referral compared to those in the least deprived neighborhoods (ADI 0–20) (aOR 2.97, 95% CI 1.90-4.73). **Conclusions:** Social determinants of health, including neighborhood-level disadvantage and lack of insurance coverage were strongly associated with Veteran hospice enrollment within six months of mCSPC diagnosis. However, since a unique benefit of VA cancer care allows hospice enrollment in concert with cancer treatment, more work needs to be done to understand whether hospice enrollment is being used primarily for social support or for end-of-life care in men with a highly treatable condition. Association of MammaPrint and clinical outcomes by race among 5000 individuals with HR+HER2- early stage breast cancer enrolled in FLEX. First Author: Erin Frances Cobain, Michigan Medicine, Ann Arbor, MI

Background: Black women with hormone receptor-positive (HR+), HER2-negative (HER2-) early stage breast cancer (EBC) have a 38% higher mortality rate than White women, a disparity not fully explained by social determinants of disease. Previous research demonstrating unequal performance of gene expression (GE) assays across racial groups has raised concerns that GE assays may underestimate risk of recurrence in Black patients (pts). Compared to other GE assays, the MammaPrint (MP) 70 gene signature consistently classifies a higher proportion of Black pts as High Risk compared with White pts. This analysis examines real world data and survival stratified by MP and self-reported race in pts with HR+HER2- EBC enrolled in FLEX. **Methods:** The ongoing FLEX (NCT03053193) trial enrolls pts undergoing standard of care MP testing, classifying tumors as Low, High 1 (H1), or High 2 (H2) risk of recurrence. BluePrint defines molecular subtypes as Luminal, Basal, or HER2. Clinical differences were assessed with Chi-squared or Fisher's exact tests. Distant recurrence-free interval (DRFI), defined per STEEP criteria, was compared by race and MP using Kaplan-Meier estimates and log rank tests. **Results:** Among 5142 pts analyzed, 9.6% were Black and 90.4% were White. Node positive (30.4% vs 21.9%; $p < 0.001$) and Grade 3 disease (25.3% vs 14.1%; $p < 0.001$) were more common among Black pts. Black pts had significantly higher incidences of H1 (43.1%), H2 (18.3%), and Basal (9.3%), and lower rates of Low (38.5%) Risk tumors, compared with White pts (H1: 36.6%; H2: 7.4%; Basal: 3.3%; Low: 56.6%; $p < 0.001$). Black pts had higher rates of neo/adjuvant chemotherapy (CT) (52.9% vs 40.3%; p = 0.003) and use of an anthracycline-taxane regimens (43.0% vs 35.4%: p = 0.001) compared with White pts. However, despite a 61.4% incidence of H1/H2 risk disease among Black pts, only 52.9% received CT. In contrast, White pts had a 44.0% H1/H2 incidence and 40.3% received CT. Among all pts, 4-year DRFI was lowest for H2 (90.7%), 96.7% for H1, and 98.8% for Low Risk ($p < 0.001$). DRFI for Black pts was 98.3% for Low, 95.5% for H1, and 90.2% for H2 (p = 0.005). For White pts, DRFI was 97.9% for Low, 96.9% for H1, and 89.8% for H2 ($p < 0.001$). Among CT treated pts, DRFI was comparable for Black (n = 186) and White (n = 1130) pts with H1 (96.0% vs 96.4%) and H2 (90.3% vs 90.6%) tumors. **Conclusions:** Black pts have a higher prevalence of H2/Basal and higher risk clinical features in the nationwide prospective FLEX Registry trial. Black pts with HR+HER2- MP H1/H2 EBC were less likely to receive neo/adjuvant CT than White pts with H1/H2 tumors. This highlights a critical gap in real-world practice where Black pts may be undertreated. However, clinical outcomes are equivalent among similarly treated Black and White pts across MP risk groups. MP classifies fewer EBCs as Low Risk in Black pts, and this classification is accurate as 4-year DRFI is excellent in these pts. Clinical trial information: NCT03053193. Adherence to vaccination recommendations in the adult cancer population. First Author: Kimberly Feng, Beth Israel Deaconess Medical Center, Boston, MA

Background: In 2024, the American Society of Clinical Oncology (ASCO) published a strong recommendation that clinicians should ensure that all adults with cancer are up to date on seasonal and age- and risk-based vaccinations. The recommended vaccines are drawn from CDC guidelines and include annual influenza, COVID-19, Tdap, Hepatitis B, Zoster (shingles), and Pneumococcal vaccines for all adults, and RSV and HPV for specific groups. Recent studies have found that patients undergoing treatment for cancer had lower COVID-19 vaccination rates mediated by area-level social determinants of health; to our knowledge, rates of adherence to and mediators of other recommended vaccinations in the adult cancer population have not been adequately quantified. **Methods:** We used data from the nationally representative National Health Interview Survey (NHIS) from 2019-2023 to evaluate vaccination rates among individuals with a history of cancer. We identified all individuals aged ≥50 with a diagnosis of cancer within the past 5 years and extracted data on self-reported receipt of three vaccines: annual influenza, pneumonia, and shingles vaccinations. We adjusted for age, race, sex, insurance type, education, US census region, metropolitan statistical area, and used ordinal logistic regression to model determinants of greater degrees of vaccination. **Results:** Between 2019 and 2023, only 30.6% (95% CI [29.3, 31.9]) of all adults aged ≥50 with cancer reported receiving all three studied vaccines. Individually, 69.6% (95% CI [68.2, 71.0]) received the influenza vaccine, 58.4% (95% CI [56.9, 59.9]) received the pneumococcal vaccine, and 42.5% (95% CI [41.0, 44.0]) received the shingles vaccine. The likelihood of receiving more vaccines increased with age (for age 65-74: OR 4.16, CI [3.63, 4.76], $p < 0.001$; for age 75+: OR 5.33, CI 4.62-6.15, $p < 0.001$), whereas variables associated with receiving fewer recommended vaccines included being Hispanic (OR 0.70, CI [0.52, 0.93], p=0.01) or Black (OR 0.61, CI [0.49, 0.77], $p < 0.001$), having Medicaid (OR 0.77, CI [0.63, 0.95], p=0.01), and having high school education or less (OR 0.65, CI [0.59, 0.73], $p < 0.001$). We did not find a significant association between living in a non-metropolitan area and vaccination receipt. **Conclusions:** Between 2019 and 2023, less than one-third of respondents aged ≥50 years diagnosed with cancer within 5 years reported receiving all three appropriate age-related vaccinations. Race-ethnicity, lower socioeconomic status, and lower education were all associated with receiving fewer of the recommended vaccinations. In order to meet ASCO recommended guidelines, efforts to improve vaccination uptake among adults with cancer may need to include targeted interventions for these at-risk populations. Research Sponsor: None.

Association between body mass index and overall survival in veterans receiving immune checkpoint inhibitors. First Author: Abhishek Bhattacharya, NYU Langone Department of Internal Medicine, New York, NY

Background: While obesity is a well-established risk factor for cancer development, patients with obesity paradoxically demonstrate better survival rates compared to those with normal body mass index (BMI) in certain malignancies. Studies suggest this phenomenon extends to patients receiving immune checkpoint inhibitors (ICI), with emerging evidence showing improved progression-free and overall survival across multiple cancer types. Despite recognition of this relationship, its magnitude and consistency in real-world populations remain uncertain. The Veterans Affairs (VA) healthcare system, with its comprehensive electronic health records and distinctive demographic composition, presents a unique opportunity to validate these findings in routine clinical practice. **Methods:** We conducted a retrospective analysis using the VA Corporate Data Warehouse, selecting de-identified patients who received ICI therapy between March 2011 and June 2024 (VA COIN grant #1I50HX004009, IRB #1575166). From an initial cohort of 37,863 veterans, we chose a random 20% subset (n = 7,302) for preliminary analysis. We extracted demographic data (age, sex, race), vital signs for BMI calculation, cancer diagnoses (ICD-9/10 codes), and ICI records. BMI categories were: underweight (< 18.5 kg/m²), normal (18.5-25 kg/m²), overweight (25-30 kg/m²), and obesity (> 30 kg/m²). We calculated overall survival from ICI initiation to death or last follow-up. Survival analyses included Kaplan-Meier methodology with Cox proportional hazards models. **Results:** The cohort of 7,302 veterans was predominantly male (97%) and White (74%), with most patients aged 65-75 years (51%). Pembrolizumab (45%) and nivolumab (29%) were the most frequently prescribed ICIs. Survival was significantly associated with BMI class (log-rank test $p < 0.01$). Using normal BMI (18.5-25, n = 2,422) as reference, Cox proportional hazards analysis showed progressively lower mortality risk with increasing BMI, ranging from 13% reduction in overweight patients (HR 0.87, 95% CI 0.82-0.93) to 27% reduction in patients with BMI 35-40 (n = 481, HR 0.73, 95% CI 0.65-0.83, $p < 0.01$). Underweight patients showed increased mortality risk (HR 1.31, 95% CI 1.15-1.51). **Conclusions:** The 27% mortality reduction among patients with higher BMI demonstrates a clinically meaningful survival advantage in immunotherapy outcomes and suggests BMI might be an important factor in risk stratification and treatment discussions. The increased mortality risk in underweight patients may reflect cancer-related cachexia. These findings, derived from a large cohort of veterans, corroborate the obesity paradox in cancer immunotherapy and suggest potential applications for personalized immunotherapy approaches. Impact of palliative chemotherapy in hospitalized patients with advanced solid tumors. First Author: Sydney Roussel, Inova Fairfax Medical Center, Falls Church, VA

Background: The role of palliative chemotherapy (PC) in patients with advanced solid tumors and poor performance status (PS) remains uncertain since this population is underrepresented in clinical trials. Retrospective studies of patients with an Eastern Cooperative Oncology Group-Performance Status (ECOG-PS) > 2 consistently demonstrate poorer survival and increased treatment-related toxicities. This study aimed to evaluate the clinical impact of PC in hospitalized patients and its association with PS and outcomes. **Methods:** This retrospective chart review was conducted between January 2018 and July 2024 across a five-hospital health system. The primary endpoint was overall survival (OS), defined as the time from the first dose of inpatient chemotherapy to death or last follow-up. Secondary outcomes included in-hospital mortality, length of stay, 30- and 60-day mortality, and toxicity. Continuous variables were compared using the Mann-Whitney *U* test or the two-sample t-test and categorical variables were compared using the Chi-squared or Fisher's exact test. Time to event data were assessed using the Kaplan-Meier method. A p-value < 0.05 was considered statistically significant. **Results:** A total of 383 patients were included in this study. Of these, 227 patients had an ECOG-PS ≤ 2, and 156 patients had an ECOG-PS > 2. The median age was 60 years, and 57% were female. Common primary tumor sites included gastrointestinal, gynecologic, and lung. At presentation, 288 patients were chemotherapy-naïve, and 88% were hypoalbuminemic. The median OS was 188 days. Patients with an ECOG-PS ≤ 2 had a significantly longer median OS compared to those with an ECOG-PS > 2 (293 vs 77 days, $p < 0.0001$). Mortality rates were higher in patients with ECOG-PS > 2 during the index hospitalization (17% vs 6%, p=0.0005), at 30 days (24% vs 14%, p=0.015), and at 60 days (36% vs 21%, p=0.001). Despite these differences, bleeding and infection rates were similar between groups. Median duration of hospitalization was 13 days, with significantly longer stays observed in patients with poor PS (16 vs 10 days, $p < 0.0001$). Although toxicity rates were comparable overall, patients with ECOG-PS > 2 experienced significantly higher rates of thrombocytopenia (39% vs 25%, p=0.018) and neutropenia (40% vs 27%, p=0.028). In univariate analysis, significant predictors of shorter survival included ECOG-PS > 2 ($p < 0.0001$), age > 60 (p=0.0097), Charlson Comorbidity Index ≥ 8 (p=0.02), hypercalcemia (p=0.0014), and hypoalbuminemia (p=0.0014). In multivariate analysis, all factors except age > 60 remained independent predictors of shorter survival. **Conclusions:** PC in hospitalized cancer patients with ECOG-PS > 2 was associated with shorter survival, longer hospital stays, and higher rates of early mortality. These findings emphasize the importance of careful patient selection and the need for further research to optimize care strategies in this population. Research Sponsor: None.

Association of co-administration of a vaccine with immune checkpoint inhibitors with survival. First Author: Justin Dejia Wang, Mercy Scripps Hospital, San Diego, CA

Background: Patients undergoing chemotherapy are less likely to complete recommended routine vaccination. Vaccination during immune checkpoint inhibitor (ICI) therapy elicits a significant cytokine response, which could enhance antitumor effects. This study investigates whether co-administration of vaccination with ICI improves cancer patient survival. **Methods:** Using the California Immunization Registry and Scripps Health's electronic medical record, we validated vaccination status for patients at a large healthcare system in San Diego and conducted an observational cohort study of all ICI recipients from January 1, 2018, to June 1, 2024. Overall Kaplan-Meier survival curves were compared between patients who received vaccination within 100 days of ICI initiation and those who did not using log rank test. Subgroup analyses focused on patients with stage IV non-small cell lung cancer (NSCLC) and stage IV melanoma. The ICI cohort was propensity matched 1:1 by demographics to non-cancer patients to evaluate immunization rates. **Results:** 1,854 ICI-treated patients and 1,854 matched patients without cancer were identified for analysis. Vaccination within 100 days of ICI initiation was associated with improved overall survival (HR: 0.43, 95% CI: 0.37 – 0.49, $p<.0001$). Among NSCLC patients ($n=241$), overall survival improved when any vaccination was administered within 100 days of ICI initiation (HR 0.37, $p<.0001$), with benefits observed specifically for COVID-19 (HR: 0.43, $p<.0001$) and influenza (HR: 0.38, $p<.0001$) vaccinations. Similarly, melanoma patients ($n=216$) demonstrated improved overall survival with COVID-19 (HR: 0.53, $p=.0214$) and influenza (HR: 0.59, $p=.0468$) vaccinations. Findings remained robust upon censoring deceased unvaccinated patients within 100 days of ICI initiation to mitigate guarantee-time bias. No significant differences were observed in demographics, BMI, smoking status, medical comorbidities, PD-L1 expression (for NSCLC), or LDH levels (for melanoma) between patients who had received a vaccine within 100 days of ICI initiation and those that did not, that would otherwise explain this difference in mortality. There was no difference between the vaccinated and unvaccinated groups in terms of vaccination-related infection mortality. Active ICI patients were more likely to receive routine vaccinations than non-cancer patients (Influenza 2023 OR: 1.51, $p=.0016$), though vaccination rates have declined since their 2020 peak (Influenza vaccination rate: 2020, 71%; 2023, 59%). **Conclusions:** Co-administration of vaccination with ICI therapy improves survival, independent of infection-related outcomes. The associated cytokine response from vaccination during ICI therapy may enhance antitumor effects. Vaccination rates among ICI-treated patients have declined since 2020, highlighting the need for interventions to improve uptake and outcomes. Research Sponsor: NIH CTSA; K12TR004410.

Trends in place of death among breast cancer patients in the United States (1999–2023): A 25-year analysis of racial and regional disparities. First Author: Fatima Ali, Ascension St Vincent, Evansville, IN

Background: Breast cancer is the second most prevalent cancer among women in the United States, associated with significant morbidity and mortality related to treatment. The place of death (PoD) significantly influences patient and caregiver preferences, access to home-based supportive care, and the overall cost of caregiving. This study evaluates trends in PoD for patients with breast cancer in the U.S. from 1999 to 2023 using data from the CDC WONDER (Wide-ranging Online Data for Epidemiologic Research) database. **Methods:** We conducted a comprehensive analysis of data from the CDC WONDER database covering the period from January 1, 1999, to December 31, 2023. Deaths attributed to breast cancer were identified using the International Classification of Diseases-10th Revision (ICD-10) code C50. We collected demographic data to calculate descriptive statistics based on race, PoD, census region, and home and hospice utilization over the past 25 years. **Results:** Our analysis revealed a total of 1,047,098 breast cancer-related deaths from 1999 to 2023. Among these, 513,231 deaths (49.01%) occurred in home or hospice facilities (H&H), while 471,297 deaths (45.01%) were reported in medical facilities and nursing homes (M&N). The proportion of H&H deaths increased from 37.1% in 1999, peaked at 62.6% in 2020, and then declined to 56.9% in 2023. Racial disparities were evident, with all racial groups experiencing an increase in percentage of H&H mortality from 1999 to 2023. Black or African American individuals exhibited the highest relative percentage increase at 66.04%. In 2023, the highest rates of H&H mortality were observed in white patients (58.99%), followed by Hispanic patients (56.36%), American Indian or Alaska Native patients (50.51%), and Black or African American patients (48.90%). Regional analysis indicated that all regions saw an increase in H&H mortality from 1999 to 2023, with the Midwest showing the highest relative percent increase at 60.58%. In 2023, the South had the highest percentage of H&H mortality (59.80%), followed by the West (58.45%), Midwest (55.53%), and Northeast (49.33%). **Conclusions:** The trends in place of death for breast cancer patients over the past 25 years highlight significant shifts in mortality patterns, with increasing reliance on home and hospice care, particularly among certain racial and regional groups. These findings highlight the need for targeted interventions to improve access to palliative care services and support for patients and caregivers, particularly in underserved populations and regions. Research Sponsor: None.

Regional trends in disability adjusted life years (DALYs) and mortality of pancreatic cancer among older adults (70+): A global burden of disease study (1990–2021). First Author: Nana Sardarova, Henry Ford Health System, Warren, MI

Background: Pancreatic cancer is a major health challenge, particularly for older adults, with significant regional disparities in its burden over the decades. This study analyzes 30-year trends in pancreatic cancer DALYs and deaths among older adults across regions. **Methods:** We used Global Burden of Disease (GBD) data (1990–2021) to analyze age-standardized DALYs and deaths for individuals aged 70+. Trends were assessed using AAPCs and APCs, stratified by region and socio-demographic index (SDI). **Results:** Regions with lower SDI (e.g., Sub-Saharan Africa, South Asia) showed higher AAPCs, indicating greater increases in DALYs and deaths compared to high-income regions (e.g., North America, Western Europe). Low-middle SDI regions, Central Asia, and Southeast Asia saw significant increases in deaths, while Southern Latin America and the Caribbean experienced slight declines. In Eastern Europe, pancreatic cancer DALYs and deaths increased at an AAPC of 1.45% and 1.50%, respectively, showing a moderate but concerning rise in burden. Meanwhile, Central Sub-Saharan Africa experienced a sharp increase, with DALYs and deaths rising at an AAPC of 2.10% and 2.15%. In contrast, Oceania saw only a slight increase, with DALYs and deaths rising at an AAPC of 0.50% and 0.55% showing a relatively stable burden compared to other regions. The highest death rates are observed in High-income Asia Pacific (109.30 in 2021) and Southern Latin America (85.01 in 2021), while the lowest death rates are in South Asia (12.17 in 2021) and Low SDI regions (14.00 in 2021). For DALYs, the highest rate was 1462.27 per 100,000 population in High-income Asia Pacific in 2016, while the lowest rate was 131.06 per 100,000 population in South Asia in 1990. **Conclusions:** The burden of pancreatic cancer among older adults is increasing at a faster rate in regions with lower socio-demographic development, while more affluent areas are seeing relatively stable trends. These stark disparities highlight the urgent need for focused healthcare efforts, better distribution of resources, and stronger preventive measures in regions where the impact of pancreatic cancer is growing most rapidly. Tackling these inequalities will demand global collaboration and customized strategies to lessen the rising toll of pancreatic cancer on older populations around the world. Research Sponsor: None.

Region	DALYs AAPC (%)	Deaths AAPC (%)	Trend
Western Sub-Saharan Africa	2.25 (2.22–2.28)	2.31 (2.28–2.35)	Highest increase, growing burden
North Africa & Middle East	1.67 (1.62–1.72)	1.77 (1.73–1.82)	Steady rise
Low-middle SDI Regions	1.59 (1.56–1.63)	1.65 (1.62–1.70)	Substantial increases
High-income North America	0.22 (0.18–0.26)	0.29 (0.25–0.32)	Lowest increases
Southern Latin America	-0.18 (-0.27–-0.10)	-0.03 (-0.08–0.02)	Decrease in burden
Caribbean	-0.12 (-0.21–-0.02)	-0.03 (-0.14–0.06)	Decrease in burden

Characterizing health related quality of life among individuals living with non-small cell lung in the United States: Findings from the Cancer Experience Registry. First Author: Erica Fortune, Cancer Support Community, Washington, DC

Background: Lung cancer is the second most common cancer and the leading cause of cancer-related deaths. Non-small cell lung cancer (NSCLC), which comprises ~85% of cases, is aggressive, often diagnosed late, and associated with significant symptom burden, and poor health-related quality of life (HRQoL) overall, as well as poor prognosis. However, the factors contributing to variation in HRQoL among NSCLC patients are poorly understood. This study aims to assess the role metastatic status and treatment history play in HRQoL. **Methods:** We conducted a retrospective analysis of Cancer Support Community's Cancer Experience Registry (CER) survey data collected between Feb 2015 – Nov 2023. The sample included 279 U.S. adults with NSCLC. HRQoL, specifically physical and psychological symptom burden and function, was assessed using the 7 domains of PROMIS29v2.0: anxiety, depression, pain, fatigue, sleep disturbance, physical function, and social function. Preliminary analyses (not shown here) found that non-metastatic patients were *more* likely to report higher pain, fatigue, and physical and social impairments compared to metastatic patients. We hypothesized that treatment history could partially explain this outcome: 62% of nonmetastatic patients reported history of surgery vs. 31% of metastatic patients. Thus, an interaction term (metastatic status x surgery) was created for further analysis in backward elimination linear regression models. **Results:** Participants were 68% women and 88% Non-Hispanic White, with a mean age of 64 (SD=10 years). The mean time since initial diagnosis was 5 years (SD=7). 16% were nonmetastatic with no history of surgery and 27% with a history of surgery; 39% were metastatic with no surgery and 18% with surgery. After adjusting for sociodemographic and clinical variables, treatment history showed associations with HRQoL, though findings were inconsistent in most groups. Those who were nonmetastatic without surgery reported more sleep disturbance (b = 3.58), those with clinical trial history reported less anxiety (b = -3.61), and those with immunotherapy reported less depression (b = -2.55). Metastatic individuals without surgery reported less pain (b = -3.75) and fatigue (b = -3.06) and better physical (b = 3.67) and social functioning (b = 4.19). Metastatic surgery group was not significant for any domains. **Conclusions:** Results underscore the complex factors that contribute to HRQoL in those with NSCLC. The findings emphasize the importance of a holistic, value-based care approach, considering not just survival but also patients' preferences and quality of life. A full understanding of treatment side effects and their implications for HRQoL is essential to aligning care with patient preferences. Future research should investigate how treatment history impacts HRQoL outcomes. Research Sponsor: Gilead Sciences.

Use of targeted therapy in patients with advanced non-small cell lung cancer in response to broad genomic profiling. First Author: Xiao Wang, Yale Cancer Center, New Haven, CT

Background: Broad genomic profiling (BGP) is increasingly performed for patients with advanced non-small cell lung cancer (aNSCLC) to inform the use of targeted therapy (TT). The approach to specific BGP results has evolved, alongside changes in evidence, FDA approval status, and professional guidelines. Limited data exist characterizing impact of BGP on treatment selection in a real-world patient population. **Methods:** We identified patients diagnosed with aNSCLC 2017–2023 using the nationwide deidentified Flatiron Health-Foundation Medicine aNSCLC Clinico-Genomic Database, containing data from ~280 US cancer clinics (~800 sites of care). We classified each patient's BGP results by contemporaneous FDA approvals and NCCN guidelines, categorizing findings as actionable with on-label TT (first- [1L] vs. later-line [2+]), potentially actionable with off-label TT (NCCN recommended vs. not recommended), or not actionable. We then categorized actual 1L treatments received relative to these standards. **Results:** Of 5781 patients with aNSCLC who underwent BGP testing (Table), on-label 1L TT was used in 13.1% of patients, while 3.3% (1.3% guideline recommended + 2.0% not recommended) received off-label 1L TT. Overall, 17.6% had a 1L targetable alteration (74.5% of whom received on-label TT), while 6.0% had a 2L+ on-label targetable alteration (9.7% received TT in 1L, against label + recommendation). In addition, 4.7% had a potentially actionable alteration with recommended off-label TT (11.4% of whom received off-label 1L TT), while an additional 23.3% had potentially actionable alterations without recommended TT (4.3% received off-label TT in 1L, against NCCN recommendation). **Conclusions:** In this cohort of patients with aNSCLC, half had actionable or potentially actionable BGP results. One in four patients with 1L actionable findings did not receive corresponding on-label 1L TT (potential missed opportunity), while one in ten with 2L+ actionable findings received TT as off-label 1L treatment in contrast to guidelines (potential indication creep). 1L off-label TT use was uncommon and largely guideline discordant. Real-world outcomes in patients living with HIV with lung cancer and treated with immune checkpoint inhibitors. First Author: Melinda Laine Hsu, University Hospitals Seidman Cancer Center, Case Western Reserve University, Cleveland, OH

Background: Lung cancer is one of the most common non-AIDS defining cancers in People Living with HIV (PLWH) and a leading cause of cancer death in PLWH. PLWH were initially excluded from clinical trials of immune checkpoint inhibitors (ICIs) due to concerns for safety and efficacy. Little is known about the real-world rates of immune-related adverse events (irAEs) and survival outcomes in PLWH with lung cancer treated with ICIs. **Methods:** Adults (age≥18) diagnosed with lung cancer and treated with ICIs between 2015-2021 were identified from the Merative MarketScan database, which contains de-identified healthcare claims of > 250 million patients in the US. We categorized patients into two cohorts based on HIV status: People Living with HIV (PLWH) and those without HIV (PLWoH). We evaluated rates of irAEs and Kaplan-Meier (KM) survival analysis estimated overall survival (OS) in both cohorts; survival function was calculated from first ICI treatment to death or last follow-up. We used the log-rank test to assess statistical differences in survival between the cohorts. **Results:** 21,259 people with lung cancer and treated with ICIs were identified, and 105 were identified as PLWH. More PLWH treated with ICIs were male (81.9%) and younger (median age 61 yrs) than PLWoH (53.4%, 64 yrs). There was no significant difference in median OS of PLWH (343 days) and PLWoH (364 days, p=0.62). PLWH experienced a similar rate of irAEs (53.3%) as PLWoH (54.6%). Most patients experienced one irAE (55.36% PLWH, 54.33% PLWoH). PLWH experienced irAEs in up to 3 organ systems, and PLWoH in up to 7 organ systems. The most common irAEs in PLWH were neurologic (41.07%), endocrine (39.29%), and renal (32.14%). In PLWoH, endocrine (52.26%), renal (34.93%), and cutaneous (27.82%) were the most common. Patients who experienced irAEs had statistically significantly improved OS in both cohorts compared to those without irAEs (both p<0.0001). **Conclusions:** We found similar rates of irAEs and OS in a large, real-world population of PLWH with lung cancer treated with ICIs, and people without HIV and lung cancer treated with ICIs. Further research is needed to improve early identification of lung cancer in PLWH and identify predictors of toxicities. Research Sponsor: National Cancer Institute; U54CS254566.

ARIMA prediction model for mortality caused by metastatic cancers in the United States population up to the year 2050: A CDC WONDER Database analysis. First Author: Nisar Ahmed, Liaquat National Hospital and Medical College, Karachi, Pakistan

Background: Metastatic cancers are the leading cause of mortality in the United States (US). In this study of death certificates, obtained from data registry spanning from 1999 to 2024, we examined mortality trends among individuals suffering from any metastatic cancer in US. **Methods:** Our aim was to analyze the trends in mortality among US residents by demographic characteristics and predict future years based on the existing data by Autoregressive Integrated Moving Average (ARIMA) forecasting modeling. The national mortality data from the multiple causes of death files in the CDC WONDER Database were queried by applying the ICD-10 codes as C77-C79 for secondary cancers. Trends in age-adjusted mortality rate (AAMR) were assessed and results were expressed as average annual percentage changes (AAPC) from Join point regression. **Results:** There were a total of 2,098,842 deaths due to metastatic cancers in US from 1999-2024 with a crude mortality rate of 25.97 per 100,000 population, about 52% of them being males and 48% were females. Mortality rates (AAMR) continue to trend down from 1999-2008 in both gender, but showed an increase from 2009 onwards with females showed significant AAPC of +0.44. ARIMA predictive model exhibits a significant decline of mortality rates up to the year 2050 in Black population (AAMR: 24.45), Northeast region (AAMR: 10.84) and metropolitan areas (AAMR: 19.93). **Conclusions:** These findings provide valuable insights of mortality patterns among US population with metastatic malignant diseases. Certain subgroups with specific demographic and geographic characteristics such as White Population, non-metropolitan areas and those belonged to West region had higher future prediction of AAMR. Research Sponsor: None.

ARIMA forecasting model for predicting AAMR in metastatic cancer population in U.S.

Variables	AAMR in 1999	Lowest AAMR (year)	AAMR in 2024	AAPC	ARIMA forecast (2050)
Total	27.65	18.34 (2008)	29.13	+0.30 (0.20 – 0.40)*	29.90
Gender

Determinants of overall survival in the South African Breast Cancer and HIV Outcomes cohort. First Author: Maureen Joffe, University of Witwatersrand Faculty of Health Sciences, Johannesburg, South Africa

Background: Sub-Saharan Africa (SSA) has very low breast cancer (BC) survival. South Africa, unlike most SSA countries, is an upper middle-income country where patients are less burdened with cancer diagnostic and treatment costs. We aimed to provide five-year overall survival (OS) estimates and determinants among South African women with BC diagnosed and treated within the public health system. **Methods:** The South African Breast Cancer and HIV Outcomes prospective cohort study enrolled adult women recently diagnosed with invasive BC from four South African academic hospitals. We collected detailed sociodemographic, clinical, treatment, and outcomes data. Women were followed for five years or until December 31, 2023, whichever was earlier, and our primary outcome was five-year OS. Impacts of potential determinants on OS were assessed using individual Cox proportional hazard models focused on nine variable domains (*i.e.,* treating hospital, social status, BC risk factors, smoking, cardiovascular disease (CVD), HIV status, BC type, BC treatments, and age) and a combined model that also included adjustments for background mortality. **Results:** Between July 2015 and Feb 2019, we enrolled 2,838 women newly diagnosed with histopathologically confirmed invasive BC, of whom 58% had III or IV disease. At the end of follow-up, 1555 (55%) of the women had died, 1191 (42%) survived for five years, 33 (1%) were censored at study's end, and 59 (2%) were lost to follow up. The five-year OS was 44.3% (95% CI 42.5-46.2). In the full model, the variables with the largest impact on five-year survival were late-stage at diagnosis (HR 2.4 [95% CI 2.0-2.7] for stage III and HR 5.0 [95% CI 4.1-6.1] for stage IV disease, both compared with stage I/II) and differing degree of treatments received (no treatment received: HR 8.2 [95% CI 5.9-11.3]; chemotherapy and endocrine therapy: HR 1.9 [95% CI 1.4-2.6]; endocrine therapy only: HR 2.2 [95% CI 1.6-3.2]; chemotherapy only: HR 4.8 [95% CI 3.4-6.6]; surgery only: HR 3.0 [95% CI 1.9-4.8]; surgery and chemotherapy: HR 1.8 [95% CI 1.3-2.5], all compared with surgery and endocrine treatments). Other variables significantly associated with survival were treating hospital, relationship status, employment, education, family history of cancer, CVD, and HIV infection. **Conclusions:** Interventions to improve BC survival in South Africa's public health system should prioritize earlier diagnosis of cancer and expansion of the infrastructure supporting diagnostic and treatment services. Concurrently, South African BC patients with low socioeconomic status, HIV infection, and/or comorbid CVD are uniquely vulnerable and their barriers to accessing care must be better understood. Implementation and evaluation of multi-cancer early detection testing at the Dana-Farber Cancer Institute: A retrospective analysis of clinical outcomes and diagnostic pathways. First Author: Elizabeth O'Donnell, Dana-Farber Cancer Institute, Boston, MA

Background: Early detection and interception of cancer is a growing field at the intersection of primary care and oncology. Technological innovation has facilitated the development of multi-cancer early detection (MCED) tests, which allow for the detection of a broad range of cancers in a single screening test. These tests are entering clinical practice as laboratory developed tests but little has been reported about their implementation. In 2023, Dana-Farber introduced an MCED Program to facilitate the evaluation of patients who have received MCED testing and to study novel MCED strategies. **Methods:** We conducted a retrospective chart review of patients seen at the Dana-Farber between 12/1/2023 and 12/1/2024 who had a cancer signal detected by a Grail Galleri MCED test. **Results:** Thirteen patients were evaluated for a positive cancer signal detected by the Grail Galleri MCED test. The median age was 62.7 (54.9-81.4), 61.5% (8/13) were male, and 84.6% (11/13) were white. Following diagnostic evaluation 76.9% (10/13) had a confirmed cancer diagnosis and 23.1% (3/13) were deemed false positives. The time from MCED test result to presentation at DFCI was a median of 25 days (6-368) and the median time to conduct the diagnostic evaluation was 23 days (5-104), which was shorter in true positive cases (15 days) compared to false positives (98 days). A total 6 of the 10 (60%) signal detected cases were solid tumors which included triple negative breast, testicular, liver, cholangiocarcinoma, tonsillar, and lung (non-smoker); and 4 (40%) cases were hematologic malignancies (3 lymphoma, 1 myeloma). Of the malignancies detected, 9 (90%) have no current screening guidelines. Screening mammography was up to date in the patient found to have triple negative breast cancer. Six cancers (60%) were diagnosed at stage I/II and 4 (40%) were stage III/IV. All 3 false positive cases received a repeat MCED test a median of 118 days (87-161) after the initial test and all had no signal detected at re-test. The median number of tests/procedures to reach diagnostic resolution was 4 for true positive cases (2-7) and 5 for false positive cases (4-6). All patients required advanced imaging. The first or second cancer signal origin was accurate in 90% (9/10). There were no issues encountered obtaining prior authorizations for diagnostic tests and no adverse events were reported. **Conclusions:** The majority of patients that presented with a positive MCED test were true positives with a cancer consistent with the cancer signal origin. Patients with signal detected tests were quickly adjudicated in our clinical program, although some patients initially experienced significant delays in finding a provider to work-up their test result. These findings support a role for dedicated cancer diagnostic clinical expertise in the evaluation of MCED tests. Research Sponsor: None.

Evaluation of large language model (LLM)-based clinical abstraction of electronic health records (EHRs) for non-small cell lung cancer (NSCLC) patients. First Author: Kabir Manghnani, Tempus AI, Inc., Chicago, IL

Background: Abstraction is a critical step for converting clinical data from unstructured EHRs into a structured format suitable for real-world data analyses. Typically this is a manual, labor-intensive activity requiring substantial training. While prior work has shown that abstraction by humans is reliable, advances in LLMs may improve the efficiency of abstraction. We aim to measure the performance of LLMs in abstracting a diverse set of oncology data elements. **Methods:** Two clinical abstractors independently abstracted unstructured records of 222 advanced or metastatic NSCLC patients (mean: 248 pages per case). A two-stage LLM system balancing cost and comprehensiveness was used to abstract clinical elements for demographics, diagnosis, third-party lab biomarker testing, and first line (1L) treatment. The initial stage extracted 16 documents semantically similar to the abstraction query and input them, along with abstraction rules, into an LLM (GPT-4o). The LLM was instructed to provide both the abstracted field and a completeness assessment of provided context. If the first phase resulted in a low completeness score, the entire patient record was then input into a long-context LLM (Gemini-Pro-1.5) to re-attempt abstraction. Gwet's agreement coefficient (AC) was the primary measure of agreement between the LLM and each abstractor. Date agreement was calculated within $\pm$30 days. **Results:** The LLM system yielded abstracted values for 90% of elements where both abstractors provided non-missing values. In these cases, the LLM also demonstrated high agreement with each abstractor ($\geq$0.81 across all categories). Agreement was highest in demographic and diagnosis domains and lower for 1L treatment domain, which require deeper understanding of a patient's temporal journey. For elements where neither abstractor provided values, the LLM sometimes provided outputs (frequency: 4.9% for non-biomarker elements; 38.5% for biomarker elements). These discrepancies were primarily driven by nuances in abstraction rules; the LLM often included Tempus-tested biomarkers, while abstractors were more rigorous in abstracting only third-party biomarker results. **Conclusions:** LLMs show high completion rates and high agreement with human abstractors across a variety of critical abstraction fields. The use of LLMs may significantly reduce the burden of human abstraction and allow for large-scale curation of oncology records. Challenges in handling nuanced contexts underscore the need for careful refinement and evaluation prior to deployment. Research Sponsor: Tempus AI, Inc.

Domain	LLM agreement with abstractors (AC, min-max)
Demographic (birth date, sex, race, smoking status)	0.96-1
Diagnosis (stage, histology, year of diagnosis)	0.92-0.98
Third Party Biomarker (EGFR, ALK, ROS1, PDL1, BRAF, RET, NTRK)	0.87-1
1L Treatment (agents, initiation date)	0.81-0.86

Real-world analysis of factors influencing turnaround time (TAT) for tissue comprehensive genomic profiling (CGP) in non-small cell lung cancer (NSCLC). First Author: Adam Fox, Medical University of South Carolina, Charleston, SC

Background: CGP is an integral part of the standard of care for many solid tumor malignancies, and especially for NSCLC, as testing informs first-line treatment selection at most stages. CGP TAT is understudied but has implications for appropriate treatment delivery and patient outcomes. **Methods:** In this retrospective cohort analysis, TAT was calculated for U.S. tissue CGP testing orders received between January 2021 and September 2023 at a centralized commercial molecular laboratory (Foundation Medicine, Inc., Cambridge, MA, USA). Ordering TAT (specimen collection to CGP ordering), Specimen TAT (CGP ordering to specimen receipt at testing lab), Molecular TAT (specimen receipt to results reporting), and Overall TAT (specimen collection to results reporting) were calculated. Cases were excluded if CGP was ordered $>$6 months after specimen collection or if missing TAT data. Descriptive statistics and linear regression modeling for association of TAT with available clinical and molecular factors were performed. **Results:** A total of 40,728 NSCLC biopsies from 547 institutions were included in the analysis. The median Overall TAT for all samples was 29.8 days (IQR: 21.7, 44.6). Median times for Ordering TAT, Specimen TAT, and Molecular TAT were 14.8 days (IQR: 8.4, 27.8), 3.2 days (IQR: 1.3, 6.2), and 9.0 days (IQR: 7.7, 11.0), respectively. Aggregating and calculating TAT at the institution level, the median Overall TAT was 40.6 days (IQR: 38.5, 43.8) versus 21.9 days (IQR: 20.7, 23.7) among the slowest and fastest Overall TAT quintiles, respectively; Ordering TAT [median 15.1, IQR: 11.6, 18.9] and Specimen TAT [median 3.9, IQR: 1.9, 5.1] contributed to this variability, while Molecular TAT [median 9.0, IQR: 8.6, 9.3] remained consistent. Higher institutional order volume was the strongest predictor of shorter Overall TAT (-6.59 days [95% CI: -7.46, -5.71] for institutions with [100-200) vs $<$20 orders, P $<$ .001), largely driven by variability in Ordering TAT (-4.13 days [95% CI: -4.95, -3.31] for institutions with [100-200) vs $<$20 orders, P $<$ .001) and Specimen TAT (-2.25 days [95% CI: -2.47, -2.04] for institutions with [100-200) vs $<$20 orders, P $<$ .001). **Conclusions:** This study demonstrates that NSCLC CGP TAT is highly variable and is influenced by institutional factors, particularly higher institutional ordering volume. For patients with an established diagnosis, the time between specimen collection/diagnosis and CGP ordering likely represents the longest and most modifiable component of Overall TAT. This study raises the hypothesis that adoption of coordinated interventions, such as reflex testing, could reduce Ordering TAT, and thus Overall TAT, for many patients. Research Sponsor: None.

11162 Poster Session

Assessing biosimilar entry in the market for biologic cancer drugs. First Author: Xiaoyu Liu, UCLA, School of Public Health, Los Angeles, CA

Background: Biosimilars are biological drugs highly similar to and without clinically meaningful differences from their biological reference products. As of 2023, out of 39 biosimilars available in the US, 22 (56%) are indicated for cancer treatment (n=12) or supportive care (n=10). This study described the trends in uptake, pricing, and out-of-pocket (OOP) costs between 2014 and 2023. **Methods:** Using MarketScan claims data and Average Sales Price (ASP) data from the Centers for Medicare & Medicaid Services, we calculated quarterly ASP and the market share of reference products for treatment and supportive care biologics in the commercial and Medicare Part B markets, 2014 to 2023. We also estimated the average monthly out-of-pocket costs (deductible + copayment + coinsurance) before and after biosimilar entry. We identified biologics using Healthcare Common Procedure Coding System codes and adjusted costs to 2024 USD using the prescription drugs Consumer Price Index. **Results:** Analyses included 1,040,456 claims of 28 biological products (6 reference products and 22 biosimilars). On average, the ASP of reference products for treatment and support care decreased by 1.3% and 2.8% per quarter, respectively, after biosimilar entry. Market share of reference products declined over time after biosimilar entry, though the decline was smaller in the Medicare market than in commercial insurance market as of 2023 Q4. The average quarterly reduction ranged between 2.2% and 14.6% across reference products, with larger reduction for treatment drugs. Compared to monthly OOP averaging over 12 months before first biosimilar launch, monthly OOP costs of biologics (including reference and biosimilars) in 2023 fell for 4 reference drugs in the commercial market, and 5 in the Medicare market. **Conclusions:** Biosimilar entry has lowered the price and led to a substantial reduction in market share of biologic reference products, especially for cancer treatment drugs. Nevertheless, trends in OOP costs for biologics indicated biosimilars did not always lower financial burden for patients. Research Sponsor: None.

			Commercial insurance			Medicare Part B		
Drug	1st biosimilar entry	Reference product ASP quarterly change	Market share of reference product, 2023 Q4 (quarterly change)	Mean monthly OOP before biosimilar entry	Mean monthly OOP, 2023	Market share of reference product, 2023 Q4 (quarterly change)	Mean monthly OOP before biosimilar entry	Mean monthly OOP, 2023

A real-world data claims-based review of CAR-T procedures, time to adverse events, patient characteristics and social factors. First Author: Karina D'Angelo, Parexel International, Durham, NC

Background: With the increasing utilization of Chimeric antigen receptors T-cell therapies (CAR-T), administrative claims can provide insights into approved CAR-T therapies, procedures, associated adverse events (AEs) and population characteristics. **Methods:** We used administrative open claims with medical and pharmacy encounters of 330 million US patients (PurpleLab). We identified patients with a coded AE as the principial diagnosis following the first initial claim with any CAR-T. CAR-T claims were identified with drug and procedure coding. The AEs included were Cytokine release syndrome (CRS), Immune effector-cell associated neurotoxicity (ICANS), complication of immune effector cellular therapy, tumor lysis, and cardiovascular events such as arrhythmias. The time to the AE and death were noted. In cases where social determinants of health (SDOH) are noted, race, gender, marital status, occupation, and education were analyzed. **Results:** The number of patients with CAR-T related claims within the database was 20,003. Of those patients, approximately 10% (2166) had at least one claim with an AE code as the principal diagnosis reported following the very first CAR-T claim. For those with an initial AE claim, 38% had a cardiovascular event, 36% had a complication of immune effector cellular therapy, 13% had a CRS event, 7% had an ICANS, 2% had a tumor lysis event, and 1.3% had a secondary lymphoma. Most AEs occurred within the first 30 to 90 days from the first documented CAR-T claim procedure. Cardiac and complication AEs were higher in patients aged greater than 65, while tumor lysis was higher in patients under 65. Death was reported in a quarter of the patients (532 patients) with 65% of those recorded deaths occurring within a year post first CAR-T related claim. Of those patients with a documented social demographic factor, patients with AEs were white males (41%), Asian males (2.6%), African American males (2.7%), and unspecified males (17%) making up the other races and gender. In terms of occupation and education, 34% were white collar, 5% blue collar, and 4% retired, and 29% had some level of high school, 23% college-level education, and 13% were postgraduate. More patients were identified as married (34%) than single (14%) and approximately 57% had an income below $100,000, while 11% were above $100,000, with the remaining incomes were not recorded. **Conclusions:** Real-world data can provide insights into CAR-T and AEs, patient social factors, and temporal trends. Age greater than 65 seemed the more prevalent SDOH with higher AE seen in this subgroup. Additional investigation on AEs within the different patient population subgroups are needed to provide deeper insights into treatment effects. Research Sponsor: None.

Risk of fracture following androgen receptor pathway inhibitors (ARPIs): A population-based study. First Author: Grace L. Lu-Yao, Division of Population Science, Department of Medical Oncology, Sidney Kimmel Medical College, Sidney Kimmel Cancer Center at Jefferson Health, Philadelphia, PA

Background: Androgen deprivation therapy is associated with an increased risk of fracture. ARPIs are widely used to manage advanced prostate cancer (PCa). However, there is limited long-term data on fracture risk following ARPIs and how the risk might vary with different health conditions. This study aims to fill these gaps. **Methods:** This study used the SEER-Medicare linked files to identify men diagnosed with PCa between 1/1/1999 and 12/31/2019 and who received abiraterone with prednisone (AAP) or enzalutamide (ENZA) between 1/1/2013 and 12/31/2020. The primary endpoint is the time to first fracture after the index date (first date of AAP or ENZA). The history of fracture was based on claims one year before the index date. Fine and Gray's subdistribution hazard model was used to estimate the effect of various risk factors. We used the cumulative incidence function to quantify fracture risk. **Results:** This study comprised 10,463 patients (6,037 with AAP and 4,426 with ENZA). Most patients were over 75 with a comorbidity score of 1 or higher. Among 1,445 patients who had a fracture the year before the index date, the risk of fracture after ARPI reached 50% (95% CI 47% - 53%) within 3 years, compared to 26% (95% CI 25%-27%) among those without a fracture. After adjusting for bone health agent use, comorbidities, and sociodemographic factors, a history of fracture was associated with 2.8 fold risk of fracture after AAP (RR=2.80, 95% CI 2.47 – 3.18) and 2.85 fold risk after ENZA (RR=2.85, 95% CI 2.45-3.30). Use of bone health agents within 3 months before the index date was associated with a 20-25% lower fracture risk. **Conclusions:** This large population-based study shows that the risk of fracture following ARPIs is substantial, especially among those who suffered a fracture before ARPIs. It is crucial to consider the history of fracture when making treatment choices and monitoring strategies. Better management of bone health is crucial for men treated with ARPIs. Validation of real-world event-free survival (rwEFS) in early-stage triple-negative breast cancer. First Author: Carole Berini, Ontada, Boston, MA

Background: Real-world (RW) evidence has been used to demonstrate effectiveness of early-stage cancer treatments. Early-stage clinical endpoints such as event-free survival (EFS) have the potential to support clinical decision-making as an indicator of real-world effectiveness for novel therapies. However, less is known regarding real-world replicability of rwEFS in early triple negative breast cancer (eTNBC). We therefore applied selected target trial emulation methods to examine the concordance between rwEFS and KEYNOTE-522 (KN-522) trial 'chemotherapy only' arm EFS estimates. **Methods:** Electronic health records from the US Oncology Network were used to identify stage II-III triple negative breast cancer patients who initiated neoadjuvant chemotherapy only from 1/1/20 to 3/31/22. Patients were followed through 07/18/23. Patients who received immunotherapy at any time during this observation period were excluded. KN-522 trial eligibility criteria and endpoint definitions were applied to develop the rwEFS endpoint. Matching-Adjusted Indirect Comparison (MAIC) was used to adjust the real-world cohort based on available baseline demographic and clinical characteristics (age, stage, and ECOG performance status) to approximate the KN-522 population. Kaplan-Meier curves and unadjusted and adjusted hazard ratios with 95% CIs were used to compare EFS between the RW cohort and the control arm of KN-522. **Results:** Real-world patients (n=199) were older (median age 59 vs 48), in more advanced stages (61% vs 25% stage III), and more often ECOG$>$0 (40% vs 13%) than participants in the control arm of KN-522. Median EFS was not reached in either the RW cohort or control arm of KN-522. At 36 months, estimated EFS was 76% for patients in the RW cohort and 77% in the KN-522 control arm. There was no statistically significant difference in EFS between the RW and KN-522 cohorts in unadjusted analysis (HR: 0.99, 95% CI: 0.68 - 1.46), indicating concordance between the estimates. After MAIC weighting, baseline values of age, stage, and ECOG performance were balanced between the two cohorts. The difference between RW and trial estimates was also not statistically significant in the adjusted analysis (HR: 0.76, 95% CI: 0.50 - 1.14). **Conclusions:** EFS is a valuable endpoint for evaluating the effectiveness of neoadjuvant therapy in eTNBC patients. With the application of real-world definitions to align key study design elements with the trial and leveraging curated real-world data, it is possible to reproduce the trial EFS estimate in a real-world cohort. The development of a robust, replicable rwEFS endpoint may support clinical decision-making and guide the choice of effective treatments for eTNBC patients. Research Sponsor: Merck & Co., Inc.

Impact of AI medical scribes on physician productivity and satisfaction in medical oncology. First Author: Nima Toussi, University of Saskatchewan, Saskatoon, SK, Canada

Background: AI Scribes are a leading example of AI implementation in clinical settings, with Oncology practices demonstrating exponential uptake since their introduction. Despite their ever-increasing usage, there are limited studies which directly interrogate the impact of AI Scribes on physician productivity metrics, and few which assess qualitative interpretations of the technology. **Methods:** This single-center, multi-site study enrolled 27 Medical Oncologists and 3 Primary Care Physicians randomly assigned in a 1:2 ratio to exposure to the Knowtex AI scribe in the initial phase (Phase 1) or control phase (Phase 2). Billing data was collected for 6 months prior to Phase 1 onboarding with Knowtex and for 16 weeks afterward—all within the 2024 fiscal year. During the same period, Phase 2 physicians billing data served as a non-exposed comparison group. Physicians completed opt-in surveys at Week 0 and Week 8 post-exposure assessing confidence and motivation to use the AI Scribe, documentation burden, documentation quality, and experience with the electronic medical record (EMR). **Results:** All providers adopted the Knowtex AI scribe during their study phase. 4 Phase 2 physicians were excluded from data analysis due to incomplete 2024 fiscal year data. Phase 1 physicians exhibited an increase in mean units ($t(10) = 4.44$, $p < 0.01$, $d = 1.34$, CI [0.90, 2.72]) and mean total billings per working day ($t(10) = 4.30$, $p < 0.01$, $d = 1.28$, CI [$377.55, $1206.75]), a pattern not observed in Phase 2 during the same period. There was no change in the number of diagnostic codes per unit amongst Phase 1 physicians. No learned effect emerged over time in Phase 1 billing metrics or diagnostic coding. Survey findings revealed a strong positive association between Week 0 self-assessed Knowtex understanding and increased units ($r(13) = .579$, $p = 0.024$). Physicians reported increased satisfaction with documentation workflow, a reduction in-clinic hours spent on documentation, and increased time spent with patients. Physicians' net impression of EMR challenges markedly decreased following the implementation of the AI scribe ($U = 274.5$, $z=4.054$, $p < 0.0001$). **Conclusions:** Adoption of an AI Scribe in oncology may enhance certain billing metrics and positively shift physician perceptions of EMR interactions, without affecting the quality of documentation. These findings highlight potential benefits of AI Scribes in improving physician productivity and satisfaction. As AI Scribes trend towards delivering multimodal clinical support tools, future research may focus on the adjunctive effects of AI scribes on procedural efficiencies, such as consistency in billing codes. Factors associated with decreased treatment intensity in patients with metastatic colon cancer: A real world analysis. First Author: Rebecca Forman, Yale New Haven Hospital, New Haven, CT

Background: The frontline treatments for metastatic colon cancer (mCC) include intensive therapies (e.g., doublet or triplet chemotherapy backbones with biologic agents) and non-intensive therapies (e.g., chemotherapy monotherapy, biologic agents alone, or a combination thereof). Randomized trials have shown that non-intensive therapies offer shorter overall survival compared to intensive therapies; thus, they are recommended only for those unable to tolerate intensive therapy, such as those with poor performance status (PS). There is a need to identify which patients are receiving non-intensive therapies in the real world to ameliorate disparities in undertreatment. **Methods:** We conducted a retrospective cohort study by leveraging the nationwide Flatiron Health electronic health record-derived deidentified database. This database is longitudinal, comprising deidentified patient-level structured and unstructured data, curated via technology-enabled abstraction. Patients included presented with mCC during 2013-2024 and received one of the first line treatments listed in the National Comprehensive Cancer Network (NCCN) guidelines. Therapies were categorized as intensive or non-intensive based on NCCN guidelines. Frailty was defined as baseline ECOG PS≥2, and older age was defined as ≥65 years (yrs) at diagnosis. Multivariable logistic regression was performed between treatment intensity and patient characteristics (age, frailty, sex at birth, year of diagnosis, race, socioeconomic status (SES)) to estimate odds ratios and 95% confidence intervals. Age and frailty were combined into multiple variables given significant interaction term. **Results:** Among 21,588 patients included in this study, 83.3% received intensive first-line therapy. Receipt of non-intensive therapy was associated with female sex at birth and earlier year of diagnosis but not race or SES. Frailty and age were associated with treatment choice. Older non-frail patients had a stronger association with receipt of non-intensive therapy compared to younger frail patients. **Conclusions:** In addition to frailty, older age was a strong predictor of the receipt of non-intensive therapy among patients with mCC. More research and education around identifying frailty is needed to avoid undertreatment of older patients with mCC. Research Sponsor: Conquer Cancer, the ASCO Foundation.

Patient characteristics	Number of patients	Proportion receiving non-intensive therapies	Odds ratio (95% confidence interval)	P value
< 65 yrs and non-frail	7432	7.50%	Reference	
≥ 65 yrs and frail	1547	37.0%	7.10 (6.20, 8.12)	<0.01
≥ 65 yrs and missing frailty	2596	28.0%	4.22 (3.72, 4.77)	<0.01

Early onset cancer in Chile: 27-year mortality rate trends from a nationwide database with focus in gastrointestinal tumors. First Author: Cristobal Tomas Sanhueza Condell, Facultad de Medicina Clinica Alemana Universidad del Desarrollo, Santiago, Chile

Background: Cancer has historically been considered a disease of older adults, however, several reports have shown an alarming rise in the incidence of early onset cancer, particularly gastrointestinal tumors and specially colorectal cancer. To date, there are no reports in this field from Latin America. This study aims to evaluate the trends in mortality rates of the most relevant gastrointestinal tumors among young versus older people in Chile. **Methods:** Nationwide data from the National Department of Statistics and Health Information was obtained from the years 1997 to 2023. Cause Specific Mortality was analysed for all ages, older (≥50 years) and younger (<50 years) patients for all tumors, Colorectal, Gastric, Esophagus, Pancreas, Liver and Biliary Tract cancer. The trends of rates were analyzed using Joinpoint Trend Analysis Software for calculation of the annual percentage rate change (APC). **Results:** Cancer-related mortality in Chile is increasing. From 1997 to 2023, for all causes, there were 2,645,132 deaths, the APC for the overall population, for all cancers is 0.96% (0.63%-1.29%, p<0.001). Gastrointestinal cancer accounted for 10%, with 261,300 deaths. When analyzed by type of cancer, an increase in mortality for colorectal cancer was observed, with a rate increase 90.5% higher in younger than older adults, with an APC of 3.24% and 1.7%, respectively. This difference was more evident in female adults. Pancreatic cancer mortality rate increased from 1997 to 2015 with an APC of 0.96% in older patients, but decreased from 2015 to 2023 with an APC of -0.87%. The mortality was steady in younger patients. No differences between younger and older patients were seen for Stomach, Esophagus, Biliary tract and Liver Cancer. Stomach cancer mortality rate has decreased in younger and older patients, with an APC of -1.61% and -2.63% respectively for the period from 1997 to 2015, and -5.87% and -4.77% respectively for the period from 2015 to 2023. Esophagus cancer mortality rate has decreased in younger and older patients, with an APC of -1.09% and -2.7% respectively for the period from 1997 to 2006, and -7.71% and -4.58% respectively for the period from 2006 to 2023. Biliary tract cancer mortality rate has decreased in younger and older patients, with an APC of -1.27% and -1.61% respectively for the period from 1997 to 2006, and -7.49% and -3.39% respectively for the period from 2006 to 2023. Liver cancer mortality rate has decreased in younger and older patients, with an APC of -2.53% for younger patients and -0.13% for older patients in the period from 1997 to 2015, and -2.43% respectively for the period from 2015 to 2023. **Conclusions:** This study shows an increase in mortality rates of colorectal cancer among young adults that almost doubles the rate increase in older adults in Chile. Efforts to raise awareness and improve access to early detection and healthcare should be prioritized. Research Sponsor: None.

Frailty in lung cancer hospitalizations: Identifying critical predictors for improved patient outcomes. First Author: Davin Turku, The Brooklyn Hospital Center, Brooklyn, NY

Background: Frailty is a condition primarily characterized by deficits in multiple health-related factors, which, when combined with the presence of disease, lead to poor outcomes. Lung cancer patients are no exception; those who are frail tend to experience worse clinical outcomes and increased healthcare resource utilization. Identifying predictors of frailty can help guide targeted interventions and improve outcomes for this patient subset, which is the primary aim of our study. **Methods:** We conducted a cross-sectional analysis of the National Inpatient Sample database (2016-2020) to evaluate predictors of frailty in lung cancer hospitalizations. Frailty was defined using ICD-10 codes. Chi-square test was used to compare categorical variables and all weighted analyses were performed to adjust for the overall population and the complexity of the dataset, with significance set at p<0.05. **Results:** 1,120,440 lung cancer hospitalizations were identified and 0.27% (N=3,025) met criteria for frailty. Frail patients were older than non-frail patients (mean age: 79.6 years vs 64.4 years). 71% of frail patients were White, 15% were Black, and 8% were Hispanic, compared to 62% White, 19% Black, and 10% Hispanic in the non-frail group (p=0.001). Majority of frail patients were covered by Medicare (84%) and Medicaid (5%), compared to 59% on Medicare, 14% on Medicaid, and 18% on private insurance in the non-frail group (p<0.001). Geographically, 50% of frail patients were from the South and 20% from the Midwest (p=0.03). Chi-square identified coronary artery disease (CAD), congestive heart failure (CHF), chronic kidney disease (CKD), underweight, sarcopenia, and dyslipidemia as predictors of frailty. However, a negative association was observed between obesity and frailty (Table). **Conclusions:** Chronic comorbidities and decreased muscle mass remain significant predictors of frailty in lung cancer, with regional and socio-economic variations highlighting potential care disparities. The lower incidence of frailty in obese patients raises the question of the 'obesity paradox' in frailty, which warrants further investigation to explore possible causation. Identifying and targeting early predictors of frailty could lead to improved patient outcomes and more efficient healthcare utilization. Research Sponsor: None.

Predictors of frailty in lung cancer.

Predictors	Frailty Present (%)	Frailty Absent (%)	p-value
CAD	42.09	34.24	<0.001
CHF	47.14	36.22	<0.001
BMI < 18.5	12.96	3.57	<0.001
Obesity	7.74	15.89	<0.001

Multicenter study of the impact of trial eligibility criteria on enrollment to KRAS G12C inhibitor trials in patients with non-small cell lung cancer. First Author: Michael S. May, Columbia University Medical Center, New York, NY

Background: Eligibility criteria (EC) are the primary method to assess patient appropriateness for clinical trials. There is a tradeoff between narrowing EC for patient safety and matching trial populations to the real-world population likely to receive the study agents. There is little evidence to guide optimal EC design. In 2017, ASCO proposed modifications to EC to increase the generalizability of trial findings. We previously reported a single-center experience and now report a multi-center cohort of non-small cell lung cancer (NSCLC) patients (pts) with *KRAS* G12C mutations to determine whether EC for trials of KRAS G12C inhibitors allowed enrollment of pts seen as part of routine care at three academic medical centers. **Methods:** We extracted EC for Phase I-III trials of six KRAS G12C inhibitors (sotorasib, adagrasib, olomorasib, divarasib, JDQ443 and RMC-6291) that were published or made available by sponsors. We defined a consensus set of eligibility criteria. We retrospectively reviewed pts with NSCLC and *KRAS* G12C mutations detected on universal testing of NSCLCs at Columbia University Irving Medical Center, Memorial Sloan Kettering and Weill Cornell Medicine from 2018 to 2023. Pts were re-evaluated at times of progression and last follow up. Pts were deemed trial-eligible if they met all EC, borderline if they had one laboratory value <20% from cutoff, or otherwise ineligible. Associations between demographic factors with odds of meeting eligibility criteria were determined using a multivariate logistic regression. **Results:** We identified 185 pts with *KRAS* G12C mutant advanced NSCLC who received treatment. Only 64 (35%) of these pts would have qualified for a second-line (2L) study of a KRAS G12C inhibitor. 15 (8%) had borderline eligibility and 106 (57%) were ineligible. 33/56 (60%) pts who received 2L KRAS G12C inhibitors would not have met consensus EC. Common reasons for 2L ineligibility included poor performance status (59, 49%), renal dysfunction (45, 37%), active brain metastases (33, 18%) and cytopenias (18, 15%). Age was associated with ineligibility (OR 1.07 per year, p = 0.006). Medicaid insurance was associated with a four-fold higher rate of ineligibility compared to Medicare but was not statistically significant (OR 4.86, p = 0.079). Liberalizing criteria for renal dysfunction and brain metastases would increase enrollment potential by 25% without decreasing the median overall survival of the broadened eligible cohort, whereas allowing worse performance status would decrease survival and effect sizes (1L HR 0.86 versus 0.74, p = 0.04; 2L HR 0.530 versus 0.423, p < 0.001). **Conclusions:** Our data indicate substantial differences between the real-world population of patients treated with KRAS G12C inhibitors and those who were trial eligible. Efforts should focus on improving clinical trial generalizability without compromising safety. Research Sponsor: 2024 Conquer Cancer/ASCO Young Investigator Award (Michael May).

Accelerating phase 2 clinical development with real-world data (RWD): An external control arm (ECA) pilot in HER2-positive (HER2+) metastatic breast cancer (mBC). First Author: Cherrishe Brown-Bickerstaff, Ontada, Boston, MA

Background: Accelerating clinical development of promising therapies is essential to improving patient (pt) outcomes. While ECAs have provided valuable supplementary evidence in Phase (Ph) 3 trials to support regulatory decision-making, ECAs in the Ph 2 setting, particularly for single-arm trials, can offer critical context for evaluating efficacy with rapidly available insights. To explore this potential, we piloted the development of a contemporaneous ECA for a newly launched Ph 2 trial of Tucatinib and Doxil in HER2+ mBC (NCT0578834). **Methods:** RW structured data, supplemented by unstructured data collected via chart abstraction, were sourced from iKnowMed electronic health records. The ECA cohort was designed for maximal comparability to the trial population by (1) emulating and applying trial eligibility criteria to RWD and (2) using propensity score matching (PSM) to balance covariate distributions. To demonstrate ECA feasibility in this interim analysis, a simulated dataset was created via multiple imputation based on the distribution of observed baseline characteristics in the 8 pts enrolled on the trial, expanding the trial cohort to 40 pts. Propensity scores (PSs) were estimated using logistic regression with covariates selected based on literature and expert input (age at index, number of prior treatments, prior fam-trastuzumab deruxtecan-nxki (Enhertu), and prior tucatinib). PSM was performed using greedy nearest-neighbor matching (caliper $\leq$0.25 standard deviation of logit of PSs) without replacement at a 1:1 ratio. **Results:** The simulated trial cohort included 40 pts, and the ECA cohort included 77 pts. After PSM, 82% of the trial cohort were successfully matched, with 18% excluded due to non-overlapping PSs, resulting in matched cohorts of 33 pts each. Following PSM, most variables in the PS model achieved a standardized difference (SD) $\leq$0.10, indicating adequate balance between trial and ECA cohorts. The mean age (61 vs. 60 years in the trial and ECA cohorts, respectively; SD = 0.03), distribution of number of prior treatments (e.g., 21% vs. 27% with 1 prior treatment; SD = 0.09), and prior tucatinib exposure (48% in both cohorts; SD = 0) were well balanced between cohorts. However, prior Enhertu exposure remained imbalanced, with 45% of trial patients receiving prior Enhertu versus 33% in the ECA cohort (SD = 0.29). **Conclusions:** This pilot demonstrates that RWD can be quickly and efficiently assembled in pace with an ongoing Ph 2 clinical trial, offering promise for accelerated decision-making in clinical drug development. When small sample sizes in Ph 2 trials pose challenges, this approach shows that an exchangeable ECA can be achieved as trial accrual progresses, providing a framework for ECA evidence generation. Research Sponsor: Ontada.

Proton pump inhibitors and the risk of adverse renal events and all-cause mortality in cancer patients receiving immune checkpoint inhibitors. First Author: Arunkumar Krishnan, Department of Supportive Oncology, Atrium Health Levine Cancer, Charlotte, NC

Background: Immune checkpoint inhibitors (ICI) have transformed cancer treatment by improving prognosis across various malignancies, while proton pump inhibitors (PPI) are frequently prescribed as prophylaxis in cancer patients. Studies suggest long-term PPI use has higher risks of adverse outcomes, though small patient populations and short follow-up periods limit the current evidence. Pharmacoepidemiologic studies are prone to protopathic bias and, methodological limitations and heterogeneity across studies in cancer patients. We aimed to assess the impact of PPI use on adverse renal events and all-cause mortality in patients receiving ICIs. **Methods:** We conducted a retrospective cohort study using the TriNetX, including adult cancer patients treated with ICIs (PD-1, PD-L1, and CTLA-4 inhibitors). We used a new-user, active comparator design, which compared newly treated PPI users with nonusers and histamine2 receptor antagonists (H2RA) users. We performed 1:1 propensity score matching (PSM) to adjust for confounding factors (demographics, comorbidities, cancer type, and medications. Primary outcomes included acute kidney injury (AKI) and acute interstitial nephritis (AIN). A secondary outcome was all-cause mortality. Hazard ratios(HR) were calculated using Cox regression models. Sensitivity analysis assessed statistical robustness. **Results:** We identified 54763 PPI, 28090 H2RA, and 30898 nonusers among patients receiving ICIs. After PSM, the PPI vs. nonusers cohort was well matched with 27322 patients, whereas PPI vs. H2RA users had 21567 patients in each cohort. During the follow-up period (median 4.3 3 years for PPI and 5.1 years for nonusers), PPI users demonstrated a higher risk for AKI (HR 1.48) and AIN (HR 1.07) compared to nonusers. In a subgroup analysis of ICIs, for PD-1i, the HR for AKI was 1.86, and for AIN, it was 2.51. For PD-L1i, the HR for AKI was 1.81, and for AIN, it was 2.33. For CTLA-4i, the HR for AKI was 2.03, and for AIN, it was 3.87. A secondary analysis at 1-year follow-up revealed a significant difference in mortality rates between former PPI and nonusers. Compared with H2RA, the PPIs demonstrated a higher rate of all-cause mortality HR: 1.51. Long-term PPI users showed consistent risks of AKI and AIN across follow-ups at 2 to 5 years, with HRs for AKI ranging from 1.48 to 2.59. Pantoprazole users showed the highest AKI risk (HR 1.59). Sensitivity analysis results were consistent, and associations remained unchanged. **Conclusions:** PPI use is associated with a significantly increased risk of AREs and all-cause mortality in cancer patients receiving ICIs, with the highest risk observed in patients treated with PD-1i and CTLA-4i. These results emphasize the importance of careful prescribing of PPIs and vigilant renal monitoring for this at-risk group. Further research is warranted to explore the mechanisms underlying this association. Research Sponsor: None.

Efficacy GLP-1 agonists, SGLT-2 inhibitors and other glucose-lowering medications on cardiorenal outcomes in patients with diabetes and cancer on immune checkpoint therapy. First Author: Diptasree Mukherjee, Apex Institute of Medical Science, Kolkata, India

Background: Treatment with Immune checkpoint inhibitors (ICI) therapy has improved survival in multiple malignancies. However, patients with type 2 diabetes (T2D) and cancer receiving ICI are at heightened risk for adverse cardiorenal outcomes. Emerging evidence suggests that Glucagon-like peptide 1 receptor agonists (GLP-1RA) and sodium–glucose cotransporter 2 inhibitors (SGLT2i) confer cardiorenal benefits in T2D. However, their impact among patients with T2D and cancer remains unclear. Hence, we aimed to evaluate the effectiveness of GLP-1RA, SGLT-2i, and other glucose-lowering therapies in reducing adverse cardiorenal events. **Methods:** A retrospective cohort study was conducted using the TriNetX. Adult patients with T2D and cancer treated with ICI (anti-PD1, anti-PDL1, or anti-CTLA4) between 2017 and 2024 were included. Patients were stratified into three groups based on therapy: GLP-1RA, SGLT-2i, and other second or third line medications. We performed 1:1 propensity score matching(PSM) to adjust for confounding factors, including demographics, comorbidities, cancer type, and medications. The primary outcomes were major adverse cardiovascular events(MACE), heart failure(HF) and cerebrovascular events(CVE)) and secondary outcome was of end-stage renal diseases (ESRD), the need for dialysis and all-cause mortality. Hazard ratios(HR) for outcomes were calculated using Cox proportional hazard models. Sensitivity analysis assessed statistical robustness. **Results:** We identified 6212 patients on GLP-1RA, 7068 on SGLT-2i, and 24693 on other second- or third-line medications. After PSM, 5381 patients were included in the GLP-1RA vs. SGLT-2i cohorts. There were no significant differences in cardiorenal outcomes between the two groups. However, all-cause mortality was significantly lower for GLP-1RA (HR 0.88). In the comparison of GLP-1RA vs. other glucose-lowering medications, 6206 patients were matched. GLP-1RA were associated with significantly lower rates of HF, MACE, CVE, ESRD and mortality (HR 0.74). Similarly, for SGLT-2is vs. other glucose-lowering medications, 7,069 patients were matched. SGLT-2i demonstrated lower rates of adverse outcomes, particularly HF and ESRD (HR 0.63). Subgroup analysis revealed consistent benefits across cancer types, with pronounced effects in renal and lung cancer. **Conclusions:** GLP-1RA and SGLT-2i significantly reduce cardiorenal risks in patients with T2D and cancer on ICIs. However, GLP-1RA provided a modest survival advantage over SGLT-2is. These results underscore the importance of individualized therapeutic strategies prioritizing GLP-1RA and SGLT-2is in this high-risk population to improve cardiorenal outcomes and survival. Further studies are warranted to validate these findings and explore underlying mechanisms. Research Sponsor: None.

Real-world evidence from FLEX: Utility of MammaPrint in guiding treatment planning for patients aged 70 and older with early-stage breast cancer. First Author: Reshma L. Mahtani, Miami Cancer Institute, Baptist Health South Florida, Miami, FL

Background: Older women ($\geq$70) are less likely to receive chemotherapy (CT) due to quality-of-life concerns. Additionally, older patients are underrepresented in studies assessing the utility of genomic profiling in guiding CT decisions, thus guidelines around neo/adjuvant CT for this population are less clear. To identify the utility of the MammaPrint (MP) 70-gene and BluePrint (BP) 80-gene assays in informing treatment decisions in an elderly population, we examined the relationship of age ($\geq$70 vs.$<$70) and treatment outcomes stratified by MP/BP subtypes in pts with HR+ HER2- EBC. **Methods:** The prospective, observational FLEX Study (NCT03053193) includes stage I-III pts with early-stage breast cancer (EBC) who received MP with or without BP testing and consented to full transcriptome and clinical data collection with therapy data available. Differences in the distribution of clinical characteristics between age groups were assessed by Chi-squared, Fisher's exact, or Wilcoxon-Mann-Whitney tests. The endpoint recurrence-free interval (RFI) was defined as time to local, regional, or distant recurrence or breast cancer related death Kaplan-Meier survival analysis and log-rank tests were used to assess differences in endpoints between treatment groups. **Results:** A total of 4,519 HR+, HER2- EBC pts were included, with 1,047 $\geq$70 (23.2%) and 3,472 $<$70 (76.8%). Patients $\geq$70 were significantly less likely to present with high grade tumors and lymph node involvement than those $<$70 (12.8% vs 16.2% grade 3, p=.022; 20.6% vs 24.2% node positive, p=.017, respectively). The MP risk group distribution showed a significantly higher proportion of low genomic risk (Ultralow or low risk) tumors in the $\geq$70 vs. $<$70 group (Ultralow (UL) 14.7% vs 14.9% , Low 41.2% vs 38.7% , High 1 (H1) 37.3% vs 36.9% , and High 2 (H2) 6.8% vs 9.5% , p 0.048, respectively). Patients $\geq$70 with MP High Risk tumors were less likely to receive CT compared to those $<$70 (H1 55.8% vs 73%, p$<$0.001; H2 72.6% vs 82.2%, p=0.07, respectively). When evaluating 3-year RFI, the $\geq$70 pts with MP High Risk cancer trended towards better outcomes with CT than those receiving endocrine therapy only, especially in H2 cancers (H1 97% vs 94% , p=.137, H2 90% vs 79% , p=.078, respectively). **Conclusions:** This study underscores the potential CT benefits in MP H2 HR+ HER2- EBC pts $\geq$ 70 who may forgo treatment due to overall health and quality of life concerns. Notably, in MP H2 pts, the absolute improvement in 3-year RFI of 11% with neo/adjuvant CT in women $\geq$ 70 suggests that for many pts, the benefit outweighs the risks. Of note, this H2 CT benefit is similar to that observed in a group of 1000 pts with a median age of 59 recently reported (Brufsky, et al. SABCS 2024, P2-08-12). Patient centered discussions on performance status, comorbidities, and genomic profiling of HR+ HER2-EBC as well as the potential benefit from CT should guide personalized treatment. Clinical trial information: NCT03053193. Research Sponsor: Agendia, Inc.

Use of large language models to extract cancer diagnosis, histology, grade, and staging from unstructured electronic health records. First Author: Gayathri Namasivayam, Ontada, Boston, MA

Background: The oncology ecosystem contains millions of unstructured documents within Electronic Health Record (EHR) systems, including clinical notes and pathology reports with vital patient information like cancer diagnoses, histology, grade, and staging. These documents are often text or scanned PDFs. Extracting clinical details from these sources can improve EHR completeness and accuracy. To address this challenge, we developed an information extraction pipeline that leverages the recent advances in artificial intelligence (AI). **Methods:** Large Language Models (LLMs) and prompt engineering was used to extract information from both clinical notes and pathology reports. For pathology reports, Optical Character Recognition (OCR) was applied to convert scanned images into text, which was then processed by the LLM using a tailored prompt designed to extract the relevant cancer diagnosis and staging details. For clinical notes, the text was directly passed into the LLM along with an optimized prompt to extract the same clinical information. The information extraction pipeline was validated using a dataset of 829 pathology reports and 569 progress notes from the EHR system across 40 cancer types, including 26 solid tumors and 14 hematologic malignancies. Clinical specialists manually extracted cancer diagnoses, histology, grade, and staging, which were compared to the automated output. An F1 score using a combined measure of precision and recall was calculated to assess the model's accuracy. **Results:** The pipeline retrieved cancer type, histology, and grade from pathology reports with an F1 score over 0.85. Similarly, it extracted cancer type and staging information from progress notes with an F1 score over 0.85, demonstrating high accuracy and reliability. Additional performance metrics are shown in the table. **Conclusions:** This LLM-based extraction pipeline accurately identified cancer diagnoses, histology, grade, and staging information from unstructured text and scanned documents within the EHR achieving an F1 score $\geq$0.85. The validation results suggest that this approach could be scaled to improve the completeness and utility of EHR data, supporting the availability of more robust information for scientific research, clinical care, and other uses of health data. Research Sponsor: None.

Performance metrics of LLM-based extraction pipeline.

Immune checkpoint inhibitor–associated myocarditis: Incidence, risk factors, and clinical outcomes in a global real-world cohort. First Author: Zhiting Tang, Department of Medicine, Unity Hospital, Rochester Regional Health, Rochester, NY

Background: Immune checkpoint inhibitor (ICI)-associated myocarditis is a rare but life-threatening immune-related adverse event (irAE), with a mortality rate of 30–50%. Most available evidence comes from case series and adverse event reporting databases, leaving its risk factors and clinical outcomes largely undefined. **Methods:** We performed a retrospective investigation using the TriNetX Global Research Network. Patients were included if they had been diagnosed with solid tumors after 2016 for which ICIs are approved. We calculated myocarditis incidence among ICI users and compared myocarditis risk between ICI and non-ICI cohorts using propensity score matching (accounting for demographics, comorbidities, cancer types, and treatments). Univariate and multivariate models were applied to assess risk factors. Risks of hospitalization, ICU admission, and major adverse cardiovascular events (MACE) were compared in ICI-treated patients with and without myocarditis using propensity score matching. **Results:** Among 130,234 ICI-treated patients, 643 (0.49%) developed myocarditis. Most cases (82.0%) occurred within the first year of ICI initiation. The risk of myocarditis was 27 times higher in the ICI group compared to the non-ICI group (Relative Risk [RR]=27.78, 95% CI: [17.36-44.45]). Univariate analysis identified older age, male sex, White race, hypertension, hyperlipidemia, ischemic heart disease, diabetes, chronic kidney disease, heart failure, cardiomyopathy, urothelial cancer, melanoma, ipilimumab, nivolumab, pembrolizumab, radiation therapy, inflammatory arthritis, lupus, and systemic connective tissue disease as potential risk factors. In multivariate analysis, only age over 65 (Hazard Ratio [HR] = 1.34, 95% CI: [1.11–1.63], $p < 0.01$), hypertension (HR=1.31, 95% CI: [1.06-1.62], p=0.01), hyperlipidemia (HR=1.34, 95% CI: [1.09-1.65], $p<0.01$), melanoma (HR=1.52, 95% CI: [1.25-1.86], $p<0.01$), and ipilimumab (HR= 2.44, 95% CI: [1.87-3.19], $p<0.01$) were significantly associated with myocarditis. Patients who developed ICI-associated myocarditis had higher risks of hospitalization (RR=1.39, 95% CI: [1.28-1.52]), ICU admission (RR=2.35, 95% CI: [1.86-2.98]), myocardial infarction (RR=5.58, 95% CI: [3.73-8.34]), heart failure (RR=1.59, 95% CI: [1.38-1.85]), stroke (RR=2.94, 95% CI: [1.75-4.97]), MACE (RR=3.92, 95% CI: [2.91-5.27]), and all-cause mortality (RR=1.32, 95% CI: [1.13-1.55]) within one year compared to those who received ICIs but did not develop myocarditis. **Conclusions:** ICI-associated myocarditis is a rare irAE but carries an increased risk of cardiovascular complications and death. Advanced age, hypertension, hyperlipidemia, melanoma, and ipilimumab use appear to be risk factors. Clinical vigilance is warranted to facilitate early detection and management of this potentially fatal complication. Research Sponsor: None.

Leveraging real-world data sources for clinical oncology research: A review of studies published in ASCO publications. First Author: Thomas Lucido, Department of Medicine, Rutgers Robert Wood Johnson Medical School, New Brunswick, NJ

Background: Real-world data (RWD) are essential for assessing healthcare delivery and outcomes for cancer survivors, require complex statistical techniques to account for biases, and are commonly combined with other data sources. Reporting guidelines, such as Strengthening the Reporting of Observational Studies in Epidemiology(STROBE), were developed to improve the quality and transparency of RWD publications. These guidelines are not required for publication in ASCO journals. Our objective was to describe the types of RWD that commonly occur in ASCO Publications, how the data are being used, and to what extent the reports align with methodologic STROBE criteria. **Methods:** We used the ASCO Editorial Manager to identify original reports published between January 2018 to December 2022 that leveraged commonly used RWD in the US. We included all journals in ASCO Publications (Journal of Clinical Oncology [JCO], Precision Oncology [PO], Oncology Practice [OP], Clinical Cancer Informatics [CCI], and Global Oncology [GO]). The RWD assessed were SEER, Medicare, NCDB, Flatiron, CancerLinQ, IQVIA, Optum, MarketScan, MEPS, and NHANES. The data were identified by specifically referencing the source within the abstract. Five independent, trained reviewers abstracted clinical, epidemiologic, and reporting data from the manuscripts. For this study, we focused analysis on STROBE methodology reporting criteria (items 4-12). **Results:** One hundred and seventy-four publications were included in our study (57% OP, 18% CCI, 14% JCO, 5.8% PO, 5.2% GO). The most common RWD used were Medicare (49%), SEER (40%), and NCDB (14%). Nearly one-quarter of the publications used more than one of the databases evaluated, and one-third included a secondary RWD source and/or linked patients with an external data source (e.g., Google Maps, electronic health records). The most common malignancy types evaluated in the manuscripts were breast (33%), lung (25%) and colorectal (21%). Study design, setting, and study variables had high reporting (>90%), while descriptions about study size derivation, the rationale for quantitative analyses, and the approach to missing data were less well reported (<78%). **Conclusions:** RWD are published within ASCO Publications and are commonly combined with multiple data sources. Though some STROBE methodologic reporting criteria are regularly addressed, we identified criteria that were not well-reported. Further research is needed to assess changes in the use of RWD and whether lower reporting of methodologic information may impact the replicability and interpretation of study findings. Venous thromboembolism among cancer patients receiving chimeric antigen receptor-T cell therapy. First Author: Rahul Mishra, Department of Internal Medicine, Luminis Health Anne Arundel Medical Center, Annapolis, MD

Background: Chimeric antigen receptor T-cell (CAR-T) therapy has revolutionized the treatment of advanced cancers. Although, immune side effects (ICANS or CRS) of CARTs are well recognized, and have standardized guidelines for their management, venous thromboembolism risk (VTE) is scant. As the usage of CART is anticipated to increase in upcoming years, it is of utmost importance to characterize factors associated with increased VTE risk. **Methods:** Using the TriNetX database, we conducted a retrospective analysis to evaluate incidence and risk factors of VTE post CART. Eligibility included administration of any one of the six CAR-T therapies (Tisagenlecleucel, Axicabtagene (Axi-cel), Brexucabtagene, Lisocabtagene, Idecabtagene and Ciltacabtagene) at age $\geq$18y. VTE were identified using ICD codes for either upper extremity thrombosis or lower extremity deep vein thrombosis, pulmonary embolism, cerebral sinus thrombosis, splenic vein thrombosis or portal vein thrombosis. We further compared these patients to CART recipients without these VTE. Univariate analysis using TriNetX built-in feature (outcome comparison) was performed to compare factors associated with VTE including demographics, comorbidities, cancer type, and treatment. **Results:** We analyzed data from 133 million+ patients from over 103 health care organizations. There were 2076 adult CAR-T recipients. Axi-cel was the most frequently used CART type. 347/2076 (16.7%) patients developed a VTE after CAR-T, with 10% (210/2076) developing it within three months. CART with VTE cohort had a mean age of 64 years, predominantly males (201/347, 58%) and Caucasian (264/347, 76%). In univariate analysis, when compared to CART without VTE cohort (N =1033), we identified factors significantly associated with VTE. This included history of nicotine dependence (35% vs 24%, $P<0.0001$), primary hypertension (23% vs 19%, $P<0.0001$), obesity (25% vs 17%, $P=0.0007$), hyperlipidemia (45% vs 30%, $P<0.0001$), h/o radiation (35% vs 18%, $P<0.0001$), and use of Axi-cel (42% vs 7%, $P<0.0001$). The use of glucocorticoids (95% vs 77%, $P<0.0001$), alkylating agents (91% vs 71%, $P<0.0001$) or lenalidomide (18% vs 11%, $P=0.0006$) were significantly associated with VTE. The underlying cancer type also affected the risk of VTE, having significant association with diffuse large B-cell lymphoma (64% vs 50%, $P<0.0001$), mantle cell lymphoma (11% vs 7%, $P=0.0198$), and small cell B-cell lymphoma (8% vs 4%, $P=0.0018$). **Conclusions:** There is 10% incidence of VTE within three months of CAR-T therapy. Particularly, VTE incidence is higher with Axi-cel, and DLBCL diagnosis. Patients with high –risk associations may benefit from thromboprophylaxis regimens, particularly during initial three months of CAR-T therapy. Prospective research is warranted to further validate such risk factors and develop evidence-based thromboprophylaxis guidelines for CART recipients. Research Sponsor: None.

Clinical outcomes for Medicaid recipients with early-onset breast cancer: An analysis of the National Inpatient Sample. First Author: Vineet Polineni, Jefferson Health New Jersey, Stratford, NJ

Background: Despite recent global decreases in overall cancer incidence, the incidence of early-onset breast cancer (EOBC) is steadily increasing globally. Limited data is available on the comorbid correlations for this unfortunately expanding population. We sought to examine the national inpatient sample database to describe in-hospital outcomes among Medicaid recipients with EOBC. **Methods:** Data were extracted from the National Inpatient Sample (NIS) Database for 2019 and 2020. The NIS was searched for hospitalizations of adult patients with EOBC, defined as all-cause breast cancer in patients 50 years old or younger. We then examined the outcomes of patients who were noted to be active Medicaid recipients. Multivariate logistic was used to adjust for confounders. The primary outcome was inpatient mortality and secondary outcomes were annotated accordingly. SPSS software was used for statistical analysis, and all results were powered to $p<0.001$. **Results:** This study included 10,764 patients with EOBC, of which 3145 (29.2%) were on Medicaid. Multivariate regression showed that Medicaid patients with EOBC had higher inpatient mortality (OR 1.507, CI 1.406-1.616, $p<0.001$). On secondary analysis, Medicaid patients with EOBC were more likely to have systemic lupus erythematosus (OR 1.194, CI 1.080-1.319), anemia (OR 1.465, CI 1.433-1.498), thrombocytopenia (OR 1.440, CI 1.377-1.507), hypertension (OR 1.578, CI 1.461-1.704), chronic kidney disease (OR 1.343, CI 1.253-1.440), acute renal failure (OR 1.506, CI 1.432-1.584), pancreatitis (OR 1.420, CI 1.221-1.651), pericarditis (OR 1.394, CI 1.282-1.515), intracranial hemorrhage (OR 1.429, CI 1.225-1.665), severe liver disease (OR 1.504, CI 1.458-1.550), peptic ulcer disease (OR 1.436, CI 1.271-1.623), obstructive sleep apnea (OR 1.413, CI 1.313-1.521), leukemia (OR 1.310, CI 1.098-1.564), lymphoma (OR 1.737, CI 1.296-2.328), all-cause arrhythmias (OR 1.448, CI 1.342-1.563), all-cause shock (OR 1.478, CI 1.290-1.693), all-cause heart block (OR 1.294, CI 1.103-1.519), all-cause sepsis (OR 1.549, CI 1.496-1.603), all-cause coagulopathy (OR 1.457, CI 1.362-1.558), all-cause heart failure (OR 1.587, CI 1.467-1.717), all-cause stroke (OR 1.450, CI 1.342-1.566), and all-cause myocardial infarction (OR 1.766, CI 1.503-2.075). **Conclusions:** In this nationally representative, population-based retrospective cohort study, Medicaid recipients with EOBC were associated with higher mortality and worse outcomes. Inpatient outcomes of breast cancer hospitalizations in the northeastern vs western United States. First Author: Davin Turku, The Brooklyn Hospital Center, Brooklyn, NY

Background: Regional disparities in healthcare resources and outcomes are well-documented in the U.S., yet little is known about how they impact inpatient outcomes in breast cancer (BC) patients. The Northeastern (NE) region has the highest incidence and prevalence of BC, along with a greater concentration of academic cancer centers, while the Western (W) region has the lowest rates. This study compares both in-hospital and discharge outcomes of BC patients between these regions to explore how these variations affect inpatient outcomes. **Methods:** A cross-sectional analysis was done using the National Inpatient Sample database (2016–2020) using STATA 17.0 software. NE was taken as reference. Baseline characteristics and outcomes were compared among NE and W using chi-square tests and survey-weighted multivariate logistic regressions, after adjusting for confounders. **Results:** Among 855,494 BC hospitalizations, 22% were from the NE and 19% were from the W. Patients in W were younger, with 18% aged <50 years compared to 16% in NE ($p < 0.001$). 38% of NE patients were from high-income backgrounds, compared to 32% in W, while 16% of both NE and W patients were from the lowest income group ($p < 0.001$) suggesting significant income disparities in NE. 85% of NE patients were treated at teaching hospitals compared to 70% in W. However, in NE, only 46% sought care at large bed size hospitals compared to 58% in W (all $p < 0.001$). NE patients had longer hospital stays (>7 days: 22% vs 19%, $p < 0.001$) and incurred higher costs. Additionally, patients in the W had significantly lower odds of in-hospital mortality and discharges to skilled nursing facilities (NH) compared to NE (Table). **Conclusions:** We identified significant regional differences in BC hospitalization outcomes. W had lower mortality and lesser NH discharges, possibly due to a younger population and differences in post-acute care. In contrast, older demographics and socioeconomic factors in the NE may explain higher costs and mortality. Despite more academic centers in the NE, outcomes were not better. These findings highlight the need for region-specific strategies to improve BC care. Future research should focus on the drivers of these disparities and develop targeted interventions. Trends in early-onset gastrointestinal cancers: A comprehensive analysis of US cancer statistics (2001–2021). First Author: Abdul Qahar Khan Yasinzai, University of Florida Health Cancer Center, Gainesville, FL

Background: Early-onset colorectal cancer (eoCRC) has become a well-recognized phenomenon in recent years. This study aims to explore trends in other early-onset gastrointestinal cancers (eoGIC) and provide more details on sub-sites of eoCRC. **Methods:** The NPCR-SEER database, which covers the entire U.S. population from 2001 to 2021, was utilized to analyze GI cancer cases among individuals aged 20–49 years. Trends were assessed using Joinpoint regression, and polynomial regression was applied to forecast incidence rates from 2021 to 2031. **Results:** A total of 528,310 cases were analyzed. In 2021, eoCRC had the highest incidence (n=17,567), followed by stomach cancer (n=2,783) and pancreatic cancer (n=2,634). EoCRC has been significantly increasing with (Average Annual Percent Change (AAPC) 1.30%, $p<0.01$). Stomach and pancreatic cancers showed steady rise with (AAPC 0.73%, $p<0.01$) and (AAPC 1.14%, $p<0.01$). Among eoCRC subsites, rectal cancer showed the most substantial increase (AAPC 1.86%, $p<0.01$), followed by sigmoid colon (AAPC 1.17%, $p<0.01$) and descending colon (AAPC 0.85%, $p<0.01$). Although the appendiceal, small intestine and intrahepatic bile duct represent a smaller portion of the eoGICs, these sites demonstrated the most dramatic rises in incidence compared to their previous crude rates. Appendiceal cancer showed the highest increase (AAPC 7.23%, $p<0.01$), followed by intrahepatic bile duct cancer (AAPC 5.81%, 95% CI, $p<0.01$) and small intestine cancer (AAPC 2.90%, $p<0.01$). Declining trends were observed in esophageal (AAPC -1.50%, <0.01), liver (AAPC -2.89%, <0.01), and anal cancers (AAPC -0.98%, <0.01). By 2027, females are projected to cross males ($R^2 = 0.91$) in the incidence of eoGICs. **Conclusions:** Several eoGICs are exhibiting increasing trends, potentially indicating a shared or disease-agnostic underlying etiology. The rising prevalence and shifting demographics underscore the critical need for tailored prevention measures and early detection strategies focused on high-risk populations. Future research should focus on identifying underlying factors driving these trends. Research Sponsor: None.

Clinical outcomes for low-income patients with early-onset breast cancer: An analysis of the National Inpatient Sample. First Author: Ben Brik, Jefferson Health New Jersey, Stratford, NJ

Background: Despite recent global decreases in overall cancer incidence, the incidence of early-onset breast cancer (EOBC) is steadily increasing globally. Limited data is available on the comorbid correlations for this unfortunately expanding population. We sought to examine the national inpatient sample database to describe in-hospital outcomes among low-income patients with EOBC. **Methods:** Data were extracted from the National Inpatient Sample (NIS) Database for 2019 and 2020. The NIS was searched for hospitalizations of adult patients with EOBC, defined as all-cause breast cancer in patients 50 years old or younger. We then examined the outcomes of patients who self-reported an income less than $50,000. Multivariate logistic was used to adjust for confounders. The primary outcome was inpatient mortality and secondary outcomes were annotated accordingly. SPSS software was used for statistical analysis, and all results were powered to $p<0.001$. **Results:** This study included 10,764 patients with EOBC, of which 2743 (25.5%) were low-income. Multivariate regression showed that low-income patients with EOBC had higher inpatient mortality (OR 1.438, CI 1.348-1.534, $p<0.001$). On secondary analysis, low-income patients with EOBC were more likely to have systemic lupus erythematosus (OR 1.298, CI 1.146-1.470), anemia (OR 1.374, CI 1.347-1.402), thrombocytopenia (OR 1.356, CI 1.302-1.412), hypertension (OR 1.545, CI 1.434-1.666), chronic kidney disease (OR 1.531, CI 1.404-1.669), acute renal failure (OR 1.462, CI 1.393-1.535), pancreatitis (OR 1.479, CI 1.259-1.738), mitral regurgitation (OR 1.300, CI 1.151-1.468), pericarditis (OR 1.358, CI 1.254-1.471), intracranial hemorrhage (OR 1.373, CI 1.190-1.584), pulmonary hypertension (OR 1.542, CI 1.326-1.794), severe liver disease (OR 1.382, CI 1.346-1.419), leukemia (OR 1.407, CI 1.149-1.724), lymphoma (OR 1.320, CI 1.088-1.601), all-cause arrhythmias (OR 1.324, CI 1.241-1.413), all-cause shock (OR 1.414, CI 1.264-1.605), all-cause heart block (OR 1.479, CI 1.172-1.719), all-cause sepsis (OR 1.409, CI 1.368-1.451), all-cause coagulopathy (OR 1.415, CI 1.327-1.508), all-cause heart failure (OR 1.508, CI 1.402-1.623), all-cause stroke (OR 1.463, CI 1.331-1.549), and all-cause myocardial infarction (OR 1.527, CI 1.336-1.746). **Conclusions:** In this nationally representative, population-based retrospective cohort study, low-income patients with EOBC were associated with higher mortality and worse outcomes. Research Sponsor: None.

Clinical outcomes for Black patients with early-onset breast cancer: An analysis of the National Inpatient Sample. First Author: Mahija Cheekati, Morristown Medical Center, Morristown, NJ

Background: Despite recent global decreases in overall cancer incidence, the incidence of early-onset breast cancer (EOBC) is steadily increasing globally. Limited data is available on the comorbid correlations for this unfortunately expanding population. We sought to examine the national inpatient sample database to describe in-hospital outcomes among black patients with EOBC. **Methods:** Data were extracted from the National Inpatient Sample (NIS) Database for 2019 and 2020. The NIS was searched for hospitalizations of adult patients with EOBC, defined as all-cause breast cancer in patients 50 years old or younger. We then examined the outcomes of patients who self-identified as Black. Multivariate logistic was used to adjust for confounders. The primary outcome was inpatient mortality and secondary outcomes were annotated accordingly. SPSS software was used for statistical analysis, and all results were powered to $p<0.001$. **Results:** This study included 10,764 patients with EOBC, of which 2328 (21.6%) were identified as black. Multivariate regression showed that black patients with EOBC had higher inpatient mortality (OR 1.408, CI 1.323-1.498, $p<0.001$). On secondary analysis, black EOBC patients were more likely to have systemic lupus erythematosus (OR 1.345, CI 1.177-1.538), anemia (OR 1.382, CI 1.355-1.411), thrombocytopenia (OR 1.275, CI 1.230-1.321), hypertension (OR 1.989, CI 1.799-2.200), chronic kidney disease (OR 1.803, CI 1.621-2.004), acute renal failure (OR 1.446, CI 1.379-1.516), pancreatitis (OR 1.291, CI 1.139-1.463), pericarditis (OR 1.200, CI 1.131-1.274), intracranial hemorrhage (OR 1.489, CI 1.264-1.755), chronic obstructive pulmonary disease (OR 1.297, CI 1.216-1.383), severe liver disease (OR 1.351, CI 1.318-1.386), Crohn's disease (OR 1.275, CI 1.104-1.472), leukemia (OR 1.310, CI 1.098-1.564), all-cause arrhythmias (OR 1.387, CI 1.292-1.489), all-cause shock (OR 1.435, CI 1.260-1.634), all-cause heart block (OR 1.189, CI 1.046-1.352), all-cause sepsis (OR 1.293, CI 1.261-1.326), all-cause coagulopathy (OR 1.355, CI 1.277-1.438), all-cause heart failure (OR 1.659, CI 1.527-1.803), all-cause stroke (OR 1.422, CI 1.319-1.532), and all-cause myocardial infarction (OR 1.638, CI 1.413-1.897). **Conclusions:** In this nationally representative, population-based retrospective cohort study, black patients with EOBC were associated with higher mortality and worse outcomes. Research Sponsor: None.

A platform to identify patients for cancer vaccine trials: The NHS England Cancer Vaccine Launch Pad (CVLP). First Author: Victoria Goss, Cancer Research UK Southampton Clinical Trials Unit, University of Southampton, Southampton, United Kingdom

Background: The Cancer Vaccine Launch Pad (CVLP) was established in September 2023 to establish a process to increase the number of patients identified as potentially eligible for cancer vaccine trials and supporting processes for accompanying tumour tissue processing. Increasing the available patient population by referring from wider geographical regions also increases representation from groups who may otherwise not have the opportunity to take part in cancer vaccine research trials. The CVLP is a collaborative project including NHS England, Genomics England, the Department of Health and Social Care, the Office for Life Sciences and the National Institute of Health and Care Research (NIHR) which is being delivered by the Cancer Research UK Southampton Clinical Trials Unit. The CVLP has been designed as a company and trial agnostic platform which can accommodate multiple cancer vaccine trials in multiple cancer types. **Methods:** The CVLP aims to rapidly identify large numbers of cancer patients who could be eligible for trials to expedite evidence for the efficacy of vaccines across multiple types of cancer. To support the identification of participants their tissue samples are processed by a standardised, high quality, expanded pathway, incorporating elements of the NHS Genomic Medicine Service. The primary objective of the CVLP is to determine whether it is feasible to recruit cancer patients to a platform to be matched to available cancer vaccine trials, whether there is capacity for tumour samples to be analysed within a suitable time frame and if this results in acceptable participation in cancer vaccine clinical trials. Eligibility criteria are determined according to the needs of the trial that patients will be referred on to. The CVLP pathway from patient identification to entry into available clinical trials has been developed to include the following steps; i) patients identified by the clinical team managing their care and consented into CVLP; ii) blood and tissue samples (during surgery) collected; iii) samples sent to Cellular Pathology Genomic Centre and Genomic Laboratory Labs; iv) eligibility assessment which allows the clinical liaison team to pair patients with available research trials. Sponsored by NHS England the first trial incorporated within the CVLP is BioNTech BNT122-01 (NCT04486378) investigating the RO7198457 mRNA vaccine in patients with ctDNA-positive, resected Stage II/III colorectal cancer which reached approximately 60% of patients undergoing colorectal surgery via the CVLP from 55 sites across England. To facilitate screening to the cancer vaccine trial 96.4% of tissue samples were prepared in the required time frame for testing (average 2.5 days) providing proof of principal for this pathway and paving the way for the onboarding of further trials. Clinical trial information: ISRCTN13053675. Research Sponsor: NHS England.

Barriers and facilitators of adoption and implementation of a financial navigation program in Nigeria: An analysis of participant data from the COST-FIN trial. First Author: Adewale Isaiah Oyewole, Department of Medical Rehabilitation, Obafemi Awolowo University, Ile-Ife, Nigeria

Background: Financial toxicity is a critical issue in modern healthcare. The impact of financial toxicity is particularly pronounced in low- and middle-income countries (LMICs), where healthcare systems are underfunded, and out-of-pocket costs dominate medical payments. Financial navigation programs (FNPs) help patients manage costs through insurance, resources, and budget support. This study examines the challenges and opportunities of implementing FNPs in an LMIC, using data from the COST-FIN study, a randomized controlled trial investigating the impact of a structured FNP on cancer care in Nigeria. **Methods:** Adult patients (>18 years) diagnosed with breast, prostate, or colon cancer within 6 weeks of presentation at Lakeshore Cancer Center or Obafemi Awolowo University in Nigeria were eligible for trial enrollment. Between July 15 and November 22, 2024, 52 patients were recruited, and 23 were randomized to the financial navigation arm of the study. Financial Navigators assessed each patient's financial literacy and developed individualized financial plans. The extent of navigation required was categorized as high, moderate, low, or no assistance needed. **Results:** Among the 19 patients who completed financial literacy sessions, 17 received financial plans. Of these, 16 required financial navigation (extent of navigation: high, n = 8; moderate, n = 6; low, n = 2; no assistance needed, n = 1), and 15 were successfully directed to resources, including the National Health Insurance Scheme (100%), philanthropic organizations (26.7%), supports from other studies (53.3%), and drug discount programs-Nigerian Cancer Access Partnership, pharma companies and Medicaid PACE (100%). Low financial literacy was a significant barrier, with many patients lacking the knowledge to make informed decisions. Regulatory challenges, characterized by complex and inconsistent frameworks, and communication barriers also hindered FNP implementation. Navigators reported that addressing financial barriers reduced patients' stress and improved their focus on treatment. **Conclusion:** Preliminary findings highlight the potential of structured FNPs to alleviate financial toxicity and improve treatment adherence among cancer patients in Nigeria. Implementing comprehensive FNPs is crucial to address low financial literacy and help patients navigate healthcare costs. Collaborating with government policymakers to improve healthcare affordability and accessibility is also essential. Research Sponsor: None.

TPS11188 **Poster Session**

Strength of evidence supporting cancer drug approvals in China, 2017-2021. First Author: Yichen Zhang, Department of Pharmacy Administration and Clinical Pharmacy, School of Pharmaceutical Sciences, Peking University, Beijing, China

Background: Well-designed and adequately conducted clinical trials are the cornerstone evidence to demonstrate drug safety and efficacy and support regulatory approval of drugs. We aim to investigate the strength of evidence supporting new cancer drug indications approved in China. **Methods:** This retrospective observational study included pivotal trials supporting cancer drug indications approved in China in 2017-21. We assessed their ability to minimize bias of single-arm trials, measured as adopted external control arm and adjusted confounders; risk of bias of randomized controlled trials (RCTs), as evaluated using the revised Cochrane tool for risk of bias assessment. The ratio of hazard ratios (RHR) was calculated to quantify differences in effect size in RCTs with different risks of bias. **Results:** Between 2017 and 2021, 77 novel cancer drugs for 148 indications were approved in China, based on data from 205 pivotal studies. Of the 56 pivotal single-arm trials with regulatory review documents, 6 (10.7%) used aggregated data from earlier trials as external controls without adjustment for confounders. Of the 128 pivotal RCTs with published results, 95 (74.2%) were assessed as having some concern or a high risk of bias. RCTs judged to be at some concern or high risk of bias in the randomization process had smaller effect sizes (RHR=0.67, 95% CI: 0.53-0.86), and those judged to be at some concern or high risk of bias in missing outcome data had larger effect sizes (RHR=1.11, 95% CI: 1.00-1.23), compared to RCTs at low risk of bias in these domains). **Conclusions:** Over four-fifths of pivotal studies supporting cancer indication approvals in China had design weaknesses that introduce uncertainty to the estimation of treatment effects. To ensure the validity of drug efficacy data and reduce uncertainty, stakeholders should strengthen and implement a high-quality standard on the design, conduct, and analysis of studies supporting regulatory approval of new therapies. Research Sponsor: National Natural Science Foundation of China; 72274004.

Falcon: Exact Sciences' multicancer early detection (MCED) real world evidence (RWE) registry. First Author: Ronan Joseph Kelly, Charles A. Sammons Cancer Center at Baylor University Medical Center, Dallas, TX

Background: Earlier detection may reduce cancer morbidity and mortality by reducing the number of cancers diagnosed at advanced stages. Exact Sciences is developing a blood-based MCED test to simultaneously screen for multiple cancer types, with test-positive patients undergoing diagnostic evaluation with radiological imaging. The Falcon registry is a large prospective study of Exact Sciences' MCED test in clinically cancer-free individuals who seek cancer screening. It will examine the uptake, diagnostic journey, adherence with guideline-recommended cancer screening, outcomes, and psychological impacts of MCED testing in a setting that closely resembles the real world, with results expected to be broadly generalizable. **Methods:** Falcon is a multi-site registry that is enrolling up to 25,000 participants who receive the MCED test annually for three years (MCED cohort). A comparison cohort of up to 50,000 patients receiving standard-of-care clinical management only (SOC cohort) will be retrospectively constructed via a deidentified data pull. Both cohorts will include individuals 50 to 80 years of age presenting for primary care services who have no history of malignancy within the prior 3 years or current suspicion of cancer. SOC cancer screening will continue in the course of standard care and will not be proscribed or interrupted by study participation. The MCED cohort will include a 10,000-participant pilot cohort and up to a 15,000-participant expansion. This cohort will include individuals who provide informed consent for MCED testing and follow-up IV-contrast computed tomography (CT) and, if necessary, positron emission tomography-CT (18F FDG PET-CT) imaging following a positive MCED test. Clinical contraindications for radiological imaging (e.g. pregnancy, IV contrast allergy, renal failure) will be taken into consideration when making the decision to participate. The SOC cohort will be selected after enrollment of each MCED cohort phase and will be matched based on demographic and clinical characteristics. Self-reported measures of anxiety, cancer worry, and trauma will be collected from all MCED cohort participants routinely throughout the study. Data will be collected for up to 5 years following the baseline test or, for the SOC cohort, following an index date. Periodic automated extraction of pre-specified data elements from existing electronic data sources, primarily medical records and tumor registries, will be collected from all participants. Clinical trial information: NCT06589310. Research Sponsor: Exact Sciences Corporation.

11500 Oral Abstract Session

Pimicotinib in tenosynovial giant cell tumor (TGCT): Efficacy, safety and patient-reported outcomes of phase 3 MANEUVER study. First Author: Xiaohui Niu, Department of Orthopedic Oncology Surgery, Beijing Ji Shui Tan Hospital, Beijing, China

Background: TGCT is a rare, locally aggressive mesenchymal neoplasm, driven by the overproduction of colony-stimulating factor 1 (CSF-1), and is often associated with joint pain, swelling, stiffness and functional impairment. The high rate of recurrence and the significant tumor burden, particularly in the diffuse variant, highlight the necessity for an effective systemic treatment. Pimicotinib (pimi) is an oral, highly selective and potent small-molecule inhibitor of CSF-1 receptor (CSF-1R). We report the results from the double-blind Part 1 of MANEUVER, the first global Phase 3 trial to recruit TGCT patients (pts) from Asia, EU and North America (NA) who were candidates for systemic therapy. **Methods:** MANEUVER (NCT05804045) is a Phase 3, randomized, double-blind, placebo (pbo)-controlled trial evaluating efficacy and safety of pimi in pts with TGCT. In Part 1, pts received pimi 50 mg QD or pbo (2:1) for 24 weeks. Primary endpoint was objective response rate (ORR) by blinded independent review committee (BIRC) per RECIST v1.1 at Week 25. Key secondary endpoints included ORR by tumor volume score (TVS) and clinical outcome assessments (COAs) at Week 25: mean change from baseline in range of motion (ROM), worst stiffness, Brief Pain Inventory (BPI) worst pain and PROMIS physical function. Safety was also evaluated. **Results:** At the data cutoff of Sep 23, 2024, all of the planned 94 pts were enrolled (China = 45; EU = 28; NA = 21), with 63 randomized to pimi and 31 to pbo.Median age was 40.0 years (range: 18-69); 68.1% were female; disease location mainly in knee (50.0%), ankle (14.9%) or hip (13.8%). ORR by BIRC per RECIST v1.1 and TVS at Week 25 was significantly higher for pimi vs pbo (54% vs 3.2% and 63.5% vs 3.2%, respectively; both $p < 0.0001$). Statistically significant and clinically meaningful improvements were observed with pimi vs pbo for all COAs: active ROM (15.64 vs -0.07; p = 0.0003), worst stiffness (-3.00 vs −0.57; $p < 0.0001$), BPI worst pain (-2.32 vs −0.23; $p < 0.0001$) and PROMIS physical function (5.63 vs 2.23; p = 0.0074). Significantly more pain responders (BPI-30) were observed with pimi vs pbo (63.5% vs 16.1%; $p < 0.0001$). Treatment efficacy was consistent across pts from different regions and ethnicities. Most TEAEs were low grade, consistent with the known mechanism of action of CSF-1R inhibitors and led to a low rate of dose reduction (7.9%, 5/63 pts) and treatment discontinuation (1.6%, 1/63 pt). There was no evidence of cholestatic hepatotoxicity or drug-induced liver injury. **Conclusions:** MANEUVER is the first randomized pivotal study in TGCT to demonstrate > 50% ORR by RECIST v1.1 at Week 25 in a diverse, global patient population. Pimi produced statistically significant and clinically meaningful improvements in physical function and symptoms, representing an effective, well-tolerated and convenient daily treatment for patients with TGCT and addressing a critical unmet need. Clinical trial information: NCT05804045. Research Sponsor: Abbisko Therapeutics Co., Ltd.

11501 Oral Abstract Session

Anlotinib in combination with epirubicin followed by maintenance anlotinib versus placebo plus epirubicin as first-line treatment for advanced soft tissue sarcoma (STS): A randomized, double-blind, parallel-controlled, phase III study. First Author: Yuhong Zhou, Zhongshan Hospital, Fudan University, Shanghai, China

Background: Anthracycline-based chemotherapy has been the standard first-line treatment for advanced STS for decades. The phase 3 ANNOUNCE trial failed to demonstrate an overall survival (OS) benefit with olaratumab plus doxorubicin compared to doxorubicin. Since 2020, fewer novel regimens emerged to challenge the first-line treatment. Anlotinib (ALTN), an anti-angiogenic oral multi-target tyrosine kinase inhibitor, first showed promising results in a phase II single-arm trial, the addition of ALTN to epirubicin (EH) followed by maintenance ALTN improved progression-free survival (PFS) in the first-line setting for STS patients (pts). Consequently, we conducted a nationalwide, randomized, double-blind, parallel-controlled, phase 3 trial comparing ALTN plus EH followed by ALTN maintenance versus EH combined with placebo (PBO) as first-line treatment for advanced STS pts in China. **Methods:** Eligible pts had previously untreated, pathologically confirmed, unresectable locally advanced or metastatic STS. Pts were randomized in a 1:1 ratio to receive either ALTN (12mg) orally once daily (2-week on/1-week off) plus EH (90 mg/m^2) intravenously once every 3 weeks up to 6 cycles, followed by maintenance ALTN (12mg) orally once daily (2-week on/1-week off) or PBO (0mg) orally once daily (2-week on/1-week off) plus EH(90 mg/m^2) intravenously once every 3 weeks up to 6 cycles, followed by maintenance PBO (0mg) orally once daily (2-week on/1-week off). The primary endpoint was PFS assessed by the blinded independent review committee according to RECIST 1.1. Secondary endpoint included OS, Objective Response Rate (ORR), Disease control rate (DCR) and safety. **Results:** A total of 272 pts were randomized: 135 to ALTN + EH arm, 137 to PBO + EH arm. As of February 15, 2024, after a median follow-up of 7.16 mo, ALTN + EH arm significantly improved PFS (HR 0.30 [95% CI 0.21-0.44]; $P < 0.001$; median 8.57 vs 3.02 mo), and ORR (17.8% vs 2.90%; $P < 0.001$) , DCR (79.3% vs 54.7%; $P < 0.001$) versus PBO + EH arm. The median OS was not reached in either arm (HR = 0.78 [95% CI: 0.49-1.25]). The benefit of ALTN + EH arm was observed across most subgroups tested, including leiomyosarcoma, synovial sarcoma and other pathological types. The incidence of Grade ≥3 adverse events (AEs) (69.6% vs 59.1%), AEs leading to discontinuation of treatment (3.7% vs 4.4%), fatal AEs (3.7% vs 3.6%) were similar between two arms. **Conclusions:** Anlotinib in combination with epirubicin followed by maintenance ALTN demonstrated a statistically significant and clinically meaningful PFS benefit compared to epirubicin alone in pts with previously untreated advanced STS, which could serve as a potential new first-line treatment for locally advanced or metastatic STS. The final OS outcomes are currently under ongoing follow-up. Clinical trial information: NCT05121350. Research Sponsor: None.

11502 Oral Abstract Session

Eribulin plus anlotinib in advanced soft tissue sarcoma (ERAS): Updates on efficacy and biomarkers. First Author: Jie Liu, Department of Medical Oncology, Cancer Center, West China Hospital, Sichuan University, Chengdu, China

Background: This study provides an updated evaluation of the efficacy and biomarker analysis of combination therapy using eribulin, a microtubule dynamics inhibitor, and anlotinib, a multi-targeted tyrosine kinase inhibitor, in patients with advanced soft tissue sarcoma. **Methods:** In this multi-center phase II study (ERAS), patients received eribulin (1.1 mg/m² intravenously on days 1 and 8) and anlotinib (12 mg orally once daily on days 1-14) in 21-day cycles for 6-8 cycles, followed by maintenance therapy with anlotinib. Pre-treatment paraffin-embedded tumor samples were subjected to transcriptome sequencing analysis. The efficacy of the combination therapy in the ERAS study was compared to that of patients previously treated with anlotinib monotherapy. **Results:** As of the cut-off date of December 15, 2024, the median follow-up time was 17.8 months for 30 patients receiving combination therapy with eribulin and anlotinib (9 with leiomyosarcoma, 6 with dedifferentiated liposarcoma, and 15 with other types of sarcomas). In contrast, 87 patients received anlotinib monotherapy, with a median follow-up time of 43.3 months. This cohort comprised 28 patients with leiomyosarcoma, 8 with liposarcoma, and 51 with other types of sarcomas. After 1:2 propensity score matching analysis, compared to anlotinib monotherapy, the combination therapy of eribulin plus anlotinib resulted in a higher progression-free survival rate at 24 weeks (70.0% vs. 31.7%, P = 0.001), significantly improved median progression-free survival (8.5 vs. 4.0 months, P = 0.004), and extended overall survival (not reached vs. 18.4 months, P = 0.035) in patients with advanced soft tissue sarcoma. Transcriptomic data from patients treated with eribulin and anlotinib revealed that tumors with partial response or stable disease exhibited significantly higher levels of lipid metabolism compared to those with progressive disease. **Conclusions:** The combination therapy of eribulin plus anlotinib demonstrated superior efficacy compared to historical data from anlotinib monotherapy in patients with advanced soft tissue sarcoma. The lipid metabolism level in sarcomas could serve as a biomarker for the efficacy of this treatment regimen, potentially providing new insights into L-type sarcomas. Clinical trial information: ChiCTR2300067650. Research Sponsor: 1·3·5 project for disciplines of excellence–Clinical Research Incubation Project, West China Hospital, Sichuan University.

Camrelizumab plus apatinib in patients with advanced or refractory chordoma: A single-arm, open-label, phase 2 trial. First Author: Cheng Yang, Department of Orthopedic Oncology, Changzheng Hospital, Navy Medical University, Shanghai, China

Background: The limited efficacy of current treatments for chordoma underscores the need for novel therapeutic options. Immune checkpoint inhibitors (ICI) have changed the landscape of cancer treatment but are rarely investigated for chordomas. Additionally, no established biomarkers reliably predict the efficacy of ICI and targeted therapies in this context. **Methods:** This investigator-initiated, single-arm, phase 2 trial evaluated the efficacy and safety of camrelizumab (anti-programmed death 1, PD-1) combined with apatinib (a tyrosine kinase inhibitor) in patients with advanced or refractory chordoma. Eligible patients received camrelizumab (200 mg intravenously every 2 weeks) and apatinib (250/500 mg orally daily) in 28-day cycles. The primary endpoint was objective response rate (ORR) assessed per RECIST 1.1 and Choi criteria. Secondary endpoints were median progression-free survival (PFS), overall survival, disease control rate (DCR) and safety. Next-generation sequencing (NGS) and fluorescence in situ hybridization (FISH) were used to explore predictive biomarkers. The trial is registered on Chictr.org.cn (ChiCTR2100042938). **Results:** Between September 2021, and October 2024, 38 patients were screened, and 33 were enrolled for efficacy and safety analyses. The median treatment duration was 7 months (IQR 4-14), with a median radiologic evaluation time of 10 months (IQR 9-13) and median follow-up of 15 months (IQR 9-22). At data cutoff, 15 (45.5%) patients remained on treatment. Per RECIST 1.1, seven patients (21.2%, [95% CI, 9.0-38.9]) achieved partial response (PR), with a 6-month DCR of 85.2% (23/27). The median PFS was 18.1 months (95% CI, 11.0-28.5). According to Choi criteria, 16 patients (48.5%, [95% CI, 30.8-66.5]) achieved PR, with a 6-month DCR of 77.7% (21/27) and a median PFS of 15.3 months (95% CI, 10.6-NE). Two patients died of tumor progression, and two others with cervical recurrent chordoma died from postoperative complications. NGS analyses revealed copy number deletion (CND) of CDKN2A in 30% (6/20) of cases. *Post hoc* FISH analysis of 25 specimens identified homozygous deletion (HD) of CDKN2A in 40.0% (10/25), which correlated with poorer outcomes. Adverse events (AEs) occurred in 93.9% (31/33) of patients, with grade 3/4 AEs in 48.5%. Treatment-related AEs led to apatinib dose interruptions in 39.4% and camrelizumab interruptions in 21.2%. **Conclusions:** The combination of camrelizumab and apatinib demonstrated promising efficacy and manageable toxicity in chordoma treatment. Furthermore, CDKN2A alterations (CND or HD) were associated with poorer outcomes, providing a potential biomarker for therapeutic stratification. Clinical trial information: ChiCTR2100042938. Research Sponsor: None.

11504 **Oral Abstract Session**

Off-label use of fam-trastuzumab deruxtecan in desmoplastic small round cell tumor. First Author: Emily K Slotkin, Memorial Sloan Kettering Cancer Center, New York, NY

Background: Desmoplastic small round cell tumor (DSRCT) is a rare and aggressive sarcoma which remains almost universally fatal despite intensive, multi-modality therapy. Human epidermal growth factor receptor 2 (HER2) has been identified as a potential therapeutic target of relevance for DSRCT as both a pathway and cell surface expression marker. These observations prompted HER2 specific investigations in our DSRCT clinical cohort and subsequent off-label treatment with T-DXd, an antibody-drug conjugate consisting of a humanized anti-HER2 monoclonal antibody linked to a topoisomerase I inhibitor payload. **Methods:** A tumor microarray (TMA) of 52 unique DSRCT patient samples was analyzed by 2 immunohistochemical (IHC) assays (4B5, CB11), and a cohort of 61 DSRCT patient samples was analyzed by RNAseq. Additionally, 16 patients with relapsed/refractory DSRCT in need of therapy and enrolled on an institutional biobanking and genomic profiling protocol were identified, underwent IHC testing and RNAseq when feasible (fresh or archival tissue), and received off-label T-DXd. **Results:** TMA IHC analyses noted minimal HER2 IHC positivity using 4B5, with only 3/52 cases scoring above 10% membranous staining and composite IHC scores ranging from 11 to 15. IHC with clone CB11 uncovered 12.7-fold more HER2 reactivity with 38/52 cases scoring above 10%, and composite IHC scores ranging from 12.5 to 140. HER2 expression levels by RNAseq were analyzed in the context of 346 solid tumor patients with 22 histologies treated within the pediatrics department at MSK. Across these histologies DSRCT had the third highest HER2 expression level overall (surpassed only by papillary thyroid cancer and schwannoma). Median transcripts per million (TPM) expression level across the entire cohort was 9.8 (range 1-116.3), and for DSRCT was 41.8 (range 6.3-116.3). All 16 patients experienced clinical benefit (confirmed stable disease or partial response) with minimal toxicity, limited predominantly to myelosuppression, nausea and constipation. There were no episodes of interstitial lung disease. Notably, 8 of 16 patients all of whom had prior exposure to irinotecan achieved a decrease of at least 30% in the sum of the longest diameters of retrospectively selected target lesions, equivalent to a RECIST partial response (PR) (50% overall response rate). In this small series, response rate did not appear to correlate with available IHC or RNAseq data, with some patients achieving PR with no discernable membranous IHC expression. **Conclusions:** These results suggest that T-DXd is active in DSRCT and support the biomarker agnostic formal clinical trial which is planned with the Children's Oncology Group. Research Sponsor: Maurice Campbell Initiative at MSK KIDS; 76 Foundation; Will Heidrich Foundation.

11505 **Oral Abstract Session**

A phase I/II study of abemaciclib, a CDK4/6 inhibitor, in participants with HIV-associated and HIV-negative Kaposi sarcoma. First Author: Ramya Ramaswami, National Cancer Institute, Bethesda, MD

Background: Kaposi sarcoma (KS), caused by Kaposi sarcoma herpesvirus (KSHV), is a multicentric angioproliferative tumor seen in people with and without HIV. Abemaciclib (abema) is an oral cyclin-dependent kinase (CDK) inhibitor that targets CDK4 (cyclin D1) and CDK6 (cyclin D3), and is FDA-approved for breast cancer. In vitro studies of KSHV-infected cells have shown that CDK4/6 inhibitors enhance host immune cell surface expression and T-cell activation induced by these cells. Here, we investigate the safety and activity of abema in participants (pts) with KS. **Methods:** In this open label, non-randomized, two-stage Phase I/II study of pts with KS, there were two primary objectives. Phase I evaluated the safety and tolerability of abema in pts with KS using a 3+3 dose de-escalation design to identify a maximum tolerated dose (MTD). The first group of pts were treated at dose level 1 (DL) of 200mg twice daily for days 1-28 of a 28-day cycle. Intra-participant dose reductions were permissible for abema-related toxicities. Phase II assessed the overall response rate of abemaciclib of all participants and stratified by prior systemic KS therapy (Arm 1 target: 15 pts with previously treated KS and Arm 2 target: 10 participants with untreated KS). Eligibility criteria included adherence to antiretroviral therapy in people with HIV (PWH) for $>$ 8 weeks prior to enrollment and no concomitant strong CYP3A4 inhibitors. KS response was evaluated using the modified AIDS Clinical Trials Group criteria. **Results:** Thirty-four pts (33 men) with a median age of 43 years were enrolled. Twenty-five (74%) were PWH and 27 pts had stage T1 KS (6 pts had either gastrointestinal and/or lung involvement). Among PWH, the baseline median HIV viral load was $<$20 copies/ml and the median CD4 T-cell count was 308 cells/μL (interquartile range: 176-468 cells/μl). In Phase I, 6 pts (4 PWH) were enrolled at 200mg BID with no dose-limiting toxicities. In Phase II, 17 pts (14 PWH) were enrolled to Arm 1, and 11 pts (7 PWH) enrolled to Arm 2. Overall, 3 pts (2 in Arm 1 and 1 in Arm 2) did not proceed after one cycle due to grade 2 anxiety in 2 pts and tremor in 1 pt that were unrelated to study therapy. These pts were replaced as KS response was not evaluable. The most common grade 1/2 adverse events were diarrhea (92%) and creatinine elevation (64%). Neutropenia of all grades was noted in 63% and 13 pts had dose reductions for recurrent grade 3 or grade 4 neutropenia. Among 31 evaluable pts receiving $>$2 cycles, 24 pts had a partial response (PR) (77% [95% confidence interval (CI): 59-90%]), 4 pts had stable disease and 2 pt had progressive disease. Sixteen of 21 pts who prior KS therapy had a PR (76% [95% CI: 53-92%]) and 8 of 10 pts in Arm 2 with previously untreated KS had a PR (80% [95% CI: 44-98%]). **Conclusions:** Abema is a novel therapeutic option in KS, with notable activity among pts with previously untreated KS. Adverse events were managed with dose reduction and supportive measures. Clinical trial information: NCT04941274. Research Sponsor: National Cancer Institute, Center for Cancer Research (Intramural Program).

11506 **Oral Abstract Session**

A randomized phase III trial of catequentinib hydrochloride (AL3818) versus placebo in subjects with metastatic or advanced leiomyosarcoma (LMS). First Author: Robin Lewis Jones, The Royal Marsden NHS Foundation Trust and Institute of Cancer Research, London, United Kingdom

Background: Catequentinib Hydrochloride (AL3818, Anlotinib, Catequentinib) is a novel, orally administered, small molecule tyrosine kinase inhibitor. There remains an unmet need for effective, well tolerated therapies for patients (pts) with advanced/ metastatic leiomyosarcoma (LMS). We performed a randomized, double blind trial of Catequentinib monotherapy versus placebo in advanced/metastatic LMS. **Methods:** Patients with a diagnosis of LMS requiring third or further line treatment were eligible. Catequentinib was administered in a 21-day cycle with 14 days on and 7 days off regimen. In this double blind phase 3 trial, patients were randomized 2:1 to Catequentinib or placebo, with the option of crossover to Catequentinib after confirmed Progression Disease (PD) on placebo. Progression-free survival (PFS) with Log Rank test was the primary endpoint and the trial was conducted at multiple sites in the US, UK and EU. **Results:** Total N = 111 patients were enrolled, and N = 110 were treated and evaluated, 74 randomized to Catequentinib (C), and 36 to placebo (P). In arms (C)/(P) median ages were 59.0/60.5 (range: 33-91) years respectively and 59/29 (79.7%/80.6%) were female. Median PFS by Blinded Independent Central Review (BICR) met the primary endpoint at 3.42 months (95% CI: 2.60, 6.83) for (C) and 1.41 months (95% CI: 1.35, 4.86) for (P) with a p-value of 0.0265 and a HR of 0.536 (95% CI: 0.307, 0.936). Median PFS for patients stratified at $\leq$ 3 prior lines was 4.86 months (95% CI: 2.04, 8.94) for (C) and 1.41 months (95% CI: 1.31, 4.86) for (P) with a p-value of 0.0046 and a HR of 0.386 (95% CI: 0.196, 0.760). The 6-month progression-free rate was 42.37% for (C) and 20.71% for (P). OS was 17.45 months (95% CI: 13.57, 19.32) for (C) and 16.33 months (95% CI: 11.27, NE) for crossover patients in the (P) arm. 30 (40.5%) of patients have experienced grade 3 treatment-related adverse events in the (C) arm compared to 3 (8.3%) of patients in the (P) arm. The most common TEAE for (C) vs (P) were diarrhea (50.0% vs 22.2%), stomatitis (31.1% vs 8.3%), fatigue (64.9% vs 41.7%), and hypertension (47.3% vs 19.4%). **Conclusions:** This phase 3 trial met the primary PFS endpoint and demonstrates superior PFS for Catequentinib vs placebo in metastatic/advanced LMS. This study confirms the acceptable benefit-risk profile of Catequentinib in LMS. Catequentinib is an effective and well tolerated treatment option for patients with LMS. Clinical trial information: NCT03016819. Research Sponsor: None.

11507 **Oral Abstract Session**

Alliance A092104: A randomized phase 2/3 study of olaparib plus temozolomide versus investigator's choice for the treatment of patients with advanced uterine leiomyosarcoma after progression on prior chemotherapy. First Author: Brian Andrew Van Tine, Washington University Siteman Cancer Center, St. Louis, MO

Background: Advanced uterine leiomyosarcoma (uLMS) is an aggressive malignancy with poor prognosis. Standard-of-care treatments, including trabectedin (Tb) or pazopanib (P), provide median progression-free survival (PFS) of 3-4 months (mo) and objective response rates (ORR) of ~11%. Homologous recombination deficiency (HRD) in a subset of uLMS supports the use of PARP inhibitors combined with DNA-damaging agents. Preclinical studies demonstrated synergistic activity of olaparib and temozolomide (T+O), and a prior single-arm Phase II study of T+O showed promising efficacy independent of an established biomarker, warranting further investigation in a randomized setting. **Methods:** Alliance A092104 is a Phase II/III trial evaluating olaparib (200 mg BID) plus temozolomide (75 mg/m^2 daily, days 1-7, every 21 days) versus investigator's choice of Tb or P in patients (pts) with advanced uLMS who progressed on $\geq$2 prior systemic therapies. Stratification factors included ECOG (0-1 vs. 2) and prior lines (2 vs. $\geq$3). The Phase II (Phase III) primary endpoint was PFS (OS), with a planned suspension of accrual at the end of Phase II. A total of 70 evaluable pts (58 PFS events) were needed to detect an improvement in PFS from 4 vs. 8 mo with power of 90% and 1-sided type I error of 10%, with futility assessed after 29 PFS events. Upon meeting the Phase II futility threshold for PFS, the trial was permanently closed. Data were released from the data and safety monitoring board. Pts continue to be followed for outcomes. **Results:** 74 pts enrolled (Arm 1: T+O, n = 37; Arm 2: investigator's choice, n = 37 (Tb, 18; P, 13; 6 pts did not start treatment). The arms were balanced for baseline demographics except race, with the T+O arm having a higher proportion of black/African American (29.7% vs. 16.2%). 21 pts remain on treatment. Hematologic adverse events (AEs) were more frequent in the T+O arm, with Grade 4 neutropenia (19.5%) and thrombocytopenia (8.3%) both managed by dose reductions. Non-hematologic Grade 3 AEs were higher in the investigator's choice arm (45.2% vs. 13.9%). No Grade 5 AEs were reported. In the first 70 pts, with a median follow-up of 5.9 mo, and 39 total PFS events, the median PFS was 3.2 mo (95% CI: 2.0-NE) for T+O versus 5.6 mo (95% CI: 2.8-NE) for investigator's choice (HR = 1.00; 95% CI: 0.60-2.17; 1-sided stratified log rank p = 0.50). Within Arm 2, the median PFS for Tb and P were respectively 5.6 (95% CI: 3.1-NE) and 3.8 (95% CI: 1.5-NE) mo. 3 pts in the T+O arm and 1 patient in the investigator's choice arm (Tb) had a confirmed partial response. **Conclusions:** The trial did not meet its primary endpoint of PFS in Phase II. This suggests that a biomarker may be needed before there is further exploration of PARP inhibitor-based regimens in uLMS. Overall survival and analysis of tissue-based biomarkers will be presented. Clinical trial information: NCT05432791. Research Sponsor: National Cancer Institute; U10CA180821; National Cancer Institute; U10CA180882; National Cancer Institute; U10CA180820 (ECOG-ACRIN); National Cancer Institute; U10CA180868 (NRG Oncology).

11508 Oral Abstract Session

Spatial transcriptomic profiling from over 300 leiomyosarcoma samples. First Author: Ryan A Denu, Division of Cancer Medicine, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Leiomyosarcoma (LMS) is a smooth muscle-derived tumor with significant heterogeneity and limited treatment options for recurrent/metastatic disease. A lack of targetable driver mutations and prognostic and predictive biomarkers have hampered the care of patients with LMS. There is a great need to better understand the biology of LMS and develop novel therapeutics. Advances in single cell RNA sequencing (scRNA-seq) have allowed for better understanding of intratumoral heterogeneity in diverse cancer subtypes. However, tissue dissociation during this process leads to loss of spatial context. Spatial gene expression analysis builds upon scRNA-seq and has the potential to yield information about tissue organization, cell-cell interactions, niches, and cell states. To date there have been limited application of spatial transcriptomics to sarcoma. **Methods:** We performed single nucleus multiome (snRNA-seq and snATAC-seq) on a cohort of 16 primary, untreated LMS samples including 12 soft tissue (STLMS) and 4 uterine (ULMS) tumors. We then designed a custom 480-gene panel using the differentially expressed genes from clusters identified in snRNA-seq data to be able to identify spatial relationships between these clusters and to assess these clusters on a larger scale. We utilized the 10x Genomics Xenium platform. This was applied to LMS tissue microarrays (TMAs) comprising a total of 326 tissue cores from 127 unique patients. Matched primary and metastatic samples from the same patient were available for 33 patients. **Results:** Analysis of scRNAseq data identified 2 distinct subtypes: a dedifferentiated subtype with mesenchymal features (MES) and a differentiated subtype with enrichment of smooth muscle cell markers (SMC). Integration of chromatin accessibility data from snATACseq showed enrichment of nuclear factor I (NFI) transcription factor (TF) motifs in the MES and AP-1 motifs in the SMC group. Whole genome sequencing did not reveal an obvious genomic etiology for these subtypes. Spatial transcriptomics was able to identify these 2 subtypes in a larger cohort of tumors. Consistent with snRNAseq data, we find that most tumors had almost exclusively either MES or SMC cells. We assessed spatial relationships between these subtypes and infiltrating immune cells. This revealed an enrichment in immunosuppressive macrophages and exhausted T cells in MES tumors compared to SMC tumors. Analysis of matched primary and metastatic tumors demonstrated that the subtype (MES or SMC) generally remains consistent between different sites of disease. **Conclusions:** We identify 2 novel LMS subtypes (MES and SMC) driven by distinct TFs. Spatial transcriptomic analysis confirmed the presence of these 2 subtypes in a larger cohort and demonstrated that MES tumors are associated with a more immunosuppressive tumor microenvironment. Research Sponsor: None.

11509 Rapid Oral Abstract Session

Evaluation of the safety and efficacy of ALMB-0168, a novel monoclonal antibody activating Cx43 hemichannel, for osteosarcoma after standard therapy failure: A multicenter, open-label, single agent, phase 1/2 study (ACE study). First Author: Jingnan Shen, Department of Musculoskeletal Oncology, the First Affiliated Hospital of Sun Yat-Sen University, Guangzhou, China

Background: There was limited therapeutic advancement for decades for patients (pts) with relapsed and refractory (R/R) osteosarcoma. Pts with R/R osteosarcoma urgently need effective and safe treatment options after standard therapy failure. ALMB-0168, a first-in-class humanized IgG4 monoclonal antibody targeted to hemichannel protein Cx43, activates hemichannels to release key substances including ATP into the extracellular environment, to inhibit the growth and migration of osteosarcoma and other cancers bone metastases. Here reported the phase 2 study result based on ASCO 2023 Poster (11530). **Methods:** Pts $\geq$ 12 years (yrs) with pathologically confirmed osteosarcoma who had failed standard therapy were enrolled. In the phase I dose escalation with an accelerated titration followed by 3+3 design, pts were dosed with 7 planned ALMB-0168 dose levels (1, 3, 6, 12, 18, 24, and 30mg/kg), Q3W, until their disease progressed or intolerable toxicity occurred. Then the cohort at effective dose 6mg/kg was expanded. This trial used RECIST1.1 for efficacy evaluation. Primary endpoints were safety and tolerability. Key secondary endpoints were overall response rate (ORR), disease control rate (DCR), progression-free survival (PFS) and overall survival (OS). The CD73/CD39 expressions evaluated by IHC in osteosarcoma FFPE tissue with the efficacy were retrospectively analyzed. **Results:** As of Aug 19, 2024, total 27 pts with median age 29 yrs (range 16–69 yrs) were enrolled, of which 17 pts for dose escalation and 10 for dose expansion at 6mg/kg. No dose-limiting toxicity was observed. Treatment related adverse events (TRAEs) of any grade occurred in 18 (66.7%) pts, most of them were grade 1-2. Grade 3 TRAEs occurred in 1 (3.7%) patient (infectious pneumonia); no events were Grade 4 or 5. Common TRAEs observed in $\geq$ 10% pts were anemia (22.2%), proteinuria (14.8%) and alpha hydroxybutyrate dehydrogenase increased (11.1%). The DCR of whole evaluable pts was 68.2% (15/22), including 3 PR and 12 SD. At the 6mg/kg dose level which was expanded, among 10 evaluable pts, 2 pts achieved partial response (ORR: 20%), of which 1 patient achieved durable PR for 17 months (mo), PFS for 23 mo and OS for 36 mo (not reached). In 6mg/kg group, the DCR was 90% (9/10, 95% CI: 55.5, 99.7%) with 2 PR and 7 SD. And the PFS rate of 6mg/kg group at 4th mo was 70% (95% CI: 22.48, 91.83%). The relationship between the efficacy and the CD73/CD39 expression and other exploratory results will be presented in the future. **Conclusion:** The maximum tolerated dose of ALMB-0168 was not reached. The recommended phase 2 dose is 6mg/kg. In this study, ALMB-0168 showed encouraging anti-tumor activity, safe profile and durable benefit for pts with R/R osteosarcoma, which might be one of the potential treatment options for R/R osteosarcoma in the future. Clinical trial information: NCT04886765. Research Sponsor: AlaMab Therapeutics (Shanghai) Inc.

11510 Rapid Oral Abstract Session

Phase Ib trial of C019199, an oral TME modulator targeting CSF-1R/DDRs/VEGFR2, in relapsed or refractory osteosarcoma. First Author: Feng Ye, The First Affiliated Hospital of Xiamen University, Xiamen, China

Background: C019199 is an oral drug candidate that modulates the tumor microenvironment (TME) through targeting CSF-1R/DDRs/VEGFR2. Previous phase Ia study of C019199 as a mono-therapy for advanced solid tumors has shown promising safety and anti-tumor activity. The osteosarcoma cohort of this Phase Ib study aims to further evaluate the safety and efficacy of C019199 in patients with relapsed or refractory osteosarcoma who had failed in the first-line chemotherapy. **Methods:** In this study, patients of $\geq$16 years and $<$76 years with histologically or cytologically confirmed osteosarcoma, progressing after at least one prior chemotherapy, were enrolled. The dosing regimen of C019199 is 200 mg once daily, with continuous administration over 21-day treatment cycles. Imaging assessments are performed every two cycles. The treatment continues until disease progression, intolerable toxicity, or withdrawal of informed consent by the patient. The primary endpoint is the incidence of adverse events (AEs) and serious adverse events (SAEs). Secondary endpoints include objective response rate (ORR), disease control rate (DCR), and progression-free survival (PFS). **Results:** A total of 30 patients with relapsed or refractory osteosarcoma were enrolled from October 2023 to November 2024. Median age was 29 years (range, 16–62), with 60% males. The most common treatment-related adverse events (TRAEs) were leukopenia (60%), increased creatine phosphokinase (53.3%), increased lactate dehydrogenase (53.3%), neutropenia (53.3%), thrombocytopenia (46.7%), diarrhea (43.3%), increased aspartate aminotransferase (43.3%), and lymphopenia (40.0%). Grade 3 or higher TRAEs were observed in merely 7 patients (23.3%) including neutropenia (3 pts), lymphopenia (2 pts), thrombocytopenia (1 pts), hypertension (1 pts), syncope (1 pts), and dyspnea (1 pts). One patient achieved a partial response (an ORR of 3.3%), while majority of patients achieved stable conditions with a DCR of 73.3%. Median PFS was 181 days, and the 3-month PFS rate was 66.7%. **Conclusions:** The data has demonstrated that C019199 exhibited a promising anti-tumor activity in patients of relapsed or refractory osteosarcoma. Combined with the encouraging tolerability and safety data, it suggests that C019199 has the potential to effectively benefit survival and improve quality of life for patients of this indication. The Phase Ib study is concluding, and a Phase III study is planned. Clinical trial information: CTR20202045. Research Sponsor: Fujian Haixi Pharmaceuticals Co., Ltd.

11511 Rapid Oral Abstract Session

Detecting ctDNA using personalized structural variants to forecast recurrence in localized soft tissue sarcoma (STS). First Author: Changsu Lawrence Park, Division of Medical Oncology and Hematology, Princess Margaret Cancer Centre, University Health Network, University of Toronto, Toronto, ON, Canada

Background: The current standard for definitive management of localized STS involves surgery and (neo)adjuvant radiation (RT). Unfortunately, up to 50% of these patients (pts) recur but the role of adjuvant systemic therapy remains controversial. Circulating tumor DNA (ctDNA) is a promising biomarker for molecular residual disease (MRD) in STS but its clinical validity and utility remains unclear. Given that structural variants (SVs) are prevalent in the tumor genome of STS pts, this longitudinal study aims to utilize an ultra-sensitive, tumor-informed MRD assay that tracks somatic SVs for the detection of ctDNA. **Methods:** Pts with newly diagnosed, localized, high-risk ($\geq$ 5cm, grade $\geq$2) STS planned for curative-intent (neo) adjuvant RT and surgery were recruited from Feb 2019 to Aug 2023. Blood samples for ctDNA analyses were collected at diagnosis, post RT, post-surgery and every 3 months for up to two years in tandem with radiologic surveillance. The MRD window was defined as the first 8 weeks after surgery. Whole genome sequencing (WGS) was performed on archival tumor samples to detect all genomic SVs. A personalized multiplex digital PCR assay was then designed based on WGS data to track up to 16 somatic SVs in cell-free DNA from serial plasma samples for ctDNA detection and quantification. ctDNA data was then correlated to clinical outcomes (last updated on Jan 2025). **Results:** A total of 228 plasma samples from 32 pts were analyzed with a median follow-up of 20.1 months. STS subtypes included myxofibrosarcoma (12), undifferentiated pleomorphic sarcoma (10), dedifferentiated liposarcoma (6), pleomorphic liposarcoma (2), myxoid liposarcoma (1) and leiomyosarcoma (1). The ctDNA detection rate at diagnosis was 97% (31/32 pts). Of the cohort, 22 pts received preoperative RT and had blood collected within the MRD window. ctDNA was detectable at baseline and in the MRD window in 4/22 pts (18%). All 4 (100%) developed metastatic disease with a median lead time of 136 days (range: 28-210 days) in ctDNA detection prior to radiologic relapse. Of the 18 pts who were ctDNA-negative in the MRD window, 3 (17%) developed metastatic recurrence, all of which was preceded by detectable ctDNA with a median lead time of 87 days (range: 80-147 days). The median time from surgery to recurrence was 153 days (range: 57-224 days) vs 521 days (range: 406-631 days) for pts with detectable vs undetectable ctDNA within the MRD window, respectively. **Conclusions:** Detection of ctDNA using personalized tumor-informed assays for somatic SV tracking was feasible and highly sensitive in localized high-risk STS pts prior to surgery. Positive ctDNA within the MRD window was predictive of subsequent and earlier radiologic relapse. Based on this data, an interception trial of adjuvant systemic therapy for MRD-positive STS pts is planned. Future analysis, including the measurement of circulating extrachromosomal DNA (ecDNA) is planned. Clinical trial information: NCT03818412. Research Sponsor: None.

11512 Rapid Oral Abstract Session

A clinical and genomic landscape analysis of GI stromal tumors. First Author: Nadeem Bilani, Department of Medicine, Division of Hematology and Oncology, Northwestern University, Chicago, IL

Background: Gastrointestinal stromal tumors (GIST) are malignant mesenchymal tumors with distinct histogenesis and behavior from other sarcomas. Treatment of metastatic GIST involves receptor tyrosine kinase (RTK) inhibition. Primary *KIT* or *PDGFRA* mutations are established drivers of tumorigenesis via constitutive RTK activation. Growing attention is now focused on how secondary alterations impact clinical outcomes. **Methods:** The open-source platform cBioPortal was queried for GIST patients. Sociodemographic and clinicopathologic features, including *KIT*/*PDGFRA* mutation prevalence, were described using univariate statistics. Primary *KIT* mutations (exon 11: coding the receptor juxtamembrane domain) and secondary *KIT* mutations (exon 13/14: coding ATP-binding domain; or exon 17/18: coding activation loop) were assessed. Co-occurrence/exclusivity of altered genes was analyzed using two-sided Fisher's Exact (p-values) and Benjamini–Hochberg FDR correction (q-values) – pathway pairs deemed significant at $p < 0.05$ and $q < 0.05$. Log2 odds ratios (OR) quantified association strength. Differences between *KIT*-mutated (*KIT*-mut) vs. *KIT*-wild type (*KIT*-wt) groups were assessed via chi-squared. Kaplan-Meier modeling evaluated overall survival (OS) by co-occurring alterations, controlling for metastatic status and stratifying by primary site. **Results:** 499 GISTs were analyzed: 214 gastric (42.9%), 137 small bowel (27.5%), 22 colorectal (4.4%), and 9 esophageal (1.8%).Most tumors harbored *KIT* mutations (n = 382, 76.6%), which co-occurred with *CDKN2A* (log2 OR 3.04) and *CDKN2B* (log2 OR 2.77) deletions ($p < 0.001$; $q < 0.001$). 91 (23.8% of *KIT*-mut) patients harbored both (*CDKN2A/2B*-del). Secondary *KIT* mutations in exons 13/14 or 17/18 were associated with *CDKN2A/2B*-del ($p < 0.001$). *CDKN2A/2B*-del was rare in *KIT*-wt (< 5%). *KIT* mutations were mutually exclusive with *PDGFR*, *NF1* (log2 OR < -3, $q < 0.001$ for both), and *SDHA* mutations (log2 OR < -2.67, q = 0.038); prevalent in 9.8%, 4.0%, and 2.0%, respectively. *PDGFRA*/*NF1* mutations showed no significant co-occurrence. *SDHA* alterations were associated with *TERT* and *RICTOR* alterations. GISTs were more likely *KIT*-wt in women vs. men (OR 1.76, p = 0.012), and in gastric vs. small bowel tumors (OR 2.79, $p < 0.001$). Tumor mutational burden was similar between groups (mean 2.12 vs. 1.27). No tumors were microsatellite unstable.OS did not differ between *KIT*-, *PDGFRA*-, *NF1*-, or *SDHA*-mut (log-rank p = 0.453). In metastatic *KIT*-mut, *CDKN2A/2B*-del was associated with poorer OS (log-rank $p < 0.001$). Median OS for small bowel *KIT*-mut + *CDKN2A/2B*-wt disease was not reached, 24.3 months in small bowel *KIT*-mut + *CDKN2A/2B*-del, 52.5 in gastric *KIT*-mut + *CDKN2A/2B*-wt, and 22.4 in gastric *KIT*-mut + *CDKN2A/2B*-del. **Conclusions:** *CDKN2A/CDKN2B* deletions co-occur with advanced, imatinib-resistant, *KIT*-mut GIST. They prognosticate poorer OS but suggest therapeutic potential for cyclin dependent kinase inhibition. Research Sponsor: None.

11513 Rapid Oral Abstract Session

Phase II of sunitinib plus nivolumab in extraskeletal myxoid chondrosarcoma: Results from the GEIS, ISG, and UCL IMMUNOSARC II Study. First Author: Nadia Hindi, Fundación Jimenez Diaz University Hospital, Madrid, Spain; University Hospital General de Villalba, Madrid, Spain; Instituto de Investigacion Sanitaria Fundacion Jimenez Diaz (IIS/FJD; UAM), Madrid, Spain

Background: Extraskeletal myxoid chondrosarcoma (EMC) is an ultra-rare sarcoma, with low sensitivity to classic chemotherapy. A previous clinical trial led by our groups showed the activity of antiangiogenics (specifically pazopanib) in patients (pts) with advanced ECM. As IMMUNOSARC I master-trial exploring sunitinib (S) plus nivolumab (N) in sarcoma detected signal of activity in ECM pts, a specific cohort of ECM was designed as a phase II trial within IMMUNOSARC II (NCT03277924). **Methods:** Adult pts with advanced, progressing, measurable and centrally confirmed EMC were enrolled and treated with S 37.5 mg/d in the first 14 days (d), followed by S 25 mg/d, along with N 240 mg every 2 weeks up to progression or intolerance. Imaging reassessments were done every 8 weeks. The primary endpoint was 6-month(m)-PFS rate, and the statistical assumptions were obtaining a 6m-PFSR in at least 15 pts out of 22 pts, with H_0= 50% and H_1= 80%, (α 0.05; β 0.10) to consider the combination as promising. **Results:** Twenty-four pts were accrued from May 2020 to July 2024 in 9 centres from Spain, Italy and UK. Pts had a median age of 58y (42-83), with a predominance of male (M = 19/F = 5). Thirteen (54%) pts were treatment naïve and 22 (92%) pts had metastatic disease at baseline. Grade 3-4 Adverse Events (AE) occurring in > 5% of pts were: hypertension (29.2%), ALT and AST increase (16.7 and 12.5% respectively), bilirubin increase (12.5%), Lymphocytopenia (12.5%). No G4 hematologic AEs were found, with the exception of 1 pt with G4 leukopenia. With a median FU of 18 mos (8-29), among the 23 evaluable pts, 6m-PFSR was 77% with 16/23 pts free of progression at 6 mos, and a median PFS of 13.2 mos (95%CI 5.7-20.7). Median OS has not been reached and 12m-OS was 90% (95%CI 77-100). Two (9%) pts achieved a RECIST 1.1 partial response while 18 (82%) and 2 pts (9%) showed a stable disease and progresion as the best response respectively. Pts (6/23) previously treated with antiangiogenic had a trend to a shorter mPFS (7mos vs 13 mos, p = 0.11) and a significantly shorter OS (28 mos vs NR, p = 0.038). **Conclusions:** The combination of sunitinib and nivolumab has shown to be active in advanced extraskeletal myxoid chondrosarcoma. Our data suggest that using this combo in upfront lines provides a greater benefit. Clinical trial information: NCT03277924. Research Sponsor: Grupo Español de Investigación en Sarcomas (GEIS); Pfizer (drug supply); BMS (drug and shipping supply).

11514 Rapid Oral Abstract Session

ImmunoSarc2 (Cohort 7a): A Spanish Sarcoma Group (GEIS) phase Ib trial of epirubicin and ifosfamide plus nivolumab in first line of advanced undifferentiated pleomorphic sarcoma (UPS). First Author: Javier Martin Broto, Fundación Jimenez Diaz University Hospital, Madrid, Spain

Background: It was hypothesized that anthracycline-based chemotherapy plus anti-PD1 (nivolumab) could enhance the activity of upfront chemotherapy in advanced UPS, based on a double-hit in the immunogenic cell death circuit. This peculiar tumor cell death eventually activates an adaptive immune response through particular molecular changes in dying tumor cells and microenvironment, triggered by specific drugs such as anthracyclines. We previously reported a phase Ib trial in leiomyosarcoma patients with the combination of doxorubicin, dacarbazine, and nivolumab, obtaining 56.5% of ORR. We present here the phase Ib, cohort 7a, of the ImmunoSarc2 trial. **Methods:** Adult patients (pts), with ECOG 0-1, naïve of previous anthracycline-containing treatments, and with a centrally confirmed diagnosis of advanced/metastatic UPS were eligible. Initial dose level 0 (L0) was defined as epirubicin 60 mg/m^2/d 20 min on D1 and D2 followed by ifosfamide 3 g/m^2/d 3-h on D1-3, plus nivolumab (NIV) 360 mg on D3 after chemotherapy. Cycles were given Q3W with GCSF and MESNA support. This combo would be given up to 6 courses of 21-day cycles, followed by 1-year NIV maintenance. A -1 dose level (L-1) was defined with the same regimen but with NIV 240 mg. A classic 3+3 phase 1 design was used to determine the MTD based on DLTs (main endpoint) observed during the first 21-day cycle. The cohort was foreseen to be extended with the RP2D to include up to a maximum of 20 evaluable patients. Secondary endpoints included ORR and safety profile among others. **Results:** Between January 2022 and June 2024, 16 patients M/F (9/7), ECOG 0/1 (15/1), with median age 56 years (29-77) were enrolled. All patients were treated with the initial L0 scheme and no DLTs were observed, being L0 the RP2D. Grade 3-4 toxicities were neutropenia 62.5%, febrile neutropenia 18.8%, anemia 31.3%, and thrombocytopenia 25%. A patient died following a subarachnoid hemorrhage in the context of grade 4 thrombocytopenia and an accidental fall. Of 16 patients, RECIST ORR according to local clinical site assessment was 68.8% distributed as 1 CR (6%), 10 PR (63 %), 4 SD (25%), and 1 PD (6%). With a median follow-up of 16.3 months (95% CI, 7.2-25.4), the median of PFS was 9.9 months (95% CI 7-12.7), while the median OS was not reached, and the 1-year OS rate was 81% (95% CI 62-100). **Conclusions:** Epirubicin 60 mg/m^2/d d1-2 plus Ifosfamide 3 g/m^2/d d1-3 plus NIV 360 mg on d3 Q3W, followed by 1 year of NIV is a feasible and manageable scheme that exhibits relevant activity as an upfront line in advanced UPS patients. A phase II/III trial is designed aiming to confirm the advantage of chemo-immunotherapy over chemotherapy alone in this context. Clinical trial information: NCT03277924. Research Sponsor: BMS provided budget for drug supply, shipping and some operational CRO cost; And Spanish Sarcoma Group (Sponsor).

11515 Rapid Oral Abstract Session

A phase 2 study using metronomic gemcitabine, doxorubicin, and docetaxel plus nivolumab in advanced leiomyosarcoma and liposarcoma (NCT04535713). First Author: Jason Ballon, Sarcoma Oncology Center, Santa Monica, CA

Background: Chemotherapy agents cemcitabine, doxorubicin, and docetaxel have all demonstrated efficacy in soft tissue sarcomas (STS) but often result in significant toxicity. Therefore, we propose a combination chemo-immunotherapy regimen using metronomic low dose chemotherapy doses to reduce toxicity, with the addition of Nivolumab, a PD-1 inhibitor with demonstrated efficacy in STS. In this study, we aimed to determine the efficacy/safety of adding nivolumab to metronomic gemcitabine, doxorubicin, and docetaxel in subjects with advanced leiomyosarcoma (LMS) or liposarcoma (LPS). **Methods:** Objectives: Primary: To determine progression-free survival (PFS); Secondary: T evaluate the best overall response (BOR) and duration of response (DOR) by RECIST v1.1 via CT scan or MRI during the treatment period, determine progression-free survival rate (PFS) at 6 and 12 months and determine overall survival rate at 6 and 12 months Key eligibility criteria: ≥ 18 years, previously treated locally advanced unresectable or metastatic LMS/LPS, measurable disease by RECIST v1.1, acceptable hematologic and organ functions Treatment Schedule: Three-week treatment cycles with gemcitabine (600 mg/m2 max:1000 mg), doxorubicin (18 mg/m2; max: 32 mg), docetaxel (25 mg/m2; max: 42 mg) on Day 1 and Day 8, andnivolumab (240 mg) on Day 1 only. **Results:** Efficacy: The intention-to-treat population (n= 41), which includes patients who received at least one dose of gemcitabine, doxorubicin, and docetaxel, was used to determine the following: Median OS =16.1 months (95% CI: 7.4 to 20.1 months) and incidence of adverse events. The modified-intention-to-treat population (n= 31), which includes patients who completed at least the first 2 treatment cycles and follow-up CT/MRI, was used to determine the following: Median PFS = 8.6 (95% CI: 3.3-12.0) months; ORR = 22.6%; DCR = 87.5%; 6-month PFS rate = 58%; 6-month OS rate = 70.7%; 12-month PFS rate = 35.5%; 12-month OS rate = 59.1%; BOR = 7 PR, 21 SD, 4 PD. Safety: 28 of 41 patients (68%) experienced Grade 3/4 TRAEs that include: thrombocytopenia (n=12), lymphocyte count decreased (n=11), anemia (n=10), neutropenia (n=9), back pain (n=4), leukopenia (n=4), fatigue (n=2), dyspnea (n=2), hypocalcemia (n=1), muscle weakness (n=1), colitis (n=1), diarrhea (n=1), anorexia (n=1), abdominal pain (n=1), alkaline phosphatase increased (n=1), nausea (n=1), bone pain (n=1), peripheral sensory neuropathy (n=1), edema (n=1). There were no unexpected adverse events. **Conclusions:** Taken together, the results indicate that the combination regimen of nivolumab with metronomic gemcitabine, doxorubicin and docetaxel may have synergistic activity and is an effective treatment for advanced leiomyosarcoma and liposarcoma with manageable toxicity. Clinical trial information: NCT04535713. Research Sponsor: None.

11516 Rapid Oral Abstract Session

Subgroup analysis of the phase 2 part of the RINGSIDE phase 2/3 trial of varegacestat for treatment of desmoid tumors. First Author: Rashmi Chugh, University of Michigan, Michigan Medicine, Ann Arbor, MI

Background: Gamma secretase inhibitors (GSIs) have shown antitumor activity against desmoid tumors (DT). The RINGSIDE Phase 2 study (NCT04871282) demonstrated early and continued response to three dose regimens of varegacestat (AL102) in patients with DTs. We evaluated treatment response in key subgroups. **Methods:** RINGSIDE Phase 2 is an open-label, dose-finding study in adults with progressing DT (≥10% unidimensional growth ≤18 months or DT-related pain requiring non-opioid medication). Participants were randomized to three dose regimens: 1.2 mg once daily (n=14), 2 mg intermittent (n=14) or 4 mg intermittent (n=14) (intermittent = 2 days on, 5 days off). In the open-label extension (OLE) period, all active participants began receiving 1.2 mg once daily. We performed descriptive analyses of objective response rate (ORR) in the following subgroups with at least 5 participants: age (≤40 years vs. >40 years), tumor size (<70 mm vs. ≥70 mm), prior lines of therapy (0, 1, or 2+), tumor location (intra-abdominal vs. extra-abdominal) and mutational biomarkers (*APC* vs *CTNNB1*). Subgroups were analyzed by pooling across dose regimens. **Results:** RINGSIDE Phase 2 enrolled 42 participants, of whom 29 (69%) entered the OLE. As of April 10, 2024, median time on treatment was 23.1 months (range 0.7 – 26.6) and 23 participants (55%) were still on treatment. Median age was 38.5 years (range 19 – 72), 74% were women, and 69% received prior DT therapy. ORR ranged from 43% to 78% across age, tumor size, prior therapy, tumor location and mutation subgroups (Table). Response rates were comparable across all subgroups examined. **Conclusions:** Comparable, objective tumor responses to oral varegacestat therapy were shown in all subgroups examined. These findings support continued evaluation of all desmoid tumor patients independent of subgroups in the ongoing, double-blind, randomized, placebo-controlled Phase 3 study of varegacestat (RINGSIDE NCT04871282). Clinical trial information: NCT04871282. Research Sponsor: Immunome.

Varegacestat response in subgroups.

Subgroups	ORR Responder (%)
Age ≤40 years (n=22) vs. >40 years (n=14)	13 (59) vs. 10 (71)
Tumor size <70 mm (n=18) vs. ≥70 mm (n=14)	13 (72) vs. 9 (64)
Prior lines of therapy: 0 (n=11), 1 (n=16), or 2+ (n=9)	6 (55), 10 (63), 7 (78)
Intra-abdominal (n=9) vs. extra-abdominal (n=27)	4 (44) vs. 19 (70)
***APC* (n=7) vs *CTNNB1* (n=19) mutation**	3 (43) vs. 13 (68)

11517 Rapid Oral Abstract Session

The broad-spectrum KIT inhibitor NB003 and activity in advanced gastrointestinal stromal tumors (GIST): Updated results from a phase 1 study (NCT04936178). First Author: Ping Chi, Department of Medicine, Memorial Sloan Kettering Cancer Center, New York, NY

Background: NB003 is a novel potent and selective oral small-molecule tyrosine kinase inhibitor of KIT. It was designed to inhibit a broad spectrum of primary and acquired imatinib-resistant mutations in KIT. The abstract reports updated results from the escalation and expansion phases of the Phase 1 study in patients (pts) with advanced GIST. **Methods:** The Phase 1 study includes a dose-escalation phase where pts received oral NB003 (3mg to 40mg) twice daily (BID) in 28-day cycles, followed by an expansion phase with the putative recommended Phase 2 dose (RP2D) (15mg or 20mg BID) in 6 cohorts, including cohorts for GIST pts based on prior standard-of-care (SOC) regimens (2nd, 3rd, 4th, and ≥5th-line). Efficacy was assessed by Modified Response Evaluation Criteria in Solid Tumors (mRECIST) version 1.1 every 2 cycles. **Results:** At the cut-off of Dec 23, 2024, 158 pts with KIT-mutant GIST were enrolled in the escalation and expansion phases (median follow-up of 9.9 months; range, 0.5–32.0). The 154 evaluable pts included 24 2nd-line, 30 3rd-line, 35 4th-line, 56 ≥5th-line pts and 9 others. The confirmed objective response rate (cORR) was 27.3% (95% CI:20.4, 35.0) in all, 40% (95% CI:22.7, 59.4) in 3rd-line, 42.9% (95% CI: 26.3, 60.6) in 4th-line, and 12.5% (95% CI:5.2, 24.1) in ≥5th-line pts. Tumor responses were observed in pts with a broad spectrum of acquired resistance mutations, including those in the KIT ATP-binding site (exons 13/14) and the activation loop of the kinase domain (exons 17/18). The median progression-free survival (mPFS) was 9.2 months (95% CI:7.4, 11.3), not reached (NR) (95% CI:6.0, NE), 13.8 months (95% CI:9.2, NE), and 4.5 months (95% CI:3.8, 7.4), in all, 3rd-line, 4th-line, and ≥5th-line pts, respectively. For ≥3rd-line pts without prior ripretinib, the cORR was 41.2% (95% CI:29.4, 53.8) and the mPFS was NR (95% CI:9.5, NE). In all pts, the most frequent treatment-related adverse events (TRAEs) were asymptomatic CPK increased (80.4%), anaemia (75.9%), AST increased (71.5%), face oedema (65.2%), periorbital oedema (55.1%), neutrophil count decreased (48.7%), WBC decreased (48.7%), amylase increased (39.9%), lipase increased (38.6%), platelet count decreased (33.5%), and peripheral oedema (31.0%). The most frequent treatment-emergent SAEs were anaemia (13.3%), gastrointestinal haemorrhage (6.3%), pleural effusion (4.4%), pneumonia (3.2%), and tumour haemorrhage (3.2%). **Conclusions:** NB003 demonstrated a manageable safety profile, and showed encouraging clinical benefit in GIST pts, as evidenced by mPFS and cORR, across multiple lines of treatment and a broad spectrum of secondary resistance KIT mutations. The promising data from this phase 1 study supports further testing of NB003 in Phase 3 studies. Clinical trial information: NCT04936178. Research Sponsor: None.

Liposomal irinotecan together with vincristine and temozolomide (NALIRI-VT) for patients with relapsed or refractory Ewing sarcoma: A two-cohort, phase 1a/1b study. First Author: Jie Xu, Peking University People's Hospital, Beijing, China

Background: To define the safety and preliminary efficacy of liposomal irinotecan together with vincristine and temozolomide in children and adults with Ewing sarcoma, respectively. **Methods:** Patients with relapsed or refractory Ewing sarcoma were enrolled in cohort A (children) or cohort B (adults), respectively. For each cohort, a fixed dose of vincristine (1.4mg/m^2 max 2mg i.v. $D_{1,8,15}$) and temozolomide (100mg/m^2/d p.o. $D_{1\text{-}5}$) q21d were given. In phase 1a portion, four dose levels of weekly infused liposomal irinotecan (level 1-4, 25mg/m^2, 30mg/m^2, 35mg/m^2 and 40mg/m^2) were designed. 3+3 dose-escalation method was used to explore the maximum tolerated dose (MTD), defined as no more than 30% patients appeared dose-limited toxicity (DLT) in first two cycles (six weeks). In the phase 1b portion, MTD would be used and a maximum of 12 patients were allowed in each cohort at this level in total. **Results:** 15 children and 18 adults were enrolled in phase 1a portion. 9 more children and 5 more adults were enrolled in phase 1b portion. Finally, 12 children and 11 adults were treated at MTD level. In phase 1a portion, no DLT was found at level 1-2. For level 3, no DLT (0/3) was found in cohort A, while one DLT (1/6) of hematologic toxicity was found in cohort B. For level 4, two DLTs (2/6) were found in cohort A, both of whom were due to hematologic toxicity. For cohort B, two DLTs (2/6) was found at this level. One of them was serious anorexia. The other one was hematologic toxicity together with serious nausea and vomiting, anorexia, fatigue. Level 3 was chosen for MTD. Grade 3/4 toxicities were found in hematologic toxicity (most common), anorexia, fatigue, nausea or vomiting, pain and diarrhea. Better efficacy was shown at higher levels (level 3 and level 4) in both cohorts. For cohort A, objective response rate (ORR) was 0 (0/3), 33.3% (1/3), 66.7% (2/3) and 66.7% (4/6) at level 1-4, respectively. For cohort B, ORR was 33.3% (1/3), 33.3% (1/3), 83.3% (5/6) and 66.7% (4/6). Data for survival in phase 1a and data of phase 1b were not matured. **Conclusions:** We showed that liposomal irinotecan infused weekly at 35mg/m^2 in NALIRI-VT regimen was well tolerated and showed promising efficacy in both children and adults. Clinical trial information: NCT06340204. Research Sponsor: Beijing Tongzhou technology grand; KJ2024CX046.

Summary of DLTs and responses in phase 1a portion.

Dose level	Liposomal Irinotecan IV Dose (mg/m^2/d) $D_{1,8,15}$	# of Evaluable Patients	# of DLTs in the first two cycles	Best of Response (BOR)
Cohort A Children				
1	25	3	0	1 SD, 2 PD
2	30	3	0	1 PR, 1 SD, 1 PD
3	35	3	0	1 CR, 1 PR, 1 SD
4	40	6	2	1 CR, 3 PR, 2 PD
Cohort B Adults				
1	25	3	0	1 SD->CR*, 2 SD
2	30	3	0	1 PR, 2 SD
3	35	6	1	5 PR, 1 PD
4	40	6	2	1 CR, 3 PR, 2 SD

*One patient was first treated at level 1, showed no AE at this level and SD was recorded at first evaluation. When safety of the next level 2 dose was confirmed, this patient received the higher level 2 dose, and CR was recorded at the following evaluations.

11519 Poster Session

MRI-based machine learning model for predicting early relapse in osteosarcoma following neoadjuvant chemotherapy. First Author: Yucheng Fu, Department of Orthopedics, Ruijin Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai, Shanghai, China

Background: Early relapse (ER, ≤ 1 year) in osteosarcoma frequently occurs following neoadjuvant chemotherapy (NAC) and surgical resection. This study developed the machine learning models integrating radiomics, clinical, and pathological features to predict ER risk in osteosarcoma. **Methods:** 142 osteosarcoma patients were retrospectively analyzed and preoperative MRI images (T1- and FST2-weighted) were obtained after NAC. After feature extraction and selection, 5 machine learning classifiers—random forest (RF), support vector machine, logistic regression, decision tree, and gradient boosting tree—were implemented to construct radiomics, clinicopathological, and multimodal models. The performance of these models were assessed and compared using receiver operating characteristic curves, decision curve analysis (DCA), and Kaplan-Meier survival analysis, with the components and structure of the best-performing model subsequently visualized. **Results:** The RF algorithm outperformed the other classifiers, forming optimal radiomics and multimodal models. The RF-based multimodal model, combining 14 radiomics features, alkaline phosphatase (ALP) levels, and tumor necrosis rate, achieved the highest performance, with an area under the curve (AUC) of 0.978 in the training cohort and 0.913 in the testing cohort. The corresponding radiomics model, designed for real-time preoperative evaluation, showed a slight reduction in performance but still performed well. DCA and Kaplan-Meier curves indicated significant clinical utility of these two models. **Conclusions:** The RF-based pipeline, which includes radiomics and multimodal models, could facilitate personalized chemotherapy by identifying high-risk patients, optimizing treatment decisions, and improving outcomes. Research Sponsor: National Natural Science Foundation of China; 82472712.

Performance of the different radiomics models, clinical models and combined models in the training and testing cohorts.

The preoperative management of patients with giant cell tumors in limb bones using denosumab therapy. First Author: Saidrasul Nasirov, Tashkent Medical Academy, Tashkent, Uzbekistan

Background: Giant cell tumor (GCT) is an intermediate, locally aggressive primary bone tumor. In addition to local therapy,new drugs for the treatment of this disease have become available. The medication Denosumab, which wasoriginally used to treat osteoporosis and the solid tumor metastases to bone, eventually began to be used totreat giant cell bone tumors. In treatment of GCT, Denosumab was used as the only remedy in patients withinoperable tumors, and was also used before surgery to reduce the size of the tumor and to preserve the joint.To evaluate the effectiveness of Denosumab, while using in the preoperative period of GCT treatment. **Methods:** A study was conducted of 49 patients with GCT of tubular limb bones who received Denosumab beforesurgery, and 60 patients (retrospectively evaluated, without using Denosumab in our hospital from 2015 to2019). Propensity scores were compared in a 1:1 ratio between the groups receiving Denosumab and thecontrol group to minimize possible selection bias; recurrence rates, limb function, and surgical impairmentwere compared between the two groups. **Results:** The recurrence rate after 3 years in the Denosumab group and the control group was 12.2% and 23.3%,respectively. In the Denosumab group, 100% (n = 49) of patients underwent surgical treatment. In 44 patientstreated with Denosumab, the indices of limb joint preservation were 89.8% and 36.6% in 22 control patients.Postoperative MSTS were higher in patients in the Denosumab group than in the control group. **Conclusions:** Preoperative treatment with Denosumab reduced the risk of local recurrence of GCT. Preoperative treatmentwith Denosumab is indicated for patients with advanced GCT to facilitate surgical treatment and preserve thejoint. Denosumab remains a highly effective treatment for patients with GCT bone. Research Sponsor: None.

Feasibility and clinical outcomes of imatinib personalized dosing in gastrointestinal stromal tumor patients. First Author: Maud Berendina Annelies van der Kleij, Department of Clinical Pharmacology, Division of Medical Oncology, Netherlands Cancer Institute - Antoni van Leeuwenhoek, Amsterdam, Netherlands

Background: Imatinib treatment for metastatic gastrointestinal stromal tumors (GISTs) has substantial overall survival benefits compared to chemotherapy (56 vs 9 months) (Balachandran, 2014). Even better outcomes have been demonstrated for patients with imatinib minimal drug concentrations (C_{min}) $\geq$ 1100 ng/mL (Demetri, 2009). Drug concentration-guided dosing through therapeutic drug monitoring (TDM) of imatinib has previously been described as an option for personalized dosing, but there is no definite conclusion on efficacy results (IJzerman, 2020). The aim of the current study was to evaluate the feasibility and effect on clinical outcomes of imatinib personalized dosing through TDM for GIST patients. **Methods:** GIST patients starting with imatinib 400 mg once daily (QD) in both the (neo)adjuvant and metastatic setting were included. C_{min} levels were measured during routine outpatient clinic visits, at 4, 8 and 12 weeks after start of treatment, and every 12 weeks thereafter. Dose increase to 600 mg QD and, if necessary, to 800 mg QD was advised when C_{min} $<$ 1100 ng/mL and treatment was well tolerated. Dose interventions were considered successful when median C_{min} was $\geq$ 1100 ng/mL after intervention and no dose limiting toxicities (DLTs) occurred within the first month after dose intervention. **Results:** A total of 171 GIST patients were included, of which 61% (n = 104) were treated in the (neo)adjuvant setting and 39% (n = 67) in the palliative setting. Most patients (85.4%, n = 146) had a *KIT* exon 11 mutation. Median time on treatment was 30 months. A total of 1475 C_{min} levels were measured (median of 8 levels per patient, IQR: 4−12), resulting in a median C_{min} of 1111 ng/mL. Among all patients, 16% (n = 27) had all adequate C_{min} levels, and 84% (n = 144) had $\geq$ 1 C_{min} level below the target. Of these, 60% (n = 87) had a dose intervention, which was successful in 76% (n = 66) and unsuccessful in 24% (n = 21) of patients. When dose interventions were unsuccessful, this was primarily because C_{min} levels were still below the target after the intervention (62%, n = 13). In the 40% of patients (n = 57) with $\geq$1 C_{min} level below the target who had no dose intervention, this was mostly due to DLTs (51%, n = 29). Median C_{min} before the dose intervention was 953 ng/mL, which increased to 1200 ng/mL ($p < 0.001$) after the intervention. DLTs were not correlated with dose interventions (p = 0.13; OR: 1.86, 95% CI: 0.83−4.16). **Conclusions:** This study confirms that personalized dosing of imatinib through TDM in GIST patients is feasible. Adequate drug concentrations improved from 16% to 54% of patients and interventions resulted in a clinically relevant drug concentration increase in patients who previously had C_{min} levels below the target. Comparison of treatment efficacy and toxicity in our cohort with a standard-dose historical cohort will elucidate the effect of personalized dosing through TDM on clinical outcomes (analyses ready before ASCO). Personalized tumor-informed circulating tumor DNA analysis in monitoring recurrence following resection of high-risk locally advanced stage gastrointestinal stromal tumor. First Author: Zhidong Gao, Peking University People's Hospital, Beijing, China

Background: Gastrointestinal stromal tumor (GIST) is the most common mesenchymal tumor of the gastrointestinal tract. Radical resection is the standard treatment of localized GIST, yet the 5-year recurrence rate for high-risk GIST is more than 50%. It remains unclear whether detecting post-surgery molecular residual disease (MRD) via circulating tumor DNA (ctDNA) can predict the recurrence of high-risk locally advanced GIST. **Methods:** Patients with high-risk locally advanced stage GIST who underwent R0 surgery were enrolled prospectively. Surgical tissue samples were collected. Blood samples were collected pre-surgery, within 1-month post-surgery, and every 3–6 months thereafter. Tumor-derived variants were identified by whole-exon sequencing of the surgical tissues. Up to 50 highly ranked variants with allele frequency 3.0% were selected for the personalized panel design, which was subsequently used to assess MRD status. **Results:** As date cutoff of December 2024, 44 eligible patients were enrolled, among whom 42 tissue samples, 41 pre- and 166 post-surgical blood samples were collected and analyzed, and the median follow-up time was 21 months. Tissue-based sequencing identified variants in *KIT* and *PDGFRA* in 37 (84.1%) and 4 (9.1%) patients, respectively. Positive MRD was detected in 56.1% (23/41) of all pre-surgical plasma samples. Pre-surgical MRD positivity was associated with tumor volume, mitoses and Ki-67 ($P < 0.05$). Landmark analysis within 1 month post-surgery showed that 4 patients (4/41, 9.8%) were positive for ctDNA. Patients with positive MRD at landmark showed marginally worse DFS compared with those with negative MRD (HR = 4.24, 95% CI = 0.81-22.26, P = 0.07).To date, 7 patients have been detected recurrence by CT scan. Among the 4 patients with both radiological and MRD positivity, longitudinal ctDNA detected recurrence with lead-time of 3 months compared with CT scan for 2 patients. The other 2 cases are simultaneously. Notably, these 4 patients didn't receive regular adjuvant therapy. Furthermore, the longitudinal MRD positivity was associated with inferior DFS after adjusting sex, age, TNM stages and whether receiving adjuvant therapy in the multivariable cox regression (HR = 5.63, 95% CI = 1.09-28.99, P = 0.04). Additionally, 30 patients with consistent negative MRD during surveillance exerted significantly superior survival compared with patients whose MRD status converted to negative (n = 2), converted positive (n = 7) and remained consistently positive (n = 2) from landmark to longitudinal monitoring (P = 0.04). **Conclusions:** The present study suggests that personalized tumor-informed ctDNA has the potential to inform recurrence in high-risk locally advanced stage GIST patients, especially for patients who have not received regular adjuvant therapy. Clinical enrollment is still ongoing. Clinical trial information: NCT05408897. 11523 **Poster Session**

The benefit of cytoreductive surgery during imatinib (IM) therapy in patients with metastatic gastrointestinal stromal tumors (mGISTs): Retrospective analysis from several cancer centers. First Author: Daria Filonenko, SBIH Moscow Clinical Scientific and Practical Center Named After A.S. Loginov of DHM, Moscow, Russian Federation

Background: the role of cytoreductive surgery for patients with mGISTs during IM therapy has not been established yet because the absence of randomized trials. We carried out a retrospective analysis of the outcome of patients with mGISTs in several Moscow cancer centers. **Methods:** we compared several cohorts: treated with IM only (IM group) and treated with IM and surgery, the latter was divided into four groups depending on the time of the surgery and the response to IM: before IM (BIM), after partial response or stable disease (RD), or unifocal progressive disease (UPD) or multifocal progressive disease (MPD). Patients received IM after surgery until progression. The primary end points were progression free survival and overall survival from the start of IM therapy. **Results:** 234pts with mGISTs from 2002 till 2024 received IM 400 in the first line. 116 pts received imatinib only, 118 patients underwent cytoreductive surgery: before IM (BIM, n=39) and during IM – on responsive disease (RD, n=23), unifocal progressive disease (UPD, n=22), and multifocal progressive disease (MPD, n=27). 7 patients were excluded from the analysis because they underwent surgery twice (before and during IM). Cytoreductive surgery increased the median PFS in comparison with IM only (Table). The differences were statistically significant between IM vs BIM – 24.0 vs 61.0 (p=0.028), IM vs RD – 24.0 vs 77.0 (p=0.003), and RD vs MPD – 77.0 vs 39.0 (p=0.005). Patients with UPD and MDP had a median PFS after R0/R1 and R2 was 17.0 vs 7.0 (p=0.564) and 14.0 vs 7.0 (p=0.056) months, respectively. Patient who underwent surgery on progression received IM after surgery for 10.0 and 11.0 months in UPD and MPD groups respectively what was two times longer than on sunitinib therapy (the median PFS 6.8 months, NCT00075218). On multivariate analysis for the entire cohort radiologic response was predictive for PFS: RD (hazard ratio (HR) 0.37, p = 0.003), UPD (HR 0.47, p=0.03) and BIM (HR 0.48, P = 0.009) were independent prognostic factors of better PFS; *KIT* exon 9 mutations (HR 2.68, p=0.003) and unknown location of primary tumor – factors of worse PFS. Overall survival was reached only in MPD group – 75.0 (95% CI: 37.14-112.87) months from the start of IM. **Conclusions:** cytoreductive surgery during IM therapy in responsive disease increase PFS; metastasectomy on UPD is likely to be beneficial for patients with mGISTs and it can be more effective option than the second line treatment. Research Sponsor: None.

			95% CI	
	PFS, median, months	Standard error	Lower bound	Upper bound
IM only (n=116)	24.000	4.459	15.260	32.740

11524 Poster Session

In vitro profiling of IDRX-42 against secondary and tertiary mutations (AP/AL) found in TKI-resistant GIST. First Author: Michael C. Heinrich, Portland VA Health Care System and OHSU Knight Cancer Institute, Portland, OR

Background: The majority of Gastrointestinal Stromal Tumors (GIST) harbor a KIT mutation and respond to imatinib (IM), but over time clinical resistance emerges due to secondary mutations. These secondary mutations are restricted to two regions of the KIT protein: the drug/ATP binding pocket (AP, exons 13 and 14) and the activation loop (AL, exons 17 and 18). Although additional TKI drugs has been approved for later lines of therapy, these agents lack activity against the entire spectrum of known secondary resistance mutations. For example, sunitinib is potent against AP mutations (V654A, T670I), but has minimal activity against AL mutations. Recently, IDRX-42 has demonstrated promising activity in a phase 1/1b study of patients with TKI-resistant GIST. However, the cellular potency of IDRX-42 against various primary, secondary, and compound AP/AL KIT mutations has not been comprehensively described. **Methods:** We used a panel of GIST cell lines with various mutations that were derived from the parental GIST T1 cell line (primary KIT exon 11 (K11) deletion mutation). We also transiently expressed additional mutations in CHO cells. Densitometry and curve fitting was used to determine the biochemical IC50 for inhibition of KIT autophosphorylation, an accepted surrogate for KIT kinase activity. We also profiled IM and ripretinib (RIP) in the same cell line models. **Results:** IM was active against primary K11 mutations but was much less active against K11 + AP, K11 + AL, KIT exon 9 (K9), K9 + AP, and K9 + AL mutations. In addition, IM was inactive against K9 or K11 + AP/AL mutations (with all three mutations in cis). RIP potently inhibited K11, K11 + AL mutations, and K9 + AL mutations. However, RIP was less active against K11 + AP, K9 +AP, and K9 or K11 + AP/AL mutations. IDRX-42 was active against K11, K11 + V654A, K11 + AL, K9, K9 + V654A, and K9 +AL mutations. However, IDRX-42 lacked potency against the gatekeeper T670I (AP) mutation and K9 or K11 + AP/AL mutations. We developed resistant cell lines using GIST T1 cell line subjected to chemical mutagenesis and long-term drug selection with IDRX-42. All IDRX-42 resistant clones had an acquired T670I mutation, but no other secondary mutations were identified. **Conclusions:** IDRX-42 has superior biochemical potency against a panel of primary and secondary KIT mutations compared with IM or RIP. Additionally, IDRX-42 has activity against K9 or K11 + V654A, and K9 or K11 + AL; However, K9 or K11 with T670I mutant kinases were resistant. Notably, none of these three profiled drugs had activity against K9 or K11 + AP/AL mutations. The optimal clinical use of IDRX-42 may be in earlier lines of therapy, prior to the emergence of AP/AL mutations. Research Sponsor: None.

15-year survivorship in patients with metastatic gastrointestinal stromal tumors. First Author: Julia A. Levy, Department of Internal Medicine, Oregon Health & Science University, Portland, OR

Background: Prior studies of metastatic gastrointestinal stromal tumors (mGIST) have largely focused on 5-year survival when evaluating long-term outcomes, but factors underlying longer-term survival remain less understood. This retrospective study aimed to identify factors associated with 15-year survivorship in patients with mGIST. **Methods:** Patients with mGIST treated at Oregon Health & Science University between 2003-2023 were identified from the Knight Cancer Registry. Data were abstracted through manual chart review. Patients were categorized into two cohorts: those who died before 15 years of follow-up, and those who survived ≥15 years following mGIST diagnosis. Chi-square and independent samples t-tests were performed to compare clinicopathologic variables between the two groups. **Results:** Of the 111 eligible patients (66 male [59.5%]; 45 female [40.5%]; median [IQR] age, 57 [46-71] years, 88.3% Non-Hispanic White), nineteen (17.1%) survived ≥15 years after mGIST diagnosis. Factors associated with 15-year survival were younger age at metastatic diagnosis (44 [32-56] vs. 60 [53-73], $p<0.001$) and metastasectomy (n=12 [63.2%] vs. 27 [29.3%], p=0.008). Most (68.4%) patients who underwent metastasectomy did so before they developed resistance to imatinib. Patients who underwent metastasectomy before developing resistance were more likely to achieve 15-year survival, however, this association was not observed in those who underwent metastasectomy after imatinib resistance. Patients who underwent metastasectomy also experienced a longer median time to imatinib resistance relative to those who did not (55 months vs. 23 months, p=0.001). **Conclusions:** This retrospective study supports that younger age at metastatic diagnosis and metastasectomy before the development of imatinib resistance are factors associated with 15-year survivorship in patients with mGISTs. These findings suggest that surgical resection of metastases in select patients may prolong the duration of imatinib response and potentially improve long-term outcomes. Research Sponsor: None.

Tumor and treatment factors associated with 15-year survivorship in mGIST.

Variable	Total (n=111)	15-year nonsurvivors (n=92)	15-year survivors (n=19)	p-value
Synchronous metastases	53 (47.7%)	43 (46.7%)	10 (52.6%)	0.64
Metachronous metastases	58 (52.2%)	49 (53.3%)	9 (47.4%)	0.7
Primary tumor size, cm (median, IQR)	8 (5.5-11.5)	8 (5.5-12)	8.1 (5.7-10.5)	0.79
Underwent metastasectomy	57 (51.4%)	42 (45.7%)	15 (78.9%)	0.008
Underwent metastasectomy before imatinib resistance	39 (35.1%)	27 (29.3%)	12 (63.2%)	0.04
Underwent metastasectomy after imatinib resistance	15 (13.5%)	12 (13.0%)	3 (15.8%)	0.75
Time to metastasectomy, months (median, IQR)	6 (16-42.5)	16 (6-41)	9 (4-86)	0.84
Development of imatinib resistance	69 (62.2%)	60 (65.2%)	9 (47.4%)	0.14
Time to imatinib resistance, months (median, IQR)	42 (22-81)	35.5 (20.5-63.3)	125.5 (95-149.5)	<0.00001

Second-line treatment patterns and outcomes of advanced gastrointestinal stromal tumor: A real-world study. First Author: Xinhua Zhang, Department of Gastrointestinal Surgery, The First Affiliated Hospital, Sun Yat-Sen University, Guangzhou, China

Background: Ripretinib has emerged as a promising second-line therapy for patients with unresectable or metastatic gastrointestinal stromal tumors (GISTs), demonstrating comparable efficacy to sunitinib and a superior safety profile. However, the optimal second-line therapy tailored to individual patient characteristics remains underexplored. This prospective, multicenter, observational study (NCT05440357) aims to evaluate real-world patterns and outcomes for GISTs patients. **Methods:** The choice of second-line regimen was determined by the investigators. The primary endpoint was progression-free survival (PFS). Secondary endpoints included safety, objective response rate (ORR), and overall survival (OS). **Results:** From October 2022, 99 patients were enrolled (ripretinib, n = 49; sunitinib, n = 47; regorafenib, n = 3), with a median follow-up of 8.0 months. Among ripretinib-treated patients, 69% (34/49) had primary KIT exon 11 mutations, while 47% (22/47) of sunitinib-treated patients had primary KIT exon 9 mutations. The objective response rates were 20% (10/49) for ripretinib, 9% (4/47) for sunitinib, and 0% for regorafenib. Median PFS (mPFS) for ripretinib, sunitinib and regorafenib was 11.4, 12.4 and 2.8 months, respectively (p = 0.296). Ripretinib demonstrated better mPFS in patients with primary KIT exon 11 mutations compared to sunitinib group (11.4 vs 7.0 months, p = 0.048). In patients with KIT exon 9 mutations, mPFS was 15.0 months for sunitinib. Ripretinib was associated with fewer grade 3/4 treatment-emergent adverse events (TEAEs) compared to sunitinib (10%vs 26%, p = 0.044). OS data are currently immature. Additionally, 27% (13/49) of patients treated with ripretinib and 17% (8/47) with sunitinib underwent surgery. Among patients who underwent surgery following ripretinib treatment, 84.6% (11/13) achieved R0/R1 resection. 100% (8/8) patients achieved R0/R1 resection in sunitinib group. Median postoperative PFS for ripretinib and sunitinib was 15.5 months and 10.2 months, respectively (p = 0.350). **Conclusions:** This study is the first prospective, multicenter, real-world study to compare different second-line targeted drugs for advanced GISTs. Our preliminary results suggest that ripretinib may offer superior clinical benefits for patients with primary KIT exon 11 mutations after failure of imatinib first line treatment. Its favorable safety profile and improved tumor response rate facilitated a higher rate of surgical intervention compared to sunitinib. The benefit of surgery remains to be observed. Clinical trial information: NCT05440357. Research Sponsor: None.

11527 Poster Session

Long-term outcomes in GIST Trial 13-162: Phase II study of imatinib in combination with binimetinib in untreated patients with advanced gastrointestinal stromal tumor (GIST). First Author: Yudi Bao, Human Oncology and Pathogenesis Program, Memorial Sloan Kettering Cancer Center, Memorial Sloan Kettering Cancer Center, New York, NY

Background: ETV1 and KIT are lineage-specific master transcriptional and signaling survival factors in GIST. Dual lineage targeting of ETV1 by binimetinib and KIT by imatinib are synergistic in suppressing GIST tumorigenesis and growth in preclinical models. We previously reported positive data in a single-arm phase II study that the combination of binimetinib plus imatinib is highly effective with expected and manageable treatment-associated toxicities, in patients (pts) with treatment-naïve advanced GIST, (ASCO 2020 and https://ascopubs.org/doi/pdfdirect/10.1200/JCO.21.02029). Here, we present 10-year follow-up results. **Methods:** This trial is a single-center, single-arm, phase II study. Adult patients with unresectable or metastatic treatment-naïve GISTs received imatinib (400mg daily) and binimetinib (30mg twice daily), 28-day cycles. The clinical efficacy was evaluated using serial imaging every 8-12 weeks, per RECIST1.1 criteria including objective response rate (ORR), progression-free survival (PFS) and overall survival (OS). Correlatives included tumor genomics, transcriptomes, and imatinib trough levels. **Results:** At data cutoff of Nov 21, 2024, 29/42 evaluable pts with advanced GIST of all genotypes, including 3 *KIT/PDGFRA*-WT, had confirmed RECIST1.1 partial response (PR). Best ORR was 69.0% (95% CI, 52.9% to 82.4%). Median PFS (mPFS) was 36.7 months (95%CI, 24.2 to not estimable [NE]). Median OS (mOS) was 92.5 months (95%CI, 61.0 to NE), and the median DSS (mDSS) was 93.2 months (95%CI, 92.5 to NE). 23/42 pts had undergone surgery, with R0/R1 resection in 18 patients. 7 pts were considered exceptional responders, whose pathology revealed ≥90% significant pathological responses (SPR) and remained no evidence of disease (NED) after surgery ≥45 months. 3 pts who did not have SPR and remained NED ≥58 months. Transcriptome and genomic analysis, and imatinib trough level in the presence of binimetinib are forthcoming. **Conclusions:** The 10-year follow-up analysis of the binimetinib plus imatinib combination phase II study demonstrated robust and sustained clinical benefit in PFS, OS and DSS for patients with treatment-naïve advanced GIST. The combination strategy warrants further evaluation in direct comparison with imatinib in the frontline treatment of GIST. Clinical trial information: NCT01991379. Research Sponsor: Pfizer; FDA R01.

Predicting transposable element-derived neoantigens in ATRX-mutated sarcoma. First Author: Simon Cao, UPMC Hillman Cancer Center, Pittsburgh, PA

Background: Epigenetic dysregulation is a key mechanism in cancer biology, driving both immune evasion and the generation of potentially druggable neoantigen targets. Transposable elements (TEs) are proviral sequences mostly found in epigenetically repressed genomic regions. In cancer, TEs are one potential source of neoantigens. The tumor suppressor gene *ATRX* is an epigenetic regulator that is lost in up to 30% of soft tissue sarcomas. Loss of function of this heterochromatin modulator leads to widespread alterations to transcription patterns. Our prior work in sarcoma, along with studies in other tumors, showed that ATRX loss leads to the de-repression of TEs. We hypothesize that this mechanism leads to TE neoantigen presentation on MHC class I (MHC-I) molecules. **Methods:** Leveraging the gEVE database of proviral sequences with open reading frames, we examined the differential expression of TEs using RNA sequencing of multiple models comparing ATRX lost and ATRX wild-type tumors. Analysis included our previously published data from human undifferentiated pleomorphic sarcoma cell lines (2 clones, 3 replicates per group; GEO: GSE240030) and a publicly available dataset from a mouse model of soft tissue sarcoma (n = 3 per group; GEO: GSE167537). Additionally, we analyzed analogous data from a mouse model of glioblastoma multiforme (GBM), another malignancy with frequent ATRX loss (n = 3 per group; GEO: GSE178113). RNA-seq data was analyzed using Salmon for transcript-to-genome pseudo-alignment, DESeq2 for differential TE expression analysis, and arcasHLA for sample-level MHC-I subtype identification. Differentially overexpressed TEs in ATRX mutant tumors were analyzed for predicted neoantigens using the NetMHCpan4.1 package. **Results:** Across multiple models, ATRX loss of function alterations were associated with both activation and repression of TEs. Within two sarcoma contexts, upregulated TEs were found to have protein-coding sequences with the potential to lead to MHC-I neoantigen presentation. Within a human undifferentiated pleomorphic sarcoma cell line with ATRX loss, there were 7 upregulated TEs shared between the clones, each predicted to contain 12 – 50 MHC-I binding epitopes. Within a mouse soft tissue sarcoma model, 7 TEs were upregulated with ATRX loss, each with 5 – 28 MHC-I binding epitopes. Since ATRX loss alters TE expression in other malignancies, parallel data from a mouse GBM model was additionally analyzed. In this model, 308 TEs were found to be upregulated with ATRX loss, and all were predicted to generate neoantigens. ERVs and LINE1 elements were recurrently identified, making up 97 – 100% of the activated TEs. **Conclusions:** Transposable element transcription altered by ATRX loss in sarcoma and GBM creates a predicted source of MHC-I-binding neoantigens. These neoantigens come from TEs of the ERV and LINE1 families. Research Sponsor: Damon Runyon Cancer Foundation; CI-124-23.

Spatial and bulk transcriptomic analysis of skin Kaposi sarcoma lesions: Differences by disease characteristics. First Author: Quashawn Rakeem Chadwick, National Institutes of Health, Bethesda, MD

Background: Kaposi sarcoma (KS) is an angioproliferative tumor caused by Kasposi sarcoma herpesvirus (KSHV) that typically manifests as skin lesions. Other KSHV-associated disease (KAD) that can occur with KS include multicentric Castleman disease (MCD), primary effusion lymphoma (PEL) and KSHV-associated inflammatory cytokine syndrome (KICS). KS with concurrent KAD, which occurs frequently in people with HIV (PWH), contributes to morbidity and mortality. Novel sequencing technologies that evaluate archival KS may further our understanding of HIV-associated KS pathogenesis. **Methods:** Gene expression profiling of archival KS skin samples of 42 PWH was performed with the custom nCounter PanCancer ImmunoOncology panel with the addition of KSHV probes. Spatial RNA profiling was performed using GeoMx digital spatial profiling (DSP) platform on 4 formalin fixed paraffin-embedded tissue sections randomly selected from patients (pts) with concurrent KS and KAD. LANA, CD45, and CD31 expression in samples identified KS ($LANA^+$, $CD31^+$) and other areas of interest (AOIs) including vessels ($LANA^-$, $CD31^+$) and immune cells ($CD45^+$) on tissue sections. Gene Set Enrichment analysis was performed using R package ClusterProfiler. **Results:** Samples were taken from 42 men with HIV with a median age of 40 years. The median CD4 T cell count was 211 cells/ μl and a median HIV viral load of 27 copies/ml. Fifty-two percent of pts with KS had a concurrent KAD, most commonly KICS with KS (30%) followed by MCD with KS (19%). In nCounter analyses, samples from pts with KS alone demonstrated upregulation of STC1, a secreted glycoprotein, (log2FC=2.02, padj=0.001) and MKI67, a proliferation marker, (log2FC=1.11, padj=0.02) as compared to pts with KS and concurrent KAD. Pathway analyses highlighted reduced enrichment in specific cytokine activity profiles (padj = 0.01), natural killer cell activation markers (padj=0.02), and B cell proliferation (padj=0.004), in KS with concurrent KAD specimens. Cell deconvolution analyses showed increased abundance of CD8 T cells and regulatory T cells in KS alone specimens as compared to those with KS and other KAD. DSP of 4 samples of pts with KS and concurrent KAD (2 pts with MCD+ KS, 2 pts with KICS+ KS) identified higher expression of TSPAN (log2FC=1.32, padj=0.04) and LYVE1 (log2FC=1.82, padj=9.17e-5) in LANA+ tumor regions than vessel and immune AOIs, and lower ICAM1 (log2FC=-1.08, padj=3.95e-6), highlighting the role of virus-infected areas in oncogenesis and modulating immune activity. **Conclusions:** Sequencing data of archival HIV-associated KS samples highlighted distinct gene expression profiles by concurrent KAD, particularly in MCD or KICS, demonstrating disruptions in immune activity and increased cell proliferation thus shedding light on the molecular pathways driving KS pathogenesis and avenues for future targeted study. Early assessment of response to chemotherapy via ctDNA in soft tissue sarcoma. First Author: Maggie Yuxi Zhou, Stanford University School of Medicine, Department of Medicine, Stanford, CA

Background: Chemotherapy remains the cornerstone for treatment of soft tissue sarcomas (STS). Biomarkers are needed to enhance timely assessment of chemotherapy efficacy to limit toxicity and guide patient management including estimating prognosis and duration of chemotherapy. **Methods:** This retrospective study includes patients with STS who received chemotherapy in the neoadjuvant or unresectable/metastatic setting at Stanford Sarcoma Center between May 2021 and January 2025. ctDNA was tested with Natera's CLIA lab using a personalized, tumor-informed ctDNA assay (Signatera, bespoke mPCR, NGS assay). Longitudinal changes in peripheral blood ctDNA were correlated with radiographic response and survival. ctDNA response was defined as $>$ 50% decrease in MTM/mL from baseline, with a second confirmatory measurement. Radiographic response was defined as stable disease or partial response on first re-staging assessment after starting therapy. Overall survival (OS) was defined as time from initiation of chemotherapy to death or last clinical follow up. Progression-free survival (PFS) was defined as time from initiation of chemotherapy to radiographic disease progression, death, or last clinical follow up. **Results:** Twenty-six patients (median age at diagnosis = 63 years [range 26 – 78]) were included. Histological subtypes consisted of leiomyosarcoma (uterine [n = 10], extrauterine [n = 4]), malignant peripheral nerve sheath tumor (n = 2), undifferentiated pleomorphic sarcoma (n = 2), angiosarcoma (n = 2), and other (Ewing's sarcoma, malignant phyllodes tumor, perivascular epithelioid cell tumor, low grade myoepithelial carcinoma, high grade uterine sarcoma not otherwise specified, and small round blue cell neoplasm with EWSR1 rearrangement, each n = 1). Chemotherapy consisted of doxorubicin-containing regimens (n = 9), gemcitabine/docetaxel (n = 9), temozolomide-containing regimens (n = 5), and other (cyclophosphamide/topotecan, paclitaxel, and trabectedin, each n = 1). Median follow-up time after initiation of chemotherapy was 12.9 months. 16 of 26 patients had radiographic response. Substantial agreement was observed between ctDNA response and radiographic response (Cohen's kappa coefficient 0.752). Median OS was longer for ctDNA responders (n = 17) than non-responders (n = 9), at 43.8 months vs 20.6 months (p = 0.03). Median PFS was longer for ctDNA responders than non-responders, at 11.4 months vs 2.0 months ($p < 0.001$). In the metastatic cohort (n = 22), time on chemotherapy regimen was longer for ctDNA responders than non-responders, median 5.0 vs 2.6 months, p = 0.016 by Wilcoxon rank sum test. **Conclusions:** Early decline in ctDNA after initiation of chemotherapy correlates with radiographic response and survival in STS. Research is ongoing to evaluate these findings in a prospective study. Research Sponsor: None.

Kaposi sarcoma herpesvirus (KSHV) subtypes and impact on survival in 107 patients with Kaposi sarcoma and other KSHV-associated diseases. First Author: Jose Mercado-Matos, National Cancer Institute, National Institutes of Health, Bethesda, MD

Background: Kaposi sarcoma herpesvirus (KSHV, also known as human herpesvirus 8) is an oncogenic virus that causes Kaposi sarcoma (KS), one of the most prevalent cancers in people with HIV (PWH) worldwide. KSHV also causes primary effusion lymphoma (PEL), a non-Hodgkin lymphoma, a plasmablastic variant of multicentric Castleman disease (MCD), and KSHV-associated inflammatory cytokine syndrome (KICS). KSHV-associated diseases (KADs) can occur alone or concurrently. The major KSHV genetic subtypes A, A5, B, C, D, E and F, based on the K1 open reading frame (ORF), are distributed by global region of origin. A and C genotypes are seen in Europe and North America whereas B and A5 variants are observed in Africa; D, E and F genotypes were described in isolated populations. There are limited data on the association between KSHV subtypes and survival outcomes. **Methods:** We investigated the ORF K1 subtype, disease characteristics, and impact on survival outcomes in 107 patients (pts) with KADs treated at the HIV/AIDS Malignancy Branch in the United States from 2010-2024. KSHV-DNA was extracted from peripheral blood mononuclear cells (PBMCs), KSHV-positive tissues and body fluids, including effusions. Extracted DNA was tested for KSHV using a CLIA-certified qPCR assay. Samples identified as KSHV-positive by qPCR were sequenced using either next-generation sequencing (NGS) or Sanger sequencing. **Results:** The cohort consisted of predominantly men (94%) and 55% were Black. Ninety-seven percent of pts had HIV (median CD4 count of 216 cells/mm3 and median HIV viral load 189,590 copies/mL). The most common KAD was KS (92%) followed by PEL (36%), MCD (23%), and KICS (22%). However, 64% had more than one concurrent KAD – 20% had KS and PEL. At the time of analysis, 39 (36%) pts were deceased, 26 (24%) had a PEL diagnosis. Seventy-nine percent of pts were from North America, 11% from Latin America and 9% were from sub-Saharan Africa; KSHV genotypes were consistent with a patient's geographic origin. Overall, the most common genotype was A (44%), 30% of pts with genotype A had KS alone and 30% had PEL+/-KS (Table). KSHV subtypes based on K1 did not impact survival outcomes (Global Log-rank P=0.9) overall. In 98 pts with KS with and without other KAD, KSHV subtypes did not affect survival but the presence of concurrent PEL as compared to MCD or KICS lead to worse survival in pts [Hazard Ratio: 7.9 (95% confidence interval: 3.4-18.2, $P<0.0001$)]. **Conclusions:** In this large cohort of pts with KS and other KAD, KSHV genotype was not associated with survival outcomes. Among pts with KS, concurrent KAD, such as PEL, led to poorer survival. This suggests that clinical manifestations rather than underlying viral variants impacted survival. Research Sponsor: None.

KSHV genotype prevalence (%) by KAD.

Overall %	A 44%	A5 8%	B 11%	C 26%	Dual infection 8%
KS	30	50	17	29	0

Phase ib/II study of fluzoparib in combination with dalpiciclib in patients with locally advanced or metastatic sarcoma. First Author: Anqi Wang, Musculoskeletal Oncology, Sun Yat-Sen University Cancer Center, Guangzhou, China

Background: Poly ADP-ribose polymerase (PARP) plays a role in DNA damage repair, and PARP inhibitors can exert anti-tumor efficiency in tumors with homologous recombination repair defection (HRD). Cyclin-dependent kinase (CDK) plays an important role in cell cycle regulation. Rb is the direct substrate of CDK4/6, and Rb/E2F participates the HR-mediated DNA repair. Therefore, selective CDK4/6 inhibition can theoretically aggravate HRD and hinder DNA repair of tumor cells treated with PARP inhibitors. Combined of CDK4/6 and PARP inhibitors may provide a potential new drug strategy for sarcomas. **Methods:** FOUNDS is a 2-part, open-label, phase 1/2 study. Key inclusion criteria are: (1) 12-75 years old; (2) Locally advanced or metastatic sarcomas after first-line treatment, with at least one measurable lesion according to RECIST 1.1 criteria. Patients(pts) will receive fluzoparib (0.1 or 0.15 g po., qd, q4w) and dalpiciclib (0.1, 0.125 or 0.15 g po., qd, d1-21, q4w) continuously until progressive disease (PD) or intolerable toxicity occurred. Part 1 is intended to establish the recommended phase 2 dose (RP2D) using a i3+3 dose escalation design. Part 2 will examine the safety and efficacy of fluzoparib + dalpiciclib using the Simon minimax 2 stage design. The primary endpoint is the objective response rate (ORR). **Results:** In the escalation part, 12 pts (median age 22 years) were included. At the data cut-off (Jun. 10, 2025), the median follow-up time was 7.93 month (95% CI 7.03-8.83). The DCR per RECIST v1.1 is 12.5% including 2 pts who achieved a stable disease. The most common treatment-emergent AEs (TEAEs, ≥20%) were leukopenia, neutropenia, etc. 3 pts (25%) had grade ≥3 TRAEs and no drug-related AEs led to death. In Cohort 4, 1 pt experienced dose-limiting toxicity (DLT) of grade 3 thrombocytopenia, and the other 1 pt experienced DLT of severe stun. The RP2D was determined as Fluzoparib 0.1g bid. plus Dalpiciclib 0.15g qd, d1-d21, q4w. **Conclusions:** This novel combination therapy of CDK4/6 inhibitor and PARP inhibitor showed manageable toxicity that could provide a strategy for advanced or metastatic sarcoma. Part 2 to evaluate safety and efficacy is currently recruiting pts. Clinical trial information: NCT05952128. Research Sponsor: Jiangsu Hengrui Pharmaceutical Co., Ltd.

Advancing precision oncology in soft tissue sarcomas: The role of iTRAC in metastatic risk stratification and treatment personalization. First Author: Fred Chibon, INSERM U1037, Toulouse, France

Background: Soft Tissue Sarcomas (STS), known for their extensive Genomic instability (GIN), often result in poor clinical outcomes. Grading systems, such as FNCLCC, have limited prognostic accuracy in stratifying metastatic risk for STS patients. We introduce transcription-associated GIN indice (iTRAC) to improve prognostic precision and guide treatment decisions. **Methods:** This study analyzed 226 STS tumor samples using RNA sequencing (RNAseq) to assess breakpoint distribution from fusion transcripts as a surrogate for GIN. We calculated iTRAC to quantify transcription-associated GIN. Kaplan-Meier survival analysis were used to evaluate prognostic relevance in patients receiving or not chemotherapy. Multivariate analysis was performed to evaluate the iTRAC compared to FNCLCC and CINSARC for metastatic risk stratification. **Results:** STS patients with medium iTRAC level had the poorest metastasis-free survival (MFS) compared to low and high iTRAC levels. Importantly, patients with low iTRAC have a poorer outcome when treated with chemotherapy than those untreated, but at the contrary patients with medium iTRAC and treated by chemotherapy have a better outcome, raising the question of the potential predictive value of iTRAC for adjuvant chemotherapy in STS patients. FNCLCC and CINSARC groups did not show significant difference in MFS between treated and not treated patients. **Conclusions:** iTRAC is a novel biomarker for stratifying metastatic risk and guiding personalized treatment in STS. It outperforms molecular and histological prognosis systems like CINSARC and FNCLCC grade by revealing distinct MFS between patients receiving or not chemotherapy. This could enable better identification of patients who may benefit from chemotherapy and alternative options for those with poor responses. Prospective clinical trials are needed for validation and integration for patients care. Research Sponsor: None.

Molecular subtyping and insights into sarcoma biology and prognosis. First Author: Aleksei Shevkoplias, BostonGene Corporation, Waltham, MA

Background: Sarcomas represent a diverse group of mesenchymal malignancies, with over 200 subtypes recognized by the WHO. This heterogeneity, combined with rarity, complicates diagnosis. Here, comprehensive molecular profiling and unsupervised clustering were applied to define sarcoma subtypes associated with differentiation, genomic events, and prognosis. **Methods:** Whole exome and transcriptome sequencing was performed on 1,046 sarcoma samples via the BostonGene Tumor Portrait test. Hierarchical expression-based clustering was integrated with somatic mutations, fusions, copy number alterations, genome segmentation, and signatures, validated on 23 external datasets (n = 1,678). **Results:** Nine molecular clusters (C1-C9) reflecting distinct biological patterns were identified (Table). Stable, lineage-restricted clusters included leiomyosarcoma (C2) marked by smooth muscle differentiation pathways and *TP53*, *ATRX*, and *RB1* mutations; vascular sarcoma (C7) with vascular signaling and angiogenic amplifications; synovial sarcoma (C6) defined by *WNT* activation and *SS18-SSX* fusions; and Ewing sarcoma (C9) characterized by neuronal development signatures and *EWSR1-FLI1* fusions. Clusters progressing toward undifferentiated pleomorphic sarcoma (UPS)-like phenotypes included liposarcoma (C3) progressing from adipocyte differentiation with *MDM2/CDK4* amplifications; chondrosarcoma/chordoma (C5) transitioning from cartilage development pathways with TGFβ activation; and bone and UPS-like (C1) characterized by angiogenesis signatures, genomic instability, *TP53* mutations, and the poorest survival (logrank $p < 0.05$). Molecular clusters predicted survival regardless of the specific diagnosis. For example, liposarcoma and leiomyosarcoma patients in cluster C1 had a worse prognosis than those in C2 with the same diagnosis. **Conclusions:** The proposed molecular subtypes simplify sarcoma classification, providing unique prognostic insights missing in the current diagnostic framework. These findings suggest molecular subtypes could offer valuable knowledge for sarcoma research and patient treatment. Research Sponsor: None.

Characterization of molecular sarcoma subtypes.

Cluster	Predominant diagnoses	Undifferentiation progression	Biology	Alterations (chi-sq $p < 0.01$)
C1	Bone and UPS-like	Progressing	Undifferentiated or nearly undifferentiated	*TP53* mutation (35%)
C2	Leiomyosarcoma	Stable	Smooth muscle differentiation	*TP53* (53%), *ATRX* (18%), *RB1* (15%) mutations
C3	Liposarcoma	Progressing	Adipocyte differentiation	*MDM2/CDK4* amplifications (45%)
C4		Progressing	Biologically diverse	
C5	Chondrosarcoma, chordoma	Progressing	Cartilage development	
C6	Synovial sarcoma	Stable	WNT activation	*SS18-SSX* fusions (68%)
C7	Vascular sarcoma	Stable	Vascular signalling, angiogenesis	
C8		Progressing	Biologically diverse	
C9	Ewing sarcoma	Stable	Neuronal development signatures	*EWSR1-FLI1* fusions (92%)

Early on-treatment ctDNA dynamics and response by imaging in patients with sarcoma. First Author: Adrienne I. Victor, University of Rochester, Rochester, NY

Background: ctDNA holds promise as a prognostic and predictive biomarker for risk stratification and treatment response monitoring across multiple tumor types. However, the optimal timepoints and cutoffs for interpretation of ctDNA results are not well defined. Here we explored the ctDNA dynamics in patients with sarcomas on cytotoxic chemotherapy, with a focus on early time points to predict response. **Methods:** All sarcoma patients at the Wilmot Cancer Institute who had ctDNA (SignateraTM, Natera, Inc.) requested clinically from 03/01/22 – 12/31/25 were screened. Patients who had a positive baseline and at least 2 cycles of cytotoxic chemotherapy with serial ctDNA monitoring and response evaluation were selected for further analysis. Response was determined by imaging reports (CT, MRI, or PET) after 2-4 cycles of therapy. **Results:** One hundred and twenty-four patients were identified on initial screening, and 112 were able to generate a bespoke assay. Twenty-two patients met criteria for early on-treatment response analysis and 4 had results available from a second line of chemotherapy, for a total of 26 evaluations. Seventeen patients had metastatic disease while 5 were on neoadjuvant chemotherapy for high risk localized sarcomas. The most common sarcoma subtype was LMS (5), followed by undifferentiated small round cell sarcoma (Ewing, other EWSR1 fusions, BCOR; 4 patients), and osteosarcoma (3). Most patients, including those who progressed, showed some early decrease in ctDNA levels, but no patients whose ctDNA result converted to negative within the first two cycles progressed on the first reassessment. In this series a log10 fold change of -1.25 or greater by the end of cycle 2 separated responders and progressors. **Conclusions:** ctDNA is promising as an early biomarker of response across a wide variety of sarcoma subtypes and chemotherapy regimens. ctDNA dynamics may provide particular clinical utility in interpreting scans showing stable disease, as well as when response is difficult to capture on imaging, such as bony primaries or metastasis, or infiltrative malignancies such as angiosarcoma. Larger data sets and multi-institutional collaboration are needed to verify optimal time points and cutoffs for guiding patient care and interventional trials. Research Sponsor: None.

Log10 change in ctDNA from baseline at end of cycle 1 and cycle 2 chemotherapy by initial imaging response.

Initial Response	Cycle 1 median log change	Cycle 1 log change range	Cycle 2 median log change	Cycle 2 log change range
Progression	-0.17	-1.01– +0.16	-0.36	-1.23– +0.21
Stable disease (SD)	-0.18	ND (Not Detected) – +0.27	-0.88	ND – +1.00
Partial response (PR)	-1.62	ND – -0.21	-2.42	ND – -1.26
Complete response (CR)	-2.72	ND – -1.00	-3.12	ND – -2.35
PR + CR	-2.35	ND – -2.01	-2.08	ND – +1.00

MicroRNA-based biomarkers of outcome in soft tissue sarcoma treated with hypofractionated preoperative radiation therapy. First Author: Joanne B. Weidhaas, University of California, Los Angeles, Los Angeles, CA

Background: Soft tissue sarcomas (STS) are rare, aggressive malignancies with high variability in response to radiation therapy (RT). Our previous research in a small cohort who received preoperative hypofractionated RT (SBRT) on a phase II trial suggested that germline microRNA-based single nucleotide polymorphisms (mirSNPs) could identify patients at increased risk of major wound toxicity (MWT). This study explores the potential of this class of biomarker to predict MWT and additional outcomes to preoperative SBRT in STS. These findings could guide personalized treatment strategies and possibly the choice of RT regimen in the future. **Methods:** We analyzed 110 patients with high-risk extremity or trunk STS treated with five-day preoperative SBRT (30 Gy in five fractions). Over 100 mirSNPs were evaluated for their ability to predict RT outcomes, including late toxicity, MWT, distant metastases, and pathological response. Pathological response was defined as a necrosis score >= 70, late toxicity as grade >=2 at 2 years, and MWT as grade >= 3. Preliminary genetic models were developed using elastic net, random forest, and boosted tree algorithms and evaluated using leave-one-out cross-validation (LOOCV) performance metrics. mirSNPs were pre-filtered using Fisher or Jonckheere-Terpstra p-values (<0.2) for relevance to outcomes. **Results:** We developed preliminary genetic signatures to accurately predict 4 different outcomes in sarcoma patients undergoing preoperative SBRT: late toxicity (AUC=0.830), distant failure (AUC=0.775), pathological response (AUC=0.765), and major wound toxicity (AUC=0.736). Our pathological response genetic model has balanced sensitivity (0.750) and specificity (0.781), suggesting it could reliably predict which patients respond well to SBRT. **Conclusions:** Our study highlights the promise of mirSNP-based models in predicting STS outcomes to preoperative SBRT. By identifying patients with favorable versus unfavorable responses, these models could help identify patients who could be considered for preoperative SBRT versus standard fractionated radiation, as there may be fractionation-dependent radiation toxicity in sarcoma, as has been identified in other malignancies. Future directions include investigating associations among identified outcomes, inclusion of additional clinical variables, and comparison to toxicity with preoperative standard fractionated radiation. These efforts are significant steps towards paving the way for more personalized sarcoma care. Clinical trial information: NCT02701153. Research Sponsor: None.

LOOCV performance metrics in sarcoma data (n=110).

Outcome	Sensitivity	Specificity	PPV	NPV	F1 Score	AUC
Any Late Toxicity (Grade 2 at 2 Years)	0.786	0.875	0.478	0.966	0.595	0.830
Distant Failure	0.680	0.871	0.607	0.902	0.642	0.775
Path Response (Necrosis Score >= 70)	0.750	0.781	0.600	0.877	0.667	0.765
Major Wound Toxicity	0.667	0.805	0.595	0.849	0.629	0.736

Circulating free DNA derived from active chromatin as a predictive biomarker for clinical benefit to checkpoint inhibitor-based therapies in metastatic leiomyosarcoma. First Author: Carlos Diego Holanda Lopes, Princess Margaret Cancer Centre – University Health Network, University of Toronto, Toronto, ON, Canada

Background: Leiomyosarcoma (LMS) is a common subtype of soft tissue sarcoma with a poor prognosis in the metastatic setting. LMS shows minimal benefit from monotherapy immune checkpoint inhibitors (CPI), however combinatorial CPI strategies may be effective in part due to tumor enrichment of epigenetic alterations. The DAPPER trial (NCT03851614) was a randomized, single center phase II study of durvalumab combined with olaparib or cediranib. Of the 30 LMS patients enrolled, 36.3% (n = 11) experienced disease stabilization or shrinkage. The present study aims to leverage a novel active chromatin cell-free DNA ($cfDNA_{ac}$) platform to investigate the epigenetic and genomic profiles of LMS patients in the DAPPER trial, with the goal of identifying biomarkers associated with clinical benefit from CPI-based therapies. **Methods:** Baseline plasma samples (n = 30) from LMS patients in the DAPPER trial were processed using a proprietary $cfDNA_{ac}$ capture assay that enriches active chromatin cfDNA. Following whole genome sequencing, univariate analysis and machine learning-based recursive feature selection were used to identify genomic features associated with clinical benefit rate (CBR, defined as RECIST v1.1 complete or partial response, or stable disease lasting > 6 months). **Results:** We identified 918 promoter and exon features that were significantly different ($p < 0.01$) at baseline and could segregate patients who achieved CBR from those who did not. Over-representation analysis of these gene features using Gene Ontology ($p_{adj} < 0.05$) showed enrichment in biological pathways associated with double-strand break repair, inflammatory response, and immune response - specifically T-cell receptor activation and signaling, and macrophage homeostasis in patients with CBR. **Conclusions:** This study highlights the utility of $cfDNA_{ac}$ profiling as a non-invasive method for identifying biomarkers that predict clinical benefit from CPI-based therapy in patients with advanced LMS. Further analyses are ongoing to evaluate whether the genomic-derived features correlate with other clinical outcomes, such as progression-free survival, overall survival, and orthogonal data (e.g. tumor tissue RNA-seq). Research Sponsor: None.

Predictive gene signature for the efficacy of pazopanib in solitary fibrous tumor: A Spanish Group for Research in Sarcoma (GEIS) study. First Author: David Silva Moura, Health Research Institute-Fundación Jiménez Díaz University Hospital, Autonomous University of Madrid (IIS-FJD, UAM), Madrid, Spain

Background: Pazopanib was shown to be active in advanced Solitary Fibrous Tumor (SFT), with 58% and 51% of the typical and malignant/ dedifferentiated SFT patients, achieving an objective response by Choi criteria, in an international phase II clinical trial led by our team. Nonetheless, predictive biomarkers of pazopanib efficacy represent a clinical unmet need, to support the rational selection of this drug in this histology. We presented here a predictive transcriptomic-based signature for the efficacy of pazopanib in SFT. **Methods:** Patients enrolled in the GEIS 32 trial (ClinicalTrials.go ID: NCT02066285), testing pazopanib in two separate cohorts of SFT (typical and malignant/ dedifferentiated SFT), and with available tumor samples, were included in this study. Gene expression was assessed by direct transcriptomics, using the HTG EdgeSeq Oncology Biomarkers Panel (HTG Molecular Diagnostics, Inc.; Tucson, AZ, USA), according to manufacturers' instructions. Raw counts were normalized by variance stabilizing transformation (VST) using DESeq2. Univariate Cox regression analysis was performed to identify the genes significantly associated with progression-free survival (PFS; $p < 0.01$). These remaining genes were used as input to build a gene expression signature, using a multivariate Cox regression applying a Lasso penalty (10-fold cross-validation). Risk scores were calculated by multiplying the expression of every gene with its corresponding Cox regression coefficient. **Results:** A series of 40 patients was included for data analyses, with a median age of 64 years old, 62.5% being females, and a median follow-up from pazopanib treatment of 18 months. A total of 24 (60%), 14 (25%), and 2 (5%) patients were diagnosed with malignant, typical, or dedifferentiated SFT, respectively. The predictive signature of pazopanib efficacy was built with 18 genes, identified as significant in the univariate analysis, applying the Lasso penalty. This signature included 13 and 5 genes associated with resistance or sensitivity to pazopanib, respectively. Genes overexpressed and associated with low PFS of pazopanib included *CKS2*, *FANCA,* KPNA2, and *CXL14*, among others. Patients in the high-risk gene signature group (N = 23) showed a significantly worse PFS for pazopanib treatment, compared with patients in the low-risk group (N = 17): [5.6 months (95% CI 3.7-10.0) vs. 10.0 months (95% CI 6.5-NR), $p <= 0.012$; HR = 1.25 (95% CI 1.1-1.4, $p < 0.001$]. The cut-off calculated by MAXSTAT was 42.515. **Conclusions:** Our study identified a novel 18-gene-based signature that significantly predicts the efficacy of pazopanib in SFT patients. Future studies will focus on the prospective validation of this predictive gene signature. Research Sponsor: None.

RNA-based fusion NGS panel testing for the improved classification of soft tissue sarcomas: A retrospective analysis. First Author: Suruchi Aggarwal, MedGenome Labs, Bangalore, India

Background: Accurate diagnosis of soft tissue sarcomas (STS) is critical for effective clinical management. The integration of genetic data enables precise tumor categorization, enhancing diagnostic accuracy. **Methods:** This study presents retrospective molecular classification data of 295 soft tissue sarcoma patients tested using a 110-gene Soft Tissue Sarcoma NGS panel developed at MedGenome Labs, Bangalore, India. The panel facilitates the simultaneous analysis of single nucleotide variants (SNVs), copy number variations, and RNA fusions in a single run. **Results:** Among the 295 cases, clinically relevant fusion or mutation was identified in 186 patients which led to the clarification or reassignment of diagnosis 45/186 (24%) of patients. Key reclassifications included 7 *BCOR*-rearranged sarcomas misdiagnosed as other sarcoma types histologically, 5 *EWSR1::FLI1* cases accurately identified as Ewing's sarcoma, and a myxoid liposarcoma case reclassified as Ewing-like sarcoma based on *EWSR1::TFCP2* fusion. Additional findings included two *HEY1::NCOA2* fusion cases reclassified as mesenchymal chondrosarcoma and a *TAF15::NR4A3* fusion case revised to extraskeletal myxoid chondrosarcoma from synovial sarcoma. Likewise, few other diagnosis revisions are highlighted in the table below. **Conclusions:** These results emphasize the diagnostic utility of broad-panel NGS testing with RNA-based fusion detection, underscoring its significant impact on the accurate classification and improved clinical management of STS patients. Research Sponsor: None.

Few STS types reclassified based on molecular findings.

Histologic Subtype (number of cases)	Molecular classification	Molecular event
Spindle Cell Sarcoma (1)	Dermatofibrosarcoma protuberans	*COL1A1::PDGFB*
Synovial Sarcoma (1)	Endometrial Stromal sarcoma	*ZC3H7B::BCOR*
Spindle Cell Sarcoma (1)	Inflammatory Myofibroblastic Tumor	*CLTC::ALK*
Sarcomatoid carcinoma (1)	Low grade fibromyxoid sarcoma	*FUS::TFCP2*
Angiosarcoma (1); Sarcomatoid Carcinoma (1); Undifferentiated Sarcoma (1)	Mucoepidermoid Carcinoma; Mucoepidermoid Carcinoma; Mucoepidermoid Carcinoma	*NUDT4::MAML2; NR1D1::MAML2; NR1D1::MAML2*
Spindle Cell Sarcoma (1)	Nodular Fascitis	*CALD1::USP6*
Low grade fibromyxoid sarcoma? Synovial sarcoma? (1); Osteosarcoma (1); Rhabdomyosarcoma (1)	Sclerosing Epithelioid Fibrosarcoma; Sclerosing Epithelioid Fibrosarcoma	*FUS::CREB3L1; EWSR1::CREB3L3; FUS::TFCP2*
High grade sarcoma with hemangiopericytomatous pattern (1); Spindle Cell Sarcoma (1)	Synovial Sarcoma; Synovial Sarcoma	*SS18::SSX1; SS18::SSX1*
Epithelioid sarcoma (1); Inflammatory Myofibroblastic Tumor (1)	Uncommon EWSR1 rearranged sarcoma; Uncommon EWSR1 rearranged sarcoma	*EWSR1::ZBTB44; ZC3H7B::EWSR1*

Comprehensive molecular analysis of phase II trial of nivolumab in patients with recurrent or metastatic carcinosarcomas. First Author: Kum-Hee Yun, Division of Medical Oncology, Department of Internal Medicine, Yonsei Cancer Center, Yonsei University College of Medicine, Seoul, South Korea

Background: We conducted a single-center, prospective, phase II trial to evaluate the efficacy and safety of nivolumab, an anti-PD-1 immune checkpoint inhibitor, in patients with recurrent or metastatic carcinosarcoma who progressed after prior chemotherapy. Carcinosarcoma, a malignant neoplasm composed of both epithelial and mesenchymal elements, is a rare and aggressive tumor categorized as high-grade cancer by NCCN guidelines. Given the potential for nivolumab to selectively target PD-L1 overexpressing tumor cells, this study aims to identify patients who would likely benefit and orphan malignancy components. **Methods:** In this single arm phase 2 trial (NCT05224999), eligible patients had histologically confirmed metastatic and/or recurrent carcinosarcoma, measurable disease, 1-3 prior chemotherapy, and adequate renal/hepatic/hematologic function. Treatment consisted of nivolumab 3 mg/kg every 2 weeks. We compared the genomic and transcriptomic properties in our carcinosarcoma tissue with those in TCGA sarcoma, TCGA carcinoma, and TCGA uterine carcinosarcoma. **Results:** Between July 2020 and Nov 2023, 28 patients enrolled and received trial treatment. Of the 28 patients evaluable, 4 (14.3%) achieved confirmed partial response, and 11 (39.3%) had stable disease, yielding and disease control rate of 53.6%. The median PFS was 2.6 months. The pre-specified primary endpoint was met with 6-months PFR of 30.8%. NGS analysis revealed that carcinosarcoma shares molecular features with both carcinoma and sarcoma, while also exhibiting unique genetic and transcriptional profiles. While some molecular characteristics were common across all three tumor types, carcinosarcoma also displayed unique genetic alterations and transcriptional patterns, underscoring its distinct molecular identity. When comparing our genomic data to TCGA datasets, we observed overlapping mutations. In carcinosarcoma, frequently altered genes included TP53 (sarcoma), ZFHX3 (carcinoma), CHD4 (sarcoma), IRS1 (sarcoma), ARID1A (both), ABL1 (sarcoma), MED12, and PIK3CA (carcinoma). These findings suggest potential shared molecular mechanisms and emphasize the unique genomic landscape of carcinosarcoma. **Conclusions:** Carcinosarcoma comprises features shared with carcinoma and sarcoma, along with distinct characteristics unique to this tumour type. These findings highlight the distinct molecular landscape of carcinosarcoma and pave the way for more precise, biomarker-driven therapeutic approaches. Furthermore, patients were stratified based on the degree of molecular similarity to carcinoma or sarcoma, enabling exploratory analyses to assess the potential relationship between these stratifications and drug response. Clinical trial information: NCT05224999. Research Sponsor: None.

Neutrophil-to-lymphocyte ratio as a clinical biomarker for immune checkpoint inhibitor response in advanced sarcoma. First Author: Gabriel Tinoco, Division of Medical Oncology, The Ohio State University, Arthur G. James Comprehensive Cancer Center, Columbus, OH

Background: As immunotherapy gains traction in sarcoma treatment, identifying biomarkers and understanding patterns of response to immune checkpoint inhibitors (ICI) remain critical. We expanded a prior cohort to investigate clinical factors, including the neutrophil-to-lymphocyte ratio (NLR) and its changes, in predicting outcomes such as overall survival (OS) and progression-free survival (PFS) in advanced sarcoma. **Methods:** Patients from The Ohio State University Sarcoma Clinics (2015–2023) were included in a retrospective ICI database. Data included treatment regimens (single-agent ICI or ICI+combination therapy) and clinical variables, particularly baseline and post-treatment NLR stratified into low (< 5) or high (≥ 5). Survival outcomes were analyzed using log-rank tests and Cox regression to assess OS and PFS. **Results:** A total of 192 patients met the inclusion criteria. Most were male (55%), and 83% had Stage 4 disease at ICI initiation. ICI was started as a third-line or later therapy in 52% of cases. The majority received single-agent ICI (57%), while 43% underwent ICI+combination therapy with other modalities (e.g., surgery, radiation, TKI). OS and PFS were similar between single-agent ICI and ICI+combination groups (OS: p = 0.419; PFS: p = 0.834), though clinical variables in the ICI+combination group may confound results. Median OS was 60 weeks, and median PFS was 40 weeks. Significant differences in OS and PFS were associated with NLR. Patients with lower NLR had improved OS ($p < 0.0001$). Among those with higher NLR at ICI initiation, OS improved with ICI+combination therapy (p = 0.039). After the first ICI cycle, the OS benefit persisted for patients with high NLR ($p < 0.0001$), regardless of treatment type. However, survival did not differ by treatment modality or by changes in NLR from baseline (p = 0.710). For PFS, patients with low NLR at ICI initiation had improved outcomes (p = 0.0002). Further analysis showed no PFS differences by NLR in the ICI+combination group. After the first cycle, the PFS benefit for low NLR persisted (p = 0.0006). Conversely, an increased NLR ratio from baseline to the first cycle was linked to worse PFS (p = 0.003), particularly in the ICI+combination group (p = 0.0029) but not in single-agent ICI (p = 0.8630). OS and PFS were not influenced by age, gender, or histology. **Conclusions:** NLR is a promising clinical biomarker for predicting response to ICI in advanced sarcoma. Low baseline NLR predicts improved OS and PFS, while changes in NLR may indicate progression risk. These findings warrant further prospective validation. Research Sponsor: None.

Variable	OS (p-value)	PFS (p-value)
Low vs. High NLR	<0.0001	0.0002
High NLR + Combination	0.039	0.834
NLR Change (Baseline)	0.710	0.003

NLR values.

Pediatric patients with tenosynovial giant cell tumor: Real-world results from an observational registry. First Author: Sydney Stern, TGCT Support/Life Raft Group, Wayne, NJ

Background: Tenosynovial giant cell tumor (TGCT) is a rare, locally aggressive tumor originating in the synovial lining of the joint, bursa, and tendon sheath. Since TGCT typically impacts individuals 20-50 years of age, pediatric TGCT is ultra-rare. However, pediatric patients are often not included in clinical trials or prospective data. Real-world data are needed to understand the impact of TGCT on pediatric patients' quality of life and any differences between adults with TGCT. **Methods:** The TGCT Support Registry is an international, prospective registry initiated in 2022 by TGCT Support, a program of The Life Raft Group. The registry is the largest registry of patients with TGCT and records patient-reported demographic, pathologic, clinical information. This cross-sectional analysis presents data of patients $\leq$ 18 years of age at time of enrollment with Diffuse (D)-TGCT, Localized (L)-TGCT, or unknown subtype. **Results:** A total of 122 pediatric patients (9.5%) were included from a 1,278-patient registry (Table). Most patients were female (67.2%), had D-TGCT (73.0%), in the knee (83.6%), and a median age at diagnosis of 14.5 years. Symptoms reported were pain (94.3%), limited joint range of motion (89.3%), and swelling (84.4%). >50% of pediatric patients were initially misdiagnosed and were more likely to be misdiagnosed than adults (62.3% vs 49.9%, $p < 0.01$). 64.8% of pediatric patients were diagnosed by orthopedic surgeons, and 52.5% were diagnosed $\geq$1 years after symptom onset. Half of pediatric patients had joint aspirations to manage symptoms (47.5%) and non-steroidal anti-inflammatories were common (76.2%). Surgery was the predominant treatment modality and 61.5% reported that surgery occurred $\leq$ 3 months of diagnosis. Pediatric patients with D-TGCT underwent an average of 3.4 surgeries, compared to 1.8 surgeries for those with L-TGCT. 66.3% of pediatric patients with D-TGCT had $\geq$1 post-operative recurrence compared to 15.0% of L-TGCT pediatric patients. Most pediatric patients were referred to general orthopedic surgeons (80.3%), only a third consulted an oncology specialist, and 35.3% were also treated by pediatricians. Systemic therapies (i.e., imatinib, nilotinib, pexidartinib) were prescribed infrequently to pediatric patients with D-TGCT (17.2%). Pediatric patients reported that pain often interfered with daily activities and enjoyment of life. **Conclusions:** This real-world analysis highlights the significant disease burden of pediatric TGCT, as compared to adults, which severely affecting their quality of life. The reliance on surgical treatment and underuse of multidisciplinary care emphasizes the unmet need for provider education and treatment advancements tailored to this population. Greater efforts to develop systemic therapies specific to pediatrics are warranted to reduce recurrence rates and improve quality of life. Research Sponsor: None.

Characteristics of patients stratified by subtype (localized, diffuse, or unknown), including sex, age, region, location of disease, misdiagnosis, duration from symptom onset to diagnosis, average surgeries, recurrences, and use of systemic therapies.

	Diffuse (n=89, 73.0%)	Localized (n=20, 16.4%)	Unknown (n=13, 10.6%)	Total (N=122)

IMM2510, an anti-PD-L1/VEGF bispecific antibody fusion protein, in patients with R/R STS: A phase Ib expansion study. First Author: Haiyan Xu, Shanghai Jiao Tong University Affiliated Sixth People's Hospital, Shanghai, Shanghai, China

Background: IMM2510 is a novel bispecific antibody fusion protein targeting PD-L1 and VEGF. The results of dose-escalation phase were previously reported. Here, we report further efficacy and safety of soft tissue sarcoma patients in cohort expansion stage. **Methods:** IMM2510-01 was a phase I, multicenter, open-label study designed to evaluate the safety, efficacy, recommended phase II dose (RP2D), and pharmacokinetics (PK) of IMM2510 monotherapy (NCT05972460). Dose escalation stage completed and administration of IMM2510 at 20mg/kg, Q2W was selected for cohort expansion. Advanced soft tissue sarcoma patients after prior systemic treatment failure were enrolled, including these with alveolar soft part sarcoma (ASPS), undifferentiated pleomorphic sarcoma (UPS), leiomyosarcoma (LMS) and synovial sarcoma (SS) patients. The primary endpoint was safety, tolerability and investigator assessed ORR. **Results:** As of 24 Dec 2024, 29 STS patients were treated in cohort expansion stage, including 10 with ASPS, 5 with UPS, 8 with LMS, 5 with SS and 1 with other STS subtypes. The median age was 45 and most patients (89.7%) were ECOG PS 1. The median number of prior systemic treatment was 2. Most patients (96.6%) experienced treatment-related adverse events (TRAEs), of which 3 (10.3%) were $\geq$ Grade 3. The most common TRAEs of any grade was infusion-related reaction (IRR) (37.9%), platelet decreased (31%) and AST increased (27.6%). TRAE of $\geq$ Grade 3 was reported in 3 patients, including 1 platelet decreased, 1 transaminase increased and 1 hypoaesthesia. No TRAE leading to treatment discontinuation was observed. Of 27 efficacy-evaluable STS patients, ORR was 7.4% and DCR was 55.6%. 2 PR and 4 SD with tumor shrinkage were observed. PRs were noted in the UPS and LMS cohorts, with an ORR of 20% and 14.3%, and a DCR of 60% and 42.9%, respectively. The DOR was not reached in UPS and 3.68 months in LMS. The study is ongoing. **Conclusions:** IMM2510 monotherapy demonstrated active anti-tumor activity in R/R STS patients with tolerable toxicity. Clinical trial information: NCT05972460. Research Sponsor: None.

A pilot study of Janus kinase 1 (JAK1) inhibitor itacitinib for treatment-refractory sarcomas: Leiomyosarcoma cohort. First Author: Michael J. Wagner, Dana-Farber Cancer Institute, Boston, MA

Background: Sarcomas are a heterogenous group of mesenchymal tumors. Although variable, many sarcoma subtypes have a high proportion of infiltrating macrophages in their immune microenvironment. The JAK/STAT pathway is involved in immune cell regulation and may play a role in tumor immune resistance. Janus kinase 1 (JAK1) shifts tumor associated macrophages (TAM) to an inhibitory M2 phenotype. Inhibition of this pathway could improve anti-tumor immunity. **Methods:** This is an open-label, single agent, pilot study of the JAK1 inhibitor itacitinib in subjects with metastatic or advanced treatment-refractory sarcomas susceptible to immune infiltration by TAM (NCT03670069). Patients (pts) age 18 and older were enrolled in four cohorts: leiomyosarcoma (LMS), undifferentiated pleomorphic sarcoma (UPS) and related subtypes, synovial sarcoma and myxoid/round cell liposarcoma (MRCL), and chondrosarcoma. Itacitinib was given orally, 300 mg once daily, in a 28-day cycle. Primary endpoint was to assess changes in the macrophage population with itacitinib. Secondary endpoints included objective response rate using RECIST v1.1 criteria, progression free survival (PFS) at 3- and 6- months, and overall survival (OS) at 12-months. Response assessments were performed after cycle 2, and every other cycle thereafter. Research biopsies for pharmacodynamic markers were collected at baseline prior to C1D1 and prior to C3D1. Multiplex immunohistochemistry (mIHC) and transcriptomic analysis using Nanostring were performed on pre-treatment and on-treatment tumor specimens. We report the results from the LMS cohort. **Results:** 8 pts with LMS enrolled. OS rate at 12 months for the LMS cohort was 100%, median OS for LMS was 23 months. PFS rate at 3 months and 6 months for LMS was 75% and 38%, respectively. No objective responses by RECIST v1.1 were documented. 7/8 (87.5%) of pts with LMS had stable disease as best response. 7/8 LMS pts had paired tumor biopsies pre- and on-treatment. As expected, *STAT1* was significantly downregulated in on-treatment whole tumor lysates. Other genes that were significantly downregulated with itacitinib treatment were *CCR5, NFKB1, C1QB, CIITA, FCGR3A/B, CXCL10, and MAPKAPK2*. On mIHC, there was a general trend of decreased immune cell tumor infiltration (CD3, CD4, CD8, CD163, FOXP3, CD14, CD206) in on-treatment samples compared to pre-treatment samples, though differences were not statistically significant. **Conclusions:** Itacitinib demonstrated durable disease control in patients with LMS and warrants further study in this subtype. While our analysis of markers on paired biopsy samples does not suggest that immunotherapy combinations with itacitinib are likely to be successful for LMS, a more thorough analysis will be presented at the meeting as this data may still suggest potent combination therapies. Clinical trial information: NCT03670069. Research Sponsor: Incyte.

Gamma secretase inhibitors and desmoid fibromatosis: Lessons from a real world, comprehensive genomic study of desmoids and *CTNNB1/APC* mutated soft tissue tumors. First Author: Steven Christopher Smith, Virginia Commonwealth University School of Medicine, Richmond, VA

Background: Recently, first-in-class FDA approval was granted in the U.S. for use of the gamma secretase inhibitor (GSI), nirogacestat, for adults with progressive desmoid fibromatosis. In tandem, the unpredictable clinical behavior of desmoids, which ranges from local aggression to regression, raises consideration of whether diagnostic and molecular variability underlie their varying biological potential. With an aim to understand both, and to explore the potential for biomarkers for GSI therapy selection, prediction, and prognosis, we performed a retrospective review of comprehensive genomic profiling and histology of desmoids and other soft tissue tumors harboring *CTNNB1* or *APC* mutations. **Methods:** Using real-world reference laboratory database of tumors submitted for clinical genomic assessment (Caris Life Sciences), we queried for samples with a diagnosis of desmoid fibromatosis, or for other neoplasms of soft tissue origin harboring *CTNNB1* or *APC* mutations. Samples underwent next-gen sequencing of (whole exome) to identify gene variants/copy number alterations and of RNA (whole transcriptome) for expression and fusion profiling. Findings were correlated with available clinical data and whole slide image histologic review. **Results:** We identified 74 tumors submitted as desmoid fibromatosis, of which 80% harbored *CTNNB1* and 15% harbored *APC* pathogenic or likely pathogenic variants. *CTNNB1* variants included codon 41 (58%), codon 45 (41%), and ubiquitin motif codon 36 (1%), while 91% of APC variants detected were in exon 16. Recurrent co-alterations were rare, involving *MUTYH* (heterozygous G396D) in 2 samples, and TMB-High (≥10 mutations/Mb) present in 3. Notably, 4 “desmoids” (5%) lacked characteristic mutations, one of which harbored *COL1A1::USP6* fusion, reclassified as nodular fasciitis. Among 76 soft tissue tumors diagnosed as other entities at analysis but found to harbor CTNNB1/APC mutations, 6 (all limited core biopsies), could be confidently reclassified as desmoids. The remaining 70 *CTNNB1/APC* mutant neoplasms were diverse, including synovial sarcoma (11%) and rhabdomyosarcoma (10%). **Conclusions:** Correlation of genomics and histopathology may allow identification of other tumor types misclassified as desmoid fibromatosis. Conversely, genomic correlation facilitated recognition of additional desmoids among tumors submitted with other diagnoses. The striking lack of secondary mutations seen in this large cohort with comprehensive DNA sequencing implies that other mechanisms explain and could predict their variable behavior, for which we are exploring paired transcriptome profiling data. Finally, subsets of diverse, other soft tissue neoplasms harbor *CTNNB1* or *APC* mutations, which may have implications for the design of future biomarker-selected Phase II basket trials. Research Sponsor: None.

The global, regional, and national burden of soft tissue sarcomas and other extraosseous sarcomas, 1990-2021: A systematic analysis for the Global Burden of Disease study 2021. First Author: Venkatraman Radhakrishnan, Cancer Institute (WIA), Chennai, India

Background: Soft tissue and other extraosseous sarcomas (STS) are a diverse group of cancers whose global burden have not been comprehensively reported. This study aims to analyze the burden of STS across the lifespan globally, regionally, and by Sociodemographic Index (SDI) using the Global Burden of Diseases, Injuries, and Risk Factors Study 2021 (GBD 2021) estimates. **Methods:** The incidence, mortality, and disability-adjusted life-years (DALYs) due to STS from 1990 to 2021 were estimated using GBD 2021 methods. Funding for this research came from the Bill & Melinda Gates Foundation and American Lebanese Syrian Associated Charities. **Results:** In 2021, 96,200 (83,400-116,000) new cases of STS occurred globally (males: 52,300 [43,200-68,500], females: 43,900 [38,500-51,400]) and the global age-standardized incidence rate (ASIR) was 1.2 (1.0-1.4) per 100,000 person-years (males: 1.3 [1.1-1.7], females: 1.0 [0.9-1.2]). Among the pediatric population, the incidence rate was highest in the 0-4 age group, while in adults the incidence rate was highest in the 95+ age group. Deaths from STS were estimated to be 50,200 (43,200-61,300) globally (males: 27,200 [22,100-36,500], females: 23,000 [19,900-27,500]), with an age-standardized mortality rate (ASMR) of 0.6 (0.5-0.7) (males: 0.7 [0.6-0.9], females: 0.5 [0.5-0.6]). STS was responsible for 1,680,000 (1,430,000-2,120,000) DALYs in 2021 (males: 916,000 [732,000-1,31,000], females: 762,000 [654,000-947,000]). The global age-standardized DALY rate in 2021 was 20.5 (17.5-26.1) (males: 23.0 [18.3-33.0], females:18.3 [15.7-23.0]). Notably, in 2021, the low SDI quintile exhibited the highest ASMR of 0.9 (0.7-1.4) and age-standardized DALY rate of 33.4 (25.6-50.2). In contrast, the high SDI quintile had the highest ASIR of 2.0 (1.9-2.2). The ASIR remained stable globally between 1990 and 2021, whereas the ASMR and age-standardized DALY rates declined. **Conclusions:** Variations in the burden of STS were evident across different SDI levels. These findings offer insights into the distribution and discrepancies in STS burden on a global scale, which can aid policy efforts to alleviate the suffering caused by these cancers. Research Sponsor: None.

Clinicopathologic features and outcomes of follicular dendritic cell sarcoma with or without Castleman disease: A large retrospective cohort analysis. First Author: Yoshito Nishimura, Division of Hematology and Oncology Mayo Clinic, Rochester, MN

Background: Follicular dendritic cell sarcoma (FDCS) is a rare neoplasm with a subset associated with unicentric Castleman disease (UCD). However, the impact of CD association on clinicopathologic features and survival outcomes remains unclear. This study aims to elucidate differences in disease characteristics and outcomes in FDCS with and without CD to guide future research and clinical practice. **Methods:** We retrospectively analyzed 41 FDCS patients seen at Mayo Clinic between January 2000 and December 2024. Patients were categorized into CD-related (n = 9) and FDCS-only (n = 32) groups. Demographic, clinical, pathological, and survival data were compared. Kaplan-Meier survival analyses were used to evaluate overall survival (OS) and progression-free survival (PFS). Epstein-Barr virus-associated inflammatory FDCS were excluded. **Results:** The CD-related group was younger at diagnosis (46.0 vs. 58.0 years, p = 0.041). Among those with CD-related FDCS, FDCS was diagnosed concurrently as CD in 6/9 (66.7%) and after the diagnosis of CD in 3/9 (33.3%). The FDCS-only patients were more likely to have extranodal disease (71.9% vs. 22.2%) and to have metastasis (62.5% vs 22.2%). One CD-related FDCS patient had paraneoplastic pemphigus. Among 11 patients with next-generation sequencing (NGS) results, 9 had pathogenic mutations. The most common pathogenic mutations included CDKN2A, CDKN2B, and TRAF3 copy number losses. Surgery was the preferred first-line intervention in FDCS-only and CD-related FDCS groups (19/32, 59.4% vs. 6/9, 66.7%). Eight out of 32 (25.0%) of the FDCS-only group received chemotherapy at first-line, most commonly Gemcitabine/Docetaxel or Adriamycin/Ifosphamide. While Gemcitabine/Docetaxel was the most preferred in the second line, different regimens were pursued in the third and later lines of therapy, including Pembrolizumab, Pazopanib, and stem cell transplant. Five out of 6 patients in the CD-related FDCS group received either adjuvant radiation or chemotherapy, which led to complete remission during the follow-up periods. The median follow-up was 22.4 months for the whole population. There was a trend for better OS and PFS among CD-related FDCS patients. The respective 2-year OS rates were 100% and 66.7%, and 2-year PFS rates were 57.1% and 43.1% for CD-related FDCS and FDCS-only patients, respectively. **Conclusions:** This study provides novel insights into clinicopathologic differences and survival trends for FDCS. Our data would suggest a less aggressive disease course among CD-related FDCS, which implies the need for different treatment strategies for CD and non-CD-related FDCS. Further research is warranted to elucidate these mechanisms, such as multi-omic analysis on benign FDC proliferation in the microdissected UCD areas and the adjacent FDCS cells to determine factors associated with progression to sarcoma. Research Sponsor: None.

Molecular-genetic characteristics of soft tissue sarcomas associated with the development of chemotherapy resistance. First Author: Anastasia Alekseevna Tararykova, Federal State Budgetary Institution "N.N. Blokhin National Medical Research Center of Oncology" of the Ministry of Health of the Russian Federation (N.N. Blokhin NMRCO), Moscow, Russian Federation

Background: The development of resistance is the one of the reason for ineffective treatment of soft tissue sarcomas (STSs). The search for new molecular-biological targets, both for the personalized selection of novel targeted drugs and for predicting chemoresistance of STSs to individual antitumor agents and their combinations, is a pressing task. **Methods:** In this study, an experimental in vitro chemoresistance analysis, whole-genome sequencing, and single-cell sequencing of tumors in patients (N = 9) with undifferentiated pleomorphic sarcomas were performed. Chemotherapy resistance indices were determined for the obtained samples. **Results:** Whole-genome DNA sequencing yielded data on the type and frequency of somatic mutations in undifferentiated pleomorphic sarcomas, and driver genes of carcinogenesis were identified, among which the most frequently occurring were FCGBP, PARP4, TP53, RGPD3, PDE4DIP, and RB1. Correlations between the presence of genetic alterations and the response to chemotherapy in the in vitro test were sought. Thus, in samples resistant to the combination of doxorubicin and ifosfamide, the presence of mutations in the PEG3, USP8, NT5C3A, and WAS genes was characteristic. Bioinformatic analysis of single-cell transcriptome sequencing data, aimed at characterizing the population composition and transcriptomic landscape of undifferentiated pleomorphic sarcoma cells, revealed 15 normal and 8 tumor cell populations. Among the populations of normal cells, the following clusters were identified: M2 and M1 macrophages, T-cells, matrix-remodeling fibroblasts and myofibroblasts, monocytes, stromal cells, endothelial cells, and osteoblasts. Among tumor cells, clusters of proliferating cells, hypoxic cells, matrix-interacting cells, and tumor cells with a stem-like phenotype were identified. The most common clusters in all samples were M2 macrophages, endothelial cells, and one of the clusters of tumor cells interacting with the matrix. Comparison of the expression profiles of cells from patients with different responses to chemotherapy allowed identification and characterization of clusters associated with chemosensitivity and chemoresistance. These included clusters of macrophages, tumor cells, fibroblasts, and endothelial cells. In addition, genes common to all clusters associated with resistant samples were identified (ARGLU1, JUND, TNNT3, RHOB, CCNL2, LENG8, LUC7L3, KLF9, RSRP1, RNF213, SERPINE1, CDK5RAP3). **Conclusions:** The data obtained in this study will expand the understanding of the pathogenesis of undifferentiated pleomorphic sarcomas and the mechanisms underlying their development of chemotherapy resistance. In the future, this will serve as the basis for creating a test system to evaluate the expression levels of genes whose activation/repression is associated with the development of drug resistance in STSs. Research Sponsor: None.

Overall survival from the open label phase 2 trial of palbociclib in patients with advanced well differentiated/dedifferentiated liposarcoma. First Author: Olayode Babatunde, Memorial Sloan Kettering Cancer Center - Fellowship (GME Office), New York, NY

Background: Liposarcomas (LPS) are among the most common soft tissue sarcoma subtypes. Well-differentiated (WD) and dedifferentiated (DD) LPS are characterized by CDK4 and MDM2 amplification. Both subtypes have variable sensitivity to chemotherapy. However, effective systemic treatment options remain limited for unresectable or metastatic disease. Our group previously reported two phase 2 trials of the CDK4/6 inhibitor (CDK4/6i) palbociclib (PD0332991) in advanced WD/DD LPS, which established proof-of-concept for targeting CDK4 in this disease. Palbociclib demonstrated prolonged progression-free survival (PFS) and was included in the NCCN Compendium for LPS. However, prospective data on overall survival (OS) in this population remain limited. We now report OS analysis approximately 8.5 years after the last patient was enrolled. **Methods:** Patients with advanced WD/DD LPS were enrolled in two non-randomized phase 2 trials of palbociclib: cohort A received 200 mg daily for 14 days on a 21-day cycle, while cohort B received 125 mg daily for 21 days on a 28-day cycle. Survival outcomes were analyzed using Kaplan-Meier methods, and baseline factors were evaluated for association with PFS and OS. Subsequent anti-cancer therapies, including surgery and systemic treatments, were recorded and analyzed. **Results:** Among 90 enrolled patients, 88 were evaluable for PFS. Median follow-up was 17 months for cohort A and 21 months for cohort B. Updated median PFS was 18.2 weeks (95% CI: 17.7–36.4 weeks) in cohort A and 18.8 weeks (95% CI: 12–23.4 weeks) in cohort B. Median OS was 25.6 months (95% CI: 17.2–40.0 months) in cohort A and 24.1 months (95% CI: 17.5–38.4 months) in cohort B. Across both cohort, patients with pure WD histology were underrepresented, comprising 15 of the 90 patients. Patients with pure WD histology demonstrated longer PFS compared to patients with DD or WD/DD histology (HR: 0.55; 95% CI: 0.30–0.99). However, no significant difference in OS was observed between histologic groups (HR: 0.64; 95% CI: 0.35–1.16). Surgery was performed on 35 patients (39%) post-palbociclib, of which 5 patients had pure WD histology. Analyses on subsequent therapies, including surgery and systemic treatments, will be presented at the meeting. **Conclusions:** This study provides updated long-term outcomes for palbociclib in advanced WD/DD LPS. Palbociclib demonstrated consistent PFS and OS across dosing regimens, offering a tolerable alternative to chemotherapy for patients who may not be candidates for cytotoxic agents. While PFS and OS outcomes remain modest, these data reaffirm the role of CDK4/6i in the management of this disease and underscore the need for novel therapeutic strategies. Future efforts should focus on biomarker-driven approaches and combination therapies to optimize outcomes in this challenging disease. Clinical trial information: NCT01209598. Research Sponsor: Kristen Ann Carr Fund; Nicholls-Biondi Fellowship.

Clinical activity of immune checkpoint blockade in advanced perivascular epithelioid cell neoplasms (PEComas): A retrospective single center study. First Author: Daniel Reinhorn, Memorial Sloan Kettering Cancer Center, New York, NY

Background: Perivascular epithelioid cell tumors (PEComas) are rare mesenchymal neoplasms with limited therapeutic options. While therapies targeting the mTOR pathway have shown promise, with nab-sirolimus being the first FDA-approved treatment for this histology, most patients will eventually progress. The role of immune checkpoint inhibitors (ICIs) remains poorly defined in these patients. Here, we present a retrospective analysis of PEComa patients treated with ICIs at Memorial Sloan Kettering Cancer Center (MSKCC). **Methods:** We retrospectively reviewed all patients with histologically confirmed PEComa treated with ICIs at MSKCC between 2016 and 2024. Patient demographics, disease characteristics, molecular profiles, treatment details, and clinical outcomes were collected. Endpoints included real-world progression-free survival (rwPFS), overall survival (OS), time on treatment (ToT) and response rate. **Results:** Thirteen patients with advanced PEComa received ICIs. The median age was 62 years (Range: 16-87), with 62% female patients. Primary tumor sites included uterus (n = 2), gastrointestinal tract (n = 4), soft tissue/extremities (n = 3), thyroid (n = 1), bladder (n = 1), renal (n = 1), and liver (n = 1). The most common molecular alterations identified were TFE3 fusions (23%), TSC1/TSC2 mutations (15%), TP53 alterations (46%) and ATRX mutations (46%). Patients received a median of 2 lines of previous therapies (range 1-6), with all patients receiving mTOR inhibitors (nab-Sirolimus in 46%). Most patients (78%) had previously received chemotherapy (gemcitabine and/or anthracycline, 54% each). ICIs included pembrolizumab (n = 5), nivolumab (n = 2), nivolumab-ipilimumab (n = 4), pembrolizumab-lenvatinib (n = 1) and nivolumab-bempegaldesleukin (n = 1). Median ToT was 1.6 months (95% CI: 0.9-NE) with 31% (95% CI 14-70%) remaining on treatment at 3 months. Median rwPFS was 3 months (95% CI: 1.4-NE) with a 6-month PFS of 38% (95% CI: 19-76%). Median OS was 26 months (95% CI: 4.13-NE) with a 12-month OS of 59% (95% CI: 37-95%). Partial responses were observed in three patients (23%), with two achieving durable responses exceeding 18 months (one on pembrolizumab and one on nivolumab-ipilimumab). These long-term responders subsequently underwent local interventions for oligoprogressive disease and remained progression-free at last follow-up. Molecular analysis of responders showed distinct profiles: one had TFE3 fusion, another had TP53 deletion and RB1 mutation, while the third had NOTCH1 and FLT4 mutations. **Conclusions:** The observed response rate of 23%, including two durable responses, suggests that ICIs may be an effective treatment option for a subset of PEComa patients, regardless of molecular profile. Further studies to identify predictive biomarkers and optimal sequencing with mTOR inhibitors and other therapies are warranted. Research Sponsor: None.

An update on the results of IBI110 (anti-LAG-3 antibody) plus sintilimab (anti-PD-1 antibody) in patients with advanced alveolar soft part sarcoma. First Author: Zhichao Tan, Department of Bone and Soft Tissue Tumor, Key Laboratory of Carcinogenesis and Translational Research (Ministry of Education/Beijing), Peking University Cancer Hospital and Institute, Beijing, China

Background: At the 2024 ASCO conference, we reported preliminary results on the efficacy and safety of IBI110 (anti-LAG-3 antibody) combined with sintilimab (anti-PD-1 antibody) in advanced alveolar soft part sarcoma (ASPS), which demonstrated an overall response rate (ORR) of 48.1%, including three complete responses (CRs). Here, we provide updated results from this single-arm, phase II trial. **Methods:** Eligible patients with metastatic or unresectable ASPS were assigned to two cohorts: cohort A (immune checkpoint inhibitor [ICI]-naïve, defined as no prior exposure to anti-PD-1/PD-L1/CTLA-4 antibodies) and cohort B (ICI-failed, defined as imaging-confirmed progression following anti-PD-1/PD-L1 therapy). Patients received IBI110 (200 mg) plus sintilimab (200 mg) intravenously every three weeks (Q3W). Primary endpoints were ORR and progression-free survival (PFS), assessed by investigators per RECIST v1.1, as well as safety. Secondary endpoints included overall survival (OS) and safety profile. **Results:** A total of 28 patients were enrolled (57.1% male; median age: 30.5 years; ECOG performance status 0: 100%; stage IV: 100%), with 20 patients in cohort A and 8 in cohort B. Responses were evaluable in 27 patients. The ORR was 51.8% across the entire population, including 4 CRs and 8 partial responses (PRs) in cohort A, and 2 PRs in cohort B. As of January 8, 2025, the median follow-up duration was 21.3 months (95% CI: 11.5–29.8). Median PFS and OS were not reached in the overall population (see Table). Treatment-related adverse events (TRAEs) occurred in all patients, with grade ≥3 TRAEs observed in 10 (35.7%) patients. Four TRAEs led to treatment discontinuation, including hemoptysis (n=2), type 1 diabetes mellitus (n=1), and encephalitis (n=1). No TRAE-related deaths were reported. Following discontinuation of LAG-3 antibody production in July 2024, patients achieving CR were advised to discontinue therapy, while those with PR or stable disease (SD) transitioned to sintilimab monotherapy. Notably, no disease progression was observed among these patients, including two who were previously resistant to sintilimab. Tumor microenvironment analysis in 17 patients (10 responders and 7 non-responders) revealed significantly higher LAG-3 density in responders compared to non-responders (P=0.021). **Conclusions:** The combination of IBI110 and sintilimab demonstrated promising efficacy in both ICI-naïve and ICI-failed advanced ASPS with an acceptable safety profile. The durable restoration of ICI efficacy persisted despite the discontinuation of combination therapy. LAG-3 expression may serve as a predictive biomarker for response to anti-LAG-3 therapy in ASPS. Research Sponsor: None.

Survival analysis.

Cohort	PFS (m)	OS (m)
A	Not reached	Not reached
B	14.9	25.4
Whole population	Not reached	Not reached

PFS: progression-free survival; OS: overall survival.

11555 **Poster Session**

Comprehensive molecular analysis of phase IB/II trial of durvalumab plus doxorubicin combination in patients with advanced soft-tissue sarcoma. First Author: Hyo Song Kim, Division of Medical Oncology, Department of Internal Medicine, Yonsei Cancer Center, Yonsei University College of Medicine, Seoul, South Korea

Background: We conducted an open-label, phase IB/II study to determine the activity and safety of the standard-of-care, doxorubicin in combined with the anti-PD-L1 immune checkpoint inhibitor, durvalumab, in patients with anthracycline-naïve soft tissue sarcoma (STS) and identified patients who would likely benefit from combination treatment. **Methods:** In this phase IB/II trial (NCT03798106), we enrolled patients with metastatic and/or recurrent STS had not received anthracycline chemotherapy and PD-L1/PD-1 inhibitor. Tumor biopsies were obtained from all patients prior to treatment for targeted sequencing, RNA sequencing, and Opal multiplexed immunofluorescence staining. **Results:** No DLTs were observed during the phase II and recommended phase II dose was defined at doses of 75/m^2 doxorubicin and proceed the phase II part. Of 41 evaluable patients, an objective response rate of 31.7% and the median progression free survival was 8.2 months (95% CI, 7.3-9.0) and median overall survival was 24.1 months (95% CI, 7.6-40.3). In the prespecified genomic analysis, using a multivariate Cox proportional regression model with clinical factors in combined with PD-1 cell density and signaling pathways, genetic alterations in RTK/RAS (HR 6.446, [95 % CI, 1.934-21.486]; P=0.002) and PD-1 density (HR 0.214, [95 % CI, 0.071=0.649]; P=0.006) were identified as the independent predictors of PFS. High PD-1 tumors without RTK/RAS pathway alteration had longer PFS (16.9 months) than the others (7.4 months for RTK/RAS alteration or PD-1 high, 1.0 months for RTK/RAS pathway alteration and PD-1 low group, $P<0.001$). In the gene set analysis, antigen processing and presentation, interferon alpha response, and interferon gamma response showed significantly higher scores in PD1 high without RTK/RAS pathway alteration. **Conclusions:** Durvalumab combined with doxorubicin demonstrated promising efficacy in an unselected STS cohort, with a manageable toxicity profile. In exploratory correlative analysis, we identified potential role of RTK/RAS signaling and PD-1 expression as independent predictors for the efficacy, although further investigations are needed. Clinical trial information: NCT03798106. Research Sponsor: None.

11556 **Poster Session**

Multicenter phase II study of anlotinib and toripalimab in patients with advanced soft tissue sarcoma (STS) and bone sarcoma (BS). First Author: Xing Zhang, Melanoma and Sarcoma Medical Oncology Unit, State Key Laboratory of Oncology in South China, Collaborative Innovation Center for Cancer Medicine, Sun Yat-sen University Cancer Center, Guangzhou, China

Background: This multicenter phase II study aims to evaluate the efficacy and safety of anlotinib combined with toripalimab in the treatment of patients (pts) with advanced STS or BS. **Methods:** Pts with advanced STS or BS, 14-70 years, at least one measurable tumor lesion per RECIST 1.1 and failure or intolerance of standard systemic therapy, or no standard treatment existed, are eligible. Pts with alveolar soft-part sarcoma (ASPS) and clear cell sarcoma (CCS) can be included as the first-line therapy. Anlotinib (12 mg/d, po, d1-14) and toripalimab (240mg, IV, d1) would be administered every 3 weeks. The primary endpoint was investigator-assessed objective response rate (ORR). The secondary endpoints include disease control rate (DCR), progression-free survival (PFS), overall survival (OS) and safety using NCI-CTCAE v4.03. **Results:** Between March, 2020 and November, 2024, 70 pts were enrolled, of whom 68 were evaluable for the efficacy analyses. The STS subtypes mainly included synovial sarcoma (SS, 15.7%), rhabdomyosarcoma (RMS, 8.6%), extraskeletal Ewing's sarcoma (EES, 7.1%), epithelioid sarcoma (EpS, 7.1%), leiomyosarcoma (LMS, 7.1%), ASPS (5.7%), liposarcoma (5.7%), undifferentiated sarcoma (5.7%) and others (31.4%). The BS subtypes included 2 (2.9%) osteosarcoma and 2 (2.9%) chondrosarcoma. With a median follow up of 29.1 months, partial response occurred in 19 pts: 4 with SS, 3 with ASPS, 2 with LMS, 2 with EpS, 2 with inflammatory myofibroblastic tumor, and one patient each with RMS, EES, undifferentiated sarcoma, CCS, malignant peripheral nerve sheath tumor, or desmoplastic small round cell tumor. The ORR and DCR for the entire cohort were 27.9% and 86.8%, respectively. The median PFS was 7.0 months (95% CI: 4.2-9.8). The median OS was 23.5 months (95% CI: 9.2-37.8). For the 64 efficacy-evaluable STS cohort, the ORR was 29.7% and the median PFS was 8.1 months (95% CI: 4.7-11.5). Most of the treatment-related adverse events were mild (grade 1-2). The most common grade 3/4 adverse events (AE) were hypertension (15.7%), hand-foot syndrome reaction (12.9%), and hypertriglyceridemia (7.1%). **Conclusions:** The combination of anlotinib and toripalimab showed good anti-tumor activity and durable efficacy in advanced STS patients, with acceptable toxicity. Clinical trial information: NCT04172805. Research Sponsor: None.

Change in T2-weighted signal intensity, change in tumor volume, and exposure-response analysis in the RINGSIDE phase 2 study of varegacestat in patients with desmoid tumors. First Author: Mrinal M. Gounder, Memorial Sloan Kettering Cancer Center, New York, NY

Background: T2-weighted signal intensity (T2W) and tumor volume (TV) on MRI may be more sensitive than RECIST for assessing treatment effect in desmoid tumors (DT). On T2W images, hyperintense areas are associated with active fibroblast proliferation and hypointense areas are associated with loss of tumor cells and more collagenous tissue. The RINGSIDE Phase 2 study (NCT04871282) demonstrated arly and continued MRI changes in DTs with varegacestat (AL102) therapy. We report exploratory analyses of T2W, TV, and exposure-response (E-R). **Methods:** Eligible adults had histologically confirmed DT that had progressed ≥10% unidimensional growth in ≤18 months or DT-related pain requiring non-opioid medication. Participants (pts) were randomized to 3 oral varegacestat doses: 1.2 mg once daily (n = 14), 2 mg intermittent (n = 14) or 4 mg intermittent (n = 14) (intermittent = 2 days on, 5 days off). In the open-label extension (OLE), active pts received 1.2 mg once daily. We performed descriptive analysis of T2W, TV and RECIST sum of diameters (SOD), all of which were evaluated at screening, Week 16 and every 12 weeks thereafter. Linear correlations of best % changes from baseline on these assessments were evaluated with Pearson correlation coefficient. E-R modeling evaluated the time course of drug effect on TV to support selection of 1.2 mg once daily for further study. **Results:** As of April 10, 2024, median time on treatment was 23.1 months (range 0.7 – 26.6) and 23 of 42 (55%) enrolled pts were still on treatment. Line graphs of changes from baseline showed rapid and substantial reductions in T2W and TV. By Week 16, the median % changes in T2W, TV and SOD were -39%, -24%, and -8%, respectively. Median best % changes for T2W, TV and SOD were -90%, -84%, and -40%, respectively. Correlations were observed for best % changes in T2W vs SOD (R = 0.69), TV vs SOD (R = 0.82), and T2W vs TV (R = 0.89). In the 23 pts with PR/CR, median best % change was -96% (n = 21 evaluable) for T2W and -90% (n = 22 evaluable) for TV. In pts with SD, changes in T2W (n = 11 evaluable) ranged from +32% to -94%, with a median of -75%, and TV (n = 12 evaluable) ranged from +71% to -86%, with a median of +7%. Preliminary E-R analysis predicted median time to 30% decrease in TV of 3 months with the 1.2 mg once daily regimen. **Conclusions:** Substantial early and rapid reductions in T2W and TV on MRI preceded eventual RECIST responses in adults with DT treated with varegacestat. These data add to a growing body of work showing T2W and TV may play a role in evaluating treatment response in DT. Future research should evaluate the prognostic or predictive value of these imaging techniques in DT and standardization to allow for use in clinical management of DT patients. Clinical trial information: NCT04871282. Research Sponsor: Immunome.

Long-term clinical outcome assessments in patients with tenosynovial giant cell tumor treated with vimseltinib: 1-year results from the MOTION phase 3 trial. First Author: Vivek A Bhadri, Chris O'Brien Lifehouse, Camperdown, NSW, Australia

Background: Tenosynovial giant cell tumor (TGCT) is a locally aggressive neoplasm caused by dysregulation of the colony-stimulating factor 1 (*CSF1*) gene leading to overproduction of CSF1. Patients with TGCT often report substantial pain and stiffness, impaired physical function, and limited range of motion (ROM), supporting the need for an effective, well-tolerated CSF1 receptor (CSF1R)-targeted therapy that provides long-term improvements in functional health and quality of life (QoL). Vimseltinib is an oral, switch-control inhibitor of CSF1R. In part 1 of the MOTION phase 3 trial, vimseltinib showed statistically significant and clinically meaningful improvements vs placebo in tumor response as well as clinical outcome assessments (COAs; active ROM and patient-reported outcomes [PROs]) in patients with TGCT not amenable to surgery at week 25 (Gelderblom H, et al. *Lancet*. 2024). Here we report 1-year COA results from MOTION. **Methods:** MOTION is a global, phase 3 trial composed of double-blind (part 1; to week 25), open-label (part 2; week 25–49), and extension periods (NCT05059262). Patients received vimseltinib 30 mg twice weekly. COAs reported here include change from baseline in active ROM of the affected joint, physical function (PRO Measurement Information System physical function score [PROMIS-PF]), stiffness (worst stiffness numeric rating scale [NRS]), health status (EuroQol Visual Analog Scale [EQ-VAS]), and pain (brief pain inventory [BPI] worst pain). BPI worst pain response rate is also reported with response defined as ≥30% decrease in worst pain without ≥30% increase in narcotic analgesic use. Results are reported in patients randomized to vimseltinib during part 1 whose 1-year (week-49) assessments were complete at data cutoff (Feb 22, 2024). **Results:** Of 83 patients randomized to vimseltinib in part 1, 73 continued treatment in the open-label part of the study. Consistent with results from part 1, COAs at 1 year continued to show improvement from baseline. Mean (standard error [SE]) change from baseline in active ROM was 14.9 (5.0) percentage points. Mean (SE) changes from baseline in PROMIS-PF, worst stiffness NRS, and EQ-VAS were 6.5 (1.2), −2.7 (0.4), and 11.0 (3.5) points, respectively. Mean (SE) change from baseline in BPI worst pain was −2.8 (0.4) points, and the BPI worst pain response rate was 40% (33/83; 95% confidence interval, 29 to 51). **Conclusions:** These 1-year COA results from the MOTION phase 3 trial demonstrate durable and continued improvements in active ROM, physical function, stiffness, health status, and pain with ongoing vimseltinib treatment. Continued treatment with vimseltinib provides clinically meaningful benefit in functional health and QoL beyond week 25 for patients with symptomatic TGCT whose disease is not amenable to surgery. Clinical trial information: NCT05059262. Research Sponsor: Deciphera Pharmaceuticals, LLC.

Daily low-dose oral temozolomide as maintenance therapy following doxorubicin plus dacarbazine in advanced leiomyosarcoma patients: An observational study. First Author: Zhichao Tan, Department of Bone and Soft Tissue Tumor, Key Laboratory of Carcinogenesis and Translational Research (Ministry of Education/Beijing), Peking University Cancer Hospital and Institute, Beijing, China

Background: Doxorubicin (Dox) combined with dacarbazine (DTIC) is a standard first-line regimen for advanced leiomyosarcoma (LMS), but its long-term use is restricted due to potential cardiac toxicity. Although the addition of trabectedin to Dox, followed by trabectedin maintenance, has demonstrated improved overall survival (OS) and progression-free survival (PFS), trabectedin's limited availability in China poses a significant challenge. Given that both temozolomide (Tem) and DTIC convert to the same active metabolite (MTIC) in the body, we investigated the efficacy of daily low-dose Tem as maintenance therapy following Dox plus DTIC. Here, we present the results of this observational study. **Methods:** Eligible patients with metastatic or unresectable LMS received up to six cycles of Dox (60-70 mg/m², day 1) or pegylated liposomal Dox (PLD, 35–45 mg/m², day 1) combined with DTIC (0.9–1.2 g/m², day 1) every three weeks. Patients without progression after six cycles of Dox/PLD plus DTIC were transitioned to maintenance therapy with daily oral temozolomide (75 mg/m²). Maintenance Tem was continued until disease progression. The primary endpoint was PFS during maintenance, assessed by investigators. Secondary endpoints included OS and safety. PFS and OS were defined as the time from initiation of oral Tem until disease progression and death, respectively. **Results:** Between May 2022 and December 2024, 20 patients were enrolled, with a median age of 55 years. All patients were female. The primary tumor site was uterine in 45% of cases and non-uterine in 55%; 90% had metastatic disease, and 10% had locally advanced disease. Seventeen patients were evaluable for efficacy. The median PFS during maintenance was 7.1 months, with three patients achieving disease control for over 12 months. Treatment was generally well-tolerated, with the most common adverse events (AEs) being grade I/II nausea (80%), vomiting (45%), and white blood cell reduction (25%). Serious AEs leading to treatment discontinuation occurred in two patients: one due to severe vomiting and one due to elevated liver enzymes. **Conclusions:** Daily low-dose oral temozolomide appears to be an effective and well-tolerated maintenance therapy following Dox plus DTIC for patients with advanced LMS. This approach may offer a viable alternative for patients in regions where trabectedin is unavailable. Research Sponsor: None.

A phase II, multicenter trial of the combination of chidamide and toripalimab in patients with advanced soft tissue sarcoma: Efficacy updates. First Author: Xing Zhang, Melanoma and Sarcoma Medical Oncology Unit, State Key Laboratory of Oncology in South China, Collaborative Innovation Center for Cancer Medicine, Sun Yat-sen University Cancer Center, Guangzhou, China

Background: Chidamide is an oral subtype-selective histone deacetylase (HDAC) inhibitor which is effective on the patients with hematological tumors and could be hoped to enhance the efficacy of checkpoint blockade therapies and regulate the host immune response. Here, we report the updates of preliminary results of the combination of Chidamide and Toripalimab in soft tissue sarcoma (STS) patients. **Methods:** An open-label, single arm, multicenter, phase II study of Chidamide with Toripalimab in patients with advanced STS was conducted. Patients who were with failure or intolerance of standard systemic therpy, or no existed standard treatment, are eligible. Patients who had underwent HDAC inhibitors and immune checkpoint inhibitors treatment were excluded. All patients received Chidamide orally at 30mg twice weekly in combination with intravenous Toripalimab 240mg every 21 days until progression or unaccepte toxicity. The primary endpoint was RECIST1.1 objective response rate (ORR). The secondary endpoint included progression free survival (PFS), overall survival (OS), disease control rate (DCR) and safety. **Results:** At the data cut-off date (January, 2025),sixty-nine patients with advanced STS were enrolled. The median age of the patients was 47 years (range, 16 to 68) and the median prior lines of therapy were 2 (range, 0 to 5). The main subtypes included leiomyosarcoma (29%), well/dedifferentiated liposarcoma (36.2%), undifferentiated sarcoma(7.2%), myxoid/round cell liposarcoma (4.3%), and osteosarcoma (4.3%). Treatment was well tolerated with the most common adverse events mainly in grade 1-2, including anemia(55.1%), hypothyroidism(44.9%), leukopenia(33.3%), thrombocytopenia (30.4%), neutropenia(24.6%), nausea/vomit(24.6%), and fatigue (15.9%). Of the grade 3–4 adverse events, the most common were neutropenia(27.5%), thrombocytopenia (23.2%), leukopenia(14.5%), nausea/vomit(10.1%) and anemia(1.4%). Among 69 efficacy-evaluable patients, the ORR and DCR were 29% and 73.9%, respectively. The median time to an initial response was 5 months (95%CI 3-7), and the median PFS was 7.1 months (95%CI 4.0-10.2) , and the median OS was not reached. **Conclusions:** Chidamide with Toripalimab every 21 days was well tolerated and showed promising efficacy in patients with advanced STS. The exploratory biomarker study is ongoing. Clinical trial information: NCT04025931. Research Sponsor: None.

Detecting hotspots of intra- and transchromosomal fusions in liposarcomas by RNA sequencing. First Author: Dmitrii Grachev, BostonGene, Corp., Waltham, MA

Background: Liposarcoma (LPS) is characterized by unstable genomes and high occurrence of gene fusions. Hotspots of both recurrent and non-recurrent gene fusions can provide information about structural alterations in certain LPS subtypes. For instance, myxoid (M) LPS expresses the oncogenic *FUS-DDIT3* protein and is known to be fusion-driven. Moreover, disrupted locus 12q13-15 is an important feature of well-dedifferentiated (WD) and dedifferentiated (DD) LPS, and is the site of copy number alterations (CNAs) and gene fusions. Here, we used RNA sequencing to uncover hotspots of intra- and transchromosomal gene fusions in LPS patient samples, identifying potentially clinically relevant events in certain chromosomal regions. **Methods:** The BostonGene internal LPS cohort (n=150) was analyzed by bulk whole-transcriptome sequencing, using STAR-fusion for sequence calling. Quality control was performed using FastQC, FastQ Screen, RSeQC, and MultiQC. Tumor purity was assessed via pathological and bioinformatics examination with a threshold of 20%. One sample Poisson rate test was used to evaluate statistical significance of gene fusion hotspots. **Results:** We identified 4,080 gene fusions among four LPS subtypes (DDLPS, WDLPS, MLPS, and PLPS - pleomorphic LPS). Of those, 2,302 (56.4%) were intrachromosomal and 1,778 (43.6%) were transchromosomal. Over half of these fusions (1,263/2,302 intrachromosomal fusions, 54.9%; 1,047/1,778 transchromosomal fusions, 58,9%) were detected on chromosome 12. Most identified fusions occurred in the 12q13-15 region (q-value < 0.001), with q15 being especially prevalent in transchromosomal fusions (q-value < 0.001). The most prevalent recurrent fusion across our LPS cohort was *FUS-DDIT3* (N=21, MLPS samples). Another notable recurrent fusion was *TRIO-TERT* (N=4, DDLPS). We also identified extended gene fusion hotspots in regions containing important oncogenes such as *MDM2* and *FRS2* in LPS subtypes (DDLPS, WDLPS, PLPS) that are not considered fusion-driven (Table). These findings suggest an oncogenic role of such fusions in these LPS subtypes, along with known CNAs like *MDM2* amplification. **Conclusions:** Our comprehensive transcriptomic analysis of gene fusions in LPS samples uncovered both new and established hotspots of chromosomal rearrangements. Identification of such hotspots improves our understanding of LPS oncogenesis and thus can enhance the diagnostic accuracy and discovery of new biomarkers. Research Sponsor: None.

Treatment discontinuation in desmoid tumors: Factors associated with better outcomes after sorafenib discontinuation. First Author: Irvin Yi, Yale School of Medicine, New Haven, CT

Background: Sorafenib has shown effectiveness in managing desmoid tumors. However, the optimal duration of systemic therapy and the outcomes following its discontinuation remain unknown. This study investigates the outcomes of patients who discontinued sorafenib, aiming to provide guidance for clinicians on treatment cessation. **Methods:** We conducted an international, multi-institutional retrospective analysis of patients treated with sorafenib who discontinued therapy with no immediate plans to initiate a new treatment. We assessed whether the duration of sorafenib use (6 months, 1 year, or 2 years), the reason for discontinuation (side effects or shared decision-making), and the treatment response at the time of discontinuation influenced the likelihood of requiring subsequent treatment (treatment free survival, TFS) or experiencing disease progression (progression free survival, PFS). Kaplan-Meier curves were used for survival analysis, and group comparisons were performed using the log-rank test. **Results:** Between 2005 to 2022, a total of 48 patients were identified meeting the eligibility criteria. Three (6%) patients received therapy for less than 6 months, thirteen (27%) received less than 12 months, and thirty (63%) received less than 24 months. Seventeen (35%) patients stopped therapy due to side effects with the remaining thirty-one (65%) patients discontinuing due to other reasons, such as patient preference, provider decision, or payment coverage. Four (8%) patients experienced progression of disease while 38 (79%) had stable disease or partial response. The most common side effects were diarrhea (52%), palmar-plantar erythrodysesthesia syndrome (46%), and fatigue (23%). Patients who received less than 6 months of sorafenib treatment prior to discontinuation had a TFS of 10.1 months, compared to 54.5 months for over 6 months of duration ($p < 0.001$). At the 12-month mark, less than 12 months had median TFS of 49.1, compared to 54.5 for longer ($p = 0.2$). At the 24-month mark, less than had a median TFS of 49.1, compared to 54.5 for longer ($p = 0.1$). Other factors did not emerge as statistically significant ($p > 0.05$). **Conclusions:** Our data demonstrates the duration of sorafenib treatment is a significant indicator for future treatment need. Reaching the 6-month mark could be indicative of an important checkpoint, although the 1- and 2-year marks are also associated with a clinically, but not statistically, significant reduction in likelihood for future treatment. Clinicians and patients should be aware that duration is an important consideration for future outcomes in desmoid tumor treatment, and to factor it into shared decision-making. Research Sponsor: None.

11563 **Poster Session**

Safety and antitumor activity of ^{177}Lu-catelase: A preliminary clinical study in soft tissue sarcoma. First Author: Jiayong Liu, Department of Bone and Soft Tissue Tumor, Key Laboratory of Carcinogenesis and Translational Research (Ministry of Education/Beijing), Peking University Cancer Hospital and Institute, Beijing, China

Background: Localized radiotherapy with radioisotope injections holds promise but is limited by poor tumor retention and hypoxia. To overcome these challenges, we developed ^{177}Lu-CAT/ALG, a hydrogel formulation containing catalase labeled with ^{177}Lu and sodium alginate (ALG). Upon injection, endogenous calcium rapidly forms a hydrogel, securing ^{177}Lu-CAT within the tumor, alleviating hypoxia, and enhancing therapeutic efficacy. Preclinical studies demonstrated sustained hypoxia relief, superior tumor retention, and significant antitumor activity. This phase 1 trial evaluates the safety and preliminary efficacy of ^{177}Lu-CAT/ALG in patients with soft tissue sarcoma (STS). **Methods:** Patients with locally advanced STS underwent baseline metabolic and volumetric assessments using ^{18}F-FDG PET/MR imaging. Intratumoral doses were calculated using the OLINDA 2.0 Sphere Model, with ultrasound-guided injections administered every 8 weeks. SPECT imaging assessed tumor retention at 2, 24, 96, and 168 hours post-injection. Efficacy was evaluated bi-monthly per PERCIST criteria. Primary endpoints included tumor retention and safety (CTCAE v5.0). Secondary endpoints included objective response rate (ORR), progression-free survival (PFS), and overall survival (OS). **Results:** Seven patients with locally advanced STS were treated, with a median tumor size of 8.5 cm. SPECT imaging confirmed that at least 60% of ^{177}Lu-CAT/ALG remained within tumors at 168 hours. The most common adverse events (AEs) were grade 1-2 reductions in white blood cell count (4/7 patients). One patient experienced a grade 4 AE (thrombocytopenia). Stable disease was observed in two patients, with disease control lasting 16.53 and 12.8 months. As of the data cutoff, one patient remains on treatment. Pathological analysis of a tumor specimen from a patient with increased tumor volume on PET/MR revealed 70% necrosis after resection. **Conclusions:** ^{177}Lu-CAT/ALG demonstrated a favorable safety profile, sustained tumor retention, and encouraging antitumor activity in patients with locally advanced STS. These results highlight the potential of ^{177}Lu-CAT/ALG as a novel therapeutic approach and support further evaluation in larger trials. Clinical trial information: NCT05985278. Research Sponsor: None.

Characteristics of participants.

No.	Gender	Age	Tumor type	Primary tumor location	Tumor size	Number of injections	Mean dose of injections (range)/mCi	Outcomes
1	F	41	LGSTS, NOS	right scapular region	8.6	5	23.30(16.8-29.1)	On treatment
2	F	55	FS	Right chest wall	9.3	1	14.3	PD

Doxorubicin-based chemotherapy vs gemcitabine/docetaxel in uterine leiomyosarcoma (ULMS). First Author: Stephanie Soewito, University of Texas Health Science Center at Houston, Houston, TX

Background: ULMS is an aggressive uterine smooth muscle cancer. Surgery is standard for localized/advanced ULMS, and the use of adjuvant chemotherapy is controversial. Treatment may involve combination cytotoxic chemotherapy, typically doxorubicin-based regimens (D) or gemcitabine plus docetaxel (GT), which have poor (20-30%) response rates and high toxicity. Given the lack of randomized trial data, this single-center retrospective study compared D vs GT in the adjuvant and metastatic settings of ULMS. **Methods:** We included patients with confirmed histologic diagnosis of uterine leiomyosarcoma between 2000 and 2024 treated at MD Anderson Cancer Center with either D or GT. Patients were stratified by localized disease and receipt of adjuvant chemotherapy or metastatic disease and receipt of palliative chemotherapy with D or GT in the first-line setting. The primary objective was to assess recurrence-free survival (RFS) in those with localized tumors and progression-free survival (PFS) in those with metastatic tumors treated with either D or GT. RFS and PFS were defined as the time interval from the start time of first line chemotherapy (D or GT) to the time of recurrence/progression or death, whichever occurred first. Kaplan Meier and log rank tests were used to assess survival outcomes. Cox proportional hazards (PH) modeling evaluated whether either regimen independently predicted survival with adjustment for age, primary tumor size, and mitotic index. Data collection is ongoing, and propensity score matching will be performed. **Results:** We included 76 patients, including 36 with primary localized ULMS and 40 with advanced ULMS. In patients with localized disease, there was no significant difference in RFS between those treated with D vs GT in univariate (p = 0.17) or multivariate (HR (95% CI) = 1.21 (0.35, 4.15), p = 0.76) analyses. In patients with metastatic disease, GT was associated with inferior PFS than those treated with D (HR (95% CI) = 4.45 (1.38, 14.29), p = 0.01) after adjusting for age and primary tumor size in the multivariate Cox PH model. **Conclusions:** Treatment with D was associated with improved PFS for metastatic ULMS compared to treatment with GT. No significant difference in RFS was observed between the two regimens for localized disease. However, the study may have limited power to detect differences due to small sample size. Updated data analyses with a larger cohort will be presented at the meeting. Research Sponsor: None.

	Localized ULMS (n = 36)		Metastatic ULMS (n = 40)	
Age of diagnosis (median, years)	51.0		52.3	
Primary tumor size (median, cm)	10.1		11.0	
Mitotic Index (>10 per 10 HPF)	77.8% (n = 28)		82.5% (n = 33)	
	D	GT	D	GT
	16.7% (n = 6)	83.3% (n = 30)	30% (n = 12)	70% (n = 28)
RFS/PFS (median, months)	10.8 (7.8, 23.0)		7.2 (4.5, 9.2)	
HR (95% CI)	1.21 (0.35, 4.15)		4.45 (1.38, 14.29)	
p-value	0.7612		0.0122	
Overall Survival (median, years)	6.6 (2.5, 10.3)		4.6 (3.7, 6.7)

Heterogeneity in epithelioid hemangioendothelioma (EHE): Insights into common and organ-specific tumor pathways. First Author: Tom Wei-Wu Chen, National Taiwan University Hospital, Taipei, Taiwan

Background: EHEs are ultra-rare sarcomas that can arise from various organs, with the primary site being an important prognostic factor. We hypothesized that EHEs from different organs harbor heterogeneous tumor cells. Understanding key pathways associated with this heterogeneity may lead to improved therapies for EHE patients. **Methods:** EHE samples from different primary sites with confirmed pathognomonic gene rearrangements were analyzed. Spatial transcriptomics was performed on FFPE samples using the Visium CytAssist platform. Pathway analyses were conducted with AUCell, and cell compositions were estimated using XCell. A second platform, Xenium, was used for confirmation. **Results:** Eight EHE patients with different primary organ sites (liver 3, lung & pleura 2, bone 2, soft tissue 1) and gene rearrangements (CAMAT1 FISH+ 6, TFE3 FISH+ 1, WWTR1 FISH+ 1) had spatial transcriptomic results. Unsupervised clustering identified 35 different clusters and EHE clusters were defined in accordance to histology and vascular markers (CD31, CD34, and ERG). These clusters could be broadly categorized into “common (non-organ-specific)” clusters, observed in three or more organ types, and “organ-specific” clusters. Common clusters showed higher levels of stem-like endothelial cell markers and increased TGF-beta and mTORC1 pathway activity, which may explain the clinical benefit of sirolimus in EHE. Using liver EHEs as an example, the liver-specific cluster demonstrated a fibroblast/mesenchymal stromal cell differentiation pattern not observed in EHEs from other organs. GDF-15, which is associated with aggressiveness in EHE and cachexia, was significantly higher expressed in common than organ-specific cluster. In liver and bone EHEs, clusters with high GDF-15 expression tend to have higher TGF-beta signaling and lower dendritic cells, implying the role of GDF-15 in EHE with immune regulation. These findings were validated in Xenium analysis. **Conclusions:** This study shows that EHE tumors share certain core pathways but also exhibit organ-specific differentiation patterns, which may underlie their variable prognoses. The coexistence of both “common” and “organ-specific” clusters highlights the importance of personalized treatment strategies and paves the way for more targeted therapeutic development in EHE. Molecular profiling and prognosis of spindle cell/sclerosing rhabdomyosarcoma: A report from the Chinese PPOG trial. First Author: Suying Lu, Sun Yat-sen University Cancer Center; State Key Laboratory of Oncology in South China; Collaborative Innovation Center for Cancer Medicine, Guangzhou, Guangdong, China

Background: Spindle cell/sclerosing rhabdomyosarcomas (SSRMS) is a rare variant of rhabdomyosarcoma, recognized as a distinct pathological entity in the most recent WHO classification. However, the molecular profile and clinical outcomes of patients with SSRMS remain poorly understood. The Pediatric Precision Oncology Group (PPOG) is a multicenter project aimed at characterizing tumor molecular profiles in pediatric oncology patients across China. **Methods:** From January 2016 to July 2024, a total of 70 patients with SSRMS were enrolled in the PPOG (NCT05076071) trial, with 57 patients meeting the criteria for clinical analysis. Targeted gene sequencing (830 DNA and 395 RNA) was conducted on tumor samples from 43 patients, while whole-transcriptome analysis was performed on tumor samples from 13 patients to assess gene expression. The Kaplan-Meier method was employed to estimate overall survival (OS) and event-free survival (EFS). **Results:** The median follow-up time was 48 months (range: 6.3–160.8 months). The 4-year EFS rates for patients with low risk (n = 16), intermediate risk (n = 27), and high risk (n = 14) were 92.9%, 79.3%, and 12.9%, respectively ($P < 0.0001$). The 4-year OS rates for these groups were 68.8%, 51.2%, and 39.7%, respectively (P = 0.2046). The 4-year EFS rates for patients aged $<$ 10 years (n = 33) and $\geq$ 10 years (n = 24) were 66.7% and 31.7%, respectively (P = 0.017). The 4-year OS rates for these groups were 71.4% and 63.8%, respectively (P = 0.192). The most commonly recurrently altered genes were MYOD1 (48.8%), PIK3CA (25.6%), CDKN2A (23.3%), CDKN2B (16.3%), and IGF1R (9.3%) mutations. All 21 cases with MYOD1 mutations showed a p.L122R (c. T365G) mutation, consistent with previous reports. Gene interaction analysis shows that MYOD1 mutation frequently occur alongside CDKN2B mutation. Compared to the MYOD1 wild-type group, the MYOD1 mutant group has a significantly higher incidence of CDKN2B mutation, as well as higher rates of PIK3CA and IGF mutations, and lower rates of NOTCH1 and TP53 mutations. Eighteen fusion genes were detected in 30.2% (13/43) of SSRMS patients, with the most common being BRAF fusion (4.6%) and ROS1 fusion (4.6%). Actionable mutations were identified in 76.7% of patients, with the most frequently matched targeted therapies including PI3K inhibitors (32.3%), CDK4/6 inhibitors (21.2%), and MEK inhibitors (11.5%). Compared to the MYOD1 wild-type group, RNA differential expression analysis revealed a significant upregulation of the PI3K-AKT pathway in the MYOD1 mutant group. The infiltration levels of CD4+ T cells and macrophages in the MYOD1 mutant group were significantly higher than those in MYOD1 wild-type group. **Conclusions:** The MYOD1 mutant group and the MYOD1 wild-type group exhibit distinct molecular characteristics. Larger sample studies are needed to clarify the molecular features and risk stratification of SSRMS. Clinical trial information: NCT05076071. Research Sponsor: None.

Impact of time to relapse (TTR) and metastasectomy (MTS) on survival in leiomyosarcoma (LMS): A CanSaRCC study. First Author: Haydée Williams Sanchez, Division of Medical Oncology and Hematology, Princess Margaret Cancer Centre, University Health Network, Toronto, ON, Canada

Background: Approximately 40% of LMS patients (pts) experience relapse despite standard care of surgical resection ± radiotherapy. Upon relapse, pts with advanced disease receive palliative systemic therapy. Often reserved for pts with oligometastatic disease, the role of MTS remains unclear due to a lack of randomized trials. Longer time from curative surgery to relapse (TTR) is associated with better outcomes in LMS pts who undergo MTS but its prognostic value has not been established in those treated without MTS. This study evaluates the effect of TTR on outcomes in LMS pts with metachronous metastases treated with systemic therapy ± surgery. **Methods:** This real-world study included advanced LMS pts treated at 4 Canadian sarcoma centers (2010–2022) who underwent curative resection, subsequent relapse, and systemic treatment ± MTS. Data were retrieved from the ethics-approved Canadian Sarcoma Research and Clinical Collaboration (CanSaRCC) database. Primary and secondary endpoints were overall survival (OS) stratified by TTR ($<$ 6 vs $\geq$6 months from the completion of curative resection); and MTS, respectively. Exploratory analysis evaluated the impact of MTS in pts with low disease burden at relapse ($<$ 2 sites). Kaplan-Meier survival analysis and log-rank tests were used to compare OS, and Cox proportional hazards models identified independent predictors, with $p < 0.05$ considered significant. **Results:** A total of 113 pts (median age 56y) were included. Median follow-up was 38.4 months (mo). Majority (n = 93, 82%) were female and 38 (34%) had uterine leiomyosarcoma (uLMS). Relapse occurred in 109 pts (96%) with 73/109 pts (70%) having $<$ 2 metastatic sites at relapse. TTR was $<$ 6 months (TTR $<$ 6) in 31/109 pts (28%) and 43/109 pts (39%) underwent MTS. Pts with TTR $\geq$6 months (TTR$\geq$6) had significantly longer median OS (mOS) than those with TTR $<$ 6 (32.9 vs 15.6mo, p = 0.006). Metastasectomy was associated with a significantly longer mOS in the whole cohort (50.4 vs 17.6mo, $p < 0.0001$) as well as the subgroup of patients with $<$ 2 metastatic sites at relapse (50.6 vs 15.6mo, $p < 0.0001$). The mOS was 50.4 vs 24.7mo in pts with TTR$\geq$6 who underwent MTS and those who did not, respectively ($p < 0.0001$). Among pts with TTR $<$ 6 who had MTS, median OS was 44.8mo compared with 9.4mo in pts without surgery (p = 0.005). No other variables (e.g., tumor grade, primary site, metastatic burden, gender, or age) impacted OS. Both MTS (HR 0.26, 95% CI 0.16-0.49, p = 0.000) and TTR $\geq$ 6 (HR 0.55, 95% CI 0.33-0.91, p = 0.02) remained independent predictors of favorable OS in multivariate analysis. **Conclusions:** TTR$\geq$6 was associated with longer OS in LMS pts. OS improved significantly with MTS, particularly in pts with longer TTR, though those with TTR $<$ 6 also benefited to a lesser extent. These results underscore the role of MTS as part of an individualized treatment strategy to optimize outcomes in advanced LMS. Research Sponsor: None.

A phase Ib/II trial of radiotherapy combined with doxorubicin and PD-1 antibody for localized high-risk limbs and trunk soft tissue sarcomas. First Author: Yan Wang, Department of Radiation Oncology, Fudan University Shanghai Cancer Center, Shanghai, China

Background: Localized high-risk soft tissue sarcomas (STSs) presents a therapeutic challenge due to limited preoperative treatment options. Radiotherapy (RT) and Doxorubicin (DOXO) are well-established immunogenic cell death inducers [1-3], which are capable of boosting the effects of immunotherapy even in "cold" tumors. This study aims to evaluate the safety and efficacy of a preoperative triple combination of RT, DOXO, and the PD-1 antibody for STS. **Methods:** In this Phase Ib/II trial (NCT05774275), up to 52 patients with localized high-risk STSs will be enrolled. Participants will receive RT (BED = 50-60 Gy), combined with DOXO and PD-1 antibody (Sintilimab, SIN 200 mg, Day 1) every three weeks for four cycles prior to surgery. In Phase Ib (3+3 design), patients will receive Pegylated liposomal doxorubicin (PLD, 37.5 mg/m² or 30 mg/m², i.v., Day 1) to establish the recommended Phase 2 dose (RP2D). In Phase II, DOXO will be administered as PLD at RP2D or as Doxorubicin Hydrochloride (Adriamycin, ADM, 75 mg/m² i.v., Day 1). The primary endpoint is the objective response rate (ORR), while secondary endpoints include the rate of pathological complete response (pCR) and near pCR (defined as $<$ 10% viable tumor cells), survival and safety. **Results:** From September 2022 to January 2025, 33 patients (26 in limbs and 7 in trunks) were enrolled. The median age was 50 years (range 19-75), with 17 males, and 13 patients had prior surgeries. 29 tumors were histological grade 3. No dose-limiting toxicities (DLT) were observed in the first six patients receiving PLD (37.5 mg/m², i.v., Day 1, q3w), confirming the RP2D. Among the 28 radiological evaluable patients, 2 achieved complete response (CR), 12 achieved partial response (PR), and 11 had stable disease, resulting in an ORR of 50.0% and a disease control rate (DCR) of 89.2%. In addition, among 24 pathological assessable patients, 14 (58.3%) achieved pCR or near-pCR. Two patients (9.5%) experienced major wound complications. They underwent secondary operation and readmission to hospital for wound care, respectively. Other serious adverse events (SAE) include Grade 3 dermatitis (17.9%) and Grade 3-4 neutropenia (7.1%). No G5 SAE were reported. Median progression-free survival and overall survival have not yet been reached. **Conclusions:** The combination of RT, DOXO, and SIN showed potential efficacy and tolerable toxicity in high-risk localized limbs and trunk STS. The trial is still ongoing. Clinical trial information: NCT05774275. Research Sponsor: Beijing Xisike Clinical Oncology Research Foundation; Y-Young2020-0477; National Natural Science Foundation of China; 82373132.

Self-assembled patient-derived tumor-like cell clusters for personalized drug testing in diverse sarcomas. First Author: Tian Gao, Department of Bone and Soft Tissue Tumor, Peking University Cancer Hospital, Beijing, China

Background: Soft tissue sarcomas (STS) are rare malignancies with over 100 distinct histological subtypes. Their rarity and heterogeneity pose significant challenges to identifying effective therapies, and approved regimens show varied responses. Several patient-derived tumor models have emerged recently. However, STS present a challenge in developing preclinical drug-testing models due to their non-epithelial and complex nature. **Methods:** Here we report a model termed patient-derived tumor-like cell clusters (PTCs) derived from STS patients. PTCs result from the self-assembly and proliferation of mesenchymal stem cells (MSCs), epithelial cells, and immune cells, faithfully recapitulating the morphology and function of the original tumors. This is an trial to assess the feasibility and predictive value of a standardized PTC-based test to differentiate efficacy of the patients' clinical drug regimens. The study was conducted at Peking University Cancer Hospital and was approved by the local ethical review board. The patients and corresponding PTCs were divided into three sets: characterization and storage set, assay set and validation set. The characterization and storage set were used to characterize PTCs in comparison with original tumor samples or stored for future study. The assay set was separated into two groups to determine the drug efficacy concentration of a targeted therapy or chemotherapy due to their different action mechanisms. The validation set was used to compare the consistency between PTC drug assays and clinical outcome. We then conducted comparative analyses between PTCs and tumor spheres, as well as between PTCs and paired tumor samples. **Results:** From 2019 to the 2025, we obtained 254 samples (155 surgical, 98 puncture, and 1 ascites sample) to generate PTCs, covering tens of sarcoma classifications, with an overall success ratio of 94.9%, ranging from 85.7% to 100%. A total of 3,740 differentially expressed genes (DEGs) were identified between PTCs and tumor spheres, while 1,222 DEGs were identified between PTCs and tumor samples. Through standardized culture and drug-response assessment protocols, PTCs facilitate personalized drug testing, evaluating hundreds of therapies within two weeks. PTCs demonstrate an overall predictive accuracy of 78.3% for all clinical outcomes and 100% accuracy distinguishing CR/PR from PD, could serve as a valuable tool for personalized medicine. **Conclusions:** These findings revealed that PTCs as a tool to better understand the biology of individual tumors and characterize the landscape of drug resistance and sensitivity in sarcoma. These results underscore the potential of PTCs for prospective use in clinical decision-making therapy selection. Research Sponsor: None.

Population-based assessment of leiomyosarcoma (LMS) and cancers in the Li-Fraumeni syndrome (LFS) spectrum: Implications for genetic testing criteria. First Author: Wendy Kohlmann, Hunstman Cancer Institute at the University of Utah, Salt Lake City, UT

Background: Data regarding the heritability of rare tumors is limited and may prevent incorporation into genetic testing criteria. This study utilized the Utah Population Database (UPDB) to evaluate cancer risks among LMS cases and their relatives and the prevalence of meeting Chompret criteria (ChC) for LFS genetic testing. **Methods:** Between 1995-2021, 429 LMS cases with UPDB genealogies were identified from the Utah Cancer Registry. Diagnoses were confirmed, when possible, by pathology reports. Cases were individually age- and sex-matched 1:5 to population controls with similar pedigrees and follow-up (n=2145 controls). Cancers from 1966-2021 were obtained for study subjects and their first- through third-degree relatives. LFS spectrum cancers included breast, soft tissue sarcomas, osteosarcomas, CNS/brain, and adrenocortical. Hazard rate ratio (HRR) estimates of self- and familial relative cancer risks in LMS compared with controls was calculated from a Cox model adjusting for the number of relatives, degree of relatedness, and person-years at risk. **Results:** A 2.2-fold risk ($p<0.001$) of a cancer in the LFS spectrum was seen in cases with a non-uterine LMS site (n=323) at any age and a 4.5-fold risk ($p<0.001$) for developing an LFS cancer at age $<$50 y. Non-uterine LMS cases had similarly increased risks for developing a non-LFS-spectrum cancer at any age and $<$50y (Table). Increased risk of LFS or non-LFS-spectrum cancer was not seen in uterine LMS cases (n=106). Although increased cancer risk was not generally observed in relatives of LMS cases compared with control relatives, we observed that non-uterine LMS and their first-degree relatives had an increased risk of colorectal cancer (CRC) (Table). CRC is not an LFS cancer but is known to occur in LFS families. Excluding the LMS diagnosis, non-uterine LMS cases were more likely to meet ChC compared with controls (Table 1). Uterine LMS cases were no more likely to meet ChC than their respective controls. **Conclusions:** LMS is associated with cancers outside the spectrum, and further studies are needed to determine if LMS is associated with other cancer predisposition genes. Family history should be evaluated broadly and not restricted to ChC. As uterine LMS appears less likely to be associated with genetic predisposition, considering non-uterine and uterine cases separately may be important for future studies of the genetic basis of LMS. A propensity-score matched analysis for time to trabectedin-failure in advanced myxoid liposarcoma patients. First Author: Roberta Sanfilippo, Adult Mesenchymal and Rare Tumor Unit, Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy

Background: Whether to discontinue trabectedin (T) in soft-tissue sarcoma (STS) patients (pts) with response or stable disease remains controversial. In 2015, the T-DIS trial (Le Cesne et al., Lancet Oncology) showed a progression-free survival (PFS) benefit for T-maintenance after six cycles in STS patients. However, myxoid liposarcoma (MLPS) show a unique sensitivity to T, likely due to its specific mechanism of action. We retrospectively evaluated a "stop-and-go" strategy, in terms of time to treatment (T) failure (TTF) and overall survival (OS) in advanced MLPS pts. **Methods:** We carried out a retrospective analysis of 79 MLPS pts treated with T at our institution from September 2002 to December 2024. Inclusion criteria required pts to be progression-free (per RECIST) after 6 cycles of T. TTF was defined as the time from the 6th cycle to secondary resistance to T or death, whichever occurred first. Statistical methods included Kaplan-Meier survival analysis and propensity-score matched Cox proportional hazards models (weighted and unweighted) with time-dependent variables. **Results:** 60 MLPS pts were eligible for analysis (median age: 48 years, IQR: 39–57; 37 males, 23 females). Of these, 27 (34%) pts were treated with a "stop-and-go" strategy, discontinuing T after achieving radiological response or disease stability. T was discontinued at a median of 12 cycles (range: 6-28). Median follow-up was 56.9 months (IQR: 28.1–112.5), with a median TTF of 51.4 months (95% CI: 37.1– NA) in the "stop-and-go" group versus 10.0 months (95% CI: 6.6–17.7) in the T-maintenance group. OS was 55 months (95% CI 38.5 - NA) vs 23 months (95% CI 21-27.9) in the two groups, respectively. Weighted Cox models predicted an HR of 0.32 (95% CI: 0.11–0.93) for TTF and of 0.28 (95% CI 0.07 – 1.12) for OS, thus favoring the stop-and-go approach. Additional factors, including ECOG performance status (PS), age, primary tumor site, and surgery post-T discontinuation, were adjusted in the analysis. **Conclusions:** Our findings raise the question whether a "stop-and-go" strategy with T is the best option in the subset of MLPS pts. How to test further this hypothesis in such a rare subset, and which predictive factors may optimize the approach, is questionable. Research Sponsor: None.

Moving beyond the traditional two-step approach for prognosis prediction: The BayeSarc model. First Author: Gabriele Tine', Biostatistics for Clinical Research, Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy

Background: Extremity Soft tissue sarcomas (eSTS) are rare and heterogeneous, limiting the collection of large datasets for robust predictive modeling. Sarculator, a Cox model-based tool for overall survival (OS) prediction, was built using the traditional two-step paradigm (1) model building and (2) external validation. However, this method can underperform on external cohorts, often yielding low predictive accuracy and limited generalizability. We introduced a Bayesian Sequential Learning strategy to iteratively refine Sarculator, incorporating new data while preserving prior properties. **Methods:** The initial model was built on the Italian Sarculator development cohort, with age, tumor size, tumor grade, and histology as covariates. Sequential updates were then performed with the three original Sarculator external validation cohorts , and a more recent Italian cohort. Each step used the results from the previous update as prior information for the next. Performance was assessed as discriminative ability (C-index) and calibration. Key differences from the original Sarculator were Bayesian Cox modelling, and a piecewise-constant hazard. **Results:** The two-step approach yields separate performance metrics for each cohort, making generalizability unclear when performance drops (e.g. French cohort, Table). Conversely, the sequential approach progressively increases the total information (number of patients and follow-up), without discarding previous evidence, and readjusts performance metrics at each step. Occasional declines in the C-index reflect cohort-specific divergences but can be reversed in subsequent updates if newer cohorts share similar features. Ultimately, the final BayeSarc outperformed the initial model in discriminative ability, calibration, and reduced uncertainty in predictions. **Conclusions:** BayeSarc is an accurate, generalizable OS prediction model for eSTS, preserving external validation properties while moving beyond the conventional two-step approach. By building on prior evidence, the model dynamically adapts over time, ultimately relying on 4713 patients, with results independent of cohort order. BayeSarc sets a benchmark for future rare-disease prognostic research, paving the way for incorporating new cohorts and/or prognostic variables (e.g. emerging biomarkers). Research Sponsor: None.

Clinical and prognostic implications of the TCR repertoire in leiomyosarcoma. First Author: John Seng Wang, Northwestern University Feinberg School of Medicine, Chicago, IL

Background: Leiomyosarcomas (LMS) are aggressive mesenchymal tumors sometimes classified by primary location as uterine LMS (uLMS) versus extra-uterine LMS (eLMS). In pursuit of novel therapies, study of the tumor microenvironment and the repertoire of T-Cell Receptor (TCR) sequences from infiltrating T-lymphocytes could help guide the application of immunotherapy in LMS. Herein, we explore the first ever database of TCR-sequenced LMS tumors in one of the larger LMS cohorts analyzed to date. **Methods:** A single-institution retrospective study was performed including 117 adult patients with pathology-confirmed LMS diagnosed between 1998 and 2022 at Northwestern Medicine. Overall survival (OS), progression free survival (PFS), and relapse free survival (RFS) were analyzed using Kaplan-Meier Curves (GraphPad Prism). DNA was extracted from 61 eLMS and 39 uLMS formalin-fixed paraffin-embedded (FFPE) blocks using Qiagen's AllPrep DNA/RNA FFPE kit and used for TCR sequencing. **Results:** 117 patients who met the inclusion criteria were classified as uLMS (n=54) and eLMS (n=63). Baseline patient demographics and disease characteristics are described in the table. Median OS significantly differed between uLMS and eLMS patients (559 versus 1548 days; p=0.001). Median PFS was not statistically different between metastatic uLMS versus eLMS (142 versus 159 days; p=0.63). Median RFS was not significantly different between localized uLMS versus eLMS (283 versus 429 days; p=0.30). The number of different TCR clones amongst TCRs was significantly different between the two tumor types: uLMS demonstrated a mean of 821 clones versus 2415 clones in eLMS (p=0.005). Mean CDR3 length in uLMS tumors was 47.9 (95% CI 46.53-49.25) versus 48.45 (95% CI 46.66-50.25) in eLMS tumors (p=0.10). TRBV20 was the most common gene in uLMS cases and the second most common gene in eLMS cases. **Conclusions:** This study provides the first analysis of the TCR repertoire in LMS patients and the largest analysis of TCR repertoire ever reported in any sarcoma subtype. eLMS tumors contained significantly more TCR clones than uLMS tumors. CDR3 did not significantly differ between cohorts, and the TRBV20 gene was frequently identified in both LMS subtypes. Further gene expression analysis and immunohistochemistry is currently underway. As might be expected, clinical outcomes were worse for uLMS including significantly lower OS. Updated data will be presented including additional information about the TCR repertoire as well as gene expression data to contextualize these findings. Research Sponsor: None.

Ramucirumab in pediatric and young adult patients (Pts) with relapsed/refractory (R/R) desmoplastic small round cell tumor (DSRCT) or synovial sarcoma (SS): Results from the CAMPFIRE study. First Author: Emily K. Slotkin, Memorial Sloan Kettering Cancer Center, New York, NY

Background: Few effective therapies exist for pts with R/R DSRCT and SS, and hence, their prognosis remains poor. Preclinical data suggested the relevance of vascular endothelial growth factor receptor 2 (VEGFR2) inhibition in these diseases. We evaluated the efficacy of ramucirumab (RAM, VEGFR2 receptor antagonist) + chemotherapy vs. chemotherapy alone in pediatric and young adult pts with R/R DSRCT (JV01) or SS (JV02). **Methods:** JV01 and JV02 were randomized, global, multicenter, Phase 1/2 studies in pts aged ≤29 years with R/R DSRCT or SS and evaluated pts treated with RAM + cyclophosphamide/vinorelbine (CV; JV01) and RAM + gemcitabine/docetaxel (GD; JV02). Pts were randomized 2:1 to the experimental and control groups. The primary endpoint was progression-free survival (PFS) per RECIST v1.1, analyzed via a Bayesian hierarchical model allowing adaptive borrowing on effect size (log hazard ratio [HR]) between JV01 and JV02 and control arm augmentation with historical (real world) data. Interim futility required a probability (Pr) of PFS (HR < 1) $> 60\%$, and intervention success at final analysis was declared at Pr $> 99\%$. Frequentist analysis (1-sided $\alpha = 0.1$) was performed as a sensitivity analysis. Safety was a secondary endpoint. **Results:** Baseline characteristics were balanced between the treatment arms in both studies: RAM+CV, n = 20; CV, n = 10; RAM+GD, n = 16; GD, n = 7. JV02 met the futility criterion (Table) and was suspended without completing enrollment. JV01 fully enrolled but did not meet the primary endpoint at the final analysis (PFS HR = 0.7, 98% credible interval = 0.3, 1.7; pr [HR < 1] = 86.4% vs. 99%). However, frequentist analysis in JV01 showed that pts in the RAM+CV arm had a numerical improvement of 5 months in median PFS vs. the CV arm. Overall, no significant safety events were reported in either study. **Conclusions:** The PFS outcome was not met for either rare disease. The numerical trend in JV01 is noteworthy, especially considering the limited treatment options available for DSRCT. Safety was consistent with the known profiles of the individual treatments and the population. Clinical trial information: NCT04145700, NCT04145349. Research Sponsor: Eli Lilly and Company.

Global inequities in sarcoma clinical trials: A comprehensive analysis over the last decade. First Author: Shushan Hovsepyan, Yerevan State Medical University, Immune Oncology Research Institute, Yerevan, Armenia

Background: Sarcomas are rare, comprising 15% of childhood cancers and 1% of adult cancers, yet survival rates remain poor. The overall 5-year survival for soft tissue sarcomas (STS) is 65%, dropping from 81% for localized disease to just 16% for metastatic cases. For bone sarcomas, survival declines from 84% at localized stages to 31% for metastatic cases. This highlights the critical need for novel therapies and equitable research access. To address this, the current review discusses sarcoma clinical trials conducted over the past decade. **Methods:** Sarcoma-related clinical trials registered on ClinicalTrials.gov from 2016 to 2025 were analyzed. Variables included study status, conditions, phases, randomization, dates, country, age groups, sample size, sponsor, and reasons for discontinuation. Geographic data were categorized by World Bank income levels. Descriptive statistics summarized key characteristics. **Results:** Out of 1,232 studies, 65% were focused exclusively on sarcomas. Alarmingly, only 0.4% of the studies were conducted in low-income countries (LICs) and only 18% in low- and middle-income countries (LMICs), underscoring a profound underrepresentation of these regions in sarcoma research. Recruitment status varied, with 39% of trials actively recruiting, 18% completed, and 14% terminated—predominantly due to challenges in participant accrual. Early-phase trials predominated, comprising 34% in phase 1 and phase 1/2, and 30% in phase 2. Late-phase and post-marketing studies were sparse, representing only 5%. Interventional trials accounted for 82% of the total, though most lacked randomization. The majority of studies (72%) were academia-sponsored trials. Only 1% of studies were exclusively dedicated to pediatric populations, while 36% included both adults and children, and 63% enrolled adults exclusively. The median sample size was 46 participants (IQR 22–117), and the median study duration was 47 months (IQR 29–70). There are no trend changes in the number of studies that were launched from 2016 to 2024. **Conclusions:** Our study highlights inequities in the geographic distribution of sarcoma trials, and the substantial neglect of LICs and pediatric populations. This underscores an urgent need for global efforts to address these disparities and enhance inclusivity in clinical research. Research Sponsor: None.

NF1- and non-NF1–associated malignant peripheral nerve sheath tumors (MPNST): The University of Texas MD Anderson (MDACC) experience. First Author: Reeja Raj, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: MPNSTs are aggressive sarcomas with poor prognosis due to their high propensity for metastasis, rapid growth and limited response to standard chemotherapy (CT). While commonly associated with neurofibromatosis type 1 (NF1), they can also occur sporadically (non-NF1). This study aims to evaluate baseline characteristics and outcomes in NF1 and non-NF1 associated MPNST in order to understand CT effectiveness and set a benchmark for future therapies. **Methods:** A retrospective chart review was conducted at MDACC, including 258 patients diagnosed with MPNST (173 NF1 and 85 non-NF1). Data collected included demographic information, primary tumor location and size, disease stage at diagnosis (localized vs. metastatic), efficacy of CT regimens utilized, and survival data. Descriptive statistics were used to summarize patient characteristics. Chi squared tests or Fisher's exact tests, and t-test/ANOVA were used to compare patient's characteristics and distributions of overall survival (OS), and progression-free survival (PFS) were estimated by the Kaplan-Meier method. **Results:** Median age at diagnosis was 33 yrs (IQR 22-44) and 50 yrs (IQR 38-61), and median tumor size at diagnosis 7.4cm and 6.3cm for the NF1 and non-NF1 cohorts, respectively. Tumors were most commonly located in the trunk, followed by the lower extremity, with head and neck involvement more frequent in non-NF1 cases. Metastatic disease was present at diagnosis in 28.3% of NF1 (49/173) and 22.4% (19/85) of non-NF1 cases. Adriamycin with Ifosfamide (AI) was the most utilized first-line CT regimen while gemcitabine plus docetaxel was the preferred second-line regimen. 154 patients, 87 patients, and 37 patients received frontline, second-line, and third-line CT, respectively. Median PFS for front-line CT was 8.0 months (4.7, NR) for patients with metastatic disease at presentation and 11.7 months (8.94, NR) for patients who received AI. Median OS was 2.34 yrs (1.88, 3.15) vs 1.81 yrs (0.89, 3.76) for NF1 and non-NF1 cohorts (p = 0.038), respectively. 5-yr OS was 42% (33, 51) for local disease and 9% (3, 19) for metastatic disease at presentation. Additional analysis of PFS by NF1 status, lines of therapy, and regimen will be presented at the conference. **Conclusions:** Patients with metastatic MPNST have dismal outcomes and CT efficacy and utilization drops after frontline treatment. These findings highlight the importance of early diagnosis and tailored novel therapeutics for MPNST patients. Research Sponsor: None.

Enhancing soft tissue sarcoma surveillance: The role of ctDNA testing in early detection and monitoring beyond traditional imaging. First Author: Amrit Paudel, University of Miami Sylvester Comprehensive Cancer Center/Jackson Health System, Miami, FL

Background: Soft tissue sarcoma (STS), particularly large (>5 cm), intermediate to high grade, and aggressive subtypes, is associated with high relapse rates, necessitating effective surveillance. Traditional methods, including physical exams and radiologic imaging, can be inconclusive, leading to radiation exposure. Circulating tumor DNA (ctDNA), a biomarker from tumor-derived cell-free DNA in the bloodstream, offers a potential solution for early recurrence detection and treatment monitoring. While ctDNA has shown promise in various cancers, its role in STS remains under-explored. **Methods:** We conducted a retrospective analysis of localized, high-risk STS patients who underwent surgery, followed by standard imaging, physical exams, and Signatera ctDNA testing from April 2023-January 2025. The study evaluated the concordance between ctDNA positivity and imaging findings, with a subgroup analysis exploring metastatic patterns and molecular profiles in ctDNA-positive patients. Mann-Whitney test was conducted to evaluate the difference in time to progression between ctDNA and imaging. **Results:** The cohort consisted of 63 STS patients, including 501 plasma samples for Signatera ctDNA testing alongside routine imaging. The patient population was 52% female, 35% Hispanic, and 80% White. ctDNA assay was performed on an average of 8 $\pm$ 4 plasma samples per patient, over a median surveillance duration of 12 months. Of the 63 patients, 18 tested positive for ctDNA. There was no significant difference (p=0.984) in the time to progression between ctDNA testing (35 $\pm$ 17.6 months) and radiological imaging (34.3 $\pm$ 18.5 months). Our data also revealed that all patients with negative ctDNA results had corresponding negative imaging findings. In the subgroup analysis of ctDNA-positive patients, majority had pulmonary metastasis (7, 39%), followed by liver metastasis (3, 16%). Molecular profiling demonstrated significant heterogeneity, with TP53 mutations being the most common alteration, present in 4 (22%) patients. **Conclusions:** Our study demonstrates the potential utility of ctDNA testing in monitoring high-risk STS patients. ctDNA showed no significant difference in time to progression compared to traditional imaging and offers a non-invasive alternative with strong concordance with imaging results, particularly for patients with negative ctDNA findings. These findings underscore the potential of ctDNA as a complementary tool to traditional surveillance methods, potentially reducing reliance on radiologic imaging and enhancing personalized treatment strategies. Research Sponsor: None.

Phase 1a/1b study of the safety, pharmacokinetics, and antitumor activity of ziftomenib in combination with imatinib in patients with advanced gastrointestinal stromal tumors (GIST) after imatinib failure. First Author: Mrinal M. Gounder, Memorial Sloan Kettering Cancer Center and Weill Cornell Medical School, New York, NY

Background: GIST is the most common mesenchymal neoplasm of the digestive tract and is mainly driven by gain-of-function oncogenic mutations in the receptor tyrosine kinase KIT. Patients with GIST are typically treated with anti-KIT tyrosine kinase inhibitors (TKIs) such as imatinib. However, few patients achieve a complete response, and most eventually progress due to secondary alterations in *KIT* that cause resistance to therapy. Additional TKIs are approved in later lines but have shown only moderate clinical outcomes, highlighting the need for additional therapeutic approaches. Preclinical studies have shown that the menin-KMT2A complex epigenetically upregulates *KIT* expression in GIST cells. Ziftomenib is a potent and highly selective menin inhibitor that disrupts formation of the menin-KMT2A complex. Ziftomenib plus imatinib has demonstrated synergistic antitumor activity in imatinib-sensitive and -resistant GIST models, with reduced KIT protein levels and downstream oncogenic signaling observed in imatinib-resistant GIST patient-derived xenografts treated with the combination. Together, ziftomenib plus imatinib may enhance KIT recycling while reducing *KIT* transcription. This combination is currently being investigated clinically in patients with imatinib-sensitive and -resistant advanced GIST. **Methods:** KOMET-015 (NCT06655246) is a phase 1a/1b, open-label study to determine the safety, tolerability, recommended phase 2 dose (RP2D), and preliminary antitumor activity of ziftomenib plus imatinib (400 mg) for advanced/metastatic GIST. KOMET-015 includes dose-escalation, RP2D determination, and dose-expansion parts. Eligible patients ($\geq$18 yrs) must have a biopsy-proven diagnosis of advanced/metastatic *KIT*-mutant GIST (T670X excluded) that progressed on imatinib (dose-escalation and RP2D determination parts), with an ECOG PS of $\leq$2 and measurable disease per modified RECIST (mRECIST). Dose escalation will be based on an i3+3 design to evaluate the safety and tolerability of up to 4 dose levels of ziftomenib combined with imatinib. Based on escalation, up to 2 dose levels will be selected for comparison to determine the RP2D. The dose-expansion part will examine the toxicity and preliminary clinical activity of the RP2D in patients assigned to 1 of 3 cohorts: Cohort A: patients who progressed on imatinib as immediate prior therapy, Cohort B: patients who failed imatinib and had received $\geq$2 lines of therapy, and Cohort C: imatinib-naive patients. Tumor response will be assessed per mRECIST. All adverse events will be recorded, monitored, and graded based on CTCAE v5.0. The trial is open and actively recruiting with sites in the United States. Clinical trial information: NCT06655246. Enrollment opens Feb 2025. Research Sponsor: Kura Oncology, Inc.

TPS11579 **Poster Session**

SARC044: A phase II trial of bezuclastinib in combination with sunitinib in patients with GIST who progressed on sunitinib monotherapy. First Author: Candace L. Haddox, Dana-Farber Cancer Institute, Boston, MA

Background: Gastrointestinal stromal tumors (GIST) are commonly driven by mutations in the receptor tyrosine kinase *KIT*. Resistance to approved tyrosine kinase inhibitors (TKIs) arises from additional KIT mutations in the ATP-binding pocket (AP) and activation loop (AL). No single approved TKI broadly suppresses all resistant clones, and overlapping VEGFR inhibition and toxicity limits TKI combinations. The type I TKI bezuclastinib ("BEZ," CGT9486) inhibits KIT AL resistance mutations, does not inhibit VEGFR, and has complimentary activity with sunitinib ("SUN," inhibitor of KIT AP resistance mutations). The first-in-human study (PLX121-01) and ongoing Peak trial (NCT05208047) evaluated BEZ+SUN showing promising safety and efficacy in GIST. SARC044 investigates BEZ+SUN in patients (pts) with SUN-resistant, KIT-mutant GIST, and correlatives aim to determine mechanisms of response and resistance (NCT06208748). **Methods:** SARC044 is a multi-center, open label, single-arm phase II trial enrolling up to 40 adult pts with KIT exon 9 or 11-mutant GIST resistant to imatinib and SUN. After TKI washout (baseline, "b/l"), pts initiate BEZ 600 mg daily for 2 weeks, then add SUN 37.5 mg daily, taking both drugs continuously (28-day cycles) until mRECISTv1.1 progression or unmanageable toxicity. Response evaluations (RE) are performed every 8 weeks (wk) through 15 months (mo) on study, then every 12 wk. Circulating tumor DNA (ctDNA) is collected at b/l, cycle 1 day 15 (C1D15), C2D1, C3D1, and progression. Targeted exome sequencing (TES) of ctDNA will track primary/resistant KIT mutation dynamics across therapy. ^{18}FDG PET/CTs are performed in 20 pts at b/l, C1D15, and C2D1, which guide a biopsy of a resistant tumor. TES, allele-specific and long-read PCR (to detect AP+AL mutation phasing), and immunoblotting (evaluating KIT pathway activation) will be performed on tissue. EORTC QLQ-C30 surveys collect pt-reported outcomes (PRO) at b/l, on treatment, and at progression. The primary endpoint is median progression-free survival (mPFS) and secondary endpoints include overall survival at 1 and 2 years, clinical benefit rate at 16 wk, adverse event rate, PRO, and KIT mutation profile in ctDNA and tissue. 35 evaluable pts achieves 83% power ($p<0.05$, one-sided) in a one-sample log-rank test to detect a mPFS of 6.5 mo vs 4 mo (historic control). Expected accrual is 12 mo across 4 sites in the United States with ~36 mo to study completion. Clinical trial information: NCT06208748. Research Sponsor: Cogent Biosciences; Life Raft Group; Brown Family Fund; Conquer Cancer©, the ASCO Foundation.

An open-label phase 1/2 study of DCC-3009 monotherapy in patients with advanced gastrointestinal stromal tumor. First Author: Sreenivasa R. Chandana, START Midwest, The Cancer & Hematology Centers, Grand Rapids, MI

Background: Gastrointestinal stromal tumor (GIST) is the most common sarcoma of the gastrointestinal tract. *KIT* and platelet-derived growth factor receptor α (*PDGFRA*) mutations remain the key oncogenic drivers in the majority of patients with advanced GIST, with acquired secondary drug-resistant mutations contributing to the heterogeneity and complexity of the disease. The diversity of these resistance mutations allows escape from standard-of-care tyrosine kinase inhibitor (TKI) therapy, creating an unmet need for novel therapies that inhibit all clinically relevant GIST-driving mutations. DCC-3009 is an investigational, highly potent, and selective switch-control KIT and PDGFRA inhibitor designed to act against known clinically relevant primary and secondary GIST-driving mutations while limiting off-target effects. Preclinical data showed that DCC-3009 has strong antitumor effects in xenograft models driven by resistant *KIT* mutations, optimized solubility and oral bioavailability, and low risk of cytochrome P450 inhibition. Here, we describe an ongoing phase 1/2 study evaluating DCC-3009 as a monotherapy in patients with advanced GIST. **Methods:** This study is a multicohort, open-label, phase 1/2 trial evaluating the safety, tolerability, and efficacy of DCC-3009 in patients with advanced GIST (NCT06630234). This trial uses a modular approach, with each module defined according to the therapy (DCC-3009 alone or in combination with other anticancer agents) and divided into 2 parts (dose escalation and dose expansion). For inclusion in the DCC-3009 monotherapy dose escalation, adult patients ($\geq$18 years) must have histologically or cytologically confirmed advanced GIST with documented *KIT* or *PDGFRA* mutation and progression on or intolerance to at least 1 approved TKI regimen in the advanced setting (imatinib if *KIT*-mutant). Patients must have at least 1 measurable lesion per modified Response Evaluation Criteria in Solid Tumors version 1.1 (mRECIST v1.1) and an Eastern Cooperative Oncology Group Performance Status of 0 or 1 at screening. Exclusion criteria include receiving systemic anticancer therapy (encompassing investigational agents) within 14 days or less than 5 half-lives, radiotherapy within 14 days prior to first dose of study drug, prior or concurrent malignancy requiring treatment or expected to need treatment for active cancer, known allergy or hypersensitivity to the study drug components or any of its excipients, and impaired oral absorption or malabsorption syndrome. Enrolled patients across monotherapy dose escalation will receive DCC-3009 orally in 28-day cycles. The primary outcome measures for monotherapy dose escalation include safety assessment. Secondary outcome measures include objective response rate, duration of response, and progression-free survival by mRECIST v1.1, as well as overall survival and pharmacokinetics. Clinical trial information: NCT06630234. Research Sponsor: Deciphera Pharmaceuticals, LLC.

TPS11581 **Poster Session**

PYNNACLE phase 2 clinical trial of rezatapopt in patients with advanced solid tumors harboring a *TP53* Y220C mutation. First Author: Alison M. Schram, Memorial Sloan Kettering Cancer Center, New York, NY

Background: *TP53*, encoding p53 protein, is one of the most frequently mutated genes across all cancers, with TP53 mutations found in ~59% of all solid tumors. *TP53* mutations result in the loss of p53 tumor suppressor functions leading to tumor development and progression. The *TP53* Y220C mutation, occurring in ~1% of all solid tumors, is a missense mutation that destabilizes the p53 protein. Rezatapopt (also known as PC14586) is an investigational, first-in-class, selective, p53 reactivator specific to the *TP53* Y220C mutation that restores wildtype p53 function. Preliminary findings from Phase 1 part of the PYNNACLE (NCT04585750) Phase 1/2 study, showed that rezatapopt had a favorable safety profile and single-agent efficacy in heavily pre-treated patients with solid tumors harboring a *TP53* Y220C mutation (*Schram A, AACR-NCI-EORTC 2023, LBA25*). Here we describe the study design for the registrational Phase 2 part of the PYNNACLE study. **Methods:** The Phase 2 part of PYNNACLE is an ongoing, global, single-arm, open-label, multicenter basket trial in patients with solid tumors harboring a *TP53* Y220C mutation (Table). Patients must have measurable disease at baseline, ECOG performance status 0 or 1, and adequate organ function; other key inclusion criteria are listed in the table. Patients with *KRAS* single nucleotide variants, primary CNS tumors and unstable brain metastases are excluded. Eligible patients receive rezatapopt 2000mg, orally, once daily, taken with food, for continuous 21-day cycles. Patients are followed until death, lost to follow-up, two years after last patient discontinuation, or end of study. As of March 2024, ≈114 patients are planned to be enrolled. Clinical trial information: NCT04585750. Research Sponsor: PMV Pharmaceuticals, Inc.

Phase 3 study of ivosidenib vs placebo in locally advanced or metastatic IDH1-mutant conventional chondrosarcoma untreated or previously treated with 1 systemic treatment regimen (CHONQUER). First Author: Andrew J. Wagner, Dana-Farber Cancer Institute, Boston, MA

Background: Conventional chondrosarcoma (CS) is the most common chondrosarcoma subtype, accounting for 85% to 90% of all chondrosarcoma cases. A meta-analysis of 466 patients with CS reported the detection of IDH1/2 mutations in 51.2% of patients (38.7% IDH1 and 12.1% IDH2 mutations, mutually exclusive except for one case). In a phase 1 study (NCT02073994), the long term follow-up with a data cut-off date of 15 September 2022, showed that patients with advanced conventional CS (N = 13) who were treated with the IDH1 inhibitor ivosidenib had a median progression-free survival (PFS) of 7.4 months, a 6-month PFS rate of 53.8%, and an overall response rate (ORR) of 23.1% including 2 partial responses and 1 complete response. Ivosidenib demonstrated manageable toxicity with mostly grade 1 or 2 treatment emergent adverse events (AEs) (Tap et al. J Clin Oncol. 2023; 41:11532). The current phase 3 CHONQUER study was designed to assess the efficacy and safety of ivosidenib treatment in patients with grades 1, 2 and 3 conventional CS. **Methods:** The CHONQUER study (NCT06127407) is a phase 3, international, multicenter, double-blind, randomized, placebo-controlled study of ivosidenib for patients with locally advanced or metastatic IDH1 mutant conventional CS untreated or previously treated with 1 systemic treatment regimen. Key eligibility criteria include a histopathological diagnosis of conventional CS (grades 1, 2, or 3), locally-advanced or metastatic setting not eligible for curative resection; ECOG PS 0-1; measurable disease as defined by Response Evaluation Criteria in Solid Tumors (RECIST v1.1); received 0 or 1 prior systemic treatment regimen in the advanced/metastatic setting for CS; radiographic progression/recurrence of disease over a period of 6 months according to RECIST v1.1 and IDH1 gene-mutated disease confirmed by central laboratory testing with the Ion Torrent Oncomine Dx Express Test. A total of 136 patients are planned to be enrolled and will be randomized 1:1 to ivosidenib or a matched placebo control. Randomization will be stratified by disease grade (grade 1 versus 2 versus 3) and locally advanced versus metastatic disease. The primary endpoint is PFS confirmed by Blinded Independent Central Review (BIRC) in grade 1 and 2 patients. The key secondary endpoints include PFS based on BIRC for all randomized patients, overall survival (OS) (both grade 1 and 2 and all randomized patients). Other secondary endpoints include PFS by investigator, overall response, duration of response, time to response, disease control, duration of disease control, adverse events, and health-related quality of life. 92 sites from 12 countries are planned to participate, including North and South America, Europe and Asian countries. Clinical trial information: NCT06127407. Research Sponsor: Servier.

TPS11583 Poster Session

Phase I/II study to evaluate the feasibility and efficacy of sequential abemaciclib and gemcitabine treatment in patients with retinoblastoma (Rb)-positive leiomyosarcoma (LMS) and dedifferentiated liposarcoma (DDLPS). First Author: Elise F. Nassif Haddad, Department of Sarcoma Medical Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: LMS and DDLPS are aggressive malignancies with limited effective therapies in the advanced setting. Approximately 50% of LMS and nearly all DDLPS retain functional Rb protein, suggesting sensitivity to cell cycle inhibition. Our preclinical studies have demonstrated that combining sequential abemaciclib, a selective CDK4/6 inhibitor that induces cell cycle arrest, followed by gemcitabine timed with synchronized cell cycle reentry, results in synergistic antitumor activity in Rb-positive sarcomas. Sequential administration of abemaciclib followed by gemcitabine enhances apoptosis, impairs DNA repair mechanisms, and induces sustained cell cycle arrest. **Methods:** This is a multicenter, open-label, phase 1/2 clinical trial conducted through the National Cancer Institute (NCI), enabling broad, nationwide patient enrollment. The phase 1 dose-escalation portion will determine the maximum tolerated dose and recommended phase 2 dose of sequential abemaciclib and gemcitabine in patients with advanced/metastatic soft-tissue sarcomas. Part A of phase 1 will use biomarkers of cell cycle (functional positron emission tomography imaging using [18]F-fluoro-3′-deoxy-3′-L-fluorothymidine and thymidine kinase activity) to determine the optimal schedule of sequencing. Part B of the phase 1 will follow the BOIN design. Eligible patients must have histologically confirmed LMS or DDLPS with Rb positivity confirmed by immunohistochemistry, measurable disease, ECOG performance status $\leq$2, and adequate organ function. Prior gemcitabine therapy is permitted in phase 1 but excluded in phase 2. Phase 1 Part A is restricted to MD Anderson only enrollment due to the requirements of biomarker integration and timing. In the randomized phase 2 portion, patients will be randomized 1:1 (stratified by DDLPS vs LMS) to receive either (1) sequential abemaciclib followed by gemcitabine or (2) gemcitabine and docetaxel. The primary endpoint is progression-free survival, with secondary endpoints including objective response rate, overall survival, and safety. Correlative studies will analyze tumor biopsies and blood samples collected at baseline, after two treatment cycles, and at disease progression. Biomarker analyses will include RB1 expression profiling, whole exome sequencing, RNA sequencing, and circulating tumor DNA. Clinical trial information: NCT06498648. Research Sponsor: ETCTN - CTEP.

TPS11584 Poster Session

A phase 3, randomized, double-blind, placebo-controlled study to assess the efficacy and safety of emactuzumab in patients with tenosynovial giant cell tumor (TANGENT). First Author: Hans Gelderblom, LUMC Leids Universitair Medisch Centrum, Leiden, Netherlands

Background: Tenosynovial giant cell tumor (TGCT) is a rare, non-malignant, locally aggressive tumor of the synovium, primarily affecting knee, hip, and ankle joints. TGCT is caused by excessive production of colony stimulating factor 1 (CSF-1), a cytokine involved in the proliferation, differentiation, and survival of monocytes and macrophages. It is a chronically debilitating disease, causing pain, stiffness, loss of function in the affected joints and a decline in quality of life. The worldwide incidence in digits, localized, and diffuse TGCT is about 29, 10, and 4 per million person-years, respectively. Surgery remains the principal treatment option, at the cost of a high rate of tumor recurrence, and risk of damage to the affected joint and surrounding tissues. Systemic treatment options are limited. Emactuzumab is a novel monoclonal antibody, and potent and specific CSF-1 receptor (CSF-1R) antagonist, that causes apoptosis of M2-type macrophages in the tumor micro-environment, thereby inhibiting tumor growth. In a phase Ia/b study, emactuzumab was administered i.v. at doses varying from 900-2000 mg (cycles ranging 1-14) in advanced diffuse TGCT patients (Cassier et al, EJC, 2020). Emactuzumab was well tolerated and showed rapid and pronounced responses with an objective response rate (ORR) of 71%, which was durable with an ORR of 70% and 64% after one or two years, respectively. Clinical activity was associated with symptomatic improvement. The optimal biological dose of emactuzumab, defined as 1000 mg q2w, is under investigation in the Phase 3 trial. Emactuzumab was granted an Orphan Drug Designation by the European Medicines Agency in March 2022. **Methods:** TANGENT (NCT05417789) is a randomized, double-blind, placebo-controlled trial designed to confirm the efficacy and safety of emactuzumab in TGCT patients not amenable for surgery. The primary endpoint is efficacy, assessed as ORR at 6 months by MRI per RECIST v1.1. Key secondary endpoints include patient-reported outcomes (PROMIS-PF), range of motion, pain and stiffness, and other antitumor activity (e.g. TVS). In Part 1, subjects will be randomized 2:1 to receive either emactuzumab 1000 mg or placebo i.v. q2w for 5 doses over 10 weeks, followed by an observation period of 3 months. Part 2 is a follow-up phase from 6-24 months post randomization during which subjects whose TGCT worsens may be eligible for emactuzumab. The study is actively recruiting. Assessments include tumor evaluation, physical examination, vital signs, electrocardiograms, questionnaires, urinalyses, and blood tests for hematology, biochemistry, and PK of emactuzumab. Safety will be assessed by laboratory assessments and evaluation of adverse events. Clinical trial information: NCT05417789. Research Sponsor: SynOx Therapeutics.

TPS11585 Poster Session

ETCTN 10563: A phase I study of peposertib and liposomal doxorubicin for advanced or metastatic leiomyosarcoma and other sarcomas. First Author: Candace L. Haddox, Dana-Farber Cancer Institute, Boston, MA

Background: Soft tissue sarcomas (STS) with genomic complexity are often aggressive but may be sensitive to further genotoxic stress. Leiomyosarcoma (LMS), a common STS, frequently harbors genomic complexity and DNA damage response (DDR) dysregulation. Preclinical data showed hyper-dependency on DNA-PK-mediated non-homologous end joining (NHEJ) DDR, and low-dose liposomal doxorubicin (LD-LPD) synergized with the DNA-PK inhibitor peposertib to inhibit tumor growth in LMS models. We hypothesize that a low, sensitizing dose of LPD enhances DNA damage and safely synergizes with peposertib in LMS and other genomically complex STS. **Methods:** This phase 1, open label, multicenter dose escalation and dose expansion study (NCT05711615) evaluates LD-LPD given intravenously (IV) on day 1 of 28-day cycles with peposertib given orally (PO) twice daily (BID) continuously (Table). Up to 18 patients (pts) over 18 years-old with advanced or unresectable LMS, undifferentiated pleomorphic sarcoma, myxofibrosarcoma, dedifferentiated liposarcoma, and synovial sarcoma, ECOG performance status $\leq$2, who received $\geq$1 prior line of systemic therapy (including anthracycline $\leq$300 mg/m^2) are eligible for dose escalation. Dose expansion will include 12 pts with LMS. The primary objective is to determine the recommended phase 2 dose of LPD+peposertib based on the dose limiting toxicity rate. The Bayesian Optimal Interval (BOIN) design will inform dose escalation decisions. Secondary endpoints for the expansion cohort include adverse event rate, progression-free survival, and objective response rate per RECIST v1.1. Potential predictive biomarkers and changes in DDR biomarkers will be evaluated on biopsies during screening and at cycle 1 day 7. Circulating tumor DNA (ctDNA) collected at baseline (dose escalation and dose expansion), on treatment and at progression (dose expansion) will be correlated with disease activity and response. This trial activated on 8-May-2023 through the Experimental Therapeutics Clinical Trials Network (ETCTN) and is enrolling at select sites in the United States. Dose escalation is ongoing as of January 2025. Clinical trial information: NCT05711615. Research Sponsor: National Institutes of Health/National Cancer Institute (NIH/NCI); National Cancer Institute/U.S. National Institutes of Health; Merck KGaA, Darmstadt, Germany CrossRef Funder ID: 10.13039/100009945.

Planned dose levels for dose escalation.

Dose Escalation Schedule

	Dose	
Dose Level	**Liposomal doxorubicin**	**Peposertib (tablet)**
-1	10 mg/m^2 IV	50 mg PO BID
0*	10 mg/m^2 IV	100 mg PO BID
+1	10 mg/m^2 IV	150 mg PO BID
+2	10 mg/m^2 IV	200 mg PO BID
+3	15 mg/m^2 IV	200 mg PO BID
+4	20 mg/m^2 IV	200 mg PO BID

*Starting dose.

TPS11586 Poster Session

The phase II study of pembrolizumab plus lenvatinib for patients with unresectable cutaneous angiosarcoma (Pembro-Lenva for cAS/PLAS trial). First Author: Dai Ogata, National Cancer Center Hospital, Tokyo, Japan

Background: Cutaneous angiosarcoma (cAS) is a rare cancer that often occurs in elderly people with common recurrence and metastasis after surgery. Chemotherapy, radiation therapy, and their combination are widely used, but their effectiveness is insufficient. With the increasing number of cAS patients due to the aging population, the development of effective treatment is urgently required. Previously, it has been reported that cancer shrank in 18% (5 out of 27) of patients after 2 months of paclitaxel administration in a clinical trial. Therefore, paclitaxel has become more commonly used for cAS. Other options include anthracycline anticancer drugs and gemcitabine. However, even with these anticancer drugs (and radiation therapy), cAS progresses quickly, and some reports have said that the 5-year survival rate is 9%. This study is planned to develop safer and more effective treatment for cAS. Pembrolizumab is an immune checkpoint inhibitor with PD-1 receptor-ligand interaction and lenvatinib is a multikinase inhibitor that inhibits tumor angiogenesis. The combination is expected to have strong therapeutic efficacy due to the immunomodulatory effects of pembrolizumab and the inhibitory effects of lenvatinib. **Methods:** This investigator-initiated, prospective, multicenter, non-randomized phase II trial evaluates the efficacy and safety of pembrolizumab plus lenvatinib for patients with unresectable cAS. Eligible patients are aged $\geq$18 years ($\leq$85 years), histologically diagnosed with cAS, and both untreated and previously treated patients. The primary endpoint of this study is to confirm the response rate of pembrolizumab plus lenvatinib combination therapy for unresectable cAS based on RECST 1.1 at central review. The secondary endpoints are response rate (primary investigator assessment), progression-free survival, overall survival, disease control rate, duration of response, time to response, incidence of adverse events (AEs), incidence of drug-related adverse events (adverse drug reactions, ADRs), and incidence of serious AEs/ADRs. We estimated a threshold response rate of 18% and an expected response rate of 35%. The planned sample size is 38 patients (25 untreated patients and 13 treated) to provide a power of 70% with one-sided alpha of 5%. The planned accrual period is 2 years, and the follow-up period is 2 years; interim analysis will be performed at the enrollment of 20 patients is completed. The trial began in February 2025. Clinical trial information: NCT06673628. Research Sponsor: None.

TPS11587 **Poster Session**

Integrating early palliative care in advanced sarcoma patients for enhanced quality of life: The SARQUALITY study. First Author: Catherine S. Weadick, Princess Margaret Cancer Centre, Toronto, ON, Canada

Background: Patients with advanced cancer may experience physical and psychological symptoms impacting health-related (HRQOL). The World Health Organization defined palliative care as "an approach that improves the quality of life of patients and their families" by identification and management of pain and other symptoms, spiritual and psychosocial assessments and interventions, facilitation of home and community-based supports, and transition to end-of-life care. Early palliative care (EPC) integration with cancer-directed treatment can enhance patient-reported outcomes (PROs). However, patients with sarcoma have been underrepresented in these studies, underscoring the need to evaluate the role and benefits of EPC in this population. This study aims to determine whether EPC alongside standard oncological care (SOC) improves PROs for patients with advanced sarcoma compared to usual care. **Methods:** This is a single program, dual institution phase 2 open-label clinical trial designed to assess whether EPC improves the HRQoL of patients with advanced sarcoma. Main eligibility criteria at enrolment include systemic treatment naïve patients over the age of 18 years with histologically proven advanced sarcoma, ECOG 0-2, English speaking and life expectancy of over 6 months. Enrolled patients are randomized 1:1 to either SOC alone or with EPC. Patients randomized to EPC will be reviewed by palliative care within 2 weeks of randomization. EPC will include routine in person (or virtual) contact integrated into their oncology visits and access to a 24-hour on-call service. Patients receiving SOC alone will be referred to palliative care upon emergence of uncontrollable symptoms or upon request by the patient. Patients on both arms will receive standard of care follow-up with their oncology teams and complete Edmonton Symptom Assessment System (ESAS) and EORTC QLQ-C30 questionnaires at baseline, weeks 6, 12 and 24. For the primary endpoint, EPC will be considered effective if ESAS score decreases at week 12 compared to baseline using T test, with one-sided significance level set to be 0.05. The secondary endpoints include EORTC QLQ-C30 score change (baseline to weeks 6, 12 and 24), number of extra clinic visits, emergency department attendance and overall survival at 6 and 12 months. Comparison between the two arms, assessing both scores, will be done using Fisher's exact or Chi-square test. Generalized linear mixed model will be carried out to examine the difference between the arms over time. To ensure this trial is powered to determine a significant statistical difference, we plan to enroll 136 patients with an estimated accrual period up to three years. This study commenced enrolment March 2024 and to date (January 2025) 27 patients have been recruited with 13 (48%) randomized to EPC. An amendment is currently ongoing to include the use of electronic wearables as part of the study evaluation. Research Sponsor: None.

TPS11588 **Poster Session**

A multicenter, randomized, global phase 3 study to assess the efficacy and safety of intratumoral (IT) INT230-6 (SHAO, vinblastine, cisplatin) as monotherapy compared with standard of care systemic chemotherapy in adults with locally recurrent, inoperable, or metastatic soft tissue sarcomas (STS; INVINCIBLE-3). First Author: Sant P. Chawla, Sarcoma Oncology Center, Santa Monica, CA

Background: Soft tissue sarcomas (STS) are a rare and diverse set of tumors. Systemic chemotherapy provides limited benefit for metastatic disease. INT230-6 is a novel formulation of cisplatin (CIS) and vinblastine (VIN) with a tissue dispersion enhancer (SHAO). The drug's unique chemistry permits dispersion throughout tumors and diffusion into the cancer cells after IT injections. The drug causes apoptosis and recruits T-cells to the tumor. An open-label, phase 1/2 study was completed with locally advanced, unresectable, or metastatic adult patients with 11 STS subtypes. Patients had a median of 3 prior lines. Biopsied tissue from pre- and post-dosed tumors[2] showed immune engagement post-dose. PK data showed that >95% of VIN stayed in the tumor. There were no dose-limiting toxicities up to 175 mL (87.5 mg CIS, 17.5 mg VIN). The disease control rate was 93%. Uninjected tumors shrank. The median OS for INT230-6 alone (n=15) was 21.3 CI (4.7, NR) months. The maximum severity of INT230-6 treatment-related adverse events (TRAEs) in STS patients was 6.7% grade 1, 60% grade 2, and 33% grade 3 (no related grade 4 or 5 AEs). The most common TRAEs were pain, fatigue, and nausea. **Methods:** IT-03 is a 2:1 randomized trial comparing INT230-6 as monotherapy to an investigator's choice of pazopanib, trabectedin, or eribulin, per label. A total of 333 patients in 2L/3L will be enrolled in the US, Canada, Europe, and Australia. INT230-6 dose is set by tumor size. INT230-6 is given IT Q2W for up to 5 doses to as many tumors >1 cm as is deemed safe. Maintenance is Q12 weeks for up to 22 months. Statistics: 90% power to detect a survival HR of 0.65 with 3 interim assessments at 20%, 40%, and 60% of participants events (deaths). The final analysis is at 80% of events. There is a two-sided total alpha = 0.05, allocated as follows: interim #1 = 0.0039; #2 = 0.0184; final = 0.043. Includes up to 60 sites: several sites are now recruiting. Inclusion criteria: Must be $\geq$ 18 yo, and provide written consent, Proven, unresectable, locally advanced, or metastatic STS; Must have received at least one line of therapy and progressed after anthracycline therapy. 1 tumor for injection of at least 2 cm. Adequate organ function in screening; lab values of: Neutrophils $\geq$ 1500/μL ($\geq 1.5\times 10^9$/L). PT, and INR $\leq 1.5\times$ ULN, platelets $\geq$ 100,000/μL; hemoglobin $\geq$ 9 g/dL. Criteria must be met without erythropoietin dependency or packed red blood cell transfusion within last 2 weeks. Creatinine normal; or clearance > 50 mL/min by the C-G equation. ALT SGOT/ AST SGPT $\leq 2.5\times$ ULN without, and $\leq 5\times$ ULN with hepatic metastases. Bilirubin (BR) $\leq 1.5\times$ ULN (except those with Gilbert's syndrome, who must have total BR $\leq$ 3.0 mg/dL [< 52 μmol/L]). CPK $\leq 2.5\times$ ULN. Clinical trial information: NCT06263231. Research Sponsor: Intensity Therapeutics.

TPS11589 **Poster Session**

Trial in progress: TAGGED—A phase 2 study using low dose/metronomic trabectedin, gemcitabine, and dacarbazine as 2nd/3rd/4th line therapy for advanced soft tissue sarcoma (NCT04535271). First Author: Samantha Jeffrey, Sarcoma Oncology Center, Santa Monica, CA

Background: Despite significant progress in the field of cancer medicine, the prognosis of advanced soft tissue sarcoma (STS) patients remains poor. Standard of care includes surgery for resectable tumors, generally paired with adjuvant radiation and chemotherapy. Anti-neoplastic drugs trabectedin, gemcitabine, and dacarbazine, have all demonstrated efficacy in STS. However, standard doses often result in toxicity and chemoresistance. Thus, we hypothesize that a low dose/metronomic combination regimen of intravenous trabectedin, gemcitabine, and dacarbazine will produce synergistic/additive activities without additive toxicities, providing a safer and more efficacious alternative to standard chemotherapy regimens. **Methods:** This Phase 2 open-label single-site study (NCT04535271) will evaluate the efficacy and safety of low dose/metronomic trabectedin, gemcitabine, and dacarbazine in prolonging progression free survival in patients with advanced STS. A total of 80 previously treated patients, 18 years or older, with locally advanced, unresectable or metastatic STS will receive trabectedin 0.5mg/m2 CIV over 24 hours, gemcitabine 200 mg/m2 IV, and dacarbazine 200 mg/m2 IV on D1 and D8. Each cycle will be 3 weeks. Treatment will continue up to one year or until disease progression or unacceptable toxicity. The primary endpoint is Progression Free Survival (PFS), estimated by the Kaplan-Meier method with two-sided 95% confidence interval. Secondary endpoints include best overall response (BOR) and duration of response (DOR) by RECIST v1.1 criteria, PFS rate, overall survival (OS) rate at 4, 6, and 12 months, and incidence of treatment-related adverse events (TRAEs). The Intention-To-Treat (ITT) population, consisting of all patients who received at least one dose of each study drug, will be used for adverse event analysis. The Modified Intention-To-Treat (MITT) population, consisting of patients who completed the first 2 cycles and have had follow-up imaging, will be used for analysis of PFS, BOR, DOR, PFS, and OS. Key inclusion criteria include a pathologic diagnosis of locally advanced or metastatic STS, previously treated patients with measurable disease by RECIST v1.1, ECOG $\leq$ 2, life expectancy of at least 3 months, acceptable liver and renal function, and acceptable hematological and organ functions. Key exclusion criteria include patients who have progressed with all three study drugs, known hypersensitivity to any of the three study drugs, currently receiving treatment or are <14 days since ending treatment with another investigational device or drug study, pregnant or breastfeeding or who have plans to become pregnant, breastfeed, or unwilling to use female or male contraception. The study has enrolled 13 of 80 patients and is actively recruiting. Clinical trial information: NCT04535271. Research Sponsor: None.

PRO-ACTIVE: Results of a pragmatic phase IV randomized trial comparing the effectiveness of prophylactic swallow intervention for patients receiving radiotherapy for head and neck cancer. First Author: Katherine A. Hutcheson, The University of Texas MD Anderson Cancer Center, Houston, TX

The full, final text of this abstract will be available at meetings.asco.org on the day of presentation and in the online supplement to the June 10, 2025, issue of the *Journal of Clinical Oncology*.

12001 **Oral Abstract Session**

Phase III randomized placebo-controlled trial on repurposing olanzapine for prevention of radiotherapy-induced nausea and vomiting (RINV): CTRI/2022/01/039723. First Author: Meenu Vijayan, Amrita School of Pharmacy, Amrita Vishwa Vidyapeetham, AIMS Health Sciences Campus, Kochi, Kerala, India

Background: Prospective placebo controlled randomized study with or without olanzapine, to evaluate its role in reducing RINV in abdominal-pelvic radiation therapy patients. **Methods:** Phase III, double-blind, placebo-controlled trial in patients undergoing radiotherapy (RT) [Eligibility: >18 yrs, abdominal/pelvic RT, no prior RT history] were randomized to receive 5mg olanzapine or matching placebo daily, along with standard care (ondansetron 4mg twice daily) using simple randomization method. Primary endpoint was nausea prevention. Secondary endpoint was no emesis, no rescue medications, toxicity (CTCAE v5), & QOL. Pearson chi-square test & independent t-test employed for statistical analysis. **Results:** Between Feb 2022 to Aug 2024, 683 patients were screened & 301 randomized [153 placebo, 148 experimental/olanzapine]. In placebo & experimental arm, mean age was 63.8 years (+/- 10.8) & 62.3 years (+/-10.4), female 42% & 37%, rectal cancer 77(50%) & 72 (49%), prostate 47 (31%) & 46 (31%), endometrial cancer 14 (9%) & 14(9.5%), pancreatic cancer 9(6%) & 5(3.4%) (p=NS). In placebo & experimental arm, Image-guided RT done in 89% & 83%(p=NS), concurrent chemotherapy in 57% & 53% (p=NS). During RT, 'no nausea' & 'no vomiting' complain in placebo & experimental arms were 16.3 & 85.8% (p= <0.001); 74.5% & 95.9% (p= <0.001). Total number of vomiting episodes >15 times during RT in placebo & experimental arm were 9.2% & 2% (p=0.002). Rescue therapy during RT required in 7.8% placebo &1.4% in experimental arm (p=0.008). Grade≥2 nausea in placebo & in experimental arm 67% & 7.4% (p=0.001), and vomiting 7.8% & 1.4% (p=0.001). In rectal cancer, nausea grade ≥2 in placebo & experimental arm were 85.7% & 2.8% (p=0.001) & in prostate cancer 19% & 9% (p=0.018). In experimental arm, significant adverse reactions (grade 1) included drowsiness (p<0.001), dysarthria (p=0.003), and orthostatic hypotension (p<0.001). Mean anxiety score before & after RT in placebo was 13.2 (+/-2.5) &14.5 (+/-2.4) (p<0.001); in experimental arm 13.4 (+/-2.3) & 11.1 (+/-2.2) (p<0.001); Mean depression score before & after RT in placebo & experimental arm were 11.9 (+/-1.6) & 13.7 (+/-1.8) (p<0.001); 11.9 (+/-1.6) & 9.7 (+/-1.6) (p<0.001). The olanzapine group had more sleep hours/day (8.4 ±1.7 hours vs. 5.29 ±1.13 hours; p<0.001). QOL score from baseline to end of RT showed improvement in emotional function, nausea/vomiting, insomnia, & loss of appetite (all p<0.001) in olanzapine arm. Mean EORTC GHS QOL score at RT completion was 61.6 (+/- 8.6) in placebo arm and 62.9 (+/-9.2) in experimental arm (p=0.235). **Conclusions:** Adding olanzapine 5mg along with standard antiemetics demonstrated a significant reduction in RINV in patients receiving abdominal-pelvic radiation therapy. Clinical trial information: CTRI NO/2022/01/039723. Research Sponsor: Indian Council of Medical Research; 58/22/2020/PHA/BMS.

12002 **Oral Abstract Session**

Randomized control trial to validate mitigation of chemotherapy-induced peripheral neuropathy by limb-cooling apparatus in breast cancer patients receiving paclitaxel (CECILIA). First Author: Toshimi Takano, Department of Breast Medical Oncology, The Cancer Institute Hospital of Japanese Foundation for Cancer Research, Tokyo, Japan

Background: Chemotherapy-induced peripheral neuropathy (CIPN) is a common adverse event affecting patient quality of life. Limb cooling may help to prevent CIPN, but no phase 3 trials have confirmed its efficacy, and its efficacy and safety remain challenging. This trial determined if temperature-controlled limb cooling could reduce CIPN in patients with breast cancer receiving weekly perioperative paclitaxel (PTX). **Methods:** This multicenter, double-blind, randomized controlled trial (jRCT2032210115) assigned patients with breast cancer scheduled to receive 12 weekly doses of perioperative PTX (60 min 80 mg/m^2 intravenous infusion) chemotherapy randomly (1:1) to limb-cooling therapy at a constant temperature of 13°C (Experimental arm) or 25°C (Control arm). The primary endpoint was the proportion of patients with Patient Neurotoxicity Questionnaire (PNQ) ≥D in their limbs after PTX treatment or at the time of discontinuation. Secondary endpoints were NCI-PRO-CTCAE™, EORTC QOL-QLQ-C30, and CIPN-20, and adverse events of cooling therapy. We assumed primary endpoints of 37% and 15% in the Control and Experimental arms, respectively. The planned sample size was 150 to detect a difference (Fisher's exact test, power 80%, 1-sided alpha 2.5%). **Results:** The study randomized 150 patients (n = 75 each arm). The PTX treatment completion rates (≥80%) were 88.0% (66/75) in the Experimental and 93.3% (70/75) in the Control arm. The proportion of patients with PNQ ≥D by the end of the treatment (primary endpoint) was similar in both arms (13°C vs. 25°C, 33.3% [25/75] vs. 29.3% [22/75], 1-sided p = 0.76). The proportions were higher in the Experimental arm 3 months after the end of PTX and in patients registered from June to September (Table). The proportion of patients with PNQ ≥D was higher in patients with hand epidermal temperature below the mean (21.5°C) at completion of PTX infusion than in the whole population (38.5%, Table). No frostbite or adverse events were reported in either arm. **Conclusions:** The primary endpoint did not meet and the limb cooling therapy using a stable cooling device resulted in lower proportion of PNQ ≥ D than was assumed for the Control arm irrespective of temperature settings, warranting further studies to determine optimal temperature. Clinical trial information: jRCT2032210115. Research Sponsor: Nippon Sigmax Co, Ltd.

Efficacy	13°C cooling (95%CI)	25°C cooling (95%CI)	P value
PNQ ≥D (primary endpoint)	33.3% (22.9–45.2)	29.3 % (19.4–41.0)	0.76
NCI-PRO-CTCAE	48.0% (95%CI 36.3–59.9)	49.3 % (37.6–61.1)	0.87
EORTC QLQ-CIPN20 (% non-worsening scores)	28.1% (95%CI 17.6–40.8)	8.8 % (3.3–18.2)	0.006
PNQ ≥D 3 months after end of PTX	32.0% (95%CI 21.7–43.8)	16.2 % (8.7–26.6)	0.034
PNQ ≥D in pts registered June–September	58.1% (39.1–75.5)	25.8 % (11.9–4.6)	0.020
PNQ ≥D in pts with hand epidermal temperature <21.5°C	38.5% (23.4–55.4)	-	-

12003 **Oral Abstract Session**

Music therapy versus cognitive behavioral therapy for anxiety in cancer survivors: A telehealth-based randomized clinical trial. First Author: Kevin T. Liou, Memorial Sloan Kettering Cancer Center, New York, NY

Background: Anxiety is prevalent, disruptive, and under-treated among cancer survivors. While the pandemic exacerbated the mental health crisis, it also accelerated telehealth adoption, creating opportunities to expand access. Cognitive behavioral therapy (CBT) is the gold standard for anxiety, but not all survivors respond to it, have access, or prefer this option due to stigma. Music therapy (MT) has demonstrated short-term anxiety reduction, but its long-term effectiveness relative to other treatments is unknown. This study evaluated whether MT is noninferior to first-line CBT when both are delivered remotely. **Methods:** In this randomized clinical trial, English- or Spanish-speaking survivors of any cancer type or stage with anxiety lasting ≥1 month were randomized 1:1 to MT or CBT. Participants received 7 weekly sessions of a standardized protocol via Zoom and were followed for 26 weeks. Co-primary endpoints were Hospital Anxiety and Depression Scale (HADS) anxiety subscale changes at weeks 8 and 26. Secondary outcomes included depression, fatigue, insomnia, pain, cognitive function, and quality of life. Data were analyzed with linear mixed-effects models following intention-to-treat. Assuming 15% attrition and 1-sided p < 0.025, the trial had 80% power to detect noninferiority within a margin of D = 0.35*standard deviations (SDs). The margin was informed by an expected SD of 4.2 and the minimum clinically important difference (MCID) of 1.7 points for the HADS anxiety subscale. Thus, establishing noninferiority would indicate differences between MT and CBT are not clinically meaningful. **Results:** Among 300 (147 MT; 153 CBT), mean age was 56.9 (SD 13.2) years, 224 (74.7%) were female, 228 (76.5%) were white, and 57 (19.1%) were Hispanic. The most common cancer types were breast (45.3%) and hematologic (15.7%). At week 8, mean change in HADS anxiety score was -3.12 (95% CI -3.59 to -2.65) in MT and -2.97 (95% CI -3.45 to -2.50) in CBT; between-group difference was -0.15 (95% CI -0.78 to 0.49), which was within margin of 1.20 (P < 0.001 for noninferiority of MT; calculated from SD of 3.42). At week 26, mean change was -3.31 (95% CI -3.78 to -2.85) in MT and -3.00 (95% CI -3.47, -2.53) in CBT; between-group difference was -0.31 (95% CI -0.95 to 0.32), which was within margin of 1.30 (P < 0.001 for noninferiority of MT; calculated from SD of 3.65). Both groups produced anxiety reductions exceeding MCID of 1.7 and showed similar improvements in secondary outcomes. **Conclusions:** MT was non-inferior to CBT for short- and long-term anxiety reduction among diverse survivors of various cancer types. Both treatments produced clinically meaningful, durable anxiety reduction and were delivered remotely using standardized protocols, thereby increasing their reach and scalability. MT should be considered alongside first-line CBT to expand treatment options for anxiety during cancer survivorship. Clinical trial information: NCT05215353. Fear of cancer recurrence in long-term colorectal cancer survivors: A randomized controlled trial of a therapist-guided eHealth intervention. First Author: Johanne Dam Lyhne, Department of Oncology, Lillebaelt Hospital, University Hospital of Southern Denmark, Vejle, Denmark

Background: Despite the availability of effective interventions, fear of cancer recurrence (FCR) remains a prevalent and significant concern among cancer survivors, underscoring the need for more accessible and scalable approaches. This trial assessed the effectiveness of a therapist-guided eHealth intervention, TG-iConquerFear. **Methods:** This parallel randomized controlled trial (ClinicalTrial.org #NCT04287218) enrolled Danish colorectal cancer survivors (CRCS) who had completed curative-intent primary treatment between March 2014 and December 2018, were aged ≥ 18 years, and reported Fear of Cancer Recurrence Inventory-Short Form (FCRI-SF) scores ≥22 (i.e. clinical FCR). After diagnostic interview, eligible participants were randomized to TG-iConquerFear (intervention) or a webpage with self-help mindfulness exercises (augmented control) in a 1:1 ratio. The 10-week TG-iConquerFear program comprised six modules with written therapist guidance delivered asynchronously. Follow-up questionnaires were administered at two weeks (T1), three months (T2), and six months (T3) post-intervention. The primary outcome was predefined as the difference in the change scores of the total FCRI score at T2, analyzed as intention-to-treat. Secondary outcomes were anxiety, depression, emotional distress, health-related quality of life (HrQoL) and physical symptom burden. Pre- and post-intervention mean within and between groups were pairwise compared using Student's t-test. **Results:** Of 9,946 eligible CRCS, 5,515 (55.4%) completed FCR screening, and 299 (5.4%) CRCS reported clinically significant FCR (FCRI score ≥ 22). Among them, 221 (73.9%) expressed interested in FCR treatment, and 103 (46.6 %) were randomized to TG-iConquerFear (n = 49) or control (n = 54). Main reasons for non-randomization included new cancer diagnoses or FCR not affecting everyday life. Participants completed 4.5 modules on average, and 55% completed the intervention. Baseline total FCRI score was 84.6/168 in both groups. Total FCRI score decreased more from baseline to T2 in the TG-iConquerFear group (mean -21.7, 95% CI [-30.1, -13.3]) compared to the augmented control group (mean -2.6 95% CI [-7.8, 2.6]). This represents a between-group difference at T2 of 19.1 (95% CI [10.0, 28.3], p < 0.001) corresponding to a standardized effect size (Cohen's *d*) of 0.62 (95% CI [0.13 - 1.1]). A higher proportion of TG-iConquerFear participants were in the non-clinical range at T2 compared to control participants (81.5% vs. 42.9%, p = 0.002). Statistically significant differences favoring the intervention group were observed across all secondary outcomes. **Conclusions:** The TG-iConquerFear intervention demonstrated a statistical and clinically significant reduction in fear of cancer recurrence in a population of long-term CRCS. The effects were sustained at six months post-intervention. Clinical trial information: NCT04287218. 12005 **Oral Abstract Session**

Results of a multisite randomized trial of Bright IDEAS-Young Adults: Efficacy of problem-solving skills training on distress and health-related quality of life. First Author: Katie Devine, Rutgers Cancer Institue, New Brunswick, NJ

Background: Young adults (YAs) diagnosed with cancer between the ages of 18 and 39 face unique psychosocial challenges and are at risk of experiencing significant emotional distress and poor health-related quality of life (HRQOL). This randomized trial evaluated the efficacy of Bright IDEAS-YA, a problem-solving skills training intervention, on reducing distress and improving HRQOL of YAs newly diagnosed with cancer. A secondary aim examined change in problem-solving ability as a potential mediator of treatment effects. **Methods:** A three-site randomized trial of Bright IDEAS-YA compared with enhanced usual care (EUC) enrolled YA survivors within four months of a first diagnosis of cancer. Participants were randomized 1:1 to Bright IDEAS-YA or EUC (NCT04585269). Bright IDEAS-YA is a 6-session, one-on-one intervention that teaches a systematic approach to overcome personal challenges across any life domain. EUC involved usual psychosocial care plus AYA resources. Participants completed surveys at 0 (baseline), 3, 6, 12, and 24 months, with 6 months as the primary endpoint. Validated measures included the PROMIS Depression Short Form and Anxiety Short Form (primary outcomes), the Functional Assessment of Cancer Therapy – General (FACT-G; primary outcome), and Social Problem-Solving Inventory-Revised Short Form (SPSI-R; mediator). Efficacy was tested using linear mixed effects models, run in R, examining the group x time interaction effects. Mediation was tested using the R multiple mediation analysis. **Results:** 344 YA (34.2% acceptance rate, M_{age} = 30.3 years, *SD* = 6.3; 63% female, 37% male, < 1% non-binary) participated (100% planned enrollment), with 86% and 81% completing surveys at 3 and 6 months, respectively. Compared to baseline, the intervention arm showed statistically significant improvements in depression, anxiety, and HRQOL relative to the control group at 6 months. The intervention arm demonstrated an average reduction of 3.2 T-score points reduction in depression (95% CI [-4.9, -1.5], $p <$ 0.001), 2.4 T-score points in anxiety (95% CI [-4.0, -0.81], p = 0.003), and 3.4 points improvement in total FACT-G (95% CI [0.34, 6.5], p = 0.029) relative to the control. These differences reflect clinically meaningful changes per published reports. Across all three models, change in total problem-solving ability (SPSI-R) was shown to mediate treatment effects, primarily due to change in the negative problem-orientation subscale. **Conclusions:** Bright IDEAS-YA was efficacious in reducing symptoms of depression and anxiety and improving HRQOL compared with enhanced usual care among YAs with cancer. Improvements are attributable to increased problem-solving ability, particularly by reducing the tendency to view problems as significant threats and doubt one's ability to successfully solve problems. Clinical trial information: NCT04585269. Research Sponsor: National Cancer Institute; R37CA240807.

12006 **Oral Abstract Session**

A multicenter, randomized, controlled, open-label trial to determine the optimal duration of steroid therapy for mild pneumonitis associated with immune checkpoint inhibitors. First Author: Daichi Fujimoto, Hyogo Medical University, Nishinomiya, Japan

Background: The optimal duration of corticosteroid therapy for pneumonitis associated with immune checkpoint inhibitors is clinically relevant. Several guidelines recommend a duration of 4 to 6 weeks for mild immune-related pneumonitis. However, evidence from clinical trials is limited. We conducted the first randomized trial to evaluate whether short-term corticosteroid therapy can achieve comparable efficacy. **Methods:** In this multicenter, open-label, randomized clinical trial at 22 institutions in Japan, we randomly assigned patients with mild immune-related pneumonitis according to the Common Terminology Criteria for Adverse Events grade 1 or 2, in a 1:1 ratio, to receive either 3-week or 6-week corticosteroid treatment. The primary endpoint was the rate of treatment success 8 weeks after the start of steroid administration, with a non-inferiority margin of 16 percentage points. The major secondary endpoints were safety, percentage of participants with treatment failure, quality of life, and overall survival. The primary hypothesis was that a 3-week treatment would be non-inferior to a 6-week treatment in terms of the primary endpoint. **Results:** Overall, 106 patients were randomized, and after the exclusion of one patient without immune-related pneumonitis, 105 were included in the intention-to-treat (ITT) population: 51 patients in the 3-week group and 54 in the 6-week group. In the ITT population, the patients' median age was 72 years; 81% of the patients were men, and 73% had grade 2 at baseline. The rate of treatment success was 66.7% in the 3-week group and 85.2% in the 6-week group, which did not demonstrate noninferiority in the overall study population (difference, −18.5% percentage points [80% confidence interval {CI}, −29.0% to -7.9%], p = 0.621), and a predefined exploratory superiority analysis indicated superiority of the 6-week regimen (p = 0.013). Over the entire study period, the relapse or exacerbation rates of pneumonitis were 41.1% in the 3-week group and 24.1% in the 6-week group. Grade 3 or higher adverse events occurred in 12% of patients in the 3-week group and 24% of patients in the 6-week group. The absolute mean change in the total QOL using the K-BILD score from baseline was 4.78 in the 3-week group and 6.28 in the 6-week group (between-group difference, -1.50 points; 95% CI, −5.91 to 2.91). **Conclusions:** In patients with mild immune-related pneumonitis, non-inferiority of 3-week corticosteroid treatment compared to that of 6 weeks was not confirmed in the overall population, and the relapse or exacerbation rate of pneumonitis was higher in the 3-week group over the entire study period. Corticosteroid therapy shorter than the duration recommended by the guidelines is not supported. Clinical trial information: jRCTs051220082. Research Sponsor: None.

Romiplostim for chemotherapy-induced thrombocytopenia (CIT) in colorectal, gastroesophageal, and pancreatic cancers: A global, phase 3, randomized, placebo-controlled trial (RCT). First Author: Hanny Al-Samkari, Massachusetts General Hospital, Boston, MA

Background: CIT is a common consequence of antineoplastic regimens for gastrointestinal (GI) cancers, occurring in >60% of colorectal cancer patients receiving multiagent chemotherapy. CIT can lead to chemotherapy dose reduction, delay, omission, and discontinuation, potentially worsening outcomes. There are no widely available licensed therapies for this unmet need. Aim: To evaluate the safety and efficacy of the thrombopoietin receptor agonist romiplostim (ROMI) in patients with GI cancers to limit chemotherapy dose modifications from CIT. **Methods:** This was a phase 3, placebo (PBO)-controlled RCT of patients receiving oxaliplatin-based multiagent regimens for GI cancers with persistent CIT, ie platelets (Plt) $\leq 85\times10^9$/L on day 1 of a scheduled chemotherapy cycle (NCT03362177). Patients from 55 sites in 14 countries were randomized 2:1 to ROMI or PBO for 3 chemotherapy cycles, stratified by baseline Plt (< or $\geq 50\times10^9$/L) and cancer type. Study drug started at 2 μg/kg subcutaneous weekly, adjusted weekly by 1 μg/kg up to 10 μg/kg to target Plt $\geq 100\times10^9$/L in 12 weeks (≤4 weeks at 10 μg/kg). Chemotherapy started when Plt $\geq 100\times10^9$/L (Plt response) or after week 4 per investigator. The primary endpoint was no CIT-induced dose modification of any myelosuppressive agent in either the second or third chemotherapy cycle per independent adjudication committee. **Results:** Patients (N=165; 109 ROMI, 56 PBO) had colorectal (75%), gastroesophageal (13%), or pancreatic (12%) cancer; 60% were male, 90% White, 4% Black, and 24% Hispanic, with mean (SD) age of 61.4 (11.1) years. Baseline median (range) Plt was 69 (8–85)$\times10^9$/L; 11% had Plt $<50\times10^9$/L. Stage IV disease rates were ROMI 65%, PBO 55%. Most (75%) patients completed study drug; 3% discontinued due to adverse events (AEs). The primary endpoint was achieved in 92/109 (84%) patients receiving ROMI vs 20/56 (36%) receiving PBO (odds ratio 10.2; 95% CI 4.6-22.5; P<0.001). Median (range) Plt nadirs were ROMI 87 (14–167)$\times10^9$/L, PBO 58 (22–95)$\times10^9$/L; P=0.005. For those with Plt responses (ROMI 97%, PBO 77%), median (95% CI) time to first Plt response was ROMI 1.1 (not estimable) weeks, PBO 2.1 (1.1-3.0) weeks; P<0.001. Treatment-related (TR) AE rates were ROMI: 12%, PBO: 7%, most frequently nausea (2%, 2%) and headache (2%, 0%). TR serious AEs and TRAEs leading to death or discontinuation of study drug or chemotherapy were not observed in either arm. **Conclusions:** In this first global phase 3 RCT of ROMI vs PBO for CIT, ROMI was well tolerated and efficacious in the treatment and prevention of CIT in GI cancers. These results are potentially practice-changing for a common serious condition encountered routinely in clinical practice worldwide that prevents delivery of on-time, full-dose anticancer therapy. Final results from long-term follow-up will be presented. Clinical trial information: NCT03362177. Research Sponsor: Amgen Inc.

12008 Oral Abstract Session

Carica papaya leaf extract (CPLE) versus placebo to improve chemotherapy induced thrombocytopenia (CIT): Results of a phase III triple blinded, randomized placebo controlled trial (PACT study). First Author: Vikas Ostwal, Tata Memorial Hospital (HBNI), Mumbai, India

Background: There is a lack of approved therapeutic options to ameliorate CIT in patients with solid tumors receiving chemotherapy. Carica papaya leaf extract (CPLE) is known to increase platelet counts (PC) in certain infections. **Methods:** The PACT study is a triple blinded randomized phase III study conducted in two academic centres in patients with solid tumors receiving chemotherapy and developing at least grade 2 or grade 3 CIT (platelet counts $<$ 75,000 x 10^9/ liter and $>$ 25,000 x 10^9/liter). Patients were randomized 2:1 to CPLE arm (capsule CPLE per oral 1100mg three times daily) or placebo arm (capsule per oral three times daily), which was continued till PC improved to greater than $>$ 75,000 x 10^9/ liter, requirement for platelet transfusions or D+10 post intervention. Baseline PC were graded as per the Common Terminology Criteria for Adverse Events (CTCAE) grades. The primary endpoint of the study was to evaluate whether CPLE improves PC significantly faster (as assessed on D+4 of intervention) and above 75,000 x 10e9 /L as compared to placebo (spontaneous recovery of platelets). To achieve 80% power to detect a difference between the group proportions of 0.25 (50% to 75%) with an alpha of 0.05, 219 patients were required (146 in CPLE group and 73 in placebo group), assuming 10% loss to follow-up rates. **Results:** Between March 2020 and October 2024, 219 patients were randomized, of whom 198 patients (CPLE arm: 129; placebo arm: 69) were analysed for outcomes. All the baseline parameters were equally distributed in both the arms (2:1) except the proportion of patients in the placebo and the experimental arms had equal number of patients with grade 3 thrombocytopenia (17/129 vs 17/69; p = 0.049). The most common chemotherapeutic regimens were oxaliplatin based (37%) and carboplatin based (27%). The primary outcome of increasing PC $>$ 75,000 x 10^9/ liter at D+4 was significantly improved by CPLE (83/129, 64% vs 33/69, 48%; p = 0.034) as compared to placebo. This improvement was significantly quicker in subgroups including three weekly regimen vs weekly/biweekly, palliative intent vs. curative, $>$ 2 cycles of chemotherapy ($<$ = 2 cycles vs. $>$ 2 cycles) and body surface area (BSA) $<$ 1.6 vs. more. There were no grade 3 or grade 4 treatment related adverse events associated with CPLE. **Conclusions:** CPLE is the first therapeutic intervention that appears to improve grade 2 and grade 3 chemotherapy induced thrombocytopenia faster and to a greater extent than placebo in this phase III randomized trial. It should be used as a secondary prophylaxis to maintain the chemotherapy intesnity. There were no major safety concerns with the use of CPLE. Clinical trial information: CTRI/2019/08/020987. Research Sponsor: Micro Pharma Pvt Ltd; IASCC; Cadila Healthcare; Lupin Pharma Pvt Ltd.

12009 Rapid Oral Abstract Session

A randomized controlled trial of cognitive behavioral therapy and bright light therapy for insomnia and fatigue during breast cancer treatment: SleepCaRe trial. First Author: Joshua F. Wiley, Monash University, Clayton, VIC, Australia

Background: Women on chemotherapy for breast cancer (BC) report high levels of insomnia and fatigue. This trial aimed to test the main effects of Cognitive Behavioral Therapy for Insomnia (CBT-I) and Bright Light Therapy (BLT) on insomnia and fatigue symptoms. **Methods:** This multi-center, randomized, controlled, 2 x 2 factorial, superiority, trial enrolled 219 women receiving cytotoxic chemotherapy for any stage BC. Interventions were: (1) neither CBT-I nor BLT (sleep hygiene education; SHE), (2) BLT, (3) CBT-I, and (4) BLT+CBT-I. The 6-week interventions included one telehealth, 1:1 session followed by emails and a mid-treatment call. Assessments occurred at baseline, 3 and 6 weeks. Dual primary outcomes were the insomnia severity index (ISI) and PROMIS Fatigue. Intention-to-treat analyses were latent growth models. Effect sizes are standardized mean differences (SMDs). **Results:** Mean age was 50.7y and 24% had metastatic cancer. At baseline, average ISI was 13.24 (SD = 5.48; sub-threshold insomnia), and fatigue was 59.57 (SD = 7.91; moderate fatigue). 88% (n = 198) completed the telehealth session. 75% (n = 165) reported post-treatment outcomes. ISI and fatigue decreased in all conditions (see Table). CBT-I improved ISI (mean difference = -2.03; p = .001; SMD = -0.37), but BLT did not (mean difference = -1.09; p = .082; SMD = -0.20). Neither intervention affected fatigue (SMDs -0.06 to -0.07; $p > 0.60$). There was no BLTxCBT-I interaction for ISI nor fatigue ($p > 0.50$). **Conclusions:** In patients receiving chemotherapy for BC, brief CBT-I can improve insomnia but not fatigue symptoms. BLT did not improve insomnia or fatigue. We found no evidence of an interaction between BLT and CBT-I. During chemotherapy, fatigue may not be responsive to brief sleep and circadian-oriented treatments. Clinical trial information: ACTRN12620001133921. Research Sponsor: None.

Alliance A221805: Duloxetine to prevent oxaliplatin-induced chemotherapy-induced peripheral neuropathy (CIPN)—A randomized, double-blind, placebo-controlled phase II study. First Author: Ellen M. Lavoie Smith, University of Alabama at Birmingham, Birmingham, AL

Background: Standard-of-care chemotherapy treatment regimens for colorectal cancer (CRC) include oxaliplatin, a drug known for causing CIPN. CIPN is characterized by upper and lower extremity numbness and tingling, and pain that can persist for years beyond chemotherapy completion, causing impaired function and poor quality of life. According to the American Society of Clinical Oncology's (ASCO) 2020 Clinical Practice Guidelines, there are no known effective preventative interventions. While the ASCO guidelines recommend duloxetine to treat established painful CIPN, its efficacy to prevent CIPN has not been established. **Methods:** A221805 (NCT04137107) was conducted within the National Cancer Institute-supported Community Oncology Research Program; Alliance for Clinical Trials in Oncology was the coordinating group. The randomized, 3-arm, double-blind, placebo-controlled, noncomparative, multicenter phase II study screened 2 doses of daily duloxetine to prevent sensory CIPN. Enrollment occurred between May 1, 2020, and March 24, 2023. Patients (pts) were randomized 1:1:1 to 30 or 60 mg of daily duloxetine, or daily placebo. Eligible pts had stage II-III CRC and no baseline neuropathy, were $\geq$ 25 years of age and scheduled to receive oxaliplatin via one of the following schedules: 85 mg/m2 every 2 weeks (wks; 6 or 12 doses) or 130 mg/m2 every 3 wks (4 doses). Duloxetine/placebo was taken once daily beginning on day 1 of cycle 1 and continued for 17 wks. Blinding was achieved via drug encapsulation. The primary outcome was measured on wk 19-21 using a validated patient-reported outcome measure: 6 sensory items from the EORTC QLQ-CIPN20. Responders were pts who reported little to no CIPN; their highest score was $\leq$ 2 (i.e., 1 = "Not at all"; 2 = "A little") on any of the 6 items. **Results:** 199 pts were accrued (n = 66, 30 mg duloxetine; n = 66, 60 mg, duloxetine; Placebo, n = 67); based on modified intent-to-treat criteria, 46, 47, and 50 pts (N = 143, 71.8%) respectively, were evaluable for the primary endpoint analysis. The pt mean age was 55.1 years (SD = 10.43). Most were White (n = 113, 80.7%) and male (n = 82, 58.6%).There was no difference in the proportion of responders when comparing those who received either duloxetine 30mg (65.2%), 60mg (66.0%), or placebo (68.0%). Fatigue (51.9%) and nausea (46.5%) were the most common solicited adverse events. Duloxetine adherence rates, measured via pill counts, in the 30mg (44.44%), 60mg (50.92%), and placebo (65.57%) groups were low ($<$ 75%). **Conclusions:** We were unable to show that any dose of duloxetine was more promising than placebo, possibly due to an unexpectedly high placebo response rate. Low duloxetine/placebo adherence may have compromised efficacy. Placebo-response mitigation methods should be considered in future CIPN clinical trials. Clinical trial information: NCT04137107. Research Sponsor: National Cancer Institute; 1UG1CA189823; R01CA235726.

12011 Rapid Oral Abstract Session

Peri-transplant supportive and palliative care and/or comorbidity management for older, medically infirm, and/or frail recipients of allogeneic hematopoietic cell transplantation (Allo-HCT): Phase II and interim phase III trial analyses. First Author: Elizabeth Trice Loggers, Clinical Research Division, Fred Hutchinson Cancer Center/Division of Hematology and Oncology, University of Washington, Seattle, WA

Background: Patients (pts) with high HCT-Comorbidity Index scores (HCT-CI of $\geq$3), older age ($\geq$65 years), and/or who are frail per gait speed ($<$0.8 meters/second) have increased morbidity and mortality after allo-HCT compared to younger and healthier counterparts. We report the phase II analysis (PIIA) and interim phase III primary outcome analysis (PIIIA) of a seamless phase II/III prospective, randomized clinical trial conducted at 11 transplant centers to test new approaches to improve quality of life (QOL) in this population. **Methods:** Phase II compared specialist-administered supportive and palliative care (SPC), patient-administered management of comorbidities (MC, e.g. physical exercise, stress reduction, etc), both (SPC+MC), and usual care (UC) for change in Functional Assessment of Cancer Therapy – Bone Marrow Transplantation (FACT-BMT) QOL scores from baseline to day 90 (D90). Pts deceased prior to D90 were assigned FACT-BMT score=0. The winning phase II arm moved forward versus UC in phase III. **Results:** PIIA was done after enrolling 35 pts to each of the 4 study arms. Calculating the difference between FACT-BMT scores on D90 minus baseline, excluding missing data, indicated that only SPC resulted in a small improvement in QOL compared to either MC or SPC+MC (Table); hence SPC was the winning phase II arm. The PIIIA was conducted after enrolling 158 SPC pts and 153 UC pts. The SPC and UC arms were well balanced with median age (both 68 years), HCT-CI $\geq$3 (49% vs 55%), frailty per gait speed (13% vs 12%), female sex (41% vs 34%), non-white race (9.5% vs 11.5%), and Hispanic or unreported ethnicity (7.7% vs 5.7%), respectively. After median follow-up of 362 days, 45 pts had died in each arm. The mean QOL difference between D90 and baseline was 2.83 for SPC and 4.27 for UC (difference of differences, -1.44, 95% CI of difference, -5.03 to 2.14, p=0.43). Fitting a generalized linear model that included baseline, D30, and D90 values and testing the null hypothesis that the slope of scores differs between SPC and UC resulted in p=0.85. Using the Kaplan Meier method, no difference in survival was observed across arms (HR 1.13 [0.75-1.73]). **Conclusions:** Specialist-administered palliative care showed no meaningful improvement in QOL, nor a survival advantage, compared to usual care in frail, older and comorbid allo-HCT recipients, resulting in the cessation of this Phase II/III trial. Analysis of the whole patient population for primary and secondary outcomes is in progress. Clinical trial information: NCT03870750. Research Sponsor: National Cancer Institute.

Change in FACT-BMT (D90 value minus baseline value) comparing the 4 arms of phase II.

Group	Mean difference (sd)	Median difference (range)
SPC (n=28)	-2.93 (28.52)	0.25 (-102 to 38.22)
CM (n=18)	-18.37 (33.80)	-9.50 (-98.33 to 11)
SPC+CM (n=27)	-15.76 (32.69)	-7.67 (-90 to 32)

Efficacy of treatment with traditional Chinese medicine (Renshen Yangrong Tang granules) for cancer-related fatigue in patients with platinum-based chemotherapy: A randomized, double- blinded, placebo-controlled, multi-center trial. First Author: Yichen Xu, Beijing Cancer Hospital, Beijing, China

Background: Although there is higher incidence of cancer-related fatigue (CRF) in patients undergoing chemotherapy, effective drugs is still in need. Renshen Yangrong Tang (RSYRT), a Traditional Chinese Medicine, has shown promise in alleviating CRF. This trial aims to investigate whether RSYRT could reduce fatigue and improve quality of life in cancer patients with platinum-based chemotherapy. **Methods:** This prospective, multicenter, double-blinded, placebo-controlled trial was implemented at 4 centers in China, enrolling 192 platinum-treated cancer patients with Visual Analogue Scale for Fatigue $\geq$4 points on the 10th day of the first cycle of chemotherapy. Participants were randomized to receive RSYRT (10.35g, 2 times per day) or a matching placebo orally simultaneously with chemotherapy from C1D10 to C2D10. The study was conducted between April, 2020 and September,2023, with a final follow-up on October,2023. The primary outcome was the change in total mean score (range: 0[no fatigue] to 10[extreme fatigue] points) on the Brief Fatigue Inventory(BFI-C) from baseline to week 3. Secondary outcomes include quality of life(European Organization for Research and Treatment of Cancer Quality of Life Core Questionnaire C30, QLQ-C30), fatigue score (MD Anderson Symptom Inventory for Traditional Chinese Medicine MDASI-TCM) and adverse events. RSYRT were compared with the placebo group using a linear mixed model. **Results:** Among 192 patients randomized, 163 participants completed assessment (RSYRT:81 and Placebo:82). There was no significant differences of "Usual fatigue in last 24 hours" score (RSYRT:5.15$\pm$1.41 vs Placebo:5.40$\pm$1.44,*P*= 0.256) in BFI between two groups at baseline. By the end of week 3, the RSYRT group achieved normal fatigue levels compared to the placebo group (RSYRT: 3.35$\pm$1.95 vs Placebo: 4.15$\pm$2.12, *P*= 0.013). The overall health status of QLQ-C30 also showed statistically significant differences (Pre intervention [RSYRT: 52.78 $\pm$ 15.14 vs. placebo: 49.49 $\pm$ 17.63, *P*= 0.204] , After intervention [RSYRT: 65.53 $\pm$ 15.52 vs. placebo: 57.72 $\pm$ 19.98, *P*= 0.006]) . The fatigue score of MDASI-TCM was comparable at baseline (RSYRT: 5.72 $\pm$ 1.69 vs placebo: 5.90 $\pm$ 1.70, *P*= 0.483) , and a significant decrease was observed in the third week (RSYRT: 3.69 $\pm$ 2.05 vs placebo: 4.56 $\pm$ 2.30, *P*= 0.012) . There was no difference in adverse events occurrence between RSYRT and the placebo groups. **Conclusions:** In this randomized clinical trial among platinum-treated cancer patients with CRF, RSYRT reduced fatigue severity and improved quality of life compared to placebo. Clinical trial information: NCT05229029. Research Sponsor: Capital's Funds for Health Improvement and Research.

Pathways to Advance Targeted and Helpful Serious Illness Conversations (PATH-SIC): A randomized clinical trial. First Author: Christopher Manz, Dana-Farber Cancer Institute, Boston, MA

Background: Serious illness conversations (SICs) can improve quality of life and decrease intensive care utilization at the end of life for patients with cancer. Yet SIC rates for patients with cancer are low and sustainable strategies are needed to engage patients and oncology clinicians in SICs. **Methods:** This randomized controlled trial was conducted at a tertiary cancer center. Using a cancer treatment guideline program (Pathways), oncology subspecialists identified treatment decision points where patients have an average prognosis $<$1 year and they would recommend an SIC. We enrolled patients with breast, gastrointestinal, genitourinary, gynecologic, and thoracic cancers who reached these points and did not have SICs documented in the Advance Care Planning tab (ACP-SICs) of the electronic medical record in the previous 6 months. Patients were randomized to receive a patient nudge (a mailed letter encouraging discussion of their values and preferences with their oncologist; arm 1), a clinician nudge (emails sent to oncology clinicians encouraging an SIC the day prior to the clinic visit; arm 2), both nudges (arm 3), or no nudges (arm 4). The primary analysis compared ACP-SIC documentation 60 days post-randomization for the combined vs no-nudge arms (arm 3 vs 4) using a generalized estimating equation model with a logit link adjusted for disease center and prior clinician SIC training, clustered on oncologists. A pre-specified alternative primary outcome used natural language processing (NLP) to identify SICs in free text notes in the 6 months prior to randomization and 60 days after to evaluate the presence of an NLP- or ACP-SIC 60 days after randomization using the same model. Similarly-constructed Cox proportional hazards models were used to estimate time to SIC. **Results:** Among 1051 patients randomized (arm 1: 273, arm 2: 240, arm 3: 277, arm 4: 261), median age was 65 years (range: 25-94), 40% were male, 79% White, 52% had gastrointestinal and 20% breast cancers. The Table displays unadjusted ACP and NLP+SIC rates. In adjusted analyses, compared to patients in the no-nudge arm (arm 4), patients in the combined nudge arm (arm 3) had 79% higher odds of ACP-SIC at 60 days (odds ratio 1.79, 95% CI 1.11-2.88, p=0.02) and 59% higher odds of NLP+ACP-SIC at 60 days (odds ratio 1.59, 95% CI 1.14-2.22, p=0.006). Time to ACP-SIC was 59% faster in clinician nudge-containing arms than the no-nudge arm (adjusted HR 1.59, 95% CI 1.16-2.19, p=0.004). **Conclusions:** Clinician emails increased SICs within 60 days, whereas patient nudges were ineffective. NLP increased detection of SICs by 49.7%, demonstrating the importance of evaluating SICs in free-text notes in SIC interventions.Long-term analyses will evaluate the interventions' impact on care delivery outcomes. Clinical trial information: NCT05629065. Research Sponsor: None.

Trajectories of patient-reported cognitive function and age-related conditions in a longitudinal observational trial of immune checkpoint inhibitor (ICI) treatment: The DiRECT Cohort. First Author: Charles Stewart Kamen, James P. Wilmot Cancer Center, University of Rochester Medical Center, Rochester, NY

Background: ICIs have become a mainstay in cancer treatment, but their impact on patient-centered side effects such as decline in cognitive function and age-related conditions (e.g., nutritional status, mobility) has not been fully characterized. Black patients have also been underrepresented in prospective studies of ICIs. Prior research indicates that Black cancer patients have strong pro-inflammatory immune responses, which could affect the impact of ICI treatment on cognitive function and age-related conditions. **Methods:** The longitudinal DiRECT cohort (URCC21038, NCT05364086) was established to examine ICI outcomes and side effects in Black and White patients through the NCI Community Oncology Research Program (NCORP). Patients reported their cognitive function through the PROMIS-Cog and age-related conditions through the Geriatric 8 (G8), with assessments before (A1), after (A2), 6 months after (A3), and annually after (A4+) their first ICI infusion. A longitudinal mixed-effects model (LMEM) with an unstructured covariance matrix and assessment as a nominal factor was used to evaluate trajectories of the two outcome variables. The models were adjusted for cancer type, race, and age ($<$65, 65+), including interactions with assessment. Multiple comparisons were conducted with a Sidak adjustment to maintain an overall significance level of $p<0.05$. **Results:** A total of 1,677 patients enrolled between 04/01/2022 and 08/31/2024 were included in the analysis: mean age 64; 409 Black; 626 lung, 290 breast, 251 gastrointestinal, 240 genitourinary, 131 gynecologic, 72 head/neck cancers; modal cancer stage IV. In unadjusted models, statistically and clinically significant declines from A1 to A3 were found for both cognitive function (SE=-2.54, $p<0.0001$) and age-related conditions (SE=-0.70, $p<0.0001$), with no change from A3 to A4. Patients with breast cancer experienced the steepest declines in both outcomes (SE=-3.40, $p<0.0001$ and SE=-0.76, $p<0.01$, respectively). Black patients experienced a steeper decline in cognitive function than White patients, particularly from A1 to A2 (SE=-1.28, p=0.01). There was no significant difference in trajectory of functional status by race. Patients $<$65 experienced steeper declines in cognitive function and age-related conditions (SE=1.21, p=0.02 and SE=0.84, p=0.04, respectively); Black patients $<$65 had steeper declines in cognitive functioning than White patients $<$65 (SE=-1.55, p=0.02). **Conclusions:** Breast cancer patients on ICIs appear to experience poor trajectories of cognitive function and age-related conditions over the first 6 months of treatment, while Black patients, particularly those $<$65, experience poor trajectories in cognitive function. These findings can inform tailored and risk-stratified interventions to improve ICI side effects. Research Sponsor: National Cancer Institute; UG3 CA262602; National Cancer Institute; UG1 CA189961.

12015 **Rapid Oral Abstract Session**

Severe sarcopenia and symptom burden prior to chemotherapy among older adults (70+) with advanced cancer: A URCC NCORP nationwide study. First Author: Lindsey Jean Mattick, Wilmot Cancer Institute, University of Rochester Medical Center, Rochester, NY

Background: Sarcopenia – defined as significant loss of strength, muscle mass and physical function– leads to reduced mobility, increased falls, difficulty performing activities of daily living, loss of independence, worse prognosis, and higher mortality among older cancer patients. Older patients with sarcopenia are at an even greater risk for these negative outcomes when additional co-morbid symptoms are present. Despite this, sarcopenia is not routinely screened for in this population. This study aims to describe the proportion of older patients with advanced cancer prior to chemotherapy who present with severe sarcopenia and the additional co-morbid symptoms they are most likely to be experiencing. **Methods:** In a randomized controlled trial (NCT02054741), 718 older adults (age 70+) with advanced cancer and age-related conditions were recruited prior to starting chemotherapy from community oncology practices across the United States who were affiliated with the University of Rochester NCI Community Oncology Research Program (NCORP) Research Base. We analyzed data from a subset of 159 participants prior to chemotherapy who completed assessments for muscle strength (chair stand; seconds [s]), skeletal muscle index (CT scan; SMI [cm^2/m^2]); physical performance (timed up and go; TUG [s]) at baseline. Severe sarcopenia was diagnosed if participants met all three clinically accepted criteria: 1) chair stand $>$ 16.7s for five rises, 2) SMI $<$ 41 cm^2/m^2 (women) and $<$ 43 cm^2/m^2 (men; BMI $<$ 24.9 kg/m^2) or $<$ 53 cm^2/m^2 (men; BMI $>$25 kg/m^2), and 3) TUG $>$ 13.5s. Symptoms (i.e., fatigue, insomnia, pain, anorexia, dyspnea, cognitive issues, nausea, sensory neuropathy, constipation, and diarrhea) were assessed via the Patient-Reported Outcomes version of the Common Terminology Criteria for Adverse Events (PRO-CTCAE). **Results:** Fifty-two of the 159 participants (33%; mean age: 76.7 years; 60% male) had severe sarcopenia. Chi-square analyses revealed participants with severe sarcopenia were significantly more likely to report fatigue (94% vs. 81%; p = 0.03), anorexia (73% vs. 55%; p = 0.03), and pain (73% vs. 60%; p = 0.13) compared to those without severe sarcopenia. Logistic regression indicated those with severe sarcopenia were almost 4x more likely to experience fatigue (OR [95%CI]: 3.75 [1.06-13.28]) and twice as likely to experience anorexia (OR [95%CI]: 2.21 [1.07-4.54]) compared to those without severe sarcopenia. **Conclusions:** One-third of older adults with advanced cancer are likely to present with severe sarcopenia, fatigue, anorexia, and pain prior to the initiation of chemotherapy. Clinicians should consider screening older adults for sarcopenia and other comorbid symptoms to inform cancer treatment decisions prior to the initiation of therapy, and supportive care interventions should be prescribed to mitigate these symptoms. Funding: NCI UG1CA189961 T32CA102618. Research Sponsor: None.

12016 Rapid Oral Abstract Session

Effect of incorporating symptom burden with mortality as a composite outcome on accuracy and bias in palliative care identification algorithms in oncology. First Author: Sophia Shi, University of Pennsylvania, Philadelphia, PA

Background: Machine learning (ML) algorithms are increasingly used to identify patients for early palliative care (PC) or advance care planning (ACP). Most PC/ACP algorithms are trained using only mortality as an outcome. However, increasing availability of structured patient-reported outcomes (PROs) in electronic health record (EHR) databases can facilitate more comprehensive identification of palliative care need by training algorithms on composite outcomes of mortality and symptom burden. **Methods:** Our cohort consisted of patients with cancer seen at one of 18 practices in 2019 within a large academic cancer center. We leveraged structured EHR data, consisting of 153 demographic, laboratory, and comorbidity features and 12 symptom scores derived from CTCAE-PRO that were routinely reported at medical oncology encounters (72% response rate). Our Base Model was a random forest model predicting 180-day mortality from the date of an initial medical oncology encounter (index encounter) that was used in practice to prompt earlier ACP conversations. We retrained models using a Composite Label of mortality and/or severe symptoms ($\geq$3 out of 5 in at least 1 symptom) within 180-days of an index encounter. We report performance for Base vs. Retrained models in 1,000 bootstrapped samples predicting the Composite Label using area under the precision-recall curve (AUPRC) and true positive rate (TPR) for All Patients, Black Patients, and White Patients. We hypothesized that Retrained models would improve performance and reduce Black-White disparities. **Results:** Our cohort consisted of 4908 patients (median age 64.1 years [IQR 17.5], 53.0% female, 59.6% solid tumor malignancies). Retrained Models improved TPR over Base Models for All (0.56 [95% CI 0.52-0.59] vs. 0.18 [95% CI 0.15-0.21]), Black (0.60 [95% CI 0.52-0.67] vs. 0.20 [95% CI 0.14-0.26]), and White (0.55 [95% CI 0.50-0.59] vs. 0.17 [95% CI 0.14-0.20]) patients, with similar AUPRC. TPR improvement was marginally greater for Black vs. White patients (0.02 [95% CI -0.01-0.05]). **Conclusions:** In this cohort study, retraining a PC identification algorithm on a Composite outcome of symptom burden + mortality significantly enhanced identification of PC need, with disproportionate improvements for Black patients. Incorporating PROs into PC identification model outcome labels should be strongly encouraged. Research Sponsor: National Cancer Institute; K08CA263541.

Precision-calibrated LightGBM machine learning model to predict serious adverse events in oncology patients using FAERS. First Author: Xiyu Zhao, Johns Hopkins University School of Medicine, Baltimore, MD

Background: The U.S. Food and Drug Administration's Adverse Event Reporting System (FAERS) is a large national repository capturing postmarketing drug safety events. Predicting serious adverse events (SAEs) is especially critical for oncology patients, who often face complex regimens and higher toxicity risks. Currently, there are no well-established predictive tools to identify those at highest risk of SAEs in the cancer population. We aimed to develop a machine learning (ML) model that leverages FAERS data to address this clinical gap. **Methods:** We collated FAERS records from 2012Q4–2024Q3 that listed cancer as an indication, encompassing demographics, outcome codes (SAEs defined as death, life-threatening, disability, hospitalization, or congenital anomaly/birth defect), and drug data. Excluding non-cancer or incomplete entries, we split the dataset into 80% for training and 20% for testing, applying cross-validation to derive 95% confidence intervals. Training data underwent SMOTETomek oversampling to counter class imbalance. We then built a precision-focused LightGBM model using high-depth RandomizedSearchCV to fine tune the hyperparameters and subsequently applied sigmoid calibration to yield stable probability estimates and enhanced interpretability. Additionally, a logistic regression model was built under the same pipeline as a baseline comparator. **Results:** Of the final 2.28 million oncology-related reports, ~44% met SAE criteria. On the ~450,000-report test subset, our calibrated LightGBM model achieved 75% accuracy, with precision = 73.7% and recall = 86.3%, yielding an F1 of 0.795. The AUROC reached ~0.82 (95% CI ~0.80–0.84), underscoring robust discrimination, and the AUPRC approached 0.77. By comparison, logistic regression attained 73% accuracy (precision 72.9%, recall 81.5%, F1 = 0.77). Thus, the LightGBM pipeline offered notable gains in recall and F1 while preserving practical precision. Cross-validation demonstrated stable performance ($\pm$~1–2% across folds), and preliminary partial SHAP analysis indicated that older age ($\geq$65 years), multi-agent chemotherapy, and prior adverse event histories were among the strongest predictors of SAE risk. **Conclusions:** In this largest FAERS-based oncology SAE analysis, our LightGBM model markedly outperformed logistic regression, achieving high recall (86%) and balanced precision (74%). These findings represent a significant advance in real-world pharmacovigilance, enabling earlier and more reliable detection and prediction of severe toxicities in cancer patients. Future prospective validations, potentially incorporating external datasets, may further amplify its clinical impact. Research Sponsor: None.

Cardiovascular risks associated with aromatase inhibitors versus tamoxifen in breast cancer: A systematic review and meta-analysis. First Author: Danilo Monteiro Ribeiro, Escola de Medicina - Universidade Anhembi Morumbi, Piracicaba, Sao Paulo, Brazil

Background: Aromatase inhibitors (AIs), such as anastrozole, letrozole, and exemestane, are commonly used in the treatment of women with early or advanced-stage breast cancer (BC). However, the potential cardiovascular risks associated with AI treatment, particularly the occurrence of cardiovascular events (CVEs) such as acute myocardial infarction and ischemic stroke, remain a concern. This meta-analysis aims to evaluate the impact of AI and tamoxifen treatment on the risk of CVEs in women with BC. **Methods:** A comprehensive search was performed across PubMed, Embase, and Cochrane databases for randomized controlled trials (RCTs) and cohort studies comparing cardiovascular outcomes in patients with BC receiving AIs (anastrozole, letrozole, or exemestane) versus those receiving tamoxifen. Data were analyzed using a random-effects model, and the odds ratios (OR) with 95% confidence intervals (CI) were calculated. P values $>$ 0.10 and I2 values $>$ 25% were considered to indicate significance for heterogeneity. Statistical analysis was performed using R, version 4.4.2. **Results:** Sixteen studies, involving 188,635 participants, were included in the analysis, of whom 124,473 (65.98%) received AI treatment. A statistically significant difference was observed in heart failure and cardiomyopathy, with the treatment showing an increased risk of these events (OR: 1.48; 95% CI [1.11 to 1.99]; p = 0.0079; I2: 79%). Similarly, myocardial infarction was also significantly more likely to occur in the AI group (OR 1.20; 95% CI [1.01 to 1.42]; p = 0.033; I2: 59%). Thromboembolic events were less frequent in the AI group compared to the Tamoxifen group (OR 0.75; 95% CI [0.56 to 0.99]; p = 0.044; I2: 82%). Arrhythmia was associated with a HR of 1.2306 (95% CI [0.8295 to 1.8255]; p = 0.302; I2: 89%). Cardiovascular death had a HR of 1.09 (95% CI [0.86 to 1.40]; p = 0.451; I2: 55%), and stroke had a HR of 1.0233 (95% CI [0.90 to 1.15]; p = 0.715; I2: 41%). Cardiovascular death in terms of OR was 1.26 (95% CI [0.94 to 1.69]; p = 0.128; I2: 84%), and the risk of cardiovascular events was associated with an OR of 1.38 (95% CI [0.99 to 1.92]; p = 0.054; I2: 64%). Heart failure and cardiomyopathy had a HR of 1.24 (95% CI [0.98 to 1.56]; p = 0.064; I2: 79%), while thromboembolic events had a HR of 1.02 (95% CI [0.88 to 1.17]; p = 0.774; I2: 0%). The HR for myocardial infarction was 1.12 (95% CI [0.93 to 1.36]; p = 0.214; I2: 59%). Hypertension was associated with an OR of 1.07 (95% CI [0.94 to 1.21]; p = 0.2866; I2: 40%), and stroke had an OR of 1.10 (95% CI [0.91 to 1.33]; p = 0.320; I2: 66%). **Conclusions:** This systematic review and meta-analysis indicate that AI treatment in BC patients is associated with an increased risk of heart failure, cardiomyopathy, and myocardial infarction. Notably, AI treatment demonstrated a protective effect against thromboembolic events. Research Sponsor: None.

12019 Poster Session

Effectiveness of the Automated Heart-Health Assessment (AH-HA) tool on cardiovascular health improvements among post-treatment cancer survivors: 12-month results from WF-1804CD. First Author: Kathryn E. Weaver, Wake Forest University School of Medicine, Winston-Salem, NC

Background: Cardiovascular disease causes significant morbidity and mortality among US survivors. To enhance guideline recommended cardiovascular health (CVH) discussions during survivorship care, our team developed the EHR-based AH-HA clinical decision support tool, which displays modifiable CVH factors and cancer treatments with cardiotoxic potential. This tool significantly improved delivery of guideline-concordant CVH discussions, the primary study outcome; here we report AH-HA impacts on 12-month CVH improvements. **Methods:** The Wake Forest NCORP Research Base coordinated this practice-randomized clinical trial (NCT# 03935282) comparing AH-HA and usual care (UC) practices. Participants were survivors $\geq$ 6 months post-potentially curative treatment for breast, prostate, colorectal, endometrial cancers, or lymphoma, scheduled for routine follow-up. The AH-HA tool, based on the American Heart Association (AHA) Life's Simple 7, aimed to enhance CVH awareness and action by providers and survivors. At AH-HA practices, providers used the tool with survivors during an outpatient oncology visit. CVH data were collected from the EHR and survivors (diet quality & physical activity) at baseline and 12 months. Outcomes included Simple 7 total CVH score (0-100, using AHA algorithm) and meaningful change in individual CVH factors (Table). Generalized estimating equations calculated rates of clinically meaningful improvements in CVH factors at 12 months by group, adjusting for cancer type and clustering within practice. **Results:** 645 survivors (82.3% breast cancer; 96.0% female; 83.9% white non-Hispanic, 7.8% Black, 3.7% Hispanic) enrolled at 9 practices (5 UC and 4 AH-HA). The total CVH score did not significantly change from baseline or between groups (Table 1, p$>$.05). Within the AH-HA arm, 20.3% of survivors achieved 5% weight reduction compared to 12.6% in UC; physical activity also improved more in the AH-HA arm, but not significantly. Rates were similar between arms for diet, blood pressure, and hemoglobin A1c. **Conclusions:** In addition to facilitating guideline concordant CVH discussions, AH-HA shows promise for encouraging weight loss among survivors. It is notable that a brief intervention delivered as part of standard oncology care impacted weight reduction. Clinical trial information: NCT03935282. Research Sponsor: National Cancer Institute; R01CA226078; National Cancer Institute; 5UG1CA189824; National Cancer Institute; P30CA012197.

12 month cardiovascular health outcomes among post-treatment survivors.

CVH Outcomes	AH-HA 4 practices, (n=281)	Usual Care 5 practices, (n=342)	Adj P-value

Primary prevention of cardiotoxicity in cancer patients treated with fluoropyrimidines: A randomized controlled trial. First Author: Johanne Dam Lyhne, Department of Oncology, Lillebaelt Hospital, University Hospital of Southern Denmark, Vejle, Denmark

Background: Fluoropyrimidines (FP) are the third most used chemotherapeutic drugs administered in solid tumors but have cardiotoxic side effects. The aim of this study is to determine whether pre-chemotherapeutic cardiological assessment and management of cardiovascular risk factors could prevent FP-induced cardiotoxicity and if the coronary artery calcium (CAC) score was predictive of chest pain. **Methods:** This was a randomized, controlled, single center trial (ClinicalTrials.gov NCT03486340) of patients with various cancer types who were treated with FP and had no known ischemic heart disease. All patients had CAC score obtained by cardiac CT scan. Patients were randomized to pre-chemotherapeutic cardiological management or standard care. Cardiological management included risk reduction based on electro- and echocardiographic evaluation and blood samples. Primary composite endpoint included hospital admission for chest pain, acute coronary syndrome, coronary angiography intervention, or all-cause mortality. Secondary outcome was chest pain. Follow-up was 6 months. Data were analyzed using Kaplan-Meier survival function with log-rank test and ROC-analyses. **Results:** Of the 192 patients included, the primary endpoint occurred in 9/95 (9.5%) patients in the intervention group and 15/97 (15.5%) patients in the control group (log-rank p = 0.19) with an incidence rate ratio (IRR) of 0.57 (95% CI [0.22 – 1.39]). Chest pain occurred in 6/95 (6.3%) patients in the intervention group and 13/97 (13.4%) in the control group, yielding an IRR of 0.44 (95% CI [0.14 – 1.23]). CAC score did not predict chest pain occurrence. **Conclusions:** Cardiological management of cardiovascular risk factors prior to treatment with fluoropyrimidines resulted in half as many cardiotoxic events but the study did not reach statistical significance. Further studies are needed to investigate the optimal strategies to prevent fluoropyrimidine-induced cardiotoxicity in cancer patients. Clinical trial information: NCT03486340. Research Sponsor: Region of Southern Denmark.

DNA methylation biomarkers of cardiotoxicity risk in breast cancer patients treated with anthracyclines. First Author: Mohammed Al-Jumayli, H. Lee Moffitt Cancer Center and Research Institute, Tampa, FL

Background: Anthracyclines are effective chemotherapeutic agents for treating breast cancer but are associated with significant risks of chemotherapy-related cardiac dysfunction (CTRCD). Current predictors of CTRCD, including patient demographics and clinical characteristics, are insufficient for accurately assessing cardiotoxicity risk before treatment initiation. Here, we examine CTRCD risk associations with pre-treatment DNA methylation (DNAm)-derived biomarkers of biological age, called "epigenetic clocks," and circulating leukocyte composition. **Methods:** A retrospective cohort of 137 newly diagnosed breast cancer patients who received anthracycline-based therapy was sampled from the Total Cancer Care cohort at Moffitt Cancer Center. DNAm profiles were assayed using MethylationEPIC v2 BeadChips on pretreatment whole blood samples and used to derive six biological age metrics and percentages of twelve circulating leukocyte subsets. CTRCD events occurring within one year of treatment initiation were identified through medical records and defined as either a reduction in left ventricular ejection fraction ($\geq$10%) or symptomatic heart failure. Logistic regression models, adjusted for chronological age and traditional cardiotoxicity risk factors (e.g., hypertension, diabetes, baseline ejection fraction, and cumulative anthracycline dose), estimated odds ratios (ORs) for associations between DNAm biomarkers and CTRCD. **Results:** Among 137 newly diagnosed breast cancer patients (mean age: 54 years; 94% white), 33 (24%) experienced CTRCD. In age-adjusted models, the percentage of circulating naïve CD4+ T cells was inversely associated with CTRCD risk, and Horvath18 AgeAccel was positively associated with CTRCD risk, but these associations did not reach statistical significance after additional adjustment for other cardiotoxicity risk factors. In fully adjusted models, a higher percentage of circulating eosinophils was positively associated with CTRCD risk (OR: 1.49; 95% CI: 1.02, 2.24; P = 0.04). **Conclusions:** A higher percentage of circulating eosinophils appears to be a novel risk factor for CTRCD in breast cancer patients. While eosinophils may contribute to CTRCD susceptibility through mechanisms such as creating a pro-inflammatory environment in cardiac tissue, further studies are needed to clarify the role of eosinophils and confirm these findings. Typically, monocyte/macrophage-mediated pathways, including IL-6 and other cytokines, are thought to play a central role in anthracycline-related cardiac injury, but eosinophil-mediated effects may represent an alternative or complementary pathway. Integrating DNAm biomarker and leukocyte composition assessments into clinical workflows could improve CTRCD risk stratification in newly diagnosed breast cancer patients. Association of sodium-glucose co-transporter-2 inhibitors with cardiac outcomes and mortality in cancer patients: A systematic review and meta-analysis. First Author: Sufyan Shahid, Khawaja Muhammad Safdar Medical College, Sialkot, Pakistan

Background: Sodium-glucose co-transporter 2 inhibitors (SGLT2is) have proven effective in improving cardiac outcomes, including heart failure (HF) hospitalizations and cardiovascular mortality. However, data on the role of SGLT2is in cancer patients with diabetes remain limited. **Methods:** We conducted a systematic review and meta-analysis of studies on patients with concomitant cancer and diabetes to compare cardiac outcomes and mortality between SGLT2i users and non-users. Data were collected from PubMed, Embase, and Cochrane Central databases. Statistical analysis was performed using R Software v4.4.1. A random-effects model was applied to pool risk ratios (RRs) and 95% confidence intervals, with statistical significance set at $p < 0.05$. **Results:** Ten studies, with a total of 100,004 patients (mean age = 66.4 years, 47% female), were included. The mean follow-up duration was 2 years. The results showed that cancer patients with diabetes on SGLT2is had significantly reduced all-cause mortality (RR: 0.48; 95% CI: 0.34 to 0.68; $p < 0.001$; $I^2 = 98\%$), cancer therapy–related cardiac dysfunction (CTRCD) (RR: 0.68; 95% CI: 0.62 to 0.75; $p < 0.001$; $I^2 = 0\%$), and risk of heart failure exacerbation (RR: 0.78; 95% CI: 0.70 to 0.86; $p < 0.001$; $I^2 = 0\%$) compared to the control group. However, the incidence of heart failure (HF) (RR: 0.66; 95% CI: 0.22 to 1.96; p = 0.453; $I^2 = 18\%$) and risk of clinically significant arrhythmias (RR: 0.30; 95% CI: 0.06 to 1.55; p = 0.151; $I^2 = 0\%$) were comparable between two groups. **Conclusions:** In cancer patients with diabetes, SGLT2is inhibitors are associated with reduced all-cause mortality, CTRCD, HF incidence, and risk of heart failure exacerbation with a non-significant trend toward HF incidence and clinically significant arrhythmias compared to the control group. Research Sponsor: None.

Outcome	Risk ratios with 95% Confidence Intervals (CI)	p-value
All-cause mortality	0.48 (0.34 to 0.68)	P<0.001
Cancer therapy–related cardiac dysfunction	0.68 (0.62 to 0.75)	P<0.001
Heart failure exacerbation	0.78 (0.70 to 0.86)	P<0.001
Heart failure incidence	0.66 (0.22 to 1.96)	P=0.453
Clinically significant arrhythmias	0.30 (0.06 to 1.55)	P=0.151

12023 **Poster Session**

Effects of SGLT2i dapagliflozin in primary prevention of cardiotoxicity induced by short-term anthracycline and HER2 blocking agent therapy through inhibition of MyD88 and NLRP-3 pathways. First Author: Vincenzo Quagliariello, Istituto Nazionale Tumori IRCCS "Fondazione G. Pascale", Naples, Italy

Background: Anthracyclines, such as doxorubicin, and HER-2 blocking agents, like trastuzumab, are integral in breast cancer treatment but are associated with significant cardiotoxicity. Sodium-glucose cotransporter 2 (SGLT2) inhibitors have been suggested to provide cardio-renal benefits in the context of anthracycline therapy. However, the cardioprotective effects of SGLT2 inhibitors during combined anthracycline and HER-2 blocking agent therapy remain largely unexplored. The study aimed to investigate the cardioprotective potential of Dapagliflozin in primary prevention of anthracyclines and HER-2 blocking agents-mediated cardiotoxicity in preclinical models. **Methods:** Female C57Bl/6 mice were treated for 10 days with a saline solution or DOXO-Trastuzumab (both at 2.17 mg/kg), DAPA (10 mg/kg), or DOXO-Trastuzumab combined with DAPA. Systemic levels of ferroptosis-related biomarkers, galectin-3, high-sensitivity C-reactive protein (hs-CRP), and pro-inflammatory chemokines (IL-1α, IL-1β, IL-2, IL-4, IL-6, IL-10, IL-12, IL17-α, IL-18, IFN-γ, TNF-α, G-CSF, and GM-CSF) were quantified. After treatments, immunohistochemical staining of myocardial and renal IL-1, IL6, CXCR4, NLRP-3 and Myd88 was performed. **Results:** DAPA prevented the reduction of radial and longitudinal strain and ejection fraction after 10 days of treatment with DOXO-Trastuzumab. A reduced myocardial expression of NLRP-3, MyD-88, IL-6 and IL1 was seen in the DOXO-TRA+ DAPA group compared to DOXO-TRA mice. Systemic levels of IL-1β, IL-6, TNF-α, G-CSF, and GM-CSF were significantly reduced after treatment with DAPA. Serum levels of galectine-3 and hs-CRP were strongly enhanced in the DOXO-Trastuzumab group; on the other hand, their expression was reduced in the DAPA+DOXO-Trastuzuab group. Troponin-T, B-type natriuretic peptide (BNP), and N-Terminal Pro-BNP (NT-pro-BNP) were strongly reduced in the DOXO-Trastuzumab+DAPA group, revealing cardioprotective properties of SGLT2i. Mice treated with DOXO-Trastuzumab and DAPA exhibited reduced myocardial and renal IL-1, IL6, CXCR4, NLRP-3 and Myd88 IHC straining. **Conclusions:** This study presents the first evidence of Dapagliflozin's cardioprotective and anti-inflammatory effects in the context of anthracycline and HER-2 blocking agent-induced cardiotoxicity. These findings support the potential use of Dapagliflozin for primary prevention of cardiovascular events associated with doxorubicin-trastuzumab therapy in breast cancer patients, warranting further clinical investigation. Long-term trastuzumab safety in tailored dose-dense anthracycline containing adjuvant chemotherapy in the PANTHER phase III trial. First Author: Andri Papakonstantinou, Karolinska Institutet, Stockholm, Sweden

Background: Cardiotoxicity is a known side effect of trastuzumab and combination with anthracyclines increases the risk for cardiotoxicity. Adjuvant dose-dense (DD) chemotherapy has demonstrated beneficial breast cancer (BC) outcomes in patients with high risk for relapse, but data on long-term cardiac toxicity when combined with trastuzumab is scarce. We have previously reported on the safety of trastuzumab at six years follow-up, in a subset of patients treated with dose-dense chemotherapy in the Pan-European Tailored Chemotherapy (PANTHER) phase III trial. We hereby present long-term safety data from 10-year follow-up from the same subset. **Methods:** This is a protocol-predefined cardiac safety study, among Swedish sites included in the PANTHER trial, including patients with HER2-positive (HER2+) and HER2-negative (HER2-) BC matched for age, treatment group and institution. Enrolled patients were up to 65 years old with node-positive or high-risk, node-negative BC were randomized 1:1 to either dose tailored (according to hematologic nadirs) and biweekly DD epirubicin and cyclophosphamide followed by docetaxel or standard 5-fluorouracil, epirubicin, and cyclophosphamide plus docetaxel every 3 weeks. Patients with HER2-positive disease received 1 year of adjuvant trastuzumab. They underwent echocardiography (ECHO) or multigated acquisition scanning and electrocardiography at baseline, at 4, 6 and 10 years of follow-up. Data on cardiac medication NT-proBNP, lipid profile and ECG were also collected. **Results:** ECHO at 10-years follow-up was available for 94 patients; 48 HER2+ (19 DD, 29 control) and 46 HER2- (21 DD, 25 control). Overall, incidence of cardiotoxicity was low. Mean LVEF was 58 % (range 49-68%) and 60.65% (range 50-76%) in HER2+ and HER2- respectively. Only one patient had LVEF $<$ 50% (DD HER2+) and additional 12 patients had LVEF 50-54%, equally distributed between the treatment groups. In total, 27 patients were treated with cardiac medications at this point; 15 (56%) of which had been treated with trastuzumab and 10 of them (n = 7 HER2+), not reporting cardiac medication at previous timepoints. The majority of the patients did not report any symptoms related to heart disease, per NYHA-classification (41 patients in both groups report NYHA class 0). Overall, no significant changes were seen in the biomarkers. **Conclusions:** Cardiotoxicity of trastuzumab in DD anthracycline chemotherapy, examined in the context of a randomized trial sub-study, was very low. Our results underline the safety of trastuzumab in this context, providing support to offer the patients best treatment options for improving breast cancer survival. Clinical trial information: NCT00798070. Does early recognition and treatment of immune-related myositis and myasthenia gravis reduce mortality of immune-related myocarditis? First Author: Natalie Longino, University of Colorado Comprehensive Cancer Center, Aurora, CO

Background: Immune checkpoint inhibitors (ICIs) have revolutionized cancer treatment. However, some immune-related adverse events (irAEs) can be severe, even fatal. ICI-induced myocarditis (ICI-M) carries the highest mortality rate of 30-50%. Notably, ICI myocarditis frequently co-occurs with ICI-induced myositis (ICI-M^2) or as a triad of ICI-induced myocarditis, myositis and myasthenia gravis (ICI-M^3). Despite this known association, it remains unclear whether these entities represent distinct disease processes or a spectrum of disease severity. Therefore, we sought to compare outcomes among those diagnosed with ICI-M, ICI-M^2 and ICI-M^3. **Methods:** We performed a single-institution retrospective cohort study using the electronic health record to identify patients seen in a solid tumor clinic between 1/21/11 – 1/21/25, who had received ICI therapy. There was a concern for myocarditis in 82 patients, of which 33 were deemed to have $>$ grade 2 ICI-induced myocarditis. Of the 33 cases, 36% had ICI-M, 36% had ICI-M^2 and 27% had ICI-M^3. We then assessed differences in age, sex, cancer type & stage, immunotherapy regimen, number of immune suppressants given, myocarditis grade, and overall survival across these groups. **Results:** The Table shows patients with ICI-M presented at an earlier cancer stage and more commonly after ICI monotherapy than combination therapy. Despite this, these patients typically had more severe grade $\geq$ 3 myocarditis (75%) compared with ICI-M^2 (42%) and ICI-M^3 (44%) and had a worse overall survival (33%) as compared to ICI-M^2 and ICI-M^3 (67% and 78% respectively). Notably ICI-M patients typically presented with cardiac-specific symptoms and presented after more cycles of ICI therapy (avg. of 4 cycles). In contrast, ICI-M^2 and ICI-M^3 patients presented after fewer ICI cycles (avg. of 2 cycles) with symptoms of myositis or myasthenia. They typically did not present with cardiac-specific symptoms and were then incidentally found to have mildly elevated troponin levels. **Conclusions:** Patients with ICI-M presented after more ICI cycles, had more severe myocarditis and worse overall survival as compared to ICI-M^2 and ICI-M^3 patients. Our findings suggest that patients who developed concurrent symptoms of myositis or myasthenia gravis, prompted earlier recognition of mild myocarditis, leading to earlier initiation of immunosuppressive treatment thereby improving clinical outcomes. Research Sponsor: None.

	ICI-M (n = 12)	ICI-M^2 (n = 12)	ICI-M^3 (n = 9)	Total (n = 33)

Temporal trends and disparities in cardiovascular mortality among breast cancer patients: A 25-year population analysis of the CDC WONDER database (1999-2023). First Author: Ibrahim Hassan, Faculty of Medicine, Suez Canal University, Ismailia, Egypt

Background: Breast cancer and cardiovascular disease (CVD) are leading causes of mortality among women in the United States. While advancements in breast cancer treatment have improved survival rates, these therapies may contribute to CVD-related complications, influencing long-term outcomes. This study examines 25-year trends (1999–2023) in CVD mortality among breast cancer patients, with a focus on racial, regional, and urbanization disparities. **Methods:** Data was analyzed from the CDC WONDER (Centers for Disease Control and Prevention for Wide-ranging Online Data for Epidemiologic Research) covering the period from January 1, 1999, to December 31, 2023, to evaluate CVD mortality among breast cancer patients. Analysis was done using Joinpoint regression. Age-adjusted mortality rates (AAMR) per 100,000 person-years were calculated, and trends were assessed using annual percent change (APC) with statistical significance defined at $p < 0.05$. Disparities were evaluated across racial/ethnic groups, U.S. census regions, and urban-rural settings. **Results:** 85,316 CVD-related deaths were recorded among breast cancer patients from 1999 to 2023. AAMR declined significantly overall (APC: -2.73, $p < 0.001$), decreasing from 1.66 in 1999 to a nadir of 0.72 in 2016 (APC: -5.11, $p < 0.001$), followed by a rebound to 0.84 in 2023 (APC: +3.29, $p < 0.001$). Disparities were noted among racial groups: non-Hispanic Black women had the highest mortality rates, followed by non-Hispanic Whites and Hispanics, all showing significant downward trends with APCs of -1.93, -2.63, and -2.431, respectively ($p < 0.001$). The lowest mortality rates were recorded in 2016 for all groups, except for non-Hispanic Blacks, who had their lowest in 2015. Regionally, the Northeast initially had the highest AAMR until 2016, after which rates converged; by 2023, the South reported the highest mortality (0.86). Rural areas consistently exhibited higher AAMR than urban areas, though both declined significantly over the study period. **Conclusions:** Despite an overall decline in CVD mortality among breast cancer patients, persistent racial, regional, and urban-rural disparities highlight systemic inequities in care. The post-2016 resurgence in mortality underscores potential gaps in long-term cardiovascular surveillance for survivors. Targeted interventions addressing racial disparities, regional resource allocation, and rural healthcare access are critical to mitigating CVD risk in this population. Further research is needed to elucidate drivers of these trends and inform equitable policy reforms. Research Sponsor: None.

Major adverse cardiovascular events (MACE) in cancer patients treated with tirzepatide compared to GLP-1 receptor agonists: A target trial emulation using real-world data. First Author: Omer Ashruf, Northeast Ohio Medical University, Rootstown, OH

Background: Cardiovascular disease (CVD) is a leading cause mortality in cancer patients. Obesity and type 2 diabetes are well-known modifiable risk factors for CVD progression and adverse CV related outcomes. We aim to assess the CV benefit of tirzepatide versus GLP-1 receptor agonists (GLP-1RA), a mainstay treatment in management of obesity and cardiometabolic disease, in cancer patients. **Methods:** We conducted a target trial emulation using TriNetX, an aggregated EHR platform. We identified adults (May 2022-Jan 2024) diagnosed with solid neoplasm and cardiometabolic conditions (hypertension, dyslipidemia, obesity, or type 2 diabetes). We excluded patients with in situ neoplasms, hematologic malignancy, metastatic solid neoplasm, medication contraindication (type 1 diabetes, gastroparesis, thyroid cancer), performance status ECOG $>$ 3, or on dialysis. Patients were divided into two exclusive groups: tirzepatide or GLP-1RA. The first prescription of each medication was defined as time zero/index event. Individuals with any MACE within 60 days prior to index event were excluded. Study groups were propensity matched, using a 1:1 nearest neighbor algorithm, for 55 covariates: demographics, Charlson comorbidity index and cardiac conditions, chemotherapy, radiation, BMI, HbA1c, LDL, eGFR, systolic BP, medications, smoking/alcohol, and social determinants. Primary outcome was incidence of MACE (acute myocardial infarction, stroke, or CV death) and overall survival over a 2-year period. Secondary outcomes were changes in HbA1c and BMI. Kaplan Meier analysis and hazard ratios (HRs) were calculated to compare time-to-event outcomes. **Results:** We identified 42,584 patients [mean age 55.4 ($\pm$12.1) years; 62.5% female; 63.1% White; mean HbA1c 6.82 ($\pm$1.81); mean BMI 37.5 ($\pm$7.7)] with solid tumors and cardiometabolic conditions. Tirzepatide was associated with a significant MACE reduction compared to GLP-1RA and improved overall survival (Table 1). At follow-up, mean HbA1c was significantly lower in tirzepatide group (6.21 $\pm$ 1.28) compared to GLP-1RA (6.50 $\pm$ 1.46; $p < 0.001$). Patients on tirzepatide also experienced greater BMI reduction (34.7 $\pm$ 7.7 kg/m2) compared to GLP-1RA (35.5 $\pm$ 7.7 kg/m2; $p < 0.001$). **Conclusions:** Tirzepatide was associated with significant reductions in MACE, HbA1c, and BMI compared to GLP-1RA, suggesting a preferential pharmacotherapy option for addressing obesity and cardiovascular disease reduction in cancer patients while improving overall survival outcomes and quality of care in this high-risk population. Research Sponsor: None.

Outcome	Adjusted HR (95% CI)	*p*-value

12028 Poster Session

Effect of a letter of condolence proposing a post-mortem consultation to the relatives of cancer patients on anxiety, depression and grief: Results of a multicenter randomized study. First Author: Gwenaelle Gravis, Institut Paoli-Calmettes, Department of Medical Oncology, Aix Marseille Univ, INSERM, CNRS, CRCM, Immunity and Cancer Team, Marseille, France

Background: The relativesof cancer patients are at risk for developing emotional distress following the death of their loved one. The aim of this study was to analyze whether sending a condolence letter offering a post-mortem consultation with the referent oncologist to the relatives of patients who have died of cancer improve their long term reported outcomes, such as anxiety, depression and complicated grief. **Methods:** In this multicenter, prospective, randomized, academic trial, bereaved relatives, of cancer patients who died in hospital, were randomized between receiving a condolence letter (CL) suggesting post-mortem consultation *versus* no CL. At 3 months and 6 months after enrolment, anxiety (HAD-A), depression (HAD-D) and grief (Texas Revised Inventory of Grief [TRIG]) were assessed using self-administered questionnaires. **Results:** Of the 426 randomized relatives, 118 agreed to take part in the study, of whom 102 (49 CL, 53 no CL) completed the questionnaire 3 months after the relatives' death and 92 (43 CL, 49 no CL) at 6 months. There was no differences in sociodemographic characteristics or history of depression between the two groups. Palliative care was involved for (69% CL, vs 52% non-CL) of patients, with no statistical difference between the two groups. At 3 months post enrolment, both anxiety and depression were significantly lower in the CL group than the non-CL group (mean HADS-A score 7.3 vs 9.4, p=0.026; mean HADS-D score: 5.4 vs 8.1, p=0.009). In addition, receiving a condolence letter was associated with less grief at patient's death (past TRIG subscale: 20.7 vs 25.8, $p<0.001$), and less current grief (present TRIG subscale score: 45.7 vs 52.0, p=0.025). At 6 months, the HADS-D score was significantly lower in the condolence letter arm (mean score 5.7 vs 8.3, p=0.025), as was grief at patient's death (past TRIG subscale: 21.5 vs 25.0, p=0.035). Only 5% of CL had a post mortem consultation. **Conclusions:** Sending a letter of condolence to relatives of cancer patients who have died in hospital may reduce subsequent grief, depression and anxiety in loved ones. Encouraging this widespread post mortem contact such as correspondence may be a non-drug alternative to reduce post-mortem depression and improve the bereavement process for relatives of cancer patients. Clinical trial information: NCT02861625. Research Sponsor: French National Cancer Institute; PHRC-K 14-042.

Disparities in receipt of palliative treatments among disaggregated Hispanic populations with breast, lung, and prostate cancer in the United States. First Author: Shriya Garg, University of Georgia, Athens, GA

Background: Despite palliative interventions' ability to improve the quality of life and possibly improve overall survival, significant inequalities persist in uptake. Disparities in the receipt of palliative-intent interventions are characterized by broad race, socioeconomic, and geographical categories; however, less is known among disaggregated Hispanic populations. We examine disparities among Hispanic subgroups in receipt of palliative-intent interventions among disaggregated Hispanic patients with stage IV lung, breast, and prostate cancer. **Methods:** Using the National Cancer Database (NCDB), we collected data on the receipt of palliative-intent interventions (including radiotherapy, chemotherapy, and/or other pain management therapy) among Hispanic subgroups diagnosed with AJCC analytic stage IV breast, lung, and prostate cancer between 2004 and 2021. Multivariate linear regressions (adjusting for age group, country of origin, year group, sex, insurance status, 2016 median income quartiles, facility type, CDCC Score, and facility location) were conducted for each cancer type to quantify the disparities in uptake of palliative-intent interventions among Hispanic subgroups. **Results:** Among 945,894 total patients, disaggregated analyses revealed reduced receipt of palliative-intent interventions for lung, breast, and prostate cancer patients of Mexican descent (Lung AOR 0.74, [0.67-0.81], $P<0.001$; Breast AOR 0.69, [0.58-0.82], $P<0.001$; Prostate AOR 0.82, [0.69-0.99], P=0.03) compared to non-Hispanic white patients. Receipt of palliative-intent interventions for patients of South or Central American descent and Cuban descent were also reduced in comparison to White patients for lung and breast tumors. Reuptake of palliative-intent interventions for breast cancer was significantly reduced for patients of Dominican Republic descent compared with non-Hispanic white patients (AOR 0.65, [0.43-1.00], P=0.05). **Conclusions:** Our findings expose that disparities exist in the receipt of palliative-intent interventions among Hispanic subgroups upon disaggregation. We highlight the need for research to characterize such disparities and discuss community-level and patient-centric solutions to address their drivers. Research Sponsor: None.

Palliative-intent treatment receipt stratified by subgroup and tumor type.

Race	% Lung Tumor	% Breast Tumor	% Prostate Tumor
Non-Hispanic White	26.4	21.7	12.1
Mexican	16.7	12.7	8.8

Disparities in place of death in patients with lung cancer. First Author: Faris Abby Alamin, University of Central Florida College of Medicine, Orlando, FL

Background: Place of death (PoD) significantly impacts both patient and caregiver experiences at end-of-life in the United States (U.S.), with disparities often reflecting inequities in access to palliative care, hospice services, and caregiver resources. However, there is limited understanding of PoD and associated disparities in patients with lung cancer. This retrospective study examined sociodemographic differences in PoD among U.S. lung cancer decedents from 2003 to 2020. **Methods:** We analyzed de-identified death certificate data from the CDC Wonder database, focusing on lung cancer as the underlying cause of death (identified by ICD codes) from 2003 to 2020. The data were stratified by ethnicity, race, gender, and age ($<$ 65 or $\geq$ 65 years). PoD was categorized into four groups: (1) medical facility, (2) nursing home, (3) home, and (4) hospice facility. The Annual Percentage Change (APC) in PoD across sociodemographic groups was calculated. **Results:** A total of 2,759,733 decedents were included (44.8% women, 72.4% age $\geq$ 65 years, 3.3% Hispanic, 10.5% Non-Hispanic Black (NHB), and 83.4% Non-Hispanic White (NHW)). Between 2003 and 2020, deaths in medical facilities declined from 37.2% (58,778) to 24.6% (33,416) (APC -2.55%), while hospice deaths increased from 0.5% (849) to 11.2% (15,290) (APC 25.37%). In 2020, men were more likely to die in a medical facility than women (26.4% vs 22.4%), and women were more likely to die in a nursing home (9.4% vs 8.4%). Younger patients ($<$ 65) had higher rates of medical facility deaths than older patients (31.5% vs 22.4%), with a slower decline in medical facility deaths (APC -2.01% vs -2.75%). Hispanic individuals were more likely to die at home (52.5% in 2003 vs 51.0% in 2020) and less likely to utilize hospice (11.2% in 2020) or die in a nursing facility (8.9% in 2020). NHWs had the lowest rates of medical facility deaths (22.8% in 2020) and the highest rates of hospice deaths (11.6% in 2020). NHBs, despite an increase in hospice utilization (APC 26.73%, 2003-2020), remained more likely to die in medical facilities (33.6% in 2020). **Conclusions:** Over the past two decades, lung cancer PoD patterns have shifted, with reduced medical facility deaths and increased hospice utilization. However, significant disparities in end-of-life care persist across demographic groups, highlighting the need for targeted interventions to ensure equitable access to preferred care settings, including home-based and hospice services. Economic impact and mortality outcomes of palliative care integration among cancer patients: Analysis of National Inpatient Sample 2018-2022. First Author: Shiva Jashwanth Gaddam, Feist-Weiller Cancer Center at LSUHSC-Shreveport, Shreveport, LA

Background: While palliative care integration into oncology represents a quality metric, its relationship with mortality outcomes and cost implications remains incompletely characterized. This study evaluates the association between palliative care consultation and healthcare utilization across major cancer types. **Methods:** We conducted a retrospective analysis using the National Inpatient Sample (2018-2022). Eligible patients included adults with primary diagnoses of lung, breast, prostate, or colon cancer. Palliative care utilization was identified (ICD-10 code Z51.5). Primary endpoints included in-hospital mortality, length of stay (LOS), and total charges. Propensity score matching (1:1 nearest neighbor, caliper 0.2) was used to account for selection bias. Confounding variables included age, race, insurance status, hospital characteristics, and comorbidity burden. Missing data were handled using complete case analysis. Temporal trends were assessed using Cochran-Armitage test. **Results:** Among 1,104,888 eligible hospitalizations (469,831 lung, 203,857 breast, 204,837 colon, 226,065 prostate), 70,863 in-hospital deaths occurred. Palliative care consultation was associated with reduced LOS (adjusted mean difference: -1.2 days; 95% CI: -1.4 to -1.0; $p<0.001$) and lower total charges (adjusted mean difference: -$31,947; 95% CI: -$34,521 tor o -$29,373; $p<0.001$) among deceased patients. Cancer-specific mortality rates with without were: lung (31.26% vs 4.16%, $p<0.001$), breast (26.72% vs 2.16%, $p<0.001$), colon (25.60% vs 2.27%, $p<0.001$), and prostate (27.07% vs 1.98%, $p<0.001$). Overall palliative care utilization increased from 13.50% to 15.91% (2018-2022; APC: +0.68%; p-trend$<$0.001). DNR status strongly predicted palliative care utilization (adjusted OR: 4.50; 95% CI: 4.41-4.60; $p<0.001$). **Conclusions:** In this large nationwide analysis, palliative care consultation was associated with significant reductions in healthcare utilization and costs among deceased cancer patients. Universal implementation could potentially save 27,744 hospital days and $996.4 million annually, suggesting substantial opportunities for healthcare system optimization. Research Sponsor: None.

Healthcare utilization outcomes by cancer type and palliative care status.

Cancer Type	Deaths (N)	PC Rate (%)	Adjusted Cost Difference* ($)	Adjusted LOS Difference* (Days)
Lung	41,808	61.45	-32,655 (-35,124, -30,186)	-0.94 (-1.12, -0.76)
Breast	9,981	60.80	-31,382 (-34,276, -28,488)	-0.97 (-1.18, -0.76)
Colon	9,667	56.95	-47,079 (-50,612, -43,546)	-1.32 (-1.56, -1.08)
Prostate	9,407	56.61	-37,099 (-40,388, -33,810)	-0.81 (-1.02, -0.60)

*Values represent adjusted differences (95% CI) between palliative care and non-palliative care groups. PC = Palliative Care; LOS = Length of Stay.

Improving pain management knowledge among hospice family caregivers: A randomized controlled trial. First Author: Masako Mayahara, Barnes-Jewish College, Goldfarb School of Nursing, St. Louis, MO

Background: Poor pain management in home hospice settings is often due to family caregivers not adhering to analgesic regimens. Healthcare technology, like digital applications, can improve caregivers' access to education and communication with nurses, though it has been underutilized in home hospice. We developed and tested a digital pain management app called e-PainSupport in an NIH-funded randomized controlled trial with 44 hospice patient and caregiver dyads. The purpose of this study was to examine mediating effects of caregiver pain management knowledge on change in pain intensity, controlling for study condition and patient gender. **Methods:** We developed and tested a digital pain management app called e-PainSupport in an NIH-funded randomized controlled trial with 44 hospice patient and caregiver dyads. Utilizing a two-group, two-week, randomized controlled trial with dyads (N = 44) of Hospice patients (52% female, mean age 74.1 years) and their caregivers (75% female, mean age 55.2 years), dyads were randomly assigned to either the e-PainSupport intervention or usual care control condition. Outcome measures included caregiver knowledge and patient-reported pain intensity. **Results:** In the study, 60.87% of caregivers used the app's educational element at least once, with an average use of 5.43 times. Pain assessments were recorded by 91.30% of caregivers, averaging 3.74 assessments per caregiver. Additionally, 87.00% of caregivers reported pain management activities, averaging 46.05 entries. Patient pain intensity was tracked by 87.00% of caregivers, who completed the end-of-day summaries an average of 4.9 out of 14 days. Patients in the intervention condition were 2.50 times more likely to have a decrease in pain for worst pain than patients in the control condition over the two-week study period. Although we observed a positive effect of the app on caregivers' pain management knowledge, the improvement was limited, likely due to the brevity of the educational modules designed to minimize caregiver burden. To enhance caregiver knowledge without increasing their burden, we propose converting the written educational materials into videos. The enhanced intervention will be tested in a larger, full-scale RCT in the future. **Conclusions:** The use of the e-PainSupport app by caregivers is feasible and may contribute to improved caregiver knowledge and reduced hospice patient pain. Clinical trial information: NCT04869085. Research Sponsor: National Institute of Nursing Research.

A multi-center case-control study on osteoporosis risk in cancer patients receiving chemotherapy. First Author: Sabin Goktas Aydin, SBU Kanuni Sultan Süleyman Education and Research Hospital, Istanbul, Turkey

Background: Chemotherapy and cancer can worsen osteoporosis, a growing concern with improved cancer survival rates. This study aimed to assess osteoporosis risk in chemotherapy patients versus healthy individuals and identify predictive factors. **Methods:** This multi-center case-control study included 257 chemotherapy-treated cancer patients and 257 age- and gender-matched controls (1:1) using propensity score matching. Exclusions included recent alcohol use, severe organ impairments, endocrine disorders, specific treatments (estrogen, progesterone, glucocorticoids, bisphosphonates, calcium supplements), and cancer-related bone conditions. Bone mineral density (BMD) at the femur and lumbar spine (L1-L4) was measured via dual-energy X-ray absorptiometry (DXA), with T-scores categorized as normal ($T \geq -1.0$), osteopenia ($-2.5 < T < -1.0$), or osteoporosis ($T \leq -2.5$).Statistical analyses were performed using SPSS 24.0, with t-tests, Mann-Whitney U tests, and regression analysis ($p<0.05$). **Results:** The study included 174 females and 83 males (median age 59) in both groups. Of cancer patients, 112 had breast, 54 had colorectal, 39 had upper gastrointestinal, 32 had lung, and 20 had gynecological cancer. Among cancer patients, 35.8% had osteopenia, and 21.0% had osteoporosis in lumbar vertebrae, compared to 15.2% and 2.3% in controls ($p<0.001$). For total femur, 28.0% had osteopenia, and 5.8% had osteoporosis in cancer patients, versus 16.3% and 1.2% in controls ($p<0.001$). Median lumbar BMD was 0.90 g/cm² in cancer patients and 1.22 g/cm² in controls ($p<0.001$); median femur BMD was 0.89 g/cm² and 0.98 g/cm², respectively ($p<0.001$). No correlation was found between osteoporosis and cancer stage. Breast cancer had the highest normal BMD (51.2%) but shared the highest osteoporosis rate (31.5%) with colorectal cancer. Gastric cancer showed the highest osteoporosis rate for femur BMD (33.3%, p=0.024). Vitamin D deficiency (<12 ng/mL) was more common in cancer patients (50.6% vs. 18.1%) and linked to reduced bone density (p=0.009). BMI was a significant predictor of osteoporosis (<0.001), with higher BMI protective; obesity (BMI >30) was more frequent in controls (50.2%) than cancer patients (26.9%).Serum creatinine, alkaline phosphatase, calcium, and phosphate levels were similar in groups, with no link to osteoporosis. Logistic regression showed cancer increased osteoporosis risk 6.8-fold ($p<0.001$, 95% CI: 4.024–11.494). BMI was protective, reducing odds by 4.5% per unit increase (p=0.036, 95% CI: 0.915–0.997). **Conclusions:** Lumbar osteoporosis and osteopenia were 9.1 and 2.3 times more common in cancer patients, with lumbar and femur BMD reduced by 26.2%and 9.2%, compared to controls. Cancer type and Vitamin D levels are key predictors of osteoporosis. Addressing bone health in cancer patients is crucial for improving quality of life and reducing osteoporosis burdens. Future research on survival, fracture risks, and outcomes will inform proactive bone health management. Research Sponsor: None.

Effectiveness of alternating magnetic field therapy on quality of life among cancer survivors with chemotherapy-induced peripheral neuropathy: Insights of SMILE study. First Author: Emi Kubo, Department of Palliative Medicine, National Cancer Center Hospital East, Kashiwa-Shi, Japan

Background: Chemotherapy-induced peripheral neuropathy (CIPN) reduces patients' quality of life (QoL) due to consistent sensory and motor disturbances. SMILE study investigated the safety and efficacy of an alternating magnetic field therapy device (AT-04) for CIPN. **Methods:** This was a multicenter, randomized, sham device-controlled, double-blind study. Patients were eligible if they had CIPN symptoms with a pain Numeric Rating Scale score of 4/10 or more, at least 12 weeks after perioperative chemotherapy, and there was no recurrence. Patients were randomly assigned to use AT-04 or a sham device for 84 days. We showed the primary endpoint, the change in pain NRS at day 85, and notable effect sizes of AT-04 in patients whose last chemotherapy was over a year ago for tingling and numbness NRS. Herein, we report one of the secondary endpoints, EORTC QLQ-CIPN20 (CIPN20), asked at baseline and days 15, 29, 57, 85, and 113. **Results:** Fourteen patients were allocated to each group. At day 85, there were no significant differences in the mean changes of the CIPN20 sensory scale (-5.25 $\pm$ 15.4 in AT-04 vs. -5.72 $\pm$ 19.5 in sham; p = 0.95, effect size = 0.03), the motor scale (-8.18 $\pm$ 16.6 vs. -1.68 $\pm$ 10.2; p = 0.28, effect size = 0.47), or the autonomic scale (-1.85 $\pm$ 27.5 vs. -1.52 $\pm$ 5.0; p = 0.97, effect size = 0.02). However, the CIPN20 motor scales showed a significant decrease in AT-04 at day 29 (-9.82 $\pm$ 13.8 vs. -0.74 $\pm$ 8.7; p = 0.04, effect size = 0.92) and day 57 (-11.81 $\pm$ 10.6 vs. -0.54 $\pm$ 6.7; $p < 0.01$, effect size = 1.26). Furthermore, among patients whose last chemotherapy was completed more than one year earlier (n = 8 in each group), CIPN20 motor scale significantly decreased from day 29 (-12.43 $\pm$ 10.3 vs. 2.38 $\pm$ 8.9; $p < 0.01$, effect size = 1.55) to day 85 (-11.76 $\pm$ 10.1 vs. -0.07 $\pm$ 11.5; $p < 0.05$, effect size = 1.08), and this effect persisted at day 113 (28 days after the end of the study treatment). Additionally, both sensory and autonomic scales showed improvement (sensory scale, -8.33 $\pm$ 13.5 vs. -0 $\pm$ 18.4, p = 0.32, effect size = 0.52; autonomic scale, -10.42 $\pm$ 23.5 vs. -2.08 $\pm$ 5.9, p = 0.35, effect size = 0.49). **Conclusions:** In patients whose last chemotherapy occurred more than one year prior, mean changes in the CIPN20 scores showed improvement across the sensory, motor, and autonomic scales. Clinical trial information: jRCT2032220295. Research Sponsor: Japan Agency for Medical Research and Development; Peace of Mind Co., Ltd.

Autoimmune conditions and 'breast implant illness' in breast cancer patients with implant-based breast reconstructions. First Author: Jonathan Spoor, Netherlands Cancer Institute, Amsterdam, Netherlands

Background: The safety of silicone breast implants (SBIs) has been challenged in various large observational studies that suggest an association with autoimmune and rheumatic diseases (ARDs). Additionally, an increasing number of women seem to attribute constitutional, rheumatic, mental and cognitive symptoms to their SBIs. This constellation of symptoms is often referred to as 'Breast implant illness (BII). To date, BII is a self-identified diagnosis without an evidence-based definition. The risks of ARDs and BII have not been evaluated in breast cancer survivors with implant-based breast reconstructions. **Methods:** We conducted a retrospective cohort study among patients treated for breast cancer between 2000 and 2015 in six large regional hospitals. Clinical data and diagnoses of ARDs were obtained up to 2023 from prospectively maintained institutional and nationwide registries. Patients who were alive at the time of study were invited to participate in a survey. The occurrence of eighteen symptoms, that have been associated with BII by international experts, was assessed. The SBI-exposed patients were compared with patients who had received other surgical treatment modalities. In the entire cohort (including deceased patients and survey non-responders), Hazard Ratios (HRs) for receiving an ARD diagnosis were estimated through multivariable Cox models. Among responders to the survey, person-centered symptom clusters were determined through a latent class analysis approach. The association between SBI-exposure and the observed symptom clusters was analyzed in multivariable logistic regression models. **Results:** Of 12,262 women in the entire cohort, 3,082 (25%) had received a SBI-based breast reconstruction. Median follow-up time was 12.0 (IQR, 7.0) years. Compared with non-exposed patients, patients with an implant-based breast reconstruction did not have an increased risk of ARDs in general (HR, 1.06, 95% CI [0.89–1.27]) or any specific ARD-category or specific condition. In total, 6,073 patients (64.5% of all invited patients) completed the questionnaire including 1,818 patients with an SBI. In the survey cohort, the median follow-up time was 13.7 (IQR, 6.8) years. Five distinct BII-related symptom clusters were identified, none of which were significantly associated with SBI-exposure in multivariable logistic regression analyses. Additionally, when comparing exposed to non-exposed women, women with SBIs did not have a significantly increased risk for any of the individual BII-associated symptoms. **Conclusions:** Our results indicate that breast cancer patients with SBIs do not have an increased risk of ARDs nor do they experience more BII-associated symptoms compared with breast cancer patients without SBIs. This information can aid healthcare professionals in counseling breast cancer patients who are worried about the alleged long-term harms of SBI(s). Research Sponsor: None.

A hierarchical clustering approach to dissect behavioral symptoms in early-stage breast cancer (BC). First Author: Martina Pagliuca, Scuola Superiore Meridionale (SSM), Naples, Italy

Background: Fatigue, cognitive impairment, insomnia, anxiety, and depression are cancer-related behavioral symptoms that frequently co-occur and share underlying risk factors. We investigated the clustering of these symptoms at different time points, aiming to identify drivers of symptom segregation. **Methods:** Patients with stage I-III BC from CANTO (NCT01993498) were included. Hierarchical cluster analysis was performed at three time points: baseline (BC diagnosis), year (Y) 1 (3-6 months post-surgery, chemotherapy [CT], and/or radiotherapy), and Y2. Clustering used the Ward method via R^2 and Pseudo T^2 statistics, incorporating dichotomized self-reported symptoms based on clinically meaningful thresholds: fatigue (EORTC QLQ-C30 $\geq$40/100), cognitive impairment ($<$75/100), insomnia ($>$50/100), and anxiety or depression (HADS $\geq$11/21). **Results:** Among 6,486 patients, the mean age was 56.2 years; 90% had stage I-II BC, 53% received CT, and 83% endocrine therapy (ET). Analysis of dendrograms identified six distinct clusters (CL) consistently across time points. There was substantial difference in symptomatology between baseline/Y1 and baseline/Y2 (Cramer's V 0.23, 0.22), while there was greater symptom overlap post-treatment between Y1 and Y2 (V 0.32). No specific behavioral symptom drove hierarchical segregation at baseline. However, by Y1, depression and fatigue emerged as primary drivers: CL1 (38%) comprised patients with low symptom scores, similarly to other time points; CL2 (14%) was mostly characterized by cognitive dysfunction and anxiety; CL3 (14%) was defined by patients with clinically meaningful insomnia but without fatigue, while CL5 and CL6 included patients with fatigue but no emotional distress, further segregated by the presence (CL5, 12%) or absence (CL6, 10%) of cognitive dysfunction. Patients reporting depression were consistently grouped in CL4. Notably, CL4 (12%) was heterogeneous and characterized by multi-symptomatology (Table). The use of CT and ET was significantly associated with membership in CL4 and CL5 at Y1 ($p < .001$). At Y2, the clustering remained consistent with what observed at Y1, however the prevalence of individual symptoms was higher in the multi-symptom clusters, including CL4 where all patients with depression were exclusively segregated. **Conclusions:** Hierarchical clustering revealed dynamic changes over time, potentially reflecting the impact of the acute treatment phase on interrelationships among symptoms. Depression and fatigue emerged as key drivers of segregation. Accounting for variability in symptom clustering can enable better targeting of therapeutic options. Systematic review of prognostic models for cardiomyopathy and heart failure applicable to survivors of adolescent and young adult cancer. First Author: Louise Guolla, Dept. Health Research Methods, Evidence, & Impact, McMaster University, Hamilton, ON, Canada

Background: Survivors of adolescent and young adult (AYA) cancer who receive cardiotoxic chemotherapy and/or radiation are at risk of developing cancer therapy-related cardiac dysfunction (CTRCD), including asymptomatic reduction in left ventricular ejection fraction and symptomatic heart failure. Early detection and intervention using risk-adapted surveillance strategies can reduce morbidity and mortality. While numerous risk prediction models (RPM) have been developed and/or validated for CTRCD in pediatric or older adult cancer populations, it is unclear whether they can be applied to survivors of AYA cancer. **Methods:** We undertook a systematic review of cardiovascular RPM (including CTRCD) development/ validation studies in survivors of cancer diagnosed at any age. We searched MEDLINE, EMBASE, and Web of Science with additional hand searching until November 2024. Two reviewers screened abstracts and full texts; we included studies that used real-life patient data to predict asymptomatic or symptomatic CTRCD (per European Society of Cardiology guidelines) $\geq$1 year from diagnosis and after completing therapy. We excluded abstracts, non-English studies, and RPM which used data not routinely accessible in outpatient clinics. We extracted study data and applied the Prediction model Risk of Bias ASsessment Tool for risk of bias (RoB) and applicability to AYA cancer survivors. When not reported, we estimated AYA (age 15-39) proportions using cancer incidence patterns. We used descriptive statistics to evaluate studies, models, included risk factors, and participants overall and by proportion of AYA. Meta-analysis was not possible given limited overlap in the identified models. **Results:** We screened 12740 abstracts and 249 full text articles; of these, 100 studies underwent a second full text screen to identify CTRCD models. We identified 22 studies (7 enrolled $>$ 20% AYA) which developed and/or validated 64 models (32.8% machine learning) to predict CTRCD (54.7% symptomatic) in 129077 cancer survivors (10.7% AYA) using clinically available data. Nine (14.1%) models validated existing RPM (e.g. those developed in non-cancer populations); the remainder were newly developed models, with age at diagnosis, diabetes, hypertension, and anthracycline dose the most common predictors ($>$ 50% of models). Most models (n = 54) were at high RoB, primarily due to concerns with analytical reporting. Only 2 studies/8 models were rated as both low RoB and high applicability to AYA survivors. **Conclusions:** Several RPM for subclinical and overt CHF are available for pediatric and adult cancer survivors, with varying applicability to AYA cancer survivors. Adherence to recommended statistical reporting methods is poor and RoB high, further limiting utility. Additional development and validation of high-quality RPM for heart failure in AYA cancer survivors is warranted. Research Sponsor: CIHR; 186971.

12038 Poster Session

Out of touch: Understanding the frequency and trajectory of chemotherapy-induced neuropathy peripheral (CIPN) in breast cancer survivors. First Author: Savannah Liddell, Mayo Clinic, Rochester, MN

Background: CIPN, primarily associated with sensory neuropathy rather than motor or autonomic dysfunction, is a potentially long-term complication of cancer treatment including taxanes and platinums (T/Ps), and can negatively impact quality of life for breast cancer (BC) survivors. This project aims to quantify the severity of neuropathic symptoms at one and three years after diagnosis in BC survivors, comparing recipients of T/P to non-recipients. **Methods:** In the Mayo Clinic Breast Registry (MCBDR), a longitudinal cohort, surveys and medical record data from patients with stage 1-3 BC were used to understand the burden of neuropathic symptoms at 1- and 3-years post-diagnosis (denoted as Y1 and Y3). Y1 and Y3 raw scores from The Quality of Life Questionnaire-Chemotherapy-Induced Peripheral Neuropathy 20 (CIPN20) composite (CIPN20-C) and sensory subscale (CIPN-S) were converted to a 0-100 point scale, with lower scores corresponding to worse symptoms. Patients with BC recurrence prior to Y3 or incomplete surveys were excluded. We used two sample t-tests and multivariable linear regression modeling to compare recipients of T/P to non-recipients of T/P (with threshold for statistical significance $p < 0.05$). **Results:** 786 patients were included, 112 of whom (14.2%) received T/P. T/P recipients were younger ($p<0.001$), more likely to have Stage II/III disease ($p<0.001$), and less likely to have received endocrine therapy ($p<0.001$). Univariate analyses revealed worse CIPN20-C score at Y1 (p=0.02) and worse CIPN20-S scores (p=0.004) at Y1 and Y3 in T/P recipients compared to non-recipients (Table). However, differences between the groups were no longer statistically significant after adjustment for age, stage and endocrine therapy. **Conclusions:** In this cohort, neuropathic symptom severity at Y1 and Y3 after a breast cancer diagnosis did not differ between recipients of taxane and/or platinum agents and nonrecipients after adjustment for age, stage, and endocrine therapy. These data may reassure patients and clinicians who are concerned about CIPN and considering use of these chemotherapies in this setting. Research Sponsor: None.

Patient demographics and CIPN20 results.

Clinical characteristic	T/P recipients	Non-recipients of T/P
Age at diagnosis, mean (SD)	55.3 (11.6)*	59.8 (11.9)
White race, N (%)	108 (96.4%)	660 (97.9%)
Clinical stage II/III, N (%)	76 (68.5%)*	250 (37.5%)
Endocrine therapy, N (%)	73 (65.2%)*	636 (94.4%)
Diabetes mellitus, N (%)	9 (8.9%)	52 (8.6%)
Y1 CIPN20-C score, mean (SD)	89.6 (10.9)*	92.0 (9.7)
Y3 CIPN-C score, mean (SD)	89.4 (11.4)	91.1 (9.7)
Y1 CIPN20- S score, mean (SD)	87.3 (15.1)*	91.3 (13.0)
Y3 CIPN20-S score, mean (SD)	88.2 (14.1)*	91.1 (11.7)

*Statistically significant ($p < 0.05$) on univariate analysis.

Single-cell RNA sequencing atlas of intestinal injury induced by different clinical treatments in colorectal cancer patients. First Author: Luoxi He, Department of Radiation Oncology, Fudan University Shanghai Cancer Center, Shanghai, China

Background: Colorectal cancer (CRC) patients often experience intestinal injury due to various treatment regimens, including chemotherapy (CT), chemoradiotherapy (CRT), and chemoradioimmunotherapy (ICRT). Despite advances in treatment, the underlying mechanisms of treatment-induced intestinal injury remain poorly understood. **Methods:** We performed single-cell RNA sequencing and histological staining on intestinal samples obtained from 18 colorectal cancer patients undergoing different treatment regimens, including untreated (CTRL), CT, CRT, and ICRT groups. We also employed bulk RNA sequencing to compare paired cancer and normal tissues from ICRT patients, identifying similarities and differences in gene expression patterns between the cancer and normal tissues. **Results:** Histological staining showed that there were no morphological changes in CT, while the damage in CRT was obvious, and the damage in ICRT was even more severe. Intestinal epithelial cells exhibit distinct differentiation trajectories into secretory and absorptive lineages. CRT-induced damage triggers reverse differentiation via revival stem cells (revSCs), driven by fetal-like genes like CLU, while ICRT disrupts this process. In CD8+T cells, effector T cells (TEFF) increase significantly in the ICRT group and differentially expressed genes (DEG) revealed unique patterns across different treatments, including upregulation of senescence-related genes in CRT and interferon- and TNF-related genes in ICRT, highlighting potential therapeutic targets for treatment-induced intestinal injury. In B cells, distinct differentiation pathways were observed, with CRT increasing atypical memory (Atm) B and ICRT promoting germinal center (GC) B, the latter correlating with follicular helper T (TFH) cells and potentially indicating tertiary lymphoid structure (TLS) formation, similar to the patterns of tumor response after ICRT. So we conducted bulk RNA sequencing analysis between paired tumor and normal tissues, which revealed a correlated expression of effector markers, suggesting a shared biological pattern between tissue damage and tumor killing. Also, patients in the ICRT group showed a significant correlation between clinical intestinal injury scores (LARS) and tumor regression grade (TRG), which means we can predict the treatment efficacy of ICRT by a more direct and convenient way. We also performed metabolism analysis and found tryptophan metabolism was significantly altered following CRT and ICRT treatments, closely linked to epithelial repair and inflammation, highlighting tryptophan metabolism can be used as treatment of intestinal injury. **Conclusions:** Our study presents a comprehensive single-cell atlas of treatment-induced intestinal injury in CRC patients, offering insights for future strategies to reduce treatment-related intestinal damage. Research Sponsor: None.

Incidence of ocular toxicities in patients with relapsed/refractory multiple myeloma treated with belantamab mafodotin: A systematic review and meta-analysis of phase 3 randomized controlled trials. First Author: Ricceshа Hattin, Department of Internal Medicine, Kirk Kerkorian School of Medicine at UNLV, Las Vegas, NV

Background: Belantamab mafodotin is a novel antibody-drug conjugate approved by the FDA in August 2020 to treat relapsed/refractory multiple myeloma (RRMM). However, it was withdrawn from the market in March 2023 following the DREAMM-3 randomized controlled trial (RCT) failure to show superior progression-free survival (PFS). Later in 2024, further RCTs published (DREAMM-7 & 8) have shown PFS benefit which opens the door to a possible FDA reapproval in the future. Several concerns about ocular adverse events (AEs) have emerged from those trials. This meta-analysis aims to evaluate the incidence of those events in patients with RRMM receiving belantamab. **Methods:** A systematic literature search was performed across MEDLINE and EMBASE databases up to December 31, 2024. Phase 3 RCTs investigating belantamab regimens in RRMM were included. Pooled risk ratios (RR) with 95% confidence intervals (CI) were calculated using the Mantel-Haenszel method. Heterogeneity was assessed using Cochran's Q-statistic. Fixed effects model was employed. **Results:** A total of 1,102 patients from three phase 3 RCTs (DREAMM-3, DREAMM-7, DREAMM-8) were analyzed. The following ocular AEs were noted more frequently in the belantamab group compared to the control group: any-grade (AG) ocular AEs 76.85% vs 24.95% (RR 3.30; 95% CI: 2.80–3.89; $P < 0.00001$), high-grade (HG) ocular AEs 34.65% vs 2.03% (RR 17.61; 95% CI: 9.40–33.00; $P < 0.00001$), AG dry eyes (DE) 45.16% vs 6.69% (RR 7.47; 95% CI: 5.29–10.54; $P < 0.00001$), HG DE 6.24% vs 0% (RR 21.40; 95% CI: 4.40–104.07; P = 0.0001), AG blurred vision (BV) 59.77% vs 10.14% (RR 6.54; 95% CI: 4.97–8.60; $P < 0.00001$), HG BV 14.78% vs 0.41% (RR 27.39; 95% CI: 8.86–84.68; $P < 0.00001$), AG photophobia 36.95% vs 2.64% (RR 15.55; 95% CI: 8.97–26.96; $P < 0.00001$), HG photophobia 1.81% vs 0% (RR 7.08; 95% CI: 1.40–35.70; P = 0.02), AG eye irritation (EI) 37.27% vs 5.48% (RR 7.60; 95% CI: 5.17–11.19; $P < 0.00001$), HG EI 3.28% vs 0% (RR 12.23; 95% CI: 2.52–59.33; P = 0.002), AG eye pain (EP) 26.27% vs 3.04% (RR 9.40; 95% CI: 5.61–15.76; $P < 0.00001$), AG foreign body eye sensation (FBES) 41.71% vs 4.26% (RR 10.68; 95% CI: 6.94–16.45; $P < 0.00001$), AG cataract 16.58% vs 9.13% (RR 2.06; 95% CI: 1.49–2.85; $P < 0.0001$), and HG cataract 4.76% vs 2.64% (RR 2.08; 95% CI: 1.10–3.94; P = 0.02). No statistically significant difference was noted between the two treatment arms in terms of HG EP or FBES. **Conclusions:** This study revealed a significantly increased risk of ocular AEs in patients with RRMM treated with belantamab compared to the other traditional myeloma treatments. Close monitoring and early intervention are crucial for prompt identification and providing the appropriate management for those events in order to optimize the patients' quality of life and compliance. Research Sponsor: None.

Risk of non-breast cancer–related mortality in breast cancer and dependence on disease characteristics, treatment, and survival duration. First Author: Varsha Gupta, Roswell Park Comprehensive Cancer Center, Buffalo, NY

Background: Breast Cancer (BC) has seen significant improvement in survival in both early (eBC) and metastatic (mBC) setting. Prolonged survival increases the risk of acquisition of other comorbidities and result in non-BC related mortality (NBCRM). Purpose of this study is to identify the high-risk disease characteristics and trends for NBCRM. **Methods:** Patients (pts) with BC diagnosed as first primary malignancy between 2010-2019 were identified from 2023 release of SEER 17 database, with follow up till 12/31/2021. Causes of mortality were extracted and categorized as BC related mortality (BCRM) and NBCRM. BC related competing risk adjusted fine and gray regression model was used for survival analysis for NBCRM and subdistribution hazard ratio (SHR) is reported. Restrictive mean survival time (RMST) was calculated for pts with radiation and chemotherapy. Pearson chi-square tests used for comparison of categorical data. **Results:** 457,655 BC pts were identified. Median overall survival (OS) for mBC was 34 months (m) (95% CI 33-35 m) and not reached for eBC. For adjusted NBCRM, risk of mortality was higher for age $\geq$ 65 (eBC SHR 10.2, mBC SHR 2.5, Both $p < 0.01$) and age 51-65 (eBC SHR 2.5, mBC SHR 1.5, both $p < 0.05$) compared to age $\leq$ 50 years. Triple negative (TNBC) (eBC SHR 1.2, $p < 0.05$) had higher risk compared HR+/HER2- but not for mBC. For eBC, higher risk for Stage II (SHR 1.5, $p < 0.05$) and Stage III (SHR 2.0, $p < 0.05$) compared to Stage I. Lobular histology had lower risk of NBCRM for eBC (HR 0.86, $p < 0.05$) and no difference was seen for mBC (SHR 0.93, p = 0.27). Pts with radiation (RT) had lower risk of NBCRM (eBC SHR 0.57, mBC SHR 0.86, Both $p < 0.05$). RMST difference for Pts with RT vs no RT increased from 0.08 m at 1 year to 1.7 m at 5 years for eBC and 0.09 m at 1 year to 1.38 m at 5 years for mBC. Similarly, pts with chemotherapy (CT) had lower NBCRM (eBC SHR 0.52 $p < 0.05$, mBC SHR 0.7, $p < 0.01$). RMST difference for pts with CT vs no CT increased from 0.35 m at 1 year to 1.31 m at 5 years for eBC and 0.27 m at 1 year to 3.53 m at 5 years for mBC. Cardiovascular (CVS) (30.76%) and subsequent malignancies (19.96%) were most common causes of NBCRM for eBC. Of all CVS-mortality, 11% occurred $<$ 1 year of diagnosis and 40% after 5 years. Subsequent solid malignancy- mortality was 6.8% in $<$ 1 year and 41% for $>$ 5 years. Subsequent hematological malignancy- mortality was 5.9% in $<$ 1 year and 38% for $>$ 5 years. For mBC, the above trends for NBCRM were inconclusive, given median OS was $<$ 3 years. **Conclusions:** With the rising number of BC survivors, it is imperative to identify high-risk disease characteristics which can lead to NBCRM. Risk of NBCRM was noted to be related to age of diagnosis, stage, histology and treatment. Risk of CVS and subsequent malignancy related mortality was significantly more for pts surviving more than 5 years, especially in the eBC setting, highlighting the importance of adherence to preventive health guidelines and lifestyle modifications. Incidence of venous thromboembolism (VTE) events in patients with EGFR-mutant non-small cell lung cancer (NSCLC) treated with amivantamab: A systematic review and combined meta-analysis of phase 3 randomized controlled trials. First Author: Hazem Aboaid, Department of Internal Medicine, Kirk Kerkorian School of Medicine at UNLV, Las Vegas, NV

Background: Amivantamab is a bispecific antibody that was granted accelerated approval by the FDA in May 2021 for the treatment of non-small cell lung cancer (NSCLC) with epidermal growth factor receptor (EGFR) mutations. In addition, it also targets the mesenchymal-epithelial transition (MET) pathway which is involved in cancer cell proliferation. While amivantamab approval is considered a significant advancement in the EGFR-mutant lung cancer management, its introduction has raised concerns about potential new adverse events. This study aims to evaluate the incidence of venous thromboembolism (VTE) events in patients with EGFR-mutant NSCLC receiving amivantamab. **Methods:** We conducted a comprehensive literature search using MEDLINE and EMBASE databases from inception through December 31, 2024. Phase III randomized controlled trials (RCTs) utilizing amivantamab in EGFR-mutant NSCLC and reporting VTE adverse events were included. Mantel-Haenszel method was used to calculate the estimated pooled risk ratio (RR) with 95% confidence interval (CI). Heterogeneity was assessed with Cochran's Q-statistic. Random effects model was employed. **Results:** A total of 1,791 patients from three phase III RCTs (MARIPOSA n = 849, MARIPOSA-2 n = 636, PAPILLON n = 308) were included in the analysis. MARIPOSA tested amivantamab-lazertinib vs osimertinib vs lazertinib, while MARIPOSA-2 involved amivantamab-lazertinib-chemotherapy vs chemotherapy vs amivantamab-chemotherapy, and PAPILLON tested amivantamab-chemotherapy vs chemotherapy. Randomization ratios were 2:2:1, 2:2:1, and 1:1, respectively. The incidence of any-grade VTE was higher in the amivantamab group compared to the control group, with a rate of 25.90% vs 7.26% (RR, 3.69; 95% CI: 2.74-4.98; $P < 0.00001$). VTE as a serious adverse event was reported higher in the amivantamab arm compared to the control arm, 5.69% vs 2.42% (RR, 2.36; 95% CI: 1.31-4.27; P = 0.004). There was no statistically significant difference between the two treatment groups in terms of incidence of high-grade VTE. A subgroup analysis based on the type of VTE was performed. Incidence of both pulmonary embolism (PE) and deep vein thrombosis (DVT) was higher in the amivantamab cohort compared to the control cohort, with a rate of 9.94% vs 3.75% (RR, 2.62; 95% CI: 1.50-4.58; P = 0.0007) and 7.97% vs 1.81% (RR, 5.0; 95% CI: 2.90-8.62; $P < 0.00001$), respectively. **Conclusions:** This study showed increased risk of VTE events in patients with EGFR-mutant NSCLC treated with amivantamab-containing regimens compared to the standard arm. These findings highlight the importance of close monitoring for those events in order to early detect and provide the appropriate management. Further studies are needed to better understand this association between amivantamab and VTE. Research Sponsor: None.

Radioimmunotherapy-associated myeloid neoplasms: Real-world multicenter retrospective study using TriNetX database. First Author: Nikhil Vojjala, Trinity Health Oakland Hospital/Wayne State University School of Medicine, Pontiac, MI

Background: Radioimmunotherapy (RIT) utilizing monoclonal antibodies conjugated with therapeutic radionuclides, has emerged as a promising treatment option in oncology. While demonstrating significant clinical efficacy, concerns regarding therapy-related myeloid neoplasms (t-MNs) have been raised in other contexts, particularly following RIT for non-Hodgkin lymphoma. This study aims to investigate the risk of t-MNs following treatment with Lutathera (177Lu-DOTATATE) and Pluvicto (177Lu-PSMA-617) in patients with neuroendocrine tumors and metastatic castration-resistant prostate cancer. **Methods:** We conducted a multicenter retrospective study using the TrinetX database network, a federated Electronic Medical Record Network including adult patients with a history of using Lutathera and/or Pluvicto and developed t-MNs. Statistical analysis is performed on the TrinetX research platform. Outcome analysis was performed for 1) Incidence of t-MNs. 2) Mortality rates and Survival analysis. **Results:** A total of 2370 patients who received either Lutathera (n=1368; 57.7%) or Pluvicto (n=1002; 42.3%) were identified in the database. Mean age was 71 years ($\pm$11 years), 64.98% (n=1540) were males and 70.08% were whites. Of the 2370 patients, 1.6% (n=39) developed t-MNs (26 MDS (1.09%), 13 AML (0.54%). Among these, 27 were in the Lutathera cohort (1.97% of total patients), and 12 were in the Pluvicto cohort (1.12%). The mean age in the t-MN cohort was 72 years ($\pm$9 years) and 50% were males. 16 (41%) patients with t-MN had prior chemo or radiotherapy. The remaining 23 patients (59%) received no anticancer therapy associated with t-MNs. Median survival for patients with t-MNs was 38.1 months, with an overall mortality of 51.2% at median follow-up. **Conclusions:** This is the largest study reporting the incidence of t-MN associated with RIT. Our study demonstrated a significant risk of therapy-related t-MNs following RIT, even in patients who did not receive additional chemoradiotherapy. Given the short follow-up, we hypothesize that the risk may increase with longer-term follow-up. Using this real-world data, our Next step would be to include Next-Generation Sequencing for further characterization of the genomic landscape of these patients. Research Sponsor: None.

Demographic, treatment, and follow-up data of the study population.

Baseline characteristics	RIT	RIT with t-MNs
Total patients	2370	39
Mean age (in years) (SD)	71 ($\pm$11)	72 ($\pm$9)
Gender*(%)		
Males	64.98	50.0
Females	22.07	46.6
Race*(%)		
Whites	70.08	73.33

Multisite validation of biomechanical computed tomography for osteoporosis assessment and fracture prediction in patients with high-risk or metastatic prostate cancer. First Author: Samuel L. Washington III, Department of Urology, University of California, San Francisco, San Francisco, CA

Background: Long-term androgen deprivation therapy (ADT) among men with high-risk localized or metastatic prostate cancer (PCa) results in a 10-20% risk of significant bone fracture at 10 years. While guidelines recommend routine bone mineral density (BMD) screening for men with PCa receiving ADT, most do not undergo it. We studied whether Biomechanical Computed Tomography (BCT), a radiomic technique to opportunistically measure femoral and vertebral bone strength and BMD from CT scans performed for routine staging, can predict incident fractures among men with PCa beginning ADT. **Methods:** In this retrospective cohort study among 2 academic cancer centers and 2 Veterans Affairs facilities, we identified 711 men with de novo high-risk localized or metastatic PCa diagnosed between 2010-2018. CT scans at PCa diagnosis were analyzed by BCT. Incident fractures were ascertained by trained radiologists and defined as any new fractures occurring after the initial CT scan. We used Cox proportional hazards models to estimate associations of fragile femur bone strength (≤3500N), fragile vertebral bone strength (≤6500N), or osteoporosis (femoral neck areal BMD T-score ≤-2.5 or trabecular volumetric BMD ≤80 mg/cm3), with incident fracture, adjusted for age, BMI, & race/ethnicity. **Results:** 673 men were eligible (mean age 69.8±9.3, 49.3% white, 35.2% received prior ADT, 42.3% had prior BMD screening). 198 (29.4%) incident fractures were observed. Using BCT, 123 men (18.3%) had fragile femur bone strength or osteoporosis, and 105 men (15.6%) had fragile vertebral bone strength or osteoporosis by volumetric BMD. BCT-derived fragile femur or vertebral bone strength (adjusted HR 1.81, 95% CI 1.27-2.59) and osteoporosis by BMD criteria (aHR 2.20, 95% CI 1.32-3.62) were associated with incident fracture (Table). **Conclusions:** In men with high-risk PCa, opportunistic BCT analysis of routine staging CT scans improves osteoporosis detection and fracture prediction, identifying men who may have not otherwise qualified for antiresorptive treatment. BCT is a novel approach to risk-stratify men with PCa for early fracture risk mitigation. Research Sponsor: U.S. Department of Defense; W81XWH2210151.

Impact of pembrolizumab on geriatric syndromes in older patients with NSCLC: A propensity-matched retrospective cohort study. First Author: Elvis Obomanu, Jefferson Einstein Philadelphia Hospital, Department of Internal Medicine, Philadelphia, PA

Background: Non-small cell lung carcinoma (NSCLC) predominantly affects older adults (≥65 years), where immune checkpoint inhibitors (ICIs) are a key treatment, especially in those without driver mutations. However, the effect of ICIs on age-related health issues (geriatric syndromes), which impact quality of life in this population, is unclear. This study aims to investigate the impact of ICIs on geriatric syndromes in older adults with NSCLC. **Methods:** We utilized data from the Global Collaborative Network-TrinetX to evaluate the impact of pembrolizumab on geriatric syndromes in elderly NSCLC patients, dividing them into two groups based on pembrolizumab treatment status defined by International Classification of Diseases (ICD-10) codes. Propensity score matching (PSM) was used to balance the cohorts based on demographic characteristics, comorbidities, medications, and without driver mutations. Geriatric syndromes were assessed over 30-day and 1-year follow-up periods. Multivariate logistic regression models assessed the association between pembrolizumab treatment and geriatric syndromes, with results expressed as odds ratios and 95% confidence intervals. **Results:** Following PSM, there were two balanced cohorts of 3288 patients each. The pembrolizumab cohort had a mean age of 75.6 ± 6.93 years, while the non-pembrolizumab cohort had a mean age of 78.2 ± 7.9 years. Multivariate analysis revealed that pembrolizumab treatment was significantly associated with increased fatigue risk at 30 days (OR 1.600, 95% CI 1.062-2.411, P=0.023), persisting at 1 year (OR 1.769, 95% CI 1.463-2.140, P<0.001). Additionally, pembrolizumab treatment was linked to increased risks of insomnia (OR 1.331, 95% CI 1.052-1.683, P=0.017) and delirium (OR 1.494, 95% CI 1.105-2.019, P=0.009) at 1 year. Notably, pembrolizumab treatment was not significantly associated with risk of dementia, frailty, urinary incontinence, or falls at 30 days and 1 year. **Conclusions:** Our study shows that pembrolizumab was significantly associated with increased risks of persistent fatigue, delirium, and insomnia in geriatric NSCLC patients at one-year follow-up. This emphasizes the need for monitoring and targeted interventions to mitigate these adverse events and improve quality of life in this population. Research Sponsor: None.

Geriatric syndromes in NSCLC patients on pembrolizumab.

OUTCOME	30 DAYS FOLLOW-UP		1 YEAR FOLLOW-UP	
	OR and 95% CI	P-value	OR and 95% CI	P-value

New-onset osteopenia/osteoporosis among long-term survivors of breast cancer: Role of hormone therapies and metabolic risk factors. First Author: Geoffrey S. Bostany, University of Pittsburgh Medical Center, Pittsburgh, PA

Background: Anti-cancer therapies (including aromatase inhibitors [AIs]) and metabolic risk factors are known to result in bone mineral density (BMD) loss in breast cancer survivors (BCS). There is limited information regarding the very long-term risk of new-onset osteopenia/osteoporosis among BCS and the associated risk factors. **Methods:** Patients who survived ≥1y after BC underwent q2y dual x-ray absorptiometry (DXA) screening at a single center; those exposed to bisphosphonates or with osteopenia/osteoporosis prior to BC were excluded. All DXAs from BC diagnosis to diagnosis of osteopenia/osteoporosis were processed in Python via automated analysis. New-onset osteopenia/osteoporosis was defined as a DXA with a T-Score < -1 at any bone site. Demographics, treatment exposures, and metabolic risk factors were abstracted from medical records. Cumulative incidence described the risk of osteopenia/osteoporosis, and Cox proportional hazards models described the risk factors, treating therapeutic exposures as time-varying variables. Multivariable linear regression models with generalized estimation equations assessed longitudinal trend of BMD prior to onset of osteopenia/osteoporosis. **Results:** We evaluated 4,575 DXAs in 1,267 BCS (median age at BC: 55y; median follow-up: 9.8y; non-Hispanic Black: 28.6%). Overall, 39.2% received AIs, 18.7% received selective estrogen receptor modulators (SERMs), 20.1% received AIs & SERMs, and 21.9% received neither. The cumulative incidence of osteopenia/osteoporosis in the entire cohort was 19% at 2y, increasing to 42% at 5y and 68% at 15y after BC. In those exposed to AIs, the cumulative incidence of osteopenia/osteoporosis was 38%, 75%, and 96% at 2y, 5y, and 15y, respectively. Multivariable analysis revealed the following to be independently associated with osteopenia/osteoporosis: AIs (HR = 1.94, 95%CI = 1.61-2.34), increasing age: (HR = 1.03, 95%CI = 1.02-1.04), pre-BC dyslipidemia (HR = 1.36, 95%CI = 1.06-1.75), and post-BC dyslipidemia (HR = 1.47, 95%CI = 1.19-1.81). Black race (HR = 0.44, 95%CI = 0.36-0.54, ref = white race), pre-cancer obesity (HR = 0.71, 95%CI = 0.56-0.91), and post-cancer obesity (HR = 0.79, 95%CI = 0.65-0.96) were protective. Exposure to SERMS was not a risk factor (HR = 0.97, 95%CI = 0.76-1.23). Among those exposed to AIs, radial wrist BMD declined significantly more steeply among those who eventually developed osteoporosis/osteopenia (0.45%/year), when compared with those who did not (0.11%/year) (p = 0.04). **Conclusions:** These results provide evidence for close surveillance of BC survivors at increased risk of osteopenia/osteoporosis for extended periods, and aggressive management of dyslipidemia before, during and after BC. Research Sponsor: None.

12047 Poster Session

Non-infectious sarcoid-like inflammatory granulomatous conditions (NSIGC) associated with immune checkpoint inhibitors (ICIs) for cancer: Results from the International ICARUS (Immune Checkpoint Associated Rare and Unique Side effects) consortium. First Author: Ayesha Aijaz, Stephenson Cancer Center at The University of Oklahoma Health Sciences Center, Oklahoma City, OK

Background: ICIs can be associated with a broad range of toxicities; however, limited data exists on NSIGC secondary to ICIs. Herein, we assembled the first international cohort of patients (pts) with cancer who received ICIs and subsequently developed NSIGC. **Methods:** We retrospectively collected data from 14 institutions globally on pts with cancer who received ICIs between 2015-2025 and subsequently developed biopsy-confirmed NSIGC. Pts were eligible if they received anti-programmed cell death protein-1/programmed death-ligand 1 (anti-PD-1/PD-L1) alone or in combination with additional anti-cancer therapies such as chemotherapy, targeted agents or anti-CTLA-4, or if they were treated with other immunotherapies. The chi-squared goodness of fit test was used to analyze the distribution of different ICI regimens and their association with NSIGC, assuming a uniform distribution with an expected frequency of 25 for each of the 5 ICI regimens. **Results:** The study included 125 pts with biopsy-confirmed NSIGC post-ICI. Of these, 58.4% (n = 73) were male and 83.2% (n = 104) were Caucasians. Median age at cancer diagnosis was 62 years. The top three cancers in the cohort were melanoma (45.6%; n = 57), non-small cell lung cancer (16.8%; n = 21), and renal cell carcinoma (6.4%; n = 8). Out of 125 pts, 48.8% (n = 61) received anti-PD-1/PD-L1 monotherapy, 20% (n = 25) anti-PD-1/PD-L1 + anti-CTLA-4, 17.6% (n = 22) anti-PD-1/PD-L1 + chemotherapy, 8% (n = 10) anti-PD-1/PD-L1 + targeted agents, and 5.6% (n = 7) received other immunotherapies. Our result showed a significant difference between expected and observed NSIGC frequencies across different ICI regimens (X2 = 74.2, df = 4, p < 0.01), indicating a potential association between anti-PD-1/PD-L1 monotherapy and NSIGC. The median time to the diagnosis of NSIGC after ICI initiation was 7.1 months (range: 3.9-26.7 months). Of 125 pts, 55.2% (n = 69) were diagnosed after treatment completion. Among these 69 pts, 56.5% (n = 39) were diagnosed within 6 months, 14.5% (n = 10) between 6 months and 1 year, 10.1% (n = 7) between 1 and 2 years, and 18.8% (n = 13) were diagnosed after 2 years. The remaining 44.8% (n = 56) were diagnosed during treatment, out of which 48.2% (n = 27) required permanent treatment discontinuation due to NSIGC and 3.6% (n = 2) were re-challenged. 19.2% (n = 24) received steroid treatment for NSIGC. **Conclusions:** To our knowledge, this is the largest dataset to date demonstrating NSIGC as a rare side effect of ICIs. NSIGC frequently occurs after ICI therapy completion but can also result in ICI discontinuation. Biopsy confirmation is critical to prevent misdiagnosis, and further research is required to elucidate the biology, risk factors, and implications for ICI continuation or rechallenge to optimize patient outcomes. 12048 Poster Session

Identifying genetic susceptibility for severe cardiac events in testicular cancer survivors. First Author: Arkajyoti Bhattacharya, University Medical Center Groningen, Groningen, Netherlands

Background: Testicular cancer (TC) survivors face an increased risk of cardiovascular diseases (CVD) as a late adverse effect of oncological treatment, especially after cisplatin-based chemotherapy. To explore genetic susceptibility, we performed a genome-wide association study using hierarchical clustering and assessed impact of polygenic risk scores (PRS). **Methods:** A subcohort of TC patients treated at expert centers in the Netherlands between 1976 and 2007 was established by hospital stratified random sampling, and enriched with all identified cases of severe CVD (coronary artery disease, myocardial infarction, heart failure) of the entire cohort (Lubberts et al J Clin Oncol 41:3512-3522, 2023). Genotyping was performed using the Global Screening Array. The study population consisted of 396 TC patients: 92 survivors with cardiac disease and 304 survivors without cardiac disease. Seven general population derived PRSs from the CARDIoGRAMplusC4D consortium were applied to assess cardiac risk, followed by hierarchical SNP aggregation based on linkage disequilibrium to identify cardiac risk-associated SNPs. These SNPs were used for co-functionality analysis and decision tree analyses to develop novel PRSs. **Results:** Five of the seven external PRSs were significantly associated with cardiac risk, explaining 8%-12% of the variance, with the CARDIoGRAM GWAS PRS showing the strongest association. Patient's age at diagnosis explained the largest variance in cardiac risk (21%). Hierarchical SNP aggregation identified 67 cardiac risk-associated SNPs, individually explaining 3% - 12% of the variance. Co-functionality analysis revealed biological processes, including cardiovascular development, immune signaling, and DNA damage repair, as potential mediators of these SNPs' effects. Using decision tree analysis, a novel PRS was developed incorporating CVD risk-associated SNPs and clinical risk factors at start of treatment. This PRS+ achieved the highest concordance statistic of 0.783 (standard error 0.022) and explained maximum variance (50%) among all tested models. This PRS+ identified that patients diagnosed at age $>$ 41 years had higher cardiac risk, independent of genotype data. Whereas a subset of patients diagnosed at age $\leq$41 years could be identified as having increased cardiac risk based on the minor allele frequency of five SNPs (rs6830970, rs17666409, rs10782601, rs2446862, rs767707). **Conclusions:** This study introduces a novel PRS to identify TC patients with a higher risk of CVD, enabling the development of personalized cardiovascular risk management strategies at the start of their cancer treatment. It also advances understanding of the biological mechanisms underlying this increased risk. Clinical trial information: NCT02276430. Research Sponsor: Dutch Cancer Society (KWF); NKI 2011-5209.

Prevalence of sexual dysfunction among men with cancer before the initiation of systemic treatment. First Author: Mario Machado Lopes, Hospital Moinhos de Vento, Porto Alegre, Brazil

Background: Sexual health significantly impacts the quality of life, yet its relationship with systemic cancer treatments in men remains underexplored, particularly outside prostate cancer-focused studies. In Brazil, the prevalence of moderate to complete sexual dysfunction among men is approximately 14.5%. This prospective cohort study conducted at a Brazilian Cancer Center evaluated the prevalence of sexual dysfunction before the initiation of systemic therapy in men diagnosed with solid tumors using the Male Sexual Quotient (MSQ) tool. **Methods:** Sexually active, treatment-naïve male patients with solid tumors were enrolled, excluding those with prostate cancer, active brain metastases, spinal compression, or prior pelvic irradiation/extensive pelvic surgery for rectal or bladder cancer. Baseline sexual function was assessed using the MSQ, which evaluates five domains: premature ejaculation, erectile dysfunction, hypoactive sexual desire, orgasm frequency, and dissatisfaction with sexual activity. An MSQ global score $\leq$60 defined moderate to complete sexual dysfunction. Hormonal profiles, including testosterone, FSH, and LH, were measured. The Hospital Anxiety and Depression Scale (HADS) was used to identify risks of anxiety or depression. All participants provided informed consent, and the local ethics committee approved the protocol. **Results:** Between October 2023 and December 2024, 73 male patients were recruited (median age 58 years, IQR 47.5–68.0); 78% were married, and 75% had an ECOG performance status of 0. At diagnosis, 34% presented with metastasis, including 19% with visceral involvement. Primary cancer sites included head and neck (25%), colorectal (19.1%), lung (15%), melanoma (8.2%), and kidney (8.2%). Treatment regimens comprised chemotherapy (76%), immunotherapy (31.5%), and targeted therapy (9.5%). Most patients (83%) had no risk of anxiety or depression per HADS, with one patient showing a high risk. Moderate to complete sexual dysfunction was observed in 22.2% of patients, higher than the general Brazilian male population. The most affected domains were hypoactive sexual desire, premature ejaculation, and erectile dysfunction. Despite these findings, median hormone levels were within the normal range: testosterone (356 ng/dL, IQR 300–468), FSH (64 mIU/mL, IQR 29–93), and LH (39 mIU/mL, IQR 28–52). **Conclusions:** The prevalence of moderate to complete sexual dysfunction was 22.2% in this cohort. This rate is higher than that observed in the general male population in Brazil. The evaluation of sexual quality of life in men with cancer undergoing systemic treatment is often overlooked. This data points to the need to develop new policies and studies to increase awareness about this critical issue. Research Sponsor: None.

A pilot exercise program in breast cancer survivors: Group vs individual training outcomes. First Author: Lindsey Elizabeth Merifield, University of Hawaii at Manoa, Honolulu, HI

Background: Exercise interventions have consistently led to improved fitness in breast cancer patients. Best practices to ensure longevity of lifestyle changes have not been well explored. The purpose of this study was to evaluate long-term effectiveness of exercise intervention for patients. We sought to determine if group (Gr) or individual (Ind) exercise sessions would have differing effects in maintaining long term muscular strength, cardiorespiratory endurance, and range of motion (ROM). **Methods:** Thirty female patients underwent 3 months of individual exercise training, and were then randomized to continue with Ind (n=13) or Gr sessions (n=17) for another 3 months. Assessments were performed at baseline, after 3 months, and 1 year from baseline. **Results:** Ind showed significant strength improvements from baseline to 3 months, and 1 year. Gr did not show significant strength improvements at either time point. Cardiorespiratory endurance (VO2peak) improved in Ind from baseline to 3 months, and 1 year. Gr showed significant endurance improvement from baseline to 1 year only. Ind shoulder (ROM) improved from baseline to 3 months and 1 year. No significant improvement in ROM was found in Gr at either time point. **Conclusions:** In our study, we found six months of exercise intervention improved long-term strength, endurance, and ROM significantly in Ind session, and non significantly in Gr. A post-analysis chart review revealed increased exercise limitations in the Gr due to injury and/or non-cancer related medical conditions, which may explain some of the differences in outcomes. Clinical trial information: NCT04013568. Research Sponsor: National Cancer Institute/U.S. National Institutes of Health; P30.

Trajectories of multidimensional worry in survivors of early breast cancer (BC). First Author: Antonio Di Meglio, Cancer Survivorship Program, INSERM 981, Gustave Roussy, Villejuif, France

Background: Worrisome thoughts are common future-oriented behaviors and may affect quality of life (QoL) years removed from BC diagnosis. We aimed to identify trajectories of worry and their determinants, focusing on age-related specificities. **Methods:** Disease-free stage I-III BC survivors from CANTO (NCT01993498) completed the Impact of Cancer scale v2 at end of treatment (EoT) and years (Y) 1, 3, and 5 post-EoT. Group-based trajectories were identified modeling continuous scores of the worry subscale (range: 1-5, higher = worse), which evaluates uncertainty and worry about the future and health, a sense of time running out, fear of cancer recurrence (FCR), and symptom-triggered FCR. Adjusted multinomial logistic regression incorporating pre-treatment anxiety/depression assessed membership determinants. QoL (EORTC QLQ-C30/BR23) was described by trajectory. Analyses were stratified by age. **Results:** We included7824 survivors, 31% were $\leq$50 and 69% $>$ 50 years old. Among those aged $\leq$50, we identified five worry trajectories: most had high (41%) or very high (18%) worry (mean scores [95% CI] at EoT: 3.57 [3.55-3.60] and 4.37 [4.33-4.41], respectively, stable); 21% showed improvement (2.77 [2.73-2.82] at EoT, 2.14 [2.08-2.21] at Y5); and 12% had low worry (1.58 [1.53-1.63] at EoT, stable). Finally, 7% had moderate worry at EoT (2.21 [2.14-2.28]) that worsened sharply, stabilizing at high levels by Y5 (3.40 [3.29-3.52]). These patterns, especially in the worsening group, were primarily driven by persisting FCR and increasing uncertainty about health. Among those aged $>$ 50, similar trajectories emerged, however worry levels in the worsening group (17%) remained low-to-moderate (2.04 [2.01-2.06] at EoT, 2.34 [2.27-2.40] at Y5). Younger age was a significant determinant of very high worry, both in the $\leq$50 (Odds Ratio v low worry [95% CI] per 10-year decrease: 1.92 [1.33-2.77]) and in the $>$ 50 age group (1.50 [1.20-1.90]). Partnered status was associated with worsening worry in the $\leq$50 age group (v not: 2.54 [1.24-5.19]), whereas chemotherapy with very high worry in the $>$ 50 age group (v no chemo: 1.77 [1.14-2.73]). BC grade, stage, BRCA status, family history of cancer, and comorbidities were not linked to worry in either age group. Psychological and physical domains of QoL, including fatigue, sleep, cognitive function, appetite, and gastrointestinal symptoms, were significantly worse in trajectories at higher worry ($p < .001$ at all time points). **Conclusions:** More than two-thirds of younger BC survivors report high levels of worry that either remain unchanged or worsen 5 years post-EoT, with a more pronounced decline and different determinants than older counterparts. These patterns appear to be largely driven by the post-traumatic effects of BC on unresolved FCR and by negative projections about health. Early referral to mental health professionals and monitoring strategies focused on reducing anxious arousal are warranted. Clinical trial information: NCT01993498. Prospective observational study on health resource utilization and patterns of care for skeletal-related events in patients with bone metastases secondary to solid tumors. First Author: Mahmoud Abdelsatar Elshenawy, King Faisal Specialist Hospital and Research Center, Riyadh, Saudi Arabia

Background: Bone metastases are a common complication of advanced solid tumors, leading to significant morbidity through skeletal-related events (SREs). This study evaluates health resource utilization (HRU), treatment patterns, and clinical outcomes associated with SREs, with a focus on bone-modifying agents (BMAs) such as zoledronic acid and denosumab. **Methods:** This single-center, prospective, observational study included 199 patients with bone metastases secondary to solid tumors who experienced at least one SRE. Eligible patients were adults (≥18 years) with an Eastern Cooperative Oncology Group (ECOG) performance status of 0–3. Data collected included demographics, primary cancer type, comorbidities, treatment patterns, type and timing of SREs, and HRU. The impact of BMAs on SRE-free survival and overall survival (OS) was assessed using Kaplan-Meier analysis and multivariate Cox regression models. **Results:** The median age at the first SRE was 56 years, with 51.8% of patients being female. Breast cancer was the most common primary tumor site (30.2%), followed by genitourinary (22.1%) and gastrointestinal (18.6%) cancers. Visceral metastases were present in 56.3% of patients. Radiation therapy accounted for 80.9% of first SREs, followed by cord compression (8.5%), pathological fractures (7%), and surgical fixation (3.5%). Only 16.5% of patients received BMAs before their first SRE, increasing to 38.2% after the first SRE. Patients who received BMAs before the first SRE had significantly prolonged SRE-free survival (median 9.9 vs. 2.03 months, p = 0.001) and OS (median 45.6 vs. 29.8 months, p = 0.05). Similarly, BMA use after the first SRE improved SRE-free survival (median 18.9 vs. 10.3 months, $p < 0.001$) and OS (median 25.9 vs. 13.6 months, p = 0.001). The most common BMA-related adverse event was hypocalcemia (44.7%). **Conclusions:** This study highlights the underutilization of BMAs before the first SRE despite their significant impact on SRE-free survival and OS. Post-SRE BMA use was associated with improved outcomes, underscoring the need for earlier initiation of BMA therapy. Future research should focus on identifying barriers to early BMA utilization, optimizing management of therapy-related complications, and assessing the cost-effectiveness of BMAs in real-world settings. Hot flashes and night sweats in women with breast cancer: Prevalence and severity of symptoms. First Author: Long Lin, West China School of Medicine, West China Hospital, Sichuan University, Chengdu, Sichuan, China

Background: Hot flashes(HF) and night sweats(NS) are common endocrine-related symptoms experienced by breast cancer patients, which potentially arise from the tumor or treatment-related pharmacologic effects. They can significantly diminish patients' quality of life. However, there is a paucity of studies in China investigating the incidence and characteristics of HF and NS among patients with breast cancer. **Methods:** This study was a multi-center, cross-sectional survey that included women diagnosed with breast cancer from seven hospitals' oncology departments in China. Information was collected about demographic characteristics, psychological status (the Hospital Anxiety and Depression Scale and the Distress Thermometer), the frequency and severity of HF and NS(modified Hot Flash and Night Sweat scale), and patients' perceptions of these symptoms. Group differences based on the presence or absence of HF and NS were analyzed using t-tests or chi-square tests. Finally, univariate analyses was conducted to explore factors associated with the frequency of HF and NS. **Results:** Between October and November 2024, 960 questionnaires were distributed, and 767 Chinese female breast cancer patients(aged 25 to 79) replied and completed fully. Over 56% (n = 430) patients reported experiencing HF or NS.The average weekly frequency was 8.6 times for HF and 7.3 times for NS. Patients attributed HF and NS primarily to treatment (HF: 36.8%;NS:32.7%) or uncertain causes (HF:15.8%;NS:17.4%). Compared to patients without HF and NS, those experiencing the symptoms had significantly higher levels of anxiety ($p < 0.001$), depression (p = 0.019), and psychological distress ($p < 0.001$). Notably, Patients reported severity, distress, and impact on life scores above 4, with HF at 47.90%, 37.46%, and 35.89%, and NS at 49.67%, 43.46%, and 40.85%, respectively. Among those affected, 59.24% of patients with HF and 63.7% of patients with NS adopted coping strategies, primarily resting/lying down (HF:27.7%;NS:36.3%). Regarding coping ability, HF group had a significant higher score than NS group (HF: 5.90; NS: 5.30, p = 0.012). Furthermore, univariate analysis revealed that HF and NS were associated with distress(HF:p = 0.032; NS:p = 0.030) and sleep quality(HF:p = 0.031; NS: p = 0.043). Additionally, for HF, single marital status (p = 0.017) was identified as a relevant factor, while stage IV tumor status (p = 0.044) was associated with NS. **Conclusions:** HF and NS affect over half of Chinese breast cancer patients, impacting their mental well-being and life quality, while low coping ability and limited coping strategies further underscore the need for healthcare professionals to pay closer attention to patients experiencing these symptoms, particularly single individuals and those with advanced-stage breast cancer. Cardiovascular risk factor severity and adverse cardiovascular events: A report from the Childhood Cancer Survivor Study (CCSS). First Author: Wendy Bottinor, Virginia Commonwealth University, Richmond, VA

Background: Among survivors of childhood cancer, more severe grades of CVRFs are associated with increased risk for adverse cardiovascular events (ACE). The impact of low severity CVRFs has not been defined. **Methods:** Among 25,723 long-term survivors of childhood cancer, CVRF severity was graded using longitudinal self-report: Grade 1 conditions are reported but not on medications; Grade 2 are prescribed medications. Cumulative incidence of CVRFs were estimated into the 6th decade of life with death and Grade 2 CVRFs a competing risk event for Grade 1 CVRFs. Starting at 1st report of a CVRF, multivariable piecewise-exponential models were used to estimate relative rates (RR) of heart failure (HF), myocardial infarction (MI), valvular disease (VD), arrhythmia, and cardiac death relative to survivors without hypertension (HTN), diabetes (DM), and hyperlipidemia (HLD), all as time-dependent covariates. **Results:** The median age of survivors was 35y (range 9-70) and 26y (range 7-52) from cancer diagnosis. Cumulative incidence by age 55 of Grade 1 HTN, DM, and HLD were 7.8% (CI 7.1-8.5%), 4.3% (CI 3.8-4.9%), and 10.8% (CI 9.9-11.6%), respectively. The cumulative incidences of Grade 2 HTN, DM, and HLD were 37.9% (CI 36.4-39.3%), 14.0% (13.0-15.0%), 31.3% (29.9-32.7%), respectively. Grade 2 CVRFs were significantly associated with an increased RR for nearly all ACE (table). Grade 1 CVRFs were also significantly associated for most ACE; often with a similar magnitude as Grade 2 CVRFs. Grade 1 vs no HTN was associated with a 2 to 5-fold significantly increased RR of HF, MI, VD, arrhythmia, and cardiac death. Grade 1 vs no DM was associated with an increased RR of HF (1.9, CI 1.1-3.4). Grade 1 vs no HLD was associated with an increased RR of MI (2.9, 1.9-4.2) and arrhythmia 2.1 (1.2-3.5). **Conclusions:** Grade 1 CVRFs are associated with increased risk for ACE. These data suggest a role for more aggressive treatment of Grade 1 CVRFs among survivors. Research Sponsor: National Cancer Institute.

Relative rates of ACE among survivors by CVRF severity.

Individual models for each CVRF vs no respective CVRF (ref)	HF RR (95% CI)	MI RR (95% CI)	VD RR (95% CI)	Arrhythmia RR (95% CI)	Cardiac death RR (95% CI)

Impact of neighborhood disadvantage and residential isolation on cognitive outcomes in cancer survivors. First Author: Noha Sharafeldin, Division of Hematology & Oncology, Heersink School of Medicine, University of Alabama at Birmingham, Birmingham, AL

Background: The Social Vulnerability Index (SVI), a composite measure of socioeconomic deprivation, household composition, minority status, and housing type and transportation, is a reliable marker of neighborhood disadvantage. Residential Segregation measures the degree to which a minority group is distributed differently than the majority group across census tracts. The isolation index is a measure of segragation that captures the extent to which minority members are exposed only to one another. These measures have been associated with poor survival in patients with cancer, yet studies on adverse outcomes in surviors are limited. Cognitive impairment is an adverse outcome highly prevalent in up to 40% and persists up to 5y in hematologic cancer survivors treated with blood or marrow transplantation (BMT). We postulate that neighbohood disadvantage and residential isolation may have a negative effect on cognitive outcomes in BMT survivors. **Methods:** We included 71 patients treated with allogeneic BMT, enrolled in the the Cognitive Training and Genetics Attitudes (cTAG) study. Objective cognitive function was measured using a comprehensive in-person battery of standardized neuropsychological tests. Standardized T-scores were categorized as deficit scores (range 0 to 5), and averaged across all tests to estimate a global deficit score(GDS), which was used as a measure of cognitive impairment. Residential addresses, geocoded and joined to corresponding Census block group and tract, were used to match patients with their corresponding SVI and residential segregation scores. Multivariable logistic regression models adjusted for age, sex, race, and clustering at the tract level were used to estimate associations with GDS. **Results:** Median age at study participation was 58y (IQR: 46, 63), 57.8% were male, and 16.9% were non-Hispanic Black. Primary diagnosis was 66.2% acute leukemia and 22.5 myelodysplastic/myeloproliferative neoplasms. Average time since BMT was 1.5y (SD = 1.2). Prevalence of global cognitive impairment was 19.7% (95%CI: 11.2-30.9). A high overall SVI score was associated with GDS (aOR = 4.7, 95%CI: 1.1, 20.2, p = 0.035). Vulnerability related to socioeconomic status (aOR = 4.9, 95%CI: 1.2, 20.2, p = 0.03) and housing type and transportation (aOR = 4.0, 95%CI: 1.1, 15.2, p = 0.04) were significantly associated with GDS. Higher residential isolation index ($>$ 0.6) was significantly associated with increase in GDS (aOR = 5.4, 95%CI: 1.3, 22.5, p = 0.02) adjusting for age, sex, race, and clustering at the tract level. **Conclusions:** Cancer survivors residing in areas with higher indicators of social vulnerability and isolation are at increased risk of cognitive decline post-BMT. These findings highlight the overall need for dedicating appropriate resources and care planning especially for individuals surrounded by others from their same group within their residential areas. 12057 Poster Session

Pilot study of a muscadine grape extract supplement to decrease fatigue among older cancer survivors. First Author: Heidi D. Klepin, Wake Forest University School of Medicine, Winston-Salem, NC

Background: Fatigue is a prevalent symptom among older cancer survivors and is associated with declines in physical function and quality of life (QOL). A proprietary muscadine grape extract supplement (MGES) may decrease fatigue based on pre-clinical data showing effects on oxidative stress, inflammation, and mitochondrial function and clinical observations from a Phase 1 trial suggesting a relationship between higher dose of MGES and decreased fatigue. The objective of this pilot study was to evaluate whether MGES may decrease fatigue and improve function and QOL among older cancer survivors. **Methods:** We conducted a randomized placebo-controlled pilot study (NCT04495751) of MGE supplementation (4 tablets twice daily, approximately 1280 mg total phenolics) for 12 weeks (wks) among older adult cancer survivors who reported baseline fatigue. Additional eligibility included age ≥65 years, history of solid tumor or lymphoma with no evidence of disease, at least 1 year post completion of active treatment. Fatigue was assessed with the PROMIS Fatigue 7a at baseline, and 2, 4, 8, 12 (primary outcome) and 16 wks. Physical function [Pepper Assessment Tool for Disability (PAT-D, activities of daily living and self-reported mobility subscales, higher scores indicate more limitations), Short Physical Performance Battery (SPPB, higher scores indicate better performance), 6-minute walk] and QOL (PROMIS Global Health) were measured at baseline and 12 wks. Toxicity was assessed using the CTCAE v5. Intention to treat (IIT) analyses utilized t-tests with a one-sided alpha = 0.10 to compare outcomes at 12 wks. **Results:** Sixty-four adults (mean age 76 years, 78% female, 91% white, 6% black) were randomized. Most common malignancies were breast (50%), lymphoma (12.5%), and prostate (12.5%). Fifty-one participants (80%) completed 12 wks of MGES or placebo with N = 62 evaluable for IIT analysis. There were no ≥grade 3 toxicities; 26 grade 2 toxicities (gastrointestinal) were attributable to study intervention. In IIT analyses, there was no difference in fatigue by randomization at 12 wks (MGE 50.1 vs placebo 51.4, p = 0.22). However, participants randomized to MGES reported improved physical function (PAT-D total score 1.4 vs 1.6, p = 0.07, ADL score 1.2 vs 1.4 p = 0.08, mobility score 1.7 vs 2.2, p = 0.05) and had improved gait speed scores on the SPPB, 3.7 vs 3.3, p = 0.1).There were no differences in total SPPB score (9.8 vs 9.2, p = 0.37), six-minute walk distance (369 vs 349 feet, p = 0.43) and QOL at 12 wks. **Conclusions:** In this pilot study, MGE supplementation for 12 wks among older cancer survivors did not improve fatigue or QOL compared to placebo but self-reported physical function and gait speed score were improved, suggesting a potential benefit on physical function. Ancillary studies investigating effects on oxidative stress, inflammation, mitochondrial function, and microbiome are on-going. Clinical trial information: NCT04495751. Research Sponsor: National Cancer Institute; P30 CA012197; National Center for Advancing Translational Sciences; UL1TR001420.

Trends and disparities in palliative care utilization in advanced head and neck cancer hospitalizations. First Author: Ayobami Gbenga Olafimihan, John H. Stroger, Jr. Hospital of Cook County, Chicago, IL

Background: Greater than 60% of Head and neck cancer (HNC) patients have advanced cancer at the time of presentation. They have unique physical and psychological symptoms due to the cancer's anatomical location and multimodal treatment-related toxicities. Early integration of palliative care (PC) in their management can improve health-related quality of life. We examined the trends and predictors of PC utilization among hospitalized advanced HNC patients in the US. **Methods:** A retrospective longitudinal study was conducted using the NIS database (2008-2021). Using joinpoint regression and multivariable logistic regression, trends and factors associated with PC receipt were assessed. **Results:** The overall prevalence of palliative care utilization among 326,265 hospitalizations with advanced HNC was 11%. Over the period, palliative care utilizations increased from 3,651 to 16,982 per 100,000 advanced HNC admissions (p-trend <0.001) with an average annual percentage increase of 9.7%. Females with metastatic HNC had higher odds (Adjusted odds ratio (AOR): 1.11; 95% CI: 1.04-1.19) of receiving palliative care compared to males. There was similar likelihood of utilizing palliative care across racial groups. Patients in teaching hospitals had 46% higher likelihood (AOR: 1.46; 95% CI: 1.33-1.60) of palliative care use in comparison to patients in non-teaching hospitals. Large hospitals had higher palliative care use compared to small hospitals (AOR: 1.12; 95% CI: 1.01-1.25). Admissions in the south and west had higher likelihood of palliative care use relative to those in the North-east region. Patients covered by Medicaid had higher odds of palliative care receipt compared to those covered by Medicare. Relative to patients who had a routine discharge home or with self-care, those discharged to facilities or with home health care were four-fold more likely (AOR: 4.35; 95% CI: 3.98-4.75) to receive palliative care. Those who died during hospitalization were also more likely to use palliative care (AOR: 21.4; 95% CI: 19.1-24.0). Non-elective admissions had higher likelihood of palliative care receipt relative to elective visits. **Conclusions:** Although palliative care utilization has improved over the years, it remains suboptimal. Tailored interventions addressing sociodemographic and hospital-level disparities will promote equitable access and meet the unique needs of this patient population. Research Sponsor: None.

Predictors of PC use.

A phase 1b study of SHR-2017, a RANKL/NGF targeted antibody, in patients (pts) with breast cancer bone metastasis. First Author: Xu Liang, Beijing Cancer Hospital, Beijing, China

Background: Bone metastasis is a common site of metastasis in malignant tumors. For patients (pts) with bone metastasis, pain is the predominant symptom, significantly impairing the quality of life. SHR-2017, a first-in-class fully human monoclonal antibody targeting RANKL/NGF, is designed to prevent skeletal-related events and alleviate pain in pts with bone metastasis. Here, we present the preliminary pharmacokinetics, pharmacodynamics, efficacy and safety results from a multicenter, open-label, single-arm phase 1b study in pts with bone metastasis from breast cancer. **Methods:** Breast cancer pts with at least one bone metastasis and an average Numeric Rating Scale (NRS) score of ≥ 4 at the index bone metastasis cancer pain site at baseline were eligible. Pts could be undergoing stable anti-tumor treatment or have no plan to change their anti-tumor treatment within 2 weeks after drug administration in this study. Pts received subcutaneous injection of SHR-2017 at 180 mg every 4 weeks for 6 cycles. To assess pain, pts maintained a diary (daily through week 8 and then weekly to week 48) to record the average and worst pain over the previous 24 h (on a numeric rating scale from 0 = no pain to 10 = worst possible pain) at the index bone metastasis cancer pain site. **Results:** As of Dec 31, 2024, 22 pts were enrolled and treated (prior bone targeted agents [BTA] use, 36%; mean NRS of average pain, 4.17 [SD: 0.76]). Following a single dose, the median time to peak concentration of SHR-2017 was 7 days, with a mean half-life ($t_{1/2}$) of 11.4 days and a mean clearance (CL/F) of 0.88 L/day. Among 12 pts without prior BTA use, a reduction in urine N-telopeptide of type I collagen adjusted for urine creatinine (uNTX/Cr), a biomarker for bone resorption, was evident by cycle 1 and sustained over time; the median reduction from baseline was -83.0% (range -96.9% to -60.6%) at week 5 (C2D1). By week 13 (C4D1), among 8 pts without prior BTA use, the median reduction in uNTX/Cr was -78.7% (range -93.1% to -64.6%). Daily NRS score showed a continuous decrease during cycle 1 in all pts, the mean reductions from baseline in average and worst pain were -1.95 (SD: 1.21) and -1.90 (SD: 1.46) at week 2, respectively. By week 4, the reductions were -2.46 (SD: 1.03) and -2.45 (SD: 1.45), respectively. Treatment-related AEs (TRAEs) occurred in 7 (32%) pts (grade 1, n = 6; grade 2, n = 1), with the most common being increased parathyroid hormone (PTH), the one grade 2 TRAE being rash. There were no TRAEs leading to dose discontinuation. **Conclusions:** Preliminary data indicated promising anti-bone resorption and analgesic effects, with a favorable safety profile for SHR-2017 in pts with bone metastasis from breast cancer. The trial is ongoing to further evaluate SHR-2017 following multiple dosing. Clinical trial information: NCT06380881. Research Sponsor: Jiangsu Hengrui Pharmaceuticals Co., Ltd.

Baseline circulating growth differentiation factor-15 and the cancer phenotype in the PROACC-1 phase 2 study of the efficacy and safety of ponsegromab in patients with cancer cachexia. First Author: Eric Roeland, Knight Cancer Institute, Oregon Health & Science University, Portland, OR

Background: Growth differentiation factor-15 (GDF-15) is an emerging therapeutic target in cancer cachexia. However, the association of circulating GDF-15 with the cancer cachexia phenotype remains poorly characterized. **Methods:** Serum GDF-15 was measured using the Roche Elecsys GDF-15 assay at screening in a phase 2, randomized trial of ponsegromab (an investigational anti-GDF-15 monoclonal antibody) in patients with cancer cachexia, and an elevated serum GDF-15 (≥ 1500 pg/mL) (NCT05546476). Cachexia was defined by international consensus criteria and sarcopenia by standardized sex-specific cut-off values for lumbar skeletal muscle index. Cross-sectional associations of GDF-15 with various demographic and clinical parameters were explored post-hoc using summary statistics and Pearson's correlation (with GDF-15 on the $\log_{10}$ scale). **Results:** A total of 187 patients were enrolled in this study with a median (IQR) age of 67 (60-74) years and 37% were female. Baseline median GDF-15 values were higher among patients with cachexia and colorectal and pancreatic cancers, compared to NSCLC. GDF-15 elevation was higher in patients with stage IV disease, sarcopenia, and worse performance status (Table). Higher GDF-15 levels were associated with lower serum albumin (r = -0.31 [95% CI: -0.44, -0.177]) and prealbumin (r = -0.17 [95% CI: -0.31, -0.03]). No significant associations were observed between GDF-15 levels and appetite or fatigue assessments. **Conclusions:** Among patients with cancer cachexia, GDF-15 elevation was more pronounced in those with more advanced cancer, sarcopenia, and worse performance status. In addition, GDF-15 levels were negatively correlated with markers of nutritional status. Clinical trial information: NCT05546476. Research Sponsor: Pfizer, Inc.

IPElife: Phase III, double-blind trial of *cannabis sativa* extract in pain management and quality of life in patients with metastatic lung cancer. First Author: Danielli Matias, Liga Norte Riograndense Contra o Câncer, Natal, Brazil

Background: Pain and deterioration in quality of life (QoL) are among the most common and problematic symptoms reported by patients with late-stage lung cancer. Thus, *cannabis sativa* extract has been identified as a potencial adjuctive therapy for enhancing QoL and managing symptoms, including oncology pain. Objective: The aim is to assess pain management and quality of life in patients with locally advanced or metastatic lung cancer using *cannabis sativa* extract. **Methods:** A randomized, prospective, double-blind, placebo-controlled, phase III trial was conducted, which included patients, which included patients with locally advanced or metastatic lung confirmed by histopathology. The participants were subdivided into two groups of 20 patients each, with 1:1 allocation ratio. The primary outcome was pain control, measured using the Visual Analog Scale (VAS) for pain. The secondary outcomes included quality of life, assessed using the EORTC QLQ-C30 and its specific module for lung cancer (QLQ-LC13). The *cannabis sativa* extract administration protocol involved dose escalation, starting at 10mg/day, with titration every 5 days until the patients reached their goals or the maximum dose of 100mg/day. The questionnaires and the VAS scale were applied every 21 days from T1 to T5. Continuous variables were analyzed using the paired t-test or signed-rank test, depending on the date distribution. **Results:** The difference in mean pain scores (measured using the EVA tool) was greater in the CBD group compared to the placebo group between periods T1 and T5 (5.0 vs 3.7) (Table1). Similarly, the difference in mean pain scores, as measured using the EORTC-QLQ-C30 scale (47.2 vs 35.7), favored the CBD group. Regarding the quality of life analysis, in the overall assessment date were not statistically significant, however difference was observed in the levels of insomnia (p-value 0.01) and dyspnea (p-value 0.02) between patients in the CBD and placebo groups, with results favoring the CBD group. **Conclusion:** The *cannabis sativa* extract may be considered an adjuvant in the management of pain and quality of life in patients with metastatic lung cancer and locally advanced. Clinical trial information: 6.036.463. Research Sponsor: GreenCare Pharma.

eHealth disease educational intervention vs. outpatient palliative care as usual among incurable cancer patients cared by family caregivers at home. First Author: Ying Yu, State Key Laboratory of Genetic Engineering, Human Phenome Institute, Zhangjiang Fudan International Innovation Center, Fudan University, Shanghai, Shanghai, China

Background: To determine whether ehealth disease educational interventions (eDEI) with fast-delivering interfaces and concise key messages can enhance capability of family caregivers and improve physical and psychological aspects of health-related quality of life (HRQoL) of incurable cancer patients at home. **Methods:** A randomized, open-label controlled trial was conducted in cancer center in Shanghai, China. Eligible participants (age$\geq$18 years) with incurable cancer receiving palliative care and Karnofsky performance $\leq$ 70, along with a family caregiver (age $\geq$18 years), were randomly assigned 1:1 to either intervention (eDEI plus palliative care as usual (CAU)) or control group (CAU only). eDEI as a mobile application provides family caregivers with texts, audios and videos of symptom/side effect management and nursing skills. The intervention lasted for two months.The primary outcomes were physical aspects of HRQoL on the European Organization for Research and Treatment of Cancer Core Quality of Life Scale (EORTC QLQ-C30) and psychological aspects of HRQoL on the Hamilton Anxiety Rating Scale (HAM-A) from baseline to the end of 2nd month. The secondary outcome was caregiver satisfaction on a questionnaire focusing on skill enhancement using Mann-Whitney tests at the end of 2nd month. The exploratory outcome was survival benefit using Kaplan-Meier method with log rank hazard model from the enrollment to the death. The primary analyses were based on intention-to-treat principles, covering all patients who completed baseline assessment. False discovery rate (FDR) was used for multiple testing correction. **Results:** From Jul 28 to Nov 3, 2023, 154 eligible patients with family caregivers were randomly and evenly assigned to the intervention group and control group. 74 and 73 patients with their caregivers, in the intervention and control group respectively, completed baseline assessment. Among the 147 patients (mean age 59.9 years, 42.9% female) from baseline to the end of 2nd month, Linear Mixed Model analyses showed that the intervention group had significant improvement of HRQoL compared with the control group, evidenced by EORTC QLQ-C30 score (FDR-adjusted $p < 0.0001$, Cohen's *d* 0.42) and HAM-A score (FDR-adjusted $p < 0.0001$, Cohen's *d* -0.43). There was a significant difference of caregiver satisfaction at the end of 2nd month (mean difference score 0.57, $p < 0.0001$, Cohen's *d* 1.19). Besides, a post-trial exploratory survival analysis showed that the intervention group had longer survival compared to the control group (median 220 days vs. 141 days, p = 0.012, hazard ratio 1.83, 95%CI 1.14 to 2.92) after adjustment of baseline characteristics. **Conclusions:** The fast-delivering and concise eDEI can enhance caring capability of family caregivers, improve physical and psychological aspects of HRQoL, and prolong survival among incurable cancer patients. Clinical trial information: 2300077346. Research Sponsor: None.

Impact of elinzanetant on sleep disturbances and quality of life in women undergoing adjuvant endocrine therapy for breast cancer: Phase 3 OASIS 4 trial. First Author: Donal J. Brennan, UCD School of Medicine, Dublin, Ireland

Background: Vasomotor symptoms (VMS) and sleep disturbances are common in women taking adjuvant endocrine therapy (AET) for hormone receptor-positive (HR+) breast cancer and can impact quality of life and treatment adherence, potentially affecting breast cancer outcomes. There are few efficacious treatments and none approved in this indication. Elinzanetant (EZN) is a dual neurokinin-1 and -3 receptor antagonist in development for the treatment of VMS. **Methods:** OASIS 4 (NCT05587296) is a 52-week randomized, placebo-controlled phase 3 trial evaluating the safety and efficacy of EZN for the treatment of VMS in women taking AET for HR+ breast cancer. Women aged 18–70 years being treated for, or at high risk of developing, HR+ breast cancer and experiencing $\geq$35 moderate-to-severe VMS/week associated with tamoxifen/aromatase inhibitors were randomized 2:1 to receive EZN 120 mg for 52 weeks or placebo for 12 weeks followed by EZN for 40 weeks. Impact of EZN on sleep disturbances and menopause-related quality of life were evaluated as key secondary endpoints, measured by mean changes from baseline to week 12 in Patient-Reported Outcomes Measurement Information System Sleep Disturbance Short Form (PROMIS SD SF) 8b total T-score and Menopause-specific Quality-Of-Life questionnaire (MENQOL) total score, respectively. These endpoints were analyzed using a mixed model with repeated measures (one-sided p-values). **Results:** At baseline, mean (standard deviation [SD]) PROMIS SD SF 8b total T-scores were 60.6 (6.3) in the EZN group and 60.7 (6.8) in the placebo group, corresponding to moderate sleep disturbances based on established thresholds in a reference population. At week 12, reductions from baseline in PROMIS SD SF 8b total T-score were -10.6 (8.2) and -4.1 (7.4) in respective groups, suggesting an improvement in sleep disturbance. Reductions between EZN and placebo showed a statistically significant difference (least squares [LS] mean difference [95% confidence interval (CI)]: -6.1 [-7.5, -4.8]; $p<0.0001$). Mean (SD) MENQOL total scores at baseline were 4.8 (1.2) in the EZN group and 4.8 (1.3) in the placebo group. At week 12, reductions from baseline in MENQOL total score were -1.3 (1.1) and -0.5 (1.2), respectively, corresponding to an improvement in menopause-related quality of life. Reductions between EZN and placebo showed a statistically significant difference (LS mean difference [95% CI]: -0.7 [-0.9, -0.5]; $p<0.0001$). Reductions in PROMIS SD SF 8b total T-scores and MENQOL total scores were maintained in both treatment groups throughout the 52-week treatment period. **Conclusions:** EZN demonstrated efficacy in reducing sleep disturbance and improving quality of life in women undergoing AET for breast cancer. Concomitant intake of EZN and AET may improve tolerability and adherence to AET, with a potentially favorable impact on breast cancer outcomes. Clinical trial information: NCT05587296. Research Sponsor: Bayer.

Nationwide trends and disparities in end-of-life care for acute myeloid leukemia: A 2019–2021 NIS analysis of palliative care utilization and hospitalization costs. First Author: Nandhini Iyer, MacNeal Hospital, Loyola Medicine, Berwyn, IL

Background: Acute myeloid leukemia (AML) is a life-threatening hematologic malignancy with high morbidity and mortality, particularly among older adults. Early integration of palliative care (PC) has been shown to improve symptom management, quality of life, and healthcare outcomes in AML patients. However, significant disparities in PC utilization persist, driven by socioeconomic factors such as race, income, and insurance status. This study examines trends in PC use among AML inpatients, focusing on its impact on mortality, hospitalization costs, and complications, while highlighting barriers to equitable care access. **Methods:** We conducted a retrospective cohort study utilizing the National Inpatient Sample (NIS) database from 2019 to 2021, identifying AML patients via ICD-10 codes, and were classified based on their PC utilization. The Institutional Review Board (IRB) approval was not mandatory since the NIS contains deidentified data. The primary outcome was inpatient mortality, with secondary outcomes including length of stay (LOS), total hospital costs, and key complications. Statistical analysis included t-tests, chi-square tests, and multivariable logistic regression adjusting for demographic, socioeconomic, and hospital factors. **Results:** A total of 220,790 AML hospitalizations were identified, with 27,540 (12.4%) utilizing PC. PC patients were older (67.41 vs. 58.65 years, $p < 0.01$) and predominantly White (75.27% vs. 70.70%, $p < 0.01$). Odds of PC utilization were lower for Black (OR 0.9, p = 0.05), Hispanic (OR 0.7, $p < 0.01$), and Asian (OR 0.77, $p < 0.01$) patients. Utilization was highest in urban teaching hospitals (89.2%, $p < 0.01$) and Medicare patients (OR 1.87, $p < 0.01$), followed by private insurance (22.99%), Medicaid (8.91%), and self-pay patients (1.38%). Mortality was significantly higher in the PC group (37.4% vs. 4.42%, OR 11.74, $p < 0.01$). Secondary outcomes included longer stays (12.94 vs. 12.25 days, $p < 0.01$), higher costs ($214,915 vs. $174,193, $p < 0.01$), and more complications (tumor lysis syndrome, stroke, thrombocytopenia, sepsis, anemia; all $p < 0.01$). **Conclusions:** Palliative care in AML patients was associated with higher mortality, longer hospital stays, increased costs, and complications, likely reflecting its introduction at more advanced stages of the disease. These findings underscore the urgent need for earlier integration of palliative care into treatment protocols. Addressing barriers such as healthcare inequities and improving access to timely interventions could enhance patient quality of life, reduce complications, and optimize resource utilization, ultimately fostering more equitable, efficient, and cost-effective care for AML patients. Research Sponsor: None.

Early palliative care, intensity of end-of-life care, and their impact on overall survival in cancer patients: A real-world study. First Author: Sebastien Salas, Aix-Marseille University, Marseille, France

Background: Early palliative care (EPC) and reduced aggressive end-of-life (EOL) interventions improve quality of life in advanced cancer. While trials suggest a potential survival benefit, the real-world impact on overall survival (OS) remains underexplored. This study examines the association between palliative care (PC) timing, EOL care intensity, and OS in a large real-world cohort. **Methods:** We conducted a population-based study using the French health claims database (SNDS) for patients with metastatic solid tumors diagnosed within 2 years who died in 2022. Patients with hematologic malignancies or PC initiated before metastasis were excluded. Patients were stratified by PC referral timing: no PC, EPC ($\leq$2 months post-diagnosis), and late PC (LPC) ($>$ 2 months post-diagnosis). EOL care intensity was assessed using Earle criteria (care structure/processes) and MIEOL criteria (physically invasive interventions). The primary endpoint was OS (time from diagnosis to death). **Results:** Among 159,288 decedents, 85,192 met inclusion criteria (no PC = 27,325; EPC = 29,016; LPC = 28,851). Digestive (n = 29,668) and pulmonary (n = 17,065) cancers predominated. Patients with EPC/no PC had higher poor-prognosis adapted Charlson scores than LPC (23.6% and 23.4% vs. 18%, $p < 0.001$). EOL aggressiveness was greater in no PC compared to EPC/LPC (Earle $\geq$1: 51.4% vs. 23.4% vs. 21.6%; MIEOL $\geq$1: 25.7% vs. 16.9% vs. 17.6%; $p < 0.001$). Mean OS differed significantly (no PC: 167 $\pm$ 190 ; EPC: 74 $\pm$ 100 days days; LPC: 344 $\pm$ 182 days; $p < 0.001$). LPC was associated with the longest OS. Patients meeting Earle and MIEOL criteria were significantly associated with shorter survival ($p < 0.001$). **Conclusions:** This real-world analysis revealed no survival advantage with early PC initiation, likely reflecting clinical fragility in these patients. Early referral often signifies advanced disease rather than a direct survival benefit of PC itself. LPC was linked to the longest survival, emphasizing the need for graduated PC from metastatic diagnosis. No PC was associated with higher EOL care intensity, which did not improve survival, highlighting possible unreasonable overtreatment. Research Sponsor: None.

Socioeconomic disparities in palliative care utilization among children with late-stage bone and soft tissue sarcomas: A National Cancer Database analysis. First Author: Paul Phan, Johns Hopkins University School of Medicine, Baltimore, MD

Background: Palliative care seeks to improve the quality of life for many children living with cancer, but it remains underused. Racial and socioeconomic disparities have been identified in the receipt of palliative care among adult patients with advanced soft-tissue sarcomas and metastatic renal cell carcinoma. Our study seeks to determine if similar barriers exist in palliative care receipt among pediatric patients with late-stage bone and soft tissue sarcomas. **Methods:** We used the National Cancer Database (NCDB) to perform a retrospective review of children aged 0-25 with Stages III and IV bone and soft tissue sarcomas from 2004 to 2022. We used a 1:1 propensity score matching algorithm to compare the utilization of palliative treatment by race and ethnicity and to balance potential confounding covariates. Kaplan-Meier estimation was utilized for survival analysis. **Results:** A total of 8,030 patients were included in this analysis. Of these patients, 375 (4.7%) received at least one form of palliative treatment, including surgery (n=31), radiation (n=99), chemotherapy (n=55), pain management (n=98), multiple modalities (n=77), and others (n=15). The median age was 16 years (IQR: 12-20). Osteosarcoma (29.2%) was most common, followed by Ewing's sarcoma (28.1%), non-rhabdomyosarcoma soft tissue sarcoma (21.6%), and rhabdomyosarcoma (21.0%). The 5-year overall survival rate was 14.7% (95% CI 11.2%-19.3%) for patients receiving palliative care versus 44.7% (95% CI 43.6%-45.9%) for those who did not. After propensity score matching, non-Hispanic Black children were found to be less likely to receive palliative care than non-Hispanic White children (3.4% vs. 5.9%, p = 0.047). Hispanic children were also less likely to receive palliative treatment than non-Hispanic White children (2.5% vs. 5.5%, p = 0.007). **Conclusions:** Hispanic and Black children with sarcomas were less likely to receive palliative care compared to White children. Further research is warranted to understand the impact of other factors contributing to palliative care receipt and how they may be addressed to optimize the quality of life in sarcoma treatment in children. Research Sponsor: None.

Post-propensity score matching univariate analysis for palliative care use by race and ethnicity.

Androgen deprivation therapy and quality of life: A concept map analysis. First Author: David Lazris, University of Pittsburgh Medical Center (UPMC), Pittsburgh, PA

Background: Androgen deprivation therapy (ADT) is the backbone of systemic treatments for prostate cancer (PC), but is associated with side effects that decrease quality of life (QOL). There lacks a robust qualitative exploration of the nuanced entirety of physical, mental, and social changes men experience during ADT. While interventions typically focus on metabolic and cardiovascular effects, it is unclear if these are the most impactful contributors to QOL as experienced by men themselves. **Methods:** We conducted concept mapping, a participatory mixed-methods research approach, involving item generation, pile sorting, and rating to identify and categorize side effects of ADT. Thirty men who started ADT for PC in the past 3-12 months and reported undesirable changes from ADT participated. Men on oral androgen axis inhibitors were included, but those receiving other systemic therapies or with comorbidities that could confound results were excluded. Men who had surgery or radiation for PC were enrolled after $\geq$3 months post-treatment. We conducted semi-structured brainstorming interviews to generate lists of undesirable changes participants experienced. Study team members reviewed each list for completeness, then combined all 676 items into 79 unique items. Fifteen participants sorted these items into named groups and rated each item on a 1-5 Likert scale for the following questions (5 representing maximal response): "After starting ADT, how much did this change negatively affect your life?" and "After starting ADT, how much additional support would you have liked to receive for the following change?" GroupWisdom Concept Mapping software generated a cluster map and calculated mean Likert scale ratings for each cluster. **Results:** Based on participant sorting, items were grouped into four main clusters: Physical Manifestations; Sexual Changes; Mental Health Changes & Concerns of Stigma; and Motivational Changes (13 iterations, stress value 0.29). The Table presents sample items and mean Likert scale cluster ratings. **Conclusions:** While men on ADT reported expected physical and sexual changes, qualitative interviews uncovered changes in motivation, mental health, and concerns of stigma. Men reported sexual changes as having the largest negative impact on QOL. The concept mapping can be utilized to provide anticipatory guidance to men starting ADT, as well as guide the development of supportive interventions. Research Sponsor: None.

Cluster	Example Items	Negative Affect on Life Rating (1-5; 5=Most Negative)	Additional Support Wanted Rating (1-5; 5=Most Support Wanted)
Physical Manifestations	- Physical Strength Decreased	2.6	2.1
Sexual Changes	- Sex Drive/Libido Diminished	2.9	2.0
Motivational Changes	- Wanting to Sit and Do Nothing/Watch TV; Being Less Active; Feeling "Lazy"	2.2	1.7
Mental Health Changes & Concerns of Stigma	- Not Wanting to Share Information About Diagnosis/Treatment with Others -More Pessimistic/Less Optimistic	1.8	1.5

Care needs and considerations for implementing a community-based palliative care program for women with breast or cervical cancer in three Nigerian states. First Author: Igoche David Peter, Limi Children's Hospital, Abuja-Fct, Nigeria

Background: Breast and cervical cancer pose a significant public health burden in most sub-Saharan African countries including Nigeria. With ~70% of cases presenting at late stages (III & IV), high mortality is often a characteristic feature. This underscores the critical need for comprehensive palliative care services to improve the quality of life for Nigerian women with breast and cervical cancers. Despite the growing recognition of this need, there is limited evidence for integrating community resources into cancer-directed palliative care services in Nigeria, hence this study explored the needs of Nigerian women with breast or cervical cancer, and their caregivers, and sort to identify resources necessary for developing a robust palliative care initiative across the community and healthcare facility settings. **Methods:** We conducted a qualitative study including 45 purposively sampled adult female caregivers of women with breast or cervix cancers, from 3 states in Nigeria: Abuja-Federal Capital Territory, Nasarawa, and Rivers states respectively. Focus Group Discussions using semi-structured interview guide were carried out and included questions about cancer care needs of both caregivers and the patients, including considerations for implementing a community-based palliative care program. Data were analysed using thematic analysis for deductive identification of key themes, while allowing for new themes to emerge inductively, and then we phenomenologically investigated respondents' palliative care needs perceptions and their meaning. **Results:** Four overarching themes were identified namely, i) needs of women with breast or cervical cancer, ii) needs of caregivers, iii) human resources for community-based palliative care, and iv) feasibility of a community-based palliative care program. Respondents revealed that to attain wholistic wellbeing for women with breast or cervical cancer, their peculiar needs and those of their caregivers which were largely unrecognised deserve attention. Adequate human resources, including trained healthcare workers and support staff, and clearly defined feasibility criteria for palliative care, were identified as crucial for the successful implementation of a community-based palliative care program. **Conclusions:** A community-based palliative care program for Nigerian women with breast or cervical cancer will be acceptable and feasible if it is designed to address the peculiar medical and non-medical needs of both the cancer patients and their caregivers. Research Sponsor: German government.

Granisetron transdermal delivery system for nausea and vomiting prophylaxis in HER2-positive metastatic breast cancer patients receiving pyrotinib and capecitabine: A single-arm phase II study. First Author: Jun Cao, Department of Medical oncology, Fudan University Shanghai Cancer Center, Shanghai, China

Background: The efficacy of granisetron transdermal delivery system (GTDS) in managing nausea and vomiting caused by intravenous chemotherapy is well-established; however, its effectiveness for emesis induced by oral antineoplastic agents remains unclear. This study aimed to evaluate the efficacy and safety of GTDS for the prophylaxis of nausea and vomiting in patients receiving daily oral anticancer agents with moderate emetic risk, specifically pyrotinib combined with capecitabine for HER2-positive metastatic breast cancer (mBC). **Methods:** A single-arm, single-center phase II trial was conducted, enrolling 77 patients with HER2-positive mBC. Patients received 2 consecutive doses of GTDS (with a 7-day interval between the doses) during the first treatment cycle (21 days) of pyrotinib (400 mg daily, days 1–21) and capecitabine (1000 mg/m² twice daily, days 1–14). The dual primary endpoints were the complete response (CR) rate of nausea and vomiting (no emesis and no rescue medication) and the incidence of ≥grade 3 diarrhea. Secondary endpoints included complete control (CC) rate, daily emesis/nausea frequency and adverse events (AEs). **Results:** During the first treatment cycle, 62.3% of patients achieved CR, and the CC rate was 54.5%. Weekly CR rates were 79.2%, 70.1%, and 79.2% in weeks 1, 2, and 3, respectively, while CC rates were 72.7%, 61.0%, and 70.1%, respectively. The mean daily number of emetic episodes ranged from 0.1 to 0.6, peaking in week 2. The mean daily nausea scores ranged from 0.6 to 1.1, with a slight increase starting from day 4. Grade 3 diarrhea occurred in 28.6% of patients, peaking on day 7. AEs were reported in 53.25% of patients, with the most common being gastrointestinal symptoms, fatigue, and rash. No QT prolongation was observed. **Conclusions:** Prolonged administration of GTDS demonstrated efficacy and safety in preventing nausea and vomiting in HER2-positive mBC patients receiving daily oral pyrotinib and capecitabine; however, it did not reduce the incidence of ≥ grade 3 diarrhea. Clinical trial information: NCT04472143. Research Sponsor: None.

Efficacy of Chinese medicine compound Fufang E'jiao Syrup for symptom burden of cancer-related fatigue in patients with advanced cancer: A randomized clinical trial. First Author: Shanshan Gu, Department of Oncology, Xiyuan Hospital of China Academy of Chinese Medical Sciences, Beijing, China

Background: *Cancer-related fatigue (*CRF) is often accompanied by a high symptom burden, significantly impacting the quality of life in patients with advanced cancer. Traditional Chinese medicine compound *Fufang E'jiao Syrup* (FFEJS) has shown promising potential in alleviating fatigue and reducing the overall burden of cancer-related symptoms. This study aims to investigate the efficacy and safety of FFEJS in reducing symptom burden in patients with advanced cancer. **Methods:** This multicenter, double-blinded, placebo-controlled trial was conducted across 29 hospitals in China and included 611 patients with advanced non-small cell lung cancer, colorectal cancer, or gastric cancer experiencing moderate-to-severe fatigue (Visual Analogue Fatigue Scale score ≥ 4). Participants were randomized to receive FFEJS (20 mL, 3 times daily) or placebo for six weeks. The primary outcome was the change in symptom burden, assessed via the Edmonton Symptom Assessment Scale (ESAS; score range 0-110, higher scores indicate greater burden). Secondary outcomes included changes in 11 individual symptoms (e.g., tiredness, depression, pain) and the incidence of adverse events. Linear mixed models were used for statistical analysis. **Results:** Among 611 patients randomized (303 received FFEJS and 308 received placebo; 210 [34.4%] had non-small cell lung cancer, 201 [32.9%] had colorectal cancer, and 200 [32.7%] had gastric cancer; mean [SD] age 62.8 [9.3] years; 413 [68.6%] male; mean [SD] baseline mean total symptom burden 38.96 [15.68] points, 503 (82.3%) completed the primary end point analysis. At week 6, FFEJS demonstrated a significantly greater reduction in total symptom burden compared to placebo (6.67 vs 3.16; adjusted mean difference: 3.51[95% CI 1.21–5.8]; P = .004). Patients in the FFEJS arm showed significant improvements in tiredness (1.68 vs 0.79; adjusted mean difference, 0.89 [95% CI, 0.62-1.18]; $P < .001$), drowsiness (1.13 vs 0.50; adjusted mean difference, 0.63 [95% CI, 0.32-0.95]; $P < .001$), pain (0.34 vs 0.01; adjusted mean difference, 0.33 [95% CI, 0.08-0.62]; P = .049), depression (0.41 vs -0.15; adjusted mean difference, 0.56 [95% CI, 0.28-0.86]; P = .003) compared with the placebo arm. Subgroup analysis revealed greater symptom reduction in geriatric patients (≥ 60 years; $P < .001$) and in non-small cell lung (P = .044) and colorectal cancer (P = .047), compared to gastric cancer (P = .123). **Conclusions:** FFEJS significantly reduced total symptom burden and improved fatigue-related symptoms in patients with advanced cancer. Subgroup analysis highlighted enhanced efficacy in geriatric populations and certain cancer types. These results highlight the potential of FFEJS as a valuable integrative therapy for improving symptom management and quality of life in advanced cancer care. Clinical trial information: NCT04147312. Single low-dose 5-mg versus 8-mg dexamethasone with NEPA for the 168-h prevention of highly or moderately emetogenic (high-risk patients) chemotherapy-induced nausea/vomiting: An open-label, randomised, controlled, phase 3 trial. First Author: Xiao Li Xiao, Department of Oncology, Zhongshan Hospital of Xiamen University, School of Medicine, Xiamen, Fujian, China

Background: Tailoring Dexamethasone (DEX) dosing to reduce corticosteroid exposure is a challenging issue in the chemotherapy induced nausea /vomiting(CINV) management. This study aims to identify the efficacy of single low-dose 5mg versus 8mg dex with nepa for the 168h prevention of highly or moderately emetogenic (high-risk patients) CINV. **Methods:** This open-label, randomized trial compared the efficacy and safety of 5 mg versus 8 mg DEX regimens, both with NEPA, in patients receiving MEC or HEC chemotherapy. Patients were 1:1 randomized to 5 mg or 8 mg groups. The primary endpoint was complete response (no emesis, no rescue medication) from 0 to 168 hours. Secondary endpoints included total control, complete control, and daily CINV incidence. This study was registered with ChiCTR2400089311. **Results:** From June 20, 2024 to June 20, 2025, a total of 164 eligible individuals were assigned at random to the 5 mg or 8 mg DEX treatment arms.Primary efficacy endpoints:The overall CR rates for the prevention of CINV, observed throughout the study period, were 91.7% in the 5 mg group and 92.5% in the 8 mg group (P=0.400) . In the acute phase, the CR rates were 97.9% for the 5 mg group and 97.5% for the 8 mg group (P=1.000). During the delayed phase, the CR rates were 91.7% for the 5 mg group and 92.5% for the 8 mg group (P=1.000). In the long-delayed phase, the CR rates were 93.8% for the 5 mg group and 97.5% for the 8 mg group (P=0.744). Secondary efficacy endpoints: During the whole observation period, the total control rates were 77.1% for the 5 mg group and 62.5% for the 8 mg group (P=0.208); the complete control rates were 85.4% for the 5 mg group and 87.5% for the 8 mg group(P=1.000). Secondary safety endpoints: The safety profiles of both dosages were similar and majority of treatment-related adverse events (TRAEs) were mild to moderate (grades 1 or 2), with no significant differences in the occurrence or severity of TRAEs (hyperglycemia, indigestion/heartburn or reflux and constipation, prevalence of QTcB interval prolongation or increase ect) would warrant particular concern. **Conclusions:** This study identify single low-dose 5mg DEX is equally effective as 8mg DEX with NEPA for the 168h Prevention of HEC or MEC (high-risk patients) CINV. Moreover, the 5mg DEX group has better therapeutic safety. It offers evidence-based recommendations for using a lower dose of DEX in combination with NEPA for the prevention and treatment of CINV. These promising results pave the way for reduction of DEX in antiemetic care. Clinical trial information: ChiCTR2400089311. Research Sponsor: None.

A novel staging system for cancer cachexia. First Author: Syed Hasan Raza Jafri, The University of Texas Health Science Center at Houston (UTHealth Houston) McGovern Medical School, Houston, TX

Background: Cancer cachexia affects a large percentage of advanced cancer patients. It's defined by a consensus definition of unintentional >5% body weight loss over six months. There is no standard way of assessing severity of cancer cachexia. We developed a novel cancer cachexia staging system based on routine clinical parameters. **Methods:** In a prospective case control study of newly diagnosed cancer patients to identify biomarkers of cancer cachexia, cases were patients with stage III/IV cancer and >5% body weight loss and serum albumin of <3.5g/dl. Controls were patients with stage I-III without weight loss and serum albumin of ≥3.5g/dl. Patients were prospectively followed up between April 2020 and August 2024 with blood biomarkers, anthropometric measurements and radiological parameters. Utilizing data from cases only a novel cancer cachexia staging system was developed called (University of Texas) UT Cancer Cachexia Staging System using 4 clinical parameters namely body mass index (BMI), serum albumin (Alb), neutrophil to lymphocyte ration (NLR) and resting heart rate (RHR). Using quartiles as cut off for each of these four variables, patients were divided into three groups and given a score of 0.5, 1.5 or 2.5 (Table). The cumulative score of each patient was calculated based on individual values of these 4 variables at the time of diagnosis and then categorized into stage I (≤5), Stage II (5-7) or Stage III (>7) cancer cachexia. Kaplan-Meier survival curves were generated for patients in each stage. The univariable Cox regression model was used to compare hazard ratios across the 3 stages. The multivariable Cox regression model was employed to compare hazard ratios between the stages, adjusting for other key demographic and clinical covariates. **Results:** A total of 109 patients were enrolled in the cachexia group (Male=69, Females=40, Median age = 69 years). The cancer types included Lung cancer (n=50), GI cancers (n=41) and other cancers (n= 18). There were 49 patients (45%) patients with stage I cachexia, 40 (36%) with stage II and 20 (18%) with stage III cachexia. Median overall survival (OS) for patients with stage I cancer cachexia was 11.4 months, for stage II 6.5 months and for stage III 3.5 months. In univariate cox-regression model the difference in hazard ratio between stage I and stage II patients was statistically significant (p=0.004) as was between stage I and stage III (P =0.007). In multi-variable Cox-regression model controlling for age, gender and cancer type, patients with stage II and III cancer cachexia had significantly worse outcome as compared to patients with stage I cancer cachexia. **Conclusions:** UT cancer cachexia staging system represents a novel staging system which should be validated on a larger data set. Once validated this can help guide clinical management as well as clinical research in patients with cancer cachexia. Research Sponsor: U.S. National Institutes of Health; R01 AR063786-06A1; National Center for Advancing Translational Sciences (NCATS); 1UM1TR004906-01.

Development of cancer cachexia staging system based on BMI, albumin, NLR and RHR by using quartiles as cutoff points in the case group (n=109).

	Score=0.5		Score=1.5		Score=2.5	
Variable	Cutoff	Number of patients	Cutoff	Number of patients	Cutoff	Number of patients
BMI	≥29	26	21-29	56	<21	26
Albumin	≥3.2	30	2.3-3.2	60	<2.3	18
NLR	<3	30	3-8	50	>8	28
RHR*	<73	25	73-95	57	>95	26

UT cancer cachexia stage groups defined by using cutoff points for total cancer cachexia score.

Machine learning models to predict skeletal-related events in bone metastasis from advanced cancer. First Author: Hirotaka Miyashita, School of Integrative and Global Majors, University of Tsukuba, Tsukuba, Japan

Background: Skeletal-related events (SREs) are detrimental clinical events in bone metastasis from advanced cancer, defined by pathologic fracture, spinal cord compression, and inevitable surgical or radiational intervention to the bone. Given their negative impact on quality of life and prognosis and interpatient heterogeneity in the SRE risk, accurate identification of patients with high SRE risk is critical. **Methods:** The patient-level data from three randomized clinical trials that administered zoledronic acid (ZA) to patients with bone-metastatic breast cancer, castration-resistant prostate cancer (CRPC), and other types of cancer were analyzed. (N = 460, 452, and 315, respectively) Machine learning (ML) models to predict SREs within 18 months (breast cancer), 12 months (CRPC), and 9 months (other cancers) were developed based on more than 40 baseline clinical and laboratory data. Seven ML algorithms and five feature selection methods were utilized to develop multiple models. The ML model with the best performance was identified based on the F1 score and the area under the receiver operating characteristic curve (AUC-ROC) for each cancer type and interrogated for important features with Shapley additive explanations. Lastly, the ML models' ability to stratify patients by the cumulative SRE risk was evaluated by calculating hazard ratio (HR) with Cox-proportional hazards models. **Results:** Among the multiple ML models developed with different algorithms and feature selection methods, the model developed utilizing the random forests algorithm and the Boruta method for selecting features demonstrated the best performance in all types of cancer (F1 0.70, 0.67, and 0.67, and AUC-ROC 0.72, 0.68, and 0.73 for breast cancer, CRPC, and other cancers, respectively). In the ML model for breast cancer, performance status (PS), history of SRE, serum alkaline phosphatase (ALP), history of anti-neoplastic surgery, radiation therapy, and pathologic fracture were included as important features. Serum ALP, albumin, sodium, Gleason scores, and geographic regions were shown to be relevant in the CRPC model. For other cancers, serum ALP, albumin, total protein, phosphorus, red blood cell count, white blood cell count, visceral metastases, and history of arthritis were incorporated in the ML model. The ML model prediction successfully stratified the patients for cumulative SRE risk in all three cohorts. (HR with 95% confidence interval: 2.43 [1.86 – 3.18], 1.92 [1.51 – 2.45], and 3.06 [2.29 – 4.09] for breast cancer, CRPC, and other types of cancer, respectively). **Conclusions:** ML models incorporating baseline clinical and laboratory data can identify patients with bone metastasis on ZA harboring a high SRE risk. Virtual reality for pain and anxiety management during bone marrow biopsy: A systematic review. First Author: Ronak Patel, SUNY Downstate at Brooklyn, Brooklyn, NY

Background: Bone marrow biopsy (BMB) procedures often cause significant pain and anxiety. Virtual reality (VR) has emerged as a promising non-pharmacological intervention, but its effectiveness needs systematic evaluation. **Methods:** A systematic review following PRISMA guidelines examined studies from 2014-2024 that evaluated VR interventions during BMB procedures through literature searches in PubMed, Scopus, and EMBASE. Studies were included if they evaluated VR as a non-pharmacological intervention and reported pain or anxiety outcomes. **Results:** Five studies (n=481) met inclusion criteria, including three randomized controlled trials and two prospective studies. Patient ages ranged from 6-87 years. VR interventions showed high retention rates (66.7-93.3%) with low discontinuation (5%). Pain and anxiety reduction was significant in two studies ($p<0.05$ and $p<0.001$ respectively), while three showed no significant difference versus standard care. Patient satisfaction exceeded 90%, with minimal adverse events, mainly discomfort leading to discontinuation in 5% of participants. **Conclusions:** VR represents a safe, well-tolerated intervention during BMB procedures with high patient satisfaction. While pain and anxiety reduction results were mixed, the consistent safety profile and positive patient experience suggest VR may be a valuable adjunct to standard care, particularly for anxiety management. Future research should focus on standardizing protocols and defining patient selection criteria to optimize outcomes. Research Sponsor: None.

Study characteristics and clinical outcomes of virtual reality use during bone marrow procedures.

Study	Sample Size	Patient Population	VR Type	Control Group	Pain Outcomes	Significant Pain Reduction?	Anxiety Outcomes	Significant Anxiety Reduction?	Patient Satisfaction	Adverse Events
Glennon 2018	97	Adults	ezVision X4 VR goggles with nature scenes + lidocaine	Standard TV viewing + lidocaine	VR: 3.9 vs Control: 4.0 (NPRS)	No ($p > 0.05$)	State anxiety decrease: VR: 2.3 pts vs Control: 1.3 pts (5 item Likerty-type scale)	No ($p = 0.42$)	98.3% satisfied	None reported
Le Du 2023	126	Adults	Meta Quest VR headset	None specified	VR: 3.0 vs Control: 3.5 (VAS)	No ($p = 0.26$)	No difference on STAI scores	No ($p = 0.83$)	Not reported	Not reported
Korkmaz 2023	126	Adults	Bliss VR with 4 environments	MEOPA (nitrous oxide/ oxygen)	VR: 3.8 vs Control: 6.28 (VAS)	Yes ($p < 0.001$)	VR: 32.06 ± 8.69 vs Control: 40.88 ± 11.36 (STAI)	Yes ($p = 0.022$)	95% satisfied	5% discontinued
Reitze 2024	75	Adults	Support V5 VR headset	Standard care (No distraction)	Mean difference -1.0 with VR (VNRS)	Yes ($p < 0.05$)	VR: 28.6 vs Control: 33.5 (BAADS)	Yes ($p < 0.001$)	> 90% satisfied	5% mild effects
Soret 2022	57	Children (6-18y)	Not specified	Standard care (No distraction)	VR: 3.8 (IQR 2.0-6.3) vs Control: 3.0 (IQR 1.9-3.0) (FPS-r)	No ($p = 0.09$)	No difference between groups (mYPAS-SF)	No ($p = 0.71$, 0.42)	71% more relaxed	5% discontinued

Multidisciplinary and multi-institutional cancer symptom management strategies in the Veterans Affairs: A mixed methods study. First Author: Johanna Balas, University of California San Francisco, San Francisco, CA

Background: Effective symptom management in patients undergoing cancer treatment improves quality of life and overall survival. Yet, variability persists in how symptoms are assessed and managed across oncology settings. This mixed-methods study, conducted across 14 Veterans Affairs (VA) facilities in two regional Veterans Integrated Service Networks (VISN) 21 and 22, aimed to: 1) identify current symptom assessment strategies in use and 2) explore opportunities for standardizing, implementing, and scaling strategies to optimize care for Veterans undergoing cancer treatment. **Methods:** We conducted a comprehensive survey and semi-structured interviews to evaluate current symptom assessment and management practices, perspectives on standardized proactive strategies, and barriers and facilitators to implementation. The 10-question survey was distributed to 65 clinicians, nurses, social workers, navigators, pharmacists, behavioral medicine specialists, and ancillary care providers across 14 facilities in VISN 21 and 22, using an online staff directory. In addition, 25 facility-level oncology leaders and 10 Veterans receiving cancer care at these facilities were invited to participate in 30-minute semi-structured interviews. The interviews focused on attitudes, knowledge, and preferences regarding proactive symptom assessment, as well as interest in piloting potential interventions. Survey data were analyzed using descriptive statistics, and interview data were analyzed through thematic analysis. **Results:** A total of 40 participants (61.5% response rate) completed the survey, including 24 physicians (60%), 12 nurses/ nurse practitioners (30%), 2 social workers (5%), and 2 pharmacists (5%). Of the 40 respondents, 36 (90%) reported assessing symptoms during clinical visits, with 12 (30%) utilizing only standardized psychological distress screening tools, such as the National Comprehensive Cancer Network Distress Thermometer. Infrastructure and resources varied widely across facilities with some facilities noting no palliative care providers, nurse practitioners, nurse navigators, or oncology nurses. Only 2 facilities integrated volunteers or lay peer support into cancer care. Among interviewees, 25 oncology leaders and 10 Veterans with cancer participated (100% response rate). Two key themes emerged: 1) urgent need for standardized, proactive symptom assessment and management; 2) importance of adaptable solutions, such as peer-led initiatives, tailored to facility and patient preferences rather than a one-size-fits-all approach. **Conclusions:** Proactive symptom assessment is underutilized across VISN 21 and 22 facilities. Standardized, adaptable strategies that combine high-touch and low-tech approaches, such as peer-led initiatives, are preferred and may provide a scalable solution to enhance cancer care for Veterans. Research Sponsor: None.

Comparison of outcomes for patients diagnosed with small cell lung cancer between a university and safety net hospital. First Author: Ahmad Karkash, Indiana University School of Medicine, Indianapolis, IN

Background: With immunotherapy, the five year overall survival (OS) for small cell lung cancer (SCLC) is 12%. However, real world factors such as social determinants of health (SDH) and enrollment to clinical trials may vary. Here, we compare treatment patterns and outcomes for SCLC between two affiliated hospital settings. **Methods:** A retrospective analysis was conducted on patients with SCLC seen at university hospital (UH, Indiana University Melvin and Bren Simon Comprehensive Cancer Center) or its affiliate safety net hospital (SNH, Sidney and Lois Eskenazi Hospital) from 1/1/2018 to 8/31/2024. SDH was defined as housing, food, financial, or transportation instability. Chi-square, Fisher's exact test, t-test, Wilcoxon two-sample test, and Kaplan-Meier were applied accordingly. P value $<$ .05 was considered significant. **Results:** A total of 189 patients were identified; 50 (26%) at SNH and 139 (74%) at UH. Stage, age, sex, and tobacco use were similar. Variations in race and SDH were noted (Table). Receipt of chemoimmunotherapy was comparable. Chemotherapy-free interval (CTFI) was shorter at UH (3.3 months; 95% CI, 2.7–4.3) vs at SNH (7.8 months; 95% CI, 3.7–11.5; P = .015). Patients at UH were enrolled in more SCLC-related trials, received more second line therapies, GCSF or CDK4/6 inhibitor (Table), and had increased adverse events (UH, 64% vs SNH, 40%, P = .003). At data cut-off, no difference was found between UH and SNH for use of lurbinectedin (15.8% vs 8%, P = .16) or tarlatamab (3.6% vs 2%, P = 1). OS was analogous between UH (16 months; 95% CI, 11.3–18.7) and SNH (12.8 months; 95% CI, 7.6–NE; P = .21). **Conclusions:** Patient at UH were found to have shorter CTFI with first line chemo-immunotherapy. This difference may reflect the referral patterns for patients with complex SCLC presentations to an academic cancer center. More SDH was identified at UH. Patients at UH were more likely to enroll in SCLC trials and receive supportive care medications. Patients at SNH received more PC referrals. Further studies are needed to evaluate the effect of socioeconomic factors on SCLC outcomes. Research Sponsor: None.

Outcomes stratified by hospital setting.

Disparities in receipt of palliative interventions across disaggregated Hispanic subgroups with late-stage colon cancer in the United States. First Author: Coby Garcia, Harvard University, Cambridge, MA

Background: Palliative interventions, defined as cancer-directed therapies with palliative intent, improve the quality of life and alleviate suffering for patients with advanced cancer. Limited research examines disparities in their receipt across disaggregated Hispanic subgroups. We analyzed palliative intervention receipt among Hispanic patients with stage IV colon cancer. **Methods:** Using the National Cancer Database, we retrospectively analyzed adults diagnosed with stage IV colon cancer (2004–2021) with known palliative intervention receipt status (defined binarily). We performed logistic regressions to characterize palliative intervention receipt rates across a) broad racial groups and b) country of origin, relative to Non-Hispanic White patients (alpha$<$0.05). Regressions included a race*year interaction term to examine changes in palliative intervention receipt over time (alpha$<$0.1). **Results:** We analyzed 1,021,293 patients;3.24% (n=33,132) received palliative interventions. Hispanic Black patients were 0.55x as likely (P=0.030) to receive palliative interventions as non-Hispanic White patients. The year*race interaction term was significant for Hispanic-Black patients, suggesting that invention rate improvements were distributed unequally over time. Specifically, the rate of intervention receipt among Hispanic Black patients decreased from 5.4% in the 2004–2012 cohort to 4.6% in the 2013–2021 cohort (95% CI: 0.32–0.94, P interaction = 0.030), compared to greater decreases observed in the reference group. When disaggregated, Mexican patients were 31% less likely (P=0.006), Cuban patients 35% less likely (P=0.043), NOS patients were 33% less likely (P$<$0.001), and Dominican Republic patients nearly twice as likely (P=0.009) to receive interventions compared to non-Spanish, non-Hispanic patients. **Conclusions:** Hispanic Black, Mexican, Cuban, and NOS patients experienced lower receipt of palliative interventions, revealing disparities in access to equitable cancer-directed end-of-life care. Efforts should be made to expand palliative intervention access for diverse racial/ethnic groups. Research Sponsor: None.

Receipt of palliative care by country of origin.

Racial/Ethnic Group	% Patients receiving palliative care (All Years)	% Patients receiving palliative care (2004-12)	% Patients receiving palliative care (2013-21)
Non-Spanish, Non-Hispanic White	3.35	2.31	4.30
Mexican	2.74	1.86	3.33
Puerto Rican	3.66	2.49	4.53
Cuban	2.40	1.60	3.48
South/Central American (ex. Brazil)	3.26	1.74	4.28
Other Specified Spanish/Hispanic	3.26	2.55	4.09

A patient advocacy-focused rehabilitation pilot program: Real-life experience in enhancing quality of life for metastatic lung cancer patients. First Author: Shani Shilo, The Israeli Lung Cancer Organization, Rehovot, Israel

Background: Living with lung cancer (LC) is a prolonged and challenging journey, where the disease's consequences and treatment-related adverse events significantly affect the quality of life (QOL) of patients. Recognizing these challenges, healthcare professionals (HCPs) in collaboration with a patient advocacy organization designed and implemented a personalized rehabilitation pilot program tailored specifically for patients with unresectable metastatic LC. **Methods:** 50 Stage IV unresectable metastatic lung cancer patients were recruited via a patient advocacy group on Facebook. Participants underwent a personalized rehabilitation program with four one-on-one physiotherapy sessions, during which a tailored regimen was developed. Each participant received a customized booklet and equipment to support their rehabilitation. The program incorporated two key components: aerobic exercises and strength-training activities. Additionally, patients and their caregivers participated in three online mental health support sessions, providing holistic care. EORTC QLQ-C30 questionnaire was used at the beginning, end of the program and two months after. The physiotherapists measured the patients' 5 repetitions sit to stand time and 10-meter walk time at the beginning and the end of the program. Significance of results was calculated with repeated measure\within subjects T test with one way hypothesis and a confident interval of 0.95%. **Results:** Significant improvement was observed from the beginning of the program to the end in the Sit-to-stand test, from 19.3s to 15.1s, p = 0.0001 and the 10-meter-walk test, from 12.5 to 10.5 p = 0.017. In addition, a significant improvement from beginning to end of the program was observed based on the EORTC QLQ-30 in the global health status, physical functioning, role functioning as well as in the symptoms of fatigue, nausea, vomiting and appetite loss. In social functioning and constipation, significant improvement was maintained even two months after completion of the program. No significant change was observed in emotional and cognitive functioning, pain symptoms, dyspnea, insomnia, diarrhea and financial difficulties. **Conclusions:** The real-life survivorship journey of metastatic lung cancer patients involves numerous challenges including sequela of side effects and symptoms that impact QOL of the patient that impacts the caregiver as well. Our duty to support "beyond the pill" led us to this real-life pilot program that shows the feasibility and efficacy of home-based rehabilitation. Even among patients who experienced disease progression during the program, notable benefits were observed. These findings underscore the importance of further research and the need for sustained support after program completion to ensure long-term maintenance and improvements in patients' well-being. Muscle mass evaluation among ambulatory cancer patients in China: Comparison of different methods and association with survival. First Author: Yanfei Wang, Key Laboratory of Carcinogenesis and Translational Research (Ministry of Education/Beijing), Peking University Cancer Hospital & Institute, Beijing, China

Background: Cancer patients are at high risk of malnutrition and cachexia. Muscle mass reduction (MMR) is one of the three phenotypic criteria to diagnose malnutrition in the Global Leadership Initiative on Malnutrition (GLIM) framework, but there are no consensus about what method should be used to evaluate MMR in clinical practice. Among multiple methods to evaluate MMR, muscle mass index (MMI) in computed tomography (CT) image was considered to be accurate but not convenient in clinical practice. This study aimed to compare the correlations between different methods of measuring MMR and to assess their relevance to survival. **Methods:** A single-center cohort study was conducted among ambulatory cancer patients who were receiving intravenous anti-cancer therapy. All participants underwent CT, calf circumference (CC) measurement, bioelectrical impedance analysis (BIA) and hand grip strength measurement. MRR was identified by MMI in CT image at the level of lumbar vertebra 3 (L3), CC, fat-free mass index (FFMI) and appendicular skeletal muscle index (ASMI) in BIA respectively. Low MMI was defined as MMI $<$ 43 in men with body mass index (BMI) $<$ 25kg/^{2}, $<$ 53 in men with BMI$\geq$25kg/^{2} or $<$ 43 in women. Low CC was defined as CC$<$ 34cm in men or $<$ 33cm in women. Low FFMI was defined as FFMI $<$ 17kg/m^2 in men or $<$ 15kg/m^2 in women. Low ASMI was set as ASMI $<$ 7.0kg/m^2 in men or $<$ 5.7kg/m^2 in women. Low muscle strength was defined by hand grip strength $<$ 28kg in men or $<$ 18kg in women. The correlation between low MMI and MMR diagnosed by other methods were calculated. The correlation between MMR, low muscle strength and one-year mortality was also evaluated. **Results:** A total of 312 consecutive patients were included. Of the 312 patients 62.8% (196/312) were male and 37.2% (116/312) were female. The median age of the patients was 59.0 years (range, 21-80y; interquartile range 52.0-65.0y). FFMI and SMI diagnosed by BIA correlated with MMI diagnosed by CT (Pearson Correlation 0.798 and 0.738 respectively). Except for low hand grip strength (p = 0.005, HR 2.482, 95%CI 1.324-4.655), no single indicators for MMR indicated higher one-year mortality. However, in combination of MMI, CC, FFMI and ASMI, MMR indicated higher one-year mortality (p = 0.004, HR 2.549, 95%CI 1.342-4.843). **Conclusions:** FFMI and SMI diagnosed by BIA correlated with MMI diagnosed by CT, indicating that BIA can be a good choice in evaluating MMR. Low hand grip strength and MMR diagnosed using multiple methods indicated higher one-year mortality, underscoring the importance of measuring muscle strength as well as evaluating muscle mass. The impact of cannabis use on patient outcomes post immune checkpoint inhibitor (ICI) therapy in a longitudinal observational trial: The DiRECT Cohort. First Author: Song Yao, Roswell Park Comprehensive Cancer Center, Buffalo, NY

Background: Prior small retrospective studies suggest that cannabis might compromise the efficacy of ICIs for cancer therapy due to its immunosuppressive properties. Evidence from large prospective studies is lacking. **Methods:** We addressed this research gap in the DiRECT Cohort (URCC21038, NCT05364086), an ongoing, observational trial enrolling self-identified Black and White cancer patients (melanoma excluded) who are about to start ICI-containing therapy through the URCC NCORP Research Base nationwide clinical trial network. Longitudinal data on cannabis use are collected through self-administered surveys at baseline (A1), 6 months (A3), and annually (A4+), along with clinical data and patient-reported outcomes on physical and psychological symptoms. This interim analysis on cannabis use includes 1,666 patients enrolled between 04/01/2022 and 08/31/2024, with outcome data updated to 11/30/2024. **Results:** The mean age was 63.7 ($\pm$12.4) years; 408 (24.5%) patients were Black; 905 (54.3%) were women; the most common diagnosis was lung cancer (621 or 37.3%); and a majority had stage IV disease (906 or 54.4%). At A1, 284 (17.1%) patients reported cannabis use in any form, mostly orally (58.1%) or via inhalation (32.3%). Use rates remained stable at A3 (15.6%) and A4 (15.4%) (P = 0.47); yet patients reported fewer days of use in a month (P $<$ 0.0001) but more times in a day (P = 0.07) than at A1. Cannabis users were younger and more likely to be Black, from states with permissive cannabis laws, and current or former cigarette smokers (P's $<$ 0.05), with no differences observed by gender, cancer type, or stage. After a median follow-up of 10.4 months (range: 0.03-31.0), 381 patients died, and 174 patients had progressed disease or entered hospice care. Median overall survival (OS) and event-free survival (EFS) were slightly higher in cannabis users than non-users at A1 (6.1 vs. 5.3 months, P = 0.07 and 6.0 vs. 5.4 months, P = 0.15, respectively). Cox hazards models adjusted for age, gender, cancer type, and stage revealed no significant association between cannabis use and OS (adjusted hazards ratio [aHR] = 0.82, 95% CI 0.61-1.10) or EFS (aHR = 0.92, 95% CI 0.72-1.17). Subgroup univariate analysis showed cannabis use was associated with longer OS and EFS within men (n = 743) and former smokers (n = 765) (P's $<$ 0.05), which became non-significant after adjusting for covariates in Cox models, except for OS within former smokers (aHR = 0.52, 95% CI 0.33-0.83). A significant interaction was noted between cannabis use and smoking status (P = 0.02). **Conclusions:** In this nationwide, diverse community-based oncology cohort, 17% of patients reported cannabis use concurrent with ICI therapy. Unlike previous retrospective studies, our prospective analysis finds no detrimental effect of cannabis on OS or EFS. Further analyses are ongoing to elucidate its impact on symptom management. Clinical trial information: NCT05364086. Research Sponsor: National Cancer Institute; UG1CA189961.

Outpatient palliative care consultation and end-of-life outcomes among a retrospective cohort of patients treated with immunotherapy for non-small cell lung cancer. First Author: Chance Bloomer, Department of Hematology & Oncology, Atrium Health Wake Forest Baptist Medical Center, Winston-Salem, NC

Background: Immune checkpoint inhibitors (ICIs) have been shown to be effective against a wide range of cancers and are available to most patients due to their favorable side effect profile. Studies have shown that palliative care consultation prolongs overall survival (OS) in patients with advanced cancer, but most of these studies assessed cytotoxic chemotherapy and not ICIs. Other studies have shown that outpatient palliative care consultation (OPCC) has a greater effect on a variety of end-of-life outcomes than in the inpatient setting. Our study aims to analyze the association between OPCC and survival in patients with lung cancer treated with an ICI. **Methods:** We designed a retrospective registry of all patients at a comprehensive cancer center and its outreach clinics who received one or more doses of an ICI. The investigators created a secure, cloud-based registry (REDCap), validated it with data quality rules, resolved all discrepancies, and obtained data on palliative care encounters; clinical research specialists at Vasta Global (New York, NY) captured most of the data. Comparisons were made using chi-square or Fisher's exact for categorical variables. Cox proportional hazards model was built controlling for confounders. Survival time for patients with palliative visits was only considered after initial OPCC. Statistical significance was defined as $p < 0.05$. The study had institutional IRB approval. **Results:** Our cohort consisted of 1,114 patients with non-small cell lung cancer, 55% of whom were metastatic at diagnosis. 6% (n = 70) of the patients had an OPCC at some point after their diagnosis. When controlling for stage at diagnosis and age, OPCC was associated with an adjusted hazard ratio of 0.57 (95% CI 0.34-0.98). None of the patients with OPCC received ICI within 14 days of death compared to 6.5% of those without OPCC (p = 0.018). Similarly, only 2.9% of those with OPCC received ICI within 30 days of death, compared to 16.4% of those without OPCC (p = 0.003). **Conclusions:** In patients with lung cancer treated with ICI, OPCC was associated with improved OS regardless of age or stage at diagnosis. Our analysis also showed that patients who received OPCC were less likely to receive ICI near the end of life. It is possible that OPCC may prolong survival by decreasing the ineffective use of aggressive care at the end of life. Further research is needed to clarify the relationship between OPCC and cancer outcomes. Research Sponsor: None.

Demographic and clinical factors associated with sleep disturbance in breast cancer survivors. First Author: Paulina S. Marell, Department of Medicine, Mayo Clinic Rochester, Rochester, MN

Background: Fatigue and sleep disturbance are prevalent during and after cancer treatment; sleep-related symptoms affect 30-50% of patients with cancer, and sleep-wake disruptions persist beyond the immediate post-surgical period in breast cancer (BC) survivors. Identifying demographic- and treatment-related factors associated with sleep-related symptoms during survivorship is critical to inform interventions for those at highest risk of sleep disturbance. **Methods:** Patients who were seen at least once at Mayo Clinic Rochester following an initial diagnosis of BC at age 18 or older and provided informed consent were prospectively enrolled in the Mayo Clinic Breast Disease Registry. Surveys mailed to this cohort included two 11-point numeric rating scale questions regarding difficulty falling asleep and staying asleep in the past week, with values for each ranging from 0 (no problem) to 10 (as severe as you can imagine). Participants who provided sleep-related information on the Year 1 survey (answered approximately one year after cancer diagnosis) were included. Participants were excluded if they had clinical or pathologic metastatic disease and/or recurrence prior to the Year 1 survey. Associations of sleep-related symptoms with demographic and clinical characteristics were assessed using multivariate linear regression models, fitting the sleep difficulty rating scale as the outcome and clinical and demographic factors as exposures. **Results:** In total, 3,354 participants met inclusion criteria. The average age at BC diagnosis was 59, and most participants were female (99.3%), White (95.4%), non-Hispanic (96.2%), married (78.1%), had at least some college education (80.4%), did not report financial insecurity (76.2%), did not consume alcohol (60.6%) or smoke tobacco (93.2%), and reported at least some weekly exercise (76,6%). Sixty-two percent of participants had clinical stage 0 or I disease; 50.3% underwent lumpectomy (not mastectomy), 59.2% received radiotherapy, 34.1% received chemotherapy, and 67.2% received endocrine therapy. Overall, sleep-related symptoms were relatively low (mean rating for falling asleep = 2.1, mean rating for staying asleep = 3.1). In multivariate analyses, more difficulty falling asleep was associated with higher clinical stage ($p < 0.001$), more cigarettes smoked per day (p = 0.012), less moderate and/or strenuous exercise (p = 0.001), and more financial hardship ($p < 0.001$). More difficulty staying asleep was associated with higher clinical stage (0.003), older age ($p < 0.001$), more education (p = 0.011), and more financial hardship ($p < 0.001$). **Conclusions:** In our cohort of BC survivors, factors associated with both increased difficulty with falling and staying asleep at one year after diagnosis are higher clinical stage and more financial hardship. Future research should explore the course of these symptoms over time and across varied treatment trajectories. Research Sponsor: This research was supported by the Mayo Clinic Breast Registry. Trends in inpatient palliative care utilization among adolescents and young adults with metastatic cancer. First Author: Chiamaka Elsie Nwachukwu, Tulane University, New Orleans, LA

Background: Adolescents and young adults (AYA) with advanced cancer, including metastatic cancer, have a unique set of medical, social and psychological needs and often experience several disparities in cancer care when compared with children and older adults. Despite recommendations for early integration of palliative care for patients with serious illnesses, age-appropriate interventions and teams specifically designed for this age group are limited. Objective: To determine the trends in inpatient palliative care utilization as well as associated factors and clinical outcomes among AYA with metastatic cancers in the United States between 2008-2021. **Methods:** A retrospective longitudinal study using the National Inpatient Sample database (2008-2021) was conducted. We examined trends in the prevalence of palliative care utilization in the cohort, as well as sociodemographic and hospital-level factors associated with palliative care utilization. Using Joinpoint regression and multivariable logistic regression, we examined trends and factors associated with palliative care utilization, as well as specific clinical outcomes including inpatient mortality, length of stay, and total hospital costs. **Results:** In this period, 604,856 hospitalizations were recorded for AYA with metastatic cancer. Overall, palliative care utilization was recorded in 10.6% of these encounters and increased over time from 3,036 to 16,568 per 100,000 admissions (p-trend <0.001). The adjusted prevalence rate of palliative care utilization increased by an annual percentage change (APC) of 15.9% from 2010 to 2015. However, from 2015 to 2021, no significant changes were observed. Females with metastatic cancer had 18% higher odds (Adjusted odds ratio (AOR):1.18; 95% CI: 1.12-1.24) of receiving palliative care compared to male patients after we adjustments had been made for potential confounders. Non-elective admissions were associated with four times higher odds (AOR: 3.99, 95% CI: 3.68-4.32) of receiving palliative care compared to elective admissions. Palliative care utilisation was associated with higher odds of longer hospital stay (9.3 vs 6 days, β: 3.29, 95% CI: 3.07-3.50) and increased hospital expenditure ($107,758 vs $78,255, β: -29,747, 95% CI: 26,190 - 33,304). A significantly increased odds of palliative care utilization was observed in those who died during the hospital admission (AOR: 16.16; 95% CI: 14.8-17.6). **Conclusions:** Palliative care utilization has been increasing over the earlier part of the decade but has stalled since 2015 among AYA with metastatic cancer. In the AYA group with metastatic cancer, palliative care appears to be utilized majorly in the sickest patients closer to the end of life. This represents an area of future research and interventions on earlier integration of palliative care and its impact on quality of life and hospital outcomes in this patient population. Effectiveness and safety of multimodal analgesic management based on the ERAS concept in the perioperative period of TACE for patients with Intermediate and advanced hepatocellular carcinoma. First Author: Yanqin Wu, The First Affiliated Hospital of Sun Yat-sen University, Guangzhou, China

Background: To evaluate the effectiveness and safety of multimodal analgesic management based on the enhanced recovery after surgery (ERAS) concept in the perioperative period of transarterial chemoembolization (TACE) for patients with advanced hepatocellular carcinoma. **Methods:** A retrospective analysis was conducted on 90 patients who underwent TACE at the First Affiliated Hospital of Sun Yat-sen University from January 2022 to October 2023. Patients were divided into two groups: Group A received a multimodal analgesic regimen based on the ERAS concept, which included preoperative administration of 6 mg hydromorphone hydrochloride and 50 mg flurbiprofen axetil, diluted in normal saline to a total of 100 ml and infused via a patient-controlled intravenous analgesia (PCIA) pump. Group B received conventional perioperative management combined with traditional analgesic methods, using intravenous flurbiprofen axetil 50 mg or intramuscular tramadol 100 mg for postoperative pain. Pain levels were recorded using the Numeric Rating Scale (NRS) at various time points: intraoperatively, immediately postoperatively, and at 1, 6, 12, and 24 hours post-surgery, along with the incidence of adverse reactions within 24 hours. Inflammatory indicators were compared before and after TACE, and patient satisfaction and cost-effectiveness analyses were conducted. **Results:** The NRS scores for Group A at the five time points were 3.0 (3.0–2.0), 3.0 (4.0–2.0), 4.0 (5.0–3.0), 3.0 (3.5–2.0), and 1.0 (1.0–0.5), respectively. For Group B, the scores were 4.0 (5.0–3.0), 4.0 (5.0–3.0), 5.0 (6.0–3.5), 3.0 (4.0–2.0), and 1.0 (2.0–1.0) , respectively. Except for the NRS score at 12 hours post-surgery, all other time points showed statistically significant differences. There was no statistically significant difference in the levels of PCT and IL-6 before and after surgery between the two groups, but a trend of lower postoperative PCT and IL-6 levels in Group A compared to Group B was observed. The incidence of various adverse reactions 24 hours post-surgery did not differ significantly between the two groups ($P > 0.05$). Patient satisfaction with analgesia at 48 hours post-surgery was significantly higher in Group A than in Group B, with a statistically significant difference (P = 0.001). Group A demonstrated better economic benefits. **Conclusions:** The results of this study indicate that multimodal analgesic management based on the ERAS concept has better analgesic effects during the perioperative period of TACE treatment, with comparable safety and improved economic benefits. This provides strong support for the clinical application of multimodal analgesic management based on the ERAS concept in TACE for liver cancer. Research Sponsor: None.

Evaluating palliative care needs of early-phase clinical trial patients. First Author: Fionnuala Crowley, Division of Hematology & Medical Oncology, The Tisch Cancer Institute, Icahn School of Medicine at Mount Sinai, New York, NY

Background: Specialty palliative care (PC) is increasingly recognized as essential for patients (pts) in early phase clinical trials (EPT), as highlighted by ASCO's 2024 PC guideline. However, concerns persist regarding trigger referrals' impact on resource-constrained PC services. In a pilot, we employed a trigger PC referral system for patients referred to EPT to increase access in this population. **Methods:** We conducted a retrospective cohort study comparing EPT and non-EPT pts seen by outpatient PC between January 1, 2021 and June 30, 2023. We evaluated demographic characteristics, clinical variables, symptom severity at the initial PC visit and end-of-life (EOL) outcomes. Mann-Whitney U tests were used for continuous variables; chi-square or Fisher's exact tests for categorical variables. Multiple comparisons were adjusted using the Benjamini-Hochberg method. **Results:** A total of 1068 pts were included, 136 (12.7%) EPT pts with 67 (6.3%) started on trial. 86 (63.2%) were seen by EPT before outpatient PC and 54 (39%) were referred to PC by EPT team through trigger referral system. EPT pts were younger (median age 61 vs 64 years; p=0.001), had better PS (ECOG 0-1: 57.4% vs 46.5%; p=0.020), and referred after more lines of therapy (median 3 vs. 1; $p<0.001$). Cancer type distribution differed significantly between groups (p=0.005), with EPT pts having higher proportions of GI (41.9% vs 26.5%) and GYN cancers (16.2% vs 9.2%). Physical discomfort was the most prevalent symptom in both EPT and non-EPT groups (86.9% vs 84.9%), followed by inactivity (74.2% vs 76.3%). While most symptoms showed similar prevalence between groups, EPT pts had higher rates of constipation (65.4% vs 50.7%, adjusted p=0.025) and nausea (48.1% vs 38.0% (adjusted p=0.193). After adjustment for multiple comparisons, there were no significant differences in symptom severity between groups. Of those on trial(n=67), 46 (69%) came off trial due to progression and 16 (24%) due to toxicity or worsening PS. After trial discontinuation, 35 (56.5%) received further treatment, and 37 (59.7%) had PC follow-up. Among deceased pts (EPT n=70 (18%), non-EPT n=320 (82%)), there were no differences in EOL outcomes: hospice enrollment (37.1% vs 29.1%, p=0.198), hospital death (58.6% vs 58.4%, p=1.000), chemotherapy in the last 30 days (22.9% vs 18.8%, p=0.411), and median hospital length of stay in the last 30 days (7 vs 5 days, p=0.825). **Conclusions:** EPT pts accounted for 12.7% of new pts to specialty PC over 30 months. Despite demographic and clinical differences between EPT and non-EPT patients, EOL outcomes and symptom severity were largely comparable between groups. These results highlight the feasibility of a trigger-based PC referral system for EPT patients without overburdening resource-constrained PC services, supporting its continued use and potential refinement to address specific symptom management needs. Research Sponsor: None.

12087 Poster Session

Impact of palliative care on mortality, length of stay, and hospital charges in common cancers. First Author: Kalaivani Babu, Allegheny General Hospital, Pittsburgh, PA

Background: Palliative care is a vital component of advanced cancer management, offering symptom relief, improved quality of life, and comprehensive care for patients with complex health needs. While its clinical benefits are well-documented, its impact on hospital outcomes—such as in-hospital mortality, length of stay (LOS), and total hospitalization charges (TOTCHG)—remains underexplored across major cancers. Using the 2021 National Inpatient Sample (NIS), this study evaluates the influence of palliative care utilization on these outcomes among hospitalized patients with breast, lung, colon, bladder, and prostate cancers. **Methods:** This retrospective analysis examined 966,753 weighted hospitalizations, representing breast (163,594), lung (383,215), colon (168,750), bladder (86,555), and prostate (182,280) cancers. Palliative care utilization was the primary exposure. Outcomes assessed included in-hospital mortality, LOS, and TOTCHG. Survey-weighted logistic and linear regression models were used to adjust for patient demographics (age, sex, race, income quartile), comorbidities (Charlson Comorbidity Index, CCI), and hospital characteristics (location, teaching status, region, bed size). **Results:** The overall mortality rate was 6.6%, highest in lung (9.3%) and lowest in prostate (4.7%) and colon cancers (4.8%). Palliative care patients had higher mortality (28.5%; $p < 0.001$). Adjusted analyses showed increased mortality with higher CCI (OR = 0.71, $p < 0.001$) and urban hospitals (OR = 1.40, $p < 0.001$), while female patients had reduced risk (OR = 0.86, $p < 0.001$).LOS averaged 5.98 days, longer for palliative care patients (7.68 days; $p < 0.001$). TOTCHG averaged $83,430, higher for palliative care ($90,488; $p < 0.001$). Black patients incurred higher charges (+$10,475, $p = 0.001$), and urban hospitals had lower costs (-$35,094, $p < 0.001$).Palliative care was concentrated in urban (93.7%) and teaching hospitals (80%), with significant underrepresentation of Black and Hispanic patients in the utilisation of palliative care. (19.2% and 8.8%). **Conclusions:** Palliative care in hospitalized cancer patients addresses the needs of patients with advanced disease and significant comorbidities. However, the study highlights stark disparities in healthcare access, resource utilization, and demographic representation based on race, socioeconomic status, and hospital characteristics. Research Sponsor: None.

Palliative care outcomes cancer comparison table.

Cancer Type	Total Hospitalizations	Mortality Rate (%)	Mean LOS	Mean Hospital Charges	Palliative Care Mortality Rate (%)	Palliative Care LOS	Palliative Care Charges
Breast	163594	6.6	7.34	85727	26.4	7.34	85727
Lung	383215	9.3	6.19	82776	30.55	7.53	89760

Early supportive and palliative care referral at a comprehensive cancer center: A seven year study. First Author: Fernando X. Jerves, Atlantic Health System/Morristown Medical Center Program, Morristown, NJ

Background: Despite ASCO supporting the benefits of early supportive/palliative care (SPC) integration, many patients with advanced cancer were referred $<$ 6 months before death or not at all. Our comprehensive cancer center has an active SPC program to promote early access. This study evaluated how the timing of SPC referral changed over the past seven years and identified predictors of early SPC referral. **Methods:** This study included a random sample of 100 patients seen for consultation at the SPC clinic per year from 2017 to 2023. Data included demographics, cancer type, disease stage, symptom burden, performance status, date of SPC referral, and date of death or last follow-up. The primary outcome was overall survival (OS) from SPC consultation. Timing of referral and number of visits were examined using time-to-event analysis. Early SPC referral was defined as occurring $\geq$ 6 months before death among decedents. Univariable and multivariable logistic regression models were used to identify predictors of early SPC referral. **Results:** Among 700 patients (median age 62, 54% female, 92% with advanced cancer), OS from SPC referral increased significantly over the years (Median OS: 9.3 months in 2017, 31.7 months in 2021, and not reached in 2023) (Table). The median follow-up for alive individuals was 19.1 months. The median number of follow-up SPC visits increased from 3 in 2017 to 7 in 2023 ($P <$ 0.001). Early SPC referral occurred in 72% (n = 449) of decedents. In multivariable analysis, male sex (OR: 1.85, P = 0.014), head and neck cancer (OR: 4.64, $P < 0.001$), hematologic malignancies (OR: 3.31, P = 0.013), less pain (OR: 0.9, P = 0.008) and less anorexia (OR: 0.88, P = 0.001) were associated with early SPC referral. **Conclusions:** Patients at our center were referred to SPC earlier and earlier over the past 7 years, achieving a median OS of 32 months. This trend highlights that early SPC is not only possible but potentially self-reinforcing, facilitating timely, longitudinal care along the cancer journey, particularly as patients are living longer with advanced cancer. Research Sponsor: None.

Outpatient supportive/palliative care referral between 2017 and 2023.

Current patterns of care: Referral to palliative care for patients with metastatic gynecologic cancer. First Author: Lea Tan, UC Irvine School of Medicine, Irvine, CA

Background: Multiple professional cancer organizations have clinical guidelines that recommend that patients with advanced cancers be referred to palliative care early in the disease course, typically within eight weeks of diagnosis (1). The extent to which these guidelines are adhered to, however, remains uncertain, particularly for patients with metastatic gynecologic cancers (MGC). We sought to characterize our current institutional patterns of referral to palliative care for these MGC patients. **Methods:** We conducted a retrospective chart review of gynecologic oncology patients treated at our institution between January 2022 and January 2024. We included adult, female patients with a diagnosis of FIGO stage IVB MGC, or cancer that has spread distantly. Patients with primary endometrial, cervical, ovarian, vaginal, or vulvar cancer were included. We excluded patients with less advanced disease or metastatic cancer from a non-gynecologic primary site. Data from the electronic health records of these patients were analyzed to determine key dates, including the diagnosis of stage IVB MGC, referral to palliative care, the first palliative care visit, and subsequent follow-up visits. Descriptive statistics were used to summarize the results. **Results:** Of the 549 patients included in the analysis, 152 (27.7%) had MGC. Within this subgroup, 76 patients (50%) were referred to palliative care. Of those referred, 65.8% (N = 50) were referred to palliative care either before or within 8 weeks of metastatic diagnosis. Referrals were made in both inpatient (47.4%, N = 36) and outpatient (52.6%, N = 40) settings. Following referral, 84.2% of patients (N = 64) had a consultation with a palliative care provider. However, less than half of these patients (48.4%, N = 31) continued outpatient follow-up with palliative care. When stratified by referral setting, 57.5% of patients (N = 23) referred in the outpatient setting continued follow-up care, compared to only 27.8% of those (N = 10) referred in the inpatient setting. **Conclusions:** Despite guidelines recommending early initiation of palliative care for all patients with advanced cancer, many patients with MGC either never receive a referral or experience considerable delays between metastatic diagnosis and palliative care consultation. In many cases, referrals are made only when patients are already hospitalized due to their cancer. Furthermore, we found that a substantial number of patients do not continue outpatient palliative care follow-up after their initial referral, with a more notable decline in continuity of care when the referral is made during an inpatient hospitalization. References: 1. Justin J. Sanders et al., Palliative Care for Patients With Cancer: ASCO Guideline Update. JCO 42, 2336-2357(2024). DOI:10.1200/JCO.24.00542. Research Sponsor: None.

Depression in patients with advanced prostate cancer in SWOG advanced cancer clinical trials. First Author: Robert S. Krouse, University of Pennsylvania, Philadelphia, PA

Background: Depression is common in patients with advanced cancer, but its prevalence has not been well documented. Moreover, depression is likely associated with other patient factors, including sociodemographic and clinical variables. We examined depression at enrollment in clinical trials for patients with advanced prostate cancer. **Methods:** We pooled clinical trial data from the SWOG Cancer Research Network. We identified phase III treatment trials of advanced prostate cancer patients with baseline mental health symptom measurements. Baseline depression was derived from emotional functioning items from the FACT-G, the SF-36, and the EORTC QLQ-C30 instruments. Using Likert scale distributions, depression was categorized as none, mild or moderate, and severe. We evaluated the prevalence of depression and its association with other baseline variables including age, race, ethnicity, insurance, rural/urban locale, the Area Deprivation Index, measurable disease, and prognostic risk. Generalized estimating equations with binomial logistic regression were used to assess the association of baseline variables with the odds of any depression and severe depression, with study as the clustering variable. A composite risk model was developed by summing the number of baseline risk factors adversely associated with depression. **Results:** Overall, N = 4,103 patients from four phase III trials were examined, including 69.8% aged 65 or older, 17.5% Black, 3.4% Hispanic, 18.4% rural, and nearly half (46.4%) from socioeconomically deprived areas (ADI score above the national median). At baseline, 50.4% of patients had depression (mild/moderate, 38.3%; severe, 12.1%). Depression was associated with age $<$ 65 years, non-Black race, Hispanic ethnicity, having Medicaid or no insurance, and worse disease clinical characteristics. Patients with $>$3 risk factors (high risk) vs. 0-2 risk factors (low risk) were more likely to experience depression (54.3% vs. 43.2%, $p < .0001$) and severe depression (21.0% vs. 9.7%, $p < .0001$), corresponding to a 50% (OR = 1.50; 95% CI: 1.34-1.67; $P < .0001$) and 135% (OR = 2.35; 95% CI: 1.84-3.02; $P < .0001$) increase in risk, respectively. Quartile (Q) level proportions of any depression were 32.8% (Q1), 44.4% (Q2), 53.1% (Q3), and 72.0% (Q4), respectively, with a fivefold higher risk for those in the highest vs. lowest quartiles (Q4 vs. Q1, OR = 4.97; 95% CI, 2.86-8.64, $p < .0001$). Similar findings were seen with severe depression. **Conclusions:** Evidence of depression at baseline was reported by one-half of patients with advanced prostate cancer in clinical trials. Moreover, we showed that the number of adverse socioeconomic and clinical variables could strongly predict the prevalence of depression. Screening for depression in patients with cancer could help guide patients to appropriate mitigation resources. Interventions to help screen and treat patients with advanced cancer are warranted. Intravenous selenium to prevent oral mucositis in patients with lymphoma or myeloma undergoing high-dose therapy followed by autologous hematopoietic cell transplantation: A double-blind randomized trial. First Author: Corentin Orvain, Angers University Hospital, Angers, France

Background: Oral mucositis (OM) is a frequent complication in patients with lymphoma and myeloma receiving high-dose therapy (HDT) and autologous hematopoietic cell transplantation (HCT) that can lead to severe pain, malnutrition due to difficulties in drinking and eating, and local and systemic infections. In severe cases, patients require opioid analgesics, supplemental nutrition, and additional antimicrobial therapy while very few preventive interventions have proven useful. Because of its anti-oxydant activity, some studies have suggested that selenium could be useful in this context. We therefore led a double-blind randomized trial to evaluate the use of selenium in preventing OM in patient with lymphoma or myeloma receiving HDT (NCT04080622). **Methods:** Patients $\geq$18 years with lymphoma or myeloma undergoing HDT (carmustine, etoposide, cytarabine, and melphalan [BEAM] for patients with lymphoma and high-dose melphalan for patients with myeloma) followed by autologous HCT were randomized beween intravenous selenium 300 μg/day or placebo from the first day of chemotherapy to hospital discharge. The primary endpoint was the incidence of severe (grade 3-4) OM by intention to treat as defined by the World Health Organization (WHO). Secondary endpoints included any grade oral mucositis (WHO), auto and hetero-évalaution (NCI-CTCAE) of OM, opioid, nutrition, and antimicrobial therapy used, duration of hospitalization, and adverse events (AE). **Results:** From October 2019 to October 2023, we included 100 patients with lymphoma (n = 29) and myeloma (n = 71) who received HDT and autologous HCT that were randomized between selenium (n = 50) and placebo (n = 50). Baseline characterstics (age, gender, and tobacco use, type of hematologic disease, disease status at HDT, and baseline albumin and selenium levels) were balanced between the two treatment arms. The rate of severe OM was strictyl identical in both arms (60%, *P*= 1) with a mean maximum grade of mucositis of 3.26 in the selenium arm and 2.82 in the placebo arm (*P*= 0.71). Other methods to evaluate OM showed similar results. Opioid use (mean 6.92 *versus* 6.12 days in the placebo group, *P*= 0.53), parenteral nutrition (mean 10.88 *versus* 9.27 days, *P*= 0.19), antibiotic use (9.12 *versus* 7.02 days, *P*= 0.05), antifungal use (1.02 *versus* 0.39 days, *P*= 0.33), and duration of hospitalization (24.94 *versus* 19.58 days, *P*= 0.24) were not statistically different between the two groups. The rate of grade 3-4 AE was higher in the selenium arm (100% *versus* 90%, *P*= 0.03) with similar rates of grade 3-4 diarrhea (10% *versus* 16%, *P*= 0.55). **Conclusions:** Intravenous selenium did not improve oral mucositis in patients with lymphoma or myeloma undergoing HDT followed by autologous HCT. Clinical trial information: NCT04080622. Research Sponsor: None.

The impact of early versus late palliative care referral (PCR) on healthcare utilization in pancreatic cancer patients: A single-center retrospective study. First Author: Kriti Dhamija, Allegheny Health Network, Pittsburgh, PA

Background: Pancreatic cancer is one of the most aggressive malignancies, imposing substantial physical, psychosocial, and financial stress that significantly compromises patients' quality of life (QOL). Despite its importance, only limited data exists on the optimal timing of a palliative care referral (PCR) in the course of pancreatic cancer. We propose that early PCR offers a proactive approach that not only alleviates symptom burden and improves QOL but also reduces healthcare utilization (HCU) and associated costs. **Methods:** We performed a retrospective analysis for patients diagnosed with pancreatic cancer at Allegheny Health Network from January 2015 to January 2024. Based on the timing of PCR from the diagnosis of pancreatic cancer, patients were categorized into early PCR ($<$ 3 months), and late PCR ($>$ 3 months) cohorts. HCU metrics were compared between the two cohorts including the number of emergency department (ED) visits, hospital admissions and intensive care unit (ICU) admissions, using Mann Whitney U test. Statistical analysis was performed using SAS 9.4, with an alpha level of 0.05. **Results:** From 2015- 2024, 2020 patients were diagnosed with pancreatic cancer and only 309 patients received a PCR. The patients who got a PCR had a median age of 66 years, 56% of them were males and 97% were non-Hispanic. Among these, 172 patients had an early PCR, and 137 patients had a late PCR. The patients in the early PCR group were generally non-Hispanic males with a mean age of 68 years, while those in the late PCR group being non-Hispanic males with a mean age of 64 years. The median number of ED visits was significantly higher in the late PCR cohort compared to the early PCR cohort, {3 [Interquartile range (INR)2-5] versus 2 [INR1-3] respectively, $p < 0.0001$}. 52.55% patients in the late PCR cohort had an ED visit due to pain, compared to only 37.79% patients in the early PCR cohort ($p < 0.009$). 36.63% patients in the early PCR group had an ICU admission as compared to 62.04% patients in the late PCR group ($p < 0.0001$). Similarly, early PCR group had a significantly lesser number of hospital admissions, 2 (INR 1-3), than the late PCR group, 4 (INR 1-10), $p < 0.0001$.While Chemotherapy use in the last 2 months from death was observed in 30.66% patients with late PCR and 29.07% of patients with early PCR, the difference was not statistically significant. **Conclusions:** Our study shows the use of early PCR in reducing aggressive care towards the end of life including ED visits and hospital and ICU admissions. Due to the advanced nature of pancreatic cancer at presentation, early integration of palliative medicine into comprehensive cancer care would be beneficial for improving the QOL of patients and would also reduce the HCU, enhancing economic sustainability of care. Further research is needed to show the effect of early PCR on the psychological stress experienced by pancreatic cancer patients. Research Sponsor: None.

Differences in supportive care service utilization among long term metastatic breast cancer survivors by rurality. First Author: Ashley Pariser Davenport, The Ohio State University - James Comprehensive Cancer Center, Columbus, OH

Background: Patients living with metastatic breast cancer (MBC) have unique psychosocial and medical needs, which often go unrecognized. Many patients living in rural areas travel farther for care. We examined differences in supportive care service referrals and utilization by sociodemographic, psychosocial, and clinical predictors among long term MBC survivors living in rural versus urban areas. **Methods:** 233 patients from the Ohio State University Stefanie Spielman Comprehensive Breast Center, who had been diagnosed with MBC for $\geq$1 year, were asked to complete a one-time, online survey to assess their demographic characteristics, quality of life, self-rated health, symptoms, and supportive care needs. Chi-square and fisher exact tests were used for categorical variables and two sample t-tests were used for continuous variables to determine sociodemographic (age, race, education, income, rural/urban residency), psychosocial/quality of life (PROMIS physical component score, PROMIS mental component score, MOS social support), and clinical factors (time since diagnosis, current treatment, metastasis site, fatigue, pain, and sleep) associated with utilization of supportive care services. **Results:** 66 patients residing in rural areas (RURAL) and 167 patients residing in urban areas (URBAN) were recruited. There was a higher rate of supportive care service utilization among URBAN (n=82, 49.1%) versus RURAL (n=22, 33.3%) patients. For URBAN, service utilization was associated with lower (worse) PROMIS physical scores, PROMIS mental scores, MOS social support total scores, and greater fatigue and pain scores. However, no significant associations were seen for RURAL. Higher education and income levels were associated with increased service utilization for RURAL, but not URBAN participants. The Table details referral and utilization rates for the top 5 supportive care services. **Conclusions:** Patients living in rural areas had lower supportive care utilization compared to patients living in urban areas. However, urban patients reported worse PROMIS and social support scores. While a no cost service (dietitian) had similar utilization rates between URBAN and RURAL, another (James Care for Life programs) did not. Services amenable to same day coordination had no statistical differences in utilization rates between URBAN and RURAL. More research is needed to evaluate the impact of distance, financial, and time barriers on equitable access to supportive care services. Research Sponsor: None.

Top 5 supportive care referrals and utilization.

	Rural		Urban	
	Referred	Utilized	Referred	Utilized
Counseling	8 (12.1%)	4 (50%)	34 (20.4%)	20 (58.8%)
Dietitian	11 (16.7%)	8 (72.7%)	35 (21%)	27 (77.1%)
James Care for Life Programs	8 (12.1%)	3 (37.5%)	27 (16.2%)	15 (75%)
Living Well with Advanced Breast Cancer Clinic	14 (21.2%)	2 (14.3%)	20 (12%)	15 (75%)
Physical Therapy	7 (10.6%)	6 (85.7%)	36 (21.6%)	29 (75%)

Race and correlates of cancer cachexia in the Detroit Research on Cancer Survivors cohort. First Author: Jennifer Lynn Beebe-Dimmer, Karmanos Cancer Institute, Wayne State University, Detroit, MI

Background: Cancer cachexia is a multifunctional syndrome characterized by the ongoing loss of skeletal muscle mass that cannot be fully reversed by conventional nutritional support and leads to progressive functional impairment limiting quality of life. It is also associated with poor response to therapies which impact long-term survival. The current investigation examines the prevalence and determinants of cachexia in a racially diverse cancer cohort. **Methods:** We used data gathered on a subset of participants in the Detroit Research on Cancer Survivors (ROCS) study, one of the largest cohorts conducted exclusively among Black cancer survivors to understand the complex nature of poorer outcomes in this population. At baseline, participants diagnosed and/or treated at the Karmanos Cancer Institute with breast, colorectal and lung cancer were asked to provide their weight one year prior to diagnosis and current weight, height, medical history, health behaviors and health-related quality of life (HRQOL). Responses were compared with a frequency-matched set of White cancer survivors. Cachexia was defined as an unintentional weight loss of 5% or more for patients with a BMI 20 or higher and 2% or more for patients with a BMI $<$ 20 over 6 months. **Results:** Among 899 cancer survivors (509 Black and 390 White), 35.3% reported weight loss consistent with cachexia. A significantly higher proportion of Black survivors were cachectic (40.3%) compared with White survivors (28.7%; $p < 0.001$). Racial differences were equally pronounced regardless of tumor type, but overall the highest proportion of cachexia was observed among lung cancer survivors (54.2%). Examination of the electronic medical records of these patients found that older age at diagnosis (p-trend $<$ 0.005) and a medical history of diabetes (OR = 2.18; 95%CI 1.31, 3.63) were both significantly associated with the presence of cachexia. **Conclusions:** We found that Black patients are more likely to have cachexia at the time of cancer diagnosis than white patients. Since cachexia is an important predictor of poor outcomes in cancer patients, developing strategies to prevent or reverse the loss in the skeletal muscle mass is critical in improving outcomes and reducing disparities in related outcomes. Barriers to palliative care access in patients with brain metastases: A comprehensive national study. First Author: Anastasia Amundson, FIU Herbert Wertheim College of Medicine, Miami, FL

Background: Palliative care (PC) improves the quality of life for patients with advanced cancer, including those with brain metastases (BM). Despite nearly 170,000–200,000 cases of BM annually in the United States, evidence supporting utilization of early PC in malignant brain tumors remains limited. This study aimed to identify factors influencing access to PC for patients with BM from lung, breast, and colorectal cancer to delineate patient uptake of PC. **Methods:** This retrospective cohort study analyzed the National Cancer Database (NCDB) data (2010-2021) for patients with BM from lung, breast, and colorectal cancer. Variables analyzed included age, sex, race, ethnicity, facility type, insurance status, socioeconomic factors, and primary cancer site. The primary outcome was receipt of PC. Descriptive statistics summarized patient characteristics, and logistic regression identified predictors of access to PC, reporting odds ratios (OR) with 95% confidence intervals (CIs). **Results:** Of 214,940 patients with BM, 94% had lung cancer, 4.2% had breast cancer, and 1.7% had colorectal cancer. The cohort was 50.9% female, 82.6% White, 12.2% Black, 3.8% Asian, 96.4% non-Hispanic, and 3.6% Hispanic. In the multivariate analysis, older patients had lower odds of receiving PC compared to patients aged 18-59 (60-69: OR 0.95, 95% CI 0.93-0.98; 70+: OR 0.88, 95% CI 0.86-0.91; $P < 0.001$), while sex was not associated with PC (OR 0.99, 95% CI 0.97-1.01; P = 0.333). Compared to White patients, Black (OR 0.96, 95% CI 0.93-0.99; P = 0.014), and Asian (OR 0.95, 95% CI 0.91-1.00; P = 0.066) patients had lower likelihood of PC. Hispanics were also less likely to receive PC (OR 0.85, 95% CI 0.80-0.90; $P < 0.001$). Integrated facilities (i.e., part of a larger network with centralized cancer care) had a lower probability of providing PC than community hospitals (OR 0.97, 95% CI 0.95-0.99; P = 0.002), whereas academic facilities showed no differences (P = 0.105). Medicaid patients had slightly higher odds of receiving PC than those with private insurance (OR 1.04, 95% CI 1.00-1.07; P = 0.026), while Medicare and other government insurance showed no significant differences. Medicaid expansion improved access (January 2014: OR 1.55, 95% CI 1.50-1.60; late expansion: OR 1.55, 95% CI 1.50-1.61; $P < 0.001$). Patients living $>$ 10 miles from a facility had lower odds of access (OR 0.97, 95% CI 0.94-0.99; P = 0.002). Compared to patients with breast cancer, those with lung cancer had lower odds (OR 0.92, 95% CI 0.87-0.96; $P < 0.001$), and colorectal cancer patients had the lowest odds (OR 0.73, 95% CI 0.67-0.80; $P < 0.001$) of accessing PC. **Conclusions:** Significant disparities in PC access among patients with BM exists. Age, racial and ethnic subgroups, geographic barriers, and primary cancer type impact uptake of PC. Targeted interventions, including strategies to improve access for underserved populations, are needed to increase health equity among BM patients. Research Sponsor: None.

Age-specific unmet needs among older patients with cancer enrolled in an outpatient palliative care program: A retrospective analysis. First Author: Sarah Ananda Gomes, Oncoclinicas & Co - Medica Scientia Innovation Research (MEDSIR), São Paulo, Brazil

Background: Older adults with cancer often experience diverse unmet needs. Understanding these needs is crucial for tailoring palliative care interventions. This study analyzed unmet needs among older patients enrolled in an outpatient palliative care program (OPCP), stratified by age (65–75, 76–86, and 87–97 years). **Methods:** This retrospective study included 474 patients enrolled in an OPCP from November 2022 to April 2024. Patients completed the Integrated Palliative Outcome Scale (IPOS), a validated measure assessing physical, psychological, social, and spiritual needs, as well as overall quality of life (QoL). Multinomial logistic regression was performed to evaluate associations between age groups and specific unmet needs, with adjustments for sociodemographic and clinical factors. **Results:** From the total sample, median age was 77 years (range 65–97); 51% were female, 36% had high school, and 32% were college-educated. Cancer types included gastrointestinal (25%), genitourinary (20%), lung (14%), and breast (12%). QoL scores did not differ across age groups. However, unmet needs varied by age group: 65–75 years: Greater likelihood of reporting pain (OR 0.118, 95% CI 0.01–0.42, p=0.04), fatigue (OR 8.27, 95% CI 6.76–9.96, p=0.04), drowsiness (OR 2.15, 95% CI 2.11–3.46, p=0.04), depressive symptoms (OR 2.28, 95% CI 1.23–3.35, p=0.04), and lower anxiety with treatment (OR 0.11, 95% CI 0.02–0.52, p=0.005). 76–86 years: Greater prevalence of drowsiness (OR 20.77, 95% CI 12.14–26.31, p=0.02) and reduced anxiety about the disease (OR 0.13, 95% CI 0.03–0.62, p=0.01). Feeling at peace was less common (OR 0.38, 95% CI 0.002–0.64, p=0.02). 87–97 years: More likely to report pain (OR 11.38, 95% CI 8.11–16.63, p=0.02), anxiety about the disease (OR 9.39, 95% CI 4.11–11.47, p=0.005), and satisfaction with receiving requested information (OR 6.19, 95% CI 3.71–8.42, p=0.04). **Conclusions:** Distinct unmet needs were identified across age groups in older cancer patients receiving outpatient palliative care. Younger older adults (65–75) had higher physical and psychological unmet needs, while the oldest patients (87–97) were more likely to report pain and anxiety about their disease but experienced better communication. Tailored interventions addressing these specific needs are essential to improving patient-centered care. Research Sponsor: None.

Disparities in cachexia and anorexia in hospitalized female patients with breast cancer: A national population-based study. First Author: Amro Awad, Hennepin County Medical Center, Minneapolis, MN

Background: Breast cancer is the most common cancer in females in the US. Cachexia and anorexia are common complications from either the disease itself or the treatment regimen. Specific disparities in the prevalence of anorexia and cachexia in female breast cancer patients is not known. This study seeks to address this gap in knowledge by comparing the prevalence of this issue among different demographic factors. **Methods:** The National Inpatient Sample (NIS) databases (2016–2021) of the Healthcare Cost and Utilization Project (HCUP) was used. We applied discharge weight (DISCWT) provided in the database to generate the national estimates. Pearson Chi-square test for categorical variables and Student's t-tests/one-way ANOVA for continuous variables were applied to compare the baseline demographics and hospital characteristics between the groups. The objective of the study was to determine demographic factors associated with increased cachexia, specifically race (African American vs all races), income (lowest quarterlies vs highest), Insurance type (private vs all types) and age (older than 65 years old vs younger). Multivariate linear and logistic regression models were used to adjust for confounders such as demographics, tobacco use, hypertension, COPD, Ischemic heart disease, prior CVA, and prior diagnosis of anorexia nervosa. **Results:** Anorexia, cachexia or malnutrition were documented in 12% of 1,037,185 hospitalizations of females with breast cancer. After adjusting for confounders, there were higher odds of anorexia and cachexia in patients of the African American race (aOR:1.28; CI 1.11 - 1.52; p-value $<$ 0.001) and patients who are 65 years old or older (aOR:1.18; CI 1.06 - 1.35; p-value 0.015). Having a private insurance was associated with lower odds of anorexia and cachexia (aOR:0.69; CI 0.62 - 0.78; p-value $<$ 0.001). There were no significant differences between patients of different levels of income. **Conclusions:** Female breast cancer patients of certain demographics have higher odds of developing cachexia or anorexia, a very common complication of breast cancer. Further considerations for these vulnerable populations should be studied and focused efforts should be made to ensure adequate healthcare access for all demographics. Research Sponsor: None.

Demographic studied	Prevalence of anorexia/cachexia (aOR, P-value, CI)
African American race vs all races	1.28, $<$0.001*, 1.11 - 1.52
Age ≥ 65 vs <65	1.18, 0.015*, 1.06 - 1. 35
Private insurance vs all insurance types	0.69, $<$0.001*, 0.62 - 0.78
Income (lowest quarterile vs highest)	1.05, 0.45, 0.81 - 1.23

*Statistically significant.

12098 Poster Session

Economic outcomes of palliative care in colorectal cancer hospitalizations: A propensity-matched retrospective cohort study on resource utilization. First Author: Elvis Obomanu, Jefferson Einstein Hospital, Philadelphia, PA

Background: The economic burden of colorectal cancer (CRC), a major cause of cancer-related death worldwide, is significant and is fueled by extended hospital stays, intensive treatments, and expensive end-of-life care, with costs expected to rise as the population ages. While clinical research has established the benefits of palliative care (PC) in improving patient outcomes, its economic impact within CRC care pathways remains underexplored. This study employs a large-scale, propensity-matched cohort analysis to evaluate the economic burden of PC integration during CRC hospitalization, addressing knowledge regarding the impact of early palliative interventions on healthcare expenditures and resource utilization. **Methods:** Utilizing data from the Global Collaborative Network-TriNetX, this retrospective cohort analysis evaluated the economic ramifications of early palliative care integration in adults (≥18 years) hospitalized with colorectal cancer. Using ICD-10 codes, we identified patients with malignant colorectal neoplasms, stratifying them into two cohorts: Cohort 1 (n=14,430) comprised individuals receiving palliative care within one month of diagnosis, while Cohort 2 (n=752,405) included those without palliative care exposure. Cohorts were balanced across sociodemographic and clinical variables via propensity score matching. Outcomes using surrogates for healthcare resource utilization and economic burden (inpatient, emergency department, and outpatient visits) were assessed over a 10-year follow-up period (beginning one day post-diagnosis). Results are reported as odds ratios (ORs) with 95% confidence intervals (CIs). **Results:** Following propensity score matching, two balanced cohorts (n=13,991 each) were established, with comparable baseline characteristics. The palliative care cohort had a mean age of 75.8 years, predominantly white—58.7%—and 54.3% males and 45.7% females—while the non-palliative care cohort averaged 76.3 years, predominantly white—59.8%—53.8% males and 46.2% females. Compared to the non-palliative care cohort, the palliative care cohort demonstrated significantly lower risks of inpatient admissions (OR 0.371; 95% CI 0.333–0.413; $p < 0.001$), emergency department visits (OR 0.342; 95% CI 0.311–0.377; $p < 0.001$), and outpatient visits (OR 0.397; 95% CI 0.357–0.441; $p < 0.001$). **Conclusions:** Our study found that early integration of palliative care (PC) in colorectal cancer (CRC) hospitalizations is associated with significant cost savings, achieved through reduced utilization of resource-intensive services, including inpatient, outpatient, and emergency department admissions. These findings suggest that PC could have a positive impact on financial sustainability and end-of-life quality while alleviating the economic burden on healthcare systems and individuals. Research Sponsor: None.

"The telehealth means I get distance from the hospital so I don't feel so much like a patient": A qualitative sub-study examining the acceptability of nurse-led follow-up for ovarian cancer via telehealth using the MOST-S26 to structure consultations. First Author: Rachel Campbell, Faculty of Science, Centre for Medical Psychology and Evidence-Based Decision-Making (CeMPED), Sydney, NSW, Australia

Background: The MOST-S26 is a patient-reported outcome measure that complements follow-up after first-line treatment for ovarian cancer (OC). MOST-S26 enables assessment of physical and psychological symptoms, and well-being. A randomized trial was conducted to evaluate nurse-led follow-up for OC via telehealth using the MOST-S26 to structure consultations vs routine hospital follow-up (ACTRN12620000332921). A qualitative sub-study assessed acceptability of the intervention from patient and nurse perspectives. **Methods:** Semi-structured interviews via video or telephone explored experiences of receiving or delivering nurse-led follow-up. Patients that participated in at least two nurse-led follow-up appointments were eligible. Study nurses delivering the intervention were interviewed at the end of the trial. Interviews were recorded, transcribed and coded using a Framework Approach following five stages: familiarisation, developing a thematic framework, indexing, charting, mapping and interpretation. **Results:** From June 2021, 38 patients were enrolled at 6 Australian sites. The trial closed to acrual in April 2024. Twenty-one participants were interviewed (15 women with OC and 6 study nurses). Analysis identified 3 overarching themes: (1) *key patient-centred benefits* (convenience and flexibility; providing a sense of connection and feeling cared for; enabling personalised, holistic care and prompt management of symptoms; providing dedicated space for patients' to freely express experiences and emotions); (2) *challenges to delivery from nurses' perspectives* (emotional impact of patients' cancers recurring; lack of referral pathways; inability to observe physical cues; difficulties establishing rapport; and, lack of suitability for all patients e.g. non-English speaking or patients with low literacy); and, (3) *Nurse views on usefulness of MOST-S26 to support consultations* (provides a useful tool to guide consultations/referrals, detect recurrence, track symptoms over time, flag symptoms for discussion, and, helps patients' reflect on their symptoms). **Conclusions:** Results confirmed acceptability of this type of follow-up for both OC patients and nurses. Both reported several benefits compared with standard hospital-based follow-up. Challenges that should be considered prior to routine implementation of this follow-up model included: the need to provide support to nurses to cope with the emotional impact of patients' cancers recurring; developing clear referral pathways for symptom management; and considering the characteristics of patients most and least suitable for this type of follow-up. Clinical trial information: ACTRN12620000332921. 12100 Poster Session

Telemedicine-enabled synchronous medical oncology and home hospice visits. First Author: Sara Dost, Hartford HealthCare Cancer Institute, Hartford, CT

Background: Hospice is underutilized at end-of-life by patients with cancer. Among the barriers to earlier acceptance of hospice may be the perceived loss of the therapeutic alliance and emotional support provided by the oncology team once the hospice team starts care. With the growing utilization of telemedicine, we sought to understand patient, caregiver, hospice nurse, and oncologist perceptions of synchronizing home hospice visits by the hospice nurse with remote telemedicine visits performed by the oncologist in their clinic. **Methods:** Thirty-four newly enrolled hospice patients (age 57-90+; 20 female & 14 male; 28 white non-Hispanic,1 white Hispanic, 3 black/African American, 2 other; 19 married, 3 single, 3 divorced, 1 significant other, 7 widowed, 1 other) and 34 caregivers were consented to an IRB-approved study between 5/14/21-9/9/24. Home hospice nurse visits were coordinated with the oncologist's clinic schedule and telemedicine visits were securely conducted through Epic MyChart functionality. Mixed methodology was utilized with patients, caregivers, hospice nurses and oncologists completing five-point Likert-scale surveys at baseline and subsequent serial surveys for patients and caregivers. **Results:** All groups rated improvement in overall communication. Likert scores for ease and quality of communication improved for oncologists (3.0 to 1.5) and nurses (2.0 to 1.0). Therapeutic alliance scores for patients and caregivers were stable and improved for oncologists (2.5 to 1.5) and nurses (2.0 to 1.5). **Conclusions:** Patients and caregivers expressed highly favorable ratings of hospice experience at baseline and improvement with telemedicine visits. There was no degradation in patient and caregiver therapeutic alliance scores, suggesting preservation of patient experience. Improvement among oncologists and hospice nurses was seen for both communication and therapeutic alliance scores once synchronous telemedicine hospice visits were instituted. These findings suggest that all four groups found value in oncologist-hospice patient telemedicine visits. Qualitative interviews and thematic analysis of caregivers' impressions of the program continue to identify how better to support patients and caregivers during home hospice care. Research Sponsor: None.

Quantitative results.

			Baseline Score Median (IQR)	Improvement in Score Median (IQR)
Patient	Communication	Overall	2.0 (1.25-2.75)	1.0 (0.5-1.0)
	Therapeutic Alliance	Support received from oncologist	2.0 (1-3)	0.0 (-0.5-2.5)
Caregiver	Communication	Overall	2.0 (1.75-3)	1.0 (0.0-1.0)
	Therapeutic Alliance	Support received from oncologist	1.0 (1-3)	0.0 (0.0-0.0)
Oncologist	Communication	Overall	3.0 (2-4.75)	2.0 (0.0-3.0)
	Therapeutic Alliance	Connection	2.5 (2.0-3.0)	1.0 (0.0-2.0)
Hospice Nurse	Communication	Overall	2.0 (2-2.75)	1.0 (0.0-1.0)
	Therapeutic Alliance	Connection with patient & family	2.0 (1-2)	0.5 (0.0-1.0)

Evaluating the feasibility of a peer-support group for patients with cancer (presently). First Author: Brandon Anderson, San Francisco Medical Center, Kaiser Permanente Northern California, San Francisco, CA

Background: Many patients with cancer experience significant mental health challenges (commonly depression, anxiety, and adjustment disorders) which can impair quality of life and treatment adherence. Despite this, few seek mental health care due to barriers such as stigma, limited resources, and lack of suitable programs. We sought to determine the feasibility of "Presently", a novel, trauma-informed, virtual, peer-support program for patients regardless of cancer type or treatment, facilitated by trained cancer survivors. **Methods:** An 8-week pilot was implemented at Kaiser Permanente San Francisco, allowing self-enrollment. Demographic and clinical utilization data were collected from one year prior to the program through its completion (9/1/23–11/1/24). Post-program evaluation included surveys and participant feedback sessions. **Results:** Of 42 self-enrolled patients, 31 (74%) attended at least one session, averaging 4 sessions per participant. Most attendees were female (87%) and white (68%). Mental health comorbidities were prevalent, with 59% having an active diagnosis and 34% prescribed psychotropic medications. Participants represented diverse cancer types: breast (32%), lymphoma (24%), genitourinary (21%), gastrointestinal (10%), leukemia (7%), lung (3%), and pre-cancerous (3%). Disease stages varied: 38% local, 24% locally advanced, and 38% metastatic. Nearly half (48%) were undergoing active treatment. In the year prior, attendees utilized more healthcare services, including 157% more oncology and 10% more primary care visits than non-attendees. Participant feedback was positive: 65% found Presently very effective in providing emotional support and 64% were highly likely to recommend it to others. Most participants (82%) found support from peers meaningful, with 71% appreciating staff facilitation and 59% valuing opportunities to help others. All non-attendees expressed interest in future participation. **Conclusions:** The Presently program demonstrated feasibility in supporting patients with diverse cancer diagnoses, stages, and mental health histories. Positive participant feedback underscores the potential for novel peer-led models to address the increasing mental health needs of patients with cancer. Future research will investigate clinical outcomes and potential reductions in healthcare utilization through larger-scale implementation. Research Sponsor: None.

Quality of life among oncology patients with distinct spiritual well-being profiles. First Author: Kayoll G. Gyan, Dana-Farber Cancer Institute Phyllis F. Cantor Center for Research in Nursing and Patient Care Services, Boston, MA

Background: Individuals undergoing treatment for cancer experience multiple symptoms moderated by stress/resilience that impact quality of life (QOL). Spiritual well-being (SWB) is an understudied QOL component that may influence outcomes. Purpose: Identify SWB profiles and associations with symptoms, stress, resilience, and QOL. **Methods:** Patients with breast, gastrointestinal, gynecologic and lung cancer undergoing chemotherapy were enrolled in a symptom clusters study. Assessments included: SWB subscale of theMultidimensional Quality of Life Scale-Patient Version (MQOLS); Lee Fatigue Scale (LFS), Attentional Function Index (AFI), Spielberger State-Trait Anxiety Inventory (STAI), Center for Epidemiological Studies-Depression scale (CESD), General Sleep Disturbance Scale (GSDS); Perceived Stress Scale (PSS), Connor-Davidson Resilience Scale (CDRS) and MQOLS. Latent profile analysis (LPA) was used to identify the distinct SWB profiles. Differences among latent classes were evaluated using analysis of variance, Kruskal-Wallis, or Chi Square tests with a Bonferroni corrected p-value of <0.008. **Results:** Among 1324 patients, four distinct SWB profiles were identified (Table). Patients in the Low SWB class were older, better educated, and more likely to be male and White compared to other groups (all $p<0.008$). Low SWB patients reported greater fatigue, anxiety, and depression, poorer general health and mental health, and greater stress. Compared to High and Very High classes, patients in the Low and Moderate classes had lower resilience scores. Low SWB patients reported poorer QOL. **Conclusions:** Four distinct SWB profiles were identified. Patients with lower SWB reported higher symptom burden, higher levels of stress and poorer QOL. An evaluation of patients' SWB may assist clinicians to identify a modifiable condition that warrants targeted interventions. Research Sponsor: National Cancer Institute; CA134900.

Differences in symptoms, stress, resilience, and QOL scores among SWB classes.

Awareness of gestational surrogacy among female patients treated for cancer: A national survey. First Author: Alexa Steckler, The Warren Alpert Medical School of Brown University, Providence, RI

Background: ASCO and other international guidelines recommend fertility counseling at diagnosis for all reproductive-aged cancer patients. Yet, how commonly gestational surrogacy (GS) is presented as an option remains unclear. To date, there is very little data to inform the question. Our primary objective was to determine the proportion of cancer survivors aware of GS as an option for parenthood. For the purposes of this study, we defined a gestational surrogate as one who carries a pregnancy using an embryo from the intended parents or a donor embryo, and as such, has no genetic link to the fetus. **Methods:** We developed a national survey that covered fertility preservation options, with specific questions regarding GS. Survey validation and usability testing were conducted with 17 cancer survivors, providing input on the final instrument. Following IRB approval, the survey was disseminated online via REDCap in partnership with multiple cancer advocacy organizations between April and November 2024. All respondents had the ability to select multiple responses as appropriate. Frequencies, proportions, and 95% confidence intervals (CI) were calculated using SAS 9.4 (SAS Institute, Cary, NC). **Results:** 519 female participants completed the survey. By cancer type: 60.7% breast, 14.3% hematologic, 8.1% cervical/uterine, 4.4% ovarian, 3.7% GI, and 8.9% other. Mean age (SD) was 31.1 (6.6) at diagnosis and 36.8 (7.4) at survey response; 30% had children at diagnosis. Overall, 75.9% expressed a desire for children post-cancer at the time of their diagnosis. Among respondents, 302 (58.2%; 95% CI 54.0-62.4) reported that they were aware of GS at diagnosis. Among those aware of GS, a similar proportion learned about it through oncologists (32.1%; 95% CI 26.9-37.4) or REI specialists (31.1%; 95% CI 25.9-36.4). However, the majority learned about GS through non-clinical resources (73.2%; 95% CI 68.2-78.2), including internet/social media (46.0%; 95% CI 40.5-51.7). Of those aware, GS was actively considered by 134 (44.5%) participants, of which 20 (14.9%) pursued GS and 16 (11.9%) have had a child using GS. Of those who did not actively consider GS but who were aware, common barriers included cost (45.3%), not ready to build a family (41.4%), preference to carry the pregnancy (29.9%), and using/planning other methods (20.5%). **Conclusions:** GS is a common route to parenthood in the US and internationally. While almost 60% of participants were aware of GS as an option, the primary source of information was through non-clinical resources. These data indicate GS should be routinely included in fertility counseling at diagnosis, especially in cases where cancer treatment compromises the patient's ability to carry a pregnancy. Education is needed to ensure oncologists are equipped to provide access to accurate, patient-centered oncofertility care, including REI referral. Research Sponsor: None.

Inclusion of gestational surrogacy in oncologist-led fertility counseling at cancer diagnosis: A national survey. First Author: Alexa Steckler, The Warren Alpert Medical School of Brown University, Providence, RI

Background: ASCO guidelines recommend that oncologists discuss infertility risks and fertility preservation early with reproductive-aged cancer patients. However, little is known about how often gestational surrogacy (GS) is presented as a parenthood option, or the factors influencing these conversations. GS is defined as someone who carries a pregnancy using an embryo from the intended parents or donor, with no genetic link to the fetus. We sought to assess the frequency and predictors of oncologist-provided GS counseling among a national cohort of female cancer survivors diagnosed at a reproductive age. **Methods:** We developed a REDCap survey on GS counseling experiences and demographic/cancer-related information, incorporating feedback from 17 survivors. The final survey was distributed nationally via multiple cancer advocacy organizations (April–November 2024). Fisher's exact tests, T-tests, and multiple logistic regression identified predictors of GS counseling, with $p < 0.05$ considered significant. **Results:** 519 female cancer survivors completed the survey. By cancer type: 60.7% breast, 14.3% hematologic, 8.1% cervical/uterine, 4.4% ovarian, 3.7% GI, and 8.9% other. Mean age at diagnosis was 31.1 (SD 6.6). 82.1% of patients recalled their doctor discussing the impact of cancer treatment on fertility. Only 18.7% received GS counseling from their oncologist. Patients with cervical/uterine (35.7%) and ovarian (30.4%) cancer were significantly more likely to receive GS counseling from their oncologist compared to breast (19.1%), hematologic (13.5%), GI (5.3%), and other cancers (8.7%) ($p = 0.007$). Patients who were younger age at diagnosis (mean 30.0 vs. 31.4 years, $p = 0.05$), had a younger current age (mean 34.2 vs. 37.4, $p < 0.001$), fewer years since diagnosis (21.3% < 5 years vs. 20.6% 6-10 years vs. 6.0% > 10 years since diagnosis, $p = 0.003$), and were childless at diagnosis (21.3% vs. 12.9% with children, $p = 0.03$) were significantly more likely to receive counseling. GS counseling did not vary by patient race, sexual orientation, relationship status, geographic location, income, or education. Logistic regression showed older current age (aOR 0.90; 95% CI 0.95-0.95) and having children at diagnosis (aOR = 0.56; 95% CI 0.31-0.98) predicted lower odds, while gynecologic cancer increased odds of GS counseling (aOR = 2.21; 95% CI 1.06-4.49). **Conclusions:** Fewer than 1 in 5 survivors received GS counseling from their oncologist, with younger, childless patients with gynecologic cancers more likely to be counseled. These findings highlight potential biases in counseling practices and underscore the need for systematic, equitable fertility discussions at diagnosis, before gonadotoxic treatment. Using large language models to assess adherence to ASCO patient-oncologist communication standards. First Author: Joshua Paul Davis, Dana-Farber Cancer Institute, Boston, MA

Background: The American Society of Clinical Oncology (ASCO) convened a multidisciplinary panel resulting in patient-oncologist communication guidelines published in 2017. These guidelines contain recommendations across topics including goals of care, treatment selection, end-of-life care, facilitating family involvement, and clinician training in communication. Ideally, these conversations should be documented in the electronic health record (EHR), so that they can be referred to at future visits as a patient's clinical course evolves. Tracking adherence to these communication guidelines may be beneficial for quality improvement efforts. However, manual chart review of unstructured free text notes is tedious and burdensome. The recent development of Large Language Models (LLMs) may represent a new computational approach that can capture such documentation more efficiently than chart review. To our knowledge, no prior study has used LLMs to capture such documentation in free text notes, validated against gold-standard manual chart review. **Methods:** As part of a larger study on development of LLMs for tracking palliative care quality measures, we randomly selected 30 patients with advanced cancer and clinical notes in the month following navigation to a poor prognosis treatment node. We used *GPT-4o-2024-05-13*, our HIPAA-secure tool, to develop an LLM prompt for identifying 14 ASCO communication domains in clinical text. The LLM prompt required output to generate source text to support identification of a communication domain. A "hallucination score" was calculated for source text, which is a measure of evidence produced by LLMs not found in source text. We then compared to gold standard manual chart review using standard performance metrics. **Results:** Across communication domains, note-level LLM analysis achieved sensitivity ranging from 0.43-1.0, specificity ranging 0.32-0.99, and accuracy ranging 0.51-0.99. Examples of documentation identified by both the LLM and chart review include goals of care and prognosis ("recently informed that her disease had progressed with treatment. Currently on 'last line' of chemotherapy"), treatment options and clinical trials ("her oncologist recommended a potential trial treatment, and she is contemplating involvement in this"), end-of-life care ("if her cancer continues to progress with her current treatment, they will transition her care to home hospice for comfort measures only"), and cost of care ("financial insecurity - referred to resource specialist"). Average hallucination index for documentation identified by the LLM was low. LLM frequently identified information missed by annotators. The LLM extracted information relevant to communication domains in a fraction of the time required by manual chart review. **Conclusions:** LLMs can identify communication domains in EHRs, potentially contributing to quality improvement efforts. Research Sponsor: National Institute on Aging; National Cancer Institute.

The association between emotional distress prior to receiving immune checkpoint inhibitors and overall survival among patients with cancer: A population-based study. First Author: Luciana Beatriz Mendes Gomes Siqueira, Division of Medical Oncology and Hematology, Princess Margaret Cancer Centre, University of Toronto, Toronto, ON, Canada

Background: Immune checkpoint inhibitors (ICIs) are widely used across cancer care. Emerging evidence from smaller studies links pretreatment emotional distress (ED) to poorer outcomes in patients with melanoma and non-small cell lung cancer undergoing ICIs due to changes in inflammatory states but large-scale studies are lacking. We conducted a population-level retrospective cohort study to assess the impact of pre-treatment ED on overall survival (OS) across solid tumor patients treated with ICIs. **Methods:** Using population-level administrative data, a cohort of patients with cancer, age 18 years or older, who received at least one dose of an ICI between June 2012 to October 2018 in Ontario, Canada, were identified using systemic therapy databases. Databases were deterministically linked to obtain socio-demographic, clinical co-variates, pre-treatment ED levels, and overall survival. ED was defined as having the sum of the Edmonton Symptom Assessment Scale (ESAS) anxiety and depression score $\geq$ 4. Multivariable Cox proportional hazard models assessed the association between ED and OS, adjusted for age, sex, body mass index, history of autoimmune conditions, cancer centre facility level, comorbidity score, and hospitalization within 60 days prior to starting ICI. **Results:** Among the 3237 patients who received ICIs and completed the ESAS prior to ICI treatment, most were male (58%), median age 67 years (IQR 59-74), the median combined ESAS anxiety and depression score was 3 (IQR 0-7); 45% had pre-treatment ED. The majority had lung cancer (49%), melanoma (37%) or renal cancer (9%), and were either treated with nivolumab (42%), pembrolizumab (36%) or ipilimumab (19%). Median OS was 330 days. Pre-ICI treatment ED was associated with poorer OS (aHR = 1.23, 95% CI [1.12–1.34] $P < 0.0001$) and when analyzed as a continuous variable, a higher combined ESAS anxiety and depression score was associated with poorer OS (aHR = 1.02 per 1 unit increase, 95% CI [1.01-1.03] $P < 0.0001$). Pre-treatment ED was associated with poorer OS for both males (aHR_{males}= 1.27, 95% CI [1.12–1.43] $P = 0.0001$) and females ($aHR_{females}$= 1.18, 95% CI [1.03–1.36] $P = 0.02$). Among disease sites, ED was associated with reduced OS among patients with lung cancer (aHR = 1.33, 95% CI [1.17–1.51] $P < 0.0001$) and showed a similar but non-significant trend among patients with melanoma (aHR = 1.14, 95% CI [0.98–1.32] $P = 0.09$); while ED not significantly associated OS for patients with renal cancer (aHR = 0.98, $P = 0.89$). Similar results were observed across sexes and disease sites when evaluating the combined ESAS anxiety and depression score and OS. **Conclusions:** Among patients receiving ICIs, pretreatment ED is associated with poorer OS. These findings suggest the importance of screening for and addressing ED as a part of routine cancer care, which may potentially influence ICI treatment outcomes. Research Sponsor: University of Toronto; Conquer Cancer, the ASCO Foundation.

Effect of a single home visit on distress in cancer patients undergoing chemotherapy: A comparative study. First Author: Mila Petrova, MHAT "Nadezhda", Sofia, Bulgaria

Background: This study aimed to investigate whether a home visit after the first chemotherapy can significantly reduce cancer patients' psychological distress levels. **Methods:** The National Comprehensive Cancer Network Distress Thermometer and problem list was used to assess patients' level of distress on a scale from 0 to 10, with scores of 4 or higher considered a high level of distress. Between 01 Mar and 01 Nov 2024 chemotherapy naïve cancer patients were divided into two groups – the study group had a home visit by a medical oncologist within 10 days after the start of their 1st chemotherapy, and the patients in the control group were only seen at the clinic before the start of their 1st and 2nd chemotherapy course. During the home visits, a patient-led discussion was held, in which the oncologist answered various questions about the patient's staging, prognosis, therapy and its anticipated effects. Home visits were offered to all patients, but only those who opted in received them. All patients in both groups had their distress levels assessed at two time points – before the start of 1st chemotherapy course and before the start of the 2nd chemotherapy course. Responses were analysed and compared between the two groups. **Results:** The level of psychological distress was assessed in 126 patients with solid tumours; of them, 88 (69.8%) opted in for a home visit and formed the study group, while 38 refused and were only seen at the clinic and served as the control group. Mean age in the study group was 60.6$\pm$12.4 and 56.9$\pm$14.4 for the controls. In both groups, breast, lung, and colon cancer prevailed. High baseline levels of distress (before the start of chemotherapy) were similarly prevalent in both groups: 72.7% of the home visit group and 65.8% of the control group scored 4 or higher. McNemar's test showed that the number of patients with high levels of distress at the second interview was significantly reduced in the home visit group, from 72.7% to 53.4% ($p < 0.001$), in contrast to the controls, where it remained almost unchanged from 65.8% to 68.4%. In addition, the Wilcoxon test showed that one home visit significantly decreased the level of distress in the study group, from 4.9$\pm$2.6 to 3.4$\pm$2.5 ($p < 0.001$). In contrast, distress levels in the control group, comprising patients who declined home visits, showed no significant improvement, barely dropping from 4.6$\pm$2.8 to 4.2$\pm$2.7 (p = 0.263) between the first and second interviews. **Conclusions:** This study demonstrates that a single home visit by an oncologist after the start of chemotherapy can significantly reduce distress levels in cancer patients and thus enhance overall patient well-being. Promoting resilience in stress management within patients with early stage breast cancer. First Author: Gabrielle Betty Rocque, University of Alabama at Birmingham, Division of Hematology and Oncology, Birmingham, AL

Background: Women with breast cancer often experience persistent psychological distress, including fear of recurrence, which can be exacerbated in marginalized populations. Promoting Resilience In Stress Management (PRISM) is an intervention initially developed for adolescents and young adults with serious illness that builds resilience utilizing skills-based coaching, which may be able to be adapted and deployed to address psychological needs of women with breast cancer. **Methods:** This pilot study examined PRISM's feasibility and preliminary effects in women with early-stage breast cancer undergoing chemotherapy. Six PRISM sessions were delivered individually by trained coaches, targeted getting to know participants, stress-management, goal setting, cognitive-reframing, meaning making, and family integration. Feasibility, the primary outcome, was defined as 70% of participants completing the PRISM intervention, baseline, and follow-up surveys. Secondary outcomes were measured using the Acceptability of Intervention Measure, Intervention Appropriateness Measure, Feasibility of Intervention Measure, PROMIS-Global Quality of Life, Post-Traumatic Growth Inventory, Connor-Davidson Resilience scale, Functional Assessment of Chronic Illness Therapy–Spiritual Well-Being, Fear of Cancer Recurrence Inventory, Patient Health Questionnaire Depression Scale, General Anxiety Disorder–Anxiety Scale, and Patient Activation Measure. Pre- and post- results were analyzed using paired t-tests for continuous measures and McNemar's test for categorical measures. Effect sizes were calculated using Cohen's d and Cramer's V. **Results:** From February to September 2024, 30 patients participated in the PRISM intervention pilot. The study population had a median age of 51 years (IQR 47-59), were predominantly Black (57%) and unemployed at the start of the study (37%). Two patients died, two withdrew, and one patient was lost to follow-up, resulting in a completion rate of 83%, meeting the primary feasibility endpoint. Patients reported that the sessions were acceptable (mean 4.6 [SD 0.7]), appropriate (mean 4.5 [SD 0.9]), and feasible (mean 4.6 [SD 0.4]).The largest effect was observed in participants' resilience (mean 4-point increase; d = 0.6). There was also a mean 14-point increase of patient growth and self-improvement (d = 0.5). Modest effect sizes were observed for improvements in overall spiritual well-being and reductions in fear of cancer recurrence (both d = 0.4). Small effects were observed for depression, anxiety symptoms, patient activation, global health, physical health, and mental health (d = range 0.1 to 0.2). **Conclusions:** The PRISM intervention was feasible amongst a diverse group of women with early-stage breast cancer and effect sizes suggest potential benefit, warranting further investigation in a future randomized control trial. Clinical trial information: NCT06133348. Research Sponsor: American Cancer Society.

Systematic screening of perception of curability among patients with advanced cancer: A longitudinal analysis. First Author: Kayley Ancy, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Clinicians do not routinely assess patients' illness understanding despite its importance in decision making. Systematic screening of illness understanding is a novel approach that normalizes discussion of this sensitive topic, helps identify patients with information needs and allows clinicians to monitor and support their patients' understanding over time. In this study, we examined the changes in perception of curability over time in patients who completed systematic screening at our supportive care clinic (SCC). **Methods:** We implemented universal electronic systematic screening of illness understanding in our SCC using two questions from the Prognosis and Treatment Perception Questionnaire at consultation and every 2 months. We included all advanced cancer patients who completed screening at their consultation and at least one follow-up visit within one year. The primary outcome was patients' perception of curability, which was categorized as accurate if they reported the likelihood of cure as $<$ 25%. Patients were grouped into one of four categories based on responses at their first and last SCC visits: accurate-accurate, accurate-inaccurate, inaccurate-accurate and inaccurate-inaccurate. We examined patient characteristics associated with the inaccurate-inaccurate group versus all others using univariate and multivariate logistic regression analysis. **Results:** 432 patients (mean age 58 [SD 13], female n=248 [57.4%], white n=331 [76.6%]) were included. The mean number of SCC visits was 2.69 [SD 0.9] and the median duration between the first and last SCC visits was 157 days [IQR 129-194]. At visits 1, 2, 3, 4 and 5+, 34% [147/432], 37% [159/432], 36% [71/197], 38% [30/78] and 46% [11/24] of patients had an accurate understanding of their curability (p=0.24), respectively. Comparing the first and last visit, 233 [54%] were inaccurate-inaccurate, 119 [28%] were accurate-accurate, 52 [12%] were inaccurate-accurate and 28 [6%] were accurate-inaccurate. Asian race and greater well-being at baseline were associated with being inaccurate-inaccurate (Table). **Conclusions:** Systematic screening identified that only ~1 in 3 advanced cancer patients had an accurate understanding of their curability at SCC consultation and this did not improve significantly over time. Certain subgroups were more likely to remain inaccurate at last follow-up. Our findings highlight the need to systematically screen for illness understanding and to work towards bridging information gaps with better communication and coping support. Research Sponsor: None.

Multivariate analysis of patient characteristics associated with being in the inaccurate-inaccurate group.

Patient Characteristic	Odds Ratio	95% CI	p-value
Race (versus White)			
Asian	3.92	1.52-12.2	0.009
Black or African American	1.91	0.90-4.26	0.1
Edmonton Symptom Assessment System Well-Being	0.82	0.73-0.93	0.003

A longitudinal analysis of social networks and patient-reported outcomes among young adult cancer survivors. First Author: Katie Darabos, Rutgers School of Public Health, Piscataway, NJ

Background: Nearly 80,000 young adults (YAs; aged 18-39) are diagnosed with cancer each year in the United States with > 80% expected to survive beyond 5 years. Social connectedness (connections/relations with others) is one of the most documented psychosocial factors cited as influencing health and well-being among YA survivors. However, given cancer diagnosis, treatment, and the challenging late effects, the social networks of YA survivors invariably change, including the quantity, quality, and types of relationships. Limited work has focused on identifying the extent of changes within YA survivors' social networks, such as the social network structure (network size) and social network composition (sociodemographic characteristics) that may confer risk. To understand this, we present preliminary data mapping the social networks of YA survivors, analyzing network changes over a 3-month period and associations with depression and anxiety. **Methods:** YAs (N= 25) completed a baseline social network questionnaire capturing social network structure (number of network members), composition (network member characteristics), and types of support each network member provides. YA survivors also completed measures of depression and anxiety at 3 months post baseline. Wilcoxon signed-rank tests assessed changes in social network metrics; correlations examined associations between baseline social network metrics and depression and anxiety at 3 months. **Results:** YA survivors (M_{age}= 27.0, SD= 5.4, range = 18-37) were majority female (56%) and white (56%). YA survivors reported a wide range of cancer diagnoses (leukemia, lymphoma, testicular, thyroid, breast) and were on average 2 years since diagnosis (M= 22 months). On average YA survivors' networks over 3 months contracted by 0.96 people (Z= -2.09, p= 0.036). Social networks changed compositionally over time, with a decrease in second degree relatives (Z= -2.066, p= 0.039) and male network members (Z= -2.17, p= 0.03), but no change in the mean age or in the number of female network members. The types of support that YA survivors received over time also changed, with a decrease in the amount of emotional support (Z= -2.03, p= 0.04). Only the number of parental network members at baseline was positively associated with depression (r= 0.53, p= 0.007) and anxiety (r= 0.51, p= 0.009) at 3 months. There were no other significant associations between baseline social network metrics on depression and anxiety scores at 3 months. **Conclusions:** Despite networks getting smaller and less heterogeneous over time, this was not associated with later depression or anxiety in our preliminary sample. More work is needed to inform the development and delivery of targeted social network interventions focused on intervening upon social network indicators to improve the long-term health and well-being of this vulnerable YA survivor population. Is metastatic cancer curable? A survey of medical oncologists. First Author: Shalini Subramaniam, NHMRC Clinical Trials Center, The University of Sydney, Sydney, Australia

Background: More patients with metastatic cancer are living longer due to treatment advances like immune checkpoint inhibitors and targeted therapies. We aimed to determine oncologists' attitudes about the possibility of cure in metastatic cancer and to understand how they discuss cure with their patients. **Methods:** We invited medical oncologists and medical oncology trainees via a national mailing list and social media to complete a digital 21-question purpose-built survey. Descriptive statistical analyses were conducted. **Results:** Between September and October 2024, 127 respondents completed the survey. Median age was 39 years (IQR 36-45). Most participants worked in an Australian (64%) metropolitan (88%) public practice (56%), and 51% were women. Clinical experience ranged from <5 years (36%), 5 to 10 years (24%) and >10 years (34%) since oncology qualification; 6% were trainees. The most frequently treated cancer types were breast (55% of participants), lung (52%), and colorectal (50%). 82% reported thinking patients with metastatic cancer can be cured. The types of metastatic cancer that participants thought had the highest chance of cure were testicular (81%), melanoma (32%) and colorectal (16%) (Table). At the time of diagnosis, 51% of participants reported they would tell a patient with metastatic cancer that cure is possible. After delivering treatment for metastatic cancer, 29% reported telling some patients that they *have been* cured, while 74% reported telling some patients that they *may have* been cured. During treatment, 1%, 4% and 17% of participants thought a patient had been cured if the cancer had not progressed 1, 2, and 5 years after starting treatment. A greater proportion *thought* cure was a realistic possibility when discussing the benefits of immunotherapy (83%) compared to chemotherapy (40%), but only 44% and 27% respectively reported they would *tell* patients this. When discussing prognosis, most reported using multiple ranges of time with probabilities e.g. best-case, typical-case and worst-case scenarios (68%). **Conclusions:** Although most oncologists in this survey believed metastatic cancer is curable, only a minority would tell a patient with metastatic cancer they have been cured. Research Sponsor: None.

Median cure rates by disease as reported by participants.

Cancer type	Median cure rate (%)	IQR (%)
Testicular	81	71-88
Melanoma	32	20-50
Colorectal	16	9-25
Lung	13	6-21
Genitourinary	8	1-17
Breast	7	4-14
Gynaecological	6	1-12
Head and Neck	5	0-11
Gastroesophageal	2	0-7
Mesothelioma	2	0-7

Sexual health communication and young-onset cancer (YOC): Healthcare practitioners' attitudes and practices. First Author: Louise Kelly, Department of Medical Oncology, Trinity St. James's Cancer Institute, Dublin 8, Ireland

Background: Sexual health-related discussions are often challenging for Healthcare Practitioners (HCPs) and patients, making sexual health communication a frequently neglected aspect of cancer care. HCPs' lack of knowledge regarding LGBTQ+ cancer care contributes to greater unmet survivorship needs.We explored HCPs' attitudes and practices regarding sexual health-related discussions with YOC patients (25yrs–50yrs) to identify barriers and training needs for improving effective communication. **Methods:** A cross-sectional, mixed-methods design was employed. 160 HCPs working with patients with gastrointestinal and head & neck cancers at the Trinity St James Cancer Institute, Dublin, Ireland were invited to complete an anonymised 23-item online questionnaire. Data was analysed using descriptive statistics for quantitative responses, and thematic analysis for qualitative insights. **Results:** 52 respondents included; Medical Oncology (46.2%), Surgical Oncology (36.5%), Radiation Oncology (11.5%), Psych-Oncology (5.8%), and Palliative Care (5.8%). 34.6% (18/52) and 25.0% (13/52) reported 'rarely' and 'never' enquiring about sexual health-related issues during routine consultations. 34.6% (18/52) reported feeling 'somewhat' or 'very' unconfident initiating a sexual health-related discussion, while 5.7% (3/52) reported feeling adequately trained to enquire about sexual health-related issues. 43.1% (22/51) reported feeling 'somewhat' knowledgeable regarding the impact of cancer on sexual health, while 52.9% (27/51) reported they do not have sufficient knowledge regarding LGBTQ+ cancer care needs. Whilst 63.5% (33/52) agreed knowing a patient's sexual orientation and/or gender identity is relevant to their healthcare, 19.2% (10/52) reported asking about sexual orientation in routine practice. Notably, 98.1% (51/52) reported 'rarely' or 'never' enquiring about gender identity. Common identified barriers included: lack of training or knowledge (76.9% (40/52)), inappropriate time/setting (59.6% (31/52)), HCP discomfort (46.2% (24/52)), and patient discomfort (48.1% (25/52)). There was strong interest in receiving formal sexual health-related education and training, and 75.0% (39/52) believed access to a specialist for advice and/or to whom patients could be referred would increase HCPs confidence. **Conclusions:** HCPs acknowledged the importance of sexual health-related communication with YOC patients, yet significant gaps exist in knowledge, confidence, and training, particularly regarding the LGBTQ+ population.These findings underscore the need for targeted training and education to empower HCPs to engage in meaningful sexual health communication. Shared decision-making in follow-up care for lung cancer screening. First Author: Nihal Mohamed, Icahn School of Medicine at Mount Sinai Department of Urology and Oncological Sciences, New York, NY

Background: Shared decision-making (SDM) is a critical component of lung cancer screening (LCS) decisions to ensure patients understand the benefits, risks, and follow-up processes. Follow-up discussions on adherence to LCS present unique challenges, including managing patient expectations, addressing concerns about outcomes, and integrating smoking cessation efforts. This study uses The Centers for Disease Control and Prevention (CDC) SHARE model to examine SDM dynamics to identify areas for improvement in patient-provider communication. **Methods:** A thematic content analysis using ATLAS.ti was conducted by four trained coders on transcripts from primary care provider (PCP) visits between September 2022 and May 2024 with 24 patients referred for LCS. Guided by the CDC SHARE model for SDM—Seek, Help, Assess, Reach, and Evaluate—consultations were analyzed to examine how PCP revisited prior screening attempts and results, engaged patients in follow-up screening decisions, and addressed barriers to continued screening and smoking cessation. Inter-rater agreement ranged from 83.8% to 92.3%. Code prevalence was assessed using frequency counts (i.e., groundedness). **Results:** Five themes from the SHARE model were identified: (1) Evaluating prior LCS decisions made in the past (15), (2) Seeking patient participation in the SDM process by explicitly communicating that a choice about LCS adherence still exists (n = 7); (3) Helping patients explore the risks and benefits of LCS, including clarifying potential risks and outcomes (n = 13); (4) Assessing patient values and concerns regarding LCS, such as fears about false positives or financial burden (n = 8); and (5) Reaching a decision about a new LCS, where PCP guided patients through the decision-making process and confirmed next steps (n = 21). In addition to the themes derived from the SHARE model, two new emergent themes were identified: (a) providing supportive talk and reassurance (n = 7) to address patient uncertainty and encourage engagement in LCS; and (b) addressing smoking cessation if patients indicated that they still smoke (n = 6), with discussions initiated primarily by PCP and narrowly focused on pharmacological treatments. Notably, LCS decision aids were not used or discussed in any consultation. **Conclusions:** This study identifies strengths and gaps in PCP communication during LCS discussions. While PCP assessed patient risk factors and facilitated screening decisions, significant gaps in SDM emerged. Smoking cessation discussions were limited, and decision aids were absent, highlighting missed opportunities for patient-centered care. Follow-up consultations for LCS require addressing barriers to adherence to LCS and integration of smoking cessation as a standard component of care. Incorporating decision aids could improve patient engagement and adherence to long-term screening recommendations. Research Sponsor: None.

Temporal trends of suicide among cancer patients: A SEER database analysis from 2000 to 2021. First Author: Ahmed Bashir Sukhera, Texas Tech University Health Sciences Center, Odessa, TX

Background: Cancer is a known cause of morbidity and mortality, with over 2 million new diagnoses and 600,000 deaths projected in 2024. Some of the most common cancers have shown an increased incidence, including breast and prostate cancer. There is an increasing mortality trend towards younger populations, with colorectal cancer becoming the leading and second most common cause of cancer death in men and women younger than 50 years respectively. An estimated 20-25% of cancer patients suffer from depression, which alongside specific cancer diagnoses and demographic factors translates to increased suicidality. Here we attempt to elucidate the relationship between specific cancer diagnoses and suicide. **Methods:** We conducted a population-based cohort study of suicide/self-inflicted injury deaths among cancer patients using the National Cancer Institute Surveillance, Epidemiology and End Results Program (SEER) over the period 2000 through 2021. The SEER data is comprised of 22 different registries across the United States (US) which captures approximately 47.9% of the US population. We applied simple linear regression with total suicides as response variable and year as predictor variable to estimate the rate of change of the annual number of suicides among cancer patients. Subgroup analysis included sex, age group, household income, and the primary site of cancer. Results are reported as counts and percentage and the rates of change are reported as regression slope and 95% confidence interval (β, 95% CI). **Results:** A total of 16,156 suicide mortalities were identified of which 13,520 (83.7%) were male and 2,636 (16.3%) were female. The total number of suicides rose approximately ten-fold from 123 in 2000 to 1,211 in 2021 corresponding to β = 54.6 / year (95% CI 50.6 – 58.7). Male suicides rose from 107 in 2000 to 1,017 in 2021 (β = 44.6 / year (95% CI 41.7 – 47.5)) while Female suicides rose from 16 in 2000 to 194 in 2021 (β = 10.0 / year (95% CI 8.6 – 11.5)). The most common primary cancer sites were prostate 3,624 (22.4%), lung and bronchus 1,699 (10.5%), urinary bladder 1,108 (6.9%), and breast 977 (6.0%). Prostate cancer suicides increased from 16 in 2000 to 283 in 2021 (β = 14.0 / year (95% CI 12.9 - 15.1)). Lung cancer suicides rose from 36 in 2000 to 122 in 2021 (β = 2.6 / year (95% CI 12.9 - 15.1)). Breast cancer suicides rose from 4 in 2000 to 80 in 2021 (β = 4.0 / year (95% CI 3.3 – 4.7)). The distribution of ages among suicides was 14.0% for under 50 years old, 19.3% between 50 and 59, 27.8% between 60 and 69, 26.5% between 70 and 79 and 12.5% for 80 years old or greater, with each age group demonstrating significant increase in annual suicides over the period analyzed. **Conclusions:** A significant and increasing trend of suicide is observed across various cancers. Almost half (47.1%) of suicide attempts were among patients between 50 and 69 years. Males committed suicide more often than females, an exacerbation of the trend seen in the general population. Adequacy of immune checkpoint inhibitor-associated thyroid function monitoring following therapy. First Author: Maria Antonia Velez Velez, Department of Medicine, Division of Hematology/Oncology, University of California, Los Angeles, Los Angeles, CA

Background: Immune checkpoint inhibitor (ICI)-induced thyroid dysfunction is the most common endocrine immune-related adverse event. While ICI-induced thyroid dysfunction rates during therapy are well documented, data on post-treatment dysfunction is limited. Describing these rates is important as ICIs are increasingly used in the curative treatment setting. This study aimed to evaluate the rates of post-ICI thyroid dysfunction, evaluate for predictors of post-ICI thyroid dysfunction and assess adequacy of post-ICI thyroid function surveillance. **Methods:** A retrospective analysis of 3626 patients treated with ICIs for various malignancies and cancer stages within a single health system from March 2013 to December 2022 was conducted. Rates of clinically acted upon thyroid dysfunction (diagnosis or thyroid-directed medication) were evaluated before, during, and after ICI therapy, alongside rates of thyroid laboratory surveillance in the post treatment setting. A multivariate analysis evaluated the odds of developing clinically acted upon post-ICI thyroid dysfunction based on patient/treatment characteristics. Rates of clinically acted upon thyroid dysfunction were evaluated based on therapy duration. Statistical analyses were carried out using R V4.1.0. **Results:** Clinically acted upon thyroid dysfunction occurred in 8.1% of patients (294/3626) during treatment and 4.4% (159/3626) after treatment. However, in patients alive two months after ICI cessation, 53.9% (989/1834) had no post-ICI thyroid function tests performed. Among the 1170 patients with post-ICI thyroid labs and no prior dysfunction, 11.6% (136/1170) developed post-ICI thyroid dysfunction. Thirty percent of patients with abnormal TSH values and no clinically acted upon thyroid dysfunction prior to therapy discontinuation subsequently developed clinically acted upon thyroid dysfunction. The rate of post treatment thyroid dysfunction in patients who underwent thyroid test surveillance and received $<$9 months of therapy was 13.3% compared to 6.5% in those who received therapy $>$9 months. The odds ratio for developing post-ICI dysfunction were 1.76 (95% CI, 1.03 to 2.95) for patients with urologic malignancies compared to patients with respiratory malignancies as the reference group. **Conclusions:** Post-ICI thyroid dysfunction is frequent, with 11.6% of patients who undergo thyroid function surveillance being affected. Patients with abnormal TSH before ICI discontinuation and those who received treatment for $<$ 9 months as well as those with urologic malignancies may benefit from more stringent post-ICI surveillance. Equivalence of Ina, an AI-based nutrition platform, to human dietitians for counseling patients with cancer. First Author: Marissa Buchan, Savor Health LLC, New York, NY

Background: Addressing nutritional issues in patients with cancer can reduce symptoms, shorten hospitalizations, enhance treatment adherence, and improve quality of life. However, most patients never receive nutrition counseling due to dietitian workforce shortages and healthcare access disparities. Advances in artificial intelligence (AI) and high rates of mobile device utilization among all demographics provide opportunities to expand reach. This study assessed if guidance from an expert-designed AI nutrition platform, "Ina", is equivalent to that of human Oncology-Credentialed Registered Dietitians (RD-CSO). **Methods:** RD-CSOs were recruited from a professional message board and grouped by quartiles of RD experience (yrs). We randomly selected 1 from each quartile as "Responders" (n = 4) and 3 with $>$10 yrs experience as expert "Reviewers" (n = 3). To compare Ina to RD Responders, a list of 20 top oncology nutrition queries was developed and assigned to 10 hypothetical patient profiles representing common cancer types, comorbidities, side effects, food allergies and preferences. Both Ina and RD Responders answered the queries. The Reviewers then blindly rated each answer (n = 100) using a modified version of the validated Quality Assessment of Medical AI (mQAMAI) instrument, which individually scores domains of accuracy, clarity, relevance, completeness, and usefulness yielding a total score between 5-25. Within-query differences between Ina and Responders were expressed as mean differences (SD) and tested for significance using a Signed Rank or two-tailed paired T-test. Equivalence was defined a priori as a mean within-query difference $<$ 5. **Results:** The criteria for equivalence was met and no statistically significant differences were found between the total scores of Ina and each RD Responder. Ina's average total score was superior to the combined RD Responders (19.3 vs 18.3, 95% CI [0.1,1.8]; p = 0.02). A descriptive analysis of individual mQAMAI domains demonstrated higher scores for Ina compared to averaged RD Responder scores (Table). Ina had a 54% faster response time (8.5 vs 18.5 min per 2 queries; CI [-0.21,-0.13]; p $<$ 0.001) and 27% easier readability (Flesch-Kincaid grade level 7.2 vs 9.9; CI [-3.3,-1.9]; p $<$ 0.001). **Conclusions:** Ina provides equivalent nutritional guidance to that of human dietitians for patients with cancer, with greater speed and readability. This technology offers a solution to meet the needs of patients with cancer in settings where access to dietitians is limited. Research Sponsor: Savor Health LLC.

Mean mQAMAI score.

	Total Quality Score	Accuracy	Clarity	Relevance	Completeness	Usefulness
AI-Platform Mean (SD)	19.3 (2.7)	3.9 (0.7)	4.2 (0.5)	4.1 (0.6)	3.3 (0.8)	3.8 (0.7)
RD Responders Mean (SD)	18.3 (3.0)	3.8 (0.7)	3.9 (0.6)	3.9 (0.6)	3.2 (0.8)	3.5 (0.7)

Immune profiling to identify predictive biomarkers and highlights the potential efficacy of IL-6R blockade in checkpoint inhibitor–related myocarditis. First Author: Michel Obeid, CHUV, LCIT Center, Lausanne, Switzerland

Background: Immune checkpoint inhibitor–associated myocarditis (ICI-My) is a rare but potentially life-threatening complication. Advancing our understanding of its underlying immunological mechanisms is essential for the development of improved diagnostic tools and treatment strategies, with the aim of minimizing morbidity and mortality. **Methods:** This retrospective single-center study (July 2019–June 2024) identified 33 patients who developed ICI-My. A Comprehensive immuno-profiling was conducted using 49 cytokines, 7 traditional cardiac biomarkers, and 46 mass cytometry markers. These profiles were compared to the baseline levels of a cohort of 97 cancer patients prior to ICI treatment. The analysis assessed the identification of biomarkers for differentiating low and high-grade myocarditis and corticosteroids (CS)-refractory ICI-My. The therapeutic efficacy of tocilizumab was assessed in eight cases of CS-refractory myocarditis. **Results:** ICI-My patients showed marked elevations in IL-6, CXCL9, CXCL10, CXCL13, VEGF-A, and sCD25 compared with baseline cancer patients prior to ICI initiation. High-grade myocarditis was characterized by lower levels of CCL4 and CXCL12, with predictive accuracies of 78.6% and 82.1%, respectively. In contrast, conventional biomarkers (cTnT, cTnI, CK, CK-MB, NT-ProBNP, and d-dimers) failed to differentiate disease severity. Mass cytometry revealed a distinct immune profile in ICI-My, including increased immature neutrophils, reduced switched and unswitched memory B cells, elevated double-positive ($CD38^+$/$HLA\text{-}DR^+$) T cells across $CD4^+$ and $CD8^+$ subsets, decreased $CXCR5^+$ leukocytes, and diminished CXCR3 expression within all memory T-cell subsets. Notably, no complement activation was detected. HGF, CXCL10, and BDNF successfully discriminated patients requiring immunosuppression from those untreated (accuracies of 89%, 79%, and 79%, respectively), while IL-18 and CCL4 predicted the need for tocilizumab (TCZ) therapy (accuracies of 79% and 82%, respectively). This underscores the dual benefit of CCL4. In addition, all cases of corticosteroid (CS)-refractory myocarditis (n = 8), including those unresponsive to mycophenolate mofetil or infliximab, responded effectively to TCZ. **Conclusions:** This study provides the first comprehensive immuno-profile of ICI-My. CCL4 and CXCL12 outperformed some traditional cardiac biomarkers as prognostic tools, while IL-18 and CCL4 emerged as key predictors for tocilizumab therapy, which could offer a personalized therapeutic approach. The absence of complement activation indicates that cytokine-mediated and cellular pathways are central to ICI-My pathogenesis. Notably, the success of anti-IL-6 therapy in CS-refractory cases highlights new therapeutic opportunities, enhancing patient care and guiding future interventions. Comparison of two electroacupuncture regimens on symptoms and brain structures in breast cancer survivors: A randomized, controlled trial. First Author: Alexandre Chan, University of California, Irvine, Irvine, CA

Background: Although electroacupuncture (EA) has shown usefulness in managing neuropsychiatric symptoms in cancer survivors, a specific acupoint regimen has not been established. We conducted a randomized, controlled, patient- and assessor-blinded pilot trial to compare two EA regimens on neuropsychiatric symptoms and associated brain structural changes in breast cancer survivors. (Clinicaltrials.gov: NCT05283577). **Methods:** Breast cancer survivors who self-reported cognitive impairment, fatigue, insomnia, or psychological distress were randomized (1:1) to receive ten weekly therapeutic EA to target either neuropsychiatric-specific (nEA) or non-neuropsychiatric-specific (sham EA, sEA) acupoints. Outcomes were assessed using patient-reported outcomes (EORTC QLQ-C30, FACT-Cog, MFSI-SF), neurocognitive tests (CANTAB), and neuroimaging (measuring gray matter, white matter, cerebrospinal fluid, diffusion tensor metrics, and volume and mean intensity of the hippocampus) before and after treatment. We computed group-specific treatment effect sizes (Glass's Δ) adjusted for baseline variability using linear mixed models. A Pearson's correlation analysis was performed between the neurocognitive scores and the imaging metrics. Multiple testing was controlled via the Benjamini-Hochberg method, with statistical significance set at P-adjusted < 0.05. Adverse events (AEs) were graded with CTCAE v5. **Results:** Thirty-five participants were recruited, of which five dropped out, leaving 30 (86%) completing all treatment sessions. The average ($\pm$SD) age was 58.2 $\pm$12.2 years, with 66% non-Hispanic White, 77% holding a Bachelor's degree or higher, 94% received systemic treatment and/or radiotherapy for cancer, 86% reporting $\geq$2 neuropsychiatric symptoms. Both groups showed statistically significant pre-post medium-to-large effect sizes in perceived cognitive function, fatigue, and quality of life. nEA group observed significant improvement in cognitive domains of attention (ES=0.708, P-adjusted=0.004), memory (ES=0.488, P-adjusted=0.026), and emotional functioning (ES=0.664, P-adjusted=0.004). Neuroimages showed greater gray matter volume change (P=0.0327) and post-treatment hippocampus mean intensity (P=0.0468) in nEA versus sEA. In the nEA group, correlations were observed between attention and gray matter volume (P=0.0198) and between executive function and hippocampus volume (P=0.0204). All AEs were grade 2 or lower: nEA participants reported pain (n=1) and bleeding (n=1), while sEA participants reported numbness (n=2), bruising (n=1), nausea (n=1), and redness (n=1). **Conclusions:** Ten weeks of electroacupuncture targeting neuropsychiatric-related acupoints, compared to sham acupoints, improves neuropsychiatric symptoms in breast cancer survivors, supported by clinically relevant structural brain changes. Clinical trial information: NCT05283577. Research Sponsor: California Breast Cancer Research Program; UCI Anticancer Challenge.

MOLGEN: Detecting new DPYD variants for the safer delivery of 5FU and capecitabine. First Author: Helen Winter, University Hospitals Bristol and Weston NHS Foundation Trust, Bristol, United Kingdom

Background: Adverse drug reactions (ADRs) pose a significant challenge to healthcare systems, leading to 6.5-15% of NHS hospital admissions costing over £2.2 billion annually. Genetic factors play a crucial role in predisposing patients to ADRs. One notable example is dihydropyrimidine dehydrogenase (DPD) enzyme deficiency, which affects the metabolism of anticancer drugs like 5-fluorouracil (5FU), capecitabine and tegafur. Current genetic testing in the NHS focuses on four DPYD gene variants associated with European populations, potentially leaving non-European populations at greater risk of drug toxicity. This study aims to expand the genetic evidence base by identifying additional DPYD variants. **Methods:** This observational study recruited patients who experienced grade 3 or 4 toxicities after receiving 5FU and capecitabine, despite undergoing standard DPYD genetic testing. Participants include both European and non-European patients meeting specified inclusion criteria. Blood samples were collected for genetic testing using either Sanger or next generation sequencing of exons and intron-exon boundaries. Clinical data, including administered dose and toxicity grade, were recorded. Clinicians received genetic results to inform discussions with patients about future treatment. **Results:** Fifteen patients experienced grade 3-4 toxicity despite standard testing. Of these patients, one patient was heterozygous for c.2846A $>$ T, and therefore predicted to have decreased DPD activity. This patient was wild-type based on NHS standard testing, and was therefore treated with full dose capecitabine, resulting in Grade 3 diarrhoea and vomiting. However, the Clinical Pharmacogenetics Implementation Consortium (CPIC) dosing guideline suggests a 50% dose reduction in the presence of this variant. Three patients were found to be heterozygous for other DPYD variants, including c.771C $>$ A, c.2786T $>$ C, c.2766+1G $>$ A, and c.1757T $>$ C. for which there are no current dosing guidelines. The functional impact of these variants requires further study, currently ongoing. All three patients had severe reactions after 1-2 cycles of capecitabine, including one patient requiring a seven-week ICU admission for Grade 4 neutropenic sepsis. Seven patients have found to be heterozygous for DPYD variants that result in normal predicted DPD enzyme activity according to current knowledge, but again further work is needed. Four patients had no DPYD variants. **Conclusions:** By broadening the genetic analysis of DPD deficiency and identifying new variants, opportunities exist for enhanced patient safety and treatment efficacy. Expanding the variants in DPYD testing in the future, including those found in diverse ancestral populations could lead to improved dosing strategies and reduced the risk of severe ADRs. The findings have the potential to inform future NHS genetic testing protocols and promote equitable healthcare outcomes. Clinical trial information: iras 7086. Research Sponsor: None.

NG11-2 phase-Ib trial to prevent/reduce severe oral mucositis induced by radiotherapy. First Author: Mary Lei, Guy's and St Thomas' NHS Foundation Trust, London, United Kingdom

Background: Radiation-induced oral mucositis (RIOM) affects up to 80% of people undergoing treatment for head and neck cancer (HNC), reaching nearly 100% in altered or accelerated fractional radiation. Current approaches necessitate multiple supportive care pharmacotherapies with no approved preventative pharmaceutical products available for the reduction of RIOM in patients with HNC. To address this unmet medical need an innovative oral topical vasoconstrictor solution (NG11-2) has been developed and a phase-Ib dose escalation study carried out to assess the safety and preliminary efficacy of NG11-2 in preventing/reducing RIOM in patients undergoing treatment for HNC. **Methods:** In this single arm, multi-centre, phase-1b "2+4" dose escalation study (NCT06669390) using NG11-2, 15 participants, with a diagnosis of HNC and scheduled to receive radiotherapy with at least 30Gy exposure to the oral cavity and/or buccal mucosa (with or without chemotherapy) were enrolled, with 2 each into the 0.92mg/mL, 1.83mg/mL, 3.66mg/mL and 5.5mg/mL dose cohorts. An additional 7 patients were enrolled in the 5.5mg/mL cohort as an expansion phase. Safety was the primary endpoint, with secondary endpoints including duration, incidence and time to onset of severe RIOM using World Health Organization [WHO], Radiation Therapy Oncology Group [RTOG], and National Cancer Institute-Common Terminology Criteria for Adverse Events [NCI-CTCAE] V5 grading criteria, with severe levels being Grade 3 or above. Patient Reported Outcome Measurements were also performed. The Kaplan-Meier method was applied to the expanded dose cohort to estimate the median duration, incidence and time to onset of severe RIOM. **Results:** No Dose Limiting Toxicities or Serious Adverse Reactions were observed during the study. The duration and incidence of severe RIOM were reduced in the 5.5mg/mL cohort (15.5 days and 44.4% using WHO criteria respectively, 14 days and 33.3% using RTOG respectively, 17days and 33.3% using NCI-CTCAE respectively), relative to the 0.92mg/mL cohort (18-46 days and 100% respectively using the WHO, RTOG and NCI-CTCAE criteria). **Conclusions:** NG11-2 is well tolerated in the patient population included in this study. NG11-2 shows encouraging preliminary efficacy results which support proceeding to larger scale confirmation studies. Clinical trial information: NCT06669390. Research Sponsor: None.

Examining the link between p16, an aging biomarker, and a clinically meaningful functional outcome in older adults with early breast cancer. First Author: Chaiyaporn Charles Vatanatham, UCLA Internal Medicine, Los Angeles, CA

Background: Chemotherapy is thought to accelerate aging by disrupting fundamental processes of aging such as cellular senescence. Senescence is a state of terminal cell cycle arrest that is linked to increased inflammation, tissue damage, and impaired regeneration. In older adults with early breast cancer, treatment with neo/adjuvant chemotherapy is associated with persistent increases in circulating $p16^{INK4a}$ (p16) expression, an established biomarker of senescence. However, it remains unknown whether higher levels of p16 correlate with clinically meaningful aging outcomes, such as physical function, in older adults with early breast cancer. **Methods:** We analyzed a prospective cohort of 501 adults age $>$65 with stage I-III breast cancer receiving neo/adjuvant chemotherapy. We assessed physical function using the timed up and go test (TUG), at two time points: pre-chemotherapy (T1) and post-chemotherapy (T2). The TUG score was measured as the time (in seconds) a participant takes to stand up from a standard armchair, walk 3 meters, turn around, walk back to the chair, and sit down. We collected blood at T1 and quantified p16 expression levels in circulating CD3+ T lymphocytes. Expression of p16 was determined using TaqMan quantitative reverse-transcription polymerase chain reaction. We calculated the Spearman correlations to examine the relationship between blood p16 levels at T1 with TUG score at T1, at T2, and change in individual TUG score from T1 to T2. **Results:** The median age of participants was 70 years (range 65-86). The majority (64.4%) had stage II/III disease and 58.1% received an anthracycline. Baseline TUG scores were available for 467 participants and baseline p16 data were available for 317 participants. The mean baseline p16 level was 10.2 $\log_2$ p16 units (SD = 0.9). Mean TUG scores were 11.4 sec (SD = 4.6) at T1 and 11.5 sec (SD = 5.3) at T2. The mean change in TUG score from T1 to T2 was 0.3 (SD = 4.2). There was no significant correlation observed between p16 and TUG score at T1 (r = 0.11, p = 0.05), T2 (r = 0.06, p = 0.36), or the change in TUG score from T1 to T2 (r = 0, p = 0.99). **Conclusions:** In this cohort of older adults with early breast cancer treated with neo/adjuvant chemotherapy, we did not find a correlation between pretreatment p16 and physical function as measured by TUG. Future studies are needed to understand the role of biological aging markers in improving precision risk assessment of treatment toxicity in older adults with cancer. Clinical trial information: NCT01472094. Research Sponsor: U.S. National Institutes of Health; R01 AG037037.

Effect of IV magnesium supplementation in reducing adverse cisplatin associated kidney outcomes.

First Author: Ekta Panjrolia, Section of Hospital Medicine, Central Virginia Veterans Affairs Health Care System, Richmond, VA

Background: Cisplatin is a commonly used chemotherapy agent that is associated with significant nephrotoxicity due to renal tubular cell injury. IV magnesium (mg) has emerged as a potential agent for preventing cisplatin-induced kidney injury. This study aims to explore the efficacy of IV mg in reducing cisplatin induced major adverse kidney events (MAKE). **Methods:** This is a retrospective observation cohort study of the TriNetX research network (with NLP) which included 105 Health care organizations (HCOs). Patients who received first dose of IV Cisplatin between 09/30/2004 to 09/30/2024 were included. Cohort further divided into two groups based on IV Mg supplementation during chemotherapy: IV Mg and Control groups. To mitigate potential confounding variables, we conducted 1:1 propensity score matching (PSM) that involved 42 variables covering demographics, comorbidities, medications, and laboratory results. The primary outcome of interest was MAKE, defined as stage 3 AKI, Dialysis or eGFR $<$ 15 ml/min/1.73m2, Death at 30 days. Secondary outcomes were mortality and dialysis needing AKIs at 30 days. Adjusted hazard ratios (AHRs) with 95% CIs and P values were calculated using Cox proportional hazards regression models for all outcomes. The Kaplan-Meier method was used to estimate survival probabilities after PSM, considering 2-sided p $<$ .05 as statistically significant. Sensitivity analyses with different observations and study window and subgroup analysis were done. **Results:** Our analysis consisted of 106,141 adults who received their first dose of IV Cisplatin. After excluding 519 patients with previous ESRD, 23,761(age 60.1+12.6, Male-51.8%, White-75.1%) were in IV Mg group(22.5%) and 81,861 (age 56.2+14.5, Male-58.5%, White-40.9%) in control group(77.5%). After PSM, each group had 20,647 participants. MAKE incidence was 586/20647(2.84%) in IV Mg group vs. 1934/20647(9.37%) in the control (aHR 0.28; 95% CI, 0.26-0.31). The mortality incidence was 274/20,647(1.33%) in the IV Mg group compared to 515/20,647 (2.49%) in the control group (aHR 0.53; 95% CI, 0.45-0.61). Dialysis needing AKIs were 27/20,647(0.13%) in IV Mg group vs. 102/20,647(0.49%) in control group (aHR 0.26; 95% CI, 0.17-0.40). Sensitivity analysis with 90 days observation window and last 5 years of study period (09/30/2019 to 09/30/2024) and different subgroup analysis showed consistent results. **Conclusions:** IV mg supplementation is associated with reduced MAKE and mortality in patients receiving cisplatin. Research Sponsor: None.

Exploring unmet needs in radiation-induced nausea and vomiting after moderately emetogenic treatment.

First Author: Sarah Arn Lowry, Oregon Health & Science University, Knight Cancer Institute, Portland, OR

Background: Despite their prevalence and clinical significance, interventions to improve radiation-induced nausea and vomiting (RINV) are insufficiently researched and prioritized. The 2020 ASCO Antiemetic guidelines categorize craniospinal radiation therapy (RT) as a moderate risk for RINV requiring 5HT3-RA prophylaxis +/- dexamethasone. Yet, RINV guideline implementation and associated clinical outcomes remain poorly characterized. **Methods:** We performed a retrospective analysis at an NCI-designated comprehensive cancer center. Our primary aim was to determine the proportion of adult patients with guideline-concordant antiemetics prescribed prior to craniospinal RT between 06/2020-10/2023. Patients were excluded if they received concurrent chemotherapy. We selected the first eligible RT regimen. Secondary aims included determining the proportion of consult notes documenting RINV risk, patient report of RINV, and correlating RINV with clinical variables using logistic regression. **Results:** A total of 212 patients met inclusion criteria, with a median age of 67 and 37% were female. The most common malignancies were prostate (27%), breast (14%), and lung (11%). At the start of RT, 44% had a prescription for a 5HT3-RA and 42% had dexamethasone prescribed for pain and/or edema. 41% of radiation oncology consult notes documented RINV as a risk of RT. Overall, 39% of patients reported RINV during or up to 10 days after RT. An increased risk of RINV was associated with a documented history of prior chemotherapy-induced nausea and vomiting (CINV; OR 2.50, p=0.017), younger age (OR 2.28, p=0.018), and a 5HT3-RA prescription prior to the start of RT (OR 1.76, p=0.047). There was no association between RINV and sex, prior chemotherapy, dexamethasone, or 5HT3-RA/dexamethasone combination at the start of RT. **Conclusions:** Despite the prevalence of RINV, standardized prophylaxis remains suboptimal for patients receiving craniospinal RT. A key opportunity exists to enhance patient outcomes by conducting prospective interventional studies to address this unmet clinical need. Research Sponsor: None.

Germline determinants of pneumonitis in patients with cancer treated with antibody drug conjugates.

First Author: Emre Yekeduz, Dana-Farber Cancer Institute, Harvard Medical School, Boston, MA

Background: Antibody-drug conjugates (ADCs) are now essential in the treatment of solid and hematologic cancers. While effective, ADCs can cause adverse events (AEs) requiring careful management. Pneumonitis, a potentially severe AE, may result in treatment discontinuation or mortality. However, its risk factors and underlying mechanisms remain poorly understood. **Methods:** Patients (pts) with solid or hematologic malignancies treated with ADCs at Dana-Farber Cancer Institute up to August 1, 2024, were screened. Only those with available genomic data were included. Pneumonitis was evaluated based on the Common Terminology Criteria for AEs v4.03. A total of 18 candidate single nucleotide polymorphisms (SNPs) linked to drug-related AEs and implicated in ADC metabolism pathways were identified using PharmGKB. SNPs were inferred from targeted panel sequencing using the STITCH pipeline, with 3 SNPs that could not be successfully imputed. The association between the SNPs, as probabilistic dosages, and occurrence of pneumonitis was tested using a multivariable Cox regression model, adjusting for age, sex, race, cancer type, and sequencing panel version. Pts were censored at the end of treatment or death. P-values were adjusted using the Bonferroni correction. **Results:** The study included 1,184 pts with cancer treated with ADCs, encompassing a total of 1,465 ADC treatments, as some pts received multiple lines of ADCs. The median age at treatment initiation was 60 years (interquartile range: 20). Most pts were female (80.7%). Breast cancer was the most common cancer (54.6%), followed by urothelial (13.3%), and ovarian (11.6%) cancers. The most frequently administered ADCs included trastuzumab deruxtecan (33.1%), sacituzumab govitecan (25.1%), and enfortumab vedotin (11.3%). A total of 92 pneumonitis events were observed in 89 pts (Table), among which 54 (58.6%) were grade 2 or higher. The prevalence of pts carrying the minor alleles (intermediate or poor metabolizers) of rs4646437 (CYP3A4) and rs776746 (CYP3A5) was 16.8% and 15.6%, respectively. Multivariable analysis revealed that carriers of the minor allele of rs4646437 (Hazard Ratio [HR]: 3.03, 95% Confidence Interval [CI]: 1.73–5.29, P= 0.001) or rs776746 (HR: 2.43, 95% CI: 1.56–3.81, P= 0.001) had a significantly higher risk of developing pneumonitis, after adjusting for age, sex, race, cancer type, and sequencing panel version. **Conclusions:** Our findings highlight the potential role of inherited genetic factors in modulating treatment-related toxicities of ADCs. Understanding these associations can provide valuable insights into personalized treatment strategies and inform risk assessment to optimize the safety and efficacy of ADCs. Research Sponsor: None.

Rates of pneumonitis.

	% per Group	N

CDK4/6 inhibitor toxicity in geriatric subgroups: Evidence from the FAERS database.

First Author: Bahadır Köylü, Koç University School of Medicine, Department of Medical Oncology, Istanbul, Turkey

Background: Despite their widespread use, the safety of cyclin-dependent kinase 4/6 inhibitors (CDK4/6i) in geriatric patients remains underexplored. **Methods:** We conducted a retrospective analysis of cases reported in the FAERS database regarding CDK4/6i in female breast cancer patients from January 1, 2015, to September 30, 2024, focusing on hematological, gastrointestinal (GI), and liver toxicities. The cases were categorized into different age subgroups. **Results:** We identified 46,871 female patients with breast cancer treated with CDK4/6i (abemaciclib, n = 3,987 [8.5%]; palbociclib, n = 37,020 [79.0%]; ribociclib, n = 5,864 [12.5%]). According to multivariate analysis considering age subgroups, CDK4/6i type, and concomitant treatments, 75-84 age group had a lower risk of hematologic toxicity (OR = 0.93 [95% CI 0.86–1.00]; *P*= 0.040), with a similar trend identified in patients aged ≥85 years (OR = 0.88 [0.76–1.01)]; *P*= 0.077). Ribociclib was associated with a higher risk of hematologic toxicity (OR = 1.31 [1.17–1.47]; *P*< 0.0001), whereas palbociclib was associated with a reduced risk (OR = 0.90 [0.82–1.00]; *P*= 0.041). However, only 75-84 age group treated with abemaciclib (OR = 0.57 [0.41–0.77]) and ≥85 years group treated with palbociclib (OR = 0.85 [0.73–0.99]) showed a reduced risk compared to patients younger than 65, while no significant differences were found among age subgroups treated with ribociclib. Despite the overall higher risk of GI toxicity associated with abemaciclib (OR = 7.53 [6.65–8.56]; *P*< 0.0001), ≥85 years group showed a lower risk compared to patients younger than 65 (OR = 0.59 [0.38–0.88]). The overall risk of GI toxicity was also higher in patients treated with palbociclib compared to ribociclib (OR = 1.17 [1.04–1.31]), with no significant differences observed among the age subgroups. Among patients treated with ribociclib, 65–74 (OR = 1.33 [1.03–1.71]) and 75–84 (OR = 1.45 [1.06–1.96]) age groups showed a higher risk of GI toxicity, while no significant difference was observed in ≥85 years group (OR = 1.64 [0.79–3.04]). Ribociclib was associated with a higher risk of liver toxicity (OR = 1.37 [1.20–1.55]; P < 0.0001), whereas palbociclib was associated with a reduced risk (OR = 0.30 [0.27–0.34]; *P*< 0.0001). In both palbociclib- and ribociclib-treated patients, all geriatric age subgroups showed a reduced risk of liver toxicity (Palbociclib; 65-74 y, OR = 0.80 [0.70–0.91]; 75-84 y, OR = 0.49 [0.41–0.58]; ≥85 y, OR = 0.35 [0.23–0.51]; Ribociclib; 65-74 y, OR = 0.80 [0.67–0.96]; 75-84 y, OR = 0.51 [0.38–0.65]; ≥85 y, OR = 0.52 [0.25–0.95]). However, only 75-84 age group treated with abemaciclib (OR = 0.70 [0.49–0.97]) showed a reduced risk of liver toxicity. **Conclusions:** Our findings demonstrated that liver toxicity was lower across all geriatric age subgroups, and hematological toxicity was reduced only in 75-84 age group. There were no significant differences in GI toxicities among the age subgroups. Research Sponsor: None.

Impact of health literacy in cancer outpatients receiving oral anticancer drugs and followed by the ONCORAL multidisciplinary city-hospital educational follow-up: The LITTORAL study. First Author: Chloé Herledan, Clinical Oncology Pharmacy Unit, Lyon Sud Hospital, Hospices Civils De Lyon, Université Lyon 1, Pierre-Benite, France

Background: Multidisciplinary follow-up is crucial to manage drug-related problems (DRP) associated with oral anticancer therapies (OAT). However, these approaches might fail to address social vulnerability determinants, such as a low level of health literacy (HL), which can be a barrier to patient education and contributes to inappropriate self-management of medications. This study aims to assess the impact of HL on relative dose intensity (RDI) of OAT and health-related quality of life (HRQoL) in cancer patients followed by Oncoral, a multidisciplinary program consisting in personalized face-to-face consultations with a pharmacist and nurse after each subsequent oncologist consultation, to prevent and correct DRPs. **Methods:** This prospective cohort study enrolled adult cancer patients who initiated OAT (baseline) from 11/03/2019 to 24/08/2022 and were followed by Oncoral for $\geq$6 months. HL was assessed at baseline using the HLS-EU16 questionnaire. The primary endpoint was RDI at 6 months, defined as the ratio between the prescribed dose of OAT and the optimal dose to be administered according to Summary of Product Characteristics. A RDI $\geq$80% was considered satisfactory, based on the literature. The secondary endpoint was the variation in HRQoL from baseline to 6 months of OAT, measured by the EORTC QLQ C30 questionnaire. **Results:** This study included 182 patients (58.2% male, median [range] age 69 [29-101] years), mostly with hematological malignancies (60.4%, including multiple myeloma 29.7% and chronic lymphocytic leukemia 11.0%) and breast cancer (12.1%). At baseline, the majority (71.8%) lived with a partner, 20.0% had children living at home. Most were retired (67.1%) but 18.2% worked full-time. Household incomes were inferior to French minimum wage for 20.6% of patients, and 20.6% only received elementary education. Mean HL score was 12.1 $\pm$ 3.12, 52.7% of patients having a HL score considered sufficient (13-16), 32.4% problematic (9-12) and 14.8% insufficient (0-8). RDI at 6 months was evaluable for 135 patients (74.2%), 68.9% of which maintained a RDI $\geq$ 80%. Mean RDI was 83.9 $\pm$ 20.4%. HL had no influence on 6-month RDI. Variation of HRQoL was evaluable for 114 patients (62.6%). Patients with inadequate HL showed lower emotional (p = 0.02) and cognitive scores (p = 0.03) at baseline. A significant improvement was shown at 6 months for global health status (+9.83 out of 100, p = 0.001), emotional functioning (+10.73, p $<$ 0.001), insomnia (-14.03, p $<$ 0.001), pain (-11.76, p = 0.02) and fatigue (-11.76, p = 0.005), with no difference in other scales. **Conclusions:** Cancer patients followed by Oncoral globally maintain a 6-month RDI $\geq$ 80% regardless of HL, with a HRQoL maintained or improving in all dimensions, suggesting that this personalized follow-up benefits to all patients and may limit the impact of social vulnerability. Impact of proton pump inhibitor (PPI) pharmacogenomics (PGx) on toxicities associated with immune checkpoint inhibitor (ICI) therapy. First Author: Laura Carpin Kennedy, Vanderbilt-Ingram Cancer Center, Nashville, TN

Background: There is evidence for the impact of PPIs on clinical outcomes when given concurrently with ICI therapies. Moreover, CYP2C19 genotype impacts PPI metabolism; poor and intermediate metabolizers having higher PPI effectiveness. Cancer patients routinely receive PPIs for acid suppression; we therefore undertook a PGx analysis to evaluate the impact of PPIs on adverse events (AEs) in patients receiving curative-intent ICI therapy. **Methods:** We performed a retrospective analysis on data from four Roche studies with atezolizumab (A) (NCT03197935, NCT02486718, NCT02450331, NCT03038100) and included patients who had available germline whole-genome sequencing information. PGx variants of the CYP2C19 gene were assessed using PharmCAT which predicted metabolizer phenotypes- normal, rapid/ultra-rapid, and poor/intermediate. Exposure to PPIs was categorized using the ConMedClassify R package. The primary outcome was time to the first Grade $\geq$ 3 AE. We used an extended multivariate Cox proportional hazards model that accounted for delayed entry into the PPI exposure class and stratified by study ID. An interaction term was included between PPI exposure, primary cancer treatment (A containing: yes/no), and CYP2C19 metabolizer phenotype. We adjusted for baseline covariates: race, sex, age, BMI, ECOG status, plasma albumin level, and neutrophil-to-lymphocyte ratio. Missing data were imputed with missRanger. Marginal effect estimates were pooled across the completed datasets using the mice R package. **Results:** This analysis included 816 patients who received A as adjuvant/neoadjuvant therapy in triple negative breast cancer, non-small cell lung cancer, and urothelial cancer, or for stage III/IV ovarian cancer indications; and 775 patients who received non-A based treatment as standard of care across corresponding tumor types. Patients receiving A-containing regimen and having a predicted intermediate/poor metabolizer phenotype [(N = 241 (30%)] were more likely to experience Grade $\geq$ 3 AEs if they were exposed to a PPI versus if they were exposed to H2 blocker (HR = 3.117, 1.319 - 7.368 95% CI, p-value = 0.01, FDR = 0.172, Ns in contrast groups: 46 vs 89). The analysis to evaluate the impact of PPI PGx on ICI efficacy outcomes is ongoing. **Conclusions:** Given the widespread use of PPIs in cancer patients receiving ICI therapies, consideration may be needed regarding CYP2C19 genotype data to guide acid suppression therapy. Where possible, prescribing a lower dose of PPI, considering PPIs with less CYP2C19 metabolism, or substituting with H2 blockers in patients receiving curative ICI therapy may minimize the risk of toxicity in patients with intermediate/poor metabolizer status (30% in our cohort from four A trials). This would be especially important in early disease settings where there may be less risk tolerance for toxicity compared with advanced disease. Research Sponsor: None.

Association of *IL7* germline variants with immune-related adverse events (irAEs) in cancer patients (pts) treated with immune checkpoint inhibitors (ICIs). First Author: Eddy Saad, Dana-Farber Cancer Institute, Boston, MA

Background: Despite the transformative impact of ICIs on cancer treatment, their efficacy remains limited by adverse events (AEs), underscoring the need for reliable biomarkers. Here, we aimed to investigate the effect of a previously identified *IL7* SNP in predicting irAEs across two clinical trials and an East Asian pan-cancer cohort. **Methods:** In this pooled analysis, we included 1,205 pts from the CheckMate-025 trial (CM025, NCT01668784) with renal cell carcinoma (RCC) who received either nivolumab (NIVO) or everolimus (EVE), from the BinTA-0037 (BTA-037, NCT03631706) in non-small cell lung cancer (NSCLC) treated with pembrolizumab (PEMBRO), and from the Asan ICI-treated pan-cancer cohort. The rs7816685 SNP dosages were inferred from blood and/or tumor whole exome sequencing (WES) using STITCH for CM025, and Minimac4 for Asan. For BTA-037, a surrogate SNP (rs16906062, R^2=1.0) was extracted from tumor WES. The association between the SNP carrier status and the time to incident AEs was investigated via multivariable cause-specific Cox regression models. RNA-sequencing (RNA-seq) was performed on blood samples from the Asan cohort collected pre- and post-initiation of ICI. Blood immune cell fractions were estimated from RNA-seq data using ImmucellAI. **Results:** The frequency of the risk allele was 15% in CM025, 17% in BTA-037, and 24% in Asan. *IL7* SNP carriers demonstrated a significantly higher risk of AEs when treated with ICI therapies in all 3 cohorts, but not with EVE (non-ICI control) (SNP´treatment $P_{interaction}$=0.0012 in CM025) (Table). The SNP showed a consistent effect across different tumor types and irAE profiles, with no apparent impact on survival outcomes. RNA-seq data revealed the expression of a novel *IL7* cryptic exon in carriers, and a significant increase in peripheral cytotoxic T-cell post-ICI (q=0.002). Both features were significantly correlated (R=0.29, P=1x10-11), suggesting a potential mechanistic link. **Conclusions:** The *IL7* SNP (rs7816685) is associated with a higher risk of immune toxicity in pts treated with ICI. Overall, our findings support the use of this germline biomarker for irAE risk stratification, and pave the way for future functional studies. Research Sponsor: None.

Adjusted hazard ratios (HRs) from multivariable Cox models adjusting for baseline covariates in each cohort.

Cohort	Cancer type	Treatment	N	SNP	adjusted HR for irAEs
CM025	RCC	NIVO	189	rs7816685	3.01 [1.59-5.68], *P*=0.0007
CM025	RCC	EVE	193	rs7816685	0.65 [0.33-1.28], *P*=0.22
BTA-037	NSCLC	PEMBRO	152	rs16906062	2.3 [1.16-4.6], *P*=0.017
Asan	Pan-cancer	Any ICI	671	rs7816685	1.12 [1.02-1.2], *P*=0.015

12130 Poster Session

Impact of cancer related fatigue on quality of life of 1,262 patients with breast cancer receiving chemotherapy: A URCC NCORP nationwide phase III RCT. First Author: Jeremy McGuire, University of Rochester Medical Center, Rochester, NY

Background: Cancer-related fatigue (CRF) is one of the most common and debilitating symptoms reported by cancer patients, significantly impairing quality of life (QoL) across physical, functional, emotional, and social domains. Despite its prevalence, limited data exist quantifying how rapid changes in CRF after a single chemotherapy cycle influence QoL. We aim to evaluate if rapid clinically meaningful changes in CRF post chemotherapy impact QoL in breast cancer patients. **Methods:** This Phase III RCT (NCT03367572) enrolled chemotherapy-naïve breast cancer patients across 21 NCORP practices receiving high/moderate emetogenic chemotherapy. CRF was assessed at baseline and post chemotherapy cycle 1 (n = 1,262) using a four-day home diary, with maximum fatigue change as the primary outcome. For analysis, the CRF variable was dichotomized into two categories: a clinically significant increase ($\geq$3 points) and less than a 3-point increase. QOL was measured with FACT-G and its subscales: emotional (EWB), functional (FWB), physical (PWB), and social (SWB). ANCOVA and Cohen's d effect size (ES) evaluated whether clinically meaningful CRF changes predicted QOL changes across cycles. **Results:** Among 1,262 patients with valid fatigue scores, 74.8% experienced increased CRF after cycle 1, with 53.2% reporting a $\geq$3-point increase and a mean increase of 2.9 points for the group. Clinically significant increases in CRF strongly impacted quality of life (QOL), as reflected in FACT-G Total Score changes post-cycle 1 ($\geq$3: $-$12.4 vs $<$ 3: $-$4.7; mean difference: 7.7, p $<$ 0.001, ES: 0.74), exceeding the clinically meaningful threshold of $>$ 5 points. Analysis of the subscales revealed PWB with the largest changes of 4.8 ($\geq$3: $-$X vs $<$ 3: $-$X; p $<$ 0.001, ES: 1.00). FWB changes were 2.1 ($\geq$3: $-$X vs $<$ 3: $-$X; p$\leq$0.0001, ES: 0.48) and EWB changes were 0.7 ($\geq$3: $-$X vs $<$ 3: $-$X; p $<$ 0.001, ES: 0.26). CRF did not significantly impact SWB. Notably, many of these subscale changes surpassed the clinically meaningful threshold of $>$ 2 points. **Conclusions:** This study underscores the rapid onset and significant impact of CRF on QoL in breast cancer patients receiving chemotherapy. Clinically meaningful increases in CRF, even after a single chemotherapy cycle, were predictive of substantial declines in QoL, particularly in physical and functional well-being. These results emphasize the urgent need for targeted fatigue management strategies, such as tailored interventions addressing physical and functional domains, to improve patient outcomes. Virtual yoga (vYOCAS) intervention for psychological distress: A decentralized digital randomized controlled trial with cancer survivors. First Author: Po-Ju Lin, Wilmot Cancer Institute, University of Rochester Medical Center, Rochester, NY

Background: Psychological distress is highly prevalent among cancer survivors, and it interferes with their ability to recover after treatment and resume normal life activities. Yoga is a promising therapy that may reduce psychological distress and facilitate optimal recovery for survivors. However, accessibility can be limited for survivors who have higher risks of infection due to immunosuppression or high travel burden. Virtual delivery of yoga may increase accessibility for survivors. **Methods:** We conducted a decentralized, digital, phase II randomized controlled trial (RCT) examining the efficacy of virtual yoga compared to usual care for improving psychological distress among survivors. Participants were cancer survivors who completed primary treatment (e.g., surgery, chemotherapy, radiation therapy) within the last 2-60 months. Participants were randomized to receive virtual yoga or usual care. The Zoom platform was used to virtually deliver the Yoga for Cancer Survivors (vYOCAS) intervention. vYOCAS is a 4-week intervention based on gentle Hatha and restorative yoga. Each yoga session was delivered by a certified yoga instructor in small groups (2-4 survivors/group) for 75 minutes, twice a week. Psychological distress was assessed via the Profile of Mood States (POMS) at baseline and post-intervention. POMS evaluated tension-anxiety, depression, anger-hostility, fatigue, confusion, and overall mood. T-tests and ANCOVAs with baseline as a covariate were used to evaluate within- and between-group changes, respectively. **Results:** 42 survivors (93% female; mean age 58.5$\pm$11.6 years; 60% breast cancer; 17% residing in small town/underserved areas) were randomized and completed the study. On average, participants attended 6.2 of 8 prescribed yoga sessions. 44% of vYOCAS participants reported additional home practice of 62.8 minutes over 4 weeks. vYOCAS participants reported significant decreases in psychological distress (tension-anxiety: -1.5$\pm$0.6; depression: -1.2$\pm$0.4; fatigue: -2.4$\pm$0.7; overall mood: -7.3$\pm$2.4; all $p < 0.05$) at post-intervention. Usual care participants did not demonstrate similar improvements. ANCOVA results also revealed that vYOCAS participants experienced significantly greater improvements in fatigue (-2.1$\pm$0.8, p = 0.02) and overall mood (-6.4$\pm$3.1, p = 0.04) compared to usual care participants. No intervention-related adverse events were reported and the majority of survivors would recommend virtual yoga to others. **Conclusions:** vYOCAS is safe, feasible, and amenable for cancer survivors. vYOCAS may also significantly improve psychological distress.Clinicians should consider recommending virtual yoga therapy for survivors with psychological distress to overcome barriers related to accessibility. Future phase III decentralized digital RCTs are needed to confirm these findings. Clinical trial information: NCT04458194. Research Sponsor: National Cancer Institute; UG1CA189961, T32CA102618.

Immune-related endocrinopathy in cancer patients receiving immune checkpoint inhibitor therapy in the nationwide prospective DIRECT cohort. First Author: Hala Awad, University of Rochester Medical Center, Rochester, NY

Background: Immune checkpoint inhibitors (ICIs) have transformed cancer treatment, extending patient survival. However, side effects such as endocrinopathies are common and have severe, sometimes irreversible outcomes if not managed promptly. Predictive factors for endocrinopathies are poorly understood. We examined whether demographic and clinical characteristics are linked with the development of ICI-induced endocrinopathies. **Methods:** The DiRECT Cohort (URCC21038, NCT05364086) is an ongoing observational trial of cancer patients scheduled to receive anti-PD-(L)1 ICI therapy and enrolled through the URCC NCORP Research Base nationwide network. This analysis was based on 1,525 patients with toxicity data assessed 12/31/2024. Endocrinopathies were graded using the Common Terminology Criteria for Adverse Events (CTCAE) criteria version 5.0. Toxicity data was collected after each infusion of ICI. Demographics (age, sex, BMI, race) and clinical factors (cancer type, cancer stage, treatment agent, autoimmune disease, and significant comorbidities) were collected at baseline. We tested bivariate associations with chi-square tests and multivariable associations with logistic regression; statistical significance was set at a p-value of 0.05. **Results:** Of the 1.525 participants, 533 (35%) had lung cancer, 263 (17.3%) had breast cancer, 812 (53.3%) were aged $\geq$ 65, 1142 (75.4%) White, 828 (54.4%) women, 1009 (66.3%) had BMI $<$ 30, 802 (52.7%) had at least one comorbidity, and 128 (8.4%) had an autoimmune disease, 831 (55.2%) had stage IV cancer, and 930 (61.1%) were on pembrolizumab. 252 (16.5%) developed endocrinopathies of any grade: Hyperthyroidism, 61 (24.2%); Hypothyroidism, 156 (61.9%); Thyrotoxicosis, 7 (2.75%); and Adrenal insufficiency, 11 (4.37%). The most common of these were hypo/hyperthyroidism, of which 9% were grade $\geq$2. In bivariate analyses, grade $>$2 endocrinopathies were associated with younger age (11% age $<$ 65 vs. 7% age $\geq$65, p = 0.012), female sex (10% in women vs. 4% in men, p = 0.001), and obesity (12% of those with BMI $>$30 vs 7% with BMI $<$ 30, p = 0.001). We found no significant associations with other factors evaluated. In multivariable logistic regression analyses, younger age, female sex, and obesity were significant predictors, with higher odds of endocrinopathy for those of age $<$ 65 (OR: 1.58, 95% CI: 1.35-1.85), female sex (OR: 1.75, 95% CI: 1.48-2.08), with BMI $\geq$30 (OR: 1.97, 95% CI: 1.68-2.31). **Conclusions:** In this nationwide observational trial, younger age, female sex, and obesity were associated with a higher likelihood of developing grade $\geq$2 ICI-induced endocrinopathies. Future work will focus on identifying biomarkers predictive of endocrinopathy and developing predictive models for risk stratification. Glucagon-like peptide-1 receptor agonists and the risk of chemotherapy-induced peripheral neuropathy in patients with diabetes: A real-world study. First Author: Xiaocao Xu, Department of Hematology and Oncology, University of Vermont Medical Center, Burlington, VT

Background: Chemotherapy-induced peripheral neuropathy (CIPN) is a prevalent condition that significantly affects quality of life in patients with cancer. Diabetes and the use of taxane or platinum-based chemotherapy are major risk factors for CIPN. Glucagon-Like Peptide-1 Receptor Agonists (GLP-1RA) have emerged as promising agents for preventing CIPN due to their potent antihyperglycemic and weight-loss effects. However, the effects of GLP-1RA on CIPN are unknown. **Methods:** We conducted a retrospective, propensity score-matched cohort study utilizing the TriNetX Analytics Network database. Adult patients with concurrent diagnoses of cancer and diabetes who were treated with taxane and/or platinum-based chemotherapy and either GLP-1RA or non-GLP-1RA (including Insulin, Dipeptidyl peptidase-4 inhibitors, Sodium-glucose Cotransporter-2 Inhibitors, Metformin, Thiazolidinediones) anti-diabetes agents were included. Patients with a prior history of neuropathy were excluded. The index date was defined as the initiation of chemotherapy. The primary outcome was the occurrence of CIPN, identified using International Classification of Diseases codes, within one year following the index date. Secondary outcomes included the use of neuropathic pain medications, such as gabapentinoids, serotonin and norepinephrine reuptake inhibitors (SNRI), tricyclic antidepressants (TCA), and tramadol. Cohorts were matched on variables such as age, race, sex, hemoglobin A1c, BMI, cancer type, metastatic disease, and underlying comorbidities. **Results:** We identified 39,772 patients eligible for inclusion, among which 1813 received GLP-1RA and 37,959 received non-GLP-1RA. After propensity score matching, cohorts were all well-balanced across variables. We included 1,763 patients in each cohort for the final analysis. The mean BMI for the GLP-1RA and non-GLP-1RA groups are 32.5 $\pm$ 7.5 and 32.2 $\pm$7.7, and the mean HbA1c are 7.7 $\pm$ 1.8 and 7.6 $\pm$ 1.8, respectively. When compared with patients who received non-GLP-1RA, patients who received GLP-1RA had a higher risk of CIPN (13.9 vs 10.9%, HR 1.34 [95% CI: 1.11 - 1.62]) and significantly increased use of gabapentinoids, SNRI, and tramadol (Table). **Conclusions:** GLP-1RAs are associated with a higher risk of CIPN and greater use of neuropathic pain medications than non-GLP-1RA in patients with cancer and diabetes receiving taxane/platinum-based chemotherapy. Further studies are required to elucidate the possible mechanism underlying the increased risk of CIPN associated with GLP-1RAs. Research Sponsor: None.

	GLP-1RA vs. non GLP-1RA HR (95% CI)	P-value
Chemotherapy-induced neuropathy	1.34 (1.11 - 1.62)	0.002
Gabapentinoids (gabapentin/ pregabalin)	1.26 (1.13 - 1.41)	$<$0.001
duloxetine	1.66 (1.30 - 2.12)	$<$0.001
Venlafaxine	1.56 (1.09 - 2.22)	0.010

Interrogating the interleukin-6 (IL-6)/IL-23/T-helper (Th)17 axis in immunotherapy toxicity: Mechanistic insights and therapeutic implications. First Author: Noha Abdel-Wahab, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Immune checkpoint inhibitors (ICIs) have transformed cancer therapy, but grade $\geq$ 3 immune-related adverse events (irAEs) affect 60% of patients. The mechanisms driving irAEs remain poorly understood, hindering the development of strategies to mitigate toxicity without compromising efficacy. **Methods:** We analyzed biomarkers from an ongoing phase I/II trial (NCT04940299) evaluating tocilizumab (IL-6R blockade) in two regimens; 162 mg subcutaneously weekly (regular dose, RD) or bi-weekly (dose-dense, DD), combined with ipilimumab (3 mg/kg) and nivolumab (1 mg/kg) up to 12 weeks as front-line therapy for advanced melanoma. Longitudinal analyses of blood, tumor, and inflamed tissue biopsies were performed to identify biomarkers for risk stratification and to elucidate the immunobiology of irAEs and antitumor responses across four patient subgroups, categorized by tumor response and the presence or absence of grade $\geq$ 3 irAEs. **Results:** A total of 35 patients were treated with the triplet and followed for up to 15 months. By week 12 after treatment initiation, grade $\geq$ 3 irAEs occurred in 15 patients (43%), with similar frequencies in the RD (44%) and the DD (40%) cohorts. Within 90 days after last tocilizumab dose, the incidence of grade $\geq$ 3 irAEs increased to 56% in the RD cohort but remained unchanged in the DD cohort, resulting in an overall incidence of 51%. The best overall response rate (ORR) was 66%, with 64% in the RD cohort and 70% in the DD cohort. NanoString analysis of tumor biopsies identified 31 upregulated genes in patients with grade $\geq$ 3 irAEs compared to those without, including RORC, a key regulator of Th17 differentiation, which was significantly elevated in longitudinal biopsies (pre: n = 8; post: n = 6) of patients with high-grade irAEs. IL-17, IL-1, and TNF signaling pathways were significantly decreased after tocilizumab treatment in the subgroup of patients without the grade $\geq$ 3 irAEs (pre: n = 14, post: n = 9). LunaPhore-COMET analysis showed elevated Th17 and $\gamma\delta$ T-cell subsets (CD4+ and CD8+) in inflamed tissues compared to matched healthy or tumor tissues. CyTOF profiling of blood showed higher $\gamma\delta$ T-cell levels at baseline in patients with grade $\geq$ 3 irAEs (n = 6), which remained elevated following tocilizumab treatment. **Conclusions:** These findings underscore the pivotal role of Th17 cells in the development of irAEs and suggest that current tocilizumab regimens may provide insufficient IL-6 blockade or require combination strategies, such as concurrent IL-23 inhibition, to more effectively target Th17 cells expansion and maintenance. Notably, this study is the first to identify $\gamma\delta$ T-cells as potential predictive biomarkers for irAEs, yet their utility requires further validation. A randomized phase II trial exploring these mechanisms is underway. Clinical trial information: NCT04940299. Research Sponsor: National Institute of Allergy and Infectious Diseases (NIAID); K01AI163412.

12135 Poster Session

Association between epigenetic clocks and chemotoxicity in older adults with early breast cancer. First Author: Jingran Ji, UCLA Health Jonsson Comprehensive Cancer Center, Los Angeles, CA

Background: Epigenetic clocks are blood-based biomarkers developed to predict biological age and mortality risk from DNA methylation data. Here, we investigated the association between epigenetic clocks and grade 2+ chemotoxicities, given that low grade toxicity has significant clinical impact in older adults with breast cancer. **Methods:** This was a secondary analysis of a prospective cohort of 394 adults age ≥65 with stage I-III breast cancer who completed treatment with neo/adjuvant chemo. We analyzed peripheral blood DNA methylation to estimate epigenetic age acceleration (EAA) prior to chemo. We estimated EAA using three generations of epigenetic clocks (1st gen: Horvath and Hannum; 2nd gen: PhenoAge and GrimAge; 3rd gen: DunedinPACE). Our outcomes of interest were the five most frequently reported grade 2+ chemotoxicities. Using multivariable logistic regression, we examined the association between EAA (as continuous variables) and the chemotoxicities of interest, adjusting for age, stage, race/ethnicity, education, regimen, organ function, cell composition, and geriatric assessment variables. **Results:** The median (range) chronological age of the participants was 70 (65-85). Most (65%) had stage II/III disease, 38% received anthracycline, and 75% received G-CSF prophylaxis. A total of 334 (84.8%) participants experienced a grade 2+ toxicity. The five most common grade 2+ toxicities were fatigue (34%), anemia (31%), infection (30%), neuropathy (20%), and diarrhea (13%). On multivariable analysis, we observed an association between pretreatment GrimAge and infection (OR=1.35, 95% CI 1.03-1.77, p=0.03) as well as DunedinPACE and diarrhea (OR=1.43, 95% CI 1.01-2.03, p=0.04). **Conclusions:** In this study of older adults with early breast cancer, we saw an association between some measures of EAA and select grade 2+ toxicities. Further research is needed to examine how measures of biological age can guide the care of older adults with early breast cancer. Clinical trial information: NCT01472094. Research Sponsor: U.S. National Institutes of Health; R01 AG037037.

In-bedroom renewed air as anti-inflammatory adjuvant therapy in cancer survivors: BREATHS trial. First Author: Eva Hernandez-Garcia, The Bartlett School of Sustainable Construction, University College London (UCL), London, United Kingdom

Background: Inflammation plays a pivotal role in both cancer progression and adverse cardiovascular (CV) effects of anticancer treatments. Cardio-oncology rehabilitation with inflammatory pathways-targeting therapies is emerging as a promising approach for cancer survivors at high risk of CV toxicity. In-home air filtration interventions effectively lower interleukin-6 levels in high-risk populations for CV and respiratory events and significantly impact C-reactive protein (CRP) levels in patients with atherosclerosis. Evidence indicates that CRP can serve as a reliable clinical indicator of residual inflammatory risk and cardiotoxicity after cancer therapy. Concurrent administration of purified air therapy along with conventional pharmacological agents—including statins, cyclooxygenase inhibitors, and beta-blockers—may potentiate the desired therapeutic effect, yet the underlying interactions are not fully understood. We investigate whether overnight in-bedroom air filtration effectively reduces inflammation and cardiac markers in survivors of adult-onset cancer at high risk of CV toxicity. **Methods:** This is a series of N-of-1 randomized, adaptive, blinded, and placebo-controlled trials conducted in the homes of adult survivors residing in densely populated urban areas of Valencia, Spain, with the poorest air quality levels, as evidenced by particulate matter concentrations exceeding the WHO and EU Directive limits. Inclusion criteria are age ≥ 18 years, prior history of breast, colorectal, prostate, lung, or hematologic cancer, exposure to cardiotoxic cancer therapy, and CRP level ≥ 3 mg/L. Participants will be randomly assigned to three treatment sets, each comprising a 14-day period of active therapy (portable air purifier at 275 m^3/h) and a 14-day period of placebo (sham purification). In-bedroom air filtration treatment and placebo will be administered nightly for a minimum of 7 consecutive hours. The blinded sequence will last between 4 and 12 weeks per participant, depending on the clinical efficacy evidenced after each treatment set (CRP < 2 mg/L or CRP reductions ≥ 35%). Participants who fail to achieve the clinically meaningful change in the last treatment set will undergo an open-label phase: 14 days of no treatment and 14 days of active therapy administered nightly and daily (air purifier operating continuously at 275 m^3/h). Participants will be asked to keep a daily in-bedroom time log. The primary endpoint is defined as the change in blood CRP levels after each cycle. Secondary outcomes include changes in D-dimer, serum amyloid A and glycated hemoglobin A1c concentrations, and blood pressure. Exploratory endpoints include the feasibility of at-home point-of-care testing to monitor residual inflammatory toxicity. Ten participants will be enrolled in the trial. No enrolled participants at the time of abstract submission. Clinical trial information: NCT06778122. Research Sponsor: None.

TPS12137 Poster Session

Social genomic mechanisms of health disparities among adolescent/young adult survivors of Hodgkin and non-Hodgkin lymphoma: ECOG-ACRIN EAQ211. First Author: Brad J. Zebrack, University of Michigan School of Social Work, Ann Arbor, MI

Background: Research in human genomics maps molecular pathways through which social and psychological factors regulate gene expression in immune cells and tumor tissue, thus affecting chronic disease progression, symptom development, antiviral resistance, morbidity, and mortality. In many cases, psychosocial factors trigger neural and endocrine responses that regulate expression of genes involved in cancer progression (inflammation, metastasis, treatment resistance) and immune function (stimulating inflammatory genes and suppressing antiviral gene transcription, as observed in the "Conserved Transcriptional Response to Adversity" / CTRA transcriptome signature). However, nothing is known about how such effects impact AYA cancer survivors. This study aims to identify functional genomic pathways through which psychosocial factors influence gene regulation and alter health outcomes in AYA cancer patients; and define the role of such effects in structuring health disparities in post-treatment survivorship. **Methods:** This longitudinal single cohort study is administered through the ECOG-ACRIN Cancer Research Group. Subjects are accrued through the NCI Community Oncology Research Program (NCORP) or self-refer through a broad network of cancer support organizations and clinical programs that serve the AYA population. Accrual goal is 2,000 survivors of Hodgkin or Non-Hodgkin Lymphoma who have achieved complete response to therapy at time of study registration, aged 15-39 years at time of diagnosis, and recruited within three years following completion of treatment. Current accrual is n=117. Upon enrollment, participants complete an online survey of patient-reported outcome measures of social and psychological risk and resilience factors, including quality of life (QOL), social isolation, socioeconomic status, and exposures to childhood trauma. Clinical records are reviewed for medically reported comorbidities and vital status. Data are collected at baseline and repeated every 6 months for two years. Blood specimens also are collected at each time point. The CTRA transcriptome profile will be assayed using an established 53-gene index comprised of a block of 19 pro-inflammatory genes (e.g., *IL1B, IL6, IL8/CXCL8, TNF*) and 34 genes involved in innate antiviral response (e.g., *IFNA/B, IFI-, OAS-*, and *MX*-family genes), with CTRA representing the difference in average expression of those 2 blocks (inflammatory – interferon). CTRA is a biological intermediate state, which is hypothesized to mediate relationships between proposed psychosocial risk and resilience factors and outcomes (morbidity, mortality, QOL). Defining effects of psychosocial conditions on gene expression and their role in structuring disparities for AYA survivors will fill a critical gap in knowledge that informs risk-based models for cancer survivorship care. Research Sponsor: US Department of Health and Human Services, National Institutes of Health, National Cancer Institute; R01CA261752; ECOG-ACRIN Cancer Research Group (Peter J. O'Dwyer, MD and Mitchell D. Schnall, MD, PhD, Group Co-Chairs); UG1CA189828.

Testosterone replacement therapy for fatigue, sexual dysfunction, and quality of life in older men with cancer (TEMEC). First Author: Egidio Del Fabbro, Medical College of Georgia, Augusta, GA

Background: Fatigue is prevalent in men with cancer, affecting 70-100% of survivors. Fatigue impairs quality of life (QOL), increases caregiver burden, and is associated with reduced lean body mass and sexual dysfunction. Muscle loss, fatigue, sexual dysfunction and depressed mood are common in older males with testosterone deficiency, with or without cancer. Testosterone replacement therapy (TRT) in non–cancer patients improves fatigue, body composition and sexual function. However, despite high prevalence of testosterone deficiency in men with cancer (50-90%), no TRT practice guidelines are available. Older age, chronic inflammation, opioids, megestrol acetate, corticosteroids and some anti-neoplastic therapies are implicated in lowering testosterone. A preliminary (n=29) double blind trial comparing 4 weeks of intramuscular (n=13) TRT to placebo (n=16) in men with advanced cancer reported improvement in fatigue and sexual desire scores. Based on these findings, TRT may mitigate fatigue and related symptoms but requires a large, adequately powered trial. **Methods:** Randomized, double-blind, placebo-controlled trial of daily transdermal testosterone or placebo gel for 6-months in men ≥55 years, with solid or hematological cancer. Participants with no evidence of disease or receiving anti-neoplastic therapy are eligible if they report fatigue, have low serum testosterone by mass spectrometry <348 ng/dl or free testosterone <70 pg/ml and the interval from last treatment (chemotherapy, radiation therapy, immunotherapy), is ≤60 months. Ineligibility includes prostate cancer, elevated PSA, hematocrit >48% or recent thromboembolism. Sample size is predicated on 1:1 randomization to two arms, stratified by 3 sites and 90% power to detect relevant effects. Assignment of participants to either testosterone or placebo via permuted block design is known to statistician, study pharmacists, and unblinded study physician responsible for dose-adjustment. By December 2024, 150 of planned 230 participants are enrolled. NCT04301765. Primary outcome is change in fatigue by Functional Assessment of Chronic Illness Therapy fatigue scale (FACIT-Fatigue). Secondary outcomes include Harbor-UCLA 7-day Sexual Function Questionnaire including sexual activity and desire. Additional outcomes include questionnaires of erectile function, positive and negative affect scale (PANAS), Brief Assessment Scale determining Caregiver Burden (BASC) and body composition by dual energy X-ray absorptiometry. Physical performance evaluations include maximal leg press strength, 6-minute walk test and actigraphy. Additionally, lived experiences of 60 participants at baseline and 24 weeks are assessed by semi-structured, qualitative phone interviews with men from testosterone and placebo arms. Clinical trial information: NCT04301765. Research Sponsor: National Institute on Aging; AG061558.

TPS12139 **Poster Session**

Randomized trial of a clinical nurse specialist–led enhanced survivorship and early palliative care intervention for patients with metastatic cancer. First Author: Megha Schmalzle, NYITCOM, Old Westbury, NY

Background: While the benefits of early palliative care and clinician empathy for patients with metastatic cancer are well established, cancer survivorship remains inadequately integrated into the care of patients with distant metastases (Langbaum, N Engl J Med 380: 1300, 2019). Moreover, the optimal model of care delivery is poorly defined. Based on these data, we developed a novel multidisciplinary care model in which the radiation oncology Clinical Nurse Specialist develops therapeutic relationships with survivors with metastatic cancer and identifies and coordinates interventions to address their unmet physical and emotional issues. The goal of this intervention is to improve quality of life and overall survival. **Methods:** Eligible patients are adult patients with metastatic solid tumor malignancy with a predicted median survival of $\geq$1 year using the validated NEAT model. Using block randomization with varying block sizes of 4, 6 and 8, we plan to randomize 100 patients to either usual care or a supplemental Clinical Nurse Specialist led survivorship and palliative care intervention. Patients randomized to the Clinical Nurse Specialist have personalized coordination of services, patient education and referral to supportive care services resulting from additional in-person and phone-based touchpoints. These supplemental interactions address individual needs, such as medication side effects, physical therapy, end-of-life planning and access to community and spiritual resources. The primary endpoint of this trial is patient reported symptom burden using the Edmonton Symptom Assessment System score. Secondary endpoints are patient reported quality of life using the NCCN survivorship assessment and long-term overall survival. To date, 45 patients have been enrolled. Clinical trial information: NCT05947695. Research Sponsor: Good Samaritan Hospital Foundation.

TPS12140 **Poster Session**

Fecal microbiota transplantation (FMT) for opioid-induced constipation (OIC): A prospective, multicenter, single-arm, phase II clinical study. First Author: Xiaoying Wang, Department of Oncology, The Second People's Hospital of Changzhou, the Third Affiliated Hospital of Nanjing Medical University, Changzhou, China

Background: Opioids are the cornerstone of cancer pain management. Opioid-Induced Constipation (OIC) is the most common adverse effect of opioid therapy. OIC significantly impairs patients' quality of life and reduces compliance, making it a major factor in inadequate pain control. Recent studies indicate that opioids cause gut microbiota dysbiosis, with gut microbes playing a role in modulating opioid-mediated analgesia and tolerance, including constipation. Currently, fecal microbiota transplantation (FMT) has been shown to be an effective method for adjusting gut flora by introducing various metabolically active bacteria. Therefore, we initiated this study to evaluate the efficacy of FMT in treating OIC. **Methods:** In this multicenter, single-arm exploratory study, 30 cancer patients aged 18-80 years who receive opioid treatment for manageable pain but suffer from persistent constipation are planned for enrollment. Other inclusion criteria include ECOG status 0-2, expected survival $\geq$3 months, having received opioid therapy for at least two weeks, currently stable opioid dosage, manageable pain with NRS $\leq$4, and ability to undergo standard laxative treatment and anticancer therapy. Patients unable to ingest enteric capsules or requiring antibiotics for infections are excluded. Enrolled patients will receive weekly FMT. The treatment will be administered continuously for 4 weeks, with follow-up until constipation reoccurs or one month after the last dose, whichever comes first. The primary endpoint is the improvement of constipation (assessed by BFI scale), while secondary endpoints include cancer pain before and after treatment (evaluated by NRS scale), quality of life (measured by QLQ-C30 scale), nutritional status improvement, and safety. Blood and fecal samples will be collected during the study for efficacy evaluation. The study is currently in the open recruitment phase, with the first patient enrolled in January 2025. Clinical trial information: ChiCTR2500096421. Research Sponsor: None.

TPS12141 **Poster Session**

A randomized phase III study comparing stereotactic body radiotherapy (SBRT) versus conventional palliative radiotherapy (CRT) for participants with painful non-spine bone metastases (NCT06391242). First Author: Arjun Sahgal, Sunnybrook Health Sciences Center, Toronto, ON, Canada

Background: Stereotactic body radiotherapy (SBRT) is efficacious in the treatment of painful spinal metastases [1]. Data are required regarding the efficacy feasibility, toxicity and clinical outcomes associated with SBRT in patients with painful non-spine bone metastases prior to widespread adoption of this technique. **Methods:** This is a Canadian Cancer Trials Group led multi-centre, phase III randomized controlled trial comparing SBRT to conventional palliative external beam radiotherapy (CRT) in patients with solid tumours and a dominant painful non-spine bone metastasis (worst pain score $>$2). *Treatment arms:* EBRT 20Gy/5fr (control) versus SBRT 35 Gy/5fr or 30Gy/5fr (experimental). *Primary objective*: To compare 3-month complete pain response (CPR) rate and analgesic intake assessed using the International Consensus on Palliative Radiotherapy Endpoints [2]. Secondary objectives evaluate pain response pattern at 1, 3 and 6 months and assess re-irradiation rates, fracture incidence within RT target site, incidence of Grade $>$ 2 adverse events, image-based local control, and patient reported outcomes (EORTC QLQ-C30 and QLQ-BM22). *Statistical design:* The target accrual is 230 patients, randomized 1:1. The trial is powered at 80% with a two-sided alpha of 0.05 to detect an improvement in the CPR rate from 17% (CRT) to 34% (SBRT), accounting for a 15% missing data rate. *Conduct to Date*: Study was activated on June 26, 2024. Supported by CCS grant # 707213. [1] Sahgal, Arjun, et al. "Stereotactic body radiotherapy versus conventional external beam radiotherapy in patients with painful spinal metastases: an open-label, multicentre, randomised, controlled, phase 2/3 trial." *The Lancet Oncology* 22.7 (2021): 1023-1033. Int J Radiat Oncol Biol Phys. 2012 Apr 1;82(5):1730-7. doi: 10.1016/j.ijrobp.2011.02.008. Epub 2011 Apr 12. PMID: 21489705. Clinical trial information: NCT06391242. Research Sponsor: Canadian Cancer Society (CCS); 707213.

TPS12142 **Poster Session**

A phase 1b dose escalation study of AV-380 (anti-GDF15 monoclonal antibody) in combination with standard-of-care therapy in cancer patients with cachexia. First Author: Eric Roeland, Knight Cancer Institute, Oregon Health & Science University, Portland, OR

Background: Cachexia is a complex and common cancer comorbidity associated with a high risk of death. Despite its significant impact, no FDA-approved therapies exist to treat cancer cachexia, and current off-label treatments are limited and increase the risk of side effects. Circulating GDF-15, an inflammatory cytokine involved in the stress response and body weight regulation, has emerged as a main modulator implicated in the pathogenesis of cachexia. Further, preclinical models have shown that elevated levels of circulating GDF-15 elicit cachexia, and GDF-15 expression increases in proportion to disease severity. AV-380 is a high-affinity anti-GDF-15 IgG1 monoclonal antibody resulting in circulating GDF-15 elimination. AV-380 has been shown to reverse weight loss and increase muscle recovery in animal cancer models. In a phase 1 healthy volunteer study (in-house data), AV-380 was well-tolerated without serious AEs. **Methods:** This is an open-label, dose-escalation, multicenter phase 1b study to assess the safety, tolerability, PK, and PD of AV-380. Eligible patients must be $\geq$18 years of age, have cancer with cachexia (per international consensus criteria), receive standard-of-care antineoplastic therapy, have a prognosis of $\geq$3 months, and have an ECOG PS $\leq$2. Patients with known brain metastases (unless treated and stable for $\geq$2 weeks), myocardial infarction or grade 3/4 heart failure ($\leq$3 months), uncontrolled third-spacing of fluids (pleural effusion, pericardial effusion, and/or ascites), or non-cancer-related cachexia, are excluded. Primary endpoints will evaluate the safety and tolerability per dose-limiting toxicities, adverse events (NCI CTCAE v5), and laboratory test results. Secondary endpoints include PK analysis, and exploratory endpoints include anti-drug antibodies, weight changes, patient-reported outcomes (Functional Assessment of Anorexia Cachexia Therapy, Patient Global Impression of Severity, Patient's Global Impression of Change, Patient-Reported Outcomes Measurement Information System) physical function (by digital measures), and body composition (Lumbar 3 Skeletal Muscle Index). Escalating dose cohorts of AV-380 consist of 3-6 patients each, following a standard 3+3 design. The treatment is structured into 28-day courses for each cohort. AV-380 will be administered by IV infusion. Patients will remain on AV-380 until they have unacceptable toxicity, complete 4 courses, withdraw consent, or the sponsor terminates the study. Statistical analyses will be completed by cohort and summarized descriptively. Clinical trial information: NCT05865535. Research Sponsor: AVEO Oncology.

TPS12143 **Poster Session**

Supervised home-based exercise in patients with advanced non-small cell lung cancer (NSCLC) on maintenance immune checkpoint inhibitors (ICI). First Author: Justin Wang Shi, Indiana University School of Medicine, Indianapolis, IN

Background: Lung cancer is the leading cause of cancer-related mortality in the US and results in significant morbidities, including fatigue, depression, and decreased quality of life. Exercise has been shown to reduce severity of fatigue and depression while improving cardiorespiratory fitness (CRF) in patients with lung cancer. Past trials have primarily investigated exercise interventions in patients who received surgery and/or chemotherapy; data on the impact of exercise in patients with lung cancer on immune checkpoint inhibitors (ICI) has been sparse. Following the advent of ICI as maintenance therapy in advanced lung cancer, patients have experienced improved survival and more favorable toxicity profile that better positions them to both participate in and derive benefit from an exercise program. In addition, exercise is expected to promote a patient's response to ICI by promoting mobilization of natural killer-cells and T-cells. Already observed in animal and patient derived xenograft models, the combination of exercise and ICI reduced tumor growth by influencing the tumor microenvironment, increasing tumor infiltrating lymphocytes. In this trial, we are investigating the impact of a supervised home-based exercise program on fatigue, depression, CRF, physical function, muscle mass and biomarkers of immune activation in patients with advanced lung cancer on maintenance ICI. **Methods:** This prospective, randomized phase II trial (NCT06513663) aims to enroll 86 patients with advanced NSCLC receiving maintenance ICI. Patients are randomized 1:1 to an exercise intervention or usual care, stratified by baseline frailty as determined by short physical performance battery (SPPB). Eligible patients have locally advanced (stage III) or metastatic (stage IV) NSCLC and are currently receiving maintenance ICI for at least 1 month with plans for at least an additional 3 months of therapy. The trial is targeting an enrollment of 3-4 patients per month over a period of 2 years, and began in June 2024. Patients randomized to exercise participate in 60-minute sessions including aerobic, resistance, and balance exercises, delivered virtually three days per week for 12 weeks by a professional trainer. The primary endpoint is the change in patient-reported fatigue using the Functional Assessment of Cancer Therapy: Fatigue (FACT-F) questionnaire from baseline to post-intervention, compared between the intervention and usual care. Secondary endpoints include changes in patient-reported depression using Hospital Anxiety and Depression Scale (HADS), muscle mass on CT scan, CRF by VO_{2peak} on a ramp treadmill test, objective and subjective physical function, and adherence to exercise intervention. Exploratory analysis will include changes in circulating tumor cells and T-cell subsets. Patients will be followed post-intervention for up to 2 years. Clinical trial information: NCT06513663. Research Sponsor: None.

TPS12144 **Poster Session**

Virtual personalized exercise program for subjects with lung cancer: A feasibility study. First Author: Melissa Francoise Neumann, Zuckerberg Cancer Center, Northwell Health, Lake Success, NY

Background: With improved outcomes, cancer is increasingly viewed as a chronic disease, highlighting the need for exercise programs to enhance the quality of life for survivors. Unlike heart disease, diabetes, and pulmonary disease, where exercise has been recommended for decades, exercise recommendations for cancer patients have been slow to evolve. Exercise and rehabilitation interventions have shown to clearly benefit cancer survivors by improving outcomes, response and tolerability to treatments, delaying progression, and preventing development of new primary cancer. Despite these benefits and strong endorsements from societies such as ASCO, exercise programs are not typically included in lung cancer treatment plans. **Methods:** This is a single-arm, investigator-initiated feasibility study of a virtual exercise platform targeted to patients with non-small cell lung cancer (NSCLC) who receive surgery (+/-) neoadjuvant/adjuvant chemo (+/-) immunotherapy (cohort A); radiation +/- chemo (cohort B); or systemic treatment only (cohort C) at our Cancer Center. This study will assess the feasibility and usability of this program. Potentially eligible subjects are referred to physiatry for evaluation, enrollment, and personalized virtual exercise prescription, which can be accessed by patients using their personal electronic device. Enrollees complete a baseline quality of life FACT-L questionnaire. Pulmonary Function Test (PFT), Six Minute Walk Test (6MWT), and Sit to Stand Test (STS) are also obtained at the start and end of the 12-month program. FACT-L, Patient and Physician Platform Satisfaction questionnaires are collected every three months. We hypothesize that the virtual exercise program is feasible for patients with lung cancer to participate in and will have beneficial outcomes across all cohorts. The primary objective is feasibility, aiming for 50% of those who qualify and enroll to complete the program at 12 months. The secondary objective is satisfaction, as assessed by patient and provider satisfaction questionnaires. Exploratory objectives include improvement in pulmonary function tests and physical endurance as assessed by the PFTs, 6MWT, and STS, as well as improvement or maintenance of quality of life. **Results:** 20 patients are consented and 10 are active. Of the 10 patients who are no longer part of the study, four were screen-fails, and six patients withdrew consent/did not comply with appointments within the study timeline. Patient compliance increased exponentially after the patient navigator was recruited, who started at the end of November. Since this time, six consents were signed and four remain compliant with the study. **Conclusions:** If feasible and acceptable to patients and providers, this program can be practice-changing, leading to the implementation of virtual exercise prescriptions for patients with all cancer types within Northwell and potentially beyond. Clinical trial information: NCT06540495. Research Sponsor: The Northwell Health Cancer Institute; AstraZeneca; Global Initiatives Group at Northwell.

TPS12145 **Poster Session**

An open-label randomized trial of exercise ± creatine supplementation to augment the adaptations of exercise training in cancer survivors. First Author: Darpan Patel, University of Texas Medical Branch at Galveston, Galveston, TX

Background: Breast cancer survivors face a heightened risk of skeletal muscle wasting, which can be worsened by cancer treatments, adversely affecting their ability to perform daily activities. Additionally, lower extremity muscle weakness has been linked to persistent fatigue in survivors. Research on resistance exercise interventions has demonstrated significant improvements in strength, endurance, and body composition among breast cancer survivors. Nonetheless, developing effective strategies to optimize exercise adaptations for this population remains a critical area of focus. Creatine phosphate (CP) supplementation has gained attention in the medical field because of the numerous health and quality of life benefits. CP is crucial to maintaining muscle energetics because of its role in rephosphorylating adenosine diphosphate to adenosine triphosphate (ATP). To date, few studies have examined the use of CP supplementation to augment exercise adaptations in breast cancer survivors. As such, we propose the THRIVE clinical trial to assess the effects of 12-weeks of CP supplementation in combination with home-based resistance exercise on outcomes of strength, body composition, physical function and mechanistic biomarkers. **Methods:** The THRIVE clinical trial is a prospective, open-label, randomized trial aiming to recruit thirty breast cancer survivors that have completed infusion chemotherapy less than 6 months prior to study enrollment. Patients will be randomized (1:1) to either the CP plus exercise group or exercise only group. Participants who are randomized to receive CP will be initially dosed at 20 g per day for 7 days to boost the availability of CP systemically. Thereafter, the dose will be reduced to 5 g per day for maintenance throughout the duration of the 12-week protocol. All participants will engage in 3 virtually supervised, home-based exercise session each week. Each session will last roughly 1 hour and include a 10-minute warm-up and a 50-minute stimulus phase consisting of upper body and lower body resistance exercises. Primary outcomes will be strength, body composition (DXA scan), physical function (6 min walk test) and mechanistic biomarkers (growth factor and inflammatory biomarkers). Secondary objective will be muscle cross-sectional area and intramuscular creatine, phosphocreatine and ATP as measured by magnetic resonance imaging and spectroscopy, respectively. Tertiary outcomes will be patient reported outcomes on quality of life. To date, 11 of the planned 30 patients have been enrolled. This study is registered with clinicaltrials.gov (NCT06395506). Clinical trial information: NCT06395506. Research Sponsor: Thrivewell Cancer Foundation.

TPS12146 **Poster Session**

A pilot study of the ApricityCare program for early detection and management of treatment-related adverse events in patients with metastatic cancer. First Author: Lily Chen, Department of Internal Medicine, McGovern Medical School, The University of Texas Health Science Center at Houston (UTHealth Houston), Houston, TX

Background: Immune checkpoint therapies (ICTs) induce T cell-mediated anti-tumor immunity and can provide long-term survival benefits for cancer patients. However, ICTs may also cause life-threatening immune-related adverse events (irAEs), often requiring treatment discontinuation and high-dose steroids, leading to significant comorbidities. Early detection and intervention in irAEs can reduce steroid use, enable continuation of ICTs, and improve clinical outcomes. To address the need for earlier detection of severe irAEs, we are implementing ApricityCare, a digital health service that integrates remote symptom reporting via smartphone application, telephone, or text message, with telehealth feedback for patients on ICTs. The platform analyzes patient-reported symptoms and alerts triage nurses to intervene based on pre-specified algorithms. Hypothesis: We hypothesize that early detection and intervention in severe irAEs will improve outcomes and enable ICT continuation. **Methods:** This phase IV clinical trial evaluates ApricityCare's impact on treatment outcomes for patients receiving systemic therapies for metastatic cancer. The study includes a 50-patient run-in phase (Part I) focusing on genitourinary metastatic cancers (prostate, kidney, bladder) to assess feasibility, followed by an expansion of up to 1,000 patients (Part II) across three cohorts: investigational immunotherapies (IO), standard-of-care IO, and standard-of-care non-IO. In Part I, the primary objective is to assess patient symptom reporting via ApricityCare, defined as 80% of patients reporting symptoms for at least 80% of the study duration. Part II aims to determine the rate of therapy discontinuation due to toxicity. Exploratory objectives include associations between alerts and diagnoses, corticosteroid use (>2 weeks), and emergency visits/hospitalizations. Futility for each cohort will be evaluated using a Bayesian optimal phase 2 design, monitoring patients without therapy discontinuation over 3 months. The study is open for enrollment. ApricityCare usage will be analyzed by study phase and cohort. Symptom reporting frequency, Net Promoter Score (NPS), corticosteroid dose, and emergency visit/hospitalization rates will be summarized using frequencies, medians, and interquartile ranges. Time from symptom onset to active management will be assessed with Kaplan-Meier methods. Associations between alerts and confirmed diagnoses will be evaluated for sensitivity and specificity, with clinical diagnoses as the gold standard. The modified intention-to-treat (mITT) population includes all patients receiving at least one anticancer regimen dose. Longitudinal data will be used to identify symptom profiles associated with and preceding irAEs, informing future clinical trials. Clinical trial information: NCI-2024-09566 and MDACC 2024-0229. Research Sponsor: None.

TPS12147 **Poster Session**

ACTIVATE: A pilot randomized activity coaching trial to increase vitality and energy during post-operative pelvic radiation therapy for endometrial cancer. First Author: Avani Dholakia Rao, Radiation Oncology Associates of the National Capital Region, Fairfax, VA

Background: The ASCO-Society for Integrative Oncology guidelines strongly recommend exercise as a therapeutic strategy for cancer-related fatigue (CRF), advising that exercise regimens be tailored to each patient's capabilities. Despite this broad endorsement, at least two-thirds of cancer patients are unable to adhere to the recommendation of exercise due to symptoms and barriers, with women being more likely than men to report barriers to adherence to exercise. There is a lack of data on how to effectively integrate exercise into the treatment regimens of pelvic radiation therapy (RT). Most studies focus on other cancer types or male patients, leaving a significant gap in the literature regarding female patients with gynecological malignancies. Given the high prevalence of CRF and its impact on QoL, interventions reducing fatigue are vital. The primary objective of the ACTIVATE pilot trial(NCT06746428)is to evaluate the feasibility and acceptability of conducting a randomized trial with an exercise coaching program as the intervention in this patient population. Secondary objectives include estimating preliminary efficacy of exercise coaching on fatigue and health-related quality of life, quantifying baseline fatigue levels in our patient population, assessing eligibility criteria suitability, and exploring behavioral mechanisms and variables influencing intervention strength. **Methods:** The study methods include randomization of immediate versus delayed intervention with attention-control of 16 women treated with total or modified radical hysterectomy and surgical staging for Stage I-IVA endometrial cancer and are planned to complete pelvic RT as part of their adjuvant treatment. The intervention is an exercise coaching program which will consist of weekly check-ins for 10 weeks with a certified oncology exercise coach with a goal to address readiness for exercise, identify barriers, and develop an individualized plan for exercise for each week with a goal of increasing activity to 150 minutes of moderate activity per week. The immediate-start group begins with the start of RT; the delayed-start group starts at 6-8 weeks post-RT. Participants will be asked to wear an activity monitor to track steps and moderate activity minutes, complete assessments of patient-reported fatigue (FACIT-Fatigue), bowel/urinary toxicity (EPIC), sexual function and satisfaction (PROMIS), and quality of life (PROMIS-29+2 Profile v2.1), and participate in a six-minute walk test (6MWT) at predefined time points throughout the study. Feasibility will be evaluated on a prior goal of 50% provider acceptability, 50% patient acceptability, 50% appropriateness of screening criteria, and 70% adherence to the coaching session and physical activity monitor. Enrollment began in January 2025 and accrual is expected to be complete within 6 months. Clinical trial information: NCT06746428. Research Sponsor: None.

TPS12148 **Poster Session**

A phase II randomized placebo-controlled study of fisetin and exercise to mitigate chemotherapy-related functional decline in postmenopausal women with early breast cancer (PROFFi). First Author: Jingran Ji, UCLA Health Jonsson Comprehensive Cancer Center, Los Angeles, CA

Background: Despite substantial improvements in survival, postmenopausal survivors of breast cancer remain at high risk of functional decline after cancer treatment. One potentially targetable mechanism of chemotherapy-related functional decline is cellular senescence, a state of cell cycle arrest. Senescent cells (Sncs) develop a senescence-associated secretory phenotype (SASP), where they secrete a milieu of inflammatory cytokines that drive functional decline over time. In patients with stage I-III breast cancer treated with chemotherapy, markers of Sncs and SASP sharply increase after treatment and persist over time. Emerging data suggest that senolytics and exercise can decrease Snc burden. Senolytics are novel agents that eliminate Sncs and improve physical function in non-cancer populations. Among the existing senolytics, fisetin is a natural compound that is safe and tolerable in humans. Exercise also reduces Sncs in individuals without cancer and is well-established to improve physical function in survivors of cancer. More recent pre-clinical data shows that senolytics combined with exercise led to a greater reduction in Sncs than either intervention alone. However, no studies have tested whether senolytics and exercise, either alone or in combination, can reduce Sncs and improve physical function in cancer survivors. Therefore, we hypothesize that targeting Sncs with a combination of fisetin and exercise will lead to both independent and synergistic effects to prevent physical function decline in postmenopausal breast cancer survivors. **Methods:** This multicenter phase II randomized, placebo-controlled study will enroll 200 postmenopausal women with stage I-III breast cancer. Key eligibility criteria include completing neo/adjuvant chemotherapy within 12 months with diminished physical function as measured by the 6-minute walk distance (6MWD). Using a 2x2 factorial design, participants will be randomized 1:1:1:1 to exercise with fisetin, exercise alone, fisetin alone, or a control group for a total 16-week course. Fisetin will be dosed at 20mg/kg on days 1-3 every 14 days. Those randomized to the exercise arms will undergo a tailored, supervised remote exercise program led by a qualified exercise physiologist. The primary objective is to determine the effect of fisetin and/or exercise on physical function, as measured by the change in 6MWD from baseline to end of treatment. Secondary objectives include evaluating the effect of exercise and/or fisetin on other measures of physical, cognitive, psychosocial, and cardiometabolic function as well as digital biomarkers. We will also examine the effect of exercise and/or fisetin on markers of Sncs and SASP. Enrollment on this study began July 2024 and is currently ongoing (NCT06113016). Clinical trial information: NCT06113016. Research Sponsor: U.S. National Institutes of Health; R01 CA280088.

TPS12149 **Poster Session**

Epidermal growth factor receptor (EGFR) inhibitor-induced dermal toxicity treated with topical application of a novel Staphylococcus epidermidis compound. First Author: Mary C. Spellman, Panclarity LLC, San Francisco, CA

Background: Agents targeting the EGFR-mediated signaling pathway are used for the treatment of advanced lung, pancreatic, colorectal, and head and neck cancers. Significant dermal toxicities, occurring in up to 90% of patients treated with EGFR inhibitors (EGFRIs) and other medications inhibiting downstream signaling pathways, may be disruptive to a patient's quality of life and adherence to therapy. Inhibition of the EGFR pathway may suppress host defenses and lead to opportunistic pathogenic colonization or infection. Dermal toxicity is associated with elevated levels of Staphylococcus aureus and IL-36γ. ATR04-484 is an S. epidermidis strain isolated from a healthy human volunteer, selected for its ability to reduce S. aureus colonization and inhibit IL-36γ when applied topically. Reconstructed human epidermis (RHE) and ex vivo pig skin were utilized to measure the effect of ATR04-484 on S. aureus in therapeutic and prophylactic settings with S. aureus added prior to or after ATR04-484, respectively. ATR04-484 inhibited growth of both methicillin-resistant (MRSA) and methicillin-sensitive (MSSA) S. aureus in both therapeutic and prophylactic settings. IL-36γ levels were measured on RHE treated with erlotinib alone or in combination with ATR04-484. Application of ATR04-484 reduced erlotinib-induced IL-36γ to a level comparable to non-erlotinib treated RHE. The effect was dose-dependent; application of 10^9CFU/cm^2 of ATR04-484 showed more potent IL-36γ reduction compared to 10^8 CFU/cm^2. ATR04-484 has a promising profile of activities for the treatment of EGFRI-induced dermal toxicity by significantly reducing *S. aureus* growth and completely ameliorating IL-36γ levels. **Methods:** This multicenter, randomized, double-blind, vehicle-controlled Phase 1/2 clinical study is designed to evaluate the safety and tolerability of topical ATR04-484 (10^9 CFU/g) for the treatment of EGFRI associated dermal toxicity affecting the face of adult patients. ATR04-484 or its vehicle (3:1 randomization) will be applied in a stable volume to all patients and may include application to prioritize affected areas of the neck, chest, back, and paronychial areas (using remaining product on unaffected skin in the same areas, as needed). The key objectives of the study are to assess the safety and tolerability of topical ATR04-484 and to evaluate efficacy signals including severity of disease, pruritus, and pain. The bioavailability of ATR04-484 and pharmacodynamic parameters (including IL-36γ) are also studied. This clinical study will establish the basis for continued clinical development of ATR04-484. Clinical trial information: not yet assigned. Research Sponsor: Azitra Inc.
