Background: Treatment options are limited for ccRCC after disease progression on immune checkpoint inhibitors (ICIs) and vascular endothelial growth factor (VEGF) inhibitors. CD70 is highly expressed on ccRCC. ALLO-316 is an investigational, healthy donor–derived allogeneic CD70 CAR T-cell product designed to recognize and kill both CD70 positive tumor cells and CD70 positive host T cells that drive allorejection. Initial data from the multicenter, phase 1a/b TRAVERSE study (NCT04696731) showed that ALLO-316 had manageable safety and promising antitumor activity. Updated results are presented. **Methods:** Patients were aged ≥18 years, had advanced ccRCC, ECOG PS of 0 or 1, and disease progression after ICI and VEGF-targeted therapy. After lymphodepletion (LD) with fludarabine and cyclophosphamide ± ALLO-647 (anti-CD52), patients received a single infusion of ALLO-316 following a 3+3 design (40-240 $\times$ 10^6 allogeneic CAR+ T cells). Primary end points were incidence of dose-limiting toxicities and adverse events. Objective response rate (ORR) was a secondary end point. **Results:** Of 44 patients who underwent LD, 39 received ALLO-316, and 38 were evaluable for disease outcome. Median age was 60 years, median of 3 prior therapies (range, 1-8), and 36 (82%) had CD70 positive ccRCC. As of January 2, 2025, median follow-up was 6.8 months (range, 0.8-39.5). Dose-limiting toxicities occurred in 2 patients (autoimmune hepatitis and cardiogenic shock in the setting of multiorgan failure). Treatment-emergent adverse events occurred in 42 patients (96%; grade ≥3, 37 patients [84%]). Grade ≥3 CRS occurred in 1 patient (2%; any grade, 25 patients [57%]), grade ≥3 ICANS in 0 patients (any grade, 4 patients [9%]), and grade ≥3 IEC-HS in 1 patient (2%; any grade, 8 patients [18%]). No GvHD occurred. As previously reported, 3 grade 5 adverse events were related to ALLO-316 (cardiogenic shock, failure to thrive, and sepsis). ORR for all LD regimens was 20% (6/30) overall for patients with CD70 positive tumors (Table). Confirmed ORR was 33% (3/9) for patients with CD70 ≥50% treated with the phase 1b regimen; all confirmed responses were ongoing (2.1, 6.7, and 8.4 months at the data cut-off). **Conclusions:** After a median follow-up of 6.8 months, a single infusion of ALLO-316 had manageable safety and encouraging antitumor activity in heavily pretreated patients. Further evaluation of ALLO-316 in CD70 positive ccRCC is warranted. Clinical trial information: NCT04696731. Exploratory analysis from NEOAVAX, a neoadjuvant trial of avelumab/axitinib in patients (pts) with localized renal cell carcinoma (RCC) who are at high risk of relapse after nephrectomy. First Author: Axel Bex, Netherlands Cancer Institute, Amsterdam, The Netherlands, Netherlands

Background: NEOAVAX (NCT03341845) is an open label, single arm, phase II trial, investigating 12 weeks of neoadjuvant avelumab/axitinib prior to nephrectomy in 40 pts with high-risk non-metastatic clear-cell (cc) RCC (cT1b-4 cN0-1 M0, Grades 3-4). Dynamic on-treatment increase of CD8+ tumor infiltrating lymphocytes (TILs) in the tumour microenvironment (TME) and the primary endpoint (radiographic partial response rate (RECIST 1.1) in the primary tumour (PT) in ≥25%) were reported previously together with safety and tolerability [1]. **Methods:** Exploratory analysis included pathologic response in the PT according to the International Neoadjuvant Melanoma Consortium (INMC) and multiplex immune histochemistry (IHC) of the TME including CD8+, CD8-granzyme-B+, CD8+CD39+, Foxp3+ cells and MHC-I in paired samples (pre-treatment biopsy and nephrectomy) from 40 pts;. IHC data were compared to RECIST 1.1 and pathologic response in the PT, and recurrence; Visium spatial transcriptomics was performed on 18 PT from pts with diverging clinical outcome. **Results:** The majority of pts (n=25 (62.5%) had no pathologic response (pNR) by INMC criteria. Twelve patients (30%) had a partial (pPR) and 3 (7.5%) a major pathological response (MPR). There was no association between pathological and radiographic response of the PT. Recurrence occurred in 1 of 3 pts (33%) with MPR at 36 mo, in 7 of 12 (58%) with a pPR at a median of 12 mo and in 14 of 25 (56%) with pNR at a median of 3 mo. Of 25 pts with pNR 7 died of disease (DoD; 28%). On IHC, intratumoural CD8+CD39+ on post-treatment PT samples was significantly associated with recurrence ($p<0.0001$). MPR associated with spatial co-localisation of tumour cells with tissue-resident macrophages, CD8+ cytotoxic T-cells, memory T-cells and B-cells. Gene Set Enrichment Analysis (GSEA) results for Reactome pathways in each Visium tumor spot cluster demonstrated intratumoural heterogeneity in post-treatment PT in select patients. **Conclusions:** Pathologic response and IHC post-treatment influx of CD8+CD39+ TILs associates with prolonged disease-free survival following neoadjuvant avelumab/axitinib. Particularly, pts with MPR had distinct spatial co-localisation gene signatures of tumour and immune cells in the TME. Despite 3 months of treatment, 62.5% of pts had no pathologic responses (defined by INMC as >50% vital tumour remaining in the tumour bed). [1] Bex A et al. Efficacy, safety, and biomarker analysis of neoadjuvant avelumab/axitinib in patients (pts) with localized renal cell carcinoma (RCC) who are at high risk of relapse after nephrectomy (NeoAvAx), in *2022 ASCO Genitourinary Cancers Symposium*. 4510 Clinical Science Symposium

Genomic characterization of baseline and post-progression tumors in IMmotion010, a randomized, phase 3 study of adjuvant (adj) atezolizumab (atezo) vs placebo (pbo) in patients (pts) with high-risk localized renal cell carcinoma (RCC). First Author: Sumanta Kumar Pal, Department of Medical Oncology & Therapeutics Research, City of Hope Comprehensive Cancer Center, Duarte, CA

Background: Although adj atezo did not prolong disease-free survival (DFS) in the IMmotion010 trial, accompanying studies identified post-nephrectomy serum KIM-1 levels to be potentially predictive of benefit with atezo. We investigated whether tissue genomics could complement these findings. **Methods:** Tumors were obtained from patients pre-treatment and (if additional consent obtained) at disease recurrence. Whole transcriptome profiles were generated using TruSeq RNA Access Technology (Illumina). Previously, non-negative matrix factorization (NMF) was performed in a separate phase 3 study in advanced RCC (IMmotion151), establishing 7 molecular subgroups (NMF 1-7) (Motzer *et al* Cancer Cell 2020). For each IMmotion010 tumor, we derived signature scores dichotomized at the median as well as NMF1-7 subtype using random forest. Clinical outcome was assessed within these groups alone and with the addition of baseline serum KIM-1 levels, dichotomized into KIM-1 high (KIM-1^H) and KIM-1 low (KIM-1^L) using the previously established cutoff of 86 pg/mL. Where possible, we sought to characterize the evolution of molecular profiles at disease recurrence. **Results:** Baseline tissue was obtained from 754 pts, reflecting 97% of the intention-to-treat population. Tumors from KIM-1^H patients were enriched in myeloid, granulocyte and proliferation gene signatures at baseline. Among 722 pts for whom both serum KIM-1 and NMF subtype could be characterized, pts in cluster 6 (stromal/proliferative) appeared to derive benefit from atezo (n=50) (Table). Across all patients, no difference in outcome was observed among baseline Teff^H and Teff^L subsets. Within the KIM-1^H population, Teff^H tumors were associated with longer DFS with atezo vs pbo. Paired baseline/recurrence tissue was obtained from 80 pts (atezo: 49; pbo: 31). At recurrence, tumors exhibited increased stromal and proliferation gene signatures, regardless of treatment, reflected in an increased proportion in NMF6 (baseline: 6%; progression: 22%). Exploratory analyses also revealed a decreased MHC-I signature after treatment with atezo. **Conclusions:** This is the first report of tissue genomic profiling in a phase 3 adjuvant immune checkpoint inhibitor study in RCC. While certain molecularly defined subsets may carry predictive value, serum KIM-1 remains the most robust predictor of outcome with atezo. Analyses of progression biopsies highlight an evolution in genomic profile and offer insights into mechanisms of relapse. Clinical trial information: NCT03024996. Research Sponsor: F. Hoffmann-La Roche Ltd.

4511 Clinical Science Symposium

An integrative analysis of circulating and tumor microenvironment (TME) determinants of patient response in the Checkmate 9ER (CM 9ER) trial of nivolumab and cabozantinib (NIVO+CABO) in advanced renal cell carcinoma (aRCC). First Author: David A. Braun, Center of Molecular and Cellular Oncology, Yale Cancer Center, Yale School of Medicine, New Haven, CT

Background: The CM 9ER trial demonstrated increased objective response rate (ORR), progression-free and overall survival in patients with aRCC treated with NIVO+CABO compared to sunitinib (SUN). For vascular modulating therapies (e.g. CABO and SUN) and immunotherapies (like NIVO), the state of the TME and activity of stromal cells can modulate tumor response to therapy. **Methods:** We investigated how the TME and circulating factors were associated with response to NIVO+CABO using pre-treatment tumor PD-L1 staining, human interpretable features (HIF) derived from H&E tissue sections, circulating immune cell populations quantified by flow cytometry, and circulating extracellular matrix (ECM) markers quantified by competitive ELISAs from 150 patients (23% of ITT) enrolled in CM 9ER. We employed principal component analysis, varimax rotation, and Feature Set Enrichment Analysis (FSEA) to identify a subset of biological measurements capturing 85% of the data variability. We constructed a logistic regression model to associate the most variable features with patient response (ORR per BICR) to NIVO+CABO or SUN therapy. **Results:** An unbiased clustering and feature extraction approach was used to identify measurements contributing to multi-modal variability in the TME across 150 patients (~4000 biological measurements reduced to 16 highly informative measurements): PD-L1 staining, 4 ECM markers, 4 PBMC markers, and 7 H&E HIF features. A final binary logistic regression model was built employing lasso regularization to associate these 16 features to short-term response to NIVO+CABO or SUN while minimizing spurious associations. Based on these regression models, the ECM marker VICM, a citrullinated fragment of vimentin released by matrix metalloproteases, and which measures macrophage activity and immune status, was prognostic across both therapies. Logistic regression models that integrated highly informatic features had AUCs of 0.76 for NIVO+CABO model and 0.72 for the SUN model. Within the NIVO+CABO arm, this integrative model uncovered high VICM (and therefore anti-tumor macrophage polarization), high PD-L1 staining, high plasma cell numbers and high cancer cell numbers at the epithelial stromal interface, low levels of circulating fragment of C-terminal type VIa3 collagen (Pro-C6), and low percentages of circulating regulatory (Foxp3+ CD4+) T cells as determinants of therapeutic response. **Conclusions:** Taken together, these findings indicate that the state of the tumor microenvironment and circulating factors together have an effect on patient responsiveness to NIVO+CABO in aRCC and provides a framework for integrative analysis for biomarker discovery. Research Sponsor: None.

4512 Clinical Science Symposium

Gut-associated checkpoint as a prognostic biomarker in metastatic renal cell carcinoma (mRCC): Results from a randomized first-line clinical trial. First Author: Renee Maria Saliby, Yale Cancer Center, New Haven, CT

Background: The gut microbiota modulates anti-cancer immune response and therefore benefit to immune checkpoint inhibitors (ICIs). Gut dysbiosis impacts the MadCAM-1/α4β7 axis leading to recirculation of immunosuppressive α4β7+Tr17 cells into tumors. From mechanistic insight to biomarker development, soluble MAdCMA-1 (sMAdCAM-1) is a circulating surrogate marker of gut dysbiosis. We aim to develop sMAdCAM-1 as a prognostic biomarker to ICI-based therapy in patients (pts) with mRCC. **Methods:** Using a Luminex assay, sMAdCAM-1 levels were measured in available plasma samples at baseline from 612 pts (69% of the intent-to-treat population) from the phase III JAVELIN Renal 101 trial (NCT02684006), which compared avelumab + axitinib with sunitinib in previously untreated mRCC pts. sMAdCAM-1 was examined on the original, per 10^4-scaled, and log-transformed scales. Linear assumption was visually checked by deviance residual and restricted cubic splines (RCS) plots. Optimal cut-off value was established based on the maximum log-rank statistic. Cox regression models were used to assess associations with progression-free survival (PFS) and overall survival (OS). The discrimination of the fitted model was assessed by time-dependent AUC index. **Results:** Higher sMAdCAM-1 levels were associated with improved PFS (median: 13.9 [11.3 - 6.6] vs 8.4 [6.0 - 9.9] months) and OS rate (at 18 months: 84.2% [80.2 - 87.4] vs 68.1% [59.2 - 75.5]). These associations remained after adjusting for IMDC risk groups (Table 1). The optimal cutoff was 180 ng/ml (25% percentile) based on the OS outcome in the whole population. Residual and RCS plots further confirmed a non-linear relationship of sMAdCAM-1 levels with OS and PFS. Median follow up was 18.9 months. The prognostic model incorporating IMDC + sMAdCAM-1 demonstrated a significant improvement in the AUC at 18 months compared to IMDC alone (0.72 vs 0.68; p=0.01). These associations were independent of study arm. **Conclusions:** Higher sMAdCAM-1 is associated with improved outcomes to 1st line regimens in mRCC. sMAdCAM-1 may have an added prognostic value to IMDC. As a diagnostic test of gut dysbiosis, it might guide the selection of pts eligible to microbiota-modulating strategies. The validation in two independent datasets and multi-omics correlation (i.e. fecal metagenomics) are ongoing under an international collaboration network. Research Sponsor: None.

Association of MAdCam-1 with clinical outcomes using Cox regression model.

ENLIGHTED phase 3 study: Interim results of efficacy and safety of padeliporfin vascular targeted photodynamic therapy (VTP) in the treatment of low-grade upper tract urothelial cancer (LG UTUC). First Author: Vitaly Margulis, UT Southwestern Medical Center, Dallas, TX

The full, final text of this abstract will be available at meetings.asco.org on the day of presentation and in the online supplement to the June 10, 2025, issue of the *Journal of Clinical Oncology*.

4514 Rapid Oral Abstract Session

Five-year follow-up results from the phase 3 KEYNOTE-564 study of adjuvant pembrolizumab (pembro) for the treatment of clear cell renal cell carcinoma (ccRCC). First Author: Naomi Balzer Haas, Abramson Cancer Center, University of Pennsylvania, Philadelphia, PA

Background: KEYNOTE-564 (NCT03142334) established pembro monotherapy as the first adjuvant regimen to significantly improve both disease-free survival (DFS) and overall survival (OS) vs placebo (pbo) after surgery for participants (pts) with ccRCC at increased risk of recurrence. We present results from the fourth prespecified interim analysis with a minimum follow-up of 5 yrs. **Methods:** KEYNOTE-564 is a randomized, double-blind, pbo-controlled, phase 3 study, which enrolled adults with ccRCC with intermediate-high (pT2 Gr 4 or sarcomatoid, or pT3 any Gr, N0 M0) or high (pT4 any Gr, N0 M0, or any pT and Gr, N+ M0) risk of recurrence or M1 with no evidence of disease (NED) who had nephrectomy and/or metastasectomy ≤12 wks prior to 1:1 randomization to pembro 200 mg or pbo IV Q3W. Treatment continued for ~1 yr (17 cycles) or until recurrence, intolerable AEs, or physician decision to discontinue treatment. The primary endpoint was DFS by investigator; the key secondary endpoint was OS. The study met its DFS and OS objectives at earlier analyses; thus, no subsequent formal statistical testing occurred. AEs were collected for 30-90 days after treatment cessation depending on severity, with serious treatment-related AEs collected regardless of timing. **Results:** A total of 994 pts were randomized to pembro (n = 496) or pbo (n = 498). The median follow-up time to data cutoff date of 25 Sept 2024 was 69.5 mo (range, 60.2−86.9). All pts completed or discontinued study treatment ≥3 years earlier. 188 DFS events in the pembro group and 241 in the pbo group had occurred. Median DFS was not reached (NR) vs 68.3 mo, respectively (HR 0.71, 95% CI 0.59−0.86); estimated DFS rate at 5 yrs was 60.9% vs 52.2%. 68 OS events in the pembro group and 99 in the pbo group had occurred. Median OS was NR in both arms (HR 0.66, 95% CI 0.48−0.90); estimated OS rate at 5 yrs was 87.7% vs 82.3%, respectively. DFS and OS outcomes were consistent across key subgroups, including by prespecified risk and sarcomatoid features (Table). No new serious treatment-related AEs have been reported for ≥3 years. **Conclusions:** With ≥5 yrs of follow-up, the benefits observed with adjuvant pembro vs pbo are consistent with prior analyses, including in all subgroups. No new serious treatment-related safety signals occurred. Adjuvant pembro remains a standard-of-care option for patients with ccRCC at increased risk of recurrence. Clinical trial information: NCT03142334. Research Sponsor: This study was supported by Merck Sharp & Dohme Corp., a subsidiary of Merck & Co., Inc., Rahway, NJ, USA.

4515 Rapid Oral Abstract Session

Zanzalintinib (zanza) + nivolumab (nivo) ± relatlimab (rela) in patients (pts) with previously untreated clear cell renal cell carcinoma (ccRCC): Results from an expansion cohort of the phase 1b STELLAR-002 study. First Author: Jad Chahoud, Moffitt Cancer Center, Tampa Bay, FL

Background: VEGFR-targeted tyrosine kinase inhibitors (TKIs) in combination with immune checkpoint inhibitors (ICIs) are standard of care for previously untreated metastatic ccRCC. Zanza (XL092) is a novel, oral, multi-targeted TKI of VEGFR, MET, and TAM kinases (TYRO3, AXL, MER), with a short half-life that may have an improved therapeutic index. In the phase 1 STELLAR-001 study, the tolerability profile of single-agent zanza was manageable and antitumor activity was observed in patients with previously treated advanced ccRCC (Pal et al, IKCS NA 2023). STELLAR-002 (NCT05176483) is a phase 1b, open-label study evaluating the tolerability and activity of zanza alone and in combination with ICIs in pts with advanced solid tumors. Here, data from the expansion cohort of pts with previously untreated ccRCC receiving zanza + nivo ± rela are presented. **Methods:** Adult patients with unresectable advanced or metastatic (adv/met) ccRCC of any IMDC risk, and no prior systemic anticancer therapy for adv/met ccRCC were enrolled into one of two non-randomized arms. Patients received zanza 100 mg orally with either nivo 480 mg IV every 4 weeks (q4w) or nivo/rela 480/480 mg IV q4w (fixed-dose combination). Primary endpoints were investigator-assessed ORR per RECIST 1.1 and safety. **Results:** In the zanza + nivo arm (n = 40), 75% had intermediate or poor IMDC risk disease. After median follow-up of 16.1 months, the ORR was 63% (4 complete responses [CRs], 21 partial responses [PRs]), and disease control rate (DCR: CR+PR+SD) was 90%. The 6- and 12-month PFS rates were 83.2% and 64.2%, respectively. The most common any grade (G) treatment-emergent adverse events (TEAEs) were diarrhea (78%), hypertension (58%), and nausea (58%). The most common G3/4 AEs related to zanza were hypertension (30%) and diarrhea (15%). Treatment-related palmar-plantar erythrodysesthesia (PPE) was reported in 28% (8% G3, 0% G4). Two (5%) pts discontinued both study treatments due to treatment-related AEs (TRAEs). Median average daily zanza dose was 49.5 mg (range: 26-100). In the zanza + nivo/rela arm (n = 40), 70% had intermediate or poor IMDC risk disease. After a median follow-up of 11.9 months, the ORR was 33% (1 CR, 12 PRs) and DCR was 90%. The 6- and 12-month PFS rates were 80.2% and 58.8%, respectively. The most common any G TEAEs were diarrhea (60%) and nausea (50%). The most common G3/4 AE related to zanza was hypertension (13%). Treatment-related PPE occurred in 5% (0% G3/4). Seven (18%) pts discontinued all study treatment due to TRAEs. Median average daily zanza dose was 54.9 mg (range: 31-100). No G5 TRAEs occurred in either arm. **Conclusions:** First-line zanza had acceptable tolerability in combination with nivo or nivo/rela with a low rate of PPE; zanza+nivo showed promising preliminary activity in pts with adv/met ccRCC. Clinical trial information: NCT05176483. Research Sponsor: Exelixis, Inc.

Ipilimumab and nivolumab in patients with metastatic clear cell renal cell carcinoma (mccRCC) treated on the phase 3 PDIGREE (Alliance A031704) trial: Results from Step 1 analysis. First Author: Tian Zhang, Department of Internal Medicine, Division of Hematology and Oncology, UT Southwestern, Dallas, TX

Background: Ipilimumab/nivolumab (ipi/nivo) is a standard of care first-line treatment (tx) for patients (pts) with mccRCC; however, ideal timing of subsequent immunotherapy txs are not well defined. We performed an analysis of patients initially treated with ipi/nivo and subsequent cohort assignments on PDIGREE (A031704). **Methods:** The PDIGREE trial treated pts with IMDC intermediate/poor risk mccRCC with first-line ipi/nivo (Step 1) at NCTN sites (categorized as academic (A), academic regional (R), and community (C)). Subsequent management was based on iRECIST responses at 12 weeks: pts with complete response (CR) received 1-year nivo maintenance; pts with progressive disease (PD) received cabozantinib (cabo) monotherapy, pts with non-CR/non-PD were randomized to nivo with or without cabo (for primary endpoint of overall survival [OS], target sample size was 1175). Enrollment was held when the randomized sample target was reached. Pts with unresolved toxicity at week 22 were managed off protocol. Step 1 pt demographics, assignments into Step 2, and adverse event (AE) data are presented. Descriptive statistics were used, and cohorts were compared using a chi-square test. These data were released with DSMB approval and do not inform the primary OS endpoint (1EP). **Results:** From May 2019 to May 2024, 1111 pts were enrolled and treated with ipi/nivo. Pt characteristics included median age 64.0 years (range 29.0-86.0); 819 (73.7%) males; White (85.1%), Hispanic (10.4%), Black (4.2%), and American Indian/Native Hawaiian (1.3%); 849 (76.8%) intermediate risk/257 (23.2%) poor risk; 458 (41.2%) at Academic, 113 (10.2%) at Regional, and 540 (48.6%) at Community centers; and 603 (54.3%) with *de novo* metastases. 364 pts (33%) stopped tx in Step 1: 160 (44%) for AEs, 46 (13%) for PD/clinical PD/suspected PD, 42 (12%) withdrawals, 39 (11%) alternative txs, 37 (10%) deaths on the study, 12 (3%) other complicating disease, 8 (2%) MD decision and 19 (5%) other reasons. Of the 37 deaths, 15 (1.4%) grade 5 SAEs were reported, 6 of which were due to PD. Of 747 (67%) pts registered to Step 2 at 3 months, 9 (1.2%) achieved CR, and 141 (18.9%) pts were assigned to the PD cohort. 597 pts (80%) were randomized for the 1EP, notable with fewer pts with poor risk [(21 vs 27%, p = 0.01] and bone metastases [24.5% vs 34.2%, p = 0.0007] compared to Step 1 pts who discontinued tx. Gr 3/4 tx-related AEs in 314/1093 (29%) evaluable pts included diarrhea/colitis (8%), transaminase elevation (3%), rash (2%), adrenal insufficiency (2%), fatigue (2%), and hypophysitis (1%). **Conclusions:** The PDIGREE trial enrolled a representative US-based population with mccRCC. Step 1 pt characteristics and associated outcomes with induction ipi/nivo reveal new insights into the tolerability and tx response of 1L ipi/nivo. Clinical trial information: NCT03793166. Research Sponsor: Alliance Group: U10CA180821, U10CA180882; SWOG: U10CA180888; https://pubs.alliancefound.org/acknowledgments.

Sasanlimab in combination with bacillus Calmette-Guérin (BCG) in BCG-naive, high-risk non–muscle-invasive bladder cancer (NMIBC): Event-free survival (EFS) subgroup analyses based on disease stage from the CREST study. First Author: Thomas Powles, Barts Cancer Centre, Cancer Research UK Experimental Cancer Medicine Centre, Queen Mary University of London, London, United Kingdom

Background: Sasanlimab in combination with BCG (induction [IND] and maintenance [MNT]) significantly improved investigator (INV)-assessed EFS vs BCG (IND and MNT) and had a manageable safety profile in patients (pts) with BCG-naive, high-risk NMIBC, according to the primary analysis results from the phase 3 CREST study. Here, we report exploratory EFS subgroup analyses not previously presented based on disease stage at randomization from Arms A and C. **Methods:** Eligible pts were randomized 1:1:1 to receive sasanlimab in combination with BCG (IND and MNT; Arm A), sasanlimab in combination with BCG (IND; Arm B), or BCG (IND and MNT; Arm C). To assess the impact on efficacy of carcinoma in situ (CIS) and T1 tumors at baseline, post hoc INV-assessed EFS analyses were conducted for the comparison of Arm A vs Arm C. EFS was defined as time from randomization to recurrence of high-grade disease, progression of disease, persistence of CIS (for patients with CIS at randomization), or death due to any cause, whichever occurred first. **Results:** At the data cutoff date (Dec 02, 2024), the median duration of follow-up for EFS was 36.4 and 36.7 months for Arm A and Arm C, respectively. A total of 176 pts with CIS (with or without papillary tumors) were in Arms A and C, 102 of whom had CIS without papillary tumors. A total of 398 pts with T1 tumor were in Arms A and C, 342 of whom had T1 tumor without CIS (Table). Three-year landmark EFS subgroup analyses not previously presented are reported in the table. For patients with CIS, with or without concomitant papillary tumors, the 3-year EFS rate was 83.0% in Arm A and 71.8% in Arm C. For patients with T1 tumors, with or without CIS, the 3-year EFS rate was 81.3% in Arm A and 72.2% in Arm C. **Conclusions:** Sasanlimab in combination with BCG (IND and MNT) improved EFS outcomes in the overall population and in the subgroups of pts with BCG-naive, high-risk NMIBC who had CIS or T1 tumors at randomization. This post hoc analysis further supports the potential of sasanlimab in combination with BCG as a practice-changing treatment in pts with aggressive disease. Clinical trial information: NCT04165317. Research Sponsor: Pfizer Inc.

4518 **Rapid Oral Abstract Session**

First results of SURE-02: A phase 2 study of neoadjuvant sacituzumab govitecan (SG) plus pembrolizumab (Pembro), followed by response-adapted bladder sparing and adjuvant pembro, in patients with muscle-invasive bladder cancer (MIBC). First Author: Andrea Necchi, IRCCS San Raffaele Hospital, Vita-Salute San Raffaele University, Milan, Italy

Background: Standard of care for MIBC is radical cystectomy (RC) with neoadjuvant chemotherapy (CT), but ~50% of patients (pts) are ineligible for/refuse CT and survival for RC alone is dismal. Neoadjuvant Pembro and SG monotherapies showed activity in MIBC within PURE-01 and SURE-01 studies. SURE-02 (NCT05535218) is a phase 2 study of neoadjuvant SG+Pembro and adjuvant Pembro, including a bladder-sparing approach depending on clinical response. We report results of a prespecified interim analysis. **Methods:** Pts age ≥18 y, ECOG PS 0-1, with histologically confirmed cT2-T4N0M0 MIBC, ineligible/refusing CT, and scheduled for RC received 4 cycles of Pembro 200 mg on D1 and SG 7.5 mg/Kg on D1 and D8, Q3W, followed by postsurgical Pembro x 13 cycles, Q3W. A reTURBT is allowed instead of RC, followed by Pembro x 13 cycles, for pts achieving a clinical complete response (cCR), stringently defined as a negative magnetic resonance imaging (MRI) and no residual viable tumor at reTURBT (ypT0). Primary outcome measure is cCR rate: H0≤30%, H1≥45%. Other outcomes: ypT≤1N0-x rate including pts undergoing RC, safety (CTCAE v.5.0), survival. The total sample size is 48 pts in a 2-stage design, with 23 pts enrolled at first stage (≥7 cCR needed). Decipher Bladder (Veracyte, San Diego, CA) was used for transcriptome-wide analyses of primary TURBT tissue. **Results:** From 10/23 to 01/25, 40 pts were treated and 31 were efficacy evaluable. 20 (64.5%) had a cT2 stage, 12 (38.7%) had a centrally confirmed variant histology. The cCR-rate was 38.7% (N = 12; 95%CI: 21.8-57.8); all these pts underwent a reTURBT; ypT≤1N0-x rate was 51.6% (N = 16). Grade ≥3 treatment-related adverse-events occurred in 4 pts (12.9%), 2 dose omissions of SG and one dose delay (1W) were recorded. No SG dose-reduction was needed. cCR varied by molecular subtype. Transcriptome results were available for 23 pts: complete pathologic (ypT0) responses varied by Genomic Subtyping Classifier (GSC) groups with luminal tumors showing higher ypT0 rates vs non-luminal (73 vs 25%, p = 0.04). Similarly, based on Lund subtypes, genomically unstable (GU) tumors had ypT0 response in 67%, vs 57% for urothelial-like, 20% for basal/squamous and 0% for neuroendocrine-like. Higher stromal signature (> median) was associated with non-ypT0 response (p = 0.004), while neither Trop2 (p = 0.15) nor *TOP1* (p = 0.79) gene expression were associated with ypT0 response. **Conclusions:** Perioperative SG+Pembro revealed a compelling cCR rate, with a manageable safety profile, allowing a bladder preservation in ~40% of pts. Pre-treatment molecular biomarker analyses suggest a unique tumor profile associated with cCR. Overall, SURE-02 interim results support the completion of study accrual and further investigation of SG+Pembro in pts with MIBC. Clinical trial information: NCT05535218. 9MW2821, a novel Nectin-4 antibody-drug conjugate (ADC), combined with toripalimab in treatment-naïve patients with locally advanced or metastatic urothelial carcinoma (la/mUC): Results from a phase 1b/2 study. First Author: Shusuan Jiang, Hunan Cancer Hospital, Changsha, China

Background: Nectin-4 is an adhesion molecule that is highly expressed in variety of solid tumors. Previous study of 9MW2821 has shown promising efficacy and tolerable toxicity in different advanced cancers, especially in urothelial cancer, cervical cancer, esophageal cancer and breast cancer. Here we report preliminary results of 9MW2821 combined with Toripalimab in treatment-naïve patients with la/mUC. **Methods:** This is an open-label, multicenter, phase 1b/2 study to evaluate the safety and efficacy of 9MW2821 combined with Toripalimab in la/mUC. Patients received 9MW2821 on D1/D8 and Toripalimab on D1, 21 days per cycle. Primary objective was safety, and secondary objectives were efficacy, pharmacokinetics and immunogenicity. **Results:** 40 treatment-naïve patients with la/mUC were enrolled and received the combination therapy of 9MW2821(1.25mg/kg) and Toripalimab(240mg). Median age was 66.5 years [36-78], and 73% patients were ECOG 1. 55% primary tumor sites were upper tract urothelial carcinoma. As of Dec 19, 2024, ORR was 87.5% [35/40, 95%CI 73.2-95.8], including 7.5% CR rate (comfirmed ORR was 80%). DCR was 92.5% [37/40, 95%CI 79.6-98.4]. Median PFS and DoR were not reached, 6-month PFS rate and 3-month DoR rate were 79.1% and 100%. Furthermore, ORR of subgroups in liver metastasis, bladder cancer and tumor with negative expression of Nectin-4 were 88.2%, 94.4%, 100%, respectively. These showed that different subgroups of treatment-naïve patients could benefit from the combination therapy of 9MW2821 and Toripalimab. The most common treatment-related AEs(TRAEs) were grade 1 or 2, 23.8% patients experienced TRAEs of grade 3 or above, including neutrophil count decreased (7.1%), rash (4.8%), ALT increased (4.8%), etc. No TRAEs led to death occurred. No new safety signals of 9MW2821 or Toripalimab were observed in this study. **Conclusions:** 9MW2821 combined with Toripalimab in treatment-naïve patients with la/mUC demonstrated remarkable efficacy and well-tolerated safety profile. A pivotal phase 3 study is ongoing currently. Clinical trial information: NCT06079112. Research Sponsor: Mabwell (Shanghai) Bioscience Co., Ltd.

4520 Rapid Oral Abstract Session

CLONEVO: Preoperative abemaciclib for cisplatin-ineligible muscle-invasive bladder cancer (MIBC) with molecular response assessment. First Author: Bishoy Morris Faltas, Weill Cornell Medicine, New York, NY

Background: Up to 40% of MIBC patients are ineligible to receive standard neoadjuvant cisplatin-based chemotherapy creating a significant unmet need. Based on our prior findings of frequent cell cycle alterations, we conducted the first window-of-opportunity, investigator-initiated trial of the CDK4/6 inhibitor abemaciclib (abema) followed by radical cystectomy (RC) in MIBC (NCT03837821). **Methods:** Eligibility was MIBC appropriate for RC and cisplatin-ineligibility or refusal. Planned treatment was abema (200mg BID PO) for 4-8 weeks prior to RC. We planned to enroll 20 patients (accounting for 20% attrition). 16 evaluable patients provided 80% power to detect 0.75 effect size (α = 0.05, r = 0.5 between pairs). Whole-exome (WES) and RNA sequencing of pre- and post-abema tissues and serial evaluation of ctDNA WES were performed on Caris Life Sciences' platform. **Results:** 20 patients received abema for a median of 36 days. Median age was 73, 16/20 were males, and 5/20 had cT4. 3 didn't undergo RC, and 1 withdrew consent. Abema resulted in pathologic complete response in 18.8% (3/16) and downstaging in 31.3% (5/16). No unexpected safety signals were detected. Grade 3 abema-related adverse events included anemia (4/20), abdominal pain (1/20) and diarrhea (1/20). Imaging Mass Cytometry of pre- and post-abema tissues showed a significant reduction in RB1 phosphorylation after abema confirming on-target activity. Variant allele frequency of somatic mutations significantly decreased after abema by 20.5% (p = 0.04), confirming its role in decreasing tumor burden. Serial ctDNA showed a significant reduction in tumor fraction (TF) following abema by 28.6%. Post-TURBT pre-abema TF increased but rapidly decreased within 2 weeks of abema (19.36%), confirming TF reduction was driven by abema not TURBT. Patients with CCND1 amplification had the most significant decrease in TF (63.8%) highlighting CCND1 as a potential response biomarker. Abema significantly downregulated MKI67, CCNA2, and PCNA proliferation markers with log-fold changes of -1.2, -0.7, and -0.6. Gene set enrichment analysis showed significant downregulation of E2F targets and G1/S transition pathways. Patients who achieved pathologic downstaging had significant decrease in E2F pathway activity (-1.6 vs. -0.4, p = 0.01) confirming that abema suppressed E2F-dependent cell proliferation. Interestingly, abema significantly inhibited homologous recombination repair of double-strand DNA break (DSBs) (FDR = 0.001), particularly TOPBP1 and RAD51. **Conclusions:** This first trial of short-term preoperative abema in MIBC demonstrated promising efficacy and tolerability while modulating cell cycle-dependent pathways. Our findings support future trials investigating sequential abema with antibody-drug conjugates such as enfortumab vedotin, where abema's effects on DSBs repair augment treatment response. Clinical trial information: NCT03837821. Research Sponsor: Eli Lilly.

4521 Rapid Oral Abstract Session

AREN1721, a randomized phase 2 trial of axitinib+nivolumab combination therapy vs. single agent nivolumab for the treatment of TFE/translocation renal cell carcinoma (tRCC) across all age groups, an NCI National Clinical Trials Network (NCTN) phase 2 study. First Author: Nicholas Cost, Denver Childrens, Denver, CO

Background: tRCC accounts for approximately 50% of pediatric RCC and 1-5% of RCC cases overall. tRCC, driven by *TFE3* or *TFEb* fusions or amplifications (*TFEb*), are often aggressive with no existing standard for systemic therapy. **Methods:** AREN1721 was a prospective randomized COG-led NCTN phase 2 trial of nivolumab/axitinib combination therapy vs. axitinib alone (closed early for feasibility) vs. nivolumab alone in children and adults with advanced unresectable or metastatic tRCC. Prior exposure to anti-PD1/PDL1 therapies or axitinib was prohibited. The primary endpoint was progression-free survival (PFS), defined as the time from randomization to the earliest of disease progression based on immune-modified RECIST criteria or death. The final protocol version targeted enrollment of 28 eligible patients to detect a hazard ratio (HR) of 0.40 for the comparison of nivolumab/axitinib vs. nivolumab alone using a one-sided log-rank test with alpha = 0.15. **Results:** Despite aggressive approaches for trial recruitment, AREN1721 was closed after enrolling 15 patients (13 eligible) from 2019 to 2023 secondary to poor accrual. Median age 16 years (range 7-42) with 9/13 age $<$ 18 years; 9/13 were male. Six patients were randomized to nivolumab+axitinib, 2 to axitinib alone, and 5 to nivolumab alone. There were no unexpected toxicities. Thirty-three percent of patients randomized to nivolumab+axitinib experienced partial response, compared to 0% in the other arms, and 0% of patients on the combination arm experienced primary disease progression. Addition of axitinib to nivolumab significantly improved PFS (p = 0.0004), extending median PFS from 1.8 to 10.5 months. Overall survival also improved (p = 0.003) with the addition of axitinib. **Conclusions:** Nivolumab+axitinib combination therapy was statistically more active than nivolumab single agent therapy, which itself was inactive. Whether anti-PD1 pathway inhibitors add benefit to anti-VEGF therapy for tRCC remains to be determined. Optimizing trial recruitment is critical for this rare but aggressive cancer. Clinical trial information: NCT03595124. Research Sponsor: U.S. National Institutes of Health; U10CA098543; :U10CA180886; U10CA098413, U10CA180899.

Ipilimumab/nivolumab versus standard of care in non-clear cell renal cancer: Results of the SUNNIFORECAST trial and potential role of the CPS score and tumor nephrectomy. First Author: Lothar Bergmann, University Hospital Frankfurt, Medical Clinic II (Hematology/Oncology), Frankfurt, Germany

Background: Non-clear cell renal cancers (nccRCC) are a rare and heterogeneous group of $>$20 histological and molecular defined entities. Due to the rarity of these entities, the clinical data are limited and large randomized trials are missing resulting in uncertainties for optimal treatment recommendations. So far, TKI therapy with or without immune checkpoint inhibitors (ICI) are considered standard of care (SOC) options in these diseases. Here we report the results of the academic prospective randomised European trial in therapy-naïve patients with advanced nccRCC entities, which compared ipilimumab/nivolumab (Ipi/Nivo) vs SOC. **Methods:** We randomly assigned patients (pts) with nccRCC in a 1:1 ratio to receive either nivolumab 3 mg/kg IV combined with ipilimumab 1 mg/kg IV every 3 weeks for 4 doses followed by a flat dose of 240 mg IV every 2 weeks or 480 mg every 4 weeks versus SOC by investigators choice until disease progression or intolerance occurred. Pts were stratified in papillary vs. non-papillary nccRCC and according to IMDC risk score. Central pathology was mandatory to confirm the correct diagnosis of the nccRCC subtype according to the WHO classification 2022.The primary endpoint was the overall survival (OS) rate at 12 months (mos), secondary endpoints were the OS rate at 6 mos and 18 mos, OS, progression-free survival (PFS) and response rate (RR). **Results:** 309 pts (70.9% male, 29.1% female) out of 316 pts were randomized to receive either Ipi/Nivo or SOC. 173 (56.0%) pts were of papillary subtype (pRCC) and 143 (44.0%) pts of non-papillary subtypes, whereas 59 pts had chromophobe (ccRCC), 20 sarcomatoid/rhabdoid, 10 collecting duct, 11 TFE3-rearranged or TFEB-altered RCC and 37 other histological features. According to the IMDC score, 23.9% were of favorable, 51.8% of intermediate and 24.3% of poor risk. The 12 mos OS rate for Ipi/Nivo of 78.3% (95%-CI 70.9%-83.9%) vs 68.3% (95%-CI 60.0%-75.3%) in the SOC arm was statistically significant (p=0.026). Median OS was 33.2 mos for the Ipi/Nivo arm and 25.2 mos for the SOC arm. The ORR of 32.8% vs. 19.4% and the median PFS of 5.4 mos vs 5.7 mos was not statistically significant different between both arms. The explorative endpoint CPS score differed between the various subentities and was associated with an advantage in OS. Pts with a CPS$\geq$1 had an OS-rate at 12 months of 79.3% in the Ipi/Nivo arm vs. 58.3% and a median OS of 38.6 mos vs. 18.8 mos (p=0.007). Furthermore, pts who did not underwent a tumor nephrectomy (possibly due to high risk) had a survival benefit with 26.3 mos in the Ipi/Nivo arm vs 16.5 mos in the SOC arm (p=0.065) in contrast to nephrectomized pts with 38.9 mos vs 34.0 mos. **Conclusions:** The OS-Rate at 12 mos was significantly superior for Ipi/Nivo in comparison to SOC and the primary endpoint was met. Additionally, pts in the Ipi/Nivo arm had a longer median OS, especially those with a CPS$\geq$1. Clinical trial information: NCT03075423. Research Sponsor: None.

Efficacy and safety of second-line cabozantinib ± atezolizumab for patients with advanced renal cell carcinoma after progression on immuno-oncology combinations: Subgroup analysis of CONTACT-03. First Author: Cristina Suárez, Medical Oncology, Vall d´Hebron Institute of Oncology (VHIO), Hospital Universitari Vall d´Hebron, Vall d´Hebron Barcelona Hospital Campus, Barcelona, Spain

Background: Cabozantinib (cabo), a vascular endothelial growth factor receptor-associated tyrosine kinase inhibitor (TKI), is a preferred treatment option for second-line (2L) treatment of advanced renal cell carcinoma (RCC) based on its superior efficacy vs everolimus (Choueiri TK, *N Engl J Med* 2015); however, its activity after contemporary first-line (1L) immuno-oncology (IO) combinations is not well characterized. CONTACT-03 was a large phase 3 study evaluating the efficacy and safety of cabo ± atezolizumab (atezo) after progression on previous IO treatment (Pal SK, *Lancet* 2023). We report the results of a subgroup analysis of the safety and efficacy of 2L cabo ± atezo in patients from CONTACT-03 who received standard of care (SOC) 1L IO-IO or IO-TKI combinations. **Methods:** In CONTACT-03, adults with metastatic RCC whose disease had progressed on IO-based regimens were randomized to cabo (60 mg PO QD) alone or with atezo (1200 mg IV Q3W). This subgroup analysis included patients who had received 1L IO-IO or IO-TKI SOC combinations prior to enrolling in CONTACT-3. Outcomes for 2L treatment included PFS by blinded independent central review (BICR), OS, ORR, duration of response, and safety. **Results:** Of 522 patients, 107 in the cabo arm and 129 in the cabo + atezo arm had received prior treatment with IO-IO (ipilimumab-nivolumab) or IO-TKI (axitinib-avelumab, axitinib-pembrolizumab, or lenvatinib-pembrolizumab). Efficacy outcomes were comparable between treatments (Table). For cabo and cabo + atezo, respectively, median PFS by BICR was 10.3 and 10.2 months, and ORR was 36% and 37%. Grade 3/4 treatment-related adverse events (AEs) were reported in 48% and 58% of patients treated with cabo and cabo + atezo, respectively, treatment-related serious AEs were reported in 13% and 25% of patients, and AEs led to dose modification in 87% and 92% of patients and discontinuation in 5% and 17% of patients, respectively. **Conclusions:** Results from this post-hoc subgroup analysis of CONTACT-03 suggest 2L cabo is effective in patients with advanced RCC previously treated with 1L IO-IO or IO-TKI regimens. Safety was consistent with the overall study. These results can inform clinicians making 2L treatment decisions for patients who have progressed on contemporary 1L IO-containing combinations. Clinical trial information: NCT04338269. Research Sponsor: Exelixis, Inc.

Comparison of ^{68}Ga-NY104 PET/CT with ^{18}F-FDG PET/CT in patients with metastatic clear cell renal cell carcinoma (NYCRM): A prospective, comparative phase II study. First Author: Wenjia Zhu, Department of Nuclear Medicine, Peking Union Medical College Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China

Background: ^{68}Ga-NY104 is a small-molecule PET agent selectively targeting carbonic anhydrase IX (CAIX), which is highly expressed on clear cell renal cell carcinoma (ccRCC). This phase II study aims to evaluate the diagnostic efficacy of ^{68}Ga-NY104 PET/CT in patients with metastatic clear cell renal cell carcinoma and compare it with ^{18}F-FDG PET/CT. **Methods:** Patients with metastatic ccRCC were prospectively recruited in this study (ClinicalTrials.gov: NCT05879471). All participants underwent ^{68}Ga-NY104 and ^{18}F-FDG PET/CT within one week. Tyrosine kinase inhibitors were stopped at least one week before the study. Any lesion that can be detected on either PET or CT is included for further analysis. The number and uptake of lesions were recorded. The diagnostic efficacy was determined at lesion level and region level based on a comprehensive reference standard protocol. **Results:** Forty-four patients (mean age, 59.6 $\pm$ 10.7) were recruited, including 40 men and 4 women. A total of 677 lesions in 172 regions were identified, of which 568 lesions and 128 regions were considered positive for ccRCC based on reference standard. The lesion-level sensitivity and specificity of ^{68}Ga-NY104 PET/CT to detect ccRCC lesion are 96.6% (95% CI, 95.2% - 98.1%) and 99.1% (95% CI, 97.3% - 100%), which is significantly higher than that of ^{18}F-FDG PET/CT (sensitivity, 77.8%, 95% CI, 74.4% - 81.2%, P < 0.001; specificity, 5.5%, 95% CI, 1.2% - 9.8%, P < 0.001). The region-level sensitivity and specificity of ^{68}Ga-NY104 PET are 98.4% (95% CI, 96.3% - 100%) and 97.7% (95% CI, 93.3% - 100%), which is also significantly higher than that of ^{18}F-FDG PET/CT (sensitivity, 82.0%, 95% CI, 75.4% - 88.7%, P < 0.001; specificity, 11.4%, 95% CI, 2.0% - 20.7%, P < 0.001).The SUVmax of ccRcc lesions (n = 568) were 12.6 $\pm$ 11.7 for ^{68}Ga-NY104 versus 7.5 $\pm$10.5 for ^{18}F-FDG (P < 0.001). The TBR is also higher (15.7 $\pm$ 14.6 v.s. 4.8 $\pm$5.5, P < 0.001). A significant SUVmax difference between ccRCC and non-ccRCC lesion was noted for ^{68}Ga-NY104 (12.6 $\pm$ 11.7 v.s. 1.2 $\pm$1.0, P < 0.001), which is not true for ^{18}F-FDG (7.5 $\pm$10.5 v.s. 6.5 $\pm$3.5, P = 0.061). **Conclusions:** ^{68}Ga-NY104 PET/CT is a promising tool with high diagnostic efficacy in patients with metastatic ccRCC. It is better than ^{18}F-FDG PET/CT in both sensitivity and specificity. Clinical trial information: NCT05879471. Research Sponsor: National Natural Science Foundation of China; No. 82202218.

Diagnostic efficacy of ^{68}Ga-NY104 and ^{18}F-FDG PET/CT.

		Sensitivity	95% CI	Specificity	95% CI
Lesion-level (n=677)	68Ga-NY104	96.6%	95.2%-98.1%	99.1%	97.3%-100%
	18F-FDG	77.8%	74.4%-81.2%	5.5%	1.2%-9.8%

Anlotinib plus everolimus as first-line treatment for advanced non–clear cell renal cell carcinoma: 1 year updated results from UC-001, a single-center, single-arm, phase II trial. First Author: Wen-Hao Xu, Fudan University Shanghai Cancer Center, Shanghai, China

Background: For patients (pts) with recurrent or stage IV non-clear cell renal cell carcinoma (nccRCC), the current guidelines recommend participation in clinical trials, or the use of tyrosine kinase inhibitors (TKIs), such as sunitinib, or mTOR inhibitors, such as everolimus. Anlotinib, a novel multi-target TKI, inhibits vascular endothelial growth factor receptors, fibroblast growth factor receptors, platelet-derived growth factor receptors, and c-kit. The ALTER-UC-001 study (NCT05124431) is a single-center, single-arm, phase II trial evaluating the efficacy and safety of anlotinib plus everolimus as first-line therapy in pts with advanced nccRCC. Data for 24 pts from Jan 2022 through Dec 2023 have been published in 2024 ASCO. Here, we present 1-year updated results. **Methods:** Eligible pts were those with advanced nccRCC and no prior systemic therapy for advanced disease, with an Eastern Cooperative Oncology Group (ECOG) performance status of 0-1. Pts received anlotinib (12 mg orally once daily on days 1-14 of each 3-week cycle) and everolimus (5 mg orally once daily). The primary endpoint was objective response rate (ORR). Secondary endpoints included disease control rate (DCR), progression-free survival (PFS), and overall survival (OS). Adverse events (AEs) were graded according to CTCAE v5.0. **Results:** Between January 2022 and December 2024, 32 pts were enrolled and received treatment. The median age was 56 years old (range: 20-79 years), and 46.9% of pts had papillary renal cell carcinoma (pRCC). Most pts (81.3%; 26/32) had a ECOG PS score of 1. At the data cutoff in December 2024, with a median follow-up of 11.9 months (95% CI 9.3-14.5), the ORR was 54.5% (95% CI 32.2-75.6), and the DCR was 100% (95% CI 84.6-100.0). The median PFS was 20.8 months (95% CI 12.0-29.6). Adverse events (AEs) of any grade occurred in 90.6% of pts, with the most common being proteinuria (40.6%), mucositis and hypertension (37.5%), and anemia, increased creatinine, elevated transaminases (18.8%), glutamic-pyruvic transaminase increased and hematuria (15.6%), and hypercholesterolemia (12.5%). Grade 3 treatment-related AEs (TRAEs) occurred in 15.6% of pts, with no treatment-related deaths. Treatment was suspended in 18.8% (6/32) and 12.5% (4/32) of pts due to TRAEs associated with everolimus and anlotinib, respectively. **Conclusions:** This study demonstrates that anlotinib combined with everolimus is an effective and tolerable first-line therapy for advanced nccRCC, achieving a high ORR and prolonged PFS, with manageable toxicity. These findings provide critical evidence supporting the use of this novel combination in nccRCC. Survival follow-up is ongoing, and further validation in larger, multi-center randomized trials is warranted. Clinical trial information: NCT05124431. Research Sponsor: None.

Anlotinib combined with sintilimab as first-line treatment in patients with advanced non-clear cell renal cell carcinoma (nccRR): Preliminary results from an exploratory prospective multicentre clinical study. First Author: Pei Dong, Department of Urology, State Key Laboratory of Oncology in South China, Guangdong Provincial Clinical Research Center for Cancer, Sun Yat-Sen University Cancer Center, Guangzhou, China

Background: Non-clear cell renal cell carcinoma (nccRCC) accounts for approximately 25% of all kidney cancers, however, the effect of systemic chemotherapy is limited. We report the first results of a single-arm, phase 2 study (NCT05220267) evaluating the efficacy and safety of anlotinib (a multi-target tyrosine kinase inhibitor) combined with sintilimab (a monoclonal antibody against programmed cell death protein 1) as first-line treatment in patients with advanced nccRCC. **Methods:** Patients with histologically confirmed advanced nccRCC and measurable disease per RECIST v1.1 who had not previously received systemic therapy were received anlotinib (12 mg qd, d1-14, repeated every 21 days) plus sintilimab (200 mg IV Q3W) till disease progression or intolerant toxicity. The primary endpoint is progression-free survival (PFS); secondary endpoints include objective response rate (ORR), disease control rate (DCR), overall survival (OS) and safety. **Results:** From April 2022 to January 2024, 44 patients were enrolled with a median age of 46 years (range: 18-79), 13 (29.5%) had Fumarate deficient RCC, 10 (22.7%) had Papillary RCC, 9 (20.5%) had TFE3 rearranged RCC and 12 (27.3%) were unclassified. Among these participants, 44 patients were evaluable. 95.5% were IMDC intermediate- or poor-risk, 72.7% had prior nephrectomy and 97.7% had synchronous metastatic disease. ORR and DCR were 56.8% (95%CI 41.6-72.1) and 86.4% (95%CI 75.8-96.9) , respectively.$\geq$1 and < 1 Combined Positive Score of PD-L1 expression were observed in 50% (22/44) and 38.6% (17/44) patients respectively, and the ORR was 72.7% (95%CI:52.2-92.9) and 41.2% (95%CI: 15.1-67.3) in the two groups. As of November 13, 2024, median follow-up time was 17.5m (95%CI 14.9-20.1). The median PFS was 13.6m (95%CI 8.6-18.6). Treatment-related grade 3/4 adverse events were observed in 22.7% (10/44) of the patients, encompassed proteinuria (3 patients, 7%), hyponatremia (2 patients, 4%), hypertension (1 patients, 2%), hepatic insufficiency (1 patients, 2%), fatigue(1 patients, 2%), rash (1 patients, 2%), decreased lymphocyte count (1 patients, 2%). Neither unexpected safety signals nor treatment-related death occurred. **Conclusions:** Our results showed promising efficacy and acceptable toxicity of anlotinib plus sintilimab for patients with advanced nccRCC. Clinical trial information: NCT05220267. Research Sponsor: None.

Investigation of tumor-associated macrophages (TAMs) and therapeutic resistance to immune checkpoint inhibitors (ICI) through single-cell analysis of renal cell carcinoma (RCC). First Author: Soki Kashima, Center of Molecular and Cellular Oncology, Yale Cancer Center, Yale School of Medicine, New Haven, CT

Background: RCC is characterized by a tumor microenvironment (TME) enriched in TAMs, which suppress antitumor immunity in RCC. We conducted a comprehensive dissection of the TME using pre- and post-ICI treatment samples to identify specific TAM populations associated with ICI treatment resistance in RCC. **Methods:** A total of 70 tumor samples (58 clear cell and12 non-clear cell) were collected from 63 patients with advanced RCC, including 9 patients who were untreated, 10 patients who received non-ICI-based systemic therapies, and 44 patients who received ICI-based therapies. We excluded 17 patients with stable disease from the 44 patients and analyzed 29 samples prior to (n = 15) or after exposure to (n = 14) ICI-based therapies (mono-ICI, n = 11; ICI + ICI, n = 11; ICI + VEGFi, n = 6; other, n = 1) from 27 patients. We performed single-cell RNA-sequencing (scRNA-seq; 10x Genomics) on all 70 samples and established a comprehensive transcriptomics atlas of the RCC TME. We utilized non-negative matrix factorization (NMF) to identify interpretable gene programs for TAMs, comparing responders (R) (n = 18; complete or partial response) with non-responders (NR) (n = 11; progressive disease) to ICI-based therapies according to the best response based on RECIST. P-values from Wilcoxon signed rank test are reported. **Results:** 443,337 high-quality viable cells were annotated to lymphoid, myeloid, tumor, endothelial, or fibroblast compartments, capturing the RCC TME landscape. Among TAMs, we discovered underlying gene programs through NMF analysis, including “antigen presentation”, “S100A8/9 inflammatory”, “stress response”, “C1Q/APOE/TREM2”, “CD163/MRC1”, “hypoxia”, “interferon-stimulated genes”, and “LILRB/SIGLEC10” programs. We identified that the LILRB/SIGLEC10-TAM subcluster was significantly increased in frequency in NR compared to R (p = 0.005). Notably, the significant increase in this program in NR was also observed in pre-treatment only samples (p = 0.014), suggesting a primary mechanism of resistance. This population was characterized by the expression of immune suppressive *LILRB1/2/3* genes, together with significant upregulation of the macrophage checkpoints *SIGLEC10* (a recently discovered “don’t eat me signal” receptor) and *VISTA* (an immune checkpoint) compared to other TAMs (p < 2.22E-16, for each). **Conclusions:** Our comprehensive dissection of the RCC TME reveals an association between TAM population with an immunosuppressive gene program and ICI resistance through analysis of a large scRNA-seq dataset. This study provides immunobiological insights into potential therapeutic targets for next-generation combination therapy with ICIs, offering a foundation for understanding treatment evolution in RCC. Assessment of time-to-treatment-failure (TTF) as a surrogate endpoint for overall survival (OS) to immune checkpoint inhibitor (ICI) regimens in metastatic renal cell carcinoma (mRCC): Findings from an IMDC analysis. First Author: Zachary Yochum, Yale Cancer Center, New Haven, CT

Background: In Phase III trials for mRCC, OS is a gold standard primary endpoint. However, for ICI-based regimens, this requires extended follow-up times, resulting in higher costs and delayed drug approvals. Identification of surrogate or intermediate endpoints for OS would be beneficial in addressing these challenges. In the current study, we investigated 6-month TTF as a potential intermediate endpoint (IE) for OS in mRCC. **Methods:** We included all patients from the International mRCC Database Consortium (IMDC) who received ICI-based regimens from 2013 to 2023. TTF was defined from ICI start until drug cessation or death or censored at date of last follow-up. The cohort was divided into 10 equal sub-cohorts based on the decile disease risk scores, calculated using multivariable Cox regression for OS, considering all relevant covariates (IMDC risk groups, presence of bone, brain, or liver metastases, histology, age, prior nephrectomy, ICI type, and year of ICI initiation). For these sub-cohorts, we used Kaplan-Meier methods to determine 18-month OS and event-free rates for 6, 9, and 12-month TTF. We then performed linear regression of stratum-specific 18-month OS against stratum-specific 6-month (and 9- and 12-month) TTF. In the landmark analysis, OS was calculated starting at 6 months after therapy initiation, excluding patients who died or had follow-up of less than 6 months. **Results:** The IMDC cohort consisted of 1667 patients with a median age of 63 years and 83% had clear cell histology. Median follow-up was 15.4 months (IQR: 7.1-28.6). Across the 10 sub-cohorts, 6-month TTF accounted for 76% of the variance in 18-month OS (R^2= 0.76, 95% CI: 0.26-0.87). Similar patterns were seen for 9 (R^2= 0.65, 95% CI: 0.11-0.81) and 12-month TTF (R^2= 0.64, 95% CI: 0.09-0.80). In the 6-month landmark analysis (evaluable n = 1255), mRCC patients experiencing treatment failure at 6 months had an 18-month OS (i.e. 12 months after the landmark time) rate of 68% (95% CI: 63%-72%), compared to 92% (95% CI: 90%-94%) for those without treatment failure (adjusted HR: 2.74, 95% CI 2.15-3.49). **Conclusions:** 6-month TTF was predictive of 18-month OS in mRCC patients. These findings suggest that 6-month TTF may be a promising intermediate endpoint for OS and provides supportive evidence of future validation in prospective studies. Research Sponsor: None.

Phase 1 results of Oncobax-AK in combination with ipilimumab/nivolumab in advanced clear cell renal cell carcinoma (ccRCC; NCT05865730). First Author: Lisa Derosa, Gustave Roussy Cancer Campus (GRCC), ClinicObiome, Villejuif, France

Background: Patients with advanced solid tumors who respond to immunotherapy are more likely to have *Akkermansia spp (Akk)* in their stools, whereas its absence (45%) is associated with worse outcome, regardless of other prognostic factors. Here, we report the safety and efficacy findings from a Phase I trial evaluating Oncobax-AK live biotherapeutics in combination with nivolumab/ipilimumab in intermediate- and poor-risk IMDC ccRCC patients who tested negative for stool *Akk*. We report first results of cohort 1. **Methods:** Intermediate- and poor-risk IMDC advanced ccRCC patients were screened across 4 centers in France for *Akk* using a qPCR stool test designed to detect specific *Akk* strains (SGB9226/SGB9228). Patients who tested negative for stool *Akk* received either 1X (cohort 1) or 6X oral capsules (cohort 2) of Oncobax-AK (a specific strain of SGB9228, p2261) for one week as monotherapy, followed by a combination treatment with nivolumab/ipilimumab administered continuously until progression in cohorts 1 and 2, respectively. The primary endpoints were safety, pharmacodynamics of Oncobax-AK, and overall response rate (ORR) according to RECIST 1.1. Blood and stool samples were collected at multiple time points for multi-omics analyses. **Results:** Among the 29 patients screened for *Akk*, 11 (38%) did not harbor gut *Akk* and were eligible. Two patients declined to continue. Ultimately, 9 patients (8 intermediate and 1 poor IMDC risk group) were enrolled in cohort 1, with a median age of 57 years (n = 9: 1 female and 8 males). No serious adverse events related to Oncobax-AK was observed. Only one patient experienced a serious immunotherapy-related adverse event that led to treatment withdrawal. After a median follow-up of 14.9 months, all patients are still alive, with 4 showing a partial response (PR) for more than 6 months (including 2 patients with ongoing PR for over 15 months, continuing the intervention). One patient had stable disease (SD), 3 had progressive disease (PD), and 1 was not evaluable (NE). Among evaluable patients, the ORR was 50%. Multi-omics analyses revealed that Oncobax-AK remains detectable over time and induced changes in the microbiome, leaky gut markers, and immune and metabolite profiles. These changes suggest potential pharmacodynamic biomarkers, reflecting the biological effects of Oncobax-AK. **Conclusions:** This is the first trial targeting patients lacking *Akkermansia spp*. in their stools. Oncobax-AK, combined with Ipilimuab/Nivolumab in intermediate- and poor-risk IMDC ccRCC, appears safe and may modulate gut microbiota, inflammation, metabolites, and immune profiles. This potentially mimics a responder's profile and leads to clinical and radiological benefits in some patients. Based on these promising results, enrollment in cohort 2 (6X) is ongoing and has now been expanded to include non-small cell lung cancer patients. Clinical trial information: NCT05865730. Research Sponsor: None.

Co-expression network-based analysis of gene programs contributing to immune checkpoint inhibitor (ICI) resistance in renal cell carcinoma (RCC). First Author: Ro Malik, Center of Molecular and Cellular Oncology, Yale Cancer Center, Yale School of Medicine, New Haven, CT

Background: There is an unmet need to characterize molecular drivers of resistance to ICIs in the RCC tumor microenvironment, especially in cell-type-specific contexts. To address this, we identified coherent gene programs in each cell type using scRNA-seq data to uncover an immune cell phenotype associated with ICI resistance. **Methods:** We performed per-cell-type weighted coexpression network analysis on scRNA-seq data of 443,337 cells from 70 RCC tumor samples, mostly from patients (pts) who received ICI (S. Kashima, ASCO, 2024), to construct mutually co-expressed gene sets (modules) and their cell-level expression. We compared module expression scores between responders (R, complete or partial response) and non-responders (NR, progressive disease) with the Wilcoxon rank-sum test plus FDR correction, and ran tests with permuted labels to rule out statistical artifacts. For validation, we performed this analysis on another scRNA-seq cohort from a phase II trial (HCRN GU16-260; NCT03117309), and further, we used CoxPH survival analysis on module signature scores computed by GSVA to assess the prognostic role of module expression in bulk RNA-seq samples from the IMmotion 150, CheckMate 009/010/025, and Javelin 101 trials, after stratifying them into immune-high (top 50%) and immune-low (bottom 50%) groups according to CIBERSORTx-inferred total immune infiltration. **Results:** Analysis of scRNA-seq (two independent datasets) from ICI-treated RCC tumors revealed a module of robustly co-expressed ribosomal and translation-associated genes that was significantly upregulated in NR in immune cells (but not tumor or stromal cells), including macrophages, CD4+ and CD8+ T, NK, and B cells (p-values ranging from 1e-20 to 1e-200). Analysis of an independent scRNA-seq cohort (HCRN GU16-260) also yielded a module of mutually co-expressed ribosomal proteins only in immune cells that was upregulated in NR (immune $p < 1e\text{-}20$, non-immune $p > .05$). Finally, validation in large-scale bulk RNA-seq data from clinical trials shows that for patients receiving any ICI-based therapy (nivolumab, avelumab + axitinib, or atezolizumab +/- bevacizumab), module signature scores were significantly associated with worse PFS only in the CoxPH analysis of immune-high samples (HR = 1.65, 95% CI, 1.18–2.3, $p < .005$), while immune-low samples showed no effect (HR = 0.93, 95% CI 0.71–1.25, $p > .5$), concordant with findings from the scRNA-seq analysis. Those receiving a TKI only (sunitinib) exhibited no association, regardless of immune infiltration. **Conclusions:** Though individual ribosomal proteins have been found to be prognostic for RCC, a cell-type-specific module-level analysis elucidated a link between a coherent translation program in immune cells and resistance and poor PFS for pts receiving ICI specifically, contributing to a model of ICI-resistant molecular phenotypes in RCC. Research Sponsor: National Cancer Institute/U.S. National Institutes of Health; 1R37CA279822.

Frailty assessment in patients with advanced/metastatic renal cell carcinoma using routine data collected during treatment with tyrosine kinase inhibitors in the STAR trial. First Author: Sophie Trotter, Weston Park Cancer Centre, Sheffield Teaching Hospitals NHS Foundation Trust, Sheffield, United Kingdom

Background: The STAR trial (ISRCTN06473203) was a phase 2/3 randomised controlled non-inferiority trial (N=920) which assessed whether treatment breaks from tyrosine kinase inhibitors (TKIs, oral sunitinib/pazopanib) could be safely used in locally advanced/metastatic renal cell carcinoma (RCC). We aimed to determine if it was possible to obtain a frailty index (FI) which could be linked to toxicity and clinical outcomes from routinely collected large trial data, using the STAR trial as an example. **Methods:** We developed the FI using Rockwood's accumulation of deficits methodology. STAR data was initially searched for variables measuring baseline health problems and functional limitations. Variables were excluded if there was a significant proportion of missing values ($>$10%); if too rare or too common ($<$1%, $>$80%); or if significantly correlated with another variable ($r>0.95$). Variables were coded from 0 (no deficit) to 1 (full deficit); these were summed then divided by the number of variables assessed to give the FI. Frailty thresholds were adopted in line with the literature: Not Frail (FI$\leq$0.08); Pre-Frail (FI 0.08-0.24); Frail (FI$\geq$0.25). **Results:** Of 57 variables screened, 35 variables remained for inclusion in the FI. 50 participants missing $>$20% of FI variables were excluded, leaving n=870. FI scores ranged from 0 to 0.43 (median 0.15, IQR 0.10-0.22). Kaplan-Meier survival analysis showed a statistically significant difference by FI for overall survival (OS) (FI$\geq$0.25: HR 2.48, $p<0.001$, 95% CI 1.89-3.26). In multivariate Cox proportional hazards regression, FI remained a statistically significant risk factor for OS (HR 1.41, P=0.047, 95% CI 1.00-1.99); other statistically significant variables included age group, sites of metastatic disease, IMDC and MOTZER scores. Toxicity was assessed over the first 6 months, while all participants were treated with continuous TKIs. The most common severe toxicities (G3+) were hypertension (200/870), hepatobiliary disorders (97/870) and fatigue (63/870). Time free of severe toxicity was statistically significantly shorter for frail participants. **Conclusions:** Amongst STAR trial participants with advanced/metastatic RCC treated with TKIs, frailty was a statistically significant risk factor for poorer survival and for shorter time to severe toxicity. It is noted that the eligibility criteria for STAR included a baseline PS of ECOG 0-1 which will have excluded many frailer patients. This data shows that it is feasible to use routinely collected trial data to create a clinically meaningful FI and this approach could be applied to other trial datasets. Clinical trial information: ISRCTN06473203. Research Sponsor: UK National Institute for Health and Care Research (NIHR).

Toxicity-free survival, by frailty group.

Toxicity	FI group	HR	p-value	95% CI
Severe toxicity (G3+)	Intermediate	1.00	0.960	0.83-1.21
	Frail	1.28	0.025	1.03-1.59
All toxicity (G1+)	Intermediate	1.11	0.031	1.01-1.22
	Frail	1.08	0.201	0.96-1.20

International Metastatic Renal Cell Carcinoma Database Consortium (IMDC) classification and regression tree analysis to characterize objective response rates (ORR) in metastatic renal cell carcinoma (mRCC). First Author: Martin Zarba, Arthur J.E. Child Comprehensive Cancer Centre, Calgary, AB, Canada

Background: Therapies for mRCC have evolved significantly, making treatment decisions more complex. We used machine learning (ML) to identify whether this could help identify subgroups of patients who have a high probability of response. **Methods:** Patients from IMDC were identified and a ML classification and regression tree analysis was conducted, in which we grew a complex tree up to a depth of 30 with a minimum node split size of 2 with no constraints on the cost-complexity parameter. The resulting tree was pruned according to the cost-complexity parameter that minimized the leave one out cross-validated error rate and had a minimum bucket size of 25 patients. **Results:** 2,549 patients were included, 73.2% male, 13.5% non-clear cell histology, 70.3% nephrectomy, and 19.4%, 54.2%, and 26.4% had favorable, intermediate and poor IMDC risk respectively. 1L treatment regimens consisted of VEGF inhibitors (51.5%), IO-IO combinations (32.3%), and IO-TKI combinations (16.2%). The ORR was 36.0% overall, with 29.6% for VEGF inhibitors, 39.1% for IO-IO, and 50.2% for IO-TKI combinations. ML identified 5 hierarchal variables —therapy type, prior nephrectomy (PN), lung metastasis (LM), other metastases, and age— that divided patients into 7 different categories with different response probabilities (see Table). VEGF therapy showed the poorest response, with no additional variables able to predict response. The best ORR was observed in patients treated with IO-TKI and PN; and in those treated with IO-IO, PN, and only lung metastasis. Factors associated with poorer responses included non-clear cell histology, older age, bone and liver metastases, poor performance status, elevated neutrophils, and poor IMDC risk score. **Conclusions:** This large-scale ML analysis identified five key clinical variables that predict treatment response in mRCC, with treatment type emerging as the primary determinant. These results suggest that treatment selection for mRCC could potentially be optimized by considering these hierarchical variables, though further validation is needed. Research Sponsor: None.

Early detection of renal cell carcinoma: A novel cfDNA fragmentomics-based liquid biopsy assay. First Author: Yulu Peng, Sun Yat-sen University Cancer Center; State Key Laboratory of Oncology in South China, Collaborative Innovation Center of Cancer Medicine, Guangzhou, China

Background: Renal cell carcinoma (RCC) is a leading cause of cancer-related mortality, with a rapidly rising global incidence. Early detection greatly improves the outcomes of RCC, yet current diagnostic methods have limitations in sensitivity, specificity, and accessibility. This study develops and evaluates a cfDNA fragmentomics-based liquid biopsy integrated with machine learning as a non-invasive and scalable tool for RCC early detection. **Methods:** This case-control cohort study recruited 442 participants (223 RCC patients and 219 non-cancer controls, including healthy individuals and those with benign renal conditions) at a single cancer referral center from December 2021 to December 2023. Plasma-derived cfDNA underwent low-pass WGS (5X coverage), and three fragmentomics features—copy number variation (CNV), fragment size ratio (FSR), and nucleosome footprint (NFP)—were extracted. A stacked ensemble machine learning model was trained on 280 participants and validated on 162 independent participants. Performance was assessed using area under the curve (AUC), sensitivity, and specificity. **Results:** The ensemble model achieved an AUC of 0.9656 in the validation cohort, with sensitivity and specificity of 90.5% and 93.8%, respectively. Stratified analyses demonstrated consistent performance across RCC stages, histological subtypes, and Fuhrman grades, with sensitivities of 87.8% for Stage I RCC and 100% for Stage IV RCC. Additionally, the model effectively differentiated malignant RCC from benign renal conditions, further validating its clinical utility. Stability evaluations confirmed the model's robustness across diverse sample types, storage conditions, and processing scenarios, underscoring its potential applicability in routine clinical practice. **Conclusions:** This cfDNA fragmentomics-based liquid biopsy represents a highly sensitive, specific, and non-invasive approach for the early detection of RCC. Its robust performance across diverse clinical scenarios highlights its potential to enhance current RCC diagnostic workflows, facilitate timely interventions, and improve patient outcomes. Future integration of this method into clinical practice could address critical gaps in RCC management, providing substantial benefits in early detection and personalized care. Efficacy and safety of neoadjuvant toripalimab plus axitinib in renal cell carcinoma with tumor thrombus: A combined analysis of two phase II trials. First Author: Liangyou Gu, Chinese PLA General Hospital, Beijing, China

Background: Tumor thrombectomy for renal cell carcinoma (RCC) with tumor thrombus (TT) is associated with high morbidity and mortality. Two trials have demonstrated the efficacy and safety of neoadjuvant toripalimab plus axitinib in patients with TT. Here, we present the pooled analysis results. **Methods:** These two phase II trials (NEOTAX and NCT04118855) shared similar target populations. Patients with clear cell RCC (ccRCC) and TT received up to 12 weeks of toripalimab plus axitinib before surgery. The primary endpoint was the downstaging rate of TT based on the Mayo classification. For level 0 thrombus, the downstaging defined as: for right RCC, the proximal end of TT retracted from the main renal vein to branches of the renal vein; for left RCC, the superior mesenteric artery (SMA) was an anatomical landmark, the TT retracted from lateral to the abdominal aorta to the level of SMA or from the main renal vein lateral to SMA or the branches of the renal vein. Secondary endpoints included response rate, change in thrombus length, surgical morbidity, progression-free survival (PFS), overall survival (OS), and safety. **Results:** A total of 40 patients were enrolled, 4 (10%), 4 (10%), 14 (35%), 7 (17.5%), 11 (27.5%) patients had level 0, I, II, III, IV tumor thrombus, respectively. After 12 weeks treatment, 45.0% (18/40) patients experienced a reduction in TT level, one patient (2.5%) had an increase in Mayo level. Thirty-six (90%) patients exhibited shrinkage in TT length, with a median reduction of 1.9 cm (IQR: 0.9 to 3.7 cm). According to the RECIST criteria, the objective response rate and disease control rate of overall tumor was 37.5% and 97.5%. In total, 35 patients underwent radical nephrectomy with IVC thrombectomy, including 16 open, 2 laparoscopic and 17 robotic. No patient had a surgery delay due to treatment-related adverse events (TRAEs). 54.3%(19/35) patients experienced changes in surgical strategy compared with planned surgery. Median operation time was 300 min (IQR: 180-420 min). Median estimated blood loss was 700 ml (IQR: 300-1800 ml). The postoperative complication rate was 60% (21/35), including three (8.6%) major complications and one (2.9%) postoperative death. The most common TRAEs included hypertension (35.0%), proteinuria (35.0%), fatigue (27.5%), and diarrhea (22.5%). Grade $\geq$3 adverse events were reported in 27.5% (11/40) of patients, no patients experienced Grade 4 or 5 TRAEs. With a median follow-up of 32.2 (IQR: 27.0-35.5) months, the median PFS and OS were not reached. The estimated PFS rate at 1 year was 87.5% (95% CI, 72.4% to 95.3%). The PFS (P = 0.20) and OS (P = 0.44) were similar between responders (partial response) and non-responders (stable disease or progressive disease). **Conclusions:** Toripalimab in combination with axitinib downstages TT level in a significant proportion of patients leading to simplification in the procedure of surgery. Clinical trial information: NCT04118855. Research Sponsor: None.

4536 **Poster Session**

First-line benmelstobart plus anlotinib versus sunitinib in advanced renal cell carcinoma: Subgroup analysis from the phase 3 ETER100 trial. First Author: Xinan Sheng, Key Laboratory of Carcinogenesis and Translational Research (Ministry of Education/Beijing), Department of Genitourinary Oncology, Peking University Cancer Hospital & Institute, Beijing, China

Background: Dual immune checkpoint inhibitors (ICIs) or ICIs plus VEGF-directed therapies, have been approved as first-line treatment in patients (pts) with advanced renal cell carcinoma (RCC). The phase 3 ETER100 trial showed that benmelstobart (PD-L1 blockade) plus anlotinib improved the progression-free survival (PFS) (19.0 months 9.8 months) and objective response rate (ORR) (71.6% vs 25.1%) of advanced clear cell RCC (ccRCC) pts significantly. Pts with factors, such as intermediate-poor International Metastatic Renal Cell Carcinoma Database Consortium (IMDC) risk, liver metastasis, or bone metastasis were considered to have a poor prognosis. Here we report PFS and ORR in clinically relevant subgroups. **Methods:** ETER100 (NCT04523272) was a multicentre, randomised, open-label, controlled phase 3 trial conducted at 37 sites in China. Eligible patients were randomly assigned in a 1:1 ratio using stratified block randomisation to receive benmelstobart plus anlotinib or sunitinib. Randomisation was stratified according to the International Metastatic Renal Cell Carcinoma Database Consortium (IMDC) risk (favourable [score of 0], intermediate [score of 1-2], or poor risk [score of 3-6]). PFS analyses of clinically relevant subgroups were assessed using Kaplan-Meier method and the 95% CIs of response rate were calculated with the Clopper-Pearson method. **Results:** Overall, 527 pts received the trial treatments (264 in the benmelstobart-anlotinib group and 263 in the sunitinib group) and were evaluated for efficacy. A total of 454 (86%) pts had intermediate-poor IMDC risk, 62 (12%) pts had liver metastasis and 111(21%) had bone metastasis. Data cutoff for the interim analysis occurred on January 31, 2024. The median follow-up was 22.8 months. Benmelstobart plus anlotinib significantly improved PFS of subgroups with intermediate-poor IMDC risk (17.0 months [95% CI 14.0-20.1] vs 9.7 months [8.0-11.3], HR 0.55, 95% CI 0.43-0.72; $p < 0.0001$), liver metastasis (11.9 months [95% CI 5.8-NE] vs 5.4 months [1.5-6.7], HR 0.44, 95% CI 0.23-0.85; $p < 0.0121$), or bone metastasis (19.5 months [95% CI 16.5-27.2] vs 8.3 months [4.2-19.8], HR 0.52, 95% CI 0.30-0.89; $p < 0.0154$). ORR of benmelstobart-anlotinib group was significantly higher in the subgroups with intermediate-poor IMDC risk (70.0% [95%CI, 63.6-75.9] vs 21.6% [16.4-27.5]), liver metastasis (60.0% [95%CI, 42.1-76.1] vs 7.4% [0.9-24.3]) and bone metastasis (63.2% [95%CI, 49.3-75.6] vs 16.7% [7.9-29.3]). **Conclusions:** The RCC pts with a poor prognosis such as intermediate-poor IMDC risk, liver metastasis and bone metastasis could significantly benefit from benmelstobart plus anlotinib. Clinical trial information: NCT04523272. Research Sponsor: None.

Ongoing phase 1/2 trial of the hematopoietic progenitor kinase 1 (HPK1) inhibitor NDI-101150 as monotherapy or in combination with pembrolizumab: Clinical safety and efficacy update in clear cell renal cell carcinoma (ccRCC). First Author: David A. Braun, Center of Molecular and Cellular Oncology, Yale University, New Haven, CT

Background: NDI-101150 is a potent and selective oral inhibitor of HPK1, a serine/threonine kinase that acts as a negative regulator of immune cell function. Pre-clinically, NDI-101150 can enhance immune cell function, leading to potent anti-tumor immunity. **Methods:** NDI-101150 is currently being investigated in a first-in-human, multi-center, open-label, phase 1/2 trial (NCT05128487) in patients with advanced solid tumors, as a monotherapy (50–200 mg once daily [QD]) or in combination with pembrolizumab (50–100 mg QD NDI-101150 + 200 mg Q3W pembrolizumab). **Results:** As of 20 November 2024, 106 patients were dosed [NDI-101150 monotherapy (n = 94) or NDI-101150 + pembrolizumab (n = 12)]. The tumor types were RCC (n = 38), NSCLC (n = 17), gastric/GEJ (n = 12), and other solid tumors (n = 39). We report here updated safety data in all patients from monotherapy and combination arms (n = 106), and efficacy data in patients with ccRCC (n = 29) receiving NDI-101150 monotherapy. NDI-101150 monotherapy was generally well tolerated, with 150 mg identified as the maximum tolerated dose. The most common treatment-related adverse events (TRAEs) of any grade were nausea (39%), diarrhea (35%), vomiting (29%), fatigue (27%), and anemia (11%). Grade ≥3 TRAEs occurred in 13 (14%) patients, of which only 1 (1%) patient experienced a grade 4 TRAE. The safety profile was comparable in the combination cohort, with 2 (17%) patients experiencing Grade ≥3 TRAE. 20 of the 29 ccRCC patients who received 50, 100, 140, or 150 mg of NDI-101150 monotherapy were response-evaluable. The objective response rate was 15.0% [CR, n = 1 and PR, n = 2]. Clinical benefit rate (CR + PR + SD ≥6 months) was 25%, which includes 2 patients who experienced durable SD for ~9 months and ~25 months. The disease control rate (CR+PR+SD) was 60%. The ccRCC patients had received a median of 2 (1-9) lines of prior therapy. A nearly dose-proportional increase in NDI-101150 exposure was observed at day 1, with steady state achieved by day 15. At all doses tested, steady state exposures inhibited the pharmacodynamic biomarker pSLP76 by > 50% and for a period consistent with preclinical efficacy predictions. To demonstrate proof of biology, a custom 12-plex immunofluorescence panel and the GeoMx whole transcriptomic assay were utilized. By day 28, on-treatment tumor biopsy samples showed immune activation when compared to pre-treatment samples, including an increased infiltration of activated CD8+ T-cells and dendritic cells. **Conclusions:** NDI-101150 continues to demonstrate an acceptable safety profile and encouraging antitumor activity in patients with ccRCC, supporting continued clinical development of NDI-101150 as monotherapy and in combination with other agents as a promising next-generation immunotherapy oral small molecule. Clinical trial information: NCT05128487. Research Sponsor: Nimbus Therapeutics.

Genomic and proteomic predictors of sites of metastases in renal cell carcinoma. First Author: Clara Steiner, Dana-Farber Cancer Institute, Boston, MA

Background: Among patients with renal cell carcinoma (RCC), the most common sites of metastasis are lung, lymph nodes, and bone. While some sites of metastases are associated with better cancer-specific outcomes than others, the underlying biology of metastatic organ tropism is not well understood. We performed genomic and proteomic analyses to investigate the biological underpinnings of different metastatic sites in RCC. **Methods:** Institutional cohorts of patients with metastatic RCC from the Dana-Farber Cancer Institute (DFCI) were analyzed using a next-generation tumor somatic mutation assay (n = 633) and with a highly multiplexed plasma proteomics assay (n = 258). Data were clinically annotated for sites of RCC metastasis. Genomic analyses were performed using a two-sided Fisher's exact test on the cBioPortal platform at DFCI with pairwise comparison of patients with versus without metastases to lung, liver, brain, bone, adrenal, and lymph nodes. The Benjamini-Hochberg method was applied for FDR-adjusted q-values. Exploratory proteomic analyses were performed using logistic regression for each metastatic site with multivariate adjustment for other sites of metastasis. For each metastatic site, the top five associated proteins were selected to build a multivariate model to predict the presence of each metastatic site. Bootstrapping with R = 1,000 was employed for the assessment of model performance. **Results:** Tumor genomic alterations in *SETD2* (q-value = 0.004) and *CDKN2A* (q-value = 0.04) were associated with lung and lymph node metastases, respectively. Logistic regression analyses of proteomic data were used to identify circulating proteins with the strongest associations with the sites of metastases. For instance, circulating collagen alpha-1(IX) chain (CO91A) and relaxin receptor 1 (RXFP1) were the top circulating proteins associated with bone metastases, while GGT2 and tenascin were associated with liver metastases and matrilysin (MMP-7) was associated with lymph node metastases. Multivariate models using the top five proteins to predict the presence of each metastatic site demonstrated bootstrapped C-statistics from 0.72 to 0.80 for lymph nodes, lung, adrenal, brain, liver, and bone, respectively. **Conclusions:** We identified genomic and proteomic predictors of organ-tropic metastases in RCC. Next, we will validate these findings in independent external cohorts. Research Sponsor: None.

Analysis of phase II study of cabozantinib (Cabo) with nivolumab (Nivo) and ipilimumab (Ipi) in advanced renal cell carcinoma with divergent histologies (RCCdh). First Author: Bradley Alexander McGregor, Dana-Farber Cancer Institute, Boston, MA

Background: We previously reported on treatment intensification with the combination of Cabo/Nivo/Ipi in 39 patients (pts) with metastatic RCCdh in a multi-center single arm phase II trial with a starting cabozantinib dose of 40 mg/day (d). Clinical utility was limited with an objective response rate (ORR) of 21% and significant treatment related adverse events (TrAEs) (77% ≥Grade 3 TrAEs). Therefore, we explored the safety and potential efficacy by using a lower starting dose of cabozantinib of 20 mg/d (NCT04413123). **Methods:** Eligible pts had metastatic RCCdh with ECOG performance status of 0-1 and may have received one line of prior therapy excluding immunotherapy or Cabo. Pts underwent a baseline biopsy and received Nivo 3 mg/kg and Ipi 1 mg/kg intravenously Q3 weeks (W) for 4 cycles followed by Nivo 480 mg IV Q4W. Cabo was given continuously at a dose of 20 mg/d; reductions to 20 mg every other day were allowed; after completion of Ipi, the Cabo dose could be increased to 40 mg/d. The primary endpoint was ORR by RECIST 1.1. Safety was a secondary endpoint. A one-stage design with 20 subjects (for 7 or more responses) would provide 75% power to distinguish an ORR of 40% versus 20% at one-sided alpha of 0.1. **Results:** 20 pts were enrolled and received at least 1 study drug at 7 sites from Feb. 2023 to Apr. 2024. Following histologic subtypes were included: papillary (n = 11), chromophobe (n = 1), translocation (n = 3), unclassified RCC (n = 2) and other (n = 3). 4 (20%) pts received prior systemic therapy. 10 (50%) pts received all 4 doses of Nivo and Ipi; 13 (65%) pts received maintenance nivolumab. Cabo was increased to 40 mg in 11/13 of these patients. Median follow-up was 9.4 (range 4.6-17.7) months. ORR was 25% (5/20, two-sided 80% CI, 13-41%, Table 1). 6- and 12-month progression free survival rates were 65% and 42% respectively. 11 (55%) pts developed grade 3 or 4 TrAEs (6 were due to elevation in liver function tests) and 1 (5%) had grade 5 TrAE (intraoperative hemorrhage) in setting of disease progression. 5 (25%) required high dose steroids (≥40 mg prednisone or equivalent) of which only 3 (15%) received for hepatitis. All therapy was discontinued due to toxicity in 1 (5%) pt. **Conclusions:** Although the study did not reach the target of 7 responses to uphold the alternative hypothesis, reduction of the starting dose of Cabo to 20 mg/d in combination with Nivo/Ipi results in numerically lower ≥ grade 3 TrAEs than starting at 40 mg/d (60% vs 77%) and clinical activity in a subset of patients. Clinical trial information: NCT04413123. Research Sponsor: Exelixis; BMS.

	Total (N=20) N(%)	Histology					Prior Systemic Therapy

4540 **Poster Session**

Efficacy of second line (2L) treatment with tivozanib (Tivo) as monotherapy or with nivolumab (Nivo) in patients (pts) with metastatic renal cell carcinoma (mRCC) previously treated with an immune checkpoint inhibitor (ICI) combination of ipilimumab (Ipi)/Nivo or vascular endothelial growth factor receptor-tyrosine kinase inhibitor (VEGFR-TKI)/ICI in the phase 3 TiNivo-2 study. First Author: Alex Chehrazi-Raffle, City of Hope Comprehensive Cancer Center, Duarte, CA

Background: In TiNivo-2, the addition of Nivo to Tivo did not prolong progression-free survival (PFS) relative to Tivo alone (Choueiri, Lancet 2024). To assess study outcomes in the context of contemporary treatment sequencing, a subset of pts treated in the 2L who failed 1L Ipi/Nivo or VEGFR-TKI/ICI therapy was evaluated. **Methods:** Pts were randomized 1:1 to receive Tivo once daily for 21/28 days at either 1.34mg alone or at 0.89 mg with Nivo at 480 mg by IV on day 1 of each 28-day cycle. We characterized PFS, objective response rate (ORR), and best percentage change from baseline in tumor size in two cohorts consisting of pts who did not previously receive adjuvant therapy and who progressed in 1L on Ipi/Nivo, or VEGFR-TKI/ICI therapy. **Results:** Among the 153 eligible 2L pts, 70 (46%) previously received Ipi/Nivo and 83 (54%) previously received a VEGFR-TKI/ICI regimen (TKI/ICI): axitinib/pembrolizumab (54.2%), cabozantinib/nivolumab (25.3%), axitinib/avelumab (12.0%), and lenvatinib/pembrolizumab (8.4%). Overall, the median follow-up was 11.6 months. More pts with lung metastasis and age <65 years were in the Tivo arm than in the Tivo+Nivo arm in both cohorts. In the Ipi/Nivo cohort, median PFS was 9.2 months (95% CI, 4.5-NR) with Tivo and 9.3 months (95% CI, 7.3-15.3) with Tivo+Nivo. ORR was 32.4% (95% CI, 18.0%-49.8%) with Tivo and 24.2% (95% CI, 11.1%-42.6%) with Tivo+Nivo. In the TKI/ICI cohort, median PFS was 7.4 months (95% CI, 3.7-9.3) with Tivo and 3.9 months (95% CI, 2.1-5.7) with Tivo+Nivo. ORR was 22.0% (95% CI, 10.6%-37.6%) with Tivo and 9.5% (95% CI, 2.7%-22.6%) with Tivo+Nivo. Target tumor size reduction from baseline was observed in both arms (Table). More pts had target tumor reductions (≥30% or ≥50%) in the Tivo arm than in the Tivo+Nivo arm in both cohorts. Of 7 pts with target tumor reduction of ≥50% from Tivo, 6 (85.7%) and 1 (14.3%) were previously treated with axitinib and cabozantinib, respectively. **Conclusions:** In this TiNivo-2 subgroup analysis, Tivo monotherapy at 1.34 mg daily showed activity in pts who previously received a contemporary 1L mRCC regimen. At this dose of Tivo, substantial tumor size reduction was observed, both after Ipi/Nivo and VEGFR-TKI/ICI regimens. There appeared to be no benefit with the addition of Nivo to Tivo in this context, akin to the results of the parent trial. Clinical trial information: NCT04987203. Research Sponsor: AVEO Oncology.

Best percentage change in target tumor size.

		Best % Change from Baseline	
	Prior Treatment	≥30% Reduction	≥50% Reduction
Tivo	**TKI/ICI**	30.5%	19.4%
	Ipi/Nivo	44.4%	27.8%
Tivo+ Nivo	**TKI/ICI**	17.5%	2.5%
	Ipi/Nivo	33.3%	12.1%

Neoadjuvant lenvatinib plus pembrolizumab for resectable clear-cell renal cell carcinoma (PELUR): A prospective phase 2 study. First Author: Shimiao Zhu Sr., Tianjin Institute of Urology, the Second Hospital of Tianjin Medical University, Tianjin, China

Background: Lenvatinib plus pembrolizumab prolongs overall survival (OS) and progression-free survival (PFS) in advanced clear-cell renal cell carcinoma (ccRCC), with significantly improved objective response rate (ORR) and survival time compared with other competitors. However, more than 80% ≥Grade 3 adverse events (AEs) were emerged during treatment. The efficacy and safety of neoadjuvant low-dose lenvatinib plus pembrolizumab (ldLP) in ccRCC at high-risk of progression has not been assessed. **Methods:** This was an open-label phase 2 clinical trial including patients with resectable high-risk ccRCC who received neoadjuvant ldLP every 21 days for 3 cycles. Tumor responses and safety were both primary end points. The secondary end points were PFS, patient-reported quality-of-life and immune biomarkers. RNA and DNA were isolated from pretreatment tumor tissue was subjected to RNA and next-generation sequencings. Single-cell RNA sequencing (scRNA-seq) was performed in both pretreatment and posttreatment specimens from 6 patients. **Results:** A total of 33 patients were enrolled, 23 received neoadjuvant therapy followed by nephrectomy were included in the intention-to-treat (ITT) analysis. All patients received neoadjuvant therapy follow the dose of protocol. There was only one grade 3 AE (hypertension) emerged during neoadjuvant therapy. The most common AEs of neoadjuvant treatment were hypertension, fatigue, rash and pruritus (n = 5, 21.7%). During adjuvant stage, three grade 3 AEs were reported, including one case of rash, ALT/AST increase and acute kidney injury. The most common AEs during adjuvant were rash, fatigue and pruritus (n = 6, 26.1%). The EORTC QLQ-C30 questionnaires showed significant improvements in all emotional function and symptom of appetite loss. Total score of FKSI-DRS was also significantly improved. Tumor and thrombus regression occurred in all patients after neoadjuvant therapy, with 11/23 (47.8%) of them got partial response. After a median follow-up of 22 months (15-35 months), five patients experienced disease progression and 2 patients had ccRCC-related died. We characterized ~11500 single cells from 6 patients (12 samples), which were categorized into partial response (PR; n = 3) and stable disease (SD; n = 3). Our analysis revealed that the ARPP21^{+}/IGLL1^{+} B cell subcluster (AI^{+} B cells) demonstrated the most substantial cellular perturbation within SD group. Furthermore, we observed AI^{+} B cells experienced a significant reduction in PR group following treatment. The AI^{+} B cells were predicted to interact with DCs to contribute to a poor therapy response. **Conclusions:** Our data preliminarily demonstrated safety and efficacy of neoadjuvant ldLP in ccRCC at high-risk of progression. Results also highlight the importance of AI^{+} B cells in effective responses to ldLP and suggests potential strategies to overcome immunotherapy resistance. Clinical trial information: NCT05485896. Research Sponsor: National Natural Science Foundation of China (82172759); Tianjin Education Commission Research Program Project (2024ZD026 & 2024KJ193); Tianjin Municipal Health Science and Technology Project (TJWJ2024ZD002).

Clear and non-clear cell renal cell carcinomas and the ability to engage in oxidative phosphorylation. First Author: Ziad Bakouny, Memorial Sloan Kettering Cancer Center, New York, NY

Background: The impairment of oxidative phosphorylation (OxPhos) and upregulation of aerobic glycolysis, mediated by the loss of *VHL*, are key features of clear cell renal cell carcinoma (ccRCC). In contrast, non-clear cell renal cell carcinoma (RCC) denotes a heterogeneous group of tumors with few known nuclear oncogenic drivers. Recent studies have shown that mitochondrially-encoded electron transport chain (ETC) genes, responsible for OxPhos, can be mutated in a range of cancers. **Methods:** Mitochondrial mutations were called using a previously published custom pipeline for variant calling (PMID: 33833465). On-target (whole genome sequencing) and off-target (whole exome and gene panel-based sequencing) reads were used. Only samples with sufficient coverage (> = 5 reads across > 90% of the mitochondrial genome) were included. This was performed (N with sufficient coverage) in TCGA (N = 3,265; N = 324 RCC), the institutional MSK-IMPACT cohort (N = 22,252; N = 568 RCC), and CCLE/Depmap (N = 377; N = 11 RCC). Mutual exclusivity between each established RCC nuclear driver gene (N = 16, PMID: 29617669) and the heteroplasmy of ETC truncating variants was evaluated using pairwise t-tests comparing heteroplasmy between the mutated and wild-type RCC samples for each nuclear driver gene. CERES scores from genome-wide CRISPR screens in Depmap were used to compare gene dependency between cell lines. Benjamini-Hochberg correction was used to control type I error. **Results:** Across all cancer types in TCGA, RCC tumors were among the most enriched in ETC truncating mutations. These mutations most frequently affected components of mitochondrial complex I and were enriched to high levels of heteroplasmy. *VHL*-driven ccRCC was relatively depleted in these mutations compared to other subtypes (ccRCC: 8.6%, chRCC: 20.0%, pRCC: 34.0%). Further, the heteroplasmy of truncating mutations was significantly increased in chRCC and pRCC compared to ccRCC ($p < 0.05$). Among all established RCC nuclear driver genes, *VHL* was found to be mutually exclusive with high heteroplasmy ETC truncating mutations ($q < 0.05$). These results were independently replicated in the MSK-IMPACT cohort. Using data from CCLE/Depmap, we find that while cell lines with high heteroplasmy (> 50%; N = 13) truncating mitochondrially-encoded ETC mutations have differential dependencies compared to other cell lines, ETC mutations were not synthetically lethal with *VHL* mutations. Further, knockout of nuclear ETC components of complex I in Depmap was associated with little to no effect on cell survival. **Conclusions:** We established that mutations in *VHL* and in mitochondrially-encoded ETC genes are mutually exclusive in RCC and that this mutual exclusivity is not accounted for by synthetic lethality. These results suggest that mitochondrial mutations may be phenocopying the effect of *VHL* on OxPhos. Research Sponsor: National Cancer Institute; T32CA009512-35; National Cancer Institute; P30-CA008748.

4543 **Poster Session**

HIF family transcription factor expression in a cohort of 4362 patients with renal cell carcinoma (RCC). First Author: Yu-Wei Chen, Moores Cancer Center at UC San Diego Health, San Diego, CA

Background: The HIF pathway drives RCC pathogenesis operating through transcription factors (TFs) that function as heterodimers of the oxygen-sensitive α (HIF1α or HIF2α) and constitutively expressed β subunits (HIF1β or HIF2β). Loss of VHL leads to HIFα stabilization, nuclear translocation, and formation of transcriptional complexes with β subunits. We aimed to characterize the molecular and clinical features associated of HIF TF mRNA expression in RCC. **Methods:** NextGen sequencing of DNA (592-gene/whole exome) and RNA (whole transcriptome) was performed on RCC specimens (n = 4362) at Caris Life Sciences. HIF-High/Low expression was defined as $> 75^{th}$ / $< 25^{th}$ quartile RNA transcripts per million (TPM). Overall survival (OS) was defined as the time of diagnosis to death/last follow-up. Time on treatment (TOT) was defined as the time from treatment start to discontinuation. **Results:** The majority of patients were male (71%), of white race (61%), with median age of 64 years. HIF2α was lower in tumors from Black vs White patients (102.3 vs 157.5 TPM, $p < 0.0001$) and higher in tumors from Hispanic vs non-Hispanic White patients (146.1 vs 195.4 TPM, $p < 0.01$). Compared to kidney primary (n = 1,784, 43.9%, 172.1 TPM), HIF2α expression was lower in lymph nodes (n = 319, 7.9%, 97.6 TPM, $p < 0.01$) but similar to distant metastatic sites (n = 1,959, 48.2%, 168.3 TPM). Compared to clear cell RCC (n = 1198, 29.5%, 224.3 TPM), HIF2α expression was lower in papillary (n = 238, 5.9%, 57.5 TPM), chromophobe (n = 83, 2.0%, 91.7 TPM), and medullary RCC (n = 15, 0.36%, 46.5 TPM) ($p < 0.01$ each). Sarcomatoid RCC (n = 119, 2.9%) had lower HIF2α (111.9 vs. 155.0 TPM, $p < 0.05$), lower HIF2β (5.6 vs 8.5 TPM, $p < 0.01$), and higher HIF1α (276.3 vs 197.4 TPM, $p < 0.01$) compared to non-sarcomatoid RCC (n = 3947, 97.2%). Compared to *VHL* wild-type (n = 1415, 34.9%), *VHL*-mutated tumors (n = 1884, 46.4%) had higher HIF2α (206.6 vs 97.7 TPM), lower HIF1α (184.9 vs 233.9 TPM), lower HIF2β (7.2 vs 10.2 TPM) ($p < 0.01$ each). Tumors with high HIF2α were enriched for *VHL*, *PBRM1*, *MTOR*, and *PTEN* alterations and had fewer *TP53*, *BAP1*, *MET*, *SMARCB1*, and *NF2* alterations. HIF1α-high tumors had fewer *VHL*, *TSC1*, and *BAP1 alterations*. HIF1β -high tumors had decreased *TP53* and *RB1* and increased *CHEK2* and *PALB2* alterations. High HIF2α and HIF2β was associated with improved OS (92.6 vs 68.1 months, $p < 0.001$ and 87.4 vs 69.8 months, $p < 0.004$, respectively), while HIF1α and HIF1β did not correlate with OS. Patients with high HIF2α had prolonged cabozantinib TOT (8.1 vs 3.9 months, $p < 0.001$). **Conclusions:** This comprehensive analysis revealed distinct HIF TF expression patterns across RCC subgroups. Notably, elevated HIF2α expression was observed in clear cell RCC, VHL-mutated tumors, and was linked to improved OS and prolonged TOT with cabozantinib, suggesting a potential prognostic role for HIF2α in RCC, warranting further clinical investigation. Baseline radiological tumor burden to sub-stratify IMDC risk groups in metastatic renal cell carcinoma treated with first-line therapy: A post hoc analysis from a randomized phase III trial. First Author: Rashad Nawfal, Dana-Farber Cancer Institute, Boston, MA

Background: Baseline radiological tumor burden (BRTB) is a measurement derived from routine CT scans and reflects baseline tumor burden. Herein we assess the utility of BRTB to help with risk assessment within IMDC risk subgroups from a randomized prospective phase III study. **Methods:** We reviewed data of 701 patients with metastatic renal cell carcinoma (mRCC) from the CheckMate 9ER trial (Choueiri, NEJM 2021). Patients with BRTB measurement per investigator using RECIST v1.1 at baseline were included. Outcomes of interest included overall survival (OS), and progression-free survival (PFS). To evaluate the impact of BRTB on OS and PFS, we used univariate and multivariable Cox regression models for each IMDC subgroup accounting for age, sex, race, stage at diagnosis, sarcomatoid features and regimen type (IO+VEGFi, VEGFi). **Results:** Favorable, intermediate and poor risk IMDC subgroups included 157/701, 392/701 and 132/701 patients, respectively. This cohort included 63, 187 and 94 OS events and 112, 290 and 103 PFS events in favorable, intermediate and poor risk groups, respectively. For the favorable risk group, BRTB was not associated with OS or PFS on multivariable analysis ($HR_{adjusted}$= 1.00, 95%CI: 0.99-1.01, p = 0.68 and $HR_{adjusted}$= 1.00, 95%CI: 0.99 – 1.00, p = 0.99, respectively). Similarly for the poor risk group, BRTB was not associated with OS or PFS on multivariable analysis ($HR_{adjusted}$= 1.03, 95%CI: 0.99-1.06, p = 0.06 and $HR_{adjusted}$= 1.02, 95%CI: 0.98 – 1.04, p = 0.54, respectively). However, in the intermediate risk group, higher BRTB was associated with worse OS (HR: 1.05 for each 1 cm increase in BRTB, 95%CI: 1.04-1.07, $p < 0.0001$) and PFS (HR: 1.03, 95%CI: 1.01-1.05, $p < 0.001$). On multivariable analysis, BRTB remained associated with both OS and PFS ($HR_{adjusted}$= 1.05, 95%CI: 1.04-1.07, $p < 0.0001$ and $HR_{adjusted}$= 1.03, 95%CI: 1.02 – 1.05, $p < 0.0001$, respectively). Further, we stratified IMDC intermediate risk group outcomes according to BRTB median value of 6.33cm (Table). **Conclusions:** While BRTB does not appear to predict outcomes in favorable and poor-risk subgroups in this study, BRTB is a useful metric for sub-stratification of the intermediate-risk IMDC subgroup. External validation is imperative to validate these findings and explore BRTB integration into clinical decision-making in mRCC. Research Sponsor: None.

Stratification of the intermediate IMDC risk group according to baseline radiological tumor burden median (6.33cm).

	Intermediate low BRTB (n=196)	Intermediate high BRTB (n=196)	Log rank p value
Median OS, months (95% CI)	NR (49.5 – NR)	30.9 (24.4 – 40)	$p < 0.0001$
Median PFS, months (95% CI)	15.84 (11.83 – 18.3)	8.41 (6.97 – 11.1)	$p < 0.001$

Efficacy of subsequent treatment after combination therapy in non-clear cell renal cell carcinoma (nccRCC). First Author: Paulo Siqueira do Amaral, Vandebilt University Medical Center, Nashville, TN

Background: The treatment landscape of front-line nccRCC has evolved with recent trials demonstrating the efficacy of combination systemic therapy. However, the efficacy of treatment after combination therapy is unknown. This study evaluates the efficacy of VEGF-based regimens in nccRCC patients (pts) previously treated with combination regimens. **Methods:** ORACLE is a real-world, multi-center, retrospective database that includes nccRCC patients that received combination systemic therapies (IO+IO, IO+VEGF and VEGF+ mTOR) in any line. Subsequent treatments were categorized as VEGF only regimens (cabozantinib vs other VEGF), IO+ VEGF and VEGF+ mTOR. The primary endpoint was objective response rate (ORR) assessed by investigator review using RECIST 1.1. Secondary endpoints included disease control rate (DCR), defined as the proportion of patients achieving complete or partial responses or stable disease, time to treatment progression (TTP), calculated from the date of VEGF-based initiation to progression or last follow-up using the Kaplan-Meier method. Differences between groups were estimated with the log-rank test, and categorical outcomes were compared with the chi-square test. **Results:** 105 pts who received VEGF – based regimens after combination therapy were included in the analysis. Baseline characteristics: median age: 59years, 71 % male, 58% white, 25% black, 87% ECOG 0-2. IMDC-risk categories included:21% favorable, 59% intermediate and 20% poor risk. Histology included papillary (40%), unclassified (32%), chromophobe (16%) and other rare subtypes (12%). Prior combination therapies included IO+IO: 62%, IO+ VEGF: 34% and VEGF+ mTORi:4%. 70% pts received combination therapy in the first line setting while the remainder received combination therapy in a second or later line. Outcomes with subsequent treatments are described in Table1. IMDC risk score correlated with TTP. **Conclusions:** Modest antitumor activity was observed with VEGF- based approaches in combination therapy refractory nccRCC. Optimal management of nccRCC remains an unmet need. Research Sponsor: None.

Integrative clinical, genomic, and transcriptomic characterization of circulating KIM-1 in metastatic RCC. First Author: Marc Machaalani, Dana-Farber Cancer Institute, Boston, MA

Background: Kidney injury molecule-1 (KIM-1) is a transmembrane protein that is overexpressed in renal cell carcinoma (RCC) and correlated with clinical outcomes in localized and metastatic disease. Nevertheless, association between circulating KIM-1 protein levels and the underlying tumor biology represented by genomic and transcriptomic correlates is not well understood. **Methods:** KIM-1 was measured in plasma at baseline (C1D1) and at C3D1 using an MSD electrochemiluminescence-based assay. Differential gene expression (DGE) and gene set enrichment analysis (GSEA) were performed using DESeq2, with KIM-1 treated as a continuous variable. Associations between circulating KIM-1 levels and clinical, genomic, and transcriptomic tissue data from the JAVELIN Renal 101 trial were evaluated using the Wilcoxon rank-sum test (for categorical groups) and Cox regression (for time-to-event outcomes). **Results:** Plasma for analysis was available from 612 patients (69% of the ITT population), including 323 treated with avelumab plus axitinib and 289 with sunitinib. Elevated baseline KIM-1 levels were correlated with higher tumor burden as assessed by the sum of tumor diameters (Spearman's $\rho = 0.55$, $p < 0.0001$), decreased with tumor shrinkage ($p < 0.0001$), and were associated with poorer PFS (HR 1.32 per unit increase in log KIM-1, 95% confidence interval (CI) 1.16–1.49, $p < 0.0001$) and OS (HR 1.96 per unit increase in log KIM-1, 95% CI 1.61–2.37, $p < 0.0001$). Higher KIM-1 levels were found in IMDC poor–risk versus intermediate–risk ($p < 0.0001$) and in intermediate–risk versus favorable–risk groups ($p < 0.001$). Loss-of-function (LOF) *BAP1* mutations, associated with more aggressive disease, were associated with higher KIM-1 RNA expression ($p < 0.0001$) and protein expression ($p = 0.038$) and remained significant after adjustment for tumor burden as assessed by linear regression residuals. Transcriptomic analysis showed that RNA expression levels of *HAVCR1*, the gene coding KIM-1, were associated with circulating KIM-1 protein (Spearman's $\rho = 0.31$, $p < 0.0001$), and that higher KIM-1 levels were associated with interferon gamma response whereas lower KIM-1 levels were associated with a hypoxia transcriptional program. Higher circulating KIM-1 was also associated with enrichment for proliferative versus angiogenic gene expression signatures ($p = 0.013$). The findings were independent of therapy arms. **Conclusions:** We present the first integrative clinical, transcriptomic, and genomic evaluation of circulating KIM-1. High KIM-1 is a biomarker of poor prognosis in RCC and correlates with specific LOF mutations and transcriptions programs. Prospective studies are needed for the clinical implementation of KIM-1 as a biomarker in RCC. KEAP1 mutated renal cell carcinoma (RCC): Characterization of an emerging molecularly defined RCC subtype. First Author: Marie Carlo, Genitourinary Oncology, Memorial Sloan Kettering Cancer Center; Weill Cornell Medical College, New York, NY

Background: KEAP1 is a tumor suppressor and negative regulator of the NRF2 pathway, and inactivating *KEAP1* mutations (mts) have been reported in patients (pts) with RCC with similar morphology to fumarate hydratase (FH)-deficient RCC (FH-RCC). In FH-RCCs, the NRF2 pathway is activated through fumarate-led inactivation of KEAP1, and we hypothesized that *KEAP1* mts are drivers in RCC, similar to FH mts in FH-RCC. We sought to characterize RCC with *KEAP1* mts as a separate RCC subtype and compare to FH-RCC and clear cell (cc)RCC. **Methods:** Among consecutive pts with RCC consented to tumor-normal DNA sequencing via MSK-IMPACT (NCT01775072), we identified patients with germline or somatic mutations in *KEAP1* or *FH* and no other known driver mts (ie *VHL, MET, TFE3* alterations), and categorized these as "KEAP1-RCC" or "FH-RCC." Clinicopathologic characteristics and outcomes were analyzed and compared to pts with FH-RCC and a previously annotated subset ccRCC (n=162). Immunohistochemical (IHC) staining for NQO1, marker of NRF2 activation, was performed. Time on systemic treatment and overall survival (OS) from time of sequencing were assessed. **Results:** Among 928 pts with RCC, 13 (1.4%) and 26 (2.8%) had RCCs with *KEAP1* and *FH* mts, respectively. *KEAP1* and *FH* mts were mutually exclusive. Median age was younger in FH-RCC (47 vs 63) (Table). When compared to ccRCC, OS was significantly worse for FH-RCC (HR 2.4, 95% CI 1.4-4.1; p=0.02) but not for KEAP1-RCC (HR 1.07, 95% CI 0.29-3.0; p=0.89). All KEAP1-RCC and FH-RCC were histologically classified as non-cc except one KEAP1-RCC that had 3p loss and no VHL mt. All available KEAP1 and FH-RCC were NQO1+ on IHC; control ccRCC were all negative. In the KEAP1-RCC cohort, we identified a female with an unclassified RCC and a germline *KEAP1* truncating variant; RCC tumor had a second *KEAP1* somatic mutation and was NQO1+ on IHC. The germline variant cosegregated to a sister with lung cancer (IHC NQO1+) and anal cancer. **Conclusions:** RCC with KEAP1 mts and no other genomic drivers are primarily non-cc with papillary features, have functional evidence of NRF2 activation, and although high-grade may have better outcomes than FH-RCC. KEAP1-RCC appears to be an emerging molecularly defined RCC subtype with clinical behavior similar to FH-RCC, likely as a result of converging on NRF2 pathway activation. Second-line outcomes in metastatic renal cell carcinoma: The role of International Metastatic Renal Cell Carcinoma Database Consortium (IMDC) prognostic factors after first-line immunotherapy. First Author: David Maj, Arthur J.E. Child Comprehensive Cancer Centre, Calgary, AB, Canada

Background: IMDC prognostic factors are well established in metastatic renal cell carcinoma (mRCC) with both VEGFR inhibitor and immunotherapy-based first-line therapies. However, the role of these prognostic factors for the second-line setting is less established in the contemporary era. **Methods:** We performed a retrospective analysis of patients with mRCC who received first-line therapy (1L) with dual immunotherapy (IPI-NIVO) or combination immunotherapy-VEGFR (IOVE) based regimens and then received second-line therapy (2L). 2L IMDC risk factors were assessed at the time of 2L therapy initiation and were composed of Karnofsky Performance Status $< 80\%$, time from diagnosis to 2L therapy start < 1 year, hemoglobin $<$ lower limit of normal, neutrophils $>$ upper limit of normal (ULN), platelets $>$ ULN, corrected calcium $>$ ULN. 2L IMDC risk groups were favorable (0 risk factors), intermediate (1-2 risk factors), or poor risk (3+ risk factors). Baseline characteristics, objective response rates (ORR), treatment duration (TD), and overall survival (OS) were collected and compared by log-rank test. **Results:** A total of 781 patients were identified of whom 66% received IPI-NIVO and 34% received IOVE in the 1L setting. 2L IMDC risk groups and changes from 1L IMDC risk are presented in Table. Amongst all patients who received 2L therapies, 10.6% had favorable risk, 57.8% had intermediate risk, and 31.6% had poor risk disease. Nephrectomy status varied significantly across groups with 99% of favourable risk, 65% of intermediate risk, and 42% of poor risk patients having undergone nephrectomy ($p<0.0001$). Overall, 66.3% of patients retained their 1L risk group, while 12.6% were in a more favorable risk group and 21.1% a less favorable risk group. Type of 1L therapy (IPI-NIVO vs IOVE) did not predict change in 2L IMDC risk group ($p=0.931$). 2L therapies were heterogeneous with 38.9% receiving cabozantinib, 22.3% sunitinib, 8.7% pazopanib, 12.7% an IO-based regimen (IO monotherapy, IOIO, IOVE), and 17.4% other therapies. 2L ORR, TD, and OS varied significantly by 2L IMDC risk group (Table). **Conclusions:** In a real-world setting amongst patients receiving 1L IO-based regimens, IMDC risk factors remain prognostic in the 2L setting. These new benchmarks may be used for patient counselling and clinical trial design in 2L. Research Sponsor: None.

Clinical characteristics and determinants of primary refractory metastatic renal cell carcinoma (mRCC): An International Metastatic Database Consortium (IMDC) study. First Author: Karl Semaan, Dana-Farber Cancer Institute, Boston, MA

Background: Immune checkpoint inhibitor (ICI)-based regimens, including ICI + ICI and ICI+VEGF-targeted therapy (VEGF-TT), represent the current standard of care for first line (1L) in mRCC. A subset of patients (pts) experiences primary refractory disease, defined as progressive disease (PD) as best response. The aim of this study is to investigate the clinical characteristics and determinants of pts with primary refractory mRCC. **Methods:** Pts with mRCC treated with 1L ICI-based regimens from the IMDC were included. Pts were categorized as primary refractory (PD as best response evaluated per RECIST 1.1 criteria) and non-primary refractory (stable disease or partial/complete response as best response). Baseline characteristics were compared using a Chi-Square test. Independent factors associated with primary refractory mRCC were identified using a logistic regression. **Results:** In total, 2001 pts were included, of which 1301 (65%) were treated with dual ICI, and 701 (35%) with ICI+VEGF-TT. Of 2001 pts, 494 (24%) experienced PD at first restaging. Primary refractory and non-primary refractory groups did not differ by age or gender. The primary refractory group had more pts treated with dual ICI (76 vs. 62%), more pts with poor IMDC risk (29 vs. 19%), and more pts with non-clear cell RCC (27 vs. 19%; all $p < 0.001$). The primary refractory group had shorter diagnosis to treatment interval (mean: 1.6 vs. 2.3 years), lower KPS (median: 80 vs. 90), higher rate of anemia (65% vs. 52%), neutrophilia (11% vs. 9%), and thrombocytosis (30 vs 22%; all $p < 0.001$). The primary refractory group had more liver (24 vs. 17%; $p < 0.001$), bone (39 vs 32%; $p < 0.001$) and lymph nodes metastasis (52 vs. 47%; p = 0.03) at the start of 1L therapy. On multivariable analysis, independent factors associated with primary refractory RCC were low KPS, and the presence of liver metastasis or bone metastasis (Table). Dual ICI regimen was associated with a 1.8-fold increase of primary refractory RCC. **Conclusions:** In pts with mRCC, low KPS and the presence of liver or bone metastasis are independent risk factors for the development of primary refractory disease. Primary refractory disease is more commonly observed in pts receiving dual ICI compared to those on ICI+VEGF-TT regimen. Research Sponsor: None.

Multivariable analysis for independent factors associated with primary refractory RCC.

	OR	Lower 95% CI	Upper 95% CI	p-value
Diagnosis to treatment interval < 1 year (yes vs. no)	1.2	0.9	1.6	0.2
Anemia (yes vs. no)	1.37	1.1	1.8	0.03
Low KPS(<80: yes vs. no)	1.9	1.4	2.5	<0.001
Neutrophilia (yes vs. no)	1.3	1	1.8	0.09
Thrombocytosis (yes vs. no)	0.9	0.7	1.3	0.6
Liver metastasis (yes vs. no)	1.7	1.3	2.3	<0.001
Lymph Nodes metastasis (yes vs. no)	1.3	1	1.6	0.07
Bone metastasis (yes vs. no)	1.3	1.03	1.7	0.03
Dual ICI (vs. ICI+VEGF-TT)	1.8	1.37	2.4	<0.001
Non-clear cell RCC (vs. clear cell)	1.3	1	1.8	0.06

Long-term clinical outcomes with nivolumab/ipilimumab with or without *Clostridium butyricum* MIYAIRI588 in metastatic renal cell carcinoma (mRCC): A randomized phase Ib clinical trial. First Author: Miguel Zugman, City of Hope Comprehensive Cancer Center, Duarte, CA

Background: In two randomized phase I trials, *Clostridium butyricum* MIYAIRI588 (CBM588), a live biotherapeutic, demonstrated preliminary activity in modulating the gut microbiome, enhancing systemic immune responses, and improving clinical outcomes in patients receiving first-line nivolumab/ipilimumab and nivolumab/cabozantinib for mRCC (Dizman *et al.* and Ebrahimi *et al.* Nature Medicine). Herein, we present the long-term follow-up data for nivolumab/ipilimumab with or without CBM588. **Methods:** Newly diagnosed patients with mRCC, clear cell and/or sarcomatoid histology, and International mRCC Database Consortium intermediate/high risk were randomized to receive nivolumab/ipilimumab with or without CBM588 in a 2:1 ratio. Response outcomes were assessed using RECIST 1.1. Clinical outcomes were secondary endpoints. Objective response rate (ORR; complete response [CR] or partial response [PR]), disease control rate (DCR; CR, PR, or stable disease [SD] $>$ 6 months), progression-free survival (PFS), and overall survival (OS) outcomes were compared across arms. **Results:** Twenty-nine patients were included in the final analysis: 19 in the nivolumab/ipilimumab with CBM588 arm and 10 in the nivolumab/ipilimumab arm. The median age was 66.2 years, 72% were male, 83% had IMDC intermediate risk and 93% had clear cell histology. Baseline characteristics were similar across arms. ORR and DCR were 58% and 79% in nivolumab/ipilimumab with CBM588 arm versus 20% and 20% in nivolumab/ipilimumab arm, respectively (p = 0.06 and p = 0.004). At a median follow-up of 60.0 (95% CI 51.9-68.1) months, the median PFS was 38.2 (95% CI 23.6-52.8) months in the nivolumab/ipilimumab and CBM588 arm versus 19.3 (95% CI 0-41.9) months in the nivolumab/ipilimumab arm (Hazard ratio [HR] 0.24, 95% CI 0.09-0.61 p = 0.003). At the time of data cutoff, 9 (47.4%) and two (20%) patients were alive in the nivolumab/ipilimumab with CBM588 and nivolumab/ipilimumab arms, respectively. The median OS with nivolumab/ipilimumab with CBM588 was 55.0 (95% CI 10.5-75.5) months versus 39.0 (95% CI 23.7-54.3) months with nivolumab/ipilimumab (HR 0.438 [95% CI 0.17-1.1] p = 0.09). **Conclusions:** Although limited by the sample size, the combination of nivolumab/ipilimumab with CBM588 demonstrated superior clinical activity over nivolumab/ipilimumab in our cohort. Additionally, ORR, PFS and OS with nivo/ipi/CBM588 exceeded those observed with nivolumab and ipilimumab in historical datasets (Motzer *et al.* NEJM). Larger efforts investigating the impact of CBM588 on clinical outcomes are underway. Clinical trial information: NCT03829111. Research Sponsor: None.

Vasculogenic mimicry as a potential indicator of drug resistance and prognosis in renal cell carcinoma. First Author: Xingang Cui, Department of Urology, Xinhua Hospital, School of Medicine, Shanghai Jiao Tong University, Shanghai, China

Background: Patients with advanced metastatic renal cell carcinoma (RCC) often develop resistance to tyrosine kinase inhibitors (TKIs). Vasculogenic mimicry (VM) refers to the formation of tubular structures by tumor cells mimicking endothelial cells. VM formation is independent of VEGF and endothelial cells, making it inherently resistant to TKIs. Furthermore, hypoxic conditions induced by TKI treatment can promote VM formation, creating a vicious cycle. This study investigates the molecular mechanisms of VM formation and its prognostic significance in RCC. **Methods:** VM incidence in RCC was assessed using PAS/CD31 staining on tissue microarrays. Single-cell sequencing data were used to identify tumor cells undergoing VM differentiation. Cluster analysis was conducted to characterize these cells, and their prognostic value was validated using TCGA data. Pseudotime trajectory analysis and SCENIC algorithms were used to infer their differentiation pathways and identify transcription factors (TFs) regulating VM formation. Tube formation assays were performed for validation. **Results:** PAS/CD31 double staining revealed a VM incidence of 15.87% (10/63) among RCC patients. Notably, VM formation was more frequent in recurrent and TKI-resistant patients, suggesting that VM may serve as a mechanism for TKI resistance. Single-cell data from 11 patients with stages T1a-T3 RCC were analyzed, identifying VM-differentiating tumor cells, termed RCC-VM. GSVA revealed that RCC-VM cells were highly enriched in angiogenesis and EMT-related pathways. GO and KEGG analyses also showed enrichment in angiogenesis pathways. Trajectory analysis of tumor cell subpopulations placed RCC-VM at the terminal differentiation state, suggesting it represents a uniquely differentiated tumor cell type. Using SCENIC, we identified FOSL2 as a key TF regulating RCC-VM differentiation. Knockdown of FOSL2 significantly impaired tube formation in 786-O cells in vitro. Additionally, we identified RCC-VM-specific signature genes (VMDEG) and used Lasso-Cox regression to select four key risk factors (PIM1, MT1G, MT-ND4, DDIT3) to construct a survival risk model. Kaplan-Meier survival analysis demonstrated that patients in the high-risk group had significantly shorter survival times compared to the low-risk group (p = 0.0013). The time-dependent ROC curve showed that the model had robust predictive ability, providing potential guidance for personalized treatment of RCC patients. **Conclusions:** Our study highlights VM as a critical mechanism of TKI resistance in RCC, regulated by the transcription factor FOSL2. VMDEG serves as a valuable prognostic marker for RCC patients. Incorporating VM into staging systems such as pT staging and Fuhrman grading may improve risk stratification and treatment planning for RCC patients. Research Sponsor: None.

Differences in patient characteristics, treatment patterns, and clinical outcomes of renal cell carcinoma patients in public vs private health care systems in Brazil: Insights from the LACOG 1120 registry. First Author: Pablo Barrios, Latin American Cooperative Oncology Group (LACOG), Porto Alegre, Brazil

Background: Brazil's dual healthcare system presents unique challenges in addressing disparities in cancer care. Understanding the differences in clinical characteristics, treatment patterns, and clinical outcomes of renal cell carcinoma (RCC) patients (pts) between public and private health systems is crucial for optimizing care. **Methods:** LACOG 1120 Registry collected data from 230 eligible RCC pts across Brazil from Sep. 2022 to Nov. 2023. Patient demographics, tumor characteristics, treatment information, and clinical outcomes were analyzed and stratified by healthcare system (public vs. private). Descriptive statistics and survival analyses were performed using Kaplan-Meier methods. **Results:** 230 pts were included. Median age at diagnosis was 61.0 (52.0–67.0), 65.2% were male, 58.7% white, 26.1% of mixed skin color and 4.3% black. 61.3% were treated in the public system, and 36.5% in the private system. Pts in the public system were more likely to present with advanced disease (stage IV: 25.5% vs. 17.9%) and had a lower proportion of early-stage disease (stage I: 20.6% vs. 33.3%) compared to the private system. Out of 230, 11 (4.8%) received adjuvant treatment, 3 (2.1%) from the public 8 (9.5%) from the private system. Pts from the public system predominantly received adjuvant sunitinib (66.7%) whereas all the 8 pts from the private systems received adjuvant immune checkpoint inhibitor (ICI) (87.5% pembrolizumab, 12.5% nivolumab). First-line treatment for metastatic RCC was given to 34.0% of public and 53.6% of private system pts. Public pts mainly received sunitinib (47.9%) or pazopanib (31.3%), while private pts predominantly received ICIs (42.2%) or ICI-Tyrosine kinase inhibitors (TKI) combos (26.6%). Treatment discontinuation due to toxicity was higher in the public system (40.9% vs. 36.4%). 20.0% and 31.7% of pts were classified as favorable risk in the public and private systems respectively according to IMDC risk criteria. At median follow-up of 41.7 months (95%CI 27.6 - 48.8), median overall survival (OS) from diagnosis was 79.4 months (95% 66.0 - NR). The 5-year (yr) median OS rate differed between systems, 89.6% (95%CI 70.1-90.6) in private and 42.0% (95%IC 31.1-56.7) in public. When stratified by clinical stage (CS), the 2-yr OS for pts with CS I-III was 87% in the public and 96.8% in the private system. For pts with CS IV, the 2-yr OS was 23.8% in the public compared to 60.0% in the private system. **Conclusions:** Significant disparities exist between RCC pts treated in Brazil's public and private health systems, with public system pts presenting with more advanced disease, with restricted access to novel therapies, and experiencing worse clinical outcomes. These findings underscore the urgent need for health policy reforms to address inequities in cancer care access and treatment in Brazil. Real-world quality of life (QOL) in patients (pts) with metastatic renal cell carcinoma (mRCC) on active surveillance (AS) in the ODYSSEY prospective observational study. First Author: Michael Roger Harrison, Duke Cancer Institute Center for Prostate and Urologic Cancers, Duke University School of Medicine, Durham, NC

Background: AS is a recognized strategy in select pts with mRCC to maximize QOL and delay potential toxicity of systemic therapy (ST); however, only 2 prospective studies of AS in mRCC have been published: only 1 with patient-reported outcomes (PRO) and none in the IO-TKI era. **Methods:** ODYSSEY is a prospective observational study of 500 US pts with mRCC. Eligible pts must have mRCC (any histology), no prior ST, age ≥19. Pts were excluded if treated for non-mRCC cancers or if not followed at a PCORnet study site. Pts completed QOL surveys at baseline, by phone every 3 months for 2 years and then every 6 months until end of follow up. The primary objective is to determine patterns of change in QOL and symptom burden of pts with mRCC. Minimally important differences (MID) are 3 points for FKSI-19 total score, 1 point for the FKSI-Disease Related Symptoms (DRS) subscale and 7 points for FACT-G. Here we report baseline pt characteristics in AS pts compared to ST pts, and baseline QOL differences between these cohorts. **Results:** As of 1/6/25, 392 pts were enrolled of whom 299 were managed with ST, and 93 pts deferred ST; of these, 53 pts (57%) were classified as AS. Pts on AS are median age 68 yrs, 66% male, 94% white, 81% clear cell, 50% favorable risk, 44% intermediate risk. Compared with ST pts, AS pts were more likely to have undergone nephrectomy (91% vs 53%), favorable risk profile (50% vs 15%), pancreatic metastasis (15% vs 5%), and longer time since RCC diagnosis (median 58 vs 3.3 months); and less likely to have bone, brain, or liver metastasis. After median 8.8 months follow-up (IQR 2.9, 16.2), 2 pts (4%) on AS had died compared with 45 pts (15%) on ST. One pt (2%) on AS started first-line therapy and 45 pts (15%) discontinued ST. Mean baseline QOL (FKSI-19 total, DRS and FACT-G) for AS and ST ODYSSEY pts is shown in the Table (higher score indicates better QOL), with RCT data for reference (NA, not assessed). ODYSSEY pts on AS had higher QOL for all measures compared with ODYSSEY pts on ST. FSKI-DRS was the same or lower for pts on AS compared to the pivotal trials, while ODYSSEY pts on ST had both lower FKSI-19 total and DRS. **Conclusions:** In our large prospective cohort from ODYSSEY, pts on AS had higher median QOL scores than pts on ST, but similar to those included in RCTs. These results suggest that some RCT pts could have benefitted from AS. Further follow up is needed to determine long term outcomes in pts on AS and how they respond to deferred ST. Clinical trial information: NCT04919122. Research Sponsor: Bristol Myers Squibb; Exelixis; Merck Sharp & Dohme LLC, a subsidiary of Merck & Co., Inc.; Pfizer.

Machine learning–derived B-cell epitopes classifiers for early detection of renal cell carcinoma. First Author: Thomas Campbell, Serimmune, Inc., Goleta, CA

Background: Renal cell carcinoma (RCC) remains a significant cause of cancer mortality in the United States, with poor outcomes for advanced-stage disease and limited tools for early detection. Tumor-specific antibodies, known to develop early in other solid tumors, offer biomarker opportunities for early RCC detection. This study aimed to leverage Serum Epitope Repertoire Analysis (SERA), an advanced platform for profiling B cell epitopes, to develop a machine learning-based classifier capable of distinguishing patients with RCC from those with benign renal masses and from individuals without known renal neoplasms. **Methods:** We obtained 564 serum or plasma samples from 1) 260 patients with pathologically confirmed RCC, spanning all stages; 2) 21 patients with benign renal masses (predominantly oncocytoma and angiomyolipoma); and 3) 283 age-matched non-RCC controls (self-reported healthy donors). The SERA platform uses a library of 8 billion unique 12-mer peptides, each expressed on a DNA-barcoded *E. coli* strain. Number and type of peptides bound by an antibody are identified by next-generation sequencing, enabling comprehensive profiling of B cell epitopes. Using machine learning, a classifier was trained on a subset of 178 samples (88 RCC and 90 healthy controls) to predict the presence of RCC in the validation cohort of 386 samples (172 RCC, 21 benign renal masses, and 193 healthy controls). The area under the receiver operating characteristic curve (AUC) served to evaluate the classifier's performance, overall and stratified by RCC stage. **Results:** Using the SERA platform, 26.4 million potential amino acid motifs were scored based on enrichment in RCC versus controls, yielding 7,244 motifs that met the predefined thresholds for inclusion in the classifier. These features were used to train a 10,000-tree random classification forest. In validation, the model achieved an AUC of 0.76 (95% confidence interval [CI]: 0.72 - 0.81), and scores were not significantly different (Mann-Whitney U test, alpha = 0.05) in the benign renal lesion control samples vs. healthy controls. Performance was consistent across both early- and late-stage RCC, with an AUC of 0.78 (95% CI: 0.70–0.85) for stage 1, 0.72 (95% CI: 0.49–0.95) for stage 2, 0.81 (95% CI: 0.70–0.92) for stage 3, and 0.75 (95% CI: 0.68–0.81) for stage 4 RCC, each compared to controls, demonstrating robust detection across all disease stages. **Conclusions:** Our findings suggest that a non-invasive SERA-based classifier can distinguish RCC from benign renal masses and healthy controls, with consistent performance across all stages of RCC. The robust detection of early-stage RCC underscores the potential of this approach to enhance early diagnosis of RCC and to guide clinical management while obviating the need for renal mass biopsy. Future studies will focus on refining the classifier and validating its performance in larger, multi-institutional cohorts. Research Sponsor: Department of Defense Kidney Cancer Research Program.

Clinical outcomes of patients with primary refractory metastatic renal cell carcinoma receiving second-line (2L) therapies: An International Metastatic Database Consortium (IMDC) study. First Author: Marc Eid, Dana-Farber Cancer Institute, Boston, MA

Background: A subset of patients (pts) with metastatic renal cell carcinoma (mRCC) receiving contemporary first line (1L) immune checkpoint inhibitor (ICI) combinations are considered to be primary refractory. The optimal sequence therapy for this patient population is not well established. Herein, we report practice patterns and clinical outcomes of second line (2L) therapy in pts with primary refractory mRCC. **Methods:** Data from pts with primary refractory mRCC to 1L ICI and who received 2L therapy were collected through the IMDC. Patients with primary refractory RCC were defined as patients who experienced progressive disease (PD) as best response per RECIST 1.1 criteria. Overall survival (OS) and time to treatment failure (TTF) were calculated from initiation of 2L therapy; their distributions were estimated by the Kaplan Meier methodology. **Results:** In total, 494 pts had primary progression on 1L ICI, of which 356 (72%) went on to receive subsequent 2L therapy. The most common regimens in the 2L setting included: cabozantinib (n = 137; 38%); sunitinib (n = 115; 32%), and pazopanib (n = 37; 10%). 22% of patients had IMDC poor risk at initiation of 2L. Median follow-up from 2L initiation was 18.8 months. Median OS was 14.5 months, and the median TTF was 5.4 months for the whole cohort. The median OS was 14.4 months (95% CI 11 – 21.4) for cabozantinib, 10.7 months (95% CI 7 -16.6) for sunitinib, and 15.3 months (95% CI 9 – 46) for pazopanib. The median TTF was 4.5 months (95% CI 3.7 -5.6) for cabozantinib, 3.1 months (95% CI 2.8 – 4.4) for sunitinib, and 2.8 months (95% CI 1.7 – 3.6) for pazopanib. The ORR was 20% for pts receiving cabozantinib, 10% for pts receiving sunitinib, and 16% for patients receiving pazopanib. For pts treated with 2L cabozantinib, 84 (61%) had prior dual ICI and 53 (39%) had prior ICI + VEGF. By contrast, for patients treated with sunitinib or pazopanib, the majority (96% and 95%, respectively) had prior dual ICI as 1L. **Conclusions:** To our knowledge, this is the first initiative to report practice patterns and outcomes of subsequent 2L therapies in patients with primary refractory mRCC to contemporary 1L ICI combinations. Cabozantinib was the most frequently used regimen in this patient population and demonstrated favorable clinical outcomes compared to sunitinib or pazopanib. Biomarker evaluation is needed to explore the mechanism of primary resistance and novel therapeutic strategies for this group. Research Sponsor: None.

Outcomes of patients with primary refractory mRCC receiving 2L therapies.

Treatment Arm	N	Median OS, months (95% CI)	Median TTF, months (95% CI)	ORR, %
2L Cabozantinib (1L dual ICI)	84	15 (11 – 26.2)	4.2 (3.4 – 6.6)	20
2L Cabozantinib (1L ICI + VEGF)	53	13.5 (9.8 – NR)	4.8 (3.6 – 5.9)	20
2L Sunitinib	115	10.7 (7 – 16.6)	3.1 (2.8 - 4.4)	10
2L Pazopanib	37	15.3 (9 – 46)	2.8 (1.7 – 3.6)	16

Refining intermediate-risk (IR) stratification in patients (Pts) with metastatic renal cell carcinoma (mRCC) receiving first-line (1L) immunotherapy (IO) within one year of diagnosis (Dx): Findings from the International Metastatic Renal Cell Carcinoma Database Consortium (IMDC). First Author: Razane El Hajj Chehade, Dana-Farber Cancer Institute, Boston, MA

Background: The IMDC risk model is pivotal for predicting clinical outcomes in pts with mRCC, yet variability exists within the IR group. Moreover, therapy initiation within < 1 year post dx, a predominant IMDC risk factor, significantly influences prognosis. Thus, this study evaluates this heterogeneity in IO era, focusing on patients receiving 1L IO within < 1 year post dx. **Methods:** Data from pts with mRCC receiving 1L IO within < 1 year post dx, with IMDC score of 1 or 2, were retrospectively collected from the IMDC. Score 1 pts were defined as those who started treatment < 1 year post dx, while score 2 pts had an additional IMDC risk factor: low hemoglobin (Hb), Karnofsky Performance Status (KPS) < 80, high neutrophil, high calcium (Ca), or high platelet (Plt) count. We assessed overall survival (OS) and time to treatment failure (TTF) using Cox regression, adjusting for age, sex, nephrectomy status, histological type, presence of one or more metastases, and 1L regimen type (IO+IO vs. IO+VEGF). The response was evaluated according to RECIST 1.1 criteria. **Results:** Of the 670 pts initiating 1L IO < 1 year post dx, 331 had an IMDC score of 1, and 339 had a score of 2, subdivided into 5 subgroups as detailed in the table. Pts' median age was 62 years (IQR: 55-69). Median follow-up was 16.6 months. Response rates, 18-month OS, and 6-month TTF rates for each group are shown in the table. Adding the factor of treatment initiation < 1 year post dx, the high neutrophil count has the most significant effect on OS (HR = 4.85, 95% CI: 2.61-9.03, p < 0.001). Also, KPS < 80 significantly affects both OS (HR = 3.93,95%CI = 2.26-6.84), p < 0.001) and TTF (HR = 1.59 95%CI = 1.02-2.61, p = 0.04). Low hemoglobin, as well as high calcium, notably worsen OS without significant impact on TTF. High Plt count shows no significant impact on OS and TTF, possibly due to the low prevalence of this risk factor (15/670). **Conclusions:** Additional risk factors can affect the prognosis of pts with mRCC receiving IO < 1 year post dx. Integrating other biomarkers or radiological features could refine risk stratification, enhancing treatment approaches for IR pts. Research Sponsor: None.

Identifying key prognostic indicators in Wilms tumor using machine learning techniques. First Author: Salsabeel Aljawabrah, University of Jordan, Amman, Jordan

Background: Wilms tumor is a rare pediatric malignancy, accounting for 6% of pediatric tumors and primarily affecting the kidneys. Its impact on quality of life and long-term outcomes complicates management. This study leveraged machine learning (ML) to identify prognostic factors with the aim of enhancing prognosis and survival rates. **Methods:** Data were obtained from the SEER database (2004-2021). Patients who met any of the following criteria were excluded: diagnosis not confirmed by histology, previous history of cancer or other concurrent malignancies, or unknown data. To identify prognostic variables, we conducted Cox regression analysis and constructed prognostic models using ML algorithms to predict the 5-year survival. Patient records were randomly divided into training (70%) and validation (30%) sets. A validation method incorporating the area under the curve (AUC) of the receiver operating characteristic curve was used to validate the accuracy and reliability of the ML models. We also investigated the role of multiple therapeutic options using Kaplan-Meier survival analysis. **Results:** A total of 4,935 children were included. Among them, 47.72% underwent surgery, radiation, and chemotherapy; 45.07% underwent surgery and chemotherapy; and 7.21% underwent surgery alone. Most patients (53.3%) were females, 75% were white, followed by black (16.3%). The mean patient age was 3 years, and the mean tumor size was 10.6 cm. Most tumors were left-sided (51.1%) and 79.8% had no metastasis. The lungs were the most frequent site of metastasis (11%), followed by the liver and lungs at the same time (1.2%), and bone involvement was rare (0.6%). Radical surgery was the most common surgical approach (76.1%), followed by nephrectomy (4.9%). Patients who underwent surgery and chemotherapy had the highest 5-year OS (96.9%) and CSS (96.9%) compared to those who underwent surgery alone (OS: 95.5%, CSS: 95.5%) or surgery with chemotherapy and radiation (OS: 92.9%, CSS: 93.2%). Asian/Pacific Islander and white patients exhibited better OS (94.3% and 95.1%, respectively) than black patients (91.9%). Multivariate Cox regression analysis identified a large tumor size and older age as poor prognostic factors. Gradient boosting and MLP classifiers were the most accurate models. The ML models identified race as the most significant prognostic factor, followed by the TNM stage and age. The performance metrics for all ML algorithms are summarized in Table. **Conclusions:** This is the first study to apply ML to Wilms tumor, effectively identifying key prognostic factors. ML models show promise in enhancing survival predictions, potentially informing personalized treatment strategies, and improving patient outcomes. Research Sponsor: None.

ML Model	Accuracy	Precision	Recall	F1 score	AUC
LR	59.5%	59.5%	99.6%	74.5%	0.573

Real-world quality of life (QOL) for patients (pts) with metastatic renal cell carcinoma (mRCC) treated with systemic therapy (ST) in the prospective observational ODYSSEY study. First Author: Benjamin L. Maughan, Huntsman Cancer Institute at the University of Utah, Salt Lake City, UT

Background: In the past 7 years, 4 immuno-oncology (IO) based combinations have been approved for mRCC. However, QOL data on these combinations are limited to trials in which collection and reporting was not standardized, which further limits cross trial comparisons. Real-world QOL data with multiple treatment regimens are needed to understand how these regimens are tolerated in practice. **Methods:** ODYSSEY is a multi-site, prospective observational study of 500 US pts with mRCC. Pts must have mRCC (any histology), no prior ST, and follow up at a PCORnet study site. Exclusion criteria include treatment for cancer except mRCC. The primary objective is to determine patterns of change in QOL and symptom burden of pts with mRCC. Minimally important differences (MID) are 3 points for FKSI-19 total score, 1 point for the FKSI-Disease Related Symptoms (DRS) subscale and 7 points for FACT-G. **Results:** As of 1/6/25, 392 pts were enrolled of whom 299 were managed with ST. Of pts on ST, 114 were treated with IO-IO, 108 with IO-TKI, 33 with IO alone, 27 with Other, and 18 with TKI alone. Median follow up for all pts is 8.8 months (IQR 2.9, 16.2). IO-IO pts are median age 64 yrs, 81% male, 84% white, 56% prior nephrectomy, 84% clear cell; IO-TKI pts median age 66 yrs, 76% male, 92% white, 43% prior nephrectomy, 66% clear cell; IMDC risk profiles are similar. IO-IO pts are more likely to be KPS 100; whereas, IO-TKI pts have a higher median number of metastatic sites and are more likely to have bone or liver metastasis. With median follow-up of 6.0 (IQR 1.8, 14.9) and 8.8 months (4.5, 17.8) in the IO-IO and IO-TKI cohorts, 17 (15%) and 21 (19%) pts had died with a median time to death of 5.4 (2.5, 6.4) and 5.7 months (4.4, 12.8), respectively. 20 (18%) and 16 (15%) pts on IO-IO and IO-TKI had discontinued therapy at a median of 3.0 (IQR 2.0, 4.0) and 6.4 months (2.4, 13.0), respectively. Rates of discontinuation for disease progression and toxicity are similar. Baseline PROs for pts on ST are shown in the Table (higher score indicates better QOL), with RCT data for reference (NA, not assessed). **Conclusions:** In our prospective multi-center ODYSSEY study, we demonstrate that real world pts treated with contemporary ST have worse baseline QOL than those enrolled on pivotal RCTs. One-third of IO-IO and IO-TKI pts died or discontinued therapy within 6 months of initiation. Our data on real world vs RCT differences in baseline QOL may partially explain the limitations of current IO combination regimens in practice and support development of alternative treatment approaches. Research Sponsor: BMS; Exelixis; Merck Sharp & Dohme LLC, a subsidiary of Merck & Co., Inc., Rahway, NJ, USA; & Pfizer.

The effect of GLP-1 receptor agonists on outcomes in metastatic renal cell carcinoma patients undergoing immune checkpoint inhibitor therapy: A retrospective multi-institutional US cohort study. First Author: Mohanad Elchouemi, Texas Tech University Health Science Center, El Paso, TX

Background: Glucagon-like peptide-1 (GLP-1) receptor agonists have played a pivotal role in the management of type 2 diabetes (T2DM). At the same time, immune checkpoint inhibitor (ICI) therapy remains one of the mainstay treatments for metastatic renal cell carcinoma (mRCC). There has been a scarcity of research on the effect of GLP-1 receptor agonists on ICI efficacy in cancer patients. This study presents the first real-world analysis of the effect of GLP-1 receptor agonists on outcomes in mRCC patients receiving ICI therapy. **Methods:** Data was retrospectively collected from TriNetX, a national electronic health record database with 120 million US patients from over 70 healthcare organizations, from 2012-2024. We included patients $\geq$ 18 years old with T2DM and mRCC who underwent ICI therapy. Patients were then stratified into two cohorts: on GLP-1 receptor agonists prior to ICI therapy and not on GLP-1 receptor agonists. Patients in each cohort were then 1:1 propensity score matched (PSM) based on age, sex, race, type of ICI therapy used, comorbidities, other diabetic medications and staging. 1 year outcomes for mortality, major adverse cardiovascular events (MACE) and various immune-related adverse events (irAEs) were reported. **Results:** A total of 2378 patients were identified who met the inclusion criteria. 535 (22%) were in the GLP-1 receptor agonist cohort compared to 2378 (68%) in the non GLP-1 receptor agonist cohort. After 1:1 PSM, 497 patients were in each group. Among both cohorts, 66% were male, 77% white and the average age was about 65 years old. After conducting Cox proportional hazard analyses, GLP-1 receptor agonist use was associated with lower mortality (HR, 0.49 [95% CI: 0.37-0.64]). Moreover, GLP-1 receptor agonist use had lower rates of irAEs, including pneumonitis (HR, 0.61 [95% CI: 0.43-0.85]), hematological complications (HR, 0.78 [95% CI: 0.64-0.95]) and renal complications (HR, 0.67 [95% CI: 0.54-0.84]). There was no significant difference in MACE or other irAEs between the two cohorts. **Conclusions:** Analysis of one of the largest US based databases showed that the use of GLP-1 receptor agonist in T2DM patients with mRCC undergoing ICI therapy, is associated with better overall survival and lower irAES such as pneumonitis, hematological and renal complications. There was no significant difference in MACE. To our knowledge, this is the first study to identify the impact of GLP-1 receptor agonists on the outcomes of mRCC patients undergoing ICI therapy. Further prospective studies are needed to validate these findings and to identify the underlying mechanisms. Research Sponsor: None.

Circulating tumor DNA (ctDNA) monitoring in patients (pts) with advanced urothelial carcinoma (aUC) treated with enfortumab vedotin +/- pembrolizumab (EVP). First Author: Kevin R. Reyes, University of California, San Francisco, San Francisco, CA

Background: CtDNA is an emerging biomarker in aUC, but its role for pts receiving EVP is unclear. **Methods:** We undertook a retrospective analysis of pts with aUC who were longitudinally tested for ctDNA (MTM/mL) with a tumor-informed assay (Signatera, Natera, Inc) while on treatment (tx) with EV+/-P. Pt data were abstracted from electronic medical record. Outcomes were compared based on changes in ctDNA from pre-tx baseline, using Kaplan-Meier method and Cox proportional hazards test to assess progression-free survival (PFS) and overall survival (OS). **Results:** Longitudinal ctDNA data were available for 36 pts (tx: 28 EV+P; 8 EV). Pts had a median (med) of 3 ctDNA tests (range: 2-14) over 8 months (mos) of med follow-up. At pre-tx baseline, 33/36 (92%) pts had detectable ctDNA. Pt characteristics and outcomes are shown in the Table. After tx start, 26 pts (79%) had a decrease in ctDNA (med time to decrease 50 days), and 11 pts (33%) achieved negative ctDNA (-) after a med of 54 days. The 11 pts with ctDNA (-) had a response rate of 91% (CR: 6, PR: 4, SD: 1). Among 14 pts with ctDNA nadir followed by a rise, 8 pts (57%) had PD on next scan, and med time from initial ctDNA rise to PD was 124 days. Pts who achieved ctDNA (-) within 2 mos of tx (n = 8) had improved PFS relative to pts with ctDNA data (n = 21) who did not (HR: 0.08, 95% CI: 0.01 – 0.59, p = 0.01). Pts with no decrease in ctDNA within 2 mos of tx start (n = 7) had inferior PFS (HR: 5.9, 95% CI: 1.9 – 19.2, p $<$ 0.01) and OS (HR: 20.8, 95% CI: 2.3 – 192, p $<$ 0.01) vs pts with a ctDNA decrease (n = 22). In the EV+P group, pts with no ctDNA decrease within 2 mos (n = 4) had inferior PFS (HR: 15.9, 95% CI: 1.6 - 154, p = 0.01) vs pts with a decrease (n = 18). **Conclusions:** In this retrospective analysis of pts treated with EV+/-P, 92% had detectable ctDNA and 79% had a ctDNA decrease after tx start. Within 2 mos of tx start, pts who achieved ctDNA (-) had improved PFS, while pts who did not have ctDNA decrease had inferior PFS and OS. These hypothesis-generating results warrant validation in larger prospective cohorts and can inform clinical decision-making. Research Sponsor: None.

Avelumab maintenance therapy in patients (pts) with advanced urothelial carcinoma (UC) in Japan: Subgroup analyses by best overall response (BOR) to prior platinum-based chemotherapy (PBC) in a post-marketing surveillance (PMS) population. First Author: Eiji Kikuchi, Department of Urology, St Marianna University School of Medicine, Kanagawa, Japan

Background: Avelumab was approved as maintenance therapy for pts with advanced UC that has not progressed after first-line PBC based on results from the JAVELIN Bladder 100 phase 3 trial. Primary analyses of PMS data demonstrated the safety and effectiveness of avelumab maintenance in clinical practice in Japan, consistent with phase 3 results. We report post hoc analyses of PMS data in subgroups defined by BOR to prior PBC. **Methods:** This prospective, multicenter, observational PMS evaluated pts with advanced UC without disease progression after prior PBC who received ≥1 dose of avelumab between Feb and Dec 2021. The observation period was ≤52 wk from the start of avelumab in all pts. Safety assessment was based on occurrence of prespecified adverse drug reactions (ADRs) deemed to be associated with avelumab. Effectiveness outcomes from the start of avelumab maintenance (time to treatment failure [TTF; defined as avelumab discontinuation for any reason] and overall survival [OS]) were estimated using the Kaplan-Meier method. Subgroups were defined by BOR to prior PBC: complete response (CR), partial response (PR), or stable disease (SD). **Results:** The study population included 453 pts from 213 institutions. Median age was 73 y (range, 21-91); 75 pts (16.6%) were aged ≤64 y, 198 (43.7%) were aged 65-74 y, and 180 (39.7%) were aged ≥75 y. Primary tumor site was the bladder in 244 pts (53.9%) and upper tract in 209 (46.1%). Prior PBC regimen was gemcitabine + cisplatin in 267 pts (58.9%) and gemcitabine + carboplatin in 163 (36.0%). BOR to prior PBC was CR in 47 pts (10.4%), PR in 242 (53.4%), and SD in 149 (32.9%). At the end of the observation period, 128 pts (28.3%) remained on avelumab treatment and 184 (40.6%) had received next-line treatment. Median duration of avelumab treatment was 5.1 mo (IQR, 2.3-12.0). Among subgroups defined by BOR to prior PBC, the longest median TTF and highest 1-y OS rate were observed in the CR subgroup; findings were comparable in the PR and SD subgroups (Table). Safety findings were similar across subgroups. **Conclusions:** This PMS population represents the largest prospective observational study of avelumab maintenance therapy in pts with advanced UC in Asia. In post hoc analyses, the safety and effectiveness of avelumab were generally consistent across subgroups defined by BOR to prior PBC. Our findings support the favorable benefit-risk profile of avelumab in clinical practice, irrespective of BOR to prior PBC. Research Sponsor: Merck Biopharma Co., Ltd., Tokyo, Japan, an affiliate of Merck KGaA, Darmstadt, Germany (CrossRef Funder ID: 10.13039/100009945).

Real-world enfortumab vedotin +/- pembrolizumab (EV+/-P)–based treatment toxicity, treatment discontinuation, and associations with survival in advanced urothelial carcinoma (aUC). First Author: Martin Kurian, Hospital of the University of Pennsylvania, Philadelphia, PA

Background: EV-based therapy is central to the standard of care for aUC, increasingly in combination with P. Current understanding of EV-related toxicity is limited to clinical trial data. Here, we use real-world data to characterize the frequency of EV-based treatment-toxicity, -discontinuation, and associations with survival. **Methods:** We performed a post-marketing retrospective cohort study of EV+/-P initiators at the University of Pennsylvania (1/2020-5/2024). The frequency of any of five toxicities (skin reaction, neuropathy, ocular disorder, hyperglycemia, and pneumonitis) and associated treatment-interruptions (hold or discontinuation), -reduction, or -hospitalization were summarized. Among pts with at ≥1 year of follow-up, overall survival (mOS) was compared between pts with vs without each toxicity via KM methods. **Results:** Among 123 EV/EV+P treated pts, median age was 68 years, 72% were male, 74% were white, 68% had bladder primary, and 71% treated with EV alone. Frequency of toxicity, time to toxicity, and proportions requiring dose interruption, reduction, and hospitalization are shown (Table). 60% of pts had skin reaction, 47% neuropathy, 28% ocular disorder, 14% hyperglycemia, and 2% pneumonitis; treatment discontinuation occurred among 20% of pts with neuropathy, 5% of those with skin reaction, 3% of those with ocular disorders, and 0% of those with hyperglycemia or pneumonitis. Among 80 pts with at least one-year of follow-up (89% EV monotherapy), mOS was 14.3 months (95% CI: 11.3-19.3). Survival was greater among those with skin reaction, neuropathy, and ocular disorders (mOS skin reaction vs. no reaction: 19.3 vs. 6.4 months, $p < 0.001$; neuropathy vs. no neuropathy: 16.5 vs. 8.2 months, p = 0.001; ocular disorder vs. no ocular disorder: 17.1 vs. 11.3 months; p = 0.001). **Conclusions:** EV+/-P treatment toxicity occurred in a majority of pts, but treatment discontinuation was infrequent. Presence of toxicity was significantly associated with improved survival. Future work is needed to prospectively validate these findings. Research Sponsor: None.

Final results of a phase 2 study of HDACi chidamide and PD-1 inhibitor for advanced urothelial carcinoma after platinum therapy. First Author: Zhuowei Liu, Department of Urology, Sun Yat-Sen University Cancer Center, Guangzhou, China

Background: Epigenetic dysregulation is commonly correlated with the pathogenesis and development in urothelial carcinoma. The preliminary results demonstrated that the combination of chidamide (CHI) and tislelizumab (TIS) was well tolerated with clinically meaningful activity in patients (pts) with advanced or metastatic urothelial carcinoma (mUC). Confirmed ORR was 41.7%, median PFS was 4.6 months. Here we present results from the final analysis. **Methods:** Eligible pts aged 18 to 75 years old had recurrend or progressed after platinum-based chemotherapy to assess the efficacy and safety of CHI and PD-1 inhibitor in mUC. All pts received 30 mg oral CHI twice weekly in combination with TIS 200mg Q3W, until progression or unacceptable toxicity. The primary endpoint was objective response rate (ORR). The secondary endpoints included progression free survival (PFS), disease control rate (DCR), overall survival (OS) , and safety. **Results:** From Jan. 2021 to Oct. 2023, a total of 45 pts were enrolled at Sun Yat-sen University Cancer center. At the data cut-off (Aug, 2024), the median duration of follow-up was 23.2 months (95%CI: 17.2-31.9). Median age was 63 years (IQR: 57-68). ORR and DCR were 44.4% (12CR, 8PR; 95%CI, 29.6-60.0%) and 60% (27/45; 95%CI, 44.3-74.3%), respectively. Median duration of response (DOR) was not evaluable (95%CI, 8.8-NE). Median PFS and OS were 7.0 months (95%CI, 2.4-10.3) and 20.3 months (95%CI, 10.7-NE), respectively. The most common treatment emergent adverse events (TEAEs) included anemia, anorexia, thrombocytopenia, neutropenia, leukopenia, fatigue, hypoalbuminemia. Grade 3 or above TEAEs (≥10%) were neutropenia 24.4%, thrombocytopenia 20.0%, anemia 13.3%.No pts died due to an adverse event attributed to study trearment. **Conclusions:** This study is the first trial to show that combining HDAC inhibitor with PD-1 antibody is a feasible and efficacious novel approach in mUC. Chidamide plus tislelizumab could be a new treatment option in this patient population. Clinical trial information: NCT04562311. Research Sponsor: None.

Fibroblast growth factor receptor 3 (*FGFR3*) alteration status and outcomes with immune checkpoint inhibitors (ICPI) in patients with metastatic urothelial carcinoma. First Author: Shilpa Gupta, Cleveland Clinic Taussig Cancer Institute, Cleveland, OH

Background: The use of immune checkpoint inhibitors (ICPIs) has expanded in the treatment of metastatic urothelial carcinoma (mUC) but response rates are variable, highlighting the need for preditive biomarkers. Tumor mutational burden (TMB) has been previously shown to predict response to ICPI but *FGFR3* alterations are common drivers in mUC and there is preclinical and anectodal evidence that they may predict less favorable outcomes to ICPIs, similar to *ALK* and *ROS1* fusions in lung cancer. We sought to explore the effect of *FGFR3* alterations alone and with TMB on response to ICPI in mUC. **Methods:** 1,416 mUC patients who received hybrid-capture NGS-based genomic profiling were evaluated for their response to ICPI and chemotherapy treatment based on the presence of *FGFR3* alterations (activating point mutations, insertions and deletions, rearrangements) and TMB. The nationwide (US-based) de-identified Flatiron Health-Foundation Medicine mUC clinico-genomic database of NGS results linked to deidentified electronic health record-derived clinical data originating from approximately 280 US cancer clincs (~800 sites of care) was used to assess treatment patterns and real-world overall survival (rwOS) and progression-free survival (rwPFS). Propensity analysis was used to match clinical characteristics between patients receiving first-line ICPI and chemotherapy and included age, disease grade, ECOG, and erdafitinib receipt as features. **Results:** Among 819 patients with mUC who received ICPI, there were no significant differences in rwOS or rwPFS between *FGFR3*-altered (alt; n = 161) and wildtype (wt; n = 658) patients. However, among patients with TMB≥10 mut/Mb, *FGFR3*-alt patients (n = 39) trended towards longer rwOS (20 vs. 14 months, aHR 0.62, 95% CI 0.37-1.02, p = 0.06) and rwPFS (5.5 vs. 4.9 months, aHR 0.66, 95% CI 0.42-1.03, p = 0.07) than *FGFR3*-wt patients (n = 244). Comparing first-line ICPI vs. chemotherapy and adjusting for imbalances, patients with TMB≥10 and *FGFR3*-alts who received ICPI (n = 21) also trended towards longer rwPFS than patients who received chemotherapy (n = 18) (14 vs. 7.1 months, HR 0.55, 95% CI 0.25-1.25, p = 0.2), although no significant difference in rwOS was observed. **Conclusions:** While *FGFR3* status alone is not predictive of response to ICPI, *FGFR3* combined with TMB emerged as a biomarker that may be predictive for response to ICPI in mUC and may have the potential to reconcile differences in previous observations regarding *FGFR3* and ICPI response. Further studies performed with larger patient populations to confirm these findings are warranted. Research Sponsor: None.

Association of tumor-informed ctDNA-based molecular residual disease (MRD) with clinical outcomes for upper tract urothelial cancer (UTUC). First Author: Adanma Ayanambakkam, OU Health, Stephenson Cancer Center, Oklahoma City, OK

Background: Upper tract urothelial carcinoma (UTUC) accounts for 5–10% of all urothelial carcinomas. Given its aggressive phenotype compared to primary bladder tumors and the lack of efficient biomarkers to guide treatment decisions, disease management remains challenging. Herein, we evaluate the prognostic value of ctDNA-based molecular residual disease (MRD) detection in UTUC. **Methods:** We conducted a retrospective analysis of real-world data from commercial ctDNA testing in a multicenter cohort of patients with UTUC using a personalized, tumor-informed, mPCR-NGS ctDNA assay (SignateraTM, Natera, Inc.). ctDNA was evaluated during the 1) MRD window (2-16 weeks post-surgery, before adjuvant therapy [AT]) and 2) surveillance windows ($>$ 16 weeks post-surgery if no AT was given or after AT completion). The correlation between ctDNA status and patient outcomes (recurrence-free survival [RFS]) was assessed using Cox regression analysis. RFS was defined as the interval from surgery to the date of radiographic recurrence or any evidence of residual/persistent disease after the completion of surgery or AT. **Results:** A total of 349 plasma samples collected from 45 patients with stages I-IV UTUC between 4/20/2021-12/16/2024 were available for analysis. Neoadjuvant therapy (NAT) was administered for 9% (4/45) of the patients, while 51% (23/45) of patients received AT post-surgery/-diagnosis [chemotherapy 57% (13/23), immunotherapy 39% (9/23), chemo-immunotherapy: 4% (1/23)] and 22% (10/45) received treatment for metastatic disease [EV-immunotherapy or immunotherapy: 40% (4/10), chemotherapy: 40% (4/10), chemo-immunotherapy: 20% (2/10)]. With a median follow-up of 17 (range: 3-71) months, the ctDNA detection rate within the MRD (N = 24) and surveillance (N = 32) windows was 70.8% and 68.8%, respectively. Patients with ctDNA-positivity within the MRD and surveillance windows showed a significantly inferior RFS compared to ctDNA-negative patients (MRD: HR = 13.4, *P*= 0.012 and surveillance: HR = 14.46, *P*= 0.01). Notably, ctDNA-positive patients showed a 12-month RFS of 32.1% (95% CI: 11.83–54.6%) and 45.5% (95% CI: 24.4–64.3%), respectively for MRD (N = 17) and surveillance (N = 22) windows, compared to 100% 12-month RFS for ctDNA-negative patients (MRD, N = 7; surveillance, N = 10). Multivariate regression analysis during surveillance revealed ctDNA-positivity as the only factor significantly associated with poor RFS (HR = 17.6, *P*= 0.011) when adjusted for clinical stage, NAT, and AT. **Conclusions:** This is the first study utilizing longitudinal, tumor-informed ctDNA testing to assess patient outcomes and disease status in UTUC. Our hypothesis-generating results suggest that ctDNA-based MRD detection via tumor-informed ctDNA testing is prognostic of patient outcomes post-surgery in UTUC and warrants further investigation in larger prospective cohorts. Research Sponsor: None.

Targeting the TGFβ signaling pathway to mitigate tumor metastasis in 9p21-loss urothelial bladder cancer. First Author: Cindy Y. Jiang, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: We previously identified that 9p21-loss (containing MTAP and CDK2NA genes) occurs in 25% of metastatic urothelial cancer (mUC) and is associated with worse survival and increased visceral metastasis. Additionally, we found significantly increased expression of the TGFβ-SMAD3 pathway in 9p21-loss UC, which is well studied to induce epithelial mesenchymal transition (EMT) and lead to metastasis. We hypothesize that the TGFβ signaling pathway mediates visceral metastasis in 9p21-loss UC. **Methods:** We included mUC patients at MD Anderson Cancer Center (MDACC) who had MTAP testing completed (surrogate for 9p21-loss) and received chemotherapy, immune checkpoint therapy (ICT), and/or antibody drug conjugate between 2012 and 2022. Survival and metastasis were compared between MTAP deficient patients and MTAP proficient patients. The Memorial Sloan Kettering-Metastatic Events and Tropisms (MSK-MET) cohort of mUC patients and IMVigor210 dataset were assessed for genomic alterations. Mouse models bearing CDKN2A-MTAP double knock out (DKO) MB49 tumors and wild type (WT) MB49 tumors, as well as corresponding in vitro models were used for mechanistic studies. **Results:** 298 mUC patients at MDACC were identified with 27% (n = 81) MTAP deficient. MTAP deficient patients experienced significantly worse overall survival (16.2 vs 21.1 months; p = 0.002; HR 1.61; 95% CI 1.2-2.2), progression-free survival (3.9 vs 5.8 months; p $<$ 0.001; HR 1.75; 95% CI 1.3-2.4) and increased visceral metastasis (62% vs 39%; p = 0.001) with lung predominance (44% vs 26%; p = 0.003) compared to MTAP proficient patients. We also found in the MSK-MET cohort that 26% (186/714) of patients with mUC to the bladder had lung metastasis and those with lung metastasis had significantly increased frequency of CDK2NA deletion compared to patients without lung metastasis (30% vs 18%; OR 2.0; 95% CI 1.3-3.0). Our preclinical data also demonstrated that CDKN2A-MTAP DKO mice resulted in significantly larger primary bladder tumors and worse survival compared to mice bearing WT MB49 tumors. Additionally, mice bearing orthotopic CDKN2A-MTAP DKO MB49 tumors readily developed lung metastasis. Analysis of the IMvigor210 dataset (N = 298) showed that 9p21-loss UC patients had significantly increased expression of TGFβ and EMT pathway genes. These data are consistent with data from our DKO MB49 tumor models. We are currently assessing the impact of a TGFβ inhibitor on mitigating CDKN2A-MTAP DKO-mediated metastasis. **Conclusions:** Our clinical and pre-clinical data demonstrates that 9p21-loss mUC leads to worse survival and increased visceral metastasis, especially to the lung. We found that the TGFβ signaling pathway may play a role in the development of metastasis. Moving forward, we plan to prospectively investigate the therapeutic potential of TGFβ inhibition in patients with 9p21-loss UC. Research Sponsor: MD Anderson; David H. Koch Center; Joan and Herb Kelleher Charitable Foundation; Williams TNT Fund; NIH/NCI R01; CA254988-01A1; NIH/NCI R01; CA269489-01A1; NIH/NCI R01; CA282282-01.

Phase 1/2 Duravelo-1 study: Preliminary results of nectin-4–targeting zelenectide pevedotin (BT8009) plus pembrolizumab in previously untreated, cisplatin-ineligible patients with locally advanced or metastatic urothelial cancer. First Author: Patrizia Giannatempo, Genitourinary Medical Oncology, Fondazione IRCCS - Istituto Nazionale dei Tumori, Milano, Italy

Background: Effective and tolerable therapies for patients (pts) with locally advanced or metastatic urothelial cancer (la/mUC) in the first-line setting are needed. Zelenectide pevedotin (zele, previously BT8009) is a highly selective Bicycle Toxin Conjugate (BTC) targeting Nectin-4 and conjugated to MMAE, and has shown an objective response rate (ORR) of 45% and a generally tolerable safety profile as monotherapy in previously treated, enfortumab vedotin-naïve pts with mUC in the ongoing Phase 1/2 study (NCT04561362, Duravelo-1; Reig et al., 2024). Here, we present preliminary data from expansion Cohort B7 of Duravelo-1, investigating zele + pembrolizumab (pembro) in pts with previously untreated, cisplatin-ineligible, la/mUC. **Methods:** Pts who were cisplatin-ineligible by Galsky criteria (Galsky et al., 2011) received zele 5 mg/m^2 on D1, D8, D15 plus pembro 200 mg D1, every 21 days. The primary endpoint was ORR as assessed by investigator per RECIST v1.1. Secondary endpoints included safety and disease control rate (DCR). Treatment-related adverse events (TRAEs) were determined for all pts who received at least one dose of study drugs. **Results:** As of 3 Jan 2025, 22 pts were enrolled from Nov 2023 to Jul 2024 with a median time on treatment of 22.9 weeks and 12 pts still receiving study treatment. Median age was 77 years; 46% of pts had an ECOG performance status (PS) of 2; 55% with CrCl $<$ 60 mL/min. With 20 efficacy evaluable pts, the ORR is 65.0% (95% CI, 40.8, 84.6), including 5 CRs (25.0%; 4 confirmed), 8 PRs (40.0%; 6 confirmed) and 5 SD (25.0%). Median follow-up was 7.1 mo (range 1.0 – 13.2) and median duration of response was not reached. DCR is 90.0%. The most common grade (Gr) $\geq$3 TRAEs included ALT increased and neutropenia (13.6% each), and diarrhea, asthenia, hypomagnesemia, and pneumonia (9.1% each). Serious TRAEs related to zele or zele + pembro occurred in 9.1%. Treatment-related peripheral neuropathy occurred in 50.0% (27.3% Gr1, 13.6% Gr2, 9.1% Gr3). Other TRAEs of clinical interest included skin reactions (4.5% Gr$\geq$3), hyperglycemia (0.0% Gr$\geq$3), and eye disorders (0.0% Gr$\geq$3). All cases of grade 3 TRAEs of clinical interest were reversible. There were no grade 4/5 TRAEs of clinical interest and no treatment related deaths. **Conclusions:** Zelenectide pevedotin + pembro shows promising anti-tumor activity as a first-line treatment in a cohort of cisplatin-ineligible pts with la/mUC including a large proportion of pts with PS = 2. The combination of zele + pembro was generally tolerable and broadly consistent with the existing safety profiles of each respective agent. No new safety signals were observed with the combination. Zele + pembro combination therapy is being investigated in previously untreated la/mUC pts in the ongoing Phase 2/3 Duravelo-2 study (NCT06225596). Clinical trial information: NCT04561362. Research Sponsor: BicycleTx Ltd.

Real-world analysis of 2IR immune response score in histologic subtype urothelial carcinoma (hsUC). First Author: Jason Robert Brown, Division of Solid Tumor Oncology, University Hospitals Seidman Cancer Center, Case Comprehensive Cancer Center, Case Western Reserve University, Cleveland, OH

Background: The 2IR immune response score was initially developed using bulk RNA sequencing of pre-treatment tissue from ImVigor 210 and CheckMate 275 trials, however these trials enrolled patients (pts) with pure urothelial carcinoma (pUC) histology. Patients with hsUC often exhibit worse response to immune checkpoint inibitors (ICI) than patients with pUC. Here, we evaluated the 2IR score as a prognostic or predictive biomarker in real-world pts with hsUC. **Methods:** Specimens from pts with pUC (n = 1677) and hsUC (n = 417) were profiled at Caris Life Sciences (Phoenix, AZ) using next generation sequencing (NGS) of DNA and RNA. HsUC histologies included majority ($>$ 50%) squamous (n = 340), sarcomatoid (n = 51), neuroendocrine (n = 20), and micropapillary (n = 6) component. 2IR was calculated by comparative RNA expression of 10 adaptive immune genes and 39 pro-tumorigenic genes. Tumors were classified as 2IR-Low (2IR $\leq$ -0.5), -Mid (-0.5 $<$ 2IR $<$ 0), and -High (2IR $\geq$ 0), as previously described (Wang et al., 2022). Spearman correlation analysis was utilized to compare 2IR with tumor mutation burden (TMB), interferon score (IFN) and the tumor microenvironment (TME) cell fractions estimated using quanTIseq. Clinical outcomes included real-world overall survival (rwOS) from ICI start to last contact and time on treatment (ToT) with pembrolizumab, obtained via matched insurance claims data and calculated using Kaplan-Meier methods, while Hazard ratio (HR) was calculated by Cox proportional model. **Results:** For patients with hsUC, distribution of 2IR score was High 5.76%, Mid 33.3%, and Low 60.9%. Median 2IR score was significantly lower in squamous (-0.60, p $<$ 0.0001) and sarcomatoid UC (-0.82, p $<$ 0.0001) compared to pUC (-0.41) and significantly higher in neuroendocrine UC (-0.15, p = 0.003). Among patients with hsUC, median rwOS was significantly longer for patients with high/mid 2IR score compared to low 2IR score (25.3 [10.9-39.3] months vs. 8.7 [6.2-11.3] months; HR 0.52, 95% CI 0.34 – 0.78, p = 0.0017). ToT with pembrolizumab was also significantly longer for high/mid 2IR score compared to low 2IR score (3.0 [1.4-5.5] months vs. 2.1 [1.4-3.3] months; HR 0.68, 95% CI 0.46-1.00, p = 0.0471). Similar to pUC, 2IR score in patients with squamous UC was positively associated with CD8 T cell infiltration (r = 0.39; p $<$ 0.0001), IFN score (r = 0.41, p $<$ 0.0001), and TMB (r = 0.20, p $<$ 0.001) and negatively associated with M1 macrophage infiltration (r = -0.25, p $<$ 0.0001). 2IR scores in hsUC correlated positively but not significantly with mutations in *TP53* (Median: -0.59 vs -0.62, p = 0.067) and *PIK3CA* (Median: -0.56 vs -0.61, p = 0.172) and negatively with mutations in *CDKN2A* (Median: -0.67 vs -0.59, p = 0.052). **Conclusions:** In a real-world cohort of patients with hsUC, we show the 2IR score may be prognostic for rwOS and predictive for pembrolizumab ToT. Prospective studies are needed to further validate this biomarker for use in this population. Research Sponsor: None.

Integrative clinico-genomic evaluation of the human epidermal growth factor receptor 2 (HER2) in urothelial cancer (UC). First Author: Samuel Black, Department of Medicine, Section of Internal Medicine, Baylor College of Medicine, Houston, TX

Background: HER2-directed therapy with trastuzumab deruxtecan is now FDA approved for UC with high HER2 expression. The interaction between HER2 expression, clinical phenotype and genomic tumor make-up is poorly understood in UC. **Methods:** We reviewed the records of 209 patients with UC and available HER2 expression status treated at MD Anderson Cancer Center between 2021 and 2024. Immunohistochemical (IHC) staining for HER2 and PD-L1 was conducted using 4B5 Ventana PATHWAY and 22C3 pharmDx antibodies, respectively. Formalin-fixed paraffin embedded metastatic or primary UC tumors were sequenced using the MD Anderson Mutation Analysis Precision Panel (MDA MAPP), a 610-gene high-throughput next generation sequencing (NGS) CLIA assay. Chi-square and wilcoxon tests were used to test correlations between HER2 expression and clinico-genomic features. P-values were adjusted for false-detection rate < 0.25. **Results:** We included 209 patients with available HER2 status (see Table). HER2 and PD-L1 had significant inverse correlation (p=0.0062). HER2 3+ status was significantly associated with bladder primary tumors compared to other sites (renal pelvis, ureter, and urethra) (p=0.0261). HER2 expression correlated with *ERBB2* amplifications (0/1+: 0%, 2+: 2%, 3+: 26%, $p<0.0001$), but not with *ERBB2* mutations. Of 13 patients with *ERBB2* amplification, 12 were HER2 3+, and 1 was HER2 2+. HER2 also correlated with *HELQ* missense mutations (0/1+: 0%, 2+: 0%, 3+: 11%, p=0.0002), *CDK12* alterations (0/1+: 0%, 2+: 0%, 3+: 20%, p=0.0003), and *BCR* missense mutations (0/1+: 0%, 2+: 0%, 3+: 11%, p=0.0002). Of 6 HER2 3+ patients with *CDK12* amplification, all had *ERBB2* amplification. **Conclusions:** Our study confirms prior observations of HER2 inverse correlation with PD-L1, but positive correlation with bladder origin. Beyond the known association with *ERBB2* amplification, we identified molecular correlations between high HER2 expression, missense mutations of *HELQ* and *BCR*, and *CDK12* alterations. The observed co-occurrence of *CDK12* and *ERBB2* amplifications may be related to their proximity (<267 kb apart) on chromosome 17q12. Only 26% of HER2 3+ patients had *ERBB2* amplifications, highlighting the importance of IHC testing, not just NGS testing, to determine therapy candidacy for trastuzumab deruxtecan. Research Sponsor: None.

A real-world picture of biomarker testing in metastatic bladder cancer: A comprehensive assessment of 19,979 patients treated in the US and Europe. First Author: Tiago Costa de Padua, Medical and Scientific Services, Hematology and Oncology Department, IQVIA, São Paulo, Brazil

Background: Recent advances in the molecular characterization of bladder cancer (BC) have led to the development and approval of several targeted therapies in metastatic BC, and biomarker testing is recommended by all guidelines for treatment decision-making. This real-world study aimed to examine patterns of biomarker testing in clinical practice and correlate testing with molecular-guided treatment in patients (pts) with metastatic BC. **Methods:** The IQVIA Oncology Dynamics database, an IQVIA oncology cross-sectional survey collecting anonymized real-world patient-level data from anonymized records of drug-treated cancer pts, was used to identify mBC pts in the US, EU4 (France, Germany, Spain, Italy), and UK from January 2017 to December 2024. We assessed biomarker testing data using descriptive analyzes. **Results:** A total of 19,979 mBC pts were included in this analysis (EU4 + UK: 11,963 pts; US: 8016 pts). FGFR testing has steadily increased over the years in EU4 + UK (from 7% in 2017 to 24% in 2024) and in the US (from 34% in 2019 to 61% in 2024); FGFR alterations were identified in 25.8% of pts in EU4 + UK versus 12.5% in the US. PDL1 testing has also increased over time in both regions; (PDL1 $>$ 10% in 58.9% in EU4 + UK and 57.6% in the US). Microsatellite Instability (MSI) testing and NTRK testing were performed in 12.5% and 8.3% of all pts from EU4 + UK (MSI: 2023-2024; NTRK: 2020-2024). Of these, 24.7% were MSI-high and 5.4% were positive for NTRK alterations. Next Generation Sequencing (NGS) data has been collected since Q1 2022, with an overall testing rate of 9.6% in EU4 + UK and 12.8% in the US. NGS testing has increased in the US over the years (from 3% in 2022 to 65% in 2024). Tumor Mutational Burden (TMB) results are available for pts from EU4 + UK, with TMB $>$ 10 in 55.2% of pts. Regarding the use of targeted therapy, only 230 pts with FGFR3 alterations received any FGFR inhibitors as current or prior treatment, representing 22.9% of positive pts. NTRK inhibitors were used in only 2 pts with positive results (5.7%). **Conclusions:** To our knowledge, this is the largest real-world study evaluating biomarker testing in mBC pts, providing meaningful insights. Our data show an overall low percentage of biomarker testing in clinical practice, but there has been an increase in ordering over the years. Despite the increase, only a limited proportion of patients are treated with targeted therapy, reflecting drug access barriers. We also noted a geographic variation in the positivity rate of FGFR3 alterations, with a higher incidence in patients from EU4 + UK compared to the US. Additionally, the rate of high TMB and positive PDL1 was higher in our data set when compared to historical data; further studies are warranted to better understand these differences. Our study has some limitations, such as the potential for bias and lack of outcome analysis. Research Sponsor: None.

EV-302: Long-term subgroup analysis from the phase 3 global study of enfortumab vedotin in combination with pembrolizumab (EV+P) vs chemotherapy (chemo) in previously untreated locally advanced or metastatic urothelial carcinoma (la/mUC). First Author: Jens Bedke, Department of Urology & Eva Mayr-Stihl Cancer Center, Stuttgart, Germany

Background: EV-302/KEYNOTE-A39 (NCT04223856) demonstrated superior efficacy of first-line (1L) EV+P vs chemo and established EV+P as the standard of care (SOC). EV+P is included in global treatment guidelines for patients (pts) with untreated la/mUC. After ≈2.5 years of median follow-up, the benefit of EV+P was sustained; median OS was maintained for $>$ 2.5 years. We present long-term efficacy and safety analyses in the following prespecified subgroups: primary disease site of origin (upper and lower tracts), lymph node (LN)–only disease, and presence of liver metastases (mets) (present and absent). **Methods:** Pts with previously untreated la/mUC were randomized 1:1 to receive EV (1.25 mg/kg; Days 1 and 8; IV) and P (200 mg; Day 1; IV) or chemo (gemcitabine with cisplatin or carboplatin) every 3 wk. Primary endpoints were progression-free survival (PFS) by blinded independent central review (BICR) and overall survival (OS). A genAI tool (01/09/25; Pfizer; GPT-4o) developed the 1st draft; authors assume content responsibility. **Results:** Pts (N = 886) were randomized to receive EV+P (n = 442) or chemo (n = 444) and were analyzed according to the subgroups shown in the Table. At data cutoff (Aug 8, 2024), median follow-up was 29.1 mo (95% CI, 28.5-29.9). PFS by BICR, OS, duration of response, and objective response rate continued to demonstrate sustained benefit of EV+P vs chemo across prespecified subgroups after long-term follow-up (Table). For EV+P, treatment-related adverse events (TRAEs) occurred in 96.0-98.5% and Grade ≥3 TRAEs in 53.4-60.7% of pts across prespecified subgroups, generally consistent with previous reports. **Conclusions:** EV+P continues to demonstrate superior long-term efficacy vs chemo in key subgroups with both favorable and poor prognoses. There were no new safety signals, and AE rates in prespecified subgroups were consistent with the overall population after an additional year of follow-up. This reinforces EV+P as the SOC for the 1L treatment of pts with la/mUC. Clinical trial information: NCT04223856. Research Sponsor: The EV-302 study was funded by Astellas Pharma Inc., Northbrook, IL, USA; Merck Sharp & Dohme LLC, a subsidiary of Merck & Co., Inc., Rahway, NJ, USA; and Seagen Inc., Bothell, WA, USA, which was acquired by Pfizer in December 2023.

Profiling treatment-associated evolutionary dynamics in advanced urothelial cancer via deep whole exome sequencing of cell-free DNA. First Author: Arvind Ravi, Dana-Farber Cancer Institute, Boston, MA

Background: Monitoring treatment response and identifying resistance mechanisms remain critical challenges in managing advanced bladder cancer. We investigated whether circulating tumor DNA (ctDNA) dynamics and deep whole exome sequencing (D-WES) could provide insights into treatment response and resistance patterns. **Methods:** We prospectively collected blood samples from 70 patients with advanced bladder cancer during treatment. Ultra-low pass whole genome sequencing (ULP-WGS) was performed on 213 plasma samples to quantify tumor fraction, with subsequent D-WES (200X) performed on 47 high-purity (i.e., at least 3% tumor fraction by ichorCNA) samples from 25 patients. Longitudinal analysis of ctDNA levels was correlated with clinical response. Phylogenetic reconstruction for samples in the D-WES cohort was used to identify candidate drivers of therapeutic response and resistance. **Results:** Changes in ctDNA tumor fraction correlated significantly with clinical trajectories: progression (median +1.3%), stable disease (-0.4%, p = 0.04 vs progression), and regression (-1.2%, p = 0.002 vs progression). Phylogenetic analysis revealed dynamic subclonal competition during treatment response. Mutation burden was significantly elevated in subclones associated with PD-(L)1 response (p = 0.04), including within a single patient. A number of novel candidate drivers of therapeutic response were identified across different therapeutic classes, with five genes meeting FDR-adjusted significance ($q < 0.05$): NLGN2, SHANK1 (chemotherapy resistance), GPR56 (taxane resistance), FOSL1, and ORC1L (chemotherapy sensitivity). **Conclusions:** Analysis of ctDNA can effectively monitor treatment response in advanced bladder cancer. D-WES of longitudinal samples revealed novel candidate drivers of therapeutic response and resistance, suggesting distinct molecular mechanisms may govern primary oncogenesis versus treatment response. These findings warrant further investigation in larger cohorts to validate their potential as predictive biomarkers. Research Sponsor: None.

Treatment patterns and clinical outcomes with platinum-based chemotherapy after enfortumab vedotin and pembrolizumab in patients with metastatic urothelial carcinoma. First Author: Michal Sternschuss, Memorial Sloan Kettering Cancer Center, New York, NY

Background: Enfortumab vedotin and pembrolizumab (EV/P) emerged as the new standard of care for previously untreated metastatic urothelial carcinoma (mUC), shifting the treatment paradigm. Currently, there are no guidelines for management after EV/P as the outcomes of subsequent systemic treatments, including platinum-based chemotherapy, remain unknown. **Methods:** Our retrospective cohort of patients with mUC treated with EV/P at Memorial Sloan Kettering Cancer Center was reviewed to identify patients receiving subsequent systemic treatments. Clinical data were collected by chart review. Response to EV/P and platinum-based chemotherapy was determined by physician assessment using RECIST v1.1. Progression free and overall survival (PFS, OS) were calculated using the Kaplan-Meier method. **Results:** Of 208 patients treated with EV/P between 10/2018 and 9/2024, we identified 56 patients that received any subsequent systemic treatments. In 68% of patients (n = 38), the initial post EV/P regimen administered was platinum-based chemotherapy. Other therapies included sacituzumab govitecan (n = 6), clinical trials (n = 5), trastuzumab deruxtecan (n = 4), erdafitinib (n = 2) and non-platinum chemotherapy (n = 1). In the 38 patients treated with platinum-based chemotherapy, median age was 74 years, 66% were men, 32% had upper tract primary and divergent histology/subtype component was reported in 47% of cases. One patient had prior platinum exposure (neoadjuvant treatment with rapid metastatic recurrence < 6 months). 16 patients had disease response to EV/P (observed response rate [ORR] 42%, 95% CI 27%, 59%). 36 patients (95%) received doublet therapy with gemcitabine and either cisplatin (n = 7) or carboplatin (n = 29), the two remaining patients received carboplatin/gemcitabine/paclitaxel and carboplatin/etoposide. 7 patients (18%) received maintenance avelumab following platinum. Median follow up was 5 months (IQR: 2.5-6.3). ORR was 50% (95% CI 34%, 66%), including one patient with complete response (CR; 2.9%) and 16 patients with partial response (PR; 47%). Among the patients with CR or PR, median duration of response was 3.8 months (IQR: 2.0-4.6). Median PFS was 4.4 months (95% CI 3.7, 7.8) and median OS was 12 months (95% CI 9.7, 17). **Conclusions:** In a real-world cohort of patients with mUC, platinum-based chemotherapy had substantial antitumor activity after EV/P, although progression-free survival and duration of response were modest. This work provides useful information to further future trial design in the post EV/P setting. Research Sponsor: None.

Cutaneous toxicity and clinical outcomes with enfortumab vedotin and pembrolizumab in patients with locally advanced or metastatic urothelial carcinoma. First Author: Alyssa Arbuiso, Memorial Sloan Kettering Cancer Center, New York, NY

Background: Enfortumab vedotin and pembrolizumab (EV/P) recently became the standard of care frontline treatment for patients with locally advanced or metastatic urothelial carcinoma (la/mUC). In patients treated with EV monotherapy, previous studies reported a potential association between cutaneous toxicities and improved clinical outcomes. While cutaneous toxicities are common with EV/P, the correlation with response has not been described. **Methods:** This is a retrospective cohort of patients treated with first line EV/P for la/mUC at Memorial Sloan Kettering Cancer Center. Clinical data were collected by chart review. Response to EV/P was defined by investigator assessment adhering to RECIST 1.1. Cutaneous toxicity events were recorded and classified as mild (managed with topical agents and/or oral antihistamines) or moderate/severe (requiring further pharmacological interventions and/or dose modifications). Association between clinical characteristics and response were analyzed using univariable and multivariable logistic regression models. **Results:** 186 patients who started EV/P between October 2018 and September 2024 were identified, 166 with distant metastases (89%) and 20 (11%) with locally advanced disease. Median age was 72 years, 68% were male, 31% had upper tract primary, and 44% had subtype/divergent histology component. Rates of bone, lung, and liver metastases were 29%, 24%, and 19%, respectively, and 27% had lymph node only disease. Observed response rate was 64% (119/186; 95% CI 57%, 71%), including a complete response rate of 18% (33/186; 95% CI 13%, 24%). Cutaneous toxicities occurred in 106 patients (57%), predominantly within the first 12 weeks (94/106), 70% of events were classified as mild and 30% as moderate/severe. On univariable analysis, cutaneous toxicity at any time, and before 12 weeks were significantly associated with response to EV/P, with odds ratio (OR) 2.6 (95% CI 1.44 - 4.94, p = 0.002) and 1.91 (95% CI 1.04 - 3.53, p = 0.037). Greater effect was seen based on severity: OR 2.24 (95% CI 1.17 - 4.42, p = 0.017) for mild events and OR 4.12 (95% CI 1.62 - 12.0, p = 0.005) for moderate/severe events compared to patients without cutaneous toxicity. Response to EV/P was less likely with distant metastatic disease (vs. locally advanced; OR 0.28, p = 0.05), and with bone metastases (OR 0.44, p = 0.015), and more likely with lymph node only disease (OR 2.89, p = 0.007). When adjusted for treatment setting (metastatic vs locally advanced) and time on treatment in multivariable analysis, the effect of cutaneous toxicity ≤12 weeks on response was no longer significant (OR 1.7, 95% CI 0.9 - 3.25, p = 0.11). **Conclusions:** In our large, real-world cohort there was a non-significant trend for response to EV/P in patients with cutaneous toxicities. Further studies are needed to define the potential correlation. Research Sponsor: None.

4575 Poster Session

Impact of histological subtypes in patients receiving first-line treatment with enfortumab vedotin/pembrolizumab in advanced metastatic urothelial cancer. First Author: Aya Abdelnaser, Dana-Farber Cancer Institute, Harvard Medical School, Boston, MA

Background: Metastatic urothelial carcinoma (mUC) represents a challenging clinical entity with significant morbidity and mortality. Enfortumab Vedotin plus Pembrolizumab (EV+P) has been established as an effective first-line (1L) treatment for mUC, but data regarding the impact of variant subtypes of UC remains limited. This study aims to describe the impact of different histological subtypes on mUC patients (pts) treated with 1L EV+P. **Methods:** This is a single-center retrospective cohort of pts with mUC treated with EV+P in first line between 6/1/2023 and 8/8/2024. Data were collected by chart review, including reviewed pathological reports and their impact on clinical outcomes (ORR, PFS, and OS). Four main histological groups were defined: 1)Transitional UC Predominant: Includes cases where transitional UC is the dominant component. 2) Transitional UC with <50% variant histologies of squamous or glandular differentiation. 3) Transitional UC with >50% variant histologies of squamous or glandular differentiation, including pure squamous or adenocarcinoma types. 4)Other Variant histologies: micropapillary vs. others (plasmacytoid, sarcomatoid, nested, and lipid-rich variants). **Results:** A total of 71 patients with mUC treated with first-line EV+P were included in this analysis, with a median age of 72.78 years. The median follow-up for the cohort was only 8 months (mos). The PFS rate at 12 mos was 43.28%, and the OS rate at 12 mos was 70%. Patients with predominant transitional UC (n=26) had a better response, with an ORR of 57.6% (15/26). Patients with UC having squamous or glandular differentiation (< or> 50%) showed inferior outcomes relative to all other subgroups. Specifically, patients with <50% squamous or glandular differentiation (n=6) had an ORR of 16.6% (1/6), while those with >50% (including pure squamous/glandular) (n=11) showed no response at all (0%, 0/11). Among the rest of the variants, only micropapillary (n=7) showed a substantial benefit with an ORR of 57.1% (4/7). Patients with other variant histologies, including sarcomatoid, plasmacytoid, nested, and lipid-rich (n=8), demonstrated inferior ORRs of 25% (2/8). ORRs based on different histologic subtypes are presented in Table. **Conclusions:** This analysis shows that histological subtypes significantly influence the treatment outcomes of Ev +P treatment. Favorable responses were observed in patients with predominant transitional histologies. Patients with mixed histologies containing squamous or glandular components showed poor responses to EVP independent of the cut-off > or < 50%, raising concern about the validity of the present cut-off value. Adequate responses were observed in the micropapillary subtype only. These findings emphasize the necessity for prospective validation and patient stratification of EV+P treatment in histological subtypes of UC. Alternative treatment strategies should be explored for patients with squamous or glandular subtypes. Research Sponsor: None.

				Variant histologies N=15	
	Transitional UC Predominant) n=37	Transitional UC <50% VH (squamous/ glandular) n=6	Transitional UC >50% VH (squamous/glandular) n=13	Other variant histologies n=8	Micropapillary Variant n=7
ORR	57.6% (15/26)	16.6% (1/6)	0% (0/11)	25% (2/8)	57.1% (4/7)

4576 Poster Session

Assessing treatment outcomes of enfortumab vedotin dose reduction in metastatic bladder cancer. First Author: Hal Difede Rives, The Fox Chase Cancer Center Foundation, Cheltenham, PA

Background: Enfortumab Vedotin (EV), an antibody drug conjugate targeting Nectin-4, has emerged as first-line treatment for advanced Urothelial Carcinoma (UC) in combination with pembrolizumab. Acute and cumulative toxicity due to EV can adversely impact quality of life. Treatment related adverse events (TRAEs) are managed with dose and schedule modifications. Current treatment paradigm is to treat until unacceptable toxicity or progression. Our single center, retrospective study, aims to assess the impact of EV dose reduction on treatment duration, AEs, and survival. **Methods:** We conducted a retrospective analysis of patients with UC treated with EV +/- pembrolizumab. Patients were divided into 3 groups: A) 1.25 mg/kg dose and not dose-reduced; B) 1.25 mg/kg dose and dose-reduced; C) EV < 1.25 mg/kg. Data was collected from the EMR and we evaluated OS, PFS, TRAEs, and number of doses received. Kaplan Meier and Cox proportional hazards regression models were used to compare PFS and OS between the 3 groups, and to evaluate treatment dose (1.25 mg or <1.25 mg) as a time-varying covariate. TRAEs (y/n) and number of doses received were examined using logistic and negative binomial regression respectively. Regression models adjusted for age, ECOG status, and receipt of concurrent pembrolizumab. **Results:** 153 patients comprised the 3 groups: A) n= 47; B) n=73; C) n=33. The cohort was majority male (78.4%) and white (79.1%) with no significant difference across groups. Median age and ECOG score were both significantly higher in group C (p<0.001 and p=0.033, respectively). Overall, 52.9% of patients received prior immunotherapy, while 35.9% of patients received concurrent pembrolizumab (similar across groups). Patients started on full dose EV then reduced (B) had significantly more TRAEs than groups A and C (Neuropathy; A: 15.2%, B:34.2%, C: 12.1%, p<0.001; Cutaneous AE; A: 4.3%, B:27.4%, C:2.1%, p=0.004). In unadjusted Kaplan Meier analyses (months), there was a trend but no statistically significant difference in PFS (A:6.4, B:10.1, C:13.1; p=0.1) or OS (A:10.5, B:15.6, C:22.9; p=0.22). In adjusted analyses (minimum 5 doses of EV), there was no difference in total doses received across groups(p=0.6867). Adjusted Cox proportional hazards regression (HR) showed significantly improved PFS and OS for the dose-reduced groups by both landmark (Table 1) and time-covarying analyses (<1.25 PFS, HR: 0.6 p=0.032; <1.25 OS, HR: 0.59 p=0.039). **Conclusions:** In adjusted analyses dose reduced groups had significantly improved PFS and OS. These results suggest that changes in dose can decrease overall AEs while maintaining efficacy, warranting prospective evaluation. Research Sponsor: None.

	1.25 mg/kg dose and dose-reduced	Significance	Started < 1.25 mg/kg	Significance
Landmark Analyses PFS (HR)	0.48	p=0.019	0.44	p=0.049
Landmark Analyses OS (HR)	0.53	p=0.038	0.47	p=0.063

Pembrolizumab (pembro) with chemoradiotherapy (CRT) as treatment for muscle-invasive bladder cancer (MIBC): Long-term follow up of secondary endpoints of efficacy including overall survival of the PCR-MIB phase II clinical trial (ANZUP 1502). First Author: Andrew James Weickhardt, Olivia Newton John Cancer Wellness & Research Centre, Austin Health, Melbourne, VIC, Australia

Background: We hypothesised pembro could be added without undue toxicity to CRT and would improve efficacy in patients (pts) with MIBC. **Methods:** This multicentre phase 2 trial included people with non-metastatic cT2-T4aN0M0 MIBC (>50% urothelial histology) who declined cystectomy or for whom cystectomy was unsuitable, with no contraindications to CRT or pembro, ECOG performance status 0 or 1, eGFR ≥40 mL/min. Neoadjuvant chemotherapy was not permitted. Pts had maximal TURBT, then whole bladder radiation therapy (RT) (64Gy in 32 daily fractions, mostly IMRT) over 6.5 weeks with weekly cisplatin (35 mg/m^2 IV, 6 doses) and pembro 200mg IV q3wk x 7 doses, both starting with RTx. Surveillance cystoscopy, urine cytology, and CT chest-abdomen-pelvis were performed 12 & 24 weeks after CRT. The primary endpoint was feasibility, determined by a prespecified satisfactory low rate of grade 3-4 non-urinary toxicity, or completion of planned CRT within defined parameters (RT < 7 weeks, >1 cisplatin dose omission). Secondary endpoints include rate of complete cystoscopic response without metastatic disease at 12 & 24 weeks, distant metastases free survival (DMFS), overall survival (OS), and loco-regional progression free survival (LRPFS). Longer term follow up (median 54 months) is presented here from the November 2024 analysis. **Results:** From 2016 – 2021, 28 pts (93% male, median age 72, 96% pure urothelial carcinoma, 29% with carcinoma in situ, 90% pT2) were enrolled at 6 sites. At 48 months, DFMS was 68% (95% CI 46-82%), OS was 64 % (95% CI 42-79%), with median OS not reached (95% CI 25.6m – NE). Local-regional failure free survival at 48 months was 84% (95% CI 63 – 94). Complete response (CR) rate 24 weeks post CRT was 88% (95% CI 70-98%, 23 CR, 3 PD, 2 NE). The The regimen was deemed feasible as previously presented: 6 pts had Gr >3 non-urinary any adverse events (AEs) during treatment or within 12 weeks after completing treatment (2 with delay in RT >7 wks), and 2 pts had cisplatin dose reductions due to G2 AEs. 1 pt had G3 colitis, 1 pt had G2 polymyalgia, 1 pt G2 nephritis. There were no additional immune related adverse events reported with longer follow-up. **Conclusions:** Longer follow up shows promising OS, DMFS and LRPFS with the combination of CRT and pembro for MIBC. There were no new immune related adverse events. Larger randomised trials to test this approach are ongoing. Clinical trial information: NCT02662062. Research Sponsor: Merck Sharp & Dohme LLC (Australia), a subsidiary of Merck & Co., Inc., Rahway, NJ (USA).

Prognostic utility of ctDNA before and after trimodality therapy (TMT) for muscle invasive bladder cancer. First Author: Brendan Raizenne, University of California, San Francisco, San Francisco, CA

Background: Outside of standard patient and tumor characteristics, biomarkers predicting outcomes after TMT for non-metastatic muscle-invasive bladder cancer (MIBC) are lacking. Tumor-informed circulating tumor DNA (ctDNA) has identified MIBC patients at risk of relapse following radical cystectomy. This study assessed the clinical utility of a ctDNA assay in predicting disease progression following TMT. **Methods:** We retrospectively identified patients (pts) with MIBC (cT2-T4, cN0-N2, cM1) who had TMT between 2019 and 2024 and ctDNA assessment with a personalized, tumor-informed assay (Signatera, Natera, Inc) before and/or after TMT. Standard clinical variables extracted include TNM stage, risk factors at TURBT (carcinoma in situ (CIS) and hydronephrosis) age of diagnosis, primary radiotherapy (RT) dose, chemotherapy regimen/duration, and if elective nodal irradiation (ENI) was received. We analyzed the impact of pre-TMT or post-TMT ctDNA (MTM/mL), as well as changes in ctDNA, on disease-free survival (DFS) using the Kaplan-Meier method. We assessed the impact of ENI on DFS in cN0 pts with positive ctDNA at baseline. Predictors of recurrence were assessed with univariate Cox proportional hazard models. **Results:** Among 34 pts, median age was 69 (interquartile range (IQR) 62-79), majority were male (91%), had cT2 (73.5%), were cN0 (85%), had no CIS (76%) or hydronephrosis (94%). The median dose of RT was 64 Gy. Ten (29%) patients had detectable ctDNA prior to TMT. Median follow-up was 13.2 months from last RT dose of TMT. Pts with detectable ctDNA after TMT had inferior DFS compared to pts with persistently undetectable (pre/post-TMT) or pts with ctDNA clearance (median survival of 5 months vs 15 and 19 months, respectively, log-rank p = 0.056). Table 1 shows results for predictors of DFS after TMT. Pts with detectable ctDNA post-TMT (n = 4) all developed distant metastatic recurrence. Local recurrences did not present with a detectable ctDNA following TMT. Pts with measurable ctDNA at baseline demonstrated potentially prolonged DFS after ENI (n = 4) compared to the non-ENI cohort (n = 6), but did not meet statistical significance (7.6 months vs not reached, p = 0.2). **Conclusions:** Persistently detectable ctDNA following TMT correlates with disease-free survival. Larger cohorts are needed to assess role of ENI in pts with detectable ctDNA prior to TMT. These results are hypothesis-generating and should be validated prospectively. Research Sponsor: None.

Predictors of DFS after TMT.

	HR (95% CI)	P-value
Histologic type (Reference (Ref) group: Pure urothelial)		
Urothelial with minor variant	0.76 (0.21-2.84)	0.69
CIS on TURBT (Ref group: No CIS)		
CIS	0.61 (0.16-2.28)	0.46
Pre-TMT Hydronephrosis (Ref group: No Hydronephrosis)		
Hydronephrosis	3.63 (0.77-17.19)	0.1
Response of ctDNA status to TMT (Ref group: Detectable to Detectable)		
Detectable to Undetectable	0.12 (0.02-1.00)	0.05
Undetectable to Undetectable	0.26 (0.04-1.75)	0.17

Quantifying patient preferences for bacillus Calmette-Guérin (BCG) and PD-(L)1 inhibitors in high-risk non-muscle invasive bladder cancer (NMIBC): A discrete choice experiment. First Author: Pam Hallworth, Adelphi Research, Bollington, United Kingdom

Background: Intravesical Bacillus Calmette-Guerin (BCG) induction + maintenance (I+M) is the standard of care for high-risk NMIBC. Disease recurrence and progression is common. The studies investigating programmed cell death-1/programmed death-ligand 1 (PD-[L]1) inhibitors + BCG aim to enhance treatment outcomes and reduce burden in BCG naïve high-risk NMIBC. There is limited evidence on patient preferences for these combination regimens. **Methods:** A discrete choice experiment quantified preferences for attribute levels related to BCG and PD-(L)1 inhibitors. Attributes and levels were informed by a literature review, patient interviews, regulatory scientific advice, clinical experts and a patient advocate. Patients completed hypothetical choice tasks describing administration mode and frequency for PD-(L)1 inhibitors and BCG (induction [I]; I+M), median event-free survival (EFS) and adverse events (AEs: bladder AEs; chronic endocrine conditions; serious immune AEs). Hierarchical Bayesian modelling estimated preference weights (PWs) for attribute levels. PWs identified level combinations with the lowest choice probability. Relative importance (RI) was calculated by systematically varying attribute levels and capturing the gain in choice probability. **Results:** 150 patients (77 BCG-naïve; 73 BCG-experienced) in the United States completed the survey. Clinician-confirmed diagnosis (17%) and/or self-reported ongoing or planned BCG I+M (99%) was obtained. The sample was 51% male, had a median age of 63 years (49-74) and diverse by race (Caucasian 46%; African American/Black 27%; Other 27%) and ethnicity (Hispanic/Latino/Spanish 21%). EFS was the most important attributes to patients (RI 17.2), followed by bladder AEs (RI 16.4) and serious immune AEs (RI 14.0). Administration attributes were important (RI 9-9.9), but less important than other attributes. PWs show that short duration (< 1 minute) subcutaneous (SC) injections was the most preferred PD-(L)1 route and shorter BCG schedule was preferred. **Conclusions:** Findings highlight the value of prolonging EFS, effective clinical management of BCG AEs and reducing administration burden in future BCG + PD(L)1 regimens. Research Sponsor: Pfizer Inc.

Attribute	Level	Mean PW	95% CI (±)	RI*(%)

Evaluation of surrogate endpoints in muscle-invasive bladder cancer (MIBC): A systematic review and meta-analysis. First Author: Matthew D. Galsky, Tisch Cancer Institute, Icahn School of Medicine at Mount Sinai, Department of Medical Oncology, New York, NY

Background: Overall survival (OS) is the gold-standard efficacy measure in oncology; however, it can take several years for OS data to mature, particularly in the clinically localized setting in patients undergoing curative intent treatment. To accelerate patient access to novel therapies, surrogate endpoints can be used to accelerate the assessment of new treatments when an early measure is reasonably likely or known to predict the clinical benefit for a target outcome such as OS. MIBC is a potentially curative disease with a complex and evolving treatment landscape involving radical cystectomy with or without systemic therapies, and bladder sparing strategies. Despite the need for surrogate endpoints in MIBC, there is limited research on their validity in this patient population. **Methods:** This study evaluated the trial-level surrogacy of event-free survival (EFS), progression-free survival (PFS), and disease-free survival (DFS) with respect to OS in MIBC. A systematic literature review (SLR) was conducted to identify randomized controlled trials (RCTs) that evaluated anti-cancer treatments (neoadjuvant, adjuvant, perioperative, and bladder sparing therapies) in MIBC and reported results for OS and ≥1 surrogate endpoint of interest. Studies published between Jan 1, 2000 and Jun 26, 2024 were identified by searching the MEDLINE, EMBASE, and CENTRAL databases. Grey-literature sources included recent conference proceedings and clinical trial registries. Study quality was assessed using the Cochrane Risk of Bias v2 tool. Data from studies with comparable outcome definitions for EFS, PFS, and DFS were combined into a broad composite outcome definition (cEFS). Trial-level surrogacy between the hazard ratio (HR) for cEFS and OS was evaluated. Analyses were conducted using a weighted linear regression (WLR) model and the bivariate Daniel & Hughes (D&H) model. Measures of surrogacy included the Pearson correlation coefficient (r) to measure the strength of association and the surrogate threshold effect (STE) to estimate the minimum HR for cEFS needed to reliably predict a HR for OS < 1. **Results:** 32 RCTs across 71 publications were included in the SLR; 14 were included in the cEFS analyses based on a feasibility assessment. Trials with a high-risk of bias (n = 1) or that evaluated the initiation of systemic therapy after disease progression (n = 4) were excluded. The HR for cEFS was strongly correlated with the HR for OS (r = 0.94; 95% CI: 0.72-0.99). Based on the STE, a HR <0.88 for cEFS would be needed to reliably predict a HR < 1 for OS. Results from the D&H model were consistent with these findings. **Conclusions:** These results suggest that at the trial level, the HR for cEFS is highly correlated with the HR for OS in MIBC across various treatment settings. cEFS may assist clinicians, regulatory agencies, and reimbursement bodies in contextualizing the benefits of novel treatment strategies in MIBC. Research Sponsor: Pfizer; Astellas Pharma Inc.

MRI radiomics to predict outcome of neoadjuvant chemotherapy in patients with muscle invasive bladder cancer undergoing radical cystectomy. First Author: Lawrence Howard Schwartz, Memorial Sloan Kettering Cancer Center, New York, NY

Background: Cisplatin-based neoadjuvant chemotherapy (NAC) before radical cystectomy (RC) is the standard of care in patients with muscle-invasive bladder cancer (MIBC). Although the administration of NAC for MIBC has increased over the years, it still does not meet actual patient's needs, particularly in cT2 BC, for which it is currently recommended in clinical guidelines. Indeed, with the development of new cytotoxic and targeted therapies, large ongoing prospective studies have been designed to test their efficacy either alone or in combination in the neoadjuvant setting. Multidisciplinary management is critical in this disease setting; including advanced imaging to assess response to treatment and outcome correlations. Despite the promising applications of radiomics in MIBC treatment outcome assessment, challenges remain, including successful harmonizing of imaging data, which impacts the consistency of radiomic features. The objective of the study is to assess the ability of radiomic features extracted from a robust magnetic resonance imaging (MRI) processing pipeline to predict the outcome of NAC prior to RC in patients with MIBC. **Methods:** A total of 105 MIBC patients (67M/38F), median age (65), clinical stage 2 (77), 3(28)) who were treated with NAC (cisplatin-based therapy) and underwent RC were included in this study. All patients underwent preNAC MRIs using the standard acquisition protocol. Tumors were segmented on T2w, T1w, and post contrast-T1w images by GU radiologists. To standardize MRI intensity values across scans, preprocessing steps were required to ensure comparability between patients. After N4-bias field correction of image intensities, images were standardized to robust z-scores using median and mean absolute deviation of intensities within respective regions of interest. IBSI-compatible pyCERR software was used to extract radiomics features. A total of 289 radiomic features, including shape, first-order statistics, and higher-order textures, were analyzed for the overall survival (OS, time between RC to death) as an outcome. To identify features associated with OS, we trained an Elastic Net Cox regression model for each MRI sequence, with performance evaluated by concordance index (c-index) on a 30% held-out test set. **Results:** The same shape feature (major axis length) from post contrast-T1w and T2w images was selected as important by the elastic net with test set c-index of 0.55 [0.42 – 0.67) and 0.56 [0.42 – 0.70], respectively. Kaplan-Meier method further confirmed the significance of this feature ($p < 0.05$) for OS risk stratification, using the median feature value as the cutoff point. **Conclusions:** The study demonstrated the value of radiomics in predicting survival to NAC with MIBC which can be further validated with a larger independent cohort. MRI radiomics may be an additional tool for prognostication. Research Sponsor: None.

Distinct genomic landscape of Lynch syndrome–associated urothelial cancer. First Author: Jussi Nikkola, Department of Urology, Tampere University Hospital, Tampere, Finland

Background: Lynch syndrome (LS) is a hereditary cancer predisposition syndrome caused by DNA mismatch repair (MMR) deficiency and associated with a 10–25% lifetime risk of urothelial cancer (UC), particularly in the upper urinary tract. We aimed to investigate the somatic genomic landscape of LS-associated urothelial cancer (LS-UC) using targeted and whole-exome sequencing (WES). **Methods:** We analyzed 41 surgical tumor samples accrued to five Finnish biobanks between April 1987 - June 2022 and 3 urine DNA samples from 34 LS-UC patients, all enrolled in the Finnish Lynch Syndrome Registry. Tumors were profiled using the UroScout assay, targeting 25 UC-associated genes, to identify somatic mutations. Immunohistochemistry was performed to assess MMR protein loss, and WES was conducted on selected cases to investigate the broader mutation landscape. A comparative analysis of the genomic and mutational landscapes in LS-UC versus sporadic UC was performed. **Results:** We show that telomerase reverse transcriptase (*TERT*) promoter mutations found in 83% of sporadic UC are almost completely absent (5%) in LS-UC ($p < 0.00001$). Instead, all LS-UC exhibited a 5-methylcytosine deamination (CG > TG) and microsatellite instability driven mutation landscape, characterized by highly frequent *ARID1A* (82%), *FGFR3* (80%), and *KMT2D* (78%) mutations, as well as preferential usage of CG > TG mutation hotspots. We propose that scarcity of *TERT* promoter mutations in LS-UC is due to inability to create the GABP binding motif 5'-GGAA through CG > TG mutation or microsatellite instability. Additionally, many mutation hotspots recurrently mutated in sporadic UC were not present in LS-UC. **Conclusions:** Our findings establish LS-UC as a distinct disease entity with a unique genomic signature driven by constrained hypermutation. Our proposed explanation that *TERT* mutations are absent in LS-UC due to constrained hypermutation is supported by our discovery that other UC driver genes also exhibit an altered mutation landscape in LS-UC. These insights advance the understanding of LS-UC tumorigenesis and support the development of tailored diagnostic and therapeutic approaches for this patient population. Study EV-103 cohort H: Neoadjuvant treatment with enfortumab vedotin (EV) monotherapy in cisplatin (cis)-ineligible patients (pts) with muscle invasive bladder cancer (MIBC)—3-year efficacy results. First Author: Nataliya Mar, University of California Irvine, Irvine, CA

Background: For cis-ineligible pts with MIBC undergoing radical cystectomy and pelvic lymph node dissection (RC+PLND), no neoadjuvant treatment options have been shown to improve survival, highlighting a clinical need. EV previously demonstrated encouraging antitumor activity in cis-ineligible pts with MIBC as neoadjuvant treatment in EV-103 Cohort H. We present updated 3-year efficacy results. **Methods:** EV-103 Cohort H enrolled cis-ineligible pts with MIBC (cT2-T4aN0M0) and ECOG PS ≤2 who were eligible for RC+PLND. Pts received neoadjuvant EV monotherapy (1.25 mg/kg) on Days 1 and 8 every 21 days for 3 cycles before undergoing RC+PLND. Primary endpoint was pathological complete response (pCR) rate by central pathology review. Secondary endpoints included event-free survival (EFS) per investigator assessment (INV), OS, and safety. A genAI tool (01/09/25; Pfizer; GPT-4o) developed the 1st draft; authors assume content responsibility. **Results:** Overall, 22 pts were enrolled. 86.4% of pts completed all 3 cycles of neoadjuvant EV treatment. Three pts (13.6%) discontinued neoadjuvant EV due to AEs. All pts underwent RC+PLND; 13 (59.1%) were in long-term follow-up at data cutoff (Nov 20, 2024). Median follow-up was 49.7 mo (range, 3.1-53.6). pCR rate was 36.4% (8/22; 95% CI, 17.2-59.3). Median EFS by INV was 40.1 mo (95% CI, 14.5-NE) for all pts, NR (95% CI, 6.5-NE) for pts with pCR, and 18.8 mo (95% CI, 6.7-NE) for pts without pCR. Estimated EFS rate by INV at 24 and 36 months was 62.0% (95% CI, 38.2-78.9) and 56.9% (95% CI, 33.4-74.8), respectively, and improved in pts with pCR. Median OS was NR (95% CI, 33.4-NE) in all pts. Estimated OS rate at 24 and 36 months was 77.3% (95% CI, 53.7-89.9) and 68.2% (95% CI, 44.6-83.4), respectively. Key updated 3-year efficacy data are shown in the Table. The safety profile was consistent with prior reports, and no new safety concerns were seen. **Conclusions:** Based on 3-year efficacy results, neoadjuvant EV monotherapy treatment continued to show encouraging antitumor activity in cis-ineligible pts with MIBC, including median EFS and OS exceeding historical real-world data in cis-ineligible patients following RC alone (Li Eur Urol Oncol 2024; Rose SESAUA 2023). The safety profile was generally manageable and consistent with the known AE profile of EV in other settings. Phase 3 trials evaluating perioperative EV + pembrolizumab in cis-eligible and -ineligible pts with MIBC (KN-905/EV-303, KN-B15/EV-304) are ongoing. Clinical trial information: NCT03288545. Research Sponsor: The EV-103 study was funded by Astellas Pharma Inc., Northbrook, IL, USA; Merck Sharp & Dohme LLC, a subsidiary of Merck & Co., Inc., Rahway, NJ, USA; and Seagen Inc., Bothell, WA, USA, which was acquired by Pfizer in December 2023.

Revolutionizing bladder cancer follow-up: Personalized urinary ctDNA analysis for detecting minimal residual disease. First Author: Xuebin Wan, HaploX Biotechnology Co., Ltd., Shenzhen, China

Background: As one of the most common malignant neoplasms of the urinary tract, bladder cancer (BC) has received widespread attention with respect to high incidence and tend to recur and progress. Circulating tumor DNA (ctDNA) serves as a valuable tool for detecting and monitoring minimal residual disease (MRD). Here, we conducted a prospective study to assess the potential of urinary ctDNA (utDNA) as a biomarker for measuring MRD in patients for non-muscle-invasive bladder cancer (NMIBC). The objective of this study was to evaluate the utility of longitudinal utDNA in informing adjuvant therapy decisions, enhancing clinical monitoring strategies, and ultimately improving BC prognosis. **Methods:** A total of 67 patients diagnosed with stage I-IV BC were recruited for the study from 2022.11 to 2024.12. For each patient, a customized panel was developed and synthesized, encompassing up to 45 baseline mutations, including SNVs and Indels. In addition to the patient-specific panel, a standardized core panel targeting hotspot regions was incorporated. Whole exome sequencing (WES) was conducted on cancer tissue samples and blood leukocytes in order to reduce the risk of false-positive findings and to exclude potential germline mutations, respectively. **Results:** The study cohort consisted of 59 patients diagnosed with BC, 7 patients with renal pelvis cancer, and 1 patient with ureteral cancer. 59 individuals, accounting for 88% of the sample, had a median age of 65 years. UtDNA was identified in 64 out of 67 preoperative patients, resulting in a detection rate of 95.5%. Furthermore, the correlation between urine samples and tissue samples was confirmed by Pearson's correlation analysis, yielding a correlation coefficient of (r = 0.31). 10 patients (14.9%) experienced a recurrence following TURBT. Residual tumors were detected in 7 of the recurrent patients who tested positive for urinary utDNA, accounting for 70% of the cases (7/10). Notably, the presence of positive utDNA in urine samples was observed 3 to 8 months prior to any indications on imaging studies. Monitoring of MRD demonstrated a consistent reduction in utDNA concentrations following surgery. Among patients with complete remission (CR), 9 individuals who initially tested positive for MRD post-surgery subsequently tested negative. **Conclusions:** The findings revealed a high level of concordance between the mutations identified in the tumor and those detected in the utDNA. Patients with positive utDNA exhibited a greater risk of cancer recurrence compared to those who tested negative for utDNA. Urine-personalized MRD detection strategies are anticipated to enhance the efficacy of adjuvant therapy and improve prognostic assessments in patients with BC. None. Clinical trial information: ChiCTR2400079704. Research Sponsor: None.

An exploratory study of clostridium butyricum combined with neoadjuvant chemoimmunotherapy in urothelial carcinoma. First Author: Xiao Yang, Department of Urology, The First Affiliated Hospital of Nanjing Medical University, Nanjing, China

Background: Neoadjuvant chemoimmunotherapy using gemcitabine, cisplatin, and anti-PD1 has shown survival benefits for advanced bladder cancer patients, though response rates remain low. Recent studies highlight the role of clostridium butyricum in anti-tumor immunity, but its potential to enhance bladder cancer therapy is unexplored. **Methods:** This exploratory study (NCT06696742) involved patients with cT2-T4aN0M0 urothelial carcinoma at First Affiliated Hospital of Nanjing Medical University. Participants were randomized into two groups, one received with GC+anti-PD1 (gemcitabine 1.0 g/m^2 D1 and D8, cisplatin 70 mg/m^2 D2-4, and tislelizumab 200 mg D8 once every 21 days for 3-4 cycles), and the other received the same regimen plus Clostridium butyricum tablets (1-2 tablets, three times a day). Primary observations were pathological complete response (pCR, ypT0) and pathological down-staging ($<$ ypT2), the second observations included imaging assessment (RECIST 1.1) and safety. **Results:** In the combination group, 23 out of 30 patients completed treatment and underwent radical cystectomy, achieving a clinical complete response (CR) rate of 52.2% (12/23) and a partial response (PR) rate of 39.1% (9/23). Two patients (8.6%) showed stable disease (SD) and seven patients are still receiving treatment. Pathological downstaging was observed in 82.6% (19/23) of the patients, with 52.2% reaching ypT0 (12/23). In the control group, all 26 enrolled patients completed treatment and underwent radical cystectomy. The clinical CR rate was 30.7% (8/26), while the clinical PR rate was 42.3% (11/26). Six patients (23.1%) had stable disease, and 1 patient (3.8%) experienced disease progression (PD). Pathological downstaging occurred in 61.5% (16/26) of the patients, with 26.9% (7/26) achieving ypT0. The combination group demonstrated significantly higher rates of clinical CR+PR (P = 0.037) and pathological downstaging (P = 0.042) compared to the control group. There was no statistical difference between the two groups in terms of demographic characteristics. **Conclusions:** Combining neoadjuvant chemoimmunotherapy with Clostridium butyricum improves pathological and clinical response rates in cT2-T4aN0M0 urothelial carcinoma patients. Clinical trial information: NCT06696742. Research Sponsor: None.

Updated efficacy and safety results from ReBirth, a phase II study of risk-based bladder-sparing therapy for MIBC. First Author: Yijun Shen, Department of Urology, Fudan University Shanghai Cancer Center; Department of Oncology, Shanghai Medical College, Fudan University, Shanghai, China

Background: Trimodal therapy (TMT) has achieved long-term survival and persistent oncologic control in selected MIBC patients, however, tailored treatment based on chemotherapy plus PD-1 inhibitor responses is currently absent. Furthermore, the safety and efficacy of hypo-fractionated radiation in combination with PD-1 inhibitors and concurrent chemotherapy is worth exploring. **Methods:** This was a two-stage, single-arm, phase II trial recruiting cT2-4aN0-1M0 MIBC pts. Based on results of cystoscopy, urine cytology and imaging after first stage (Tislelizumab (T) 200 mg on D1, Cisplatin (C) 70 mg/m^2 on D1 and Gemcitabine (G) 1000 mg/m^2 on D1 and D8 Q3W for 3-4 cycles), pts achieving cCR (cT0, cTa) were treated with T, while the other pts received T and chemoradiotherapy (whole bladder 44Gy/16 fractionation combined with C as radiosensitizer, if lymph node was positive, it could be dosed to the maximum tolerable dose, such as tumor boost 11Gy/4 fractionation). The primary endpoint was 1-year bladder-intact event-free survival (BI-EFS) rate in the intention to treat (ITT) population (from enrolment to muscle-invasive recurrence, nodal or distant metastasis, radical cystectomy (RC) or death). Secondary endpoints included 1-year BI-EFS rate in the per-protocol (PP) population, metastasis-free survival, recurrence-free survival and safety. **Results:** As of January 16, 2025 (median follow up: 14.3 months), 32 pts with a median age of 64 (36-79) years were enrolled (cT2: 71.8%; cT3: 21.9%; cT4: 6.3%; cN1: 6.3%). One pt withdrew consent and were not evaluated for efficacy. In the ITT population, 22 (71.0%) pts achieved cCR and 9 (29.0%) pts were non-cCR. Four pts underwent RC before finishing the first-stage treatment. 1-year BI-EFS rate was 86.9% (95%CI, 68.8-94.9) in the ITT population and 95.8% (95%CI, 73.9-99.4) in the PP population. In the PP population, 1-year BI-EFS rate for cCR pts and non-cCR pts was 100% and 80% respectively. Overall, 5 pts had T1HG recurrence. Meanwhile, 3 pts developed distant metastases (Bone:3; distant lymph node:2). TRAEs of any grade were found in 78.1% pts and 42.3% experienced grade 3-4 TRAEs. No new safety signs were discovered. **Conclusions:** The updated findings continued to show promising efficacy and manageable toxicity via the two-stage treatment. Non-cCR pts might avoid RC through intensified treatment with chemoradiotherapy and T. Follow-up for long-term survival outcomes is still ongoing. Clinical trial information: NCT05531123. Research Sponsor: None.

Postoperative assessment using urinary tumor DNA (utDNA) to identify potential candidates for repeat transurethral resection of bladder tumor (re-TURBT) in non-muscle invasive bladder cancer (NMIBC): A retrospective analysis. First Author: Zihan Xue, The Second Hospital of Tianjin Medical University, Tianjin, China

Background: The role of routine repeat transurethral resection of bladder tumor (re-TURBT) in managing non-muscle invasive bladder cancer (NMIBC) remains controversial, especially when the initial resection includes the detrusor muscle. Urinary tumor DNA (utDNA) seem really promising in urothelial carcinoma diagnosis and detection of minimal residual disease. Here, we investigated the correlation between post-initial TURBT utDNA results and the pathology of secondary resection to assess utDNA's potential for precisely identifying patients who may benefit from re-TURBT. **Methods:** A retrospective analysis was conducted on patients with HG Ta/T1 bladder carcinoma (BCa) who underwent re-TURBT in 2 to 6 weeks after initial TURBT at The Second Hospital of Tianjin Medical University between 2020 and 2024. All visible tumor were completely resected and detrusor muscle was collected at the initial surgery. Urine samples were collected and utDNA analysis was performed using a validated next-generation sequencing (NGS) platform a week after initial TURBT. The secondary resection includes the base of the primary tumor, resection margins, excision scar and any suspicious lesion. The results of utDNA testing were compared with the histopathology from re-TURBT. **Results:** 130 patients met the study inclusion criteria. Re-TURBT was successfully performed in all study participants. Urinary tumor DNA test was positive in 39 patients; of whom 35 (89.7%) showed positive repeat biopsy (HR = 7.42, 95%CI = 2.94-18.67, P $<$ 0.001). The sensitivity, specificity, positive and negative predictive value of utDNA test for re-TURBT histopathology were 76.1% (95%CI : 64-88) , 95.2% (95%CI : 91-99) , 89.7% (95%CI : 80-99) , 87.9% (95%CI : 81-95) , respectively. On a median (range) follow-up of 23 (3-47) months , 15 cases of tumor recurrence were encountered in 14 (10.7%) patients. On multivariate Cox regression analysis, the post-initial-TURBT utDNA test was significantly associated with tumor recurrence (HR = 4.48, 95%CI : 2.0-9.8, P $<$ 0.001). **Conclusions:** Our findings suggest that utDNA analysis after initial TURBT can effectively identify patients with residual disease who are likely to benefit from re-TURBT and that utDNA is an independent predictor of tumor recurrence. This non-invasive liquid biopsy method has the potential to identify beneficiaries of re-TURBT, and optimize the management of HG Ta/T1 bladder cancer. Further prospective studies are warranted to validate the clinical utility of utDNA in this setting. Research Sponsor: None.

Updated results from a phase II study of perioperative disitamab vedotin (RC48-ADC) plus cadonilimab (AK104) for HER2-expressing muscle-invasive bladder cancer (MIBC). First Author: Sujun Han, Department of Urology, National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China

Background: Several current ongoing clinical trials have shown promising efficacy and safety of antibody-drug conjugates (ADCs) alone and in combination with immune checkpoint inhibitors (ICIs) as neoadjuvant treatment for patients with MIBC (ASCO 2024). Disitamab vedotin (RC48-ADC) is a novel humanized anti-HER2 ADC. RC48-ADC combined with cadonilimab (AK104), known as the PD-1/CTLA-4 bispecific antibody ICI, may have enhanced synergistic antitumor effects attributed to the mechanism of action and achieve more clinical benefit. Here, we report updated results from a phase II study of perioperative RC48-ADC plus AK104 in HER2-expressing MIBC (NCT06074484). **Methods:** This single-arm, open-label, multicentre study evaluates the efficacy and safety of RC48-ADC plus AK104 as a novel neoadjuvant and adjuvant therapy in patients (pts) with treatment-naïve HER2-expressing (immunohistochemistry, IHC 1+, 2+, 3+) MIBC (T2-T4a, N0-1, M0; ECOG PS score 0-1). Eligible pts received neoadjuvant RC48-ADC (2.0 mg/kg D1 Q2W, 4 cycles) + AK104 (6.0 mg/kg D1 Q2W, 4 cycles) followed by radical cystectomy and pelvic lymph node dissection (RC+PLND), and postoperative adjuvant RC48-ADC (2.0 mg/kg D1 Q3W, 6 cycles) + AK104 (10.0 mg/kg D1 Q3W, 14 cycles). The primary endpoint was pathologic complete response (pCR, pT0N0M0). Secondary endpoints were pathologic downstaging rate (pDS, yp$\leq$T1N0), disease-free survival (DFS), overall survival (OS), objective response rate (ORR), and safety. **Results:** By January 2025, 43 pts had been successfully enrolled. Of these, 81.4% (35/43) were male and 18.6% (8/43) were female, with a median age of 65 years (range, 44-78). HER2 expression was positive (IHC 2+ or 3+) in 72.1% of pts and PD-L1 positive (CPS $\geq$ 10) in 34.9%. The pCR rate was 64.71% (22/34, 95% CI, 47.85-78.58) in all evaluable pts, 81.82% (9/11) in HER2 1+ and 56.57% (13/23) in HER2 2+/3+ pts, meanwhile 77.78% (14/18) in cT2, 30.00% (3/10) in cT3, and 83.33% (5/6) in cT4a/N1 pts. The overall pDS rate was 76.47% (26/34). Treatment-related adverse events (TRAEs) of any grade occurred in 90.7% of pts (39/43), with $\geq$ Grade 3 TRAEs in 18.6% (8/43), including fever, rash, bone marrow hypocellular, alanine aminotransferase increased, and immune-mediated myocarditis or pneumonitis. No Grade 4 or Grade 5 TRAEs occurred. At a median follow-up of 11.3 months (95% CI, 9.0-12.1), 2 pts had died, but the median DFS and OS were not reached which remained stable on study and would be updated. **Conclusions:** Neoadjuvant and adjuvant RC48-ADC plus AK104 demonstrated favorable efficacy and a manageable safety profile, supporting its potential as a valuable treatment modality for HER2-expressing MIBC. Long-term benefits and further understanding the role of this combination therapy in the perioperative setting of MIBC will be critical to advance treatment strategies. Clinical trial information: NCT06074484. Research Sponsor: RemeGen; Akesobio.

Microbiota proteomics profiles in muscle-invasive bladder carcinoma related to response to neoadjuvant chemotherapy. First Author: Alvaro Pinto, Oncology Department, Hospital La Paz Institute for Health Research-IdiPAZ, Hospital Universitario La Paz, Madrid, Spain

Background: Muscle-invasive bladder carcinoma (MIBC) poses significant challenges due to high recurrence and mortality rates, coupled with the toxicity of neoadjuvant chemotherapy (NACT). This has driven the search for biomarkers to improve treatment management and patient quality of life. **Methods:** Fifty-eight FFPE samples from MIBC patients obtained from transurethral resection (TURBT) were studied. Microbiota analysis was performed by amplification and sequencing of the V4 variable region of the 16S rRNA gene and using Qiime2 software for taxonomic identification. Proteins were extracted and digested from TURBT samples and analyzed by mass spectrometry with data-independent acquisition. For protein identification, a reference database was built, including both the human proteome and bacteria genera proteomes identified by 16S experiments. Proteomics data were processed with Perseus and analyzed using probabilistic graphical models (PGMs) and hierarchical clustering. **Results:** We have information about treatment response for 56 patients. Twenty-four patients achieved a pathological complete response (43%), with a median disease-free survival of 22 months, and a median overall survival of 29.23 months. 151 bacteria genera identified by 16S experiments, were included in the metaproteomics database. In proteomics experiments, 42 bacteria and 5,111 human proteins were identified. After applying quality criteria, 13 bacteria proteins were used for the subsequent analyses. Hierarchical clustering analysis identified three groups with different microbiota protein profiles: Microbiota1, Microbiota2 and Microbiota3. These groups showed significant differences in response to NACT. A higher proportion of non-responders (73%) vs. responders (27%) was observed in Microbiota2 compared to the other groups (54% in Microbiota1 and 36% in Microbiota2), whereas a predominance of responders (64%) was observed in Microbiota3 (46% in Microbiota1 and 27% in Microbiota2) (p= 0.0481). In a previous work, our group defined three proteomics-based groups related to response to NACT (Layer1 (1.1, 1.2 and 1.3)) (Pinto et al., SEOM 2024). Significant differences were also observed in the distribution of Layer1 between the microbiota clusters. Microbiota2 had a higher representation of patients belonging to Layer1.3, characterized by a majority of non-responders and Microbiota3 had a higher proportion of patients from Layer1.1. **Conclusions:** To our knowledge, this is the first metaproteomics study in FFPE samples from bladder carcinoma patients for biomarker discovery. Three distinct microbiota protein profiles were identified, one with higher proportion of non-responders. The potential role of these bacteria in NACT response needs further study, highlighting metaproteomics as a promising avenue for biomarker development. Research Sponsor: None.

Efficacy and safety of disitamab vedotin (RC48) combined with toripalimab as adjuvant therapy after radical surgery for patients with HER2-overexpression upper tract urothelial cancer (UTUC): A single-arm, prospective, phase 2 clinical trial. First Author: Shouyong Liu, Department of Urology, Jinling Hospital, Affiliated Hospital of Medical School, Nanjing University, Nanjing, China

Background: UTUC is rare and highly aggressive. The prognosis is poor, especially for high-risk patients, even after radical surgery. Adjuvant chemotherapy is the standard therapy, but with limited efficacy, indicating a need for more effective regimens. RC48, an anti-HER2 antibody-drug conjugate, combined with toripalimab, an anti-PD-1 monoclonal antibody, has shown promising results in locally advanced or metastatic urothelial carcinoma (C014 trial). We evaluate the efficacy and safety of RC48 combined with toripalimab as adjuvant therapy for patients with HER2 IHC 2+/3+ UTUC after radical surgery. **Methods:** This is a single-arm, prospective, phase 2 clinical trial (NCT05917158). Eligible criteria were patients with histologically confirmed HER2 IHC 2+/3+ UTUC after radical surgery and were staged as T2-4NanyM0 or TanyN1-2M0, with no prior neoadjuvant therapy. The intervention was intravenous RC48 (2 mg/kg) combined with toripalimab (3 mg/kg) triweekly for 6 cycles, followed by toripalimab (3 mg/kg) triweekly for up to 1 year. The primary endpoint was DFS, and the secondary endpoints were OS, safety, and MRD analysis. **Results:** 45 patients (35 males [77.8%], median age 68 years [IQR 58-71]) were enrolled. The patients were staged as: 43 (95.6%) in II, 1 (2.2%) in III, and 1 (2.2%) in IV. All patients were HER2-overexpression (80% in IHC 2+, 20% in IHC 3+). 25 patients (55.6%) met cisplatin-ineligibility. By the data cutoff date on January 14, 2025, the median follow-up time was 12.2 months (IQR 6.7-17.6). 4 relapses occurred: 2 in lymph nodes, 1 in the prostate, and 1 in lymph nodes and the bladder. The 1-year DFS rate was 90.0%, and the median DFS has not been reached. All patients experienced treatment-related adverse events (TRAEs). The most common TRAEs were hypoesthesia (51.1%), increased blood glucose (48.9%), anemia (46.7%), increased creatinine (46.7%), and hypertriglyceridemia (46.7%). TRAEs of grade $\geq$3 occurred in 20% of patients. 8.9% of patients experienced immune-related adverse events, including rash and hypothyroidism. Among the patients, 16 (35.6%) completed treatment, 19 (42.2%) were still undergoing intervention, 4 (8.9%) discontinued therapy due to TRAEs: 1 with hypoesthesia, 1 with lymphocytopenia and hypoesthesia, 1 with nausea, vomiting, and decreased appetite, and 1 with pruritus and diarrhea, and 2 withdrew after completing 4 cycles of combined regimen due to personal reasons. No deaths occurred during the follow-up period. **Conclusions:** This is the first prospective clinical trial evaluating the efficacy and safety of the new adjuvant regimen for patients with HER2-IHC 2+/3+ UTUC. It showed promising DFS outcomes and a manageable safety profile, highlighting its potential as a new adjuvant therapy in patients with HER2-IHC 2+/3+ UTUC. Clinical trial information: NCT05917158. Research Sponsor: None.

First survival outcomes and biomarker results of SURE-01: Neoadjuvant sacituzumab govitecan (SG) monotherapy, followed by radical cystectomy (RC), in patients with muscle-invasive urothelial bladder cancer (MIBC). First Author: Brigida Anna Maiorano, IRCCS San Raffaele Hospital, Milan, Italy

Background: Standard of care for MIBC is RC with neoadjuvant chemotherapy (NAC), but ~50% of pts are ineligible for NAC and 5y survival for RC alone is $\leq$50%. SG is an antibody-drug conjugate composed of an anti-trophoblast cell surface antigen 2 (Trop-2) antibody coupled to SN-38 (a topoisomerase-I inhibitor). SURE-01 (NCT05226117) is an ongoing study testing neoadjuvant SG before RC. Preliminary pathological response rates suggested activity (Cigliola et al., ASCO 2024). Here, we report first results on survival and biomarkers. **Methods:** Pts age $\geq$18 y, ECOG PS 0-1, with histologically confirmed cT2-T4N0M0 MIBC, ineligible/refusing NAC and scheduled for RC, received 4 cycles of SG 7.5 mg/kg intravenously (reduced dose in protocol amendment 1) on days 1 and 8, Q3W, followed by RC. Primary study endpoint was the proportion of ypT0N0. Secondary endpoints included event-free survival (EFS), relapse-free survival (RFS) post-surgery, overall survival (OS), and safety. EFS included relapse/progression, inability/unwillingness to undergo RC in pts with residual disease, and death. Pts refusing RC with evidence of ypT0 response were censored. Decipher Bladder (Veracyte, San Diego, CA) was used on primary TURBT tissue for transcriptome-wide analyses. Signatera was used for ctDNA assessment. **Results:** From 03/22 to 01/25, 37 pts were enrolled and 33 were efficacy-evaluable. Median age was 71y and 16 pts (48.5%) had cT3-4N0 stage. Twelve pts (36.4%) had mixed variant histology. Grade $>$ 3 treatment-related adverse events (TRAE) occurred in 9 pts (27.3%), including one Grade 5 (at 10mg/Kg dose). Nine pts (27.3%) refused RC and were assessed with a reTURBT. The ypT0N0-x rate was 36.4% (12/33, 95%CI: 20.4-54.9%) and ypT $<$ 1N0-x rate was 39.4% (13/33). 8/10 pts with a high-risk disease at RC had ctDNA-negative status post-RC. Median follow-up was 14 (range 10-17) months. For the intention-to-treat (ITT) population, 12m-EFS was 78.8% (95% CI: 66-94%). 12m-Relapse-free survival (RFS) post-RC/reTURBT was 100% in pts with an ypT $<$ 1N0-x response vs 81.2% in pts with an ypT2-4N0 or ypTanyN1-3 response. Transcriptome-wide data for 27 pts revealed 12m-RFS rate of 100% in N = 8 Infiltrated-Luminal (IL), 86% in N = 7 Claudin Low, 83% in N = 6 Basal and 75% in N = 6 Luminal cases (Log-rank, p = 0.24), with consistent associations found for ypT0 response (IL: 71% ypT0 rate). Lower ($<$ median) *TOP1* gene expression (N = 14) was associated with 100% 12m-RFS rate (Log-rank, p = 0.05). Trop-2 gene expression did not associate to neither ypT response (p = 0.69) nor RFS. **Conclusions:** SURE-01 revealed compelling survival outcomes. While survival estimates or transcriptome results were not overtly associated with pathological response (interim endpoint), molecular subtypes and *TOP1* gene expression may be putative biomarkers of SG efficacy. Clinical trial information: NCT05226117. Research Sponsor: None.

Prognostic impact of histological subtypes in non-muscle-invasive UTUC: Propensity matched analysis. First Author: Shiwang Huang, The Second Hospital of Tianjin Medical University, Tianjin, China

Background: Upper tract urothelial carcinoma (UTUC) is a rare malignancy with poor outcomes. While histological subtypes are known to influence bladder cancer prognosis, their impact on non-muscle-invasive UTUC remains underexplored. This study evaluates the effect of histological subtypes on survival outcomes after radical nephroureterectomy (RNU). **Methods:** This retrospective multicenter study included 399 patients with non-muscle-invasive UTUC who underwent RNU between August 2019 and April 2024. Patients were stratified into pure UTUC (pUTUC) and histological subtype UTUC (hsUTUC) groups. Propensity score matching (PSM) in a 1:2 ratio balanced baseline characteristics. Cancer-specific survival (CSS) was the primary endpoint; recurrence-free survival (RFS) and intravesical recurrence-free survival (IVRFS) were secondary endpoints. Kaplan-Meier curves and Cox regression models were applied for statistical analysis. **Results:** Among 399 patients (median age 69 years; interquartile range [IQR], 63–75), 57 (14%) had hsUTUC. After PSM (166 patients), Kaplan-Meier analysis showed comparable CSS between hsUTUC and pUTUC groups before and after matching ($p >$ 0.05). However, hsUTUC patients exhibited significantly worse RFS and IVRFS. Multivariable Cox regression revealed hsUTUC was independently associated with worse RFS (hazard ratio [HR] 2.38, 95% confidence interval [CI] 1.29–4.36; p = 0.005) and IVRFS (HR 2.06, 95% CI 1.04–4.10; p = 0.039), but not CSS (HR 1.84, 95% CI 0.60–5.61; p = 0.283). **Conclusions:** Histological subtypes in non-muscle-invasive UTUC significantly increase recurrence risk but do not affect CSS. These findings highlight the need for tailored surveillance and more aggressive management strategies in hsUTUC patients. Research Sponsor: None.

The association between histological subtypes and survival outcomes.

	Cancer-specific survival		Recurrence-free survival		Intravesical recurrence-free survival	
hsUTUC vs. pUTUC	HR (95% CI)	*p value*	HR (95% CI)	*p value*	HR (95% CI)	*p value*
Unadjusted	1.76 (0.61-5.12)	0.297	2.30 (1.28-4.13)	0.005	1.94 (0.99-3.79)	0.053
Adjusted	1.84 (0.60-5.61)	0.283	2.38 (1.29-4.36)	0.005	2.06 (1.04-4.10)	0.039

Model was adjusted for Tumor T stage (Ta/Tis/T1), lymph node status, lymphovascular invasion, concurrent CIS, concurrent bladder cancer, and hydronephrosis.

Inferring FGFR status from H&E images using digital pathology to identify patients for early-stage bladder cancer targeted therapies. First Author: Albert Juan Ramon, J&J Innovative Medicine, San Diego, CA

Background: The identification of susceptible FGFR (Fibroblast Growth Factor Receptor) alterations may be critical in guiding treatment decisions for patients with bladder cancer. Current nucleic acid-based tests used to detect FGFR+ patients have limitations, including a slow turnaround time and high nucleic acid input requirement, especially in NMIBC, where tissue is often scarce. This study aims toevaluate the performance of an AI-based digital pathology algorithm, MIA:BLC-FGFR, adapted to investigate FGFR alterations in NMIBC patients from routine hematoxylin and eosin (H&E) stained whole slide images (WSIs). This approach may provide a rapid, low-cost, and effective alternative to nucleic acid testing. **Methods:** MIA:BLC-FGFR consists of an image quality control preprocessing stage, a Foundation Model (FM) pre-trained on ~55k unlabeled digital WSIs from various sources (multiple scanners, hospital systems, labs, diseases, tissue sites), and a classification module to enable inference of FGFR status from H&E-stained images. The classification module was trained on datasets (n = 3,067 WSIs) that included a mix of WSIs from multiple sources and disease stages (i.e., NMIBC, muscle-invasive and metastatic bladder cancer), and genetic classification provided by nucleic acid-based test. The algorithm was tuned to achieve a balanced specificity and sensitivity by selecting the operating point with highest F1 score (i.e., balanced sensitivity/specificity) in the training data. As part of this study, we then applied this model to WSIs of biopsies from 3 independent testing datasets (n = 578 WSIs) with varied NMIBC disease settings (i.e., high risk (HR) or intermediate risk (IR)) to evaluate the performance at predicting FGFR status, quantified by the Area Under ROC Curve (AUC). **Results:** MIA:BLC-FGFR demonstrated good concordance with nucleic acid testing methods. The results are summarized in the table below: **Conclusions:** The MIA:BLC-FGFR algorithm adapted to NMIBC can infer the presence or absence of select FGFR alterations from routine H&E images. This AI-based approach may offer a rapid, low-cost, and accurate alternative to traditional nucleic acid testing, particularly benefiting NMIBC patients with limited tumor tissue. By integrating into standard pathology workflows and providing results within minutes, the algorithm has the potential to significantly enhance FGFR testing rates and patient care decisions for emerging FGFR-targeted therapies. Research Sponsor: None.

Testing datasets	Independent Dataset 1	Independent Dataset 2	Independent Dataset 3

Overall survival and biomarker results of NURE-Combo: A phase 2 study of neoadjuvant nivolumab (NIVO) and nab-paclitaxel (ABX) followed by post-surgical adjuvant NIVO in patients (pts) with muscle-invasive bladder cancer (MIBC). First Author: Chiara Mercinelli, IRCCS San Raffaele Hospital, Vita-Salute San Raffaele University, Milan, Italy

Background: The first results of NureCombo revealed the combination of NIVO + ABX followed by RC and adjuvant NIVO was active in pts with MIBC (Mercinelli, JCO 2024). We report key secondary endpoints after study completion including adjuvant NIVO for all pts (NCT04876313). **Methods:** Eligible pts who were cisplatin unfit or declined cisplatin-based treatment had previously untreated MIBC (clinical stage T2-T4a, N0-1, M0), Eastern Cooperative Oncology Group performance status $\leq$ 1, and predominant ($>$ 50%) UC histology. Pts received 4 cycles of NIVO 360 mg Q3W + ABX 125 mg/m2 on Day 1 and 8, Q3W, followed by RC and by 13 administrations of adjuvant NIVO 360 mg Q3W. Transcriptome-wide analyses with Decipher Bladder (Veracyte, San Diego, CA) on primary TURBT tissue samples are presented. Continuous scores were dichotomized by median splits. **Results:** 31 pts were enrolled from 12/2021 to 06/2023, of which 17 (54.8%) had cT3-4 and 14 (45.2%) cT2. N = 2 (6.4%) had cN1 and 15 (48.4%) had a variant histology component. In total, 9 pts (29%) never started the adjuvant NIVO and 15 pts (48.4%) completed it: reason for discontinuation were treatment-related adverse events (TRAE; 5 pts, 16.1%) and relapse (2 pts; 0.6%). Median follow-up was 25 months (IQR: 21-32) and the minimum follow up was 19 months. In total, 7 pts experienced a relapse, 2/7 consisting of an intravesical relapse in those who refused to undergo RC (N = 3). 24-month (24m) event-free survival (EFS) was 73.7% (95%CI 59.6-91.2), corresponding to the 24m relapse-free survival (RFS) post-RC; 24m overall survival (OS) was 89.7% (95%CI 79.3-100; median OS was not reached). There were no additional/late TRAE compared to the initial report. Transcriptome profiles were available for N = 24: Genomic Subtyping Classifier (GSC) stratification revealed ypT0 was highest (50%) in N = 18 Non-luminal (claudin low, basal & infiltrated-luminal) subtypes and lowest (17%) in N = 6 luminal subtype ((p = 0.34). Based on Consensus MIBC classification, none of N = 4 luminal-papillary tumors had a ypT0 response (p = 0.09). Higher Immune190 and higher ESTIMATE-stromal signature trended to better RFS (HR 0.39 & 0.38, respectively). **Conclusions:** Long-term follow-up results of NureCombo revealed sustained efficacy of ABX-NIVO combination therapy followed by adjuvant NIVO in pts with MIBC. Molecular classification of baseline tumors revealed less favorable pathologic response rates for luminal MIBC. Differences in molecular correlates compared to PURE-01 may be related to different checkpoint inhibition (nivo vs pembro) or due to addition of ABX. Clinical trial information: NCT04876313. Research Sponsor: Bristol Myers Squibb.

4595 **Poster Session**

Five-year median follow-up update of PURE-01: A phase 2 study of neoadjuvant pembrolizumab followed by radical cystectomy in patients with muscle-invasive bladder cancer (MIBC). First Author: Valentina Tateo, IRCCS San Raffaele Hospital, Milan, Italy

Background: In patients (pts) with MIBC, the PURE-01 study pioneered the use of neoadjuvant immunotherapy by administering 3 courses of pembrolizumab before radical cystectomy (RC). Multiple reports have outlined various results of this trial, but assessment of the very long-term benefit of this strategy was pending and potentially noteworthy. **Methods:** Pts age $\geq$18 y, ECOG PS 0-1, with histologically confirmed cT2-T4N0M0 MIBC, ineligible/refusing chemotherapy (CT), and scheduled for RC received 4 cycles of pembrolizumab 200 mg on D1 Q3W, followed by RC and standard-of-care management. A total of 155 pts were included in the study. Even-free survival (EFS), relapse-free survival (RFS) in the RC population and overall survival (OS) are reported. Cumulative risk of recurrence (CRR) by competing risk analyses was also reported. Updated results from transcriptome-wide profiling using the Decipher Bladder assay (Veracyte, San Diego, CA) on primary TURBT tissue are presented. **Results:** From 02/17 to 07/20, 155 pts were treated (12.9% females). Remaining clinical and pathological features yet have been reported. Median follow-up was 61.8 months (IQR: 53.6-68.2). In the intention-to-treat (ITT) population, 5y-EFS was 68.3% (95%CI: 61.1-76.4) and 5y-OS was 77.4% (95%CI: 70.6-84.8). Pathological response categories were significantly associated with both RFS ($p < 0.001$) and OS: 5y-OS for ypT0N0 responders was 89.5% vs 90.3% for ypTa/Tis/T1N0 vs 72.2% for ypT2N0 vs 58.8% for ypT3-4N0 vs 41.9% for ypTanyN+ ($p < 0.001$). Out of 31 total relapses, three were very late relapses $>$ 5y post-RC, of which all were visceral relapses including isolated brain metastases in one case. The 5y-CRR was 19% (95%CI: 13-26). 7/8 pts who refused to undergo RC and received a reTURBT are alive and disease-free. Transcriptome-wide profiles were available for 102 pts. Stratification by Genomic Subtyping Classifier (GSC) allowed significant separation of RFS curves: Claudin Low subtype (N = 14) confirmed to portend the highest 5y-RFS (Log-rank Claudin-Low vs others vs NE-like p = 0.02), with 5y-OS for Claudin Low subtype being 93% (Log-rank Claudin-Low vs others vs NE-like p = 0.29). Higher immune infiltration scores quantified by Immune190 signature were associated with improved OS (HR (95% CI) per 0.1 increase = 0.60 (0.42-0.87); p = 0.006) Biologic evaluation among N = 604 MIBC GRID patients revealed highest Immune190 scores for Claudin Low subtype ($p < 0.001$). **Conclusions:** After $>$ 5y median follow-up, PURE-01 study revealed a sustained response and survival in pts with MIBC. Important updates are the validation of pathological response as a surrogate of OS in post-IO setting, the validation of molecular subtypes in association with RFS (and possibly OS) benefit, and the need to prolong follow-up at long term due to few pts with delayed recurrences. Clinical trial information: NCT02736266. Research Sponsor: Merck Inc.

4596 **Poster Session**

A phase II prospective, open-label, multi-center, single-arm study of sasanlimab plus sacituzumab govitecan in BCG-unresponsive non-muscle invasive bladder cancer (NMIBC) pts: SSANTROP (APRO07-2022). First Author: Joaquim Bellmunt, Bladder Cancer Center, Dana Farber Cancer Institute, Harvard Medical School, Boston, MA

Background: Radical cystectomy (RC)is the standard treatment forBCG unresponsive high-risk (HR) NMIBC patients (pts). Pembrolizumab (Pem) was approved by the FDA based on Keynote-057 (41% complete response rate (CRR)) and offers a non-surgical option for pts who decline or are ineligible for RC. Nadofaregene firadenovec and Nogapendekin alfa inbakicept have been recently approved in this setting. Sacituzumab govitecan (SG) demonstrated encouraging efficacy and safety in metastatic urothelial cancer (mUC) in the TROPHY-U-01 trial. Combining ADCs with immunotherapy showed promising results in mUC. We hypothesized if the combination of sasanlimab (Sa), a subcutaneous (SC) anti-PD1 agent, and SG would improve the CRR of Pem in BCG-unresponsive NMIBC pts who refuse or are ineligible for RC. **Methods:** SSANTROP is a phase II study conducted across 18 sites in Spain to assess the CRR at 3 months (mo) of the combination of Sa (5 cy of Sa 300 mg SC on day 1 every 28 days) plus SG (7 cy of SG 10 mg/kg IV on days 1 and every 21 days) in BCG unresponsive HR NMIBC. Pts achieving CR at 3 mo received maintenance therapy: Sa 300 mg SC every 28-day for up to 2 years. Primary endpoint was CRR at 3 mo with plan for percentage of response assessment maintained at 12 and 15 mo. Key eligibility criteria: ECOG PS 0-1, histologically confirmed BCG-unresponsive HR NMIBC, refusal or ineligibility for RC, urothelial carcinoma histology, and no prior anti-PD1/L1 or anti-CTLA-4 therapy. The sample size of 116 pts was calculated to demonstrate a 53% CRR for the combination, based on a Pem historical control of 41% (one-sided alpha 0.05, power 82%). Design was modified to finally include 40 pts based on a change in the treatment landscape of UC. **Results:** As of January 21, 2025, 59 pts were screened, and 41 initiated treatment and were included in the safety analysis. Among them, 32 (78%) male, median age of 70.6 years (SD 7.8). Types of BCG-unresponsive disease included: persistent/recurrent CIS alone or with recurrent HG Ta/T1 within 12 mo post-BCG (22 pts, 53.7%), recurrent HG Ta/T1 within 6 mo post-BCG (16 pts, 39%), and T1 HG disease at first evaluation post-induction BCG (3 pts, 7.3%). The most common adverse events (AEs) were diarrhea (58.5%), asthenia/fatigue (58.5%), alopecia (41.5%), neutropenia (36.6%), anemia (24.4%) and stomatitis (22%). Most common grade $\geq$ 3 AEs included neutropenia (9 pts, 22%), febrile neutropenia (5 pts, 12.2%). G-CSF prophylaxis was implemented as of 09/2024. As of 12/2024 and based on 25 evaluable pts, CRR at 3 mo was 68% (17/25). **Conclusions:** This trial is the first to evaluate the combination of Sa and SG in BCG-unresponsive HR-NMIBC. With preliminary 3 mo CRR of 68%, the safety analysis identified no unexpected concerns, with severe AEs mainly involving neutropenia and febrile neutropenia. No treatment related toxic deaths occurred. Clinical trial information: 2022-002998-28. Research Sponsor: Pfizer, Gilead.

Impact of tumor burden or focality in recurrent low-grade intermediate-risk non-muscle invasive bladder cancer on response to treatment with UGN-102: A substudy of the phase 3 ENVISION trial. First Author: John Sfakianos, Department of Urology, Icahn School of Medicine at Mount Sinai, New York, NY

Background: In the ENVISION pivotal phase 3 study (NCT05243550) patients with low-grade intermediate-risk non-muscle invasive bladder cancer (LG-IR-NMIBC) were treated with UGN-102, a reverse thermal hydrogel containing mitomycin. Primary efficacy and safety results were previously reported. Complete response rate (CRR) at 3 months was 79.6%, with an 82.3% probability of remaining in response at 12 months by Kaplan–Meier estimate. Here, we present a post-hoc analysis evaluating if multifocality and tumor size influenced response rate and durability. **Methods:** In the single-arm ENVISION study, 240 patients with LG-IR-NMIBC received 6 weekly intravesical instillations of UGN-102; 3 months after the first dose, patients were examined for the presence of bladder cancer using cystoscopy, urine cytology testing, and for-cause biopsy. Patients achieving complete response (CR; no detectable disease) underwent follow-up with surveillance cystoscopy. In pre-specified subgroups, comparisons of patients with tumor burden (calculated as total length of all tumors) ≤3cm vs > 3 cm and single vs multiple tumors were performed for CRR at 3 months and hazard ratios (HRs) of duration of response (DoR) at 12 months after achieving CR. For the comparison of CRR, p values were calculated using Fisher's Exact Test. HRs of DoR were calculated using a Cox proportional hazards model, and p values calculated using a log-rank test. Comparisons were not powered to identify a difference and p values were unadjusted for multiple comparisons. **Results:** CRR at 3 months was 82.8% vs 73.2% for patients with tumor burden ≤3 cm and > 3 cm, respectively. Of patients with CR at 3 months with tumor burden ≤3 cm and > 3 cm, 15.4% vs 20%, respectively, experienced either recurrence of LG disease, progression (either stage or grade), or death by 15 months. In patients with multiple vs single tumors, 3-month CR was 79.3% vs 82.9%; recurrence rates were 18.5% vs 11.8%. DoR HRs were not statistically significant for any comparison made (Table). **Conclusions:** The CRR and DoR were favorable in all subgroups and no significant differences were observed. Study limitations were the small sample size of comparator groups, single arm design, and post-hoc nature of the analysis. UGN-102 may represent a valuable treatment option for many patients with LG-IR-NMIBC. Clinical trial information: NCT05243550. Research Sponsor: UroGen Pharma.

Duration of response (DoR) following treatment with UGN-102 in patients with recurrent, low-grade, intermediate-risk, non-muscle invasive, bladder cancer: 18-month DoR data from the phase 3 ENVISION trial. First Author: Sandip M. Prasad, Morristown Medical Center/Atlantic Health System and Garden State Urology, Morristown, NJ

Background: Low-grade, intermediate-risk non-muscle invasive bladder cancer (LG-IR-NMIBC) is a recurrent cancer inadequately controlled by the current standard of care: transurethral resection of bladder tumor (TURBT). ENVISION (NCT05243550), is an ongoing prospective, phase 3, multinational, single-arm trial, evaluating UGN-102 in patients with a history of LG-NMIBC requiring TURBT. Primary efficacy and safety results have been published previously,[1] here we report long term efficacy data with 18 months follow-up after complete response (CR) to UGN-102 at 3 months. **Methods:** Patients received6 weekly intravesical instillations of UGN-102, a reverse thermal hydrogel containing mitomycin (75 mg). 3 months after the first instillation of UGN-102, patients underwent cystoscopy, urine cytology testing, and for-cause biopsy, to determine the presence or absence of bladder cancer. Secondary endpoints included duration of response (DoR), defined as the time from CR at 3 months to the earliest date of disease recurrence, progression, or death from any cause, whichever occurred first. DoR data was calculated for all patients with a minimum follow-up of 18 months after 3-month CR was calculated using Kaplan–Meier (KM) method. **Results:** 240 patients with recurrent LG-IR-NMIBC were enrolled and received at least one dose of UGN-102; 95% (228) received all 6 doses. Patients were mainly white (98%), male (61%) and aged over 65 years old (68%). CR at 3 months was achieved by 191 patients (79.6%; 95% CI: 73.9–84.5). For these patients, the probability of remaining in response 18-months after CR was 80.6% (95% CI 74.0-85.7; KM estimate). Of those who experienced recurrence post CR, most experienced LG disease (17.3%). **Conclusions:** In the ENVISION study treatment with UGN-102 in patients with recurrent LG-IR-NMIBC resulted in a high and clinically meaningful CR rate. Patients who achieved an initial CR at 3 months had a high probability of remaining disease-free 18 months later. This data confirms that UGN-102 represents a valuable treatment option for patients with LG-IR-NMIBC. Clinical trial information: NCT05243550. Research Sponsor: UroGen Pharma. Pharmaceutical/Biotech Company.

Determinants in trimodality therapy for bladder cancer: Overcoming chemoradiotherapy resistance via ferroptosis. First Author: Takuya Tsujino, Osaka Medical and Pharmaceutical University, Takatsuki, Japan

Background: Expanding bladder preservation therapy can improve quality of life in patients with bladder cancer. This study aims to identify genetic determinants associated with trimodality therapy (TMT) for bladder preservation in bladder cancer (BC) patients and develop novel strategies to overcome chemoradiotherapy (CRT) resistance. **Methods:** Multi-omics analysis integrating RNA sequencing and whole exome sequencing (WES) was performed on clinical BC samples from 200 patients who underwent TMT in the OMPU-NCC dataset. The genomic profile of CRT-resistant BC cell lines was also analyzed. Ferroptosis signature scores were calculated using genes curated from the FerrDbV2 database. **Results:** WES revealed frequent alterations in DNA damage response (DDR) genes (Fig. 1A). Kaplan-Meier analysis showed significantly improved progression-free survival (PFS; HR 0.5840, 95% CI 0.3891-0.8765, P = 0.0157) and overall survival (OS; HR 0.5384, 95% CI 0.3331-0.8700, P = 0.0296) in patients with DDR alterations (Fig. 1B). Transcriptomic analysis identified distinct expression profiles between responders and progressors post-TMT. Gene Ontology analysis showed downregulation of immune response and lipid metabolism pathways in progressors (Fig. 2A). Analysis of the ferroptosis signature, which links these pathways, indicated that a high ferroptosis-suppressor signature score was correlated with worse survival outcomes (PFS: HR 2.713, 95% CI 1.818-4.047, $P <$ 0.0001; OS: HR 2.311, 95% CI 1.502-3.557, P = 0.0001), in contrast to the driver signature (Fig. 2B). RNA-sequencing of cell lines revealed significant differences in ferroptosis signature between parental and CRT-resistant strains (Fig. 2C). The combination of the ferroptosis inducer and irradiation overcame resistance in the T24R cell line, which is enriched with ferroptosis-suppressor genes. **Conclusions:** Key survival determinants post-CRT were highlighted, positioning ferroptosis as a target for overcoming resistance (Fig. 2D). Combining ferroptosis inducers with irradiation could offer a new therapeutic avenue for expanding bladder preservation. Survival outcomes of whole pelvic vs. bladder-only radiation in muscle-invasive bladder cancer: A nationwide large-scale study. First Author: Mohammad Arfat Ganiyani, Miami Cancer Institute, Baptist Health South Florida, Miami, FL

Background: Muscle-invasive bladder cancer (MIBC) is an aggressive malignancy traditionally managed with definitive surgery combined with systemic therapy. However, bladder-preservation approaches, including concurrent chemoradiation, offer alternatives for patients unfit for surgery. Within bladder-preservation, the choice between whole pelvic radiation (WP-RT) and bladder-only radiation (BO-RT) remains debated. WP-RT may address microscopic lymphatic disease, while BO-RT minimizes radiation toxicity. This study aims to compare survival outcomes between WP-RT and BO-RT utilizing the National Cancer Database. **Methods:** This retrospective study included patients with MIBC (T1-4a, N0-2, M0) from 2004-2020. It focused on individuals who received radiation therapy and underwent the maximum feasible local resection without definitive surgery. Kaplan-Meier analysis and a multivariate Cox proportional hazards model were used to evaluate survival outcomes based on the radiation field in patients with MIBC. **Results:** This study analyzed 18,659 patients with MIBC, including 18,092 who received BO-RT and 567 who underwent WP-RT. Among these, 71.76% received systemic therapy. Notably, the use of systemic therapy was more common in the WP-RT group (89.24%) compared to the BO-RT group (71.21%). The median overall survival was 23.33 months for patients treated with BO-RT compared to 38.7 months (Log rank P<0.001) for those who underwent WP-RT. In our adjusted analysis, patients treated with WP-RT had a 35% lower risk of death (HR: 0.65, 95% CI: 0.55–0.76, P < 0.001) compared to those receiving BO-RT, irrespective of receiving systemic therapy. Additionally, the use of concurrent chemoradiation was associated with a 50% reduction in the risk of death (HR: 0.50, 95% CI: 0.48–0.51, P < 0.001). **Conclusions:** This study found that in patients with MIBC, WP-RT was independently associated with better overall survival compared to BO-RT. These findings highlight the survival benefits of targeting microscopic lymphatic disease with WP-RT, while weighing the risks of associated toxicity. Additionally, Concurrent systemic therapy significantly reduced the risk of death, emphasizing its vital role in improving survival outcomes. Research Sponsor: None.

Assessing real-world recurrence in high-risk (HR) non-muscle-invasive bladder cancer (NMIBC) treated with bacillus Calmette-Guérin (BCG) in the United States through a recurrence algorithm: A SEER-Medicare study. First Author: Yair Lotan, Department of Urology, UT Southwestern Medical Center, Dallas, TX

Background: Assessing bladder recurrences in real-world setting can be challenging due to the lack of readily available data on recurrence in large real-world databases (e.g., SEER-Medicare), which limits the ability to evaluate the long-term real-world outcomes. To address this, this study developed an algorithm using linked SEER-Medicare data (2007–2020) to identify and classify recurrence events. **Methods:** A retrospective cohort study in patients with HR-NMIBC treated with BCG was conducted, with BCG initiation as the index date. A recurrence algorithm was developed to identify and classify recurrence events including NMIBC recurrence, muscle-invasive bladder cancer (MIBC) progression, and distant metastasis (DM). NMIBC recurrence and MIBC progression were identified based on repeat TURBT procedures occurring ≥30 days after the last BCG treatment, supplemented by cancer diagnoses in the urethra or upper tract. Subsequent treatments were used to further classify them as NMIBC recurrence (intravesical BCG after a ≥6-month gap from the last BCG, or intravesical chemotherapy) and MIBC progression (systemic therapy, radiotherapy, or cystectomy). DM was identified by urothelial cancer diagnoses outside the urinary bladder, urethra, or upper tract. Cumulative incidence rates from the index date for each recurrence type were calculated accounting for competing events, such as death and more severe types of recurrences (e.g., MIBC or DM for NMIBC recurrence). **Results:** A total of 5,490 patients (median follow-up: 2.9 years) were included. Median age at index diagnosis was 76.5 years. NMIBC recurrence was the most common type of recurrences, followed by MIBC progression and DM. The cumulative incidence rates were 15.9% for NMIBC recurrence, 4.1% for MIBC progression, and 3.7% for DM at 1 year, reaching 33.6%, 15.9%, and 16.7% at 10 years, respectively (Table). **Conclusions:** Using linked SEER-Medicare data, an algorithm was developed to identify and classify disease recurrences, facilitating long-term outcomes analyses in a large, real-world cohort. Notably, most recurrences occurred within the first 5 years from BCG initiation, after which rates plateaued. These findings underscore the importance of routine imaging for early detection and timely intervention and the need for better treatments to reduce recurrence and progression burden in this population. Research Sponsor: Merck Sharp & Dohme LLC, a subsidiary of Merck & Co., Inc., Rahway, NJ, USA.

Cumulative incidence rates by type of recurrences (N = 5,490)[1].

Recurrence type	Number of events during the follow-up period	1 year	3 years	5 years	7 years	10 years
NMIBC recurrence	1528	15.9%	28.7%	31.6%	32.6%	33.6%
MIBC progression	552	4.1%	9.3%	12.1%	14.0%	15.9%
DM	528	3.7%	8.1%	11.5%	13.5%	16.7%

[1]Patients were censored at the end of continuous eligibility or the end of data availability, whichever occurred earlier.

Correlation of circulating tumor DNA (ctDNA) dynamics with clinical response in muscle-invasive bladder cancer (MIBC) patients (pts) undergoing trimodality therapy (TMT). First Author: Ilana Bensussen Epstein, Dana-Farber Cancer Institute, Boston, MA

Background: TMT is a curative treatment option for pts with MIBC. Plasma circulating tumor DNA (ctDNA) is associated with treatment response and clinical outcomes following cystectomy for MIBC, but the association of plasma ctDNA with treatment response and clinical outcomes in pts treated with TMT is poorly understood. We hypothesize that ctDNA dynamics are correlated with clinical outcomes in pts with MIBC treated with TMT. **Methods:** Pts with MIBC who received TMT at Dana-Farber/Brigham and Women's Cancer Center or Massachusetts General Hospital, consented to a research protocol, and underwent ctDNA evaluation with the commercially available Signatera assay were included in the analysis. Individual chart review was performed to collect demographic and clinical data. **Results:** A total of 67 pts had at least one ctDNA evaluation and were included in this analysis. Cohort characteristics are summarized in Table 1. Forty-eight pts had at least one ctDNA evaluation prior to TMT, and 17 (35%) were ctDNA(+). Of the pts who were ctDNA(+) prior to TMT, 12 had at least one post-TMT ctDNA evaluation and 7 of 12 (58%) converted to ctDNA(-). Thirty-one pts were ctDNA(-) prior to TMT: 24 (77%) have had ≥1 post-TMT ctDNA evaluation and all 24 remained ctDNA(-) at the first post-TMT evaluation (median 8 weeks after TMT completion). Of the 55 pts with ≥1 post-TMT ctDNA result, 46 (84%) have remained ctDNA(-) during subsequent follow-up and do not have clinical evidence of recurrence (median number of ctDNA evaluation, 2; median follow up, 44 weeks). Nine pts had a ctDNA(+) result in the post-TMT setting: 5 were also ctDNA(+) prior to TMT, 2 did not have a pre-TMT ctDNA assessment but were ctDNA(+) at first-post TMT assessment, and 2 were ctDNA(-) before and initially after TMT but subsequently converted to ctDNA(+). Of these 9 ctDNA(+) cases, 6 pts (67%) have developed clinical evidence of metastatic disease to date with a median lead time of 5.3 weeks (range, 0-27 weeks) between first ctDNA(+) assessment and clinical evidence of metastatic disease. Overall, the sensitivity of plasma ctDNA testing in the post-TMT setting was 100% and the specificity was 94%. **Conclusions:** Most pts with MIBC treated with TMT in this cohort were ctDNA(-) following TMT and did not develop evidence of recurrent invasive or metastatic disease. Pts with ctDNA(+) status in the post-TMT setting frequently developed clinical evidence of metastatic disease. Larger cohorts with longer follow-up will be required to determine whether ctDNA status may be useful in guiding clinical decisions in MIBC pts undergoing TMT. Research Sponsor: None.

Pathologic response and safety of neoadjuvant pembrolizumab with or without entinostat in muscle-invasive urothelial cancer (MIUC). First Author: Tracy L. Rose, The University of North Carolina at Chapel Hill, Chapel Hill, NC

Background: Entinostat (Ent) is a selective histone deacetylase 1/3 inhibitor that potentiates immune checkpoint inhibitor activity in immunocompetent mouse models of urothelial cancer through immune editing of tumor neoantigens resulting in tumor immune microenvironment remodeling and associated changes in immune gene signature expression (J Clin Invest. 2021). Pembrolizumab (P), an immune checkpoint inhibitor, has demonstrated activity as neoadjuvant therapy for muscle-invasive urothelial cancer (MIUC) with the potential for combination treatment with Ent to improve outcomes. **Methods:** LCCC1827 is a window of opportunity trial of P with or without Ent in cisplatin-ineligible patients with T2-4aN0M0 MIUC prior to definitive therapy with radical cystectomy (RC) or trimodality therapy (TMT) with maximal TURBT followed by chemoradiation (NCT03978624). Patients were treated with P 200mg IV on day 1 and day 22 alone (Arm 1) or P 200mg IV on day 1 and 22 in combination with Ent 5mg po on days 1, 8, 15 (Arm 2) followed by definitive treatment within 10 weeks of day 1. The primary endpoint was change in immune gene signature expression in pre- and post-treatment tumors in Arm 2 compared to Arm 1. Here, we report clinical and secondary endpoints of pathologic response rate (pRR, < pT2N0) and pathologic complete response (pCR, pT0N0) for patients with RC, clinical complete response rate (cT0) at repeat TURBT for patients with TMT, and safety. **Results:** 20 patients (10 P; 10 P-Ent) were enrolled between 09/2020 and 10/2023 (85% male; median age 76 years; 25% black; 75% clinical T2) with all patients completing protocol-defined neoadjuvant therapy. 19 patients underwent definitive therapy (1 refused; 14 RC and 5 TMT). For RC, pRR was 43% and pCR was 29% in each arm. For TMT, cT0 was 100% in Arm 1 (n = 2) and 66% in Arm 2 (n = 3). Most common treatment-related AEs were diarrhea (20% in both arms), nausea (10% Arm 1, 30% Arm 2), and fatigue (10% Arm 1, 20% Arm 2). Grade 3 or higher treatment-related adverse events occurred in two patients (10%) (myalgias and back pain in one patient on Arm 1, hyponatremia in one patient on Arm 2). No patients had RC or TMT delayed due to treatment-related adverse events. All patients completed RC within 10 weeks of study initiation, except for 1 patient who delayed cystectomy for logistical reasons. One patient died after RC due to complications unrelated to study treatment. **Conclusions:** Neoadjuvant pembrolizumab with or without entinostat is active in MIUC with an acceptable safety profile. Analysis of the primary endpoint and other translational endpoints is ongoing. Clinical trial information: NCT03978624. Research Sponsor: Merck.

Subsequent treatments and outcomes in bacillus Calmette-Guerin–unresponsive patients with high-risk non-muscle invasive bladder cancer with carcinoma in situ: A real-world data analysis. First Author: Ariel B. Bourla, Johnson & Johnson, New Brunswick, NJ

Background: Intravesical (ives) Bacillus Calmette-Guerin (BCG) is the recommended first-line treatment (tx) option for patients (pts) with high-risk (HR) non-muscle-invasive bladder cancer (NMIBC). Despite initial activity, BCG fails in up to 50% of pts. Pts with BCG unresponsive HR NMIBC with Carcinoma in situ (CIS) are at high-risk of disease progression. Limited evidence is available about tx patterns and outcomes of these pts. The objective of this study is to characterize real-world tx patterns and assess corresponding outcomes. **Methods:** This retrospective cohort study utilized comprehensive claims augmented with electronic health records in the US HealthVerity dataset from Oct 2015 to Dec 2022. This analysis included NMIBC pts who received adequate BCG (> = 7 doses) and had a CIS recurrence within 12 months of last BCG dose. Recurrence with CIS is defined as a transurethral resection of bladder tumor (TURBT) followed by a CIS diagnosis (dx) within 30 days. Descriptive analysis to characterize subsequent tx post BCG was performed for pts with at least 1 year of follow up post-recurrence. Time to recurrence or progression (defined as a TURBT followed by a BC dx within 30 days or starting a new line of tx) was used to assess outcomes of subsequent tx using Kaplan-Meier analysis. **Results:** We identified 23,280 pts with NMIBC who were treated with BCG between 2015 and 2022. Overall, 11,116 pts (48%) received > = 7 BCG doses and 1,094 pts recurred with CIS within 12 months of last BCG dose. Among them, 486 pts (44.4%) with BCG unresponsive HR NMIBC with CIS [79% males, median age 66 years (IQR: 60, 75)] received subsequent therapy. Median time from recurrence to tx initiation was 91 days (IQR: 41, 346). The most frequently administered tx was ives chemotherapy (ctx), accounting for 45% of cases (Table 1). Among pts receiving ives ctx (n = 217), 68% experienced recurrence or progression within 12 months with a median time to recurrence or progression of 174 days [139, 196]. **Conclusions:** Although guidelines recommend radical cystectomy for BCG unresponsive HR NMIBC patients with CIS, this RWD analysis revealed that over half of these patients received no further treatment for at least 1 year after their disease recurrence or progression. Among those treated, ives ctx was the most common tx. Therefore, the majority of patients were either undertreated or received ives ctx with only modest outcomes. This highlights the need for novel, more effective bladder-sparing therapies in this pt population. Research Sponsor: None.

Subsequent line of treatment for BCG unresponsive HR NMIBC patients with CIS post BCG.

Subsequent Treatment	N =486 pts
Intravesical ctx	217 (45%)
Radical cystectomy	121 (25%)
Intravesical BCG*	66 (14%)
Interferon alpha + BCG	60 (12%)
Systemic immunotherapy	22 (4%)

*BCG treatment starting > 12 months post the last BCG dose is considered a new line of treatment.

Intravesical disitamab vedotin (RC48) for patients with HER2-expressing high-risk non-muscle-invasive bladder cancer: A dose-escalation phase I trial. First Author: Xu Chen, Sun Yat-sen Memorial Hospital, Guangzhou, China

Background: HER2 expression is associated with poor efficacy of Bacillus Calmette-Guérin (BCG) instillation in patients (pts) with high-risk non-muscle-invasive bladder cancer (HR-NMIBC). Developing effective treatment for HER2-expressing HR-NMIBC is of great urgency. Our previous study demonstrated that intravesical disitamab vedotin (DV, RC48, an anti-HER2 antibody-drug conjugate) had promising anti-tumor effects in the orthotopic BCa mouse model (Hong, X. et al., *Advanced Science*, 2023). We aimed to evaluate the safety and efficacy of intravesical DV in pts with HER2-expressing HR-NMIBC. **Methods:** Key eligibility criteria included HR-NMIBC (stage: cTa/T1±CIS, N0, M0) pts who were unsuitable for cystectomy, 18-75 years of age, HER2-expressing (IHC 1/2/3+) , BCG naive or BCG-unresponsive, and conducted transurethral resection of bladder tumor (TURBT) within 3 weeks prior to study treatment. Pts received intravesical DV (60, 120, or 180 mg) following a 3+3 design once weekly for six weeks (induction), followed by optional DV maintenance treatment once monthly until disease recurrence/progression, intolerable toxicity, or completion of nine treatments. The primary objective of this study was to assess the safety and tolerability of DV. The scheduled efficacy assessment included ultrasound and cystoscopic examination every three months. This study was registered with ClinicalTrials.gov, NCT06378242. **Results:** Between August 15, 2023 and December 1, 2024, nine pts were enrolled and completed the induction treatments at designated doses; no dose-limiting toxicities (DLTs) or any≧grade 3 treatment-related adverse events (TRAEs) occurred. The most common TRAEs included urinary tract infection (55.6%, 5/9), pollakiuria (11.1%, 1/9) and hematuria (11.1%, 1/9). All the patients underwent regular efficacy assessments, except for one patient who withdrew from the study in advance. As of December 1, 2024, after a median follow-up of 12.0 months (interquartile range [IQR]: 9.0–12.3), two pts developed recurrent disease, and no disease progression occurred. At 6 months, 8 pts were assessed for efficacy; both recurrence-free survival (RFS) and progression-free survival (PFS) were 100%. At 12 months, 6 pts were efficacy-evaluable; RFS rate was 83.3% (95% CI: 27.3, 97.5) and PFS rate was 100%. **Conclusions:** Intravesical DV was well-tolerated and showed preliminary efficacy in pts with HER2-expressing BCG-naive/unresponsive HR-NMIBC. The maximum tolerated dose was not reached, further dose exploration is ongoing in RC48-C029 study (NCT06378242). Clinical trial information: NCT06378242. Research Sponsor: None.

IL-15RαFc superagonist SHR-1501 with or without bacille Calmette Guerin (BCG) for high-risk non-muscle invasive bladder cancer (NMIBC): A phase 1/2 study. First Author: Yuke Chen, Peking University First Hospital, Beijing, China

Background: BCG is the standard therapy after transurethral resection of bladder tumor for high-risk NMIBC. IL-15 agonists can enhance the immune response induced by BCG via stimulating the proliferation and activation of natural killer cells and CD8+ cytotoxic T cells, without inducing regulatory T cells. SHR-1501 is an IL-15 agonist fusion protein, composed of a humanized antibody Fc region fused with IL-15 and IL-15Rα sushi domain. In this phase 1/2 study, we assessed the safety, tolerability, and efficacy of SHR-1501 in patients (pts) with high-risk NMIBC. **Methods:** The study comprised dose-escalation phase 1a and 1b parts of SHR-1501 alone or in combination with BCG in pts with high-risk NMIBC, followed by a phase 2 part of SHR-1501 plus BCG in multiple cohorts, including pts with BCG-naive NMIBC (cohort A), BCG-unresponsive NMIBC carcinoma in situ (CIS; cohort B), and BCG-unresponsive high-grade Ta/T1 NMIBC without CIS (cohort C). All pts received intravesical study treatment weekly for 6 weeks during induction period. During maintenance period, instillations occurred weekly for the first 3 weeks at 3, 6, 12, 18, and 24 months after the initial induction instillation. Primary endpoints were dose-limiting toxicity (DLT), maximum tolerated dose (MTD), and recommended phase 2 dose in phase 1a and 1b parts; and was complete response (CR) rate for cohort B and 12-mo disease-free survival (DFS) rate for cohorts A and C in phase 2 part. **Results:** As of Sep 7, 2024, 84 pts were enrolled (n = 8 in phase 1a; n = 6 in phase 1b; n = 29, 17, and 24 in cohorts A, B, and C in phase 2). In phase 1a part of SHR-1501 alone (200, 400, and 600 μg) and phase 1b part of SHR-1501 (600 μg) plus BCG (120 mg), no DLTs were observed, and MTD was not reached. Thus, 600 μg of SHR-1501 plus 120 mg of BCG was used in phase 2 part. Treatment-related adverse events (TRAEs) occurred in 4 (50.0%) of 8 pts with SHR-1501 and 53 (69.7%) of 76 pts with SHR-1501 + BCG. Grade 3 TRAEs were reported in 1 (12.5%) pt with SHR-1501 (urinary tract infection) and 7 (9.2%) pts with SHR-1501 + BCG (urinary tract infection and hypertension occurred in $>$ 1 pt). No grade 4 or 5 TRAEs were reported. No serious TRAEs occurred. Of the efficacy evaluable pts in cohort B, the CR rate at 3 or 6 months was 90.9% (10/11). In cohorts A and C, the 12-month DFS rate was not reached. The 9-month DFS rate was 94.4% (95% CI, 66.6-99.2) in cohort A and 53.9% (95% CI, 15.5-81.4) in cohort C. **Conclusions:** SHR-1501 alone or in combination with BCG was well-tolerable and demonstrated a favorable efficacy in BCG-naive and BCG-unresponsive high-risk NMIBC pts, supporting further investigations. Clinical trial information: NCT05410730. Research Sponsor: Jiangsu Hengrui Pharmaceuticals.

Results of BH011 after intravesical administration in patients with CIS and/or papillary non-muscle invasive bladder cancer (NMIBC) after BCG failure: Interim results from a phase I/II clinical trial. First Author: Dingwei Ye, Fudan University Cancer Hospital, Xuhui, Shanghai, China

Background: Treatment options are limited for patients (pts) with high risk NMIBC (HR NMIBC) after BCG failure. BH011 is a novel docetaxel formulation for intravesical administration that significantly increased the concentration of free docetaxel and bladder tissue permeability compared to TAXOTERE, which may result in a more efficient and effective tumor response. BH011 is administered intravesically to providing durable efficacy in high-risk NMIBC while avoiding systemic toxicities. This phase I/II study evaluates the safety, preliminary efficacy of intravesical BH011 in pts with HR NMIBC after BCG failure. **Methods:** This phase I/II study enrolled BCG failure (including refractory, recurrence, non-responsive, and intolerant) HR NMIBC pts. The papillary tumors should be removed all visible lesions by TURBT. The purpose of this study was to assess the preliminary efficacy under 17.5mg. Within 2-8 weeks after TURBT, eligible pts receive BH011 on day 1, once a week for 6 weeks during the induction treatment and once a month for 12 months during the maintenance treatment. The primary efficacy endpoint was 3 month Complete Response Rate (CRR). **Results:** To date, 25 pts have been treated with 17.5 mg of BH011, including 7 pts with CIS (±Ta/Ta) and 18 pts with papillary tumors alone (high-grade Ta or T1). All patients had been previously treated with BCG and failed. BH011 was well tolerated by all pts. All treatment-related adverse events (TRAE) were grade ≤ 2 and there were no TRAEs leading to discontinuation. Common TRAEs include urinary tract infection, glucosuria, proteinuria, urinary frequency, haematuria, cholesterol high, creatinine increased, and anaemia. A total of 24 evaluable pts were included in the efficacy analysis, which showed that pts had a CRR of 96% at 3 months and 71% at 12 months. RFS and PFS were analysed using the Kaplan-Meier method, and the 12-month RFS rate was 70%, with a median RFS of 20.21 months and a PFS rate of 100%. Six evaluable pts with CIS (±Ta/Ta) were analysed and the CRR was 100% (6/6) at 3 months and 83% (5/6) at 12 months. Analysis of the different pathology type subgroups and BCG failure type subgroups showed that the clinical efficacy of BH011 was independent of pathology type and BCG failure type (P > 0.05). **Conclusions:** Interim results show that intravesical BH011 is well tolerated and that it has strong significant and durable clinical efficacy in patients with HR NMIBC after BCG failure, particularly in pts with CIS (CRR = 100%). BH011 has the potential to have a transformative effect on the treatment landscape of NMIBC. Clinical trial information: NCT06732531. Research Sponsor: Zhuhai Beihai Biotech Co.,Ltd.

AURORA: A single arm, multicentre, phase II clinical trial of atezolizumab immunotherapy for advanced squamous cell carcinoma of the bladder and urinary tract. First Author: Simon J. Crabb, Southampton Clinical Trials Unit, University of Southampton and University Hospital Southampton NHS Foundation Trust, Southampton, United Kingdom

Background: Urinary tract squamous cell carcinoma (UTSCC) is a rare disease, comprising approximately 3% of histological subtypes from the bladder and urinary tract. Limited data exist to support treatment choices and no prospective trials, dedicated specifically to this histology, have been undertaken to evaluate immunotherapy. Prior data indicate high PD-L1 expression and tumour immune cell infiltration in a proportion of UTSCC cases. We report the Stage 1 outcome for the AURORA clinical trial, which tested atezolizumab immunotherapy for patients with incurable UTSCC. **Methods:** Patients had progressive, measurable, UTSCC and ECOG performance status 0-2. Mixed histology was permitted but with no urothelial carcinoma component. One prior line of systemic chemotherapy was permitted for advanced disease but no prior immunotherapy. Treatment comprised atezolizumab (1680 mg IV, q28d) until disease progression and for up to one year if tolerated. The primary endpoint was best overall objective response rate (ORR; RECIST v1.1) with a Simon 2 stage statistical design, and planned, independent, interim efficacy review after 19 patients were assessable for response (without a recruitment pause). If ≥4 of the first 19 patients (Stage 1) achieved an objective response (confirmed partial or complete response), then recruitment would continue through Stage 2, where ≥8 responses in 33 patients were required to indicate further investigation was warranted (p1 = 15%, p2 = 35%, 1-sided alpha = 0.1, power = 90%). Secondary endpoints included progression free survival (PFS), overall survival (OS), duration of response, safety and tolerability (CTCAEv5). **Results:** 3 of the first 19 recruited patients achieved an objective response (15.8%, 95% confidence interval (CI) 3.4 - 39.6; 3 partial and no complete responses) leading the Independent Data Monitoring Committee to recommend closure to recruitment. 3 further patients (15.8%) achieved a best response of stable disease. With a median duration of follow up of 10.1 months (95% CI 3.5 - not calculated), 17 PFS events have occurred, with a median PFS of 3.0 months (95% CI 1.4 - 3.8). 13 patients have died, with a median OS of 5.2 months (95% CI 2.7 - 8.5). Duration of objective response was 8.4 months in one patient and is ongoing in the other 2 responding patients. Adverse events were predominantly disease related. Atezolizumab was well tolerated with no new safety signals observed relating to this treatment. **Conclusions:** The objective response rate, and other efficacy endpoints, did not meet protocol defined thresholds for activity and so do not support further development of atezolizumab immunotherapy as a monotherapy for unselected patients with UTSCC. Translational endpoint analyses are ongoing. Clinical trial information: ISRCTN83474167. Research Sponsor: Cancer Research UK; CRCPJT\100018; Roche Products Ltd.

Prevalence of histology-agnostic biomarkers in pure squamous cell carcinomas of the genitourinary tract. First Author: Saad Omar Atiq, Genitourinary Malignancies Branch, CCR, NCI, NIH, Bethesda, MD

Background: Pure squamous cell carcinomas (SCC) of the genitourinary (GU) tract are less responsive to chemotherapy with limited therapeutic options for systemic disease. SCCs account for 2-8% of bladder cancer cases and treatment mirrors urothelial carcinoma despite significantly lower responses. There are 8 FDA-approved histology-agnostic treatments based on biomarker profiling: dostarlimab (dMMR/MSI-H), pembrolizumab (dMMR/MSI-H; TMB-H), larotrectinib (NTRK fusion), entrectinib (NTRK fusion), selpercatinib (RET fusion), trastuzumab deruxtecan (HER2 positive), and dabrafenib plus trametinib (BRAF V600E mutation). Data are limited on gene alterations associated with SCC of the GU tract. This study aimed to explore the prevalence of biomarkers in pure SCCs of the GU tract. **Methods:** A retrospective analysis was performed to identify bladder cancer patients with SCCs of the GU tract that underwent comprehensive molecular profiling. Cases were reviewed by a GU pathologist to confirm pure SCC, and biomarker profiling was conducted to assess prevalence of markers with available histology-agnostic treatments as well as areas of potential future exploration through clinical trials. NextGen DNA sequencing (592-gene panel or whole exome) was performed at Caris Life Sciences (Phoenix, AZ). **Results:** Of 8000 bladder cancer cases, 655 (8.2%) were coded as having components of SCC. After excluding mixed histologies, 275 (2.4%) cases were reviewed by a GU pathologist, and 169 (2.1%) cases of pure SCC of the GU tract were identified. Of these, 88 were females (51.1%) and 81 males (47.9%), with a median age of 70 (range 34-89). Of the histology-agnostic biomarkers with FDA approvals, 45 patients (27%) were TMB-H and 2 patients (1%) harbored dMMR/MSI-H status. No patients harbored *NTRK* fusions, *RET* fusions, or *BRAF* V600E mutations. HER2 IHC data were not available for cases, but *ERBB2* mutation was present in 4 patients (2%) and 1 patient (0.6%) had ERBB2 amplification. Other notable mutations included *TP53* (70%), *pTERT* (64%), *PIK3CA* (30%), *CDKN2A* (22%), *FAT1* (19%), *KDM6A* (10%), *FGFR3* (5%), and *PTEN* (5%). HRD-associated mutations included *BRCA1* (2%), *BRCA2* (4%), *ATM* (4%), *PALB2* (1%), *CHEK2* (2%), *RAD51* (1%), and *BRIP1* (1%). *AKT* mutation was present in 2% of patients. *BAP1* was mutated in 3% of patients. Six of 20 (30%) patients were P16+ by IHC. No significant difference in mutation prevalence was observed between specimens from bladder tumors and metastatic sites. **Conclusions:** This study provides a comprehensive analysis of the genetic landscape of pure SCC of the GU tract that may inform future therapeutic strategies for this rare tumor with limited treatment options. Almost one-third of patients were TMB-High, reflecting a population that may benefit from immune checkpoint inhibitors monotherapy or combination strategies. Other histology-agnostic targets for current therapies were relatively infrequent. Research Sponsor: None.

4610 **Poster Session**

Sasanlimab in combination with bacillus Calmette-Guérin (BCG) in BCG-naive, high-risk non–muscle-invasive bladder cancer (NMIBC): Patient-reported outcomes (PROs) from CREST. First Author: Jens Bedke, Department of Urology & Eva Mayr-Stihl Cancer Center, Stuttgart, Germany

Background: Sasanlimab with BCG (induction [IND] + maintenance [MNT]) significantly improved investigator-assessed EFS vs BCG (IND + MNT) and had a manageable safety profile in patients (pts) with BCG-naive, high-risk NMIBC in the phase 3 CREST study primary analysis. We report PRO data not previously presented from CREST for Arms A and C assessing the impact of sasanlimab with BCG on QOL. **Methods:** Eligible pts were randomized 1:1:1 to receive sasanlimab with BCG (IND + MNT; Arm A), sasanlimab with BCG (IND; Arm B), or BCG (IND + MNT; Arm C). PROs were secondary endpoints and not included in the testing hierarchy. PROs were assessed prior to first dose (baseline [BL]), and at scheduled visits until an event or end of treatment (every 4 wk until Wk 28, every 12 wk until Wk 100) and at disease follow-up using the EORTC QLQ-C30 and QLQ-NMIBC24. Longitudinal mixed effect-model analyses were used to assess change from BL in the EORTC QLQ-C30 and NMIBC24 items. **Results:** At data cutoff (Dec 2, 2024), 695/703 pts randomized to Arms A (n = 348) and C (n = 347) had a BL score and ≥1 post-BL score. Completion rates were > 84% for all visits through the end-of-treatment visit (Cycle 25). QLQ-C30 Global Health Score QOL scores were numerically similar between arms (mean difference: −2.345; 95% CI: −4.058, −0.632; P = 0.007). No clinically meaningful differences (≥10-point change; Osoba et al. JCO 1998) were observed across urinary symptoms (NMIBC24; mean difference: 0.851; 95% CI: −1.030 , 2.731; P = 0.375), intravesical treatment issues (NMIBC24; mean difference: 1.271; 95% CI: −0.587, 3.130; P = 0.180), and EORTC QLQ-C30 items (Table) between arms, except in a small sample for female sexual problems (NMIBC24; mean difference: 18.502; 95% CI: 6.228, 30.775; P = 0.007). Results were statistically significant but not clinically meaningful. **Conclusions:** PROs from CREST showed QOL was maintained when combining sasanlimab with BCG vs BCG (both IND + MNT). These results can help inform the benefit-risk assessment of CREST. Clinical trial information: NCT04165317. Research Sponsor: Pfizer Inc.

STARLITE-1: Phase 1b/2 study of combination ^{177}Lu girentuximab plus cabozantinib and nivolumab in treatment naive patients with advanced clear cell RCC. First Author: Eric Jonasch, Department of Genitourinary Medical Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Complete response (CR) is a rare event in advanced clear cell renal cell carcinoma (ccRCC). The combination of nivolumab plus cabozantinib was approved for first-line treatment of ccRCC based on the CheckMate 9ER phase 3 study demonstrating improved progression-free survival (PFS) and objective response rate (ORR) in comparison to sunitinib. However, CR rate was only 9%. Drugs that could synergize with T cell anti-tumor activity can improve CR rates. Radiation-induced DNA damage to activate the cGAS-STING pathway is a promising mechanism. ^{177}Lu-girentuximab is an antibody-radioisotope that targets CAIX, a cell surface glycoprotein expressed in > 95% of ccRCC. As a single agent in metastatic ccRCC, ^{177}Lu-girentuximab was safe and effective in stabilizing disease in 57% of patients. We hypothesize ^{177}Lu-girentuximab-induced DNA damage will potentiate the STING pathway, synergizing with nivolumab and cabozantinib to promote trafficking and infiltration of activated T cells and achieve higher CR rates. **Methods:** Up to 100 adults with treatment-naive, locally advanced or metastatic ccRCC, adequate organ/marrow function, and ≥1 measurable lesion by RECIST 1.1 will be enrolled. Patients will receive ^{177}Lu-girentuximab IV on day 1 of cycles 1, 4, and 7 (every 12 weeks) for up to 3 cycles. The starting dose of ^{177}Lu-girentuximab will be 1480 MBq/m^2 (61% of single agent maximum tolerated dose); subsequent doses in the same patient may be reduced to 1110 MBq/m^2 or 740 MBq/m^2 based on adverse events. Starting day 1 of cycle 2 (week 5), patients will receive nivolumab 480 mg IV every 4 weeks and cabozantinib 40 mg PO every day. All cycles are 28 days. A 5-patient safety lead-in will evaluate myelosuppression. The co-primary endpoints are safety and CR rate by RECIST 1.1. Secondary endpoints are ORR, PFS by RECIST 1.1, and overall survival. The sample size was chosen for reasonable operating characteristics to distinguish a desirable CR rate of 18% as better than the standard CR rate of 9%. To explore the effects of the treatment on inducing activated T cell infiltration, patients will undergo pre/post-treatment PET scan with ^{18}F-AraG radiotracer and biopsies will be obtained for single cell, spatial transcriptomics, and proteomics studies. Clinical trial information: NCT05663710. Research Sponsor: Telix Pharmaceuticals; DOD Kidney Cancer Research; W81XWH-22-1-0456.

TPS4612 **Poster Session**

STARLITE 2: Phase 2 study of nivolumab plus ^{177}lutetium-labeled anti–carbonic anhydrase IX (CAIX) monoclonal antibody girentuximab (^{177}Lu-girentuximab) in patients with advanced clear cell renal cell carcinoma (ccRCC). First Author: Darren R. Feldman, Memorial Sloan Kettering Cancer Center, New York, NY

Background: CAIX is a cell surface glycoprotein expressed in > 95% of ccRCC but rarely in normal tissues. Radiolabeling girentuximab, a CAIX-targeting monoclonal antibody, with ^{177}Lu has shown promise as a therapeutic agent in ccRCC. Targeted delivery of radiation to ccRCC cells may prime the immune response, providing rationale for combining ^{177}Lu-girentuximab with nivolumab. This phase 2, open-label, single arm study will evaluate ^{177}Lu-girentuximab in combination with nivolumab in patients with previously treated ccRCC. **Methods:** Eligible patients have locally advanced unresectable or metastatic ccRCC, ≥1 prior line of therapy (including ≥1 anti-PD-1 or anti-PD-L1 antibody), adequate organ function, and ≥1 evaluable lesion as defined by RECIST 1.1 on ^{89}Zr-girentuximab PET/CT. Patients will receive ^{177}Lu-girentuximab (max 3 cycles; IV on day 1 of cycles 1, 4, and 7) and nivolumab (240mg IV q2 weeks starting cycle 1 day 15) until disease progression or unacceptable toxicity. FDG-PET and CT CAP will be performed prior to cycles 1, 4, and 7, and then q12 weeks. All cycles are 28 days. Patients will be evaluated in a 24-week safety lead-in phase followed by an expansion phase. In the safety lead-in phase, the primary endpoint of maximum tolerated dose (MTD) of ^{177}Lu-girentuximab in combination with nivolumab will be determined with a 3+3 design using a starting dose of 1804 MBq/m^2 (75% of single agent MTD). Based on dose limiting toxicities (DLTs), the starting ^{177}Lu-girentuximab dose will be either escalated to 2405 MBq/m^2 (cohort 2; single agent MTD) or de-escalated to 1353 MBq/m^2 (cohort -1) for the next cohort. Due to expected cumulative myelosuppression, each subsequent ^{177}Lu-girentuximab dose given to the same patient will be reduced by 25% (dose 2 = 75% of dose 1; dose 3 = 75% of dose 2). In the expansion phase, a Simon 2-stage optimal design will be used to evaluate the primary endpoint of best objective response rate by RECIST 1.1 within 24 weeks. With ≥1 response in the first Simon stage of 10 patients (includes patients treated at MTD during safety lead-in), a second stage will open (n = 19) for a total of 29 patients. The regimen will be considered worthy of further study if there are ≥4 responses in the 29 patients. Secondary endpoints include PFS, OS, and safety. Exploratory imaging with ^{89}Zr-girentuximab PET/CT will be performed at baseline and before each ^{177}Lu-girentuximab dose with results correlated with RECIST response on conventional imaging. In addition, whole body planar and SPECT imaging will be performed after each ^{177}Lu-girentuximab dose to evaluate distribution, lesion uptake, and dosimetry. The pre-specified number of DLTs was exceeded in cohort 2 such that dosing reverted back to 1804 MBq/m^2, in which accrual is ongoing. Clinical trial information: NCT05239533. Research Sponsor: Telix Pharmaceuticals.

TPS4613 **Poster Session**

A phase 1/2 first in human study of ADI-270, an armored allogeneic anti-CD70 chimeric antigen receptor γδ T cell therapy, in relapsed or refractory (R/R) clear cell renal cell carcinoma (ccRCC). First Author: Sumanta Kumar Pal, Department of Medical Oncology, City of Hope Comprehensive Cancer Center, Duarte, CA

Background: CD70 is a type II transmembrane protein of the tumor necrosis factor superfamily normally transiently expressed in activated lymphocytes, including B, T, NK, and mature dendritic cells. CD70 is aberrantly expressed in solid and hematologic cancers and is implicated in enhanced growth, metastasis, immune evasion, and suppression. In ccRCC, CD70 expression is increased in the tumor microenvironment and on malignant cells. Despite advancements in the treatment of patients with metastatic RCC, the 5-year survival rate is 15% and there remains an unmet need. ADI-270 is an investigational, allogeneic, CD70-targeting (CD27 receptor-based) Vδ1 γδ chimeric antigen receptor (CAR) T cell product expressing a dominant negative form of the TGFβ receptor II (dnTGFβRII) to mitigate the immunosuppressive effects of TGFβ within the tumor microenvironment. γδ T cells possess innate and adaptive immunity, a natural role in immune surveillance, and the ability to home to tissues. γδ T cells are ideal for an allogeneic cell therapy as their TCR recognizes MHC-independent antigens, thereby avoiding the risk of graft versus host disease. ADI-270 has demonstrated potent preclinical activity against CD70 expressing hematological and solid tumors expressing a range of CD70 levels both in vitro and in mouse xenograft models. Furthermore, ADI-270 demonstrated superior activity against tumors expressing low levels of CD70 when compared to scFv-based αβ CAR T cell benchmarks currently in clinical development. **Methods:** ADI-202427001 (NCT06480565) is a multi-center, phase 1 / 2 open-label, dose-escalation and -expansion study evaluating ADI-270 in adult patients with R/R ccRCC. Selected inclusion criteria include confirmed diagnosis of R/R advanced/metastatic ccRCC, previous treatment with an immune checkpoint inhibitor and a VEGF inhibitor, and Karnofsky performance status ≥ 70. Selection exclusion criteria include receipt of CD70 targeting treatment and autoimmune disease requiring systemic immunosuppressive therapy. Objectives of phase 1 include characterizing the safety and tolerability of ADI-270, identifying the recommended phase 2 dose (RP2D), and assessing cellular kinetics (CK), immunogenicity, pharmacodynamics (PD), and anti-tumor activity. Objectives of phase 2 include characterizing the anti-tumor activity, safety, immunogenicity, CK, and PD profile of ADI-270 at the RP2D. The totality of data from Phase 1 will be used to determine the RP2D for the Phase 2 part of the study. Responses will be evaluated per the RECIST 1.1 criteria. Additional efficacy analyses include duration of response, progression-free survival, and overall survival. Enrollment in study ADI-202427001 is ongoing. Clinical trial information: NCT06480565. Research Sponsor: AdicetBio, Inc.

TPS4614 **Poster Session**

A phase 1b, open-label, safety, tolerability, and efficacy study of HC-7366 in combination with belzutifan in patients with advanced or metastatic renal cell carcinoma (NCT06234605). First Author: Neil J. Shah, Genitourinary Oncology, Memorial Sloan Kettering Cancer Center; Weill Cornell Medical College, New York, NY

Background: HC-7366 is a novel, highly selective and potent activator of general control nonderepressible 2 (GCN2) kinase, a core regulator of metabolic stress through activation of the integrated stress response (ISR). Prolonged or hyper-activation of GCN2 suppresses general protein synthesis and induces cell cycle arrest, ultimately leading to apoptosis. HC-7366 decreases HIF expression in tumor and immunosuppressive myeloid cells and inhibits glycolysis, oxidative phosphorylation, and TCA cycle function in tumor cells. In CDX RCC xenografts, HC-7366 combined with belzutifan (BLZ) exhibited tumor regression, and in BLZ-resistant PDX models, HC-7366 demonstrated monotherapy (mono) antitumor activity. These preclinical effects of HC-7366 suggest potential therapeutic benefit in clear cell renal cell carcinoma (ccRCC) and rationale for combinations with HIF2α antagonists. Mechanism of action studies identified biomarkers of pathway engagement which may be predictive of efficacy (Stokes, AACR 2024, Abstract 4615). HC-7366 75 mg was determined to be the maximum tolerated dose (MTD) in a previous phase 1a study in patients (pts) with solid tumors which did not include ccRCC (*data on file with sponsor*). **Methods:** This is a multicenter, open-label, phase 1b dose escalation and expansion study evaluating safety, tolerability, MTD, recommended phase 2 dose (RP2D) of HC-7366 + BLZ (combo) in pts with advanced / metastatic RCC, predominantly clear cell histology. Additionally, HC-7366 60 mg mono (up to 20 patients) is assessed in parallel. In dose escalation, HC-7366 (20, 40, 60 mg po qd) + BLZ (120 mg po qd) is evaluated using a modified Toxicity Probability Interval design in up to 20 pts. Dose expansion will evaluate two HC-7366 doses selected from escalation + BLZ (15 pts/dose level). Tumor response will be assessed by CT scans every 8 wks (RECIST v1.1). Secondary endpoints include ORR, DOR, TTR, DCR, PFS, and OS. PK data will be profiled, and exploratory objectives include pharmacodynamic marker evaluation in tumor biopsies and peripheral blood samples. Key eligibility criteria include 1-3 prior therapies for the combo cohorts (naïve to BLZ/ HIF-2α inhibitors) and 1-4 prior therapies for the mono cohort (may include BLZ/ HIF-2α inhibitors), >1 measurable lesion, and willingness to provide biopsy or archival tumor samples at two timepoints. Escalation Dose levels 1 and 2 of the combination cohorts have been cleared and enrollment is ongoing for Dose level 3 (60 mg + BLZ), Expansion Dose Level 1 (40 mg + BLZ) and the mono cohort (60 mg HC-7366) at 20 US sites. The trial is sponsored by HiberCell, Inc. in collaboration with Merck Sharp & Dohme LLC, a subsidiary of Merck & Co., Inc., Rahway, NJ, USA. Sponsor contact: Paulette Mattson pmattson@hibercell.com, 651.312.5831. Clinical trial information: NCT06234605. Research Sponsor: None.

TPS4615 **Poster Session**

Transforming kidney cancer treatment through AI-enabled functional precision medicine: The PEAR-TREE2 trial. First Author: Matthew Williams, Ourotech Ltd t/a Pear Bio, London, United Kingdom

Background: Advanced renal cell carcinoma (RCC) presents a significant clinical challenge, with limited predictive biomarkers for treatment response. Pear Bio's innovative platform utilizes 3D immune-microtumors and computer vision to predict therapeutic responses using patient-derived tumor and blood samples. This study builds upon the initial PEAR-TREE trial, aiming to validate the platform's predictive capabilities for systemic therapies, including immune checkpoint inhibitors and tyrosine kinase inhibitors, in advanced RCC. **Methods:** PEAR-TREE2 (NCT06264479) is a multicenter, observational trial conducted in the UK and US, enrolling up to 200 patients with metastatic RCC. Participants must provide fresh tumor biopsies and blood samples prior to initiation of the next line of systemic therapy. Samples are cultured in Pear Bio's platform, which uses time-lapse microscopy and AI-driven computer vision analysis to assess functional metrics including viability, cell killing, migration, culture size, immune infiltration and clustering. Predictive metrics for overall response rate (ORR) based on RECIST 1.1 criteria are the primary endpoints. Secondary objectives include predictive accuracy for progression-free survival (PFS), durable response rates, and overall survival (OS). Exploratory analyses will evaluate molecular biomarker correlations (e.g. protein expression of therapeutic target, cell subpopulation analysis, etc.) and subgroup dynamics. Statistical methods include Receiver Operating Characteristic (ROC) curve analysis and subgroup logistic regression. Patient enrollment commenced in June 2024, with interim analyses planned after 50 and 100 enrollments. Eligibility criteria include patients aged ≥18 years with advanced RCC eligible for systemic therapy. Exclusion criteria comprise early-stage RCC, patients who have commenced treatment, or non-RCC diagnoses. Additional core needle biopsies (minimum 4x 18G cores) and blood samples (40 mL) are mandatory. Recruitment is ongoing at 7 trial sites, with a target duration of 4.5 years. This novel assay could fill the gap in predictive biomarkers by enabling personalized therapy selection. By validating its patient stratification potential, the study paves the way for interventional trials, with the promise of optimizing treatment regimens and improving outcomes for kidney cancer patients. We have ongoing trials in other high-unmet-need indications including early-stage breast cancer (NCT05435352), metastatic breast cancer (NCT06182306) and gliomas (NCT06038760) hoping to revolutionize precision oncology via improved treatment selection. Clinical trial information: NCT06264479. Research Sponsor: Ourotech (t/a Pear Bio).

TPS4616 **Poster Session**

A randomized trial of radium-223 dichloride and cabozantinib in patients with advanced renal cell carcinoma (RCC) with osseous metastases (RADICAL/Alliance A031801). First Author: Chinmay Jani, University of Miami Sylvester Comprehensive Cancer Center, Miami, FL

Background: Osseous metastases (OM) occur in approximately 30% patients with advanced RCC. Despite therapeutic advances, OM are associated with poor survival and risk of symptomatic skeletal events (SSEs). Cabozantinib targets multiple tyrosine kinases, including vascular endothelial growth factor (VEGF) receptors and MET (Mesenchymal-Epithelial Transition factor), which are overexpressed in OM, contributing to cabozantinib's enhanced bone activity. Radium-223, an alpha-emitting bone-seeking radioisotope, prolongs survival in men with metastatic castration-resistant prostate cancer to the bone. Building on this therapeutic approach targeting OM, our pilot study of radium-223 with VEGF inhibition in RCC with OM has also shown safety, improvement in circulating bone turnover markers, and early efficacy (McKay et al, CCR 2018). To address the unmet need to improve SSE rates and outcomes in RCC and OM, we designed a study investigating cabozantinib with or without radium-223 in patients with RCC with OM (NCT04071223). **Methods:** This is an open-label, multicenter randomized phase-2 study. Key inclusion criteria include metastatic RCC of any histology with ≥1 OM, at least 1 OM without prior radiation, any number of prior therapies, and Karnofsky performance status ≥ 60%. Use of a bone protecting agent is required unless contraindicated. Patients are randomized 1:1 to cabozantinib with (Arm A) or without (Arm B) radium-223. The starting dose of cabozantinib for Arm A is 40 mg by mouth daily to be escalated to 60 mg daily after cycle 1 (1 cycle = 28 days) if no persistent grade 2 or grade ≥3 toxicity. Radium-223 is administered at a fixed dose of 1.49 microcurie/kg IV every 28 days x 6 doses. The starting dose for cabozantinib in Arm B is 60 mg daily. The primary endpoint is SSE-free survival. Secondary endpoints include safety, progression-free survival, overall survival, time to first SSE, objective response rate, time to subsequent anticancer therapies, quality of life (QoL) measures, and correlative analyses including liquid biopsy and tumor tissue analysis. The study is designed to have 85% power to detect an improvement in 6-month SSE-free survival rate from 65% to 78% with one-sided α = 0.05 significance. To ensure 124 evaluable patients, target accrual is 134 (67 per arm). The group-sequential design includes a safety run-in and an interim analysis for futility when 50% of the expected number of events have been observed. The safety run-in, performed in the first 12 patients randomized to combination therapy, did not demonstrate dose limiting toxicities. Final data analysis will occur when 99 events have been observed. The study was activated in July 2020 and accrual is ongoing throughout the National Clinical Trials Network (NCTN). Continued site participation and enrollment are essential to evaluate this therapeutic strategy. Clinical trial information: NCT04071223. Research Sponsor: None.

TPS4617 **Poster Session**

Clinical effectiveness of urine DNA for minimal residual disease (MRD) monitoring of urothelial carcinoma in urine: A multicenter, prospective, observational study. First Author: Xuanjun Guo, Peking University First Hospital, Beijing, China

Background: Limited methods and poor compliance are major issues in urothelial carcinoma (UC) surveillance. Non-invasive monitoring of minimal residual disease (MRD) using urine tumor DNA (utDNA) represents a significant advancement, potentially reducing reliance on invasive cystoscopy and low-sensitivity imaging. Preclinical studies have demonstrated the utDNA multidimensional bioinformatic algorithm's high sensitivity (92.8%) and specificity (96.0%) by integrating copy-number variations (CNVs) and genetic mutations, showcasing its potential to improve cancer detection accuracy. However, large prospective clinical trials validating its clinical utility in postoperative recurrence and treatment efficacy monitoring remain scarce. Clinically, UC patients with similar manifestations and pathology often show divergent outcomes. Accurately assessing recurrence risk, metastasis, and treatment efficacy is an urgent need. This study aims to validate the clinical utility for recurrence monitoring and efficacy assessment in larger cohorts. **Methods:** This multicenter, prospective, observational trial evaluates the algorithm's efficacy in MRD detection among UC patients. The trial design incorporates stratification by clinical stage, including non-muscle-invasive bladder cancer (NMIBC), muscle-invasive bladder cancer (MIBC), and upper tract UC (UTUC). We divided the study population into four cohorts: Cohort 1 includes patients with high-risk UTUC (pT3-4 or N+) who have undergone surgery; Cohort 2 consists of NMIBC patients after transurethral resection of bladder tumor (TURBT); Cohort 3 comprises MIBC patients scheduled for neoadjuvant therapy; Cohort 4 includes patients assessed as complete response (CR) after standard trimodality treatment (TMT). In each Cohort, the accuracy for recurrence monitoring is evaluated using cystoscopy $\pm$ biopsy/surgical pathology, combined with imaging (CT/MRI) as the gold standard. Morning urine samples were collected from patients who had met the eligibility criteria and volunteered to participate in the study. Next-generation sequencing (NGS) was carried out on cell-free urinary DNA (ucfDNA) and urinary exosomal DNA (uexDNA). The minimal residual disease (MRD) score was computed by the algorithm, developed based on a feature matrix incorporating genetic alterations and copy number variations (CNVs). A classification threshold of 60 was established for clinical decision-making in the context of this study. We planed to enroll a total of 400 patients in this study. The sample sizes for the four cohorts were as follows: 100 for cohort 1, 200 for cohort 2, 50 for cohort 3, and 50 for cohort 4. As of January 2025, enrollment is ongoing, with cohorts actively monitored. The study was registered under ChiCTR2400081246. Reference: DOI: 10.1186/s12943-023-01729-7. Clinical trial information: ChiCTR2400081246. Research Sponsor: Peking University First Hospital High Quality Clinical Research Specialization.

TPS4618 **Poster Session**

A phase 2, open-label, randomized study of livmoniplimab in combination with budigalimab versus chemotherapy in patients with metastatic urothelial carcinoma. First Author: Terence W. Friedlander, University of California, San Francisco Medical Center, San Francisco, CA

Background: Urothelial carcinoma (UC) has a high mortality rate in patients (pts) with metastatic disease. While immune checkpoint inhibitors (CPI), including programmed cell death protein 1 (PD-1) inhibitors combined with chemotherapy (CTx) or enfortumab vedotin (EV), have been approved for first-line treatment of metastatic (m)UC, many pts have de novo or develop acquired resistance. For pts without response to frontline treatment or whose disease has progressed on prior CPI combinations, optimal treatment is unclear and new therapies are urgently needed. Glycoprotein A repetitions predominant (GARP) is a membrane-bound receptor that complexes with latent transforming growth factor (TGF)-β1; the release of active TGF-β1 from this complex suppresses antitumor responses. Livmoniplimab (livmo), an antibody targeting the GARP:TGF-β1 complex, prevents release of active TGF-β1, thereby promoting antitumor activity. A first-in-human phase 1 study (NCT03821935) demonstrated that combining livmo and the anti–PD-1 mAb budigalimab (budi) resulted in a manageable safety profile and promising antitumor activity in pts with PD-1–refractory advanced UC (J Clin Oncol 2024;42[suppl 4]: abs 617). Herein, we describe the phase 2 study that is evaluating livmo + budi vs CTx in pts with mUC (NCT06632951). **Methods:** This multicenter, open-label, randomized study is enrolling pts aged $\geq$18 years who have mUC, measurable disease per RECIST v1.1, ECOG PS 0–1, and have experienced disease progression on anti–PD-1 or anti–PD-1 ligand 1 therapy. Platinum (Pt)-eligible pts must have received a Pt-containing regimen; pts who can receive EV must have experienced disease progression on/after receiving EV treatment. Primary objectives are to identify the recommended phase 3 livmo dose in combination with budi and evaluate overall survival. Secondary objectives include evaluating progression-free survival, best overall response of complete or partial response, duration of response, and assessment of safety and tolerability, pharmacokinetics, and immunogenicity of the combination. Pts will be randomized 1:1:1 to 3 arms: 1) livmo dose 1 Q3W + budi Q3W; 2) livmo dose 2 Q3W + budi Q3W; or 3) investigator's choice of CTx (paclitaxel, docetaxel, or gemcitabine). Pts will be stratified by ECOG PS (0 vs 1) and first-line therapy (pembrolizumab + EV vs CTx). Treatment for pts in Arms 1 and 2 will continue until a maximum of 35 cycles. For pts in Arm 3, treatment will continue for the duration that is consistent with local guidelines/practice for this pt population. No crossover between arms will be permitted. For all pts, treatment is discontinued at disease progression or if other protocol-defined discontinuation criteria are met. In total, approximately 150 pts (50 pts/arm) are planned for enrollment globally. Clinical trial information: NCT06632951. Research Sponsor: AbbVie, Inc.; n/a

TPS4619 **Poster Session**

A phase 2/3 study of bicycle toxin conjugate zelenectide pevedotin (BT8009) targeting nectin-4 in patients with locally advanced or metastatic urothelial cancer (la/mUC; Duravelo-2). First Author: Yohann Loriot, Gustave Roussy Institute, University Paris-Saclay, Villejuif, France

Background: Zelenectide pevedotin (zele; BT8009) is a Bicycle Toxin Conjugate (BTC), comprising a highly selective bicyclic peptide targeting Nectin-4 linked to the cytotoxin monomethyl auristatin E (MMAE) via a cleavable linker. Nectin-4 is an adhesion molecule commonly expressed in many tumor types, including la/mUC, and is a validated therapeutic target (Hoffman-Censits 2021). Zele has a low molecular weight and short plasma half-life, with potential to rapidly penetrate solid tumors and reduce toxicity by minimizing exposure to normal tissue (Rigby 2022). Results from the ongoing phase 1/2 clinical trial of zele (NCT04561362) indicate preliminary antitumor activity and a tolerable safety profile in patients (pts) with advanced malignancies including UC (Baldini 2023). This global, open label, phase 2/3 multicenter adaptive study aims to evaluate the safety and efficacy of zele as monotherapy, or combined with pembrolizumab (pembro), vs chemotherapy in pts with la/mUC (NCT06225596/BT8009-230; Duravelo-2). **Methods:** The trial will enroll n$\leq$956 adult pts in 2 cohorts. Cohort 1 will include n$\leq$641 previously untreated pts eligible for platinum-based chemotherapy. Cohort 2 will include n$\leq$315 pts with $\geq$1 prior systemic therapy, excluding enfortumab vedotin or other MMAE-based therapy. Pts must have la/mUC of the renal pelvis, ureter, bladder, or urethra, ECOG performance status $\leq$2 (Cohort 1) or $\leq$1 (Cohort 2), and adequate organ function. Cohort 1 will be randomized 1:1:1 to receive: 1) zele 5 mg/m^2 on days [D]1, 8, and 15 + pembro 200 mg on D1; 2) zele 6 mg/m^2 on D1 and 8 + pembro 200 mg on D1; or 3) chemotherapy (gemcitabine + cisplatin / carboplatin, followed by avelumab maintenance in appropriate patients). Cohort 2 will be randomized 1:1 to receive: 1) zele 5 mg/m^2 on D1, 8, and 15 or 2) zele 6 mg/m^2 on D1 and 8. Cycle lengths will be 21D (28D for avelumab). After 30 pts in each dose arm have 9 weeks follow up, an interim analysis will determine the optimal dose of zele + pembro (Cohort 1) or zele monotherapy (Cohort 2) to be used for the rest of the study. An additional Cohort 2 arm, optimal dose of zele + pembro, will open after completion of the interim analysis. Treatment discontinuation criteria include planned completion of therapy, progressive disease, and intolerable toxicity. Primary endpoints are progression-free survival (PFS; Cohort 1) and objective response rate (ORR; Cohort 2) assessed by blinded independent central review. Secondary endpoints are ORR (Cohort 1), PFS (Cohort 2), overall survival, duration of response, disease control rate, safety/tolerability, and health-related quality of life (Cohorts 1 and 2). Pharmacokinetics, incidence/titers of antidrug antibodies, and tumor/peripheral biomarkers are exploratory endpoints. Efficacy endpoints will be assessed per RECIST v1.1. This study is actively recruiting. Clinical trial information: NCT06225596. Research Sponsor: BicycleTx Ltd.

TPS4620 **Poster Session**

A randomized phase 2 study of the efficacy and safety of stereotactic body radiation therapy (SBRT) in patients with metastatic urothelial carcinoma and oligoprogression on maintenance therapy with avelumab (VOLGA 2). First Author: Ilya Tsimafeyeu, Bureau for Cancer Research - BUCARE, New York, NY

Background: For metastatic urothelial cancer (mUC) with multiple metastases, the standard treatment involves platinum-based chemotherapy followed by maintenance avelumab. Despite this, disease progression occurs in approximately half of patients at a median of 5.5 months, often requiring a switch to second-line therapy. The concept of oligoprogressive mUC and its optimal management remain poorly defined compared to other tumor types. The VOLGA 2 study aims to assess the preliminary efficacy and safety of SBRT in patients with mUC and oligoprogression during maintenance therapy with avelumab. **Methods:** VOLGA 2 is a randomized, prospective, multicenter phase 2 trial. Patients with histologically confirmed mUC and measurable lesions according to RECIST 1.1, undergoing avelumab maintenance therapy with extracranial oligoprogression, are randomized to receive SBRT targeting oligoprogressive lesions or to second-line therapy of the physician's choice. Oligoprogression is defined as disease progression due to the appearance of up to five new metastases or a significant increase in up to five existing lesions, with other disease sites remaining stable under ongoing systemic or local therapy. For patients in the SBRT arm, repeat SBRT to previously non-irradiated lesions is allowed and recommended if the interval between progressions exceeds four months. Patients with brain metastases and cord compression are excluded from the study. The primary endpoint is 2-year overall survival (OS) rate. Secondary endpoints include median OS and progression-free survival, overall and irradiated lesion response rates, and safety. The study will enroll 58 patients (H0 = 45%, Ha = 80%, alpha = 0.05, power = 0.8). Clinical trial information: KCRB10122024. Research Sponsor: Bureau for Cancer Research - BUCARE.

TPS4621 **Poster Session**

A phase II trial to evaluate clinical efficacy, pharmacodynamics and exploratory analysis of pemetrexed in relation to MLL4 and UTX alteration status in patients with relapsed/refractory metastatic urothelial carcinoma and other solid tumors. First Author: Carolyn Moloney, Development of Therapeutics, Robert H. Lurie Comprehensive Cancer Center, Northwestern University Feinberg School of Medicine, Chicago, IL

Background: MLL4 (encoded by KMT2D) and UTX (encoded by KDM6A) are protein components of the epigenetic chromatin modifier complex COMPASS. MLL4 alterations are found in ~10% of all cancers including ~29% of bladder cancer (BLCA). UTX alterations are found in up to ~5% of all cancers including ~29% of BLCA. These alterations have not been previously therapeutically targeted as a precision oncology strategy in humans despite their frequency. We recently published the results of a CRISPR/Cas9 knockout screen in cells lacking MLL4/UTX-COMPASS function, which revealed synthetic lethality upon loss of genes that encode enzymes involved in de novo nucleotide synthesis (dnNS) [Zhao et al. J Clin Invest. 2023; Zhao et al. PNAS. 2023]. We also reported that MLL4 truncation mutations confer an inhibitor-targetable dependence on dnNS in colorectal cancer (CRC) and BLCA. We demonstrated sensitivity to lometrexol, which targets the enzyme GART (glycinamide ribonucleotide formyltransferase), in animal models of CRC and BLCA with MLL4 truncation. Our preclinical results clearly indicated the potential for dnNS inhibition as a targeted therapy for patients stratified by MLL4 or UTX status. Pemetrexed was identified as a more clinically relevant purine synthesis inhibitor for further development due to its well-established safety profile and prior use in BLCA. **Methods:** We have initiated an investigator-initiated, open-label phase II basket clinical trial at Northwestern University (NCT06630416). Patients with advanced, treatment-refractory tumors with MLL4 (KMT2D) or UTX (KDM6A) mutations (as identified by next generation sequencing) are enrolled in 2 cohorts: a) BLCA and b) other solid tumors. Other key inclusion criteria include ECOG performance status 0-2 and adequate organ function. Prior pemetrexed use is a key exclusion criterion. Patients are treated with pemetrexed 500mg/m2 IV Q 3 weeks. We intend to enroll up to 64 patients to allow for 58 evaluable patients (29 in each cohort) to achieve the null hypothesis. We will use a Simon 2-stage design, with 10 patients enrolled in each cohort in the first stage. The null hypothesis is that the true response rate is 0.1, and the alternative hypothesis is that the true response rate is 0.3. If there are 5 or more responses among these 29 patients, we reject the null hypothesis and claim that the treatment is promising. The design controls the type I error rate at 0.05 and yields a power of 0.8. This clinical trial has accrued 1 patient as of January 28th, 2025. Correlative studies will be carried out alongside the study to assess for mechanisms of resistance to pemetrexed. Molecular analysis of ctDNA will be performed on plasma for both arms and for plasma and urine for cohort A (bladder cohort) at pre-determined time points during treatment. Clinical trial information: NCT06630416. Research Sponsor: Robert Lurie Cancer Center, Northwestern Memorial Hospital, Chicago, IL, 60611.

TPS4622 **Poster Session**

Adjuvant sacituzumab govitecan (SG) plus nivolumab (N) in patients (pts) with muscle-invasive urothelial carcinoma (UC) at high-risk for recurrence. First Author: Nataliya Mar, University of California Irvine, Irvine, CA

Background: Pts with muscle-invasive UC of the bladder or upper genitourinary tract who undergo radical cystectomy or nephroureterectomy are at high risk for cancer recurrence if residual pathologic advanced disease is identified at the time of surgery. Emerging data demonstrates that pts with minimal residual disease following curative-intent surgery, as detected by circulating tumor DNA (ctDNA), may be at a particularly high risk of UC recurrence. Adjuvant N has been approved post curative-intent surgery, with or without prior neoadjuvant chemotherapy (NAC), in pts with muscle-invasive UC at high risk of recurrence based on results of the CheckMate 274 study, which demonstrated a disease free survival (DFS) at 6 months of 74.9% with N versus 60.3% with placebo. SG is an antibody-drug conjugate with activity in UC. Evaluating intensification of adjuvant therapy in order to reduce the chance of metastasis development is of great interest. **Methods:** This is an IRB-approved, prospective, multi-center, single-arm phase 2 study of combination therapy with SG plus N. To be eligible, pts must have documented muscle-invasive UC, with variant and mixed histology allowed, except small cell. Pts must have undergone curative-intent surgery within 180 days prior to study therapy initiation and be radiographically free of metastasis. Pts who received prior NAC must have T2-T4 or node positive disease on surgical pathology, while those without NAC must have pathologic T3-T4 or node positive disease. Pts must also be ineligible or refuse platinum-based adjuvant chemotherapy. Additional selected eligibility criteria include creatinine clearance of at least 30 ml/min and adequate bone marrow function. If eligible for the study, pts will receive SG 7.5 mg/kg on day 1 and 8 combined with Nivolumab 360 mg on day 1 given every 21 days for 4 cycles, followed by single-agent Nivolumab 480 mg on day 1 given every 28 days for an additional 11 cycles. Use of growth factor support is allowed, as per institutional practice. Primary study endpoint is investigator-assessed DFS at 6 months. Secondary study endpoints include DFS, distant metastasis-free survival (MFS), overall survival (OS), incidence of grade 3 or higher adverse events, rate of ctDNA clearance in baseline ctDNA positive patients as well as exploratory biomarker analysis. The sample size calculation was based on a one-sided one sample test for exponential hazard rate when the probability of DFS at 6-months in the experimental group is 85% and in the historical control group is 75% in order to detect a hazard ratio of 0.565 with a power of 80% at a 0.05 significance level. Projected study accrual time is 24 months and per pt follow-up time is 36 months. Out of 23 anticipated pts, 3 have been enrolled to date since study activation in 11/2024. Clinical trial information: NCT06682728. Research Sponsor: None.

TPS4623 **Poster Session**

Neoadjuvant stereotactic radiotherapy and enfortumab vedotin: A phase I/II study for localized, cisplatin ineligible, muscle invasive bladder cancer (STAR-EV). First Author: Tian Zhang, Department of Internal Medicine, Division of Hematology and Oncology, UT Southwestern, Dallas, TX

Background: Patients with muscle invasive bladder cancer (MIBC) may not be candidates for cisplatin-based chemotherapy based on their comorbidities and clinical status. Based on EV-103 cohort H, patients with localized, cisplatin ineligible MIBC respond well to enfortumab vedotin (EV), with 36% pathologic complete responses (pCRs). Radiation (XRT) is also an effective therapy for MIBC, with recent retrospective data showing safety when combining XRT-EV. Therefore, we designed a trial with EV and XRT to improve pCR rates. **Methods:** STAR-EV is a single center, phase 1/2 trial open at UT Southwestern Medical Center. Patients will receive EV 1.25mg/m2 IV days 1/8 every 3 weeks for 3 cycles, with either sequential or concurrent stereotactic body XRT (SBRT) in 5 fractions. The safety lead-in phase starts with SBRT given at cycle 3 day 21 and then escalated forward to start at cycle 2 day 15 (level 1) or cycle 1 day 15 (level 2). All patients undergo radical cystectomy (RC). Dose limiting toxicities during the safety portion include non-hematologic adverse events grade 3 or higher, not completing 3 cycles of EV, delaying SBRT over 2 weeks, or delaying RC over 8 weeks. Rate of pCR is the primary endpoint for efficacy, with a goal of 60% pCR. In a Simon's two-stage design, if more than 3 pCRs are seen in the first 8 patients, 11 additional patients will be enrolled (total n = 19). The null hypothesis will be rejected if more than 10 pCRs are found. Main inclusion criteria include urothelial cancer of the bladder, cT2-4aN0M0, $>$ 50% urothelial histology, and cisplatin ineligible; main exclusion criteria include any small cell/neuroendocrine histology, prior systemic therapy for bladder cancer, prior pelvic XRT, baseline grade 2 or higher neuropathy, prior allergic reaction attributed to EV, or uncontrolled intercurrent illness. Secondary endpoints include safety of combining EV and SBRT, rate of pathologic down-staging; and exploratory objectives include quality of life, disease free survival after RC, and delay of RC $>$ 8 weeks from end of EV/SBRT. Serum and urinary biomarkers will be explored. The study is open and enrolling. Clinical trial information: NCT06394570. Research Sponsor: Astellas.

TPS4624 **Poster Session**

PUNCH03: A phase II study of disitamab vedotin combined with tislelizumab and bacillus Calmette-Guerin (BCG) in Her2-positive high-risk non-muscle-invasive bladder cancer (HR NMIBC). First Author: Zongren Wang, Department of Urology, The First Affiliated Hospital, Sun Yat-sen University, Guangzhou, China

Background: Disitamab vedotin (RC48) was a novel antibody drug conjugate that targets the Her2 protein. The KEYNOTE-057 study has supported the benefits of PD-1 inhibitor in HR NMIBC patients (pts). Our study was established to evaluate the efficacy and safety of RC48 combined with tislelizumab and BCG as a bladder-preserving treatment for Her2-positive HR NMIBC pts. **Methods:** This open-label phase II study enrolled BCG-naïve HR NMIBC pts with multiple papillary tumors (high-grade Ta or T1 tumors), and all pts were Her2-positive (IHC 2+ or 3+). Firstly, the papillary tumors should be removed all visible lesions by transurethral resection of bladder tumor (TURBT). Secondly, pts were administered RC48 (2.0 mg/kg, ivgtt), every 2 weeks for 1 cycle, and were administered tislelizumab (200 mg, ivgtt), every 3 weeks for 1 cycle. Then, pts received second TURBT, and pts were administered 3 cycles of RC48 (2.0 mg/kg, Q2W, ivgtt) and tislelizumab (200mg, Q3W, ivgtt). Finally, pts received 18 instillations of BCG plus at least 1 year of tislelizumab (200 mg, Q3W, ivgtt). Specifically, pts were started on an induction course of BCG with 6 instillations every week, followed by maintenance with 3 instillations every 2 weeks and 9 instillations every 4 weeks. The primary end point was recurrence-free survival (RFS) rate at 12 months. Secondary end points were bladder-preservation rate, OS and safety. Our study estimated a RFS rate at 12 months was no less than 85% and the study would enroll 38 pts. Clinical trial information: ChiCTR2400093839. Research Sponsor: None.

TPS4625 **Poster Session**

Updates to CORE-008: A phase 2 multi-arm, multi-cohort study to evaluate intravesical cretostimogene grenadenorepvec in patients with high-risk non-muscle invasive bladder cancer. First Author: Gary D. Steinberg, Department of Urology, Rush University, Chicago, IL

Background: Treatment for High-Risk Non-Muscle Invasive Bladder Cancer (HR NMIBC) includes Transurethral Resection of Bladder Tumor (TURBT) followed by intravesical Bacillus Calmette–Guérin (BCG). Despite high initial response rates, over 50% of patients will recur and 20-40% are at risk for progression. Treatment of HR NMIBC is challenged by the ongoing BCG shortage, thus there exists a need for clinically effective, well-tolerated, and readily available treatment options. Cretostimogene grenadenorepvec is an oncolytic immunotherapy with a dual mechanism of action. It selectively replicates in and lyses bladder cancer cells with Retinoblastoma (Rb)-E2F pathway alterations. The subsequent release of virus- and tumor-specific antigens initiate antitumor immune activation which is further amplified by the GM-CSF transgene. Cretostimogene received Fast Track and Breakthrough Therapy Designations by the US FDA for HR BCG-Unresponsive NMIBC with CIS indication. Given the strength of these data, the CORE-008 clinical trial (NCT06567743) was developed as a Phase 2, multi-arm, multi-cohort trial to further evaluate the efficacy and safety of cretostimogene in patients with HR NMIBC. **Methods:** Eligibility criteria: pathologic confirmation of HR NMIBC, both CIS containing and papillary only, as defined by the American Urologic Association guideline. Cohort A (BCG-naive) includes patients who have not received prior BCG. Cohort B (BCG-exposed) consists of patients who have received prior BCG and recurred at the initial clinical evaluation or at a delayed timepoint. Cohort CX, recently added, will evaluate safety and High-Grade Event-Free Survival (HG-EFS) of cretostimogene in combination with intravesical gemcitabine, either concurrent (Arm 1) or sequential (Arm 2) in BCG-exposed and BCG-unresponsive patients. The combination is believed to leverage complementary mechanisms and potential immune modulating synergy to enhance outcomes. Intravesical cretostimogene will be instilled with n-dodecyl-β-D-maltoside (DDM), an excipient that enhances adenoviral delivery, for six weekly doses during the induction phase, followed by three weekly maintenance cycles quarterly through month 12, then every six months through month 36. Re-induction is permitted. The primary endpoint for CIS is Complete Response (CR) at any time and HG-EFS for papillary-only disease. Secondary endpoints will include Duration of Response, all-cause Event-Free Survival, Bladder Cancer Specific Survival, Cystectomy-Free Survival, safety, and tolerability. Exploratory outcome measures include Health-Related Quality of Life, Overall Survival, and biomarker assessments. All cohorts are open for enrollment. Cohort B has received collaborative support from the Society of Urologic Oncology-Clinical Trials Consortium (SUO-CTC). Clinical trial information: NCT06567743. Research Sponsor: CG Oncology.

Sasanlimab as bladder-sparing maintenance treatment after neoadjuvant chemotherapy in patients with muscle invasive bladder cancer (MIBC): The phase 2, SASAN-SPARING trial. First Author: Elena Sevillano, HM CIOCC MADRID (Centro Integral Oncológico Clara Campal), Laboratorio de Innovación en Oncología, Instituto de Investigación Sanitaria HM Hospitales, Madrid, Spain

Background: Radical cystectomy (RC), traditionally considered the gold standard for MIBC, carries significant morbidity, negatively impacting patients' quality of life. Recent studies have demonstrated that neoadjuvant cisplatin-based chemotherapy combined with immunotherapy can induce a complete or major pathological response in a subset of patients, allowing consideration of less invasive therapeutic alternatives. High comorbidity rates in MIBC often preclude radical cystectomy. Sasanlimab, a PD-1 inhibitor, may enhance the efficacy of neoadjuvant chemotherapy, potentially enabling bladder preservation in responding patients and improving outcomes. **Methods:** The SASAN-SPARING trial is a single-arm, non-randomized, non-blinded, phase 2 trial that evaluates the efficacy and safety of sasanlimab as a maintenance treatment in patients with localized MIBC that undergo a bladder sparing strategy with neoadjuvant cisplatin-based chemotherapy. A total of 70 patients will be accrued in 10 hospitals of Spain. Patients are $\geq$ 18 years, ECOG 0-1 and treatment-naïve for MIBC candidates to receive neoadjuvant cisplatin/gemcitabine followed by RC. All patients receive 4 cycles of neoadjuvant chemotherapy with cisplatin (70 mg/m2) on day 1 every 3 weeks and gemcitabine (1000 mg/m2) on days 1 and 8 of a 3-week cycle. After neoadjuvant chemotherapy, patients are restaged and those achieving a clinical response (absence of disease by cytology, imaging, and cT0/Ta/T1/Tis) are allowed to proceed without RC and receive maintenance with sasanlimab 300 mg subcutaneous every 4 weeks for up to 12 cycles. Tumor assessments including MRI, cystoscopy and cytology are scheduled every 12 weeks. The primary endpoint is the bladder-intact overall survival (biOS) rate at 12 months after the first dose of sasanlimab. Assuming a 12-month biOS of 81% (H0) and an increase with sasanlimab up to 93% (H1), the study requires 70 patients included of which 47 are treated with sasanlimab (one arm survival test; α = 0.05 β= 0.8). The study includes an ambitious biomarker substudy to evaluate the use of ctDNA in blood and urine samples for tumor assessment and molecular dynamics under therapeutic pressure. In addition, gut microbiome and tumor samples will be used for this end. Study of biomarkers will provide a useful tool to corroborate achievement of a clinical complete response, contributing to personalized treatments. The study is approved and started with recruitment of patients in December 2024. Clinical trial information: NCT06623162. Research Sponsor: Fundación de Investigación HM Hospitales supported by a grant (#87884561) from Pfizer.

Intravesical sacituzumab tirumotecan in participants with intermediate-risk non–muscle-invasive bladder cancer: The phase 1/2 TroFuse-027 study. First Author: Joshua J. Meeks, Northwestern University Feinberg School of Medicine, Chicago, IL

Background: Standard treatment for patients with intermediate-risk (IR) non–muscle-invasive bladder cancer (NMIBC) is transurethral resection of bladder tumor (TURBT) with or without adjuvant intravesical chemotherapy or bacillus Calmette-Guérin. However, 30% to 50% of patients experience disease recurrence, which leads to repeated endoscopic resections and intravesical therapies that contribute to patient morbidity and decreased urinary quality of life. Therefore, novel therapies with favorable efficacy and safety profiles are needed. Trophoblast cell-surface antigen 2 (TROP2) is a transmembrane glycoprotein expressed broadly in several tumors, including all stages of bladder cancer, making it a viable therapeutic target. Sacituzumab tirumotecan (sac-TMT; MK-2870) is an antibody-drug conjugate consisting of a humanized anti-TROP2 monoclonal antibody, a linker, and a cytotoxic belotecan-derivative topoisomerase I inhibitor. In *in vivo* mouse models, intravesical sac-TMT demonstrated antitumor activity, tolerability, and minimal systemic exposure. TroFuse-027 (NCT06637423) is a nonrandomized, open-label, phase 1/2 study designed to evaluate the safety and efficacy of intravesical sac-TMT as ablative therapy in participants with IR NMIBC. **Methods:** Eligible participants are adults with prior history of pathologically confirmed low-grade Ta diagnosed with recurrence by visual inspection on cystoscopy who have not yet undergone TURBT and have urine cytology negative for high-grade urothelial carcinoma. In the phase 1 dose-escalation part, approximately 32 participants will be sequentially enrolled into 4 escalating sac-TMT dose groups using the Bayesian optimal interval design with a target dose-limiting toxicity rate of 30%; 3 to 14 participants are planned for each dose group. Sac-TMT will be administered by intravesical instillation weekly for 6 weeks unless there is unacceptable toxicity or withdrawal of consent. Disease assessments (per local urine cytology, cystoscopy, and biopsy as indicated for visible tumors) will occur at week 12 in all participants, then every 12 weeks for the first year and every 24 weeks thereafter for up to 2 years unless progression to high-grade NMIBC or muscle-invasive bladder cancer occurs. Participants with low-grade Ta that persists at week 12 or recurs anytime after that will undergo TURBT and remain in efficacy follow-up. The primary objectives are to evaluate safety and tolerability and to establish the recommended phase 2 dose. Secondary objectives are pharmacokinetics and complete response rate (the proportion of participants with the absence of visible tumors at the 12-week assessment after initiating treatment) and duration of complete response per local assessment. Future studies (phase 2) will be initiated on completion of dose escalation and based on the totality of data. Clinical trial information: NCT06637423. Research Sponsor: Merck Sharp & Dohme LLC, a subsidiary of Merck & Co., Inc., Rahway, NJ, USA.

TPS4628 **Poster Session**

SOGUG-NEOWIN: A phase 2, open-label, multicenter, multinational interventional trial evaluating the efficacy and safety of erdafitinib (ERDA) monotherapy and the combination of ERDA and cetrelimab (CET) as neoadjuvant treatment in cisplatin-ineligible patients with muscle-invasive bladder cancer (MIBC) harboring FGFR gene alterations. First Author: Guillermo de Velasco, Hospital 12 de Octubre, Madrid, Spain

Background: The standard treatment for nonmetastatic MIBC is neoadjuvant cisplatin-based chemotherapy followed by radical cystectomy (RC). However, many patients are ineligible for cisplatin-based therapy. Immune checkpoint inhibitors (ICIs) have transformed the treatment of metastatic urothelial cancer (mUC), particularly for cisplatin-ineligible patients. Emerging evidence suggests that ICIs may also have potential as neoadjuvant therapy in resectable urothelial cancer, with preliminary data showing antitumor activity. Erdafitinib (ERDA), an FGFR inhibitor, has demonstrated efficacy in advanced urothelial cancer with FGFR2/3 mutations or fusions. In the phase 2 NORSE trial, ERDA combined with CET showed clinically meaningful activity in newly diagnosed FGFR-altered mUC. This study evaluates whether ERDA $\pm$ CET improves the pathological complete response (pCR) rate in FGFR-positive MIBC patients eligible for RC but ineligible for or declining cisplatin-based neoadjuvant therapy. **Methods:** SOGUG-NEOWIN is a prospective, non-comparative, open-label, multicenter trial assessing 9 or 12 weeks of neoadjuvant ERDA (cohort 1) or ERDA + CET (cohort 2) in patients with MIBC (cT2–T4a N0/1 M0) and FGFR alterations. Eligibility criteria include ECOG PS 0–1; predominant urothelial carcinoma histology; cisplatin ineligibility (GFR $<$ 60 mL/min, $\geq$grade 2 hearing loss, or $\geq$grade 2 neuropathy) or refusal; fitness for RC; no prior FGFR-targeted or anti-PD-(L)1 therapy, systemic therapy, or surgery (except TURBT or biopsies); prior BCG therapy allowed if completed $\geq$6 weeks before study treatment; and no current retinopathy. A total of 45 patients per cohort will be centrally allocated. Co-primary endpoints are pCR rate and pathological downstaging response ($<$ ypT2). Secondary endpoints include event-free survival, overall survival, response rate, safety, tolerability, and delay to surgery. Exploratory endpoints include biomarkers of response and resistance (baseline tissues, blood, urine), quality of life (FACT-BI, EQ-5D-5L), and PET-MRI tumor response in a subset of patients. This trial is approved in 4 countries (6 sites in Spain, 3 in Italy, 5 in the UK, 5 in France) and is the first to systematically evaluate ERDA $\pm$ CET in FGFR-positive MIBC. The first patient was pre-screened on January 31, 2024. As of January 21, 2025, 68 patients were pre-screened, 6 were FGFR2/3-positive, and 4 were enrolled. (EU CT Number 2024-512573-27-01). Clinical trial information: 2024-512573-27-01. Research Sponsor: Johnson & Johnson.

TPS4629 **Poster Session**

The uTRACT registry: A single-arm, multicenter, prospective, and retrospective registry study to evaluate the real-world use of UGN-101 in participants with upper tract urothelial carcinoma (UTUC) in the United States. First Author: Adam Feldman, Massachusetts General Hospital, Boston, MA

Background: Upper tract urothelial carcinoma (UTUC) constitutes 5–10% of primary urothelial carcinomas, affecting two in 100,000 people in the US annually. Peak incidence occurs in patients 70–90 years of age.[1-3] Low-Grade (LG) UTUC represents 40% of the total disease burden.[3] Endoscopically-guided ablation is often used to treat LG-UTUC, however recurrence is common, and the long-term surveillance risks potential complications in this elderly patient population. UGN-101 is a reverse thermal hydrogel formulation of mitomycin approved for chemoablative treatment of LG-UTUC, administered as a liquid in a chilled state, which converts to a gel depot at body temperature, resulting in a dwell time of 4–6 hours. In the phase 3 OLYMPUS trial, 42 of the 71 LG-UTUC patients treated with UGN-101 achieved complete response (CR) at 3 months.[4] Among the 41 patients followed after CR, median follow-up was 28.1 months (95% CI, 13.1-57.5), and median duration of response (DoR) was 47.8 months (95% CI, 13.0-not estimable).[5] **Methods:** The uTRACT registry (NCT05874921) is evaluating real-world data from patients administered UGN-101, post-FDA approval(15 Apr 2020). Approximately 400 patients >18 years old with UTUC who received ≥1 dose of UGN-101 will be enrolled at ~20 sites. Retrospective data will be collected from patients that received UGN-101 after approval as well as prospective data from newly eligible patients. UGN-101 is administered as 6 once weekly pyelocalyceal instillations retrograde via ureteral catheter or antegrade via a nephrostomy tube. Instillation volume is based on volumetric measurements, not to exceed 15 mL (60 mg of mitomycin). For participants with a CR 3 months after the first dose, once monthly maintenance instillations may be administered (up to 11 additional doses). Participant history and disease status are collected at baseline (prior to UGN-101 dosing), and dosing information, surveillance endoscopy and imaging results will be captured over a period of 3 years post baseline, at approximately 3, 6, 12, 24, and 36 months after the first instillation. Assessment of response will be based on endoscopic surveillance, imaging, cytology, and/or for-cause biopsy. Data analysis will be performed on the overall cohort (~400 participants) and the LG-UTUC cohort (expected to be ~340 participants). Outcomes collected include no evidence of disease at 3-months, DoR, recurrence free survival, time to recurrence/progression and adverse events. The uTRACT registry started enrollment in 2023 with 228 patients recruited to date. 1. Siegel RL, et al. CA Cancer J Clin. 2022;72:7-33. 2. Rouprêt M, et al. Eur Urol. 2023;84:49-64. 3. TPS4630 **Poster Session**

ABLE-22: Safety and efficacy evaluation of nadofaragene firadenovec alone or in combination with chemotherapy or immunotherapy—A randomized, open-label, phase 2 study. First Author: Siamak Daneshmand, Keck School of Medicine of USC, Los Angeles, CA

Background: Bacillus Calmette-Guérin (BCG) is the standard first-line therapy for patients with high-risk non–muscle-invasive bladder cancer (NMIBC) with carcinoma in situ (CIS) ± papillary tumors; however, patients whose disease is unresponsive to BCG therapy are unlikely to benefit from further courses of BCG. Bladder-preserving treatment options for patients with BCG-unresponsive NMIBC with CIS ± Ta/T1 include intravesical gene therapy (nadofaragene firadenovec-vncg), intravesical chemotherapy (gemcitabine and docetaxel), and immunotherapy (intravenous pembrolizumab and intravesical nogapendekin alfa inbakicept-pmln). In a pivotal phase 3 study, 53.4% of participants (55/103) with BCG-unresponsive NMIBC with CIS ± Ta/T1 achieved a complete response (CR) within 3 months of a single instillation of nadofaragene firadenovec, and of them, 45.5% (25/55) maintained a CR at 12 months. Nadofaragene firadenovec in combination with chemotherapy or immunotherapy may further improve clinical efficacy. ABLE-22 (NCT06545955) is an interventional study evaluating the safety and efficacy of nadofaragene firadenovec alone or in combination with chemotherapy (gemcitabine and docetaxel) or immunotherapy (pembrolizumab) in participants with high-risk BCG-unresponsive NMIBC. Participants not responding at month 3 will be offered reinduction. **Methods:** ABLE-22 will include approximately 40 to 75 sites across the United States and Canada; sites in Asia, Australia, and Europe may be included. Participants (anticipated N = 150) will be randomly assigned 1:1:1 to receive nadofaragene firadenovec (n = 50), nadofaragene firadenovec plus gemcitabine and docetaxel (n = 50), or nadofaragene firadenovec plus pembrolizumab (n = 50). Adults aged ≥18 years with documented NMIBC with CIS ± Ta/T1 that is unresponsive to ≥2 courses of BCG therapy within the last 12 months are eligible to enroll. The primary endpoint is CR (defined as absence of low- and high-grade NMIBC) at months 3 or 6, as participants with persistent NMIBC (any CIS, low-grade Ta, and > 3 cm or multifocal high-grade Ta) will be offered reinduction once, at month 3. Secondary endpoints include durability of CR, incidence of muscle-invasive progression, cystectomy-free survival, pathologic staging, overall survival, and safety. Durability of CR will be followed up to month 36 (assessed quarterly for the first 24 months); all other secondary endpoints will be assessed up to and including month 36. Exploratory endpoints include changes in expression of potential biomarkers in blood and urine. Results from this investigational, randomized, multicenter, open-label study evaluating the safety and efficacy of nadofaragene firadenovec alone or in combination with chemotherapy or immunotherapy are expected July 2028. Clinical trial information: NCT06545955. Research Sponsor: Ferring Pharmaceuticals, Inc.

TPS4631 **Poster Session**

LEGEND: A phase 1/2 study of detalimogene voraplasmid (EG-70), an intravesical monotherapy for patients with high-risk non–muscle-invasive bladder cancer (NMIBC). First Author: Jen-Jane Liu, Oregon Health & Science University, Portland, OR

Background: High-risk NMIBC is generally treated with adjuvant intravesical Bacille Calmette-Guérin (BCG). However, ~50% of patients experience recurrence and/or progression afterwards and are considered unresponsive. Detalimogene voraplasmid (EG-70) is an investigational, non-viral, non-integrating, intravesically administered gene therapy designed to elicit local stimulation of anti-tumor immune responses in the bladder and drive durable efficacy in NMIBC, while mitigating the risk of systemic toxicities from immune stimulation. The Phase 1 (dose-escalation) portion of the first-in-human Phase 1/2, open-label, multicenter study (LEGEND; NCT04752722) of detalimogene voraplasmid is complete. The Phase 2 dose was identified, treatment was generally well tolerated, with an overall complete response (CR) rate of 73% [Kalota S, et al. AUA 2024]. Herein, we describe the ongoing Phase 2 portion of the study, which opened to enrollment in May 2023, which recently added a new cohort of BCG-unresponsive HG Ta/T1 papillary only (no carcinoma *in situ* [CIS]) disease. **Methods:** Eligibility criteria: age ≥18 years; ECOG PS 0−2; NMIBC, with/without resected coexisting papillary tumors, ineligible for, or elected not to undergo, cystectomy; satisfactory bladder function. Patients receive detalimogene voraplasmid 0.8 mg/mL in 50 mL (intravesical administration, Weeks 1, 2, 5 & 6, 12-week cycle) for 4 cycles, and patients with CR at the end of the 4th cycle will enter maintenance treatment to receive 2 instillations per cycle (at Weeks 1 and 2) for up to another 8 cycles: BCG-unresponsive with CIS (Cohort 1); BCG-naïve with CIS (Cohort 2A) or BCG-exposed with CIS (Cohort 2B); BCG-unresponsive NMIBC with high-grade papillary disease without CIS (Cohort 3). Phase 2 primary endpoints: efficacy (CR rate at Week 48); safety. Secondary endpoints: progression-free survival; CR rate at Weeks 12, 24, 36, and 48; duration of response. The study is being conducted in accordance with the ethical principles of the Declaration of Helsinki and is consistent with ICH/GCP. All patients provide written informed consent. The Phase 2 portion of the study is enrolling and will recruit approximately 300 patients across all cohorts, from sites in the USA, Canada, Europe, and the Asia-Pacific region. Clinical trial information: NCT04752722. Research Sponsor: enGene Inc.

TPS4632 **Poster Session**

ABLE-32: A randomized, controlled, phase 3b clinical trial of nadofaragene firadenovec-vncg versus observation in patients with intermediate-risk non–muscle-invasive bladder cancer. First Author: Neal D. Shore, Carolina Urologic Research Center, Myrtle Beach, SC

Background: There is currently no Food and Drug Administration (FDA)-approved treatment for intermediate-risk non–muscle-invasive bladder cancer (IR NMIBC), defined as recurrence of low-grade (LG) Ta within 1 year, solitary LG Ta > 3 cm, multifocal LG Ta, high-grade (HG) Ta (≤3 cm), and/or LG T1. Nadofaragene firadenovec-vncg is the first FDA-approved intravesical nonreplicating gene therapy for treating high-risk BCG-unresponsive NMIBC with carcinoma in situ (CIS) ± papillary tumors. In a non-randomized, multicenter, open-label, repeat-dose, phase 3 study, 53.4% of participants (55/103) with CIS ± HG Ta/T1 achieved complete response 3 months after the first instillation. Nadofaragene firadenovec was well tolerated, with no grade 4/5 study drug-related AEs. Because maintenance treatment with nadofaragene firadenovec following tumor resection may improve clinical outcomes in patients with IR NMIBC, the ABLE-32 open-label randomized study is being conducted to evaluate the efficacy of nadofaragene firadenovec administered every 3 months versus observation in participants with IR NMIBC. **Methods:** This phase 3 study includes approximately 100 global sites with 454 anticipated participants. Adults aged ≥18 years, diagnosed with new or recurrent IR NMIBC, and having undergone transurethral resection of bladder tumor within 60 days prior to randomization are eligible. Participants will be randomly assigned 1:1 to receive nadofaragene firadenovec or continue observation. The nadofaragene firadenovec group will receive quarterly doses unless disease recurs or progresses. The observation group will be followed quarterly and may receive nadofaragene firadenovec if IR NMIBC recurs within 24 months. All participants will be evaluated for recurrence and progression using cytology, cystoscopy, and for-cause biopsy for up to 5 years. The primary endpoint is recurrence-free survival (RFS), from randomization to first documented recurrence, progression, or death. Secondary endpoints include RFS at 12 and 24 months and safety. Exploratory endpoints include effect on potential biomarkers and health-related quality of life. Final results are expected in 2031. Clinical trial information: NCT06510374. Research Sponsor: Ferring Pharmaceuticals.

5000 Oral Abstract Session

Phase 3, randomized, placebo-controlled clinical trial of CAN-2409+prodrug in combination with standard of care external beam radiation (EBRT) for newly diagnosed localized prostate cancer. First Author: Theodore L. DeWeese, Johns Hopkins University School of Medicine, Baltimore, MD

Background: Standard of care (SoC) for intermediate to high-risk localized prostate cancer (PrCa) includes surgery or external beam radiation (EBRT) +/- androgen deprivation therapy (ADT). Nearly 30% of men undergoing EBRT will experience recurrence requiring ADT and salvage therapies that negatively impact quality of life. CAN-2409 is a replication-defective adenovirus encoding the HSV-tk gene that, when combined with valacyclovir (prodrug), results in immunogenic cell death. This results in immunization against tumor antigens and long-term tumor control. **Methods:** We conducted a phase 3, multicenter, double-blinded, randomized, placebo (PBO)-controlled clinical trial in PrCa patients (pts) planning to receive EBRT+/- short course ADT (<6 mos); NCT01436968. 745 pts were randomized 2:1 (496 in CAN-2409+prodrug and 249 in PBO+prodrug) and stratified by NCCN risk group and ADT use. Three intraprostatic injections of CAN-2409 (5x10 ^{11}v/2mL) or PBO were administered, each followed by 14 days of prodrug. Follow-up included a prostate biopsy 2 years after EBRT. Primary endpoint was disease-free survival (DFS), defined as time from randomization to PrCa recurrence (local/regional failure or distant metastasis) or death in the intent-to-treat population. Median follow up time was 50.3 mos. The study was conducted under a special protocol assessment (SPA) granted by the FDA. **Results:** Treatment with CAN-2409 reduced the risk of PrCa recurrence or death by 30% (median DFS not reached vs 86.1 mos, p=0.0155, HR 0.7, 95% CI 0.52 to 0.94). PrCa-specific DFS (exclusion of non PrCa- related deaths) demonstrated an even greater effect with a 38% decreased risk in the CAN-2409 arm vs. PBO (p=0.0046; HR 0.62, 95% CI 0.44 to 0.87). Statistically significant secondary endpoints included increased percentage of patients achieving prostate-specific antigen nadir (67.1% vs 58.6%, p=0.0164) and an increase in pathological complete responses in the 2-year biopsies in the CAN-2409 arm vs. PBO (80.4% vs. 63.6%, p=0.0015). Most common treatment-related adverse events included chills (33.4% vs. 8.6%), flu-like symptoms (30.5% vs. 13.8%), and fever (25.1% vs. 3.9%), mostly Gr 1-2 and self-limited. Serious adverse events (SAEs, 5.8% vs. 7.3%) and treatment-related SAEs (1.7% vs. 2.2%) were uncommon across treatment groups. **Conclusions:** In this randomized, double-blind, Phase 3 trial, CAN-2409 significantly reduced the risk of PrCa recurrence or death when added to SoC EBRT+/- ADT. The addition of CAN-2409 was not associated with significant added toxicity. These data represent the first potentially new therapy for patients with intermediate and high risk PrCa in over 20 years. Clinical trial information: NCT01436968. Research Sponsor: Candel Therapeutics, Inc.; National Cancer Institute.

5001 Oral Abstract Session

Multimodal artificial intelligence (MMAI) model to identify benefit from 2nd-generation androgen receptor pathway inhibitors (ARPI) in high-risk non-metastatic prostate cancer patients from STAMPEDE. First Author: Charles Thomas Andrew Parker, University College London Cancer Institute, London, United Kingdom

Background: The STAMPEDE trials showed that adding abiraterone acetate + prednisolone (AAP) ± enzalutamide (ENZ) to standard of care androgen deprivation therapy (SOC) improves metastasis-free survival (MFS) in high-risk non-metastatic (M0) prostate cancer (PCa) patients (pts). However, variable responses & adverse events underscore the need for prognostic & predictive biomarkers. We evaluated performance of a validated MMAI algorithm (ArteraAI Prostate Test v1.2) to identify pts who benefit most from the addition of AAP ± ENZ (ARPI). **Methods:** High-risk M0 STAMPEDE pts treated with SOC+ARPI (N=555) or SOC (N=781) with sufficient quality H&E biopsy images & clinical data (T stage, age, PSA) were included. MMAI score association with PCa specific mortality (PCSM, primary outcome measure) & distant metastasis (DM) was analyzed using Fine-Gray regression & cumulative incidence curves, with other cause mortality treated as competing risks. MFS was assessed using Cox regression & Kaplan-Meier curves. An optimal cut-point was identified via grid search to maximize ARPI benefit separation across biomarker positive (pos, MMAI in top quartile) & negative (neg) subgroups. Hazard ratios [95% CI] & p values are reported. **Results:** PCSM median follow-up was 6.0 years (N=1336). Continuous MMAI scores were statistically significantly associated with poorer PCSM (1.65 [1.43-1.90], p<0.001), MFS (1.42 [1.29-1.56], p<0.001) & DM (1.54 [1.36-1.74], p<0.001). Using clinically-established prognostic cut-offs, 89% of pts were MMAI high-risk. The optimal ARPI MMAI cut-point identified 334 biomarker-pos pts who had significantly higher PCSM than biomarker-neg pts. A statistically significant biomarker-treatment interaction for PCSM (p-int=0.04) revealed that biomarker-pos pts treated with ARPI had improved PCSM (0.42 [0.24-0.74], p=0.003), while biomarker-neg pts did not derive a treatment benefit (0.85 [0.56-1.29], p=0.45). Estimated 5-year PCSM was 9% for biomarker-pos pts receiving ARPI vs. 17% with SOC, compared to 4% & 7% for biomarker-neg pts, respectively, with similar results observed in M0N0 pts (Table 1). **Conclusions:** For the first time, we demonstrate that a validated MMAI algorithm can identify high-risk non-metastatic PCa pts most likely to benefit from the addition of ARPI. Notably we identify a positive biomarker-treatment interaction in the highest MMAI score quartile, which in cases of clinical equipoise could inform clinical decision-making. We highlight MMAI's potential to optimize treatment decisions & spare biomarker-neg pts from unnecessary therapy & toxicities. Clinical trial information: NCT00268476. Research Sponsor: Prostate Cancer Foundation; Artera, Inc.; John Black Charitable Foundation; UK Medical Research Council; Prostate Cancer UK; Cancer Research UK; Sanofi Aventis; Janssen; Astellas; Novartis.

Estimated 5-yr absolute risk reduction from ARPI vs SOC-treated patients by biomarker groups in M0 (M0N0) pts.

	Biomarker-neg	Biomarker-pos
PCSM	3% (1%)	8% (9%)
MFS	2% (-1%)	17% (16%)
DM	5% (3%)	12% (15%)

5002 Oral Abstract Session

Prognostic significance of PSA>0.2 after 6-12 months treatment for metastatic hormone-sensitive prostate cancer (mHSPC) intensified by androgen-receptor pathway inhibitors (ARPI): A multinational real-world analysis of the IRONMAN registry. First Author: Michael Ong, The Ottawa Hospital Cancer Centre, Ottawa, ON, Canada

Background: Phase III post-hoc analyses show poor prognosis of PSA >0.2 in mHSPC treated by androgen deprivation therapy (ADT) and ARPI, but it remains unclear 1) when PSA cutoffs should be interpreted for prognostic significance, and 2) how PSA cutoffs may differ in real-world multinational data. IRONMAN (International Registry for Men with Advanced Prostate Cancer) prospectively enrolled mHSPC patients from 16 countries and is a unique large data set to investigate these questions. **Methods:** Patients with mHSPC who received ADT, ARPI +/- docetaxel with PSA data enrolled in the IRONMAN registry were included. 3 PSA strata (>0.2, 0.02 to 0.2, and <0.02ng/ml) were defined at 6- and 12-months (primary analysis) after treatment start. Multivariable Cox proportional hazard regression models were constructed for overall survival (OS) and progression-free survival (PFS, as defined by any of biochemical, radiographic or clinically progression) with adjustment for disease characteristics. A 12-month landmark population was constructed to determine conditional OS and PFS in each PSA stratum. **Results:** 1288 patients received ADT and ARPI within 90 days of IRONMAN enrolment and met inclusion. Key characteristics were median age 70 years, 69.5% de-novo metastatic, 59% Gleason 8-10, 73% Caucasian, 8.2% Black, 1.5% Asian, 7.3% lung metastases, 3.4% liver metastases, and 53.2% enrolment from centers outside US/Canada. Intensification agents were: abiraterone acetate (576, 44.7%), apalutamide (283, 22.0%), darolutamide (135, 10.5%), or enzalutamide (294, 22.8%), and 122 (8.7%) received docetaxel in addition to ADT-ARPI. PSA at 6, 12 month landmarks respectively were: <0.02 (10%, 21%); 0.02-0.2 (41%, 45%); >0.2 (49%, 34%), with 70% of patients with 6-month PSA >0.2 retained at 12-months. Outcome data in the 12-month landmark cohort are detailed in Table 1, with 3-year OS for the PSA >0.2 stratum significantly worse than the PSA<0.02 stratum (45.3 vs 92.7%, p<0.001), representing a 7-fold mortality risk in the Cox model adjusted hazard ratio (aHR) and 8-fold risk of progression. **Conclusions:** IRONMAN provides large real-world data validating the poor prognosis of mHSPC with PSA>0.2 after 6-12 months ADT-ARPI treatment and these patients could be targeted for intensification in future trials. Conversely, PSA<0.02 at 6-12 months defines the best prognosis and may be of interest for de-intensification strategies. Research Sponsor: Movember Foundation; Amgen, Astellas, AstraZeneca, Bayer, Janssen, Merck, Novartis and Sanofi.

OS and PFS outcomes by 12-month PSA strata.

12-mo PSA (ng/ml)	n	3-yr OS [95%CI]	3-yr PFS [95% CI]	OS Cox model mortality risk [95% CI]
>0.2	264	45.3% [36.7-55.9]	36.7% [28.6-47.1]	aHR 7.34 [3.66-14.71]
0.02-0.2	585	80.0% [74.5-85.9]	72.9% [66.9-79.1]	aHR 2.16 [1.06-4.41]

5003 Oral Abstract Session

Transcriptome classification of PTEN inactivation to predict survival benefit from docetaxel at start of androgen deprivation therapy (ADT) for metastatic prostate cancer (PC): An ancillary study of the STAMPEDE trials. First Author: Emily Grist, University College London Cancer Institute, London, United Kingdom

Background: Docetaxel (Doce) is effective for metastatic (M1) PC but its effect is varied. Combining Doce and hormone therapy can improve overall survival (OS) but is not appropriate for all. We previously reported the mRNA Decipher test predicts benefit from Doce. We then used transcriptome-wide data to interrogate differential associations with outcome for biologically-relevant pathways. **Methods:** PTEN inactivation using a previously described signature (Liu et al JCI, 2021; active score <= 0.3, inactive: score > 0.3) and Decipher score (high > 0.8, lower <= 0.8) was determined from transcriptome-wide expression data generated in a clinically-accredited lab on prostate tumor from M1 patients (pts) randomized 1:1 to ADT vs ADT + Doce +/- zoledronic acid (ZA) or ADT vs ADT + Abi (abiraterone acetate + prednisone) in the STAMPEDE protocol (Oct 2005-Jan 2014). Cox survival models were fitted with an interaction between treatment allocation and PTEN activity, adjusted for age, WHO PS, pre-ADT PSA, Gleason score, T-stage, N stage (N0, N1), metastatic volume (CHAARTED definition, high [HV] or low [LV]). Hypotheses were tested using partial likelihood ratios. Primary endpoint was OS. **Results:** We generated transcriptome-wide profiles on 832 M1 pts with no notable differences from the full M1 trial cohort (N=2224). 657 (79%) were reported to have died. 50% of tumors were classified as PTEN inactive (N=419). PTEN mRNA score distribution was similar across HV and LV disease (p=0.310). PTEN inactivity associated with shorter OS in pts allocated ADT+Abi (N=182; HR=1.56, 95%CI: 1.06-2.31) but not in pts allocated ADT+Doce+/-ZA (N=279; HR=0.93, 95%CI: 0.70-1.24). We found strong evidence (p=0.002) of an interaction between PTEN inactivation and Doce sensitivity: PTEN inactive pts benefited from Doce (HR=0.57, 95% CI 0.42-0.76) unlike PTEN active pts (HR=1.05, 95% CI 0.77-1.43). This was consistent in LV (N=244; PTEN inactive HR=0.53, 95% CI 0.33-0.86; PTEN active HR=0.82, 95% CI 0.48-1.40) and HV (N=295; PTEN inactive, HR=0.59, 95% CI 0.39-0.88; PTEN active HR=1.23, 95% CI: 0.83-1.81). In pts randomized to Abi, treatment effect was uniform (PTEN inactive HR=0.52, 95% CI 0.36-0.73; PTEN active HR=0.55, 95% CI 0.39-0.77; p=0.784). We estimated adding Doce for tumors classified as PTEN inactive and high Decipher reduced the hazards of death by 45% (HR 0.55, 99% CI 0.34-0.89). **Conclusions:** Prostate tumors classified as high Decipher and PTEN inactive have a 45% reduction in hazard of death when Doce is added to ADT. This biomarker should be tested in pts considered for triplet therapy of ADT + Abi + Doce. 5004 **Oral Abstract Session**

Health-related quality of life (HRQoL) outcomes with darolutamide in the phase 3 ARANOTE trial. First Author: Alicia K. Morgans, Dana-Farber Cancer Institute, Boston, MA

Background: Effective and well tolerated treatments to maintain HRQoL are essential for patients with metastatic hormone-sensitive prostate cancer (mHSPC). Darolutamide (DARO) + androgen deprivation therapy (ADT) significantly reduced the risk of radiological progression or death (primary endpoint) by 46% (hazard ratio [HR] 0.54; 95% confidence interval [CI] 0.41–0.71; $P<0.0001$) vs placebo (PBO) + ADT in ARANOTE (NCT04736199). The incidence of adverse events (AEs) was low and similar to PBO, with fewer study drug discontinuations due to AEs in the DARO vs PBO group (6.1% vs 9.0%). We report HRQoL and pain outcomes in ARANOTE. **Methods:** Patients were randomized 2:1 to DARO 600 mg twice daily or PBO, with ADT. HRQoL was measured using the Functional Assessment of Cancer Therapy–Prostate (FACT-P). Deterioration in FACT-P total score by $\geq$10 points was a prespecified exploratory endpoint; deteriorations in FACT-P subscales by $\geq$3 points were analyzed *post hoc*. Pain was assessed using the Brief Pain Inventory–Short Form (BPI-SF), including the pain severity and pain interference subscales. Pain progression (secondary endpoint) was defined as an increase of $\geq$2 points in BPI-SF worst pain score (WPS) from nadir observed at 2 consecutive evaluations $\geq$4 weeks apart or initiation of opioid use for $\geq$7 consecutive days. Association of HRQoL and pain progression with prostate-specific antigen (PSA) response was assessed *post hoc*. HRs and 95% CIs were calculated using a Cox regression model, stratified by visceral disease (present vs absent) and prior local therapy (yes vs no) for FACT-P total score and pain progression, unstratified for FACT-P and BPI-SF subscales and association with PSA. **Results:** DARO extended time to deterioration in FACT-P total score (overall well-being) by 5.1 months vs PBO: median 16.6 vs 11.5 months; HR 0.76, 95% CI 0.61–0.93. The treatment benefit of DARO in FACT-P total score was strongly driven by longer time to deterioration in the subscales of social/family well-being (HR 0.79, 95% CI 0.64–0.98), functional well-being (0.78, 0.63–0.96), and urinary symptoms (0.78, 0.61–0.99). Additionally, DARO extended time to pain progression vs PBO: HR 0.72, 95% CI 0.54–0.96. In patients treated with DARO, achievement of PSA response $<$0.2 ng/mL at any time was associated with longer time to deterioration in FACT-P total score and longer time to pain progression vs detectable PSA response ($\geq$0.2 ng/mL) at any time. **Conclusions:** To our knowledge, DARO is the first and only androgen receptor inhibitor to demonstrate clinically meaningful delays in deterioration of important patient-relevant HRQoL outcomes vs PBO in men with mHSPC. Patients treated with DARO had improvements in overall well-being (FACT-P total score), social/family well-being, functional well-being, urinary symptoms, and pain. Combined with the efficacy and safety profile, these findings suggest that DARO also confers a positive impact on HRQoL. Clinical trial information: NCT04736199. Research Sponsor: Bayer and Orion Pharma.

5005 **Oral Abstract Session**

ARCHES: 5-year follow-up overall survival (OS) analysis of enzalutamide (ENZA) plus androgen-deprivation therapy (ADT) in patients (pts) with metastatic hormone-sensitive prostate cancer (mHSPC). First Author: Andrew J. Armstrong, Duke Cancer Institute Center for Prostate and Urologic Cancers, Duke University School of Medicine, Durham, NC

Background: In 2021, final prespecified OS (key secondary endpoint; defined as time from randomization to death from any cause) analysis of the global phase 3, randomized, double-blind, placebo (PBO)-controlled ARCHES trial (NCT02677896) demonstrated that ENZA + ADT significantly reduced risk of death by 34% versus PBO + ADT in pts with mHSPC (medians not reached [NR]; hazard ratio [HR] 0.66; 95% confidence interval [CI]: 0.53–0.81; $p<0.0001$; median follow-up, 44.6 months). To assess long-term efficacy of ENZA + ADT, we report an updated OS analysis as of July 31, 2024 (median follow-up, 61.4 months). **Methods:** In ARCHES, 1150 enrolled pts with mHSPC were randomized 1:1 to ENZA (160 mg once daily) + ADT or PBO + ADT. After primary analysis of radiographic progression-free survival (primary endpoint), ARCHES was unblinded to allow eligible patients who were randomized to PBO + ADT to cross over to ENZA + ADT in an open-label extension. Using extended follow-up data with median follow-up $>$5 years (cut-off date: July 31, 2024), Kaplan–Meier method was used to summarize the OS endpoint by treatment, with two-sided 95% CIs calculated by the Brookmeyer–Crowley method. HRs relative to PBO + ADT were determined using Cox regression model stratified for prior docetaxel use and disease volume. **Results:** ENZA + ADT (n=574; median [range] age = 70.0 [46–92] years) and PBO + ADT (n=576; median [range] age = 70.0 [42–92] years) cohorts had similar baseline characteristics. 184 (31.9%) PBO + ADT pts crossed over to open-label ENZA + ADT (median [range] age = 69.0 [51–89] years). After a median follow-up of 61.4 months, ENZA + ADT extended survival compared with PBO + ADT (medians NR; HR 0.70; 95% CI: 0.58–0.85; p=0.0003), with consistently improved survival across clinically relevant subgroups analyzed (Table), including a 36-month improvement in median OS in high-volume patients. **Conclusions:** Long-term follow-up of ARCHES demonstrated results consistent with previous OS analyses, with marked benefit in all study subgroups, including high- and low-volume patients, despite a substantial cross-over cohort. These findings further support ENZA + ADT as a standard-of-care for pts with mHSPC. Clinical trial information: NCT02677896. Research Sponsor: Astellas Pharma Inc.; Pfizer Inc.

Phase 3 AMPLITUDE trial: Niraparib (NIRA) and abiraterone acetate plus prednisone (AAP) for metastatic castration-sensitive prostate cancer (mCSPC) patients (pts) with alterations in homologous recombination repair (HRR) genes. First Author: Gerhardt Attard, Cancer Institute, University College London, London, United Kingdom

The full, final text of this abstract will be available at meetings.asco.org on the day of presentation and in the online supplement to the June 10, 2025, issue of the *Journal of Clinical Oncology*.

5007 **Oral Abstract Session**

A multicenter, randomized, phase 2, investigator-initiated ETCTN trial of olaparib + radium-223 vs. radium-223 in men with castration-resistant prostate cancer (CRPC) with bone metastases (BM) (COMRADE): Initial efficacy and biomarker analysis. First Author: Rana R. McKay, University of California San Diego, San Diego, CA

Background: Radium-223 is an α-emitting radioisotope which has improved overall survival (OS) in men with CRPC with BM. PARP inhibitors demonstrate synergy with radiation. Our phase 1 trial established olaparib 200 mg twice daily + radium-223 (55 kBq/kg IV q4weeks x 6) as the recommended phase 2 dose. Here, we report the phase 2 results (NCT03317392). **Methods:** Patients were randomized 1:1 to olaparib + radium-223 (Arm A) vs. radium-223 (Arm B), stratified by prior docetaxel and BM extent ($\leq$20/$>$20). Crossover was permitted in Arm B. Eligibility included any line of prior therapy, $\geq$2 BM by CT/MRI or bone scan, and at least 1 BM without prior radiation. Visceral metastases or lymphadenopathy $>$ 4 cm were excluded. Bone protecting agents (BPA) were required unless contraindicated. Homologous recombination repair gene (HRR) mutation status was determined using FoundationOne Monitor with algorithmic clonal hematopoiesis determination from baseline plasma (reported here) and Oncopanel assay from baseline biopsy or archival tissue. The primary endpoint was radiographic progression-free survival (rPFS). With 120 patients, the study was designed to have 88% power to detect an improvement in rPFS from 6.0 to 10.5 months (1-sided α=0.10). **Results:** 120 patients enrolled across 9 centers (Arm A=61, B=59). 96% received prior ARPI, 53% prior docetaxel, 32% with nodal disease, 46% had $>$ 20 BM, and 90% with concurrent BPA. Of the 103 evaluable patients, 18.5% in Arm A and 26.5% in Arm B had an HRR gene alteration by ctDNA, with 7.4% and 10.2% with *BRCA1/2* mutations, respectively. Olaparib + radium-223 had a significant improvement in rPFS vs. radium-223 (median 8.6 vs. 4.0 months, HR 0.51, 80% CI 0.37-0.70, 2-sided p=0.005). Secondary endpoints are in Table 1. The addition of olaparib improved rPFS regardless of HRR status (HRR+: HR 0.52, 80% CI 0.26-1.04; HRR-: HR 0.54, 80% CI 0.38-0.77). 56% of patients in Arm A and 35% of patients in Arm B had grade $\geq$3 treatment-related adverse events, the most common on Arm A/Arm B being: anemia (22.0%/18.0%), lymphocyte decrease (30.5%/9.1%), platelet decrease (6.8%/3.6%), and neutrophil decrease (5.1%/7.3%). **Conclusions:** In this phase 2, multicenter trial, olaparib + radium-223 demonstrated superior rPFS to radium-223, in both HRR+ and HRR- groups, with manageable side effect profile in CRPC patients with BM. Tissue and serial ctDNA analyses are underway and will be presented. Clinical trial information: NCT03317392. Research Sponsor: National Cancer Institute.

	Arm A median (months)/%	Arm B median (months)/%
rPFS	8.6	4.0
rPFS (HRR+)	5.5	3.8
rPFS (HRR-)	8.8	4.5
PSA response (confirmed)	13.1%	13.6%
Alkaline phosphatase response (confirmed)	49.2%	50.8%
Time to PSA progression	3.6	3.3
Time to Alkaline phosphatase progression	7.9	7.4
Time to next treatment	12.0	7.7
1-year symptomatic skeletal event	11.0%	22.1%
12-month OS	74%	71%

5008 Oral Abstract Session

C3NIRA: Randomized phase II study of carboplatin-cabazitaxel-cetrelimab (anti-PD-1) induction followed by niraparib +/- cetrelimab maintenance in men with aggressive variant prostate cancers (AVPC). First Author: Ana Aparicio, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: AVPC have limited therapeutic options and a dismal prognosis. Although early data indicate that adding carboplatin (Carb) to cabazitaxel (Cab) benefits men with AVPC, responses are short-lived. In a previous study (NCT03263650) a subset of AVPC patients had long-term responses to CabCarb induction followed by PARP inhibitor maintenance. Tumor tissue analyses revealed upregulation of inflammatory and immune pathways in post-CabCarb treated tumors from prolonged responders. We therefore hypothesized that adding anti-PD-1 (cetrelimab, Cet) would increase the efficacy of CabCarb induction plus niraparib (Nira) maintenance in AVPC patients, and that correlates would expose tumor cell intrinsic and microenvironment pathways implicated in therapy response and resistance. **Methods:** In a single-institution study, men with CRPC meeting $\geq$ 1 of 9 AVPC criteria (listed in https://clinicaltrials.gov/study/NCT04592237) and ECOG performance status 0-2 received 6 cycles of Cab 20-25mg/m^2 and Carbo (AUC 3-4). Cet (360mg) was added to Cycles 2-6 of CabCarb. Men completing 6 cycles without progressive disease (PD) were randomized 1:1 to Nira 300mg BID $\pm$ Cet. The primary endpoint was progression free survival (PFS) in randomized patients. Subgroup comparisons between patients with PD in the first 6 cycles (Early PD) vs. patients who achieved randomization (Randomized) were made with chi-square and Kruskal-Wallis tests. Paired tumor biopsies were obtained after 1 cycle of CabCarb and 2 cycles of CabCarbCet. **Results:** 120 patients started CabCarb. Their median age was 68 years (30-83). Most were White/non-Hispanic (78%) and had not received prior docetaxel (58%). Of the 120, 20 (16.7%) went off study for reasons other than PD and 40 (33.3%) had Early PD and were not randomized. The Early PD group did not differ from the Randomized group in terms of age, race ethnicity, prior docetaxel, or baseline PSA. Post randomization median follow up was 20.5 months; median PFS was 3.4 months (95% confidence interval: 2.0, 4.4) with Nira (n=30) and 5.6 (3.7, 16.8) months with Nira+Cet (n=30, p=0.01); median overall survival was 10.2 (6.4, 19.6) with Nira and 24.3 (9.5, not reached) months with Nira+Cet (p=0.01). Single-cell RNA sequencing of paired biopsies revealed increased progenitor-like exhausted CD8+ T cells and decreased FoxP3+ Treg cells in Randomized patients (n=5) while Early PD patients (n=5) showed the opposite following the addition of Cet to CabCarb. **Conclusions:** A subset of men with AVPC derive meaningful benefit from the addition of anti-PD-1 to PARP inhibitor maintenance following platinum-taxane-anti-PD-1 induction. Ongoing correlates aim to identify biomarkers to select patients for this treatment strategy and reveal candidate mechanisms of resistance to guide future therapeutic combinations. Clinical trial information: NCT04592237. Research Sponsor: U.S. Department of Defense; W81XWH-20-1-0257; Janssen Scientific Affairs, LLC.

5009 Clinical Science Symposium

Lutetium-177-PSMA-617 in oligo-metastatic hormone sensitive prostate cancer (BULLSEYE trial). First Author: Bastiaan M. Privé, Radboudumc, Nijmegen, Netherlands

Background: [^{177}Lu]Lu-PSMA-617 (Pluvicto) is a novel treatment for patients with metastatic castration resistant prostate cancer. In a phase 1 dosimetry study, we previously showed that [^{177}Lu]Lu-PSMA-617 could be offered to patients with PSMA-expressing, recurrent, oligometastatic hormone-sensitive prostate cancer (oHSPC) with encouraging outcomes (Privé et al, CCR 2021). We here report the results of the following randomized phase 2 trial. **Methods:** This was an investigator initiated, international, multicenter, open-label, randomized phase 2 trial (NCT04443062). Fifty-eight oHSPC patients ineligible for salvage treatments, were randomized in a 1:1 fashion to [^{177}Lu]Lu-PSMA-617 vs. the standard of care (SoC) of deferred androgen deprivation therapy (ADT). Eligibility consisted of fast-progressing oHSPC (prostate specific antigen [PSA] doubling time $<$6 months) following radical prostatectomy or radiotherapy, with a maximum of 5 metastases on PSMA-PET/CT. Patients received 2 (+2 optional) cycles of 7.4 GBq [^{177}Lu]Lu-PSMA-617. The primary outcome was progression-free survival (i.e. time without ADT). Progressive disease (PD) was defined as a 100% increase in PSA since randomization, radiographic or clinical progression or earlier necessitation of subsequent therapy (e.g. ADT). Secondary outcomes were PSA response, adverse events and quality of life. **Results:** Between April 20, 2020 and July 29 2024, 58 of 78 screened men were eligible. Data cut-off was set on December 24th 2024. Median age was 72 years (range 51-82) with a median baseline PSA of 3.6 (1.2-29). Two patients received 2 cycles whereas 27 patients underwent 4 cycles of [^{177}Lu]Lu-PSMA-617. At a median follow-up time of 7 months (range 1-31), 93% (27/29) and 38% (11/29) of the SoC and arm, respectively, reached the definition for PD. The median progression free survival was 5 months (95% CI 4-6 months) for the SoC group whereas the median progression free survival was not reached for the [^{177}Lu]Lu-PSMA-617 group (HR, 0.07 [95% CI, 0.02 to 0.19]; P $<$.001). The median percentage PSA change was +125% vs. -91% in the SoC vs. [^{177}Lu]Lu-PSMA-617 arm, respectively. Twenty-one percent (6/29) of [^{177}Lu]Lu-PSMA-617 arm patients had a complete remission. The most common treatment-related adverse events were grade (G) 1 dry mouth (59%), G 1 fatigue (55%), G 1 nausea (48%), G 1 bone marrow toxicity (24-30%) which generally normalized during follow-up. G $\geq$2 adverse events were seldom observed ($<$15%) and not clinically relevant. **Conclusions:** [^{177}Lu]Lu-PSMA-617 showed promising efficacy as monotherapy in oligometastatic hormone sensitive prostate cancer patients to defer from androgen deprivation therapy, with minimal and mostly transient side effects. Following surgery and external beam radiotherapy, could become a third metastases-directed therapeutic option for oligometastatic prostate cancer patients to prolong ADT-free interval. Clinical trial information: NCT04443062. Research Sponsor: Novartis; Dutch Prostate Cancer Foundation.

5010 Clinical Science Symposium

First-in-human results of terbium-161[^{161}Tb]Tb-PSMA-I&T radioligand treatment in patients with metastatic castration-resistant prostate cancer (VIOLET): A single-centre, single-arm, phase I/II study. First Author: James Patrick Buteau, Molecular Imaging and Therapeutic Nuclear Medicine, Cancer Imaging; Prostate Cancer Theranostics and Imaging Centre of Excellence, Peter MacCallum Cancer Centre; and Sir Peter MacCallum Department of Oncology, University of Melbourne, Melbourne, VIC, Australia

Background: Terbium-161 (^{161}Tb) is a novel radionuclide emitting beta-radiation comparable to lutetium-177 (^{177}Lu), with additional higher-energy, ultra-short path-length Auger electrons which may better target micrometastases. ^{161}Tb has superior in-vitro and in-vivo efficacy in comparison with ^{177}Lu. We aim to evaluate the safety and effectiveness of [^{161}Tb]Tb-PSMA-I&T in patients with metastatic castration-resistant prostate cancer (mCRPC). **Methods:** Eligible patients in this investigator-initiated, single-centre, single-arm, phase I/II trial had progressive mCRPC previously treated with taxane chemotherapy (unless medically unsuitable) and an androgen receptor pathway inhibitor, PSMA-positive disease on PSMA PET/CT (SUVmax $\geq$20), no sites of discordance on FDG PET/CT, adequate bone marrow, hepatic and renal function, and ECOG performance status $\leq$2. The dose-escalation followed a 3+3 design to establish safety of three prespecified administered radioactivities of [^{161}Tb]Tb-PSMA-I&T (4.4, 5.5, and 7.4 GBq). Up to six cycles of [^{161}Tb]Tb-PSMA-I&T were administered intravenously every six weeks, with each subsequent radioactivity per cycle reduced by 0.4 GBq. The co-primary objectives were to establish the maximum tolerated dose (MTD) and safety profile (CTCAE v5.0) of [^{161}Tb]Tb-PSMA-I&T. Key secondary objectives for this interim analysis were PSA $\geq$50% and $\geq$90% response rates (PSA50-RR and PSA90-RR), PSA and radiographic progression-free survival (PSA-PFS and rPFS). **Results:** Between October 14, 2022 and February 15, 2024, 30 eligible patients were enrolled. Median (IQR) age 69.0 years (66.0-74.8), median baseline PSA 26.9 ng/mL (10.1-70.0), PSMA SUVmean 8.2 (7.4-10.8) and 20 patients (67%) had received prior docetaxel. There were no dose-limiting toxicities. The MTD and recommended phase 2 dose was 7.4 GBq. There were no treatment-related deaths and few grade 3 or higher treatment-related adverse events, which included pain flare and lymphopenia only. The remaining AEs are summarised in the table. PSA50-RR and PSA90-RR occurred in 21 (70% [95%CI 51-85]) and 12 (40% [95%CI 23-59]). Median PSA-PFS and rPFS were 9.0 months (95%CI 5.7-15.1) and 11.1 months (95%CI 6.6-11.7) with median follow-up of 11.2 and 11.0 months, respectively. **Conclusions:** [^{161}Tb]Tb-PSMA-I&T displayed highly encouraging efficacy with few Grade 3 or 4 adverse events. An additional cohort to assess a higher administered radioactivity is planned. Clinical trial information: NCT05521412. Research Sponsor: Prostate Cancer Foundation; Peter MacCallum Cancer Foundation; National Health and Medical Research Council; Isotopia Molecular Imaging.

5011 Clinical Science Symposium

Predictive and prognostic value of baseline PSMA-PET total tumor volume and SUV mean within ENZA-p, a randomized phase II trial of enzalutamide versus enzalutamide plus [^{177}Lu] Lu-PSMA-617 (ANZUP1901). First Author: Louise Emmett, Department of Theranostics and Nuclear Medicine, St Vincent's Hospital; Faculty of Medicine, UNSW, Sydney, Australia

Background: [^{68}Ga]Ga-PSMA-11 PET (PSMA-PET) standardized uptake value (SUV)mean and total tumor volume (PSMA-TTV) have been respectively identified as predictive and prognostic of response to [^{177}Lu]Lu-PSMA-617 (LuPSMA) monotherapy. The addition of LuPSMA to enzalutamide (enza + LuPSMA) improved overall survival (OS) compared to enza-alone in mCRPC in the ENZA-p trial. This pre-specified sub-study of ENZA-p evaluated baseline PSMA-PET quantitative parameters as predictive and prognostic biomarkers for enza+ LuPSMA and enza-alone. **Methods:** ENZA-p is an open-label, randomized, phase 2 trial. Participants (pts) with mCRPC not previously treated with chemotherapy or AR antagonist (abiraterone permitted) and [^{68}Ga]Ga-PSMA-avid disease were randomized (1:1) to either enza-alone or enza + LuPSMA using adaptive-dosed [^{177}]Lu LuPSMA-617 7.5 GBq for (2 or 4 doses). All pts had a baseline [^{68}Ga]Ga-PSMA-11 PET/CT to assess eligibility (SUVmax $>$14 at a single site and SUVmax $>$10 at all larger tumor sites). PSMA-PET were quantified with semi-automated software to derive PSMA-TTV and SUVmean. The pre-specified tertiary study objective was to evaluate associations between quantitative parameters on the baseline PSMA-PET and both PSA progression-free survival (PSA-PFS) and OS. Prespecified cut-points were based on SUVmean highest quartile (Q4 vs Q1-3) and PSMA-TTV median at baseline. We used the Kaplan-Meier method and Cox regression models. **Results:** This sub-study included the 160 of 162 randomized pts who received study treatment. Median follow-up was 34 months with 96 OS events. Baseline PSMA-PET SUVmean Q4 was 9.8 and median PSMA-TTV was 234 mL. Median OS for PSMA-TTV above or below the median for enza-alone were 20 vs 39 months respectively (p$<$0.001). The corresponding median OS for enza + LuPSMA were 28 vs 35 months (p=0.18). The test for interaction between PSMA-TTV and treatment arm for OS was p=0.008. Median OS for SUVmean Q4 vs Q1-3 for enza alone were 29 vs 25 months (p=0.59). For enza + LuPSMA median OS for SUVmean Q4 vs Q1-3 were 32 vs 34 months (p=0.56). The test for interaction between SUVmean (Q4 vs Q1-3) and treatment for OS was p=0.88. Results for PSA-PFS are also tabulated below. **Conclusions:** Baseline PSMA-TTV was prognostic of shorter OS with enza-alone, but not with the addition of LuPSMA-617. In contrast to LuPSMA-617 monotherapy, PSMA SUVmean was neither predictive nor prognostic of improved OS, nor of PSA-PFS when LuPSMA-617 was given together with enza as first line treatment for mCRPC. Clinical trial information: NCT04419402. Research Sponsor: Prostate Cancer Research Alliance (PCRA): An Australian Government and Movember joint alliance and Australian and New Zealand Urogenital and Prostate Cancer Trials Group (ANZUP); GenesisCare, Roy Morgan Research; St Vincent's Clinic Foundation; Cancer Australia; Astellas and Endocyte - a Novartis Company Pharmaceutical/Biotech Company.

An open label randomized non-inferiority trial comparing adjuvant platinum plus paclitaxel to platinum plus 5-FU after curative resection in high-risk penile carcinoma. First Author: Aditya Dhanawat, Tata Memorial Centre, Mumbai, India

The full, final text of this abstract will be available at meetings.asco.org on the day of presentation and in the online supplement to the June 10, 2025, issue of the *Journal of Clinical Oncology*.

5013 **Rapid Oral Abstract Session**

Docetaxel with androgen deprivation therapy (ADT) and radiotherapy (RT) for high-risk localized prostate cancer (HRLPC): An ICECaP individual patient-data (IPD) meta-analysis of randomized controlled trials (RCTs). First Author: Praful Ravi, Dana-Farber Cancer Institute, Boston, MA

Background: There is no established role for the use of docetaxel with ADT and RT for HRLPC, with mixed results seen in prior RCTs. Prior work from ICECaP (Ravi et al, Eur Urol 2024) has shown that patients (pts) with very high-risk disease (i.e. 2 or 3 risk factors [RFs]: Gleason ≥8, PSA >20, ≥cT3 and/or cN1) have the poorest outcomes with RT+ADT for HRLPC, with 5-year metastasis-free survival (MFS) of ≤80%. We aimed to perform an IPD meta-analysis of the role of docetaxel with ADT+RT for HRLPC and specifically evaluate whether patients with very high-risk disease benefit from the addition of docetaxel. **Methods:** IPD from RCTs involving pts with HRLPC treated with RT+ADT +/- docetaxel collated by ICECaP were analyzed. "High-risk" disease was defined as presence of 1 RF and "very high-risk" disease as 2-3 RFs and/or cN1 disease. The primary outcomes of interest were MFS and overall survival (OS). Hazard ratios (HR) for MFS and OS were estimated using Cox regression, stratified by year of randomization and adjusted for age at randomization and ECOG performance status. 5-year MFS and OS rates were estimated using the Kaplan-Meier method. Subgroup analyses were performed according to the severity of disease (high- and very high-risk), and p-values for interaction were tested using the likelihood ratio test. **Results:** 1690 pts treated on 4 RCTs (GETUG-12, DFCI 05-043, STAMPEDE, RTOG-0521) between 2002-2015 were eligible. Median age was 65, median PSA was 23 (IQR 10-48); 154 (9%) pts had cN1 disease and 1444 (85%) received long-term ADT with RT. Median follow-up was 10 years (range: <1-15). Overall, the addition of docetaxel to RT+ADT was not associated with a significant benefit in MFS (HR=0.89 [0.76-1.05], p=0.160) or OS (HR=0.88 [0.74-1.05], p=0.167). Though there was some evidence for favoring docetaxel in pts with very high-risk disease (n=1054; MFS HR=0.86 [0.71-1.05]; OS HR=0.85 [0.68-1.07]) compared to high-risk disease (n=636; MFS HR=0.97 [0.74-1.27]; OS HR=0.95 [0.71-1.28]), there was no evidence of a significant difference in treatment effect by risk group (p-interaction >0.1). 5- and 10-yr MFS and OS in pts with high- and very high-risk disease, stratified by receipt of docetaxel, are shown in the Table. **Conclusions:** Some HRLPC pts with very high-risk disease may benefit from the addition of docetaxel to RT+ADT. Biomarker evaluation within this group may identify those who are candidates for treatment intensification with docetaxel with RT+ADT (+/- androgen receptor pathway inhibitors) in HRLPC. Intensified hormonal blockade with SBRT in PSMA-PET detected oligometastatic prostate adenocarcinoma: Results from the phase II Metacure trial cohorts B2 and the B2 expansion. First Author: Eric Huttenlocher Bent, Memorial Sloan-Kettering Cancer Center, New York, NY

Background: Metastasis directed therapy (MDT) with stereotactic body radiotherapy (SBRT) is a standard of care in patients with oligometastatic hormone-sensitive prostate cancer (HSPC) and can delay the use of ADT. Combining SBRT with a defined period of systemic therapy may lead to durable control of oligometastatic disease and is often used in this setting, however the optimal intensity and duration of hormonal blockade with SBRT remains unclear. **Methods:** Metacure is a multi-center, multi-arm randomized phase 2 trial that tests novel systemic therapies in the context of a multimodality approach, including SBRT to oligometastatic sites. The B2 and B2 expansion cohorts of Metacure tested SBRT +/- salvage RT to prostate bed/nodes with time-limited ADT+ARPI hormonal blockade in patients (pts) with PSMA-PET detected metachronous oligometastatic HSPC. Eligible pts had biochemical recurrence or persistence (PSA >0.2) after prostatectomy with metastases treatable within max 3 RT plans. Cohort B2 randomized pts to metastasis-directed SBRT with either 10 months of ADT + apalutamide + abiraterone acetate plus prednisone (ADT+APA+AAP) or ADT + apalutamide (ADT+APA). In the B2 expansion cohort pts received 6 months of ADT+APA with SBRT. The primary endpoint was proportion of pts with undetectable PSA (PSA<0.1) at 12 months from treatment start in pts with recovered testosterone (T). Secondary objectives included PSA<0.1 at 24 months, time to PSA progression (PSA 0.2), time to T recovery, rPFS, and PFS (PSA, radiographic, or clinical progression or death). **Results:** 36 pts were treated in the combined B2 (10 pts) and B2 expansion (26 pts) cohorts. Median follow-up was 35 months for cohort B2 and 19 months for the B2 expansion. T recovery (>150ng/dl) at 12 months from treatment start occurred in 3/5 (60%) ADT+APA+AAP and 2/5 (40%) ADT+APA pts on cohort B2 and 14/26 pts (54%) on the B2 expansion (ADT+APA). Of those, 2/2 (100%) B2 ADT+APA+AAP pts, 3/3 (100%) B2 ADT+APA and 11/14 (79%) B2 expansion pts had PSA <0.1. This met the pre-specified threshold for activity for the B2 expansion of 4 pts. Median time to PSA progression and PFS was 26 months for the B2 ADT+APA+AAP arm and not reached for the B2 ADT+APA arm or B2 expansion cohort. Median rPFS was not reached in any group. At 12 months, all patients on B2 and B2 expansion were progression free. At 18 months, PFS for B2 was 100% (ADT+APA) and 60% (ADT+APA+AAP) and was 85% for the B2 expansion. At 24 months, PFS was 60% for ADT+APA and 60% for ADT+APA+AAP pts on cohort B2. Median T recovery was 3.0 and 5.5 months for the B2 and B2 expansion cohorts. Grade 3 TRAEs were seen in 0/10 B2 and 1/26 B2 expansion subjects (lymphopenia). **Conclusions:** SBRT with short course intensified hormonal blockade was well tolerated and led to durable disease control in pts with PSMA PET-detected metachronous oligometastatic prostate cancer. Clinical trial information: NCT03436654. Research Sponsor: Janssen.

DB-1311/BNT324 (a novel B7H3 ADC) in patients with heavily pretreated castrate-resistant prostate cancer (CRPC). First Author: Andrew Ohyama Parsonson, Macquarie University, Sydney, Australia

Background: There is a high unmet need for effective therapy for patients (pts) with heavily pretreated CRPC. B7H3 ADCs have reported early clinical activity in CRPC, including DB-1311/BNT324, an investigational B7H3 ADC that received FDA Fast-Track Designation for previously treated CRPC. **Methods:** This phase 1/2 study (NCT05914116) enrolled pts with advanced/metastatic solid tumors, including previously treated CRPC (post docetaxel/hormonal therapy). Dose optimization cohorts randomized pts to receive 6 mg/kg or 9 mg/kg Q3W DB-1311/BNT324 until progression or unacceptable toxicity. The primary endpoints were objective response rate (ORR, based on investigator assessment per RECIST 1.1 and PCWG3 criteria) and safety. Secondary endpoints included disease control rate (DCR), duration of response (DOR) and radiographic progression-free survival (rPFS). **Results:** As of 3 Jan 2025, of 393 pts treated with DB-1311/BNT324, there were 65 pts with CRPC. Median age was 71 years (range 45–84), 49%/34%/14% were White/Asian/Black, 32%/37%/31% from Australia/USA/East Asia, 71% had ECOG PS 1, 29% had bone only disease. Median number of prior lines was 3 (range 1–14) and 28% had ≥5 prior lines. Most pts received prior docetaxel (93.8%) and hormonal therapy (96.9%); other therapies included PARP inhibitors (PARPi, 15.4%), Lutetium-177 (Lu-177, 15.4%), immunotherapy (IO, 13.8%). Among 43 response-evaluable pts (measurable disease at baseline per RECIST 1.1), best overall response was PR in 12 pts and SD in 29 pts for an unconfirmed ORR of 27.9% (95% CI 15.3, 43.7; 12/43, 8 confirmed) and DCR of 95.3% (95% CI 84.2, 99.4). Median DOR was not reached (95% CI 4.2, ne). After a median follow-up of 5.7 months (m) (range 0.6–16.0), median rPFS (N=57) was 8.3 m (95% CI 6.7, ne) with a 6-m rate of 86.6% (95% CI 67.8, 94.8). Outcomes were similar by dose (6 mg/kg [ORR 26.3%, DCR 100%, 6-m rPFS rate 88.7%], 9 mg/kg [ORR 29.2%, DCR 91.7%, 6-m rPFS rate 80.0%]), by line of treatment (≤3L [ORR 33.3%, DCR 77.8%], ≥4L [ORR 26.7%, DCR 100%]), and by type of prior treatment (ORR/DCR: Lu-177 [25.0%/100%], IO [33.3%/100%], albeit lower for PARPi [16.7%/100%]). The CRPC safety profile (N=65) is supported by the safety in the larger overall population (N=393). Treatment-related adverse events (TRAEs) occurred in 56 (86.2%) and 343 (87.3%) pts and were Grade ≥3 (G≥3) in 26 (40.0%) and 156 (39.7%) pts, respectively. TRAEs led to dose reduction in 8 (12.3%) and 39 (9.9%) pts, to discontinuation in 4 (6.2%) and 23 (5.9%) pts, and to death in 0 and 2 (0.5%) pts, respectively. Nausea and hematological events, primarily G1–2, were the most common TRAEs. Hematological TRAEs occurred more frequently with 9 mg/kg vs 6 mg/kg, both in the CRPC and overall populations. **Conclusions:** DB-1311/BNT324 showed encouraging efficacy and a manageable safety profile in heavily pretreated CRPC and is currently being evaluated in post Lu-177 CRPC and in taxane-naïve CRPC. Clinical trial information: NCT05914116. Research Sponsor: Sponsored by Duality Biologics and conducted in collaboration with BioNTech SE.

5016 Rapid Oral Abstract Session

^{177}Lu-PSMA-617 with ipilimumab (ipi) and nivolumab (nivo) in metastatic castration-resistant prostate cancer (mCRPC): An investigator-initiated phase 2 trial (EVOLUTION; ANZUP2001). First Author: Shahneen Sandhu, Peter MacCallum Cancer Center and the University of Melbourne, Melbourne, Australia

Background: LuPSMA improves progression-free survival (PFS) and overall survival (OS) in patients with mCRPC. Immune checkpoint inhibitors (ICI) have limited single-agent activity in mCRPC. Radiation may enhance ICI activity by inducing immunogenic tumor cell death and altering the tumor microenvironment. We evaluated the activity and safety of ipi plus nivo plus LuPSMA in mCRPC. **Methods:** Eligibility: prior androgen receptor pathway inhibitor therapy, PSMA-positive disease, normal organ function, no contraindications to ICIs, <= 1 line of chemotherapy. Randomized (1:2) to LuPSMA alone (7.4 GBq every 6 weeks, up to 6 doses) or LuPSMA plus induction ipi (3 mg/kg every 6 weeks for 4 doses) and nivo (1 mg/kg every 3 weeks for 8 doses) followed by maintenance nivo (480 mg every 4 weeks for 18 doses) (LuPSMA+ICI). Primary endpoint: PSA PFS at 12 months (PSA-PFS 12m). Secondary endpoints: PSA response rate (PSA-RR), adverse events (AEs), radiographic-PFS (rPFS), PSA-PFS, and OS. **Results:** 93 of 100 planned participants (pts) were randomized from July 2022 to July 2023. Recruitment was stopped early due to 4 cases of treatment-related myocarditis in pts assigned LuPSMA+ICI. Of 93 randomized, 30 pts received LuPSMA, 57 pts received LuPSMA+ICI. 6 pts who did not receive assigned LuPSMA+ICI (1 ineligible; 5 ceased ICI at the direction of the central study team) were excluded from the efficacy intention to treat analysis. However, 5 were included in the safety analysis. Median age was 70 years [range: 45-83]; 80% had prior docetaxel. The median follow-up was 18 months (IQR: 16-22). PSA-PFS 12m was higher in pts assigned LuPSMA+ICI than LuPSMA-alone (33% vs. 17%, see table). Grade 3-4 AEs were reported in more pts assigned LuPSMA+ICI than LuPSMA-alone (75% vs 29%). Among those assigned LuPSMA+ICI, Grade 3-4 AEs in ≤5% were: colitis (19%), anemia (11%), hypophysitis (14%), lung infection (9%), fatigue (7%), thrombocytopenia (7%), hepatitis (7%), pneumonitis (7%), thromboembolic event (5%) and rash (5%). Myocarditis was reported in 4 pts (7%) assigned LuPSMA+ICI. There were 2 deaths during LuPSMA+ICI treatment: myocarditis (treatment related) and sepsis (not treatment related). **Conclusions:** LuPSMA+ICI was associated with improved PSA-PFS 12m in mCRPC. The spectrum of AEs were keeping with established toxicities however significantly higher with LuPSMA+ICI, and frequency of ICI-related myocarditis lead to early trial cessation. Clinical trial information: NCT05150236. Research Sponsor: Bristol Myers Squibb; Novartis; Cancer Australia; Prostate Cancer Foundation of Australia (PCFA); Australasian Radiopharmaceutical Trials Network (ARTnet); MIM Software Inc.; ANSTO.

5017 Rapid Oral Abstract Session

Phase 1 study results of JNJ-78278343 (pasritamig) in metastatic castration-resistant prostate cancer (mCRPC). First Author: Capucine Baldini, Drug Development Department (DITEP), Institut Gustave Roussy, Villejuif, France

Background: Human kallikrein 2 (encoded by the *KLK2* gene and hereafter referred to as KLK2) is a novel target expressed on PC cells with limited normal tissue expression. Pasritamig is a first-in-class T-cell-redirecting bispecific antibody that simultaneously binds KLK2 on PC cells and CD3 receptor complexes on T cells. We report dose escalation and expansion results from a first-in-human study (NCT04898634) evaluating pasritamig in pts with mCRPC. **Methods:** Pasritamig target doses (TDs) were escalated from 0.5-2000 mg SC and 150-900 mg IV QW-Q6W, with various step-up (SU) dosing schedules. Pre-medication with dexamethasone (16 mg) was required in SU and 1st TD. The primary objective was to determine the safety and RP2D. Secondary objectives included preliminary assessment of antitumor activity. **Results:** As of October 7, 2024, 174 pts (median [range] age 69 [36-89] years) had received ≥1 pasritamig dose (Table). Pts had a median of 4 prior therapies (range 1-13; 99.4% ARPI, 78.2% taxane chemotherapy, 17.2% lutetium Lu 177 vipivotide tetraxetan). There were no pasritamig-related deaths. One pt experienced a DLT of transient Gr 3 ALT/AST elevation after 50 mg SU2 SC administration. While most pts reported ≥1 TRAE (82.2% overall; 68.1% IV; 92.2% SC), these were mostly low grade, with only 9.2% of pts (6.9% IV; 10.8% SC) experiencing a Gr ≥3 TRAE. In the RP2D safety population (n=45; 3.5 mg [Day 1], 18 mg [Day 8], 300 mg Q3W or Q6W IV), the most common TRAEs were infusion-related reactions (22.2%; Gr 1/2), fatigue (15.6%; Gr 1/2), and CRS (8.9%; all Gr 1, no tocilizumab was administered), no TRAEs led to treatment discontinuation, no ICANS was observed, and 2 serious TRAEs (Gr 1 CRS) were reported. In the RP2D efficacy population (n=33; 3.5 mg [Day 1], 18 mg [Day 8], 300 mg Q6W IV), PSA50 was 42.4% (14/33) and median rPFS was 6.77 (95% CI 2.89, NE) months with 39.4% of pts ongoing (13/33). ORR in the 85 pts with measurable disease was 16.1% (n=5/31) in pts with lymph node +/- bone and 3.7% (n=2/54) in pts with visceral disease, with a median DOR of 11.27 (95% CI 3.58, NE) months. **Conclusions:** Pasritamig was very well tolerated (<10% of pts experienced CRS [all Gr1] at the RP2D) with promising antitumor activity, demonstrating proof of concept for KLK2 as a target amenable to T-cell redirection. These results address an unmet need for a targeted T-cell based therapy that is safe to administer in an outpatient setting with clinically meaningful benefit in mCRPC. Phase 3 trials are planned. Clinical trial information: NCT04898634. Research Sponsor: Johnson & Johnson.

5018 Rapid Oral Abstract Session

CA209-8TY trial, a randomized phase 2 trial of nivolumab and ipilimumab with or without stereotactic body radiation therapy in metastatic castration-resistant prostate cancer. First Author: Rikke Løvendahl Eefsen, Department of Oncology, Experimental Cancer Therapy Unit, Herlev, Copenhagen, Denmark

Background: Metastatic castration-resistant prostate cancer (mCRPC) is among the leading causes of cancer related mortality in men worldwide. Treatment options include chemotherapy and androgen receptor pathway inhibitors (ARPIs). Prostate cancer is considered an immunosuppressive tumor. As of today, immune checkpoint inhibitors (ICIs) have not demonstrated effect in patients with mCRPC. The use of stereotactic body radiation therapy (SBRT) may increase the expression of tumor associated antigens and enhance potential immune responses following systemic therapy. **Methods:** Patients with mCRPC, who had previously progressed on at least one taxane regimen and one ARPI, were screened for the trial. Eligible Patients were randomized to receive either ipilimumab 1mg/kg and nivolumab 3mg/kg every 4 weeks for the first 12 weeks followed by nivolumab monotherapy 480mg every 4 weeks for up to 52 weeks (arm B), or the same ICI with SBRT of a metastasis, 24Gy in 3 fractions (arm A). The co-primary endpoints were prostate specific antigen (PSA) response rate, defined as a ≥50% decline in PSA compared to baseline, confirmed after ≥4 weeks, and objective response rate (ORR) according to modified Response Evaluation Criteria in Solid Tumors (RECIST) 1.1 and Prostate Cancer Working Group (PCWG) 3. Secondary endpoints included overall survival (OS), radiologic progression free survival (rPFS), and toxicity. **Results:** Between November 2019 and January 2024, 91 patients were randomized in the CheckPRO trial (NCT 05655715). A total of 81 patients received at least one treatment cycle and were eligible for evaluation. The confirmed PSA response rate was 21.6% in arm A and 20.5% in arm B. ORR was 16.7% (95% CI [4.7-37.4] %) and 22.2% (95% CI 10.1-39.2) in arm A and B, respectively. Median OS was 10.2 months (95% CI [7.1-14.1] %) in arm A and 9.2 months (95% CI [7.1-14.1] %) in arm B. rPFS was 2.1 months and 1.9 months in arm A and B, respectively. Serious adverse events related to ICIs occurred in 29.7% of patients in arm A and 31.8% in arm B. **Conclusions:** Objective responses were demonstrated in patients with mCRPC treated with combination ICI, however PFS was short and treatment-related toxicity significant. While the addition of SBRT was safe, it did not improve treatment outcomes in this study. Further analyses are ongoing to identify patients with mCRPC, who are most likely to respond to ICI. Clinical trial information: NCT05655715. Research Sponsor: Bristol Myers Squibb.

5019 Rapid Oral Abstract Session

Exploratory analyses of homologous recombination repair alterations (HRRm) by gene subgroup and potential associations with efficacy in the HRR-deficient population from TALAPRO-2. First Author: Stefanie Zschaebitz, National Center for Tumor Diseases (NCT), Heidelberg, Germany

Background: In TALAPRO-2, talazoparib (TALA) + enzalutamide (ENZA) significantly improved radiographic progression-free survival (rPFS) and overall survival (OS) vs ENZA + placebo (PBO) in patients (pts) with mCRPC harboring HRRm assessed prospectively. Here we report exploratory biomarker analyses which assessed HRR by gene subgroup and potential associations with efficacy in pts enrolled in the HRR-deficient cohort from TALAPRO-2. **Methods:** Pts were randomized 1:1 to TALA 0.5 mg (N=200) or PBO (N=199) + ENZA 160 mg QD. HRRm testing used a 12-gene HRR panel (HRR12; clinical trial assays based on FoundationOne CDx and FoundationOne Liquid CDx). HRRm status categorization by gene incorporated all available tumor and prescreening/screening ctDNA records using an algorithm similar to that previously used by others (Fallah et al, JCO 2024 PMID: 38484203). For non-*BRCA* gene analyses, pts with co-occurring *BRCA1/2* alterations were excluded. For *BRCA1*, pts with co-occurring *BRCA2* alterations were excluded. The efficacy endpoints assessed were overall response rate (ORR), rPFS, and OS. Data cutoff Sept 3, 2024. **Results:** For all HRRm pts, TALA + ENZA was superior to ENZA + PBO across all efficacy endpoints: ORR, 69.4% vs 39.1% (odds ratio [OR], 0.28 [95% CI, 0.13–0.61]); rPFS, median 30.7 vs 12.3 months (mo) (hazard ratio [HR]=0.47 [0.36–0.62]); OS, median 45.1 vs 30.8 mo (HR=0.60 [0.46–0.78]). TALA + ENZA vs ENZA + PBO demonstrated benefit for *BRCA2m* across endpoints: ORR, 86.4% vs 31.0% (OR, 0.07 [95% CI, 0.01–0.35]); rPFS, median not reached (NR) vs 10.9 mo (HR=0.25 [0.15–0.42]); OS, median NR vs 28.5 mo (HR=0.47 [0.29–0.76]). Similar rPFS and OS benefit was seen for *BRCA1m* and *PALB2m* (allowing for small n in the groups); for ORR, evaluable n of 8 across arms for each gene was too low to meaningfully assess ORR differences. Benefit for TALA + ENZA was also evident for *CDK12m*: ORR, 63.6% vs 22.2% (OR, 0.16 [95% CI, 0.01–1.61]); rPFS, 19.3 vs 13.8 mo (HR=0.36 [0.19–0.70]); OS, 36.4 vs 22.8 mo (HR=0.41 [0.23–0.74]). *ATMm* also showed benefit for TALA + ENZA: ORR, 75.0% vs 33.3% (OR, 0.17 [95% CI, 0.02–1.32]); rPFS, 30.4 vs 18.3 mo (HR=0.66 [0.37–1.18]); OS, 45.1 vs 39.5 mo (HR=0.70 [0.38–1.29]). *CHEK2m* showed modest overall benefit for TALA + ENZA: ORR, 53.3% vs 42.9% (OR, 0.66 [95% CI, 0.07–5.59]); rPFS, 24.8 vs 18.3 mo (HR=0.65 [0.34–1.22]); OS, 34.2 vs 39.5 mo (HR=0.96 [0.51–1.81]). The remaining six HRR12 genes could not be meaningfully assessed for efficacy benefit by gene with TALA + ENZA vs ENZA + PBO due to low mutational prevalence. **Conclusions:** An efficacy benefit was evident for TALA + ENZA vs PBO + ENZA across multiple mutational subgroups assessed by gene, and was most pronounced for the *BRCA1-PALB2-BRCA2* axis and *CDK12*, with benefit also apparent for *ATM*. Analyses of additional efficacy endpoints are planned and will be presented. Clinical trial information: NCT03395197. Research Sponsor: Pfizer.

5020 Rapid Oral Abstract Session

Clonal hematopoiesis (CH) in participants with metastatic castration-resistant prostate cancer (mCRPC) receiving ^{177}Lu-PSMA-617 or cabazitaxel: An exploratory post-hoc analysis of a randomized phase II trial (TheraP; ANZUP 1603). First Author: Aslı Doğa Munzur, Vancouver Prostate Centre, Vancouver, BC, Canada

Background: The prostate-specific membrane antigen (PSMA)-targeted radioligand [^{177}Lu]Lu-PSMA-617 (^{177}Lu-PSMA-617) is an effective new standard-of-care for mCRPC. Since radiation may cause CH, an age-related preleukemic condition, we hypothesized that ^{177}Lu-PSMA-617 drives an increase in CH compared to other mCRPC treatments. Here, we explored CH in the TheraP trial randomizing participants (pts) with docetaxel-refractory mCRPC to cabazitaxel or ^{177}Lu-PSMA-617 (NCT03392428). **Methods:** We performed targeted DNA sequencing with a CH gene panel on blood samples from trial baseline (n = 176) and disease progression (n = 103; 56 post-^{177}Lu-PSMA-617, 47 post-cabazitaxel). Baseline CH mutations were detected in both cell-free DNA (cfDNA) and leukocyte DNA with variant allele frequency (VAF) ≥0.25%. Progression leukocyte DNA was unavailable at analysis, so progression CH mutations were identified via cfDNA only. We used Fisher's exact test to compare proportions, and the Mann-Whitney U test for changes in VAF. **Results:** Data was evaluable in 174/176 pts with baseline samples, and 103/103 with progression samples. Median time between baseline and progression blood draws was 28 and 27 weeks for ^{177}Lu-PSMA-617 and cabazitaxel arms, respectively. CH was detected in 77% (135/174) of pts at baseline (median age: 72). 71 (41%) pts had baseline CH mutations with VAF≥2%. The most commonly mutated genes at baseline were *DNMT3A* (n = 67 pts, 38%), *TET2* (n = 44, 25%), *PPM1D* (n = 26, 15%) and *ASXL1* (n = 19, 11%), with no difference in gene mutation frequency between arms. At progression, new mutations of presumed CH origin were detected in 83% and 46% of ^{177}Lu-PSMA-617 and cabazitaxel pts, respectively (47 vs 22 pts, p=0.0001). The most frequently mutated gene at ^{177}Lu-PSMA-617 progression was the DNA damage repair gene *PPM1D*; and new *PPM1D* CH mutations were 8 times more common after ^{177}Lu-PSMA-617 than cabazitaxel (p = 0.00032). Progression mutations in *ATM* or *CHEK2* were also 5 times more commonly observed after ^{177}Lu-PSMA-617 (p = 0.01). Among CH variants concordantly detected at baseline and progression on ^{177}Lu-PSMA-617, the median VAF change for mutations in DNA damage repair genes was higher than in canonical CH genes *DNMT3A*, *TET2* and *ASXL1* (1.53% *vs.* 0.15%, p = 0.01). **Conclusions:** ^{177}Lu-PSMA-617 was associated with a greater number of new CH mutations, especially in DNA damage repair genes, compared to cabazitaxel. Whilst the clinical relevance of this finding in a population of patients with heavily-treated mCRPC is unclear, CH emergence and expansion may have implications as radioligand therapy is used as an earlier line of therapy. Association of hormone therapy usage with adverse cardiovascular events in prostate cancer patients of the All of Us Research Program cohort. First Author: Yuanchu J Yang, Vanderbilt University School of Medicine, Nashville, TN

Background: Hormone therapies (HT) such as GnRH agonists, GnRH antagonists, and/or anti-androgens have led to improved overall survival for prostate cancer patients. However, the usage of these drugs may also increase cardiovascular (CV) risk. **Methods:** This study examined participants in the All of Us Research Program who were diagnosed with prostate cancer, had no prior history of adverse cardiovascular events (ACE), and were either treated or not treated with HT. We defined ACE as myocardial infarctions, strokes, or heart failure. Covariates used in our analysis were age, dyslipidemia, type 2 diabetes, hypertension, chronic kidney disease, peripheral vascular disease, statin usage, and smoking history. Time-to-ACE was defined using longitudinal electronic health record data. Participants who did not develop ACE were right censored at the date of their last medical visit. We evaluated whether HT use affected the risk of ACE using a Cox proportional hazards model with adjustment for established CV risk factors as covariates. **Results:** The final cohort included 5156 *All of Us* participants. Of these participants, 851 received HT treatment, 624 received only non-HT treatment (other medical, radiation, or surgical treatment for their prostate cancer), and 3681 received no known treatment. In our overall survival analysis, HT was associated with increased risk of ACE (HR, 1.22; 95% CI, 1.01-1.48; P = 0.03). In participants with pre-treatment dyslipidemia (Table), HT usage was associated with increased risk of ACE (HR, 1.52; 95% CI, 1.19-1.95; P <0.001). In participants without pre-treatment dyslipidemia, no association was found between HT usage and ACE (HR, 0.96; 95% CI, 0.71-1.30; P = 0.81). **Conclusions:** In a study cohort with no prior history of ACE, HT was associated with increased risk of ACE in participants with pre-treatment dyslipidemia. These results suggest that risk stratification by dyslipidemia status may help improve CV outcomes when selecting treatment regimens for prostate cancer patients. Research Sponsor: NHGRI.

Cox model for adverse cardiovascular time-to-event stratified by pre-treatment dyslipidemia.

	Pre-treatment Dyslipidemia (n=2377)		No Pre-treatment Dyslipidemia (n=2779)	
	Hazard Ratio (95% CI)	P-Value	Hazard Ratio (95% CI)	P-Value

Comprehensive genomic profiling of Black and non-Hispanic White (NHW) men with prostate cancer (PCa). First Author: Sharon H. Choi, University of California, San Diego, San Diego, CA

Background: Racial disparities are evident in PCa, with Black men experiencing a higher incidence and worse survival compared to NHW patients (pts). The molecular alterations that distinguish these groups remain incompletely characterized. Herein, we investigate the clinical-genomic features that potentially contribute to the differences in outcomes between Black and NHW pts with PCa. **Methods:** Comprehensive next-generation sequencing of DNA (592-gene panel/whole exome) and RNA (whole transcriptome) was performed at Caris Life Sciences on PCa tissue samples (n = 5,412), collected from 2015 to 2023. Transcriptomic signatures – Androgen Receptor (AR), Neuroendocrine PCa (NEPC) scores – were calculated. Real-world overall survival (OS) data was obtained from insurance claims and was analyzed using Kaplan-Meier estimation. **Results:** Overall, 1,078 pts with PCa identified as Black, while 4,334 were NHW. Black pts were younger at biopsy collection than NHW pts (median age 66 vs 71 years, P < 0.001). The proportion of metastatic samples was higher in Black pts compared to NHW pts (43% vs 38%, P < 0.01). The prevalence of castrated PCa specimens was similar between Black and NHW pts (26.0% vs 25.4%, P = 0.72). Among non-castrated PCa tumors, tumors from NHW pts had more frequent alterations in *TP53*, *PTEN*, *PIK3CA*, and *CHEK2*, while tumors from Black pts had more *SPOP* and *CTNNB1* mutations. In the castrate setting, *TP53* and *PTEN* alterations were more frequent in tissue samples from NHW pts, while *CDK12* and *SPOP* mutations were more frequent in tumors from Black pts. *TMPRSS2* fusions were more prevalent in the NHW cohort across both castrated and non-castrated tumors. Tumors from Black pts had higher *FOLH1/PSMA* and *STEAP1* expression, elevated AR scores, but lower *CD276/B7H3* expression and NEPC scores. In the overall cohort, Black pts demonstrated a shorter median OS from diagnosis compared to NHW pts (86 vs 94 mos, P = 0.03). Black pts had a significantly longer time on treatment with enzalutamide in both the non-castrate (HR 0.82, P= 0.04) and castrate subgroups (HR 0.77, P= 0.03). Among pts with homologous recombination repair (HRR) deficiency-harboring tumors, PARP inhibitors provided a numerically longer survival benefit in Black pts than in NHW pts (21 vs 13 mos, P = 0.09). **Conclusions:** This multi-institutional study reveals distinct molecular profiles between Black and NHW pts with PCa. Despite having molecular features associated with better prognosis, Black men demonstrated worse survival outcomes, pointing to multifaceted determinants of disease outcomes. Notably, Black pts had improved outcomes on enzalutamide and showed potential benefit from PARP inhibitors in the presence of HRR mutations. These findings highlight genomic differences in diverse PCa populations and suggest therapeutic opportunities to address outcome disparities. Research Sponsor: None.

Prognostic impact of brain metastases on survival rates in patients with metastatic testicular cancer: A comprehensive registry-based analysis. First Author: Rohan Garje, Miami Cancer Institute, Baptist Health South Florida, Miami, FL

Background: Testicular cancer (TC) is a rare malignancy that accounts for less than 1% of all cancers. Advances in the treatment paradigm have improved survival rates. However, oncologic outcomes may vary based on the extent and location of metastasis. Brain metastases (BM) are rare but may lead to worse survival outcomes. We aimed to conduct the largest retrospective study of patients with metastatic TC (mTC) to evaluate the prognostic impact of brain metastasis on survival rates in patients with IGCCC intermediate or poor risk mTC. **Methods:** We utilized the National Cancer Database (2010-2021) to identify patients with mTC(T1-4, any N0-2, M1). Patients with isolated lung metastases were excluded, as lung involvement alone was considered a surrogate marker for patients with good risk disease. We utilized Kaplan Meier analysis and cox proportional hazard modelling to study the impact of BM on survival outcomes in patients with mTC. **Results:** A total of 4,076 patients with mTC met our study criteria, of which 11.14% (454) had BM. Among these, 36.11% (1,472) had seminoma, 27.16% (1,107) had non-seminomatous histology, and 36.73% (1,497) had mixed germ cell tumors. The 2- and 5-year survival rates for patients without BM were 82.63% (95% CI: 81.26–83.91) and 78.26% (95% CI: 76.72–79.71), respectively. For patients with BM, the 2- and 5-year survival rates were 51.01% (95% CI: 45.99–55.79) and 42.78% (95% CI: 37.72–47.72), respectively. In our adjusted analysis, patients with BM had 2.35-fold increased risk of death (HR: 2.35, 95% CI: 1.96–2.82, p<0.001), compared to those without BM. Additionally, compared to seminoma, non-seminomatous histology had a 1.72-fold increased hazard of death (HR: 1.72, 95% CI: 1.42–2.09, p<0.001), while mixed germ cell tumors had a 1.34-fold increased hazard of death (HR: 1.34, 95% CI: 1.10–1.62, p = 0.003). **Conclusions:** In this large-scale retrospective cohort study, patients with BM had 135% increased risk of death in patients with mTC compared to patients without BM. Additionally, non-seminomatous and mixed germ cell histology were associated with significantly worse outcomes compared to seminoma. These findings highlight the importance of aggressive, tailored treatment strategies to address the higher mortality risk posed by BM in patients with intermediate and poor risk metastatic testicular cancer. Research Sponsor: None.

Use of GIP and GLP-1 receptor agonists in prostate cancer patients. First Author: Amy L. Shaver, Department of Medical Oncology, Thomas Jefferson University, Philadelphia, PA

Background: The use of glucagon-like peptide 1 receptor agonist (GLP-1 RA) and dual glucose-dependent insulinotropic polypeptide (GIP) and GLP-1 RA (GIP/GLP-1 RA) classes has increased over the past several years. The GLP1 receptor is expressed in metastatic prostate tissue, and GLP-1 RA and GIP/GLP-1 RA medications may have an impact on prostate cancer (PCa) outcomes. However, a use analysis among patients with prostate cancer in a large, diverse, current, real-world database has not been published. **Methods:** This national, retrospective study analyzed adult patients in the Epic Cosmos database with an active diagnosis of PCa who initiated a GLP-1 RA or GIP/GLP-1 RA medication from January 1, 2015, to December 31, 2024. The primary endpoint was percent use and change in use over time. Secondary endpoints included factors associated with use. Data were reviewed from Epic Cosmos, a Health Insurance Portability and Accountability Act-defined limited data set using deidentified electronic health record (EHR) data from more than 293 million patients served by 1,633 hospitals and more than 37,900 clinics. **Results:** This study includes 1,533,762 patients with a median age of 75. 30.3% (464,477) of the patients had a concurrent diagnosis of T2DM. The percentage of PCa patients utilizing a GLP-1 RA or GIP/GLP-1 RA increased from 0.43% in 2015 to 6.1% in 2024. Odds of receiving a GLP-1 RA or GIP/GLP-1 RA in PCa patients with a T2DM diagnosis were higher among those with a low social vulnerability index (SVI) percentile (<25) compared to patients with an SVI 75 or above (OR 1.20, 95% CI 1.16, 1.24) and among obese compared to non-obese (OR 1.88, 95% CI 1.85, 1.90). Odds were lower in PCa patients with T2DM 65 years and above compared to those under 65 (OR 0.41, 95% CI 0.40, 0.42). Odds of an opioid medication were higher in T2DM PCa patients receiving a GLP-1 RA or GIP/GLP-1 RA compared to those who weren't (OR 1.14, 95% CI 1.12, 1.16). While most PCa patients who received a GLP-1 RA or GIP/GLP-1 RA had T2DM, the percentage with neither T2DM nor obesity has increased (Table 1). **Conclusions:** This study showed that GLP-1 RA and GIP/GLP-1 RA use is on the rise. Use is associated with age and social vulnerability and may impact opioid receipt. Ongoing and future investigations examine the impact of GLP-1 RA and GIP/GLP-1 RA use on PCa progression. Research Sponsor: U.S. National Institutes of Health; 5P30CA056-036; U.S. National Institutes of Health; 1L30CA284329-01.

PCa patients receiving GLP-1 RA or GIP/GLP-1 RA by year.

Year	PCa	T2DM*	BMI ≥30*	No T2DM+BMI<30*
2016	2,085	1,905 (91.37)	1,497 (71.80)	31 (1.49)
2017	3,436	3,168 (92.20)	2,448 (71.25)	50 (1.46)
2018	5,594	5,183 (92.65)	3,946 (70.54)	77 (1.38)
2019	8,594	7,975 (92.80)	5,861 (68.20)	109 (1.27)
2020	11,881	11,086 (93.31)	7,494 (63.08)	129 (1.09)
2021	18,460	17,033 (92.27)	11,820 (64.03)	298 (1.61)

5025 Poster Session

Barbados' first next-generation sequencing of a prostate cancer sample. First Author: Joanne Nicholls, Columbia University, New York, NY

Background: According to the WHO (2022), Prostate cancer is the most frequent of all cancers in Barbados. In 2022, it accounted for over 45% of the reported cancer cases on the island, second being colorectal cancer at an alarming, contrasted prevalence rate of 13.5%. Today, cancer is fought at the cellular level across the globe. Reportedly nearly 40% of prostate cancer may be attributed to inherited genetic susceptibility, yet only hand full of clinically relevant genes have been associated with risk and/or adverse outcomes after diagnosis with this type of cancer (NCI, 2025). NGS is not widely available in Barbados. The primary aim of this research was to evaluate the feasibility of providing Next Generation Sequencing capability to the patients and practitioners on the island and to discover more about the genomics of the prostate cancer present on the island at molecular, ethnic, and geographic levels. **Methods:** A genomic sequencing protocol was conducted to determine the feasibility of delivering Next Generation Sequencing to patients receiving oncological care on the island. A Barbadian multi-disciplinary team inclusive of a pathology group, prostate cancer surgical center and healthcare system partnered with their South American medical equipment distributor and a global genomics and human health innovation company to conduct the pilot study. Forty prostate cancer archive tissue samples were identified from a local tissue bank. The samples were donated to future use research by previously treated surgical cases. Patients provided written consent to future use research. Of the forty samples, 25 were batched and shipped to a genomics laboratory for DNA extraction. DNA was then shipped to Illumina Laboratories in Baltimore where the NGS sequencing was performed. The OncoReveal Multi-Cancer with CNV & RNA Fusion Panel on the Illumina MiniSeq system was utilized. **Results:** OncoReveal Multi-Cancer with CNV & RNA Fusion Panel had the capability to detect 60 variants and CNVs detected from DNA. Of the 25 cases sequenced, new actionable data were found on 52% (13 of 25) with 33.3% (3 of 12) of tests detecting a ATM. The remaining data found following variants APC, CDKN2A, JAK3 V722I, PIK3CA, TP53, PTEN, SMO, CDKN2A, TP53, ERBB2 and PTEN. All of which were 7.6% (1of 13) in therapeutics actionability. **Conclusions:** Next Generation Sequencing in Barbadian men is not performed as part of routine diagnostic care due to a lack of access to this companion diagnostic resource. Providing NGS to local patients was proven to be feasible utilizing a central laboratory transport and testing model. OncoReveal Panel performed on a random sample revealed new actionable data were found on 52% (13 of 25) with 33.3% (3 of 12) of tests detecting a ATM. This suggests approximately 50% of this male population may find clinical utility in the use of NGS as a companion diagnostic and more research is needed in the region to better understand the high prevalence of the ATM variant. Research Sponsor: None.

BEP in intermediate- and poor-risk advanced non-seminomatous germ cell tumor (NSGCT): Standing the test of time. First Author: Aditya Dhanawat, Advanced Centre for Treatment, Research and Education in Cancer (ACTREC), Tata Memorial Centre, Mumbai, India

Background: Bleomycin, etoposide, and cisplatin (BEP) has been the cornerstone of treatment for advanced NSGCT for decades. With the advent of newer regimens such as VIP (Etoposide, ifosfamide and cisplatin) and improved outcomes over the years, it is imperative to assess whether BEP has truly stood the test of time, especially for those in the intermediate and poor risk. **Methods:** This was a retrospective analysis of a prospectively collected dataset of NSGCT patients treated at a comprehensive cancer care centre in India. Adolescent and adult males with intermediate or poor-risk as per IGCCCG were included. The progression-free survival (PFS) and overall survival (OS) were calculated from date of diagnosis to date of progression and death respectively. Log-rank method was used to compare outcomes between BEP and VIP. **Results:** A total of 351 patients were analysed. The median age was 28 years (IQR: 23-34 years) (Table 1). Primary high-inguinal orchidectomy (HIO) was done in 208 (59.3%) and after completion of chemotherapy in 63 (17.9%) patients. There were 209 (59.5%) patients with poor-risk. Forty-seven (13.4%) received less than 4 cycles of chemotherapy. Retroperitoneal lymph node dissection (RPLND) was done in 195 (55.6%) patients. Overall, 45 (12.8%) patients had toxicities requiring hospitalization. Viable residual disease was seen in 33 (9.4%) patients. The median follow-up of the cohort was 58.9 + 3.6 months (95% CI: 51.9 – 65.9 months). Patients who received BEP had better 7-year PFS (68.4% vs 47.5%, p< 0.001) and 7-year OS (77.9% vs 55.2%, p<0.001) as compared to VIP albeit higher lung toxicities and deaths due to chemotherapy. The cohort which received VIP had higher percentage of smokers, mediastinal primary, visceral metastases and S3 tumor markers. **Conclusions:** BEP has stood the test of time and remains the standard of care. However, for patients who are smokers, or have aggressive disease, VIP is a good alternative. Research Sponsor: None.

Epidemiology, treatment patterns, and survival outcomes of spermatocytic seminoma: A National Cancer Database analysis. First Author: Nikhil A Furtado, Creighton University School of Medicine, Omaha, NE

Background: Spermatocytic seminoma (SS) is a rare germ cell tumor, representing 2-5% of seminomas. Unlike classical seminomas, SS primarily affects older men (median age: 55 years) and exhibits low metastatic potential, though rare sarcomatoid transformations can lead to aggressive behavior. Treatment typically involves orchiectomy, with adjuvant therapies reserved for advanced cases. Despite its distinct clinical behavior, SS remains understudied, with limited data on its epidemiology, demographic patterns, and socioeconomic influences. Leveraging the National Cancer Database (NCDB) could provide critical insights into its epidemiology and management. **Methods:** A retrospective cohort study using the 2004–2020 NCDB identified patients with histologically confirmed SS (ICD-O-3 code 9063). Demographic, socioeconomic, and clinical variables were analyzed descriptively, with incidence trends evaluated via regression analysis. **Results:** A total of 541 patients with histologically confirmed SS were identified in the NCDB from 2004–2020. The incidence rate remained stable (R^2 = 0.012). All patients were male, with a mean age of 58.9 years (SD = 16.6). The cohort was predominantly White (91.5%) and non-Hispanic (89.6%), with 49.2% privately insured and 38.6% covered by Medicare. Most patients (55.1%) resided in metropolitan areas, and treatment was primarily delivered at comprehensive community cancer programs (43.5%) and academic/research programs (26.1%). Most patients (67.8%) were diagnosed at Stage I, with 82.4% having a Charlson-Deyo comorbidity score of 0. Surgery was performed in 98.9% of cases, with 95.2% achieving no residual tumor. Radiation therapy (18.3%) and chemotherapy (5.9%) were rarely used. The 30-day mortality rate was 0.6%, and the 90-day mortality rate was 1.0%. Survival rates were 98.0% (2-year), 96.0% (5-year), and 91.5% (10-year). **Conclusions:** This represents the first NCDB in-depth demographic analysis of spermatocytic seminoma (SS), addressing a significant gap in the literature on this rare malignancy. The study shows that SS predominantly affects males, with a strong predilection for non-Hispanic White individuals, consistent with prior case reports and small-scale studies. Additionally, this analysis provides novel insights into the socioeconomic profile of SS patients, revealing a tendency toward higher income brackets, residence in urban metropolitan areas, and treatment at community-based cancer programs rather than academic institutions. Future research should explore how demographic and socioeconomic factors influence diagnostic pathways, treatment decisions, and survival outcomes in this patient population. Research Sponsor: None.

Racial and socioeconomic disparities in testicular cancer survival outcomes: A SEER database analysis. First Author: Charmi Bhanushali, Saint Vincent Hospital, Worcester, MA

Background: Testicular cancer, the most common malignancy in men aged 15 to 45 years, has a high cure rate exceeding 95% with early diagnosis and proper treatment. However, these favorable outcomes are not equitably distributed across all racial and socioeconomic groups. This study aims to analyze these disparities in testicular cancer survival outcomes from 2014 to 2021. **Methods:** The Surveillance, Epidemiology, and End Results (SEER) database was queried to identify patients diagnosed with testicular cancer (ICD-O-3 site codes C620-C629) from 2014 to 2021. Variables including stage, treatment, ethnicity, income level, and geographic location (urban/rural) were extracted. Patients with missing data were excluded from the analysis. Statistical methods included chi-square tests, Kaplan-Meier survival curves, and Cox proportional hazards models. Analyses were conducted using R (v4.4.1). **Results:** A total of 20,508 patients were included in the study. The population was predominantly White (87%), followed by Asian/Pacific Islanders (5%) and African Americans (3%). The majority of patients were aged 20–39 years (60%), with T1 disease (42.89%) and no nodal involvement (N0-53.93%). Seminomas accounted for 52.7% of cases, followed by mixed germ cell tumors (25.88%) and embryonal carcinoma (7.73%). Primary treatments included surgery (95%) and chemotherapy (38%). Advanced disease stages (T3–T4, M1, Stage II–III) and extensive nodal involvement were significantly associated with poor survival outcomes ($p<0.001$). Multivariate stratified analyses revealed higher overall mortality (OM) among African Americans (HR = 1.75, $p < 0.001$) and Asian/Pacific Islanders (HR = 1.25, p = 0.003) compared to White patients. The Hispanic population exhibited an 8.8% higher hazard compared to non-Hispanics (HR = 1.088, p = 0.02). Patients with annual incomes below $40,000 had significantly elevated OM (HR = 2.41, $p < 0.001$), whereas those with incomes of $120,000 or more demonstrated better survival outcomes (HR = 0.77, p = 0.019) compared to the reference group ($40,000- $120,000). Multivariate analyses of cancer-specific mortality (CSM) revealed similar findings, with African American patients (HR = 1.69, $p < 0.001$) and individuals in lower-income brackets (HR = 2.12, $p < 0.001$) experiencing worse outcomes. **Conclusions:** This study highlights racial and socioeconomic disparities in testicular cancer survival outcomes, with African American patients and individuals in lower-income brackets experiencing significantly worse overall and cancer-specific mortality. It underscores the need for future research to investigate structural inequities and insurance-related barriers contributing to these disparities and develop actionable strategies to achieve equity in cancer outcomes. Research Sponsor: None.

Therapeutic decisions and outcome of patients with stage I testicular germ cell tumor: Single-centre experience. First Author: Isabella Cavaglià, Università degli studi di Torino, Torino, Italy, Italy

Background: Testis cancer (TC) is the most common solid neoplasm affecting men aged 15 to 40, with most of diagnosis occurring at stage I. Despite excellent prognosis, optimal post-surgical management remains controversial, comprising adjuvant therapy (AT) or active surveillance (AS). **Methods:** Our study aimed to compare relapse-free survival (RFS) in patients (pts) with stage I TC undergoing AT [chemotherapy (CT) or radiotherapy (RT)], versus AS, between 2000 and 2023. Evolution of AT choices for seminomas was evaluated over different time periods (before 2014, 2014-2018, after 2018). Clinical histories of stage I TC treated at our institution were retrospectively collected. Traditional histopathological prognostic factors for relapse were assessed, and seminomas were reclassified according to the new EAU risk group classification. Overall survival (OS) was a secondary endpoint. Pts with inadequate follow-up, insufficient information, or histologies other than seminoma and nonseminoma were excluded. **Results:** Out of 240 cases, 184 (129 seminomas, 54 non-seminomas, 1 burned-out tumor) were eligible. AT was administered to 58.1% of seminomas and 57.4% of nonseminomas. In seminomas, AT was represented by CT in 40.3% and RT in 17.8% of cases. RT administration significantly decreased over time, representing 66.7% of AT before 2014, 9.1% between 2014 and 2018, and 0% after 2018. With a median follow-up of 56.9 months, 5-yr RFS rate was 94.6% and 84.7% for pts undergoing AT and AS, respectively (p=0.005). Particularly, 5-yr RFS rate was 92.5% vs 86.7% in seminomas (p=0.07), and 100% vs 79.9% in nonseminomas (p=0.015). Proportion of seminomas undergoing AT was 20.7% among those with $T<4$ cm and no rete testis invasion, 56.4% among those with 1 risk factor, and 82.2% among pts with 2 risk factors. AT was received by 3.2% and 96.8% of nonseminomas without and with lymphovascular invasion, respectively. In the new EAU classification, 31.4%, 48.8% and 19.8% of seminomas were classified into the very low, low, and high risk categories (8 cases not evaluable). Compared to the traditional classification, a lower proportion of pts resulted in the poorest risk category (19.8% vs 34.9%). AT receipt significantly increased with risk: very low 27.0%, low 67.8%, high 83.3% ($p<0.001$). 5-yr OS rate was 98.1% (99.1% in seminoma and 95.1% in nonseminoma). **Conclusions:** AT was associated with higher RFS rates across both histological types. AS and AT are both associated to excellent survival. A temporal trend in reduction of RT was observed. Further evaluations are needed to individualize treatment decisions. Histopathological risk factors and the new EAU risk classification provide valuable prognostic information, aiding in treatment stratification. Additionally, the EAU risk group classification emerges as a potential tool to better stratify seminoma pts and support the implementation of AS in lower risk categories. Research Sponsor: None.

Risk factors and causes of early death among patients with germ cell testis tumors (GCTs): An international collaborative study supported by the Global Society of Rare Genitourinary Tumors. First Author: Michal Mego, Department of Oncology, Faculty of Medicine, Comenius University and National Cancer Institute, Bratislava, Slovakia

Background: GCTs are the most common solid tumor in young men aged 20 to 40 years and are curable in most cases. However, a small proportion of patients with very advanced or aggressive disease, die early after starting chemotherapy. These patients are often not included in clinical trials and therefore accurate data on their risk factors and causes of death are critically lacking. **Methods:** This retrospective cohort study included patients with GCTs who died within 3 months from the completion of first-line systemic chemotherapy. Anonymized patients were included in an international database from tertiary cancer centers. Inclusion criteria were age $\geq$18 years, diagnosis between 2000-2024, death within 3 months from the last cycle of first-line chemotherapy, and treatment with systemic anticancer therapy and/or intention to treat. The database included data on patient and tumor characteristics, treatment and outcomes. **Results:** We identified 94 patients who experienced early death. Majority had IGCCCG poor prognosis and 16 (17%) had extragonadal GCTs. The proportion of these patients ranged from 0.4% to 2.1% of all patients treated with first line chemotherapy. Median time from starting of platinum based-therapy to death was 32 days (range: 2-301 days). Initial chemotherapy dose was reduced in 44.3% of patients. The most common causes of death were acute respiratory failure (ARF) due to acute respiratory distress syndrome (35.1%), disease progression (18.1%), febrile neutropenia (FN) with septic shock (13.8%), fatal extrapulmonary hemorrhage (13.8%), venous thromboembolism and myocardial infarction, each with an incidence of 2.1%. Approximately 11.7% of patients died from other causes and in 3.2% of cases the cause of death remains unknown. Factors associated with ARF development were older age (median age 43 years), lung involvement >50%, resting dyspnea and hemoptysis, but not choriocarcinoma histology, and less likely received bleomycin and/or initial dose reduction. Death within 30 days from starting chemotherapy (n=47, 50.0%) was associated with liver metastases, lung involvement >50%, beta-HCG > 50,000 mIU/mL, ECOG performance status 2-3, higher neutrophil/lymphocyte ratio and intensive or ventilated care (all $p<0.05$). Beyond ARF, fatal extrapulmonary hemorrhage (19.6%) and FN with septic shock (17.4%) were the most common cause of death within 30 days of starting therapy, while disease progression (29%) was more common in patients who died later. **Conclusions:** The proportion of patients with early death is low, but this group presents significant clinical challenges. Among advanced GCTs, high beta-HCG levels, liver metastases, massive lung involvement, poor ECOG and/or need of intensive care are associated with a higher risk of early death and need targeted intervention to improve their therapeutic outcomes. TROP-2 expression in germ cell tumors (GCT). First Author: Noah Richardson, Indiana University Melvin and Bren Simon Comprehensive Cancer Center, Indianapolis, IN

Background: Trophoblast cell surface antigen 2 (TROP-2) is a tumor associated antigen overexpressed in several malignancies including breast and urothelial cancer. The TROP-2 antibody-drug conjugate (ADC) Sacituzumab govitecan is approved for treatment of metastatic breast cancer. The expression of TROP-2 in GCT is unknown. We present immunohistochemistry results of TROP-2 expression in GCT. **Methods:** Patients who underwent resection for GCT at Indiana University were included. Sixty formalin-fixed paraffin-embedded (FFPE) GCT samples were available. FFPE slides were selected from differing GCT histology and surgical sites including primary tumor, retroperitoneal lymph node, and distant metastases. Immunohistochemical (IHC) staining for TROP-2 (clone 1, mouse monoclonal, Enzo Life Sciences) was conducted and scored by intensity on a 0-3 scale by an experienced pathologist. **Results:** Samples from 60 individual specimens were available for IHC analysis. TROP2 expression was detected in 29 (48%) of these samples. Intensity expression differed from pure seminoma, mixed non-seminoma (NSGCT), teratoma, yolk sac tumor, and choriocarcinoma samples. Both primary and metastatic samples had TROP-2 expression of varying degrees. **Conclusions:** TROP-2 expression varies across histology in GCT. Seminoma appears to have the lowest expression of TROP-2. Higher TROP-2 expression was noted in choriocarcinoma and yolk sac tumor samples indicating potential as a target in these histologic subtypes in future clinical trials. Research Sponsor: John Cleland Fellowship.

Detectable TROP-2 by histology.

Sample histology (N)	Total detectable TROP-2 expression (%)	3+	2+	1+
Seminoma (20)	3 (15)		2	1
NSGCT (19)	12 (63)	9 (6*)	2*	1*
Teratoma (9)**	6 (66)	3*	3*	
Yolk sac (9)	5 (56)	2	3	
Choriocarcinoma (3)	3 (100)	1	1	1

*In epithelial elements of teratoma.

**Three negative samples with only small fragments of teratoma and false negative may be present.

Clinical utility of a tumor-naïve circulating tumor DNA (ctDNA) test to predict outcomes in patients with advanced testicular germ cell tumors. First Author: Vitor Fiorin de Vasconcellos, Instituto do Câncer do Estado de São Paulo, São Paulo, Brazil

Background: Serum tumor markers (STM) used in the management of Testicular Germ Cell Tumors (TGCT) lack sufficient specificity and are not altered in up to 60% of patients (pts). We evaluated the clinical utility of a tumor-naïve ctDNA test to predict outcomes in pts with advanced TGCT. We also analyzed the correlation between ctDNA detection and STM levels. **Methods:** Blood samples were collected from 31 pts before and after first-line treatment (chemotherapy, primary radiotherapy or retroperitoneal lymphadenectomy). ctDNA detection was performed using a ddPCR assay to identify copy number gains in chromosome 12p, present in 90% of TGCTs. Progression-free survival (PFS) and overall survival (OS) were estimated using the Kaplan-Meier curves and the log-rank test. The correlation between ctDNA status and STM alterations was analyzed using Pearson's correlation test. **Results:** The median age of participants was 31 years, 81% were non-seminoma, 48% stage III, 45% IGCCCG intermediate-poor risk, 39% Sx-S0 stage, 83% received first-line chemotherapy, and the median follow-up time was 53 months. The ddPCR assay showed 88% sensitivity and 100% specificity for ctDNA detection. ctDNA detection before first-line treatment significantly correlated with altered LDH levels (r=0.78, $p<0.001$) but did not correlate with altered AFP (r=0.33, p=0.16) or bHCG levels (r=-0.03, p=0.88). Detection of ctDNA before first-line treatment was significantly associated with a shorter 2-year PFS rate (ctDNA positive 64% vs. ctDNA negative 100%, p=0.022) and 2-year OS rate (ctDNA positive 64% vs. ctDNA negative 100%, p=0.014). None of the patients who tested negative for ctDNA detection experienced disease progression or died. Elevated STM levels before first-line therapy were not significantly associated with PFS (p=0.07) or OS (p=0.053). Detection of ctDNA after first-line therapy did not significantly correlate with PFS (p=0.27) and OS (p=0.29), and was not predictive of viable tumor or teratoma in the surgical specimen. **Conclusions:** This is the first study to use a tumor-naïve ctDNA test to assess outcomes in pts with TGCT. ctDNA detection before first-line therapy may serve as a valuable prognostic biomarker, complementing STM for pts with advanced TGCT. Further prospective studies are needed to validate our findings. Research Sponsor: Hospital Sírio-Libanês.

Initiation of high dose chemotherapy at rising tumor markers compared with radiographic progression in patients with relapsed germ-cell tumors (GCT). First Author: Rebecca Hassoun, Indiana University Melvin and Bren Simon Comprehensive Cancer Center, Indianapolis, IN

Background: Patients with GCT who relapse after first-line therapy can be cured with salvage high-dose chemotherapy (HDCT). We evaluate the outcomes of patients who received HDCT based on tumor maker rise only compared to radiographic progression only or both. **Methods:** The Indiana University Testicular Cancer database was queried for pts with GCT who were treated with salvage HDCT between 2004-2024. 2-yr progression free survival (PFS) and overall survival (OS) were analyzed among subgroups of patients who had tumor markers rise only (group 1) at start of HDCT compared to those who had radiological progression only or both (group 2). The Kaplan-Meier method was used to analyze PFS and OS. Comparisons between groups were done using the log-rank test. **Results:** 316 pts with GCT treated with salvage HDCT between March 2004 and May 2024 and had detailed information regarding progression leading to HDCT were included. Median age was 32.05 (16-70). Histology was non-seminoma in 237 (75.0%) pts and seminoma in 79 (25.0%) pts. Primary site was testis in 273 (86.4%) pts, retroperitoneum in 20 (6.3%) and mediastinum in 23 (7.3%). 156 (49.4%) pts had IGCCCG good risk disease at diagnosis, 28 (8.9%) had intermediate risk disease, and 132 (41.8%) had poor risk disease. 101 (32.0%) patients were platinum refractory at start of HDCT. HDCT was 2nd line therapy in 264 (83.5%) pts, 3rd line in 49 (15.5%), 4th line in 2 (0.6%) and 5th line in 1 (0.3%). At initiation of HDCT, 98 (31.0%) pts had tumor marker (AFP and/or hCG) rise only, 69 (21.8%) had radiographic progression only, and 149 (47.2%) had both. Median follow-up from start of HDCT was 3.67 years (0.03-19.5). For the overall population, 2-yr PFS was 62.4 with 95% CI (56.7-67.5) and 2-yr OS was 71.9 with 95% CI (66.3-76.8). 60 (59.4%) of patients in group 1 had platinum refractory disease compared to 41 (40.6%) in group 2. 2-yr PFS for group 1 was 44.8% (34.6-54.4%) vs 70.3% (63.6-76%) for group 2 ($P<0.001$). 2-yr OS was 58.8% (47.5-68.6%) for group 1 vs 77.4% (70.9-82.7%) for group 2 (P=0.001). **Conclusions:** Patients with relapsed GCT with rising tumor markers only at time of initiation of salvage HDCT had inferior 2-yr PFS and OS likely due to higher rates of platinum refractory disease in this population. Research Sponsor: None.

Treatment of poor-risk non seminomatous germ-cell tumors (NSGCT) adapted by tumor marker decline: A 7-year multicenter real-world experience. First Author: Sara Faouzi, Gustave Roussy, Villejuif, France

Background: Since 2014, adaptation of chemotherapy based on tumor marker decline after the cycle of BEP (Bleomycin, Etoposide, Cisplatin) is a standard for patients with IGCCCG poor-risk NSGCT based on data from the GETUG-13 phase 3 trial (Fizazi et al, Lancet Oncol 2014; J Clin Oncol 2024). The aim of this multicenter study was to evaluate the GETUG-13 algorithm when used in routine practice. **Methods:** We collected data from all poor-risk NSGCT patients treated consecutively in 13 expert centers from 2013 to 2019. After one cycle of BEP, tumor marker levels were assessed at day 18-21. Pts with a favorable decline continued with BEP for 3 additional cycles (Fav group), whereas those with an unfavorable decline received up to 4 cycles of dose-dense chemotherapy (Unfav group). Data was analysed descriptively, and the Kaplan-Meier method was used to estimate progression-free (PFS) and overall survival (OS). **Results:** Data from 146 patients were collected (46 with PS $\geq$ 2, 35 with mediastinal NSGCT): 111 (76%) had an Unfav decline and 35 (24%) had a Fav decline. More pts with hCG $>$ 50 000 UI/L and AFP $>$ 10 000 were in the Unfav group (44.9% vs 17.6%, p=0.0045, and 26.9% vs 8.8%, p=0.0282). Surgery of residual masses was performed in 85.7% and 74.3% in the Fav and Unfav groups, and the procedure was complete in 83.3% and 59%, respectively. With a median follow-up of 5.8 years (95% CI,63.2-77.2), 5-year PFS rates were 68.6% (95% CI, 50.5-81.2) and 61.1% (95% CI, 51.2-69.6) in the Fav and Unfav groups, respectively. Five-year OS rates were 73.8% (95% CI, 55.6-85.4) and 64.6% (95% CI, 54.6; 73.0), respectively. In the short term, neuropathy, anemia and thrombopenia were more frequent in the Unfav group. Treatment-related deaths were reported in 2 (5.7%) and 5 (4.5%) (including 2 post-surgery deaths) pts in the Fav and Unfav groups, respectively. Peripheral neuropathy evolved favorably, with 4 (5.9%), 2 (3.8%) and no pts in the Unfav group reporting grade 3 toxicity at 6 months, 1 year and at last follow-up, respectively. Long-term side effects were infrequent with only one pt with grade 3 cardiovascular toxicity in the Unfav group. Late grade 2 toxicities included cardiovascular toxicity (1.4%), hypoacousia (1.4%), peripheral neuropathy (4.2%), chronic renal failure (CRF) (9.9%) in the Unfav group, and grade 2 CRF (8.3%) in the Fav group. In both groups, almost 80% pts had returned to work. Among pts with progression or relapse, salvage high-dose chemotherapy with stem-cell transplant was used in 4/11 (36.4%) and 13/33 (43.3%) in the Fav and Unfav groups, respectively. **Conclusions:** The GETUG-13 algorithm can be safely used in routine practice by expert centers, with a high cure rate similar to that reported in the original phase 3 trial and rare long-term toxicity. This data confirms that this algorithm is standard for poor-risk NSGCT. Research Sponsor: None.

Predicting teratoma histology in postchemotherapy residual lesions of non-seminoma testicular cancer (NSTC) patients using integrated CT radiomics and circulating MicroRNAs modelling. First Author: Guliz Ozgun, British Columbia Cancer Agency, Vancouver, BC, Canada

Background: Chemotherapy is the primary treatment for metastatic NSTC, but patients often have residual masses afterward. Accurate non-invasive models are needed to predict the histology of these masses, guiding treatment and reserving surgery for those with teratoma. This study aims to enhance predictive accuracy by integrating CT-driven radiomics features with miRNAs 371 and 375 (miR371-375) to distinguish between teratoma and non-teratoma histologies in post-chemotherapy residual masses. **Methods:** We retrospectively reviewed 52 patients with teratoma (n=56), fibrosis/necrosis (n=34), vGCT (n=11), and seminoma (n=10) lesions, divided into training (N=78) and test (N=33) cohorts with equal class distribution. Lesions included lymph nodes (n=68 retroperitoneum, n=11 mediastinum, n=4 pelvic, n=4 neck), lung (n=21), and brain (n=3) with a median size of 1.6 cm (Q1-Q3 interval=1.2-2.73 cm). Using 3D Slicer version 5.6.1, metastatic masses $>$1 cm (short axis) were segmented and radiomics features were extracted from venous phase CT images. Plasma miR371 and miR375 levels were measured by RT-PCR before resection. Four machine learning models evaluated the predictive value of radiomics alone (R-only) and combined with miR371/miR375 levels for teratoma histology, and the best performer, Cat Boosting (CB) method, is reported. **Results:** The analysis of datasets revealed a consistent pattern of superior performance in training sets compared to test sets across all metrics. The CB model R+371+375 dataset demonstrated the most robust overall performance, with the highest AUC values (0.96 [95% CI 0.88-1.0] for training, 0.83 [95% CI 0.68-0.98] for test) and a well-balanced sensitivity (0.71) and specificity (0.76) in the test set for predicting teratoma histology. R+375 followed closely with an AUC of 0.82 (95% CI 0.66-0.97). **Conclusions:** Combining miR 371 and 375 with CT-driven radiomics features improves the accuracy of classifying teratoma histology in metastatic NSTCs. This method can help characterize teratoma in residual metastatic disease, aiding treatment decisions and minimizing under or over-treatment risks. Further refinement, including the integration of clinical features, will be reported. Research Sponsor: None.

Survival outcomes of patients with mNSGCTs with and without teratoma in the primary tumor: An international retrospective study. First Author: Manuel Pedregal, Hospital Universitario Fundación Jimenez Diaz, Madrid, Madrid, Spain

Background: Recent studies have reported conflicting findings on the outcomes of patients with metastatic nonseminomatous germ cell tumors (mNSGCT) and the presence of teratoma in the primary tumor. To further investigate this association, we conducted an analysis using data from a distinct multicenter hospital databases. **Methods:** Clinical-pathological data of mNSGCT patients whose primary tumors were available for histologic review and who underwent cisplatin based chemotherapy between 1992-2014 were retrospectively collected from the IRB approved Dana Farber Cancer Institute (DFCI), Vall D'Hebron University Hospital (VHIO), University Hospital Virgen Del Rocio (HUVR) and Instituto Nacional Cancerologia (INC), GCT databases. We stratified NSGCT patients by the presence or absence of teratoma in the primary tumor(T+ vs T-) Demographic, clinical and pathological characteristics were analyzed using X2 test for categorical variables and T test for continuous variables. Kaplan-Meier methods estimated survival. **Results:** A total of 662 patients were included with a median follow-up of 8 years. 305 (46.1%) patients had teratoma in the primary tumor. Median ages were 28,7 (+- 8,61) and 31,0 years (+- 9,19) in T+ in T- groups respectively. The T+ group was more likely to have a testicular primary (94,4% vs 86,3%, p=0.003). There were no major differences in IGCCCG risk between the two groups, T+ vs T-, good: 155 (50,8%) versus 190 (53.2%); intermediate: 75 (24,6%) versus 60 (16,8%); poor: 66 (21,6%) versus 87 (24,4%), p=0.041. First line chemotherapy consisted of bleomycin, etoposide and cisplatin (BEP) in 233 (76,4%) and 286 (80,1%) of each group. The T+ group had more post- chemotherapy retroperitoneal lymph node dissections and other local resections n=211, 69,2% (95% CI: 59% - 74%) compared to the T- group n=160, 44,8% (95% CI: 37%-50%). There was no significant diference in 10-year survival between T+ and T- patients 79% (95%CI: 77% - 89%) vs. 82% (95% CI: 80% - 91%), p= 0,976 (log-rank). **Conclusions:** The presence of teratoma in the primary tumor was not an adverse prognostic factor in a series of 662 patients with mNSGCT with a median follow-up of 8 years treated in the modern era with predominantly BEP. Longer follow-up beyond 10 years is needed to see if there is an increased incidence of teratoma related deaths in patients with T+. Research Sponsor: None.

Bilateral germ cell tumor of the testis (TGCT): Implications for a stem cell versus genetic origin of cancers. First Author: Jamaal Christopher Jackson, Department of Urology, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Bilateral TGCT provides a unique opportunity to elucidate a stem cell versus genetic origin of cancer. Comparison of the epigenetics and genetics of disparate tumors in either synchronous or metachronous bilateral TGCT from the same patients is feasible and may be informative. **Methods:** We examined the clinical characteristics and natural history of 38 patients with bilateral TGCT. We performed reduced representation bisulfite sequencing (RRBS) of FFPE DNA and whole exon sequencing (WES) of 9 of those patients whose tumor samples were available for the study. **Results:** From the database at MDACC, we identified 38 patients with bilateral TGCT, who underwent their first orchiectomy between January 1984 and April 2022 and the second between August 1997 and April 2022. Median follow-up was 134.2 months (IQR 69.5–222.1 months). Seven patients had synchronous, while 31 had metachronous bilateral TGCT. There were 13 bilateral seminomas, 14 bilateral nonseminomas, and 11 bilateral seminoma and nonseminoma. For those patients with metachronous bilateral TGCT, the median time between the two TGCT was 47.7 months (IQR 19.6–108.9). Out of approximately 20,000 genes investigated, 189 ($<$1%) had a detectable mutation in the 9 paired cases (n=18). A total of 8 genes were mutated in more than 1 sample, including KIT (n=4, 22%) and KRAS (n=6, 33%). Among the 4 bilateral TGCT showing a similar methylation profile in the RRBS analysis, the pattern of single nucleotide variants and type of specific genetic mutations were dissimilar between the right and left TGCT from the same patients in the WES study. Among the 5 bilateral TGCT that did not cluster in the RRBS study, there was differential methylation of the JUP and MAGE-A4 genes between the right and left TGCT from the same patients. **Conclusions:** The clinical course of our patients with synchronous and metachronous bilateral TGCT and the results of our RRBS and WES reaffirmed that a preponderance of TGCT was curable and suggested that epigenomic findings may supplement, if not complement, genomic data to elucidate a stem-cell versus genetic origin and nature of GCT and cancers in general. Spatial transcriptional dynamics of CD74$^+$ B cells in tertiary lymphoid structures and effects on immune evolution in penile squamous cell carcinoma. First Author: Zaishang Li, Shenzhen People's Hospital, Shenzhen, China

Background: Antitumor immunity has become a critical focus in improving Penile squamous cell carcinoma (PSCC) patient outcomes. Among various immune features, tertiary lymphoid structures (TLS) have emerged as crucial players in tumor immunity. Nevertheless, the specific role of B cells within TLS and their interaction with naive T cells in PSCC remain largely unclear. Therefore, this study aims to elucidate the role of CD74$^+$ B cells in TLS and their impact on immune regulation in PSCC. **Methods:** Spatial transcriptomics produced 519,608 cellular profiles from tumor samples of 18 patients. Additionally, scRNA-seq on tissues from 21 patients yielded 150,540 cells. Bulk RNA-seq was performed on tissues from 55 patients. TLS were identified and visualized using the DBSCAN algorithm, which clusters B cells, T cells, and DCs. Survival analyses were conducted to examine the association between TLS density and patient outcomes. Moreover, immune activity and cell infiltration were assessed via AUCell and CIBERSORT, while pseudotime analysis was used to explore dynamic gene expression changes during cell development. Additionally, pathway enrichment analysis identified key signaling pathways, and intercellular signaling was analyzed through cell communication models. **Results:** TLS, accurately identified using the DBSCAN algorithm, were significantly associated with improved prognosis in PSCC patients (Internal cohort, n = 152, $P < 0.01$; External cohort, n=63, $P < 0.05$). The spatial distribution, a high density of B cells was observed within the TLS regions. Notably, CD74$^+$ B cells were enriched within TLS, particularly during early developmental stages. Mapped the spatially in situ developmental trajectory of CD74$^+$ B cells and uncovered the dynamic changes in gene expression throughout their maturation process, we observed that CD74$^+$ B cells within the TLS of PSCC patients predominantly exhibited features of early developmental stages. In line with this, scRNA-seq data further validated these observations. These cells, through their HLA molecules, interacted with CD4/CD8 ligands on naive T cells, thereby activating critical transcription factors such as NFKB1, NFKB2, NFATC1, NFATC2, FOS, and RUNX1. This interaction ultimately amplified immune responses within the tumor microenvironment. Furthermore, patients with higher CD74$^+$ B cell expression exhibited better responses to immunotherapy (pCR : $P < 0.01$and CR: $P < 0.01$) and underscoring the therapeutic relevance of these cells. **Conclusions:** By activating naive T cells through antigen presentation, CD74$^+$ B cells within TLS significantly enhance local immune responses in PSCC. Thus, CD74$^+$ B cells not only serve as a promising biomarker but also represent a potential therapeutic target, providing novel insights into the immunological mechanisms underlying PSCC progression and response to immunotherapy. Long-term outcomes of dynamic sentinel lymph node biopsy in clinically node-negative penile cancer. First Author: Vivaan Dutt, Cancer Institute (WIA), Adyar, Chennai, India

Background: Dynamic sentinel lymph node biopsy (DSLNB) has emerged as a viable alternative in management of clinically node-negative (cN0) penile cancers owing to the high morbidity associated with radical inguinal lymphadenectomy. However, data on efficacy of DSLNB in penile cancer is limited. This study analyses the long-term outcomes of DSLNB in patients with cN0 penile cancer. **Methods:** A retrospective analysis of patients who underwent DSLNB with dual technique (blue dye + radiocolloid) for cN0 penile cancer was done. Data was collected between 2010 to 2018 from a prospectively maintained database with a median follow up of 70.36 months (range - 4 to 150 months). Patients under all risk groups of the European Association of Urology (EAU) Risk Stratification were included. **Results:** The study included 168 consecutive patients who underwent DSLNB (307 groins). Glans penis was the commonest site of disease (92.9%). Partial penectomy was the most common type of surgery for the primary (72.1%). Median number of sentinel nodes identified was three. Based on the EUA risk stratification, 57.2% of the cases were in the high-risk group. Identification rate with dual technique DSLNB in our study was 98.5%. Clavien-Dindo score of 2 or more was seen in 3.57% of patients. A nodal recurrence was seen in 8 groins (8 patients) with a mean time to recurrence of 430 days (69 to 1355 days). This corresponds to a DSLNB false negative rate of 2.6% with median inguinal node recurrence-free survival of 74.4 months. **Conclusions:** In our institution, DSLNB was done with a false negative rate of 2.6% and an acceptable morbidity. The low rate of inguinal nodal recurrence shows the utility of SLNB in staging cN0 groins. By using DSLNB we have avoiding a potentially morbid inguinal dissection in 81.4% of patients with clinically node negative disease. Research Sponsor: None.

Dedicated resources for veteran clinical trial participation: The Prostate Cancer Analysis for Therapy Choice (PATCH) program. First Author: Julie N. Graff, VA Portland Health Care System and Knight Cancer Institute, Oregon Health & Science University, Portland, OR

Background: The Veterans Affairs (VA) hospital system is the most extensive integrated healthcare system in the United States. It serves 9.1 million Veterans and has over 170 healthcare centers and 1,193 outpatient sites. Traditionally, clinical trial access has been limited at the VA. The Prostate Cancer Foundation (PCF) and the VA worked together to create the Precision Oncology Program for Cancer of Prostate (POPCaP) within the VA Healthcare System. By 2021, they had funded 21 Centers of Excellence. The program not only strived to bring cutting-edge clinical trials to Veterans but also sought to develop careers for VA investigators and encourage clinical trial participation by a more diverse group of men. **Methods:** PCF and VA-funded sites paid for genomic testing and established clinical trial infrastructure. PATCH developed centralized clinical trial resources- biostatistics, scientific advisory committees, and young investigator development meetings. PATCH also created a budget working group and hired a research nurse to help open complicated investigator-sponsored studies. POPCaP/PATCH provided two monthly meetings for investigators to discuss their research and for industry partners to review trials and drugs in the pipeline. Here, we report on the change in Veteran participation in clinical trials and the demographics of this population from December 2022 to October 2024. **Results:** Since the development of POPCaP/PATCH, Veteran participation in clinical research has rapidly increased from 100 to 400 men enrolled in clinical trials. The number of clinical trials increased from eight clinical trials to 21. Using an existing database containing genomic results, it enrolled patients in trials requiring specific genomic mutations (e.g., MSI-H, BRCA2). We efficiently screened patients for clinical trials, and more than half of those screened enrolled in trials (60%). Patients of different races and ethnicities participated- white 52.6%, black 36.1%, Hispanic/Latino 4.9%, Asian 2.2%, Native American 1.7%, unknown 2.5%. VA stations opened all phases of clinical trials. Through collaboration with other specialties, interventions included targeted oral therapies, immunotherapies, chemotherapies, radiation, and radiopharmaceuticals. **Conclusions:** The VA has dramatically increased clinical trial opportunities and participation over the past two years. We used VA databases of genomic results to enroll patients in studies with restrained eligibility requirements, such as the presence of microsatellite instability (3%). Sixty percent of patients screened for studies ultimately enrolled in those studies. The diversity of VA trials relative to other US prostate cancer trials makes the results of VA studies more generalizable to the US population. Research Sponsor: Prostate Cancer Foundation; Veterans' Affairs.

Cardiovascular (CV) event risk in patients (pts) with metastatic castration-resistant prostate cancer (mCRPC) treated with enzalutamide (ENZA) or abiraterone acetate (AA) in the United States (US). First Author: Alan Haruo Bryce, City of Hope, Phoenix, AZ

Background: Prior studies suggest that chemotherapy-naïve pts with mCRPC treated with AA have a higher CV event-related hospitalization risk than those treated with ENZA. To further explore this association, this real-world, comparative causal inference study used a large US dataset to assess CV event risk in chemotherapy-naïve pts with mCRPC who initiated treatment (Tx) with ENZA or AA and provide outcome data based on history of (h/o) CV disease (CVD). **Methods:** Using US Medicare fee-for-service claims (Jan 2010–Dec 2022), we identified chemotherapy-naïve pts aged ≥65 years with mCRPC who initiated ENZA or AA between Sep 2014 and May 2017. The primary endpoint was a 4-point major adverse CV event (MACE-4; composite of acute myocardial infarction [AMI], stroke, unstable angina/revascularization [UA/R], and heart failure). Atrial fibrillation (AFib), venous thromboembolism (VTE), and all-cause death were also analyzed. Groups were propensity score matched (PSM) to adjust for differences in pt characteristics, assessed using standardized mean difference (SMD). Cause-specific Cox proportional hazards models were used to comparethe risk of CV outcomes between intention-to-treat cohorts, with death as a competing event. Subgroup analyses were conducted based on h/o CVD. Sensitivity analysis was performed with a MACE-5 endpoint, defined as MACE-4 or CV-related death. **Results:** Of 6319 pts in the total study population (ENZA: 2934; AA: 3385), 2913 PSM pts were included from each group. The ENZA and AA cohorts had similar baseline characteristics even before PSM (SMD<0.1), with a mean (standard deviation) age of 78.8 (7.3) years; 76% of pts had prior CVD. Compared with pts on ENZA, pts on AA had a significantly higher risk of experiencing MACE-4—particularly UA/R—as well as a higher risk of AFib and VTE (Table). Similar results were found in the subgroup of pts with a h/o CVD and the sensitivity analyses. Additionally, pts on AA had a higher risk of all-cause death than pts on ENZA, regardless of CVD history (h/o CVD hazard ratio [HR]: 1.14, 95% confidence interval [CI]: 1.07–1.21, *P*=0.0001; no h/o CVD HR: 1.12, 95% CI: 1.01–1.26, *P*=0.036). **Conclusions:** This matched analysis of US Medicare beneficiaries showed an increased risk for MACE-4, AFib, and VTE in pts with mCRPC treated with AA compared to ENZA, in the overall pt population and pts with a h/o CVD. The risk of all-cause death was higher with AA in all pts. These findings provide insights into Tx decision-making for pts with mCRPC, especially those at high risk of CV events. Research Sponsor: Astellas Pharma Inc.; Pfizer Inc.

Outcomes	HR* (95% CI)	*P*-value
MACE-4	1.12 (1.02–1.24)	**0.028**
AMI	1.01 (0.76–1.32)	0.987
Stroke	0.92 (0.70–1.20)	0.505
UA/R	1.13 (1.01–1.26)	**0.041**
Heart failure	1.19 (0.90–1.58)	0.237
AFib	1.73 (1.31–2.29)	**0.0001**
VTE	1.37 (1.02–1.85)	**0.037**
All-cause death	1.13 (1.07–1.19)	**0.0001**

A phase Ia/Ib study of talazoparib in combination with tazemetostat in metastatic castration-resistant prostate cancer (mCRPC). First Author: Atish Dipankar Choudhury, Department of Medical Oncology, Dana-Farber Cancer Institute, Boston, MA

Background: Enhancer of zeste homolog 2 (EZH2) is frequently overexpressed in metastatic castration-resistant prostate cancer (mCRPC), and is linked to lineage plasticity and therapy resistance. In pre-clinical studies, EZH2 directly regulates DNA damage repair (DDR) gene expression, and inhibition of EZH2 sensitizes prostate cancer cells to genotoxic stress as induced by poly-ADP ribose polymerase (PARP) inhibition. Here we report results of a Phase 1a/1b study of the combination of the PARP inhibitor talazoparib (tala) with the EZH2 inhibitor tazemetostat (taz) in mCRPC. **Methods:** Eligible patients (pts) had progressive disease after at least one secondary hormonal therapy and taxane-based chemotherapy (or felt not to be more appropriate for taxane), disease evaluable for response (PSA ≥ 2 ng/ml or measurable disease by RECIST 1.1) and a metastatic lesion amenable to biopsy adequate for next generation sequencing. The starting dose level (DL 0) in Phase 1a was tala 0.75 mg QD + taz 600 mg BID with dose escalation/de-escalation of both agents by up to 2 dose levels based on a 3+3 design to define the recommended phase 2 dose (RP2D). In Phase 1b, an additional 20 pts were treated at the RP2D to assess preliminary safety and efficacy. **Results:** 12 pts were treated in Phase 1a, of whom 2 of 11 DLT-evaluable pts experienced DLT (both Grade 4 thrombocytopenia): 0 of 3 at DL 0, 1 of 6 at DL +1 (tala 0.75 mg QD + taz 800 mg BID), and 1 of 2 at DL +2 (tala 1 mg QD + taz 800 mg BID). The other pt treated at DL +2 experienced Grade 3 anemia requiring transfusion just outside the DLT period, so DL +1 was selected as the RP2D. 27 pts were treated at the RP2D: 7 in Phase 1a (1 of whom was replaced due to progression prior to completion of the DLT period) and 20 pts in Phase 1b. Median PSA at enrollment was 21.8 ng/ml (range 0-3287), and median number of prior treatments was 4 (range 1-10). Grade ≥3 treatment-related AEs were reported in 59% of pts (16/27), including thrombocytopenia (8/27, 29.6%), anemia (8/27, 29.6%), fatigue (4/27, 14.8%), neutropenia (3/27, 11.1%), lymphopenia (1/27, 3.7%), and hyperglycemia (1/27, 3.7%). 14 of 27 pts (51.8%) required dose reduction. Confirmed PSA50 response was seen in 3 of 23 PSA-evaluable pts (13.0%), and PSA30 in 4 of 23 (17.4%). 1 of 12 pts with measurable disease (8.3%) experienced unconfirmed radiographic response, and 6 of 27 pts (22.2%) remained on study treatment for > 270 days. **Conclusions:** In a heavily pretreated biomarker-unselected population, the RP2D of talazoparib 0.75 mg daily and tazemetostat 800 mg BID was associated with expected myelosuppression but otherwise acceptable safety profile, with clinical benefit seen in a minority of patients. Companion blood and tissue-based correlative studies to characterize pharmacodynamic biomarkers of combined PARP+EZH2 inhibition and biomarkers of response and resistance are ongoing. Clinical trial information: NCT04846478. Research Sponsor: Pfizer; Prostate Cancer Foundation; Ipsen (drug only); National Cancer Institute; P50CA272390.

Does cytoplasmic AR-V7 circulating tumor cell (CTC) detection add utility in predicting AR pathway inhibitor benefit in men with mCRPC? A retrospective analysis of the PROPHECY study. First Author: Santosh Gupta, Epic Sciences, San Diego, CA

Background: Androgen receptor splice variant-7 (AR-V7) is a constitutively active truncated protein that emerges during hormone therapy resistance in prostate cancer. We have shown that circulating tumor cell (CTC) AR-V7 nuclear localization is strongly associated with worse responses, PFS, and overall survival with AR pathway inhibitors (ARPIs) such as abiraterone or enzalutamide in the metastatic castration-resistant prostate cancer (mCRPC) setting. The measurement of cytoplasmic AR-V7, however, has unclear predictive value and we thus sought to determine whether an AR-V7-agnostic CTC scoring criterion would identify more patients with ARPI resistance as compared to nuclear AR-V7 in the PROPHECY study (NCT02269982). **Methods:** Blood samples were available from 110 of 118pre-ARPI mCRPC patients and evaluated for both nuclear and cytoplasmic CTC only AR-V7 detection utilizing Epic's CTC platform and associated with confirmed PSA50 response, overall survival (OS), and progression-free survival (PFS). We also assessed the correlation between AR overexpression and AR-V7 detection. The proportional hazards model was utilized to explore the prognostic significance of nuclear, cytoplasmic AR-V7 in predicting OS and PFS adjusting for Halabi clinical risk score and CellSearch CTCs≥5. **Results:** At baseline, 11/107 (10%) mCRPC samples had AR-V7 nuclear expression, 15/107 (14%) had cytoplasmic only AR-V7 detection, and thus 26/107 (24%) cases were CTC AR-V7 positive. All of the nuclear AR-V7 positive cases had AR overexpression, while only 67% of cytoplasmic AR-V7 positive cases exhibited AR overexpression. We observed a confirmed PSA50 in 0%, 13%, and 29.6% of nuclear V7+, cytoplasmic V7+, and V7- patients. See the table for PFS and OS outcomes. **Conclusions:** Cytoplasmic AR-V7 detection in CTCs is more prevalent than nuclear only scoring. Cytoplasmic AR-V7 positive cases appear to have worse PFS, PSA50, and OS as compared to AR-v7 negative cases. However, men with cytoplasmic only CTC AR-V7 detection were more likely to have post-ARPI short term PSA declines and improved overall survival, despite a similar poor PFS as compared to nuclear AR-V7 positive patients with mCRPC. Knowledge of both CTC nuclear and cytoplasmic AR-V7 status could be helpful for improved risk stratification of patients with mCRPC prior to ARPI therapy. Clinical trial information: NCT02269982. Research Sponsor: None.

N=107 baseline	Median (95% CI), months	Univariate HR (95%CI)	Multivariate HR (95%CI)
OS based on AR-V7 status			
Nuclear AR-V7	8.4 (7.0, NR)	3.6 (1.9, 7.0)	3.7 (1.7, 8.4)
Cytoplasmic AR-V7 only	14.7 (10.8, 27.3)	2.0 (1.1, 3.6)	1.2 (0.6, 2.5)
AR-V7 negative	21.8 (18.9, 29.2)	Reference	Reference
PFS based on AR-V7 status			
Nuclear AR-V7	3.7 (2.3, NR)	2.6 (1.4, 5.1)	2.9 (1.3, 6.2)

Effect of HLA class I expression on the tumor immune microenvironment and prognosis in prostate cancer. First Author: Pornlada Likasitwatanakul, University of Minnesota, Minneapolis, MN

Background: Human leukocyte antigen (HLA) class I comprises a family of peptide-binding proteins that regulate T-cell interactions. Here, we examined HLA class I mRNA expression and gene zygosity in prostate cancers (PCs), exploring associations with clinical outcomes, molecular features, and tumor microenvironment. **Methods:** We analyzed 10,790 PC samples, of which 8,040 (75%) contained HLA transcription data, and 2,792 (26%) contained HLA genotypes in the Caris Life Sciences database. Samples were stratified into HLA-high (>75th percentile) and -low (<25th percentile) groups. Genomic and transcriptomic alterations were compared at an adjusted significance level of 0.05. Immune cell fractions were inferred by quanTIseq. Overall survival was obtained from insurance claims data and computed using Cox proportional hazards. **Results:** Among 66 cancer types, PC ranked 2nd, 11th, and 19th lowest with respect to HLA-A, HLA-B, and HLA-C expression. In PC, genes related to AR signaling, immunoglobulins, and cell-surface antigens (CTLA4, PD-L1, TROP2, B7-H3, and PSMA) were significantly increased in HLA-high tumors. HLA-high status was associated with increased interferon-gamma scores and more cytotoxic and regulatory T cells, B cells, and NK cells. HLA-high tumors also exhibited a 2-fold depletion in CDK12 and AR/FOXA1 mutations but were enriched in tumor suppressor gene (RB1, PTEN) alterations. HLA-A high tumors exhibited increases in MSI-H/dMMR status (4.8% vs. 3.3% and 5.1% vs 3.1%, p=0.04 and 0.01), while dMMR was also increased in HLA-B high tumors (5.1% vs. 3.4%, p=0.03). HLA class I expression was generally lower in metastatic biopsies (Bx) compared to primary prostate Bx. Upon examining the zygosity of HLA alleles, metastatic Bx exhibited a higher proportion of homozygous HLA-B (7.2% vs. 5.1%, p=0.03) compared to prostate Bx. Last, worse overall survival was seen in prostate Bx that were high in HLA-A or HLA-B (HR = 1.36, 1.21, p<0.0001, 0.008) or metastatic Bx that were HLA-A high (HR = 1.18, p = 0.019). **Conclusions:** HLA class I expression is lower in PCs compared to other cancers, but elevated HLA class I levels correlate with immune cell activity, somatic alterations, and clinical outcomes. Unexpectedly, HLA-A and HLA-B high tumors portended shorter survival, perhaps due to significant enrichment of PTEN/RB1 alterations. Altogether, HLA status, immunogenicity, and tumor suppressor alterations should be considered in tandem when considering patient prognosis. Research Sponsor: University of Minnesota.

Updated prostate cancer risk groups by PSMA-PET PROMISE (PPP2): Results from an international multi-centre registry study. First Author: Wolfgang Peter Fendler, Department of Nuclear Medicine, University of Duisburg-Essen, and German Cancer Consortium (DKTK), University Hospital Essen, Essen, Germany

Background: We previously established prognostic two-tier risk nomograms based on PSMA-PET and Prostate Cancer Molecular Imaging Standardized Evaluation (PROMISE) criteria in a large single-centre cohort. Here, we validate three-tier risk stratification by PSMA-PET PROMISE (PPP2) in a large international multi-centre registry study for prostate cancer survival. **Methods:** We included prostate cancer patients who underwent PSMA-PET at 20 hospitals in EU, USA or Australia between 2013 and 2022. PSMA-PET was standardized by PROMISE version 2 (V2). Total lesion count, total tumour volume, PSMA expression score, and overall survival follow-up were obtained. Investigator sites were split 2:1 into development and validation cohorts, considering site characteristics. In the development cohort we assessed PPP predictors and created version 2 for visual and quantitative PPP nomograms (PPP2) based on Cox regression models with least absolute shrinkage and selection operator penalty for overall survival. Performance of both nomograms was measured in the validation cohort using Harrell´s C-index and calibration plots. Head-to-head comparison to the National Comprehensive Cancer Network (NCCN) risk score was examined by ROC-curves. **Results:** We analyzed 6128 male patients (4044 development and 2084 validation cohorts) across all disease stages with 1915 (31·2%) reported deaths and median follow-up of 4·8 years (IQR 3·4-6·4). Predictors in the visual PPP2 nomogram were presence of distant metastases (extrapelvic nodal metastases [M1a], bone metastases [M1b; oligometastatic, disseminated or diffuse marrow involvement], and visceral metastases [M1c]), PSMA expression score, and total lesion count. Predictors in the reassessed quantitative PPP2 nomogram were distant metastases (M1a, M1b, and M1c), total tumour volume, and PSMA expression score. C-indices (95% CI) in the validation cohort were 0·80 (0·78-0·82) for the visual and 0·80 (0·79-0·82) for the quantitative nomogram, respectively. In the validation cohort for three-tier stratification (high, intermediate, low risk), accuracy of both PPP2 nomograms was superior when compared to the NCCN risk score (n=1034, AUC 0·84 vs. 0·76; p<0·0001, respectively). Performance of both PPP2 nomograms was independent from radiopharmaceutical (68Ga vs. 18F) or PROMISE version (V1 vs. V2; n=2084, visual: both AUC 0·79, respectively, p=0·11; quantitative: both AUC 0·79, respectively, p=0·56). **Conclusions:** PSMA-PET PROMISE nomograms were improved in an international multi-centre study to accurately stratify high vs. intermediate vs. low risk for overall survival across all stages of prostate cancer. PPP2 yields superior accuracy compared to the NCCN risk score. Follow-up continues in the PROMISE Registry (NCT06320223, promise-pet.org). Research Sponsor: Prostate Cancer Foundation; Innovative Health Initiative Joint Undertaking; AstraZeneca.

5046 Poster Session

Safety and pharmacokinetics of mevrometostat (M) in combination with enzalutamide (E) in patients with metastatic castration-resistant prostate cancer (mCRPC). First Author: Nobuaki Matsubara, National Cancer Center Hospital East, Chiba, Japan

Background: M is a potent and selective small molecule inhibitor of enhancer of zeste homolog 2 (EZH2). In the randomized dose-expansion part of a phase 1 study, M (1250 mg BID on an empty stomach) + E (160 mg QD) improved outcomes versus E alone, with a manageable safety profile in patients (pts) with mCRPC (NCT03460977). We report safety and pharmacokinetics for M at 875 mg with food + E from this study. **Methods:** This was an open-label, phase 1 dose escalation and dose expansion study. Pts with mCRPC who received prior treatment with abiraterone or E, with evidence of progression per modified Prostate Cancer Working Group 3 criteria were included. Pts received M (875 mg BID with food) + E (160 mg QD) + androgen deprivation therapy. Safety and pharmacokinetics of the food effect cohort were primary and secondary endpoints, respectively. **Results:** As of Nov 15, 2024, 29 pts received M at 875mg with food + E. Median (interquartile range [IQR]) duration of treatment was 5.5 (4.1–7.4) months. Overall, 28 (96.6%) pts experienced a treatment-emergent adverse event (TEAE; Table). The most common TEAEs of any grade related to M were diarrhea (41.4%), thrombocytopenia (41.4%), and dysgeusia (37.9%). Serious TEAEs related to M were reported in 3 (10.3%) pts (anemia, ECG QT prolonged, and hemorrhagic enterocolitis), all were grade 3. There were no grade 4 TEAEs. TEAEs led to withdrawal from M in 4 (13.8%) pts. One patient had a fatal event of osteonecrosis of the jaw (present at baseline) that was not considered related to M. Plasma exposures of M + E after multiple doses were comparable between M 1250 mg on an empty stomach (n=51) and M 875 mg with food (n=12) (geometric mean [coefficient of variation]: AUC_{tau}, h*ng/mL: 1250 mg, 8690 [54]; 875 mg, 8984 [48]; C_{max}, ng/mL:1250 mg, 2371 [54]; 875 mg, 1868 [85]). **Conclusions:** In pts with mCRPC treated with M + E, M 875 mg with food had an improved safety profile compared with M 1250 mg on an empty stomach. M 875 mg with food has similar plasma exposures to M 1250 mg on an empty stomach. M 875 mg with food + E was selected as the recommended dose for pivotal phase 3 studies. Clinical trial information: NCT03460977. Research Sponsor: This study is sponsored by Pfizer Inc. Enzalutamide for the study was provided by Astellas Pharma Inc. Editorial support was provided by Megan Christian, MBiolSci, and Rosie Henderson, MSc, of Onyx (a division of Prime, London, UK), funded by Pfizer Inc.

5047 Poster Session

Final overall survival (OS) with talazoparib (TALA) + enzalutamide (ENZA) as an initial treatment in unselected patients (pts) with metastatic castration-resistant prostate cancer (mCRPC) in the China cohort of the phase 3 TALAPRO-2 trial. First Author: Xiaojie Bian, Fudan University Cancer Hospital, Xuhui, Shanghai, China

Background: In the China cohort of the TALAPRO-2 study, unselected pts with mCRPC who received TALA + ENZA had improved radiographic progression-free survival per BICR (rPFS; HR=0.30; 95% CI, 0.17–0.56; $P<0.0001$; data cutoff: Nov 15, 2023), consistent with the global population (HR=0.63; 95% CI, 0.51–0.78; $P<0.0001$; data cutoff: Aug 16, 2022). In final prespecified analyses, TALA + ENZA significantly improved OS vs PBO + ENZA in the global population. Here we report final OS, a descriptive update of rPFS, and an extended follow-up of secondary outcomes in the China cohort. **Methods:** The China cohort includes pts from the unselected cohort 1 of TALAPRO-2 and China extension (unselected homologous recombination repair [HRR] gene status). Pts had asymptomatic/mildly symptomatic mCRPC, received ongoing androgen deprivation therapy, and were prospectively tested for HRR alterations in tumor tissue. Pts were randomized 1:1 to TALA 0.5 mg/day (moderate renal impairment 0.35 mg/day) or placebo (PBO); all pts received ENZA 160 mg/day. Primary endpoint was rPFS by BICR. OS was a key secondary endpoint. Other secondary endpoints included BICR-assessed objective response rate (ORR), time to prostate-specific antigen (PSA) progression, safety, and pt-reported outcomes. All reported P values are 2-sided. **Results:** Overall, 125 pts were randomized (TALA + ENZA, 63; PBO + ENZA, 62). At data cutoff (Sep 3, 2024; median follow-up, 33.2 mo in both arms) 35 pts (56%) in the TALA + ENZA arm and 41 pts (66%) in the PBO + ENZA arm had died. Clinically meaningful benefit in OS with TALA + ENZA vs PBO + ENZA was observed: HR=0.591 (95% CI, 0.369–0.944; $P=0.0262$); median OS (95% CI), 36.9 mo (21.7–42.4) vs 24.1 mo (16.8–30.5), respectively. Updated rPFS by BICR continued to favor TALA + ENZA vs PBO + ENZA (HR=0.312; 95% CI, 0.173–0.561; $P<0.0001$, median rPFS, 33.3 vs 10.5 mo, respectively). TALA + ENZA was favored vs PBO + ENZA in ORR by BICR (50% vs 32%, respectively; $P=0.2845$) and time to PSA progression (HR=0.540; 95% CI, 0.298–0.976; $P=0.0411$). Consistent with global and China cohort primary results, the most common grade ≥3 treatment-emergent adverse events (TEAEs) with TALA + ENZA were anemia (57%) and neutropenia (32%). TEAEs were generally manageable; 14 pts (22%) discontinued TALA due to TEAEs. No clinically meaningful between-arm differences were observed in global health status/quality of life (QoL) measured by EORTC QLQ-C30, except for role functioning, which favored TALA + ENZA. **Conclusions:** At extended follow-up, initial treatment with TALA + ENZA resulted in clinically meaningful improvement in OS, rPFS by BICR, and secondary efficacy endpoints vs PBO + ENZA in unselected pts with mCRPC in the TALAPRO-2 China cohort. No new safety signals were identified; QoL was maintained. Clinical trial information: NCT03395197. Research Sponsor: Pfizer.

Long-term safety of radium-223 (Ra-223) in metastatic castration-resistant prostate cancer (mCRPC): 7-year follow-up from the largest global prospective study. First Author: Alton Oliver Sartor, Mayo Clinic, Rochester, MN

Background: Ra-223, an alpha-emitting radionuclide, is the first agent of its kind approved for the treatment of mCRPC. Although a pivotal phase 3 study evaluated its short-term safety, there is a need to investigate its long-term safety. The REASSURE study prospectively examined the long-term safety of Ra-223, including secondary primary malignancies (SPMs), in a large patient (pt) population enrolled across Europe, the United States, Israel, and Latin America. **Methods:** We report final analyses (data cut-off Oct 24, 2024) of REASSURE (NCT02141438), a global, noninterventional study (enrolment 2014–2017). Primary outcomes were the incidence of SPMs, short- (30 days) and long-term (7 years) safety events, and bone marrow suppression (BMS) management in pts who had ≥1 Ra-223 dose. Secondary outcomes included overall survival (OS). **Results:** Analyses included 1472 pts; median follow-up was 17 months (range 0.3–95.4). Median age was 73 years and 80% of pts had an ECOG PS of 0/1. In evaluable pts, median alkaline phosphatase, prostate-specific antigen, and lactate dehydrogenase levels were 133 U/L, 59 ng/mL, and 266 U/L, respectively. Overall, 81% of pts had bone-only metastases at baseline; 19% of pts had metastases in the bone plus other sites (mostly lymph nodes). Prior treatments included abiraterone (48% of pts), enzalutamide (39%), docetaxel (39%), and cabazitaxel (9%). Pts received a median of 6 Ra-223 doses; 67% received ≥5 doses. SPMs occurred in 2% of pts (25 SPMs in 24 pts). Of these pts, 16 (67%) and 1 (4%) had received prior or concomitant radiotherapy, respectively. Overall, 3% of pts had drug-related serious adverse events >30 days after completing Ra-223. Fractures were reported in 10% of pts and were less common in pts with (7% of 605) than without (12% of 867) concomitant BHA use. During Ra-223 and up to 30 days after the last dose, there was no notable difference in the incidence of abnormal platelet counts between pts with (3%) or without (2%) prior chemotherapy; similar findings were seen for abnormal neutrophil counts (5% and 5%, respectively). BMS treatments, assessed from the start of Ra-223, were more common in pts who had received prior taxanes (38%) than in those who had not (26%). The most common life-prolonging therapies received after Ra-223 were docetaxel (18%), enzalutamide (15%), abiraterone (11%), and cabazitaxel (11%). Median OS was 15.6 months (95% CI, 14.6, 16.4); pt subgroups that survived the longest will be characterized and presented. **Conclusions:** This real-world safety analysis of pts with mCRPC is the longest follow-up of a radiopharmaceutical reported to date and supports the well-established favorable safety profile of Ra-223. The incidence of SPMs was low. The rate of fracture was low, especially in the presence of BHAs. Prior taxane chemotherapy use had no impact on hematological toxicity. Clinical trial information: NCT02141438. Research Sponsor: Bayer.

Uptake of targeted therapy in a large cohort of patients with advanced prostate cancer and germline pathogenic variants. First Author: Hiba M. Khan, University of Washington/Fred Hutch Cancer Center, Seattle, WA

Background: Men with advanced prostate cancer (PrCa) and pathogenic germline variants (PGV) in homologous recombination repair (HRR) or mismatch repair (MMR) genes are eligible for targeted therapies, namely poly (ADP-ribose) polymerase inhibitors (PARPi), platinum chemotherapy, or immune checkpoint inhibitors (ICI). The influence of these PGV on uptake of targeted therapies is understudied and necessary to identify and intervene upon possible disparities. We describe PrCa targeted treatment patterns in men with advanced PrCa. **Methods:** Germline genetic testing (GGT) (Labcorp) and insurance claims data (Komodo Healthcare MapTM) were assembled for advanced PrCa (defined by ICD10/CPT codes) patients diagnosed from 2015-2024 with ≥ 1 year of claims pre-diagnosis. Treatment uptake by GGT result were compared with *X*2 tests (negative/variant of uncertain significance (VUS), vs HRR/MMR PGV) and multivariable logistic regression (negative/VUS vs *BRCA1/BRCA2*, other HRR/MMR PGV) (Table). **Results:** 11,545 men with advanced PrCa underwent GGT: 66% White, 50% commercial insurance, 27% PrCa family history, mean age at diagnosis: 65. 924 (8%) and 145 (1%) of men had ≥1 PGV in a HRR or MMR gene, respectively. 1,246 (11%) men received platinum chemotherapy, 332 (3%) received PARPi and 521 (5%) received ICI. Men with HRR PGV were more likely than men with VUS/negative results to receive platinum chemo (14% vs. 11%, p=0.001) and PARPi (16% HRR, 25% *BRCA1/2* vs. 2%, p<0.001 for both) and men with MMR PGV were more likely to receive ICI (19% vs. 4%, p<0.001). Black men had lower odds of platinum chemo and ICI than White men, but higher odds of PARPi . Among men with HRR PGV, Black men and those with *BRCA1/2* PGV were more likely to receive PARPi (Table). **Conclusions:** Less than 1 in 4 men with advanced PrCa and HRR/MMR PGV received appropriate targeted therapies. PARPi uptake among eligible patients was twice as high among Black men compared to White men, perhaps reflecting clinician perception of more aggressive disease; rates of platinum chemo and ICI were not similarly higher. These findings raise questions about appropriate receipt of targeted agents and future studies should qualitatively assess clinician prescribing patterns, including sequencing of therapies as approvals for first line PARPi expand. Research Sponsor: None.

Molecular and clinical characterization of KLK2 mRNA expression in prostate cancer (PC). First Author: Rana R. McKay, Moores Cancer Center, University of California San Diego, La Jolla, CA

Background: KLK2 is an androgen-regulated gene that plays a critical role in PC biology. Given the development of KLK-2 targeted therapies, we sought to characterize the molecular and clinical features associated with KLK2 mRNA expression in PC. **Methods:** NextGen sequencing of DNA (592-gene/whole exome) and RNA (whole transcriptome) was performed on PC specimens (n=6,978) at Caris Life Sciences. KLK2-High/Low expression was defined as >75th /<25th quartile RNA transcripts per million (TPM). Castrate resistant PC (CRPC) and hormone sensitive PC (HSPC) were defined based on androgen deprivation therapy (ADT) duration prior to tissue collection: HSPC < 3 and CRPC ≥ 3 months from ADT start. Overall survival (OS) was defined as the time of collection or first androgen receptor pathway inhibitor (ARPI) to death/last follow-up. **Results:** Specimens were derived from primary prostate (n=4,464, 64.0%), lymph nodes (n=828, 11.9%) or other metastatic sites (n=1,686, 24.2%). Higher KLK2 was observed in tumors from Black vs. White patients (8.88 vs. 8.75 log_2[TPM+1], p<0.001). KLK2 was enriched in adenocarcinoma vs. mixed vs. NEPC (8.79 vs. 7.58 vs. 0.33 log_2[TPM+1], p<0.001). Relative to primary tumors (8.93 log_2[TPM+1]), KLK2 varied by metastatic site, with lowest expression in GI (7.46 Log_2[TPM+1], p<0.001), liver (7.88 log_2[TPM+1], p<0.001), and CNS (8.25 log_2[TPM+1], p<0.001). In primary tumors, high KLK2 associated positively with *SPOP* and negatively with *PI3K/PTEN*, *TP53*, and *RB1* alterations. Across primary, lymph node, and distant metastatic tumors, high KLK2 associated positively with AR signaling and negatively with NEPC signaling (all p<0.001). KLK2 strongly correlated with KLK3 (PSA) expression (R=0.87). KLK2 expression was higher in HSPC (n=1504) vs. CRPC (n=4519) tumors (1.78 Log_2[TPM+1], p<0.001). Among HSPC, KLK2-high tumors had decreased *TP53*, *RB1*, *AKT1*, *BRCA1* and increased *SPOP*, *CTNNB1*, *PTEN*, *BRCA2* mutations. CRPC tumors with high KLK2 had decreased *RB1*, *TP53*, *PIK3CA* and increased *RAD54L* and *ATM* mutations compared to low tumors. High KLK2 was associated with improved OS from collection time (median 69.7 vs. 35.9 months, p<0.001) and first ARPI initiation (median 48.9 vs. 39.5 months, p<0.001). KLK2-high HSPC and CRPC tumors had improved OS compared to low tumors (median 82.0 HSPC KLK2-high vs. 54.3 HSPC KLK2-low vs. 23.7 CRPC KLK2-high vs. 16.3 CRPC KLK2-low months, q<0.01). The combination of KLK2-high/AR-high was associated with increased OS compared to KLK2-high/AR-low, KLK2-low/AR-high, and KLK2-low/AR-low tumors (median 70.8 vs. 48.8 vs. 43.5 vs. 20.8 months, respectively, p<0.001). **Conclusions:** This large-scale clinic-genomic analysis reveals distinct patterns of KLK2 expression in PC. The correlation between high KLK2 expression, favorable genomic features, and improved OS supports its potential utility as a prognostic biomarker and may inform selection for KLK2-directed therapy. Promising early results of MHB088C (B7-H3 ADC) in patients (pts) with metastatic castration-resistant prostate cancer (mCRPC) from a phase 1/2 multicenter study. First Author: Lin Shen, Beijing Cancer Hospital, Beijing, China

Background: MHB088C is a novel B7-H3-targeted antibody-drug conjugate (ADC) incorporating the potent SuperTopoi payload, which is 5 to 10 times more potent than Dxd. Early data from an ongoing phase 1/2 study have shown that MHB088C is generally well tolerated, with early signs of clinical activity (ASCO 2024, abstract #3012). Here, we present preliminary findings from the subset of pts with mCRPC. **Methods:** This study consisted of 2 parts: dose-escalation (part 1) and expansion (part 2). Part 1 evaluated the safety and tolerability of MHB088C at doses ranging from 0.8 to 4.0 mg/kg, administered intravenously every 2 (Q2W) or 3 weeks (Q3W). Part 2 explored multiple doses to assess safety and prospective efficacy of MHB088C in selected tumor types, including mCRPC. **Results:** As of January 3, 2024, 36 pts with mCRPC were enrolled and received at least one dose of MHB088C (1.6~2.4 mg/kg, n=35; 3.0 mg/kg, n=1). The median age was 69 years (range: 51-83) and all pts had an ECOG performance status ≤1. These pts were heavily pretreated, with 100% having received novel androgen axis drugs (NAAD) and 80% having received docetaxel. The objective response rate (ORR) was 14.3%, and the disease control rate (DCR) was 95.2% in pts with measurable disease (n=21). At data cutoff, 19 pts (52.8%) remained on the treatment. Six-month radiographic progression-free survival (rPFS) was 87%. Preliminary data also indicate improvements in prostate-specific antigen (PSA) levels. Safety data were consistent with previous reports. The most common grade≥3 treatment-related adverse events were neutropenia (24.2%), platelet count decreased (11.1%) and anemia (15.2%). **Conclusions:** MHB088C demonstrated a manageable safety profile and promising antitumor activity in heavily pretreated pts with mCRPC. The preliminary safety and efficacy data are encouraging and warrant further investigation. Clinical trial information: CTR20231298. Research Sponsor: None.

Evaluating the prognostic utility of cell-free (cf)DNA tumor fraction (TF) in metastatic castration-resistant prostate cancer (mCRPC). First Author: Daniel Boiarsky, Yale New Haven Hospital, New Haven, CT

Background: Accurate prognostication is essential for guiding treatment decisions. cfDNA TF provides a non-invasive quantitative assessment of tumor burden without the need for tissue biopsies, which are notoriously challenging to obtain in mCRPC patients. This study evaluates the utility of cfDNA TF as a prognostic biomarker in mCRPC. **Methods:** Patients treated for mCRPC at the Dana-Farber Cancer Institute with available plasma were identified. Plasma samples underwent (epi)genomic profiling using the Guardant360 platform. TF was estimated by normalizing cancer-specific differentially methylated regions with appropriately matched control regions within each sample. The association of TF with clinical prognostic biomarkers and overall survival (OS) from the time of plasma collection was assessed. Survival analysis was performed using cox proportional hazards methodology, continuous variables were compared using Mann-Whitney test, and linear correlations were calculated using Pearson correlation coefficient. Decision tree (DT) models were developed to evaluate the benefit of incorporating clinical prognostic biomarkers with TF in predicting OS at 12 months. A 70/30 split was used to separate the training and testing cohorts and hyper-parameters were optimized for the F1 score (harmonic mean of precision and recall). **Results:** A total of 103 patients with mCRPC were identified (median age at plasma collection: 72; median prior lines of therapy: 3; median mTF: 3.7%). 36%, 34%, and 30% of patients had TF $<$1%, 1-10%, and $>$=10% respectively. Compared to patients with TF $<$1% (median OS: 28 months), OS was significantly shorter among patients with TF 1-10% (median: 16 months; HR=2.6, p=.00032) and $>$=10% (median: 10 months; HR=7.8, p=6.0x10-12). TF was significantly correlated with max variant allele frequency (mVAF) (rho=0.79 ,p=2.1x10-23), a traditional genomic-based cfDNA measure of tumor burden; however, on multivariable analysis, only TF (HR=5.8,p=2.8x10-9), and not mVAF (HR=0.97,p=0.95), was independently associated with worse OS. Elevated TF was associated with known poor-risk disease features, including visceral metastases, higher ECOG scores, and elevated serum markers (alkaline phosphatase, PSA, LDH). Multivariable analysis identified TF $>$ median as the strongest negatively prognostic marker for OS (HR=3.5,p=.00029). TF alone demonstrated comparable predictive accuracy for 12-month OS (F1: 0.72) to a model including all clinical prognostic markers plus TF (F1: 0.72). Decision tree models identified an optimal TF cutoff of 5.6%, with 88% (53/60) of patients with TF $<$5.6% alive at 12 months, compared to 36% (11/42) for those with TF $\geq$5.6%. **Conclusions:** Our findings suggest that methylated tumor fraction is a robust independent non-invasive prognostic biomarker in mCRPC, outperforming traditional clinical markers and genomic metrics. Future studies should explore the integration of TF into standard prognostic workflows and its potential to guide therapeutic decisions. Research Sponsor: None.

Real world outcomes for patients with metastatic castration resistant prostate cancer (mCRPC) and *AR* T878A alterations treated with enzalutamide. First Author: Matthew Siskin, Perlmutter Cancer Center, NYU Langone Health, New York, NY

Background: Androgen receptor (AR) antagonists such as enzalutamide (enza) are standard therapy for mCRPC. *AR* alterations such as amplification (amp) and ligand binding domain (LBD) point mutations (PMs) can cause resistance to hormonal therapies such as enza. The most prevalent *AR* PMs are T878A and L702H. Preclinical evidence suggests that *AR* T878A retains sensitivity to enza compared to *AR* L702H which confers resistance by increasing activation by glucocorticoids. Clinical data evaluating the efficacy of enza in patients with these AR PMs is limited. Here, we analyzed real world data from patients with *AR* T878A compared to *AR* L702H, *AR* amp, or no detected *AR* mutations (*AR* no alt), as identified by circulating tumor DNA (ctDNA), to assess enza efficacy in patients with *AR* T878A versus *AR* L702H. **Methods:** We used GuardantINFORM, a real-world database that combines genomic data from deidentified patients tested via ctDNA with clinical data taken from commercial-payer health claims. Adult mCRPC patients treated with enza who had baseline ctDNA testing and at least 2 claims post ctDNA testing were included. Patients with $\geq$2 *AR* PMs were excluded. Matched cohorts were used to assess real-world overall survival (rwOS), time to treatment discontinuation (rwTTD), and time to next treatment (rwTTNT). Propensity score matching was conducted using age and NCI comorbidity index, race, ethnicity, testing location, and enzalutamide line-of-therapy, and was evaluated using Wilcoxon tests. **Results:** 1,316 mCRPC patients met inclusion criteria. 59 had *AR* T878A, 56 had *AR* L702H, 231 had *AR* amp, and 970 had *AR* no alt. T878A was compared to L702H, amp, and no alt. Patients with T878A demonstrated significantly improved rwTTD (median 8.0 vs 3.5 mo, *P*=0.001) and rwTTNT (median 15.8 vs 4.3 mo, *P*=0.003), but not significantly different rwOS (19.1 vs 13.6 mo, *P*=0.066) relative to L702H. Patients with T878A demonstrated significantly improved rwTTD (7.7 vs 4.8 mo, *P*=0.022), but not statistically improved rwTTNT (10.4 vs 6.4 mo, *P*=0.059) or rwOS (20.2 vs 14.9 mo, *P*=0.14) relative to *AR* amp. Patients with T878A demonstrated significantly shorter rwOS (median 19.2 vs 43.6 mo, *P*=0.03), but no difference in rwTTD (7.7 vs 7.8 mo, *P*=0.88) or rwTTNT (10.4 vs 14.4 mo, *P*=0.423) relative to *AR* no alt. **Conclusions:** To our knowledge, this is the largest study assessing outcomes of mCRPC patients with *AR* PMs subsequently treated with enza. Using real-world evidence, we show that *AR* T878A patients have longer time on therapy with enza relative to patients with *AR* L702H. rwOS following enza was numerically longer for T878A versus L702H. These findings suggests that *AR* T878A is relatively more sensitive to enza compared to other resistance mutations. Future work in larger prospective cohorts comparing hormonal treatments in *AR*-altered patients will help confirm the clinical significance of different *AR* alterations. Research Sponsor: None.

'One button push' fully automated PSMA PET quantification: Correlation with progression free and overall survival in patients undergoing [^{177}Lu] Lu PSMA therapy for metastatic castrate resistant prostate cancer. First Author: Louise Emmett, St Vincent's Hospital Sydney, Sydney, NSW, Australia

Background: [^{177}Lu]Lu-PSMA is an effective treatment in metastatic castrate-resistant prostate cancer (mCRPC). Whole body standardized uptake value (SUV)mean and total tumor volume (PSMA-TTV) are valuable screening biomarkers for ^{177}Lu-PSMA therapy but require labour intensive semi-quantitative software. This study aims to compare PSMA SUVmean, and PSMA-TTV from fully automated and semi-automated methods of PSMA-PET quantification for predictive and prognostic capability. **Methods:** Datasets of participants (pts) from ethics approved trials with mCRPC post androgen receptor signaling inhibition and post taxane (or unfit for taxane), treated with [^{177}Lu]Lu-PSMA with a prior screening ^{68}Ga-PSMA-11 PET/CT, and outcome data including PSA progression-free (PSA-PFS) and overall survival (OS) were included. Screening ^{68}Ga-PSMA-11 PET/CT of participants were quantified using MIM LesionID Pro to derive SUVmean and PSMA-TTV with a fully automated quantification process (Method A) and semi-automated quantification adjusted manually for error (Method B). Both methods utilised software that segmented all lesions above SUVmax 3 and a CT-based deep learning method to identify normal organs for automatic physiological uptake removal. SUVmean and PSMA-TTV were evaluated in quartiles. Associations between SUVmean and PSMA-TTV above and below the 75th percentile (Q4 vs Q1-3) were examined with Kaplan Meier estimates and log-rank tests. **Results:** Data from 139 pts were analysed, median age 72 years (IQR: 67–77) and median PSA 94 ng/ml (IQR: 34–325). The median time to PSA-PFS (120 events) 5.5 months (95%CI: 4–6.0) and OS (82 events) 13.5 months (95%CI:11– 18). With method A (fully automated), SUVmean Q4 was 9.7 and PSMA -TTV Q4 was 1156ml. The corresponding results with method B (manually adjusted) were SUVmean Q4 9.9 and PSMA-TTV Q4 1203ml. With-method A, median PSA-PFS for SUVmean Q1-3 was 4.5 (95%CI:3–6) vs 7 months (mo) (95% CI:5–11) for SUVmean Q4 (p=0.003). Median OS for SUVmean Q1-3 was 12.0 (95%CI:10–6) vs 20 mo (95%CI:12.0–NE) for SUVmean Q4 (p=0.011). For PSMA-TTV Q4 vs Q1-3, median OS was 8.5 (95%CI:7 –12.0) vs 18 mo (95%CI: 13–20) (p$<$0.001). With method B, median PSA-PFS for SUVmean Q1-3 was 4.5 (95%CI:3– 6) vs 7.5 mo (95%CI:5–11) for SUVmean Q4 (p=0.002). Median OS for SUVmean Q1-3 was 13 (95%CI:10–17) vs 20 mo (95%CI:11 – NE) for SUVmean Q4 (p=0.03). For PSMA-TTV Q4 vs Q1-3, median OS was 8.5 (95%CI:7–12) vs 18 mo (95%CI:13 – 20) (p$<$0.001). **Conclusions:** PSMA SUVmean and PSMA-TTV with a fully automated quantification method predicted both PSA-PFS and OS in patients undergoing [^{177}Lu]Lu-PSMA therapy. Fully automated vs manually adjusted predictive capability was not different. This is an important step in moving PSMA-PET quantitative biomarkers from research tool to routine clinical care. Research Sponsor: None.

First-in-human study of ^{177}Lu-JH020002 in patients with metastatic castration-resistant prostate cancer. First Author: Fangning Wan, Department of Urology, Fudan University Shanghai Cancer Center, Shanghai, China

Background: ^{177}Lu-JH020002 is a novel radioligand therapy that delivers beta-particle radiation to PSMA-expressing tumor cells and the surrounding microenvironment, demonstrating high affinity and antitumor activity in preclinical studies. JH020002-01C is an ongoing, multicenter, open-label phase I/II study investigating the safety, tolerability, pharmacokinetics, dosimetry and preliminary antitumor activity of ^{177}Lu-JH020002 in patients (pts) with metastatic castration-resistant prostate cancer (mCRPC). Here, we reported the preliminary safety and efficacy results of phase I. **Methods:** Eligible pts for phase I had mCRPC, were refractory to or had progressed following at least one androgen receptor pathway inhibitor (ARPI) and chemotherapy, and had at least one PSMA-positive tumoral lesion (PET imaging). Pts received an intravenous dose of ^{177}Lu-JH020002 at the beginning of each 6-week cycle, up to a maximum of 6 cycles. Dose escalation and determination of the maximum tolerated dose (MTD) in phase I were based on an accelerated titration and 3+3 dose-escalation design, including 5 dose cohorts. The primary objective of phase I is to evaluate the safety and tolerability of ^{177}Lu-JH020002 and determine the recommended phase 2 dose. Secondary objectives are dosimetry, pharmacokinetics, efficacy and safety. Tumor response is assessed per PCWG3 criteria. **Results:** As of Jan 22, 2025, 12 pts received ^{177}Lu-JH020002 with a median cumulative dose of 18.06 GBq. 91.7% pts with bone, 33.3% nodal, 8.3% peritoneal metastases. 100% with $\geq$1 prior ARPI therapy, 50% $\geq$ 1 prior chemo regimen, 16.7% ^{223}Ra, 33.3% PARPi. No DLT was reported and MTD was not reached. The most common treatment related adverse events (TRAEs) were Grade1-2. No grade 4/5 AEs were reported. TRAEs of note were hematologic TRAEs, including lymphocyte count decreased (91.7%), platelet count decreased (50.0%), anaemia (66.7%) and white blood cell count decreased (16.7%). With follow-up ongoing, across cohorts 2-5, 63.6% with $\geq$ 50% PSA decline; 27.3% with $\geq$ 90% PSA decline. Seven pts were evaluated per PCWG3. None of them had progressive disease, and all of them remain under treatment follow-up. Among all pts, 1 was with measurable disease and had a partial response. **Conclusions:** ^{177}Lu-JH020002 exhibited excellent antitumor activity in heavily pre-treated pts with mCRPC. Toxicity was well tolerated and generally manageable. Further clinical trials are under planning. Clinical trial information: NCT06139575. Research Sponsor: Bivision Pharmaceuticals, Inc.

Substudy C of the Canadian cancer trials group (CCTG) IND.234: PC_BETS (Prostate Cancer Biomarker Enrichment and Treatment Selection)—A phase II study of darolutamide (DARO) selected by androgen-receptor (AR) circulating tumor DNA (ctDNA) in patients (PTS) with metastatic castration-resistant prostate cancer (mCRPC) after prior AR pathway inhibitors (ARPIs).

First Author: Michael Ong, The Ottawa Hospital Cancer Centre, Ottawa, ON, Canada

Background: DARO is a unique AR antagonist, with preclinical studies suggesting activity in mCRPC models resistant to abiraterone or enzalutamide due to *AR* amplification (amp) or ligand binding domain mutations. In this substudy (SS) of the (PC-BETS) master protocol, we explored DARO in ARPI-resistant mCRPC stratified by ctDNA *AR* status. **Methods:** Pts had mCRPC, ECOG PS 0–1, evaluable disease, biochemical or radiographic progression, prior ARPI, and no cytotoxic chemotherapy in mCRPC. Genomic screening tested plasma cell-free DNA and matched leukocyte DNA via targeted sequencing with a prostate cancer panel including the *AR* exons, introns, and flank. Only patients with evidence of ctDNA ≥1% were eligible. Pts were assigned to SS by molecular tumor board if biomarker (BM)+; otherwise, BM- pts were randomized to BM- SS. SS-C tested DARO 600mg od in three cohorts—AR amp (C1), AR mutation (C2), or BM- (C3) in a 2-stage design. Primary endpoint was clinical benefit rate (CBR), defined by PSA50 response, RECIST CR/PR, or SD ≥12 weeks. **Results:** PC-BETS Arm C opened in Jan 2018 and closed Feb 2024; 72 pts were enrolled: 27, 26, and 19 in C1, C2, and C3, respectively. Median age was 74 y (53–88), 100% ECOG PS 0-1. Sixteen pts (22%) had docetaxel for hormone-sensitive disease and none for mCRPC. Prior ARPI were abiraterone (31/72, 43%), enzalutamide (37/72, 51%), or apalutamide (4/72, 6%). Pts had bone (67/72, 93%), lung (9/72, 13%), and/or liver (5/72, 7%) metastases. Baseline PSA was 2–20 in 13/72 (18%), 20–100 in 32/72 (44%) or >100 in 27/72 (38%). CBR was more frequent in AR amp or mutated cohorts than BM– (Table 1). DARO median exposure was 4 months (range 1–29). Common related AEs were fatigue (38%), diarrhea (18%), nausea (15%), and anorexia (11%). Median ctDNA fraction of CBR vs no CBR was: C1: 5 vs 16%, p=0.059; C2: 5 vs 19%, p=0.042; C3: 13 vs 13%, p=0.944. C1 CBR was higher with SPOP mutations (3/5, 60%) and all CBR pts had >10 AR copies. C2 CBR was seen with L702H (3/7, 43%) and T878A (4/7, 57%) but not F877L, W724C/L, or V716M. By data cutoff, all had discontinued therapy (radiographic ± biochemical 61%, biochemical only 22%, symptomatic 7%). DARO was well tolerated, with only 6% discontinuing for AEs. **Conclusions:** DARO demonstrates modest activity for unselected mCRPC following ARPIs. ctDNA analysis enriched for pts more likely to benefit from DARO including SPOP alterations, AR amp, and AR mutations L702H and T878A. Clinical trial information: NCT03385655. Research Sponsor: Bayer.

5057 **Poster Session**

Substudy F of the Canadian Cancer Trials Group (CCTG) IND.234: PC_BETS (Prostate Cancer Biomarker Enrichment and Treatment Selection)—A biomarker-selected phase II study of durvalumab and tremelilumab (DT) in patients (pts) with previously treated metastatic castration-resistant prostate cancer (mCRPC) resistant to AR pathway inhibitors (ARPI).

First Author: Sebastien J. Hotte, Juravinski Cancer Institute, McMaster University, Hamilton, ON, Canada

Background: mCRPC with high neoantigen burden due to DNA mismatch repair deficiency (MMRd) and somatic hypermutation, or *CDK12* mutations, may respond best to immune checkpoint inhibition (ICI). CCTG IND.232 suggested that combination ICI with DT has efficacy in a subset of mCRPC but should be biomarker-directed. In this sub-study (SS) of the PC-BETS master protocol, we explored DT in ARPI-resistant mCRPC stratified by circulating tumor DNA (ctDNA) analysis. **Methods:** Pts had ECOG PS 0–1, evaluable disease, biochemical or radiographic progression, prior ARPI ± cytotoxic chemotherapy (max 1 in castrate resistant setting). Genomic screening tested plasma ctDNA and matched leukocyte DNA via deep targeted sequencing with a prostate cancer-specific panel including coding regions and introns of selected mismatch repair genes and estimating tumor mutational burden. Only pts with evidence of ctDNA ≥1% were eligible. Pts with a positive biomarker (BM+) on ctDNA were assigned to a specific SS by a molecular tumor board (MTB); BM- pts were randomized between SS. SS- F tested DT in 2 cohorts of pts: cohort 1: BM+ pts had either somatic hypermutation (HM) ± concomitant MMR gene alterations, or *CDK12* mutations, cohort 2: BM- pts without these alterations, in a 2-stage design. Primary endpoint was clinical benefit rate (CBR), defined by PSA50 response, RECIST CR/PR, or SD ≥12 weeks. Pts received T 225mg IV once on cycle 1, day 1 and D 1500mg IV day 1 every 4 weeks. **Results:** From January 2020 to February 2024, 25 pts were enrolled: 15 and 10 to cohort 1 and 2, respectively. Median age was 69y (63-84). Five pts had liver mets, 15 pts had had prior cytotoxics. 9 pts in cohort 1 had HM and the remainder had *CDK12* mutations only. Median N cycles given was 4 (1-45). 12 pts had a delayed or interruption of DT dosing. The most common related AEs were fatigue (36%), rash (36%), and diarrhea (32%). CBR was seen in 53% of BM+ pts: all also had PSA response and significantly higher median ctDNA% (34% vs 5%; 5-69%); no patient selected as BM+ due to *CDK12* mutations had CBR, while 8 of 9 pts selected based on HM had CBR. **Conclusions:** Liquid biopsy biomarker-informed treatment with DT demonstrated very promising efficacy in mCRPC pts with HM and merits further evaluation. *CDK12* mutations were not predictive of CBR. Toxicities experienced were characteristic of ICI. Clinical trial information: NCT03385655. Research Sponsor: AstraZeneca.

Substudy G of the Canadian cancer trials group (CCTG) IND.234: PC_BETS (V)—A circulating tumor DNA (ctDNA)–directed phase II study of carboplatin in patients (Pts) with previously treated metastatic castration-resistant prostate cancer (mCRPC).

First Author: April A. N. Rose, McGill University, Montreal, QC, Canada

Background: PC-BETS registered pts with mCRPC for ctDNA-based genomic screening. A molecular tumor board (MTB) assigned pts to sub-studies (SS) based on prespecified biomarker (BM) criteria: BM-positive (BM+), or by randomization if BM-negative (BM-). IND.234G investigated carboplatin in 2 cohorts (C): C1 included BM+ pts with deleterious DNA damage response (DDR) gene alterations and C2 included BM- pts. **Methods:** Key inclusion criteria were: mCRPC, ECOG 0-1, evaluable disease, biochemical and/or radiological disease progression, received prior next-generation AR pathway inhibitor; prior chemotherapy allowed (max I regimen for mCRPC). The primary endpoint was clinical benefit rate (CBR: PSA50 response, RECIST CR/PR, or SD ≥12 weeks). Secondary endpoints included time to PSA progression (TTP-PSA), and overall survival (OS). Plasma ctDNA and matched leukocyte DNA underwent deep targeted sequencing with a prostate cancer specific panel that included ATM, BRCA1/2, and 22 other DDR genes. Patients with ctDNA <1% were not eligible unless they carried a germline DDR gene alteration. Pts received IV carboplatin (AUC5) on day 1 of 21-day cycles. **Results:** From 09/2020 to 02/2024, 36 pts were enrolled: 19 and 17 in C1 and 2, respectively. All pts were evaluable for safety while 1 pt was not evaluable for CBR (biochemical only disease). Median age was 69y (55-83) and 66y (54-77); 67%/82% had prior chemotherapy; 21%/6% had prior PARPi, and 6%/0% had liver metastases in C 1/2, respectively. In C1, qualifying gene alterations were: ATM (n=8 pts), BRCA2 (8), BRCA1 (1) and ATR (1). Median number of cycles was 4 (1-31). The most common adverse events (AEs) were anemia (97%), thrombocytopenia (89%), lymphopenia (69%), nausea (58%), neutropenia (42%), diarrhea (22%), vomiting (22%), and constipation (33%). Grade ≥3 non-hematologic AEs occurred in 28% of patients; 1 pt died from an unrelated myocardial infarction. 22 pts had dose delays and 15 pts had dose reductions for hematologic AEs. A summary of results is shown in Table 1. For C1, CBR was observed in 5/8 pts with BRCA2 alterations (4 pts had PSA response), 2/8 pts with ATM alterations (0 PSA responses), and 0/2 pts with ATR/BRCA1 alterations. CBR (with PSA response) was observed in 1 pt enrolled to C2 who did not have DDR gene alterations. **Conclusions:** Carboplatin was associated with meaningful clinical benefit in mCRPC pts with DDR alterations detected in ctDNA, but not in pts without DDR alterations. Carboplatin warrants further evaluation in mCRPC pts with DDR gene alterations. Clinical trial information: NCT03385655. Research Sponsor: Canadian Cancer Society.

Phase 1b/2 KEYNOTE-365 cohort I: Pembrolizumab (pembro) plus carboplatin and etoposide chemotherapy (chemo) or chemo alone for metastatic neuroendocrine prostate cancer (NEPC).

First Author: Gunhild Von Amsberg, University Medical Center Hamburg-Eppendorf, Hamburg, Germany

Background: Patients with NEPC are often treated with platinum-based chemotherapy but novel therapies with favorable efficacy and safety profiles are needed. Cohort I of the phase 1b/2 KEYNOTE-365 study (NCT02861573) was designed to evaluate the safety and efficacy of adding pembro to chemo in participants (pts) with NEPC. Preliminary data are presented. **Methods:** Adultpts with pathologically (morphology and immunohistochemistry) confirmed treatment-emergent (t-NE) or de novo metastatic NEPC (small cell, large cell, or mixed morphology per central review), disease progression ≤6 mo before screening, and ECOG PS of 0 or 1, with or without prior androgen deprivation therapy, are included. Enrollment is ongoing. Prior treatment (Tx) with ≤2 chemo regimens for metastatic castration-resistant prostate cancer and ≤2 next-generation hormonal agents are allowed. Prior Tx with platinum-containing regimens is not permitted. Pts are randomly assigned 1:1 to receive 4-6 cycles of carboplatin AUC 5 IV on day 1 Q3W + etoposide 100 mg/m^2 IV on days 1-3 Q3W with or without pembro 200 mg IV Q3W for ≤35 cycles. Primary end points are safety, ORR per RECIST v1.1 by blinded independent central review (BICR), and confirmed prostate-specific antigen (PSA) response rate (≥50% decrease from baseline [BL] measured twice ≥3 wk apart). Secondary end points include rPFS per PCWG3-modified RECIST v1.1 by BICR and OS. No formal hypothesis testing was performed. **Results:** As of August 26, 2024, 40 pts have been randomized; 19 pts received ≥1 dose of pembro + chemo and 18 pts ≥1 dose of chemo. Of treated pts, 29 (78%) had t-NE. Median follow-up was 11.7 mo (range, 0.5-28.7); 7 and 2 pts remain on Tx with pembro + chemo or chemo, respectively. For pts with RECIST-measurable disease, confirmed ORR was 33% (6/18; 95% CI, 13-59; 6 partial responses [PRs]) with pembro + chemo versus 6% (1/16; 0-30; 1 PR) with chemo. For pts with a BL PSA measurement, confirmed PSA response rate was 37% (7/19; 95% CI, 16-62) versus 18% (3/17; 4-43). In all treated pts, median rPFS was 5.1 mo (95% CI, 3.9-8.1) with pembro + chemo versus 4.0 mo (2.0-4.3) with chemo; 6-mo rPFS rate was 49% versus 21%. Median OS was 11.4 mo (95% CI, 5.1-not reached) versus 7.8 mo (3.6-8.5); 6-mo OS rate was 80% versus 65%. Grade 3 or 4 Tx-related AEs (TRAEs) occurred in 58% of pts with pembro + chemo versus 78% with chemo, most commonly anemia (32% vs 39%); no grade 5 TRAEs occurred. Immune-mediated AEs and infusion reactions occurred in 32% of pts with pembro + chemo versus 11% with chemo, most commonly hyperthyroidism (16% vs 6%) and infusion reactions (16% vs 6%). **Conclusions:** Based on these preliminary data in pts with NEPC, the addition of pembro to chemo is associated with promising efficacy outcomes compared with chemo alone and does not result in new or unexpected safety signals. Updated data from cohort I will be presented at the meeting. Clinical trial information: NCT02861573. Research Sponsor: Merck Sharp & Dohme LLC, a subsidiary of Merck & Co., Inc., Rahway, NJ, USA.

5060 **Poster Session**

Impact of germline vs somatic BRCA mutation status on the efficacy of rucaparib vs physician's choice in the TRITON3 study of patients with metastatic castration-resistant prostate cancer. First Author: Simon Chowdhury, Guy's and St. Thomas' NHS Foundation Trust, London, United Kingdom

Background: Rucaparib significantly improved radiographic progression-free survival (rPFS) in men with BRCA-mutated chemotherapy-naïve metastatic castration-resistant prostate cancer (mCRPC) vs a control arm of physician's choice of therapy (docetaxel or androgen-receptor pathway inhibitor [ARPI] therapy: abiraterone acetate or enzalutamide) in the randomized, multicenter, open-label, phase 3 TRITON3 (NCT02975934) study. Herein, we conducted an analysis to determine the impact of germline vs somatic mutation status on the efficacy of rucaparib. **Methods:** Patients were randomized 2:1 to receive rucaparib 600 mg BID or physician's choice of docetaxel or ARPI following progression while on 1 prior second-generation ARPI in any setting. The primary endpoint was rPFS. Color Health did genetic testing. Treatment-emergent adverse events (TEAEs) were reported for the BRCA subgroup. **Results:** In the rucaparib arm, 201/270 patients had BRCA mutations, and in the physician's choice arm, 101/135 patients had BRCA mutations. Of patients with BRCA mutations: in the rucaparib arm, 80/201 (40%) were germline and 116/201 (58%) were somatic with 5/201 (2%) BRCA mutation status unknown, while in the physician's choice arm, 39/101 (39%) were germline and 48/101 (48%) were somatic with 14/101 (14%) BRCA mutation status unknown. rPFS was significantly improved with rucaparib treatment vs physician's choice in both the germline and somatic mutation groups (germline: HR, 0.52 [95% CI, 0.32–0.84]; somatic: HR, 0.38 [95% CI, 0.25–0.59]). Incidence rates of TEAEs were similar overall between patients with germline and somatic BRCA mutations in both arms. **Conclusions:** Rucaparib improves progression-free survival for patients with mCRPC with either germline or somatic BRCA mutations with a manageable safety profile. These data support the use of rucaparib as a beneficial treatment option for patients with BRCA-mutated mCRPC with germline or somatic mutations. Clinical trial information: NCT02975934. Research Sponsor: pharma& GmbH.

Prognostic relevance of Aurora kinase A (*AURKA*) expression in prostate cancer (PCa). First Author: Maroun Bou Zerdan, Winship Cancer Institute, Emory School of Medicine, Atlanta, GA

Background: Amplification and overexpression of the *AURKA* gene characterize aggressive variants of prostate cancer, such as castration-resistant (CR) PCa and neuroendocrine PCa (NEPC), representing both a marker of progression and a promising therapeutic target. **Methods:** 7755 PCa specimens were sequenced for DNA and RNA at Caris Life Sciences and stratified into top (Q4) and bottom quartiles (Q1) based on *AURKA* expression. Castration status was defined as castrate (CS) if a specimen was androgen deprivation therapy (ADT)-naïve or collected within 90 days from the initiation of 1st generation ADTs. Additionally, specimens that received 2nd generation ADTs prior to collection were excluded from the CS cohort. All other ADT treated specimens (excluding the CS cohort) were considered CR. AR and NEPC scores were calculated as previously reported (Beltran, Nat Med 2016) and categorized into highest (H) and lowest (L) quartiles. Real-world survival was obtained from insurance claims data, and Kaplan–Meier estimates were calculated from specimen collection to last clinical contact for overall survival (OS) and from initiation to termination of specific ADTs to estimate time on treatment (TOT). Hazard ratios (HR) and p-values were calculated using the Cox model and log-rank test, with multiple testing corrections applied ($q<0.05$). **Results:** Compared to Q1, Q4 was associated with a higher median age (69 vs 67 years) and a higher proportion of non-Hispanic/Latinos (75 vs 70%), NEPC-H (42 vs 15%), metastatic (60 vs 22%), CR (46 vs 20%, all $q<0.05$) disease. *Q4* was also associated with poor prognosis independent of race and ethnic backgrounds. Despite the significant enrichment of aggressive disease, *Q4* was associated with poor prognosis independent of metastatic, NEPC-L or castration status. Further within NEPC-H specimens, *Q4* was prognostic only among those that were also AR-L (Table 1). Relative to Q1, Q4 samples were enriched for mutations in *TP53* (48 vs 23%), *RB1* (10 vs 1%) and *PTEN* (11 vs 7%, all $q<0.05$). Interestingly, *Q4* was associated with a longer Leuprolide-TOT (HR: 0.9(0.8-0.97), $p<0.01$) and a shorter Enzalutamide-TOT (HR: 1.2 (1-1.4), $p<0.05$). **Conclusions:** Analysis of a large dataset revealed that high *AURKA* expression correlates with poor prognosis across clinical and demographic subpopulations. *AURKA* inhibitors might enhance outcomes of metastatic PCa treated with AR pathway inhibitors by intensifying AR inhibition, increasing DNA-damage-related cell death, and/or preventing escape mechanisms like NEPC. Further studies are needed to identify contexts where *AURKA* inhibitors can improve metastatic PCa outcomes. Research Sponsor: None.

PSA and alkaline phosphatase changes in the EORTC-1333 PEACE-3 study evaluating the addition of six cycles of radium 223 in metastatic castration-resistant prostate cancer (mCRPC) starting enzalutamide. First Author: Ananya Choudhury, The Christie NHS Foundation Trust, Translational Radiobiology and University of Manchester, Manchester, United Kingdom

Background: The EORTC/UNICANCER/CTI/CUOG/LACOG Peace 3 showed that adding Ra233 to enzalutamide significantly improves investigator-assessed progression-free survival (PFS) and overall survival (OS) in mCRPC with bone metastases. We examined the effect of the combination on the decline in prostate-specific antigen (PSA) and alkaline phosphatase (ALP). **Methods:** From 11/2015 to 03/2023, 446 men with mCRPC and bone metastasis were randomized 1:1 to enzalutamide alone (ENZ) or combined with 6 cycles of Ra223 (ENZ-RAD). The PSA/ALP response rate is estimated at 6/12 months based on the drop from baseline in all PSA/ALP evaluable patients. For PSA, any decline $\geq$ 50 or 90% from baseline is considered a PSA response. For ALP, any decline of $\geq$30% from baseline is regarded as a response. Each response needed to be confirmed by a second evaluation at least three weeks later. Time to response is from treatment start until the first date a response was observed. ALP normalization is a decline to $\leq$ 115 U/L in patients with baseline ALP >115 U/L. **Results:** PSA: The baseline median (Q1-Q3) for ENZ-RAD was 24.0 (7.8-68.8) ng/dl, and 21.4 (8.0-57.6) ng/ml for ENZ. The median time (95%CI) to a PSA response > 50% in months (mo.) was 2.79 (2.56-3.02) in the ENZ-RAD arm and 2.76 (2.63-2.79) in the ENZ arm (HR (95%CI) 1.00 (0.80-1.24)). PSA response rates $\geq$50% at 6 and 12 months were 77.1% (145/188) and 76.8% (109/142) in the ENZ-RAD arm, compared to 69.9% (127/182) and 66.2% (88/133) in the ENZ arm. The median time (95%CI) to a PSA response $\geq$ 90% in mo. was 1.87 (1.44-2.53) in the ENZ-RAD arm and 7.44 (3.67-NE) in the ENZ arm (HR (95%CI 1.48 (1.13-1.93)). PSA response rates $\geq$90% at 6 and 12 mo. were 50.5% (95/188) and 54.9% (78/142) in the ENZ-RAD arm, compared to 34.1% (62/182) and 37.6% (50/133) in the ENZ arm. ALP: The baseline median (Q1-Q3) ALP in the ENZ-RAD arm was 106 (78-183) UI/L, and in the ENZ arm, 124.5 (85-216). In the ENZ/RAD and ENZ arms, 45.6% (99/217) and 54.4% (122/224) of patients had ALP $\geq$ 115 UI/L at baseline. The ENZ-RAD arm had a median time (95%CI) to ALP response > 30% of 2.40 (1.97-2.79) mo., while the ENZ arm had a median of 3.71 (2.83-5.49) mo. (HR (95%CI) 1.42 (1.13-1.80)). ALP >30% response rates at 6 and 12 mo. were 56.5% (108/191) and 50.0% (71/142) in ENZ-RAD and 50.8% (93/183) and 47.4% (63/133) in ENZ. The median (95%CI) time to ALP normalization in the ENZ-RAD arm is 1.97 (1.87-2.50) mo. and 4.47 (2.99-14.06) mo. In the ENZ arm(HR 1.42 (1.13-1.80)). At 6 and 12 mo., the ENZ-RAD arm ALP normalization rates were 76.2 (64/84) and 77.4 (41/53), while 50.5% (47/93) and 61.3% (38/62) in the ENZ arm. **Conclusions:** The addition of six cycles of RA 223 to enzalutamide in the PEACE-3 trial improves PSA response time and rates ($\geq$90%), ALP reduction time ($\geq$30%), and ALP normalization time and rates at 6 and 12 months. Clinical trial information: NCT02194842. Research Sponsor: Bayer Healthcare, Astellas.

A novel prognostic model to optimize the timing of docetaxel (Doc) following an androgen receptor pathway inhibitor (ARPi) in metastasic castration-resistant prostate cancer (mCRPC). First Author: Lola Rodríguez Nogueira, Oncology Department, Hospital Universitario 12 de Octubre,, Madrid, Madrid, Spain

Background: ARPi has become a standard of care for advanced prostate cancer due to its activity and safety profile. DoC is a therapeutic alternative as first-line in unselected mCRPC patients (pts) after a first ARPi. Best timing to initiate Doc following an ARPi remains uncertain, with most predictive models based on baseline characteristics and without variables related to the disease evolution. We have developed and validated a tool to predict progression-free survival (PFS) and overall survival (OS) with Doc to capture individual tumor behavior and guide the optimal timing of Doc. **Methods:** mCRPC pts from PROREPAIR-B (NCT03075735) treated with an ARPi followed by Doc were selected for a derivation cohort (n=111). Those pts from PROSTAC (NCT02362620), PROSABI (NCT02787837) and/or PROSENZA (NCT02922218) not included in PROREPAIR-B treated with an ARPi followed by Doc were included in the validation cohort (n=243). Baseline characteristics at ARPi initiation, type and time of response/progression to ARPi and prognostic variables at initiation of Doc were collected. All variables underwent univariate Cox regression for PFS and OS from Doc in the derivation set. Only significant variables underwent the least absolute shrinkage and selection operator (LASSO) method to select the most relevant. Individual risk scores for PFS and OS were generated using Cox to classify patients into low- and high-risk groups and to construct a nomogram. Finally, an external validation was conducted in our second independent cohort. Predictive accuracy was assessed using Harrell's C-index. **Results:** The Lasso method identified 6 variables associated to PFS and OS: age at diagnosis, time to (t)mCRPC, development of new nodal and/or new visceral metastasis during ARPi, elevated LDH and ECOG at Doc initiation (Table). After bootstrap correction for internal validation the PFS and OS model showed a C-index of 0.71 (CI95% 0.66–0.77) and 0.74 (0.68–0.80), respectively. The model was validated in our second cohort with c-index of 0.62 (0.6-0.7) and 0.64 (0.6-0.7) for PFS and OS, respectively. **Conclusions:** Our validated model provides a pragmatic and widely accessible tool for physicians to estimate the potential benefit of Doc after an ARPi according to pts age and time to mCRPC, particularly in settings where targeted therapies at the time of progression to ARPi are not available. Research Sponsor: None.

Variable	PFS risk coefficient (rc)	PFS (HR CI95%)	OS rc	OS (HR CI95%)
Age (<60, 60-70, >70)	.35	1.5 (1.1-1.9)	.33	1.6 (1.2-2.3)
tmCRPC (>98, 98-23, <23)	-.17	0.7 (0.5-0.9)	-.49	0.4 (0.2-0.7)
Visceral MTS (never, persistent, new)	.48	1.2 (0.9-1.6)	.54	1.9 (0.9-3.9)
Nodal MTS (never, persistent, new)	.58	1.4 (1.0-1.9)	.66	2.0 (1.0-4.2)
LDH (xULN)	.10	1.2 (1-1.2)	.8	1.9 (1.0-2.4)
ECOG at Doc	.63	2.1 (1.4-2.9)	.74	4.1 (2.1-8.2)
Total Score (Low vs high)		**1.9 (1.2-3.1)**		**2.13 (1.3- 3.5)**

5064 Poster Session

Additive clinical utility of tissue biomarkers of microsatellite instability (MSI) status and tumor mutational burden (TMB) to predict immune checkpoint inhibitor (ICI) effectiveness for real-world patients with metastatic castration-resistant prostate cancer (mCRPC). First Author: Nicolas Sayegh, Huntsman Cancer Institute, University of Utah Health Care, Salt Lake City, UT

Background: FoundationOneCDx (F1CDx) supports two FDA-approved biomarkers to guide treatment decisions for ICI for patients with mCRPC: MSI status and TMB. MSI-H and TMB-H (10+ mut/MB) have strongly overlapping prevalence. We sought to better characterize ICI outcome associations of TMB-H / non-MSI-H population and relative effectiveness of taxanes & ICI among patients who received these agents in sequence. **Methods:** Following a prespecified analysis plan, this study used the nationwide (US-based) de-identified Flatiron Health-Foundation Medicine mCRPC clinico-genomic database (FH-FMI CGDB), with data originating from ~280 US cancer clinics (~800 sites of care). Inclusion criteria included patients with mCRPC treated with single-agent anti-PD(L)1 therapy in the FH network between 1/1/2011 - 3/30/2024. This study used the MSI and TMB algorithms from the tissue based F1CDx. Time to next treatment (TTNT) and OS were assessed with Kaplan-Meier plots and in multivariable Cox models adjusted for ECOG performance score, socioeconomic status, prior treatment history, and baseline PSA. Among patients who received taxanes in a prior line of therapy, the effectiveness (TTNT1 vs. TTNT2) of taxane and ICI were compared. **Results:** Among 2995 prostate cancer tissue specimens in the database, 95 (3.1%) were MSI-H and 142 (4.7%) were TMB-H. 94 (3.1%) were MSI-H & TMB-H, 1 was MSI-H & TMB-L, and 48 (1.6%) were TMB-H & not MSI-H. Among these, 84 patients with mCRPC were treated with ICI and met inclusion criteria, including MSI-H & TMB-H (n = 30), non-MSI-H & TMB-H (n = 8), and non-MSI-H and TMB-L (n = 46). The respective median TTNT on ICI was 8.0 vs. 9.6 vs. 3 months. The respective median OS from initiation of ICI was 10.9 vs. not reached vs. 4.4 months. In multivariable models evaluating ICI only, compared to non-MSI-H & TMB-L, the MSI-H & TMB-H group had more favorable TTNT (HR: 0.20, 95%CI: 0.10 – 0.41, $p < 0.001$) and OS (HR: 0.33, 95%CI: 0.16 – 0.70, p = 0.004), and the non-MSI-H & TMB-H group also had more favorable TTNT (HR: 0.13, 95%CI: 0.04 – 0.45, p = 0.002) and OS (HR: 0.20, 95%CI: 0.05 – 0.75, p = 0.017). 50 of the 84 (60%) patients treated with ICI had prior mCRPC taxane treatment. Better TTNT2 on subsequent ICI vs. prior taxane was observed for MSI-H (HR: 0.49, 95%CI: 0.23 – 1.01, p = 0.051) and TMB-H (0.54, 95%CI: 0.30 – 0.98, p = 0.044), but the opposite was true for non-MSI-H and TMB-L subgroups, with significant treatment interactions for each (p = 0.0018, p = 0.00052). **Conclusions:** TMB-H (4.7%) is more prevalent than MSI-H (3.1%) by F1CDx in mCRPC. Non-MSI-H / TMB-H (1.6%) in the routine practice cohort have similar outcome associations on ICI to MSI-H. Both MSI-H and TMB-H by F1CDx are predictive of differential benefit for ICI vs. taxanes in later mCRPC treatment lines. Research Sponsor: None.

Suboptimal suppression of serum androgen levels among men treated with apalutamide and abiraterone acetate plus prednisone compared with abiraterone acetate plus prednisone alone. First Author: Elahe A. Mostaghel, VA Puget Sound Health Care System, Seattle, WA

Background: Phase III studies of dual therapy with an androgen receptor (AR) antagonist, apalutamide (Apa) or enzalutamide (Enza) with abiraterone acetate (AA) plus (+) prednisone (P) in metastatic castration resistant prostate cancer (mCRPC) have not shown a survival benefit vs single agent therapy. Apa and Enza induce CYP3A4 activity, resulting in decreases in serum AA and P levels. The decrease in AA levels has not been considered clinically significant, but the potential impact of AR antagonist-mediated CYP3A4 induction on serum steroid levels, in context of clinical studies combining an AR antagonist with AA, has not been previously reported. **Methods:** We measured levels of AA, its metabolites and androgens using LC/MS-MS in available serum samples obtained at baseline and at 4 weeks of therapy in the PANTHER phase II study (n=86) of Apa (240 mg daily) and AA (1000mg daily) + P (10mg daily), and in the Abi Race phase II study (n=75) of AA (1000mg daily) + P (10mg daily) among men with mCRPC. Samples were batched and all sera assessed contemporaneously. Comparison of metabolite levels between studies used the Mann-Whitney test, and within study the Wilcoxon matched-pairs signed rank test. **Results:** At 4 weeks, median (med) levels of AA and its primary metabolites delta-4 and keto-Abi in PANTHER vs Abi Race were 13.1 vs 39.6 ng/ml, 0.49 vs 1.93 ng/ml, and 0.75 vs 8.98 ng/ml ($p=<0.0001$ for all), equating to 66%, 75%, and 92% lower levels with Apa and AA + P vs AA + P. Baseline steroid levels did not differ between the studies, but steroids downstream of CYP17A were suppressed markedly less effectively in the dual therapy PANTHER study: DHEAS was detectable in 80% vs 14% of samples (med 1.23 vs 0.49 ng/ml, $p=<0.0001$), DHEA in 90% vs 26% (med 0.44 vs 0.01 ng/ml, $p=<0.0001$), AED in 70% vs 11% (med 0.017 vs 0.010 ng/ml, $p=<0.0001$), and testosterone in 50% vs 17% (med 0.006 vs 0.005 ng/ml, p=0.0005). Despite the decrease in AA levels, steroids upstream of CYP17A in PANTHER were markedly elevated vs treatment with AA + P alone: pregnenolone (4.1 vs 0.79ng/ml, $p=<0.0001$), consistent with a suboptimal prednisone-mediated suppression of ACTH. **Conclusions:** Serum AA levels at week 4 are substantially lower, and androgen levels substantially higher, among men with mCRPC treated with Apa and AA + P vs AA + P. Our data suggest that Apa decreased P levels to the point that circulating ACTH remained sufficient to mediate ongoing basal adrenal androgen synthesis. Suboptimal suppression of steroids may explain why AA and AR antagonist combination studies have not been more effective. The clinical activity when both treatment strategies are at full efficacy remains to be fully tested, and will likely require use of dexamethasone or higher than standard dosing of prednisone. This may be particularly important for treatment of prostate cancers with greater dependence on AR signaling. Research Sponsor: Janssen Scientific Affairs, LLC.

Canadian Cancer Trials Group (CCTG) IND.234/223: PC_BETS (Prostate Cancer Biomarker Enrichment and Treatment Selection)—A molecularly selected cooperative group platform study. First Author: Alexander William Wyatt, Vancouver Prostate Centre, Vancouver, BC, Canada

Background: PC-BETS registered patients (pts) with metastatic castration-resistant prostate cancer (mCRPC) for circulating tumour (ct)DNA-based genomic screening to biomarker select and stratify pts for enrolment in a multi-arm platform trial testing clinical activity of investigational therapies. **Methods:** Pts ($\geq$ 18 years old, ECOG PS 0-1, life expectancy $\geq$ 6 months) had mCRPC, disease progression (PD), no CNS involvement or serious illnesses and had received AR pathway inhibitor therapy +/- chemotherapy. Eligible pts were registered and screened using plasma ctDNA and enrolled to a substudy (SS) based on the presence (or absence) of a prespecified biomarker (BM), using a prespecified algorithm and a virtual web-based Molecular Tumour Board (MTB). ctDNA testing used an established targeted sequencing approach customised for mCRPC. Pts without BM positive genomic alteration(s) for an open SS were randomized to a BM negative SS cohort; pts who were never enrolled were followed for outcomes. Pts without detected ctDNA were not eligible for enrolment but could be rescreened after >8 weeks. Pts who discontinued a SS could be rescreened. Primary endpoint was clinical benefit rate (CBR; PSA50 response, RECIST CR/PR, or SD $\geq$12 weeks). Eight SS opened between 2017-2020. **Results:** From 2017-2024, 568 pts were screened from 11 centres across Canada. Pts: median age 71.5 (range 47.7-94.7), prior chemotherapy in 47.0%, and median ctDNA fraction was 7%. 216 pts were enrolled to 1 or more SS (3 pts enrolled to >1). See Table for summary of results. For all SS, toxicities were as expected. In SS-E, 1 pt had CBR and 1 pt received 25 cycles but did not meet CBR (both pts had AKT mutations). Clinical and genomic correlations will be presented. SS C, F and G are reported separately. **Conclusions:** Biomarker selected platform designs are an efficient way to screen potential new therapeutics, are well suited to multi-centre cooperative group settings and are strongly supported by patients advocates. CBRs were not reported for SS 223, B and D while modest clinical activity was seen for SS A (in the BM- cohort only) and E. Clinical trial information: NCT03385655. Phase 1 study of gotistobart (BNT316/ONC-392) in combination with lutetium Lu 177 vipivotide tetraxetan (Lu 177) in patients with metastatic castration-resistant prostate cancer (mCRPC). First Author: David R. Wise, Perlmutter Cancer Center, NYU Langone Health, New York, NY

Background: When used in combination with physician's choice of care, Lu 177 showed significant PFS and OS improvements in mCRPC. Combinations with novel agents are being explored to extend the therapeutic benefit. Preclinical models have demonstrated that radiotherapy selectively expands and functionally activates regulatory T cells (Tregs) in the tumor microenvironment (TME). Given the role of gotistobart (a unique pH-sensitive anti-CTLA-4 antibody that preserves CTLA-4 recycling and avoids lysosomal degradation) in selective depletion of Tregs in the TME, this study will initially test the safety and toxicity of gotistobart plus Lu 177 in mCRPC. **Methods:** PRESERVE-006 (NCT05682443) is an open-label, randomized, active control, multi-center, phase 1/2 study of gotistobart in combination with Lu 177 in patients with mCRPC who have progressed after androgen receptor pathway inhibition. Patients were randomized to receive gotistobart at 3 mg/kg, Q4W, 6 mg/kg Q6W, or 10 mg/kg Q6W for up to 13 doses plus Lu 177 7.4 GBq (200 mCi) Q6W for up to 6 doses, or to the control arm to receive Lu 177 7.4 GBq (200 mCi), Q6W for up to 6 doses. Here we report results from the dose escalation phase (Phase 1) that aims to assess safety and select two dose regimens for the Phase 2 dose optimization study. **Results:** As of December 20, 2024, 24 patients received at least 1 drug dose with a median 6.21 (range 1.2–11.3) months on study. Median age was 70.5 (range 52–86) years, and 62.5%, 25.0% and 4.2% were White, Black, and Asian, respectively. Median follow-up was 10.9, 2.6 and 5.4 months for the 3 mg/kg Q4W (N = 6), 6 mg/kg Q6W (N = 5) and 10 mg/kg Q6W (N = 6) combination regimens, respectively, and 6.5 months for Arm B Lu 177 (N = 7). No deaths, dose-limiting toxicity, or Gr 4–5 treatment-related AEs (TRAEs) were observed at any gotistobart dose. TRAEs related to gotistobart or Lu 177 were Gr 1–2 at 3 mg/kg Q4W and 6 mg/kg Q6W; one patient (16.7%) in the 3 mg/kg regimen had Gr 2 colitis leading to treatment discontinuation. At 10 mg/kg Q6W, two patients (33%) had Gr 3 colitis (both of whom discontinued treatment) and one patient (16.7%) had Gr 3 fatigue. Infusion-related reactions (Gr 1–2) were seen in 6 mg/kg (40.0%) and 10 mg/kg (66.7%) regimens. In the efficacy-evaluable population, confirmed PSA50 (a key secondary endpoint for Phase 2) was observed in 4 of 6 patients and 3 of 6 patients in 3 and 10 mg/kg regimens, respectively versus 1 of 6 patients in the Lu 177 control group. **Conclusions:** With known limitations in sample size during dose escalation,gotistobart in combination with Lu 177 demonstrated a manageable safety profile and promising preliminary PSA50 rates in patients with mCRPC during the dose escalation phase. Overall findings support combination regimens with gotistobart doses less than 10 mg/kg in the ongoing Phase 2 randomized dose optimization study. Clinical trial information: NCT05682443. Research Sponsor: OncoC4 Inc; BioNTech SE.

Survival and hospitalizations with lutetium (Lu)-177 vipivotide tetraxetan in veterans with underlying genomic alterations. First Author: Sumrah Khan, Saint Louis University School of Medicine, St. Louis, MO

Background: Lutetium-Lu 177 vipivotide tetraxetan (^{177}Lu-PSMA-617) is a radioligand therapy used to treat metastatic castration resistant prostate cancer (mCRPC) with limited real-world survival data outside of large academic centers. Emerging data suggests outcomes are associated with somatic tumor genomic profiles, such as status of tumor suppressor gene (TSG) alterations, including TP53, PTEN, or RB1. We utilized a nationwide retrospective cohort within the Veterans Health Affairs (VHA) to evaluate overall survival of patients treated with ^{177}Lu-PSMA-617 and considered tumor suppressor gene alteration status, which could serve as a biomarker for personalized treatment. **Methods:** Veterans with mCRPC treated in the VHA who received at least one dose of ^{177}Lu-PSMA-617 through November 2024 were included. The National Precision Oncology Program (NPOP) was used to identify patients who underwent tumor sequencing and had TSG alterations. Age, Charlson comorbidity index (CCI), and number of hospitalizations were collected. The Kaplan-Meier method was used to estimate overall survival (OS), logistic regression for risk of hospitalization, and Cox proportional hazards models to estimate mortality. **Results:** A total of 228 Veterans who had received at least one dose of ^{177}Lu-PSMA-617 were identified. Mean age was 76.5 years (SD 7.6) with median CCI of 2 (IQR 1-4). Median OS was 11.4 months (95% CI 8.6-14.2) in the entire cohort and 29.8% of Veterans (68/228) were hospitalized in the year after first dose. Age was not associated with mortality or hospitalization, however CCI was associated with mortality (HR 1.12, 95% CI 1.01-1.24) and any hospitalization (OR 1.21, 95% CI 1.05-1.41). There were no differences in OS based on receipt of NPOP testing (HR 0.97, 95% CI 0.62-1.5). In 108 patients with NPOP testing, 44% (48/108) were found to have at least one TSG alteration. Median OS was shorter in patients with TSG alterations (5.8 vs. 18.0 months, p=0.001, HR 2.8, 95% CI 1.5-5.3) compared to patients without TSG alterations. When accounting for age and CCI, risk of death was increased in Veterans with TSG alterations (aHR 3.0, 95% CI 1.6-5.9). **Conclusions:** In US Veterans treated with ^{177}Lu-PSMA-617, median OS was 11.4 months, shorter than observed in other cohorts, although the mean age was higher. Comorbidities were prognostic for mortality and hospitalization while age was not. Veterans who had TSG alterations had significantly shorter OS in unadjusted and adjusted analyses, suggesting that patients with TSG alterations are less likely to benefit from ^{177}Lu-PSMA-617 and could consider different treatment modalities. Prospective studies are needed to identify additional clinical outcomes over time. A phase I and randomized phase II trial of radium-223 dichloride, peposertib, and avelumab in advanced metastatic castrate-resistant prostate cancer (mCRPC): Phase I results. First Author: Hiram Alberto Gay, Washington University School of Medicine, Department of Radiation Oncology, St. Louis, MO

Background: Ra-223 improves the overall survival in patients with mCRPC to the bone. We assessed the safety of standard-of-care Ra-223 in combination with peposertib, a DNA-dependent protein kinase inhibitor, with or without avelumab, an anti-PD-L1 antibody. **Methods:** Patients with mCRPC and two or more skeletal metastases identified by bone scintigraphy with or without lymph node metastases up to 3 cm in size, but no visceral metastases, were eligible. Progression after progression after at least one androgen receptor pathway inhibitor or taxane was required. Phase 1 consisted of a two-step sequential safety lead-in using a 3+3 design. Step 1 combined 6 standard cycles of Ra-223 (55 kBq/kg), with increasing doses of peposertib: 50, 100, and 200 mg PO bid on days 3-26 of each cycle. Step 2 combined Ra-223 with the maximum tolerated dose of peposertib and added standard avelumab 800 mg IV every 14 days, starting at cycle 2 of Ra-223. **Results:** A total of 9 patients participated in Step 1, where the maximum tolerated peposertib dose of 200 mg PO bid with Ra-223 was deemed tolerable. A total of 6 patients participated in Step 2 and the combination of Ra-223, peposertib at 200 mg PO bid, and standard avelumab was deemed tolerable. Of the 15 patients in Phase 1, none experienced grade 4 or higher treatment-related toxicities, while 7 experienced grade 3 toxicities, including neutropenia (1), anemia (1), cardiac chest pain (1), fall (1), maculopapular rash (2), and lymphopenia (2). The median (Q1, Q3) PSA velocity from the beginning to the end of treatment was lower for Step 2 versus Step 1: 2.1 (-0.1, 4.6) versus 23.5 (18.6, 77.1) ng/mL/month (p = 0.0067). OS and PFS were calculated with the limitation that the Phase 1 was non-randomized. Median OS was not reached for Step 2, as only 1 of 6 patients had died, versus 15.2 months for Step 1, where 8 out of 9 patients had died (p = 0.0537). The patient who died in Step 2 discontinued therapy prematurely after 3 cycles due to progression and survived 15.2 months (the 5 alive completed all 6 cycles). The median radiographic PFS was 7 months for Step 2 versus 12.7 months for Step 1 (p = 0.8910). **Conclusions:** The combination of Ra-223 and peposertib, with or without avelumab was well tolerated. The triplet combination showed the most promising results at this early evaluation. We continue to accrue in the randomized Phase II portion of the trial. Clinical trial information: NCT04071236. PSMA-targeted actinium-225 therapy in metastatic castration-resistant prostate cancer (mCRPC): Baseline and follow-up PSMA PET parameters associated with outcomes. First Author: Valentina Marulanda Corzo, Molecular Imaging & Therapeutics, Department of Radiology, Weill Cornell Medicine, New York, NY

Background: Prostate-specific membrane antigen (PSMA) is a validated therapeutic target in mCRPC. 225Ac-J591, an alpha-emitting radionuclide linked to an anti-PSMA antibody, has been studied in several early phase clinical trials. We evaluated baseline and follow-up (12 weeks post 225Ac-J591) PSMA PET metrics (SUVmax, SUVmean, and total tumor volume [TTV]) and their association with biochemical response (PSA50), overall survival (OS), and adverse events. **Methods:** Patients enrolled in phase I dose-escalation trials of 225Ac-J591, either as a single agent (NCT03276572, NCT04506567; n = 87) or in combination (with 177Lu-PSMA-I&T, NCT04886986, n = 18; or pembrolizumab and androgen receptor (AR) inhibitors, NCT04946370 n = 12), were included. 68Ga-PSMA-11 PET metrics were quantified using MIM Encore software. Outcomes assessed included PSA50, OS, and adverse events. Statistical analyses utilized univariate and multivariate logistic regression for PSA50, Cox regression for OS and Kruskal-Wallis and Wilcoxon rank sum tests for adverse events. **Results:** 117 patients were included with a median age of 71 yr and median baseline PSA of 58 ng/mL (range 0.67–9614). Prior therapies included chemotherapy (62%), >1 AR pathway inhibitor (53%), immunotherapy (42%), 177Lu-PSMA (28%), and radium-223 (17%). Metastatic sites included bone (88%), lymph nodes (63%), and visceral organs (29%). High CALGB (Halabi) risk in 56% of patients. Median baseline SUVmax, SUVmean, and TTV on PSMA-PET were 50 (31-85), 8.3 (5.7-11.8), and 308 (105-1066), respectively. Baseline SUVmean (OR 1.13, 95% CI 1.04–1.24, p = 0.006) and SUVmax (OR 1.01, 95% CI 1.00–1.02, p = 0.018) were associated with higher odds of PSA50, though only SUVmean remained significant on multivariable analysis (OR 1.11, p = 0.023). Baseline SUVmean and TTV were associated with OS (HR 0.95, p = 0.025; HR 1.000, p < 0.001), TTV remaining significant on multivariable analysis (HR 1.00, p = 0.007), along with prior chemotherapy (HR 1.45, p < 0.001) and CALGB high risk group (HR 1.84, p = 0.014). In multivariable analysis controlling for injected radioactivity, prior chemotherapy, and CALGB risk, TTV reduction was associated with PSA50 (OR 1.31, 95% CI 1.1–1.7, p = 0.015), but changes in SUVmean or SUVmax were not. Higher baseline TTV was more likely to have higher grade myelosuppression (anemia Gr 3/4 673 vs Gr 1/2 203, Gr0 284, p = 0.041), but less nausea and xerostomia. **Conclusions:** Higher baseline PSMA PET metrics, including SUVmean, SUVmax, and TTV are associated with PSA50 response and survival in patients receiving antibody-delivered alpha emitter 225Ac. Higher TTV, yielding more radionuclide delivery to tumor (most commonly bone) is associated with higher grade myelosuppression. However, the tumor antigen sink effect may decrease exposure to other PSMA+ organs leading to less xerostomia and nausea. Clinical trial information: NCT03276572, NCT04506567, NCT04886986, NCT04946370. Preliminary phase 2 results of PT-112 monotherapy in late-line metastatic castration-resistant prostate cancer (mCRPC). First Author: Alan Haruo Bryce, City of Hope, Phoenix, AZ

Background: Late-line mCRPC has shown poor outcomes as a result of disease heterogeneity, metastases in bone and viscera including liver, and limited immunotherapeutic options. PT-112 is a novel therapy that inhibits ribosome biogenesis, induces robust immunogenic cell death, concentrates in bone and soft tissue, and previously exhibited clinical activity in patients (pts) with mCRPC. We report the results of a Phase 2 study of monotherapy PT-112 in the late-line mCRPC population. **Methods:** mCRPC pts with ≥3 prior standard of care treatments, including ≥1 androgen receptor pathway inhibitor (ARPI) and 1-2 taxanes with radiographic progression at entry were randomized to one of three dosing arms: Arm 1 (360 mg/m² Q2W), Arm 2 (250 mg/m² Q2W), and Arm 3 (360 mg/m² Q2W in cycle 1, then 250 mg/m² D15 of subsequent 28-day cycles). The primary endpoint was to determine the optimal dosing regimen based on safety and efficacy per FDA Project Optimus. **Results:** Pts on the study (N=111) had a median of 4 prior lines of therapy, 69% with ≥2 ARPis, 59% with 2 taxanes, and 24% with PSMA-Lu-177. At entry, pts had liver metastases (19%), bone-only metastases (28%), and evidence of bone progression (74%). The most common treatment-related adverse events (TRAEs) were fatigue (53%), nausea (42%), and anemia (41%); no G5 TRAEs. Discontinuation due to AEs was 12%. Due to superior balance of efficacy and tolerance at interim analysis, Arms 2 and 3 proceeded to full enrollment, while Arm 1 was discontinued. Safety and efficacy metrics are summarized in Table 1. In the more mature Arm 2, OS in pts without prior cabazitaxel (22 pts) was 16.4m and without cabazitaxel or PSMA-Lu-177 (17 pts) was 20.5m. 4% of pts had confirmed PCWG3 bone progression on study. A signal of immune response was observed via TCR sequencing with a statistically significant 20% increase in the percentage of TCR+ blood cells. **Conclusions:** PT-112 treatment resulted in a manageable and reasonably low rate of G3-4 TRAEs and was active in pts with very late-line mCRPC. The better balance of safety and efficacy in Arms 2 and 3 is indicative of an optimized RP3D. Biomarker responses (ALP, CTC and T cell) may reflect broad activity of PT-112. ctDNA analyses are ongoing. OS duration in these heavily pretreated patients, with low rates of bone progression and symptomatic skeletal events (SSEs) on study, are encouraging and supportive of a Phase 3 study of PT-112 vs standard of care. Clinical trial information: NCT02266745. Research Sponsor: Promontory Therapeutics Inc.

Molecular characterization of STEAP1 and -2 in advanced prostate cancer. First Author: Kevin Kayvan Zarrabi, Department of Medical Oncology, Sidney Kimmel Cancer Center, Thomas Jefferson University Hospital, Philadelphia, PA

Background: *STEAP*1 and 2 (six-transmembrane epithelial antigen of prostate) are metalloreductase proteins involved in a variety of biologic processes. *STEAP1/2* are tumor-associated cell surface antigens highly expressed in prostate cancer (PC), although their role in cancer is poorly understood. *STEAP1/2* have emerged as successful targets for adoptive T-cell therapy trials for PC. We employed a multi-omics approach to investigate the molecular features associated with *STEAP1* and *STEAP2* expression in PC. **Methods:** NextGen Sequencing of DNA (592 genes or whole exome) and RNA (whole transcriptome) was performed for PC tumors (n = 7089) submitted to Caris Life Sciences (Phoenix, AZ). PC samples were stratified by *STEAP1/2* mRNA levels into top (high) and bottom quartile (low). Immune cell infiltration in the tumor microenvironment (TME) was inferred by quanTIseq. Transcriptomic signatures of androgen receptor signaling (AR), neuroendocrine classification (NEPC), and interferon gamma signaling (IFN) were calculated. Mann-Whitney U and X2/Fisher-Exact tests were applied where appropriate, with P-values adjusted for multiple comparisons (q< .05). **Results:** Of 7,089 samples, 63.2% were from the prostate; 11.7% from lymph node metastases (LNM); 7.3% from bone; and 17.8% from visceral/soft tissue metastases (V/STM). *STEAP*-1 and -2 were significantly correlated to each other (R= 0.90, p<.001), with significantly higher expression of *STEAP1* observed in primary prostate and LNMs, compared with reduced expression in V/STM (*STEAP1* TPM: 105.2 vs 140.6 vs 91.9 p<.001). Mutations in *AR* (3.8% v 1.9%), *KDM6A* (4.2% v 2.2%), *SPOP* (10.9% v 8.4%) and *ARV*7 (23.0% v 10.5%) were enriched in *STEAP1* high PC (each q<.01). Mutations in *KDM6A* (3.8% v 2.5%) and *ARV*7 (17.6% v 14.3%) were enriched in *STEAP2* high PC (each q<.05). *STEAP1/2* expression negatively correlated with TMB count (R =-0.03, p<.05) and IFN score (R = -0.26, p<.001). Concordantly, fewer proinflammatory immune cell fractions (M1 Macrophages, NK cells, CD4+/CD8+ T cells, myeloid dendritic cells) were observed within the TME of *STEAP1/2* high PC (p<.0001). However, *STEAP1/2* expression correlated positively with the AR signature (R = 0.39, p<.001) and androgen response pathways, while correlating negatively with the NEPC signature (R = -0.15, p<.001). **Conclusions:** PC tumors expressing high *STEAP1/2* display distinct genomic and transcriptomic profiles compared to *STEAP1/2*-low PC, and *STEAP 1/2* expression varies across sites of metastases. Immune biomarkers and immune cell infiltration data suggest that STEAP1/2 may be associated with a cold TME. The recent success of STEAP1-targeting T-cell redirecting therapies mechanisms by which adoptive T-cell strategies may overcome immunosuppressive factors within the TME. Ongoing development of T-cell immunotherapeutics targeting STEAP1 may account for the differential expression profiles in guiding patient selection and combination strategies. Research Sponsor: None.

Characterization and impact of B7-H3 (*CD276*) expression across disease states and racial groups in prostate cancer. First Author: Justin Hwang, University of Minnesota, Masonic Cancer Center, Minneapolis, MN

Background: B7-H3 (*CD276*) is an immunomodulatory protein overexpressed in prostate cancer (PC), representing a promising therapeutic target. However, expression of B7-H3 across PC disease states (hormone sensitive [HSPC], castration resistant [CRPC], neuroendocrine [NEPC]) and across races is poorly understood. We analyzed PC samples from a large clinico-genomic database to comprehensively characterize B7-H3 expression and elucidate its therapeutic potential in PC patients. **Methods:** We analyzed 7,682 PC samples with paired DNA/RNA profiling from Caris Life Sciences. Using *CD276* mRNA expression measured by transcripts per million (TPM), samples were stratified into B7-H3-high (>75% centile) or low (<25% centile) groups. Annotations of HSPCs and CRPCs were based on time of biopsy collection relative to first use of androgen deprivation therapies. NEPC was defined histologically (Epstein, AJSP 2014). Transcriptomic alterations were compared using Mann-Whitney U tests. Overall survival (OS) was obtained from insurance claims data and assessed by Kaplan-Meier and Cox proportional hazards analyses. **Results:** B7-H3 was expressed at similar levels across specimen sites (prostate, lymph node, bone, liver, lung). HSPCs and CRPCs had similar levels of B7-H3 expression, but was reduced in NEPCs (TPM = 5.07, 4.96, 4.48; q<0.0001). While B7-H3-high was associated with worse OS in HSPCs (HR 1.32, 95CI 1.14-1.53, p=0.0002), it was associated with better OS in CRPC (HR 0.82, 95CI 0.69-0.97, p=0.018). B7-H3 expression was comparable in white, African American (AA), and Asian patients. However, Asian patients with high B7-H3 had worse outcomes (HR 4.08, 95CI 2.10-7.93, p<0.0001) while AA patients had improved outcomes (HR 0.74, 95CI 0.57-0.97, p=0.027). In co-expression analyses, B7-H3 was positively correlated with AR transcriptional co-factors (*HOXB13*, *FOXA1*) (R=0.59, 0.47; q<0.0001) but had weaker correlations with lineage plastic factors (*EZH2*, *SOX2*, *ASCL1*) (R=0.26, 0.11, -0.02). Further, B7-H3-high correlated with high AR-score and low-NEPC. Given emergent bi-specific therapeutics in PC, we examined co-expression of B7-H3 with other cell surface targets. TROP2 (*TACSTD2*) and NECTIN-4 (*PVRL4*) exhibited the greatest correlation with B7-H3 (R=0.42, 0.40; q<0.0001); whereas PD-L1 (*CD274*), *CTLA4*, *DLL3*, and *CEACAM5* had weaker correlations (R=0.18, 0.08, 0.14, 0.09). **Conclusions:** High B7-H3 expression worsens prognosis in HSPC but improved prognosis in CRPC. Outcomes differed by race, with B7-H3-high Asian patients exhibiting worse OS while AA patients had better OS. The positive correlation between B7-H3 and AR co-factors suggests that B7-H3 is AR-regulated, at least in CRPC. Lastly, bi-specific approaches may be valuable against B7-H3-high tumors, with co-targeting of TROP2 and/or NECTIN-4. Plasma epigenomic profiling to reveal molecular correlates of response and resistance to 177Lu-PSMA-617 in metastatic castration-resistant prostate cancer (mCRPC). First Author: Jacob E. Berchuck, Winship Cancer Institute of Emory University, Atlanta, GA

Background: The PSMA-directed radioligand therapy, 177Lu-PSMA-617, is the most recent FDA approved therapy in mCRPC. Despite prolonging progression-free survival (PFS) and overall survival (OS) at a population level, response to therapy is heterogeneous and resistance remains poorly understood. Benchmarking molecular correlates of clinical outcomes following 177Lu-PSMA-617 could provide critical insights into predicting response and resistance to therapy. We applied a multimodal epigenomic liquid biopsy platform to plasma samples from mCRPC patients treated with 177Lu-PSMA-617 to characterize molecular features associated with treatment response. **Methods:** Baseline plasma samples were collected from patients with mCRPC at the time of PSMA PET imaging and initiation of 177Lu-PSMA-617 therapy. Epigenomic profiling of genome-wide signals from promoters, enhancers, and DNA methylation was performed on 1 mL of plasma (N=85, ctDNA ≥ 0.5%). Plasma epigenomic signals were analyzed to evaluate pathway activity, their association with treatment response using Cox proportional hazards model and neuroendocrine transformation. Response to 177Lu-PSMA-617 was determined by investigator-assessed clinical-radiographic (CR)-PFS. **Results:** We observed a significant association between predicted PSMA PET SUV_{mean} from plasma epigenomic signals (using a previously derived model) and response to 177Lu-PSMA-617 (hazard ratio [HR] = 0.27, P<0.05). Further, unbiased analysis of plasma epigenomic signal across the genome identified *FOLH1* (the gene encoding PSMA) as being significantly associated with CR-PFS (P<0.05). Low circulating tumor fraction was also independently associated with favorable CR-PFS (HR = 0.42, P<0.05). Pathway analysis identified activation of estrogen signalling and cellular plasticity to be associated with shorter CR-PFS, and immune signalling gene signatures to be associated with longer CR-PFS (all FDR<0.1). A subset of patients (n=4) exhibited increased plasma epigenomic signal at neuroendocrine genes, such as *CHGA*, *DLL3* and *SEZ6*. While too small to draw statistical conclusions, elevated neuroendocrine gene activity in plasma was associated with numerically shorter OS. **Conclusions:** Epigenomic profiling of plasma cfDNA enabled minimally-invasive characterization of molecular correlates of response and resistance, identifying genes and pathways associated with favorable and poor outcomes to 177Lu-PSMA-617 in mCRPC. By providing real-time insights into tumor biology and therapeutic efficacy, this platform supports precision medicine approaches for optimizing outcomes in PSMA-targeted therapies. Exploring PSMA heterogeneity and alternative targets expression in PSMA-negative prostate cancer. First Author: Yelin Mulati, Department of Urology, Peking University First Hospital, Beijing, China

Background: This study aimed to systematically characterize the heterogeneity of PSMA expression in hormone-sensitive prostate cancer (HSPC) and metastatic castration-resistant prostate cancer (mCRPC), and to explore the expression profiles of alternative well-established tumor-associated antigens (TAAs) in PSMA-negative cases. **Methods:** Formalin-fixed paraffin-embedded (FFPE) real-world clinical samples were retrospectively collected from prostate biopsies and bone metastasis surgeries at Peking University First Hospital from 2013 to 2023. Standard immunohistochemistry (IHC) was performed to evaluate PSMA expression, quantified using membranous H-score (MHscore) and cytoplasmic H-score (CHscore).Intra-patient PSMA expression heterogeneity was assessed by Shannon diversity index (SDI) . The normalized membrane ratio (NMR) was defined as: MHscore / (MHscore + CHscore). PSMA-negative PCa was defined as PSMA MHscore ≤ 20. PSMA-negative samples were further assessed the expression of alternative TAAs: HER2, NECTIN4, TROP2, TF, B7H3 and STEAP1. **Results:** A total of 127 HSPC and 76 mCRPC cases were identified, including 27 pairs of matched samples. High PSMA expression heterogeneity (SDI >1) was observed in 86 (67.7%) HSPC and 23 (30.1%) mPCa, while moderate heterogeneity (0.5<SDI<1) was found in 20 (15.7%) HSPC and 25 (32.9%) mPCa. PSMA-negative cases were identified in 15.0% of HSPC and 36.8% of mCRPC. PSMA MHscore in HSPC was significantly higher than in mPCa (p < 0.001). The expression profiles of alternative TAAs in PSMA-negative cases are shown in Table 1. Additionally, the NMR of PSMA in HSPC was significantly higher than in mPCa (p < 0.001). STEAP1 and B7H3 exhibited consistently high NMR in PSMA-negative cases. No significant correlations were observed between PSMA alteration and novel anti-androgen therapy, chemotherapy, or radiation history in matched samples. **Conclusions:** PSMA expression exhibit notable inter- and intra-patient heterogeneity in both HSPC and mCRPC. B7H3 and TROP2 may have relatively more advantageous expression levels in PSMA-negative HSPC, while B7H3 and STEAP1 may potentially show better complementarity in PSMA-negative mCRPC. Research Sponsor: National High Level Hospital Clinical Research Funding (Interdepartmental Clinical Research Project of Peking University First Hospital), Beijing, China.

Comparative effectiveness of cabazitaxel (C) vs. lutetium Lu-177 vipivotide tetraxetan (Lu) in patients (pts) with metastatic castration-resistant prostate cancer (mCRPC). First Author: Zeynep Irem Ozay, Huntsman Cancer Institute at the University of Utah, Salt Lake City, UT

Background: C and Lu are both life-prolonging therapies for pts with mCRPC after progression on androgen receptor pathway inhibitor (ARPI) and docetaxel (D). Herein, our objective was to assess the comparative effectiveness of C vs. Lu in pts with mCRPC with prior progression on D and ARPI in real-world pts in the USA. **Methods:** A de-identified nationwide Flatiron Health electronic health record (EHR)-derived database was used to extract pt-level data. Eligibility: pts with mCRPC who progressed on D and ARPI and received for the first-time single-agent C or Lu. Pts who received alternative Lu or C in a later line of therapy (LOT) were excluded. Endpoints: real-world time to next therapy (rwTTNT) and real-world overall survival (rwOS). These were summarized via Kaplan-Meier survival estimates with a 95% confidence interval (CI) and compared in the context of propensity score (PS) matching weighted analysis using the Cox proportional hazard model. PS model included the following covariates: age, race-ethnicity, socioeconomic status, treatment year, Gleason score, ECOG performance status, log2PSA, alkaline phosphatase, hemoglobin, creatinine, LOT, insurance, and practice type. All the covariates achieved balance after PS matching weighting. **Results:** Among 24,105 pts with metastatic prostate cancer in the dataset, 1,445 met the eligibility criteria and were included (1,227 treated with C, 218 treated with Lu). In C cohort: median age was 73 (IQR 67 – 78), 66.9% had Gleason score $\geq$ 8, and median LOT was 4 (IQR 3-4). In Lu cohort: median age was 75 (IQR 67.25 – 80), 68.1% had Gleason score $\geq$ 8, and median LOT was 4 (IQR 3-5). In PS matching weighting analysis, there was evidence that pts receiving Lu had a significantly improved rwTTNT (median 8.3 months [mo], 95% CI 6.3 – 9.8) compared to those receiving C (median 4.7 mo, 95% CI 4.2 – 5.4) (HR 0.49, 95% CI 0.37 – 0.63, $p < 0.001$), which persisted after adjusting for covariates (HR 0.43, 95% CI 0.32 – 0.57, $p < 0.001$). Additionally, there was evidence that rwOS was longer in pts receiving Lu (median 10.3, 95% CI 8.9 – 12.8) compared to those receiving C (median 8.8 mo, 95% CI 6.6 – 10.8) (HR 0.69, 95% CI 0.51 – 0.92, p = 0.01). This improvement in rwOS with Lu compared to C persisted after adjusting for covariates (HR 0.61, 95% CI 0.44 – 0.84, $p < 0.001$). **Conclusions:** This is the largest real-world data to date assessing the comparative effectiveness of Lu vs. C, and it showed significantly longer rwTTNT and rwOS with Lu compared to C in pts with mCRPC pretreated with ARPI and D. Limitations: retrospective nature, selection bias, missingness, lack of randomization, etc. and residual confounding in real-world datasets. Upon external validation, these findings could guide treatment selection in the clinic and design of clinical trials. Research Sponsor: None.

5077 **Poster Session**

Real-world prevalence of homologous recombination repair alterations (HRRa) and poly (ADP-ribose) polymerase inhibitor (PARPi) use/outcomes in patients (pts) with metastatic prostate cancer (mPC) by race and ethnicity. First Author: Qian Qin, Department of Internal Medicine, Division of Hematology and Oncology, UT Southwestern, Dallas, TX

Background: Racial/ethnic (R/E) disparities in prostate cancer incidence and outcomes have long been noted. Increasing evidence points to underlying genetics/biology as potential drivers, which could influence response to targeted tx such as PARPi. Here, we used real-world evidence (RWE) to assess R/E variations in the prevalence of HRRa and outcomes of PARPi therapies in pts with mPC. **Methods:** This retrospective, RWE study used GuardantINFORM, a deidentified clinical genomic database combining claims and genomic data reported from the liquid biopsies, Guardant360 (G360) CDx (HRRa: *BRCA1/2, ATM, CDK12, MLH1*) and LDT (HRRa: *BRCA1/2, ATM, CDK12, CHECK2, FANCA, MLH1, PALB2, RAD51D*). Pts with mPC, age >18, and tested between July 2014 - Sep 2024 were included and grouped into non-Hispanic Black (NHB), non-Hispanic White (NHW), Asian/Other, and Hispanic (any race) cohorts. HRRa and frequency of PARPi treatment (tx) were assessed with two-sided Fisher's exact tests. Outcomes were assessed for PARPi tx overall, as monotherapy, or in combination with androgen receptor pathway inhibitor (ARPI) using pairwise comparisons and log-rank tests. **Results:** 30,913 pts with G360 liquid testing were identified. The rates of HRRa on the LDT panel were significantly higher for NHW (22.8%) when compared to NHB (18.1%, $p<0.0001$) and Hispanic (19.6%, p=0.017) cohorts. This was similarly seen on the CDx panel for NHW (16.7%) vs. NHB cohorts (15.0%, p=0.018). Similar *BRCA1/2* detection rates (range 5.2-5.8%) and frequencies of PARPi use were observed among R/E groups. No significant differences were observed in real world overall survival (rwOS), time to tx discontinuation, or time to next tx among R/E groups. While not significant, there was a numerical rwOS improvement for NHB when compared to NHW pts treated with PARPi/ARPI combinations (CDx panel, median NR vs. 20.5m, p=0.09), with no NHB pts known to be deceased at the end of follow up (median 10.5 months). **Conclusions:** Using a RWE dataset, we demonstrate distinct rates of HRRa between R/E groups identified using ctDNA analysis. Similar PARPi use among R/E groups suggest tx equity for pts receiving genomic sequencing. The numerically improved rwOS for NHB pts on combination PARPi/ARPI tx is hypothesis generating. This may support other studies demonstrating distinct outcomes in Black vs. White pts treated with ARPI, with potential added benefit in a combination paradigm. Research Sponsor: None.

Assessment of PSMA PET/CT derived predictive markers for ^{177}Lu-PSMA-617 treatment outcomes: Results from the U.S. Expanded-Access program. First Author: Koichiro Kimura, Ahmanson Translational Theranostics Division, Department of Molecular and Medical Pharmacology, David Geffen School of Medicine at UCLA, Los Angeles, CA

Background: ^{177}Lu-PSMA-617 (Lu-PSMA) contributes to prolong progression-free survival (PFS) and overall survival (OS) in metastatic castration-resistant prostate cancer (mCRPC) patients who progressed after chemotherapy. Pretherapeutic prostate-specific membrane antigen (PSMA) PET/CT information can be used to predict Lu-PSMA therapy response patterns and outcomes, with various quantitative and visual methods proposed. We aimed to test various proposed PSMA PET/CT-derived outcome predictors in the U.S. expanded-access program (EAP) cohort. **Methods:** Patients enrolled in the EAP (NCT04825652) for Lu-PSMA at 3 institutions with available pretherapeutic PSMA PET/CT and outcomes were included in this analysis. Quantitative analysis was performed for all tumor lesions on PSMA PET/CT with semi-automatically contouring. Total tumor volume (TV), total tumor SUVmean, total tumor SUVmax, total lesion uptake (TLU = TV * SUVmean), total lesion quotient (TLQ = TV / SUVmean), and quantitative PSMA PET tumor–to–salivary gland ratio (qPSG: high, $\geq$ 1.5; intermediate, 0.5–1.5; low, $\leq$ 0.5) were calculated for each patient. For visual analysis, visual PSG (vPSG: high, most of the lesions showed higher uptake than the parotid glands; intermediate, neither low nor high; low, most of the lesions showed lower uptake than the parotid glands) and heterogeneity and intensity of tumors (HIT: 1, SUVmax $<$ 15; 2, 15–79 with heterogeneous intensity; 3, 15–79 with homogeneous intensity; 4, $\geq$ 80) scores were used for assessment. Outcomes included a prostate-specific antigen (PSA) PFS, and OS. We evaluated the predictive performance of each model using Cox proportional hazards regression analysis and assessed their performance with the concordance index (c-index). **Results:** In total, 88 patients who received Lu-PSMA within the EAP between May 2021 and March 2022 were eligible and included in this analysis. For the PSA PFS, the total tumor SUVmean achieved the highest c-index of 0.678 (HR 0.91 [95% CI, 0.85–0.97], p = 0.004), followed by the total tumor SUVmax with a c-index of 0.640 (HR 0.99 [95% CI, 0.99–1.00], p = 0.034). For OS, the TLQ achieved the highest c-index of 0.658 (HR 1.01 [95% CI, 1.00–1.01], $p < 0.001$), followed by the total tumor SUVmean with a c-index of 0.634 (HR 0.89 [95% CI, 0.83–0.96], p = 0.004). The HIT score showed the third highest c-index of 0.632; however, when using score 1 as the reference, the HR did not exhibit a sequential trend across ordinal categories as anticipated. **Conclusions:** Quantitative analysis outperformed visual analysis in predicting the outcome of mCRPC with Lu-PSMA therapy in the EAP cohort. Total tumor SUVmean was identified as the most robust predictor for PSA PFS, while TLQ showed promise as a predictor for OS. Incorporating these predictors into clinical decision-making for pre-Lu-PSMA therapy could aid in patient selection and treatment planning. Clinical trial information: NCT04825652. Molecular correlates of response in patients with metastatic castration-resistant prostate cancer treated with olaparib with or without cediranib (NCI9984). First Author: Alok Tewari, Dana-Farber Cancer Institute, Boston, MA

Background: The phase 2 NCI 9984 study (NCT02893917) randomized patients with progressive metastatic castration resistant prostate cancer (mCRPC) 1:1 to the PARP inhibitor (PARPi) olaparib (O) +/- the vascular endothelial growth factor receptor inhibitor (VEGFRi) cediranib (C+O). (C+O) improved radiographic progression free survival (rPFS) compared to (O). Though further development of this combination was precluded in part by toxicity, we hypothesized that defining molecular correlates of response in this study could suggest alternative combination strategies, including alternative VEGFRi, to improve the therapeutic efficacy of PARPi in prostate cancer. **Methods:** Tumor biopsies were reviewed by a pathologist to ensure adequate tumor content. Whole exome DNA sequencing (WES) was performed on pre-treatment biopsies and germline DNA from blood, and RNA sequencing (RNA-seq) was performed on both pre- and on-treatment biopsies. Sequencing data was analyzed using standard computational pipelines to determine tumor-specific DNA variants and gene expression. Mutational signatures were inferred using SigMA, and clonal architecture was inferred using PhylogicNDT. Transcriptome changes were inferred using gene set enrichment analysis and DESeq2. Molecular features were associated with rPFS using descriptive statistics. **Results:** 23 pre-treatment biopsies– 11 (O) and 12 (C+O) – yielded WES data that passed quality control (QC). 62 RNA-seq samples passed QC – 28 (O) and 34 (C+O) – with 30 pair pre-post samples. After stratifying patients with WES data by response above or below the median rPFS for each treatment arm, no genomic alteration was significantly associated with response. We detected evidence of COSMIC mutational signature 3 (Sig3), indicative of HRR deficiency, in 9 pre-treatment samples – 4 (O) and 5 (C+O), only 2 of which contained a *BRCA2* alteration. The presence of Sig3 was not associated with improved rPFS in either treatment arm. RNA-seq demonstrated decreased in HRR and double strand DNA break repair gene sets as well as an increase in interferon signaling with (C+O) treatment. **Conclusions:** Molecular profiling of pre- and on-treatment tumor biopsies confirms prior preclinical observations that the addition of cediranib suppresses the expression of genes associated with HRR, which may explain the improved rPFS of (C+O) treatment relative to (O). No DNA alterations were significantly associated with therapeutic response in this more limited genomic cohort, but we confirm findings from other studies that mCRPC tumors possess mutational signatures of HRR deficiency in the absence of *BRCA2* alterations, which has implications for PARPi deployment in mCRPC. Additionally, our work broadly demonstrates the both the feasibility and sample attrition rate of correlative studies on clinical trials. Research Sponsor: National Cancer Institute.

Clinical implications of HER3 overexpression in a diverse patient cohort with prostate cancer. First Author: Hannah Maluvac, University of Illinois, Chicago, IL

Background: Prostate cancer (PCa) contributes to almost 15% of US cancer cases annually with significant racial disparities, where black men are more likely to develop and die from prostate cancer than any other cohort. Previously, we reported that *HER3/ERBB3* overexpression (OE) was enriched in the tumors of Black/ African American patients and was correlated with a unique androgen receptor signature as well as worse clinical outcomes. Here, we evaluate an expanded and more mature patient cohort to understand the effect of HER3 OE on clinical outcomes. In vitro experiments further support the targeting of HER3 in prostate cancer disease. **Methods:** Chart review was performed on a diverse cohort of PCa patients from the University of Illinois Health (n=106). Tempus laboratories performed whole transcriptome RNA sequencing, and HER3/*ERBB3* OE status was determined by Tempus as compared to a reference database. Patients were grouped into HER3 OE and wild-type groups, and clinical outcomes were analyzed between groups using students' t-test and Kaplan Meier plots with the Gehan-Breslow-Wilcoxon test. LNCaP cells were virally transduced with HER3 overexpression and non-targeting control vectors and validated via Western blot. Cell growth was quantified via nuclear fluorescence object count using Incucyte instruments and software. Drug treatment efficacy was validated via Western blot. **Results:** The final cohort (n= 71 Black/AA, 19 white, and 5 other) demonstrated 42% of patients presenting with HER3 OE. A majority of patients presented with de novo metastases (55% of HER3 OE, 45% of HER3 WT). Of patients who initially presented with localized disease, time to metastasis was significantly faster in the HER3 OE group (p=0.04). HER3 OE was also associated with faster time to the development of castration resistance (p=0.02). In preclinical PCa models, HER3 OE cells grew significantly faster than control($p \leq 0.01$), and were less sensitive to enzalutamide($p \leq 0.01$). Additionally, we found that by inhibiting HER3 signaling (patritumab, erlotinib, trastuzumab, capivasertib) PCa cells become more sensitized to enzalutamide($p \leq 0.01$), suggesting a role for dual AR and HER3 targeting in PCa treatment. **Conclusions:** Our clinical and translational data supports the role of HER3 overexpression as a novel and targetable prognostic marker in diverse patients with PCa. Future studies should further evaluate HER3 inhibition in combination with AR targeted therapies to improve therapy sensitivity and reduce development of resistant disease. Research Sponsor: None.

Ceramides and response to dual secondary hormonal therapy in metastatic castration-resistant prostate cancer (mCRPC) among Black men. First Author: Jennifer A. Freedman, Duke Cancer Institute Center for Prostate & Urologic Cancers, Durham, NC

Background: Multiple reports suggest that Black patients with mCRPC have different responses to radiation, immunotherapy, chemotherapy, and secondary hormonal therapy compared with White patients with mCRPC. In our prospective trial of combination therapy with apalutamide (Apa) and abiraterone acetate (AA) plus prednisone (P) among Black and White men with mCRPC (PANTHER, ClinicalTrials.gov identifier NCT03098836), we previously reported the 24-month radiographic progression-free survival (rPFS) for Black and White men were 61% (95% CI 49, 78) and 38% (95% CI 27, 54), while the 36-month overall survival (OS) rates were 68% (95% CI 55, 83) and 50% (95% CI 37, 66), respectively. Our previously reported exploratory genome-wide analysis identified genetic ancestry-related single nucleotide polymorphisms in genes that were known to play a role in ceramide metabolism that associated with time to prostate specific antigen (PSA) progression on AA + P therapy in mCRPC. Ceramides are associated with cancer biology and therapeutic outcomes, with ceramide Cer(d18:1/20:0), in particular, having been reported as a biomarker for colon cancer. Ceramide Synthase 4 (CerS4), which produces Cer(d18:1/20:0), has been reported to be associated with worse prognosis in colorectal cancer. We therefore hypothesized that expression of distinct ceramide species may be associated with rPFS or OS among Black and White patients with mCRPC treated with combination Apa and AA + P in the PANTHER study. **Methods:** Serum from 37 White and 28 Black patients enrolled in the PANTHER study who had fasted for 8-12 hours was collected and evaluable at baseline. Metabolomic profiling was done using the Biocrates MxP Quant 500 Kit. Median levels for each of 26 ceramides were calculated using the study population and used as a cut point. Cox proportional hazard models were used to calculate the hazard ratio for rPFS and OS associated with above or below median ceramide expression. Models were stratified by race. **Results:** In the PANTHER study, among Black patients, expression of Cer(d18:1/20:0) was associated with rPFS (HR 4.02; 95% CI 1.06, 15.2; p value = 0.041), but there was no significant association found among White patients. Expression of Cer(d18:1/20:0) was also associated with improved OS among Black patients (HR 4.82; 95% CI 1.51, 15.4; p = 0.008), but there was no significant association found among White patients. No significant associations were found with any other ceramides. **Conclusions:** Our study showed that Cer(d18:1/20:0) associated with prolonged rPFS and OS among Black patients with mCRPC treated with the combination of Apa and AA + P therapy. Pending validation, this distinct ceramide species has potential to serve as a predictive indicator of response to combination Apa and AA + P therapy among Black mCRPC patients. Integrated CTC- and EV-based detection of PSMA protein and efficacy of ^{177}Lu-PSMA-617 radioligand therapy. First Author: Ali Arafa, University of Minnesota, Minneapolis, MN

Background: Blood-based predictive biomarkers of sensitivity to ^{177}Lu-PSMA-617 are lacking, and may facilitate clinical decisions. Here, we studied whether integrated PSMA protein detection in circulating tumor cells (CTCs) and extracellular vesicles (EVs) is associated with outcomes in patients receiving ^{177}Lu-PSMA therapy. **Methods:** We enrolled 100 metastatic castrate-resistant prostate cancer (mCRPC) pts who were candidates for ^{177}Lu-PSMA into a prospective biomarker trial. Blood samples were collected for CTC and EV analysis at baseline, at the time of response, and at progression. Baseline characteristics included serum PSA, alkaline phosphatase (ALP), hemoglobin, albumin, and radiographic tumor burden. PSMA+ CTCs were enumerated using an AI-empowered holographic imaging platform combined with in-flow protein marker analysis (Astrin Biosciences, St. Paul, MN); PSMA protein was quantified in plasma EVs using shotgun proteomics via mass spectrometry (Arafa et al., *Cancers* 2024; 16: 4261). We assessed the impact of PSMA+ CTCs and EV-derived PSMA protein on PSA_{50} responses, PFS, and OS. Multivariable Cox regressions were used to adjust for baseline PSA, ALP, and hemoglobin. Exploratory analyses of other EV-derived proteins were also conducted. **Results:** Of 100 enrolled pts, 47% had Gleason sum 9-10, 62% had >10 bone mets, 12% had visceral mets, 72% had received ≥3 prior systemic therapies, and median PSA was 57 (range 1.5–5,000) ng/mL. High PSMA+ CTC counts (> median) were associated with shorter overall survival (OS) (HR 2.71, 95%CI 1.18–6.21, p=0.02). PSA_{50} response rates were similar for those with high and low PSMA+ CTC counts (39% vs 42%, p=0.8). Shotgun proteomics from plasma EV samples identified >11 000 unique proteins, of which 12% represented the cell surfaceome. EV-PSMA protein correlated with baseline PSA, ALP, and tumor burden (all $p<0.05$). High EV-PSMA protein (> median) was associated with worse OS (1.81, 95%CI 0.97–3.35, p=0.06). PSA_{50} response rates were similar for those with high and low EV-PSMA protein (48% vs 42%, p=0.5). After multivariate adjustment, nonsignificant trends for shorter OS persisted for pts with high PSMA+ CTCs (HR 1.71, 95%CI 0.72–4.05) and high EV-PSMA levels (HR 1.49, 95%CI 0.78–2.84). Worse OS was also observed in pts with high EV levels of B7-H3 (HR 2.85, 95%CI 1.58–5.14, p=0.002), Trop-2 (HR 2.23, 95%CI 1.22–4.05, p=0.008), and STEAP1 (HR 1.69, 95%CI 0.93–3.06, p=0.08) proteins. **Conclusions:** In mCRPC pts receiving ^{177}Lu-PSMA, high PSMA+ CTC counts and high EV-derived PSMA levels portended poor survival. PSMA protein may be a novel blood-based biomarker of ^{177}Lu-PSMA sensitivity, facilitating treatment decisions, with relevance for other PSMA-targeting strategies. The robust detection and prognostic impact of additional cell-surface proteins (*e.g.* B7-H3, Trop-2, STEAP1) may fuel the development of alternative novel therapeutics. Transcriptional profiling to identify a program of enzalutamide extreme non-response in lethal prostate cancer. First Author: Anbarasu Kumaraswamy, Rogel Cancer Center, University of Michigan, Ann Arbor, MI

Background: The androgen receptor pathway inhibitor (ARPI) enzalutamide is one of the principal treatments for metastatic hormone-naïve and castration-resistant prostate cancer (CRPC). Most patients respond to enzalutamide. However, tumors from a subset of patients exhibit extreme non-response and are primary refractory to treatment. We sought to understand the gene expression program of enzalutamide extreme non-response (ENR) and identify alternate therapeutic approaches for tumors driven by this program. **Methods:** We analyzed gene expression by RNA-sequencing in pre-treatment metastatic biopsies from men with CRPC treated on a prospective enzalutamide clinical trial (NCT02099864). We focused on those with ENR (progression within 3 months) vs. long-term response (progression after 24 months) and identified a gene program linked to enzalutamide ENR. We validated the utility of this program in additional patient cohorts using a multivariable analysis and in preclinical models. **Results:** Unsupervised clustering correctly classified ENR patients whose tumors harbored proliferative, epithelial-to-mesenchymal transition, and stemness genes sets. Using a supervised approach, we developed a gene signature to measure the ENR program. High expression of this program in CRPC patient validation cohorts was independently associated with poor tumor control with AR targeting in multivariable analysis. Conversely, high expression of the program was independently associated with benefit with docetaxel chemotherapy, suggesting the ENR program is predictive and not merely prognostic. In support of our findings, high expression of the ENR program was strongly linked to docetaxel sensitivity in a large panel of CRPC models. Finally, we identified putative regulators of the ENR program—several of which can be targeted pharmacologically with agents that are FDA-approved or in clinical trials. **Conclusions:** The enza ENR program we identified is independently predictive of ENR to AR targeting. However, patients whose tumors harbor this program may be good candidates for docetaxel chemotherapy or clinical trials testing agents that block putative regulators of this program. Integrated analysis of tissue genomic sequencing and high purity circulating tumor cell RNA sequencing for prostate cancer lineage states as a prognostic factor for survival and resistance to 177Lu-PSMA-617 in patients with metastatic castrate resistant prostate cancer. First Author: Marina Nasrin Sharifi, University of Wisconsin, Madison, WI

Background: Genomic mutations, including *RB1*, *PTEN*, and HRR genes, associate with poor prognosis and treatment resistance in metastatic prostate cancer (mPC). mPC lineage states such as neuroendocrine prostate cancer (NEPC) also drive resistance and poor survival. Identifying the timing and association of genomic mutations with lineage states has been limited by the challenges of obtaining serial tumor biopsies. We report an integrated analysis of clinical next-generation sequencing (NGS) data, ctDNA, and mPC lineage state phenotypes with a novel high purity circulating tumor cell (CTC) RNA sequencing method. **Methods:** We collected 273 CTC samples from 117 patients with mPC in a prospective biomarker trial. 69 patients had clinical NGS from a recent tissue biopsy and 60 patients treated with $PSMA^{LU}$. CTCs were purified via immunomagnetic capture on a microfluidic platform and analyzed via RNA-seq. We compared CTC lineage states, somatic mutation status and median overall survival (mOS). **Results:** Gene expression analysis of high CTC purity samples identified four CTC phenotypes: luminal A-like (LumA), luminal B-like (LumB), low proliferation (LP), and neuroendocrine (NE). Compared to patients with low CTC burden/purity (mOS NR), patients with LumA and LP phenotypes had similar survival ((LumA: mOS 13mo, p=ns, LP: mOS: 11.8mo, p=ns), while patients with LumB and NE phenotypes had shorter survival (LumB: mOS 6mo, HR 9.1[3.8-21.8], $p<0.0001$, NE: mOS 3.7mo, HR 11.8[2.4-57.2]), p=0.0019). mOS for patients with high-risk genomic mutations (*RB1*, *PTEN*, *TP53*) and a LumA or LP lineage state was 12.7mo versus 4mo for patients with high-risk mutations and a LumB or NE lineage state (HR 3.59 [1.51-8.51], p=0.004). mOS was not reached for patients without high-risk mutations and a LumA or LP lineage state vs 8mo for patients without high-risk mutations but a LumB or NE lineage state (HR 19.7 [1.99-1.95], $p<0.0001$). Among patients treated with 177Lu-PSMA-617 in a prospective substudy (n=37), no patients had pretreatment CTC NE phenotype, but pre-treatment CTC LumB phenotype was associated with decreased rPFS (3.5mo vs 11.7mo, HR 4.8 [95% CI 1.4-16.1], $p<0.005$) and OS (7.6mo vs NR, HR 9.3 [95% CI 2.3-37.8], $p<0.0005$) compared to pre-treatment LumA/LP/Low CTC burden phenotypes. **Conclusions:** Lineage states detected by high purity CTC RNAseq are prognostic for poor OS and decreased benefit from 177Lu-PSMA-617. The presence of high-risk genetic mutations including *RB1* is prognostic for poor OS and combined evaluation of high-risk genetic mutation status with lineage state phenotype identifies patients with the worst clinical outcomes that would benefit from treatment intensification and early disease monitoring for these more aggressive subtypes of mCRPC. Research Sponsor: None.

Association between epigenomic biomarkers and baseline clinical characteristics in patients with mCRPC treated with rucaparib in TRITON2. First Author: Brooke Overstreet, Guardant Health, Palo Alto, CA

Background: TRITON2 is a phase 2 study evaluating rucaparib in 277 patients with metastatic castration resistant prostate cancer (mCRPC). PSA has been used to predict radiographic progression free survival (rPFS), overall survival (OS) and monitor response, however, new approaches are needed to improve performance. Recently, it has been demonstrated that hypermethylated tumor DNA in the peripheral blood can be used to detect and monitor response and as a prognostic marker. Here, we evaluate the association between baseline methylation-based tumor fraction (TF) and clinical outcomes in patients with mCRPC. **Methods:** Pre-treatment plasma samples from patients participating in TRITON2 were sequenced using Guardant Infinity, a next-generation sequencing platform that evaluates genomics and epigenomics with ~15Mb of coverage for methylation-profiling and quantification. TF is calculated from thousands of cancer-type specific differentially hypermethylated regions. Patient outcomes were evaluated using the median-split baseline values for TF and PSA vs rPFS and OS by Cox proportional hazard model. **Results:** Two hundred thirty of 277 patients were eligible for baseline analysis and were successfully sequenced. Methylation-based TF was detected in 229/230 patients (99.6%). TF ranged from 0.02% to 99%, with a median of 25.1%. Baseline methylation-based TF was associated with Gleason score (p=0.012) but was only very weakly correlated with PSA levels (R^2=0.09). Patients with baseline TF $\leq$ median demonstrated superior rPFS and OS vs those $>$ median (HR=0.54, p=0.013; HR=0.42, p= 3.72e-07), respectively. In contrast, baseline PSA was only associated with superior OS (HR=0.52, p=1.31e-04), but not rPFS (HR=0.71, p=0.186). **Conclusions:** In patients from TRITON2, methylation-based TF appeared superior to PSA for tracking disease activity, both in terms of rPFS and OS. This suggests that methylation-based TF is a candidate disease monitoring tool that should be further investigated as a potential replacement for both radiological and PSA-based disease monitoring. Clinical trial information: NCT02952534. Research Sponsor: None.

Genomic landscape and clinical characteristics of patients (pts) with neuroendocrine prostate cancer (NEPC) with or without aggressive variant prostate cancer characterized by molecular signature (AVPC-MS). First Author: Hedyeh Ebrahimi, City of Hope Comprehensive Cancer Center, Duarte, CA

Background: NEPC is a rare, aggressive subtype that can arise *de novo* or after treatment with androgen receptor inhibitors. Recent NEPC clinical trials have also included pts who have AVPC-MS (Aggarwal *et al*, ASCO 2024). However, the prevalence and clinical characteristics of NEPC with or without AVPC-MS need further investigation. **Methods:** The de-identified Tempus Lens dataset was used to retrieve records of pts diagnosed with NEPC. Pts were classified as having AVPC-MS if they had $\geq$2 alterations in *TP53*, *RB1*, and/or *PTEN*. Demographic and clinical characteristics were summarized using descriptive statistics and compared between individuals with and without AVPC-MS using chi-square and Fisher's exact tests. The prevalence of genomic alterations between pts with and without AVPC-MS was compared using a two-proportions Z-test with False Discovery Rate (FDR) correction to account for multiple comparisons. **Results:** A total of 308 pts diagnosed with NEPC were identified and included in this analysis. Among them, 124 (40.3%) had *RB1*, 141 (45.8%) had *TP53*, and 64 (20.8%) had *PTEN* alterations. A total of 109 (35.4%) pts met the criteria for AVPC-MS whereas 81 (26.2%) pts harbored only a single alteration in either *TP53*, *RB1*, or *PTEN* and thus did not meet the criteria. The proportion of individuals aged $>$60 years was similar between those with and without AVPC-MS (56.0% vs. 58.8%, p=0.70). Additionally, 48.6% of pts with AVPC-MS were white, compared to 60.8% of those without AVPC-MS (p=0.03). Mortality rates did not significantly differ between the groups (66.1% in AVPC-MS vs. 61.8% in non-AVPC-MS, p=0.40). Individuals with AVPC-MS had significantly higher alterations of *TMPRSS2* (38.5% vs. 18.1%) and *PIK3CA* (8.3% vs. 2.5%) compared to those without AVPC-MS (FDR-adjusted $p < 0.05$). However, no significant difference was observed for alterations in *FOXA1* and *BRCA2* in the AVPC-MS group compared to non-AVPC-MS (10.1% vs. 10.1% and 8.3% vs. 11.1%, respectively). Among pts with available data, high tumor mutational burden (TMB) was observed in 7.8% (8 of 103) of pts with AVPC-MS compared to 2.1% (2 of 97) of those without AVPC-MS (p=0.10). Similarly, microsatellite instability-high (MSI-high) was detected in 6.6% (7 of 106) of pts with AVPC-MS and 1.9% (2 of 106) of those without AVPC-MS (p=0.17). **Conclusions:** Approximately one in three patients with NEPC also meet the criteria for AVPC-MS. Our findings suggest that the biological drivers for NEPC are mutually exclusive from AVPC-MS in most patients, and highlight the importance of utilizing pathologic confirmation of NEPC rather than relying on genomic surrogates. Further research is warranted to explore the clinical implications of these genomic differences and to develop personalized treatment approaches for pts with AVPC-MS. Research Sponsor: None.

Triplet versus doublet therapy in older patients with metastatic hormone-sensitive prostate cancer: A network meta-analysis. First Author: Susu Zhou, Mount Sinai West/Morningside, New York, NY

Background: Multiple treatment options are now available for metastatic hormone-sensitive prostate cancer (mHSPC) with the expanded approval of androgen receptor axis-targeted (ARAT) agents. Comparing the therapeutic benefits of these treatments in older patients would contribute to selecting the optimal treatment for this population. **Methods:** We performed a systematic search of PubMed, Embase, Web of Science and Cochrane library for randomized controlled trials (RCTs) evaluating the efficacy of androgen deprivation therapy (ADT) in combination with ARAT agents and/or docetaxel in older patients (aged ≥70 or ≥75 years) with mHSPC. A network meta-analysis (NMA) was conducted to compare and rank the efficacy of the available treatment options. The first NMA compared four treatment classes, grouping ARATs as a single class: ARAT + ADT + docetaxel, ARAT + ADT, ADT + docetaxel, and ADT alone. The second NMA analyzed seven treatment options, treating different ARAT agents as independent regimens: two triplets (abiraterone or darolutamide) + ADT + docetaxel, three doublets (abiraterone, enzalutamide, or apalutamide) + ADT, ADT + docetaxel, and ADT alone. A random effects model was used to estimate hazard ratio (HR) for overall survival (OS) for each treatment. **Results:** 10 RCTs comprising 3,496 patients were analyzed. In the first NMA (grouping ARAT agents as a single class), triplet therapy was associated with a significant 30% lower risk of death compared to ADT + docetaxel (HR 0.70, 95% CI 0.50-0.96), and a non-significant 31% lower risk of death compared to ARAT + ADT (HR 0.69, 95% CI 0.43-1.11). In the second NMA (treating different ARAT agents as independent treatments), darolutamide + ADT + docetaxel was associated with a significant improvement in OS with HRs of 0.47 (95% CI: 0.28-0.78) and 0.61 (95% CI: 0.40-0.94) compared to ADT alone and doublet (ADT + docetaxel), respectively. However, the triplet of abiraterone + ADT + docetaxel was associated with a non-significant OS benefit, with HRs of 0.61 (95% CI 0.36-1.04) and 0.80 (95% CI 0.51-1.25) compared to ADT alone and ADT + docetaxel, respectively. The triplet therapies with darolutamide and abiraterone ranked first and second, with P score of 0.92 and 0.69, respectively, followed by apalutamide + ADT (0.62), enzalutamide + ADT (0.59), ADT + docetaxel (0.42), abiraterone + ADT (0.21) and ADT alone (0.05). Further, our data suggest a clear additional benefit from adding docetaxel as a component of doublet and triplet therapies, as shown by the superiority of ADT + docetaxel over ADT alone (P score 0.42 vs 0.05) and abiraterone + ADT + docetaxel over abiraterone + ADT (P score 0.69 vs 0.21). **Conclusions:** Triplet therapy of darolutamide + ADT + docetaxel should be prioritized over other treatment options for fit older patients with mHSPC. Further research utilizing real-world effectiveness data is essential to validate this recommendation. Research Sponsor: None.

Prognostic validation of six androgen production, uptake, and conversion genes (APUC-6) in the CHAARTED prostate cancer trial. First Author: Xiaolei Shi, University of Maryland School of Medicine, Baltimore, MD

Background: Metastatic prostate cancer (mPC), whether synchronous or metachronous, remains incurable. Persistent androgen receptor (AR) activation promotes tumor progression and metastasis and impacts patient survival. A group of six genes (*HSD3B1, HSD3B2, CYP3A43, CYP11A1, CYP11B1, CYP17A1*) involved in androgen production, uptake, and conversion (APUC-6) has been identified, exhibiting cohesive behavior that may define a subset of mPC with distinct clinical outcomes. Our study investigates the association of APUC-6 genes with clinical outcomes in metastatic hormone-sensitive prostate cancer (mHSPC) and their potential to predict differential therapeutic responses. **Methods:** We analyzed APUC-6 and *AR* expression in microarray data from the phase 3 ECOG-ACRIN E3805 CHAARTED trial (n=160). Synchronous high-volume disease patients (n=113 or 70%) composed the majority of profiled cases. Patients were stratified into four subgroups based on APUC-6 and *AR* gene expression: APUC-6 high/*AR* low (n=34), APUC-6 high/*AR* high (n=6), APUC-6 low/*AR* low (n=86) and APUC-6 low/*AR* high (n=34). Key clinical outcomes included progression-free survival (PFS), time-to-castration resistance (ttCR) and overall survival (OS), with subgroup analyses based on the timing of metastasis. **Results:** Standard clinicopathologic factors were balanced between subgroups except lower proportion of patients with Gleason score ≥8 in APUC-6 high/*AR* low subgroup (68.8% versus 81.0%-100% other subgroups).APUC-6 expression was significantly negatively correlated with *AR* expression (R= -0.26, p=0.001). Patients with APUC-6 high/*AR* low expression represented a distinct subgroup that showed significantly improved PFS (median PFS 47.3 months, $p<0.0001$), ttCR (median ttCR 17.3 months, p=0.0011) and OS (median OS 58.1 months, $p<0.0001$) compared to other subgroups, including APUC-6 low/*AR* high (PFS: median PFS 17.7 months, hazard ratio (HR) 0.43, CI 0.22-0.82, p=0.0092; ttCR: median ttCR 12.0 months, HR=0.56, CI 0.32-1, p=0.049; OS: median OS 29.4 months, HR 0.31, CI 0.16-0.61, p=0.00032). Similar survival benefits of APUC-6 high/*AR* low subgroup were observed within patients with synchronous high-volume disease (median PFS 23.1 months, p=0.0022; median ttCR 14.9 months, p=0.021; median OS 57.6 months, p=0.00038). **Conclusions:** In the CHAARTED mHSPC cohort, APUC-6 expression was inversely correlated with *AR* expression. The APUC-6 high/*AR* low subgroup exhibited favorable PFS, ttCR and OS outcomes and maintained the survival benefits in synchronous high-volume disease. These findings suggest that high APUC-6 expression with low *AR* expression may define a favorable-risk mHSPC subgroup with distinct therapeutic implications. 5090 **Poster Session**

8-year outcomes of enzalutamide (ENZA) versus a non-steroidal anti-androgen (NSAA) for metastatic, hormone-sensitive prostate cancer (ENZAMET; ANZUP 1304). First Author: Alison Yan Zhang, NHMRC Clinical Trials Centre, University of Sydney, Sydney, NSW, Australia

Background: We previously reported that ENZA improved overall survival (OS) after median follow-up times of 34 and 68 months, in comparison with a NSAA, when added to testosterone suppression, with or without concurrent early docetaxel, for mHSPC. We now report outcomes after median follow-up of 98 months. **Methods:** Participants (pts) with mHSPC were randomly assigned (1:1) from 31MAR2014-24MAR2017 to treatment with ENZA 160 mg or NSAA, in addition to testosterone suppression. Concurrent early docetaxel was used in 45%. OS was the primary endpoint and analysed with the Kaplan-Meier method, log-rank test for p-values, and Cox regression for hazard ratios (HR). Secondary outcomes included deaths due to prostate cancer (PC) versus (vs) other causes. The numbers of pts experiencing specified adverse events (AE) of grade 3-5 are expressed per 100 person-years of study treatment exposure to account for differing treatment durations. **Results:** After a median follow-up of 98 months, data cut-off 30JUN2024, death was reported in 285/563 (51%) pts assigned ENZA vs 337/562 (60%) assigned NSAA. OS was longer among those assigned ENZA than NSAA (medians 95 vs 70 months; OS at 96 months 50% vs 40%; HR 0.73, 95% CI 0.63 to 0.86; p=0.0001). Clinical PFS also continued to favour ENZA over NSAA (HR 0.49; 95% CI 0.42 to 0.57; p<0.0001). PC accounted for 468 of all 622 deaths, and were less frequent among those assigned ENZA than NSAA (207 vs 261). Deaths due to other causes accounted for a total of 154 deaths, and were similarly frequent among those assigned ENZA vs NSAA (78 vs 76). Mean duration of study treatment was longer for ENZA than NSAA (58 vs 36 months). 185/562 (33%) remain on ENZA with 88% on full dose. G3-5 AE of interest were reported in the following numbers of pts per 100 years of study treatment with ENZA vs NSAA: cardiac disorder 2.2 vs 2.2, nervous system disorder 2.3 vs 2.0, fall 0.70 vs 0.24. Causes of death according to PSA at 7 months are tabulated below. Among those with PSA at 7 months ≤0.2, deaths were due to PC in 29%, and other causes in 13%. Among those with PSA at 7 months >0.2, deaths were due to PC in 60%, and other causes in 13%. **Conclusions:** Treatment with enzalutamide continues to confer substantial OS benefits at 8 years. These findings highlight long-term safety, toxicities, non-PC causes of death, and survival outcomes of those with and without PSA ≤0.2 at 7 months. ClinicalTrials.gov Identifier NCT02446405. Clinical trial information: NCT02446405. Research Sponsor: Astellas; Cancer Council Australia; The Australian and New Zealand Urogenital and Prostate Cancer Trials Group (ANZUP).

Landmark analysis by PSA at 7 months	ENZA (N=555)	NSAA (N=549)	ALL (N=1104)
Deaths due to prostate cancer, PSA ≤0.2	100/375 (27%)	87/270 (32%)	187/645 (29%)
Deaths due to other causes, PSA ≤0.2	54/375 (14%)	33/270 (12%)	87/645 (13%)
Deaths due to prostate cancer, PSA >0.2	104/180 (58%)	170/279 (61%)	274/459 (60%)
Deaths due to other causes, PSA >0.2	22/180 (12%)	39/279 (14%)	61/459 (13%)

Prognostic value of PSMA PET against CHAARTED criteria in an ENZAMET sub-cohort. First Author: Zahra Sabahi, St Vincent's Hospital Sydney and Garvan Institute of Medical Research, Sydney, Australia

Background: CHAARTED criteria using CT and bone scan are widely recognized as prognostic in metastatic, hormone-sensitive prostate cancer (mHSPC) and can guide decisions about treatment, including intensification. However, clinicians are increasingly using PSMA PET/CT (PSMA-PET) instead of conventional imaging. Currently, PSMA-PET criteria for identifying poor prognostic mHSPC has limited evidence. The aim of this study is to identify features on PSMA PET/CT that correlate to progression free survival (PFS) and overall survival (OS) in the context of CHAARTED criteria in an ENZAMET sub-cohort. **Methods:** ENZAMET (ANZUP 1304, NCT02446405) is an international, open-label, randomized, phase 3 trial. Eligible participants had mHSPC evident on CT and/or bone scan. Participants (pts) were randomly assigned (1:1) to receive testosterone suppression plus enzalutamide or a non-steroidal antiandrogen (NSAA). Pts who underwent PSMA-PET prior to study enrolment were identified for this substudy. Imaging (PSMA-PET, CT, bone scan) were de-identified, and centrally evaluated by three imaging experts blinded to clinical outcomes for number, site, and intensity of metastatic deposits. Additional correlative findings on bone scan and PSMA-PET/CT were determined. A semi-automated quantitative imaging analysis was undertaken to derive PSMA-total tumor volume (PSMA-TTV). The analysis evaluated the association between PSMA-TTV (analysed continuously and as quartiles Q1-3 vs Q4), site (lymph node, bone, viscera) with PFS, OS, and CHAARTED criteria. Kaplan-Meier survival estimates, log-rank tests, and Cox regression after adjusting for treatment arm were used for analysis. **Results:** 100 pts (51 enzalutamide, 49 control NSAA) had a PSMA-PET/CT prior to enrolment. In this sub-cohort, median age was 69 years, 36 were synchronous, 74 patients were low volume on CHAARTED criteria. On PSMA-PET 19 pts had bone only disease, 37 had lymph node (LN) only, 33 bone and LN and 9 visceral involvement. In 54 pts with bone involvement on PSMA-PET, 53 had concordant findings on bone scan. Median PSMA TTV in the study cohort was 28 mL (61 mL vs 22 mL in CHAARTED high vs low volume) with the highest PSMA TTV quartile (Q4) >71mL. 5-year PFS for PSMA TTV Q4 vs Q1-3 was 36% vs 61% (p=0.011), with HR per doubling of TTV = 1.19 (95%CI: 1.03 – 1.38). In the pts with CHAARTED criteria low volume mHSPC, 5-year PFS for PSMA TTV Q4 vs Q1-3 was 21% vs 57% (p<0.001). 5-year OS for PSMA TTV Q4 vs Q1-3 was 60% vs 74% (p=0.18) with HR per doubling of TTV = 1.10 (95%CI: 0.91 – 1.32). **Conclusions:** PSMA-TTV is associated with PFS in mHSPC in this ENZAMET sub-cohort with the highest volume quartile (>71mls) showing significantly shorter PFS, including within the CHAARTED criteria low volume cohort. Further validation of PSMA-TTV as a prognostic biomarker with potential to identify patients for intensification is warranted in larger mHSPC cohorts. Clinical trial information: NCT02446405. Research Sponsor: Astellas; Cancer Council Australia; The Australian and New Zealand Urogenital and Prostate Cancer Trials Group (ANZUP).

5092 Poster Session

How low do you need to go? Association between various prostate-specific antigen (PSA) response measures and clinical outcomes in metastatic castration-sensitive prostate cancer (mCSPC) in the Veteran Health Administration (VHA) data. First Author: Stephen J. Freedland, Cedars-Sinai Medical Center, Los Angeles, CA; Durham VA Medical Center, Durham, NC

Background: Clinical trials show that combined treatment (tx) with androgen deprivation therapy (ADT) and androgen receptor pathway inhibitors (ARPIs) improves PSA response and overall survival (OS) in patients (pts) with mCSPC. Our real-world study assessed the impact of PSA response on OS and progression in pts receiving ADT ± other tx. **Methods:** VHA data (2017–2024) were analyzed for adults with mCSPC who initiated index tx, ie, ADT ± other tx (ARPI, nonsteroidal antiandrogen [NSAA], docetaxel), and had PSA values at baseline (365 days prior to ADT initiation [index date]) and during index tx. PSA response was examined as: 1) ≥90% decline from baseline PSA; 2) PSA <0.2 ng/mL during index tx. Progression was defined as PSA progression (≥25% rise and ≥2 ng/mL increase from nadir PSA during PSA follow-up [index date to 8/31/2024]), initiation of a new tx, hormone resistance or death. Landmark analyses with Cox proportional hazards regressions assessed the association of PSA response (by 9 months [mo] post index date) with OS and time to progression after 9 mo post index date. **Results:** Overall, 4890 pts started first line mCSPC tx: ADT alone, 47%; ADT + ARPI, 40%; ADT + NSAA, 7%; ADT + docetaxel (± ARPI ± NSAA), 6%. Median follow-up was 24.7 mo, with a median PSA follow-up of 14.6 mo. During PSA follow-up, 44% of pts reached PSA <0.2 ng/mL and 74% had ≥90% PSA decline from baseline. PSA decline of ≥90% was related to a 22% reduced risk of death but was unrelated to progression (Table). In contrast, PSA <0.2 ng/mL was associated with greater reduction in the risk of death (54%) and progression (55%). **Conclusions:** In a real-world mCSPC setting, pts who achieved PSA <0.2 ng/mL within 9 mo of initiating ADT ± other tx had lower risk of death and progression than pts who did not. Reaching ≥90% PSA decline was modestly associated with improved OS but not progression, suggesting a PSA nadir of <0.2 ng/mL is needed for optimal outcomes. Association of circulating immune and metabolic markers with clinical outcomes in the ENZAMET trial (ANZUP 1304). First Author: Lisa Horvath, Chris O'Brien Lifehouse, University of Sydney, Sydney, NSW, Australia

Background: ENZAMET showed that enzalutamide (ENZ) significantly improves overall survival (OS) of metastatic hormone-sensitive prostate cancer (mHSPC) compared to conventional non-steroidal anti-androgen (NSAA). However, intrinsic and acquired resistance to ENZ are ongoing problems. In the CHAARTED mHSPC cohort, elevated circulating IL8 and IGFBP1, and a low IGF1:IGFBP1 ratio, were associated with shorter OS and shorter time to castration-resistance. The aim of this study was to confirm the prognostic association of IL8, IGFBP1, and IGF1:IGFBP1 in mHSPC, and also explore the relationship of a set of immune markers with ENZ treatment by post-hoc analysis of ENZAMET. **Methods:** Baseline plasma levels of IL8, IGF1, IGFBP1, C-reactive protein (CRP), and 14 other cytokines were profiled in 852 participants of ENZAMET (ENZ n=420; NSAA n=432) using Milliplex antibody assays (Merck). The association of these markers with OS and clinical progression-free survival (cPFS) was assessed by Cox regression. **Results:** In the whole study cohort, we confirmed that high IGFBP1 and IL8, and low IGF1:IGFBP1 were significantly associated with shorter OS and shorter cPFS (p≤0.029). High CRP, CXCL16, IL6, MIC1 and YKL40, and low IL28A were also associated with shorter OS (p≤0.015). These markers were independently associated with OS in multivariable analysis with treatment arm, volume of disease, concurrent docetaxel, and presence of visceral metastases (p≤0.047, Table). None of these markers were predictive of ENZ response. In subgroup analyses by treatment arm, IGFBP1 and IGF1:IGFBP1 were prognostic in the ENZ arm (OS p≤0.042, cPFS p≤0.02) but not in NSAA (OS p=0.08, cPFS p≥0.2). IL8 was prognostic in the NSAA arm (OS p=0.02, cPFS p=0.006) but not in ENZ (OS p=0.5, cPFS p=0.5). MIC1 was the only marker that was prognostic in both treatment arms (OS & cPFS p≤0.002). **Conclusions:** These data validate IL8, IGFBP1, and IGF1:IGFBP1 as prognostic biomarkers in mHSPC. Furthermore, pro-inflammatory and macrophage-associated cytokines are associated with poorer clinical outcomes. Clinical trial information: NCT02446405. Research Sponsor: Astellas; Cancer Council Australia; The Australian and New Zealand Urogenital and Prostate Cancer Trials Group (ANZUP).

Impact of somatic/germline homologous recombination repair (HRR) alterations on metastatic hormone-sensitive prostate cancer (mHSPC) outcomes by disease volume. First Author: David Olmos, Hospital Universitario 12 de Octubre. Instituto de Investigación Sanitaria Hospital 12 de Octubre, Madrid, Spain

Background: The impact of HRR mutations in castration-resistant prostate cancer has previously been reported, but their role in mHSPC patients (pts) contemporaneously treated has not been established. Here we report the prevalence of somatic/germline HRR mutations, and their effect on the outcomes in mHSPC pts stratified by CHAARTED disease volume and BRCA/HRR alterations. **Methods:** Eligible mHPSC pts diagnosed between Jan. 2018 and Dec. 2023 underwent paired somatic/germline DNA sequencing. Cases with alterations in ≥1 HRR gene were hierarchically classified as BRCA, non-BRCA, HRR non-BRCA, or non-HRR. Radiographic progression free survival (rPFS), time to castration resistance (TTCR), and overall survival (OS) were reported for all subgroups; associations between mutations and outcomes were assessed using inverse probability of treatment weighting (IPTW) models, which were controlled for treatment modality and other baseline characteristics. **Results:** Of 556 pts, 69 (12.4%) harbored alterations in *BRCA1* and/or *BRCA2* genes (BRCA) and 90 (16%) had alterations in HRR non-BRCA genes. mHSPC was synchronous in 451 pts (81.1%) and was classified by conventional imaging as high-volume (HV) in 306 (55%) and low-volume (LV) in 250 (45%) pts as per CHAARTED criteria. Most pts (44.8%) were treated with androgen deprivation therapy (ADT)+androgen-receptor-pathway inhibitor (ARPi), 30.4% received docetaxel (Doc)+ADT, and 11.3% were treated with ADT+ARPi+Doc. Only 13.5% received ADT alone. Baseline pt characteristics and treatments administered were similar across all subgroups after adjustment. BRCA pts had significantly shorter rPFS, TTCR, and OS compared with non-BRCA in all groups (Table) using IPTW models. Similar significant differences were observed when BRCA pts were compared with HRR non-BRCA pts, but no clinically relevant differences were observed between HRR non-BRCA and non-HRR pts. **Conclusions:** Presence of BRCA mutations significantly worsened survival outcomes in HV and LV mHSPC treated with doublet or triplet therapy or ADT alone. ^{177}Lu-PSMA-617 consolidation therapy post docetaxel in patients with de-novo high-volume metastatic hormone-sensitive prostate cancer: A randomized, phase 2 trial. First Author: Ashwani Sood, Department of Nuclear Medicine, PGIMER, Chandigarh, India

Background: De-novo high-volume metastatic hormone-sensitive prostate cancer (mHSPC) presents a therapeutic challenge with a dismal five-year survival rate. Till recently, androgen deprivation therapy (ADT) with docetaxel had been the standard-of-care for such patients. Nevertheless, a substantial proportion of patients continue to harbour residual disease after completion of docetaxel. ^{177}Lu-PSMA-617 has shown positive survival outcomes in the metastatic castrate-resistant setting. Here, we intended to evaluate the role of upfront ^{177}Lu-PSMA-617 as consolidation therapy for residual disease following docetaxel in de-novo high-volume mHSPC patients. **Methods:** This was an investigator-initiated randomized, parallel-group, open-label, phase 2 trial. Patients with de-novo high-volume mHSPC who were initiated on ADT plus docetaxel (75 mg/m^2/cycle x 6) and had residual non-progressive disease after completion of six cycles of docetaxel (defined as serum PSA >0.2 ng/mL with PSMA-positive disease on ^{68}Ga-PSMA-11 PET/CT) were randomized in 1:1 ratio to the experimental arm (^{177}Lu-PSMA-617, 7.4 GBq/cycle x 2, 6 weeks apart with continued ADT) or control arm (continued ADT only). The primary end-point was the proportion of patients achieving a serum PSA of ≤0.2 ng/mL at 6 months from randomization. Major secondary end-points included radiographic progression-free survival (rPFS), PSA-PFS, and treatment-emergent adverse events (TEAEs). A total sample size of 78 patients was estimated to be recruited assuming a 30% improvement in the primary end-point in the experimental arm with two-sided alpha of 5% and power of 80%. **Results:** The trial was terminated early due to poor accrual COVID-19 pandemic and following the change in standard of care from doublet to triplet therapy incorporating an androgen-receptor pathway inhibitor along with ADT plus docetaxel. Thirty high-volume mHSPC patients (15 in each arm) were recruited between January 2021 and May 2024. The primary end-point was achieved in 9/15 (60%) patients in the experimental arm versus 2/15 (13.3%) patients in the control arm (risk ratio: 4.5, 95% CI: 1.2-17.4, p=0.008). The median rPFS was 18 months in the experimental arm versus 9 months in the control arm, while the median PSA-PFS were 15 months and 9 months, respectively. No major grade 3/4 TEAEs were seen in the experimental arm. **Conclusions:** In de-novo high-volume mHSPC patients treated with docetaxel and having residual disease, ^{177}Lu-PSMA-617 consolidation therapy demonstrated remarkable efficacy in terms of biochemical response. Larger phase 3 trials are needed to definitively establish its survival benefits. Clinical trial information: CTRI/2021/01/030267. Research Sponsor: None.

Real-world patient (pt) characteristics, treatment patterns, and overall survival (OS) in metastatic hormone-sensitive prostate cancer (mHSPC): Insights by *PTEN* status. First Author: Dana Rathkopf, Memorial Sloan Kettering Cancer Center, New York, NY

Background: The loss of function of the tumor suppressor gene *PTEN* is associated with an increased risk of recurrence and poor clinical outcomes in advanced prostate cancer (PC). Current understanding of *PTEN* prevalence and pt characteristics, treatment patterns, and survival outcomes by *PTEN* status in mHSPC is limited. **Methods:** This cohort study used retrospective longitudinal data from the US-based deidentified Flatiron Health-Foundation Medicine mPC clinicogenomic database. Male pts diagnosed (dx) with mHSPC between January 1, 2018, and March 31, 2024, who underwent comprehensive genomic profiling of a solid tumor specimen were included. Pts with *PTEN* alterations were classified as *PTEN*-homs del (homozygous deletion, defined as a copy number variant [CNV]=0) or *PTEN*-mut (CNV=1, pathological short variant alterations or rearrangements). Pts without *PTEN* alterations identified were classified as *PTEN*-nonaltered. Pt characteristics and treatment patterns were descriptively analyzed. Kaplan-Meier survival probabilities for real-world overall survival (rwOS; unadjusted) were estimated by *PTEN* status (*PTEN*-homs del, *PTEN*-mut, and *PTEN*-nonaltered). **Results:** Of 1630 included pts, 39.8% had tumors with *PTEN* alterations (*PTEN*-homs del, 23.2%; *PTEN*-mut, 16.6%). Overall, pts were predominantly non-Hispanic White with a mean (SD) age of 69 (9.1) years at mHSPC dx. At initial dx, 66.7% presented with a Gleason score of 8 to 10, and 68.1% had de novo metastatic disease. Median (IQR) prostate-specific antigen level (ng/mL) at metastatic diagnosis was lower in *PTEN*-homs del (47 [9-193]) and *PTEN*-mut (42 [11-157]) mHSPC relative to *PTEN*-nonaltered (68 [15-337]) mHSPC. *BRCA* mutations were less frequent in *PTEN*-homs del (6.1%) tumors relative to *PTEN*-mut (9.6%) and *PTEN*-nonaltered (10.3%) tumors. All other pt characteristics were generally similar across *PTEN* groups. The most common first-line treatments across all *PTEN* groups were ADT alone and ARPI ± ADT. Median (95% CI) rwOS (months) was 29.0 (24.1-33.6) in *PTEN*-homs del, 32.7 (27.8-37.9) in *PTEN*-mut, and 42.3 (38.7-46.0) in *PTEN*-nonaltered mHSPC groups. Pts with *PTEN* alterations tended to have lower landmark survival probabilities than pts without *PTEN* alterations (Table). **Conclusions:** Among pts with mHSPC, worse survival was observed in pts with tumors harboring *PTEN* alterations relative to pts without *PTEN* tumor alterations, despite similar pt characteristics and treatment patterns across *PTEN* groups. Research Sponsor: AstraZeneca.

Outcomes of initial vs delayed docetaxel therapy in veterans with metastatic hormone sensitive prostate cancer and high volume of disease. First Author: Jasnoor Malhotra, Saint Louis University School of Medicine, St. Louis, MO

Background: Docetaxel (DOC) continues to demonstrate efficacy in metastatic hormone sensitive prostate cancer (mHSPC), particularly in combination with androgen deprivation therapy (ADT) ± androgen receptor pathway inhibitors (ARPI). However, a paucity of data exists evaluating treatment sequencing with DOC for patients with high volume disease. We assessed overall survival (OS) of patients with mHSPC treated with either DOC followed by ARPIs or ARPIs followed by DOC. **Methods:** A nationwide retrospective study of 696 US Veterans with de novo (synchronous) mHSPC who received both DOC and an ARPI in combination with ADT in the Veterans Health Administration between 2015-2023. Of these, 581 (83.5%) had high-volume disease. Patients either received DOC (1) within 4 months of and (2) greater than 4 months after ADT. The early DOC group received an ARPI after the initial 4 months while the late DOC group received an ARPI within 4 months of ADT. Age, baseline PSA, Charlson comorbidity index (CCI) and BMI values were acquired for each patient. Survival analysis was performed using the Kaplan-Meier method. **Results:** Of the 581 Veterans with high-volume disease, 400 received DOC early (68.8%) and 181 received DOC later (31.2%). Patients who received DOC early had a significantly longer OS than those who received it later (median 36.3 vs 29.3 months, $p<0.001$, HR 0.65, 95% CI 0.53-0.80). Findings were similar when adjusted for age, baseline PSA, and CCI (aHR 0.69, 95% CI 0.56-0.85). Additionally, patients who received DOC early had a significantly longer rwPFS than those who received it later (median 17.0 vs 12.5 months, $p<0.001$, HR 0.63, 95% CI 0.52-0.76). Findings were similar when adjusted for age, baseline PSA, and CCI (aHR 0.64, 95% CI 0.53-0.78). Evaluation of baseline characteristics between DOC vs ARPI combination therapy showed that the early DOC group was younger (mean 66.4 vs 69.6 years, $p<0.001$). However, no other statistically significant differences were found between the two groups when comparing baseline PSA, BMI, and CCI. **Conclusions:** Initial DOC in Veterans with de novo high volume mHSPC was associated with longer survival. While all patients were candidates for chemotherapy, the Veterans who were treated early with DOC were younger. These finding support early docetaxel in patients with aggressive disease that are likely to develop castration-resistance and require subsequent therapies. Research Sponsor: None.

Patient characteristics.

	Docetaxel Early (n=400)	Docetaxel Late (n=181)	p-value

Prospective monitoring of prostate specific membrane antigen–positive biochemically recurrent prostate cancer (PSMA+ BCR): Preliminary data from 6-month PSMA follow-up. First Author: Ravi Amrit Madan, Genitourinary Malignancies Branch, Center for Cancer Research, National Cancer Institute, National Institutes of Health, Bethesda, MD

Background: PSMA imaging can identify recurrent prostate cancer after definitive surgery/radiation prior to detection on computed tomography (CT) or bone scan. Radiation to PSMA+ findings is common but lacks clear data demonstrating long term benefit. PSMA+ biochemically recurrent prostate cancer (PSMA+ BCR) is often defined and treated as metastatic castration sensitive prostate cancer (mCSPC), yet PSMA imaging alone as an eligibility criteria was never studied in the mCSPC trials. PSA+ BCR requires better understanding to define at-risk patients (pts). **Methods:** NCT05588128 enrolls pts after definitive and possibly salvage therapies. Pts are required to be 1 year removed from definitive therapy with a PSA>0.5 ng/ml, testosterone>100 ng/dL, and negative CT/bone scans. Lymph nodes (LNs) up to 1.5 cm and prior therapies are permitted. At enrollment pts have a baseline PSMA, which is repeated every 6 months (mos) if positive. If negative PSMA is done annually. CT and bone scan are also repeated annually. Pts are allowed to have radiation therapy or systemic therapies for ≤6 mos and remain on-study. Up to 350 pts will be enrolled and followed for up to 5 years. **Results:** Over 120 pts have enrolled since 3/2023 and 86 pts are evaluable after the 6-month PSMA scan/follow-up. The pts have a median age of 71 years, PSA=3.05, PSA doubling time=11.1 mos (29% less than 6 mos). In an overlapping descriptive analysis 10 pts were PSMA- and 17 pts had only local disease. For PSMA+ LNs, 17 pts had 1 LN, 9 pts had 2-3 LNs+, 5 pts had 4 LNs+, and 18 pts had 5+ LNs. 7 pts had bone findings, but negative bone scan. 4 pts had PSMA+ serosal nodules. 4 pts had radiation to solitary LNs. 1 pt elected androgen deprivation and 1 pt had salvage radiation. 4 pts enrolled on a clinical study at the NCI without androgen deprivation. At 6 mos PSMA scan only 1 pt had metastatic disease (bone scan findings). No pts had LNs beyond eligibility size criteria. No pts had new visceral findings. **Conclusions:** These preliminary data from an ongoing study suggest PSMA+ BCR is an indolent disease process and pts are at limited risk for clinically relevant progression within 6 mos. This study continues to accrue at the NCI and will seek to better define high risk PSMA+ BCR. These preliminary data may better inform the risk/benefits of aggressive treatment of PSMA+ BCR and clinical studies in PSMA+ BCR. Clinical trial information: NCT05588128. Research Sponsor: NCI Intramural Porgram.

Evaluation of de novo oligometastatic, oligorecurrent, and oligoprogressive prostate cancer patients managed with radiation therapy: A multi-institution, real-world dataset. First Author: Sophia C. Kamran, Massachusetts General Hospital, Harvard Medical School, Boston, MA

Background: Oligometastatic prostate cancer (omPCa) is historically defined as ≤5 metastases, with non-standard treatment approaches and unknown prevalence in the molecular diagnostic imaging (MDI) era. Clinical trials in advanced PCa based on conventional imaging modalities (CIM) complicate extrapolation of findings to omPCa detected by MDI. We evaluated outcomes of omPCa patients (pts) treated with radiotherapy (RT) in a multi-institutional cohort. **Methods:** Pts presenting with de novo (synchronous), oligorecurrent (OR, metachronous), or oligoprogressive (OP, progressive) omPCa (<5 non-visceral lesions), detected by CIM and/or MDI and treated with RT across 7 institutions were identified. RT was metastasis-directed (MDT) only (or in the case of de novo pts, prostate-only or prostate + MDT) using conventional, hypofractionated or stereotactic body RT (SBRT) regimens. Clinical outcomes, including disease (dz) progression (any biochemical recurrence or distant metastasis, DM) and survival were assessed. Progression-free survival (PFS), DMFS, and overall survival (OS) were determined using the Kaplan-Meier method; univariable analyses were performed with Cox proportional hazard regression. **Results:** 625 omPCa pts (193 de novo, 342 OR, 90 OP) received RT between 2014-2024. Most pts (415/625, 66%) were diagnosed using MDI. 25% presented with pelvic lymph nodes (LNs) only, 7% non-regional LNs only, 56% bone-only dz, and 12% with a combination. Most pts (551/625) received systemic therapy with RT: 51% androgen deprivation therapy (ADT) alone, 43% ADT + androgen receptor signaling inhibitor (ARSI, n=239), and 6% ADT + ARSI + docetaxel. Median FU post-omPCa diagnosis was 26 months (range, 1-225) for 613 pts with details available. 153 pts developed new DM (outside of documented OM). Five-year OS post-diagnosis was 87% (95%CI 81,91). 5-year PFS post-RT was 34% (95%CI 24,44), with median PFS of 43 months. Concurrent ARSI use improved PFS (HR 0.67, 95%CI 0.50,0.91, p=0.01) on Cox proportional hazard regression. Use of any systemic therapy improved DMFS (HR 0.46, 95%CI 0.29,0.72, p<0.001). Both OR and OP dz were associated with worse DMFS (HR 2.2, 95%CI 1.4,3.5; HR 6.3, 95% CI 3.7,10.6, respectively, p<0.001 for both) and OP dz was associated with poor OS (HR 5.8, 95%CI 2.7,12.7). There was no impact by RT approach on outcomes. **Conclusions:** In this multi-institutional omPCa cohort reflecting real-world practice patterns of detection and treatment, the addition of ARSI to RT improved PFS, and use of any systemic therapy with RT improved DMFS. De novo omPCa had more favorable clinical outcomes compared to OP/OR presentations. Research Sponsor: None.

Assessment of the impact of delays to radiotherapy on prostate cancer mortality in localized prostate cancer. First Author: Yang Xu, Arthur J.E. Child Comprehensive Cancer Centre, Calgary, AB, Canada

Background: Resource constraints and patient preferences may lead to delays in the treatment of localized prostate cancer, but the implications of such delays remain unclear. We aimed to investigate the impact of time from diagnosis to treatment initiation (TTI, including neoadjuvant ADT) on prostate cancer-specific mortality (PCSM) in patients receiving radiotherapy for localized prostate cancer. **Methods:** Patients diagnosed with localized prostate cancer from 2004 to 2020 who received radiotherapy as part of their first course of treatment were identified from the SEER 17 database. Those who initially underwent active surveillance or surgery, as well as those whose TTI exceeded 24 months, were excluded. The remaining patients were divided into cohorts with prespecified TTI intervals of 0-3 months, 4-6 months, and >6 months. Covariates were age, race, county median income, county remoteness, diagnosis year, T stage, PSA, Gleason grade, and treatment modality (external beam radiotherapy, brachytherapy, or a combination). Missing covariates were imputed 50 times using multiple imputations with chained equations, after which propensity score weighting using Bayesian additive regression trees was performed for each imputed dataset. Pooled marginal Cox models, in accordance with Rubin's rules, were used to compare the PCSM of the three TTI cohorts. Additionally, a prespecified subgroup analysis based on NCCN risk classification was completed. **Results:** A total of 230,278 patients with a median follow-up of 7.8 years were eligible for analysis, of whom 168,432 (73.1%) had a TTI of 0-3 months, 46,738 (20.3%) had a TTI of 4-6 months, and 15,108 (6.6%) had a TTI of >6 months. After propensity score weighting, the maximal standardized mean difference across all covariates and imputations was less than 0.03. Weighted 10-year PCSMs were 5.9%, 5.6%, and 7.1% for patients with TTIs of 0-3 months, 4-6 months, and >6 months, respectively. The PCSM of patients with a TTI of 4-6 months did not differ from that of patients with a TTI of 0-3 months (HR 0.95, 95% CI 0.89-1.01; P=0.09). However, patients with a TTI of >6 months had a higher risk of PCSM than those with TTIs of 0-3 months (HR 1.22, 95% CI 1.09-1.36; P<0.001) or 4-6 months (HR 1.28, 95% CI 1.13-1.45; P<0.001). There was no significant interaction between TTI and NCCN risk group (P=0.49). **Conclusions:** A TTI exceeding 6 months was associated with an increased risk of prostate cancer mortality. These findings support the timely initiation of treatment for patients undergoing radiotherapy for localized prostate cancer. Research Sponsor: None.

PCSM by NCCN risk subgroup.

Subgroup	4-6 months vs. 0-3 months HR (95% CI)	>6 months vs. 0-3 months HR (95% CI)	>6 months vs. 4-6 months HR (95% CI)
Overall	0.95 (0.89-1.01)	1.22 (1.09-1.36)	1.28 (1.13-1.45)
Low risk	1.02 (0.89-1.17)	1.05 (0.86-1.29)	1.04 (0.83-1.30)
Intermediate risk	0.94 (0.86-1.03)	1.19 (1.02-1.38)	1.27 (1.07-1.50)

Five-year outcomes of SABR in intermediate- and high-risk prostate cancer without ADT. First Author: Nidal Salim, European Medical Center, Moscow, Russian Federation

Background: Stereotactic ablative body radiotherapy (SABR) is emerging as a prominent treatment option for localized prostate cancer (PCa). Most existing studies have primarily focused on low- and intermediate-risk PCa patients, who typically have favorable prognoses regardless of treatment. Additionally, the necessity of adding androgen deprivation therapy (ADT) remains a subject of ongoing debate, given its associated side effects and limited impact on overall survival (OS). In this study, we present the long-term outcomes of patients predominantly with intermediate- and high-risk PCa who were treated with SABR without ADT. **Methods:** This was a single-center prospective study of 87 patients with localized PCa who underwent SABR without subsequent ADT. SABR was delivered in an ultra-hypofractionation regimen (36.0 – 42.7 Gy) using Varian TrueBeam/EDGE linear accelerators between July 2015 and June 2024. The primary endpoint was biochemical recurrence-free survival (bRFS), with secondary endpoints including toxicity and overall survival (OS). **Results:** A total of 87 patients, with a median age of 68.8 years (range: 50–86 years), were included. The median follow-up period was 31 months (range: 3–105 months). The distribution of patients by risk group was as follows: low-risk (21.8%), intermediate-risk (55.1%), and high-risk (17.9%). The 1-, 3-, and 5-year bRFS rates were 97.6%, 92.2%, and 90.0%, respectively. Importantly, no patient died as a result of PCa progression during the observation period. No clinically significant toxicity was reported. **Conclusions:** The findings of this study suggest that SABR as a standalone treatment modality is a safe and effective approach for localized PCa, providing durable biochemical control without significant toxicity. However, further investigations involving larger patient cohorts and longer follow-up periods are needed to confirm these results and enhance their reliability. Research Sponsor: None.

COBRA: Assessment of the efficacy of ^{64}Cu-SAR-bisPSMA using histopathology and standard of care imaging as reference standard in patients with biochemical recurrence of prostate cancer following definitive therapy. First Author: Luke Nordquist, XCancer/Urology Cancer Center, Omaha, NE

Background: Accurate staging of recurrent prostate cancer (PC) is essential to inform the best treatment strategy. ^{64}Cu-SAR-bisPSMA may offer several advantages over the currently approved PSMA positron emission tomography (PET) agents due to its bivalent structure (SAR-bisPSMA) and longer half-life of ^{64}Cu (12.7h vs. <2h for ^{18}F and ^{68}Ga), as previously reported (2-3x higher tumor uptake and detection of additional PC lesions vs. approved PSMA PET agents). **Methods:** This was a Phase 1/2 study assessing the safety/efficacy of ^{64}Cu-SAR-bisPSMA (200 MBq) in PC patients with biochemical recurrence (BCR) and negative/equivocal standard of care (SOC) imaging (NCT05249127). PET/computed tomography (CT) imaging was performed on Day 0 and Day 1 (1-4h and 24±6h post-dose, respectively) and interpreted by 3 blinded central readers. PET/CT results were assessed against a composite Reference Standard (histopathology, SOC imaging [interpreted by 2 readers], prostate specific antigen response post-focal therapy). Efficacy endpoints included detection rate (DR; % participants with a positive scan out of all scanned participants) and correct detection rate (CDR; % participants with a true positive scan out of all scanned participants with at least one evaluable Reference Standard). **Results:** Fifty-two participants were enrolled (50 had ^{64}Cu-SAR-bisPSMA PET results); 39 and 30 had follow-up SOC imaging by Day 90 and by Day 180, respectively, and 9 had histopathology. ^{64}Cu-SAR-bisPSMA DR range across readers on Day 0 was 44–58% (95% confidence interval [CI]: 30–71.8), increasing on Day 1 to 58–80% (95% CI: 43.2–90). DR on follow-up SOC imaging by Day 90 ranged from 15-31% and 7-10% by Day 180. CDR as assessed against the composite Reference Standard on Day 0 was 19.0–26.2% (95% CI: 8.6; 42.0), increasing to 26.2–33.3% (95% CI: 13.9; 49.5) on Day 1. CDR was considerably higher when using histopathology as the Reference Standard (44.4–55.6% and 55.6–77.8% for Day 0 and Day 1, respectively), than SOC imaging (10.3–20.5% and 23.1%–25.6% for Day 0 and Day 1, respectively). **Conclusions:** ^{64}Cu-SAR-bisPSMA is effective in detecting PC in BCR of PC, with lesions identified in up to 80% of participants with negative/equivocal baseline SOC imaging. CDR was considerably higher when using the gold standard of histopathology to verify ^{64}Cu-SAR-bisPSMA PET lesions vs SOC imaging, which highlights the limitations of using less sensitive methods to verify the ^{64}Cu-SAR-bisPSMA PET findings. These results have important clinical implications, as the identification of lesions in BCR patients can inform different treatment pathways. Clinical trial information: NCT05249127. Research Sponsor: Clarity Pharmaceuticals.

Secondary outcomes by prior definitive treatment (tx) in patients (pts) with high-risk biochemically recurrent prostate cancer (hrBCR) treated with enzalutamide (enza) monotherapy (mono): EMBARK post hoc analysis. First Author: Stephen J. Freedland, Department of Urology, Samuel Oschin Comprehensive Cancer Institute, Cedars-Sinai Medical Center, Los Angeles, CA

Background: The phase 3 EMBARK trial demonstrated clinically meaningful improvement in metastasis-free survival and secondary efficacy endpoints with enza mono vs leuprolide alone. Herein, we descriptively report secondary endpoints for enza mono vs leuprolide alone across prior definitive tx subgroups. **Methods:** Eligible pts had hrBCR, with a prostate-specific antigen (PSA) doubling time of ≤9 months. Pts were randomized 1:1:1 to enza + leuprolide, leuprolide alone, or enza mono. Secondary endpoints included time to PSA progression, first use of new antineoplastic tx, distant metastasis, resumption of any hormonal therapy after tx suspension, and symptomatic progression. Post hoc subgroup analyses descriptively compared secondary endpoints for enza mono vs leuprolide alone in pts with radical prostatectomy (RP) only, radiotherapy (RT) only, or RP + RT. **Results:** In both tx groups (enza mono and leuprolide alone), nearly half of pts had prior RP + RT (Table). Enza mono vs leuprolide alone numerically reduced the risk of PSA progression, first use of new antineoplastic tx, distant metastasis, and symptomatic progression in all prior definitive tx subgroups (Table). Time to resumption of any hormonal therapy favored leuprolide alone vs enza mono across all prior definitive tx subgroups. **Conclusions:** Tx with enza mono showed improvements in all secondary endpoints except time to resumption of any hormonal therapy vs leuprolide alone, regardless of prior definitive tx. The small sample sizes of the nonrandomized prior tx subgroups and low event numbers should be considered when interpreting the results. Interaction analyses of secondary endpoints across prior definitive tx subgroups will be reported in the presentation. Disclosure: A genAI tool (10/01/24; Pfizer; GPT-4o) developed the 1st draft; authors assume content responsibility. Clinical trial information: NCT02319837. Research Sponsor: The study was sponsored by Pfizer Inc. and Astellas Pharma Inc., the co-developers of enzalutamide. Neoadjuvant niraparib in men with DNA repair gene deficient clinically localized prostate cancer: Clinical and molecular results from a phase 2 investigator-initiated trial. First Author: Marc Dall'Era, Department of Urology, University of California, Davis, Sacramento, CA

Background: Many men with clinically localized prostate cancer experience disease progression and recurrence despite curative local therapy. Neoadjuvant treatments may reduce recurrence risk and the need for salvage therapy. Primary prostate cancer is genomically diverse and PARP inhibitors (PARPi) represent a novel class of targeted cancer therapy with known activity in advanced prostate cancers, particularly in the setting of DNA damage repair (DDR) gene alterations. **Methods:** Men with National Comprehensive Cancer Network unfavorable intermediate to high-risk prostate cancer were screened for somatic or germline DDR gene alterations. Consenting men were enrolled into a single arm phase II pilot study (NCT04030559) of neoadjuvant niraparib 200mg per day for 90 days prior to planned radical prostatectomy (RP). The primary endpoint was complete or partial pathologic response [minimal residual disease (MRD) defined as $<$0.5 cc of residual tumor]. Secondary endpoints were toxicity and biochemical progression free survival (bPFS). Raw tissue and ctDNA sequencing data was obtained by the clinical NGS vendor and analyzed. **Results:** Eleven (of planned 30) men were enrolled with a median age of 68 years and median PSA at diagnosis of 10.7 ng/mL. Germline-mutations were noted in *BRCA2* (n=3 patients with loss-of-function, 2 with additional loss-of heterozygosity detected), *MSH6* (n=1), *CHEK2* (n=1); somatic mutations were noted in *ATM* (n=3), *SPOP* (n=4), *PPP2R1A* (n=1), *ZFHX3* (n=1), and *ZMYM3* (n=2). No complete or partial pathologic responses were observed. PSA responses were variable on niraparib. There was one grade 3+ adverse event (thrombocytopenia) requiring a dose reduction. After a median follow up of 27 months, bPFS is 56% for the overall cohort. One patient with bi-allelic loss of *BRCA2* (germline and somatic) and a coincident *ATM* mutation had the most dramatic change in PSA (-76%) with notable radiographic regression on MRI. We detected a decline in ctDNA for the somatic mutations seen in the pre-niraparib prostate biopsy NGS (*ATM* and PIK3R1) within 7 weeks of niraparib treatment. A new reversion mutation in *BRCA2* was detected in the serum of this patient by 12 weeks which disappeared after stopping niraparib. This BRCA2 reversion mutation was also detected in the prostatectomy tissue. **Conclusions:** In this small study, neoadjuvant niraparib did not result in substantial pathologic response after RP in a group of men with prostate cancer and heterogeneous mutations in genes involved in DDR. Variable responses even in the face of bi-allelic BRCA2 loss suggest that additional biomarkers including ctDNA analysis to identify patients who may benefit are needed. Early reversion mutations may contribute to PARPi resistance in hormone sensitive prostate cancer. Clinical trial information: NCT04030559. Research Sponsor: Janssen.

A randomised clinical trial to improve healthy lifestyle adherence in prostate cancer patients undergoing radiotherapy (Microstyle study). First Author: Sara Gandini, Department of Experimental Oncology, European Institute of Oncology IRCCS, Milan, Italy

Background: The standard non-surgical approach for localized Prostate Cancer (PCa) is radiotherapy (RT) but PCa patients may experience worsening of bowel disorders affecting quality of life and attributable to RT. The main aim of the study was to examine whether personalized dietary and physical activity counselling, provided at the start of RT, improves adherence to a healthy lifestyle, according to the standardised WCRF/AICR score[1] that assists clinicians in providing evidence-based recommendations to reduce risk of morbidity and improve quality of life in cancer patients. **Methods:** We designed a randomized controlled cross-over trial with two arms – MicroStyle[2]: an intervention (IG) and a control (CG) group, which were enrolled at the start of RT and followed for six months (T6) and 12 months (T12) respectively. Clinical data, questionnaires and circulating biomarkers were collected at two Italian Cancer Centres (Milan and Naples) on different time points. Linear regression models and logistic models were applied to estimate differences by arms in the WCRF/AICR score and its association with toxicity and circulating biomarkers. **Results:** Of the 308 patients enrolled, 299 completed the baseline evaluation, and 286 completed the six-month follow-up. The intervention showed at T6 a greater WCRF adherence compared to the CG: change from baseline 0.2 95%CI: 0.03, 0.36, p =0.02 IG vs CG) adjusting for baseline. The proportion of adherent subjects significantly increase at T6 with IG (26% vs 19%, P=0.04) and at T12 (28% vs 13%, P=0.01) more than CG. A high WCRF score at T6 was found to be associated with a significantly reduced rectal toxicity (P=0.03). IG at T12 was associated with lower Testosterone (P=0.04) and lower Estradiol (P=0.02) adjusting for hormonal therapy and baseline values. Patients with WCRF improvement were associated with lower IL6 and higher adiponectin Improvement of WCRF adherence is significantly associated with improvement in quality of life (P=0.04, IPSS) and prostate symptom (p=0.05, IPSS), sexual function (P=0.01, IIEF) and in particular erectile dysfunction (P=0.03, IIEF) and functional assessment of cancer therapy (P=0.01, FACT-P), adjusting for baseline values. **Conclusions:** This innovative trial showed that that a personalized dietary and physical activity counselling during RT significantly improves adherence to a healthy lifestyle, influencing rectal toxicity and circulating biomarkers. Future analyses will explore the toxicity associated with RT, changes in microbiome and its potential interactions with lifestyle factors. External validation of a pathology-based multimodal artificial intelligence biomarker for predicting prostate cancer outcomes after prostatectomy. First Author: Chien-Kuang Cornelia Ding, University of California, San Francisco, San Francisco, CA

Background: Radical prostatectomy (RP) improves survival and delays metastasis in localized prostate cancer (PCa) patients (pts), yet 20-40% of men experience biochemical recurrence (BCR) within 10 years, with one-third of these progressing to metastatic disease. Predictive tools for risk stratification and treatment-decision making in this population remain limited. We previously developed and validated an RP digital pathology-based multimodal AI (MMAI) model using RP H&E images and select clinical variables to predict post-surgical outcomes in BCR pts (RP MMAI v1.1). We present the first external validation of this model in both BCR and non-BCR post-RP pts. **Methods:** Surgical pts with localized disease, clinical data, and long-term follow-up we re identified at UCSF (n=738). MMAI scores were generated from RP H&E images and clinical data (age, Gleason grade group (GG), pT-stage, surgical margins (SM), post-RP PSA). Fine & Gray regression with other-cause mortality as a competing risk was performed to determine the ability of MMAI score to predict any metastasis (primary analysis), bone metastasis (BM), and disease progression (DP: 2 consecutive PSA $\geq$0.2 ng/ml or salvage treatment) after RP. Hazard ratios, 95% confidence intervals, and p-values (for primary analysis) are reported. **Results:** MMAI scores were returned for 640 (87%) cases with images and clinical data. Median (IQR) post-RP follow-up was 11.5 (7.7-24.8) years. Post-RP Cancer of the Prostate Risk Assessment (CAPRA-S, range 0-12) scores were 56% low (0-2), 31% intermediate (3-5) and 13% high ($\geq$6) risk. Characteristics at RP were 71% GG1/2, 64% pT2, and 79% negative SM. The majority of pts had undetectable PSA$<$0.05 after RP (87%). Cumulative incidence of DP and metastasis were 27% and 7% at 10 years, respectively. After adjusting for CAPRA-S, MMAI was independently associated with any metastasis (HR 1.76, [95% CI 1.23-2.53], p$<$0.001) and BM (HR 2.72, [95% CI 1.71-4.32]) in post-RP pts, as well as with DP in 561 pts with undetectable PSA after RP (HR 1.51, [95% CI 1.27-1.80]). Using a cutoff previously defined in BCR pts, 10-yr risk of any metastasis or BM after RP was higher in RP MMAI high risk (18% and 16%) vs. low risk pts (3% and 1%). In a subgroup of 211 salvage-eligible pts (detectable PSA and/or salvage treatment), MMAI remained independently associated with any metastasis (HR 1.71, [1.18-2.47]) and BM (HR 2.71, [1.74-4.23]) after CAPRA-S adjustment. **Conclusions:** This study validates the RP MMAI model, originally developed in BCR pts, as an independent prognostic tool in both BCR and general post-RP settings, even when controlling for a validated clinical risk model. These findings support its potential to guide personalized management strategies for post-RP pts, while offering advantages in accessibility, efficiency, and cost compared to existing platforms. Utility of the PROSTest, a novel blood-based molecular assay, versus PSA for prostate cancer stratification and detection of higher grade disease. First Author: Pawel Rajwa, Division of Surgery and Interventional Sciences, University College London, London, United Kingdom

Background: Prostate cancer (PCa) is the most common solid organ cancer in men and the fifth leading cause of cancer-related deaths globally. PSA has utility for identifying men at risk but has low specificity and is associated with significant biopsy-related morbidities through over-investigation and over-diagnosis of disease. The PROSTest is a novel 27-gene mRNA expression machine learning-based liquid biopsy assay that was developed to help detect PCa. We evaluated the utility of this assay to predict prostate cancers in symptomatic men undergoing biopsy or surgery for PSA $>$2ng/mL. **Methods:** One hundred and twenty-three men were evaluated, 105 (85%) met eligibility criteria (age $>$55 years, PSA $>$2ng/ml, symptomatic) and underwent image-guided biopsy or surgery. Samples for PSA and PROSTest were collected prior to biopsy. PROSTest was measured following RNA isolation and cDNA production from RNA stabilized blood samples. The PCR results were fed into a machine learning algorithm that reports a score on a scale 0-100, and with the use of cutoff 50, the score is transformed into a binary readout; positive or negative. In addition to the 2x2 table below, the diagnostic value of the PROSTest was demonstrated by ROC curve. Separately, we examined whether scores could be used to differentiate Gleason Grade 1 vs Gleason Grade 2-5 patients. **Results:** The median age of the cohort was 68 years (55-86 years). Baseline PSA median was 8.2ng/mL (IQR: 7.2-92ng/mL). Sixty-five (62%) had a PCa diagnosis (27 GG1; 38 GG2-5) as confirmed by biopsy or after surgery. Baseline PROSTest results were $>$50 in 65 (62%). The distribution of PROSTest versus outcomes is included in Table 1. PROSTest sensitivity was 97% and specificity of 96% for detecting PCa. The AUROC for PROSTest was 0.39 higher than PSA (PROSTest: 0.99 vs. PSA: 0.61, p$<$0.0001). GG2-5 exhibited significantly higher (p$<$0.0001) PROSTest scores (92$\pm$3.8) than GG1 and BPH (41$\pm$41). PROSTest scores $>$93 were 79.1% accurate and 92.5% specific for detecting higher risk disease. **Conclusions:** In this head-to-head comparison, baseline PROSTest was a more sensitive and more specific biomarker than PSA in the diagnosis of all Gleason's grades and may have value for differentiating GG1 from GG2-5. This requires validation in a larger, prospectively collected cohort. Research Sponsor: None.

2x2 table identifying PROSTest score relationship with PCa detection (tissue diagnosis).

	Biopsy/Surgery	
	Prostate cancer detected (n=65)	No Prostate cancer (including 5 prostatitis, 35 BPH) (n=40)
PROSTest +ve (score ≥50)	63 (96.9%)	2 (5.0%)
PROSTest -ve (score <50)	2 (3.1%)	38 (95%)

A large language model (LLM)-based multi-agent framework for risk stratification and treatment recommendations in localized prostate cancer (locPCa). First Author: Umair Ayub, Mayo Clinic Arizona, Phoenix, AZ

Background: We previously proposed a hybrid framework combining LLMs and rule based algorithm (RBA) for automating risk stratification in locPCa. Herein, we aim to validate the risk stratification agent (RSA) in a prospective cohort, develop & evaluate the treatment recommendation agent (TRA) based on NCCN guidelines, and develop an interactive interface to facilitate clinicians for accurate risk stratification and treatment recommendations at the point of care. **Methods:** This study included pts with locPCa (2004-2024) presenting at Mayo Clinic with at least 1 positive prostate biopsy and MRI report available. For RSA prospective validation, GPT4 extracted key phenotypic variables (PSA, T stage, prostate volume, number of cores, Gleason patterns, grade group) from unstructured MRI and biopsy reports using a zeroshot prompt. An RBA then classified pts into NCCN risk groups. The agent performance was compared with the treating clinician's documentation and evaluated against gold-standard labels manually annotated by two independent clinicians. For development of TRA, two experiments were performed using GPT4 with and without retrieval-augmented generation (RAG) to generate treatment plans. Generated treatment plans were evaluated using NCCN guideline-informed treatment decision tree based algorithm (DTA). Evaluation metrics, weighted – accuracy (acc) and F1, were computed. A clinician facing interface (lisr.org/risk) was developed to provide accurate risk stratification and treatment plans. **Results:** A total of 858 pts were included (500 for prospective validation, 358 for treatment recommendations). Prospective validation for RSA demonstrated a higher F1 score of 0.89 compared to the treating clinician (F1: 0.58). Treatment recommendation experiments showed that GPT4 with RAG achieved higher acc (64% full – all correct treatment options and 36% partial – at least 1 correct treatment option) compared to GPT4 alone (35% and 65%, respectively). Sensitivity analysis using DTA-informed GPT4 note generation achieved 94% full acc and 6% partial acc. GPT4 alone generated hallucinated treatment options in 71% of cases, while GPT4 with RAG reduced this to 32%. **Conclusions:** The multi-agent framework based on LLM and RBA achieves high accuracy in risk stratification and treatment recommendation for locPCa. A multi-agent framework with an interactive interface holds high promise to enable efficient, accurate decision-making, and improve locPCa management at the point of care Research Sponsor: None.

Insight into the global mortality trends due to prostate cancer among the under-55 population: An analysis of the Global Burden of Disease-2021. First Author: Amar Lal, Penn State Health Milton, St. Hershey Medical Center, The Pennsylvania State University, Hershey, PA

Background: Prostate cancer (PC) is the most prevalent non-skin cancer among males, and it is increasingly diagnosed in those under 55. This younger demographic often faces more aggressive disease progression and a higher risk of metastasis, driven by genetic predispositions, family history, and racial factors. **Methods:** Data were systematically collected from the GBD-2021 covering key metrics such as incidence, prevalence, death rates, Disability-Adjusted Life Years (DALY), Years of Life Lost (YLL), and Years Lived with Disability (YLD) across the age group of 20-54 years. Global estimated and stratified data based on 204 regions were further analyzed to assess average annual percentage changes (AAPC) and 95% confidence interval (CI) from 1990 to 2021. **Results:** There were 2,06,612 deaths due to prostate cancer among those aged 20-54 from 1990-2021. Between 1990 and 2021, the global PC incidence in individuals aged 20-54 increased from 0.82 to 1.55 per 100,000, with an AAPC of 2.03 (CI: 1.65-2.41, $p<0.0001$). The highest incidence was recorded in Lithuania, Bermuda, and Australia, while Vietnam, Bhutan, and Algeria reported the lowest. Notable AAPC increases were observed in Cabo Verde (7.26, CI: 6.80-7.72, $p<0.0001$), followed by the Republic of Korea and Vietnam. Conversely, Somalia experienced a significant decline (-1.73, CI: -2.04 to -1.43, $p<0.0001$). During the same period, the global prevalence of PC rose from 7.18 to 13.94 per 100,000, with an AAPC of 2.13 (CI: 1.75-2.54, $p<0.0001$). Prevalence trends across countries were similar to incidence trends. Between 1990 and 2021, the global mortality rate for prostate cancer in individuals aged 20-54 rose slightly from 0.37 to 0.41 per 100,000, with an AAPC of 0.20 (CI: 0.07-0.32, p=0.003). Significant increases were observed in Cabo Verde (AAPC 4.24, CI: 3.89-4.58, $p<0.0001$) and the Northern Mariana Islands. Conversely, Sweden and Luxembourg showed declines, with AAPCs of -2.55 (CI: -3.11 to -1.98) and -2.28 (CI: -2.49 to -2.06), respectively. The highest increases across DALY, YLD, and YLL were observed in Cabo Verde, Zambia, and the Republic of Korea, while Somalia, Sweden, and Luxembourg observed significant declines. **Conclusions:** There has been a rise in mortality rates among young prostate cancer patients aged 20-54, along with increasing morbidity indicators such as YLD, DALY, and YLL. African countries have consistently noted significant rises in both incidence and mortality rates, while a decline was noted in European countries. This could be attributed to the lack of screening protocols and the inadequacy of treatment. The global incidence and prevalence of prostate cancer in this age group have nearly doubled over the past 30 years. Future research should focus on regional disparities and develop strategies to reduce the impact of this disease on younger populations. Research Sponsor: None.

Study protocol: Phase 2 trial of re-treatment with 177Lu-PSMA-617 molecular radiotherapy for metastatic castration resistant prostate cancer (RE-LuPSMA trial). First Author: John Nikitas, University of California, Department of Radiation Oncology, Los Angeles, CA

Background: The phase III VISION trial demonstrated that ^{177}Lu-PSMA-617 radioligand therapy (RLT) improved overall survival (OS) in patients with metastatic castration-resistant prostate cancer (mCRPC) who previously received taxane-based chemotherapy and at least one androgen receptor pathway inhibitor (ARPI). As a result, ^{177}Lu-PSMA-617 therapy has been approved in this patient population by the U.S. Food and Drug Administration for up to six cycles (7.4 GBq per cycle) every 6 weeks. Unfortunately, this treatment is not curative and patients relapse even after initially favorable responses. When this occurs, patients have limited treatment options given they have had prior chemotherapy and ARPI regimens. Re-administration of ^{177}Lu-PSMA-617 in patients who previously benefited from therapy and had limited toxicity seems to be a promising option. Small retrospective studies have reported favorable outcomes. Further prospective data with larger sample sizes are needed to confirm these findings. **Methods:** RE-LuPSMA is an investigator-initiated, single-arm, single-center, open-label, phase 2 clinical trial (NCT06288113). This study plans to enroll 40 patients with progressive mCRPC who previously completed 4-6 cycles of ^{177}Lu-PSMA-617 therapy with a favorable response. Favorable response is defined as a prostate-specific antigen (PSA) decline $\geq$50% during the first regimen. Progression following the first regimen is defined using imaging or PSA (two consecutive PSA increases $\geq$3 weeks apart). Patients who received another line of prostate cancer therapy within two months of completing the first regimen of ^{177}Lu-PSMA-617 are excluded. Patients must meet PSMA PET/CT VISION criteria. PSMA PET/CT must have been completed within 8 weeks of the planned first cycle of re-challenge therapy. Upon enrollment, participants will receive up to 6 additional cycles of ^{177}Lu-PSMA-617 (7.4GBq every 6 weeks). Patients will follow-up every 6 months until 2 years from the end of re-challenge therapy. The primary endpoint is 12-month OS measured from the start of re-challenge therapy. The study will have 80% power to detect a difference between the null hypothesis of 50% and the study hypothesis of 71%. Secondary endpoints include adverse event rates, PSA response rates (proportion of patients with a PSA decrease of $\geq$50%), biochemical progression-free survival (time until PSA level increases 25% and 2 ng/mL above the nadir), radiographic progression-free survival, and health-related quality of life changes (measured using Functional Assessment of Cancer Therapy - Radionuclide Therapy [FACT-RNT] and Brief Pain Inventory [Short Form]). Enrollment has started with a planned study duration of 4 years of which subject accrual occurs in the first 12 months. Clinical trial information: NCT06288113. Research Sponsor: UCLA Ahmanson Translational Theranostics Division; Novartis.

TPS5111 Poster Session

Phase 1, open-label, first-in-human study of ABBV-969, a dual variable antibody-drug conjugate, in patients with metastatic castration-resistant prostate cancer. First Author: Anthony W. Tolcher, NEXT Oncology San Antonio, San Antonio, TX

Background: Metastatic castration-resistant prostate cancer (mCRPC) is an incurable disease with high unmet need. Six-transmembrane epithelial antigen of prostate 1 (STEAP1) is highly enriched in $>$ 85% of prostate cancer (PC),[1] and prostate-specific membrane antigen (PSMA) expression is $>$ 100-fold higher in patients (pts) with mCRPC.[2] These are well-established and actionable targets in mCRPC. ABBV-969, a dual variable domain IgG1 drug conjugate, targets STEAP1 and PSMA and includes a topoisomerase-1 inhibitor (Top1i) payload. Based on preclinical data, ABBV-969 is expected to have greater efficacy and wider activity than targeting either antigen alone. We describe a first-in-human study of ABBV-969 in pts with mCRPC. **Methods:** This phase 1 open-label study (NCT06318273) of ABBV-969 monotherapy evaluates safety, pharmacokinetics (PK), pharmacodynamics (PD), and efficacy. Eligible pts, $\geq$ 18 years of age, have mCRPC treated with and progressed on $\geq$ 1 prior novel hormonal agent for mPC/CRPC and $\geq$ 1 taxane for PC (or have refused, are intolerant to, or unable to access taxanes). Pts must have a life expectancy $>$ 6 months, serum testosterone levels $\leq$ 50 ng/dL, $\geq$ 1 metastatic lesion at baseline, and serum prostate-specific antigen (PSA) levels $\geq$ 1.0 ng/mL. Part 1 (dose escalation) of the study will enroll up to ~80 pts and is guided by the Bayesian optimal interval design primarily based on the dose-limiting toxicity rate. Part 2 (dose expansion) will randomize up to 60 pts in 2 (1:1) or 3 (1:1:1) dose levels (determined in part 1). Part 1 will enroll pts in US, Israel, Japan, and Australia with Canada, France, and Spain added in part 2. Optimal (recommended phase 2) dose will be determined by the totality of PK, PD, safety, and efficacy data. Pts will receive intravenous ABBV-969 until disease progression, intolerable toxicity, or other study discontinuation criteria are met. The study objectives and endpoints are shown in the Table. 1. Xu M, et al. Cancers 2022;14:4034. 2. Sweat SD, et al. Urology 1998;52:637–40. Clinical trial information: NCT06318273. Research Sponsor: AbbVie Inc.

Objectives and endpoints.

Objective	Endpoint
Primary	
Safety and tolerability	Adverse events and dose-limiting toxicities Clinical laboratory parameters, vital signs, ECG
Secondary	
Preliminary efficacy	**Primary** $\geq$ 50% prostate-specific antigen (PSA) decrease from baseline **Secondary** Confirmed complete response(CR)/partial response (PR) per RECIST v1.1 PSA response duration Duration of response for pts with CR or PR Overall survival Progression-free survival
Pharmacokinetic (PK) characterization	PK parameters including C_{max}, T_{max}, $t_{1/2}$, and area under the curve using noncompartmental methods Determination of antidrug antibodies
Dose optimization	Recommended phase 2 dose determined using all available information

TPS5112 **Poster Session**

VALOR study: A phase II trial of vorinostat to augment response to 177Lutetium-PSMA-617 in the treatment of patients with PSMA-low metastatic castration resistant prostate cancer. First Author: Ruben Raychaudhuri, University of Washington and Fred Hutchinson Cancer Center, Seattle, WA

Background: ^{177}Lu-PSMA-617 (LuPSMA), a prostate specific membrane antigen (PSMA) targeting radioligand therapy, is approved for men with mCRPC. However, responses are only observed in ~50% of patients, with pre-clinical and clinical data indicating that those with high, homogenous PSMA expression experience the greatest benefit. Therefore, therapeutic strategies to increase PSMA expression may improve outcomes to LuPSMA and potentially other PSMA targeting therapeutics. Our group recently showed that epigenetic repression of the *FOLH1* (PSMA gene) promoter was associated with decreased PSMA expression and that treatment with a histone deacetylase inhibitor (HDACi) consistently resulted in increased PSMA protein expression both in vitro and in vivo. Based on these results, we are conducting a proof-of-concept clinical trial testing whether the HDACi vorinostat can increase PSMA expression in patients and prime them for improved response to subsequent therapy with LuPSMA. **Methods:** This single-arm, single-center, open label pilot trial seeks to enroll 15 patients with PSMA-low mCRPC who are otherwise eligible for LuPSMA. PSMA-low is defined as baseline total tumor PSMA SUVmean $<$10, a threshold that has been correlated with inferior outcomes with LuPSMA compared to those with higher SUVmean (PSMA-high). patients receive a 28-day treatment cycle of vorinostat (400mg PO daily) followed by repeat ^{68}Ga-PSMA-11 PET. Patients will then proceed to receive subsequent treatment with LuPSMA per investigator's discretion. The primary endpoint is to determine the conversion rate of PSMA-low to PSMA-high expression as determined by ^{68}Ga-PSMA-11 PET. The target enrollment provides 86% power to detect a conversion rate of 33% with vorinostat- a rate believed to be clinically meaningful and would justify a future randomized trial- relative to an assumed null conversion rate of 5% based on a 1-sample test of binomial proportions with 2-sided α=5. Key secondary endpoints include clinical efficacy of LuPSMA (e.g., radiographic and PSA response rates, PFS, OS) following vorinostat and safety and tolerability of the proposed sequential therapy. Patients enrolled on the trial undergo serial blood collection and metastatic tissue (if safe and feasible) at baseline, post-vorinostat treatment, and following progression on LuPSMA. Blood samples will be processed for analysis of circulating tumor cells (CTC) and (ct) DNA. Detailed analyses of these biospecimens will include orthogonal assessments of PSMA expression (including IHC, CTC staining), RNA sequencing, and methylation profiling. These molecular studies will be correlated with the pre/post vorinostat PSMA PET images and clinical outcomes with LuPSMA. Clinical trial information: NCT06145633. Research Sponsor: Novartis.

TPS5113 **Poster Session**

Mevrometostat in combination with enzalutamide in patients with metastatic castration-resistant prostate cancer (mCRPC) previously treated with abiraterone acetate: The phase 3, randomized MEVPRO-1 study. First Author: Neeraj Agarwal, Huntsman Cancer Institute (NCI-CCC), University of Utah, Salt Lake City, UT

Background: Resistance to androgen receptor (AR) pathway inhibitors (ARPI; e.g., abiraterone, enzalutamide) in mCRPC may be driven by preservation of AR signaling through various mechanisms. Enhancer of zeste homolog 2 (EZH2) is implicated in the pathogenesis of prostate cancer and ARPI resistance. Combining ARPI with therapies that modulate alternative signaling pathways, including epigenetic modifiers such as EZH2, could be a promising treatment approach to overcome resistance. Mevrometostat is a potent and selective small molecule EZH2 inhibitor. The optimal treatment sequence for patients with mCRPC who progress after first-line treatment with ARPI is not defined; a second ARPI or docetaxel are options used in real-world settings. Results from the dose-escalation period of a phase 1 study (NCT03460977) showed promising activity for mevrometostat combined with enzalutamide, with a manageable adverse-event profile in abiraterone-exposed patients with mCRPC (Schweizer MT, et al. *J Clin Oncol*. 2024;42(16_suppl):5061). Diarrhea, dysgeusia, and anemia were the most common adverse events considered to be related to mevrometostat. The current trial aims to evaluate radiographic progression-free survival (rPFS), overall survival (OS), and safety of mevrometostat plus enzalutamide compared with standard of care in patients with mCRPC previously treated with abiraterone. **Methods:** MEVPRO-1 (NCT06551324) is a global, open-label, phase 3 trial in patients with mCRPC aged $\geq$18 years with progression on $\geq$12 weeks of abiraterone, castration testosterone levels $\leq$50 ng/dL, ECOG performance status 0–2, and life expectancy $\geq$6 months. Approximately 600 patients will be randomized 1:1 to receive mevrometostat (875mg twice daily with food) with enzalutamide (160 mg once daily [QD]), or physician's choice of enzalutamide (160 mg QD) or docetaxel (75 mg/m^2 intravenously every 21 days). Randomization will be stratified by previous docetaxel in the metastatic castration-sensitive setting, physician's choice of comparator (enzalutamide/docetaxel) prior to randomization, and presence of hepatic metastases. The primary endpoint is blinded independent central review-assessed rPFS per RECIST 1.1 (soft tissue) and PCWG3 (bone) assessed by blinded central radiology review. Key secondary endpoint is OS. Secondary endpoints include antitumor activity by objective response rate and duration of response, safety, pharmacokinetics, ctDNA, and patient-reported outcomes. Time to event endpoints will be compared between treatment arms using a stratified log-test. HRs and 95% CIs will be estimated using a stratified Cox proportional hazard model, and Kaplan–Meier analysis will summarize time-to-event endpoints. Clinical trial information: NCT06551324. Research Sponsor: This study is sponsored by Pfizer Inc. Enzalutamide for the study is provided by Astellas Pharma Inc. Medical writing support was provided by Michelle Mancher, Allison TerBush, and Rosie Henderson of Onyx (a division of Prime), funded by Pfizer Inc.

Precision diagnostics in prostate cancer treatment (PREDICT): A phase 2 multi-arm biomarker based study (Alliance A032102). First Author: Rana R. McKay, Moores Cancer Center, University of California San Diego, La Jolla, CA

Background: Advances in genomic sequencing have allowed for a deeper understanding of the molecular complexity of metastatic castration-resistant prostate cancer (mCRPC) with several actionable alterations now identified, fueling new biomarker-based treatment strategies. For this reason, it is recommended that all patients with mCRPC undergo germline and somatic tumor profiling. In addition to DNA aberrations, gene expression changes can capture actionable targets and activated pathways. The phase 2 PREDICT trial is using both DNA and RNA aberrations to select patients with mCRPC for rationally designed biomarker-based therapeutic strategies. **Methods:** This is a multi-center, multi-arm, biomarker-driven phase 2 umbrella study with a primary objective of objective response rate for patients with mCRPC and measurable disease. Secondary objectives include radiographic progression-free survival, PSA response, time to first symptomatic skeletal event, overall survival, safety, and correlative studies. Eligible patients must have progressive mCRPC of any histology, received a prior androgen receptor pathway inhibitor (ARPI), and received or refused taxane chemotherapy. Patients with measurable and non-measurable disease are eligible. Patients must have standard of care next generation DNA sequencing via any CLIA-certified tissue or circulating tumor DNA assay for initial trial enrollment. For arm allocation based on RNA alterations, testing will be via the CLIA-certified Caris MI Tumor Seek assay, which includes whole exome and whole transcriptome sequencing, derived from tissue obtained within 12 months of enrollment. A real-time molecular tumor board will convene to review genomic reports and confirm arm allocation on a rolling basis as biomarker results become available. Patients with Rb loss (DNA), Rb functional loss signature (RNA), NEPC signature (RNA) will be allocated to treatment with the EZH1/2 inhibitor valemetostat. Patients with at least 2 of 3 tumor suppressor gene DNA alterations (TP53, RB1, PTEN), FANC alteration (DNA), or SLFN11 overexpression (RNA) will be allocated to cabazitaxel plus carboplatin. Patients without any study-defined alterations will be allocated to physician choice treatment with either cabazitaxel, ARPI, or ^{177}Lu-PSMA-617. The study is designed to accommodate future biomarker arms. A maximum of 64 patients with measurable disease and 94 patients with non-measurable disease for a total of 158 patients will be accrued to each treatment arm. A Simon two-stage minimax design per arm was used to determine whether the response rate for measurable disease patients was greater than 0.20. This design has a type 1 error equal to 0.05 and has power equal to 0.90 if the probability of response is 0.37. Clinical trial information: NCT06632977. Research Sponsor: https://acknowledgments.alliancefound.org; Daiichi Sankyo; U10CA180882.

An oral prostate cancer RIPTAC therapeutic in phase 1 for metastatic castrate resistant prostate cancer (mCRPC). First Author: Katherine J Kayser-Bricker, Halda Therapeutics, New Haven, CT

Background: New therapies are urgently needed to treat prostate cancer, especially for patients progressing on existing drugs that inhibit the activity of the Androgen Receptor (AR) (e.g. Androgen Receptor Pathway Inhibitors (ARPIs)). Metastatic Castration-Resistant Prostate Cancer (mCRPC) is a more aggressive stage of the disease, characterized by increased AR expression and signaling. To address this unmet medical need, we have developed a Regulated Induced Proximity Targeting Chimera (RIPTAC™) Therapeutic HLD-0915. HLD-0915 is a heterobifunctional small molecule that leverages full length AR (FL-AR) expression in tumor cells to form a trimeric complex with an Essential Protein (EP) needed for cell survival. This results in EP loss of function in prostate cancer cells and a selective antitumor effect. HLD-0915 activity requires only the presence of FL-AR and retains activity regardless of whether there are AR or non-AR aberrations that may otherwise serve as drivers of disease. Preclinically, HLD-0915 treatment results in tumor shrinkage and PSA declines following oral dosing in murine models of castration-resistant and ARPI-resistant forms of the disease, while delivering a favorable therapeutic index. The Phase 1 trial in mCRPC will investigate safety and early signs of efficacy in the intended patient population. **Methods:** This first-in-human, multicenter, open label Phase 1/2 study evaluates the safety, tolerability, and clinical activity of HLD-0915 in patients with mCRPC. Phase 1 consists of monotherapy dose levels employing a Bayesian Optimal Interval (BOIN) design with each dose level starting with a minimum of 3 patients per cohort with the primary objectives of defining the maximal tolerated dose and/or recommended dose for expansion and characterizing safety and tolerability of HLD-0915. This study also aims to characterize the PK profile and assess clinical activity by PSA declines and objective response rate per RECIST and will explore ctDNA, tumor cell genetics, and PD biomarkers. Patients with progressive mCRPC who may or may not have received prior novel antiandrogen therapy, a taxane, or PSMA targeted radioligand will be enrolled. Cohort 1 enrollment begins in January 2025. The Phase 2 portion of the study will confirm the RP2D and clinical activity in up to 3 cohorts which will be decided in the future based on emerging data. Clinical trial information: NCT06800313. Research Sponsor: None.

TPS5116 **Poster Session**

Mevrometostat in combination with enzalutamide for androgen receptor pathway inhibitor (ARPI)-naïve patients with metastatic castration-resistant prostate cancer (mCRPC): The phase 3, randomized MEVPRO-2 study. First Author: Neal D. Shore, Carolina Urologic Research Center, Myrtle Beach, SC

Background: Mevrometostat is a potent, selective inhibitor of the histone methyltransferase enhancer of zeste 2 (EZH2), which is canonically involved in epigenetic repression of target genes. In prostate cancer, EZH2 overexpression is associated with poor prognosis, contributing to disease progression through transcriptional repression of tumor suppressor genes and androgen receptor (AR) activation, co-regulation of AR-mediated transcriptional programs, and cell cycle deregulation through methylation of non-histone targets. Given the associations between EZH2 and the AR, the addition of an EZH2 inhibitor to ARPI is hypothesized to extend the duration of clinical response and delay antiandrogen resistance compared with ARPI alone. In a nonrandomized, phase 1 dose-escalation study, objective responses to mevrometostat with enzalutamide were observed in patients with CRPC and prior abiraterone or enzalutamide treatment (NCT03460977; Schweizer MT, et al. *J Clin Oncol*. 2024;42(16_suppl):5061). The most common adverse events considered to be related to mevrometostat were diarrhea, dysgeusia, and anemia. Despite guideline recommendations for treatment intensification with ARPIs or chemotherapy for metastatic castration-sensitive prostate cancer (mCSPC), many patients do not receive ARPIs at the mCSPC stage. MEVPRO-2 (NCT06629779) will evaluate mevrometostat plus enzalutamide compared with enzalutamide alone in ARPI-naïve patients with mCRPC. **Methods:** MEVPRO-2 is a global, double-blind, randomized, phase 3 trial. Key inclusion criteria are males, ≥18 years, with progressive mCRPC, castrate testosterone of ≤50 ng/dL, Eastern Cooperative Oncology Group performance status of 0 or 1, and life expectancy of ≥12 months. Patients with systemic treatments for mCRPC (except androgen deprivation therapy and first-generation antiandrogens) are excluded. Approximately 900 patients will be randomized 1:1 to receive mevrometostat (875 mg, twice daily) with enzalutamide (160 mg, once daily) or placebo with enzalutamide. The primary endpoint is blinded independent central review-assessed radiographic progression-free survival per Response Evaluation Criteria in Solid Tumours 1.1 (soft tissue) or Prostate Cancer Working Group 3 criteria (bone). Key secondary endpoints are overall survival and time to pain progression (Brief Pain Inventory – Short Form question 3 or opioid use). Hazard ratios and 95% confidence intervals will be estimated using a Cox proportional hazard model, stratified by prior docetaxel and presence of hepatic metastases. *P*-values will be provided using a stratified log-rank test. Safety and tolerability will also be assessed. Clinical trial information: NCT06629779. Research Sponsor: This study is sponsored by Pfizer Inc. Enzalutamide for the study will be provided by Astellas Pharma Inc. Medical writing support was provided by Michelle Mancher, Allison TerBush, and Rosie Henderson of Onyx (a division of Prime), funded by Pfizer Inc.

TPS5117 **Poster Session**

A first-in-human, phase 1 dose escalation and expansion study evaluating the safety, tolerability, and anti-tumor activity of [225Ac]Ac-FL-020, an anti-PSMA radioconjugate, in patients with metastatic castration-resistant prostate cancer (mCRPC). First Author: Andrei Iagaru, Division of Nuclear Medicine and Molecular Imaging, Stanford University, Stanford, CA

Background: Prostate-specific membrane antigen (PSMA) targeted radioligand therapy is an emerging treatment modality for metastatic castration-resistant prostate cancer (mCRPC). Alpha emitting [^{225}Ac]Ac-FL-020 represents a new generation of PSMA-targeted radioconjugates (RDC) with potential improvements in pharmacokinetics and pharmacodynamics, aiming to enhance tumor uptake while minimizing healthy tissue exposure, including the salivary glands. This novel compound was discovered using our proprietary Clear-X technology platform. This Phase 1 study evaluates the safety, tolerability, and anti-tumor activity of [^{225}Ac]Ac-FL-020 in patients with mCRPC. **Methods:** This first-in-human, open-label, multicenter Phase 1 study consists of two parts: dose escalation (Part 1) and cohort expansion (Part 2). In Part 1, the study aims to establish the safety profile and maximum tolerated dose/recommended Phase 2 dose (MTD/RP2D) of [^{225}Ac]Ac-FL-020, guided by a Bayesian logistic regression model (BLRM) with overdose control. Eligible patients must show PSMA-positive lesions on a PSMA PET/CT scan, have histologically confirmed mCRPC with documented progression, and have received prior treatments including androgen receptor signaling inhibitors or CYP17 inhibitors, along with at least 1 previous taxane regimen. Exclusion criteria include patients with extensive PSMA-negative disease. The dose escalation follows cohorts starting with 1-3 patients, expanding to 3-6 patients, with provisional dose levels from 1 to 5 MBq. Part 2, the cohort expansion, will commence once the RP2D is established, enrolling an additional 18 patients to further evaluate safety and gather preliminary efficacy data. The primary objective is to establish the safety profile and determine the MTD/RP2D of [^{225}Ac]Ac-FL-020 in mCRPC patients. Secondary objectives include assessing pharmacokinetics, dosimetry, and anti-tumor activity, with the overarching goal of exploring the potential of this novel actinium RDC for improving outcomes in patients with mCRPC. The study is enrolling in Australia and US, with European sites planned to open later in 2025. Clinical trial information: NCT06492122. Research Sponsor: Full-Life Technologies GmbH.

TPS5118 **Poster Session**

Trial in progress (XALute): Phase 3 study of xaluritamig vs investigator's choice of cabazitaxel or second androgen receptor directed therapy (ARDT) in post-taxane metastatic castration-resistant prostate cancer (mCRPC). First Author: William Kevin Kelly, Thomas Jefferson University Hospital, Philadelphia, PA

Background: The median overall survival of patients with mCRPC remains under 2 years even with newer therapies. Xaluritamig, an XmAb 2+1 T-cell engager that targets the six-transmembrane epithelial antigen of prostate 1 (STEAP1), facilitates lysis of STEAP1-expressing cancer cells, such as those in advanced prostate cancer. In a first-in-human study, xaluritamig demonstrated encouraging efficacy and a manageable safety profile for patients with mCRPC refractory to standard of care therapies (Kelly WK, et al. Cancer Discov. 2024;14(1):76-89). **Methods:** XALute is a randomized, multicenter, open-label, phase 3 study to evaluate the efficacy and safety of xaluritamig vs cabazitaxel or second ARDT in men with mCRPC previously treated with taxane chemotherapy. Enrollment in the control arm treatments will be split evenly between cabazitaxel and second ARDT. Stratification factors include LDH ≤ or > 260 IU/L, liver metastases (Y/N), prior prostate-specific membrane antigen radioligand therapy (PSMA-RLT) (Y/N) and the intention to treat with cabazitaxel or ARDT switch. Approximately 675 patients will be enrolled. Participants will be randomly assigned in a 2:1 ratio to xaluritamig monotherapy or standard care. Participants will receive treatment until radiographic disease progression per Prostate Cancer Clinical Trials Working Group 3 (PCWG3), unacceptable toxicity, initiation of other anticancer therapy, withdrawal of consent, death, or end of study as determined by the sponsor. The primary efficacy endpoint is overall survival. The key secondary efficacy endpoint is radiographic progression-free survival per PCWG3 by blinded independent central review. Key inclusion criteria are pathological/cytological confirmation of prostate adenocarcinoma; mCRPC with at least one metastatic lesion; evidence of progressive disease; prior treatment with at least one ARDT; one taxane therapy in the mCRPC setting, and ongoing androgen deprivation with serum testosterone levels (<50 ng/dL or <1.7 nmol/L). Prior treatment with PSMA-RLT, poly ADP-ribosylation inhibitors, and immune checkpoint inhibitors are permitted. Exclusion criteria include prior STEAP1-targeted therapy, any anticancer therapy within 4 weeks prior to first dose of study treatment (not including androgen deprivation therapy), prior PSMA-RLT within 2 months of first dose of study treatment unless less than 2 cycles received, and prior radionuclide therapy (radium-223) within 2 months of first dose of study treatment To mitigate risk of cytokine release syndrome, xaluritamig will be administered with step dosing. Cabazitaxel or second ARDT will be administered according to regional prescribing information. Funded by Amgen Inc. Clinical trial information: NCT06691984. Research Sponsor: Amgen Inc.

TPS5119 **Poster Session**

A phase 3 trial of the androgen receptor ligand-directed degrader, BMS-986365, versus investigator's choice in patients with metastatic castration-resistant prostate cancer (CA071-1000 - rechARge). First Author: Kim N. Chi, Department of Medical Oncology, BC Cancer Agency, Vancouver, BC, Canada

Background: Prostate cancer relies on the androgen receptor (AR) pathway as a key oncogenic driver. BMS-986365 is a heterobifunctional, orally bioavailable ligand-directed degrader targeting the AR via a first-in-class dual mechanism of AR degradation and antagonism. Results from the first-in-human phase 1 study showed that BMS-986365 was well tolerated with a manageable safety profile and demonstrated antitumor activity in heavily pretreated patients with metastatic castration resistant prostate cancer (mCRPC) regardless of AR gene alterations (Rathkopf et al. *Ann Oncol* 2025;36:76–88). Here, we present the study design of rechARge (NCT06764485), a phase 3, 2-part, randomized, open-label trial evaluating the efficacy and safety of BMS-986365 versus investigator's choice of AR pathway inhibitor (ARPI) or docetaxel, in patients with mCRPC who have failed treatment with 1 prior ARPI. **Methods:** Approximately 960 patients will be randomized in this phase 3, 2-part study. In Part 1 (dose selection), patients will be randomized 1:1:1 to receive either BMS-986365 400 or 300 mg BID Q28D, or investigator's choice comprising ARPI (enzalutamide [160 mg QD] or abiraterone [1000 mg QD + prednisone] Q28D); or docetaxel 75 mg/m^2 + prednisone Q21D up to a maximum of 10 cycles. In Part 2, patients will be randomized 1:1 to receive either BMS-986365 (dose determined from Part 1) or investigator's choice treatment (same as Part 1). Randomization is stratified by prior type of ARPI and investigator's choice (2nd ARPI vs docetaxel). Patients will be treated until radiographic progressive disease by blinded independent central review (BICR) or unacceptable toxicity; all patients must continue androgen deprivation therapy as part of the standard of care. Key inclusion criteria include no more than 1 previous ARPI, confirmed progressive mCRPC defined by having ≥1 of the following: prostate-specific antigen (PSA) progression or radiographic disease progression in soft tissue based on RECIST 1.1 criteria or bone defined as the appearance of ≥2 new lesions on a bone scan; ECOG PS of 0–1, asymptomatic or mildly symptomatic from prostate cancer (Brief Pain Inventory-Short Form, worst pain in last 24 hr <4), no liver metastases, and no prior chemotherapy in the mCRPC setting (docetaxel permitted for mCSPC if >12 months since completion). The primary endpoint is radiographic progression-free survival by BICR using RECIST 1.1 (soft tissue) and PCWG3 (bone) criteria. The key secondary endpoint is overall survival. Other secondary endpoints include safety, overall response rate, confirmed PSA response rate (PSA30 and PSA50), and patient reported outcomes. The study is recruiting at 230 sites in 24 countries/territories across North America, Europe, Latin America, and East Asia. Clinical trial information: NCT06764485. Research Sponsor: Bristol Myers Squibb.

TPS5120 **Poster Session**

The impact of DNA repair genetic alterations identified by circulating tumor DNA on sensitivity to radium-223 in bone metastatic, castration-resistant prostate cancer. First Author: Steven M. Blinka, Fred Hutchinson Cancer Center, Seattle, WA

Background: Selection, timing, and sequencing of therapy for men with bone metastatic castration-resistant prostate cancer (mCRPC) for optimal clinical outcomes is not well-defined. Accordingly, identification of predictive biomarkers for response and outcomes to a given therapy is critical to guide clinical decision-making. Prior research from our group and others has demonstrated that a high proportion (up to 25%) of mCRPC patients harbor aberrations in DNA damage repair (DDR) genes. These findings are clinically meaningful given the efficacy of PARP inhibitors in treating a subset of mCRPC patients with DDR defects. Radium-223 acts by delivering high-energy alpha particles selectively to bone metastases leading to double-stranded DNA breaks. Retrospective studies have shown patients with DDR alterations who are treated with radium-223 have overall survival benefit, improved alkaline phosphatase (ALP) response, and more commonly complete radium-223 treatment. Therefore, we hypothesize that mCRPC with alterations in DDR genes should be particularly vulnerable to treatment with radium-223 and should be evaluated for resultant outcomes prospectively. **Methods:** This Phase 2, multi-center, prospective single-arm biomarker trial aims to enroll 60 patients. Eligible patients must have mCRPC, radiographic evidence of bone disease, symptoms, and PSA $\geq$10 to ensure successful ctDNA analysis. All patients will receive radium-223 (55 kBq/kg) for up to 6 doses. Patients who have received prior platinum containing chemotherapy will be excluded. ctDNA will be obtained for OncoPlexCT to determine if a patient has a DDR gene alteration (results will not affect treatment plan). Leukocyte analysis will be performed to confirm whether specific alterations are germline vs somatic. The primary objective is to determine the response rate of bone mCRPC with DDR deficiency to treatment with radium-223. Response will be defined as having PSA and/or ALP decline of $\geq$30% from baseline. The null hypothesis is that the true response rate is 0.40, and the alternate hypothesis is the true response rate is 0.80 (TOPARP, NCT01682772). It is estimated that 25% of the patient population will have DDR alterations and outcomes will be compared with those who are DDR proficient. Using 90% power and an alpha of 0.05, we will accrue 60 patients to ensure the goal of 12 patients with DDR alterations is met. Secondary objectives include determining whether patients who received a prior PARP inhibitor have no decrement in response, overall survival, number of cycles of radium-223 received, and effect of germline vs somatic alterations on response. This trial is currently open to enrollment at Fred Hutch, University of Wisconsin, and Johns Hopkins, and 22/60 patients have already been enrolled. Clinical trial information: NCT04489719. Research Sponsor: Fred Hutch Cancer Center is the primary sponsor of this study. Bayer provided some financial support for this research.

TPS5121 **Poster Session**

A randomized phase 2 trial of flexible and extended dosing of ^{177}Lu-PSMA-617 molecular radioligand therapy in mCRPC (FLEX-MRT): Trial in progress update. First Author: Adrien Holzgreve, Ahmanson Translational Theranostics Division, University of California, Los Angeles, Los Angeles, CA

Background: The U.S. Food and Drug Administration (FDA) approved ^{177}Lu-PSMA-617 radiopharmaceutical therapy (RPT) for patients with metastatic castration-resistant prostate cancer (mCRPC) with a fixed dosing schedule: Six cycles of 7.4 GBq administered in six-week intervals. However, a patient-tailored more flexible and extended dosing schedule of ^{177}Lu-PSMA RPT may increase treatment efficacy. In this randomized trial in men with mCRPC, we aim to determine the efficacy of a response-based flexible dosing schedule of ^{177}Lu-PSMA-617 RPT administered up to 12 treatment cycles compared to the current standard of care. **Methods:** This is an investigator-initiated prospective phase 2, open-label, randomized, controlled, parallel group, single-center trial. The aim is to assess the 2-year survival rate in mCRPC patients treated with a flexible dosing schedule of ^{177}Lu-PSMA RPT up to 12 cycles in comparison to the fixed dosing schedule of 6 cycles. Patients with progressive mCRPC post-ARSI, post taxane-based chemotherapy are eligible by PSMA positron emission tomography (PET) VISION trial criteria. Exclusion criteria include prior RPT and less than 6 weeks since the last myelosuppressive therapy. We hypothesized 2-year survival rates of 55% in the investigational group and 30% in the control group. A two-sided log rank test with an overall sample size of 90 subjects (45 treatment group, 45 control group) achieves 80.3% power at a 0.05 significance level to detect a hazard ratio of 0.050. Patients will be randomized in a 1:1 ratio: The investigational arm is treated with up to 12 cycles including potential "treatment holidays" depending on the treatment response (n=45); the control arm receives 6 cycles administered in six-week intervals (n=45). Imaging response to RPT is assessed using ^{177}Lu-PSMA-617 SPECT/CT after each cycle and PSMA PET/CT during treatment holidays (every 12 weeks), respectively. In the investigational arm, RPT will be re-started after a treatment holiday if the patient experiences a $\geq$25% PSA progression and an imaging progression according to the Response Evaluation Criteria in PSMA PET/CT (RECIP). Primary endpoint is the 2-year survival rate calculated from the date of the first cycle of RPT. Secondary endpoints include safety by Common Terminology Criteria for Adverse Events (CTCAE) and dosimetry, and determination of overall and progression-free survival (evidence of progression as defined by either radiographic, PSA, or clinical progression, or death from any cause). The FLEX-MRT trial has been approved by the FDA (IND #168362), and the UCLA IRB (#23-000931). The trial is registered on ClinicalTrials.gov (NCT06216249). The FLEX-MRT trial is currently recruiting. Start of enrollment was in August 2024. As of January 27th, 2025, 19 patients have been enrolled. Clinical trial information: NCT06216249. Research Sponsor: Prostate Cancer Foundation; Deutsche Forschungsgemeinschaft (DFG, German Research Foundation); 545058105; Novartis.

TPS5122 **Poster Session**

A randomized phase III trial investigating platinum and taxane chemotherapy in metastatic castration resistant prostate cancer (mCRPC) patients with alterations in DNA damage response (DDR) genes (OPTION-DDR) CCTG-PR-25 NCT06439225. First Author: Michael Paul Kolinsky, Cross Cancer Institute, University of Alberta, Edmonton, AB, Canada

Background: For patients (pts) with mCRPC there are numerous treatment options including single agent docetaxel after treatment with androgen receptor pathway inhibitors (ARPI). Despite the availability of varied treatments, overall survival (OS) for pts with mCRPC after ARPI remains poor (12-19 months). Improvements in outcomes are desperately needed. 25% of pts have alterations in DDR genes and are potentially sensitive to treatment with platinum agents. Carboplatin has been previously evaluated in smaller trials in pts with mCRPC and shows promise in patients with DDR gene alterations. PR-25 leverages standard of care testing for DDR genes to evaluate in a rigorous manner whether addition of carboplatin to docetaxel improves overall survival (OS) in pts with DDR gene alterations and mCRPC. **Methods:** PR25 is a phase III randomised controlled trial led by the Canadian Cancer Trials Group comparing docetaxel to docetaxel and carboplatin in pts with DDR alterations. Pts have to receive prior ARPI for mCRPC, and demonstrate radiographic or PSA progression prior to enrollment. Qualifying DDR gene alterations include: BRCA1, BRCA2, ATM, ATR, BRIP1, BARD1, CDK12, CHEK1, CHEK2, ERCC2, FANCA, FANCC, FANCD2, FANCL, PALB2, RAD51B, RAD51C, RAD51D, RAD54L. The primary endpoint is OS. Secondary endpoints include: radiographic progression free survival (PCWG3 and RECIST 1.1), PSA response, time to next systemic therapy, patient reported quality of life and economic evaluation. Statistical design: The target accrual is 236 patients over 3.25 yrs with 2 year follow-up to detect a HR of 0.65 in OS, using a 5% (2 sided) level test with power of 80%. Conduct to date: Study activation – October 2024. First patient enrolled - December 2024. Accrual to date: 2 Supported by CIHR grant #189966, NCTN grant #CA180863 and CCS grant #707213. Clinical trial information: NCT06439225. Research Sponsor: Canadian Institutes of Health Research; 189966; NCI's National Clinical Trials Network; CA180863; Canadian Cancer Society; 707213.

TPS5123 **Poster Session**

A randomized, open-label, phase 2b study of the BET bromodomain inhibitor (BETi) ZEN-3694 plus enzalutamide vs. enzalutamide in patients with metastatic castration resistant prostate cancer (mCRPC). First Author: Rahul Raj Aggarwal, University of California, San Francisco, San Francisco, CA

Background: Androgen receptor signaling inhibitors (ARSI), such as enzalutamide (Enza), and abiraterone (Abi), are standard therapies for metastatic hormone-sensitive and metastatic castration-resistant prostate cancer (mHSPC, mCRPC). Patients who respond to the initial ARSI are frequently prescribed a 2nd ARSI upon progression. A suboptimal response to first line ARSI, including the ~ 20% treated with an ARSI for mHSPC who progress within 12 months of treatment initiation, may enrich for cancers harboring AR-independent mechanisms of resistance including treatment-emergent neuroendocrine prostate cancer (t-NEPC). BETi have been shown pre-clinically to block the neuroendocrine prostate cancer lineage plasticity program through modulating E2F1, a transcription factor involved in stemness and cell differentiation. Prior results from a mCRPC Ph. 1b/2a trial of ZEN-3694+ Enza support this notion, as lower AR transcriptional activity in baseline tumor biopsies was associated with longer radiographic progression-free survival (rPFS). Additionally, mCRPC patients who were primary refractory to 1st line abiraterone had prolonged rPFS with ZEN-3694 + Enza, suggesting that the patients with primary resistance may benefit from the combination. To test this hypothesis, a Ph. 2b randomized trial was initiated, enriching for mCRPC with suboptimal response to 1st line ARSI. **Methods:** This is a multi-national (USA and China), open-label, randomized, two cohort, Ph. 2b study of ZEN-3694 + Enza vs. Enza in mCRPC patients who have progressed on Abi (NCT04986423). Cohort A (N = 150): Patients with poor response to Abi defined either as progression in $<$ 12 months or failure to achieve PSA nadir of 0.2 ng/mL while taking Abi in HSPC setting, or progression in $<$ 6 months and/or failure to achieve a PSA50 response while taking Abi in the CRPC setting. Cohort B (N = 50): Patients who responded to Abi, defined as $>$ 12 months duration without progression while on Abi in the HSPC setting and achieving a nadir PSA $<$ 0.2 ng/mL, or $>$ 6 months duration without progression while on Abi in the CRPC setting and confirmed PSA50 response. The primary endpoint is radiographic progression-free survival (rPFS) by blinded independent central review (BICR) in Cohort A evaluated by PCWG3. Key secondary endpoints include rPFS by BICR for Cohorts A + B, PFS by investigator assessment, overall survival, PSA50 response rate, objective response rate by RECIST 1.1, efficacy endpoints for only USA patients, and patient-reported health status and quality of life, evaluated in Cohorts A, and Cohorts A + B together. The trial, conducted in collaboration with Newsoara has dosed approximately 150 of 200 patients to date. Astellas is providing enzalutamide for this study. Clinical trial information: NCT04986423. Research Sponsor: Newsoara Biopharma Co., Ltd; Zenith Epigenetics; Astellas Pharma Inc.

TPS5125 **Poster Session**

SECuRE: A dose escalation/expansion study to assess the anti-tumor efficacy of ^{67}Cu-SAR-bisPSMA in patients with metastatic castrate resistant prostate cancer. First Author: Geoffrey Bates Johnson, Department of Nuclear Medicine, Mayo Clinic in Rochester, Rochester, MN

Background: Prostate cancer (PC) is common and despite recent advances in treatment options, patients with metastatic disease still have poor outcomes. The double PSMA binding moiety of SAR-bisPSMA in ^{64}Cu-SAR-bisPSMA (imaging) and ^{67}Cu-SAR-bisPSMA (therapy) may offer advantages compared to currently used single-target PSMA agents. Clinical evidence demonstrated 2-3 times higher uptake of ^{64}Cu-SAR-bisPSMA compared to the single-target PSMA agent, ^{68}Ga-PSMA-11. Pre-clinical efficacy data of ^{67}Cu-SAR-bisPSMA in mice showed statistically significant tumor growth inhibition and increased survival in a PC xenograft study. These results led to the development of the SECuRE trial, which aims to assess the safety and anti-tumor efficacy of ^{67}Cu-SAR-bisPSMA in patients with metastatic castrate resistant PC (mCRPC). **Methods:** SECuRE is a Phase I/IIa multi-center, open-label, non-randomized, dose-escalation and cohort expansion study of ^{64}Cu-SAR-bisPSMA and ^{67}Cu-SAR-bisPSMA in patients with mCRPC. The target population is patients who have progressed despite having at least one androgen receptor pathway inhibitor and demonstrate positivity on ^{64}Cu-SAR-bisPSMA PET. The study comprises 3 phases: Dosimetry (N=6), Dose Escalation (N~24) and Cohort Expansion (N=24). The ^{67}Cu-SAR-bisPSMA dose levels investigated in the Dose Escalation Phase are: 4 GBq (cohort 1, single dose), 8 GBq (cohort 2, single dose), 12 GBq (cohort 3, single dose) and 24 GBq across two doses (cohort 4, two doses at the maximum tolerated dose or maximum feasible dose [MTD/MFD] established in cohorts 1-3; two additional doses may be offered in case of radiological non-progression). In the Cohort Expansion phase, participants will receive 2 doses of ^{67}Cu-SAR-bisPSMA at the recommended dose determined in the Dose Escalation Phase (those with radiological non-progression may be offered up to 2 additional doses). A recent protocol amendment increased the number of participants from 14 to 24 in the Cohort Expansion phase, in which 8 will receive combination therapy of ^{67}Cu-SAR-bisPSMA with enzalutamide. The primary and key secondary objectives include assessment of ^{64}Cu- and ^{67}Cu-SAR-bisPSMA's safety and dosimetry and determining the anti-tumor efficacy of ^{67}Cu-SAR-bisPSMA. Response to ^{67}Cu-SAR-bisPSMA will be assessed biochemically ($\geq$50% decline in prostate-specific antigen) and radiographically (by RECIST V1.1 and PCWG3). Clinical trial information: NCT04868604. Research Sponsor: Clarity Pharmaceuticals.

TPS5126 **Poster Session**

A phase 3 study of 177Lu-rosptamab plus standard of care vs. standard of care alone in patients with metastatic castration-resistant prostate cancer (ProstACT Global). First Author: Scott T. Tagawa, Weill Cornell Medical College of Cornell University, New York, NY

Background: The treatment of advanced prostate cancer (PC) is challenging, with undesirable side effects that impact patient quality of life. Radioimmunotherapy (RIT) can localize therapy to specific tumor cells in multiple organs to reduce or eliminate damage to normal tissue. The cell surface glycoprotein prostate-specific membrane antigen (PSMA) is an ideal therapeutic target as it is highly expressed by malignant prostate cells. There is a strong rationale for further investigation of the ^{177}Lu-labeled, chelator-conjugated antibody, ^{177}Lu-rosopatamab, as a potential first-line RIT candidate for the treatment of PC. **Methods:** This multinational, multicenter, prospective, randomized, open label phase 3 study will have 2 parts: a dosimetry and safety lead-in (n=30) and a randomized treatment expansion (n=490). In Part 1, patients will be divided into 3 groups (n=10 each) to receive 2 single intravenous (IV) injections of 76 millicuries (mCi) each, 14 days apart, of ^{177}Lu-rosopatamab with best standard of care (SoC) combinations with abiraterone, enzalutamide, or docetaxel to fully characterize biodistribution and safety profiles of ^{177}Lu-DOTA-rosopatamab + SoC. SoC received will be determined prior to treatment with ^{177}Lu-rosopatamab. In Part 2, patients will be enrolled in a 2:1 ratio to receive either the best SoC or 2 single IV injections of 76 mCi each of ^{177}Lu-rosopatamab, given 14 days apart, plus best SoC. SoC will be determined prior to randomization. Eligible patients must have PSMA-expressing metastatic castration-resistant PC (mCRPC) that have progressed despite prior therapy with either enzalutamide or abiraterone plus prednisone, and 1 line of prior taxane therapy or have refused or are ineligible for taxanes. Patients must have adequate organ function including at least 150x10^9/L platelets, hemoglobin 10 g/dL, and have PSMA-positive disease on ^{68}Ga-PSMA-11 PET/CT imaging as confirmed by a central reader. Key exclusion criteria include small cell histology, increased risk of hemorrhage or bleeding, known brain or hepatic metastases, or history of stroke, seizure, or treatment with radioisotopes within 6 months prior to randomization. The primary endpoint is radiographic progression-free survival (rPFS). Key secondary endpoint is OS. Additional secondary endpoints include 5-year overall survival, tumor objective response rate, time to symptomatic skeletal event, and health-related quality of life. An alpha control and 95% confidence intervals will be used; patients will be substratified between TLX591 + 2nd ARPI or TLX591 + docetaxel. This study is currently enrolling. Clinical trial information: NCT06520345. Research Sponsor: Telix Pharmaceuticals.

TPS5127 **Poster Session**

PSMA-delay castration (DC): An open-label, multicenter, randomized phase 3 study of [^{177}Lu]Lu-PSMA-617 versus observation in patients with metachronous PSMA-positive oligometastatic prostate cancer (OMPC). First Author: Alton Oliver Sartor, Mayo Clinic, Rochester, MN

Background: Androgen deprivation therapy (ADT) $\pm$ androgen receptor pathway inhibitor therapy is a primary treatment for metastatic hormone-sensitive prostate cancer, but is non-curative and has significant toxicities when used long-term. In patients with OMPC for whom delaying ADT is appropriate, metastasis-directed therapy such as stereotactic body radiation therapy (SBRT) has been shown to provide local disease control. However, many patients do not experience a complete prostate-specific antigen (PSA) response and develop poly-metastatic disease. [^{177}Lu]Lu-PSMA-617 (^{177}Lu-PSMA-617) is a prostate-specific membrane antigen (PSMA)-targeted radioligand therapy with demonstrated efficacy and a manageable safety profile in patients with PSMA-positive metastatic castration-resistant prostate cancer in the VISION and PSMAfore trials. PSMA-DC (NCT05939414) is an ongoing, international, randomized phase 3 trial to evaluate the efficacy of ^{177}Lu-PSMA-617 versus observation after SBRT in delaying castration and disease progression in patients with PSMA-positive OMPC. **Methods:** Eligible patients have histologically confirmed prostate cancer, biochemical recurrence post-definitive treatment, OMPC with $\leq$ 5 PSMA-positive metastatic lesions including $\geq$ 1 distant metastasis on PSMA PET/CT scans (all must be amenable to SBRT), PSA doubling time $<$ 10 months and non-castration testosterone levels ($>$ 100 ng/dL). Exclusion criteria include distant metastasis by conventional imaging (CI; CT/MRI and bone scans) at screening, prior ADT (except adjuvant ADT completed $>$ 12 months before randomization), or other systemic therapy for metastatic prostate cancer. Patients (N = ~450) will be randomized 2:1 to ^{177}Lu-PSMA-617 or observation and will receive SBRT to all metastatic lesions within 14 days, completed within 3 weeks. Patients will then receive either intravenous ^{177}Lu-PSMA-617 (7.4 GBq/6 weeks; 4 cycles), starting 7–21 days after SBRT, or undergo observation only. Additional SBRT for new lesions is allowed. ADT is allowed after a metastasis-free survival (MFS) event by CI confirmed by blinded independent review committee (BIRC). Safety follow-up will occur 42 days after the last ^{177}Lu-PSMA-617 dose and at the week 24 visit for the observational arm. Long-term follow-up for the ^{177}Lu-PSMA-617 arm will include safety assessments every ~32 weeks. The primary endpoint is MFS by CI as assessed by BIRC using RECIST v1.1, or death. To provide 90% power to detect a hazard ratio of 0.6, 187 MFS events are required. The key secondary endpoint is time to next hormonal therapy. Additional secondary endpoints include time to PSA progression, radiographic progression-free survival, symptomatic progression, patient-reported health-related quality of life, overall survival and safety. Shore et al. PSMA-delay castration (DC): an open-label, multicenter, randomized phase 3 study of [^{177}Lu]Lu-PSMA-617 versus observation in patients with metachronous PSMA-positive oligometastatic prostate cancer (OMPC). METANOVA: A phase II trial of metastasis-directed radiotherapy for de novo oligometastatic prostate cancer treated with long-term androgen deprivation therapy in the STAMPEDE trial. First Author: Angela Y Jia, University Hospitals Seidman Cancer Center, Case Western Reserve University, Cleveland, OH

Background: Men with de novo oligometastatic hormone-sensitive prostate cancer (omHSPC) represent a unique subgroup where metastasis-directed radiotherapy (MDRT) may improve outcomes when added to systemic therapy. Retrospective data suggest potential survival benefits of MDT in oligometastatic prostate cancer (PCa), but prospective randomized evidence in the de novo setting is lacking. The METANOVA trial aims to determine whether MDRT, combined with standard systemic therapy (SST) and prostate-directed local therapy, improves outcomes for these patients. **Methods:** METANOVA is a phase II, randomized, open-label trial enrolling 200 men with histologically confirmed de novo omHSPC (NCT06150417). Oligometastatic disease defined as 1–5 metastatic sites by traditional imaging (MRI, CT, or ^{99m}Tc bone scan) or 1–10 sites by PSMA PET/CT. Patients are allowed up to 30 days of androgen deprivation therapy (ADT) prior to enrollment. Patients are randomized 1:1 to standard of care (SOC) or SOC + MDRT to all metastatic sites. SOC includes 12 months of SST (ADT, with addition of an androgen receptor signaling inhibitor; triplet therapy is not allowed) and definitive treatment of the primary. Planned local therapy may be prostate-directed radiation therapy with definitive dose (moderate hypofractionation and ultra-hypofractionation allowed) or radical prostatectomy (maximum 50 patients to receive surgery), determined prior to randomization. MDRT will be delivered using stereotactic body radiation therapy (SBRT) to all metastatic lesions on conventional imaging or PSMA PET/CT. Patients are stratified to the use of PSMA PET/CT to stage, number of bone metastasis (0 vs 1-3 vs 4-10), local treatment (RT vs RP), and plan to MDRT all sites of PSMA disease (yes vs no). The primary endpoint is failure-free survival (FFS), defined as the time from randomization to biochemical failure, local or distant progression, skeletal-related event, any salvage intervention after 12 months planned SOC therapy, or death from prostate cancer. Secondary endpoints include overall survival, radiographic progression-free survival, quality of life (EPIC-26 domains), and toxicity. Correlative studies will explore imaging and molecular features from the primary, metastasis, and circulating disease to develop a predictive biomarker of which patients would derive the greatest benefit from MDRT. This study is designed to demonstrate a 34% relative reduction in the hazard of FFS from the addition of MDRT to SOC, providing 80% power at a one-sided alpha level of 0.05. The trial activated in July 2024, aims to complete accrual within 3 years. Data from this trial is pre-planned to be pooled with the STAMPEDE2 (NCT06320067) trial in the United Kingdom, which is assessing overall survival benefit of MDRT in men with de novo omHSPC. Funding: NIH U01CA257638. Clinical trial information: NCT06150417. Research Sponsor: NIH-NCI.

TPS5129 **Poster Session**

TRIPLE-SWITCH (SWOG/CCTG-PR26): A randomized phase III clinical trial for the addition of docetaxel to androgen receptor pathway inhibitors in patients with metastatic castration sensitive prostate cancer (mCSPC) and suboptimal PSA response (NCT06592924). First Author: Michael Ong, The Ottawa Hospital Cancer Centre, Ottawa, ON, Canada

Background: Management of patients (pts) with mCSPC remains a challenge due to its incurable nature and heterogeneous response to androgen deprivation therapy (ADT) and androgen receptor pathway inhibitors (ARPI). Recent analyses of phase III ADT + ARPI trials show that mCSPC with suboptimal PSA response (≥0.2ng/ml at 6-12 months) have poor prognosis, short time to castration-resistance (CRPC) and 30-36 month median overall survival (OS). While docetaxel could also be utilized in mCSPC, there is equipoise about its use in ARPI-treated pts because of 1) an absence of randomized data for docetaxel in this setting, 2) toxicity of docetaxel with impact on quality of life for pts, and 3) selection of docetaxel treatment by disease volume rather than disease biology. CCTG-PR26 (TRIPLE-SWITCH) is a joint CCTG-SWOG trial run through the NCI National Clinical Trials Network. This study investigates whether adding docetaxel prior to development of CRPC, regardless of disease volume, will improve OS in ARPI-treated mCSPC pts that show evidence of suboptimal response. **Methods:** This international, open-label, randomized phase III trial compares standard ADT + ARPI against the addition of docetaxel to ADT + ARPI in mCSPC pts with suboptimal PSA response, defined as PSA ≥0.2 ng/mL after 6-12 months of ADT and ≥4 months of ARPI. Stratification will be based on PSA levels, ARPI type, presence of liver metastasis, disease recurrence status, and time since ADT initiation. Arm 1 will continue standard ADT + ARPI (abiraterone acetate with prednisone, apalutamide, enzalutamide or darolutamide). Arm 2 will receive docetaxel 75mg/m^2 IV every 3 weeks for up to 6 cycles in addition to continuing standard ADT + ARPI. Sample size is 830 pts in order to detect a targeted 33% improvement in overall survival (hazard ratio 0.75) using a 1-sided 0.025 level test with 85% power. Key eligibility criteria are: ≥18 years, histologically confirmed prostate adenocarcinoma, metastatic disease present and confirmed by conventional imaging (CT and/or bone scan), PSA ≥5.0 ng/mL prior to ADT, receipt of ADT for 6-12 months and ARPI for ≥4 months, PSA ≥0.2 ng/mL within 14 days of enrolment, adequate organ and marrow function, ECOG performance status 0-2, eligible for docetaxel chemotherapy, no evidence of disease progression or biochemical progression on ADT prior to enrolment. Primary endpoint is overall survival. Secondary endpoints include PSA response, PSA kinetics, and clinical progression free-survival. Correlative studies will explore the prognostic and predictive value of circulating tumor DNA (ctDNA) and the association between molecular signatures in primary prostate cancer tissue and clinical outcomes. Enrolment has been initiated in January 2025 and is ongoing. Clinical trial information: NCT06592924. Research Sponsor: Canadian Institutes of Health Research; 195838; NCI National Clinical Trials Network (NCTN); CA180863; Canadian Cancer Society; 707213.

TPS5130 **Poster Session**

A phase II study of niraparib (N), abiraterone acetate (AA) plus prednisone (P) for Hispanic/Latino (HL) and non-Hispanic Black (NHB) patients with metastatic hormone sensitive prostate cancer (mHSPC) and deleterious homologous recombination repair alterations (HRRa; HARMONY). First Author: Qian Qin, Department of Internal Medicine, Division of Hematology and Oncology, UT Southwestern, Dallas, TX

Background: Patients with prostate cancer and deleterious HRRa have poorer prognosis but derive benefit from poly (ADP-ribose) polymerase (PARP) inhibition. However, prevalence of HRRa and response to PARP inhibition are less well defined in racial/ethnic minorities. We designed the HARMONY trial to evaluate the efficacy of N/AA/P in HL and NHB patients with mHSPC and deleterious HRRa. **Methods:** This multicenter, open label, phase II study is open through the Hoosier Cancer Research Network in the United States. The trial enrolls patients who self-identify as HL or NHB and have mHSPC with HRRa including *BRCA 1/2, BRIP1, CHEK2, FANCA, PALB2, RAD51B,* and/or *RAD54L.* Eligible patients will have hormone sensitive, treatment naïve or minimally treated prostate cancer (i.e., bicalutamide ≤ 45 days, androgen deprivation therapy [ADT] ± AA plus P ≤ 45 days allowed). Prostate cancer variants, other therapy in mHSPC setting, or symptomatic brain metastases are exclusionary. Enrolled patients will receive 24 weeks (w) of ADT plus N/AA dual action tablet (DAT) plus P, followed by an adaptive approach based on prostate specific antigen (PSA) response. Subjects in Arm A (PSA > 4.0 ng/mL at 24 w) can continue ADT/N/AA/P for max 2 years or stop N and escalate therapy to ADT/AA/P plus 6 cycles of docetaxel followed by standard of care (SOC) therapy. Subjects in Arm B (PSA ≤ 4.0 ng/mL at 24 w) will continue ADT/N/AA/P for a total of 12 months. At 12 months in Arm B, subjects with PSA ≥ 0.2 ng/mL will continue ADT/N/AA/P for max 2 years, and subjects achieving PSA < 0.2 ng/mL have the option to continue ADT/N/AA/P for max 2 years or discontinue all therapy with the option to start SOC treatment at disease progression. PSA decline to < 0.2 ng/mL at 24w (primary endpoint) will be evaluated for each racial/ethnicity group against a historic rate of 50%. Thirty patients per racial/ethnic cohort will give 80% power at 0.1 significance to determine noninferiority with a no-inferiority margin of 0.185. Estimating 5% drop out, 64 patients will be enrolled (n=32 HL and n=32 NHB). Key secondary/exploratory endpoints include PSA reduction ≥ 90%, overall response rate, PSA/radiographic progression free survival, overall survival, time to subsequent anti-cancer therapy, quality of life and safety. Key genomic correlatives will be evaluated. ClinicalTrials.gov: NCT06392841. Study support of drug and funding: Janssen Scientific Affairs LLC. Clinical trial information: NCT06392841. Research Sponsor: Janssen Scientific Affairs LLC.

TPS5131 **Poster Session**

Darolutamide plus androgen deprivation therapy (ADT) in patients with high-risk biochemical recurrence (BCR) of prostate cancer: A phase 3, randomized, double-blind, placebo-controlled study (ARASTEP). First Author: Alicia K. Morgans, Dana-Farber Cancer Institute, Harvard Medical School, Boston, MA

Background: Patients with prostate cancer treated with radiotherapy (RT) or radical prostatectomy (RP) as primary therapy may develop BCR – a prostate-specific antigen (PSA) increase with no evidence of metastases on conventional imaging (e.g. magnetic resonance imaging/computed tomography). Prostate-specific membrane antigen positron emission tomography/computed tomography (PSMA PET/CT) is more sensitive than conventional imaging and may detect lesions in patients with BCR that conventional imaging cannot. BCR is an indicator of disease progression and warrants effective treatment to delay further progression, particularly if lesions are detected by PSMA PET/CT. The androgen receptor inhibitor darolutamide is structurally different by design to deliver robust clinical efficacy with a differentiated tolerability profile. In the phase 3 ARAMIS trial, darolutamide significantly improved metastasis-free survival (MFS) and overall survival (OS) in patients with nonmetastatic castration-resistant prostate cancer (nmCRPC). ARASTEP is a phase 3 trial (NCT05794906) evaluating whether darolutamide plus ADT improves radiological progression-free survival (rPFS) by PSMA PET/CT vs placebo plus ADT in patients with high-risk BCR and PSMA PET/CT-positive lesions following primary therapy. **Methods:** Key eligibility criteria included: prior primary RT or RP ± adjuvant RT (ART) or salvage RT (SRT), with high-risk BCR (PSA doubling time [PSADT] <12 months and PSA ≥0.2 ng/mL after primary RP [± ART/SRT] or PSA ≥2 ng/mL above nadir after primary RT only), ≥1 PSMA PET/CT-positive prostate cancer lesion with no visible lesions on conventional imaging, and serum testosterone ≥150 ng/dL. ARASTEP is planned for 750 patients from 23 countries to be randomized 1:1 to oral darolutamide 600 mg twice daily or placebo, both with ADT, for 24 months or until disease progression, unacceptable toxicity, or withdrawal of consent. During the 24-month treatment period, patients will be monitored for safety every 12 weeks, and every 24 weeks for PSMA PET/CT and conventional imaging events. After 24 months, patients with PSA values ≥0.2 ng/mL will continue study treatment as part of active follow-up until PSMA PET/CT progression is confirmed by blinded independent central review (BICR), followed by long-term follow-up for conventional imaging progression. Patient stratification factors are PSADT (<6 vs ≥6–<12 months), intent to treat baseline PSMA PET/CT lesions with image-guided RT/surgery (Yes vs No), and distant ± locoregional vs locoregional-only lesions. The primary endpoint is rPFS by PSMA PET/CT assessed by BICR. Secondary endpoints include MFS on conventional imaging by BICR, time to CRPC, OS, quality of life, and safety. As of January 2025, 458 patients have been randomized from 220 sites. Clinical trial information: NCT05794906. Research Sponsor: Bayer.

Androgen suppression combined with elective nodal irradiation and dose escalated prostate treatment: A non-inferiority, phase III randomized controlled trial of stereotactic body radiation therapy versus brachytherapy boost in patients with unfavourable risk localized prostate cancer (ASCENDE-SBRT; CCTG PR24; NCT06235697). First Author: Andrew Loblaw, Sunnybrook Health Sciences Centre, Toronto, ON, Canada

Background: External beam radiotherapy (EBRT), brachytherapy boost and androgen deprivation therapy (ADT) is the evidence-based standard of care for unfavourable (unfavourable intermediate, high and very high) risk non-metastatic prostate cancer. Preliminary data demonstrate that treatment with 5 fractions of stereotactic body radiotherapy (SBRT) delivered to the pelvis and prostate with ADT is efficacious and tolerable in this patient population (Murthy Int J Rad Onc Biol Phys 2025) Other potential advantages associated with this treatment strategy include fewer treatment visits, lower cost, avoidance of a general anesthetic and decreased resource utilization. Rigorous evaluation of this treatment strategy within a clinical trial is required to inform adoption in practice. **Methods:** PR24 is a Canadian Cancer Trials Group led, intergroup, randomized phase III, non-inferiority study comparing pelvic EBRT + brachytherapy boost to SBRT (5 fractions delivering 40Gy to prostate and 25Gy to pelvis) in brachytherapy eligible, unfavourable risk, non-metastatic prostate cancer patients. All patients will receive risk-adapted duration of ADT. The primary objective is to determine if SBRT is non-inferior to conventional EBRT with brachytherapy boost in terms of disease progression free survival (PFS). Secondary objectives include a comparison between arms of: safety and tolerability; efficacy including PSA response rate at 4 years, metastasis-free survival, prostate cancer cause-specific survival, overall survival; patient-reported and economic outcomes. Biobanking for future correlative studies is included in study design. Statistical design:The target accrual is 710 patients over 3.6 years with 5-year follow-up up to rule out a target HR 1.65 (6.5% inferiority difference at 5-years) in PFS, using type 1 error rate 5% (one sided) and 80% power with 5% lost to follow-up. Conduct to Date: Study activation - March 2024. First patient enrolled - April 2024. Accrual to date: 45. Supported by CIHR grant #183644, NCTN grant #CA180863 and CCS grant #707213. Clinical trial information: NCT06235697. Research Sponsor: CIHR; 183644; NCTN; CA180863; CCS; 707213.

Ultrasensitive detection and tracking of circulating tumor DNA (ctDNA) and association with relapse and survival in locally advanced cervical cancer (LACC): Phase 3 CALLA trial analyses. First Author: Jyoti Mayadev, University of California San Diego Medical Center, La Jolla, CA

Background: In LACC, there is an unmet need for prognostic biomarkers as about 1/3 of patients (pts) relapse after chemoradiotherapy (CRT). The global randomized CALLA trial (NCT03830866) of durvalumab (D) in combination with CRT followed by D (D+CRT arm) vs CRT (CRT arm) did not significantly improve progression-free survival (PFS) in a biomarker unselected intent-to-treat (ITT) population. We analyzed the association of ultrasensitive ctDNA detection with relapse and survival in the largest ctDNA data set in LACC to date. **Methods:** Adult women with Stage IB2-IIB node positive (N+) or IIIA-IVA any N LACC (ITT) were randomized 1:1 to D+CRT or CRT alone. NeXT Personal (Personalis, Fremont, CA), an ultrasensitive tumor-informed MRD assay with up to 1,800 patient-specific variants from WGS, was used for ctDNA analysis from Cycle 1 Day 1 (C1D1; baseline [BL]), C3D1, and 6 mo post treatment initiation. Correlations were analyzed between ctDNA detection and outcomes (PFS, overall survival [OS]). **Results:** Of 770 pts randomized, the biomarker-evaluable population (BEP) comprised 185, 186, and 130 pts at BL, C3D1, and 6 mo, respectively. BL pt characteristics, PD-L1, PFS, and OS between BEP and ITT populations were generally similar. ctDNA was detected in 99% of pts at BL and decreased after treatment, reaching 23% in the D+CRT and 36% in the CRT arm at 6 mo. The lower detection rate in the D+CRT arm was associated with the PD-L1 tumor area positivity (TAP) $\geq$20% subpopulation. At BL, pts with low ($<$BL median [5268.2 ppm]) ctDNA levels had a reduced risk of progression vs pts with high ($\geq$median) ctDNA levels (PFS hazard ratio [HR] D+CRT 0.58 [95% CI, 0.27-1.24]; CRT 0.66 [0.34-1.28]). Pts with detectable ctDNA at C3D1 or 6 mo had a higher risk of progression independent of treatment arm (Table). No differences in risk of progression between the D+CRT vs CRT arms were observed based on ctDNA detection. Correlations between ctDNA and OS will be presented. **Conclusions:** This pre-planned analysis of a large, global LACC population from CALLA demonstrates the high sensitivity of a personalized ctDNA assay. High ctDNA levels at BL were associated with higher risk of progression or death. Lower ctDNA detection rates after treatment with D+CRT and CRT correlated with improved survival and highlight increased tumor control by D, especially in the PD-L1 TAP $\geq$20% subpopulation. This analysis supports the potential utility of ultrasensitive ctDNA analysis to guide treatment decisions in LACC. Clinical trial information: NCT03830866. Research Sponsor: AstraZeneca.

Patient-reported outcomes (PROs) in locally advanced cervical cancer (LACC): Insights from the OUTBACK trial. First Author: Rebecca Mercieca-Bebber, NHMRC Clinical Trials Centre, The University of Sydney, Camperdown, Australia

Background: OUTBACK (ACTRN12610000732088), an open-label, international, randomized phase 3 trial of 919 participants (pts) with LACC, showed that adding adjuvant chemotherapy (ACT) after chemoradiotherapy (CRT) increased adverse events without improving overall survival compared to CRT alone. PRO objectives of OUTBACK were to determine the: 1) prevalence of patient-reported moderate-severe symptom issues at years 1-3 post-randomisation 2) duration of common issues; 3) long-term psychosexual health. **Methods:** Pts completed the EORTC core questionnaire QLQ-C30; cervical cancer module QLQ-CX24 (questions 50-54 only for sexually active pts); EORTC Item Library questions on abdominal, urinary, bowel and chemotherapy side-effects; & FACT-GOG-NTX4 neurotoxicity over 36 months. A moderate-severe long-term symptom issue was defined as a score in the worst 2 response categories (EORTC items), a total score $\leq$8/16 on FACT-GOG-NTX4 at years 1, 2 or 3 for Objectives 1-2, or equivalent subscale score for Objective 3. The availability of PROs for analysis was not related to 11 pre-specified demographic/clinical variables so no imputation for missing data was performed. **Results:** PRO completion rates were 94% at baseline, 64% at year 1 & 37% by year 3. Table 1 shows the 10 top-ranked issues at year 1 & their persistence or resolution by years 2-3. These may be underestimates, due to lower PRO completion rates at years 2-3. Issues and frequencies were similar across treatment arms by year 1. Moderate-severe peripheral neuropathy affected 24% post CRT+ACT & 18% post CRT (year 1); 19% post CRT+ACT & 12% post CRT (year 3). At baseline, 77% reported no sexual activity in the past 4 weeks. Overall, 92% of pts reported low sexual activity at years 1, 2 or 3; 68% reported low enjoyment, 40% moderate-severe vaginal tightness, 37% vaginal dryness during sex and 32% were moderately-severely worried sex would be painful. **Conclusions:** Long-term symptom issues & sexual health concerns are common & persistent following CRT +/-ACT for LACC and need dedicated survivorship care. Clinical trial information: 12610000732088. Research Sponsor: National Health and Medical Research Council; National Cancer Institute; SHCC MU NCORP Grant.

Benmelstobart plus carboplatin/paclitaxel with or without anlotinib, followed by maintenance benmelstobart with or without anlotinib, as first-line treatment for advanced or recurrent endometrial cancer: A randomized, open-label, phase II trial. First Author: Xiaojun Chen, Shanghai Tenth People's Hospital, Shanghai, China

Background: Immunotherapy combined with chemotherapy has demonstrated efficacy in treating endometrial cancer (EC), with greater benefit in mismatch repair (MMR)–deficient (dMMR) tumors compared to MMR-proficient (pMMR) disease. Adding an anti-angiogenic inhibitor could potentially enhance treatment outcomes, particularly in patients with pMMR tumors. Benmelstobart (BMSB, TQB2450) is a humanized monoclonal antibody against PD-L1 and Anlotinib (ALTN) is an anti-angiogenic oral multi-target tyrosine kinase inhibitor. Here, we report the results of a randomized, open-label, phase 2 trial comparing BMSB plus carboplatin/paclitaxel ± ALTN followed by maintenance BMSB ± ALTN as first-line treatment for advanced or recurrent EC patients. **Methods:** Eligible patients with primary advanced stage III/IV or recurrent EC, who had not received first-line systemic anticancer therapy, were randomized in a 1:1 ratio to receive either BMSB 1200mg, Carboplatin (CBP, AUC=5 mg/ml.min) and Paclitaxel (PTX, 175mg/m^2) every 3 weeks for 6-8 cycles plus ALTN 8mg orally once daily (2-week on/1-week off), followed by maintenance BMSB 1200mg every 3 weeks and ALTN 10mg once daily (2-week on/1-week off) (BMSB + ALTN arm); or BMSB 1200mg, CBP (AUC=5 mg/ml.min) and PTX 175mg/m^2 every 3 weeks for 6-8 cycles followed by maintenance BMSB 1200mg every 3 weeks (BMSB arm). Stratification factors included MMR status (dMMR or pMMR). The primary endpoint was objective response rate (ORR) as assessed by investigator according to RECIST 1.1. **Results:** As of November 1, 2024, a total of 71 patients were enrolled: 38 in the BMSB + ALTN arm, and 33 in the BMSB arm. The median duration of follow-up was 16.2 mo vs. 14.2 mo in the two arms respectively. The ORR was 86.1% (95% CI: 70.5-95.3) in the BMSB + ALTN arm and 80.6% (95% CI: 62.5-92.5) in the BMSB arm. A significant PFS benefit was observed in the BMSB + ALTN arm (HR 0.38 [95% CI 0.18-0.81]; median not reached (NR) vs. 8.41 mo) compared to the BMSB arm. The median overall survival (OS) was not reached in either arm (HR=0.29 [95% CI: 0.07-1.16]). PFS benefit was also observed in subgroups with pMMR tumors (HR 0.35 [95% CI 0.15-0.79]). The incidence of Grade ≥3 TEAEs was similar between the two arms (81.58% vs 75.76%). The most frequent Grade ≥3 TEAEs(≥20%) were decreased white blood cell count (52.63% vs 60.61%), thrombocytopenia (28.9% vs 27.2%) and anemia (26.3% vs 27.7%). **Conclusions:** Benmelstobart combined with carboplatin/paclitaxel and anlotinib, followed by maintenance benmelstobart and anlotinib, demonstrated clinically meaningful ORR and PFS benefits in patients with previously untreated advanced or recurrent EC. The regimen was particularly helpful in improving outcomes for patients with pMMR tumors, potentially providing a new treatment option. Clinical trial information: NCT05481645. Research Sponsor: None.

5509 Rapid Oral Abstract Session

Cadonilimab plus platinum-based chemotherapy ± bevacizumab for persistent, recurrent, or metastatic cervical cancer: Subgroup analyses of COMPASSION-16. First Author: Yang Sun, Clinical Oncology School of Fujian Medical University, Fujian Cancer Hospital, Fuzhou, China

Background: The phase 3 COMPASSION-16 trial demonstrated statistically significant progression-free survival (PFS) and overall survival (OS) benefits with cadonilimab plus chemotherapy ± bevacizumab in patients with persistent, recurrent, or metastatic cervical cancer (R/M CC). This analysis assessed efficacy in several key clinical subgroups. **Methods:** R/M CC pts who had no prior systemic treatment were randomized 1:1 to receive cadonilimab (10 mg/kg) or placebo Q3W plus platinum-based chemotherapy ± bevacizumab (15 mg/kg). The dual primary endpoints were PFS per RECIST v1.1 assessed by blind independent central review and OS in the ITT population. Treatment effects on PFS and OS were evaluated in subgroups including age (<65 or ≥65 years), bevacizumab use (yes or no), prior concurrent chemoradiotherapy (CCRT; yes or no), metastatic disease at baseline (yes or no), PD-L1 CPS (<1, ≥1, or ≥10), and platinum use (cisplatin or carboplatin). Hazard ratios (HRs) and 95% CIs were estimated from an unstratified Cox model. **Results:** 445 patients were randomized (222 to the cadonilimab group and 223 to the placebo group). At the Apr 30, 2024 data cutoff, the median follow-up was 26 months. The addition of cadonilimab prolonged PFS and OS in all investigated subgroups (Table). **Conclusions:** Subgroup analyses of COMPASSION-16 showed that the addition of cadonilimab to chemotherapy ± bevacizumab improved PFS and OS across subgroups defined by age, bevacizumab use, prior CCRT, metastatic disease, PD-L1 CPS, and platinum use, consistent with results for the overall population. Cadonilimab plus standard treatment is a potential treatment option for patients with R/M CC. Clinical trial information: NCT04982237. Research Sponsor: Akeso Biopharma.

5510 Rapid Oral Abstract Session

Nimotuzumab combined with chemotherapy in the first-line treatment for patients with stage IVB, recurrent or persistent cervical squamous cell carcinoma: A multi-center, randomized, double-blind, and controlled study. First Author: Jusheng An, Department of Gynecologic Oncology, National Cancer Center /National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, Beijing, China

Background: Stage IVb, recurrent or persistent cervical cancer patients have limited treatment options and poor survival prognosis. Additionally, 70-90% of cervical cancers have overexpression of EGFR (epidermal growth factor receptor), a promising therapeutic target. Nimotuzumab (nimo), an EGFR antibody, 95% humanization degree, had applied in the treatment of various advanced solid tumors. So, we conducted the study to investigate its efficacy and safety. **Methods:** This trial is a prospective study with a total of 118 patients enrolled. There were 55 patients (pts) in the experimental group (nimo+chemotherapy) and 63 pts in the control group (chemotherapy alone). Primary efficacy endpoint is overall survival (OS). Secondary endpoints included progression-free survival (PFS), objective response rate (ORR), quality of life (QoL) and exploratory endpoints including the relationship between EGFR expression level and clinical efficacy and prognosis. The study of NCT approval number is 06781073. **Results:** The median age of the study population was 51.3 (range, 24.7-69.5) years. The average number of organs involved in the lesion was 2. The disease stage at initial diagnosis (2018 FIGO stage) was Ia-IVb. According to the disease status at the time of enrollment, IVB/recurrence/persistence accounted for 14.4%, 92.4%, and 9.3%, respectively. The results showed that the median OS was 15.7 (95% CI, 11.8-26.9) months in the nimo arm and 12.4 (95% CI, 7.9-21.0) months in the control arm. For recurrence pts, median OS was 21.7 (95% CI, 21.1-32.9) months vs. 12.4 (95% CI, 8.0-21.4) months for both groups. Median PFS was 7.4 (95% CI, 4.9-8.9) months in the nimo arm and 5.6 (95% CI, 4.1-6.1) months in the control arm. For recurrence pts, median PFS was 7.9 (95% CI, 5.6-12.0) months vs. 5.2 (95% CI, 3.7-8.0) months for both groups. In terms of safety, SAEs occur as follows. There were 8 pts (14.5%) in the nimo and 13 pts (23.6%) in the control group, respectively. For AEs above grade 3, there were 43 pts in the nimo and 45 pts in the control group. Adverse events related to the study drug, there were 6 cases in the nimo group with neutropenia. Among all AEs, the highest frequency was in the nimo group with 20 cases of leukopenia, 16 cases of nausea, 23 cases of anemia, and 11 cases of alopecia. In the control group, there were 17 cases of leukopenia, 21 cases of nausea, 23 cases of vomiting and 20 cases of alopecia. There was no significant difference between the two groups for adverse events. **Conclusions:** Adding nimotuzumab to chemotherapy in the first-line treatment for stage IVB, recurrent or persistent cervical squamous cell carcinoma could have an improvement trend on progression-free and overall survival with well tolerated toxicity, and should be considered as a new first-line therapy option. Research Sponsor: None.

5511 Rapid Oral Abstract Session

Primary results of a phase 2 study of cisplatin-sensitized radiation therapy and pembrolizumab for unresectable vulvar cancer. First Author: Oladapo O. Yeku, Massachusetts General Hospital, Harvard Medical School, Boston, MA

Background: Locally advanced vulvar cancer is a rare but lethal disease more common in underserved populations. In contrast to other gynecologic cancers, the incidence and mortality of this disease has increased over the past decade. Treatment for locoregional disease involves surgery and chemoradiation, while systemic chemotherapy and immunotherapy are reserved for patients with distant metastases. Cisplatin and radiation (cis-RT) have been reported to have anti-tumor immunomodulatory properties in addition to their cytotoxic effects. We hypothesized that immune checkpoint inhibitors could synergize with chemotherapy and improve outcomes for this disease. **Methods:** In this single-arm phase II trial (NCT04430699), patients with primary unresectable, incompletely resected, recurrent, or metastatic squamous cell carcinoma of the vulva undergoing RT were eligible. Patients who had received prior chemotherapy were also eligible. Patients received cisplatin 40 mg/m2 weekly concurrently with intensity modulated (IM) RT, and pembrolizumab 200 mg was administered every three weeks for a total of 12 cycles. The primary endpoint was overall response rate (ORR), and the secondary objective was six-month recurrence free survival (RFS). PD-L1 expression and T-cell receptor beta clonality were assessed among other translational endpoints. An ORR ≥ 60% was considered worthy of further study. **Results:** The study closed to accrual on 10/11/2024 after 24 patients had enrolled. Twenty-two patients (92%) had primary unresectable disease and two (8%) had recurrent disease. All patients were treated with definitive intent RT, with a median dose to the primary of 68.4 Gy (range, 26.2, 70.2) and 45 Gy to pelvic, inguinal, vulva CTV (range, 21.6, 50.4). One patient stopped RT early due to disease progression. At the data cutoff on 01/22/2025, the ORR (CR+PR) was 75%. The 6-month RFS rate was 70% (95% CI: 48 – 85%). The median PFS has not been reached. Any grade adverse events (AE) occurred in all patients. Grade (G) 3 or 4 AEs occurred in 19 (78.6%) patients, most of which were related to cisplatin. The most common treatment-emergent adverse events were nausea (88%), diarrhea (71%), fatigue (67%) and anemia (50%). There were 6 serious AEs, only 2 of which were related the treatment (both AKI). Most immune related toxicities were G1/2, except for G3 diarrhea (4%). Immune mediated colitis led to discontinuation in 1 patient (4%). PD-L1 (CPS ≥ 1) was positive in all patients. There was an increase in mean TCR clonality after 2 cycles. **Conclusions:** The study met its primary endpoint. Concurrent treatment with chemoradiation and pembrolizumab improved ORR and 6-month RFS in vulvar cancer. The addition of pembrolizumab did not lead to any unexpected AEs. Chemoradiation with pembrolizumab could be considered in patients with primary unresectable or incompletely resected vulvar cancer. Clinical trial information: NCT04430699. Research Sponsor: Merck Sharp & Dohme Corp.

5512 Rapid Oral Abstract Session

Durvalumab plus carboplatin/paclitaxel followed by durvalumab with or without olaparib as first-line treatment for endometrial cancer: Longitudinal changes in circulating tumor DNA. First Author: Shannon Neville Westin, Department of Gynecologic Oncology and Reproductive Medicine, The University of Texas MD Anderson Cancer Center, and GOG-F, Houston, TX

Background: DUO-E (NCT04269200) showed statistically significant and clinically meaningful progression-free survival (PFS) with carboplatin/paclitaxel (CP) plus durvalumab (D) followed by D (CP+D) ± maintenance olaparib (O) vs CP in endometrial cancer (intent-to-treat [ITT] population; primary endpoints). The greatest benefit for CP+D was in mismatch repair deficient (dMMR) patients (pts); addition of O (CP+D+O) further enhanced PFS in MMR proficient (pMMR) pts (prespecified exploratory analyses). We present exploratory longitudinal circulating tumor (ct)DNA analyses. **Methods:** Pts were randomized 1:1:1 to CP (CP alone), CP+D, or CP+D+O arms. ctDNA was analyzed in plasma at baseline (BL; Cycle 1 Day 1 [C1D1]), during the chemotherapy phase (C3D1), prior to maintenance initiation (C7D1), and during the maintenance phase (C9D1) using the methylation-based Guardant Infinity assay (Guardant Health, Palo Alto, CA). **Results:** Of 718 pts randomized, the biomarker-evaluable population (BEP) comprised 347, 349, 350, and 349 pts at BL, C3D1, C7D1, and C9D1, respectively. Pt characteristics were similar to the ITT population but fewer pts had Eastern Cooperative Oncology Group status 1. ctDNA was detectable in 80% (278/347) of C1D1 samples, and presence of BL ctDNA was associated with shorter PFS across treatment arms. In both dMMR and pMMR pts, CP+D treatment during the chemotherapy phase led to numerically greater reductions in detectable ctDNA vs CP at C3D1; continued treatment with D led to lower ctDNA detection at C9D1 (Table) due to a lower proportion of pts switching from no detectable ctDNA to detectable (re-emergence) ctDNA between C7D1 and C9D1. The addition of maintenance O to CP+D had limited effect on ctDNA levels in dMMR pts; however, in pMMR pts, the ctDNA detection rate was lower at C9D1 vs CP or CP+D due to increased ctDNA clearance from C7D1 to C9D1 (CP+D+O vs CP+D: 48% vs 17%). **Conclusions:** In this post hoc exploratory analysis, BL ctDNA was associated with shorter PFS. The addition of D was associated with rapid reductions in ctDNA detection during chemotherapy and less re-emergence of ctDNA during maintenance. The addition of maintenance O was associated with further reduction of detectable ctDNA and increased ctDNA clearance in pMMR pts, reflecting an additional activity of the combination. Clinical trial information: NCT04269200. Research Sponsor: AstraZeneca.

ctDNA detection rates (% [n/N]).

Population	Treatment arm	C1D1	C3D1	C7D1	C9D1

5513 Rapid Oral Abstract Session

Phase 2 study of letrozole, abemaciclib, and metformin in estrogen receptor (ER)−positive recurrent endometrial cancer (EC). First Author: Panagiotis A. Konstantinopoulos, Dana-Farber Cancer Institute, Boston, MA

Background: Preclinical studies have demonstrated synergism with simultaneous inhibition of the estrogen receptor (ER), CDK4/6 and PI3K pathways. Metformin suppresses PI3K signaling directly via activation of the AMP-activated protein kinase (AMPK) and indirectly via downregulating the insulin/IGF-1 signaling pathway. We conducted a phase 2 study of letrozole/abemaciclib/metformin in ER positive EC. **Methods:** Patients (pts) with recurrent ER positive (≥1% immunoreactive tumor nuclei) endometrioid EC, measurable disease, any number of prior therapies and any prior hormonal therapy but no prior CDK4/6 inhibitor received abemaciclib 150 mg PO bid, metformin 500mg PO qd and letrozole 2.5 mg PO qd until progression or unacceptable toxicity. Primary endpoints were objective response (OR) rate (ORR) and progression-free survival (PFS) rate at 6 months (PFS6). A safety lead-in was included, and target accrual was 25 pts; if there were ≥6 ORs or ≥9 pts without disease progression or death at 6 months, letrozole/abemaciclib/metformin would be considered worthy of further investigation. Correlative studies included pharmacokinetic (PK) analyses of metformin alone and in combination with letrozole/abemaciclib, molecular profiling using Oncopanel targeted NGS, and progesterone receptor (PrgR) expression by IHC. **Results:** As of 10/4/2024, all 25 pts received protocol therapy. Median follow up was 17 months, median number of prior lines was 2 and 18 (72%) pts had previously received hormonal therapy. Eight pts exhibited OR: 3 complete responses (CRs) and 5 partial responses (PRs),ORR 32% (95% CI 14.9% to 53.5%). Sixteen (64%) pts had stable disease (SD) and 1(4%) pt progressive disease (PD) as best response. Kaplan Meier estimate of PFS6 was 69.7% and median PFS was beyond 19.3 months. Most common G3+ treatment-related toxicities were G3 neutropenia (24%) and G3 fatigue (16%). No pts discontinued therapy because of toxicity. PK analyses demonstrated that metformin plasma concentrations were ~3-fold higher when combined with letrozole/abemaciclib compared to metformin monotherapy. Molecular profiling showed no objective responses in *TP53* mutated ECs and no objective responses in pts with NSMP ECs with *RB1* or *CCNE1* alterations; median PFS was only 3.8 months in these tumors. All objective responses were observed in pts with NSMP ECs without *RB1* and *CCNE1* alterations; these pts exhibited an ORR of 50% and PFS6 of 87.5%. There were no MMRD and no *POLE*-mutated tumors. Responses were observed regardless of PrgR expression. **Conclusions:** Addition of metformin (at plasma concentrations sufficient to inhibit the PI3K pathway) to letrozole/abemaciclib is feasible and safe, and appears to induce deeper responses (including complete responses) and more prolonged PFS than letrozole/abemaciclib alone. NSMP tumors without *RB1* and *CCNE1* alterations derive the most benefit from this regimen. Clinical trial information: NCT03675893. Research Sponsor: None.

5514 Rapid Oral Abstract Session

Safety and preliminary efficacy from a phase 1 study of INCB123667, a selective CDK2 inhibitor, in patients with advanced platinum-resistant and refractory ovarian cancer (OC). First Author: Silvia Damian, Department of Medical Oncology and Hematology, Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy

Background: Inhibition of cyclin-dependent kinase 2 (CDK2), the binding partner of cyclin E1 (CCNE1), is a potential therapeutic approach for cancers with increased CCNE1 activity. In an ongoing phase 1 study, the potent and selective CDK2 inhibitor, INCB123667, has shown acceptable safety and preliminary efficacy in patients (pts) with advanced solid tumors (NCT05238922). Here, we present safety and preliminary efficacy data for enrolled pts with OC. **Methods:** Eligible pts had ECOG PS ≤1 and measurable disease (RECIST V1.1). Part 1A (dose escalation) enrolled pts with advanced/metastatic solid tumors with no maximum prior lines of treatment; *CCNE1* amp (locally tested) was not mandatory. INCB123667 dosing started at 50 mg and escalated up to 150 mg daily. In part 1B (dose expansion), selected RDEs from part 1A were expanded in 6 tumor cohorts, including platinum-refractory/resistant (r/r) OC with ≤4 prior lines of systemic treatment; pts must have had locally tested *CCNE1* amp or centrally confirmed CCNE1 overexpression. Blood samples were collected for ctDNA analysis. **Results:** As of Dec 19, 2024, 90 pts with advanced/metastatic platinum-r/r OC received INCB123667: 45 in part 1A (50 mg qd, n=1; 50 mg bid, n=4; 75 mg qd, n=12; 75 mg bid, n=4; 125 mg qd, n=18; 150 mg qd continuous or intermittent, n=6) and 45 in part 1B (RDEs: 50 mg bid, n=16; 100 mg qd, n=14; 125 mg qd, n=15). Sixty one pts (67.8%) had prior PARPi. Median number of prior systemic therapies was 4 (1-12). Median duration of treatment was 4.9 months (0.1-13.6), with 17 pts (18.9%) still on treatment. Overall, 88 pts (97.8%) had treatment-emergent adverse events (TEAEs), predominantly nausea (n=51 [56.7%]), anemia (n=34 [37.8%]), and vomiting (n=33 [36.7%]). Of 38 pts (42.2%) with grade ≥3 TEAEs, most common were intestinal obstruction (n=8 [8.9%]), anemia (n=6 [6.7%]), neutropenia (n=5 [5.6%]), and thrombocytopenia (n=5 [5.6%]). Treatment was discontinued due to TEAEs in 3 pts (3.3%). Overall response rate (ORR) among all pts in parts 1A and 1B was 21.1% (19/90; complete response, n=4; partial response, n=15) and 43 (51.2%) achieved stable disease, with an ORR of 33.3% (10/30) at selected RDEs of 100 mg daily (ie, 50 mg bid and 100 mg qd) in part 1B. All but 1 responder had CCNE1 overexpression (18/19); responses were observed in pts with *CCNE1*-amp (6/19) and in pts without *CCNE1*-amp but with CCNE1 overexpression (13/19). Consistent decreases in ctDNA were observed on treatment compared with baseline. **Conclusions:** In this phase 1 study of pts with heavily pretreated advanced/metastatic platinum-r/r OC, single agent INCB123667 at various doses showed an acceptable safety profile including expected cytopenia and nausea. The encouraging antitumor activity in this difficult-to-treat population support the advancement of INCB123667 into pivotal studies in pts with platinum-resistant OC. Clinical trial information: NCT05238922. Research Sponsor: Incyte Corporation.

5515 Rapid Oral Abstract Session

A phase II trial of pembrolizumab and lenvatinib in recurrent or persistent clear cell ovarian carcinoma (NCT05296512). First Author: Elizabeth Katherine Lee, Dana-Farber Cancer Institute, Boston, MA

Background: Clear cell ovarian carcinoma (CCOC) is a chemoresistant subtype of ovarian cancer. Immune checkpoint inhibitors have been reported to have clinical activity in CCOC. Additionally, CCOC harbors molecular alterations suggesting a role for anti-angiogenic agents. We therefore conducted a single-arm two-stage phase 2 trial to investigate the clinical activity of the combination of the PD-1 inhibitor pembrolizumab with the anti-angiogenic tyrosine kinase inhibitor lenvatinib in patients (pts) with CCOC. **Methods:** Pts with CCOC and measurable disease received pembrolizumab 200 mg IV every 3 weeks and lenvatinib 20 mg daily. Pts could have received an unlimited number of prior therapies; prior bevacizumab and immune checkpoint inhibitors were allowed, but prior lenvatinib was exclusionary. Malignant bowel involvement was not allowed. Co-primary endpoints were objective response rate (H_0 5%; H_a 25%) and rate of PFS at 6 months (mo) per RECIST v1.1 (H_0 10%; H_a 30%), restricting the probabilities of type I and type II errors to 10% and 10%, respectively. Two pts with objective responses or 3 pts progression-free and alive at 6 mos were needed to proceed from stage 1 (n=18) to stage 2 (n=13); 5 pts with objective responses or 6 pts progression-free and alive at 6 mos were needed to declare the combination worthy of further study. **Results:** Data cut-off occurred 22-Oct-2024. Of 30 enrolled pts, 83.3% were white; the mean age among all pts was 54.1 years. 30% of pts (9/30) experienced a confirmed response (2 CR, 7 PR); an additional 3 pts (10%) experienced unconfirmed PRs and 4 pts (13.3%) had SD ≥6 mo. As of data cut-off, 3 pts (10%) had not yet reached their first radiographic assessments, and 17 pts were still receiving study therapy. With a median of 9.72 mo of follow up, 16 pts were alive and progression-free at 6 months. The estimated 6-month PFS was 75.96% (95% CI 53.82-88.51%). Median PFS was 10.9 mo. The estimated 12-month PFS was 48.86% (95% CI 23.67-70.04%). The most common any-grade TRAEs were hypertension (71%), hypothyroidism (66%), and fatigue (60%). There were no unanticipated TRAEs. **Conclusions:** The combination of pembrolizumab/lenvatinib demonstrates encouraging evidence of clinical activity in CCOC, with 9 pts experiencing a confirmed response and 16 pts alive and progression-free at 6 months. As both co-primary endpoints of the study were met, enrollment closed with 30 pts. Updated data for all pts will be reported. There were no new safety signals. Clinical trial information: NCT05296512. Research Sponsor: Merck.

5516 Rapid Oral Abstract Session

A phase I/II study of the safety and efficacy of intraperitoneal IMNN-001 in combination with neoadjuvant chemotherapy (NACT) of paclitaxel and carboplatin in patients newly diagnosed with advanced epithelial ovarian cancer (EOC): Updated survival analysis from OVATION-2 trial. First Author: Premal H. Thaker, Division of Gynecologic Oncology, Department of Obstetrics and Gynecology, Washington University School of Medicine, St. Louis, MO

Background: OVATION-2 (NCT03393884) is a randomized, controlled phase I/II study evaluating IMNN-001 in newly diagnosed advanced epithelial ovarian cancer (EOC) patients. The study's purpose was to assess safety and efficacy of IMNN-001, an interleukin-12 (IL-12) gene therapy in combination with standard of care (SoC) chemotherapy. **Methods:** Patients were randomized 1:1 to NACT alone or NACT +IMNN-001. Carboplatin/paclitaxel IV was administered every 21 days for 3 cycles before and after interval debulking surgery (IDS) in the control arm, and concurrently with intraperitoneal IMNN-001 given weekly for 8 weeks prior to and for 9 weeks after IDS in the experimental arm. PFS was the primary endpoint with secondaries of OS, chemotherapy response score (CRS), surgical response score (SRS) and overall response rate (ORR). Hazard ratios are reported for PFS and OS as the study was not powered for statistical significance. Additional statistical methods quantified Totality of Evidence (ToE, Wang et al 2023, Claggett 2022) by considering PFS and OS outcomes simultaneously. Data lock was June 2024, with OS updated with data through November 2024. **Results:** 112 patients were enrolled with a median follow-up 31 months. Stage IV disease (31.0% vs 22.2%) and ECOG PS≥1 (48.3% vs 35.2%) were more common in the experimental arm. PARPi maintenance was less frequent in the experimental arm (32.8% vs 44.4%) despite balanced HRD status. IMNN-001 was well-tolerated with common adverse events (AEs) primarily including abdominal pain, nausea, and vomiting. There was no report of cytokine release syndrome or elevated risk of immune-related adverse events. Median PFS was 14.9 vs 11.9 months (HR:0.79, 95% CI: 0.51-1.23), and median OS was 46.0 vs 33.0 months (HR:0.69, 95% CI: 0.4-1.19) favoring the experimental arm. Rates of CRS with CRS3 outcome (complete or near complete response) and SRS R0 Section outcome were higher in the experimental arm; ORR was similar. In investigator choice PARPi subgroups, median PFS was 33.8 vs 22.1 months favoring the experimental arm (HR:0.79, 95% CI: 0.51-1.23), median OS was not reached in the experimental arm vs 37.1 months in the control arm (HR:0.38, 95% CI: 0.13-1.06). By simultaneously considering individual patients' progression and death times (ToE), the experimental arm shows 6.5 months improvement (less time lost) compared to the control arm with one-sided p = 0.375. **Conclusions:** IMNN-001 demonstrated trends towards material improvement in overall survival and acceptable safety in advanced EOC, especially in HRD+ patients. These results are supportive of further development in the upcoming pivotal phase 3 study. Clinical trial information: NCT03393884. Research Sponsor: None.

5517 Rapid Oral Abstract Session

Safety and efficacy of BAT8006, a folate receptor α (FRα) antibody drug conjugate, in patients with platinum-resistant ovarian cancer: Update on the dose optimization/expansion cohort of BAT-8006-001-CR trial. First Author: Songling Zhang, Department of Gynecologic Oncology, Gynecology and Obstetrics Center, The First Hospital of Jilin University, Changchun, Jilin Province, China

Background: This report presents an update results of the BAT-8006-001-CR trial, which evaluated the safety and clinical activity of BAT8006, an antibody drug conjugate (ADC) consisting of a humanized anti-folate receptor alpha (FRα) monoclonal antibody linked to the topoisomerase I inhibitor exatecan, in patients with platinum-resistant ovarian cancer (PROC). **Methods:** Patients with platinum-resistant epithelial ovarian, fallopian tube, or primary peritoneal cancer received BAT8006 monotherapy every 3 weeks. The adverse events, incidence of dose interruptions or reductions, tumor response, progression-free survival (PFS) and overall survival (OS) were determined. **Results:** As of January 1st, 2025, 131 PROC patients were enrolled across various cohorts: 1.8 mg/kg (n=2), 2.1 mg/kg (n=16), 2.4mg/kg(n=15), 84 mg/m^2 (n=50) or 93mg/m^2(n=48) cohorts during the dose escalation and dose optimization/expansion study. The most common treatment-emergent adverse events (TEAEs) were anemia (82%), leukopenia (80%), neutropenia (77%), vomiting (67%), nausea (60%) and thrombocytopenia (55%). The most frequent grade ≥3 treatment related adverse events (TRAEs) were neutropenia (42%), leukopenia (33%), anemia (30%) and thrombocytopenia (26%). Notably, no cases of interstitial lung disease (ILD), ocular toxicities, or treatment-related deaths were reported. In the 84 and 93 mg/m^2 dose cohorts, selected for further exploration in the dose optimization/expansion study, the incidences of grade ≥3 neutropenia, anemia and thrombocytopenia were 35% vs 45% ,20% vs 32% and 18% vs 32%, respectively. Among 108 efficacy-evaluable patients with PROC (regardless the FRα expression and prior lines of treatments), the objective response rate (ORR) was 32.4% (35/108) and disease control rate (DCR) was 75.9% (82/108). The median PFS was 6.9 months (95% CI: 4.3-7.9), while the median OS was not reached (NR). In cohort 1 (n = 77), PROC patients with ≤3 lines of prior systemic anti-tumor therapies and FRα expression ≥1% were randomly assigned to received BAT8006 at 84 mg/m^2 (n=40) or 93mg/m^2 (n=37) every 3 weeks. Among 64 efficacy-evaluable patients in this cohort, the ORRs were 30.6% (11/36) and 32.1% (9/28) for the 84 mg/m^2 and 93mg/m^2 doses, respectively, while the DCRs were 75.0% (27/36) and 78.6% (22/28). The median PFS were 7.5 months (95% CI: 4.0-NR) and 5.5 months (95% CI: 2.9-NR), respectively. The median OS were NR. **Conclusions:** The safety profile is consistent with previous results, with no reports of ILD or ocular toxicity. The preliminary efficacy of BAT8006 appears promising in PROC patients with FRα expression ≥1%. On the basis of these findings, the target population, dose and schedule have been identified for a phase III trial of BAT8006 monotherapy in PROC patients. Clinical trial information: NCT05378737. Research Sponsor: Bio-Thera Solutions.

5518 Poster Session

A phase II study of tumor microenvironment profiling at single cell level in patients with locally advanced cervical cancer (LACC) treated with immunotherapy combined with concurrent chemoradiotherapy (CICRT). First Author: Yuhan Sheng, Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, China

Background: Concurrent chemoradiotherapy (CCRT) followed by intrauterine brachytherapy is the standard treatment for LACC, while the therapeutic efficacy can be limited by an immunosuppressive tumor microenvironment (TME). PD-1 inhibition has displayed efficacy and a clinically manageable safety profile in patients with cervical cancer. Single-cell RNA sequencing (scRNA-seq) of paired pre-treatment and on treatment samples offers a dynamic and detailed examination of the transcriptomic changes in the TME under different treatment conditions. Here, we present the results of patients with LACC treated with either CCRT or CICRT, along with the paired analysis of various cellular components in the TME from pre-treatment and on-treatment samples through scRNA-seq. **Methods:** Patients with untreated, high-risk stage III–IVA and stage IVB cervical cancer (limited to groin lymph nodes metastasis) according to FIGO 2018, with measurable disease per RECIST 1.1 and ECOG performance status ≤1, were included and randomly assigned (1:1) to receive either tislelizumab combined with chemoradiotherapy, followed by tislelizumab (200mg, Q3W for 6 cycles), or chemoradiotherapy alone (cisplatin 40 mg/m^2, Q1W for 3-5 cycles; pelvic external beam radiation therapy 50.4 Gy in 28 fractions; brachytherapy 28 Gy in 4 fractions). Single-cell transcriptomic profiles were obtained from paired biopsies at two time points: pre-treatment and on-treatment. **Results:** A total of 18 patients were included, with 12 single-cell analysis samples collected (6 CCRT and 6 CICRT). At the end of pelvic radiotherapy, the CICRT group exhibited a trend toward a greater reduction in tumor volume compared to the CCRT group (7.4% vs. 3.0%; p = 0.08), albeit not reaching statistical significance. Cancer cells in CICRT group exhibited with an increased expression of MHCII genes and chemotaxis-related genes on treatment. CICRT reduced the proportion of immunosuppressive regulatory CD4+ T cells and exhausted CD8+ T cells compared to CCRT. In myeloid cells, TNF-α signaling via NF-κB and inflammatory response pathways were enriched following CICRT, and tumor-associated macrophages were reprogrammed to a relatively pro-tumorigenic phenotype. The cancer-associated fibroblast (CAF) subset CAF_FTH1, characterized by a pro-inflammatory gene signature, was increased during CICRT. Moreover, CICRT induced higher expression of MHC-II-related molecules and chemotaxis-associated genes in CAFs compared to CCRT. **Conclusions:** The CICRT treatment group demonstrated a trend toward improved local control during the early phase of treatment compared to the CCRT group. Single-cell profiling revealed the differences in the potential to reshape the TME between CCRT and CICRT, with CICRT showing a greater ability to reduce immune suppression. Clinical trial information: ChiCTR2200067166. Research Sponsor: None.

Impact of pre-treatment counseling on uptake of hormone replacement therapy in patients undergoing chemoradiation for cervical cancer. First Author: Keizra Mecklai, NYU Langone, New York, NY

Background: Chemoradiation therapy (CRT) for cervical cancer can lead to premature ovarian insufficiency (POI) in premenopausal women, accelerating the onset of menopause and its related symptoms, and adversely affecting sexual health. This study aimed to assess the impact of pre-CRT counseling on the initiation of hormone replacement therapy (HRT) in patients with cervical cancer, and to describe common practice patterns in the management CRT-related side effects. **Methods:** This retrospective cohort study included patients treated for cervical cancer at four New York City hospitals (one public and three private) from 2010 to 2024. Patients were included if they underwent CRT as first-line treatment and were premenopausal before treatment initiation. Data were extracted from medical records including demographics, pretreatment counseling, CRT side effects, and HRT use. Descriptive statistics and chi-square were used for analysis, with $p<0.05$ as significant. **Results:** Of the 2,009 patients identified with a history of cervical cancer at our institutions, 81 premenopausal patients who underwent CRT were included, with a median age of 41.9 years at diagnosis. Prior to CRT, 69.1% of patients (n=56/81) were counseled on potential vaginal toxicity (e.g., stenosis/shortening), 63% (n=51/81) on the risk of POI, and 11.3% (n=9/81) on CRT's impacts on sexual health. Following treatment, 46.9% of patients (n=38/81) experienced menopausal symptoms, including vasomotor symptoms (84.2%, 32/38), vaginal dryness (36.8%, 14/38), and mood alternations (18.4%, 7/38). Among symptomatic patients, 55.3% (n=21/38) were prescribed HRT. Common regimens included vaginal estrogen (33.3%, 7/21) and combined estrogen/progestin pills (28.6%, n=6/21) followed by systemic estrogen patches (19%, n=4/21) and systemic estrogen pills (19%, n=4/21). Factors statistically significantly associated with HRT use after CRT included pre-treatment counseling on vaginal toxicity (X^2=13.77, p=0.008) and POI (X^2=13, p=0.011), as well as vaginal dilator use after CRT (X^2=31.68, $p<0.01$). Compared to patients at the public hospital, private hospital patients were more likely to be prescribed HRT (18.5% vs 40%, p=0.046). No significant differences were noted in HRT initiation rates by language (p=0.201), insurance type (p=0.234), or race (p=0.617). **Conclusions:** In this study we demonstrate that pre-CRT counseling on risks of vaginal toxicity and POI leads to a significant increase in HRT uptake after treatment. Further, we highlight a notable gap in counseling, as only two-thirds of premenopausal patients at our institutions undergoing CRT were counseled on side effects. To enhance patient care, vigilant screening on vaginal toxicity and vasomotor symptoms should be performed with each surveillance visit to ensure rapid treatment initiation and reduce morbidity from CRT. Research Sponsor: None.

Toripalimab with chemoradiotherapy followed by toripalimab maintenance therapy for newly diagnosed, high-risk, locally advanced cervical cancer (TorCH-CC): A single-arm phase II study. First Author: Shuangzheng Jia, Cancer Hospital Chinese Academy of Medical Sciences, Beijing, China

Background: Despite concurrent chemoradiation (CRT) being the standard treatment, patients with high-risk locally advanced cervical cancer (FIGO 2018 III-IVA, HR-LACC) experience suboptimal survival outcomes. This phase II clinical trial aimed to evaluate the efficacy and safety of toripalimab, an innovative and cost-effective PD-1 inhibitor, combined with CRT and followed by toripalimab maintenance, in patients with HR-LACC. **Methods:** Patients with untreated HR-LACC were enrolled. All patients were treated with cisplatin-based CRT combined with toripalimab, and followed by toripalimab maintenance therapy. Toripalimab is administered at a fixed dose of 240mg every 3 weeks intravenously, with the concurrent CRT and immunotherapy phase not exceeding 8 weeks. The primary endpoint was 2-year PFS rate, with secondary endpoints including overall response rate (ORR), duration of response (DoR), treatment-related adverse events (TRAEs), immune-related adverse events (irAEs), 2-year OS, and quality of life. **Results:** From October 2023 to December 2024, 43 patients were enrolled, with a median age of 52 years (range: 28–72). Most patients (79%) were at stage IIIC, while others were stage IIIB (16.3%) or IVB (with inguinal or supraclavicular lymph node metastasis, 4.7%). PD-L1 expression was CPS <10 in 32.6% and CPS ≥10 in 67.4%. All received VMAT radiotherapy and image-guided high-dose-rate intracavitary/interstitial brachytherapy, with 74.4% receiving 5-6 cycles of concurrent chemotherapy and 90.7% receiving 3 cycles of concurrent toripalimab. The median CRT duration was 52.7 days (range: 43–62), and the median D90 HR-CTV was 93.9 Gy (EQD2, range: 84–114). With a median follow-up of 8 months (range: 3–15 months), the ORR was 97.1% at 3 months post-treatment, with 32 complete and 2 partial responses, and 1 stable disease. The best ORR after CRT was 100%, with 41 complete and 2 partial responses. Grade 3 or 4 hematologic TRAEs occurred in 27.9% of patients, and non-hematologic in 2.3%, with no discontinuations or deaths. Grade 3 or 4 hematologic irAEs occurred in 7% of patients. **Conclusions:** Toripalimab combined with cisplatin-based CRT followed by toripalimab maintenance was well-tolerable and demonstrated promising antitumor efficacy in patients with HR-LACC. Trial registration: The study was registered at ClinicalTrials.gov, NCT06416696. Clinical trial information: NCT06416696. Research Sponsor: None.

Nimotuzumab with chemoradiotherapy for newly diagnosed, high-risk, locally advanced squamous cervical cancer (CC11): A prospective single-arm phase II study. First Author: Shuangzheng Jia, Cancer Hospital Chinese Academy of Medical Sciences, Beijing, China

Background: Cervical cancer ranks as the fourth most common cancer, with 32% of cases being locally advanced (stage IIB-IVA, LACC). The standard treatment is concurrent chemoradiotherapy (CCRT) with platinum drugs, but many patients only achieve partial or short-term remission. Nimotuzumab has shown promise in treating LACC, but few studies focus on high-risk cases (FIGO 2018 III-IVA). This study aims to evaluate the efficacy and safety of combining nimotuzumab with CCRT for high-risk LACC. (NCT06771596). **Methods:** Patients aged 18-75 with confirmed cervical squamous cell carcinoma, an ECOG status of 0-2, and at least one measurable lesion were eligible. All patients received nimotuzumab 400 mg weekly for 4-6 weeks combined with CCRT. CCRT included external beam radiotherapy (45 Gy/1.8Gy/25 fractions) using volumetric modulated arc therapy (VMAT), concurrent with weekly cisplatin (40mg/m^2 for 4-6 weeks), followed by image-guided high-dose-rate brachytherapy, aiming for a cumulative dose $\geq$87 Gy (EQD2). The primary endpoint was 1-, 2-year progression free survival (PFS) per RECIST 1.1. The secondary endpoints were 1-, 2-year overall survival (OS), objective response rate (ORR), disease control rate (DCR) rate per RECIST v1.1, and safety per CTCAE v5.0. **Results:** In total, 40 patients were enrolled. The baseline characteristics are shown in the table. 36 (90%) patients had CR, 3 (7.5%) patients had PR, ORR was 97.5% (95% CI: 86.84%-99.94%), and DCR was 97.5% (95% CI: 86.84%-99.94%). The median follow-up time was 21.32 months (95% CI: 20.01~24.34) months, with mPFS and mOS not yet reached. The 1-, 2-year PFS rates were 79.11% (95% CI: 62.53%-88.97%) and 76.29% (95% CI: 59.33%-86.91%), respectively, and 1-, 2-year OS rate were 100% (95% CI: 100%~100%) and 85.27% (95% CI: 64.8%~94.32%). The most common AEs were leukopenia (42.5%), myelosuppression (40%), and anemia (37.5%), all of which were graded 1-2. **Conclusions:** Nimotuzumab combined with chemoradiotherapy in the treatment of high-risk squamous LACC demonstrated prolonged PFS and favorable safety profile. Clinical trial information: NCT06771596. Research Sponsor: None.

Enlonstobart in patients with PD-L1 positive recurrent/metastatic cervical cancer: Updated survival results of the phase II study. First Author: Jing Zuo, National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China

Background: Enlonstobart is a PD-1 inhibitor that has demonstrated durable anti-tumor activity and acceptable safety in patients with PD-L1 positive recurrent/metastatic cervical cancer in a multicenter, single-arm, open-label, phase II study. At primary cutoff date (May 27, 2023), the overall survival (OS) was not reached. Here, we report results from a pre-planned further follow-up (August 20, 2024). **Methods:** Eligible patients were $\geq$18 years old with PD-L1-positive (combined positive score $\geq$ 1) cervical cancer who had progression during or after or intolerance to the first-line platinum-based therapy. A total of 107 patients received enlonstobart 240 mg every two weeks for up to 24 months or until disease progression, intolerable toxicities, or other study discontinuation criteria were met. At the updated cutoff date, analyses of progression-free survival (PFS) and OS in the full analysis set (FAS), which consisted of all patients who had received at least one dose of enlonstobart treatment, and the per protocol set (PPS), which consisted of all patients in the FAS who had at least one available postbaseline tumor assessment were conducted. **Results:** At the cutoff date of August 20 2024, the median follow-up time was 15.84 months (range 0.4 ~ 35.6 months). In FAS, the median PFS was 3.06 (95 % CI 2.23–6.90) months. The median OS was 19.38 (95 % CI 14.95–25.40) months and the estimated OS rate was 68.14 % (95 %CI 58.20–76.19) at 12 months, 50.78 % (95 % CI 40.46–60.20) at 18 months, and 42.84 % (95 % CI 32.76–52.53) at 24 months. In PPS, the median PFS was 3.81 (95 % CI 2.63–7.49) months. The median OS was 21.26 (95 % CI 15.44–27.66) months and the estimated OS rate was 71.53 % (95 %CI 61.48–79.40) at 12 months, 53.32 % (95 % CI 42.64–62.87) at 18 months, and 44.98 % (95 % CI 34.50–54.89) at 24 months. **Conclusions:** Enlonstobart monotherapy showed a promising survival in patients with PD-L1 positive recurrent/metastatic cervical cancer, whose disease experienced progression after first-line platinum-based therapy. Clinical trial information: NCT04886700. Research Sponsor: CSPC Zhongqi Pharmaceutical Technology Co., Ltd.

miRNA(s) expression as predictive biomarkers in recurrent/metastatic cervical cancer: The NRG Oncology/GOG-0240 NIH Cancer Moonshot. First Author: Alyssa Bujnak, University of California, Irvine, Orange, CA

Background: Chemotherapy + pembrolizumab +/- bevacizumab (BEV) is the standard treatment for recurrent/metastatic (R/M) cervical cancer (CC). GOG-0240 was a predecessor registration trial demonstrating survival benefit with incorporation of BEV with chemotherapy in R/M CC. In the wake of KEYNOTE A18, prior exposure to immunotherapy (I-O) via incorporation of pembrolizumab with ChemoRT for frontline therapy (FIGO stage III-IVA) may limit I-O use in 1st-line R/M CC. The need for new agents and predictive biomarkers to guide BEV use is implicit. Aberrant expression of miRNAs in CC can drive oncogenic pathways and/or suppress tumor suppressor genes, highlighting their potential as therapeutic targets. Here we present miRNA differential expression from the NIH Cancer Moonshot, which aims to identify biomarkers and predictors of survival outcomes in R/M CC through evaluation of miRNA differential expression among patients treated with Chemotherapy +/- BEV. **Methods:** miRNA-sequencing of R/M CC tumors from GOG-0240 was performed. miRNA expression was profiled and correlated with overall survival across all cohorts and differentials among tumors treated with ChemoRx+BEV or ChemoRx-alone were compared. **Results:** In the ChemoRx-alone group, lower expression of miR443 was associated with improved survival. miR-4443 may play a role in modulating tumor progression and metastasis through its impact on cell migration/invasion mechanisms. In the ChemoRx+BEV group, lower miR-196b-3p was associated with better overall survival. MiR-196b-3p has been implicated in the progression of various cancers, acting as an oncogene by regulating gene expression pathways that promote cell proliferation, inhibit apoptosis, and enhance metastatic potential. In the overall study population, higher expression of miR-10a and miR-1307 was associated with better survival. miR-1307 is thought to down-regulate ING5, which in turn may regulate the PIK3A pathway. In contrast, higher expression of several miRNAs, notably miR-584, mi-223, miR-144 was associated with worse survival. Multiple miRNAs that interact with ARID1A, VEGFA, and PIK3A were implicated. Higher expression of miR-223-5p was associated with worse outcomes. miR-223-5p is hypothesized to inhibit ARID1A expression and has been suggested to affect inflammatory response. Similarly, miR-144-5p and miR-144-3p are thought to affect both ARID1A and VEGFA. expression. Higher miR-144-3p expression was associated with lower survival, which may imply that more suppression of ARID1A expression by miR-144-3p results in a worse outcome. Finally, miR-193-5p negatively effects survival and is suggested to affect PIK3CA. **Conclusions:** Low expression of miR443 (ChemoRx-alone group) and miR196b-3p (ChemoRx+BEV group) track with survival in R/M CC and may serve as biomarkers to guide bevacizumab use in this orphan disease. Research Sponsor: National Cancer Institute/U.S. National Institutes of Health; 75N91019D00024.

An NCDB study examining disparities in the administration of immunotherapy among advanced cervical cancer patients. First Author: Alicia Youssef, Massachusetts General Hospital, Boston, MA

Background: The addition of immunotherapy (IO) to standard therapy has demonstrated substantial survival benefits in the upfront treatment of advanced cervical cancer. Our primary objective was to investigate the role of race on the administration of IO among patients with stage IV cervical cancer, following the publication of KEYNOTE-826 in 2021. Secondarily, we aimed to describe additional factors that may be associated with disproportionate administration. **Methods:** This was a retrospective cohort study utilizing the National Cancer Database (NCDB). We included all patients diagnosed in 2022 with stage IV adenocarcinoma, adenosquamous carcinoma, and squamous cell carcinoma of the cervix. Proportions were used to estimate the administration of IO. Multivariable models adjusted for age, insurance, education, Charlson-Deyo comorbidity scores, geography, distance to treatment center, as well as treatment facility type, location, and volume. **Results:** There were 937 cases identified, of which 368 (39.3%) received IO and 569 (60.7%) did not. A higher proportion of patients received IO at age $<$ 65 compared to $>$ 65 (74.5% vs 25.5%). Patients with Medicaid received IO at similar rates compared to privately-insured patients, at 33.4% verses 34.5%, respectively. When controlling for all other variables, higher education was associated with a greater likelihood of receiving IO (RR 1.46, CI 1.10 – 1.95, p=0.01). Patients with comorbidity scores $>$ 2 were less likely to receive IO than those with lower scores (RR 0.71, CI 0.52 – 0.98, p=0.038). Proportions of patients receiving IO in urban verses rural communities was also similar, at 33.3% and 39.4%, respectively. There were no significant differences in administration of IO associated with treatment center type (RR 1.05, CI 0.89 – 1.23, p=0.55) or volume (RR 0.95, CI 0.79 – 1.13, p=0.55). Mean distances to treatment centers were similar between patients who did and did not receive IO (29.31 vs 30.0 miles). Hispanic patients received IO at higher rates than non-Hispanic White, non-Hispanic Black, and Asian patients at a rate of 47.2% compared to 37.6%, 38.5%, and 38.1%, respectively. Even after adjusting for demographic and tumor factors, the increased receipt of IO among Hispanic patients could not be explained. **Conclusions:** Not only were there no racial disparities observed in the administration of IO among racial groups, but there were no disparities recognized among traditionally marginalized groups. Interestingly, the overall administration IO was lower than expected. The population included in KEYNOTE-826 had a PD-L1 combined positivity score of $>$1 among approximately 88% of participants. This difference in overall IO administration may be explained by PD-L1 positivity, however our study was limited by the lack of this data. Further investigation is warranted to understand trends in IO administration. Research Sponsor: None.

Clinicopathological and prognostic characteristics of gastric-type endocervical adenocarcinoma: A single-center retrospective study. First Author: Yang Liu, Obstetrics & Gynecology Hospital of Fudan University, Shanghai, China

Background: Gastric-type endocervical adenocarcinoma (G-EAC) is a rare and highly aggressive subtype of cervical cancer. Limited screening methods often lead to late-stage diagnosis, contributing to its poor prognosis. This study reviews cases of G-EAC managed at a tertiary gynecological oncology center over the past six years, focusing on prognostic characteristics and responses to adjuvant therapies. **Methods:** We reviewed demographic, pathological, clinical, and prognostic data from patients diagnosed with cervical adenocarcinoma and treated surgically at Obstetrics and Gynecology Hospital Fudan University from January 1, 2018, to December 31, 2023. G-EAC patients were assigned to the study group, while those with usual endocervical adenocarcinoma (UEA) served as the control. The groups were matched 1:1 using propensity score matching to compare prognosis. Primary endpoints were 3-year progression-free survival (PFS) and overall survival (OS). Kaplan-Meier and Cox regression analyses were used to assess survival, and univariate and multivariate analyses were conducted to identify risk factors for G-EAC. **Results:** A total of 960 patients were included in this study, comprising 195 cases of G-EAC and 765 cases of UEA. After matching, the G-EAC group exhibited significantly lower 3-year OS and PFS compared to the UEA group (OS: 74.9% vs. 84.6%, PFS: 66.1% vs. 79.8%, χ^2 = 4.59/6.04, p = 0.032/0.014). Parametrial involvement (OS/PFS: HR = 3.19/2.54, p = 0.003/0.009) and pelvic lymph node metastasis (OS/PFS: HR = 2.64/2.26, p = 0.012/0.013) as independent risk factors for death and recurrence in G-EAC patients. G-EAC patients treated with combined radiotherapy and chemotherapy had significantly better 3-year OS and PFS than those receiving either modality alone (OS: 74.3% vs. 54.5%, PFS: 65.2% vs. 43.6%, χ^2 = 4.86/4.23, p = 0.028/0.039). Cox regression analysis showed that G-EAC patients receiving radiotherapy or chemotherapy alone had significantly higher risks of death and recurrence compared to UEA patients (OS/PFS HR: 5.88/8.37, p = 0.037/0.009). Similarly, G-EAC patients treated with combined radiotherapy and chemotherapy exhibited slightly higher risks of death and recurrence than UEA patients (OS HR: 2.61 vs. 1.63, PFS HR: 3.91 vs. 2.66). **Conclusions:** G-EAC is a rare pathological subtype of cervical cancer with an exceptionally poor prognosis, significantly worse than that of UEA. Parametrial involvement and pelvic lymph node metastasis are independent risk factors for recurrence and death in G-EAC patients. Postoperative combined radiotherapy and chemotherapy reduce the risks of recurrence and death compared to single-modality treatments. However, G-EAC remains less responsive to adjuvant chemoradiotherapy than UEA. Further research to develop more effective therapeutic strategies for this rare and aggressive subtype. Adjuvant, neoadjuvant and surgical treatment for locally advanced cervical cancer: A network meta-analysis. First Author: Rafael Lara Nohmi, University of São Paulo, São Paulo, Brazil

Background: Concurrent chemoradiotherapy (CCRT) is the standard treatment for locally advanced cervical cancer (LACC). Alternative strategies, including induction chemotherapy followed by CCRT (IC + CRRT) and CCRT with immune checkpoint inhibitors (CCRT + ICI), have shown promising yet conflicting results. This study used a network meta-analysis (NMA) to compare the efficacy of these treatments. **Methods:** A systematic review identified RCTs published until November 25, 2024, comparing treatments for FIGO stage IB2-IVA LACC, including neoadjuvant chemotherapy, adjuvant chemotherapy (ACT), radiotherapy (RT), CCRT+ICI, surgery, or combinations. Progression-free survival (PFS) and overall survival (OS) were evaluated. Hazard ratios (HRs) were extracted or reconstructed from Kaplan–Meier curves using IPDfromKM. Bayesian NMA was conducted with random-effects models using the gemtc package. Three chains were run for 600,000 iterations, discarding the first 60,000 as burn-in. Results included 95% credible intervals (CrIs) for HRs. Treatment rankings were derived using the surface under the cumulative ranking curve (SUCRA), and probabilities of treatment superiority (SP) were calculated. **Results:** A total of 46 trials (49 reports) involving 13,895 patients were included in the analysis, with 89% having squamous cell histology. CCRT and RT were the most frequently used comparator treatments. Data from 39 trials (11,727 patients) were analyzed for OS, comparing 10 treatment regimens. CCRT significantly improved OS compared to RT (HR 0.76; 95% credible interval [CrI] 0.63–0.94) and showed a trend toward superiority over surgery (HR 0.71; 95% CrI 0.49–1.02; SP = 96.9%). However, no significant differences were observed between CCRT and either CCRT + ICI (SP = 6.2%) or IC + CCRT (SP = 28.3%). CCRT + ACT further improved OS compared to RT (HR 0.60) and surgery (HR 0.56). CCRT + ICI also demonstrated superiority over RT and surgery. Based on SUCRA scores, CCRT + ICI ranked highest for OS. For PFS, data from 37 trials (12,025 patients) were analyzed. CCRT demonstrated superiority over RT (HR 0.77; 95% CrI 0.65–0.92). No significant differences were observed between CCRT and other regimens, including CCRT + ICI (SP = 5.4%), IC + CCRT (SP = 34.1%), and CCRT + ACT (SP = 29.2%). Both CCRT + ACT and CCRT + ICI were superior to RT alone (HR 0.71 and HR 0.59, respectively). Additionally, CCRT + ICI was more effective than IC + RT. In a subgroup analysis of trials limited to squamous cell carcinoma, CCRT was superior to CCRT + ACT (HR 0.4; 95% CrI 0.2–0.85). Based on SUCRA scores, CCRT + ICI ranked highest for PFS. **Conclusions:** CCRT demonstrates consistent superiority in OS and PFS over RT and surgery, with comparable efficacy to regimens such as CCRT + ACT, IC + CCRT, and CCRT + ICI. These findings reaffirm CCRT's position as the cornerstone treatment for LACC, while supporting the potential of novel strategies in select populations. Research Sponsor: None.

A phase II study of anlotinib plus penpulimab as first-line treatment for persistent, recurrent, or metastatic cervical cancer: Results from ALTER-GO-020 trial. First Author: Dengfeng Wang, Sichuan Clinical Research Center for Cancer, Sichuan Cancer Hospital and Institute, Sichuan Cancer Center, Affiliated Cancer Hospital of University of Electronic Science and Technology of China, Chengdu, China

Background: In patients with recurrent, or metastatic cervical cancer, atezolizumab combined with bevacizumab and chemotherapy has significantly enhanced progression-free survival (PFS) and overall survival (OS) regardless of PD-L1 status. ALTER-GO-020 trial was designed to evaluate the efficacy and tolerability of anlotinib (a multitarget anti-angiogenic TKI) and penpulimab (anti-PD-1 antibody) as a chemotherapy-free regimen for patients (pts) with recurrent or metastatic gynecological cancer. This report presents the latest efficacy and safety data from the completed cervical cancer cohort. **Methods:** ALTER-GO-020 is a single arm, open-label, multi-cohort, multi-center phase II clinical study. In cervical cancer cohort, 26 pts were planned to be enrolled. Eligible pts were histologically confirmed persistent, recurrent, or metastatic cervical cancer (including adenocarcinoma, adenosquamous carcinoma, or squamous-cell carcinoma), not amenable to curative treatment, and had no prior systemic treatment for metastatic, persistent, or recurrent disease. Pts were treated with anlotinib (12mg, po qd, d1-14, q3w) plus penpulimab (200mg, IV, d1, q3w) until disease progression or unacceptable toxicity. The primary endpoint was objective response rate (ORR) and the secondary endpoints included PFS, duration of response (DOR), disease control rate (DCR), OS and safety. **Results:** 26 pts were enrolled. The median age was 52 years (range, 31-70), 65% of pts were squamous-cell carcinoma, 88% received previous chemoradiotherapy with or without surgery, and 71% had previously received neoadjuvant/adjuvant platinum-containing chemotherapy. As of date cutoff (Dec, 2024), the median follow-up time was 11.7 months (range, 1.3-30.0 months). In the efficacy analysis (n=26), the preliminary ORR was 50% (95% CI: 32.1%-67.9%), DCR was 92.3% (95% CI: 75.9%-98.6%). The mPFS was 11.0 months (95% CI: 5.8m-16.2m months). The mOS was not reached. Treatment-related adverse events (TRAEs) of any grade occurred in all 26 pts, in which 12 (46.2%) were grade $\geq$3. The most common grade $\geq$3 TRAEs were hypertension (19.2%), hand foot syndrome (11.5%), fatigue (3.8%), and diarrhea (3.8%). TRAEs led to dose reduction and interruption were 15.4%, and 38.5% of pts, respectively. No TRAEs leading to death. **Conclusions:** Anlotinib combined with penpulimab as a chemotherapy-free regimen showed a significant improvement in ORR, a trend towards longer PFS, and favorable safety in the treatment of pts with recurrent or metastatic cervical cancer. Clinical trial information: NCT05028504. Research Sponsor: None.

Preliminary results of ZG005, a bispecific antibody targeting PD-1 and TIGIT, as monotherapy in patients with advanced cervical cancer. First Author: Hanmei Lou, Zhejiang Cancer Hospital, Hangzhou, China

Background: ZG005, a PD-1 and TIGIT dual-specific antibody, is a promising immunotherapy for tumors. By blocking both pathways, it can synergistically activate T cells and enhance the anti-tumor activity of NK cells. Preliminary results of this first-in-human (FIH) study were presented at ASCO 2023 and ASCO 2024. Here, we report the efficacy and safety results in patients with advanced cervical cancers. **Methods:** Following the dose-escalation phase, patients with specified tumor types were enrolled into dose-expansion stage. Within each tumor type cohort, subjects were randomized 1:1 to receive ZG005 10 mg/kg Q3W or 20 mg/kg Q3W by intravenous infusion. Efficacy was assessed by both the investigator and the independent radiology committee (IRC) according to RECIST v1.1. **Results:** As of December 05, 2024, a total of 55 patients with advanced cervical cancer had been randomized to receive at least one dose of ZG005 10 or 20 mg/kg. The median age was 52.0 years. Of these patients, 98.2% had failed to at least one prior line of therapy, and 24.7% had previously received immune checkpoint inhibitor (ICI) treatments. 87.3% patients were squamous cell carcinoma, 9.1% adenocarcinoma and 3.6% adenosquamous carcinoma. Among the total 22 patients on the 20 mg/kg group who hadn't treated any prior ICI treatments before, 3 achieved a complete response (CR) and 6 partial responses (PR) per the IRC's assessments. The confirmed objective response rate (ORR) was 40.9%, and the disease control rate (DCR) was 68.2%. The median progression free survival (mPFS) has not yet been reached. Among the 55 patients for the safety analyses, 46 (83.6%) reported treatment related adverse events (TRAEs), with 5 (9.1%) grade 3-4, including one patient each with hypocalcemia, myositis, rash, hypertension and anemia. Serious adverse events (SAEs) occurred in 8 subjects (14.5%), with one myositis case (1.8%) was the only SAE related to ZG005 and also the sole TRAE that led to treatment discontinuation. No death was attributed to ZG005. Grade 3-4 Immune-related adverse events (irAEs) were observed in 4 patients (7.3%), including myositis, rash, hypertension and anemia. No new safety signals were observed compared with other ICIs. **Conclusions:** ZG005 has demonstrated a tolerable safety profile and promising anti-tumor activity at the 20 mg/kg dose as monotherapy in patients with advanced cervical cancer. Clinical trial information: NCT06233293. Research Sponsor: None.

Preliminary results of ZG005, a bispecific antibody targeting PD-1 and TIGIT, in combination with chemotherapy with or without bevacizumab as first-line treatment for advanced cervical cancer. First Author: Hanmei Lou, Zhejiang Cancer Hospital, Hangzhou, China

Background: ZG005, a PD-1 and TIGIT dual-specific antibody, is a promising immunotherapy for tumors. By blocking both pathways, it can synergistically activate T cells and enhance the anti-tumor activity of NK cells. This report presents the results for the combination of ZG005 and the chemotherapy with or without bevacizumab as a first-line systematic treatment in patients (pts) with advanced cervical cancer. **Methods:** ZG005-003 was a multicenter, open-label, phase I/II clinical trial. In the Part 1, the escalating doses were 10 mg/kg and 20 mg/kg. In the Part 2, pts were randomized at 1:1 ratio to receive ZG005 at 10 mg/kg or 20 mg/kg in combination with the standard chemotherapy (paclitaxel [175 mg/m^2] plus carboplatin [AUC 5] or cisplatin [50 mg/m^2]), with or without bevacizumab (15 mg/kg) every 3 weeks for six cycles, followed by the maintenance therapy of ZG005 with or without bevacizumab for up to 2 years. Safety and efficacy (per RECIST v1.1) were assessed. **Results:** As of December 19, 2024, the Part 1 had completed and the Part 2 was ongoing, a total of 41 pts had been enrolled for the both Parts, with 12 pts in Part 1 and 29 pts in Part 2. The median age was 54 years, and 87.8% of pts were squamous carcinoma. 53.7% of pts received bevacizumab during the trial. No dose-limiting toxicity (DLT) were observed during the Part 1. Among all the 41 pts, 31 (75.6%) experienced treatment-related adverse events (TRAEs) which attribute to ZG005. Most TRAEs were grade 1-2, while 12 pts (29.3%) reported grade 3 or higher TRAEs. There was no treatment discontinuation or death due to TRAEs. Only one serious adverse event (SAE) of bilateral lung pneumonia in the 10 mg/kg group was assessed related to ZG005 by the investigator. No ZG005-related SAE was reported in the 20 mg/kg group. Of the 28 pts evaluable for efficacy, 13 on 10 mg/kg and 15 on 20 mg/kg, the unconfirmed overall response rates (ORR) was 69.2% for the 10 mg/kg group, and 80.0% for the 20 mg/kg group. **Conclusions:** ZG005 in combination with the chemotherapy, with or without bevacizumab, demonstrated favorable safety and tolerability profiles at both 10 mg/kg and 20 mg/kg dosages. Additionally, this regimen exhibited a significant antitumor activity in first-line cervical cancer pts, with the 20 mg/kg dose group showing a notably better efficacy in comparison with the 10 mg/kg dose group. Clinical trial information: NCT06241235. Research Sponsor: None.

Induction cadonilimab combined with chemotherapy followed by chemoradiotherapy for locally advanced cervical cancer: A multicenter, single-arm, phase II trial. First Author: Lin Ding, Sun Yat-sen University Sun Yat-sen Memorial Hospital, Guangzhou, China

Background: Short-course weekly induction chemotherapy followed by chemoradiotherapy (CCRT) improves survival for locally advanced cervical cancer (LACC) in the CxII and INTERLACE trial. However, only 70% patients achieved objective response (CR or PR) whereas 20% grade 3-4 adverse events were reported during induction chemotherapy in the CxII study. Cadonilimab is a bi-specific antibody targeting both PD-1 and CTLA-4. The COMPASSION-16 trial has recently demonstrated the encouraging effectiveness and safety of cadonilimab combined with chemotherapy in recurrent/metastatic cervical cancer. This study was aimed to assess the combination of induction cadonilimab and chemotherapy before CCRT. **Methods:** In this multicenter, single-arm, phase 2 study, we used a Simon two-stage design. Previous studies of induction chemotherapy showed a ORR of 68.8%-80% in LACC. Null hypothesis of ORR 80% was adopted in this study. Estimating a ORR of 95% would be achieved following induction therapy, a total of 29 patients (including 9 in the first stage) were required with type I and type II errors set at 0.05 and 0.2, respectively. Eligible patients were women aged 18 years or older, newly diagnosed disease with stage IB3-IVA (International Federation of Gynecology and Obstetrics [FIGO] 2018), with histologically confirmed cervical carcinoma, and had an ECOG performance status of 0 or 1. Patients received 2 cycles of induction therapy consisting of cadonilimab at a dose of 10mg/kg plus nab-paclitaxel at a dose of 260 mg/m² and cisplatin at a dose of 75mg/m² followed by CCRT. The primary endpoint was objective response rate (ORR) at 2 weeks after the completion of induction therapy and secondary endpoints included progression-free survival (PFS) and overall survival (OS). **Results:** Between January and October 2024, 29 patients were enrolled, with a median age of 58 years (range 32–70). All patients were ECOG performance status of 1. Of these, 26 had squamous cell carcinoma, and 3 had adenocarcinoma. FIGO stages included stage II (9 [31.0%]), III (18 [62.1%]), and IVA (2 [6.9%]). As of January 19, 2025, 26 patients completed CCRT. Median PFS and OS were not reached. At 2 weeks post-induction therapy, ORR was 93.1% (27 PR, 2 SD). Thirteen patients underwent evaluation at 3 months post-CCRT, all achieving CR (100%). Grade 3–4 treatment-related adverse events occurred in 10.3% of patients (3/29), including leukopenia (n=2) and primary adrenal insufficiency (n=1) during induction therapy. **Conclusions:** Cadonilimab combined with chemotherapy as induction therapy shows promising anti-tumor activity and manageable safety profile in LACC patients. These findings suggest the potential of induction chemoimmunotherapy followed by CCRT and warrants further follow-up. Clinical trial information: NCT06511726. Research Sponsor: None.

A real-world analysis of the effectiveness of pembrolizumab by type of associated treatment in patients with metastatic cervical cancer: Added value of bevacizumab. First Author: Alberto Farolfi, IRCCS Istituto Romagnolo per lo Studio dei Tumori (IRST) "Dino Amadori", Meldola, Italy

Background: Pembrolizumab (pembro) showed a statistical significant survival benefit in persistent, recurrent, or metastatic cervical cancer (CC) when added to chemotherapy. In this real-world study we aimed to evaluate if the effectiveness of pembro may vary according to the type of platinum used or by the incorporation of bevacizumab (bev). **Methods:** The analysis was conducted with the TriNetX Global Collaborative Network. In our study, we defined different cohort of patients by type of platinum (cisplatin or carboplatin) and bev use (yes or no). First, we compared 597 CC patients treated cisplatin with 1.080 CC patients treated with carboplatin, in addition to paclitaxel and pembro. After this analyses, we evaluated the addition of bev (701 patients) to a platinum-based regimen compared to a cohort of patients treated without bev (562 patients). A propensity score matching (PSM) was used to balance the cohorts by age, race, previous radiotherapy, body mass index and treatment (bev for first analyses and cisplatin for the second). Subsequently, a COX analyses, adjusted for the same factors, was used in unmatched cohorts to validate our results. Hazard ratio (HR) was used to compare the overall survival (OS) and the development of fistulae, bowel perforation or pulmonary embolism (PE) in the matched cohorts. **Results:** PSM generated 583 pairs of CC patients treated with cisplatin (mean age of 50.6, +/-12.6 standard deviation, SD) or carboplatin (mean age of 50.2, +/-12.7 SD). Median OS was not statistical different between the groups (HR 0.92, 95% CI 0.75-1.28), confirmed also by the Cox model (HR 0.95, 95% CI 0.79-1.15). Among the 386 matched pairs of CC patients treated with (mean age of 53.8, +/-13.1 SD) or without bev (mean age of 53.8, +/-13.4 SD), median OS was 35.7 months versus 20.1 months (HR 0.64, 95% CI 0.49–0.84, p = 0.001), without differences in the rate of fistulae (HR 0.77, 95% CI 0.50-1.18), but an increased risk in bowel perforation (HR 3.08, 95% CI 1.01-9.38, p = 0.037) and a lower risk of PE (HR 0.57, 95% CI 0.35-0.93, p = 0.022). In multivariate analyses, bev significantly reduced the risk of death (HR 0.75, 95% CI 0.61-0.94, p = 0.01). **Conclusions:** The survival rates associated with immunotherapy treatment in our real-world study are consistent with those reported in previous studies. Specifically, we showed that the effectiveness of pembro is not influenced by the type of platinum used. However, the addition of bev may extend OS in patients with CC, without increasing the risk of fistulae or PE. Research Sponsor: None.

A non-invasive metabolomic biomarker for detecting cervical intraepithelial neoplasia and cervical cancer. First Author: Jihoon Kang, Oncocross., Ltd., Seoul, South Korea

Background: Cervical intraepithelial neoplasia (CIN) is a precancerous lesion that can progress to cervical cancer, a leading malignancy affecting women worldwide. Although current screening strategies and diligent follow-up are essential for identifying high-grade CIN, there remains a critical need for minimally invasive tests to aid in both early detection and disease monitoring. This study evaluated the utility of a blood-based metabolomic liquid biopsy for differentiating CIN from cervical cancer and investigated the role of 2,3,6-Trichlorobenzaldehyde as a novel biomarker. **Methods:** From September 2023 to December 2024, 177 participants (cervical cancer, n=18; CIN, n=49; healthy controls, n=110) were enrolled at Soonchunhyang University Hospital in Cheonan, South Korea. All participants were adults ($\geq$18 years) with no cancer history in the previous five years and were not receiving anticancer therapy at the time of serum collection. Serum samples underwent untargeted metabolomic profiling via headspace gas chromatography–mass spectrometry (GC–MS). Relative metabolite abundances were compared among the groups, and pairwise t-tests ($p < 0.05$) assessed statistical significance. **Results:** Six metabolites demonstrated strong detection and classification performance, with 2,3,6-Trichlorobenzaldehyde emerging as the most prominent biomarker. This metabolite effectively differentiated among cervical cancer, CIN, and healthy controls (ANOVA, $p < 0.0001$). Specifically, 2,3,6-Trichlorobenzaldehyde yielded a sensitivity of 94.5% and a specificity of 95% for detecting cervical cancer, and a sensitivity of 95.9% and a specificity of 95% for identifying CIN. It also significantly distinguished Stage I cervical cancer from CIN grades 1, 2, and 3, as well as from adenocarcinoma in situ (AIS) (t-test, $p < 0.0001$). Five additional metabolites—p-Xylene, 3,6,9,12-Tetraoxahexadecan-1-ol, Ethylbenzene, Indole, and Cyclohexanone—were significantly elevated in both the cervical cancer and CIN groups compared to healthy controls (t-test, $p < 0.0001$), although they did not differ substantially between the cancer and CIN groups (t-test, $p > 0.05$). **Conclusions:** These findings highlight 2,3,6-Trichlorobenzaldehyde as a promising candidate for a blood-based metabolomic panel aimed at distinguishing cervical cancer from CIN and healthy controls. A minimally invasive assay incorporating this biomarker may improve cervical disease screening, refine risk stratification, and support continuous disease surveillance. Further prospective validation in larger cohorts is warranted to establish its clinical applicability. Research Sponsor: None.

GT101 autologous TIL therapy in patients with recurrent and metastatic cervical cancer: A phase 1 study. First Author: Haifeng Qin, The Fifth Medical Centre of Chinese PLA General Hospital, Beijing, China

Background: GT101 is Grit's tumor-infiltrating lymphocyte (TIL) product. Adoptive cell therapy using autologous TILs has shown efficacy and long-term responses in patients with certain advanced solid tumors that have progressed after conventional therapies. We present data from 11 patients with recurrent or metastatic cervical cancer enrolled in a Phase 1, open-label, single-arm, multicenter trial (NCT05430373) of GT101. The study aims to investigate the safety profile, efficacy trends, and duration of response. **Methods:** Eleven patients with recurrent or metastatic cervical cancer were enrolled in the study, receiving a lymphodepletion regimen followed by GT101 infusion and IL-2 administration. The study's primary endpoints were treatment-emergent adverse events (TEAEs), including serious adverse events (SAEs) and adverse events (AEs), assessed using the CTCAE version 5.0 grading scale. Secondary endpoints included objective response rate (ORR), disease control rate (DCR), progression-free survival (PFS), duration of response (DoR), and overall survival (OS) based on RECIST version 1.1. **Results:** As of August 1, 2024, 11 patients received treatment, with a median age of 48 years and two prior therapy lines. Following FC lymphodepleting chemotherapy, patients received GT101 infusion at doses of $\geq 5\times10^9$ viable cells, with a median dose of 4.1×10^{10} viable cells, followed by high-dose IL-2 (600,000 IU/kg, up to 6 doses). Most adverse events (AEs) were Grade 1 or 2. Grade $\geq$3 AEs, primarily related to lymphodepleting chemotherapy and IL-2, included decreased lymphocyte, white blood cell, and neutrophil counts, anemia, pyrexia, and decreased platelet count. Most Grade $\geq$3 AEs resolved or downgraded to Grade $\leq$2 within 14 days. Among 11 cervical cancer patients, the objective ORR was 45.5% (5/11), with disease control in 10/11 patients (90.9%). Four patients (36.4%) had confirmed PR, one (9.1%) achieved CR, and five (45.5%) had SD; one patient had unconfirmed PD. The median PFS was 4.83 months, and median OS has not yet been reached. A patient with CR maintained this response for 14.5 months, diagnosed with stage IIIC2 cervical squamous cell carcinoma, and underwent surgical resection of metastatic lymph nodes. The SOD at baseline was 71.57 mm, reduced to 29.12 mm after 28 days. At week 12 post-GT101 treatment, imaging showed complete response of the lesion, achieving CR. **Conclusions:** In the GT101 Phase 1 study, no treatment-related SAEs or DLTs were observed. GT101, infused after FC lymphodepleting chemotherapy and high-dose IL-2, exhibited a manageable safety profile. It demonstrated clinically meaningful activity and durable responses in patients with recurrent and metastatic cervical cancer. These promising results indicate favorable long-term survival outcomes, durable responses, and no long-term safety concerns related to GT101. Clinical trial information: NCT05430373. Research Sponsor: None.

Management of loop electrosurgical excision procedure with positive margins. First Author: Christopher M Mayer, University of Alabama at Birmingham, Birmingham, AL

Background: Loop Electrosurgical Excision Procedure (LEEP) is a primary management for preinvasive cervical disease. While often successful, around 10% will have disease extend to the margin of the LEEP specimen, leaving the possibility of pathology extended beyond the excised region. The American Society for Colposcopy and Cervical Pathology (ASCCP) provides management options for LEEP with positive margins, which include hysterectomy, repeat LEEP, or follow-up in 6 months with either: HPV-based testing or colposcopy with endocervical curettage. Limited data exists in the comparison of management options. **Methods:** This retrospective study included patients with cervical preinvasive disease referred to a single academic institution between 1/2022 to 12/2024 who underwent LEEP found to have a positive margin. Demographics and pathology results were obtained from medical records. The primary outcome was follow-up colposcopy pathology in patients who had a positive margin from LEEP. Statistical analysis was performed using GraphPad. **Results:** 67 patients underwent follow-up colposcopy after a LEEP with a positive margin. At time of LEEP, the median age was 34.5 years with 36% Hispanic, 34% African American, 22% White, and 2% Asian. With HPV status prior to LEEP, 72% were non-genotyped high risk (HR), 6% HPV16+, 6% HPV18+, and 3% were other HR+. Positive margins were either CIN 2 (N=12) or CIN 3 (N=55) and either endocervical (N=40), peripheral (N=15), both endocervical and peripheral (N=7), or unspecified (N=5). Pathology at follow-up colposcopy was primarily negative/low-grade disease (83.6%) with a minority being high-grade disease (16.4%). CIN 2 or CIN3 at the margin was not associated with high-grade disease on follow-up colposcopy (0% vs. 26.7%; p=0.108). The median age at time of LEEP did not significantly differ between CIN 2 or CIN3 positive margins (37.5 vs 34.9y; p=0.274) and was not associated with negative/low-grade or high-grade disease at follow-up colposcopy (38.4 vs 35.7y, p=0.251). Race was not associated with high-grade disease on follow-up colposcopy (p=0.239). There was no difference between high-grade lesion on colposcopy and location LEEP positive margin (p=0.998). HPV 16+ or 18+ was not associated with high-grade pathology at follow up colposcopy (p=0.289). **Conclusions:** In our diverse population, the prevalence of high-grade disease on follow-up colposcopy is low regardless of having CIN 2 or CIN 3 at any margin at time of LEEP. Numerically, CIN 2 margins were less likely to have positive high-grade colposcopy when compared to CIN 3 margin. Race nor age were associated with high-grade disease on follow-up colposcopy. While ASCCP offers follow-up repeat colposcopy in the setting of positive margins, prospective studies could be beneficial in determining if less-invasive options, such as HPV testing are sufficient for follow-up in this population. Research Sponsor: None.

Global cervical cancer outcomes and national cancer system characteristics. First Author: Erin Jay Garbes Feliciano, Department of Medicine, NYC Health + Hospitals/Elmhurst, Icahn School of Medicine at Mount Sinai, Queens, NY

Background: Significant global health disparities persist in cervical cancer, with over 85% of cases and deaths occurring in low- and middle-income countries (LMICs). In many settings, access to screening, vaccination, and treatment is limited. Despite being largely preventable through HPV vaccination and early detection, many women around the world still face inadequate healthcare infrastructure, lack of awareness, cultural stigma, and gender barriers to seeking care. Therefore, we evaluated global health system metrics that may inform efforts to improve equity in access to cervical cancer care globally. **Methods:** Estimates of age-standardized mortality-to-incidence ratios (MIR) were derived from GLOBOCAN 2022 for female patients of all ages with cervical cancer. We collected health spending as a percent of gross domestic product, physicians/1000 population, nurses and midwives/1000 population, surgical workforce/1000 population, GDP per capita, Universal Health Coverage Service Coverage Index (UHC index), availability of pathology services, human development index (HDI), gender inequality index (a combined metric of health, empowerment, and economic agency), radiotherapy centers/1000 population, and out-of-pocket expenditure as percentage of current health expenditure. We evaluated the association between MIR and each metric using univariable linear regressions. Metrics with $p<0.0045$ (Bonferroni corrected) were included in multivariable models. Variation inflation factor (VIF) allowed exclusion of variables with significant multicollinearity. R2 defined goodness of fit. **Results:** On univariable analysis, all 11 metrics were significantly associated with MIR of cervical cancer (<0.001 for all). After including metrics that were significant on univariable analysis, HDI demonstrated significant collinearity (VIF=19). Therefore, after correcting for multicollinearity, the final multivariable model with 10 variables had R2 of 0.79. On multivariable analysis, the following variables were independently associated with lower (improved) MIR for cervical cancer: 1) nurses/midwives per 1000 population ($\beta=-0.0071$, p=0.029) and 2) UHC index ($\beta=-0.0023$, P=0.013). In addition, greater gender inequality was associated with greater (worse) MIR ($\beta=0.30$, P=0.002). **Conclusions:** This global analysis of health-system metrics suggests promoting progress towards UHC and strengthening the nursing/midwifery workforce may be independently associated with improved cervical cancer mortality-to-incidence ratio. Furthermore, greater gender inequality was associated with worse MIR. These findings may inform further efforts to improve global cervical cancer care and underscore the importance of gender equity in improving global cancer outcomes. Research Sponsor: None.

Atezolizumab and stereotactic body radiation in metastatic, recurrent, or persistent cervical cancer: Results from a phase II multi-institutional study. First Author: Kamran A. Ahmed, H. Lee Moffitt Cancer Center and Research Institute, Tampa, FL

Background: Pembrolizumab is approved for PD-L1+ but not PD-L1 negative metastatic, recurrent, or persistent cervical cancer. Response rates to single agent anti-PD-1/PD-L1 therapy have been modest with no responses noted in PD-L1 negative tumors. **Methods:** The study is designed as a prospective, phase II multi-institutional trial of SBRT followed by atezolizumab (1200 mg intravenously q3 weeks). Key eligibility criteria included patients with metastatic, recurrent, or persistent cervical cancer with at least 2 distinct lesions. The primary objective was objective response rate measured at the unirradiated target lesion. Secondary endpoints included overall response, progression free survival (PFS), overall survival (OS), and adverse events. Clinical trial information: NCT03614949. **Results:** A total of 21 patients were enrolled. Median follow-up is 23.6 months. The majority of patients had adenocarcinoma (n=10; 48%) and were PD-L1 negative (n=15; 71%). The best overall response was a partial response in 5 (24%) and stable disease in 12 (57%) patients. The median duration of response was 8.6 months (95% CI: 4.5-13.6 months). An objective response at the unirradiated target lesion was observed in 8 patients (38%), meeting the study defined endpoint. Responses were noted in PD-L1 negative tumors. The median PFS was 4.7 months (95% CI: 3.9- 7.4) with a 6-month PFS of 48%. The median OS was 26 months (95% CI 7.6 – 54) with a 6-month OS of 76%. No differences were noted in OS or PFS by PD-L1 status. The most common grade $\geq$ 2 toxicities at least possibly attributed to study therapy included lymphopenia (n=6; 29%), nausea/vomiting (n=3; 14%), and hyponatremia (n=3; 14%). **Conclusions:** In this first trial of SBRT and atezolizumab in metastatic cervical cancer unselected for PD-L1, combination therapy was well tolerated. Responses were noted in PD-L1 negative tumors. Combination therapy may allow for improved response rates to immune checkpoint inhibition in metastatic cervical cancer particularly in PD-L1 negative tumors. Clinical trial information: NCT03614949. Research Sponsor: Genentech; ML40521.

Real-world efficacy and safety of cadonilimab (PD-1/CTLA-4 bispecific antibody) in patients with advanced, recurrent, and metastatic cervical cancer. First Author: Dapeng Li, Shandong Cancer Hospital and Institute, Shandong First Medical University and Shandong Academy of Medical Sciences, Jinan, China

Background: Immune checkpoint inhibitors have become one of the important treatment modalities for advanced, recurrent and metastatic cervical cancer (A/R/M CC). Cadonilimab, a PD-1 and CTL-4 bispecific antibody, has showed considerable efficacy for treatment of A/R/M CC. This study aims to investigate the real-world efficacy and adverse event profile of cadonilimab in the treatment of A/R/M CC. **Methods:** We enrolled patients with histologically confirmed CC, who had received at least two cycles of cadonilimab for A/R/M disease and had imaging evaluation at Department of Gynecologic Oncology in Shandong Cancer Hospital and Institute in China, between July 2022 and March 2024. Efficacy including objective response rate (ORR), disease control rate (DCR), progression-free survival (PFS), overall survival (OS) and adverse events (AEs) were analyzed. **Results:** 96 patients treated with cadonilimab monotherapy or cadonilimab plus chemotherapy with/without radiotherapy were enrolled. The median follow-up duration was 12.5 months. The overall ORR was 69.8%, the DCR was 89.6%. (Table 1). The median PFS was 12 months (95%CI 8.4-15.6), and the median OS was not reached. The ORR of first and second line's treatment was 77.7% and 56.6%, respectively. DCR was 91.7% and 80.0%, respectively. Among the 18 patients treated with third-line and above, four (22.2%) patients achieved CR, ORR was 72.2%, and DCR was 88.8%. Among all patients, PD-L1 positive patients had a higher ORR (74.4%, P=0.049). Comparing with non-SCC, patients with SCC had better ORR (78.6% vs.38.0%, P=0.001). It's also worth noting that, among 19 patients who had progressed on first or second line's therapy of PD-1 monospecific antibody, cadonilimab mono or combination therapy achieved an overall ORR of 63.1% (1 CR, 11 PR) and a DCR of 94.7%, and a median PFS of 15.2 months (95% CI 5.7-24.7). Among them, 16 patients with SCC had a 100% DCR and a median PFS of 15.2 months (95%CI 5.1-25.3). The incidence of immune-related adverse events (irAEs) was 33.3%, mainly including 21 hypothyroidism (21.9%), seven hyperthyroidism (7.3%), etc. Two (2.1%) had ≥ grade 3 irAEs (one pneumonia and one myocardial injury). No death was caused by irAEs. **Conclusions:** Cadonilimab showed encouraging efficacy and manageable safety in the treatment of A/R/M CC in real world, even in patients with PD-L1 negative. And it also present promising disease control in patients who have progressed on previous PD-1 monospecific antibody. Research Sponsor: None.

The best overall response, PFS and OS in first-, second-, ≥ third-line and total patients.

Best overall response, PFS and OS	First-line (n=48)	Second-line (n=30)	≥Third-line (n=18)	Total
CR (%)	16.6	16.6	22.2	17.7
PR (%)	60.4	40.0	60.0	52.0
ORR (%)	77.7	56.6	72.2	69.8
DCR (%)	91.7	80.0	88.8	89.6
mPFS (months)	12.0	8.9	18.7	12.0

Integrative analysis of VB10.16 and atezolizumab in advanced HPV16-positive cervical cancer: Linking biomarker insights to clinical outcomes. First Author: Kristina Lindemann, Department of Gynecological Oncology, Oslo University Hospital & Institute of Clinical Medicine, Faculty of Medicine, University of Oslo, Oslo, Norway

Background: Therapeutic cancer vaccines combined with immune checkpoint inhibitors offer a promising strategy to enhance anti-tumor responses. We recently demonstrated the safety and clinical efficacy of VB10.16, a DNA-based therapeutic cancer vaccine encoding HPV16 E6/E7 oncoproteins fused to CCL3L1 for antigen-presenting cell targeting, in HPV16-positive persistent, recurrent or metastatic cervical cancer[1]. This analysis explores the association between HPV16-specific T cell responses, tumor microenvironment (TME) characteristics, and clinical outcomes in the phase 2a trial. **Methods:** In this multicenter, open-label trial, 52 patients with advanced HPV16-positive cervical cancer received VB10.16 (3 mg intramuscularly) combined with atezolizumab (1200 mg intravenously) for up to 48 weeks. Primary endpoints were safety and objective response rate per RECIST v1.1. Secondary endpoints included overall survival (OS) and HPV16-specific T cell responses via IFN-γ ELISpot (n=36). Predefined exploratory endpoints included systemic immunosuppression and TME inflammatory status in baseline tumors, assessed via myeloid cell counts (baseline to ~week 9, n=47), flow cytometry (T cell/myeloid-derived suppressor cells [MDSC] ratio, n=21), and gene expression analyses (n=29). **Results:** Patients with reduced on-treatment systemic immunosuppression demonstrated stronger HPV16-specific T cell responses than patients without (myeloid cell counts decreased in 17/47 patients; T cell/MDSC ratio increased in 12/21 patients). On-treatment reduction in systemic immunosuppression was associated with a higher clinical benefit rate (complete response [CR]/partial response [PR]/stable disease [SD] in 17/28 vs 4/19 patients by myeloid counts and 10/12 vs 2/9 by T cell/MDSC ratio), suggesting associations between T cell response, systemic immunosuppression and effect of immunotherapies. Among the 9 responders in the efficacy population (n=47; 3 CR; 6.4% and 6 PR; 12.8%), 5 patients had available gene expression data from baseline tumors. Patients with pro-inflammatory/proliferative TME signatures demonstrated higher CR/PR rates (4/14 vs. 1/15) and longer OS compared to patients with stromal/immunosuppressive signaling (mOS not reached vs 8.3 months). Clinical benefit was also observed in stromal/immunosuppressive TMEs (1/15 CR, 6/15 SD), highlighting VB10.16's potential to overcome local immunosuppression. **Conclusions:** VB10.16 combined with atezolizumab induces durable responses, mitigates local and systemic immunosuppression, and demonstrates synergy between biomarkers and clinical outcomes. High CR/PR rates with favorable immune and TME characteristics highlight the promise of this combination therapy, warranting further exploration. [1]Hillemanns P *et al*, 2025 doi:10.1136/jitc-2024-010827. Clinical trial information: NCT04405349. A meta-analysis of induction chemotherapy (ICT) followed by chemoradiotherapy for locally advanced cervical cancer: The role of ICT type and duration on efficacy outcomes. First Author: Matheus de Oliveira Andrade, Instituto do Câncer do Estado de São Paulo (ICESP), Faculdade de Medicina da Universidade de São Paulo (FMUSP), São Paulo, Brazil

Background: The treatment of locally advanced cervical cancer (LACC) is based on concomitant chemotherapy and radiotherapy (CCRT). While the recent incorporation of pembrolizumab for stage III-IVA disease has expanded treatment options, immunotherapy remains inaccessible in many regions with high cervical cancer prevalence. The addition of induction chemotherapy (ICT) prior to CCRT is controversial, as trials have yielded conflicting results. This study aims to evaluate the impact of the type and duration of the ICT for LACC. **Methods:** We systematically searched PubMed, Embase and Cochrane for studies with patients diagnosed with LACC receiving ICT followed by CCRT. Studies that included surgery, definitive radiotherapy (without concurrent chemotherapy), or immunotherapy were excluded. We compared ICT regimens between each other based on drug type and duration, and conducted a meta-analysis of trials comparing ICT followed by CRT versus CRT alone. Meta-analyses were carried out using random-effects model, with heterogeneity assessed via I^2 statistics and Cochran's Q test. Sensitivity analyses were performed using the leave-one-out approach, and meta-analyses of proportions with subgroup analyses. **Results:** Among 5,282 screened studies, 20 met the inclusion criteria, representing 1,543 patients treated with ICT. Meta-analysis of proportions revealed a 2-year overall survival (OS) of 84.1% for studies utilizing platinum–paclitaxel compared to 72.2% for platinum–gemcitabine (p-value for subgroup difference = 0.022). Studies with ICT duration of ≤6 weeks showed a 2-year OS of 84.8% compared to 71.7% for ICT duration >6 weeks (p = 0.003). Other subgroup comparisons (cisplatin versus carboplatin, cycle duration of ≤14 days versus >14 days, and cisplatin dose intensity <25 mg/m²/week versus ≥25 mg/m²/week) did not show statistically significant differences in 2-year OS. A meta-analysis of the five controlled studies exhibited high heterogeneity in OS and progression-free survival (PFS), driven by the CIRCE trial — the only study employing a platinum–gemcitabine ICT regimen lasting >6 weeks. Sensitivity analysis excluding this trial demonstrated a significant improvement in OS (HR 0.68; 95% CI 0.47–0.99; p = 0.049) and PFS (HR 0.46; 95% CI 0.31–0.69; p = 0.0002) with the addition of ICT to CCRT, compared to CCRT alone. **Conclusions:** In patients with LACC, the addition of ICT to CCRT significantly improves PFS and OS compared to CCRT alone, provided that the ICT involves a platinum doublet with paclitaxel and is administered within ≤6 weeks. Research Sponsor: None.

A TORC1/2 inhibitor onatasertib combined with toripalimab in patients with advanced cervical cancers with prior anti-PD-(L)1 therapy. First Author: Li Zheng, Clinical Trial Center, West China Hospital, Chengdu, China

Background: Clinical findings on onatasertib (ATG-008), an oral TORC1/2 inhibitor, showed promising anti-tumor efficacy and manageable safety when used in combination with toripalimab, an anti-PD-1 monoclonal antibody, in treatment-naïve cervical cancer (CC) patients who had not received prior anti-PD-(L)1 therapy. Here, we present results from the anti-PD-(L)1 therapy treated CC cohort of the TORCH-2 study who had at least prior 1 line of anti-PD-(L)1 therapy with the combination of onatasertib and tori. **Methods:** The TORCH-2 study is a phase 1/2 open-label, dose escalation and expansion trial of onatasertib in combination with tori in patients (pts) with advanced solid tumours (NCT04337463). Eligibility criteria included at least one measurable lesion, ECOG 0-1 and adequate organ function. Pts with prior PI3K/AKT/mTOR inhibitor therapy were excluded. CC pts with at least prior 1 line of anti-PD-(L)1 therapy and 1 line of platinum chemotherapy regardless of PD-L1 expression, were enrolled and received onatasertib 15mg orally once a day (QD) in combination with tori 240 mg, once every 21 days (Q3W). Efficacy assessments were reported based on RECIST1.1 criteria and the endpoints included overall response rate (ORR), disease control rate (DCR), duration of response (DOR), progression free survival (PFS) and overall survival (OS). **Results:** As of Nov 25, 2024, 30 advanced CC pts who had at least prior 1 line of anti-PD-(L)1 therapy and 1 line of platinum chemotherapy were enrolled. Median age was 56.5 years. Baseline ECOG scores were 0 (26 pts) and 1 (4 pts). There were 14 and 16 pts who had received 1 and ≥2 prior lines of systemic therapy, respectively. Additionally, 16 pts had prior abraxane treatment and 11 pts had prior bevacizumab therapy. The median time since initial diagnosis was 37 months(m). The efficacy-evaluable population (27 CC pts) had an ORR of 22.2% (6/27, all confirmed). The DCR was 85.2%. The median time to response was 1.7 m (1.4, 4.2) and median DOR was 5.7 m (95% CI: 2.7, NE). Median PFS and median OS was 4.2 m (95% CI: 3.3, 5.8) and 21.4 m (95% CI: 15.5, NE), respectively. The ORRs of PD-L1 positive and PD-L1 negative populations were 30% (3/10) and 33.3% (2/6), respectively. Thirty pts (100%) had ≥ 1 TEAEs; 22 (73.3%) pts had grade ≥ 3 TRAEs. The most common all grade TRAEs included hyperglycaemia (56.7%), rash (43.3%) and white blood cell decreased (43.3 %). No TEAE led to death. **Conclusions:** Onatasertib in combination with tori is tolerable with encouraging response rate and disease stabilisation in advanced CC pts with prior anti-PD-(L)1 therapy, regardless of PD-L1 expression. The expansion cohorts are ongoing. Clinical trial information: NCT04337463. Research Sponsor: Antengene.

Evolving global burden and trend of cervical cancer in G20 countries: Age, sex, regional disparities from 1990-2021. First Author: Jahnavi Chaudhari, HCA Oak Hill Hospital, Brooksville, FL

Background: Cervical Cancer (CC) is the 6th leading cause of death and 4th leading cause of disability amongst all cancer in G20 countries. The G20 nations, which represent about 85% of the global GDP, hold a pivotal role in shaping the world's economic and health landscapes. This economic dominance underscores the substantial impact that public health issues, like CC, can have not only on individual countries but on global stability and productivity. **Methods:** We estimated the incidence, prevalence, deaths, disability-adjusted life years (DALYs), and years lived with disability (YLDs) attributed to CC across the G20 countries from 1990 - 2021, disaggregated by age, sex, year, and location, using the standardized methodology of the Global Burden of Disease Study 2021. Non-fatal health outcomes were modeled using DISMOD MR 2.1, a machine learning tool, while fatal health outcomes were assessed using the Cause of Death Ensemble Model (CODEm). The results are reported as absolute counts and age-standardized rates per 100,000 population. **Results:** The total prevalence count of cervical cancer increased from 1.3 (95% uncertainty interval: 1.2–1.3) million in 1990 to 2.2 (2.0–2.5) million in 2021. Deaths rose from 140,740 (128,861–152,835) to 183,343 (166,174–200,956), while disability-adjusted life years (DALYs) increased from 4.8 (4.4–5.2) million to 5.9 (5.3–6.4) million during the same period. The highest annual percentage change (APC) in the age-standardized incidence rate (ASIR) was observed in Italy (1.59%), followed by South Africa (1.14%), China (0.43%), Argentina (0.3%), Bulgaria (0.2%), and Canada (0.1%). In contrast, the majority of countries, including the United States, experienced a decline in ASIR, with the United States showing a 1.5% reduction from 1990 to 2021. For age-standardized mortality rate (ASMR), South Africa (1.12%) and Italy (0.47%) demonstrated an increase in APC, while all other countries observed a decline. Age-wise analysis revealed that for the 20–54 age group, APC in incidence increased by 1.12%, while for the 55+ age group, it rose by 1.77%. In terms of mortality, the 20–54 age group recorded a 0.26% increase in APC, and the 55+ age group experienced a 1.25% increase. Regarding DALYs, APC for the 20–54 age group increased by 1.4%, while the 55+ age group saw a rise of 2.15% from 1990 to 2021. **Conclusions:** Death due to Cervical Cancer accounted for 2.35% of all cancer causalities in 2021. Study findings underscore the need for urgent public health interventions. Disparities in incidence and mortality trends reflect unequal access to healthcare, screening, and HPV vaccination. The higher APC in older age groups (55+ years) highlight the importance of targeted healthcare access, while modest increases among younger populations (20–54 years) emphasize sustaining vaccination and screening efforts. Research Sponsor: None.

5542 Poster Session

Ceralasertib (cerala) + olaparib (ola) in patients (pts) with homologous recombination repair (HRR)-deficient platinum-sensitive relapsed ovarian cancer (OC) after progression on prior PARP inhibitor (PARPi) treatment (tx). First Author: Rene Lynnette Roux, Department of Oncology, Churchill Hospital, Oxford University Hospitals NHS Foundation Trust, Oxford, United Kingdom

Background: Combining an ATR inhibitor (ATRi) and a PARPi may overcome acquired PARPi resistance based on preclinical and clinical data. We report a Phase 1 study (NCT02264678) of cerala (ATRi) + ola (PARPi) in pts with HRR-deficient OC who had progressed on prior PARPi tx. **Methods:** Pts had histologically confirmed high-grade serous/endometrioid epithelial ovarian, fallopian tube, or primary peritoneal cancer, with deleterious or suspected deleterious *BRCA* or HRR mutations (*BRCA*m; HRRm: *RAD51C/D*m, *PALB2*m) or HRR-deficiency (HRD+). Pts received oral cerala 80 mg (d 1–14 every 28 d) + ola 150 mg (throughout) twice daily without/with (Cohort [Co] 1/2) intervening platinum-based tx after initial response and subsequent progression on prior PARPi tx. Primary endpoints were safety/tolerability; ORR per RECIST v1.1 and PFS were secondary endpoints. Emergence of PARPi resistance mechanisms was analyzed in archival/pre-study tx tissue samples. **Results:** 32 pts were treated, 30 in Co1 (7 ongoing tx at data cutoff: Mar 5, 2024) and 2 in Co2 (cohort closed early). Median age was 63.0 yrs; 68.8% (22/32) had *BRCA*m/HRRm and 31.3% (10/32) HRD+/non-*BRCA*m by local assessment. All pts had adverse events (AEs); 40.6% had grade ≥3 AEs (most common were anemia and platelet count reduced, each 21.9%); 6.3% discontinued tx due to AEs. Table shows efficacy in Co1. 24 pts had post-PARPi biopsies evaluable for genomics analysis: 3 (12.5%) had *BRCA* reversions (rev; 13 pts were *BRCA*m); 3 (12.5%) had loss of function alterations in DNA damage response (DDR) rewiring genes. Of 16 pts with post-PARPi biopsies evaluable for RAD51 foci, 81.3% (13) had RAD51 high status suggesting HRR functional proficiency as a prevalent PARPi resistance mechanism; of these 13, 61.5% (8; 80% CI, 40.2–79.9) responded to cerala + ola, while no responses occurred in 3 RAD51 low pts (80% CI, 0.0–53.6). Responders included patients with *BRCA* rev or *TP53BP1*m, indicating cerala + ola activity in pts with *BRCA* rev and alterations in DDR rewiring genes. Other PARPi resistance mechanisms were rare. **Conclusions:** In this setting of high unmet need, cerala + ola had acceptable safety, a low discontinuation rate, and clinical activity in both *BRCA*m/HRRm and HRD+/non-*BRCA*m pts after progression on a prior PARPi. Exploratory analyses highlighted emerging PARPi resistance mechanisms; ongoing assessments of PARPi resistance to inform pt selection and novel combination strategies in post-PARPi settings will be presented. Clinical trial information: NCT02264678. Research Sponsor: AstraZeneca.

Hyperthermic intraperitoneal chemotherapy combined with cytoreductive surgery versus cytoreductive surgery alone for ovarian cancer: An updated meta-analysis. First Author: Osama Ijaz, Services Institute of Medical Sciences, Lahore, Pakistan

Background: Hyperthermic Intraperitoneal Chemotherapy (HIPEC) delivers high-dose chemotherapy directly to the abdominal cavity to treat cancers that have spread to the peritoneal lining. When combined with cytoreductive surgery (CRS), HIPEC has been shown to improve survival outcomes in patients with advanced and recurrent ovarian cancer. This updated meta-analysis compares the efficacy and adverse events of CRS with HIPEC to cytoreductive surgery alone. **Methods:** A comprehensive literature search was conducted across Medline, Embase, Google Scholar, Cochrane CENTRAL, Scopus, and ClinicalTrials.gov up to December 2024. Only observational studies and randomized controlled trials (RCTs) involving adult patients with advanced or recurrent ovarian cancer treated with HIPEC in combination with CRS were included. The primary outcomes assessed were overall survival and the incidence of grade 3 or higher adverse events. A meta-analysis using a fixed-effects model was performed to calculate the pooled odds ratio (OR) and pooled hazard ratio (HR), with 95% confidence intervals (CI), to estimate the overall treatment effect. **Results:** A total of twelve studies involving 1,893 participants were included, with 1,067 participants in the control group and 826 in the treatment group. Regarding overall survival, the pooled HR was 0.67 (95% CI: 0.57–0.78; $p<0.00001$; $I^2=42\%$). In subgroup analyses, the HR was 0.67 (95% CI: 0.54–0.83) for treatment-naïve patients and 0.66 (95% CI: 0.52–0.84) for patients undergoing secondary cytoreduction for recurrent ovarian cancer. The test for subgroup differences showed no significant heterogeneity ($I^2=0\%$). In terms of adverse events, the pooled OR was 1.01 (95% CI: 0.89–1.14; $p<0.00001$; $I^2=82\%$). **Conclusions:** This updated meta-analysis demonstrates that HIPEC combined with CRS significantly improves overall survival in patients with ovarian cancer. Subgroup analysis indicated that this treatment enhances survival in both treatment-naïve patients and those undergoing secondary cytoreduction for recurrent ovarian cancer, aligning with findings from previous meta-analysis. However, in contrast to earlier meta-analysis, this study shows that HIPEC plus CRS does not increase the risk of adverse events. Therefore, HIPEC combined with CRS is both an effective and safe treatment option for patients with advanced and recurrent ovarian cancer. Research Sponsor: None.

Gynecologic oncology referral rates of adnexal masses suspicious for ovarian cancer in an academic health system: A cohort study. First Author: Anna Jo Bodurtha Smith, University of Pennsylvania, Philadelphia, PA

Background: Ovarian-Adnexal Reporting Data System (O-RADS) is an international lexicon and risk stratification tool. O-RADS 4 or 5 lesions are complex adnexal masses that a 10-90% risk of malignancy, and national guidelines recommend gynecologic oncology referral. Our objective was to examine patient, clinician, and imaging factors associated with referral to gynecologic oncology for complex adnexal masses. **Methods:** This retrospective cohort study was exempt from IRB review. We identified all patients with O-RADS 4 or 5 lesions on ultrasound (US) or MRI from July 1, 2020 to December 31, 2023. Our primary outcome was referral to gynecologic oncology. We gathered patient demographic data and ordering clinician characteristics from electronic health records. We performed descriptive statistics and multivariate logistic regression of patient demographics and ordering clinician characteristics associated with gynecologic oncology referral. **Results:** Our cohort included 373 patients with O-RADS 4 or 5 lesions and no prior gynecologic oncology care. The referral rate to gynecologic oncology was 68%, and referral within 30 days of abnormal imaging was 43%. Time from abnormal imaging to referral ranged from 0 to 407 days (mean 15.3, median 4 days). In multivariate analyses, the likelihood of referral to gynecologic oncology was higher among patients with repeat abnormal imaging compared to those with single instance of abnormal imaging (aOR 20.61, 95%CI 2.63-161.6), O-RADS 5 lesions compared to O-RADS 4 lesions (aOR 9.15, 95%CI 3.47-24.85) and detection on MRI compared to US (aOR 7.79, 95%CI 1.57-38.65). The likelihood of referral to gynecologic oncology was lower among non-white patients (aOR 0.24, 95%CI 0.08-0.76). There were no differences by Hispanic ethnicity, rurality, insurance, or language. Referral was higher among patients whose imaging was ordered by an internal medicine clinician (aOR 3.89, 95% CI 1.48-10.20) compared to ob/gyn. **Conclusions:** One-third of patients with complex adnexal masses were not referred to gynecologic oncology. Disparities in referral to gynecologic oncology for complex adnexal masses rates based on patient race and ordering clinician specialty highlight the need for system-based approaches including clinician education or automated referrals. Research Sponsor: Conquer Cancer, the ASCO Foundation.

Progression-free survival as a surrogate outcome for overall survival in ovarian cancer maintenance therapy randomized controlled trials. First Author: Rachel P. Mojdehbakhsh, University of Wisconsin Carbone Cancer Center, Madison, WI

Background: A traditional primary outcome in prospective trials is progression-free survival (PFS). PFS often functions as a surrogate outcome for overall survival (OS) to speed up the translation of research findings into practice. While PFS has been validated as a surrogate for OS in contemporary therapeutic trials for patients with advanced ovarian cancer, there is little evidence to support the validity of PFS as a surrogate for OS in contemporary trials of maintenance therapies. Our objective was to evaluate whether PFS is a reliable surrogate outcome for OS in patients with ovarian cancer receiving maintenance therapy after platinum-based chemotherapy. **Methods:** In May 2024, MEDLINE was queried for all phase 3 trials evaluating poly (ADP) ribose polymerase (PARP) inhibitors and bevacizumab in the maintenance setting for ovarian, fallopian tube and primary peritoneal cancers. Included trials studied PARP inhibitors, bevacizumab or both as an intervention compared to control. Enrollment numbers, median follow up, PFS, OS and hazard ratios were abstracted. Using a meta-analytic approach, correlation analysis was performed using weighted linear regression and Pearson's correlation coefficient. Trials included contained complete survival data. Criteria for PFS surrogacy required R^2 >0.8. **Results:** Sixty trials were identified, 11 of which met inclusion criteria. Six trials investigated PARP inhibitors in the maintenance setting, while 4 trials investigated bevacizumab. One trial investigated both a PARP inhibitor and bevacizumab. The pooled sample size from all trials was n=6,243. Median follow up time was 60.35 months. Across all trials, the relationship between OS and PFS HRs was approximately linear. Corresponding R^2 values were low (R^2=0.35, 95% CI 0-0.63). Pearson correlation when weighted by total study sample size, was of low strength (r=0.59, 95% CI -0.05-0.87). Four trials evaluating bevacizumab as a maintenance therapy demonstrated favorable PFS benefit with no statistically significant difference in OS, while only one PARP inhibitor trial demonstrated a statistically significant benefit in PFS and OS. Weighted Pearson correlation coefficient for bevacizumab trials demonstrated moderate correlation between PFS and OS HRs (r=0.81, 95% CI -0.75-0.99) while PARP inhibitor trials demonstrated a low strength of correlation (r=0.26, 95% CI -0.71-0.88). **Conclusions:** Phase 3 clinical trials assessing maintenance therapies for ovarian cancer demonstrate poor correlation between PFS and OS. This effect may be modulated by type of maintenance therapy and the inclusion of platinum-based chemotherapy in trial arms. PFS as a surrogate outcome in maintenance therapy ovarian cancer clinical trials must be supported by additional studies and caution should be taken prior to regulatory approval based on PFS data alone. Development and validation of a proteo-metabolic panel for detection of asymptomatic ovarian cancer with minimal serum sample requirements: A multi-center prospective study. First Author: Ruomeng Bi, Tongji University, Shanghai, China

Background: Early diagnosis is crucial for improving the prognosis of ovarian cancer (OC). However, most patients (pts) are diagnosed at advanced stages due to subtle symptoms and traditional biomarkers' limitations. We aimed to develop an serum panel using multi-omics data for cost-effective detection of asymptomatic OC (asym-OC). **Methods:** Participants were recruited from the Shanghai Ovarian Cancer and Family Care Project (NCT06118307) involving five centers. A total of 843 individuals were included: 135 asym-OC pts and 708 non-OC individuals (290 pts with benign lesions and 418 healthy controls). Fasting serum samples (1 μL each) were analyzed using MALDI-TOF MS to generate proteo-metabolic (pro-met) data. For each sample, the original MS have ~43,900 data points from 100-13,000 Da. Preoperative data from three centers (N=680) were used to develop Light Gradient Boosting Machine (LGBM) models to identify key signals differentiating OC from non-OC. An independent external validation set (N = 163) was assembled by the other two centers. To develop a biologically interpretable and generalizable panel, the model was further refined to minimize biomarkers while maintaining efficacy. Validation of the panel was conducted using postoperative pro-met data from 42 asym-OC pts, transcriptomic data from 89 with asym-OC and 39 with benign lesions, supported by bioinformatic analyses. **Results:** Ten biomarkers, which are involved in coagulation, complement system, carcinogenesis, epithelial-mesenchymal transition, and the Warburg effect, were selected in the panel. The panel achieved an AUC of 0.90 (95% CI: 0.82-0.98) in the external validation set. The enhanced model that integrating the panel, age, BMI and HE4 achieved an AUC of 0.94 (95% CI: 0.90-0.99). In subgroup analyses, the enhanced model outperformed CA125, HE4, and ROMA, with AUCs of 0.96 (early-stage OC vs. non-OC) and 0.96 (OC vs. endometriosis) (See Table). Moreover, postoperative levels of the biomarkers in the panel approached those of the non-OC ($p < 0.05$). Transcriptomic data of the tissues corresponded to the pathophysiological alterations associated with OC development or progression. **Conclusions:** This study introduces a novel, non-invasive, and cost-effective serum panel that demonstrates high sensitivity and specificity for detecting asym-OC, offering a promising tool for early diagnosis of the disease. Comparison of predictive models in women with advanced epithelial ovarian cancer triaged to primary debulking or neoadjuvant chemotherapy. First Author: Shalini Rajaram, All India Institute of Medical Sciences (AIIMS), Rishikesh, India

Background: Triaging women with advanced epithelial ovarian cancer (AEOC) into primary debulking surgery (PDS) or neoadjuvant chemotherapy (NACT) remains largely subjective. **Methods:** This prospective observational study recruited women over 18 years with stage III-IV AEOC. Decision for PDS or NACT was based on patient-specific factors and radiological parameters. The agreement between clinical decisions and predictive models—Aletti's surgical complexity score, MSKCC Team Ovary criteria, Mayo triage algorithm, and Integrated Predictive Model (IPM) was assessed using kappa statistics. **Results:** 72 women with AEOC were included, with 17 (23.6%) assigned to the PDS and 55 (76.4%) to NACT. Amongst NACT patients, interval debulking surgery (IDS) was feasible in 30 women (54.5%), while 25 (45.5%) did not undergo surgery due to reasons such as disease progression, death, poor performance status, stable disease, or loss to follow-up. No difference was observed between the NACT and PDS groups in demographic parameters. Performance scores differed significantly, with higher scores observed in the NACT group compared to the PDS group: median ECOG (2 [1–2] vs. 1 [1–1], $p < 0.001$), ASA score (2 [2–3] vs. 2 [2–2], p = 0.005), and frailty index (0.26 ± 0.11 vs. 0.15 ± 0.05, $p < 0.001$). Serum albumin levels were lower (3.0 ± 0.51 vs. 3.7 ± 0.30 g/dL, $p < 0.001$), and median CA125 levels were higher (1170 [341–2637] vs. 494 [219.7–1000] U/mL, $p < 0.001$) in the NACT group. Radiological parameters, including median peritoneal carcinomatosis index (PCI) scores (16 [10–23] vs. 5 [3–8], $p < 0.001$), volume of ascites, pleural effusion, and disease at challenging operative sites, were also higher in the NACT group ($p < 0.05$). Surgical outcomes, including surgical PCI scores (5[2-6] vs 6[3-11], =0.35), residual disease rates (complete/optimal debulking: 96.6% vs. 88.2%, p = 0.42), surgical complexity score (4.7 ± 1.45 vs. 4.4 ± 1.33, p = 0.82), blood transfusion rates (80% vs. 70.6%, p = 0.76), and grade 2-3 complications (60% vs. 58.8%, p = 0.58) were similar in both groups. Baseline predictive scores were significantly higher in the NACT group compared to the PDS group: Aletti's surgical complexity score (8.4 ± 2.80 vs. 5.2 ± 1.25, $p < 0.001$), MSKCC Team Ovary criteria (6.4 ± 3.31 vs. 1.9 ± 1.49, $p < 0.001$), Mayo triage algorithm (0.87 ± 0.39 vs. 0.24 ± 0.44, $p < 0.001$), and IPM final score (high-risk: 69.1% vs. 52.8%, $p < 0.001$). Clinical decisions showed moderate concordance with the Mayo triage algorithm (κ = 0.57) and IPM score (κ = 0.51) and fair concordance with Aletti's score (κ = 0.33) and MSKCC criteria (κ = 0.23). **Conclusions:** Triage decisions based on patient performance status, nutritional factors, and disease extent demonstrated moderate concordance with predictive models. Both PDS and IDS had excellent cytoreductive outcomes with similar perioperative performance aligning with results from literature. Research Sponsor: None.

Concordance of circulating tumor DNA and tissue genomic profiling in ovarian cancer: Influencing factors and clinical significance. First Author: Hao Su, Department of Obstetrics and Gynecology, National Clinical Research Center for Obstetric & Gynecologic Diseases, Peking Union Medical College Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College, Beijing, China

Background: Next-generation sequencing of plasma circulating tumor DNA (ctDNA) shows promise in ovarian cancer management as a minimally invasive alternative to tissue sequencing. However, concordance between genomic alterations detected in tissue and ctDNA remains incompletely characterized, with limited understanding of influencing factors and clinical implications. **Methods:** We analyzed 29 matched pretreatment tissue and plasma samples from treatment-naïve ovarian cancer patients using a customized 2365-gene panel. Overall and individual concordance rates were calculated as the ratio of total concordant mutations to total tissue mutations, with patients stratified into high concordance (≥50%) and poor concordance (<50%) groups. Clinicopathological and tumor molecular factors influencing concordance were analyzed. Relationship between concordance rates and clinical outcomes, including chemosensitivity (KELIM score) and progression-free survival (PFS), was assessed in advanced-stage patients. **Results:** The cohort predominantly comprised FIGO III-IV disease (89.7%) and high-grade serous histology (89.7%), with median follow-up of 306 (66-570) days. Overall tissue-plasma concordance rate was 42%, with shared variants exhibiting identical abundance patterns across sample types (r=0.25, p=0.0074) and encompassing 66.1% of tissue driver mutations. Tissue-specific mutations displayed lower variant allele frequencies than shared mutations (median 4.4% vs 28.7%). Single nucleotide variants showed higher plasma detection rate than structural variants (47.3% vs 25.4%). Individual concordance rates varied substantially (0-83.3%). High concordance group exhibited higher tumor Ki-67 index (median 85% vs 70%), tissue tumor mutation burden (TMB, median 5.1 vs 4.1 muts/Mb), and plasma ctDNA fraction (median 8.1% vs 0.9%). No significant differences were observed in largest tumor diameter, CA125 levels, tumor sample locations (from primary site or metastatic site), or BRCA mutation/homologous recombination status between groups. By multivariable analysis, higher TMB (OR 1.931, 95% CI 1.064-3.504) and plasma ctDNA fraction (OR 1.416, 95% CI 1.060-1.893) independently associated with high concordance rates. In advanced-stage patients, poor concordance group showed lower KELIM scores (median 0.7 vs 1.2; 15.4% vs 69.2% of patients with score ≥1), indicating reduced chemosensitivity. Concordance rates strongly correlated with KELIM scores (r=0.71, p<0.0001). Poor concordance group demonstrated shorter PFS (median 436 days vs not reached, p=0.037). **Conclusions:** Our study revealed moderate concordance between pretreatment tumor tissue and plasma ctDNA mutation profiles in ovarian cancer, influenced by technical and biological factors. Tissue-plasma concordance may serve as a novel chemosensitivity and prognostic indicator. Research Sponsor: Beijing Xisike Clinical Oncology Research Foundation.

Validation of the performance of Ovarian Cancer Score for diagnosing ovarian cancer in a multicenter study. First Author: Haixia Wang, Department of Gynecologic Oncology, Chongqing University Cancer Hospital & Chongqing Cancer Institute & Chongqing Cancer Hospital, Chongqing, China

Background: Early detection is crucial for improving survival of patients with ovarian cancer (OC), yet current diagnostic tools lack adequate sensitivity and specificity, especially for early stage disease. The Ovarian Cancer Score (OCS) is a newly developed serum extracellular based diagnosis marker for detection of ovarian cancer. The study aimed to explore the performance of OCS in detecting OC. **Methods:** This multicenter study included 1183 adult females with adnexal masses from four hospitals in China (October 2019 - April 2023). Of these, 1,024 samples were prospectively collected, and 159 were from biobanks. All serum samples were collected before surgery. The concentrations of sEV carbohydrate antigen 125 (CA125), human epididymis protein 4 (HE4) and complement component 5a protein (C5a) were quantified using chemiluminescence immunoassay and then used for calculating OCS. Sensitivity, specificity, positive predictive value (PPV), and negative predictive value (NPV) were calculated. CA125, HE4, and ROMA index results were retrieved from the medical record system at each hospital. The differences was calculated using. **Results:** The OCS demonstrated high sensitivity (95.5%, 95% CI: 93.3%-97.7%) and specificity (90.2%, 95%CI: 88.2%-92.2%) in OC in the cohort (n = 1183), significantly outperforming CA125 (90.0%, 95%CI: 86.8%-93.3% and 69.1%, 95%CI: 65.9%-72.2%) and ROMA (89.2%, 95%CI: 83.2%-95.2% and 83.1%, 95%CI: 79.3%-86.8%, all $p<0.05$). OCS was superior to HE4 in sensitivity (75%, 95%CI: 70.1%-79.9%, $p<0.001$), but not specificity (94.8%, 95%CI: 93.2%-96.5%, $p<0.001$). Subgroup analysis revealed that in premenopausal women, OCS showed higher sensitivity (94.3%, 95%CI: 90.2%-98.4%) compared to HE4 (79.0%, 95%CI: 71.5%-86.4%, $p<0.001$) and ROMA (83.0%, 95%CI: 72.2%-93.7%, $p<0.05$). The specificity of OCS was higher than CA125 and ROMA, but lower than HE4 (all $p<0.05$). In postmenopausal women, OCS showed higher sensitivity (96.2%, 95%CI: 93.6%-98.8%) than CA125 (89.9%, 95%CI: 85.8%-94.0%, $p<0.05$) and HE4 (72.6%, 95%CI: 66.2%-79.0%, $p<0.001$), but there was no significant difference in sensitivity between OCS and CA125 or ROMA ($p>0.05$). In early-stage OC (FIGO I+II), OCS's sensitivity (91.4%, 95%CI: 86.8%-96.1%) was significant higher than CA125 (78.4%, 95%CI: 71.6%-85.3%, $p<0.01$), HE4 (63.5%, 95%CI: 55.1%-71.9%, $p<0.001$) and ROMA (77.8%, 95%CI: 65.6%-89.9%, $p<0.05$). Particularly in FIGO Stage I patients, OCS demonstrated significant higher sensitivity than CA125 (89.7%, 95%CI: 83.0%-96.5% vs.70.1%, 95%CI: 59.9%-80.4%, $p < 0.01$), HE4 (51.4%, 95%CI: 39.8%-62.9%, $p < 0.001$) and ROMA (74.2%, 95%CI: 58.8%-89.6%, $p < 0.05$). The specificity of OCS was higher than CA125 and ROMA (all $p<0.001$), but lower than HE4 across all stage subgroups. **Conclusions:** This multicenter study demonstrated that the OCS is a promising non-invasive diagnostic tool for the detection of OC. Clinical trial information: NCT06366997. Research Sponsor: Chongqing Science and Technology Bureau; Talent Program of Chongqing; Chongqing Municipal Education Commission; Chongqing Health Commission; Beijing Health Alliance Charitable Foundation.

Impact of disease progression on health-related quality of life (HRQOL): Updated results from the PRIMA/ENGOT-OV26/GOG-3012 trial of niraparib first-line (1L) maintenance therapy in patients with newly diagnosed advanced ovarian cancer (aOC). First Author: Mark S. Shahin, Hanjani Institute for Gynecologic Oncology, Abington Hospital–Jefferson Health, Asplundh Cancer Pavilion, Sidney Kimmel Medical College of Thomas Jefferson University, Willow Grove, PA

Background: The phase 3 PRIMA trial (NCT02655016) demonstrated that niraparib 1L maintenance therapy significantly extended progression-free survival (PFS) compared with placebo in patients with newly diagnosed aOC that responded to 1L platinum-based chemotherapy. Using data from the Nov 2019 cutoff (median follow-up, ≈1.7 y), pooled results from both treatment arms found that disease progression negatively affected HRQOL. Here we report updated HRQOL results from the PRIMA final analysis. **Methods:** In PRIMA, patients were randomized 2:1 to niraparib or placebo 1L maintenance once daily. HRQOL was assessed as a prespecified secondary endpoint using patient-reported responses to multiple instruments, including the European Organisation for Research and Treatment of Cancer QOL Core Questionnaire (EORTC QLQ-C30) and the EORTC QLQ Ovarian Cancer Module (EORTC QLQ-OV28). Assessments were collected at baseline, at designated intervals while on study treatment; at the end of treatment (EOT); and at 4, 8, 12, and 24 weeks after the last dose of study treatment. Post hoc analysis results are reported herein (clinical cutoff: Apr 8, 2024; median follow-up, 6.2 y). **Results:** In the overall population (niraparib, n=487; placebo, n=246), EOT survey completion rates exceeded 80% across both instruments. In both treatment arms, disease progression significantly reduced overall HRQOL per the EORTC QLQ-C30, with marked decreases from the last on-treatment visit (LOTV) for global health status/QOL that never recovered to LOTV levels (Table). Disease progression was also associated with deterioration across all 5 functional scales of the EORTC QLQ-C30 and worsening symptoms of fatigue, nausea/vomiting, pain, dyspnea, appetite loss, diarrhea, and financial difficulties. On the EORTC QLQ-OV28, progression was associated with decreased scores for body image, sexuality, and attitude toward disease/treatment functional scales and worsening abdominal/gastrointestinal symptoms. **Conclusions:** Disease progression negatively impacted HRQOL across treatment arms in PRIMA. These results support PFS as a clinically relevant endpoint in patients with aOC, as delays in disease progression help preserve HRQOL. Clinical trial information: NCT02655016. Research Sponsor: GSK.

HER2 and HER3 expression in ovarian cancer: Evolution across chemotherapy exposure and implications for targeted therapies. First Author: Felix Blanc-Durand, Institut Gustave Roussy, Villejuif, NA, France

Background: HER2 and HER3 are critical members of the ERBB receptor family, playing pivotal roles in tumorigenesis across multiple cancers, including ovarian cancer (OC). While their potential as therapeutic targets is under investigation, the clinical significance of their expression in OC remain understudied. This study investigates the expression patterns of HER2 and HER3 in OC tissues and evaluates the impact of neoadjuvant chemotherapy (NACT) on their expression levels. **Methods:** Patients with advanced epithelial ovarian cancer were identified and included in this study. Tumor samples were collected at three timepoints: prior to NACT, during interval debulking surgery and at relapse. HER2 and HER3 expressions were assessed using immunohistochemistry and scored with the gastric Herceptest scoring system (1+, 2+ or 3+), where 3+ expression was considered positive. **Results:** A total of 163 patients were analyzed, of whom 73% had high-grade serous histology and 21% harbored *BRCA* mutations. Tumor samples were available for analysis at the following timepoints: 110 pre-NACT, 81 post-NACT, and 22 at relapse. HER2 expression was rare, with 2.3% of tumors exhibiting HER2 1+ expression and 3.1% exhibiting HER2 3+ before NACT. HER2 expression remained stable at interval debulking surgery and relapse. In contrast, HER3 expression was more common with 2.7% of samples exhibiting HER3 1+ expression, 1.8% with 2+ expression and 60.9% with 3+ expression. HER3 expression remained consistent across timepoints, with 65.4% at interval debulking and 63.6% at relapse. HER3-positive samples were significantly associated with high-grade serous histology (81.5% vs 65%, p = 0.005), while *BRCA* mutation rates did not differ significantly between both groups (16.2% vs 28%, p = 0.267). Progression-free survival (PFS) and overall survival (OS) were comparable between HER3-positive and negative groups. Median PFS was 11.1 months versus 11.2 months (p = 0.537) and median OS was 44.9 months versus 44.3 months (p = 0.734). **Conclusions:** This study confirms that HER2 overexpression is rare in OC and remains stable throughout the treatment timeline. Conversely, HER3 is frequently expressed, with over 60% of tumors exhibiting 3+ HER3 expression. HER3 expression is strongly associated with serous histology, is stable across NACT exposure, and does not appear to impact clinical outcomes. These findings highlight HER3's potential as a promising therapeutic target in the OC landscape. Research Sponsor: None.

Final analysis of SCORES, a phase III randomized, double-blinded, placebo-controlled study of suvemcitug combined with chemotherapy for platinum-resistant ovarian cancer. First Author: Guangwen Yuan, National Cancer Center/ National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China

Background: At the SCORES interim analysis, suvemcitug (a recombinant humanized anti-VEGF rabbit monoclonal antibody) plus chemotherapy demonstrated a significant improvement of progression free survival (PFS) compared with single-agent chemotherapy (CT) in patients with platinum-resistant Ovarian Cancer (PROC). Here we present the preplanned final analysis of OS for the SCORES along with the updating analysis of safety, PFS, and other endpoints. **Methods:** This randomized, double-blind, placebo-controlled, phase 3 trial (SCORES) conducted at 55 centers in China enrolled women with histologically-confirmed epithelial ovarian, fallopian tube or primary peritoneal cancer. Patients were required to have platinum- resistant or refractory disease with at least one measurable lesion. Eligible patients were randomly assigned (2:1) to either Suvemcitug (1.5 mg/kg q2w) or placebo combined with investigators chose CT (weekly paclitaxel, topotecan or pegylated liposomal doxorubicin) until progression or unacceptable toxicity. The primary endpoint was progression-free survival (PFS) by blinded independent review committee (BIRC) according to the RECIST 1.1. And the key secondary endpoint is the overall survival (OS). **Results:** Between June 5, 2021 and October 11, 2024, 421 patients were enrolled. At the data cutoff for the final analysis (October 11, 2024), the median follow-up duration was 23.7 and 23.4 months for the suvemcitug arm and the placebo arm. A total of 279 OS events (66.3%) occurred, the median OS was 15.31 months versus 14.03 months (stratified hazard ratio, 0.768; 95% CI, 0.595-0.991; P = 0.0304). Suvemcitug plus chemotherapy led to a significant improvement of OS versus placebo plus chemotherapy, with a 23% reduction in the risk of death and a more than 10% improvement of the 24-month OS rate (33.0% vs 22.3%). The efficacy results are summarized below. The most common grade ≥ 3 TEAEs (treatment-emergent adverse events) in suvemcitug arm included neutrophil count decreased, white blood cell count decreased, and hypertension. No Suvemcitug-related grade 5 TEAE occurred. **Conclusions:** The addition of suvemcitug to chemotherapy significantly improved the outcomes of patients with PROC with manageable toxicities. To the best of our knowledge, this is the first phase III study demonstrated a significant OS benefit of anti-angiogenic agent in patients with PROC. Clinical trial information: NCT04908787. Research Sponsor: Shanghai Xianxiang Medical Technology Co., Ltd.

	Suvemcitug + CT (N = 281)	Placebo+CT (N = 140)

Assessment of tumors, blood, and ascites to establish correlations with treatment benefit in platinum resistant or refractory ovarian cancer patients treated with igrelimogene litadenorepvec and pembrolizumab combination therapy. First Author: Victor Cervera, TILT Biotherapeutics Ltd., Helsinki, Finland

Background: Platinum-resistant/refractory ovarian cancer presents a significant therapeutic challenge and despite several attempts, immunotherapies have not delivered satisfactory results to be approved. Identifying biomarkers of response to novel therapies is crucial for personalizing treatments and improving patient outcomes, especially since certain patients do experience long term benefit after the treatment with pembrolizumab and igrelimogene litadenorepvec (TILT-123; an oncolytic adenovirus coding for TNF and IL-2). **Methods:** Tumor biopsies (n=62), ascites (n=8) and blood (n=234) were collected from 15 patients treated in the PROTA trial (Phase I, NCT05271318). These patients received pembrolizumab intravenously plus igrelimogene litadenorepvec intravenously, followed by local administration intratumorally or intraperitoneally. Sampling took place prior to therapy, during therapy and after it. Tumor proteome (IHC, mIF) and transcriptome was analyzed to assess immune changes and virus presence. Ascites and blood samples were assayed to measure cell counts, phenotypes, cytokine and protein counts, as well as for the presence of antiviral neutralizing antibodies (NAbs). Biological parameters were correlated with overall survival (OS), RECIST 1.1 evaluations and tumor size changes. For analysis of OS, logrank test was used. For group comparisons two-tailed Mann-Whitney U-test was used. Pearson or Spearman tests were used for correlations. **Results:** Patients experiencing a drop in circulating lymphocytes 8-24 hours after treatment were more likely to experience longer OS (p=0.044). Additionally, patients with a higher lymphocyte count at baseline experienced similar OS benefit (p=0.018) plus a positive correlation with disease control (p=0.023). Most patients (11/15) showed antiviral immunity at baseline but eventually all patients developed neutralizing activity, and the same was observed in ascites. The presence of NAbs at baseline as well as development of highest titers were positively correlated with longer OS (p=0.004) and disease control (p=0.003). **Conclusions:** Igrelimogene litadenorepvec and pembrolizumab are therapies designed to attract, activate and/or protect lymphocyte-mediated antitumor activity. These findings suggest that having a fit immune system able to mobilize effector immune cells as well as responding to immunostimulant agents increases therapeutic success. As a disease with few therapeutic options, ovarian cancer patients often receive multiple lines of chemotherapy that might decrease the efficacy of immediate immunotherapies. The potential use of these biomarkers will be studied in larger studies to validate their utility in guiding the use of immunotherapy in this challenging patient population. Clinical trial information: NCT05271318. Research Sponsor: None.

5556 Poster Session

Biomarker results from the KGOG3056/NIRVANA-R trial: Maintenance niraparib plus bevacizumab in patients with platinum-sensitive, recurrent ovarian cancer previously treated with a PARP inhibitor. First Author: Hyun-Woong Cho, Korea University Guro Hospital, Seoul, South Korea

Background: While poly(ADP-ribose) polymerase inhibitors (PARPi) have demonstrated clinical success in prolonging progression-free survival (PFS) in ovarian cancer, the efficacy of subsequent chemotherapy following progression from PARPi maintenance is markedly decreased. Modest PFS benefits with PARPi rechallenge following a response to platinum-based chemotherapy has been reported, but the efficacy of PARPi rechallenge with bevacizumab remains unknown. **Methods:** NIRVANA-R, a phase 2 study, evaluated niraparib rechallenge with bevacizumab in patients with platinum-sensitive recurrent ovarian cancer previously treated with PARPi. Eligibility required a response to the most recent platinum regimen. The primary endpoint was 6-month progression-free rate. Biomarker exploration included the analysis of BRCA status, homologous recombination deficiency (HRD) status, circulating tumor DNA (ctDNA), and circulating tumor cells (CTCs) using whole-exome sequencing, as well as CA-125 levels. **Results:** Between 2019 and 2023, 44 patients were enrolled; over 65% had received ≧3 lines of chemotherapy. The estimated 6-month progression-free rate was 68% [95% confidence interval (CI) 55–85%]. Key prognostic factors included treatment-free interval after penultimate platinum-based chemotherapy (TFI_P) ($TFI_P \geq 24$ months vs. $TFI_P < 24$ months; 82% vs. 56%), achieving a complete response (CR) [CR vs. partial response; 86% vs. 57%] or normal CA-125 levels (0–35 vs. >35 U/mL; 72% vs. 25%) in response to the most recent chemotherapy. Median PFS was 11·5 months [95% CI 7.9-not reached (NR)]. Ongoing biomarker analysis includes BRCA status, HRD status, ctDNA and CTCs, and these results will be updated in subsequent reports. No new safety signals were identified with niraparib rechallenge plus bevacizumab. **Conclusions:** Niraparib rechallenge with bevacizumab showed promising efficacy, particularly in patients with $TFI_P \geq 24$ months, CR, or normal CA-125 levels following previous chemotherapy, supporting further clinical research. Ongoing exploration of HRD, ctDNA, CTCs, and other biomarkers will provide further insights into treatment stratification and outcomes. Clinical trial information: NCT04734665. Research Sponsor: None.

Estimated 6-month progression-free rate according to prognostic factors.

Factors		N	6 month PFS rate (95% CI)	p-value
1. Response to most recent chemotherapy	CR	17	85% (69-100%)	0.148
	PR	27	57% (40-82%)	
2. platinum-free interval from penultimate chemotherapy	<24 months	24	56% (38-83%)	0.018
	≥24 months	20	82% (65-100%)	
3. BRCA status	BRCA wild-type	16	56% (35-90%)	0.806
	BRCA mutation	22	73% (55-96%)	
	unknown	6	80% (52-100%)	
4. Progression during/after previous PARPi therapy	Progression during previous PARPi	30	68% (52-89%)	0.846
	Progression after previous PARPi	14	68% (50-100%)

JSKN003, a biparatopic anti-HER2 antibody drug conjugate (ADC), in the treatment of platinum-resistant ovarian cancer (PROC): Updated findings from two clinical trials. First Author: Xiaohua Wu, Fudan University Shanghai Cancer Center, Shanghai, China

Background: JSKN003 is a biparatopic HER2-targeting ADC conjugated to a topoisomerase I inhibitor with an average DAR of 4, who has preliminarily exhibited promising efficacy and safety in the treatment of PROC (QX Rao, et al. 2024 ESMO). This update presents the latest findings in patients (pts) who were not primary platinum-refractory. **Methods:** A pooled analysis of pts with PROC was performed from the phase I JSKN003-101 trial conducted in Australia (NCT05494918) and phase I/II JSKN003-102 trial conducted in China (NCT05744427), which enrolled pts with advanced solid tumors to receive JSKN003 monotherapy. Tumor tissue samples were collected for central lab assessment of HER2-expression. **Results:** As of November 29, 2024, the median follow up time was 6.9 months. A total of 46 PROC pts received JSKN003 Q3W, with 2, 2, 40, 1 and 1 pts in 4.2, 5.2, 6.3, 7.3 and 8.4 mg/kg dose groups, respectively. Median age was 59.0 years, 65.2% had ≥ 3 prior lines of systemic therapy, 80.4% and 63.0% had previously received bevacizumab and PARP inhibitor, 39.1% were classified as HER2-expressing (IHC: 1+/2+/3+), with 21.7%, 10.9% and 6.5% in 1+, 2+ and 3+, respectively; 45.7% as HER2-no-expressing (IHC: 0), and 15.2% had no tissue samples for assessment. For 45 efficacy-evaluable pts, the overall response rate (ORR) was 64.4%, the median progression-free survival (PFS) was 7.1 months, and the 9-month overall survival (OS) rate was 84.9% (Table). JSKN003 demonstrated effectiveness across various HER2 expression subgroups. Notably, for pts with HER2-expression, the ORR reached 72.2%, with a median PFS of 9.4 months. Grade 3/4 treatment-related adverse events (TRAEs) occurred in only 6 (13.0%) pts. Serious TRAE occurred in only 4 (8.7%) pts. No TRAEs led to treatment discontinuation or death. The most common TRAE was Grade 1/2 Nausea (39.1%). Additionally, Grade 1/2 Interstitial lung disease (ILD) was observed in 4 (8.7%) pts, with no cases of Grade 3/4 reported. **Conclusions:** The maturer updated efficacy data reveal that JSKN003 provided substantial improvement in ORR, as well as benefit in PFS and OS in heavily treated PROC, irrespective of HER2 expression. The well tolerated toxicity with long-term observation was consistent with prior experience. A confirmatory trial (NCT06751485) is ongoing in all comers at any HER2 expression level to further support JSKN003 as a treatment option in this population. Clinical trial information: NCT05494918 and NCT05744427. Research Sponsor: Alphamab Oncology.

Efficacy summary.

	HER2 IHC			
	1+/2+/3+ (n = 18)	0 (n = 20)	Unknown (n = 7)	Total (n = 45)
ORR, % (95% CI)	72.2 (46.5, 90.3)	55.0 (31.5, 76.9)	71.4 (29.0, 96.3)	64.4 (48.8, 78.1)
CR, n (%)	2 (11.1)	0	0	2 (4.4)
PR, n (%)	11 (61.1)	11 (55.0)	5 (71.4)	27 (60.0)

Analyzing the relationship between glutaminase expression and features of the immune tumor microenvironment in epithelial ovarian cancer using imaging mass cytometry. First Author: Neha Verma, Johns Hopkins University School of Medicine, Baltimore, MD

Background: Immunotherapy has thus far shown limited efficacy in epithelial ovarian cancer, likely driven in part by an immune suppressive tumor microenvironment (TME). Increased glutamine metabolism by cancer cells via upregulation of the drug-targetable enzyme glutaminase (GLS) may contribute to an immune suppressive TME. Inhibiting GLS may not only inhibit tumor growth but also enhance the anti-tumor immune response in patients with epithelial ovarian cancer. We investigated the relationship between GLS expression and features of the immune TME in epithelial ovarian cancer using imaging mass cytometry. **Methods:** Tissue microarrays constructed from 41 epithelial ovarian cancer (38 high-grade serous, 3 low-grade serous) surgical specimens were stained by immunohistochemistry for GLS, which was quantified using modified histologic score (H-score). Imaging mass cytometry was then performed on tissue microarrays using a panel of 43 channels, including markers for delineating tissue architecture and assessing lymphoid cells, myeloid cells, and stromal fibroblasts. Resulting multiplexed images were segmented into a single-cell dataset to quantitatively compare between specimens, according to GLS H-score, abundances of cell types and average shortest distances between cell types. **Results:** Median GLS H-score was 150. Compared to GLS-low (H-score 0-150) specimens, GLS-high specimens (H-score >150) demonstrated lower T cell abundance (9.18% vs. 16.84% of cells; p=0.010) and lower B cell abundance (1.09% vs. 6.66% of cells; p=0.022). Compared to GLS-low (H-score <130) and GLS-medium (H-score 130-150) specimens, GLS-high specimens (H-score >150) demonstrated the lowest T cell abundance (high: 9.18% < medium: 10.46% < low: 21.28% of cells; p=0.0015) with subtype analysis showing the lowest effector helper T cell abundance (high: 0.11% < medium: 0.25% < low: 3.39% of cells; p=0.040). On spatial analysis, based on average shortest distances between cell types, GLS-high specimens demonstrated longer distances between tumor cells and lymphoid/myeloid immune cells and shorter distances between tumor cells and stromal cells than GLS-low/medium specimens. **Conclusions:** In this cohort of patients with epithelial ovarian cancer, higher levels of GLS expression were associated with several features of an immune suppressive TME, including lower T cell abundance with lower effector helper T cell abundance on subtype analysis, lower B cell abundance, and decreased proximity between tumor cells and immune cells. Further clinical studies investigating the use of GLS inhibitors to modulate the immune TME in patients with epithelial ovarian cancer are warranted. Re-VOLVE: Phase II clinical trial in women with ovarian cancer progressing post-PARP inhibitor with treatment adapted to real-time assessment of evolving genomic resistance. First Author: Pamela Soberanis Pina, Division of Medical Oncology and Hematology, Princess Margaret Cancer Centre, University Health Network, Toronto, ON, Canada

Background: As the use of PARPi increases in high-grade serous ovarian cancer (HGSOC) resistance mechanisms ultimately arise. Emerging therapeutic strategies to overcome PARPi resistance is a pressing concern. Re-VOLVE study is a phase II in HGSOC women post-PARPi with treatment adapted to real-time assessment of evolving genomic resistance to guide treatment decision (NCT05065021). **Methods:** It enrolled patients (pts) with HGSOC progressing post-PARPi to receive induction phase (IP) 2-3 cycles of niraparib 200-300mg/bevacizumab 7.5mg/kg followed by personalized phase based on initial RECIST response and real-time assessment of evolving genomic resistance from baseline biopsy (whole genome RNA sequencing/WGTS) and ctDNA (12 gene panel). If progression/stable disease after IP pts were assigned to cohort A (niraparib/bevacizumab/dostarlimab 500mg) if no resistance mechanisms and to B (weekly paclitaxel 80mg/m2/bevacizumab/dostarlimab) if any present and to cohort C (continue niraparib/bevacizumab) if partial response after IP. Primary endpoint was to assess response rate of combination therapies. **Results:** 50 pts were screened; 7 were screen fail and 43 were enrolled. Of the 43, 3 pts were taken off due to progression during IP, 1 withdrew from study, 3 are on IP and 36 continued to personalized phase. Of these 36, 78% were white, 20% Asian, 2% others; 69% *BRCA* wild-type (25/36); 61% platinum-resistant (PR; 22/36) and 39% platinum-sensitive (PS;14/36). Median age 62.5 years (33-87). Pts had median 2 prior therapy lines (1-5); 22% (8/36) prior bevacizumab. Median days from collection to ctDNA results were 59 days and to WGTS 54 days. Twenty-seven pts (75%) had biopsy and ctDNA to guide therapy. 36 pts were assigned to personalized phase: 78% cohort A, 14% to B (4 *CCNE1* amplification and 1 *CHEK2* mutation) and 8% to C (3 with response during IP). Of the 31/36 pts assessed for response during personalized phase (others too early) 10 achieved partial response (32.2%; 7 PR, 3 PS). Nineteen pts (61.3%; 11 PR, 8 PS) had stable disease. By cohort, 3 pts had partial response (12.5%; 3/24) cohort A, 4 partial response cohort B (100%; 4/4 all with resistance mechanisms) and 3 partial response (100%; 3/3) cohort C. Median PFS in the personalized phase was 7.8 months (m) for those in cohort A, 6.2m for B and 13.1m for C. Median PFS for PR pts was 6.9m (4.4-13.1) and for PS pts not reached. Grade (G) 3 AE related to therapy per cohort: A) 4 pts with anemia, 2 neutropenia, 1 thrombocytopenia, 1 nausea; B) 2 pts neutropenia; C) no G3. No G4 AE. No G3-G4 immune related AE. **Conclusions:** These findings highlight the potential clinical activity of a chemo-free approach and confirmed the feasibility of guiding personalized therapy in real-time in recurrent OC pts post-PARPi. This strategy was safe and provided clinical benefit to some pts. Further translational analysis is ongoing. Clinical trial information: NCT05065021. Research Sponsor: GSK; Apobiologix; Princess Margaret Cancer Foundation; OICR.

Phase I study of sustained and local delivery of intraperitoneal IL-2 using encapsulated cells in patients with platinum-resistant high-grade serous carcinoma. First Author: Helen D. Clark, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Platinum-resistant high-grade serous carcinoma's (HGSC) propensity to metastasize throughout the peritoneal cavity has generated interest in the development of high-intensity locoregional treatment administered intraperitoneally. Prior efforts have been limited by administration difficulties and potential for local toxicity. We describe a phase I trial using AVB-001, a novel intraperitoneally administered, alginate-encapsulated, allogeneic cell line modified for constitutive expression of human interleukin-2 (hIL-2). Preclinically, this new platform allows self-limited anti-tumor immune-activation without the toxicities associated with systemic administration or prior intraperitoneal formulations. The primary objectives of this study were to investigate the feasibility, safety, and tolerability of treatment with AVB-001. Secondary objectives included evaluation of clinical efficacy and translational correlates. **Methods:** This was an open-label, multicenter, phase I dose escalation study. A single dose of AVB-001 was administered via laparoscopy at 1 of 4 dose levels ranging from 0.6 to 3.6 μg hIL-2/kg/day. Escalation to a higher dose was based upon Bayesian optimal interval 3+3 design. Toxicity was evaluated via NCI CTCAE v5.0 and response was assessed via RECIST v1.1. Translational analyses were performed to evaluate serum hIL-2 concentration and immunological changes in peripheral blood. **Results:** The trial enrolled 14 patients. Eleven patients had ovarian cancer, two had fallopian tube cancer, and one had peritoneal cancer. Median age was 68 (range 47-75). In terms of safety, 4 of 14 patients (28.6%) experienced a grade 3 treatment-related adverse event (TRAE). There were no grade 4 or 5 TRAEs. One patient exhibited an unconfirmed partial response lasting 29 days (ORR 1/14, 7.1%). Stable disease was observed in 7 patients with a median duration of clinical stability lasting 2.57 months (range 2.03-4.23). On translational analyses, dose-dependent immunologic changes were noted in the peripheral blood. CTLA-4 receptor expression was upregulated with increasing dose levels in both CD8+ and CD4+ T cells, however significant upregulation was not observed for either PD-1 or TIM-3. The study was terminated early due to funding limitations. **Conclusions:** The administration of AVB-001 is safe, feasible, and shows potential for meaningful clinical activity. A dose-dependent upregulation of the CTLA-4 checkpoint on CD8+ and CD4+ T cells was noted after administration, suggesting a rationale for combination therapies involving cytokines as "priming agents" to engage checkpoint inhibition. Finally, we demonstrate feasibility of this approach for delivery of hIL-2 and other future biologics via our ability to reproducibly manufacture multiple clinical batches of AVB-001 and deliver at point of patient care. Clinical trial information: NCT05538624. Research Sponsor: Avenge Bio, Inc; MD Anderson T32 Training Grant; T32CA101642; MD Anderson CCSG Core Grant; P30CA016672.

Circulating tumor DNA (ctDNA) monitoring in participants (pts) with ovarian cancer treated with neoadjuvant pembrolizumab (pembro) + chemotherapy (chemo) ± anti–immunoglobulin-like transcript 4 (ILT4) monoclonal antibody MK-4830. First Author: Jung-Yun Lee, Yonsei Cancer Center and Severance Hospital, Yonsei University College of Medicine, Seoul, South Korea

Background: ctDNA is a promising biomarker for predicting disease progression, survival, and surgical outcomes in patients with solid tumors. In a phase 1 study (NCT03564691), ILT4 inhibitor MK-4830 + pembro had a manageable safety profile and showed antitumor activity in pts with solid tumors. We present results from a global, randomized phase 2 study (NCT05446870) evaluating quantitative change in ctDNA in pts with high-grade serous ovarian cancer (HGSOC) who received neoadjuvant pembro + chemo ± MK-4830. **Methods:** Eligible pts were female, aged ≥18 y, with previously untreated histologically confirmed FIGO stage 3 or 4 HGSOC and an ECOG performance status of 0 or 1, and were candidates for interval debulking surgery. Pts were randomly assigned 1:1 to receive neoadjuvant MK-4830 800 mg + pembro 200 mg + chemo (paclitaxel 175 mg/m^2 and carboplatin AUC 5-6) (arm 1) or pembro + chemo (arm 2) IV Q3W for 3 cycles. Pts underwent interval debulking surgery followed by 3 cycles of adjuvant therapy with the neoadjuvant regimen; adjuvant bevacizumab IV Q3W was permitted. ctDNA was assessed at each cycle using the Signatera assay (Natera, Inc.). A constrained longitudinal data analysis model was used to estimate the posterior probability that the coefficient for treatment assignment was <0, evaluating whether the reduction in ctDNA from cycle 1 (C1) was larger in arm 1. The primary end point was change in ctDNA from C1 at C3 in pts with detectable ctDNA; safety was a secondary end point. **Results:** At data cutoff (Dec 20, 2023), 160 pts were enrolled; 159 pts received treatment (arm 1, n = 79; arm 2, n = 80). Median study follow-up was 8.3 months (range, 1.9-16.4) in arm 1 and 8.3 months (range, 2.1-16.3) in arm 2. Median age was 61.5 y in both arms. 64 pts (80.0%) in arm 1 and 68 pts (85.0%) in arm 2 had available ctDNA data at C1; 51 pts (63.8%) and 63 pts (78.8%), respectively, had available ctDNA data at C3. Median ratio of ctDNA C3 to C1 was 0.02 (range, 0-1.53) in arm 1 and 0.01 (range, 0-0.60) in arm 2. The posterior probability that the coefficient for treatment assignment was <0 in the model was 38.8%, indicating a low posterior certainty of larger ctDNA reduction in arm 1. AEs occurred in 75 pts (94.9%) in arm 1 and all pts (100%) in arm 2. TRAEs occurred in 74 pts (93.7%) in arm 1 and in 79 pts (98.8%) in arm 2; grade 3-5 events occurred in 37 pts (46.8%) and 44 pts (55.0%), respectively. TRAEs led to death in 2 pts in arm 1; no treatment-related deaths occurred in arm 2. **Conclusions:** In pts with HGSOC, reductions in ctDNA were similar between neoadjuvant/adjuvant MK-4830 + pembro + chemo vs pembro + chemo. Real-time tumor-informed ctDNA testing may be feasibly incorporated into future clinical trials as a surrogate outcome to evaluate response. The safety profile of MK-4830 + pembro + chemo was comparable to pembro + chemo. Clinical trial information: NCT05446870. Research Sponsor: Merck Sharp & Dohme LLC, a subsidiary of Merck & Co., Inc., Rahway, NJ, USA.

Preliminary analysis of disitamab vedotin combined therapy for HER2-expressing platinum-sensitive recurrent ovarian/peritoneal/fallopian tube cancer (Diversity study): A single-arm, multicenter phase II trial. First Author: Tong Shu, Key Laboratory of Carcinogenesis and Translational Research (Ministry of Education), Department of Gynecologic Oncology, Peking University Cancer Hospital & Institute, Beijing, China

Background: Platinum-sensitive recurrent epithelial ovarian/peritoneal/fallopian tube cancer (PSROC) patients often exhibit reduced responsiveness to chemotherapy following initial platinum-based regimens, necessitating the development of more effective treatment strategies. Disitamab vedotin (DV; RC48) is a novel humanized anti-HER2 antibody-drug conjugate (ADC) with greater specificity than conventional agents like paclitaxel. This study (NCT06420973) evaluates the efficacy and safety of DV-based combination therapy in patients with HER2-expressing PSROC. **Methods:** This single-arm, open-label, multicenter phase II study examines DV combination therapy in patients with HER2-expressing (IHC 1 to 3+) PSROC. Patients received DV (2.5 mg/kg) plus carboplatin (AUC 5), with or without bevacizumab (7.5–15 mg/kg), every 21 days for six cycles. Maintenance therapy included DV (up to eight cycles) with or without bevacizumab until disease progression. The primary endpoint is PFS. Secondary endpoints include ORR, DCR, OS and safety. An exploratory endpoint assesses quality of life using the EORTC QLQ-CIPN20 (excluding Item 20). **Results:** As of January 2025, 15 patients (median age 58 years, range 47-73) were enrolled, with 86.7% diagnosed with ovarian cancer and 93.3% having high-grade serous carcinoma. Genetic analysis identified 4 gBRCA1 mutations, 1 sBRCA2 mutation, 5 wild-type cases, and 5 with unknown status. HER2 expression was 73% for IHC 1+ and 27% for 2+. The median number of prior treatment lines was one, with a median follow-up of 3.2 months (range 1-6.8m). Efficacy was evaluated in 10 patients, while safety was assessed in all 15. The ORR was 70% (1 CR, 6 PR), with a DCR of 100%. The ORR for both BRCA mutations and wild-type was 66.7%. Among patients with HER2 IHC 1+, the ORR was 71.4%, while for 2+, it was 66.6%. Patients with PFI >12 months had a 75% ORR, compared to 50% for those PFI <12 months. Treatment-related adverse events (TRAEs) were reported in 80% of patients, with ≥ Grade 3 TRAEs at 26.7%, including neutropenia (n=1), thrombocytopenia (n=2), and diarrhea (n=1). No Grade 4 or 5 TRAEs were observed. The EORTC QLQ-CIPN20 score showed no significant impact on quality of life compared to baseline. As of January 23, 2024, one patient had disease progression. **Conclusions:** The preliminary findings indicate that DV combined therapy is effective and safe for the treatment of HER2-expressing PSROC, highlighting its potential as a valuable therapeutic option. Further research in this area is essential to validate these results. Clinical trial information: NCT06420973. Research Sponsor: Clinical Research Fund for Distinguished Young Scholars of Peking University Cancer Hospital; QNJJ2023003.

IBI354, an anti-HER2 antibody-drug conjugate, in patients with locally advanced unresectable or metastatic ovarian cancers: Updated results from a phase I trial. First Author: Jin Shu, Chongqing University Cancer Hospital, Chongqing, China

Background: IBI354 is an antibody-drug conjugate consisting of trastuzumab (anti-HER2 antibody) conjugated to a topoisomerase I inhibitor. It has showed manageable safety and encouraging efficacy in patients (pts) with advanced gynecologic cancers (including ovarian cancers [OC], Shu et al, abstract No. 720MO at 2024 ESMO annual meeting). Here, we present the updated safety and efficacy in OC. **Methods:** Eligible OC pts with HER2 alteration (IHC 1+, 2+, 3+ and/or ISH+ and/or NGS confirmed mutation or amplification) who failed or were intolerant to standard treatment were enrolled from China and Australia. Pts received IBI354 at 2−12 mg/kg every three weeks (Q3W) or Q2W. Primary endpoint was safety. Secondary endpoints were objective response rate (ORR), disease control rate (DCR), duration of response (DoR), and progression-free survival (PFS) per RECIST v1.1. **Results:** As of November 12, 2024, 92 pts were enrolled (median age, 58.0 years; Asian, 95.7%; White, 4.3%; ECOG PS 1, 73.9%; IHC 1+, 65.2%; IHC 2+, 29.3%). The median follow-up time was 11.0 months (range: 8.0−19.0). Median treatment duration was 24.1 (range: 3.1−60.3) weeks with 21 (22.8%) pts still on treatment. Treatment-related adverse events (TRAEs) occurred in 79 (85.9%) pts with grade ≥ 3 TRAEs in 27 (29.3%) pts. The most common TRAEs were anemia (51.1%), white blood cell count decreased (45.7%), neutrophil count decreased (40.2%), and nausea (35.9%). Serious TRAEs occurred in 10 (10.9%) pts. Interstitial lung disease or pneumonitis was observed in 1 (1.1%) pt, which was grade 2 and not related to IBI354 considered by the investigator. TRAEs led to dose reduction in 2 (2.2%) pts. No TRAEs led to treatment discontinuation or death. For efficacy-evaluable pts (who had at least 1 post-baseline tumor assessment) dosed at 12 mg/kg Q3W (n = 40), confirmed ORR and DCR reached 55.0% (95% CI: 38.5−70.7) and 90.0% (95% CI: 76.3−97.2), respectively. In 22 pts with confirmed response in 12 mg/kg Q3W dose group, the median DoR was not reached with events occurred in 6 (27.3%) pts, and 9-month DoR rate of 58.1% (24.2−81.2). The median PFS was 7.1 months (95% CI: 5.2−not reached) with events occurred in 21 (51.2%) pts. The median overall survival (OS) was not reached with events occurred in 12 (29.3%) pts, and the 9 month OS rate was 70.7% (95% CI: 54.3−82.2). For the pts with HER2 IHC 1+ OC dosed at 12 mg/kg Q3W (accounting for 67.5% [27/40] of efficacy-evaluable pts at 12 mg/kg Q3W), ORR and DCR reached 55.6% (95% CI: 35.3−74.5) and 88.9% (70.8−97.6), respectively. **Conclusions:** IBI354 was well tolerated with a manageable safety profile and showed promising efficacy in pts with locally advanced unresectable or metastatic OC, especially in pts with HER2 lower expression. Clinical trial information: NCT05636215. Research Sponsor: None.

5566 **Poster Session**

Successful induction of tumor-directed immune responses in high grade serious ovarian carcinoma patients after primary treatment using a whole tumor cell vaccine. First Author: Annegé Vledder, University Medical Centre Groningen, Groningen, Netherlands

Background: Improving disease free and overall survival in advanced high grade serous ovarian carcinoma (HGSOC) after primary treatment remains challenging. This phase 1 trial (NCT04739527) evaluated safety and immunogenicity of a whole tumor cell vaccine, vididencel, to prime or boost immune responses in HGSOC after primary treatment. Vididencel expresses tumor associated antigens (TAA) frequently upregulated in HGSOC. **Methods:** Patients with advanced HGSOC who completed primary treatment received 6 intradermal injections with vididencel: 4 biweekly doses of 25 million cells (week 0, 2, 4 and 6) followed by 2 boosters of 10 million cells (week 14 and 18). Peripheral blood mononuclear cells were obtained at week 0, 4, 10, 14, 18 and 22. Disease status was evaluated at week 22 using clinical assessment and CA125 levels. Primary endpoint was safety and the induction of immune responses, measured by IFNγ ELISPOT, to at least one TAA (i.e. WT-1, PRAME, NY-ESO, or MAGE-A3/4). Secondary endpoints were disease status at week 22 and survival. **Results:** Primary analysis at week 22 has been completed for all 17 patients. In total,16 received all 6 planned injections and 1 patient discontinued treatment after 4 injections due to disease progression. Vididencel showed in 12 out of 17 patients a vaccine-induced response (VIR) to at least one of the tested antigens and 7 of these patients showed a sustained immune responses to the same antigen (sVIR). Table 1 shows the distribution of induced immune responses. Five patients were also given maintenance treatment with PARP inhibitors and all these patients showed a VIR. Vididencel was well-tolerated, with no trAEs above grade 2. The most common trAEs were mild to moderate local injection site reactions, characterized by redness, swelling and inflammation. Two unrelated serious AEs occurred, both linked to disease progression. At week 22, 4 weeks after last vididencel treatment, 10 patients (59%) had stable disease, and 7 had progressive disease, with all patients still alive. Patients with a VIR or sVIR had a higher rate of SD than patients without a vaccine-induced immune response (67% and 71% versus 40%, respectively). Long-term follow of patients continues of which a swimmers plot will be shown. **Conclusions:** Vididencel is well tolerated and effective in eliciting or boosting a broad T-cell response in HGSOC patients after primary treatment. Short-term evaluation of clinical response at week 22 suggests better responses in patients developing a VIR or sVIR compared to those patients not having a detectable immune response to the vaccine. Clinical trial information: NCT04739527. Research Sponsor: Mendus AB.

Immune response outcome (N=17)		Responses to individual TAAs			
		WT1	PRAME	NY-ESO	MAGEA3/A4
Immune responders (N=12)	VIR (n=12)	6 of 12	3 of 12	4 of 12	7 of 12
	sVIR (n=7)	4 of 7	2 of 7	1 of 7	2 of 7
Non-responders (N=5)	No VIR (n=5)				

(s)VIR; (sustained) vaccine induced response.

Optimizing an NGS low-pass–based method to detect genomic instability as a PARP inhibitor predictive biomarker in high-grade serous ovarian cancer. First Author: Ignacio Romero, Instituto Valenciano de Oncología (IVO) and GEICO, Valencia, Spain

Background: In high-grade serous ovarian cancer (HGSOC) PARP inhibitors constitute a standard treatment in tumors harboring Genomic Instability (GI). This biomarker constitutes a valuable predictive tool for the use of PARP inhibitors. Available commercial solutions to determine the GI status, present some caveats that must be overcome. This study aims to set up an academic test in a cost-effective manner by applying open-source R libraries to establish GI status in Formalin-Fixed and Paraffin-embedded (FFPE) samples. **Methods:** The study was carried out in two stages, technical and analytical setup and clinical validation. Firstly, 16 FFPE samples, 8 tumoral tissue from gynecological malignancies, and 8 from healthy tissues were sequenced. This step aimed to establish favorable sequencing conditions followed by the tune-in of specific parameters for the analytical pipelines, QDNA, and Shallow-HRD (R v.4.3.11). Secondly, 44 FFPE samples from patients diagnosed with HGSOC and known GI score (GIS) were used for clinical validation. For this analysis, GIS determined by GIInger from Sophia Genetic was considered the gold standard. The series was constituted of 23 samples carrying genomic instability (GIS>=0) and 21 stable samples (GIS<0). Of note, intermediate libraries from targeted sequencing performed in clinical routine were used as input for sequencing. Individual libraries were then pooled and sequenced in a NextSeq 2000 (2x100 paired-end) (Illumina, San Diego, CA, USA) to achieve a 0.5x coverage. Recalibration of the method was performed using Maxstat algorithm implemented in R. All the analyses were performed in Python v3.8 or R v.4.3.11. **Results:** Best technical and analytical results were obtained for the QDNA pipeline without an X chromosome and bin size of 1 mb plus shallowHRD. By using this parameter, clinical validation comparing the GI results with GIS score obtained from the Sophia Genetics test was performed. In-house determination of GI resulted in 23 samples classified as unstable (score>=20) and 21 stable samples (score < 20). Re-calibration of the score using 20 as a new cut-off to dichotomize the variable, showed an optimum performance with a concordance of 86.4 % (p < 6.2 -6) with GIS classification. Thus, borderline samples called by shallowHRD pipeline (5/44) were re-classified as stable. Both continuous scores showed a correlation of 0.855 (p < 1.5 -13) and an Area Under the ROC curve of 0.906, presenting an excellent performance as a biomarker for genomic instability. **Conclusions:** We present a validated, routine-based and cost-effective test to determine GI in HGSOC, being easily transferrable to daily practice. Real-world analysis of folate receptor alpha (FRα; FOLR1) expression in pan-tumor samples from over 6000 patients in the US. First Author: Thomas C. Krivak, Division of Gynecologic Oncology, Allegheny Health Network Cancer Insitute, Pittsburgh, PA

Background: FRα is overexpressed in several cancers, including ovarian and endometrial. The FRα-targeted antibody-drug conjugate mirvetuximab soravtasine-gynx (MIRV) showed survival benefit vs chemotherapy in patients with platinum-resistant ovarian cancer (PROC) with high FRα expression (Moore K, et al. *N Engl J Med*. 2023;389(23):2162-2174). Greater understanding of FRα expression and distribution in real-world (RW) settings may help enable FRα testing implementation for biomarker-guided treatment strategies. Here, we present analyses of FRα expression in RW patient tumor samples referred for FRα testing by immunohistochemistry (IHC). **Methods:** Uniquepatient tumor samples across different malignancies (N=6695) were acquired from RW healthcare settings in the US over a 12-month period. FRα expression was assessed by IHC using the VENTANA FOLR1 (FOLR1-2.1) RxDx Assay. Trained pathologists scored samples with ≥75% tumor cells with ≥2+ membrane staining as FRα positive. The clinicopathological features of each case, FRα prevalence, and impact of sample age were evaluated. **Results:** From the entire dataset (N=6695), 41% of samples were FRα positive, 54% were negative, and 5% were not evaluable. Of 2000 samples with known primary tumor origin: 1632 (82%) were primary or metastatic sites of disease from patients with ovarian cancer (39% FRα positive); 266 (13%) originated from distinct non-ovarian tumor types, including primary peritoneal, Müllerian, pelvic, and gynecological sites of unspecified origin (combined 33.1% FRα positive); the remaining 102 (5%) had unconfirmed tumor origin. Of 1678 samples with known histological subtype, FRα positive expression was observed in samples from serous (43.5% [646/1486]), mixed (37% [14/38]), and endometrioid (10% [5/48]) histology, whereas FRα positive expression was absent across all clear cell (0/91) and mucinous subtypes (0/15). FRα positive expression was detectable in unique patient samples across all sample ages, which ranged from <1 to >5 years. **Conclusions:** RWanalysis of 6695 patient tumor samples referred for FRα testing demonstrated FRα prevalence of 41%. Ovarian cancers represented most cases evaluated, and the 39% FRα positive rate was consistent with the FRα positive prevalence observed in MIRV clinical trials (35%). This RW analysis demonstrates that FRα is measurable in samples ranging from <1 to >5 years, suggesting prior samples may be utilized for FRα testing if a recent sample is unattainable. This is consistent with previous analyses from MIRV clinical trials where most patients with PROC were selected for enrollment based on high FRα expression from archival tumor specimens. Collectively, this large RW data set helps to characterize the RW prevalence of the clinically actionable biomarker FRα and supports using FRα testing for personalized ovarian cancer treatment plans. Association of HIPEC response in ovarian cancer with PI3K/RAS/Notch gene signatures: A whole transcriptomic analysis of U.S. and French HIPEC treated ovarian cancer patients. First Author: Thanh Hue Dellinger, City of Hope, Duarte, CA

Background: Hyperthermic intraperitoneal chemotherapy (HIPEC) is associated with improved overall survival in Stage III epithelial ovarian cancer (EOC) patients. We set out to evaluate the gene signatures associated with HIPEC response in EOC patients. **Methods:** Ninety-one EOC patients who underwent HIPEC with pre-operative tumor samples at City of Hope (51) and CHU Lyon (40) were identified between 2014 and 2022. RNA isolation was performed from formalin-fixed paraffin-embedded samples, followed by Whole-transcriptome library construction. Following exclusion of non-high grade serous (HGS) samples, and quality control steps, twenty-four samples were excluded. Progression-free survival (PFS) was used to define HIPEC response. Cut-off PFS values were used to distinguish good vs poor responders in primary EOC patients (18 months, based on KGOG, CARCINO-HIPEC trials), and recurrent EOC patients (12 months, based on MSK, CHIPOR HIPEC trials). Differential Gene Expression Analysis comparing good and poor HIPEC responders identified significantly changed genes. Pathway analysis was conducted using gene set enrichment analysis (GSEA) against Hallmark. **Results:** A total of sixty HGS tumor samples with available survival data were analyzed. 63.3% were primary EOC, 36.7% recurrent EOC. Germline BRCA mutations affected 21.7% of patients. With a median follow up of 31.9 months, median PFS was 29.3 (95%CI: 15.3, 63.5) months in primary EOC patients and 26.0 (95%CI: 14.7, 37.1) months in recurrent patients. Median OS was not reached in either group. 60.0% had a recurrence. Thirty-eight patients were identified as good responders, with a median PFS of 37.1 mos. (95%CI: 26.4, NR); 18 patients were identified as poor responders, with median PFS of 11.4 months (95%CI: 7.5, 14.2). Differential gene expression analysis between good and poor responders revealed 29 significantly upregulated 35 downregulated genes in HIPEC responders. Top upregulated genes in HIPEC responders include MAPK signaling pathway genes (RIB2, ETV5, CAPN8, IGFR1), in addition to CCND1 and CEACAM1. In HIPEC responders, the top-ranking gene sets in the transcriptional signature included Notch, KRAS, and Wnt/beta-catenin signaling pathways. In poor HIPEC responders, the DNA damage repair associated pathways E2F targets and G2M checkpoint, were activated. Similar transcriptomic pathway signatures were observed in Non-recurrent versus Recurrent HIPEC patients: Non-recurrent tumors were enriched with Notch signaling, while Recurrent tumors were enriched with E2F target and G2M checkpoint pathways. **Conclusions:** Good HIPEC response is characterized by transcriptional signatures consistent with Type I EOC characteristics of PI3K/RAS/Notch signaling. Recurrence after HIPEC in HGS ovarian cancer is higher in patients with E2F/G2M transcriptional signatures. Research Sponsor: None.

Immunotherapy with anti-PD-1 or PD-L1 in advanced ovarian cancer (OC): A meta-analysis of randomized trials. First Author: Riccardo Vida, Department of Medical Oncology, Centro di Riferimento Oncologico (CRO), IRCCS; Department of Medicine (DMED), University of Udine, Aviano, Italy

Background: Immunotherapy (IO) has shown promising results in several solid tumors, including gynaecological malignancies. While PARP inhibitors and bevacizumab had deeply improved outcomes in OC, prognosis remains poor, underscoring the need for innovative treatment strategies. Anti-PD-1 and PD-L1 monoclonal antibodies have been evaluated in randomized trials across both first-line and recurrent OC settings. This meta-analysis summarizes the available evidence to assess progression-free survival (PFS) benefits from IO-based strategies. **Methods:** Phase II and III randomized clinical trials (RCTs) evaluating IO-based strategies using PD1 or PDL1 inhibitors published between 2019 and 2024 were identified through PubMed, Embase, and the Cochrane Library, as well as conference proceedings. Eight trials with PFS as primary endpoint, conducted in first-line and recurrence settings, were included. Data on PFS by PD-L1 status were available in seven trials. Three trials included two experimental arms and were analysed separately. Hazard ratios (HRs), 95% confidence intervals (CIs), and PFS events were extracted for overall populations and subgroups. A random-effects model was employed for data analysis, with sensitivity analyses performed to explore outcome variability. **Results:** The meta-analysis included 8 trials comprising 6,205 patients. The addition of IO to chemotherapy or placebo showed no improvement in PFS (HR = 1.02, 95% CI 0.86-1.22). Subgroup analyses indicated no significant differences in PFS in first-line (HR = 0.99, 95% CI 0.78-1.26) or recurrence settings (HR= 1.07, 95% CI 0.80-1.44). In trials reporting PD-L1 status (47.5% PD-L1 positive population), IO-based therapies demonstrated a non-significant trend towards PFS improvement (HR = 0.94, 95% CI 0.77-1.13). Excluding IO-only arms yielded similar results (HR = 0.94, 95% CI 0.79-1.11). **Conclusions:** IO-based strategies did not provide a substantial PFS benefit in advanced OC, irrespective of disease setting or PD-L1 status. Identifying effective combination strategies and patient subgroups that may benefit from IO remains an open research question. Research Sponsor: None.

Harnessing EHR for goals of care: The role of electronic alerts for care optimization in gynecologic cancer patients at risk of death in 6 months. First Author: Katherine Fitch, Duke University, Durham, NC

Background: This study employed the validated Surprise Question to evaluate the ability of an electronic health record (EHR) alert to predict 6-month mortality, prompt goals of care (GOC) documentation, and facilitate high-quality end of life (EOL) care for patients with gynecologic cancer. **Methods:** EHR coding identified patients in an outpatient academic gynecologic oncology practice seen more frequently than annually with scheduled imaging, CA125 values, or chemotherapy. Patients without a diagnosis of primary gynecologic cancer were excluded. An outpatient EHR alert posed the modified Surprise Question: "Would you be surprised if the patient passed away in the next 6 months?" Choices were "Yes" and "No" (both considered meaningful responses) and "Show me next time" (deferral response; excluded). "No" responders were instructed on-screen to document a GOC discussion and consider palliative care referral. We analyzed EHR alert data from August 1, 2021-December 31, 2022, and clinical events up to 22 months after this period. Continuous variables were compared using Wilcoxon rank-sum tests, categorical variables were compared with chi-square tests, and both Cox proportional hazards regression and log-binomial models were used to predict death/time to death. **Results:** Meaningful responses were elicited for 804 unique patients, of which 130 (16.2%) were "No" (not surprised). Among patients whose providers replied "No", 35.4% died within 6 months of that encounter, compared to 4.2% of "Yes" replies ($p<0.001$). Among patients with a documented GOC conversation, the median time from first "No" response to documented conversation was 0 days (IQR 0.0, 84), compared to 255 days (IQR 81, 501) for "Yes". Among patients who died, subjects in the "No" group were more likely to be enrolled in hospice at EOL than those in the "Yes" group (79.0% vs 63.5%, p=0.014). A "No" response to the Surprise Question had a higher RR for death at 6 and 12 months compared to age, race, or cancer type. **Conclusions:** For patients with gynecologic cancer, responses to a Surprise Question EHR alert effectively predict 6-month mortality and are associated with increases in both GOC discussions and hospice utilization. Research Sponsor: None.

Log-binomial predictors of death at 6 months (univariate model).

		Risk Ratio (RR)	95% CI of RR	p-value	% deaths

Safety and effectiveness of fuzuloparib in patients with ovarian cancer: A nationwide, multicenter, prospective real-world study. First Author: Qinglei Gao, Department of Gynecological Oncology, Tongji Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, China

Background: Fuzuloparib, a poly (ADP-ribose) polymerase (PARP) inhibitor, is approved in China for the treatment of platinum-sensitive recurrent (PSR) ovarian cancer (OC) and for maintenance therapy in newly diagnosed advanced and PSR OC. This study aims to evaluate the safety and effectiveness of fuzuloparib in OC patients under real-world settings. **Methods:** This multicenter, prospective real-world study included patients from 27 centers across China between January 2022 and August 2024. Eligible patients were aged ≥18 years and suitable for fuzuloparib treatment (monotherapy or combination therapy). Patients also had histologically or cytologically confirmed epithelial OC, primary peritoneal or fallopian tube cancer. The outcomes observed in this study included the incidence of treatment-related adverse events (TRAEs), progression-free survival (PFS), and overall survival (OS). **Results:** A total of 260 patients who received fuzuloparib (171 on monotherapy, 66 on combination therapy, and 23 with unknown treatment type) were analyzed. Of these, 97 (37.3%) received first-line maintenance therapy, 112 (43.1%) received maintenance therapy for PSR disease, 23 (8.8%) received treatment for PSR disease, 20 (7.7%) received treatment for platinum-resistant recurrent disease, and 8 (3.1%) received other treatments. The median age was 57 years (interquartile range [IQR]: 51.0, 65.0). Among the patients, 215 (82.7%) had epithelial OC, 169 (65.0%) were diagnosed at stage III/IV. Of the 239 patients with available safety data, 149 (62.3%) reported at least one TRAE. The most common TRAEs were anemia (23.4%), thrombocytopenia (23.4%), leukopenia (18.8%), and lymphopenia (12.6%). Fifty-four patients (22.6%) reported grade 3 or higher TRAEs. The median follow-up time for the first-line maintenance therapy group was 11.4 months (IQR: 6.0, 17.4), with median PFS and OS not yet reached; the 1-year PFS rate was 90.7%, and the 1-year OS rate was 97.1%. In the PSR maintenance therapy group, the median follow-up time was 9.1 months (IQR: 4.2, 15.9), with median PFS of 17.3 months (95% confidence interval [CI]: 12.1-26.3) and median OS not yet reached; the 1-year PFS rate was 66.2%, and the 1-year OS rate was 92.0%. In the PSR treatment group, the median follow-up time was 12.7 months (IQR: 5.6, 19.9), with median PFS and OS not yet reached; the 1-year PFS rate was 77.8%, and the 1-year OS rate was 90.2%. In the platinum-resistant relapse treatment group, the median follow-up time was 8.9 months (IQR: 5.1, 13.2), with median PFS and OS not yet reached; the 1-year PFS rate was 59.1%, and the 1-year OS rate was 80.0%. **Conclusions:** This is the first large-scale real-world study assessing the safety and effectiveness of fuzuloparib. In the real-world setting, fuzuloparib shows favorable safety, with no new safety signals. The effectiveness outcomes align with trends observed in key clinical trials. Clinical trial information: NCT05206890. Research Sponsor: None.

EON: Phase II trial of etigilimab (MPH313) in combination with nivolumab in patients with recurrent platinum-resistant clear cell ovarian cancer. First Author: Ji Son, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: A predictor of response to anti-PD1 therapy is the extent of CD8+ infiltration within the pretreated tumor. TIGIT has shown to suppress anti-tumor immune responses via increased CD4+ Tregs and disruption of CD226 co-stimulation. We hypothesized inhibition of TIGIT may reverse the immune suppressive tumor microenvironment thereby potentiating the efficacy of PD-1 blockade in ovarian cancer. We sought to explore toxicity and efficacy of the combination of TIGIT inhibitor, etigilimab, and PD-L1 inhibitor, nivolumab. **Methods:** Eligible patients (pts) had platinum-resistant recurrent clear cell ovarian cancer with no prior immunotherapy and unlimited prior lines. Measurable disease and adequate end organ function were required. Pts received etigilimab 1000mg IV and nivolumab 240mg IV every 2 weeks. Bayesian optimal phase 2 design was used to conduct the trial. Dual primary end points were toxicity assessment by CTCAE v5.0 and objective response per modified RECIST v1.1. Clinical benefit (CBR) was defined as objective response or stable disease (SD) for >/= 4 months. Progression-free survival was defined as time from first treatment to documented disease progression. NCT05715216. **Results:** 23 pts received at least one cycle of treatment. Median age was 54 years (range 38-73); 65.2% of pts were Non-Hispanic white, 17.4% Hispanic, 8.7% Black and 8.7% Asian. Median lines of prior therapy was 2 (range 0-8). No patient received prior PARP inhibitor. Grade 3 or 4 adverse events were observed in 47.8% of pts, the most common of which was abnormal liver function tests. Other common adverse events of any grade included nausea/vomiting (34.8%), fatigue (30.4%), and anemia (30.4%). Of 20 pts evaluable for response, objective response rate was 15.0% (95% CI 3.2-37.9%) with 1 complete response (CR) and 2 partial responses (PR). CBR was 30.0% (95% CI 11.9%-54.3%). Median duration of response was 8.6 months, with ongoing responses in 2 pts at 20.0 and 8.6 months. Median duration of clinical benefit was 7.5 months. Single-cell RNA seq analysis of tumor tissues from 9 pts (CR/PR=2, SD=4, PD=3) revealed immunologic changes in the tumor microenvironment after treatment. Notably, an increased frequency of plasma B cells (p=0.02) was associated with clinical response. **Conclusions:** The combination of etigilimab and nivolumab was well tolerated. Promising clinical response and duration of benefit was observed in a heavily pretreated population of pts with clear cell ovarian cancer. Our data highlight a potential role of B cells in clinical response. Further analysis on the association of benefit by molecular features is ongoing. Clinical trial information: NCT05715216. Research Sponsor: Mereo BioPharma Group PLC; U.S. National Institutes of Health; Focus Fund; U.S. National Institutes of Health; U.S. National Institutes of Health.

Potential of tumor-informed ctDNA as an early predictive indicator for relapse in advanced ovarian cancer. First Author: Christina Victoria Isabella Tauber, Department of Obstetrics and Gynecology and Comprehensive Cancer Center Munich, LMU University Hospital, LMU Munich, Bayern, Munich, Germany

Background: Prediction of relapse following firstline treatment in patients (pts) with high-grade serous ovarian cancer (HGSOC) remains a major challenge despite recent advances. Reliable markers for assessment of recurrence risk are urgently needed to tailor treatment strategies with circulating tumor DNA (ctDNA) emerging as a promising candidate. **Methods:** In this prospective feasibility study, pts with advanced HGSOC who underwent primary surgical and systemic treatment at two large-volume centers for gynecologic oncology were evaluated between July 2021 and September 2024. Whole genome sequencing was used to develop a personalized multiplex digital polymerase chain reaction fingerprint assay by identifying structural variants, single nucleotide variants and indels in FFPE tumor tissue. Longitudinal blood samples were collected perioperatively (preop, postop day 2 and 10), during firstline chemotherapy (cycle 1, 3 and 6 [c6]) and follow up. CA-125 levels were tested accordingly. For statistical analyses, chi squared, log rank tests and Kaplan-Meier method for PFS were applied as appropriate. **Results:** As of 21st January, 2025, a total of 31 pts have available samples from preop through c6 with completed ctDNA data. In this cohort, 11 recurrences (35%) have been diagnosed at a median clinical follow-up of 16.8 months [mo] (range 5.7-38.4 mo), median progression-free survival (PFS) was 11.8 mo (range 5.7-22.9 mo). At c6, levels of CA-125 were $<$35 kU/L in 25 (81%) and $\geq$35 kU/L in 6 (19%) of the 31 pts. Clearance of ctDNA was noted for 19 out of 31 pts (61%). 16 of these 19 pts (84%) had previous complete cytoreduction. While rates for recurrence did not align with CA-125 levels $<$35 kU/L (63.6%) and $\geq$35 kU/L (36.4%, *P*=0.075) at c6, a significantly lower recurrence rate was observed for patients with ctDNA clearance at c6 (4 of 19, 21.1%) compared to 7 of 12 patients with persistent ctDNA (58.3%, *P*=0.034). In 21 patients with complete cytoreduction, five pts still had detectable ctDNA levels at c6. Three of these five pts had recurrence (60%), compared to two of 16 pts with ctDNA clearance (12.5%, *P*=0.023). Detection of residual ctDNA at c6 was strongly associated with an increased risk for recurrence in the overall cohort compared to pts with ctDNA clearance (HR: 5.78, 95%CI: 1.93 – 31.99, *P*=0.004). This effect appears to be more pronounced in pts with macroscopic complete cytoreduction, but was not seen in pts with residual tumor. **Conclusions:** Findings of this interim analysis underline the potential of tumor-informed ctDNA as a powerful tool for recurrence risk assessment in pts undergoing primary treatment for HGSOC. In contrast to CA-125, ctDNA evaluation at the time of completed firstline chemotherapy might serve as an early predictive marker for relapse. This information could help to develop patient-specific treatment strategies, especially in the subgroup of pts with complete macroscopic cytoreduction. Research Sponsor: None.

AI-powered quantification of tumor-infiltrating lymphocytes from H&E stained images in ovarian cancer and its association with PARP inhibitor therapy outcomes. First Author: Hiroshi Asano, Department of Obstetrics and Gynecology, Hokkaido University Graduate School of Medicine, Sappro, Japan

Background: Maintenance therapy with PARP inhibitors improves the prognosis of patients with advanced or recurrent ovarian cancer. However, a simple biomarker detectable at treatment initiation remains unclear. This study evaluated the relationship between prognosis and artificial intelligence (AI)-powered quantification of immune cells in tumor and stroma areas in hematoxylin and eosin (H&E) slides. **Methods:** We evaluated 28 ovarian cancer patients treated with PARP inhibitors in our institution from 2019 to 2021. We developed an AI model to detect the epithelium and lymphocytes, specifically T cells (CD3+) and B cells (CD20+), from H&E-stained slides. This model was trained using annotated datasets, which included 26,509 images of the epithelium and 12,273 images of lymphocytes. The tumor bed areas were precisely defined by pathologists. Subsequently, the AI model identified epithelial and lymphocyte regions within these predefined areas. Using a treatment duration of PARP inhibitor with 12 months or more as the criterion, we identified the most relevant immune cell type based on the AUCs of the ROC curve and determined cutoff values. Furthermore, tumor BRCA1/2 status was assessed by a custom-targeted NGS testing panel. A log-rank test with a p-value $<$ 0.05, considered statistically significant, examined the relationship between prognosis and tumor characteristics. **Results:** A total of 61 H&E slides were analyzed by AI: 28 slides before first-line chemotherapy, 25 after first-line chemotherapy, and 8 were the recurrent sample. The highest AUC was the lymphocyte-to-tumor area ratio (tumor-infiltrating lymphocyte score in tumor area, tTIL score) before the initial treatment, with an AUC of 0.73. The cutoff value of the tTIL score was set to 0.000534 based on the Youden index, dividing patients into tTIL-low (n=14) and tTIL-high (n=14) groups. The median follow-up period of the censored cases was 62.5 months vs. 77.3 months (p = 0.71). There were no significant differences in age, histological subtype, initial treatment method, proportion of R0 surgery, or that of tumor BRCA1/2 pathogenic mutations between groups. PARP inhibitors were used as maintenance therapy for recurrent settings in 71.4% of cases in both groups. The 5-year overall survival (5-y OS) rate of tTIL-high was significantly better than that of tTIL-low (84.4% vs. 30.8%, p = 0.0068). The median duration of OS after initiation of PARP inhibitors was significantly longer in the tTIL-high group (23.8 months vs. not reached, p = 0.046), and especially in tumor BRCA1/2-negative cases, tTIL-high had a significantly better 5-y OS rate of 90% vs. 12.5% (p = 0.0015). **Conclusions:** AI-powered tTIL score may predict the prognosis of ovarian cancer patients treated with PARP inhibitors. Future efforts will focus on increasing sample size and optimizing the tTIL score cutoff to improve accuracy. Research Sponsor: None.

Genomic instability score (GIS) and benefit from olaparib (ola) and bevacizumab (bev) maintenance in high-grade ovarian cancer (HGOC): Phase III PAOLA-1 GINECO/ENGOT-ov25 trial exploratory analysis. First Author: Jose Sandoval, Oncology Department, Geneva University Hospitals and Department of Medicine, Division of Oncology, Faculty of Medicine, University of Geneva, Geneva, Switzerland

Background: The PAOLA-1 trial showed that adding ola to bev as maintenance therapy improved overall survival (OS) of HGOC patients with *BRCA1/2* mutations (BRCAm) or homologous recombination (HR) deficiency (HRD) defined by the MyChoice HRD Plus assay with a GIS threshold of 42. This post hoc analysis of PAOLA-1 explored if alternative thresholds could better identify patients who benefit most from ola. **Methods:** New cutoffs were determined through OS analyses using Cox proportional hazards models with an interaction term for GIS. Tumors were categorized into HRP (GIS$<$42), HRDlow (42–60 for *BRCA1/2* wild-type [BRCAwt], 42–67 for BRCAm), and HRDhigh ($>$60 for BRCAwt, $>$67 for BRCAm). Genomic analyses included promoter methylation, BRCA loss of heterozygosity (LOH) and HR repair gene mutations. **Results:** Among 623 patients, 194 (31%) were BRCAm and 429 (69%) BRCAwt. Main clinical prognostic features were well-balanced across BRCAwt/HRDhigh, BRCAwt/HRDlow and BRCAwt/HRP as well as among BRCAm/HRDhigh, BRCAm/HRDlow and BRCAm/HRP. Ola+bev improved progression-free survival (PFS) and OS in BRCAwt/HRDhigh and BRCAm/HRDhigh (Table). Ola+bev improved PFS but not OS in BRCAwt/HRDlow and BRCAm/HRDlow. HRP tumors showed no PFS or OS benefit regardless of BRCA status. *BRCA1*/*RAD51C* promoters were methylated in 75% of BRCAwt/HRDhigh, 47% of HRDlow, and 3% of HRP. HRDlow tumors had fewer HR repair gene mutations than HRDhigh. Among HRP/BRCAm, 37% lacked BRCA LOH, suggesting functional BRCA. **Conclusions:** Our post-hoc subgroup analyses suggest that refined GIS thresholds identify three distinct populations of HGOC patients with varying survival benefits from ola+bev maintenance. Optimized GIS cutoffs may further improve patient stratification in future PARP inhibitors trials. Research Sponsor: None.

Survival outcomes of advanced ovarian cancer treated with neoadjuvant chemotherapy versus primary cytoreductive surgery using a quality-assured decision-making approach. First Author: Ji Hyun Kim, Gynecologic Oncology, National Cancer Center Korea, Goyang-Si, Gyeonggi-Do, South Korea

Background: Neoadjuvant chemotherapy (NACT) is recommended for advanced ovarian cancer patients with a low likelihood of achieving complete cytoreduction through primary cytoreductive surgery (PCS) or those with high perioperative risk profiles. The decision between NACT and PCS requires careful evaluation of the feasibility of achieving optimal cytoreduction, emphasizing an individualized approach. This study evaluates whether quality-assured decision-making regarding PCS, based on institutional protocols, improves survival outcomes. **Methods:** This retrospective study included 1,256 patients diagnosed with FIGO stage IIIB-IVB ovarian, fallopian tube, or primary peritoneal carcinoma who underwent either primary or interval cytoreductive surgery at the National Cancer Center Korea between January 2016 and December 2023. The institutional criteria approach determined NACT eligibility based on patient performance status and/or computed tomography findings indicative of suboptimal cytoreduction. The primary objective was overall survival (OS), while the secondary objective was progression-free survival (PFS). **Results:** Of 1,256 patients, 666 (53.0%) received NACT followed by ICS, while 590 (47.0%) underwent PCS. Median PFS was significantly longer in the PCS group than in the NACT group (28.6 vs 17 months; HR: 0.63, 95% CI: 0.55–0.73, $p < 0.001$). Median OS was also longer in the PCS group compared to the NACT group (92.8 vs 62.1 months; HR: 0.61, 95% CI: 0.51–0.74, $p < 0.001$). Five-year PFS and OS rates were 33.8% and 65.1% in the PCS group vs. 18.3% and 51.3% in the NACT group, respectively. Complete resection of macroscopic disease was achieved in 70.7% of patients overall, with comparable rates between the two groups ($p = 0.1$). **Conclusions:** PCS demonstrates superior OS and PFS compared to ICS following NACT in advanced ovarian cancer patients, underscoring its critical role within an individualized decision-making approach. Research Sponsor: None.

Summary of key outcomes.

Outcome	PCS (n = 590)	NACT + ICS (n = 666)	p-value	Hazard Ratio (HR, 95% CI)
Median PFS (months)	28.6 (24.2–31.7)	17.0 (16.1–18.6)	< 0.001	0.63 (0.55–0.73)
Median OS (months)	92.8 (89.1–NR)	62.1 (53.8–67.9)	< 0.001	0.61 (0.51–0.74)
5-year PFS rate (%)	33.8%	18.3%	-	-
5-year OS rate (%)	65.1%	51.3%	-	-
Complete Resection (%)	70.7%	70.7%	0.1	-

Impact of rucaparib on circadian rhythms and adverse events in ovarian cancer: Insights from the MAMOC trial. First Author: Deeksha Malhan, Institute for Systems Medicine and Faculty of Human Medicine, MSH Medical School Hamburg, Hamburg, Germany

Background: Ovarian cancer (OC) is a leading cause of gynaecologic cancer mortality, with most cases diagnosed at an advanced stage. Standard treatment involves cytoreductive surgery followed by chemotherapy. In high-grade OC, maintenance therapy, including PARP inhibitors (PARPi), plays a crucial role in delaying disease progression. PARP1, the primary target of these agents, interacts with the CLOCK-BMAL1 complex, which regulates circadian rhythms. This study investigates circadian disturbances in BRCA wild-type OC patients receiving rucaparib compared to placebo and evaluates their impact on patient-reported outcomes. **Methods:** This study is part of the Phase III, randomized, double-blind, placebo-controlled MAMOC trial (NCT04227522), which enrolled 42 patients with advanced high-grade OC after platinum-based chemotherapy and bevacizumab maintenance. Rucaparib was given to 28 patients, while 14 received placebo. Daily activity data and patient-reported outcomes, including quality of life (EORTC-QLQ-C30/OV28), Fatigue Symptom Inventory (FSI), and adverse event (AE/SAE) data, were collected for all patients. A subset of 15 patients (5 placebo, 10 rucaparib) underwent molecular circadian clock analysis using saliva samples collected pre-, during, and post-treatment to assess changes in the clock and cancer-related pathways via qPCR and NanoString technology. Mathematical modelling was used to determine 24-hour toxicity profiles. **Results:** Rucaparib treatment caused significant disruptions in circadian gene expression, notably a reduction in *BMAL1* expression, followed by an increase in *BMAL1* and *PER2* levels post-treatment. Dysregulation of *BMAL1* and *PER2* correlated with the frequency and severity of side effects, including fatigue. Circadian parameters such as amplitude, MESOR, and phase were predictive of patient-reported outcomes. In the rucaparib group, circadian parameters exhibited opposing associations with outcomes compared to placebo. Clock-associated genes, including *NFIL3* and *GSK3B*, showed altered expression patterns that normalized after treatment. Additionally, rucaparib induced phase shifts and amplitude changes in clock and cancer-related genes like *CRY2*, *RORC*, and *TP53*, which were associated with increased adverse effects, particularly fatigue and nausea. Mathematical modelling revealed variability in toxicity profiles based on individual circadian rhythms pointing to the relationship between clock disruption and side effect severity. **Conclusions:** Our findings highlight the role of circadian rhythm dysregulation in the toxicity of PARPi in OC. The study suggests that chronotherapy, aligning drug administration with patients circadian rhythms, may reduce side effects. Incorporating circadian biology into treatment strategies could thus contribute to optimize cancer therapies by enhancing efficacy while minimizing toxicity. Clinical trial information: NCT04227522. Efficacy of third-line and later (3L+) therapies post poly (ADP-ribose) polymerase inhibitor (PARPi) exposure in recurrent platinum-sensitive ovarian cancer (PSOC): A pooled clinical trial database analysis. First Author: Robert Louis Coleman, Texas Oncology, US Oncology Research, The Woodlands, TX

Background: Patients (pts) with PSOC often experience reduced efficacy and tolerability with each successive treatment (tx). While PARPi therapies have demonstrated clinical benefit in frontline and maintenance settings, most pts eventually experience progression of disease (PD) with limited tx options. Data establishing standard of care for PSOC was published prior to the PARPi era. This study evaluated the efficacy of tx in PSOC subsequent to PARPi exposure. **Methods:** Pooled pt-level data from <5 multinational clinical trials (CT) involving PARPi tx were sourced from the Medidata Clinical Cloud and included pts with PSOC diagnosis, ≥2 prior lines of platinum-based chemotherapy (PBC), most recent platinum-free interval (PFI) ≥6 months (mo), prior PARPi tx, initiation of tx subsequent to PARPi (defined as the index tx), and ECOG Performance Status (PS) ≤1 prior to the index tx. Index date was defined as the initiation of index tx. Outcomes included overall response rate (ORR), progression-free survival (PFS), and overall survival (OS). PFS was defined as the time from the index date to PD, death or start of new tx; pts with no PFS event were censored at the end of follow-up. PFS and OS were estimated using the Kaplan-Meier method and compared across subgroups with the log-rank test. Exploratory subgroup analyses of PFS and OS were conducted per factors identified in multivariable Cox models. **Results:** Among 130 pts (≥65 years, 36.9%; White, 87.7%; FIGO Stage III/IV, 89.2%; ECOG PS 0/1, 59.2%/40.8%; ≥3 prior lines of PBC, 23.8% [range, 2-5]; PFI ≥12 mo, 61.5%), the median duration of PARPi use was 13.24 mo (IQR, 9.22), and 96.9% experienced PD ≤106 days from PARPi discontinuation. Index tx included PBC (74.6%) and non-PBC (25.4%); 61.5% received combination tx. Median duration of index tx was 4.01 mo (95% CI, 3.71-4.93). ORR on index tx was 16.9% (95% CI, 10.9-24.5). Median PFS was 6.11 mo (95% CI, 5.06-7.39), with longer PFS in pts with PFI ≥12 mo vs 6 to <12 mo (7.39 mo [95% CI, 6.08-8.77] vs 4.44 mo [3.25-6.14]; *P*=0.002) and in pts with combination therapy vs monotherapy index tx (7.39 mo [95% CI, 6.21-8.61] vs 3.71 mo [95% CI, 3.12-5.75]; *P*=0.026). Median OS was 19.35 mo (95% CI, 17.77-22.08), with longer OS in pts with PFI ≥12 mo vs 6 to <12 mo (23.03 mo [95% CI, 19.29-33.81] vs 15.08 mo [95% CI, 11.89-19.68]; *P*<0.0001). PFS and OS were similar in PBC vs non-PBC as index tx. **Conclusions:** Median PFS with 3L+ tx for PSOC following PARPi exposure was 6.11 mo, establishing an efficacy benchmark for tx subsequent to PARPi exposure in this unique pt population and highlighting the need for more effective tx. Due to the lack of regular per-protocol imaging assessments after the start of non-trial tx, PFS values may be overestimated. However, pooled CT data with long-term follow-up provide valuable insights not available from other sources. Research Sponsor: AbbVie.

A multi-omics approach using lipids and proteins for early detection in individuals with signs and symptoms of ovarian cancer. First Author: Rachel Culp-Hill, AOA Dx, Denver, CO

Background: Late-stage ovarian cancer (OC) is diagnosed in 80% of patients, leading to a five-year survival rate below 30% and ranking OC as the fifth leading cause of cancer-related deaths in women. Non-specific abdominal symptoms overlap with benign disorders, delaying diagnosis. Testing symptomatic individuals can detect low disease burden, enabling high complete cytoreduction rates. However, current diagnostic tools lack sensitivity and specificity for early-stage OC, underscoring the critical need for novel biomarkers and approaches. **Methods:** We conducted a multi-omics analysis of serum from two independent, clinically annotated cohorts. Specimens were analyzed using UHPLC-MS untargeted lipidomics and a protein biomarker panel. Cohort #1 (N=544) from the University of Colorado Gynecologic Tissue and Fluid Bank and commercial vendors included patients diagnosed with OC (N=219: 80 early-stage I/II, 139 late-stage III/IV), and non-cancerous controls (N=325) for biomarker discovery. Cohort #2 (N=423) from Manchester University NHS Foundation Trust and commercial vendors included prospectively enrolled individuals with signs and symptoms of OC. Samples included patients diagnosed with OC (N=109 total: 52 stage I/II, 57 stage III/IV), and non-cancerous controls (N=314). Cohorts were processed independently. **Results:** Over 1000 features were identified in both cohorts. There was a significant overlap in common features confirming importance in indication for use population. The top features confirmed in both cohorts enabled machine learning-based modeling. Biomarker classes were modeled separately (lipids only, proteins only) and in combination (lipids and proteins), employing 20-fold cross validation. Models containing multi-omic features consistently exhibit the highest AUC compared to individual biomarker classes. AUC for the top-performing model applied to both cohorts was 95% (CI 94-96) for all controls vs. all OC, and 92% (CI 89-95) for all controls vs. early-stage OC. When compared with normal individuals, the AUC vs all OC across stages and sub-types was 97% (CI 96-98). **Conclusions:** Our top-performing models contain >50 multi-omic features common across two independent cohorts, comprised of 967 unique individuals. Combining LC-MS-based lipidomic profiling of serum with proteins represents a promising new approach as a clinical diagnostic for detecting OC in this complex patient population. Early detection in women with signs and symptoms of OC and faster triage to specialty care may lead to improved patient outcomes. Research Sponsor: None.

Early detection of ovarian cancer: An accurate high-throughput extracellular vesicle test. First Author: Carlos Salomon, Translational Extracellular Vesicles in Obstetrics and Gynae-Oncology Group, Centre for Clinical Diagnostics, UQ Centre for Clinical Research (UQCCR), Royal Brisbane and Women's Hospital, Faculty of Medicine, The University of Queensland, Brisbane, Australia

Background: The high mortality of Ovarian cancer (OC) has been attributed to late-stage diagnosis and the lack of an effective early detection strategy, particularly for asymptomatic women. In this study, we developed and validated a high-throughput OC detection test based on plasma extracellular vesicle (EV)-associated biomarkers. **Methods:** A case-control study was conducted to evaluate blood-borne EV-associated ovarian cancer biomarkers, including miRNAs, proteins, lncRNAs, miscRNAs, MtrRNAs, MttRNAs, rRNAs, scaRNAs, snRNAs, and tRNAs. Protein and RNA biomarkers were identified by mass spectrometry and RNA sequencing, respectively. Training (n=453) and independent test (n=471) sample sets were used to develop and validate a multivariate index assay (MIA). The MIA was further validated using a high-throughput, pathology laboratory compatible, EV isolation platform (EXO-NET) and two independent sample cohorts (n=97 and n=532). The classification accuracy, sensitivity and specificity of the MIA was compared to that of CA125 levels. **Results:** Discovery and Training phases - more than 100,000 EV-associated biomarkers were identified from 453 EV samples. The classification performance of these biomarkers was assessed using machine learning algorithms. EV-associated protein and miRNA biomarkers delivered the highest performing classifiers and, therefore, were used in subsequent MIA development and training. During the training phase, multivariate classification algorithms were validated using a 10-fold cross-validation method. The highest performing classifiers for EV-associated protein and miRNA, at specificity of 98%, achieved sensitivities of 90% and 82%, respectively. Validation phase: Locked classification algorithms (*i.e.* MIAs) were validated using two independent sample cohorts and reported classification accuracies of 92-98%, significantly outperforming CA-125 (CE = 62%, $p<0.001$). Automated high-throughput MIA – All stages OC: the best performing automated high-throughput MIA demonstrated an overall sensitivity of 92% (95% CI, 75–96%) and specificity of 93% (95% CI, 86–96%) for all stages of OC, Positive Predictive Value of 95% (CI, 93-96%) and Negative Predictive Value of 80% (CI, 76-89%) at 98% specificity (n=532). Stage I OC: Importantly, the MIA displayed a sensitivity of 90% (95% CI, 76–100%) and specificity of 96% (95% CI, 40%–99%) for stage I OC. While CA125 have an overall sensitivity for all stages of OC of 61% (95% CI, 53–69%), with a sensitivity of 44% for stage I (95% CI, 28–62%). **Conclusions:** In this study we report the development and validation of an accurate, automated high-throughput EV-based test for early detection of ovarian cancer. The test delivers significant improvements in sensitivity and specificity compared to CA-125, especially in detecting early-stage OC. Hyperthermic intraperitoneal chemotherapy (HIPEC) for primary advanced-stage or recurrent ovarian cancer: A systematic review and meta-analysis of randomized controlled trials. First Author: Gabriela Branquinho Guerra, Escola Superior de Ciências da Saúde, Brasília, DF, Brazil

Background: Ovarian cancer is the gynecologic malignancy with the highest mortality rate. Despite cytoreductive surgery (CRS) and adjuvant or neoadjuvant systemic therapy, the rate of peritoneal recurrence remains high. Hyperthermic intraperitoneal chemotherapy (HIPEC) has emerged as a potential treatment option, delivering high concentrations of heated chemotherapy directly to the tumor site, enhancing local cytotoxicity. **Methods:** We searched PubMed, Embase, and Cochrane for randomized clinical trials (RCTs) comparing CRS plus HIPEC versus CRS alone. Hazard ratios (HR), odds ratios (OR) and mean differences (MD) were pooled using Review Manager software version 5.4. Heterogeneity was assessed with I^2 statistics. The main outcomes were overall survival (OS), median OS, progression-free survival (PFS), median PFS, operative time in minutes, Grade 3 or higher adverse events, time from surgery to adjuvant chemotherapy and length of hospital stay (LOS) in days. Subgroup analysis was performed for primary and recurrent cancer outcomes. **Results:** A total of 1,259 patients from 8 RCTs were included, with 636 (50.52%) undergoing CRS with HIPEC. The median follow-up period ranged from 32 to 121.2 months. CRS plus HIPEC significantly improved OS (HR 0.76; 95% CI 0.62-0.93; p = 0.009; I^2 = 27%), with a significant benefit also observed in the subgroup analyses of primary ovarian cancer (HR 0.66; 95% CI 0.52-0.85; p = 0.001; I^2 = 0%). However, no significant difference was observed for recurrent ovarian cancer (HR 0.87; 95% CI 0.63-1.19; p = 0.38; I^2 = 39%). Median OS also significantly favored CRS plus HIPEC (MD 9.99; 95% CI 2.40-17.58; p = 0.01; I^2 = 0%). PFS was not significantly different between groups (HR 0.74; 95% CI 0.52-1.06; p = 0.10; I^2 = 76%). In subgroup analysis, PFS was significantly improved for primary ovarian cancer (HR 0.62; 95% CI 0.49-0.79; p = 0.0001; I^2 = 0%), but not for recurrent ovarian cancer (HR 0.80; 95% CI 0.41-1.56; p = 0.52; I^2 = 84%). Median PFS showed no statistical difference (MD 1.98; 95% CI -1.20-5.15; p = 0.22; I^2 = 29%). Time from surgery to adjuvant chemotherapy was not statistically different (MD -0.13; 95% CI -4.49-4.23; p = 0.95; I^2 = 0%). Operative time was significantly shorter in the control group (MD 127.75; 95% CI 89.61-165.89.; $p < 0.00001$; I^2 = 51%), as were LOS (MD 1.49; 95% CI 0.12-2.87; p = 0.03; I^2 = 0%) and Grade 3-5 adverse events (OR 1.50; 95% CI 1.05-2.16; p = 0.03; I^2 = 40%). **Conclusions:** In patients with ovarian cancer, HIPEC significantly improved OS, particularly in the subgroup of primary ovarian cancer. PFS was also significantly improved in this subgroup. However, these benefits were associated with higher rates of adverse events and longer LOS. Our analysis supports the use of HIPEC in the treatment of ovarian cancer, especially for patients with primary ovarian cancer. Research Sponsor: None.

Hyperthermic intraperitoneal chemotherapy in recurrent ovarian cancer: An updated systematic review and meta-analysis. First Author: Yemesrach Mekonen, St. Barnabas Hospital, Bronx, NY

Background: Ovarian cancer is the leading cause of mortality among gynecological malignancies in women. Disease recurrence remains a formidable challenge in the management of primary ovarian cancer. This systematic review and meta-analysis evaluate the impact of hyperthermic intraperitoneal chemotherapy (HIPEC) on overall survival (OS) and progression-free survival(PFS) in patients with recurrent ovarian cancer. **Methods:** A comprehensive literature search was conducted in PubMed, Embase, and Cochrane databases to identify randomized controlled trials (RCTs) published up to November 2024, comparing the outcomes of HIPEC combined with cytoreductive surgery (CRS) versus CRS alone in patients with recurrent ovarian cancer. A total of 459 articles were screened in accordance with the PRISMA guidelines. The primary endpoints analyzed were OS, PFS, and postoperative complications. Hazard ratios (HR) and 95% confidence intervals (CI) were calculated using the inverse variance method for time-to-event outcomes, while the Mantel-Haenszel method was applied for binary outcomes to estimate relative risk (RR) and corresponding 95% CIs. Statistical heterogeneity was assessed using Cochrane's Q test and Higgins' I^2 statistic. Statistical significance was set at a p-value < 0.05. Data analysis was performed using R software version 4.4.2. **Results:** Following the screening process, four RCTs involving a total of 801 patients were included in the meta-analysis, and 398 patients (49.6%) received HIPEC. The pooled analysis demonstrated a non-significant improvement in OS for the HIPEC group (HR 0.8; 95% CI [0.55, 1.17]; p=0.159). Similarly, PFS did not significantly differ between the treatment and control groups (HR 1.04; 95% CI[0.46, 2.35];p=0.867). In terms of postoperative complications, patients who underwent HIPEC were at a significantly increased risk of developing anemia (RR 1.36; 95% CI[1.08, 1.72];p=0.028) and sepsis (RR 2.11; 95% CI[1.44, 3.08];p=0.014). However, no significant differences were observed between the treatment and control groups regarding other postoperative complications, including urinary tract infection (RR 0.95;95% CI[0.19, 4.69];p=0.895), bowel obstruction (RR 0.77; 95% CI [0.25, 2.37]; p=0.426), pleural effusion (RR 1.49;95% CI[0.16, 14.16];p=0.525), and thrombosis (RR 1.99;95% CI[0.98, 4.07];p=0.053). **Conclusions:** The findings suggest that while HIPEC may offer a potential, albeit statistically non-significant, survival benefit in patients with recurrent ovarian cancer, it is associated with an increased risk of anemia and sepsis. Research Sponsor: None.

Impact of body mass index, diabetes, and tumor mutational burden in ovarian, fallopian tube, and primary peritoneal carcinoma with BRCA1/2 alteration on poly(ADP-ribose) polymerase inhibitors. First Author: Ryan Tan, Memorial Sloan Kettering Cancer Center, New York, NY

Background: Obesity and hyperinsulinemia are associated with increased fallopian tube (FT) epithelial DNA damage in women carrying germline BRCA1/2 mutations. Whether these states impact survival in patients with ovarian, FT, or primary peritoneal carcinoma (PPC) with BRCA1/2 mutations, particularly when treated with Poly (ADP-ribose) polymerase inhibitor (PARPi), remains unclear. Research on tumor mutational burden (TMB) in these malignancies and survival have yielded inconsistent results. **Methods:** Ovarian/FT/PPC patients with germline/somatic BRCA1/2 mutation who received ≥1 dose of PARPi therapy between 2015-2023 were included in this retrospective cohort. Clinical characteristics abstracted include age, ethnicity, histology, DM status, pre-treatment TMB (pTMB) on MSK-IMPACT, PARPi use. Progression-free survival (PFS) was estimated using Kaplan-Meier. Cox regression was used to evaluate associations with PFS. **Results:** 202 patients treated between March 2015 – Aug 2024 were included; median age was 60 (interquartile range 50.3-67.2), 117 (57.9%) were overweight/obese (body mass index [BMI] ≥ 25) and 21 (10%) had DM. 160 (79%) and 33 (16%) had ovarian and FT cancer respectively. 182 (90.1%) had high grade serous carcinoma. 80 (40%) had germline BRCA1, 48 (24%) had germline BRCA2, 50 (25%) had somatic BRCA1 and 28 (14%) had somatic BRCA2 mutations. 91 (58%) had pTMB ≤5 mutations/megabase [mut/Mb], 56 (36%) had pTMB >5 to <10 mut/Mb and 9 (6%) had pTMB ≥10 mut/Mb. Median pTMB was higher in overweight/obese than normal BMI (4.9 vs 4.3 mut/Mb, p=0.093). 118 (58%) received PARPi as first-line and 59 (29%) received PARPi as second-line maintenance. 190 (94%) received PARPi as monotherapy, 6 (3%) in combination with bevacizumab and 6 (3%) in combination with immunotherapy +/- bevacizumab on a clinical trial. 168 (83%) received olaparib, 24 (12%) received niraparib and 9 (4.5%) received rucaparib. In multivariable (MV) Cox regression analysis, somatic BRCA status (BRCA1 hazard ratio [HR]=2.22, 95% confidence interval [95% CI]: 0.55-8.98; BRCA2 HR=0.66, 95% CI: 0.12-3.77; p=0.022; reference was somatic BRCA wildtype) was independently associated with PFS, pTMB (>5 to <10 mut/Mb HR=0.62, 95% CI: 0.32-1.19; ≥10 mut/Mb HR=0.19 95% CI: 0.02-1.56; p=0.088) had borderline significance while BMI and DM status were not associated. A MV Cox model additionally including the interaction between BMI and DM illustrated worse PFS in overweight/obese DM patients with borderline significance (p=0.094). **Conclusions:** Higher pTMB trended toward longer PFS in ovarian/FT/PPC patients with BRCA1/2 mutations receiving maintenance PARPi and was more common in overweight/obese. Prospective trials should evaluate if TMB may predict for response to PARPi and whether obesity-mediated DNA damage alters treatment outcomes. Research Sponsor: None.

Survival outcomes for ovarian cancer patients in the post–poly ADP-ribose polymerase inhibitor (PARPi) era in the US. First Author: Henry Becerra, Brookdale University Hospital and Medical Center, Brooklyn, NY

Background: PARPi introduction in clinical practice has led to major changes in the therapeutic landscape for ovarian cancer (OC)[1]. Olaparib is approved alone or in combination with bevacizumab for the first line maintenance therapy of BRCA-mutated or homologous repair deficient (HRD) OC. We hypothesize that the introduction of PARPi in routine clinical practice for maintenance therapy in OC has resulted in improvements in survival outcomes among OC patients (pts) treated in the real world. **Methods:** Pts with a diagnosis of stage III/IV epithelial OC age ≥18 years between 2000-2021 were obtained from the Surveillance, Epidemiology, and End Results (SEER) Database. A cutoff on 2017 was made based on the initial approval of PARPi for maintenance therapy. Statistical analyses were conducted with SPSS. Pts characteristics were reported in frequencies and compared with the Chi-squared test. The Kaplan-Meier method was used to estimate median OS. Cox Regression was used identify independent prognostic factors of survival. P-value ≤0.05 was considered statistically significant. **Results:** 59,913 pts were included with median age 63 years, 60.9% non-hispanic white, and 55.8% with serous histology. 44,873 pts were diagnosed in the pre-PARPi cohort and 15,040 in the post-PARPi cohort. 76.3% and 76.1% of pts received any chemotherapy and surgery, respectively. Similar distribution in analyzed variables was found when comparing among eras. The median OS for pre-PARPi pts was 37 months (95%CI: 36.4-37.6) and post-PARPi pts was 38 months (36.6-39.4), p=0.023. In multivariate analysis, pts diagnosed in the post-PARPi era had improved OS compared with pts in pre-PARPi era (HR=0.93, 95%CI:0.91-0.96, p<0.001). **Conclusions:** To the extent of our knowledge, this study is the first real world analysis of survival outcomes in OC pts after the introduction of PARPi at a population level in the US. The introduction of PARPi maintenance therapy has resulted in a modest improvement in OS in the overall OC population unselected for BRCA or HRD status. 1. Tew WP et al. Oregovomab in combination with non-platinum chemotherapy for the treatment of PARP inhibitor– and platinum-resistant ovarian cancer: A two-cohort, single-arm phase 2 study (OPERA/KGOG3065/APGOT-OV6). First Author: Junsik Park, Soonchunhyang University Bucheon Hospital, Bucheon, South Korea

Background: Oregovomab, an investigational murine monoclonal antibody against CA-125, has shown promising efficacy in a phase 2 study in patients with recurrent ovarian cancer. Herein, we report the primary results of OPERA/KGOG 3065/APGOT-OV6 on oregovomab in combination with non-platinum-based chemotherapy in patients with PARP inhibitor (PARPi)- and platinum-resistant epithelial ovarian cancer (EOC). **Methods:** This multicenter, investigator-initiated, two-cohort, single-arm phase 2 trial evaluated the efficacy and safety of oregovomab in combination with PLD or weekly paclitaxel in patients with PARPi- and platinum-resistant EOC. Patients who received one to three prior lines of chemotherapy will be assigned to Cohort 1 (oregovomab [C1,2,3,5,7 for five doses] + PLD q4w, n=28), whereas patients who received more than three prior lines of chemotherapy will be assigned to Cohort 2 (oregovomab [C1,2,3,5,7 for five doses] + weekly paclitaxel [D1,8,15 q4w], n=28). The primary endpoint of the study was objective response rate (ORR) based on RECIST version 1.1. The secondary endpoints are progression-free survival (PFS), overall survival (OS) and safety. For the exploratory endpoints, immunologic response was measured at pretreatment and at C2, 3, 5, 7, or EOT by assessing serum HAMA levels and performing flow cytometric analysis of PBMCs. This trial is registered with ClinicalTrials.gov (NCT05407584). **Results:** A total 56 patients (Cohort 1, n=28; Cohort 2, n=28) have been enrolled between July 12, 2022 and September 19, 2023. Median age was 59 years (range, 36–79). Fifty-two (92.9%) patients had high-grade serous adenocarcinoma. At the data cut-off, the median follow-up was 8.0 months for Cohort 1 and 6.5 months for Cohort 2. The ORR was 0.0% (95% CI: 0.0–12.3) in Cohort 1, and 28.6% (95% CI: 13.2–48.7) in Cohort 2. Eight patients (28.6%) in Cohort 2 achieved a partial response, while 12 (42.9%) patients in Cohort 1 and 3 (10.7%) patients in Cohort 2 had stable disease. Three patients withdrew from the study due to treatment-related adverse events (TRAEs). These included one case of neutropenia in Cohort 1 and cases of anemia and lymphedema in Cohort 2. No TRAEs leading to death were reported. The median PFS was 2.5 months (95% CI: 2.1–4.7) in Cohort 1, and 2.6 months (95% CI: 2.0–3.7) in Cohort 2. Serum HAMA levels significantly increased after C3 exclusively in Cohort 2, but no significant changes in peripheral T cells have been observed. **Conclusions:** Oregovomab plus weekly paclitaxel chemotherapy demonstrated encouraging activity and safety in heavily pre-treated PARPi- and platinum-resistant EOC. Clinical trial information: NCT05407584. Research Sponsor: Canariabio Inc.

Platinum or non-platinum therapy in post-olaparib recurrent ovarian cancer: Analysis in matched cohorts. First Author: Alexey Rumyantsev, Federal State Budgetary Institution "N.N. Blokhin National Medical Research Center of Oncology" of the Ministry of Health of the Russian Federation (N.N. Blokhin NMRCO), Moscow, Russian Federation

Background: Due to potential cross-resistance mechanisms efficacy of platinum agents may be dramatically reduced in patients with ovarian cancer which progressed during maintenance therapy with PARP-inhibitors. We conducted this study to examine whether administration of platinum compounds has clinical value in post-olaparib setting of treatment for epithelial ovarian cancer treatment. **Methods:** This was a single center retrospective study in matched cohorts. We selected ovarian cancer patients from N.N. Blokhin NMRCO ovarian cancer who were treated in 2014-2024 years for any FIGO stage high-grade serous or endometrioid advanced epithelial ovarian cancer and progressed during olaparib maintenance therapy. Patients were treated with standard platinum-based or non-platinum chemotherapy for recurrent advanced epithelial ovarian cancer. Cardinality matching was considered to ensure adequate balancing of the study arms. The primary endpoint of the study was progression-free survival (PFS) in patients treated with platinum-based and non-platinum chemotherapy. Overall survival was a secondary endpoint. **Results:** Cardinality matching with 1:2 ratio resulted in 126 matched patients for further analysis. Groups were well balanced without any significant differences in baseline characteristics. Median age in both treatment arms was 50 years with no differences in patients' age, risk groups, prevalence of BRCA-mutations, duration of olaparib therapy and platinum-free interval. With a median follow up of 7.4 mo. median PFS was 6.0 in the non-platinum chemotherapy arm and 6.5 mo. in the platinum-based therapy arm (HR 1.17; 95% CI 0.77-1.77; p=0.46). Estimated 1-year PFS was 13.1% and 8.3%, respectively. Median OS was 21.3 mo. and 23.1 mo. in platinum-based chemotherapy arm and non-platinum arm (HR 0.98; 95% CI 0.55-1.76; p=0.96). Subgroup analyses revealed no heterogeneity in therapy efficacy. **Conclusions:** Our study suggest no additional benefit from platinum-based chemotherapy in post-olaparib ovarian cancer, further prospective trials are warranted to find optimal therapeutic approaches for these patients. Research Sponsor: N.N. Blokhin NMRCO.

5589 **Poster Session**

A prospective, single-arm, phase 2 trial exploring the use of pamiparib combined with surufatinib as neoadjuvant therapy for advanced, unresectable ovarian cancer (PASSION). First Author: Bairong Xia, The First Affiliated Hospital of USTC, Division of Life Sciences and Medicine, University of Science and Technology of China, Hefei, China

Background: Pamiparib is a selective PARP1/2 inhibitor, while surufatinib targets VEGFR1-3, FGFR1, and CSF-1R. We evaluated the efficacy and safety of combining pamiparib and surufatinib in neoadjuvant therapy (NAT) for advanced unresectable ovarian cancer (OC) in a broad, molecularly unselected population. **Methods:** This phase 2, single-arm study enrolled patients aged 18–70 with newly diagnosed OC in China. Participants received pamiparib (40 mg twice daily, 3 cycles) combined with surufatinib (250 mg twice daily, 2 cycles), followed by interval debulking surgery (IDS) and 4 cycles of platinum-based chemotherapy. Primary endpoint: complete resection (R0). Secondary endpoints: objective response rate (ORR), pathological complete response (pCR), progression-free survival (PFS), overall survival (OS), and safety. Tumor samples before and after treatment were analyzed by transcriptomics, proteomics, and single-cell transcriptomics. **Results:** Between Nov 2022 and Jan 2025, 32 patients were enrolled, 31 treated, and 1 withdrew. 26 patients completed NAT and underwent IDS, while 5 switched to other chemotherapy due to adverse events. Among resected patients (median age 56, 10 with stage IV), all showed objective responses. R0 was achieved in 24 (92.3%), R1 in 2 (7.7%). Median PFS and OS are not yet reached. Common grade 3/4 adverse events: leukopenia (32.2%), neutropenia (29%), and anemia (29%). No treatment-related deaths were recorded. Post-treatment, B and T cell proportions increased, associated with improved PFS and clinical outcomes. TLS formation was observed, and higher TLS density correlated with better prognosis and reduced tumor biomarkers. **Conclusion:** Pamiparib and surufatinib show promising efficacy and manageable toxicity in advanced OC, reshaping the tumor microenvironment and promoting immune infiltration. Clinical trial information: NCT05652283. Research Sponsor: None.

A comparative study of the real-world safety and effectiveness of metronomic cyclophosphamide and bevacizumab with or without pembrolizumab for recurrent ovarian cancer. First Author: Alicia Youssef, Massachusetts General Hospital, Boston, MA

Background: Metronomic cyclophosphamide and bevacizumab (CB) alone or in combination with pembrolizumab (CBP) are active regimens in heavily pretreated patients with recurrent ovarian cancer. However, it is unknown to what extent the addition of pembrolizumab augments the effectiveness or increases the toxicity compared to CB alone. **Methods:** We conducted a multi-institutional retrospective cohort study utilizing electronic medical records of patients treated for recurrent ovarian cancer in oncology practices affiliated with four New England hospitals from 2012 through 2024. We included patients who received either CB or CBP and abstracted baseline characteristics, outcomes, and adverse events. The overall response rate (ORR) was defined as the proportion of patients with a complete or partial response. Net benefit (NB) was defined as the proportion of patients with a response or stable disease based on clinician assessment. Kaplan Meier curves were used to summarize progression-free survival (PFS) and overall survival (OS). Cox regression models were used to calculate and estimate the relative hazard of death (OS) and death or progression (PFS). Multivariable models adjusted for age, number of prior lines of therapy, time since diagnosis, platinum sensitivity, BRCA status, and Charlson comorbidity index. **Results:** We identified 163 patients, of whom 126 (77.3%) received CB and 37 (22.7%) received CBP. The median age at enrollment was 65.4 in the CB arm and 62.9 in the CBP arm (p=0.21). Most patients were non-Hispanic White (85.9%), with high grade (96.6%) serous (87.1%), platinum-resistant (76.7%) ovarian cancer. There were no statistically significant differences in BRCA status (21.4% vs. 18.9%, p=0.04), the median number of prior lines (3 vs. 3, p=0.25), or the proportion of platinum-resistant patients (77.8 % vs. 73.0%, p=0.41) between the CB and CBP arms. The ORR was 19.8 vs 21.6 % (p=0.81), and NB was observed in 44.8% in the CB arm and 41.2% in the CBP arm (p=0.71). The median PFS was 5.2 versus 4.8 months in the CB and CBP groups (HR 1.02; CI 0.67 - 1.55, p=0.37). Median OS was 17.3 vs 15.2 months, respectively (HR 1.51; CI 0.93 – 2.46, p=0.96). Adjustment for potential confounders produced similar results for PFS (adjusted HR=1.25, CI 0.77 – 2.02, p=0.37) and OS (adjusted HR=1.56, 95% CI 0.91 – 2.70 p=0.16). Seventeen (45.9%) patients in the CBP arm developed an immune reaction during treatment, but hospitalization rates were similar in both groups (25.4% vs 21.6%, p = 0.64). **Conclusions:** The addition of pembrolizumab to metronomic cyclophosphamide and bevacizumab was not associated with an improved response rate, PFS, or OS among patients with heavily pretreated recurrent ovarian cancer. Research Sponsor: None.

Folate receptor alpha (FRα; FOLR1) expression and persistence in ovarian cancer in clinical trial samples and real-world patient cohort. First Author: Elizabeth M. Swisher, University of Washington, Seattle, WA

Background: The FRα-directed antibody-drug conjugate mirvetuximab soravtansine-gynx (MIRV) provides survival benefit vs investigator's choice chemotherapy for FRα-high, platinum-resistant ovarian cancer (PROC). Understanding targetable FRα expression is important to inform patient care and guide trial development. FRα protein expression patterns, consistency over time, association with mRNA expression, and prognostic value in patients (pts) with ovarian cancer was evaluated. **Methods:** FRα protein expression was retrospectively established by immunohistochemistry (IHC) using the VENTANA FOLR1 (FOLR1-2.1) RxDx Assay (FOLR1 CDx) in high-grade serous ovarian cancer tumors from pts in the VELIA trial (NCT02470585) and a real-world (RW) cohort. RW tumors were tested at Caris Life Sciences and linked to health record data from the ConcertAI RWD360 product. FRα-high positivity was defined by a cutoff of ≥75% of viable tumor cells with ≥2+ membrane staining (used for MIRV treatment eligibility with approved FOLR1 CDx). RNA was measured using whole transcriptome RNAseq. IHC and mRNA concordance was determined using Receiver Operating Curve (ROC) analysis. **Results:** In the RW cohort (N=611), 40.9% were FRα-high. FRα-high prevalence was 40.3% and 40.5% in tumors with and without *BRCA1* mutations, respectively (mutation prevalence, 12.4%). FRα-high prevalence was 47.4% and 39.8% in tumors with and without *BRCA2* mutations, respectively (mutation prevalence, 8.8%). Thirty-six pts had 2 biopsies longitudinally collected with IHC results. Consistency of FRα IHC status across biopsies was 86%. FRα mRNA expression associated with IHC status (ROC area under the curve [AUC]=0.88; 95% CI, 0.84-0.91), with sensitivity and specificity of 83% using a cutoff maximizing Youden's Index. To understand the prognostic nature of pts with tumors with FRα-high expression, samples from the VELIA trial were used. FRα IHC was conducted on a subset of tumors, and 56/186 (30%) were FRα-high. FRα mRNA could robustly predict IHC status (ROC AUC=0.82; 95% CI, 0.75-0.88) with sensitivity of 85% and specificity of 72%. An mRNA cutoff best associated with FRα-high IHC was applied to an extended VELIA cohort in newly diagnosed pts with mRNA data available (N=709), and FRα mRNA was identified as a negative prognostic factor for progression free survival (Hazard Ratio=1.27; 95% CI, 1.05-1.5). **Conclusions:** FRα-high expression at both the protein and mRNA level was common and concordant in VELIA trial samples and RW patient samples. The expression status was consistent in longitudinally collected samples in most pts, suggesting that IHC on the diagnostic tumor sample may effectively establish FRα protein expression status over time. High FRα mRNA expression was a negative prognostic factor in VELIA despite positive association with homologous recombination deficiency and *BRCA* mutations. Research Sponsor: None.

Distinguishing tumor vs. clonal hematopoiesis (CH)–derived *TP53* and *BRCA1/2* alterations in ovarian cancer liquid biopsies with a predictive algorithm to inform clinical decision-making. First Author: Natalie Danziger, Foundation Medicine, Inc., Boston, MA

Background: CH results from mutations in hematopoietic stem cells and can occur in clinically relevant genes that are detected in liquid biopsy (LBx) of solid tumor patients. *TP53* and less frequently *BRCA1/2* can be detected in tumor and as CH potentially confounding interpretation of LBx results. Using an algorithmic method for CH prediction in a cohort of tubo-ovarian carcinoma (OC) LBx, we evaluated the prevalence of CH and non-CH alterations in *TP53* and *BRCA1/2* genes, CH frequency by circulating tumor DNA tumor fraction (ctDNA TF) and concordance in samples with paired tissue biopsies. **Methods:** Patients (pts) with a diagnosis of OC and LBx via FoundationOne Liquid CDx were included. ctDNA was quantified via TF. A machine learning model incorporating fragmentomics and other sequencing features was trained using LBx samples with equal-depth sequencing of plasma and white blood cells for short variant origin prediction (VOP) with output probabilities of origin (germline, tumor-somatic, or CH). Oncogenic short variants (i.e. mutations [mut]) with probability of being CH >0.5 were classified as CH and with probability <0.5 as tumor. Detection of CH and tumor *TP53*mut in paired tissue samples (FoundationOne CDx) was evaluated (n=355). **Results:** 1,405 pts met criteria for study inclusion. 498 (35%) had TF≥1%. Overall, *TP53*mut was detected in 74% (origin 30% tumor only, 23% CH only, and 21% both CH and tumor *TP53*mut), and 26% had no detected *TP53*mut Prevalence of VOP *TP53*mut groups varied by TF with TF<1% having more pts with no detected *TP53*mut (35% vs 9%) or only CH *TP53*mut (33% vs 4%) and fewer pts with only tumor *TP53*mut (18% vs 51%) or both CH and tumor *TP53*mut (13% vs 36%) than TF≥1%. The emerging drug target *TP53* Y220C was predicted to be CH in 42/68 (62%) LBx samples. Of the 333 individual *TP53*mut predicted to be CH on LBx, 310 (93%) were not detected in corresponding tissue. Of the 200 *TP53*mut predicted to be tumor on LBx, 176 (88%) were detected in paired tumor tissue. Overall, 9% of pts had at least one germline *BRCA1/2*mut, 4% had no germline *BRCA1/2*mut but had a tumor-somatic *BRCA1/2* alteration (51 with mut, 4 with truncating rearrangements or copy number loss), and 1% had only CH *BRCA1/2*. Of patients with non-germline *BRCA1/2*mut, 12/63 (19%) had only CH-derived *BRCA1/2*mut. **Conclusions:** >60% of OC LBx with *TP53*mut, including *TP53* Y220C, had evidence of CH contributing to cell free DNA. TF <1% was associated with higher rates of CH only *TP53*mut, but tumor-derived variants in *TP53* and other genes were still detected. The majority (93%) of TP53mut predicted to be CH were not detected in tissue biopsies of paired samples. While the majority of LBx with a *BRCA1/2*mut had germline or tumor-somatic muts, 6% of *BRCA1/2*mut LBx only harbored *BRCA1/2*mut predicted to be CH. Together, CH prediction and TF can be used to correctly contextualize LBx findings to support informed clinical decision making. Research Sponsor: Foundation Medicine Inc.

Neoadjuvant pamiparib in patients with newly diagnosed advanced ovarian cancer: A single-arm, prospective phase II trial. First Author: Jing Liu, De-Department of Gynecologic Oncology, Clinical Oncology School of Fujian Medical University, Fujian Cancer Hospital, Fuzhou, China

Background: While PARP inhibitors have shown robust efficacy as maintenance therapy in newly diagnosed ovarian cancer, their potential benefit in the neoadjuvant setting remains unclear. The Chemotherapy Response Score (CRS) serves as an important prognostic indicator following neoadjuvant chemotherapy. This study aims to investigate the efficacy and safety of combining pamiparib with neoadjuvant chemotherapy and bevacizumab in patients with newly diagnosed advanced ovarian cancer. **Methods:** In this single-arm, prospective phase II trial, eligible patients have newly diagnosed FIGO stage III–IV ovarian, fallopian tube, or primary peritoneal cancer; histologically confirmed high-grade serous or endometrioid adenocarcinoma; are ineligible for optimal primary debulking; have an ECOG performance status of 0–2; are aged ≥18 years; and have measurable lesions per RECIST 1.1. The treatment regimen comprises paclitaxel (175 mg/m^2, Day 1) and carboplatin (AUC 5, Day 2) every three weeks for up to six cycles. Bevacizumab (15 mg/kg, Day 1) is given every three weeks and discontinued six weeks before surgery. Pamiparib (40 mg twice daily) is administered for up to six cycles. Patients who tolerate therapy and become surgical candidates undergo interval debulking surgery, followed by consolidation and maintenance therapy at the investigator's discretion. The primary endpoint is the proportion of patients with CRS 3, assessed via postoperative pathology. Secondary endpoints include the pathological complete response (pCR) rate, the R0 resection rate, progression-free survival (PFS), and safety. The trial is ongoing. **Results:** Between March 2023 and January 2025, 29 patients (median age 61 years, range 44–79) were enrolled. FIGO stages were III in 19 patients (65.5%), IVA in 1 (3.4%), and IVB in 9 (31.0%). Of these, 28 had high-grade serous adenocarcinoma and 1 had endometrioid adenocarcinoma. Two patients withdrew consent after receiving one cycle of neoadjuvant therapy. Of the remaining 27, 17 received four cycles, 7 received three cycles, and 3 received two cycles. Interval debulking surgery was performed in 24 patients—all achieved R0 resection—while 2 patients declined surgery and 1 had the treatment regimen changed due to elevated CA125. Among the 24 surgical cases, CRS 3 was observed in 8 (34.8%), CRS 2 in 15 (65.2%), and CRS 1 in 1 (4.3%). No patient achieved pCR. Common adverse events included leukopenia (96.6%), neutropenia (96.6%), anemia (96.6%), and thrombocytopenia (72.4%), with grade 3–4 incidences of 58.6%, 72.4%, 27.6%, and 24.1%, respectively. No treatment-related deaths were reported. **Conclusions:** The preliminary results suggest that the addition of pamiparib to neoadjuvant chemotherapy plus bevacizumab offers promising efficacy and acceptable safety in newly diagnosed advanced ovarian cancer. Further data will be provided as the study progresses. Clinical trial information: 2200059119. Research Sponsor: None.

Characterization of copy number variations (CNV) patterns and pseudotime trajectories in high-grade serous ovarian cancer (HGSOC). First Author: Luca Mastrantoni, Medical Oncology, Comprehensive Cancer Center, Fondazione Policlinico Universitario Agostino Gemelli–IRCCS, Catholic University of the Sacred Heart, Rome, Italy, Italy

Background: HGSOC is characterized by genomic instability, resulting in frequent CNVs. This study aimed to characterize CNV patterns and derive pseudotime trajectories in HGSOC. **Methods:** Patients with a diagnosis of HGSOC enrolled in the CGP program (NCT06020625) at Fondazione Policlinico Universitario A. Gemelli between March 2022 and December 2023 were analyzed using the TruSight Oncology 500 (TSO500) platform, covering CNVs across 523 genes. CNVs were classified as high- or low-level based on log2 segmented CN profiles. An absolute log2 value of 0.3 was used to define the fraction of altered genes. High-variability genes were identified using a variance threshold. The Leiden algorithm was applied to identify clusters based on modularity, and connectivity structures were mapped using the partition-based graph abstraction (PAGA) method. Pseudotime trajectories were modeled using diffusion-like random walks, with the root cluster chosen based on the fraction of altered genes. Non-negative matrix factorization (NMF) was used to identify gene-level CNV patterns. The number of altered genes per region was normalized to the total number of genes per chromosome arm. Chi-squared test was used to compare categorical variables. **Results:** A total of 597 HGSOC patients, 91% of whom were FIGO stage III-IV, were included. *TP53* mutations were identified in 96% of patients. *MYC* (13%) and *CCNE1* (9%) were the most frequently high-level amplified genes. 104 highly variable genes were included in the trajectory analysis. The Leiden algorithm identified 7 patient clusters, with a significant trend observed across clusters in the fraction of altered genes ($p<0.001$, Kendall's test for trend). Clusters 2 and 3 showed the lowest fraction of altered genes and were the most connected in the PAGA analysis. Using cluster 3 as the root, trajectory analysis revealed divergent branching patterns, with a significant Spearman correlation between pseudotime and the fraction of altered genes ($\rho=0.20$, $p<0.001$). Clusters also showed different percentages of homologous recombination (HR)-proficient patients ($p<0.001$) and mutations in *BRCA1* (p=0.02) and *BRCA2* (p=0.006). NMF identified 4 gene clusters based on CNV patterns, with distinct amplification and deletion profiles. Each cluster showed a different ratio of low/high-level CNVs. In the cluster characterized by high-level amplifications, *CCNE1* and *MYC* low/high-level ratios were 1.1 and 2.0, respectively. While specific chromosomal regions were enriched in the cluster characterized by low-level CNVs ($p<0.001$), clusters with high-level CNVs lacked specific regional associations. **Conclusions:** This study suggests that distinct patterns of CNVs in HGSOC are linked with genomic and clinical features. This application of CGP for CNV profiling could offer a cost-effective strategy to stratify HGSOC patients and guide personalized treatments. Clinical trial information: NCT06020625. Research Sponsor: None.

Analysis of serous carcinoma subgroup in FRUSICA-1: Fruquintinib plus sintilimab in treated advanced endometrial cancer (EMC) patients (pts) with pMMR status. First Author: Xiaohua Wu, Fudan University Shanghai Cancer Center, Shanghai, China

Background: Serous carcinoma represents approximately 10% of all EMC, has the highest recurrence rate and is responsible for a disproportionate 40% of mortality in EMC. Additionally, the overall 5-year survival rate is only 33% for stage III-IV serous carcinoma. Fruquintinib (F, a highly selective VEGFR inhibitor) plus sintilimab (S, an anti-PD-1 monoclonal antibody) was evaluated in an open-label, single-arm phase 2 pivotal study (FRUSICA-1, NCT03903705), and demonstrated encouraging efficacy and favorable safety profile in treated advanced EMC pts with pMMR (proficient mismatch repair) status (Wu X, et al; 2024 ASCO). Here, we report the ad hoc updated analysis results of the serous carcinoma subgroup (data cutoff: May 15, 2024). **Methods:** Eligible pts had histologically confirmed, previously treated advanced EMC with pMMR status confirmed by central lab. They received F (5 mg QD, 2 weeks on/1 week off, orally) plus S (200 mg, IV, Q3W) in 21-day cycles until disease progression or unacceptable toxicity. Ad hoc analyses were conducted to evaluate the primary endpoint (ORR) and secondary endpoints (DCR, DoR, TTR, PFS, OS, and safety) of F+S in pts with endometrial serous carcinoma. **Results:** As of data cutoff date (May 15, 2024), 98 EMC pts with pMMR status were enrolled and received the combination treatment (ITT population), among them, 27 pts had serous carcinoma. In these 27 pts, median age was 63.1 years, 22 (81.5%) pts were in stage IV disease, 7 (25.9%) pts had received prior bevacizumab therapy, and 5 (18.5%) pts had received prior pelvic radiotherapy. IRC-assessed ORR was 37.0% (95%CI: 19.4%, 57.6%), DCR was 88.9% (95%CI: 70.8%, 97.7%). Median DoR and TTR was 17.9 (95%CI: 3.3, not estimable [NE]) months, and 2.4 (95%CI: 1.2, 4.0) months, respectively. With the median PFS and OS follow-up of 8.3 and 21.7 months, the median PFS and OS was 8.8 (95%CI: 6.9, 19.2) months and 19.0 (95%CI: 11.4, NE) months, respectively. These efficacy findings were similar with those observed in ITT population. Grade $\geq$3 treatment related adverse events (TRAE) occurred in 63.0% pts, and the most common $\geq$Grade 3 TRAEs included palmar-plantar erythrodysesthesia syndrome (22.2%) and hypertension (11.1%). **Conclusions:** F+S was tolerable and showed clinically meaningful efficacy in endometrial serous carcinoma, characterized by durable responses that were comparable across the ITT population. Clinical trial information: NCT03903705. Research Sponsor: HUTCHMED Limited.; Innovent Biologics, Inc.

A phase II trial of pembrolizumab plus olaparib for the treatment of patients with persistent/recurrent endometrial cancers. First Author: Maria M Rubinstein, Memorial Sloan Kettering Cancer Center, New York, NY

Background: Copy number-high (CNH) ECs are characterized by high levels of copy-number alterations and *TP53* mutations, and a subset may have a homologous recombination-deficiency (HRD) phenotype. The presence of an HRD-phenotype within CNH EC provides the rationale for using OLA in combination with PEM, as this exploits the mechanism of immune priming which creates further genomic instability and drives immune response. **Methods:** This is an investigator-initiated, single- arm, open-label, phase II trial evaluating the efficacy and safety of PEM + OLA in pts with persistent/recurrent *TP53*-mutant EC. Key eligibility criteria included age $\geq$18 years, measurable disease, £3 prior lines of therapy, all histologic types allowed with aberrant p53 IHC and/or mutant *TP53*. Carcinosarcomas were eligible if the epithelial component met the p53/*TP53* criteria. dMMR/MSI-H and *POLE* hotspot tumors were not eligible. All were PEM and OLA naïve and received OLA orally at 300mg every 12 hours and PEM 200mg every 3 weeks IV. Primary endpoint was objective response rate (ORR) by 24 weeks per RECIST 1.1. **Results:** At data cut off (December 12, 2024), 26 patients (pts) initiated therapy and 25 pts were evaluable for efficacy. Median age was 68 years (range:59-83). 13 pts (50%) had serous, 8 pts (31%) were mixed/high grade, and 4 pts (15%) had carcinosarcoma histology. 24 pts (92%) had 1 line of prior chemotherapy. 1 pt had a germline *BRCA2* and 1 pt had a somatic *BRCA1* mutation. 2 pts achieved complete response (CR), 6 pts achieved partial response (PR), resulting in an ORR of 32% (90% one-sided CI: 19.6-100%). Median duration of response was 10.5 months (80% CI:6.4-11.8). Median progression-free survival (PFS) was 4.8 months (80% CI: 3.6-5.9), and median overall survival (OS) was 21.2 months (80% CI: 9.4-NE). 50% (2/4) of carcinosarcoma pts achieved CR and PR, respectively. Most common $\geq$ grade 3 treatment related adverse events were anemia (12%), neutropenia (19%). 1 pt developed grade 3 pneumonitis, 2 pts developed grade 2 adrenal insufficiency. No new safety signals were identified. **Conclusions:** The combination of PEM + OLA has promising activity with durable responses observed in pts with persistent/recurrent *TP53*-mutant EC, including carcinosarcomas. Molecular subtype selection is critical in further investigation of this combination. Clinical trial information: NCT05156268. Research Sponsor: Merck; AstraZeneca.

Molecular testing in primary advanced or recurrent endometrial cancer: A cost-effectiveness analysis. First Author: Yilin Chen, Curta Inc., Seattle, WA

Background: The Proactive Molecular Risk Classifier for Endometrial Cancer (ProMisE) algorithm is a classification scheme for endometrial cancer (EC) based on sequential testing for DNA mismatch repair deficiency (dMMR), *POLE* exonuclease domain mutations, and p53 mutations. The cost-effectiveness of ProMisE vs no molecular testing to inform initial systemic treatment choice in patients with stage III/IV primary advanced/recurrent EC (pA/rEC) was assessed from payer and societal perspectives. **Methods:** A hybrid model comprising a decision tree for molecular classification (ProMisE vs no testing) followed by partitioned survival models (PSM; progression-free disease, progressed disease, and death) was developed. Lifetime costs and outcomes following first-line systemic treatments were estimated using this model. Patients in the no-testing arm were assigned to receive carboplatin-paclitaxel (CP), dostarlimab + CP, pembrolizumab + CP, or hormonal therapy (everolimus/letrozole). Patients in the ProMisE arm were assigned to the same treatments or bevacizumab + CP, according to their molecular profile. Survival functions were derived from published trial results. EQ-5D-5L utility values were sourced from the RUBY trial (NCT03981796). Costs were sourced from US-focused databases and publicly available literature. The base case presented a US third-party payer perspective. A scenario analysis presented a modified societal perspective. Model outcomes were total costs, total life-years (LYs), total quality-adjusted LYs (QALYs), and the incremental cost-effectiveness ratio (ICER) of ProMisE vs no testing. An annual discount rate of 3% per year was applied to future costs and outcomes. Uncertainty was evaluated using one-way (OWSA) and probabilistic sensitivity analyses (PSA). **Results:** From a third-party payer perspective, total LYs and total QALYs were 5.36 and 4.08, respectively, with ProMisE vs 3.83 and 2.89 with no testing. Total costs were $233,989 with ProMisE vs $155,305 with no testing. Thus, incremental LYs and QALYs were 1.53 and 1.19 greater with ProMisE vs no testing; incremental costs over a lifetime were $78,684 greater with ProMisE. Assuming a cost-effectiveness threshold of $150,000 per QALY gained, ProMisE was cost-effective with an ICER of $66,321 per QALY gained compared with no testing. In the OWSA, ProMisE remained cost-effective over all parameter ranges ($\pm$10%). In the PSA, ProMisE was below the threshold of $150,000/QALY for 97.7% of iterations. From a societal perspective, lifetime costs were lower ($-$$22,973) and QALYs greater with ProMisE vs no testing. **Conclusions:** ProMisE testing is cost-effective vs no testing when using a $150,000/QALY-gained threshold. Given the heterogeneity of molecular subtypes in stage III/IV pA/rEC, molecular testing enables personalized treatment that is clinically meaningful and high value from payer and societal perspectives. Research Sponsor: GSK.

5599 Poster Session

E7386 study 102: Global dose-expansion cohort of E7386 + lenvatinib (LEN) in patients (pts) with advanced endometrial cancer (aEC) that progressed on platinum-based chemotherapy (chemo) and an anti-PD-(L)1 immunotherapy (IO). First Author: Jung-Yun Lee, Yonsei Cancer Center and Severance Hospital, Yonsei University College of Medicine, Seoul, South Korea

Background: There is a need for novel therapies for aEC that recurs after chemo and IO. LEN has antitumor activity in pts with aEC after platinum-based chemo [Vergote 2020] and is approved in combination with pembrolizumab for aEC following prior systemic therapy. E7386 is a novel oral anticancer agent that inhibits the interaction between β-catenin and CREB-binding protein. Study 102 evaluates E7386 + LEN in pts with solid tumors including aEC. A preliminary analysis of Study 102 (n=16) showed manageable safety and promising antitumor activity in aEC that progressed after platinum-based chemo and anti-PD-(L)1, including responses in pts with prior LEN. We report safety and antitumor activity for the complete dose expansion cohort (n=30) of pts with aEC. **Methods:** Pts with aEC that progressed after platinum-based chemo and IO received E7386 120 mg BID + LEN 14 mg QD (amended from 20 mg during enrollment). The primary endpoint was safety; secondary endpoints included ORR, duration of response (DOR), clinical benefit rate (CBR), and PFS by investigator per RECIST v1.1. **Results:** 30 pts were enrolled; 16 (53.3%) previously received LEN. By data cutoff (Oct 22, 2024), 9 (30.0%) pts had treatment ongoing. 29 (96.7%) Pts had treatment-related adverse events (TRAEs), most commonly vomiting (n=21, 70.0%). 12 (40.0%) Pts had grade 3 TRAEs, most commonly nausea/proteinuria/diarrhea/hypertension/anemia (n=2 each, 6.7%). No grade 4-5 AEs were observed. TRAEs led to study drug withdrawal of LEN and E7386 in 1 patient. Overall, 9 pts (3 with prior LEN) had a confirmed response (1 complete and 8 partial) for an ORR of 30.0%. In pts without prior LEN (n=14), the ORR was 42.9%. Additional data are in the Table. **Conclusions:** E7386 + LEN showed promising antitumor activity with a manageable safety profile in heavily pretreated pts with aEC following platinum-based chemo and IO. The dose-optimization phase of Study 102 for E7386 + LEN in pts with aEC is currently enrolling pts (NCT04008797). Clinical trial information: NCT04008797. Research Sponsor: None.

5600 Poster Session

Time to quality of life (QoL) improvement or deterioration in patients (pts) with primary advanced or recurrent endometrial cancer (pA/R EC) treated with dostarlimab plus chemotherapy in the ENGOT-EN6-NSGO/GOG-3031/RUBY trial. First Author: Florian Heitz, Kliniken Essen-Mitte, Essen, and Center for Oncologic Surgery Charité Campus Virchow-Klinikum, Charité – Universitätsmedizin Berlin, Humboldt-Universität zu Berlin, and Berlin Institute of Health, Berlin, Germany

Background: In Part 1 of the phase 3 RUBY trial (NCT03981796) in pts with pA/rEC, dostarlimab + carboplatin-paclitaxel (DOST+CP) significantly improved progression-free survival and overall survival vs placebo (PBO)+CP. Patient-reported outcomes were a secondary endpoint. Here we present a post hoc analysis comparing timing of QoL improvement or deterioration by treatment. **Methods:** Pts were randomized 1:1 to receive DOST+CP or PBO+CP Q3W (6 cycles) followed by DOST or PBO monotherapy Q6W for ≤3 y. QoL was collected at each visit. Using data from the Sept 22, 2023 data cut (median follow-up 37.2 mo), analyses on time to first QoL improvement (TTI1) or deterioration (TTD1) were conducted for the EORTC QoL Questionnaire Core 30 (QLQ-C30) and Endometrial Cancer 24 (EN24) assessments using Cox regressions. Improvement or deterioration was classified ≥10-point change in the appropriate direction, per domain, from baseline. Results are reported for the primary study populations (overall and mismatch repair deficient/microsatellite instability-high [dMMR/MSI-H]). **Results:** A total of 494 pts were randomized, of which 118 were dMMR/MSI-H. For all QLQ-C30 and EN24 domains, TTI1 was similar between arms except pain in the overall population and role function in the dMMR/MSI-H population which reached nominal significance for earlier improvement in the DOST+CP arm (Table). The overall population had similar TTD1 in both arms, while time to deterioration was delayed in the DOST+CP arm for several domains (eg, global QoL, pain) in the dMMR/MSI-H population. **Conclusions:** With over 3 years of follow-up, DOST+CP was comparable to PBO+CP for TTI1 and TTD1 in the overall population of the RUBY trial and TTD1 was delayed in several QoL domains in the dMMR/MSI-H population. These results on patient experience of treatment further support the efficacy and safety data of dostarlimab for use in patients with pA/rEC. Clinical trial information: NCT03981796. Research Sponsor: GSK.

Time to subsequent therapy in patients (pts) with primary advanced or recurrent endometrial cancer (pA/rEC) receiving dostarlimab plus carboplatin-paclitaxel (DOST+CP) compared with pts receiving placebo plus CP (PBO+CP) in the ENGOT-EN6-NSGO/GOG-3031/RUBY trial. First Author: Cara Amanda Mathews, Legorreta Cancer Center, Alpert Medical School of Brown University, Providence, RI

Background: In Part 1 of the phase 3 RUBY trial (NCT03981796), DOST+CP significantly improved progression-free survival (PFS) and overall survival (OS) in pts with pA/rEC, leading to approval for frontline treatment in the US and the EU. Time to first subsequent therapy (TFST) and second subsequent therapy (TSST) can provide further insights on the clinical benefit of a regimen as well as any clinical impact beyond first progression. **Methods:** Pts were randomized 1:1 to receive DOST+CP or PBO+CP Q3W (6 cycles) followed by DOST or PBO monotherapy Q6W for ≤3 years. Primary endpoints were PFS and OS in the overall population and PFS in the mismatch repair deficient/microsatellite instability-high (dMMR/MSI-H) population. Post hoc TFST and TSST analyses were performed at the second interim analysis (data cut, Sept 22, 2023) in the overall, dMMR/MSI-H, and mismatch repair proficient/microsatellite stable (MMRp/MSS) populations. TFST and TSST were defined as the time from randomization to the date of the first dose of first or second subsequent anticancer therapy after study drug, respectively, or death by any cause, whichever occurred first. **Results:** Of 494 pts randomized, 118 were dMMR/MSI-H and 376 were MMRp/MSS (Table). TFST and TSST were improved in all three populations. Median TFST was 5.1 and 2.5 mo longer in pts treated with DOST+CP vs PBO+CP in the overall and MMRp/MSS populations, respectively; median TFST was not reached (NR) in the DOST+CP arm of the dMMR/MSI-H population. Median TSST was extended by 11.4 and 8.1 mo in pts treated with DOST+CP vs PBO+CP in the overall and MMRp/MSS populations, respectively; median TSST was NR in the DOST+CP arm of the dMMR/MSI-H population. Hazard ratios favoring DOST+CP remained consistent between TFST and TSST in all populations evaluated. **Conclusions:** These results indicate prolonged TFST and sustained benefits through TSST with DOST+CP compared with PBO+CP across the overall, dMMR/MSI-H, and MMRp/MSS populations in the RUBY trial. Together with the statistically significant PFS and OS benefits, these findings support the frontline use of dostarlimab + CP as a standard of care in all pts with pA/rEC. Clinical trial information: NCT03981796. Research Sponsor: GSK.

A phase II efficacy and safety study of HB0025 (a PD-L1/VEGF bispecific antibody) in combination with chemotherapy as first-line treatment for advanced or recurrent endometrial cancer. First Author: Judong Li, Sun Yat-sen University Cancer Center, Guangzhou, China

Background: HB0025, developed by Huaota, is a novel anti-PD-L1/VEGF bispecific antibody, with VEGFR1D2 linked at the N-terminal of anti- PD-L1 antibody. Carboplatin and paclitaxel (CP) alone or in combination with PD-(L)1 is a recommended regimen for first-line treatment of advanced endometrial carcinoma (EC) that the ORRs were 40%-68% regardless MMR status. This study assesses the efficacy and safety of HB0025 in combination with chemotherapy in EC patients. **Methods:** This open-label, multi-center phase II study of HB0025 with CP in primary advanced (stage III or IV) or first recurrent EC. Patients received 20mg/kg HB0025 every 3 weeks with CP for 4-6 cycles, followed by maintenance therapy with HB0025. The primary endpoint was objective response rate (ORR), assessed by RECIST v1.1. **Results:** As of Dec 25, 2024, 39 patients were enrolled. The median age was 59.0 years (range, 32.0-71.0). The median follow-up time was 3.3 months (range: 0.6-6.9). 31 patients had at least one post-baseline tumor assessment. The ORR and disease control rate (DCR) were 83.9% (26/31) and 100.0% (31/31), respectively. The ORR were 84.0% (21/25) in pMMR patients and 100.0% (4/4) in dMMR patients. Median duration of response (DOR) and progression-free survival (PFS) were not reached. Grade ≥3 treatment-related adverse events (TRAEs) occurred in 18 patients (46.2%), The most common grade ≥3 TRAEs (≥10%) included neutropenia (30.8%), leukopenia (15.4%), thrombocytopenia (10.3%). Any-grade immune-related adverse events (irAEs) only occurred in 2 patients (5.1%). Treatment-related serious adverse events (SAEs) were observed in 5.1% (2/39) of patients. No TRAE led to treatment discontinuation or death. Any-grade hemorrhage events occurred in 7 (17.9%) patients which were all grade 1 in severity. **Conclusions:** HB0025 in combination with chemotherapy demonstrated promising anti-tumor efficacy with good safety profile. Regardless MMR status, ORR with HB0025 plus CP improved significantly over histologically reported data. A multicentre, randomized, double-blind, controlled phase III trial will commence in 2025. Clinical trial information: NCT06758557. Research Sponsor: Shanghai Huaota Biopharmaceutical Co., Ltd.

Interim safety and antitumor activity data from a phase 1 study of INCB123667, a selective CDK2 inhibitor, in patients with metastatic recurrent endometrial cancer. First Author: Domenica Lorusso, Fondazione Policlinico Universitario Agostino Gemelli IRCCS, Rome and Humanitas San Pio X, Milan, Italy

Background: Cyclin E1 (CCNE1) overexpression or *CCNE1* amplification is a predictive indicator of poor prognosis in some endometrial cancers. Inhibition of cyclin-dependent kinase 2 (CDK2), the binding partner of CCNE1, is a potential therapeutic approach for cancers with increased CCNE1 activity. In an ongoing phase 1 study, INCB123667, a potent and selective CDK2 inhibitor, has shown acceptable safety and preliminary efficacy in patients (pts) with advanced solid tumors (NCT05238922). Here, we present interim safety and efficacy data from enrolled pts with metastatic recurrent endometrial cancer. **Methods:** Eligible pts had ECOG PS ≤1 and measurable disease (RECIST V1.1). Part 1A (dose escalation) enrolled pts with advanced/metastatic solid tumors; CCNE1 amplification (locally tested) was not mandatory. INCB123667 dosing started at 50 mg and escalated to 150 mg daily. In Part 1B (dose expansion), selected RDEs from Part 1A were expanded in 6 tumor-specific cohorts, including an ongoing cohort of pts with metastatic recurrent endometrial cancer with ≤3 prior lines of systemic treatment; pts were required to have locally tested *CCNE1* amplification or centrally confirmed CCNE1 overexpression. Blood samples were collected for ctDNA analysis. **Results:** As of Dec 19, 2024, 17/30 pts with metastatic recurrent endometrial cancer have been enrolled and received INCB123667: 3 in Part 1A (50 mg bid, n=2; 150 mg qd, n=1) and 14 in Part 1B (RDEs: 50 mg bid, n=9; 125 mg qd, n=5). Histologies included carcinosarcoma (n=5), high grade serous (n=6), endometroid (n=4), clear cell (n=1), and mixed serous and clear cell (n=1). Median number of prior systemic therapies was 3 (1-5), including 11 pts pretreated with anti-PD-1 based therapy. Median duration of treatment was 2.3 months (0.3-19.4) and 4 pts (23.5%) are still on treatment. Overall, 16 pts (94.1%) had treatment-emergent adverse events (TEAEs), predominantly anemia (n=8 [47.1%]), nausea (n=6 [35.3%]); thrombocytopenia, abdominal pain, and asthenia (n=5 [29.4%] each). Seven pts (41.2%) had grade 3-4 TEAEs, including neutropenia and thrombocytopenia (n=2 each). No pts discontinued due to TEAEs. Four out of 17 pts had a partial response and 3 had stable disease. Three responders had prior immunotherapy. Cyclin E1 overexpression was present in 3/4 responders, and 2/4 had *CCNE1* amplification and overexpression. Decreases in ctDNA were observed on treatment compared with baseline. **Conclusions:** In this interim analysis, single-agent INCB123667 at various doses has shown an acceptable safety profile in pretreated pts with metastatic recurrent endometrial cancer, including expected cytopenia. The encouraging antitumor activity including post-PD-1 based therapy failure supports future development of INCB123667 in advanced/metastatic endometrial cancer. Clinical trial information: NCT05238922. Research Sponsor: Incyte Corporation.

Clinicopathological features and survival outcomes in women with endometrial neuroendocrine tumors. First Author: Morgan Bou Zerdan, University of Texas MD Anderson Cancer Center, Houston, TX

Background: Endometrial neuroendocrine tumors (ENET) are rare, representing about 0.8% of endometrial cancers. Due to their aggressive nature, they are often diagnosed at an advanced stage with no standardized treatment guidelines. This study provides data on the clinicopathological features and survival outcomes of ENETs. **Methods:** This IRB-approved retrospective cohort study evaluated patients with ENETs seen at MD Anderson Cancer Center between 1994 and 2024. All patients with a histology-confirmed diagnosis of ENET were included. Descriptive statistics was used to summarize patients' clinicopathologic features. Event-free survival (EFS) was defined as the time from 1st treatment to recurrence, progression, or death. Overall survival (OS) was defined as the time from start of 1st treatment to death. Kaplan-Meier was used to estimate OS and EFS, and Cox regression was used to estimate hazard ratios for prognostic factors. **Results:** A total of 97 patients were included. Median age at diagnosis was 60 years (range: 30–85). Median BMI was 30.3 kg/m2 (range: 17.1 - 76.7). 87% were white. FIGO stage at diagnosis was 31% stage I/II, 62% stage III/IV, and 5% unknown. 84% underwent primary surgery and 16% had neoadjuvant chemotherapy. For those who underwent surgery, 59% had chemotherapy and 39% had radiotherapy. 39% of patients were NED after completion of primary treatment, 38% progressed and 23% recurred. Median follow-up was 1.4 years (range 6 days to 15.7 years). Median EFS was 0.8 years (95% CI: 0.6–1.3). On multivariate analysis, patients treated with carboplatin/paclitaxel (C/P) (HR= 0.43, 95% CI: 0.24–0.79, p =0.006), or cisplatin/etoposide (C/E) (HR = 0.35, 95% CI: 0.20–0.62, p = 0.001) had a decreased risk of recurrence compared to no adjuvant therapy. Among Stage I/II patients treated with C/E had a decreased risk of recurrence compared to patients treated with C/P (HR= 0.16 (95% CI: 0.03–0.80), p=0.025). Median OS was 1.6 years (95% CI: 1.2–3.0). Multivariate analysis showed stage III/IV disease had almost 3 times the risk of death (p=0.0008). Treatment with C+P (HR =0.40, 95% CI: 0.22–0.74, p=0.003) or C+E had a HR= 0.35 (95% CI: 0.20–0.63), p= 0.0005, compared to patients receiving other or no chemotherapy. **Conclusions:** This study highlights the aggressive nature of ENETs, often diagnosed at advanced stage. Adjuvant therapy with cisplatin/etoposide was associated with reduced the risk of death compared to other treatments. Despite chemotherapy, median EFS was short, highlighting the need for improved treatment strategies. Research Sponsor: None.

Quality of life and lifestyle changes during and after therapy in women with endometrial cancer: A global study of 1,066 patients (NOGGO, ENGOT, GCIG, ENGAGe-IMPROVE/EXPRESSION XI). First Author: Lukas Chinczewski, North-Eastern German Society of Gynecological Oncology (NOGGO) & Department of Gynecology with Center for Oncological Surgery, Charité-Universitätsmedizin Berlin, Berlin, Germany

Background: Endometrial cancer (EC) affects many women worldwide, yet the impact of the disease and its treatment on symptoms, lifestyle and quality of life is still poorly understood. This study aims to explore differences in symptoms, lifestyle and perceptions between patients undergoing active treatment and those undergoing follow-up care in order to better understand their needs. **Methods:** Patients diagnosed with EC were invited to complete an 80-item survey, available in both paper and online formats. General patient characteristics such as comorbidities, tumor stage and therapy as well as symptoms during and after treatment were recorded. Participants were categorized into two cohorts: those undergoing active treatment (cohort A) and those in follow-up monitoring (cohort B). **Results:** A total of 1,660 patients with EC from 17 countries participated between December 2021 and December 2024. The median age of the participants was 66 years [range: 20–94]. Of these, 581 (35%) were in cohort A, and 1,079 (65%) were in cohort B. No differences in common comorbidities were observed between cohorts. Anticoagulant use was higher in cohort A (22.7%) compared to cohort B (17.0%), while vitamin intake was more common in cohort B (32.4% vs. 25.8%). Quality of life was lower in cohort A, with 68.5% currently experiencing side effects compared to 45.8% in cohort B. Symptoms such as fatigue (39.6% vs. 15.1%), pain (23.6% vs. 10.8%), constipation (16.7% vs. 8.3%), loss of appetite (14.6% vs. 1.6%), and weight loss (11.5% vs. 2.1%) were more prevalent in cohort A. Physical activity levels increased after diagnosis for 49.7% in cohort B compared to 34.1% in cohort A. Smoking habits remained largely unchanged, with 15.3% (cohort A) and 14.0% (cohort B) reporting current smoking, and only 4.9% of all patients quitting after diagnosis, despite 19.2% acknowledging potential benefits. Interest in nutritional counseling was higher in cohort A (26.2% vs. 21.7%). Patients in cohort A perceived EC as a greater health threat compared to their other comorbidities (69.2% vs. 43.6%). **Conclusions:** Patients tend to recover from the physical and psychological burden of active treatment, showing improvements in physical activity levels and a reduction in symptoms. However, structured programs in follow-up care are essential to achieve long-term lifestyle changes, including enhanced physical activity and dietary habits. The observed interest in nutritional counselling during treatment presents an opportunity to develop targeted interventions. Despite encouraging increase in physical activity during follow-up, additional efforts are needed to maintain and reinforce these positive changes over time. Clinical trial information: DRKS00025954. The landscape of chromosomal instability in uterine leiomyosarcoma. First Author: Sara Moufarrij, Memorial Sloan Kettering Cancer Center, New York, NY

Background: Uterine leiomyosarcoma (uLMS) has heterogeneous clinical presentations and outcomes. Although most uLMSs are associated with chromosomal instability, limited data exist on chromosomal instability patterns and their association with clinical outcomes. We sought to examine the chromosomal and genomic landscape of uLMSs and their association with survival outcomes. **Methods:** We identified 162 patients with uLMS who underwent matched tumor-normal next-generation sequencing at our institution between 2007 and 2024. Allele-specific copy number analysis was performed using the FACETS algorithm with genome-wide summary data as well as focal copy number data extracted and compared with clinical variables and survival outcomes. Appropriate statistical analyses were performed. **Results:** The median age at diagnosis was 55 years (range, 30-92). The uLMS in the cohort predominantly had conventional spindle cell morphology (n=122/162, 75%). At the time of diagnosis, 42% presented as FIGO stage I disease (68/162) followed by FIGO stage IV disease (60/162, 37%). ER expression data was available for 155 cases, with the majority of cases being ER positive (106/155, 68%). PR expression data was available for 145 cases, with most of the tumors expressing PR (87/145, 60%). The most common alterations in the cohort were *TP53* (117, 72%), *RB1* (78, 48%), *ATRX* (62, 38%), and *PTEN* (31, 19%). FACETS analysis showed that 15% of tumors (25/162) were hypoploid and 12% had whole-genome duplication (20/162). The median telomeric size was 50.1 Mb (interquartile range [IQR]: 40-59.3). The median number of telomeric allele imbalances was 6 (IQR: 3-9). The median fraction of genome with loss of heterozygosity was 0.28 (IQR: 0.14-10.5). Centromeric allele imbalance, whole-genome duplication, and fraction of copy number altered were associated with ER expression (adjusted P=0.025, 0.015, and 0.002, respectively). Multivariate survival analysis demonstrated that hypoploidy (hazard ratio: 3.3) and copy number alterations in *PIK3CD* (hazard ratio: 1.82) were associated with worse overall survival ($P<0.001$ for both). **Conclusions:** Although most uLMSs are caused by underlying chromosomal instability, the patterns in these tumors are variable, with some of the chromosomal instability configurations having prognostic implications. Further studies are needed to better understand the role of chromosomal instability in the stratification of the disease. Research Sponsor: None.

Post-hoc analysis evaluating selinexor maintenance therapy in patients with *TP53*wt endometrial cancer: Progression-free survival by clinical factors in the ENGOT-EN5/GOG-3055/SIENDO study. First Author: Jalid Sehouli, Charité Universitätsmedizin Berlin, Berlin, Germany

Background: At primary analysis of the phase 3 study of selinexor (SEL) maintenance treatment in patients (pts) with advanced/recurrent endometrial cancer (EC), improvement in median progression-free survival (PFS) for the intent-to-treat population was not clinically meaningful. However, a promising efficacy signal was seen in a pre-specified exploratory analysis of *TP53*wt EC. We present further exploratory PFS analyses of long-term follow-up data in *TP53*wt EC. **Methods:** ENGOT-EN5/GOG-3055/SIENDO (NCT03555422) was a double-blind randomized (2:1) study evaluating SEL vs placebo as maintenance treatment in pts with advanced/recurrent EC following response to prior systemic therapy. Post-hoc exploratory subgroup analyses include response to prior systemic chemotherapy, disease at time of prior systemic therapy, Eastern Cooperative Oncology Group (ECOG) performance status, histopathological subtype at initial diagnosis, and duration of last systemic therapy. Additional subgroups will be reported at the time of presentation. **Results:** Of 263 pts in the study, 113 (43.0%) had *TP53*wt EC (SEL, n = 77; placebo, n = 36). At data cut-off (April 1, 2024), PFS subgroup analyses generally showed benefit for SEL compared with placebo in the *TP53*wt subgroup regardless of clinical factor (table). Adverse events (AEs) were generally manageable and reversible. The most common AEs (overall/Grade ≥3) with SEL were nausea (89.5%/13.2%), vomiting (60.5%/2.6%), and diarrhea (44.7%/3.9%). Dual anti-emetics were not mandated. No meaningful differences in AEs were observed across subgroups. 17.1% of pts discontinued SEL due to AEs; 1 death occurred in the placebo group. **Conclusions:** A strong PFS signal was observed in the *TP53*wt subgroup across a range of key clinical factors at long-term follow-up. Efficacy and safety of SEL maintenance therapy were generally comparable across subgroups. A phase 3 trial is ongoing to further investigate SEL as maintenance therapy in pts with advanced/recurrent *TP53*wt EC (ENGOT-EN20/GOG-3083/Xport-EC-042, NCT05611931). Clinical trial information: NCT03555422. Research Sponsor: Karyopharm Therapeutics.

The role of platinum-free interval in advanced endometrial cancer treatment: A real-world study of 843 patients. First Author: John K. Chan, Palo Alto Medical Foundation, California Pacific Medical Center Research Institute, San Francisco, CA

Background: Time between completion of last platinum-based chemotherapy (PBC) and recurrence is predictive of outcomes in recurrent ovarian cancer; however, its applicability to endometrial cancer (EC) remains uncertain. This retrospective real-world study assessed (1) platinum-free interval (PFI) duration between first-line (1L) PBC and second-line (2L) therapy for EC, (2) differences in patient (pt) and clinical characteristics by PFI, and (3) the association between PFI and outcomes. **Methods:** Using the US Flatiron Health electronic health record–derived deidentified database, we analyzed pts with advanced or recurrent EC who received 1L PBC between 1/1/2013 and 8/31/2022. PFI was defined as the time between completion of PBC and the start date of any 2L therapy. Overall survival (OS), time to treatment discontinuation (TTD), and time to next treatment (TTNT) were analyzed using Kaplan-Meier methods. The association between PFI and clinical outcomes was examined using Cox regression models. **Results:** Of 843 pts, 575 (68%), 147 (17%), and 121 (14%) had a PFI of <6, ≥6 to <12, and ≥12 months (mo), respectively. Pts with advanced disease, carcinosarcoma histology, or a history of surgery or radiation were more likely to have shorter PFI; those with a body mass index of ≥40 kg/m^2 or PD-L1 negative/not detected were more likely to have longer PFI ($P<.05$ for all). Pts with a PFI of <6, ≥6 to <12, or ≥12 mo had a median OS of 12.7, 17.9, or 30.5 mo and median TTNT of 9.8, 8.3, or 12.6 mo, respectively. Compared with pts with a ≥12-mo PFI, those with shorter PFI had a significantly higher risk of death, after adjusting for potential confounders (HR, 1.71 [95% CI, 1.27-2.29] for PFI of <6 mo; HR, 1.57 [95% CI, 1.12-2.20] for PFI of ≥6 to <12 mo). Median OS, TTD, and TTNT, and their association with PFI, are summarized in the Table. **Conclusions:** Our data suggest that platinum sensitivity is an applicable concept in advanced or recurrent EC and is associated with OS. These results may have implications for treatment selection and informing clinical trial designs in EC. Research Sponsor: GSK.

Adverse effects of immune checkpoint inhibitors in advanced endometrial cancer: A systematic review and meta-analysis. First Author: Fizza Mohsin, Maimonides Medical Center, Brooklyn, NY

Background: Immune checkpoint inhibitors (ICIs) in combination with chemotherapy have become a standard first-line treatment for advanced endometrial cancer with increased response rate and progression free survival. While immune-related adverse effects (irAEs) are expected, it is interesting to know the rate of all treatment-related adverse effects (TRAEs). This meta-analysis evaluates the spectrum of adverse effects related to ICIs. **Methods:** Search of the PubMed, EMBASE and Cochrane Library for publications up to December 2024 yielded six randomized controlled trials (RCTs), namely RUBY, NRG-GY018, DUO-E, KEYNOTE-B21, AtTend, and MITO END-3 for this analysis. Uniformly, the experiment arms were ICIs plus paclitaxel and carboplatin, while the control arms were same chemotherapy agents, except the DUO-E trial included Olaparib in one of the experimental arms. The primary outcomes of this study were the pooled events of TRAEs and irAEs, analyzed using a random-effects model with RevMan 5.4. **Results:** A total of 3952 patients were included from 6 RCTs. The use of ICI was associated with irAEs, such as hypothyroidism, hyperthyroidism, rash and pneumonitis(Table). It was also associated with increased incidence of serious TRAEs (RR 1.64, 95%CI 1.09-2.48, p=0.02) and higher treatment discontinuation rates (RR 1.44, 95%CI 1.13-1.83, p=0.004). There was greater risk of hematologic toxicities, including anemia (RR:1.25, 95% CI 1.05-1.49), leukopenia (RR:1.40, 95% CI 1.10-1.77), and thrombocytopenia (RR:1.43, 95% CI 1.06-1.93) in ICI arm. ICI arm was at greater risk of hepatotoxicity (RR: 4.47, 95% CI 1.17-17.15), vomiting (RR: 1.43, 95% CI 1.19-1.73) and hypertension (RR:1.93, 95% CI 1.11-3.36). There were no significant differences in peripheral neuropathy (RR:0.96, 95%CI 0.89-1.04), fatigue (RR:1.04, 95%CI 0.95-1.13), infusion related reactions (RR: 1.11, 95% CI 0.51-2.39), arthralgias (RR:0.58, 95% CI 0.21-1.57), or fatal TRAEs between the two treatment groups(RR: 1.21,95% CI 0.69-2.12). **Conclusions:** Advanced endometrial cancer treatment with ICIs is linked to a diverse array of adverse effects. Patients in the ICI and chemotherapy arm demonstrated an increased risk of hematologic toxicity, hepatotoxicity, irAEs and higher treatment discontinuation rate compared to chemotherapy alone. However, no notable difference was observed in fatal TRAEs. Research Sponsor: None.

	Events	Number of studies (n)	Number of patients included (N)	Risk Ratio, 95% Confidence Interval	P value

The impact of prior neoadjuvant/adjuvant chemotherapy (NACT/ACT) on fruquintinib plus sintilimab outcomes in advanced endometrial cancer (EMC) patients with pMMR status: A subgroup analysis of FRUSICA-1. First Author: Jing Wang, Hunan Cancer Hospital, Changsha, China

Background: FRUSICA-1 (NCT03903705) was an open-label, single-arm, pivotal phase 2 study to evaluate the efficacy and safety of fruquintinib (F, a highly selective VEGFR inhibitor) plus sintilimab (S, an anti-PD-1 monoclonal antibody) in previously treated advanced EMC patients (pts) with pMMR (proficient mismatch repair) status. The primary results of FRUSICA-1 have demonstrated encouraging efficacy (objective response rate [ORR]: 35.6%; median progression-free survival [PFS]: 9.5 mo; median overall survival [OS]: 21.3 mo) in the overall population (Wu X, et al; 2024 ASCO). In this updated exploratory analysis (data cutoff: May 15, 2024), we evaluated the association between prior NACT/ACT and clinical outcomes in this study. **Methods:** Pts who had histologically confirmed advanced EMC with pMMR status confirmed by central lab and had progression on 1 standard systemic therapy were eligible. They received F (5 mg QD, 2 weeks on/1 week off, orally) plus S (200 mg, IV, Q3W) in 21-day cycles until disease progression or unacceptable toxicity. The efficacy subgroup analysis was performed by prior NACT/ACT (Yes vs No). **Results:** As of May 15, 2024, a total of 98 EMC pts with pMMR status were enrolled and received the treatment with the median follow-up of 22.0 mo (95%CI: 20.5, 23.7). Based on pts with or without prior NACT/ACT (Yes vs No = 47 pts vs 51 pts), the baseline demographics and disease characteristics were well balanced. Independent Review Committee (IRC)-assessed ORR (34.0% vs 31.4%) and disease control rate (DCR, 85.1% vs 82.4%) were comparable, respectively. Median duration of response (DoR) in pts with NACT/ACT was 11.1 mo while not reached for pts without NACT/ACT. Median PFS were 7.1 mo (95%CI: 4.7, 13.8) vs 9.5 mo (95%CI: 5.5, not estimable), respectively with two 95%CIs highly overlapped. The 6-mo PFS rates were also comparable at 56.8% vs 59.7%. Median OS pending maturity, the 18-mo OS rates were nearly identical (58.7% vs 59.1%). **Conclusions:** In this updated exploratory analysis of pts with advanced EMC enrolled in FRUSICA-1 study treated with F plus S, encouraging outcomes were achieved in the overall population, including patients who had received prior NACT/ACT and those who had not, with durable and clinically meaningful responses. Clinical trial information: NCT03903705. Research Sponsor: HUTCHMED Limited; Innovent Biologics, Inc.

SHR-A1811 in patients (pts) with HER2-expressing advanced gynecological cancers (Gynecol C): A phase 2 study. First Author: Beihua Kong, Qilu Hospital of Shandong University, Jinan, China

Background: SHR-A1811 is a novel an antibody-drug conjugate consisting of a humanized HER2-directed monoclonal antibody, cleavable tetrapeptide-based linker, and DNA topoisomerase I inhibitor. We assessed SHR-A1811 in HER2-expressing advanced Gynecol C. **Methods:** Pts with ovarian cancer (OC) that had recurrence within 6 mo of last platinum-based therapy, and recurrent/metastatic endometrial cancer (EC) or cervical cancer (CC) that failed standard therapy were enrolled. Pts received SHR-A1811 at 4.8 or 6.4 mg/kg (Q3W, IV). The primary endpoint was ORR per RECIST v1.1. **Results:** As of Dec 25, 2024, 108 pts were enrolled (ECOG PS 1: 71.3%, prior VEGFR inhibitors: 53.7%, prior immunotherapies: 24.1%) including 46 pts with OC, 27 EC, and 35 CC. Rate of pts with HER2 IHC 3+ was 10.9%, 14.8%, and 31.4%; IHC 2+ was 54.3%, 70.4%, and 37.1%, respectively. The median follow-up was 8.1 mo (IQR, 4.7–10.7). For pts with OC, EC, and CC, ORR was 56.1%, 50.0%, and 63.6%, and PFS was 8.5 mo (95% CI, 5.7–NR), 5.6 mo (95% CI, 4.1–NR), and 10.7 mo (95% CI, 6.9–NR), respectively. In the 4.8 mg/kg cohort, for OC, EC, and CC, ORR was 56.8%, 52.0%, and 61.3%, and PFS was 8.5 mo (95% CI, 5.6–11.3), 7.2 mo (95% CI, 4.1–NR), and 10.7 mo (95% CI, 6.2–NR), respectively. Among OC, EC, and CC pts, ORR was 66.7% in 30 pts, 43.5% in 23 pts, and 66.7% in 24 pts with HER2 IHC 2+/3+, respectively. Additional antitumor activities are shown in Table. Treatment-related adverse events (TRAEs) of grade ≥3 occurred in 84 (77.8%) pts, with the most common being decreased neutrophil count (62.0%), decreased white blood cell count (48.1%), and anemia (28.7%). No TRAEs leading to discontinuation of treatment or deaths were reported. **Conclusions:** SHR-A1811 showed encouraging activity and manageable safety profile in pts with HER2-expressing advanced Gynecol C. Clinical trial information: NCT05896020. Research Sponsor: Jiangsu Hengrui Pharmaceuticals Co., Ltd.

Evaluating the safety and efficacy of CRISPR/Cas9-modified tumor infiltrating lymphocytes (GT300) as monotherapy in advanced solid tumors. First Author: Pin Wang, Grit Biotechnology, Shanghai, China

Background: Adoptive cell therapy using autologous tumor-infiltrating lymphocytes (TILs) has shown promising results in melanoma patients. However, its effectiveness in other solid tumors, especially "cold" tumors, is still being explored. GT300, a next-generation TIL product, is engineered using CRISPR/AaCas12bMax to disrupt two key immunoregulatory targets identified through genome-wide CRISPR screening. This modification aims to enhance TIL function and overcome the suppressive tumor microenvironment, potentially expanding its use to cold tumors like ovarian and colorectal cancer. Therefore, two studies were initiated to assess the preliminary safety and efficacy of GT300 in advanced solid tumors. **Methods:** The first-in-class study aims to enroll patients with advanced, treatment-refractory solid tumors, focusing on gynecological cancers. After determining the optimal biological dose (OBD), a monotherapy expansion phase will begin for patients with various solid tumors. Participants undergo nonmyeloablative (NMA) lymphodepletion and receive an infusion of the G300 TIL product, followed by IL-2 administration. **Results:** As of September 5, 2024, five patients have been enrolled in these two studies, with a median age of 55 years and a median of two prior therapy lines. After FC lymphodepleting chemotherapy, patients received GT300 infusions at doses of $\geq 1 \times 10^9$ viable cells. Four out of five patients subsequently received IL-2. Most adverse events (AEs) were Grade 1 or 2, with Grade 3/4 AEs including fever, rash, dental ulcer, anemia, and decreased platelet count. No DLTs were observed. The ORR was 60% (3/5 evaluable patients). Two patients (40%) achieved CR in cervical cancer and peritoneal papillary serous carcinoma, while one patient (20%) with ovarian cancer had a PR. Despite variations in TIL doses (3.2×10^9 to 1.90×10^{10} cells) and IL-2 regimens (up to 3.0×10^5 IU/kg), robust TIL proliferation was consistently observed post-infusion. Responders showed biphasic CD45+CD3+ T cell expansion, indicating sustained immune activation. An early increase in IFN-γ levels from days 3 to 10 strongly correlated with positive outcomes, suggesting its potential as an early efficacy biomarker. **Conclusions:** In patients with previously treated gynecological cancer, GT300, administered after FC lymphodepleting chemotherapy and followed by higher-dose IL-2, exhibited a manageable safety profile. GT300, a CRISPR/Cas9 dual knockout anti-exhaustion TIL product, showed favorable clinical outcomes with a 60% objective ORR, including 40% CR and 20% PR, with no DLTs observed. The infusion led to robust TIL expansion and IFN-γ secretion. These promising results indicate favorable long-term survival outcomes, durable responses, and no long-term safety concerns associated with GT300. Clinical trial information: NCT06145802, NCT06397963. Research Sponsor: None.

5614 Poster Session

Feasibility of ChatGPT-4o in management of gynecologic oncologic patients in the emergency department. First Author: Junhwan Kim, Center for Gynecologic Cancer, National Cancer Center, Goyang-Si, Korea, Republic of

Background: Recent studies have highlighted the diagnostic and reasoning capabilities of ChatGPT in medicine. This study aims to evaluate the feasibility of using ChatGPT-4o to assist in managing emergency care for gynecologic oncologic patients, focusing on its potential to support physicians and generate patient education materials. **Methods:** We retrospectively reviewed real cases of gynecologic cancer patients who visited the emergency department of the National Cancer Center in Korea between 2005 and 2024 and identified 15 common cases for evaluation. For each case, four physicians (two gynecologic oncologists and two obstetrics and gynecology residents) assessed the cases based on nine criteria: relevance of differential diagnosis, relevance of suggested necessary examinations, speed in suggesting differential diagnoses and necessary examinations, relevance of examination interpretations, relevance of the final diagnosis, relevance of treatment plans, speed in suggesting the final diagnosis and treatment plans, relevance of prescribed orders, and speed of prescribing orders. Each criterion was scored on a scale of 0, 1, or 2, and total scores were calculated along with the total time taken to generate diagnoses, treatment plans, and actual order prescriptions. The same cases were then evaluated using ChatGPT-4o, with prompts specifically developed to enable consistent assessment. In addition to the nine criteria, ChatGPT-4o was also evaluated on the relevance and speed of patient education, with scores assigned on a scale of 0, 1, or 2. Furthermore, physicians provided feedback on their satisfaction with ChatGPT-4o's generated answers and patient education materials using the same scale. **Results:** ChatGPT-4o demonstrated a mean score of 17.1 (range, 14–18) across the 15 cases, outperforming physicians, who achieved a lower mean score of 13.4 (range, 5–17). The mean time taken by ChatGPT-4o to respond to all nine criteria was 108.4 (range, 69–142) seconds, significantly faster than physicians, who required an average of 391.4 (range, 126–786) seconds. For relevance of patient education, ChatGPT-4o achieved a mean score of 1.9 (range, 1–2) across the 15 cases, with response times consistently under 1 minute per cases. Physicians rated their satisfaction with ChatGPT-4o's generated diagnoses, treatment plans, and order recommendations at a mean score of 1.9 (range, 1–2). Similarly, their satisfaction with ChatGPT-4o's patient education materials was rated at a mean score of 1.8 (range, 1–2). **Conclusions:** ChatGPT-4o demonstrates feasibility as a promising supportive tool for managing emergency care in gynecologic oncologic patients, offering fast and relevant diagnoses, treatment plans, and patient education materials. Future research warrants developing practical applications and conducting prospective evaluations to optimize its integration in emergency departments. Research Sponsor: None.

5615 Poster Session

Clinical and demographic profiles and predictors of survival in epithelioid trophoblastic tumors: A population-based analysis. First Author: Zhuoran Xiao, Tulane School of Public Health, New Orlean, LA

Background: Epithelioid trophoblastic tumor (ETT) is a rare form of gestational trophoblastic neoplasia. Existing studies on ETT have been limited by small sample sizes and a lack of robust socioeconomic and demographic analyses. This study aims to characterize the clinical and demographic profiles of ETT patients and evaluate survival outcomes. **Methods:** ETT cases diagnosed between 2000 and 2021 were extracted from the Surveillance, Epidemiology, and End Results (SEER) database. Survival outcomes were analyzed with Kaplan-Meier survival analysis, and the statistical significance of key variables was assessed using the log-rank test. Hazard ratios (HR) were calculated using Cox proportional hazards regression models. This data is compared to what is currently known based on the published literature. **Results:** A total of 100 patients with ETT were identified. The majority of cases (76%) were in patients aged 30 to 49 years. The cohort was predominantly white race (60%), with 72% identifying as Non-Spanish-Hispanic-Latino. Of patients with staging information (57%), 30% had localized disease. Socioeconomic analysis revealed that 60% of patients had a median household income below $80,000 annually, and 71% resided in metropolitan areas with populations exceeding one million. Black patients had risk of mortality compared to white patients [HR = 3.233; 95% CI: (1.021, 10.240), p = 0.046]. Patients with distant metastases or nodal involvement had significantly worse survival outcomes compared to those with localized disease [HR = 11.813; 95% CI: (1.379, 101.190); p = 0.024]. Among treatment modalities, 65% of patients underwent surgery, 33% received chemotherapy, and 3% received radiation therapy. Patients who received chemotherapy demonstrated a higher risk of mortality compared to those who did not [HR = 5.937; 95% CI: (1.788, 19.710); p = 0.004]. **Conclusions:** ETT patients exhibit significant survival differences based on race, distant disease at diagnosis, and chemotherapy use. These findings highlight the importance of addressing racial disparities, early diagnosis, and optimizing treatment strategies to improve outcomes for this rare malignancy. Further research is warranted to refine our understanding and guide clinical management. Research Sponsor: None.

Effects of surgery on the prognosis of patients with locally advanced vulva cancer: A retrospective study of the SEER database and a Chinese multi-centre registry. First Author: Yuqin Wang, Clinical Oncology School of Fujian Medical University, Fujian Cancer Hospital, Fuzhou, China

Background: Vulva cancer is a rare gynecologic oncology, and lacks uniform recommendations in current guidelines, especially for locally advanced cases. This study seeks to explore prognostic factors and optimize treatment strategies for vulva cancer. **Methods:** This multicenter, cross-ethnic retrospective study collected patient data from 2003–2023 in the China Multi-center Registry and from 2004–2021 in the SEER database. Only pathologically confirmed cases of vulva cancer were included in the analysis. Patients lost to follow-up, under 20 years of age, were excluded. Survival outcomes were compared using Kaplan-Meier analysis, while prognostic factors were evaluated through the Cox proportional hazards model. Baseline characteristics between groups were balanced using inverse probability of treatment weighting (IPTW). The primary endpoint of the study was overall survival. **Results:** A total of 19,682 patients with vulva cancer were included in the study, comprising 604 patients in the Chinese cohort and 19,078 patients in the SEER cohort. Multivariate Cox regression models (China cohort: HR=0.46,95%CI:0.33-0.64, $P < 0.001$; SEER cohort: HR=0.43,95% CI:0.41–0.46, $P < 0.001$) indicated that surgery was associated with improved prognosis. In both cohorts of patients with locally advanced vulva cancer, surgery remained a protective prognostic factor (China cohort: HR =0.43,95%CI:0.27-0.69, $p < 0.001$; SEER cohort: HR=0.52 ,95%CI:0.47-0.57, $p < 0.001$). And the protective effect of surgery in patients with locally advanced disease remained significant after IPTW (China cohort: HR= 0.38 ,95%CI:0.24-0.63, $p < 0.001$; SEER cohort: HR=0.50 ,95%CI:0.44–0.56, $p < 0.001$). **Conclusions:** Although guidelines recommend non-surgical treatment as the preferred approach for patients with locally advanced vulva cancer, this large-scale, multicenter, cross-ethnic retrospective study demonstrates that surgery significantly improves prognosis and offers new insights for clinical practice. Research Sponsor: None.

Temporal and regional mortality trends due to pulmonary embolism in female patients with genital cancers in the United States from 1999 to 2020. First Author: Marcos Alberto Jr., Indiana University Southwest Internal Medicine, Evansville, IN

Background: The involvement of pulmonary vessels by tumor emboli has been described from different primary sites of malignancy. Pulmonary embolism (PE) is a severe and potentially fatal complication in patients with female genital cancers, including ovarian, cervical, uterine, and vulvar malignancies. These cancers, along with associated treatments such as major abdominal surgery, chemotherapy, and hormone therapy, significantly increase the risk of venous thromboembolism (VTE), including PE. While previous studies detail the advancements in cancer detection and treatment, temporal and regional trends of PE-related mortality among female genital cancer patients remain poorly characterized. **Methods:** This retrospective study analyzes national mortality data from the CDC WONDER database to assess mortality trends from 1999 to 2020 across different demographic subgroups in the United States. Patients with a known history of genital cancer were identified and PE related mortality data was retrieved. Age-adjusted mortality rates (AAMRs) per 100,000 individuals were calculated further stratified based on sex, age (15-64 years and >64 years), race and census region. Rstudio was used to perform t-test and Mann Kendall test. **Results:** From 1999 to 2020, a total of 13,692 deaths were reported in female genital cancer associated pulmonary embolism in the US (AAPC: 0.421 (95% CI: 0.414-0.428)). The AAMR has risen from 0.363 in 1999 to 0.590 in 2020, indicating a worsening trend over the study period (τ: 0.680, $p<0.001$). AAMR varied greatly by region, with the Northeast having the highest AAMR (9.928). This was followed by the West (0.488), Midwest (0.43) and South (0.366). Black females had consistently higher AAMR than white females, with rates of 0.763 vs. 0.329 in 1999 and 0.976 vs. 0.523 in 2020, respectively. Females older than 65 years demonstrated a much higher total AAMR (1.506) compared to females between the ages of 15 and 65 (0.212) ($p<0.001$). Within the age group of 15-25 years, black females had higher AAMRs compared to white female ($p<0.001$). Black females of the age group >65 years demonstrated much higher mortality (total AAMR: 2.745) than white females of the same age group (1.419), and the highest AAMR overall ($P<0.001$). **Conclusions:** The analysis of AAMR for female genital cancer associated pulmonary embolism highlights a concerning disparity in this dangerous cancer related complication, particularly after 2015. This underscores the need for greater attention to be directed towards reproductive health and cancer related complications faced by black women and to address systematic inequalities in intervention and healthcare access. This can improve early detection and timely interventions in order to reduce mortality and improve outcomes for these patients. Research Sponsor: None.

TPS5618 **Poster Session**

TroFuse-020/GOG-3101/ENGOT-cx20: A phase 3, randomized, active-controlled, open-label, multicenter study comparing sacituzumab tirumotecan monotherapy vs treatment of physician's choice as second-line treatment for recurrent or metastatic cervical cancer. First Author: Ritu Salani, Department of Obstetrics and Gynecology, University of California Los Angeles, Los Angeles, CA

Background: Sacituzumab tirumotecan (sac-TMT; formerly MK-2870/SKB264) is an antibody–drug conjugate comprising a trophoblast cell-surface antigen 2 (TROP2)–antibody, a hydrolytically-cleavable linker, and the cytotoxic drug KL610023 (average drug/antibody ratio, 7.4). In an ongoing phase 1/2 study (MK-2870-001), sac-TMT monotherapy showed promising antitumor activity in participants with locally advanced unresectable/metastatic solid tumors that were refractory to standard therapies. This phase 3, randomized, open-label, multicenter study (NCT06459180) evaluates the efficacy and safety of sac-TMT monotherapy vs treatment of physician's choice (TPC) as second-line treatment in participants with recurrent/metastatic cervical cancer. **Methods:** Eligible participants are aged ≥18 years with progressive recurrent/metastatic cervical cancer, measurable per RECIST version 1.1 by the investigator, and had received 1 prior line of platinum doublet chemotherapy (±bevacizumab) and anti–PD-1/anti–PD-L1 therapy as a part of cervical cancer regimens. Participants must provide tissue from a core or excisional biopsy of a not previously irradiated tumor lesion. Approximately 666 participants will be randomly assigned 1:1 to receive either sac-TMT 4 mg/kg intravenously (IV) Q2W or TPC (pemetrexed 500 mg/m^2 IV Q3W; tisotumab vedotin 2 mg/kg IV Q3W; topotecan 1 or 1.25 mg/m^2 on days 1–5 of each 3-week treatment cycle; vinorelbine 30 mg/m^2 on days 1 and 8 of each 3-week treatment cycle; gemcitabine 1000 mg/m^2 on days 1 and 8 of each 3-week treatment cycle; or irinotecan 100 or 125 mg/m^2 on days 1, 8, 15, and 22 of each 6-week treatment cycle). Tumor imaging will be performed ≤28 days before treatment allocation/randomisation, then Q9W until week 54 and Q12W thereafter. The primary endpoint is OS; secondary endpoints include PFS assessed by blinded independent central review, objective response, duration of response, safety, time to deterioration, and patient-reported outcomes. Enrollment began in Q3 2024. Clinical trial information: NCT06459180. Research Sponsor: Merck Sharp & Dohme LLC, a subsidiary of Merck & Co., Inc., Rahway, NJ, USA.

TPS5619 **Poster Session**

Randomized phase II study to evaluate treatment with induction therapy with nivolumab plus ipilimumab, followed by nivolumab with chemoradiotherapy versus standard of care with chemoradiotherapy for women with locally advanced cervical cancer. First Author: Henrique Alkalay Helber, HIAE, Sao Paulo, Brazil

Background: Cervical cancer (CC) is one of the leading cause of death in developing countries, largely due to insufficient HPV vaccination coverage. The majority of patients are diagnosed with locally advanced disease. Current standard of care (SOC) for those patients is cisplatin-based chemoradiotherapy (P-XRT). Recent advances have shown improved overall survival (OS) with addition of pembrolizumab administered concurrently with P-XRT and as adjuvant therapy (Lorusso, Domenica et al., KN A18 - LANCET, 2024) as well as neoadjuvant chemotherapy with carboplatin and paclitaxel (McCormick et al, LANCET, 2024). In the metastatic setting, the phase I/II CheckMate 358 trial demonstrated high responses rates with the combination of nivolumab (N) and ipilimumab (I) (Oaknin Ana et al, LANCET, 2024). Currently, no trials have evaluated the use of immune checkpoint inhibitors as a neoadjuvant and concurrent strategy with P-XRT in locally advanced CC. Therefore, we hypothesized that induction N/I followed by nivolumab and P-XRT in locally advanced CC can improve clinical outcomes with a manageable toxicity profile. **Methods:** This is a phase II, randomized, clinical trial, including 116 patients with locally advanced cervical cancer (FIGO stages IIB-IVA). Treatment arms: Patients who are eligible for the study was randomized to one of the following treatment arms: - Experimental: Induction Nivolumab (N) 1mg/kg IV plus Ipilimumab (I) 3mg/kg IV every 3 weeks x 4 cycles followed by N 240mg every 2 weeks concurrently with P-XRT. - Control: P-XRT. Endpoints: Primary endpoint: 3-year Progression-Free Survival (PFS). Secondary endpoints: 3-year overall survival (OS), complete response rate (CRR), objective response rate (ORR), duration of response (DoR), health related quality of life (HRQoL) and toxicity profile. Statistics considerations: A total of 116 participants were randomized 1:1 (experimental arm Vs SOC), considering a dropout rate of 10%. A two-sided log-rank test at a 0.05 significance level provides 80% power to detect a difference between a 3-year PFS rate of 75% in the experimental arm versus 50% in the control arm. This calculation assumes a recruitment period of 24 months, and a total study duration of 60 months (up to 24 months of recruitment and 36-month follow-up after the end of treatment). Current Status: The study is ongoing, and the recruitment phase has been completed. The first patient was enrolled in September 2022, and the last patient in April 2024. All participants have finished the treatment phase and are currently in the follow-up phase. Final study results are expected by mid-2028 Clinical trial information: NCT05492123. Research Sponsor: BRAVA institute (BRAZIL).

TPS5620 **Poster Session**

A prospective, randomized control trial of concurrent paclitaxel and carboplatin along with radiotherapy versus concurrent cisplatin along with radiotherapy in carcinoma cervix patients at a tertiary care hospital of central India. First Author: Praghnya Subhash Tejale, Government Medical College, Nagpur, India

Background: In India, cervical cancer accounted for 9.0% of all cancers and 18.3% (127,526) of new cases in 2022 as per GLOBOCAN. It is leading cause of cancer-related deaths in women in low and middle-income countries. Concurrent chemoradiotherapy (CCRT) with Cisplatin is standard for LACC but is often limited by nephrotoxicity & ototoxicity. Hence, the combination of paclitaxel and carboplatin has been explored for its potentially favorable toxicity profile and effectiveness. Thus comparative analysis of two concurrent chemoradiotherapy regimens examining their efficacy, toxicity profiles and suitability for patients. is assessed. The results can have significant implications for clinical practice, particularly in resource-limited settings where treatment- related toxicity and patient compliance are critical concerns. **Methods:** Simple randomization with open label study conducted to compare the efficacy and toxicity of concurrent radiotherapy with paclitaxel and carboplatin versus concurrent radiotherapy with cisplatin in patients with locally advanced cervical cancer. Conducted in Department of Radiation Oncology, GMC Nagpur from July 2024 to December 2026. Sample size 100 (50 each group assuming 10% dropout) Inclusion criteria: Age 18-70 years, histologically confirmed diagnosis, FIGO stage IB1 to IVA, ECOG 0-3, written informed consent, baseline audiometry. Exclusion criteria: Prior chemo-radiotherapy for cervical cancer, severe comorbid conditions, pregnant or breastfeeding women, and known hypersensitivity to study drugs. Intervention: Arm A: Concurrent Cisplatin with EBRT to pelvis with dose of 45-50 Gy/ 23-25 fractions followed by brachytherapy. Chemotherapy: Cisplatin 40 mg/m² IV weekly for up to 6 cycles. Arm B: Concurrent RT with Paclitaxel and Carboplatin. RT: Same as Arm A. Chemotherapy: Paclitaxel 50 mg/m² and carboplatin AUC 2 IV weekly for up to 6 cycles. Primary Outcomes: Locoregional control (RECIST criteria at 3,6,12 and 24 months post-treatment). Secondary Outcomes: Overall Survival, Progression-Free Survival, Disease-free survival, Toxicity, Quality of Life (EORTC QLQ-C30) questionnaire. Data Collection and Analysis: Baseline assessments-Medical history, physical examination, laboratory tests, imaging studies. During treatment- Weekly clinical assessments, laboratory tests and toxicity evaluations. Follow-up: Clinical assessments, Imaging studies and QoL at 0, 3, 6, 12 and 24 months post-treatment. Ethical Considerations: Ethical approval is obtained from relevant institutional review boards on 04/12/2024. Patients are under accrual. Research Sponsor: None.

TPS5621 **Poster Session**

ANA trial: Development of a diagnostic test and dynamic evaluation of ctDNA to optimize follow-up and tailor treatment in patients with HPV-related cervical and anal tumors. First Author: Renata Colombo Bonadio, Instituto do Câncer do Estado de São Paulo, Faculdade de Medicina da Universidade de São Paulo, São Paulo, Brazil

Background: Cervical and anal cancers treated with definitive radiotherapy (RT), with or without chemotherapy, frequently exhibit persistent disease or recurrence. Post-treatment imaging—the current gold standard for assessing response—faces limitations due to local inflammatory processes, necessitating repeated imaging and invasive biopsies, which increase complexity and costs. Circulating tumor DNA (ctDNA) has emerged as a promising biomarker for assessing recurrence or disease progression in HPV-associated cancers. This study proposes the development of a low-cost HPV ctDNA test. Additionally, it aims to evaluate ctDNA's accuracy compared to standard imaging and its role in guiding immunotherapy for patients at high risk of recurrence. **Methods:** ANA trial seeks to establish a novel, affordable diagnostic approach to optimize follow-up and treatment strategies for HPV-associated cancers, potentially improving outcomes while reducing costs. This is a prospective, single-center study with two components: 1. Non-interventional phase: Development and validation of a low-cost HPV ctDNA test. The test's accuracy will be compared with commercially available ctDNA tests and standard imaging in monitoring patients with HPV-associated cervical and anal cancers post-definitive RT or chemoradiotherapy. 2. Interventional phase (Phase II trial): A single-arm study evaluating the efficacy of early complementary immunotherapy in patients with persistent ctDNA positivity post-treatment. Eligibility criteria include patients with HPV-positive cervical or anal cancers undergoing definitive RT or chemoradiotherapy. The study will enroll 110 participants, stratified into two groups based on post-treatment ctDNA results: 68 ctDNA-negative patients for serial ctDNA monitoring and 16 ctDNA-positive patients for Phase II immunotherapy intervention. In this phase, patients will receive Pembrolizumab 200mg IV every 3 weeks for twelve months. Endpoints: The primary endpoint for the non-interventional phase is the sensitivity and specificity of the HPV ctDNA test compared to commercial ctDNA tests and imaging. Secondary outcome is cost-effectiveness of HPV ctDNA as a follow-up tool. For the interventional phase, the primary endpoint is the 6-month disease progression rate in ctDNA-positive patients receiving immunotherapy. Secondary outcomes include recurrence rates, and survival outcomes. Clinical trial information: NCT06640283. Research Sponsor: National Council for Scientific and Technological Development (CNPq); Process No. 444027/2023-8.

TPS5622 **Poster Session**

A phase II, single-arm, open-label clinical trial to evaluate the combination of cadonilimab injection and gut microbiota modulation in the treatment of persistent, recurrent, or metastatic cervical cancer following second-line therapy. First Author: Qin Xu, Department of Gynecologic Oncology, Clinical Oncology School of Fujian Medical University, Fujian Cancer Hospital, Fuzhou, China

Background: Current treatment options for cervical cancer include surgery, radiotherapy, and chemotherapy. For persistent, recurrent, or metastatic disease, systemic therapies such as targeted agents and immune checkpoint inhibitors (ICIs) play a crucial role. The NCCN 2023.V1 guidelines recommend PD-1/CTLA-4 bispecific antibody Cadonilimab as a second-line option for recurrent or metastatic cervical cancer. In April 2024, China's NMPA accepted an application for Cadonilimab plus platinum-based chemotherapy (± bevacizumab) as second-line treatment, based on the global phase III AK104-303 trial. Cadonilimab monotherapy demonstrated a 33.0% objective response rate (ORR) and a 12% complete response rate (CR) in platinum-resistant cervical cancer, with an ORR of 43.8% in PD-L1+ patients. Recent research highlights the gut microbiome as a key modulator of immunity and ICI responses across multiple cancers. Gut microbiota modulation may enhance antitumor immunity, improve ICI efficacy, and reduce immune-related adverse events. Fecal microbiota transplantation (FMT) has been shown to restore immune homeostasis by increasing short-chain fatty acid (SCFA) production, particularly butyrate, which strengthens the intestinal barrier and suppresses inflammation. Despite promising findings in other malignancies, no clinical studies have assessed the impact of gut microbiota modulation in advanced cervical cancer immunotherapy. Further investigations are needed to evaluate its therapeutic potential and underlying mechanisms, warranting clinical trials in this field. **Methods:** This study is a Phase II, single-center clinical trial conducted at Fujian Cancer Hospital. Patients will receive gut microbiota transplantation combined with intravenous (IV) administration of Cadonilimab. The recommended dosage of Cadonilimab is 10 mg/kg, with a treatment cycle of 21 days. On Day 1, patients will receive gut microbiota transplantation, followed by Cadonilimab administration on Day 3.Imaging assessments will be conducted every six weeks. The primary objective of the study is to evaluate the Objective Response Rate (ORR). Secondary objectives include Progression-Free Survival (PFS), Disease Control Rate (DCR), Duration of Response (DOR), Overall Survival (OS), PFS rate (≥6 months), and safety (assessed by CTCAE v5.0).Inclusion criteria: Patients with recurrent, metastatic, or persistent cervical cancer; histological types including squamous cell carcinoma, adenosquamous carcinoma, or adenocarcinoma, who are not candidates for curative surgery or radiotherapy. Trial status: The study is in the initiation phase, with plans to enroll 20 patients. As of this submission, patient enrollment has not yet begun. Research Sponsor: Joint Funds for the innovation of science and Technology, Fujian province; 2023Y9449.

TPS5623 **Poster Session**

A single-center, open-label, single-arm, phase I study with dose expansion cohort of sacituzumab govitecan in combination with cisplatin for patients with platinum sensitive recurrent ovarian and endometrial cancer. First Author: Melanie Wain Kier, Division of Hematology and Medical Oncology, Icahn School of Medicine at Mount Sinai, New York, NY

Background: Sacituzumab govitecan (SG) is an antibody-drug conjugate (ADC) composed of the irinotecan active metabolite SN-38 (govitecan) covalently linked to a humanized monoclonal antibody (hRS7) targeting trophoblastic cell-surface antigen-2 (Trop-2). Sacituzumab govitecan has demonstrated in vitro and in vivo activity against multiple solid tumors, including ovarian cancer and endometrial cancer. The Basket Trial, a phase I/II study of single agent sacituzumab govitecan in patients with epithelial cancers, showed clinical efficacy in endometrial cancer patients (n = 18) with an ORR of 22.2% (6.4-47.6) and median OS of 11.9 months (4.7 months – NR). Insufficient ovarian cancer patients were enrolled for response parameters to be met. The combination of platinum agents and topoisomerase inhibitors, such as irinotecan, has showed complementary effects in preclinical studies, however, the use in clinical practice has been limited by intolerable toxicity. Early trials have found that compared to irinotecan, a prodrug for SN-38, sacituzumab govitecan allows for improved targeted delivery of SN-38 to tumor tissue and increased therapeutic activity with relatively moderate toxicity. The tempering of the toxicity by this ADC may allow for the combination of cisplatin with sacituzumab govitecan to capitalize on the synergy between platinum agents and topoisomerase I inhibitors. The most common grade ≥ 3 adverse events that are seen with sacituzumab govitecan include leukopenia, neutropenia, and thrombocytopenia, thus the less myelosuppressive platinum agent cisplatin is the preferred platinum choice for this combination. **Methods:** Sacituzumab govitecan is being evaluated in combination with cisplatin in an open-label, non-randomized, dose de-escalation (phase 1) study with a planned dose expansion cohort in platinum sensitive, recurrent epithelial ovarian and endometrial cancer patients. Platinum sensitivity for both cancers is defined as cancer recurrence/progression occurring more than 6 months after the last dose of prior platinum therapy. The safety run in phase utilizes a 3+3 design with a de-escalated dose level if the starting dose of sacituzumab govitecan shows toxicity. The primary endpoint for the safety run-in is to determine the dose-limiting toxicity (DLT) and dose expansion cohort dose of sacituzumab govitecan when administered with a fixed schedule of cisplatin. The dose expansion cohort is designed to indicate proof of concept regarding the ORR, CBR, PFS, and safety of the combination regimen at the dose established in the safety run-in phase of the study. The study began enrolling patients October 2024 at our institution and is currently in phase 1 at the starting dose level of sacituzumab govitecan. Clinical trial information: NCT06040970. Research Sponsor: Gilead Sciences, Inc.

TPS5624 **Poster Session**

Rationale and study design of the KOV-HIPEC-04: A phase III randomized controlled trial in primary stage three and four ovarian cancer after interval cytoreductive surgery (FOCUS). First Author: Myong Cheol Lim, National Cancer Center, Goyang, Gyeonggi, South Korea

Background: The addition of hyperthermic intraperitoneal chemotherapy (HIPEC) during interval cytoreductive surgery increases progression-free and overall survival for patients with stage III ovarian cancer in two randomized controlled trials (OV-HIPEC-01 and KOV-HIPEC-01). This trial aims to identify the survival benefit of HIPEC in stage III & IV ovarian cancer in the era of maintenance therapy of bevacizumab and/or PARP inhibitors. **Methods:** Ovarian cancer patients will be randomized at the time of interval cytoreductive surgery with achieving complete cytoreduction or cytoreduction with no more than 2.5mm size of residual disease to receive HIPEC (41.5 cisplatin 75mg/m^2, 90 minutes) or not (Control arm). After recovery from surgery, patients will receive postoperative platinum-based adjuvant chemotherapy followed by maintenance therapy with PARP inhibitor or bevacizumab. The primary objective of the trial is to evaluate OS in two groups. Secondary objectives are PFS, cancer-specific survival, time to first subsequent therapy (TFST), safety, CA-125 KELIM, and quality of life. Assuming that the enrollment period is 5 years and the follow-up period is 3 years, the total number of events required is 263. Based on the log-rank test, the total number of subjects required to prove HR 0.67 with a two-sided alpha of 0.05 and 90% power is 494. Considering 5% drop-out, 520 patients are finally studied. **Results:** The first patient was randomized on June 06, 2023. Until Jan. 26, 2025, 279 (53%) patients are randomized. There are no available results at the time of submission. **Conclusions:** The role of HIPEC during interval cytoreductive surgery will be discovered in stage III & IV ovarian cancer with this randomized trial (KOV-04, FOCUS) in the era of maintenance therapy of bevacizumab and/or PARP inhibitors for the first time. Clinical trial information: NCT05827523. Research Sponsor: National Cancer Center Korea (NCC2110790, NCC2110770).

TPS5625 **Poster Session**

A phase Ib, open-label trial of MOv18 IgE in patients with advanced ovarian cancer. First Author: Rebecca Kristeleit, Department of Oncology, Guy's and St Thomas' NHS Foundation Trust, London, United Kingdom

Background: All antibodies currently approved for cancer therapy are monoclonal IgGs. MOv18 IgE is a first-in-class therapeutic IgE antibody to have entered the clinic, successfully completing a Phase I trial in patients with advanced solid tumours. MOv18 IgE targets folate receptor alpha (FRa), an antigen present on a variety of cancers including ovarian, endometrial, lung and triple negative breast cancer. In the first-in-human Phase I trial, MOv18 IgE was well tolerated (up to 12 mg), with urticaria the most frequent toxicity [Spicer, J., *et al. Nat Commun* 14, 4180 (2023)]. These results demonstrated the potential of MOv18 IgE as an anti-cancer therapy supporting further clinical development. MOv18 IgE's unique mechanism of action includes high affinity binding to its main cognate receptor, FcεR1, enabling immunosurveillance and potent myeloid cell driven tumour FRa killing. Additionally, IgE antibodies drive modulation of the tumour immune microenvironment to a more pro-inflammatory phenotype, increasing intra-tumoral levels of activated T cells and tumour killing macrophages. **Methods:** EPS101-10-02 is a two-part, Phase Ib, open-label, dose escalation and expansion trial in patients with PROC, whose disease has progressed after ≤4 prior regimens of anti-cancer therapy. Tumours must express FRa at ³5%, (1+, 2+ or 3+ membrane staining on at least 5% of tumour cells by IHC using the BN3.2 antibody), and patients must have a negative basophil activation test to stimulation with MOv18 IgE prior to Cycle 1, Day 1. Approximately 45 patients with measurable disease will be recruited. MOv18 will be given by IV infusion (starting dose 3 mg) on Days 1, 8 and 15 of a 21-day cycle. Treatment will continue until disease progression, unacceptable toxicity, withdrawal of consent or death. A range of translational endpoints will be evaluated. Primary objectives are to evaluate the safety and tolerability of MOv18 IgE and make a preliminary assessment of efficacy in PROC. Clinical trial information: NCT06547840. Research Sponsor: None.

TPS5626 **Poster Session**

SALVOVAR: A pragmatic randomized phase III trial comparing the salvage weekly dose-dense regimen to the standard 3-weekly regimen in patients with poor prognostic ovarian cancers (GINECO-OV130b; ENGOT-ov78). First Author: Benoit You, Centre Hospitalier Universitaire Lyon Sud, Hospices Civils de Lyon, Oullins-Pierre-Bénite, France

Background: The patients with an advanced epithelial ovarian cancer (EOC) treated with a neo-adjuvant platinum-based chemotherapy who are not amenable to a complete interval debulking surgery (IDS) due to a poorly chemosensitive disease (CA-125 KELIM score $<$1.0) have a particular poor prognosis (~20% overall survival at 5 years). Several studies suggested that these patients may have a benefit from a chemotherapy densification with the weekly dose-dense carboplatin-paclitaxel regimen. **Methods:** SALVOVAR trial (NCT06476184) is an academic pragmatic open-label multicentre international randomized phase III trial, including stage III-IV high-grade EOC patients who present 2 poor prognostic features after 3-4 cycles of standard neo-adjuvant chemotherapy with carboplatin-paclitaxel administered every 3 weeks: 1) an unfavorable standardized KELIM score $<$1.0; and 2) a disease considered to be not amenable to a complete IDS. The enrolled patients are randomly allocated (ratio 1:1) to an experimental arm (weekly dose-dense regimen: carboplatin AUC5 and paclitaxel 80 mg/m^2 on day1, day8, and day15, with 3 week cycles) or a control arm (continuation of the standard regimen given every 3 weeks) for 3 cycles. Bevacizumab will be added at investigator discretion. The stratification factors are: Planned administration of bevacizumab (yes, vs no); BRCA mutation (yes, vs no/unknown); and KELIM score strate (moderately unfavorable $\geq$0.7, vs very unfavorable $<$0.7). The objective is to show the superiority of the experimental arm with 2 co-primary endpoints: 1) percentage of patients achieving late complete cytoreductive surgery after chemotherapy densification (15% increase), and of overall survival (Hazard-ratio, 0.61). 250 patients will be randomized. The secondary endpoints include overall response rate, progression-free survival, percentage of patients receiving PARP inhibitor and safety. Social human sciences are planned with assessment of the patient/physician perceptions in the shared-decision-making; quality-of-life/patient-reported-outcomes; medico-economic investigation, along with surgical definition of standardized criteria for non-resectability, and inventory of BRCA/homologous-recombination assays used in real-life. The trial is activated in France and Japan. It will be open in United Kingdom, The Netherlands, Italy, Czech Republic, Slovenia, Hungary, Slovakia, and Israel. The recruitment started in July 2024. On January 15 2024, 62 patients had been pre-screened and 18 patients had been randomized. SALVOVAR trial is funded by a European Union HORIZON-MISS-CANCER-2022-01 research program, sponsored by ARCAGY-GINECO (France), and coordinated by Lyon University Hospital (HCL, France). Clinical trial information: NCT06476184. Research Sponsor: None.

TPS5627 **Poster Session**

A phase 3, open-label, randomized study of rinatabart sesutecan (Rina-S) vs investigator's choice (IC) of chemotherapy in patients with platinum-resistant ovarian cancer (PROC). First Author: Angeles Alvarez Secord, Duke Cancer Institute, Durham, NC

Background: Ovarian cancer (OC) is the fifth leading cause of cancer-related death among women in the United States, with 12,730 estimated deaths in 2025. In patients (pts) with advanced OC, 70% experience recurrence and many develop platinum-resistant OC (PROC) after standard platinum-based treatment. Rinatabart sesutecan (Rina-S) is an antibody-drug conjugate targeting folate receptor alpha (FRα) with a novel hydrophilic protease-cleavable linker and exatecan, a topoisomerase I inhibitor. In cohort B1 of a phase 1/2 trial (NCT05579366), Rina-S 120 mg/m² every 3 weeks (Q3W) showed encouraging anti-tumor activity with a 50% objective response rate (ORR; 95% CI, 26-74), including 1 complete response, and was well tolerated in a heavily pretreated OC population, with $>$90% having PROC. Responses were observed regardless of FRα expression status. Here we report the design of an open-label, randomized, phase 3 study (NCT06619236) to investigate Rina-S vs IC chemotherapy in pts with PROC. **Methods:** This phase 3 study will enroll ~530 pts with platinum-resistant, high-grade serous or endometrioid epithelial OC, primary peritoneal cancer, or fallopian tube cancer regardless of FRα expression status (Table). Pts will be randomized 1:1 to receive Rina-S 120 mg/m² IV Q3W or IC chemotherapy (paclitaxel, topotecan, pegylated liposomal doxorubicin, or gemcitabine). Primary endpoint is progression-free survival. Secondary endpoints include overall survival, ORR, duration of response, CA-125 response, adverse events, and time to second disease progression. Additional endpoints include QTc changes and overall change from baseline and time to deterioration in Global Health Status/Quality of Life, and patient-reported outcomes. Follow-up visits will occur every 12 weeks for up to ~1 year after the treatment period. Clinical trial information: NCT06619236. Research Sponsor: Genmab A/S.

Key study criteria.

Inclusion Criteria	Exclusion Criteria
High-grade serous or endometrioid epithelial OC, primary peritoneal cancer, or fallopian tube cancer	Primary platinum-refractory disease, defined as OC that did not respond to a first-line platinum-containing regimen
Received 1 to 4 prior lines of therapy, including:	OC that progressed ≤91 days after last dose of a first-line platinum-containing regimen
Platinum chemotherapy	History of another malignancy ≤3 years or evidence of residual disease
Bevacizumab	Known active central nervous system metastases or carcinomatous meningitis
PARP inhibitor (if applicable)	
MIRV (if eligible)	
Platinum-resistant disease defined as:	
Pts who received ≥4 cycles of first-line platinum-based therapy who had a response and then progressed 91-183 days after last dose	
Pts who received 2 to 4 lines of platinum-based therapy and have progressed <183 days after last dose	

MIRV, mirvetuximab soravtansine; PARP, poly-ADP ribose polymerase.

TPS5628 **Poster Session**

Rationale and study design of the KOV-HIPEC-02R (RECOVER): A randomized, multicenter, open-label phase III trial of cytoreductive surgery and hyperthermic intraperitoneal chemotherapy in platinum-resistant recurrent ovarian cancer. First Author: Myong Cheol Lim, Center for Gynecologic Cancer, National Cancer Center, Goyang-Si, Korea, Republic of

Background: Hyperthermic intraperitoneal chemotherapy (HIPEC) administered during interval cytoreductive surgery following neoadjuvant chemotherapy has shown to increase progression-free survival (PFS) and overall survival (OS) rates, as indicated by the OV-HIPEC-01 and KOV-HIPEC-01 trials. A recent meta-analysis (Kim SI, Kim JH, et al., GO 2023) demonstrated a survival benefit associated with HIPEC, particularly after recent exposure of chemotherapy. Moreover, in ovarian cancer, HIPEC is suggested to be effective in overcoming chemotherapy resistance. **Methods:** This trial (KOV-02R, RECOVER) is a multicenter, open-label, 1:1 randomized, phase III trial that will enroll 140 patients with platinum-resistant recurrent epithelial ovarian cancer (NCT05316181). After cytoreductive surgery, patients undergo the HIPEC procedure at 41.5°C, with doxorubicin at 35mg/ m^2 and mitomycin at 15mg/m^2. Enrolled patients receive non-platinum compound systemic chemotherapy until disease progression. The primary objective is to evaluate progression-free survival between the HIPEC group and the control group. Secondary objectives include overall survival, cancer-specific survival, and safety and quality of life. Considering a 5-year enrollment period, 2-year follow-up, and a statistical power of 80%, 140 patients are needed, accounting for a 10% dropout rate. As of January 10, 2025, 115 patients (82.1%) have been randomized. Clinical trial information: NCT05316181. Research Sponsor: None.

TPS5630 **Poster Session**

SynKIR-CAR T cell advanced research (STAR)-101 phase 1 clinical trial for patients with advanced mesothelin-expressing ovarian cancer, mesothelioma, or cholangiocarcinoma. First Author: Janos Laszlo Tanyi, University of Pennsylvania Abramson Cancer Center, Philadelphia, PA

Background: Chimeric antigen receptor (CAR) T cells have transformed treatment of hematologic malignancy but have shown limited efficacy in solid tumors due to T cell exhaustion and lack of functional persistence. Second-generation CAR T cells targeting mesothelin via the SS1 scFv demonstrate safety and early tumor reduction but lack durable clinical benefit (1-3). SynKIR-110, a novel natural killer cell-signaling based CAR T therapy, employs a multichain signaling system designed to reduce exhaustion by activating T cells only upon tumor engagement. In vitro, SynKIR-110 matches CD3-based CAR T cells in cytokine production and tumor lysis, and in conventional CAR T-cell-resistant mesothelioma mouse xenograft models, SynKIR-110 eliminates tumors without observed toxicity (4). **Methods:** This first-in-human, Phase 1, multicenter, open-label, dose-escalation study evaluates the safety and feasibility of SynKIR-110 in patients with advanced mesothelin-expressing tumors, including ovarian cancer, cholangiocarcinoma, and mesothelioma. Participants receive non-myeloablative lymphodepletion with cyclophosphamide and fludarabine, followed by a single intravenous infusion of SynKIR-110. Up to six dose cohorts (3+3 design) will establish the maximum tolerated dose (MTD) or maximum feasible dose (MFD), with an expansion cohort at the recommended phase 2 dose to confirm safety and assess activity. Participants are followed for 12 months to evaluate best overall response, survival, drug persistence, immune function and potential correlation with pre-treatment tumor mesothelin levels, through exploratory analyses. Eligible patients must have recurrent or relapsed ovarian cancer, cholangiocarcinoma, or epithelial pleural or peritoneal mesothelioma after at least one prior systemic therapy. Additional eligibility criteria include measurable disease by iRECIST or mRECIST, ECOG performance status of 0-1, and adequate organ and bone marrow function. Cohort 1 completed without dose-limiting toxicities (DLTs). Enrollment in Cohort 2 initiated in 2025 and is ongoing. SynKIR-110 represents a promising approach to overcoming the limitations of CAR T cells in solid tumors. 1. Beatty GL et al. *Cancer Immunol Res*. 2014 Feb;2(2):112-20. PMID: 24579088. 2. Wang E et al. *Cancer Immunol Res*. 2015 Jul;3(7):815-26. PMID: 25941351. Clinical trial information: NCT05568680. Research Sponsor: Verismo Therapeutics.

TPS5631 **Poster Session**

Evaluating zAvatar test-guided chemotherapy vs. standard of care in relapsed ovarian cancer and metastatic breast cancer: A multicenter randomized clinical trial (zAVATAR-FLUIDS). First Author: Marcio Debiasi, Breast Unit, Champalimaud Clinical Centre, Champalimaud Foundation, Lisboa, Portugal

Background: Relapsed ovarian cancer and metastatic breast cancer (MBC) present significant challenges due to tumor heterogeneity and limited treatment efficacy. Despite numerous recent achievements in personalized medicine, we still lack real-time molecular biomarkers to guide therapeutic decision-making, often resulting in multiple lines of trial-and-error chemotherapy (CT), which ultimately exposes patients to unnecessary toxicities. The zAvatar test – a patient-derived zebrafish xenograft model – has shown to accurately predict tumor response to treatment, providing a real-time and non-invasive means of guiding personalized therapy in advanced cancers (Fior R, et al, 10.1038/s41467-024-49051-0). This trial evaluates the clinical utility of zAvatar as a predictive tool to optimize therapeutic decisions for patients with relapsed ovarian cancer or MBC, presenting with malignant pleural effusion or ascites. **Methods:** In this multicenter, open-label, randomized clinical trial, patients with relapsed ovarian cancer or metastatic HER2-negative breast cancer, ECOG performance status 0-2, measurable disease by RECIST 1.1 and 2 or more equally effective CT options, who need drainage of ascites or pleural effusion, are randomized (1:1) into two groups: the control group will receive CT based on physicians´ choice, while the experimental group will receive treatment guided by the zAvatar-test results. Both groups will have zAvatars generated from tumor cells isolated from ascitic or pleural effusion fluids. The trial will include 276 patients (138 per cancer type). The study aims at determining whether zAvatar-guided decisions lead to improved progression-free survival (PFS) compared to standard of care, as primary endpoint. Recruitment started in January 2025, with an anticipated recruitment period of 3 years (2025–2028). The first patient is expected to be randomized in February 2025 and undergo zAvatar-test evaluations in centralized lab. This trial paves the way for an innovative approach for personalized medicine by validating the zAvatar test's ability to tailor treatment options in advanced cancers, which shall in the future bring into practice a real-time, patient-specific decision-making functional test. Clinical trial identification: EU-CTR n. 2023-509598-22. Legal sponsor: Champalimaud Clinical Centre, Lisbon, Portugal. Funding: Liga Portuguesa Contra Cancro. Protocol FC2024-001. Clinical trial information: 2023-509598-22. Research Sponsor: Liga Portuguesa Contra Cancro.

TPS5632 **Poster Session**

Randomized study evaluating optimal dose, efficacy and safety of E7386 + lenvatinib versus treatment of physicians' choice in advanced/recurrent endometrial carcinoma previously treated with anti−PD-(L)1 immunotherapy. First Author: Ramez Nassef Eskander, Division of Gynecologic Oncology, Department of Obstetrics, Gynecology and Reproductive Sciences, University of California, San Diego, Moores Cancer Center, La Jolla, CA

Background: E7386 is an inhibitor of protein-protein interaction between β-catenin and CREB binding protein (CBP). E7386 + lenvatinib has demonstrated manageable safety and promising antitumor activity in the dose-expansion cohort of Study 102 that included patients with advanced endometrial cancer previously treated with immunotherapy (Lee JY et al., *Ann Oncol* 2024). Considering these results, we are conducting a dose-optimization part of Study 102 (NCT04008797) in patients with advanced/recurrent endometrial carcinoma (aEC). **Methods:** Eligible patients (≥18 years) must have a confirmed diagnosis of aEC, and prior treatment with platinum-based chemotherapy and PD-(L)1-directed therapy. Up to 3 prior lines of therapy, regardless of setting, are allowed; prior hormonal therapy and radiation do not count as lines of therapy. Patients will be randomized (1:1:1:1) to E7386 120 mg BID + lenvatinib 14 mg QD (n=30); E7386 60 mg BID + lenvatinib 14 mg QD (n=30); lenvatinib 24 mg QD monotherapy (n=30); or treatment of physician's choice (TPC, doxorubicin 60 mg/m^2 Q3W or paclitaxel 80 mg/m^2 QW [3 weeks on/1 week off]; n=30 in total). Randomization will be stratified by region (Asia/North America/Rest of the World). The primary objective is to determine the optimal dose of E7386 + lenvatinib in aEC; additional objectives include: safety, assessing the contribution of E7386 to the overall treatment effect of E7386 + lenvatinib, and assessing the efficacy of E7386 + lenvatinib relative to TPC. Tumors will be assessed by investigators (per Response Evaluation Criteria in Solid Tumors [RECIST] version 1.1) every 8 weeks from the first dose. Adverse events will be monitored and graded according to Common Terminology Criteria for Adverse Events (CTCAE) version 5.0. This multinational study is actively recruiting. Clinical trial information: NCT04008797. Research Sponsor: Eisai Inc.

TPS5633 **Poster Session**

Sapanisertib and serabelisib (PIKTOR) with paclitaxel and a diet substudy in patients with advanced/recurrent endometrial cancer (GOG-3111). First Author: David Starks, Avera Cancer Institute, Sioux Falls, SD

Background: Patients with advanced/recurrent endometrial cancer have limited 2L+ treatment options. The PI3K/mTOR pathway regulates glucose homeostasis downstream of insulin/insulin receptor signaling and is mutated in >80% of endometrial cancer. Multi-node inhibition of this pathway with the combination of sapanisertib, an mTORC1/2 inhibitor, and serabelisib, a PI3Kα inhibitor, (PIKTOR) achieves more complete PI3K pathway blockade compared to single node inhibition in preclinical models. In a Phase 1b trial (NCT03154294) of triplet combination paclitaxel, serabelisib, and sapanisertib, the combination led to an overall response rate of 80% with 3 CR and 1 PR in 5 patients with advanced, treatment refractory endometrial cancer. This study evaluates whether PIKTOR with paclitaxel improves efficacy outcomes in participants with advanced/recurrent endometrial cancer with mutation(s) in the PI3K/AKT/mTOR pathway and who have failed prior systemic therapies. **Methods:** GOG-3111 is a Phase 2 (ClinicalTrials.gov ID NCT06463028), multi-center, open-label, single-arm trial evaluating the efficacy and safety of PIKTOR plus paclitaxel in participants with advanced/recurrent endometrial cancer. Approximately 40 participants will be enrolled in the main study and up to 50% of participants will have the option to receive triplet combination therapy with a diet. Eligible participants will have histologically confirmed diagnosis of advanced/recurrent endometrioid endometrial carcinoma and documented genetic mutation(s) in the PI3K/AKT/mTOR pathway by next generation tumor testing. Participants must have received >1 but no more than 3 prior systemic therapies for advanced/recurrent disease (ie, including platinum-based therapy and an immune checkpoint inhibitor either together or separately). Study interventions are 28-day cycles with: Paclitaxel: 80 mg/m2 IV weekly on Days 1, 8, and 15; PIKTOR (sapanisertib [1] 3mg and serabelisib [2] 100 mg) oral with food on Days 2-4, 9-11, 16-18, and 23-25. Radiographic imaging and RECIST v1.1 response assessment will be performed every 8 weeks starting at C1D1. The primary objective is to evaluate the objective response rate (ORR) and secondary objective is to evaluate efficacy via progression-free survival (PFS), PFS at 6 months, overall survival, clinical benefit rate, duration of response; and safety/tolerability of PIKTOR + paclitaxel. The substudy rationale is to evaluate the impact of diet on treatment tolerability and efficacy. Clinical trial information: NCT06463028. Research Sponsor: Faeth Therapeutics.

TPS5634 **Poster Session**

Debio 0123, a highly selective WEE1 inhibitor in adult patients with advanced solid tumors: A phase 1 dose escalation and expansion monotherapy study. First Author: Maria M. Rubinstein, Memorial Sloan Kettering Cancer Center, New York, NY

Background: Debio 0123 is an oral, highly selective WEE1 inhibitor. WEE1 inhibition leads to S phase and G2/M cell cycle checkpoint bypass, allowing mitosis to occur without DNA repair, leading to mitotic catastrophe and cell death. This Phase 1 study (NCT05109975) is evaluating Debio 0123 monotherapy in patients with advanced solid tumors who have recurred or progressed following prior therapy and/or without available standard therapy. During the recently completed dose escalation, Debio 0123 was given once daily over a 21-day cycle and had a manageable safety profile with dose proportional pharmacokinetics. The recommended phase 2 dose is 260 mg (Papadopoulos, et al. ASCO2024,#2426). **Methods:** Following selection of RP2D, a 3-arm expansion phase is ongoing and currently enrolling patients, in both biomarker selected and unselected cohorts. Arm A includes patients with recurrent uterine serous carcinoma progressing after at least one prior line of platinum-based chemotherapy. Arm B includes patients with high-grade epithelial ovarian cancer, primary peritoneal cancer, or fallopian tube cancer that recurred to at least one prior line of platinum-based chemotherapy with high cyclin E1. Lastly, a biomarker-driven cohort (arm C) will enroll patients with specific locally advanced or metastatic solid tumors who have recurred or progressed following prior therapy and/or for whom no standard therapy is available. Additional key inclusion criteria are ECOG Performance Status 0-1, and measurable disease per RECIST 1.1. Debio 0123 will be administered once daily until disease progression, unacceptable toxicity, or withdrawal from the study. Primary endpoints are safety and tolerability and overall response rate (ORR) at recommended dose. Secondary endpoints include duration of response (DOR), progression-free survival (PFS), and overall survival (OS). Enrolment is ongoing in Spain, Switzerland and US. Clinical trial information: NCT05109975. Research Sponsor: None.

TPS5635 **Poster Session**

PENELOPE: A randomized phase II trial of first-line carboplatin and paclitaxel in combination with pembrolizumab, followed by maintenance pembrolizumab with or without nesuparib, in patients with newly diagnosed advanced or recurrent MMR-proficient endometrial cancer. First Author: Se Ik Kim, Seoul National University College of Medicine, Seoul, South Korea

Background: Clinical trials have demonstrated antitumor activity of the immune checkpoint inhibitors in endometrial cancer patients. Two landmark phase III RCTs, NRG-GY018 and RUBY, proved that the addition of pembrolizumab or dostarlimab to standard chemotherapy resulted in significantly longer progression-free survival (PFS) than with chemotherapy alone in patients with advanced or recurrent endometrial cancer. Meanwhile, both two trials consistently showed that the effective size of adding an immune checkpoint inhibitor to combination chemotherapy on PFS was smaller in MMR-proficient (pMMR) cohort, compared to those in MMR-deficient (MMRd) cohort. As poly(ADP-ribose) polymerase (PARP) inhibitors enhance the effects of immune checkpoint inhibitors when combined, improvement of PFS is expected by dual maintenance with pembrolizumab and a PARP inhibitor. Although the phase III DUO-E trial demonstrated elongated PFS from paclitaxel/carboplatin plus durvalumab followed by maintenance durvalumab with or without olaparib in patients with advanced or recurrent endometrial cancer, this trial is not designed to prove that addition of olaparib maintenance provides extra survival benefits. Nesuparib is a newly synthesized small-molecule chemical compound that inhibits both PARP-1&2 and tankyrase. The PENELOPE trial will investigate whether the addition of nesuparib to pembrolizumab maintenance after paclitaxel/carboplatin plus pembrolizumab treatment further improves PFS in patients with advanced or recurrent pMMR endometrial cancer. **Methods:** In this multicenter, open-label phase II clinical trial, patients with pMMR, stage III/IV or recurrent endometrial cancer, naïve to first-line chemotherapy, will be enrolled. Six patients will be enrolled in Stage 1 (safety run-in) and treated with TCP (paclitaxel/carboplatin + pembrolizumab 200 mg; q3w for six cycles) followed by maintenance treatment with P (pembrolizumab 400 mg; q6w up to 14 cycles) + N (nesuparib 150mg PO once a day; up to 14 months). The study will proceed to Stage 2 (dose expansion) if less than 33% of patients in Stage 1 experience a dose-limiting toxicity. Otherwise, additional patients will be enrolled in Stage 1 at lower dose level. In Stage 2, 80 patients will be randomized (1:1) to: arm A) TCP followed by maintenance treatment with P; arm B) TCP followed by maintenance treatment with P + N (150mg or 100mg PO once a day; up to 14 months). Patients will receive maintenance treatment until disease progression. Primary endpoint is investigator-assessed PFS (RECIST 1.1) of arm B vs. arm A, and key secondary endpoints are overall survival, overall response rate, disease control rate, duration of response, and safety. Enrollment began in Q4 2024. Clinical trial information: NCT06502743. Research Sponsor: Onconic Therapeutic INC.

TPS5636 **Poster Session**

IMMUNORARE[5]: A national platform of 5 academic phase II trials coordinated by Lyon University Hospital to assess the safety and the efficacy of the immunotherapy with domvanalimab + zimberelimab combination in patients with advanced rare cancers—The Gestational Trophoblastic Tumors Cohort. First Author: Benoit You, Medical Oncology Department, Institut de Cancérologie des Hospices Civils de Lyon, CITOHL, Université Lyon 1, Lyon, France

Background: For patients with rare cancers, there is an unmet medical need to investigate innovative therapeutics beyond standard first-line treatment. These diseases are rarely evaluated in clinical trials. High-risk gestational trophoblastic tumors (GTT) are treated with polychemotherapy (especially EMA-CO) with high cure rate (~95%). However, patients resistant to polychemotherapy have a poor prognosis, and no validated regimen has been defined. Several case reports suggest that immune checkpoint inhibitors (ICIs) may be active, and a phase II trial with Camrelizumab + Apatinib showed a 50% cure rate. There is a strong rationale for concurrent blockade of the TIGIT and PD1 pathways in this disease. **Methods:** IMMUNORARE[5] (NCT NCT06790706) is a platform of 5 single-arm phase II trials testing the efficacy and tolerability of DOMVANALIMAB (anti-TIGIT) and ZIMBERELIMAB (anti PD-1) in 5 independent cohorts of rare cancers. The trial, sponsored by Lyon University Hospital, will be conducted in 15 French centers, in collaboration with the respective French national reference centers. The gestational trophoblastic tumor cohort, led in collaboration with the French Gestational Trophoblastic Disease Center, will enroll 27 patients with resistance or relapse after at least one line of polychemotherapy (e.g. EP low-dose, BEP, EMA-CO), assessable for biological response with serum hCG (human chorionic gonadotropin). Patients previously treated with immunotherapy are not eligible. Patients will receive intravenous DOMVANALIMAB and ZIMBERELIMAB, every three weeks, until hCG normalization followed by 5 consolidation cycles. The primary objective is the successful hCG normalization rate at 6 months. The secondary objectives are the resistance-free survival, overall survival and tolerance. The trial is designed with a two-stage Simon design, with the possibility of early termination for futility (5% one-sided alpha level, 80% power). The treatment will be considered interesting if the percentage of patients experiencing hCG normalization at 6-months is statistically higher than 35% (H0); 60% is expected (H1). Translational research projects will be developed to unravel the cellular and molecular mechanisms involved in treatment response. Moreover, data from the prospectively implemented database of the French Gestational Trophoblastic Disease Center will be analyzed to create a synthetic historical arm representative of the efficacy of the standard treatments in a similar patient population. Clinical trial information: NCT06790706. Research Sponsor: None.

TPS5637 **Poster Session**

Stratification of vulvar squamous cell carcinoma (VSCC) by HPV and P53 status to guide excision: CCTG VU.2 STRIVE study (NCT06358469). First Author: Amy Jamieson, Vancouver Coastal Health, Vancouver, BC, Canada

Background: Early VSCC is treated surgically. The optimal approach to margin re-excision may depend on molecular subtype. HPV associated (HPV-A) VSCC has a good outcome and is radiosensitive; HPV independent (HPV-I) p53 abnormal(p53abn) VSSC has a worse outcome and is less radiosensitive. **Methods:** Prospective, international, multicentre, phase II platform study enrolling participants with VSCC stratified by HPV status: HPV- Associated (HPV-A) vs HPV-Independent (HPV-I). Criteria: Key eligibility: Primary diagnosis VSCC; surgically staged I-II (FIGO 2021), molecular/ tumour features known: HPV, margin assessment for tumour clearance, dVIN (differentiated-type vulvar intraepithelial neoplasia), p53. Key ineligibility: tumour HPV-I p53 wild-type, recurrent VSCC, stage III-IV, non squamous histotype, planned or previous RT or chemotherapy. Treatment arms: Cohort HPV-A: Margin negative for cancer but $<$ 8mm (regardless of high grade squamous intra epithelial lesion): Active surveillance (AS). Cohort HPV-I p53abn margin: negative for cancer but $<$8 mm and/or positive for dVIN and/or positive p53abn: 2:1 randomization to re-excision versus AS. Primary objective: To estimate the 3-year local recurrence rate (LRR) for HPV-A and HPV-I VSCC surgically managed based on dVIN/p53 status, tumour margin clearance. Secondary objectives: recurrence free and disease specific survival, OS, economics, patient reported outcomes. Statistical design: Cohort HPV-A: n=120 enrolled over 3 years; the upper limit of a one-sided 95% CI for 3-year LRR would be 26% when the observed 3-year LRR=20%. Interim analyses (IAs) planned at 12, 24, 36 months after 1st enrollment and final analysis (FA) at 3 years after last enrollment. Cohort HPV-I: n=129, including 10% loss to follow-up, randomized over 3 years to re excision and surveillance arms in 2:1 ratio. 86 on re-excision arm would have at least 85% power with 95% confidence to exclude a 40% 3-year LRR in favour of a lower rate of 25%, while 43 on surveillance arm will enable an estimate of 3-year LRR at an accuracy that the half length of a two-sided 90% CI will be less than 13% when the observed rate is 40%. IA planned at 36 months after 39th patient enrolled to re-excision arm and FA at 3 years after last enrollment. Conduct to Date**:** This trial was activated Oct 1, 2024. Two enrollments as of Jan 19 2025. Supported by CCS grant #707213; CIHR #195984. Clinical trial information: NCT06358469. Research Sponsor: Canadian Cancer Society (CCS); 707213; Canadian Institutes of Health Research (CIHR); 195984.

Evaluation of indocyanine green (ICG) and handheld fluorescence imager in the management of early-stage gynecological cancer. First Author: Shalini Rajaram, All India Institute of Medical Sciences (AIIMS), Rishikesh, India

Background: Current management in most early-stage cancers is complete lymphadenectomy for staging. Since surgery is the mainstay of treatment tailoring extent of surgery is vital. Only 15-20% of early-stage gynecologic cancers have lymph node metastases yet complete lymphadenectomy is recommended. Sentinel lymph (SLN) node evaluation is a bridge to avoid morbidity due to lymphadenectomy. Fluorescence imaging utilizing near-infrared (NIR) spectrum (700–900 nm) is a valuable tool for mapping lymphatics and lymph nodes and fluorescence imaging is available on robotic and laparoscopic platforms. However, open surgery is the preferred approach for most early-stage gynecological cancers except endometrial malignancy. This research plans to assess hand-held fluorescence imager using ICG dye for feasibility, ergonomics, accuracy and applicability in all gynecologic cancers. Indocyanine green (ICG) is a valuable agent for NIR lymphatic mapping and is used in routinely for sentinel node mapping of breast, skin and gastrointestinal carcinomas with superior safety profile. **Methods:** This exploratory study plans to recruit 30-50 women with early stage endometrial, cervical, ovarian, and vulvar malignancies for intraoperative evaluation of sentinel nodes using ICG and hand held fluorescence imager with SPY-PHI camera and pinpoint video processor(Stryker). Eligibility criteria include women aged 18 years and older, biopsy proven cases of endometrial, cervical & vulvar cancers. For women with suspected ovarian malignancy, sentinel node mapping will be done after laparotomy but SLN biopsy will be done once frozen section report is available. Indications for SLN biopsy are those with uterine confined malignancy (aggressive and non-aggressive endometrial histotypes), stage I cervical cancer with tumor size less than 4 cm, unifocal vulvar tumors less than 4 cm with negative groin nodes and women with stage I and II ovarian cancers and suspicious ovarian masses planned for hysterectomy and or salpingo-oophorectomy. 25 women of early-stage cancers have been enrolled. Fluorescence is detected by tracing fluorescent lymphatics to sentinel node prior to opening retroperitoneal spaces or incising skin in cases of vulvar cancer. Data is being captured and final analysis awaited. The distribution of cancer types till date are endometrial cancer n=12, cervical cancer n= 6, vulvar cancer n=1 and ovarian masses n=6. Sentinel lymph nodes were mapped in 23 out of 25 cases intra-operatively. Clinical trial information: CTRI/2023/03/051086. Research Sponsor: Indian Council of Medical Research; 9618.

6000 Oral Abstract Session

Phase 3 randomized trial (KEYNOTE-630) of adjuvant pembrolizumab (pembro) versus placebo (pbo) for high-risk locally advanced cutaneous squamous cell carcinoma (LA cSCC) following surgery and radiation (RT). First Author: Shlomo A. Koyfman, Cleveland Clinic, Cleveland, OH

Background: Patients with high-risk LA cSCC are standardly treated with surgical resection followed by postoperative RT. Up to 30% of pts experience recurrence and/or metastasis. PD-1 inhibitors including pembro are approved in the US for recurrent/metastatic or LA cSCC not curable by surgery or radiation. We present results from the randomized, double-blind, phase 3 KEYNOTE-630 trial (NCT03833167) that evaluated the efficacy and safety of the addition of adjuvant pembro for participants (pts) with high-risk LA cSCC. **Methods:** Adults with histologically confirmed LA cSCC with ≥1 protocol-defined high-risk feature who underwent complete macroscropic resection and completed adjuvant RT ≥4 and ≤16 weeks from randomization were randomly assigned 1:1 to receive pembro 400 mg or placebo (pbo) IV Q6W for ≤9 cycles. The primary end point was recurrence-free survival (RFS), defined as the time from randomization to the first event of local or regional recurrence of index lesion, distant metastasis, or death due to any cause. Secondary end points included overall survival (OS) and safety. The data cutoff date was June 28, 2024. **Results:** A total of 450 pts were enrolled (n = 225 in each arm). All pts completed surgery and RT and 224 in each arm received ≥1 dose of adjuvant treatment. Median study follow-up was 28.6 mo (range, 2.0-62.5). The 24-mo RFS rate was 78.3% (95% CI, 71.5-83.7) for pembro vs 68.6% (95% CI, 61.1-75.0) for pbo (HR 0.76 [95% CI, 0.53-1.10] P = 0.07243, which did not cross the p-value boundary of 0.0160 for statistical significance). On subset RFS analysis, pts with extracapsular extension (HR 0.44; 95% CI, 0.24-0.79), pts aged ≥65 years (HR 0.61; 95% CI, 0.41-0.91), and non-smokers (HR 0.58; 95% CI, CI 0.37-0.90) appeared to benefit most from pembro. Locoregional recurrence occurred in 13.8% of pts receiving pembro vs 25.3% receiving pbo; distant metastasis in 4.4% vs 11.6% of pts; and new high-risk primary cSCC in 0% vs 2.7% of pts. The 24-mo OS rate was 87.3% (95% CI, 81.5-91.5) in the pembro arm vs 90.7% (95% CI, 85.2-94.3) in the pbo arm (HR 1.47 [95% CI, 0.87-2.48]). Treatment-related AEs (TRAEs) occurred in 63.8% of pts in the pembro arm and 41.1% in the pbo arm (grade 3-4 in 7.6% and 2.7%). No pts died due to TRAEs. TRAEs led to treatment discontinuation in 5.4% of pts in the pembro arm and in 1.3% in the pbo arm. **Conclusions:** Pembro did not provide significant benefit in the adjuvant setting for pts with resected, high-risk LA cSCC. The safety profile of adjuvant pembro was consistent with reports from similar studies and there were no treatment-related deaths. The study was stopped for futility as the benefit/risk profile did not support continuing the trial based on recommendations from the data monitoring committee. Clinical trial information: NCT03833167. Research Sponsor: Merck Sharp & Dohme LLC, a subsidiary of Merck & Co., Inc., Rahway, NJ, USA.

6001 Oral Abstract Session

Phase 3 trial of adjuvant cemiplimab (cemi) versus placebo (pbo) for high-risk cutaneous squamous cell carcinoma (CSCC). First Author: Danny Rischin, Department of Medical Oncology, Peter MacCallum Cancer Centre, Melbourne, VIC, Australia

Background: Cemiplimab is standard of care for treatment of patients (pts) with advanced (metastatic/unresectable) CSCC. There is no approved systemic treatment for pts with CSCC at high risk of recurrence after definitive local therapy. **Methods:** C-POST, a double-blind, multicenter, phase 3 study (NCT03969004), enrolled pts with local and/or regional CSCC, after surgery and post-operative radiation therapy, deemed to be at high risk of recurrence due to nodal (extracapsular extension with largest node ≥2 cm or ≥3 involved lymph nodes) and/or non-nodal (in-transit metastases, T4 lesion, perineural invasion, or locally recurrent tumor with ≥1 additional risk feature) criteria. Pts were randomized 1:1 to cemi 350mg or pbo every (Q) 3w for 12w, then cemi 700mg or pbo Q6W up to 36w (up to 48w total). Original protocol had cemi 350mg or pbo Q3W up to 48w. Crossover was allowed after disease recurrence. Primary endpoint was disease-free survival (DFS). Secondary endpoints included freedom from local-regional recurrence (FFLRR), freedom from distant recurrence (FFDR), overall survival (OS), and safety. Data cutoff for pre-specified interim analysis 1 (IA1; ~50% of final DFS events) was Oct 4, 2024. Per IDMC, the pre-specified threshold for DFS was crossed at IA1. **Results:** From Jun 2019 to Aug 2024, 415 pts (209/206 cemi/pbo) were randomized: median age, 71 yrs (range 33–95); 84% male; 83% head and neck primary; 58%/42% high-risk nodal/non-nodal categories. Median follow-up was 24 mos (range 2–64). DFS was superior with cemi vs pbo: hazard ratio (HR) 0.32 (95% CI 0.20–0.51); p<0.0001 (Table). Estimated 24-mo DFS was 87% (95% CI 80–92) for cemi and 64% (56–71) for pbo. Cemi improved FFLRR (HR 0.20; 95% CI 0.09–0.40) and FFDR (HR 0.35; 0.17–0.72) vs pbo. At IA1, OS HR for cemi vs pbo was 0.86 (95% CI 0.39–1.90). Grade ≥3 treatment-emergent adverse events (TEAEs) occurred in 23.9% and 14.2% and discontinuations due to TEAEs occurred in 9.8% and 1.5% of pts receiving cemi and pbo, respectively. In exploratory analyses, DFS benefits were observed in pts with tumoral PD-L1 ≥1% (HR 0.28; 95%CI 0.15–0.52; n=309) and <1% (HR 0.32; 0.12–0.86; n=85). **Conclusions:** Cemiplimab is the first systemic therapy to demonstrate a statistically significant and clinically meaningful reduction in disease recurrence as adjuvant therapy for high-risk CSCC, and has an acceptable safety profile in this setting. Clinical trial information: NCT03969004. Research Sponsor: Regeneron Pharmaceuticals, Inc. and Sanofi.

6002 Oral Abstract Session

A phase II (Alliance/A091802) randomized trial of avelumab plus cetuximab vs. avelumab alone in advanced cutaneous squamous cell carcinoma (cSCC). First Author: Dan Paul Zandberg, UPMC Hillman Cancer Center, University of Pittsburgh, Pittsburgh, PA

Background: There is a need for continued improvement in outcomes with systemic therapy for advanced cSCC. Pre-clinical data suggest immunologic synergy between IgG1 mAb therapy targeting EGFR and PD-1:PD-(L)1 blockade. **Methods:** Alliance A091802 is a randomized phase II trial of avelumab (AV) (800 mg) plus cetuximab (C) (500 mg/m2) vs. AV alone every 2 weeks for up to 2 years (yrs). C was given for 1 yr in the AV+C arm. Crossover at progression to AV+C was allowed in the AV arm. Randomization was 1:1 and stratified by PD-L1 [+(>1%) vs. -] and HIV status (+ vs. -). Eligible patients (pts) had distant metastatic or unresectable locally advanced cSCC, anti-PD-1/PD-L1 mAb naive, no prior cetuximab in the advanced setting, ECOG PS 0-2, HIV+ if CD4 >200 and VL <200. Pts with CLL, immunosuppression, or active autoimmune diseases were excluded. The primary endpoint was progression-free survival (PFS) (Ho: Median=12 mo vs Ha: 21 mo or a 75% improvement, power of 80% with one-sided alpha 0.2, n=57, 37 PFS events required). Secondary endpoints were overall survival (OS), confirmed response rate (ORR), clinical benefit rate, and toxicity. After 31/37 events, an early unplanned analysis (along with sensitivity analyses) was performed because it became apparent that 37 events would not be reached. These results were submitted to the Alliance Data and Safety Monitoring Board, which recommended releasing the data. Data cutoff was 1/16/25. **Results:** 60 pts were enrolled between 2019-2023; 57 pts were evaluable. Median age was 72 yrs (41–93), 96.5% were white, 91.2% male, all HIV-; 75.4% PD-L1+. 84.2% were head/neck origin, 47.1% had distant metastasis, and there were no differences in baseline characteristics by arm. AV+C significantly improved PFS compared to AV [median 11.1 months (mo) (7.6–not reached (NR)) vs. 4.8 mo (2.8–NR) hazard ratio (HR) 0.53 95% CI (0.26–1.09), one-sided p=0.041]. The median OS of AV+C vs. AV was NR (25.2–NR) vs. 35.8 mo (18.6–NR) HR 0.77 (0.33–1.78) p=0.267. ORR was 31.0% in the AV+C arm and 21.4% in the AV arm. Treatment-related adverse events (TRAE) of any grade (G) occurred in 93% and 78.6%, respectively, and were G>3 in 48.3% and 21.5% of pts in the AV+C [most common G3 TRAEs were rash (20.7%) and infusion-related reaction (20.7%)] and AV arms, respectively. There were no G5 events. Outcomes after crossover and by PD-L1 status will be presented subsequently. **Conclusions:** Avelumab plus cetuximab significantly improved PFS vs. avelumab alone in advanced cSCC pts, without unexpected toxicity. Alliance A091802 supports a larger confirmatory study with combination cetuximab and PD-1:PD-(L)1 blockade. Support: U10CA180821, U10CA180882, U24CA196171; U10CA180868 (NRG Oncology); U10CA180888 (SWOG); https://acknowledgments.alliancefound.org. EMD Serono CrossRef Funder ID: 10.13039/100004755. PD-1 blockade with toripalimab incorporated into induction chemotherapy and radiotherapy with or without concurrent cisplatin in locoregionally advanced nasopharyngeal carcinoma (DIAMOND): A multicenter, non-inferiority, phase 3, randomized controlled trial. First Author: Jun Ma, Department of Radiation Oncology, Sun Yat-sen University Cancer Center, State Key Laboratory of Oncology in South China, Guangdong Key Laboratory of Nasopharyngeal Carcinoma Diagnosis and Therapy, Guangdong Provincial Clinical Research Center for Cancer, Guangzhou, China

The full, final text of this abstract will be available at meetings.asco.org on the day of presentation and in the online supplement to the June 10, 2025, issue of the *Journal of Clinical Oncology*.

6004 Oral Abstract Session

Tagitanlimab versus placebo in combination with gemcitabine and cisplatin as first-line treatment for recurrent or metastatic nasopharyngeal carcinoma (R/M NPC): Results from a randomized, double-blind, phase 3 study. First Author: Yuankai Shi, National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College, Beijing Key Laboratory of Clinical Study on Anticancer Molecular Targeted Drugs, Beijing, China

Background: The addition of PD-1 inhibitor to gemcitabine and cisplatin (GP) showed promising activity as first-line therapy for R/M NPC. Here, we first report the PD-L1 inhibitor Tagitanlimab (KL-A167) plus GP compared with placebo plus GP in a randomized phase 3 study (KL167-III-08, NCT05294172). **Methods:** Eligible patients (pts) with previously untreated R/M NPC were in 2:1 ratio randomly assigned to receive tagitanlimab or placebo (1200 mg, D1) in combination with cisplatin (80 mg/m^2, D1) and gemcitabine (1000 mg/m^2, D1 and D8) every 3 weeks (Q3W) for up to 6 cycles followed by tagitanlimab or placebo monotherapy Q3W until disease progression, unacceptable toxicity, or withdrawal of consent. After disease progression, pts from the placebo arm could crossover to receive tagitanlimab monotherapy. The primary endpoint was progression-free survival (PFS) assessed by the blinded independent central review (BICR) according to RECIST version 1.1. **Results:** Between Jun 16, 2022, and May 27, 2023, 295 pts were assigned to tagitanlimab plus GP arm (n = 197) or placebo plus GP arm (n = 98). The median age was 52 years, and 79.7% were male. As of Feb 4, 2024, 47.2% of pts in tagitanlimab plus GP arm vs 23.5% of pts in placebo plus GP arm were still on treatment, 36.7% of pts in placebo plus GP arm were crossed to receive tagitanlimab monotherapy after disease progression. The median follow-up time was 11.7 months. The PFS per BICR was met at the prespecified interim analysis with a 53% reduction in risk of progression or death (HR 0.47; 95% CI, 0.33 to 0.66; one-sided P $<$0.0001). The median PFS was not reached (95% CI, 10.9-NE) in tagitanlimab plus GP arm and 7.9 months (95% CI, 6.9-8.3) in placebo plus GP arm; the 12-month PFS rate was 56.7% vs 26.7%. The objective response rate (ORR) per BICR was 81.7% (95% CI, 75.6-86.9) in tagitanlimab plus GP arm and 74.5% (95% CI, 64.7-82.8) in placebo plus GP arm, with a median duration of response (DoR) of 11.7 months (95% CI, 8.2-NE) and 5.8 months (95% CI, 5.6-6.9; HR 0.48, 95% CI, 0.32-0.70), respectively. The overall survival (OS) benefit was observed in tagitanlimab plus GP arm vs placebo plus GP arm (median OS not reached for either arm; HR 0.62, 95% CI 0.32-1.22). The most common $\geq$ grade 3 treatment-related adverse events (tagitanlimab plus GP arm vs placebo plus GP arm) were neutrophil count decreased (57.9% vs 49.0%), white blood cell count decreased (52.8% vs 46.9%), and anemia (38.6% vs 40.8%). **Conclusions:** The addition of tagitanlimab to GP demonstrated superior PFS efficacy compared to GP alone, supporting that tagitanlimab, as a PD-L1 inhibitor, could be the new standard of treatment for pts with R/M NPC in the first-line setting. The safety profile of tagitanlimab combined with GP was manageable and consistent with previous reports, with no new safety signals identified. Clinical trial information: NCT05294172. Research Sponsor: Sichuan Kelun-Biotech Biopharmaceutical Co., Ltd.

6006 Oral Abstract Session

SHR-A1811 in HER2-expressing salivary gland cancers: Preliminary efficacy and safety results. First Author: Guangliang Chen, Department of Head & Neck Tumors and Neuroendocrine Tumors, Fudan University Shanghai Cancer Center, Shanghai, China

Background: Salivary gland cancer (SGC) is a rare and heterogeneous malignancy with limited treatment options in advanced stages. Overexpression of human epidermal growth factor receptor 2 (HER2) is linked to aggressive histological subtypes and poor prognosis in SGC, making HER2 a promising target for precision therapy. This study evaluates the efficacy and safety of SHR-A1811, a HER2-targeted antibody-drug conjugate (HER2-ADC), in patients with advanced SGC through a molecular subtype-guided approach (NCT05924256). **Methods:** Patients with advanced SGC were stratified into four arms based on genetic subtypes. This analysis focuses on Arm 1 (HER2 overexpression: IHC 3+ or IHC 2+/ISH+) and Arm 4 (HER2-low: IHC 1+ or IHC 2+/ISH-). In Arm 1, patients received SHR-A1811 at 4.8 mg/kg IV on Day 1 of a 21-day cycle. In Arm 4, patients received 4.8 mg/kg or 5.6 mg/kg (if tolerated). The study followed Simon's two-stage design, with the primary endpoint of objective response rate (ORR) per RECIST v1.1. Secondary endpoints included disease control rate (DCR), progression-free survival (PFS), overall survival (OS), and safety. **Results:** As of January 1, 2025, 33 patients were enrolled (baseline characteristics in Table 1). In Arm 1 (21 evaluable patients), the ORR was 85.7%, and the DCR was 100%. In Arm 4 (10 evaluable patients), the ORR was 30.0%, and the DCR was 100%. After a median follow-up of 9.9 months (range: 1.2–16.6) for Arm 1 and 6.0 months (range: 4.7–9.2) for Arm 4, neither median OS nor PFS was reached. Only one patient in Arm 4 experienced disease progression. Treatment-related adverse events (TRAEs) occurred in 32 patients (97%). The most common grade 3/4 TRAEs included neutropenia (36%), leukopenia (15%), anemia (12%), and lymphopenia (12%). Two patients (6%) experienced treatment-related serious adverse events (SAEs), and one patient (3%) developed grade 1 interstitial lung disease. No patient discontinued treatment due to TRAEs, and no treatment-related deaths were reported. **Conclusions:** SHR-A1811 demonstrated promising efficacy in both HER2-positive and HER2-low advanced salivary gland cancers, achieving high ORRs and DCRs with an acceptable toxicity profile. Clinical trial information: NCT05924256. Research Sponsor: None.

6007 Oral Abstract Session

Darolutamide plus goserelin for androgen receptor-positive salivary gland cancers: Results of phase 2 study (DISCOVARY). First Author: Susumu Okano, Department of Head and Neck Medical Oncology, National Cancer Center Hospital East, Kashiwa, Japan

Background: No standard treatment exists for unresectable locally advanced (LA) or recurrent/metastatic (R/M) salivary gland cancer (SGC). Previous findings suggest that combined androgen blockade (CAB) provides promising clinical activity in patients with androgen receptor (AR)-positive SGC. However, no AR-targeted drug is currently approved for SGC. This multi-center phase 2 study investigated two approaches in patients with unresectable LA or R/M SGC: darolutamide monotherapy followed by the combination of darolutamide and goserelin. In the monotherapy phase, darolutamide showed an objective response rate (ORR) of 20.8% as determined by independent central review (ICR) with tolerable toxicity (ASCO 2023). We now report the results from the combination phase. **Methods:** Eligible patients had histologically confirmed AR-positive LA or R/M SGC, ECOG performance status (PS) 0–2, adequate organ function, and no local therapy options. Patients received darolutamide orally at 1,200mg daily, combined with goserelin at 3.6 mg every four weeks. The primary endpoint was ORR by ICR in patients verified to have AR positivity through central assessment. Secondary endpoints included clinical benefit rate (CBR), disease control rate (DCR), progression-free survival (PFS), overall survival (OS), and safety profiles. **Results:** Between Sep 2022 and Aug 2023, 33 patients were enrolled in the combination phase. Median age was 63 years; 26 were male; ECOG PS 0/1/2 in 28/4/1. Histology included salivary duct carcinoma (n=32) or adenocarcinoma not otherwise specified (n=1). Prior treatment included surgery (n=23), radiotherapy (n=21), and chemotherapy (n=15). The ORR by ICR was 45.2% (14/31; 95% CI, 27.3–64.0), meeting the primary endpoint. CBR was 51.6% (95% CI, 33.1–69.8), and DCR was 64.5% (95% CI, 45.4–80.8). At a median follow-up of 13.7 months, the median PFS was 13.1 months (95% CI, 2.0– not calculable [NC]). Thirteen patients continued treatment at the data cutoff (August 9, 2024). Median OS was not reached (95% CI, 20.0–NC), and 12 months OS rate was 87%(95% CI, 68.9–94.9). Treatment was generally well tolerated, with six patients (18.2%) experiencing grade 3 adverse events. **Conclusions:** This is the first prospective CAB trial in SGC which has met its primary endpoint. Darolutamide plus goserelin demonstrated clinically meaningful efficacy and a favorable safety profile, suggesting it may be a compelling option before initiating chemotherapy, which can significantly diminish a patient's quality of life. Clinical trial information: NCT05694819. Research Sponsor: Bayer.

6008 Oral Abstract Session

Neoadjuvant pembrolizumab in combination with dabrafenib and trametinib (DTP) for *BRAF* V600E-mutated anaplastic thyroid cancer (*BRAF*m-ATC): A multicenter phase 2 trial. First Author: Mark Zafereo, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: ATC patients present with advanced, often surgically unresectable disease with historically dismal prognosis. Median PFS and OS of DT without pembrolizumab were 6.7 and 13.5 months, respectively, in the ROAR trial. Neoadjuvant DTP achieved locoregional control without radical surgery in a retrospective series of *BRAF*m-ATC patients, providing rationale to evaluate efficacy and safety in a phase 2 prospective trial. **Methods:** In this single-arm multicenter phase 2 trial, patients with *BRAF*m-ATC stage IVB/IVC were enrolled in 5 US centers. Following a 3-6 week run-in with D (150 mg BID) and T (2 mg daily), P (200 mg Q3W) was added, with restaging every three (21-day) cycles. Post-operatively, patients continued P (or DTP) with radiotherapy or transitioned directly to adjuvant DTP (up to 26 cycles). Primary endpoints included R0/R1 resection rate (historically 5%) and overall survival (OS). Secondary endpoints included RECIST 1.1 response after DTP and progression-free survival (PFS). **Results:** Between 9/2021-1/2025, 42 patients were enrolled; 36 are included in the current analysis (3 not evaluable, 3 pending surgery) (Table). Patients received median 4 (range: 2-7) neoadjuvant DTP cycles, with 26 (72%) achieving radiographic PR/CR. 30 patients (83%) had surgery after neoadjuvant DTP, achieving R0/R1 resection in 29/30 (97%). Mean surgical morbidity score (0-4 scale, 4=unresectable) improved from 3.3 to 1.6 after DTP ($p<0.01$). Complete ATC pathologic response occurred in 20/30 patients (67%), while 10/30 (33%) had residual ATC in the surgical specimen. Postoperatively, 11/30 (37%) received adjuvant neck radiation, and 28/36 (78%) completed a median of 11 (range: 1-26) adjuvant DTP cycles. With median follow up 18 months, 15/36 (42%) patients died. Median OS was 20 months (95% CI: 12.6-NR); 1- and 2-year OS were 71% and 48%. Complete pathologic responders had better 2-year OS than those with residual ATC (69% vs. 22%, p=0.02). Median PFS was 13.9 months (95% CI, 7.5-NR); 1- and 2-year PFS were 57% and 36%. Grade 5 adverse events occurred in 8 patients (22%), including one possible (duodenal perforation), one probable (kidney injury with sepsis), and 6 unlikely/unrelated treatment-related deaths. **Conclusions:** Neoadjuvant DTP enables surgical resection in *BRAF*m-ATC compared with historical controls, and leads to improved PFS and OS. This approach should now be considered a standard of care for *BRAF*m-ATC. Clinical trial information: NCT04675710. Research Sponsor: Merck; Gateway for Cancer Research; G-20-1200; MD Anderson Petrick Philanthropy.

6009 Clinical Science Symposium

Risk-adapted therapy guided by human papillomavirus (HPV) circulating tumor DNA in patients with HPV-positive oropharyngeal cancer (ReACT 1.0). First Author: Glenn J. Hanna, Department of Medical Oncology, Dana-Farber Cancer Institute, Boston, MA

Background: Human papillomavirus-positive oropharyngeal cancer (HPV+ OPC) has favorable outcomes with platinum-based concurrent chemoradiation (CRT), but long-term toxicity can be significant. Various treatment de-intensification strategies have been explored to maintain survival and mitigate treatment-related morbidity. We present the first study using tumor tissue modified viral (TTMV)-HPV DNA in real-time to stratify non-surgical patients (pts) to receive de-intensified, curative-intent CRT. **Methods:** This phase 2 two-cohort, clinical trial (NCT04900623) enrolled pts with AJCC 2017 8th ed. stage I-III (no fixed nodes) HPV+ OPC treated with CRT if they had detectable TTMV-HPV DNA (type 16) pre-treatment (pre-tx). Pts were assigned to the low-risk (LR) arm with T0-3 N0-2 disease, a $\leq$10 pack-year smoking history, and any detectable HPV DNA result pre-tx. Pts were assigned to the intermediate-risk (IR) arm with T4 disease or a $>$10 pack-year smoking history if they had a pre-tx HPV DNA score of $>$200. LR arm pts received de-intensified CRT (54-66 Gy with reduced dose platinum or RT alone). IR arm pts who cleared their pre-tx HPV DNA by $>$95% were also de-intensified; those $\leq$200 pre-tx or who failed to clear received standard 70 Gy CRT with up to 300 mg/m^2 cisplatin. Primary endpoint was 2-year progression-free survival (PFS) among all de-intensified LR and IR pts. Group-sequential testing for non-inferiority (NI) was performed Q4 months after the first 40 pts completed $>$6 months of follow-up. Interim analyses (IAs) were declared NI if the 2-year PFS lower CI bound was $>$80% among de-escalated LR/IR pts (Bootstrap approach; alpha 0.05). Secondary endpoints: safety, overall survival, distant metastasis-free survival, quality of life (QoL) metrics, and exploratory radiomic data. **Results:** From 7/2021 to 5/2024, 138 pts screened, 71 accrued (cohort 1). Most were male (62, 87%) and white (70, 99%) with a median age of 63 (range: 46-80). Forty-four (62%) were assigned to the LR arm (23% had N2 disease) with a median pre-tx HPV DNA of 439 (range: 6-221995). Twenty-seven (38%) pts were assigned to the IR arm (33% T4, 78% smokers) with a median pre-tx HPV DNA of 2346 (range: 207-84971). Among the 27 IR pts, 18 (67%) had $>$95% DNA clearance and were de-escalated. At a median follow-up of 14 months, the 2-year PFS estimate at IA2 was 92% (95%CI, 85-100) among 62 de-escalated LR/IR pts including 18 (29%) T4/smokers and 15 (24%) with N2 disease. Two distant and 2 locoregional plus distant failures occurred; with no isolated locoregional failures. QoL data is forthcoming; 1 patient died from disease. Cohort 2 explores further de-escalation and is ongoing. **Conclusions:** Using HPV DNA-guided CRT de-intensification we achieved our primary endpoint and report a favorable 2-year PFS $>$90%, which included T4 pts and smokers. HPV DNA as a biomarker to guide de-intensification warrants further study. Clinical trial information: NCT04900623. Research Sponsor: Dana-Farber Cancer Institute.

6010 Clinical Science Symposium

Dynamic circulating tumor DNA-driven, risk-adapted systematic therapy in nasopharyngeal carcinoma: The EP-STAR trial. First Author: Ying Sun, Sun Yat-sen University Cancer Center; Collaborative Innovation Center for Cancer Medicine; State Key Laboratory of Oncology in South China; Guangdong Key Laboratory of Nasopharyngeal Carcinoma Diagnosis and Therapy, Guangzhou, Guangdong, China

Background: Circulating tumor-derived Epstein-Barr virus (EBV) DNA (ctDNA) during treatment has been established as a biomarker in nasopharyngeal carcinoma (NPC). However, how this information would facilitate individualized management remains unknown. We designed EP-STAR, a multicentre, phase II, adaptive trial to investigate whether the dynamic on-treatment ctDNA-driven, risk-adapted treatment strategy improved survival for NPC patients. **Methods:** Locoregionally advanced NPC (stage III-IVA) with detectable pretreatment EBV DNA (excluding T3N0 with EBV DNA$<$2000 copy/mL), who received gemcitabine plus cisplatin induction chemotherapy (IC) concurrently with longitudinal on-treatment EBV DNA monitoring were enrolled and classified into different ctDNA risk subgroups. Low-risk patients (EBV $DNA_{post\text{-}IC1\text{-}3}$=0) did not undergo treatment adaptation and continued standard therapy (chemoradiotherapy, CCRT) (No_adaptive_Arm-control). At-risk patients (intermediate/high-risk) underwent risk-based treatment adaptation (Adaptive population): intermediate-risk patients (EBV $DNA_{post\text{-}IC1}>0$, EBV $DNA_{post\text{-}IC3}$=0 or EBV $DNA_{post\text{-}IC1}$=0, EBV $DNA_{post\text{-}IC2}>0$, EBV $DNA_{post\text{-}IC3}$=0) started treatment intensification with addition of adjuvant metronomic capecitabine to CCRT (650 mg/m² orally twice daily) (Adaptive_Arm-I_cap); high-risk patients (EBV $DNA_{post\text{-}IC1}>/=0$, EBV $DNA_{post\text{-}IC3}>0$) started treatment intensification with addition of 12 cycles sintilimab to CCRT (anti-PD-1 drug, 200 mg intravenously every three weeks) (Adaptive_Arm-II_sin). Primary endpoint was failure-free survival (FFS) of adaptive population; co-primary endpoint was FFS of Adaptive_Arm-II. **Results:** A total of 142 patients were enrolled (58 in Adaptive_Arm-I, 52 in Adaptive_Arm-II, 32 in No_adaptive_Arm-control). Primary endpoint was met, 3-year FFS of adaptive population was 89.0% (88.4–89.6%) at a median follow-up of 41.5 months (Table 1). Data compared favorably with historic cohort of the similar populations but did not undergo adaptive therapy (3-year FFS: 74.7% [68.8–80.6%]), Table 1). Toxicity was manageable with grade 3-4 adverse events recorded in 56.1% and 59.6% patients in Adaptive_Arm-I/II during adaptive phase, respectively; no treatment-related death was observed. **Conclusions:** The ctDNA-driven, risk-adapted paradigm was highly likely to result in improved survival outcomes than conventional unchanging treatment strategy in NPC. Clinical trial information: NCT04072107. Research Sponsor: Major Research Plan of the National Natural Science Foundation of China; 92259202.

Summary of FFS in EP-STAR and the similar population in historic control.

	EP-STAR	Historic control (*Prospective, Cancer Cell, 2024*)
Recruitment year	2020-2021	2019-2021
3-year FFS		
Intermediate & high-risk patients with or without adaptive therapy	89.0% (88.4–89.6%)	74.7% (68.8–80.6%)
High-risk patients with or without adaptive therapy	86.5% (77.3–95.7%)	64.8% (55.0–74.6%)
Low-risk patients	93.8% (91.0–100.0%)	90.8% (85.9–95.7%)

6011 Clinical Science Symposium

REMATCH2201: A phase II study on reducing surgical margins in HPV-negative advanced HNSCC with neoadjuvant PD-1 inhibitor and AP chemotherapy. First Author: Kunyu Yang, Cancer Center, Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, China

Background: The standard of care for resectable HNSCC includes extensive surgical margins to ensure complete oncologic resection, often at the expense of significant functional impairment. Recent advancements in neoadjuvant PD-1 inhibitors with chemotherapy, have shown potential in achieving substantial tumor regressions. This study posits that such neoadjuvant immunochemotherapy can allow for narrower surgical margins without compromising oncological outcomes, potentially preserving vital anatomical structures and function. **Methods:** This single-center, phase II clinical study (NCT05459415) enrolled 52 patients with operable, HPV-negative locally advanced HNSCC. Participants received three cycles of the AP chemotherapy regimen combined with 200 mg of the PD-1 inhibitor Penpulimab. Tumor response was assessed via MRI and laryngoscopy after the second cycle. Patients achieving greater than 50% reduction in tumor size were selected for conservative-margin surgical resection. Surgical Protocol: If imaging or endoscopy identifies residual tumor, margins will be expanded 5-10mm beyond the tumor edges to ensure clear margins, confirmed by intraoperative frozen section analysis by dual pathologists, ensuring maximal oncologic safety and functional preservation. For patients achieving CR, surgical planning relies on prior diagnostic imaging and endoscopic outcomes to guide precise resections of the larynx and hypopharynx. Post-surgical adjuvant treatment was based on final pathology results, including further immunotherapy for nine cycles. **Results:** Of the initial cohort, 50 patients were evaluable for response; the objective response rate (ORR) stood at 96%, and a pathologic complete response (pCR) was observed in 40.7% of patients. Forty-seven patients proceeded to surgery, all maintaining laryngeal function, and 91.5% underwent reduced-margin resection based on deep imaging response, with a pCR achieved in 44.2% of these cases. The study noted clinical adverse events, including three unrelated deaths and two instances of severe postoperative complications. The 12-month and 24-month Event-Free Survival (EFS) rates were calculated at 97.62% and 89.28% respectively. The overall survival (OS) rate at 24 months was 92.85%. **Conclusions:** The REMATCH2201 trial supports the feasibility of reduced-margin surgery in patients with HPV-negative advanced HNSCC following effective neoadjuvant immunochemotherapy, without increasing the risk of oncologic recurrence. This approach importantly spares critical functional anatomy, advocating for a paradigm shift in the surgical management of these tumors. Nevertheless, further research in a multi-center, randomized controlled trial setting is required to substantiate these findings and refine protocols for broader application in clinical practice. Clinical trial information: NCT05459415. Research Sponsor: Chia Tai Tianqing Pharmaceutical Group Co., Ltd.

6012 Rapid Oral Abstract Session

Neoadjuvant and adjuvant pembrolizumab plus standard of care (SOC) in resectable locally advanced head and neck squamous cell carcinoma (LA HNSCC): Exploratory efficacy analyses of the phase 3 KEYNOTE-689 study. First Author: Douglas Adkins, Washington University School of Medicine, St. Louis, MO

Background: The addition of immune checkpoint inhibitors to neoadjuvant/adjuvant SOC has led to efficacy benefits across multiple tumor types. The randomized phase 3 KEYNOTE-689 study (NCT03765918) showed significantly improved event-free survival (EFS) with neoadjuvant/adjuvant pembrolizumab + SOC vs SOC alone for participants (pts) with resectable LA HNSCC independent of PD-L1 combined positive score (CPS ≥10 population: HR 0.66, 95% CI 0.49–0.88, *P*=.00217; CPS ≥1 population: HR 0.70, 95% CI 0.55–0.89, *P*=.00140; all pts: HR 0.73, 95% CI 0.58–0.92, *P*=.00411). We present exploratory efficacy endpoints for the intention-to-treat population of the study. **Methods:** Adults with SCC of the larynx/hypopharynx/oral cavity (stage III/IVA) or oropharynx (stage III/IVA p16− or stage III T4 N0-2 p16+) were randomized 1:1 to SOC (consisting of surgery + postoperative radiotherapy [PORT] ± concurrent cisplatin 100 mg/m^2 Q3W) with or without 2 cycles of neoadjuvant pembrolizumab, 3 cycles of pembrolizumab concurrent with PORT ± cisplatin and 12 cycles of adjuvant pembrolizumab (200 mg IV Q3W). The primary endpoint is EFS per RECIST 1.1 by blinded independent central review. Safety is a secondary endpoint. Prespecified exploratory efficacy endpoints include locoregional control (time from randomization to first locoregional radiographic progression or recurrence by imaging or biopsy), distant metastases-free survival (DMFS; time from randomization to first distant metastasis or death), and incidence of second head and neck or other cancers. **Results:** A total of 714 pts were randomized (363 to pembrolizumab + SOC, 351 to SOC). At first interim analysis (data cutoff date 25 Jul 2024), median follow-up was 38.3 mo (range, 9.0–66.5). In all pts, cumulative incidence of locoregional progression or recurrence at 36 mo was 13.4% with pembrolizumab + SOC and 14.3% with SOC. The HR for risk of a locoregional failure event with pembrolizumab + SOC vs SOC was 0.92 (95% CI 0.61–1.41). Median DMFS was 51.8 mo with pembrolizumab + SOC vs 35.7 mo with SOC (HR 0.71, 95% CI 0.56–0.90). Estimated DMFS rate at 36 mo was 59.1% vs 49.0%, respectively. Second head and neck or other cancers occurred in 9 (2.5%) and 18 pts (5.1%), respectively. Incidence of treatment-related adverse events was similar with pembrolizumab + SOC and SOC (any grade, 81.4% vs 81.9%; grade ≥3, 44.6% vs 42.9%). **Conclusions:** Among all pts with resectable LA HNSCC in KEYNOTE-689, DMFS results and incidence of second cancers favored the addition of neoadjuvant/adjuvant pembrolizumab to SOC surgery and (chemo)radiotherapy, consistent with the primary EFS results of the study. Locoregional control was similar between arms. No new safety signals for pembrolizumab were observed. Clinical trial information: NCT03765918. Research Sponsor: This study was funded by Merck Sharp & Dohme LLC, a subsidiary of Merck & Co., Inc., Rahway, NJ, USA.

6013 Rapid Oral Abstract Session

Long-term results of the randomized, phase 3 KEYNOTE-412 trial of pembrolizumab (pembro) or placebo (pbo) plus concurrent chemoradiotherapy (CRT) for unresected, locally advanced head and neck squamous cell carcinoma (LA HNSCC). First Author: Yungan Tao, Institut Gustave Roussy, Villejuif, France

Background: In the final efficacy analysis of the randomized, double-blind, phase 3 KEYNOTE-412 trial (NCT03040999), pembro + CRT did not significantly improve event-free survival (EFS) vs pbo + CRT (HR 0.83; 95% CI 0.68-1.03) in unresected LA HNSCC. We present results for KEYNOTE-412 with >2 yrs of additional follow-up. **Methods:** Adults with newly diagnosed high-risk unresected LA HNSCC (any T3-T4 [N0-N3] or any N2a-3 [T1-T4] larynx/hypopharynx/oral cavity/p16-negative oropharynx cancers and T4 or N3 p16-positive oropharynx cancer) were randomly assigned to receive CRT (70 Gy in 35 fractions + 3 cycles cisplatin 100 mg/m^2 Q3W) + 17 cycles of pembro 200 mg or pbo IV Q3W: first cycle 1 week prior to CRT, 2 cycles during CRT, then 14 cycles of maintenance. The primary end point was EFS assessed by blinded independent central review. The key secondary end point was overall survival (OS). Efficacy was analyzed in all randomly assigned pts (ITT population). Exploratory analyses included locoregional control (LRC), distant metastasis-free survival (DMFS), incidence of second malignancies in the ITT population, and efficacy in pts with PD-L1 CPS ≥1. **Results:** 402 pts were assigned to each arm; and 398 received ≥1 dose of study treatment in each arm. As of data cutoff date (August 21, 2024), median study follow-up was 74.4 mo (range, 63.7-88.1). EFS was longer with pembro vs pbo (HR 0.79; 95% CI 0.65-0.96). Overall, 186 (46.3%) and 217 (54.0%) EFS events occurred in the pembro and pbo arms, which represents an additional 15 events in the pembro arm and 25 in the pbo arm since the previous analysis. Full efficacy results for the ITT population are in the table. LRC HR was 0.80 (95% CI 0.57-1.14). Overall, 36 pts (9.0%) in the pembro arm and 45 (11.2%) in the pbo arm developed a secondary malignancy. In pts with PD-L1 CPS ≥1 (pembro, n = 339; pbo, n = 346), median EFS was 70.9 mo (95% CI 55.4-not reached [NR]) for the pembro arm and 48.3 mo (95% CI 26.8-66.8) for the pbo arm (HR 0.80; 95% CI 0.64-0.98); median OS was NR (NR; 95% CI NR-NR) for the pembro arm and NR (95% CI 70.0-NR) for the pbo arm (HR 0.84; 95% CI 0.66-1.06). The safety profile was consistent with previously reported adverse events at the time of the final analysis. **Conclusions:** At end of trial, with >2 yrs of additional follow-up, results showed a clinically meaningful EFS benefit with pembro + CRT versus pbo + CRT and no new safety signals in pts with LA HNSCC. Clinical trial information: NCT03040999. Research Sponsor: Merck Sharp & Dohme LLC, a subsidiary of Merck & Co., Inc., Rahway, NJ, USA.

6014 Rapid Oral Abstract Session

A randomized, open-label, multicenter, blank-controlled, phase IV clinical trial of Biyan Qingdu Granula in attenuating acute nose and oral damage in patients undergoing radiotherapy for nasopharyngeal carcinoma. First Author: Zhigang Liu, Cancer Center, the tenth Affiliated Hospital of Southern Medical University (Dongguan People's Hospital), Southern Medical University, Dongguan, China

Background: This randomized, open-label, multicenter, blank-controlled, phase IV trial aimed to evaluate the efficacy and safety of Biyan Qingdu Granula (BQG) in attenuating acute radiation-induced nasal and oral injuries in nasopharyngeal carcinoma(NPC) patients receiving radiotherapy, and to explore the potential advantages and application values of BQG through comparison with conventional treatments. **Methods:** This trial was conducted at 30 hospitals in China between July 21st, 2022 and May 21st, 2024.This trial was registered with the Chinese Clinical Trial Registry, ChiCTR2200060900. A total of 1000 NPC patients with first-time radiotherapy or chemoradiotherapy for NPC were randomly assigned (1:3) to receive routine cure (the control group, n=250) or that with additional BQG (the treatment group, n=750). All patients received basic oral hygiene guidance, gargled the oral cavity with normal saline and flushed the nasal cavity with normal saline. The treatment group patients were instructed to take BQG twice daily from the initiation to the end of radiotherapy for 6 weeks. The primary end points were the incidence of nasopharyngeal secretion and the incidence of Oral Mucositis (OM). The second end points were the grade of nasal mucosal congestion, the Visual Analog Scale (VAS) score for sore throat pharyngeal pain, the grade of symptom in dry and burning throat, the incidence of nasal comorbidities, and the incidence of adverse events (AEs). **Results:** 731 patients in the treatment group and 250 patients in the control group completed the trial, baseline patient characteristics were similar. After six weeks, the incidence of severe nasopharyngeal secretion (grade middle or higher)in the treatment group was significantly lower as compared with the control group(12.4% vs 20.0%, P=0.0033). The incidence of severe OM (World Health Organization grade 3 or higher) was significantly lower in the treatment group than in the control group (12.3% vs 22.4%, P=0.0001). The intergroup rate difference and 95% CI of the incidence of OM between the two groups was -10.1% (-15.8%, -4.4%). The upper limit of the 95% CI was greater than -10%, so it could not be concluded that the experimental group was superior to the control group. However, compared with the control group, the treatment group showed a certain trend in reducing oral mucositis. The BQG group also remarkably reduced the incidence of severe VAS score for sore throat pharyngeal pain and the grade of symptom with dry and burning throat compared to the control group. The incidence of AEs were similar between the groups. **Conclusions:** BQG significantly attenuated the incidence of nasal secretions in NPC patients undergoing radiotherapy, improved pharyngeal pain and the symptoms with dryness and burning, with a good safety profile. Clinical trial information: ChiCTR2200060900. Research Sponsor: Supported by Hutchison Whampoa Guangzhou Baiyunshan Chinese Medicine Co., Ltd.

6015 Rapid Oral Abstract Session

Phase 2 open-label study of brentuximab vedotin (BV) + pembrolizumab (pembro) in patients (pts) with treatment (tx)-naive metastatic head and neck squamous cell carcinoma (HNSCC). First Author: Cristina P. Rodriguez, Fred Hutchinson Cancer Center, Seattle, WA

Background: BV, an antibody-drug conjugate (ADC) targeting CD30, is hypothesized to deplete T regulatory cells (Tregs) that express CD30 and resensitize tumors to anti–PD-1 therapy. SGN35-033 (NCT04609566) is an ongoing multicohort study evaluating the efficacy and safety of BV + pembro in pts with solid tumors; we report results for cohort 6 in tx-naive HNSCC with PD-L1 combined positive score (CPS) ≥1, where pembro has historically demonstrated ORR of 19% and mPFS of 3.2 months. **Methods:** Cohort 6 included pts with metastatic HNSCC with PD-L1 CPS ≥1 by local testing and no prior therapy for metastatic disease or exposure to a PD-1/PD-L1 inhibitor. Pts received BV 1.8 mg/kg + pembro 200 mg every 3 wks. The primary endpoint was confirmed ORR assessed by investigator per RECIST 1.1. Secondary endpoints included DOR, PFS, and safety. Exploratory endpoints included OS and biomarker analyses. A genAI tool (01/02/25; Pfizer; GPT-4o) developed the 1st draft; authors assume content responsibility. **Results:**As of 10/25/24, 32 pts received ≥1 dose of BV + pembro. In all pts, the confirmed ORR was 34% (95% CI, 18.6-53.2), with median follow-up duration of 9.7 mo and median DOR not reached (95% CI, 3.9 mo-not estimable [NE]). BOR is in the Table. Responses were seen regardless of HPV status and across PD-L1 CPS ≥1 subgroups, with responses in 11 of 32 (34%) vs 9 of 25 (36%) in CPS ≥1 vs CPS ≥20, respectively. The KM estimate of DOR ≥6 mo was 89%. Median PFS was 7.2 mo (95% CI, 3.2 mo-NE); 6-mo PFS rate was 56%. Biomarker analyses of peripheral blood showed that Tregs expressed relatively higher CD30 vs other T cells. There was a trend of Treg depletion and increased T-cell proliferation and activation after BV + pembro. Observed PK of BV when combined with pembro in HNSCC was similar to that of BV monotherapy. All pts had ≥1 tx-emergent adverse event (TEAE); 24 pts (75%) had a grade ≥3 TEAE; 10 pts (31%) had tx-related grade ≥3 TEAEs. The most common tx-related grade ≥3 TEAEs were lymphocyte count decreased (13%), ALT increased, fatigue, neutropenia, and neutrophil count decreased (6% each). Tx-related serious TEAEs were reported in 2 pts (6%). No new safety signals were identified. **Conclusions:** BV + pembro demonstrated promising clinical efficacy with a safety profile consistent with each individual agent in pts with tx-naive metastatic HNSCC with PD-L1 CPS ≥1. Biomarker analyses support the hypothesized immunomodulatory mechanism of action of BV + pembro. These encouraging data are consistent with prior findings in PD-1–refractory NSCLC and melanoma and support continued investigation of CD30-directed ADCs + anti–PD-1 therapy in solid tumors. Clinical trial information: NCT04609566. Research Sponsor: Pfizer.

6016 Rapid Oral Abstract Session

Randomized phase I trial of adjuvant personalized cancer vaccine TG4050 in resected locally advanced (LA) head and neck squamous cell carcinoma (HNSCC) patients (pts). First Author: Christophe Le Tourneau, Department of Drug Development and Innovation (D3i), Institut Curie, Paris-Saclay University, Paris, France

Background: Approximately one third of pts with resected LA HNSCC recur. T-cells targeting tumor specific mutations drive anti-tumor immune responses. TG4050 is a viral-based personalized cancer vaccine, encoding up to 30 tumor-specific DNA sequences bearing in-silico predicted class I and class II epitopes. We hypothesized that TG4050 prime an adaptive immune response against tumor antigens and prevent relapse in pts with resected LA HNSCC after treatment with curative intent (NCT04183166). **Methods:** The multicenter, open label, randomized, 2-arm Phase I trial evaluated TG4050 in LA HNSCC pts achieving complete remission following surgery and adjuvant radiotherapy +/- chemotherapy. Pts were randomized to receive (Arm A) weekly doses of TG4050 for 6 weeks followed by a maintenance period of one dose every 3 weeks for up to 20 doses or no vaccine (Arm B, vaccination at relapse in combination with SOC). Safety, efficacy and immunogenicity were evaluated. In selected pts, exploratory characterization of the T cell response was performed using tetramer staining, bulk and single-cell (sc)TCR sequencing. **Results:** 33 pts were randomized between January 2021 and April 2023, 17 pts to Arm A and 16 pts to Arm B. Median age was 61 years (26-79 years), tumor location was oral cavity in 24 pts (72.7%), hypopharynx and oropharynx in 4 pts (12.1%), respectively and larynx in one pt (3.0%). TG4050 was safe and well tolerated with only grade 1 or 2 treatment-related adverse events (AEs). The most frequently reported were injection site reactions. After a median follow-up of 28.5 months, all 16 pts receiving TG4050 in Arm A remained disease-free whereas 3 out of 16 pts in Arm B relapsed. Disease Free Survival (DFS) data at 24 months for all patients will be presented. Exploratory qualitative analyses of the neoantigen-specific T cell response by ELISpot were presented previously. In-depth characterization of the neoantigen-specific T cells including clonal expansion by TCR sequencing and longitudinal analysis by tetramer staining will be presented. **Conclusions:** TG4050 is safe and induces immune responses in pts with resected LA HNSCC. No relapse occurred in the vaccine arm as opposed to 19% in the control arm. With the evolution of the landscape, adjuvant anti-PD1 therapy may become standard in resected LA HNSCC. TG4050 warrants further evaluation in combination with anti-PD1 therapy in phase III trials. Clinical trial information: NCT04183166. Research Sponsor: None.

6017 Rapid Oral Abstract Session

Ficerafusp alfa with pembrolizumab in patients with recurrent or metastatic head and neck squamous cell carcinoma: Updated results from an expansion cohort of an open-label, multicenter, phase 1/1b trial. First Author: Christine H. Chung, Moffitt Cancer Center and Research Institute, Tampa, FL

Background: HPV-negative head and neck squamous cell carcinoma (HNSCC) is an aggressive disease characterized by high recurrence, metastasis (R/M), and resistance to standard treatments. While anti–PD-1 therapies have improved outcomes, the prognosis for R/M HNSCC remains poor, necessitating novel approaches to achieve deeper, more durable responses and improved overall survival (OS). Ficerafusp alfa is a first-in-class bifunctional antibody targeting EGFR and TGF-β. **Methods:** This single-arm, multicenter, dose expansion of an ongoing phase 1/1b study (NCT04429542) enrolled patients (pts) aged ≥18 years with treatment-naive, unresectable R/M HNSCC, with a CPS ≥1. Pts received ficerafusp alfa (1500 mg IV on days 1, 8, and 15) combined with pembrolizumab (200 mg IV on day 1) every 21 days. Study objectives included objective response rate (ORR) per RECIST v1.1, duration of response (DOR), progression-free survival (PFS), OS, safety (CTCAE v5), and pharmacodynamic analyses. This report presents updated findings after two years of follow-up. **Results:** As of December 16, 2024, 42 pts were treated (71% male, median age: 63 years [range: 31–84]); 39 were efficacy evaluable (EE). Among the EE pts, the ORR was 54% (21/39; 95% CI: 37–70) in the overall cohort and 64% (18/28; 95% CI: 44–81) in HPV-negative pts. Notably, 21.4% of HPV-negative pts achieved a complete response (CR). A confirmed durable response of ≥6 and ≥12 months was observed in 72% (13/18) and 56% (10/18) of overall and 73% (11/15) and 60% (9/15) of HPV-negative responders, respectively. Median PFS was 7.4 months (95% CI: 2.9–14.5 overall, and 9.8 months (95% CI: 4.4–23.2) in the HPV-negative subgroup. The 12-month OS rate was 61.5% (95% CI: 44.5–75.7) across the cohort and 60.7% (95% CI: 40.4–76.0) for HPV-negative pts. At data cutoff, all evaluable pts had been followed for at least 20 months. Median OS and DOR had not been reached yet in HPV-negative pts, with mOS surpassing 20 months. Safety findings were consistent with the known safety profile of ficerafusp alfa plus pembrolizumab, while pharmacodynamic analyses demonstrated encouraging post-treatment downregulation of pSMAD2 supporting targeted TGF-β inhibition. **Conclusions:** Ficerafusp alfa combined with pembrolizumab continues to show promising efficacy relative to historical data on the current standard of care, particularly in HPV-negative HNSCC. Median PFS and 12-month OS, ORR, and CR rates are encouraging relative to historical benchmarks in pts with HPV-negative HNSCC. 24-month OS and mature OS/DOR outcomes are anticipated. These findings provide compelling rationale for FORTIFI-HN01, the ongoing multicenter, randomized, double-blind phase 2/3 clinical trial evaluating this combination in first-line PD-L1–positive, HPV-negative R/M HNSCC. Clinical trial information: NCT04429542. Research Sponsor: Study funded by Bicara Therapeutics Inc. with access to pembrolizumab in collaboration with Merck Sharp & Dohme LLC, a subsidiary of Merck & Co., Inc., Rahway, NJ, USA (NCT04429542).

6018 Rapid Oral Abstract Session

Neoadjuvant PD-1 inhibitor combined with Nab-paclitaxel and cisplatin in resectable locally advanced head and neck squamous cell carcinoma (NCT05522985): A randomized, controlled, open label, phase II clinical trial. First Author: Hongling Wang, Department of Maxillofacial and Otorhinolaryngological Oncology, Tianjin Medical University Cancer Institute and Hospital, Key Laboratory of Cancer Prevention and Therapy, Tianjin Cancer Institute, National Clinical Research Center of Cancer, Tianjin, China

Background: More than 60% of head and neck squamous cell carcinoma (HNSCC) patients (pts) were locally advanced at diagnosis. Many previous clinical trials have confirmed that induction chemotherapy can improve the functional retention rate of HNSCC and improve the quality of life. However, pts have no long-term survival benefits from it. In recent years, immunotherapy has brought hope for long-term survival to pts with recurrent and metastatic HNSCC. The exploration of neoadjuvant immunotherapy in HNSCC is also gradually carried out. **Methods:** This was a randomized, controlled, open label, phase II study. 122 pts were panned to enrolled. Key inclusion criteria: pts aged ≥18 years; histologically or cytologically confirmed stage III or IV resectable HNSCC; without prior system anticancer therapy; ECOG≤1. Eligible pts were randomized 1:1 to receive toripalimab (240mg, D1, q3w) in combination with nab-paclitaxel (260 mg/m2,d1,q3w) and cisplatin (75mg/m^2,q3w) for 3 cycles (experimental arm) or nab-paclitaxel (260 mg/m^2,d1,q3w) and cisplatin (75mg/m^2, q3w) for 3 cycles (control arm). Then surgery and pathological remission evaluation was performed. The primary endpoint was pathologic complete response (pCR) rate. Secondary endpoints were major pathological response (MPR), objective response rate (ORR), 2-year progression-free survival (PFS) rate, 2-year overall survival (OS) rate, and safety. **Results:** A total of 122 pts were enrolled (experimental 61, control 61). Median age was 59.5 years (range: 34–83) and 80.33% were male. After neoadjuvant treatment, 88 pts underwent surgery (experimental 45, control 43). pCR rate was significantly different between the two arms (experimental 57.78%, control 34.88%, p = 0.03). More pts achieved MPR (experimental 82.22%, control 53.46%, p = 0.004) in experimental arm. In experimental arm, 2-year DFS (experimental 86.67%, control 71.95%) and 2-year OS (experimental 90.61%, control 77.74%) were higher, the statistical significance was undetermined. The proportion of Grade ≥3 treatment-related adverse events (TRAEs) in the experimental and control arms were 16.39% and 9.84%, respectively. The most common TRAEs are Agranulocytosis, Nausea, Alopecia and Vomiting. No new safety signals were observed and no TRAEs leading to death. There was no significant difference in TRAEs of two arms. **Conclusions:** Comparing to chemotherapy, neoadjuvant immunochemotherapy can significantly improve the pCR and MPR rate of HNSCC. Moreover, adverse events are controllable. And immune neoadjuvant therapy demonstrates a trend towards improving survival. Clinical trial information: NCT05522985. Research Sponsor: None.

6019 Rapid Oral Abstract Session

An open-label, phase Ib trial of the SIRPα inhibitor BI 765063 in combination with the PD-1 inhibitor ezabenlimab and cetuximab in patients (pts) with head and neck squamous cell carcinoma. First Author: Katerin Ingrid Rojas L, Hospital Universitari Vall d'Hebron, Barcelona, Spain

Background: BI 765063 is a first-in-class, humanized IgG4 monoclonal antibody that binds the V1 allele of signal regulatory protein α (SIRPα) and blocks the 'don't eat me' signal of the SIRPα/CD47 axis. This leads to reactivation of innate antitumor responses, restoring phagocytosis and antigen presentation. In a Phase Ia/Ib trial in pts with advanced solid tumors (NCT03990233), BI 765063 ± ezabenlimab was well tolerated with no dose-limiting toxicities and preliminary efficacy was observed (Kotecki et al, ESMO 2021). This Phase Ib study (NCT05249426) is investigating the efficacy and safety of BI 765063 in combination with ezabenlimab + cetuximab (Cohort A) or ezabenlimab + chemotherapy (Cohort B) in pts with recurrent/metastatic (R/M) head and neck squamous cell carcinoma (HNSCC), or in combination with ezabenlimab ± BI 836880 (anti-VEGF/Ang2) in pts with hepatocellular carcinoma. Here, we focus on pts with HNSCC who received BI 765063 combined with ezabenlimab + cetuximab (Cohort A). **Methods:** In Cohort A, adult pts with R/M HNSCC who had received 1 previous systemic therapy (excluding immune checkpoint inhibitors) were eligible. Other inclusion criteria included SIRPα V1/V1 homozygosity (detected in plasma), ≥1 measurable lesion (RECIST v1.1) and ECOG performance status of 0/1. Pts received BI 765063 (24 mg/kg every 3 weeks [q3w]), ezabenlimab (240 mg q3w) and cetuximab (per local guidelines). Primary endpoint was confirmed objective response (OR; RECIST v1.1). Secondary endpoints included disease control (DC) and treatment-emergent adverse events (TEAEs). **Results:** At data cut-off (Dec 2, 2024), 18 pts had been enrolled to Cohort A and received BI 765063 plus ezabenlimab + cetuximab (1 pt was subsequently found to be ineligible). Of the 17 eligible pts, median age was 51 years (range, 33–81), 88% were male and all had received 1 prior therapy. Eight pts (47%) achieved a confirmed OR (3 complete and 5 partial responses) and a further 7 (41%) achieved stable disease to give a DC rate of 88%. Median duration of DC was 7.6 months. TEAEs were reported in all 17 pts. Most common TEAEs were acneiform dermatitis (any grade/grade ≥3, 53%/0%), anemia (35%/24%), hypokalemia (29%/6%), hypothyroidism (29%/0%) and rash (29%/0%). Most common BI 765063 treatment-related AEs (TRAEs) were hypothyroidism (24%) and acneiform dermatitis (18%), all grade 1/2. Grade 3 TRAEs (asthenia, cardiac failure, epistaxis, hypoalbuminemia, lymphopenia, mouth hemorrhage, post-procedural hemorrhage and suspected drug-induced liver injury) were each reported in 1 pt. There were no grade 4/5 TRAEs. **Conclusions:** These preliminary data indicate that BI 765063 in combination with ezabenlimab and cetuximab has a manageable safety profile and promising efficacy as second-line treatment in pts with R/M HNSCC. Biomarker data will be presented at the meeting. Clinical trial information: NCT05249426. Research Sponsor: Boehringer Ingelheim.

6020 Rapid Oral Abstract Session

Dose expansion data from iintune-1, a phase 1/2 study of the STING agonist dazostinag plus pembrolizumab as first-line (1L), in patients with recurrent/metastatic squamous cell carcinoma of the head and neck (RM-SCCHN). First Author: Jérôme Fayette, Centre Léon Bérard, Lyon, France

Background: Checkpoint inhibitors (CPIs) such as pembrolizumab (pembro) can lead to improved outcomes and durable responses in patients (pts) with RM-SCCHN. However, only a subset of pts with RM-SCCHN experience this benefit, and an unmet need for better treatments remains. STimulator of INterferon Genes (STING) agonism enhanced the response to CPIs preclinically. Dazostinag (dazo) is a small molecule STING agonist that has shown antitumor activity and activation of innate and adaptive immune responses in pts with solid tumors in the dose escalation part of iintune-1, with a recommended dose for expansion of 5 mg in combination with pembro. We report data from the ongoing dose expansion cohort 2A of iintune-1 in the first 30 pts with incurable 1L RM-SCCHN with a PD-L1 combined positive score (CPS) $\geq$1, treated with dazo in combination with pembro (NCT04420884). **Methods:** Pts receive dazo 5 mg IV on Days 1, 8, 15 plus pembro 200 mg IV on Day 1, in 21-day cycles. Primary endpoints are safety and tolerability. Secondary endpoints include investigator-assessed overall response rate (ORR) per RECIST 1.1 and duration of response (DOR). Dose optimization is planned as part of expansion. **Results:** As of Dec 16, 2024, 30 pts had been enrolled and received treatment. Median age was 64 years and 73% of pts were male. The most common primary tumor locations were oral cavity (n=10, 33%), oropharynx (n=8, 27%), and larynx (n=6, 20%). Median CPS score was 13.5 (range, 1–101). A median of 4.5 treatment cycles (range 1–15) were received. Treatment-emergent adverse events (TEAEs) occurred in all pts (grade $\geq$3 in 37%); the most common were fatigue (40%), nausea (27%), cough (23%), and headache (20%). Dazo-related TEAEs occurred in 80% of pts (grade $\geq$3 in 13%); the most common was fatigue (30%). Cytokine release syndrome was reported in 4 pts (13%; all dazo-related and grade 1–2). TEAEs led to dazo discontinuation in 1 pt. No treatment-related deaths were reported. Among 29 response-evaluable pts, 1 had a confirmed complete response and 7 had confirmed partial responses (+2 unconfirmed), for an ORR of 34%. Median DOR was not reached. Pharmacodynamic analyses revealed biomarker changes consistent with the expected mechanism of action and dose escalation data, including induction of a STING gene signature, cytokine induction, peripheral immune cell activation and CD8+ T cell recruitment to the tumor. Analyses of changes in peripheral ctDNA pre- and post-treatment are ongoing. **Conclusions:** This early study of dazo 5 mg IV in combination with pembro showed a manageable safety profile with an encouraging ORR in pts with RM-SCCHN. Pharmacodynamic findings demonstrate peripheral and intratumor changes consistent with STING agonism. Clinical trial information: NCT04420884. Research Sponsor: Takeda Development Center Americas, Inc. (TDCA), Lexington, MA.

6021 Poster Session

Real world utilization of comprehensive genomic profiling (CGP) in head and neck squamous cell carcinoma (SCCHN). First Author: Connie Jiayu Zhou, University of California, San Francisco, San Francisco, CA

Background: In Head and Neck Cancer, practice trends of utilizing comprehensive genomic profiling (CGP) vary depending on physician preference and test availability. Here, we examined the impact of CGP on treatment decision-making and patient outcomes in SCCHN at a single institution. **Methods:** Patients with suspected SCCHN underwent tumor-based CGP using the UCSF500 or TEMPUS xT NGS panel. In addition to demographic and clinicopathologic data, we obtained the reason for CGP when noted, disease stage and line of therapy at the time of CGP, CGP results, and post-CGP treatments. OncoKB was used to annotate actionable mutations in Head and Neck Cancer, in addition to other biomarkers when available (microsatellite instability (MSI), tumor mutation burden (TMB), and EGFR amplification). **Results:** Between January 2016 and December 2023, 301 unique patient tumor specimens underwent CGP in the setting of suspected or known SCCHN. Sequencing was performed to refine a diagnosis in 57 samples (18.9%). CGP influenced the determination between cutaneous and mucosal primary in 35 samples, clarified the histology in 9, and clarified the origin of a metastatic lesion in 13. For patients with confirmed SCCHN (N = 246), CGP was performed for therapy selection in 193 (78.5%) of patients. Of these, 19 (9.8%) patients were TMB-high (TMB$>$10), 2 (1.0%) patients were MSI-high, 77 (39.9%) patients were found to have actionable genomic alterations, and clinicians had access to OncoKB-specified agents for 50 (25.9%) of the patients. Anti-PD-1 antibody therapy was administered to 15/20 (75%) of TMB-high and/or MSI-high patients compared to 38 (53.5%) with low TMB or MSI-stable disease. The most common actionable individual gene alterations were in *CDKN2A* (37.3%), *PIK3CA* (14.5%), *PTEN* (7.2%), *FBXW7* (6.0%), and *HRAS* (6.0%) genes. Six of 77 (7.8%) patients with actionable genomic alterations received targeted therapy based on drug availability and the clinical discretion of the treating physician.In these, the overall response rate was 50% (3/6), and the median PFS was 2.6 months. Thus, at this site, the number needed to treat to gain one response in SCCHN patients undergoing sequencing for oncogene-targeted options was 64.5 patients. **Conclusions:** CGP in HNSCC was used most commonly to increase diagnostic accuracy, often providing diagnostic information that guided therapeutic decision-making. It was used infrequently for therapy selection, but in the few patients selected for targeted therapy based on NGS, objective responses were observed. Research Sponsor: None.

Pembrolizumab plus nab-paclitaxel and platinum as first-line treatment in patients with recurrent or metastatic nasal cavity and paranasal sinus squamous-cell carcinoma: A prospective phase II study. First Author: Yuquan Qian, National Cancer Center, National Clinical Research Center for Cancer, Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China

Background: Patients with recurrent or metastatic sinonasal squamous-cell carcinoma (R/M SNSCC) lack standardized systemic treatment protocols and prospective studies. While pembrolizumab with platinum and fluorouracil is established as first-line treatment for R/M head and neck squamous-cell carcinoma, and its combination with carboplatin and paclitaxel shows promise, we evaluated the efficacy and safety of pembrolizumab with nab-paclitaxel and platinum in R/M SNSCC. **Methods:** This is a single-arm phase 2 study, patients with R/M SNSCC received pembrolizumab 200mg, nab-paclitaxel 260mg/m^2 plus cisplatin 75 mg/m^2 or carboplatin AUC5 on day 1 every 21 days for up to six cycles followed by pembrolizumab maintenance therapy until progression or unacceptable toxicity or 35 cycles, whichever occurred first. The primary endpoint was objective response rate (ORR). Secondary endpoints were disease control rate (DCR), progression-free survival (PFS), overall survival (OS) and safety. Immunohistochemistry and high-resolution sequencing of the tumor samples were performed. **Results:** From 10 March 2022 to 31 October 2024, 20 patients were enrolled. The ORR was 60% (95%CI: 0.36-0.81) and two patients (2/20, 10%) achieved CR. The DCR was 100%. Median follow-up was 18.05 months(range:5.2-31.7), with a median PFS of 12.2 months (95%CI: 9 months-not estimated) and an unreached median OS. Patients with PD-L1 CPS $\geq$20 exhibited better ORR (80% vs 28.6%, p=0.144), median PFS (not reached vs 7 months, p=0.0137), and median OS (not reached vs 17.8 months, p=0.0401) compared to those with PD-L1 CPS $<$ 20. ORR was 50% (2/4) in HPV-positive patients and 53.8% (7/13) in HPV-negative patients. The most common genetic alterations were TP53, EGFR, CDKN2A mutations and amplifications in the 11q13 region (including CCND1, FGF19, FGF4, and FGF3 genes). Median TMB was 4 mut/Mb (range 2-13), with no significant difference observed between responders and non-responders. Grade 3/4 Treatment-Related Adverse Events (TRAEs) only accounted for 30% (6/20), and all come from hematologic toxicity. Hypothyroidism was the most common irAEs (12/20, 60%). **Conclusions:** Pembrolizumab plus nab-paclitaxel and platinum shows promising antitumor activity and manageable safety in first-line R/M SNSCC patients. Clinical trial information: ChiCTR2200057343. 6023 Poster Session

Phase 2 trial of dual EGFR inhibition with cetuximab and afatinib in patients with recurrent/metastatic head and neck squamous cell cancers (HNSCC). First Author: Aarti K. Bhatia, Yale School of Medicine and Yale Cancer Center, New Haven, CT

Background: Cetuximab is a monoclonal antibody targeting the epidermal growth factor receptor (EGFR) but its clinical activity is limited by resistance mechanisms. Our previous HNSCC trial of chemotherapy, cetuximab and erlotinib demonstrated a 62.5% objective response rate (ORR) including 2 durable complete responses (CR), with greater inhibition of phosphorylated EGFR in post-treatment biopsies. Because human epidermal growth factor receptor (HER)-2 and HER3 are overexpressed in cetuximab-resistant HNSCC, we postulated that the combination of cetuximab and afatinib, an irreversible, pan-HER inhibitor, would overcome resistance by inhibiting EGFR/HER dimers and inhibiting nuclear translocation and resulting non-canonical EGFR activities in R/M HNSCC. **Methods:** The primary objective of this single-arm phase II trial was ORR to the combination of cetuximab and afatinib in patients with R/M HNSCC refractory to platinum-based chemotherapy and/or immune checkpoint therapy. Cetuximab was administered at standard doses weekly/bi-weekly. Afatinib was initially dosed at 40 mg orally daily, amended to 30 mg orally daily after 25 patients, to improve tolerability. Key secondary endpoints were median progression-free survival (mPFS), median overall survival (mOS) and toxicity. Radiographic tumor assessment was performed, using RECIST version 1.1 every 8 weeks. Biopsy was obtained at baseline, 4 weeks after treatment initiation and at end of treatment, where medically feasible. **Results:** The study protocol was approved by the institutional review board and written informed consent was obtained from all participants. Fifty patients were enrolled between 7/3/2017 and 10/16/2024 at Yale Cancer Center, 47 were evaluable for response. Median age was 63 years (range 43-81 years), 39 (83%) were male, 21 (44.7%) had p16 positive tumors, 26 (55.3%) were p16 negative. Most common primary tumor location was oropharynx (n, %: 21, 44.7). ORR was 23.4% (2 complete responses, 9 partial responses, 95% CI: 12.3%-38%) for the entire population, 10 responses were in p16- patients (ORR 38.5%) and 1 response (4.8%) in a patient with p16+ disease. Median PFS was 3.8 months (95% CI: 2.1-not reached) for p16- patients and 1.8 months (95% CI: 1.7-8.9) for p16+ patients. Median OS was 7.5 months (95% CI: 4.8-12). Commonest adverse events (n, %) were diarrhea (19, 40), anemia (17, 36) rash (14, 30) and fatigue (13, 28). Correlative analyses are underway. **Conclusions:** This trial of dual EGFR targeting demonstrated high clinical efficacy, especially in the p16- population. Adverse events were consistent with those associated with EGFR inhibitor treatment. Clinical trial information: NCT02979977. Research Sponsor: NCCN; Boehringer Ingelheim.

Petosemtamab (MCLA-158) with pembrolizumab as first-line (1L) treatment of PD-L1+ recurrent/metastatic (r/m) head and neck squamous cell carcinoma (HNSCC): Phase 2 trial. First Author: Carla M.L. van Herpen, Department of Medical Oncology, Radboud University Medical Center, Nijmegen, Netherlands

Background: EGFR is a known oncogenic driver in HNSCC, and the leucine-rich repeat-containing G-protein coupled receptor 5 (LGR5) is associated with cancer stem cells in solid tumors and expressed in HNSCC. Petosemtamab is a human, common light chain, IgG1 bispecific antibody with ADCC-enhanced activity, targeting EGFR and LGR5. Promising interim data from this phase 2, single-arm trial of petosemtamab 1500 mg every 2 weeks (Q2W; 28-day cycles) with pembrolizumab (400 mg Q6W) as 1L treatment in PD-L1+ HNSCC (NCT03526835) demonstrated a 67% overall response rate (ORR) in 24 efficacy evaluable patients (pts) [Fayette, ASCO 2024]. **Methods:** Primary endpoints are investigator-assessed ORR (RECIST v1.1) and safety. Secondary endpoints include duration of response (DOR), progression-free survival (per investigator), and overall survival (OS). Key eligibility criteria were r/m HNSCC with no prior systemic therapy in the r/m setting, PD-L1 combined positive score $\geq$1, ECOG PS 0–1, measurable disease, and primary tumor location in oropharynx (regardless of p16 status), oral cavity, hypopharynx, or larynx. **Results:** A total of 45 pts were treated; as of a September 16, 2024 data cutoff, 18 pts continuing on therapy. Median age was 64 years (range 23–80), ECOG PS 0/1 in 16/29 pts, and 78% were male. The most frequent primary tumor locations were oropharynx (31%), oral cavity (31%), larynx (16%), and hypopharynx (11%). A median of 8 cycles (range 1–17) were administered. Among 43 pts evaluable for efficacy (pts with $\geq$1 dose and $\geq$1 post-baseline scan, or who discontinued early due to progressive disease or death), the ORR was 60% (26/43) with 5 complete responses; median DOR was 11 months with 17 responders still on treatment at data cutoff. Of the 8 pts with p16+ oropharyngeal disease, 4 had confirmed responses (ORR 50%). The median follow-up for OS was 9.6 months; median OS was not reached. Kaplan–Meier estimate of OS at 6 months was 93%. The combination was well tolerated, and no significant overlapping toxicities were observed. Treatment-emergent adverse events (AEs) were reported in 45 pts, most were Grade (G) 1 or 2 in severity; one previously reported unrelated G5 AE occurred. The most frequent AEs (all G/G$\geq$3) were acneiform dermatitis (49%/7%), asthenia (49%/7%), and rash (44%/0%). Infusion-related reactions (composite term) were reported in 38% (all G) and 7% (G3) of pts, mainly occurred at first infusion, and all resolved. Updated data to be presented. **Conclusions:** Petosemtamab, a first-in-class EGFR x LGR5 bispecific antibody, in combination with pembrolizumab continues to demonstrate promising clinical efficacy and a well-tolerated safety profile as 1L treatment for pts with r/m PD-L1+ HNSCC. A global phase 3 trial, LiGeR-HN1 (NCT06525220), is ongoing to evaluate petosemtamab in combination with pembrolizumab in 1L PD-L1+ r/m HNSCC. Clinical trial information: NCT03526835. Research Sponsor: Merus N.V.

6025 **Poster Session**

Using longitudinal spatial-omics to demonstrate in-situ Epstein-Barr virus reduction in responders to immunotherapy treated nasopharyngeal cancer. First Author: Yang Wu, Institute of Molecular and Cell Biology (IMCB), Agency for Science, Technology and Research (A*STAR), Singapore, Singapore, Singapore

Background: Epstein-Barr virus (EBV) related nasopharyngeal cancer (NPC) is endemic in Southern China and Southeast Asia. Limited studies of tumor-immune microenvironment (TIME) modulated by dual checkpoint inhibitors (CPI) exist in relation to intratumoral EBV viral load. **Methods:** Spatial-omic analysis on longitudinally collected fresh frozen tissue from a phase 2 study of nivolumab/ipilimumab in NPC (NCT03097939) was done. Serial sections (10 μm) were cut for both H&E staining, and Stereo-seq assay (BGI, USA) that uses DNA nanoballs to capture mRNA which is amplified & reverse transcribed into cDNA, and then sequenced to a depth of 1 billion reads. Sequencing data was mapped to the human genome GRCh38.p14 and EBV-1 genome to identify Unique Molecular Identifiers (UMI), summarized into BIN100 niches (50μm by 50μm), processed into counts per million (CPM) and normalized for analysis. Cell type composition was estimated for each BIN100 using EBV+ NPC scRNA-seq datasets and *cell2location*. EBV viral load and the proportions of different cell types were associated with pre/post CPI in responders (R) and non-responders (NR) using Generalized Estimation Equation to account for repeated measures in the same slide. Colocalizations of different cell types within each BIN100 were also evaluated, adjusting for cell type proportions across all samples. P-value $<$ 0.05 on two sided testing was considered statistically significant. **Results:** Samples were collected at baseline pre-treatment, and 2 weeks into treatment, and associated with clinical response. Although 21/40 patients were biopsied, only 7 pairs of pre- and on-treatment samples (3R vs 4NR) had sufficient tissue quality for analysis. The most abundant EBV genes were RPMS1, EBNA1.1, LMP2B, LMP2A, and LMP1 (using mean expression). In pre/post treatment comparisons, the EBV viral load significantly reduced in R, as reflected by EBNA1.1 (p=4.9E-11) and LMP2A (p=7.4E-23), controlling for the proportion of epithelial cells (EC), but it did not change in NR. In R, a significant reduction of B cells (p=8.2E-71) and increase of myeloid (p=1.3E-3) and natural killer cells (p=3.1E-3) was observed, while no changes in cell composition were seen in NR. Colocalization analysis of EC with two immune cell (IC) types, CD4+ T cell and CD8+ T cell, identified significantly increased colocalization only in NR (CD4+ T cell: p=4.1E-7; CD8+ T cell: p=4.6E-4), suggesting IC infiltration is induced by CPI in NR but insufficient for cell kill. **Conclusions:** This is the first study to suggest intratumoral viral transcriptional activity reflected by reduction in EBNA1.1 and LMP2A on CPI treated NPC correlates with response and changes in immune cell composition and colocalization. Validation of these findings at protein level using multiplex IHC/IF and spatial analysis of the virus and epithelial/immune cell neighborhood is being completed. Clinical trial information: NCT03097939. 6026 **Poster Session**

Cetuximab plus dalpiciclib in patients with HPV-negative, anti-PD-1-resistant recurrent or metastatic head and neck squamous cell carcinoma. First Author: Houyu Ju, Shanghai Ninth People's Hospital Affiliated to Shanghai Jiao Tong University School of Medicine, Shanghai, China

Background: Human papillomavirus (HPV)-negative head and neck squamous cell carcinoma (HNSCC) is characterized by hyperactivation of the cyclin-dependent kinase 4/6 (CDK4/6) pathway. As immunotherapy has become the first-line treatment for HNSCC, resistance to anti-programmed death-1 (PD-1) agents has emerged as a pivotal challenge. This phase II study evaluated the efficacy and safety of dalpiciclib, a CDK4/6 inhibitor, combined with cetuximab in patients with anti-PD-1-resistant, HPV-negative recurrent or metastatic (R/M) HNSCC. **Methods:** Patients diagnosed with p16-negative R/M HNSCC resistant to first-line anti-PD-1 therapy and cetuximab-naïve were enrolled. Patients received oral dalpiciclib 150 mg daily for 21 consecutive days and intravenous cetuximab (400 mg/m² on day 1 of cycle 1, followed by 250 mg/m² weekly) in 28-day cycles. The primary endpoint was the objective response rate (ORR). Secondary endpoints included safety, progression-free survival (PFS), and overall survival (OS). Simon's two-stage design was used, with study termination planned if $\leq$1 response was observed among the first 14 patients. If met, an additional 12 patients were enrolled. **Results:** A total of 28 patients were enrolled, with a median age of 58 years (range 30-75 years). Among 28 evaluable patients, 3 had disease progression, 6 had stable disease, and 19 achieved partial response. The ORR was 67.9% (95% confidence interval [CI], 49.0%-82.0%), and the disease control rate was 89.3% (95% CI, 72.0%-97.0%). As of December 31, 2024, 9 patients remained on treatment. With a median follow-up of 7.34 months, the median PFS was 5.3 months (95% CI, 1.33-9.27), and the median OS was 17.0 months. Treatment-related adverse events (TRAEs) occurred in all patients, predominantly grade 1-2. The most common TRAEs were neutrophil count decreased (25/28, 89.3%), white blood cell count decreased (25/28, 89.3%), and acneiform rash (16/28, 57.1%). Grade 3 TRAEs included neutrophil count decreased (9/28, 32.1%) and white blood cell count decreased (9/28, 32.1%). No grade 4/5 TRAEs were observed. **Conclusions:** Dalpiciclib combined with cetuximab was well-tolerated and demonstrated potentially favorable efficacy in patients with anti-PD-1-resistant, HPV-negative R/M HNSCC. Clinical trial information: NCT05721443. Research Sponsor: Clinical Research Special Project of Shanghai Municipal Health Commission.

Analysis of gene mutations, TMB, and PD-L1 in relation to ICI response in HNSCC. First Author: Daniel Beau Stamos, Wake Forest Baptist Medical Center, Winston-Salem, NC

Background: Immune checkpoint inhibitors (ICI) have changed the treatment of incurable advanced, recurrent, or metastatic (R/M) head and neck squamous cell carcinoma (HNSCC). Yet only a subset of patients respond, and predicting response remains challenging. We analyzed tumor genomic profiles and PD-L1 expression in a retrospective cohort of R/M HNSCC patients treated with ICI to evaluate the association with treatment response. **Methods:** We evaluated a single-institution cohort of 119 patients with R/M HNSCC treated with PD-1 inhibitors as monotherapy or in combination with palliative radiotherapy or chemotherapy, and who had genomics tested in tumor (tDNA) and/or in blood (ctDNA) samples. We analyzed clinical characteristics, treatment outcomes, PD-L1 expression, tumor mutation burden (TMB), and genomic profiles. Treatment response was assessed using iRECIST criteria. Responders were defined as complete response (CR), partial response (PR) $\geq$ 6 months, or stable disease (SD) $\geq$1 year. TMB and tDNA were tested by FoundationOne and ctDNA by Guardant. PD-L1 IHC used DAKO 22C3 antibodies. **Results:** Of 119 patients, 43 (36.1%) were considered responders (24 CR, 11 PR, and 8 SD $\geq$ 1 year). 97 patients had tDNA and TMB and 93 patients had ctDNA tested. 91 patients had PD-L1 results. In binary analysis, TMB $\geq$ 10 was significantly associated with response (P = 2.15e-5), while PD-L1 $\geq$ 20 was not (P = 0.83). A combined analysis of tDNA and/or ctDNA evaluated 273 genes. Univariate analysis showed that mutations in DNMT3A (P = 0.005), RET (P = 0.021), FAM123B (P = 0.021), and KDM6A (P = 0.043) were significantly associated with response. In a Lasso Logistic Regression model of the 27 most frequently mutated genes, 7 genes were significantly mutated in responders: DNMT3A (P = 0.0001), MAP2K4 (P = 0.025), FANCA (P = 0.036), ASXL1 (P = 0.019), EGFR (P = 0.0008), STK11 (P = 0.022), and BARD1 (P = 0.042), while TP53 was significantly mutated in non-responders (P = 0.010). Adding TMB to the multivariate model retained the significant association of DNMT3A (P = 0.021) and MAP2K4 (P = 0.015) mutations with response, and included ERBB4 (P = 0.037) mutations and TMB (P = 0.001) as additional significant indicators of response. DNMT3A was mutated only in responders (4 CR and 1 PR), with a positive predictive value of 1.00 and a negative predictive value of 0.74. In the multivariate analyses for tDNA and ctDNA, DNMT3A remained the only gene mutation significantly associated with response (P = 0.004 and P = 0.012). **Conclusions:** In this cohort of 119 patients with R/M HNSCC treated with PD-1 inhibitors, TMB, but not PD-L1, was associated with treatment response in univariate and multivariate analysis. Multivariate models identified eight genes significantly associated with treatment response. DNMT3A was the most remarkable gene, consistently associated with response in univariate and multivariate models. Further, larger studies are needed to validate these findings. 6028 Poster Session

Personalized biomarker-based treatment strategy in patients with recurrent/metastatic squamous cell carcinoma of the head and neck: Results of the biomarker-driven cohorts of the EORTC-HNCG-1559 trial (UPSTREAM). First Author: Rachel Galot, Service d'oncologie médicale, Laboratoire d'Oncologie médicale (IREC/MIRO/ONCO), Brussels, Belgium

Background: Platinum-refractory recurrent/metastatic squamous cell carcinoma (R/M SCCHN) has a poor prognosis. Several molecular pathways are dysregulated in SCCHN, providing potential targets for treatment. The UPSTREAM trial aimed to develop a personalized treatment strategy for R/M SCCHN. **Methods:** UPSTREAM was a biomarker-driven umbrella trial for post-platinum R/M SCCHN, investigating the activity of targeted agents in patients (pts) with tumors harboring pre-defined biomarker(s) identified on a fresh biopsy. Five biomarker-driven (B) cohorts were conducted as distinct phase 2 trials. The first 4 cohorts focused on p16-negative disease: cohort B1 investigated afatinib in pts with *EGFR* amp/mut and/or *HER2* amp/mut and/or PTEN high; cohort B2 investigated afatinib in cetuximab-naïve pts; cohort B3 investigated palbociclib in pts with *CCND1* amp and cohort B4 investigated niraparib in platinum-sensitive disease. Cohort B5 investigated niraparib in p16 positive oropharyngeal carcinoma. Cohorts B1, B2 and B3 were randomized (versus physician's choice of treatment) with progression-free survival rate at 16 weeks (PFSR 16W) as primary endpoint. Cohorts B4 and B5 were single-arm trials with objective response rate (ORR) over the first 16 weeks as primary endpoint. **Results:** A total of 250 pts were enrolled in UPSTREAM across 5 European countries, of whom 152 were allocated to a biomarker-driven cohort. Only B1 met its primary endpoint. In B1 (n=38 under afatinib), the PFSR 16W was 34.2%. B2 cohort experienced slow recruitment, with only 8 patients treated with afatinib, the PFSR 16W was 12.5%. In B3 (n=12 under palbociclib), PFSW 16W was 16.7%. In B4 (n=28) and B5 (n= 33), the ORR with niraparib was 3.6% (1/28) and 6.1% (2/33), respectively. More detailed results are shown in the table. **Conclusions:** UPSTREAM demonstrated the feasibility of conducting a biomarker-driven clinical trial in R/M SCCHN. The clinical activity observed across the biomarker-driven cohorts is limited. Potential explanations for these results include the absence of clearly identified high-level drivers in SCCHN, the limited evidence supporting some biomarkers (mainly derived from genomic data), and the use of single-agent treatment approaches. These findings highlight the need for further research to identify and refine biomarkers to explore new treatment strategies. Clinical trial information: NCT03088059. Research Sponsor: Boehringer Ingelheim; Pfizer; GSK.

Cohort	Biomarker	Drug	N evaluable patients	ORR	Median PFS (months)	Median OS (months)
B1	p16- and *EGFR* amp/mut or *HER2* amp/mut or PTEN high	afatinib	38	10.5%	2.2	7.2
		physician's choice	17	5.9%	2.4	5.0
B2	p16- and cetuximab-naïve	afatinib	8	0%	2.6	10.7
		physician's choice	4	0%	4.0	4.0
B3	p16- and *CCND1* amp	palbociclib	12	8.3%	1.9	4.3
		Physician's choice	6	0%	1.9	5.1

Retlirafusp alfa-a bifunctional anti-PD-L1/TGF-βRII agent plus nab-paclitaxel and carboplatin in pre-treated recurrent/metastatic head and neck squamous cell carcinoma (R/M HNSCC): A prospective, single-arm, phase II clinical trial. First Author: Dongmei Ji, Department of Medical Oncology, Fudan University Shanghai Cancer Center, Shanghai, China

Background: Treatment for pre-treated patients (pts) with recurrent/metastatic head and neck squamous cell carcinoma (R/M HNSCC) is an important unmet clinical need. Dual blockade of PD-L1 and TGF-β could reshape the tumor microenvironment. The aim of this study is to evaluate the efficacy and safety of retlirafusp alfa (SHR-1701, a bifunctional anti-PD-L1/TGF-βRII agent) plus nab-paclitaxel and carboplatin in platinum-refractory R/M HNSCC pts. **Methods:** Patients with R/M HNSCC who received ≥1 line of prior systemic anti-tumor therapy were included. Pts received retlirafusp alfa 30mg/kg, once every 3 weeks, combined with nab-paclitaxel (125mg/m^2) and carboplatin (AUC=1.5), on day 1 and day 8 of a 21-day cycle for up to six cycles, followed by retlirafusp alfa maintenance therapy. The primary endpoint was objective response rate (ORR). Secondary endpoints comprised progression free survival (PFS), overall survival (OS), disease control rate (DCR) and safety. **Results:** From September 5, 2023 to September 25, 2024, 12 eligible pts were enrolled. The median age was 60 (range: 35-72). Among these 12 patients, 11 (91.7%) had received prior immune checkpoint inhibitors (ICIs) and 8 (66.7%) had undergone at least two previous lines of treatment. The median follow-up was 5.45 (95%CI 3.93-6.97) months, and data cutoff was December 31, 2024. All the 12 pts had at least one post-baseline assessment, and 4 pts achieved partial response with a confirmed ORR of 33.33% (95%CI 13.81%-60.93%). Disease control was observed in 8 patients resulting in a DCR of 66.67% (95%CI 39.07%-86.19%). The median PFS was 4.21 (95%CI 0.59-7.83) months. The median OS was immature. Treatment-related adverse events (TRAEs) occurred in 11 (91.67%) pts, mainly grade 1-2. The most common TRAEs (≥30%) were anaemia (8/12, 66.67%), white blood cell count decreased (5/12, 41.67%), hypoalbuminaemia (5/12, 41.67%), haemoptysis (5/12, 41.67%) and epistaxis (4/12, 33.33%). Grade 3-4 TRAEs were observed in 4 (33.33%) pts, with more than 1 patient experiencing white blood cell count decreased (3/12, 25%), neutrophil count decreased (2/12, 16.67%) and anaemia (2/12, 16.67%). **Conclusions:** Even as most pts have progressed on ICIs before enrollment, retlirafusp alfa plus nab-paclitaxel and carboplatin demonstrated promising anti-tumor efficacy and manageable toxicities in pre-treated R/M HNSCC. Long-term efficacy needs to be confirmed by further follow-up. Clinical trial information: ChiCTR2300070675. Research Sponsor: None.

Camrelizumab combined with cetuximab and chemotherapy in recurrent or metastatic head and neck squamous cell carcinoma (R/M HNSCC): 1-year outcomes from the phase II trial. First Author: Dongmei Ji, Department of Medical Oncology, Fudan University Shanghai Cancer Center, Shanghai, China

Background: Pembrolizumab or cetuximab combined with platinum-based-chemo are standard first-line regimen for R/M HNSCC, but the efficacy is far from optimal. We conducted an open-label, single-arm, Simon' s two-stage, phase II study of camrelizumab (PD-1 monoclonal antibody) with cetuximab and cisplatin-based chemotherapy as first-line treatment in R/M HNSCC (NCT05673577). The outcomes from the 1st stage showed promising efficacy. **Methods:** Eligible patients with R/M HNSCC not amenable to curative treatment were enrolled. Patients were treated with camrelizumab 200mg Q3W, cetuximab 400mg/m^2 loading dose followed by 250mg/m^2 weekly, cisplatin 75mg/m^2 Q3W, and nab-paclitaxel 125mg/m^2 on d1, d8 (21-day cycle), for up to 6 cycles. Maintenance therapy with camrelizumab 200mg Q2W, cetuximab 500mg/m^2 Q2W were given until intolerable toxicity or disease progression. Primary endpoint of this study is objective response rate (ORR). Secondary endpoints include progression-free survival (PFS), overall survival (OS), disease control rate (DCR), adverse events (AEs) (CTCAE v5.0) andmolecular biomarkers will be tested as exploratory endpoints. **Results:** Between April 2023 and September 2024, 41 patients were enrolled. The confirmed ORR per RECIST 1.1 was 90.0% (95% CI: 75.0-97.0), which met the prespecified criteria for the primary endpoint of ORR. The confirmed DCR was 100.0%. With the median follow-up duration of 14.5 months, the median PFS was 13.2 months (95% CI: 9.3-NR). The 1-year PFS rate was 54.6% (95% CI: 39.1-76.1). The median OS was not reached. The 1-year and 2-year OS rates were 88.4% (95% CI: 78.2-100.0) and 84.6% (95% CI: 72.8-98.3), respectively. The most common grade 3-4 AEs related to chemotherapy included neutropenia (16.7%), anemia (7.1%). Possible grade 3-4 targeted therapy-related AE was rash (7.1%). Additionally, 14.3% of the patients were administered anti-angiogenic medications to treat reactive cutaneous capillary endothelial proliferation mucositis that was specifically induced by camrelizumab. These AEs were manageable with dose modification. **Conclusions:** Camrelizumab combined with cetuximab and cisplatin-based chemotherapy showed encouraging efficacy and tolerability in the scenario of first-line R/M HNSCC. Further evaluation including a phase III study is warranted. Clinical trial information: NCT05673577. Research Sponsor: Clinical Research Project of Shanghai Municipal Health Commission in Health Industry, 202340122, (2023-2026); National Health Commission: Special Research Project for Clinical Studies of Innovative Drugs After Market Launch, WKZX2024CX01206, (2004-2007)).

Combination of Tim-3 blockade TQB2618 with penpulimab and chemotherapy in the first-line treatment of recurrent/metastatic nasopharyngeal carcinoma (R/M NPC): A multicenter, single-arm, two-cohort, phase 2 study. First Author: Cheng Xu, Sun Yat-sen University Cancer Center; Collaborative Innovation Center for Cancer Medicine; State Key Laboratory of Oncology in South China; Guangdong Key Laboratory of Nasopharyngeal Carcinoma Diagnosis and Therapy, Guangzhou, China

Background: T cell immunoglobulin and mucin domain molecule 3 (Tim-3) is an inhibitory immune checkpoint receptor that negatively regulates the immune response. This multicenter, single-arm, two-cohort, phase 2 study (NCT05563480) aimed to explore the efficacy and safety of TQB2618, a novel monoclonal antibody blockading Tim-3, plus PD-1 blockade penpulimab as subsequent-line treatment in immunotherapy-resistant R/M NPC (cohort 1) or as first-line treatment by incorporating into chemotherapy in treatment-naïve R/M NPC (cohort 2). Here, we report the results of cohort 2. **Methods:** Eligible pts were ECOG PS 0–1, aged 18–70, diagnosed with histologically confirmed R/M NPC with ≥ 1 measurable lesion. Previous systemic treatment was not allowed, except as a part of curatively intended treatment for locoregionally advanced NPC and develop disease progression at least 6 months after last dose. TQB2618 and penpulimab were administered intravenously at doses of 1200 mg and 200 mg, respectively, on the first day of a 21-day cycle until disease progression or unacceptable toxicity while gemcitabine (1000 mg/m^2, d1&8) and cisplatin (75mg/m^2, d1) were given intravenously for the first 4–6 cycles. The primary endpoint is progression-free survival (PFS). **Results:** Between February 2023 and October 2023, 30 pts were enrolled (median [range] age, 52 [33–70] years; 16.7% women). Seventeen were diagnosed with metastatic disease at the first visit and others developed disease recurrence after definitive treatment. Liver metastasis was found in 10 pts. Median follow-up was 12.5 months (mo) (95% CI: 12.4–NE) at the data cut-off date on December 20, 2024. The median PFS reached 10.8 mo (95% CI, 9.6–16.4) and the 12 mo- and 15 mo-PFS were 40.9% and 34.1%, respectively. For the 17 pts with PD-L1 positive expression, the median PFS was 13.6 mo (95% CI: 8.4–16.6). The tumor response was complete response in 4 pts (13.3%), partial response in 21 pts (70.0%), stable disease in 4 pts (13.3%), and 1 could not be estimated, giving an objective response rate of 83.3%. A total of two pts died, both due to disease progression after 7.9 mo of enrollment. All pts experienced at least one adverse event (AE) and 25 pts (83.3%) were observed ≥ grade 3 (G3) AEs. The most common AEs of all grades (G1–4) or ≥ G3 were chemotherapy-related, including leukopenia (G1–4: 96.7%; ≥ G3: 40.0%), neutropenia (G1–4: 90.0%; ≥ G3: 36.7%), and anemia (G1–4: 93.3%; ≥ G3: 33.3%). **Conclusions:** To our knowledge, this is the first study to evaluate the addition of Tim-3 blockade to the standard first-line treatment of R/M NPC. The results demonstrated that this combination therapy provided clinical benefits comparable to those observed in the historical cohort treated with PD-1 blockade plus chemotherapy, while maintaining a manageable safety profile. Clinical trial information: NCT05563480. Research Sponsor: Chia Tai TianQing Pharmaceutical Group Co., Ltd; Basic and Applied Research Project of Science and Technology of Guangzhou city.

6032 **Poster Session**

The molecular landscape of immunotherapy treatment and advanced disease in head and neck squamous carcinoma (HNSCC). First Author: George Laliotis, University of Jamestown, Jamestown, ND

Background: Advanced head and neck squamous cell carcinoma (HNSCC) exhibits variable responses to immunotherapy, highlighting the need to understand its complex molecular landscape. While immune checkpoint inhibitors show promise, optimizing treatment and predicting outcomes requires deeper molecular insights. Here, we leverage the cBioPortal for Cancer Genomics, analyzing ~800 HNSCC genomic and transcriptomic profiles, to investigate the molecular landscape influencing immunotherapy response in advanced disease. **Methods:** In this retrospective study, we analyzed publicly available data from 825 HNSCC patients treated with immunotherapy, enrolled in participating institutions between 2017 and 2022, sourced from the cBioPortal for Cancer Genomics. We investigated the frequency of most common mutations, copy number alterations, and mRNA expression levels, along with clinicopathological factors and overall survival (OS). **Results:** Genomic analysis of 809 HNSCC samples revealed TP53 as the most frequently mutated gene (63.5%, 514/809), followed by TTN (37.4%), FRG1BP (20.7%), FAT1 (19.3%), and CDKN2A (19.0%). Other genes were mutated at frequencies between 18.7% and 15.2%. Copy number alterations analysis (n=673) showed frequent homozygous deletions in 9p21.3, affecting CDKN2A-AS1 (30.3%, 158/673) and CDKN2A (26.0%, 175/673), and amplifications in 11q13.3, including PPFIA1 (25.7%), FADD (25.3%), CTTN (25.1%), and ANO1 (25.1%). Notably, TP53 mutations and CDKN2A-AS1 deletions were associated with inferior OS (log-rank $P < 0.001$; mOS mutated vs wild-type 45.93 vs 156.37 months and $P = 0.006$; mOS altered vs non-altered 35.45 vs 65.77 months, respectively). Transcriptomic and GSEA profiling linked these alterations to dysregulation of oncogenic pathways, including DNA replication stress, p21 activation, apoptosis, and immune evasion. **Conclusions:** This study of immunotherapy-treated advanced HNSCC provides a valuable resource for understanding the complex genomic landscape of this disease. We identified frequent mutations and copy number alterations which were associated with inferior OS and linked to dysregulation of key oncogenic pathways. These findings underscore the potential of this to facilitate biomarker discovery and the development of personalized medicine approaches to improve outcomes in advanced HNSCC. 6033 **Poster Session**

Initial safety and efficacy of PDL1V (PF-08046054), a vedotin-based ADC targeting PD-L1, in combination with pembrolizumab in patients with recurrent or metastatic (R/M) HNSCC. First Author: Maura L. Gillison, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: PDL1V is a novel investigational antibody-drug conjugate that delivers monomethyl auristatin E (MMAE) to cells that express programmed cell death ligand 1 (PD-L1) without anticipated checkpoint blockade. Immunogenic cell death via the MMAE payload can be further amplified by traditional immune checkpoint inhibitors, providing strong scientific rationale for combination with pembrolizumab. The objective of Part D of the phase 1 trial is to assess the safety/tolerability and preliminary antitumor activity of PDL1V and pembrolizumab combination in patients with R/M HNSCC. **Methods:** C5851001 (NCT05208762) includes a phase 1 safety run-in cohort (Part D) enrolling patients with untreated R/M HNSCC with PD-L1 CPS $\geq$1 and no prior therapy with anti-PD-1/PD-L1 antibodies in any setting. Measurable disease per RECIST v1.1 and ECOG PS $\leq$1 were required. The first patient group received PDL1V 1.25 mg/kg on days 1 and 8 every 21 days (2Q3W) using adjusted ideal body weight (AIBW). Once safety was demonstrated, a second cohort was initiated at 1.5 mg/kg 2Q3W AIBW. All patients received pembrolizumab 200 mg every 3 weeks. The primary objectives of this study are safety/tolerability and pharmacokinetics. A secondary objective is antitumor activity. **Results:** As of December 20, 2024, 14 patients were dosed; median age was 61 years (range 36–76). Eight patients received 1.25 mg/kg and 6 received 1.5 mg/kg; 92.9% were male, 71.4% had ECOG PS 0, 64.3% were P16 positive oropharyngeal, and 57.1% had CPS 1–<20. Eight patients remain on active therapy at the data cut time. No dose-limiting toxicities (DLTs) were observed. The most frequent PDL1V treatment-related adverse events (TRAEs) were fatigue and nausea (50.0% each), peripheral sensory neuropathy (35.7%), diarrhea (28.6%), and anemia, constipation, decreased appetite, muscle spasms, pneumonitis, and pyrexia (14.3% each); pembrolizumab TRAEs were fatigue (42.9%), diarrhea, and nausea (28.6% each); and abdominal pain, decreased appetite, peripheral sensory neuropathy, pneumonitis, and pyrexia (14.3% each). The most frequent grade $\geq$3 TRAEs for either agent were diarrhea (14.3%) and anemia, decreased appetite, fatigue, and neutropenia (7.1% each). Treatment-related immune-mediated AEs by investigator assessment were observed in 7.1% of patients; 7.1% grade 3. Investigator-assessed, objective response rate at this time for 14 response-evaluable patients was 50.0%; complete response (CR) rate was 21.4%. The median duration of response has not been reached. **Conclusions:** The combination of PDL1V and pembrolizumab was generally well tolerated with no DLTs. Early encouraging objective responses were observed in half of the patients treated, including 21.4% with a CR. Enrollment in multiple combination expansion cohorts in PD-L1 expressing tumors is ongoing. Clinical trial information: NCT05208762. Research Sponsor: Pfizer Inc.

6034 **Poster Session**

A prospective, single-arm, phase II study of adebrelimab plus carboplatin and albumin-bound taxanol as neoadjuvant therapy in patients with resectable locally advanced head and neck squamous cell carcinoma. First Author: Yilin He, Yat-sen Memorial Hospital of Sun Yat-sen University, Guangzhou, China

Background: Currently, clinical studies have shown that patients with tumor remission after preoperative induction chemotherapy have a higher survival rate and a lower risk of distant metastasis, but the pathological complete remission rate of tumor after surgery is low. With the rise of tumor immunology, more and more immunotherapy methods have been applied to the treatment of clinical tumors. In terms of head and neck squamous cell carcinoma, we hereby investigate the efficacy of a PD-L1 inhibitor (Adebrelimab) combined with chemotherapy in patients with resectable advanced head and neck squamous cell carcinoma. **Methods:** This study hypothesized that preoperative induction of PD-L1 inhibitors combined with chemotherapy in patients with resectable advanced head and neck squamous cell carcinoma was superior to conventional chemotherapy regiments recommended by NCCN guidelines. As a course of treatment every three weeks, albumin-bound paclitaxel 260 mg/m2, carboplatin AUC=5 and Adebrelimab 1200 mg were given intravenously on the first day of every three weeks. After three doses, surgery was performed and radiotherapy was performed according to the stage of the tumor. The main index observed in this study was postoperative pathological complete response rate (PCR), and the secondary index was major pathological response rate (MPR) and 2-year survival rate (OS). **Results:** As of December 31, 2024, a total of 30 patients were enrolled in the study. Among them, the median age was 52 years, and 23 patients were male. During immunochemotherapy, the most common adverse reactions were alopecia (100%, 30/30), pruritus (16%, 5/30), and limb weakness (60%, 18/30). At present, 26 patients have completed all preoperative neoadjuvant therapy and successfully received surgical treatment. By comparing the MRI imaging images of these patients before and after medication, the efficacy evaluation of 14 patients was PR (53.9%, 14/26), 1 patient was CR (3.8%, 1/26), 1 patient was PD (3.8%, 1/26), and 10 patients was SD (38.5%, 10/26). In postoperative pathological specimens, 12 patients achieved pathological complete response (PCR: 46%, 12/26) and 3 patients achieved major pathological response (MPR: 11.5%, 3/26). We will follow up these patients and calculate their 2-year survival rate (OS). This study is still ongoing. **Conclusions:** In terms of head and neck squamous cell carcinoma, Phase I clinical studies have confirmed the therapeutic safety and tumor activity of PD-L1 inhibitors. In this Phase II study, the PD-L1 inhibitor (Adebrelimab) demonstrated a favorable therapeutic response to locally advanced head and neck squamous cell carcinoma, and we look forward to final therapeutic data. Clinical trial information: NCT06016413. Research Sponsor: Jiangsu Hengrui Pharmaceutical Co., Ltd.

Survival for head and neck squamous cell carcinoma treated with versus without neoadjuvant systemic therapy: A national propensity score–matched analysis. First Author: Vanessa Helou, Department of Otolaryngology-Head and Neck Surgery, University of Pittsburgh, Pittsburgh, PA

Background: Neoadjuvant systemic therapies, including immunotherapy and chemotherapy, offer a promising approach for treating head and neck squamous cell carcinoma (HNSCC). These therapies aim to reduce tumor burden and enable personalized treatment. While pivotal studies like KEYNOTE 689 may redefine therapeutic paradigms, the survival outcomes associated with neoadjuvant systemic therapies in HNSCC remain underexplored. **Methods:** A retrospective cohort analysis using the National Cancer Database evaluated patients with HNSCC surgically treated with versus without neoadjuvant systemic therapies from 2015 to 2022. Overall survival (OS) was compared by using a Cox proportional hazards regression model. Propensity score matching was performed to adjust for stage, age, sex, race, insurance status, urban/rural, Charlson–Deyo score. **Results:** Among 3,569 patients (74% male, 26% female), 1,311 received neoadjuvant chemotherapy, 632 received neoadjuvant immunotherapy, 114 received a combination of neoadjuvant chemotherapy and immunotherapy, and 1,512 were matched HNSCC patients who did not receive any neoadjuvant therapy prior to surgery. Most patients had overall stage IVa/b (59%) tumors of the oral cavity (62%). On univariate analysis, neoadjuvant immunotherapy alone was associated with a 43% reduced the risk of mortality, compared to neoadjuvant chemotherapy alone (HR: 0.57; 95% CI: 0.48–0.68, $P < .001$). Combination therapy was not significantly associated with lower mortality than chemotherapy alone (HR: 0.87; 95% CI: 0.63–1.21, $P = .41$). After adjustment using a propensity matched cohort of patients with HNSCC treated without neoadjuvant therapy, neoadjuvant immunotherapy was associated with significantly improved OS (HR: 0.55; 95% CI: 0.35-0.75, $P < .001$). However, neoadjuvant chemotherapy (HR: 1.07; 95% CI: 0.96–1.18, $P = .23$) and combination therapy (HR: 0.84; 95% CI: 0.49-1.19, $P = .33$) were not significantly associated with improved OS. **Conclusions:** Neoadjuvant immunotherapy may potentially provide improved survival in HNSCC. Further research is needed to assess these findings through prospective trials. Research Sponsor: None.

Overall survival for patients with head and neck squamous cell carcinoma treated with versus without neoadjuvant systemic therapy.

Overall Survival	HR (95% CI)	P
No neoadjuvant therapy	Ref.	
Neoadjuvant chemotherapy	1.07 (0.96–1.18)	0.23
Neoadjuvant combination therapy	0.84 (0.49-1.19)	0.33
Neoadjuvant immunotherapy	0.55 (0.35-0.75)	<0.001

ctDNA-based clinicogenomic analysis of advanced head and neck cancer patients treated with immune checkpoint inhibitors. First Author: Atul Bharde, OneCell Dx, Pune, India

Background: Head and Neck cancer (HNC) is among the diverse group of malignancies affecting the head and neck region including the oral cavity. Being the most prevalent malignancy in Southeast Asia, it has a high mortality rate. Despite the advancement in treatment, 5 years survival rate for HNC remains below 50%, and the majority of Pts receiving frontline therapy experience locoregional or incurable metastatic relapse. Immune checkpoint inhibitors (ICI) are recommended for relapsed patients, but only 20% of patients show measurable response. Currently, no predictive biomarkers are available to predict ICI response and there is an urgent need for genomic markers to predict ICI outcomes. Here we report comprehensive genomic profiling (CGP) of advanced HNC patients receiving ICI. **Methods:** ctDNA from 69 advanced HNC patients receiving combinational immune-chemotherapy were serially profiled at the baseline (BL) and post-treatment (Tx) by targeted, hybridization-based CGP using OncoIndx comprehensive gene panel (CGP) comprising 1080 genes. The ctDNA differential features at BL and post-Tx as well as among responders (R) and non-responders (NR) were correlated with Progression-free survival (PFS) and Overall survival (OS) using Kaplan-Meier statistics and multivariate analysis. **Results:** Among total patients, 58% (40/69) were responders (R) while the remaining were non-responders (NR). At the population level, HRR pathway tumor suppressors and epigenetic modifiers were the most frequent pathogenic variants. At BL, the NR population was enriched with oncogenic gene mutations compared to the R population. TP53 and BRCA pathway mutations (mTP53 + BRCA) showed a strong association with progression-free survival (PFS) and overall survival (OS). Pts with cooccurring mTP53 + BRCA had significantly lower PFS (median PFS: 2.77 months for mTP53 + BRCA pathway vs 9.1 months for wt TP53 + BRCA pathway. P=$<$0.0001, HR=3.2-11.6) and OS (median OS: 4.67 months for mTP53 + BRCA pathway vs 12.63 months for wtTP53 + BRCA pathway. P=$<$0.0001, HR = 11.18-55.27). NOTCH 1 or 2 variants were enriched in R population, with a beneficial effect on survival outcomes. Elevated ctDNA alterations and Tumor fraction (TF) concentrated in the NR population disproportionately contained subclonal potential drivers of immunotherapy resistance including NF1, STAT5 B, and STK11 mutations, and were associated with short survival. Univariate and multivariate analysis suggested that ctDNA mutations, TF, and high mutational heterogeneity emerged as risk factors for shorter PFS and OS. In contrast, total Indel burden and NOTCH mutations had beneficial effects on PFS and OS. **Conclusions:** Minimally invasive plasma ctDNA CGP showed heterogenous actionable mutations at BL and post Tx and identified immunotherapy resistance conferring genomic markers for stratifying potential responders for immunotherapy guidance. Research Sponsor: None.

Versatile-002: Overall survival of HPV16-positive recurrent/metastatic head and neck squamous cell carcinoma patients treated with T cell stimulating immunotherapy PDS0101 and pembrolizumab. First Author: Jared Weiss, The University of North Carolina at Chapel Hill, Chapel Hill, NC

Background: The incidence of HPV-associated head and neck squamous cell carcinoma (HNSCC) continues to rise with over 90% of cases being driven by HPV16. Median overall survival (OS) with pembrolizumab in first-line recurrent/metastatic (R/M) HNSCC is 12.3 months in subjects with CPS $\geq$1, 10.8 months for CPS $\geq$1-19, and 14.9 months for CPS $\geq$20. There is an urgent need to improve survival rates in the growing population of HPV16-positive R/M HNSCC. PDS0101 (Versamune HPV) is an investigational T cell stimulating immunotherapy that unleashes a potent, durable attack against HPV16-positive cancers and is being studied in combination with pembrolizumab. Preliminary results were presented at ASCO 2023. (Price KAR, et al. ASCO 2023. Abstract 6012). **Methods:** VERSATILE-002 is a single-arm phase 2 study evaluating PDS0101 and pembrolizumab for first-line HPV16-positive R/M HNSCC with CPS $\geq$1. Subjects received pembrolizumab 200 mg IV Q3W with PDS0101 1 mL SC administered concurrently during Cycles 1, 2, 3, 4, and 12 and pembrolizumab alone for all other Cycles up to Cycle 35 (approx. 2 years). The primary study endpoint is confirmed objective response rate (ORR) per RECIST 1.1. Secondary endpoints include progression-free survival (PFS), OS, and safety. **Results:** The median follow-up is 18.4 months (range 0.2-42.7 months). The efficacy population consists of 53 subjects: 32 (60%) with CPS $\geq$1-19 and 21 (40%) with CPS $\geq$20. The median OS for subjects with CPS $\geq$1 is 30 months (95% CI 23.9, NE). For the CPS $\geq$1-19 subgroup, the median OS is 29.5 months (95% CI 15.3, NE). For the CPS $\geq$20 subgroup, the median OS is 39.3 months (95% CI 18.4, NE). Confirmed response rates by investigator assessment are shown in the Table. Twenty-three subjects are still on study: 3 on treatment and 20 in long-term follow-up. No new safety signals have emerged. The most common TRAEs are injection site reactions, fatigue, headache, and pruritus. Only 19% of subjects experienced Grade $\geq$3 TRAEs. No subject had a Grade 5 TRAE. **Conclusions:** These data represent one of the most extended follow-up periods to date of subjects receiving an HPV16-targeted therapy for HPV16-positive R/M HNSCC. The PDS0101 and pembrolizumab combination is well tolerated and has demonstrated deep and durable clinical responses. Median OS is promising in light of historic expectations, both overall and relative to PD-L1 subgroup, and remains durable with continued follow up. The results support further evaluation in a randomized phase 3 study with OS as the primary endpoint. Clinical trial information: NCT04260126. Research Sponsor: PDS Biotechnology Corporation.

Summary of results.

	CPS ≥1-19 (N=32)	CPS ≥20 (N=21)	CPS ≥1 (N=53)
ORR, %	28.1	47.6	35.8
DCR, %	75.0	81.0	77.4
Median DOR, months (95 % CI)	21.8 (4.2, NE)	NE (5.6, NE)	21.8 (11.5, NE)
Median PFS, months (95% CI)	5.1 (2.4, 8.1)	14.1 (2.1, NE)	6.3 (3.5, 9.0)
Median OS, months (95% CI)	29.5 (15.3, NE)	39.3 (18.4, NE)	30.0 (23.9, NE)

Assessing the safety and efficacy of GT201: A first-in-class autologous tumor-infiltrating lymphocyte monotherapy in advanced solid tumors. First Author: Pin Wang, Grit Biotechnology, Shanghai, China

Background: For patients with unresectable recurrent or metastatic solid tumors that progress after chemotherapy, immune checkpoint inhibitors (ICIs), or targeted therapy, treatment options are limited. GT201, featuring membrane-bound IL-15 (mbIL-15) expressed on TILs, aims to enhance immune activation in the tumor microenvironment and may demonstrate efficacy and durable responses in these advanced cases. We present data from nine patients enrolled in open-label, single-arm studies to investigate the safety and efficacy trends of GT201 therapy. **Methods:** The GT201 study's primary endpoint was to assess TEAEs, including SAEs and AEs, using the CTCAE version 5.0 grading scale. The secondary endpoint focused on preliminary efficacy parameters, including ORR, DCR, PFS, DOR, OS following RECIST v1.1 guidelines. **Results:** As of January 15, 2025, nine patients have been enrolled in the study, with a median age of 52 years and a median of two prior therapy lines. Among them, one patient had bone metastases, two had liver metastases, and one had brain metastases. After standard FC lymphodepletion, patients received GT201 infusions at doses of $\geq 5\times10^9$ viable cells. Seven patients subsequently received IL-2 post-infusion. Most adverse events (AEs) were Grade 1 or 2. Grade $\geq$3 AEs, related to lymphodepleting chemotherapy and IL-2, included decreased lymphocyte, neutrophil, and white blood cell counts, pyrexia, and tachycardia. All Grade $\geq$3 AEs resolved or downgraded to Grade $\leq$2 within 14 days. Among the nine response-evaluable patients with various cancers, including head and neck squamous cell carcinoma (HNSCC), non-small-cell lung cancer (NSCLC), melanoma, cervical cancer, and ovarian cancer, the objective ORR was 55.6% (5/9), and the disease control rate (DCR) was 77.8% (7/9). One patient (11.1%) achieved complete response (CR), four (44.4%) had partial responses (PR), and two (22.2%) had stable disease (SD) as their best response. Notably, in the HNSCC subgroup, both patients achieved objective responses (CR and PR) (2/2, 100%). In the NSCLC subgroup, all three patients achieved disease control (SD $\geq$24 weeks or PR) (3/3, 100%). GT201 cells were detected in all patients, indicated by IL15RA protein staining on peripheral T cells and transgene copy number in peripheral white blood cells. GT201 cells expanded robustly and persisted in peripheral blood for at least six months post-infusion. **Conclusions:** In patients with heavily pretreated advanced or metastatic solid tumors, GT201, infused after FC lymphodepleting chemotherapy and high-dose IL-2, exhibited a manageable safety profile. GT201 demonstrated a favorable clinical profile in HNSCC, with an encouraging objective response rate and durable responses. No Grade $\geq$3 adverse events related to GT201 treatment were observed, supporting its potential as a treatment option worth further exploration. Clinical trial information: NCT05729399, NCT06190275. Research Sponsor: None.

Two cycles of neoadjuvant therapy with low-dose radiotherapy, PD-1 inhibitor tislelizumab, albumin-bound paclitaxel, and cisplatin for resectable locally advanced head and neck squamous cell carcinoma (NeoRTPC02): A phase II, open-label, single-arm trial. First Author: Zhigang Liu, Cancer Center, the tenth Affiliated Hospital of Southern Medical University (Dongguan People's Hospital), Southern Medical University, Dongguan, China

Background: Despite standard treatments, mortality rates remain high in locally advanced head and neck squamous cell carcinoma (LA HNSCC). Neoadjuvant immunotherapy combined with chemotherapy has improved response rates, but further enhancement is needed. Recent studies suggest that low-dose radiotherapy (LDR) can reprogram the tumor microenvironment, reversing immune suppression and improving the efficacy of PD-1 inhibitors. This study aims to evaluate the safety and efficacy of neoadjuvant LDR combined with tislelizumab and chemotherapy in LA HNSCC. **Methods:** This was an open-label, single-arm, phase II clinical trial for patients with untreated, histologically confirmed stage III-IVB HNSCC. Patients received neoadjuvant low-dose radiotherapy (1 Gy/1F, days 1, 2, 8, and 15, Q3W) combined with tislelizumab (200 mg, day 1, Q3W), albumin-bound paclitaxel (100 mg/m^2, days 1, 8, and 15, Q3W), and cisplatin (25 mg/m^2, days 1, 8, and 15, Q3W) for two cycles. Afterward, patients underwent radical surgery approximately 4 weeks later. The primary endpoint was the pathological complete response (pCR) rate, while secondary endpoints included major pathological response (MPR) rate, ORR, R0 resection rate, safety, and treatment-related surgical delay rate. The exploratory endpoints were the 3-year progression-free survival and 3-year overall survival. To further investigate the underlying mechanisms of treatment effects, we used single-cell RNA sequencing (scRNA-seq) to explore how this combination modulates the tumor microenvironment(TME) in HNSCC. **Results:** A total of 37 patients were assessed for eligibility, of which 28 patients were enrolled and received the assigned neoadjuvant treatment. A total of 23 patients proceeded to surgery, and pathological response evaluation was conducted in these patients. Among the 23 patients, 14 (60.9%) achieved pCR, and the MPR and pCR/MPR rates were 21.7% and 82.6%, respectively. The ORR was 64.3% (18/28), including 2 (7.1%) complete response and 16 (57.1%) partial response. The R0 resection rate was 100%. Treatment-related adverse events (TRAEs) were manageable, with grade 3 or 4 TRAEs occurring in 12 (42.9%) patients. The main side effects included neutropenia and decreased white blood cell count. No surgical delays were observed. ScRNA-seq results suggested that this neoadjuvant regimen may reshape the HNSCC TME by enhancing adaptive immunity and potentially increasing FOLR2$^+$ macrophage infiltration. **Conclusions:** Neoadjuvant LDR combined with tislelizumab, albumin-bound paclitaxel, and cisplatin resulted in an impressive pCR rate and demonstrated promising efficacy with manageable toxicity in patients with resectable LA HNSCC. Long-term survival data are still follow-up. Clinical trial information: NCT05343325. Research Sponsor: Beijing Xisike Clinical Oncology Research Foundation.

6040 Poster Session

Effect of induction chemo-immunotherapy on the chance for re-irradiation in high-risk recurrent nasopharyngeal carcinoma: A prospective, single-arm, phase II trial. First Author: Jingjing Miao, Department of Nasopharyngeal Carcinoma, Sun Yat-Sen University Cancer Center, State Key Laboratory of Oncology in South China, Guangdong Key Laboratory of Nasopharyngeal Carcinoma Diagnosis and Therapy, Guangdong Provincial Clinical Research Center, Guangzhou, China

Background: The PRANCIS model has been shown to be robust for identifying patients with recurrent nasopharyngeal carcinoma (rNPC) who are at high risk of treatment-related adverse events from re-irradiation (reRT). Here, we investigate the efficacy of combination doublet gemcitabine-cisplatin (GP) and PD-1 inhibitor (Toripalimab) to down-classify PRANCIS high risk (>252) to low-risk post-3 cycles of treatment, and the survival outcomes of these patients. For patients who converted to low-risk, reRT may be considered (NCT03930498). **Methods:** Eligibility criteria included diagnosed as local ± regional recurrence after ≥1 year of radical treatment, not suitable for surgery, histologic or clinically diagnosis of NPC, stage rII-IVa (AJCC/UICC 8th), PRANCIS model > 252 points. All patients received 3 cycles of GP + PD-1 inhibitor, then received reRT (GTV, 60-66Gy, 1.8-2.0Gy/f) plus PD-1 inhibitor if got CR/PR (reRT group), or received another 3 cycles of GP+PD-1 inhibitor if got SD (no reRT group), finally all got 4 cycles of PD-1 inhibitor maintenance. Primary end point was 2-year overall survival (OS). **Results:** Between Mar 2020 to Nov 2023, 68 high-risk patients were recruited (Table 1). After 3 cycles of GP + PD-1 inhibitor, 44 (64.7%) patients got PR (34 down-classify to low-risk and 10 still high-risk) and received full-course reRT, 22 (32.4%) got SD (all high-risk) and kept receiving GP + PD-1 inhibitor, and 2 (2.9%) could not be evaluated due to 1 died of COVID-19 and 1 withdrew after 2 cycles of treatment. 56 (82.4%) patients finished the scheduled treatment, and 12 discontinued chemo-immunotherapy. With a median follow-up time of 32.7 months, the 2-year OS of whole cohort was 67.2%, and 73.8% vs 51.2% (P = 0.019) in reRT group vs no reRT group. The 2-year progression-free survival (PFS) of whole cohort was 47.9%, and 61.0% vs 24.3% (P < 0.0001) in reRT group vs no reRT group. The most common ≥grade 3 toxicities included neutropenia (30.9%), lymphopenia (22.1%), and xerostomia (16.2%). The incidences of grade 3 nasopharyngeal necrosis was 5.9%. Two (2.9%) patients died of massive nasal bleeding. **Conclusions:** Induction chemo-immunotherapy offered the chance of reRT for high-risk rNPC patients and improved their overall survival with acceptable toxicities. Clinical trial information: NCT03930498. Research Sponsor: National Natural Science Foundation of China for Young Scholars; Sun Yat-sen University Young Teachers Cultivation Program; Sun Yat-sen University Cancer Center 308 Program.

Optimal maintenance therapy strategy for metastatic nasopharyngeal carcinoma: Insights from a cohort study in an endemic region. First Author: Zhuoying Luo, Sun Yat-sen University Cancer Center, Guangzhou, Guangdong, China

Background: Managing metastatic nasopharyngeal carcinoma (mNPC) remains challenging due to its high incidence and mortality rates. While maintenance therapy shows promising potential, the optimal strategy remains unclear. A prior ranking question is if combined therapy of anti-PD-1 antibodies and capecitabine an effective maintenance strategy for mNPC patients who achieved disease control after first-line therapy. **Methods:** Eligible patients with mNPC who achieved disease control following first-line therapy and subsequently received maintenance therapy were included at Sun Yat-sen University Cancer Center between 2018 to 2023. Progression-free survival and overall survival were analyzed using the Kaplan–Meier method and log-rank test. Cox proportional hazards model and inverse probability of treatment weighting analysis were applied to adjust for confounders. Based on interaction effects, stratification analysis was performed. A sensitivity analysis was based on the E-value from the weighted Cox proportional hazards model. **Results:** This cohort study included 300 mNPC patients receiving maintenance therapy with monotherapy (n=211), anti-PD-1 immunotherapy (n=94) or capecitabine (n=117), and their combination (n=89). 234 patients (78.0%) were male, and the median age was 45 years (interquartile range [IQR]: 36–54). At median follow-up of 37.8 months (IQR: 35.6–40.1), combination maintenance significantly improved progression-free survival (PFS) compared to single-drug maintenance [median PFS: not reached *vs* 27.0 months; weighted hazard ratio (HR): 0.569, 95% Confidence Interval (CI): 0.368-0.878, *P* = 0.011; E-value, 2.32], though no improvement in overall survival was observed. Stratification analysis revealed enhanced efficacy of combination maintenance in patients without prior local treatment (HR: 0.411, 95% CI: 0.266–0.748, *P* = 0.004) or with elevated pre-maintenance Epstein-Barr virus (EBV) DNA levels (HR: 0.312, 95% CI: 0.106–0.917, *P* = 0.034). No significant difference in prognosis was observed between capecitabine and anti-PD-1 monotherapy groups. Combination regimen obtained significantly superior progression-free survival compared to either monotherapy alone. The safety profile was similar between combination maintenance and single-drug groups. **Conclusions:** Combined anti-PD-1 and capecitabine maintenance therapy significantly improved prognosis in mNPC with disease control after first-line therapy, particularly in patients with elevated premaintenance EBV DNA levels or those without local treatment. Major pathological response to neoadjuvant immune-related therapy and influence on long-term survival in patients with locally advanced oral squamous cell carcinoma. First Author: Lai-ping Zhong, Department of Oromaxillofacial Head and Neck Surgery, Center for Oromaxillofacial Head and Neck Disorders, Huashan Hospital, Fudan University, Shanghai, China

Background: In neoadjuvant immune-related therapy (NAIT) for patients with locally advanced oral squamous cell carcinoma (LAOSCC), it has been highly anticipated whether major pathological response (MPR) can translate into long-term survival benefits. The aim of this study was to demonstrate the relationship between MPR to NAIT and long-term survival in LAOSCC. **Methods:** Two single-arm trials were included in this study on NAIT of neoadjuvant immunochemotherapy (NAICT) with Toripalimab plus albumin paclitaxel/cisplatin (NCT04473716) or neoadjuvant immunotarget therapy (NAITT) with Camrelizumab plus Apatinib (NCT04393506) in LAOSCC patients at clinical stage III and IVA (AJCC 2018). The patients received two cycles (21 days each) of NAICT with intravenous albumin paclitaxel (260mg/m^2), cisplatin (75mg/m^2) and Toripalimab (240mg) on day 1 and day 22; or three cycles of NAITT with intravenous Camrelizumab (250mg) on d1, d15, d29, and oral Apatinib daily, initiating on d1, ending on the 5th day before surgery. Then, radical surgery and post-operative radiotherapy/chemoradiotherapy was performed. Primary tumors were assessed for the percentage of residual viable tumor that was identified on HE staining, and tumor with no more than 10% viable tumor cell was considered as MPR. **Results:** From April 2020 to April 2021, 40 patients received NAIT and radical surgery. The rate of CPS>10 in the biopsy and the MPR rate was 20% and 60% in the NAICT group, 24% and 40% in the NAITT group, respectively. The follow-up period ranged from 45 to 53 months. The 4-year OS and DFS rate was 90% and 85% in the NAICT group, 90% and 80% in the NAITT group. In the patients archived MPR, the 4-year OS and DFS rate was 100% and 95%, in the non-MPR patients, the 4-year OS and DFS rate was 80% and 70%. In the nine patients with CPS>10, they were all alive without local tumor recurrence or metastasis. **Conclusions:** NAICT and NAITT are safe and effective, the LAOSCC patients with CPS>10 or archiving MPR could have long-term survival benefit from NAIT. Clinical trial information: NCT04473716, NCT04393506. Research Sponsor: None.

Neoadjuvant immunotherapy in combination with chemotherapy in resectable locally advanced head and neck squamous cell carcinoma: A randomized, open label, phase II clinical trial. First Author: Lei Liu, Division of Head & Neck Tumor Multimodality Treatment, Cancer Center, West China Hospital, Sichuan University, Chengdu, China

Background: The efficacy and safety of neoadjuvant immunotherapy (NAI) for resectable locally advanced head and neck squamous cell carcinoma (LAHNSCC) remain unclear, requiring further exploration. While PD-1 inhibitors combined with chemotherapy have shown promise, most regimens focus on single-target inhibitors. Dual-target inhibitors, such as PD-1/CTLA4 or PD-1/VEGF combinations, demonstrated superior efficacy in recurrent/metastatic HNSCC. This study aims to compare the efficacy and safety of single- and dual-target NAI combined with chemotherapy for resectable LAHNSCC to identify the optimal strategy. **Methods:** This phase II randomized trial will enroll resectable LAHNSCC patients eligible for surgery. Patients will be randomized into three cohorts: Cohort 1 will receive ivonescimab (PD-1/VEGF antibody, 10 mg/kg), Cohort 2 will receive cadonilimab (PD-1/CTLA-4antibody, 6 mg/kg), and Cohort 3 will receive penpulimab (PD-1 antibody, 200 mg), all in combination with cisplatin and nab-paclitaxel. Dose adjustments are allowed based on toxicity, and surgery will be performed within 2-4 weeks after 3 cycles of neoadjuvant treatment. Patients achieving pCR will receive 16 cycles of adjuvant immunotherapy. Those without pCR will undergo adjuvant radiotherapy or chemoradiotherapy, followed by 16 cycles of adjuvant immunotherapy. The primary endpoints were pCR and safety. Secondary endpoints include MPR, ORR, EFS and OS. **Results:** A total of 24 patients were enrolled, with 13 evaluable for analysis. The median age was 58 (range 34-70). The primary site included oral cavity (n=7), oropharynx (n=2, including 1 HPV-positive), and larynx (n=4). The clinical stages were as follows: T2 (n = 3), T3 (n = 6), T4a (n = 5), and cN0/1 (n = 3), cN2 (n = 9), cN3 (n = 1). The pCR rates were 80% (4/5), 0% (0/2), and 66.7% (4/6) in Cohort 1, 2, and 3, respectively. The major pathologic responses (MPR) rates were 80% (4/5), 100% (2/2), and 66.7% (4/6) in Cohort 1, 2, and 3, respectively. Pathological non-response (pNR) occurred more frequently in Cohort 3 (2/6) and absent in Cohorts 1 (0/5) and 2 (0/2). The ORR was 100% in Cohort 1 (CR: 3/5, PR: 2/5) and Cohort 2 (100%, PR: 2/2), while Cohort 3 showed a lower ORR of 83.3% (CR: 3/6, PR: 2/6, SD: 1/6). There were no Grade ≥3 TRAEs or unexpected surgical delays/complications. **Conclusions:** Neoadjuvant single- or dual-target immunotherapy combined with chemotherapy showed promising pathological responses in resectable LAHNSCC. While dual-target therapy showed potential benefits, the small sample size limits definitive conclusions. The treatment was well-tolerated, with no serious TRAEs. Further analyses will be conducted as patient enrollment continues in larger cohorts. Clinical trial information: NCT06444009. Research Sponsor: None.

Spatial transcriptomics analysis to predict response to immune checkpoint blockade (ICB) in recurrent or metastatic head and neck squamous cell cancer (RM-HNSCC). First Author: Grégoire Marret, Division of Medical Oncology and Hematology, Princess Margaret Cancer Centre, University Health Network, University of Toronto, Toronto, Canada

Background: Spatial transcriptomics (ST) revealed conserved malignant leading edge (LE) and tumor core (TC) architectures in primary oral squamous cell carcinoma (OSCC) with potential for biomarker discovery. Spatial organization of tumor cells, as well as composition and prognostic significance of neighboring stromal cells in RM-HNSCC remain unknown. **Methods:** 21 tumor biopsy samples (14 baseline, 7 paired on-treatment) from 14 ICB-naive RM-HNSCC patients (pts) treated with pembrolizumab in INSPIRE (NCT02644369) were profiled using 10x Visium. Spatial organization was refined by scoring LE and TC gene sets identified in OSCC (Arora and Bose et al. Nat Comm 2023). Malignant (2,671 spots) and nonmalignant (8,177 spots) subclusters were annotated, with the latter classified into five cell subtypes using canonical markers: tumor-associated macrophages (TAMs) (*CD68*, *CD14*, *SCF1R*), regulatory stromal cells (reg) (*KRT17*, *COL10A1*, *SRBP1*), plasma cells (*CD38*, *IRF4*, *PRDM1*), T cells (*CD3D*, *CD3E*, *PTPRC*), and cancer-associated fibroblasts (CAFs) (*FAP*, *COL1A1*, *PDGFRB*). Neighborhood analyses compared normalized counts of stromal cells adjacent to LE and TC, accounting for variations in cell density and sampling differences. A signature was built through *k*-means clustering of the five cell subtypes. Pts were stratified into high/low signature-score groups using the median cutoff and tested for association with progression-free survival (PFS). **Results:** Spatial organization revealed conserved malignant subclusters (C0 and C1) in 19/21 samples from 13 pts (11 non-responders). Top C0 genes were *COL21A1*, *S1PR3*, *LIFR*, and *ZEB1*. Top C1 genes were *KRT6B*, *KRT6C*, *KRTDAP*, and *LCN2*. Pathway analysis predicted activation of cell cycle and glycoprotein 6 in C0, and keratinization and neutrophil degranulation in C1. Comparative expression of OSCC-related gene sets revealed LE correlation with C0, and TC correlation with C1 (both $p <$ 0.0001); stronger overlap was seen with the latter highlighting TC as a more conserved feature in HNSCC. Among non-responders, dominant communication patterns in LE and TC included claudins, cadherins, WNT, and IL-6, linked to cell adhesion, migration/invasion, and immune evasion. Signature generated by neighborhood analysis was enriched in TAMs and T cells, depleted in CAFs and reg near LE and TC, while plasma cells were depleted near LE but enriched near TC. Pts with high signature scores (6/13) exhibited improved PFS compared to low scores (7/13), median PFS 6.0 months [95% CI, 2.3-NA] versus 1.9 months [95% CI, 1.8-NA] (p = 0.059). **Conclusions:** To our knowledge, this is the first report using ST analysis to characterize LE and TC architectures in RM-HNSCC, along with heterogeneous neighboring stromal cells with prognostic potential for ICB. Ongoing cohort expansion will elucidate the clinical significance of these findings. Research Sponsor: G. M. is supported by CRIS-Princess Margaret Cancer Centre Drug Development Fellowship Program.

Effect of fusion of radiomic, pathomic, and clinical biomarkers on multi-scale tumor biology and OS stratification in HNSCC receiving standard of care (SOC). First Author: Omid Haji Maghsoudi, Picture Health Inc., Cleveland, OH

Background: SOC immunotherapy (IO) for head and neck squamous cell carcinoma (HNSCC) has limited efficacy with inadequate biomarkers (BMs), necessitating improved strategies. Routine radiology and pathology scans provide underutilized tumor data that can address this need. BMs built from these scans can be integrated - along with existing BMs and clinical data - into multimodal predictors for improved stratification by clinical benefit. We evaluated (1) separate BMs using radiomics, pathomics, or clinical data, (2) their cross-modality correlations, and (3) a fused multimodal predictor of overall survival (OS). **Methods:** 100 HNSCC patients (96% male; mean age: 55 yrs; mean BMI: 22.6) treated primarily with pembrolizumab or nivolumab $\pm$ chemotherapy in 1L setting were analyzed. Radiomic and pathomic features were extracted via the Picture Health Px Platform. Tumors and adjacent vessels were segmented on pre- and on-treatment CT. Radiomic features (shape, texture, quantitative vessel tortuosity) were extracted, and longitudinal changes were distilled into feature clusters. Pathomics features of tumor and immune cell nuclei morphology and spatial interactions were extracted from baseline H&E whole-slide images. Clinical variables included: PD-L1 CPS, local/regional/distant recurrence, M stage, oral/non-oral cavity site, P16 status, and BMI. Uni- and multimodal models were trained and evaluated by cross-validation to predict OS. **Results:** Radiomics and pathomics models outperformed the clinical model, P16 (HR=0.9, p=0.82) and PD-L1 status (HR=0.7, p=0.08) alone. A fused multimodal model of 6 radiomic clusters, 10 pathomic features, and 6 clinical variables achieved strongest OS stratification (Table 1). High pathomic tumor-immune cell interaction - indicating immune activation - was associated with PD-L1 (p=0.020) and P16 status (p$<$1e-5), and tied to on-treatment decreases in radiomic wavelet-entropy features of heterogeneity (r=-0.30, p=0.044) and increases in radiomic structural homogeneity (r=0.27, p=0.024). Despite these correlations, each modality contributed independently to the multimodal prediction (R2$<$0.03), emphasizing complementarity. **Conclusions:** A multimodal BM integrating radiology and pathology to capture tumor properties (heterogeneity, angiogenesis, immune infiltration, nuclei morphology) refined understanding of tumor behavior and IO outcome. Findings suggest an interpretable multimodal BM may better identify high-risk patients who would benefit from alternative therapies, enabling more personalized and effective HNSCC management. Research Sponsor: Genmab.

ctDNA tumor fraction (TF) to predict response to nivolumab in recurrent or metastatic (R/M) head and neck squamous cell carcinoma (HNSCC): An analysis of the multicentric phase 2 TOPNIVO trial. First Author: Filippo Gustavo Dall'Olio, Institut Gustave Roussy, Villejuif, France

Background: Anti-PD1 provides clinical benefits in HNSCC, yet biomarkers of response remain poorly defined. In other cancer types, measures of ctDNA shedding, such as TF, have been shown to correlate with treatment outcomes. Little is known about ctDNA shedding in HNSCC and its prognostic role. TOPNIVO was a single-arm phase 2 trial designed to assess the tolerability of nivolumab in pretreated R/M HNSCC. The aim of this study is to explore plasma estimation of TF with plasmatic ctDNA and its prognostic role in HNSCC patients receiving nivolumab at 2nd line or later. **Methods:** Plasma samples were obtained at baseline in the phase 2 TOPNIVO study (NCT03226756), just before treatment initiation. Genomic copy number alteration and TF were investigated using low-pass Whole Genome Sequencing performed with ctDNA extracted from plasma. Bioinformatic analysis was based on the ichorCNA (V0.2.0). TF $>$ 3% was considered positive. For Tumor Volume (TV) assessment, primary and secondary lesions were analyzed. When available, all lesions were included if fewer than five were present; otherwise, at least five per organ were manually delineated by two experienced physicians. Volume of each lesion were extracted using LIFEx software V.3.44 (Local Image Feature Extraction, www.lifexsoft.org). Patient's TV was then defined by the sum of the volume of all measured lesions. Primary endpoint was overall survival (OS). **Results:** Plasma samples were available for 86 out of 343 patients, with no major differences compared to the overall cohort in terms of baseline characteristics. In particular, 65 (76%) were male, 12 (14%) had an ECOG PS of 2, 42 (49%) had locally recurrent disease only, and 9 (10%) had HPV-positive oropharyngeal disease. ctDNA TF was positive in all patients (median TF 7.4%, range 4.8% to 35.9%). Median OS of the selected population was 7.4 months (95% CI 5.4 - 11.2). TF was correlated with TV (Spearman 0.31, p = 0.008). Moreover, it was higher in patients with liver metastasis (n = 8, median TF 14% vs 7 %,) and, for oropharynx, higher in patients with HPV positive disease (n= 9 vs 30, median TF 17% vs 6.7%,). TF was correlated with OS both in univariate (Hazard Ratio - HR 1.9, p = 0.015) and multivariate Cox models (HR 3.12, p = 0.003). **Conclusions:** In HNSCC patients of the TOPNIVO study, ctDNA TF was always detectable and depends on tumor volume and on the biology of the disease. TF retains independent prognostic validity. More translational data will be presented on biological correlates of ctDNA shed. Research Sponsor: None.

Phase 2 trial of ozuriftamab vedotin (BA3021), a conditionally binding ROR2-ADC, in patients with heavily pretreated squamous cell carcinoma of the head and neck. First Author: Douglas Adkins, Washington University School of Medicine, St. Louis, MO

Background: Recurrent or metastatic squamous cell carcinoma of the head and neck (R/M SCCHN) represents a marked unmet need. ROR2 is a cell-surface transmembrane receptor protein tyrosine kinase highly expressed in several tumor types including HNSCC. Ozuriftamab vedotin is a conditionally binding ROR2 antibody-drug conjugate designed to reduce off-tumor toxicity and improve pharmacokinetics by conditionally binding to ROR2 under low-pH conditions (pH$<$6.7) of the tumor microenvironment, thus sparing normal tissue. This novel mechanism avoids tissue-mediated drug disposition and improves pharmacokinetics. The recommended Phase 2 dose of 1.8 mg/kg was determined from the Phase 1 trial (NCT03504488). **Methods:** This multi-center, open-label, single-arm Phase 2 trial evaluated ozuriftamab vedotin in patients (pts) with R/M SCCHN previously treated with anti-PD-1 agents. Patients with SCCHN were enrolled and received 1.8 mg/kg of ozuriftamab vedotin given in 2 schedules: once every two weeks (Q2W) or days 1 and 8 of a 21-day cycle (2Q3W). Tumor assessments were conducted by CT or MRI every 6 weeks from Cycle 1 Day 1 until week 12, then every 8 weeks up to 1 year. Evaluable pts included those with at least one post-treatment scan. ROR2 expression was characterized by immunohistochemistry. Additional assessments included pharmacokinetic, pharmacodynamic, immunogenicity, and biomarker evaluations to characterize efficacy and safety. **Results:** As of May 31, 2024, 31 pts received ozuriftamab vedotin either Q2W (n=12) or 2Q3W (n=19) for a median of 84 days. Pts had a median of 3 prior lines of therapy, and all had experienced failure of anti–PD-1 therapy. Among 28 evaluable pts (evaluable as defined as having complete 1 post dose tumor assessment) for best overall response, there were 10 responders (36%; 1 confirmed complete response, and 5 confirmed/4 unconfirmed partial responses, and 14 stable disease. A disease control rate of 86% was observed. Median duration of response for all confirmed responders has not been reached ($>$3.6 months; 95% CI, 0.4–NE). Most adverse events (AEs) were grade 1-2, with fatigue (59%), anemia (34%), and nausea (34%) being the most frequent. Six pts (19%) experienced grade 3 treatment-related AEs (TRAEs). Two pts experienced a grade 4 TRAE (1 pt with hyponatremia in 2Q3W cohort, and 1 pt with neuropathy in Q2W cohort). No grade 5 TRAEs were observed. **Conclusions:** Pts treated with ozuriftamab vedotin achieved a high rate of disease control with acceptable tolerability. Shows promising efficacy, including in pts refractory to anti-PD1 and warrants further evaluation in SCCHN. Clinical trial information: NCT03504488. Research Sponsor: None.

Establishment and validation of a dynamic prognostic model using serial circulating tumor DNA (ctDNA) for endemic EBV-related nasopharyngeal carcinoma (NPC): A secondary analysis of EP-SEASON. First Author: Zi-Cheng Zhen, Department of Radiation Oncology, Sun Yat-sen University Cancer Center, State Key Laboratory of Oncology in South China, Guangdong Key Laboratory of Nasopharyngeal Carcinoma Diagnosis and Therapy, Guangdong Provincial Clinical Research Center for Cancer, Guangzhou, China

Background: Published risk prediction tools have focused on pretreatment factors, whereas the accuracy remains challenging in cancer care. Emerging evidences emphasize the dynamic rather than static recurrence risks during treatment course, and non-invasive diagnostics tools have advanced opportunities for serial tumor assessments. Here, we present an effective dynamic risk individualized prediction model (NPC-DRIM) incorporating serial ctDNA data, using the endemic EBV-related NPC as a model. **Methods:** This study included 1000 patients (pts) enrolled from a prospective biomarker study EP-SEASON, with complete longitudinal ctDNA data at 11 timepoints across treatment: after each neoadjuvant chemotherapy (NAC) circle (T1-3), every week during radiotherapy (T4-T9), within 1 week after radiotherapy (T10), and 1-3 months after radiotherapy (T11). Pts were divided into subcohort$_{NAC}$ (n=752) and subcohort$_{no\text{-}NAC}$ (n=248) according to receiving NAC or not, and randomly 70/30% split into training and validation cohort. Time-series and statistical features characterizing the dynamic change of ctDNA at each timepoint were extracted. The NPC-DRIM at T3-T11 were developed using the features selected via Cox univariate analysis in training cohort and then validated. The performance of NPC-DRIM was determined by C-index, time-dependent AUC, calibration curves, and decision curves, and compared with existing models. **Results:** The NPC-DRIM incorporated 4 clinical variables, 8 time-series features and 10 statistical features of ctDNA data. The C-index for predicting recurrence increased with time: 0.64 at T2, 0.69 at T3-T4, 0.70 at T5, 0.71 at T6, 0.73 at T7-T9, 0.77 at T10, and 0.76 at T11 in subcohort$_{NAC}$; 0.70 at T5, 0.68 at T6, 0.82 at T7, 0.78 at T8, 0.73 at T9, 0.74 at T10, and 0.83 at T11 in subcohort$_{no\text{-}NAC}$. The NPC-DRIM at T11 had statistically improved outcome prediction compared to other dynamic models (Landmark Cox and Joint Model), and static models (AHR_Chen, RPA_Guo, RPA_Lee, and AJCC_8th staging system) (Table). For individualized dynamic risk prediction, we developed a web-based calculator to visualized the estimated changing recurrence risks. In addition, we showed that the high-risk pts identified by NPC-DRIM benefit from immune checkpoint inhibitors (ICI), while the low-risk pts did not. **Conclusions:** We introduce for the first time that the dynamic risk prediction model NPC-DRIM outperformed the conventional models, facilitating personalized therapeutic paradigms. Mechanisms of resistance to anti-PD1 treatment in recurrent and/or metastatic squamous cell carcinoma of the head and neck: A multi-omics IMMUCAN/EORTC analysis. First Author: Athenais van der Elst, Université Catholique de Louvain, Bruxelles, Bruxelles, Belgium

Background: Anti-PD1 therapies improve overall survival (OS) in recurrent/metastatic (R/M) squamous cell carcinoma of the head and neck (SCCHN), but only a minority of patients (pts) achieve durable responses. The mechanisms driving resistance to anti-PD1 in SCCHN remain poorly understood. **Methods:** Using the IMMUcan multi-omics workflow combining WES, RNAseq, multiplex immunofluorescence and Imaging mass cytometry, we characterized the molecular and immune profiles of R/M SCCHN progressing on anti-PD1 treatment and compared them to an anti-PD1-naïve cohort. **Results:** 74 R/M SCCHN patients who progressed on PD1 inhibitors at the time of tumor biopsy were analysed and compared to a different cohort of 79 R/M SCCHN patients naïve of any anti-PD1 treatment. Among the 74 anti-PD1 resistant patients, 60 patients had primary resistance, and 14 had secondary resistance. Compared to anti-PD1 naïve SCCHN, tumor biopsies from anti-PD1 resistant SCCHN patients exhibited significantly more *EGFR*, *MYCL* and *RRAGC* amplifications, and more genomic alterations of the MYC pathway. Tumor samples harboring MYC pathway alterations were characterized by lower T cell infiltration compared to MYC pathway wild type (WT) tumors, and those harboring an amplification of *EGFR* had less B cells and dendritic cells in the tumor microenvironment compared to *EGFR*-WT. Moreover, transcriptomic and proteomic analyses revealed that secondary resistant SCCHN had increased CD8+ T cell infiltration and higher levels of immune exhaustion markers compared to anti-PD1 primary resistant and to anti-PD1-naïve SCCHN. 48 pts from the anti-PD1-naïve cohort were subsequently treated with PD(L)1 inhibitors. In this subgroup, pts with high B2M expression on tumor cells had better OS. SCCHN with high B2M expression on tumor cells also showed greater T cell infiltration compared to SCCHN with low B2M expression. **Conclusions:** Our data provide a rational to guide the development of therapeutic strategies aimed at reversing acquired resistance to PD-1 blockade in SCCHN. Our data suggest the potential use of B2M expression on tumor cells as predictive biomarker of response to anti-PD1 therapy. Research Sponsor: None.

Comprehensive profiling of circulating tumor DNA and microbial landscapes in nasopharyngeal cancer across Asia: NCCH1905/A-TRAIN study. First Author: Thinh Huy Nguyen, Ho Chi Minh City Oncology Hospital, Ho Chi Minh City, Viet Nam

Background: Nasopharyngeal cancer (NPC), a malignancy of the nasopharynx, is strongly associated with Epstein-Barr virus (EBV) infection. Although rare in Western countries, NPC is significantly more prevalent in Southeast Asia, likely due to a combination of environmental and dietary factors, though these remain incompletely understood. Current treatments, primarily radiation and chemotherapy, may not fully address the unique challenges posed by NPC. This study aims to conduct a comprehensive genomic analysis, including circulating tumor DNA (ctDNA), and microbial analysis to clarify NPC pathogenesis by examining patient backgrounds in Asian populations. **Methods:** This is an Asian multicenter prospective observational study conducted by nine institutions in Japan, Philippines, Malaysia, Thailand, Singapore, Taiwan and Vietnam. Eligible patients had histological diagnosis of NPC with metastatic and/or recurrent disease. ctDNA will be analyzed in blood samples collected at newly initial diagnosis of metastatic disease and/or at disease progression. Genomic profiling will be analyzed using TruSight Oncology 500 ctDNA for plasma (Illumina) and TruSight Oncology 500 (Illumina) for tumor tissue, respectively. Furthermore, we analyzed more than 3,000 viral genes using tumor tissue. **Results:** Seventy-two samples from 72 NPC patients were analyzed. The median age of the patients was 52 years old (range, 25-78), with 53 (73.6%) males. All the patients were Asian, and the details are as follows: 23 Vietnamese, 15 Chinese, 7 Thai, 6 Taiwanese, 5 Iban, 4 Filipino, 3 Japanese and 3 Malay. The number of patients with a history of surgery and radiotherapy was 10 (13.9%) and 45 (62.5%), respectively. Forty-nine patients (68.1%) had a history of chemotherapy, and all had a history of platinum-based drug administration, while eight (11.1%) had a history of immuno-checkpoint inhibitors administration. Pathogenic variants in ctDNA were detected in 40 out of 72 patients (55.6%). The most frequently deleterious mutations were *TP53, NRAS* and *TGFBR2*. Copy number alteration was observed in 33 patients (45.8%). Comprehensive viral and bacterial analysis was available in 20/72 patients (27.8%), with EBV found in 17 patients and none of the viruses in 3 patients. Actinomyces was dominant in all cases, although the bacterial flora was somewhat different. **Conclusions:** In this study, we conducted comprehensive genomic and microbial analyses of samples collected from NPC patients in Asia, and detected various genomic features as well as elucidating the characteristics of the microbial flora present in the background. As a result, it was shown that anaerobic bacteria may be involved in the pathogenesis of NPC. These bacterial groups form a tumor microenvironment through inflammation and immune modulation, and it is suggested that they promote tumor formation. Clinical trial information: NCT05099978. Research Sponsor: AMED (Japan Agency for Medical Research and Development).

6052 Poster Session

Characterizing the prevalence and prognostic significance of MTAP loss in endemic nasopharyngeal cancer using immunohistochemistry (IHC) versus fluorescent in situ hybridization (FISH). First Author: David Johnson, Department of Clinical Oncology, State Key Laboratory of Translational Oncology, Charlie Lee Precision Immunooncology program, Sir Y.K. Pao Centre for Cancer, The Chinese University of Hong Kong, Hong Kong, Hong Kong

Background: Methylthioadenosine phosphorylase (MTAP) loss has been associated with poor outcomes in various cancers, including nasopharyngeal carcinoma (NPC). Homozygous deletion of the MTAP locus is one of the most frequent somatic changes in NPC, creating opportunities for therapeutic targeting. However, the concordance between MTAP IHC and FISH for detecting MTAP loss, and the prognostic impact of partial MTAP loss, has not been fully explored. This study evaluated the prevalence of MTAP loss, correlation between IHC and FISH, and association of MTAP expression with time to progression (TTP), progression-free survival (PFS) and overall survival (OS). **Methods:** MTAP expression was analyzed by IHC, and locus loss was confirmed using FISH in tumors M0 (non-metastatic) NPC patients. Correlations between MTAP IHC and FISH results were analyzed to assess concordance, sensitivity, and specificity. Kaplan-Meier survival curves and log-rank tests compared survival distributions, while Cox proportional hazards models were applied for univariate and multivariate analyses. Subgroup analyses were performed by tumor, nodal and overall stage (AJCC 8th edition). **Results:** Among 175 patients, 65 (36.0%) exhibited IHC 0 and FISH-negative MTAP loss. Concordance rate between IHC 0 and FISH-negative was 94.9%. MTAP loss was significantly correlated with higher N2–3 and stage III–IVA disease (Pearson correlation coefficients: 0.81 and 0.73, respectively; $p < 0.0001$). Based on receiver operating curve (ROC) analysis, the optimal MTAP cutoff for progression was 110. Partial MTAP loss (MTAP 0–109) was significantly associated with shorter TTP compared to MTAP 110–300 (median TTP: 4.6 years vs. 15.8 years; p = 0.04). In multivariate analysis, MTAP <110 remained significant for TTP (HR = 0.65; CI 0.48-0.98 p = 0.04) after adjusting for grouped N stage. Subgroup analyses demonstrated that MTAP <110 was significantly associated with shorter PFS in N2–3 patients (HR 0.5 CI 0.28-0.9 p = 0.02) and shorter TTP in stage III–IVA patients (HR 0.61 CI 0.37-1.0 p = 0.05). **Conclusions:** Partial MTAP loss (IHC <110) is associated with worse outcomes in NPC, particularly shorter TTP and PFS, with significant prognostic value in advanced nodal and overall stage disease. High concordance between IHC and FISH supports IHC as a reliable diagnostic tool. These findings highlight MTAP expression as a potential prognostic biomarker for NPC, warranting further validation and exploration of targeted therapies. Tracking circulating tumor DNA through liquid biopsy after radiotherapy for dynamic risk monitoring in cancer patients. First Author: Renyuan Huang, Sun Yat-sen University Cancer Center; Collaborative Innovation Center for Cancer Medicine; State Key Laboratory of Oncology in South China; Guangdong Key Laboratory of Nasopharyngeal Carcinoma Diagnosis and Therapy, Guangzhou, Guangdong, China

Background: Circulating tumor DNA (ctDNA) analysis provides a useful tool for non-invasive tumor burden assessment. However, the management of detectable ctDNA without clinical or radiographic evidence of disease during follow-up remains poorly studied and clinically challenge. Here, we explored whether monitoring ctDNA dynamics can differentiate phenotypes in these patients. Nasopharyngeal carcinoma (NPC) is an ideal model for the sensitive detection of cell-free Epstein-Barr virus DNA (cfEBV DNA). **Methods:** The study analyzed medical records of 14,611 non-metastatic NPC cases treated with definitive radiotherapy with or without chemotherapy from two cohorts: a discovery cohort (n = 4,485) and an independent validation cohort (n = 10,126). Cox regression and recursive partitioning analysis (RPA) were used for survival analyses and patient stratification. **Results:** In the discovery cohort, 23.1% of cases presented detectable cfEBV DNA during follow-up and experienced significantly worse survival compared to those with longitudinally undetectable cfEBV DNA (5-year DFS: 39.1% vs. 91.5%, $p< 0.001$). Pre-treatment cfEBV DNA level ($\geq$2000 vs. $<$ 2000 copies/ml) and the maximum level during follow-up ($\geq$500 vs. $<$ 500 copies/ml) were significantly associated with disease failure. Based on the longitudinal dynamic changes, patients with bounce of cfEBV DNA after its clearance had worse survival than those without bounce (HR_{DFS}= 4.3 [3.1-6.0], $p< 0.001$), and patients with persistent cfEBV DNA had the worst survival (HR_{DFS} = 11.5 [8.3–15.9], $p< 0.001$). RPA was then conducted incorporating other clinical prognostic factors and four distinct prognostic phenotypes were identified (Table). The model showed a significantly higher positive predictive value (96.6% vs. 60.5%) and similar negative predictive value (67.4% vs. 65.8%) compared to single-point cfEBV DNA assessments. Patients who had clearance of low cfEBV DNA burden had a favorable prognosis (5-year DFS, 83.4%). In contrast, most patients with persistent cfEBV DNA had disease failure (5-year DFS, 8.0%); this subgroup can be defined as molecular relapse. The results were consistent in the validation cohort. Notably, patients in the molecular relapse group benefited from early salvage therapy with improved DFS, whereas patients in other phenotypes responded poorly. **Conclusions:** Tracking longitudinal ctDNA dynamics after definitive treatment can enable more precise risk assessment and facilitate risk-adapted, individualized patient management. Research Sponsor: None.

Induction chemotherapy followed by chemoradiotherapy with cisplatin or cetuximab for unresectable locally advanced head and neck cancer (TTCC-2007-01 trial): Analysis of genomic biomarkers by next-generation sequencing after long-term outcomes. First Author: Alejandro Olivares Hernández, Medical Oncology Department, University Hospital of Salamanca, Biomedical Research Institute of Salamanca (IBSAL), Salamanca, Spain

Background: Induction chemotherapy (ICT) may provide survival benefit in some patients (pts) with unresectable locally advanced squamous head and neck carcinoma (LA-SCCHN). Objective: Study the benefit of ICT followed by radiotherapy plus cetuximab versus (vs) cisplatin (RT/CET vs RT/CDDP) by profiling predictor biomarkers of response from pts of TTCC-2007-01 trial (NCT00716391). **Methods:** Design TTCC-2007-01: studied the non-inferiority of RT/CET (70Gy + 400mg/250mg/m2 weekly) vs RT/CDDP (70Gy + 100mg/m2 d1-22-43) after ICT (docetaxel 75mg/m2 + platinum 75mg/m2 + 5-FU 750mg/m2 d1-5) in unresectable LA-SCCHN (Oral Oncology, 2022 Nov:134:106087). A cohort of samples were analyzed after DNA extraction and processed using OncoScan platform and TruSight Panel (next-generation sequencing). Survival analysis was performed using Kaplan-Meier (log-rank or Breslow test, survival in months 'm') and Cox regression (HR 95% CI). Statistical significance was $p<0.05$ (SPSSv28). **Results:** In total, 70 pts (male 90% / female 10%) were analyzed in RT/CDDP arm (mean age 55 [45-68]) versus 72 pts (male 88,9% / female 11.1%) in RT/CET arm (mean age 60 [32-70]). The most frequent localizations in RT/CDDP arm were oropharynx (44.3%) and hypopharynx (21.4%). In RT/CET were oropharynx (37,5%) and hypopharynx (23,6%). In RT/CDDP arm HPV was positive in 17.1% of tumors versus 13,1% in RT/CET. In RT/CDDP arm the median overall survival (OS) was 65m [25.6-105.4] vs 36.8m [14.3-59.2] in the RT/CET arm. The progression-free survival (PFS) was 33.2m [16.2-50-1] in the RT/CDDP arm vs 18.3m [9.1-28.6] in the RT/CET arm. *TP53* was the most frequent mutation without differences in OS in either arm. However, mutations were associated with unfavorable PFS in the RT/CDDP arm (22.6 vs 66.2; p=0.025 Breslow), with no difference in RT/CET arm (20.1 vs 15.2; p=0.885 Breslow). HPV+ tumors were associated with better OS (83.9 vs 33.2; p=0.027 Breslow) in RT/CDDP arm. There was no difference in the RT/CET arm (28.1 vs 23.9; $p>0.05$). In the RT/CDDP arm the chromosomal biomarker that was associated with worse OS was 18q12.2- (22.7 vs 85.6; HR 3.3 [1.6-6.6]). Focal alterations 3p14.2- had superior OS (83.9 vs 22.9m; HR 0.1 [0.04-0.30]). In the RT/CET arm the 6p25.3+ biomarker was associated with superior OS (not reached vs 26.6m; HR 0.42 [0.2-0.8]). In terms of PFS in RT/CDDP arm, gains in 2p were associated with worse PFS (12.0 vs 41.7m; HR 2.9 [1.4-6.2]). 6p25.3+ alterations had better PFS in the RT/CET arm (38.8 vs 11.5; HR 0.40 [0.2-0.8]). **Conclusions:** ICT plus RT/CDDP was shown most beneficial in pts with *TP53* wild type, HPV+ and 3p14.2-. In contrast, ICT plus RT/CET is not influenced by *TP53* or HPV. 6p25.3+ is a robust biomarker of response in RT/CET arm in terms of OS and PFS. Correct pts selection may allow for further standardization of ICT in LA-SCCHN. Research Sponsor: Carlos III Health Institute; PI18/01476.

Characterization of dynamic changes in tumor-infiltrating lymphocytes (TIL) after neoadjuvant administration of CUE-101, an HPV16 E7-HLA-IL2 fusion protein, to patients with HPV+ locally advanced oropharyngeal squamous cell carcinoma (LA-OPSCC). First Author: Jesse M Zaretsky, Department of Medicine, Division of Oncology, Washington University School of Medicine, St. Louis, MO

Background: CUE-101 is a novel fusion protein designed to selectively engage and expand HPV16-specific T-cells to promote an anti-tumor immune response in HPV+ malignancies. CUE-101 is comprised of the HPV16 $E7_{11-20}$ epitope, HLA-A*0201, and a reduced affinity human IL2. In this single-arm Phase 2 trial (NCT04852328), CUE-101 is administered to HLA-A*0201+ patients with HPV16+ LA-OPSCC in three schedules (A, B, and C) before curative-intent surgery and adjuvant therapy or definitive chemoradiation therapy. Primary endpoints were safety of CUE-101 and changes in the frequency of HPV16 $E7_{11-20}$-specific CD8+ T cells in blood and tumor. Correlates in TIL for Schedules A and B are presented here. **Methods:** CUE-101 (4 mg/kg IV) was administered 14 days (Schedule A), 14 and 7 days (Schedule B), or 7 days (Schedule C) before curative-intent treatment. Biopsies of the primary tumor were collected before CUE-101 administration and within 2 days prior to curative-intent therapy. Single-cell RNA and T-cell receptor (TCR) sequencing (scRNAseq, 10X Genomics) was performed on fresh sorted CD8 T-cells. HPV16 $E7_{11-20}$ dextramer staining and flow cytometry assessed reactivity to HPV E7. Multiplex immunofluorescent (mIF) tissue staining with a 30-marker Phenocycler panel (Akoya Biosciences) assessed tumor, myeloid, and T-cell states. Changes in T-cell clonal frequency were significant if fold change >2 and fisher exact test adjusted p <0.05. Changes in cell populations after treatment were evaluated by two-tailed paired student's t-test. **Results:** Of 20 total patients enrolled, paired biopsies from 13 of sufficient quality were analyzed by scRNAseq, flow cytometry, and mIF. In a joint analysis of Schedules A (n=7) and B (n=6), we identified multiple T-cell clones that significantly expanded following CUE-101 treatment, representing 4-51% (mean 18.3%) of tumor-infiltrating CD8 cells by scRNAseq. Among these, we found significant enrichment for phenotypes of chronic T cell activation (PD1+CD39+, often associated with tumor reactivity, p =0.041). In agreement with this finding, flow cytometry of TIL showed increased CD8+CD39+ cells (mean 10.9%, p =0.026) among CD45 cells, and a small increase in NK cells (1.7%, p =0.005). Absolute cell counts by mIF confirmed these trends. Direct dextramer staining of TIL samples has not specifically identified HPV $E7_{11-20}$ reactive T cells pre- or post-treatment, therefore cloning of TCRs from expanded T-cells is being performed to enable functional testing of HPV reactivity. **Conclusions:** Significant clonal expansion of intra-tumoral CD8 T-cells with signatures associated with tumor reactivity were observed within 2 weeks of CUE-101 administration in HPV16+ LA OPSCC. Studies in blood and of T-cell specificities are ongoing. Clinical trial information: NCT04852328. Research Sponsor: CUE Biopharma.

Survival association of PIK3CA in HPV-driven head and neck squamous cell carcinoma (HNSCC). First Author: Kelly Bridgham, Department of Otolaryngology Head & Neck Surgery, Thomas Jefferson University, Philadelphia, PA

Background: Across many solid tumor malignancies, including head and neck squamous cell carcinoma (HNSCC), clinical trial data has supported the integration of PD1 Immune Checkpoint Inhibitors (ICIs) into treatment algorithms; however, durable response to single agent therapy occurs in only a fraction of patients. Thus, there is a great need to understand the molecular underpinnings of response and resistance mechanisms. PIK3CA mutation is a common driver of HPV+ mediated malignancy. We sought to understand the prevalence and clinical impact of PIK3CA mutation in HPV+ and HPV- cancer by applying a multi-omics approach to a large, clinically appended dataset. **Methods:** HNSCC (N = 1901) patient who underwent DNA (592-gene or whole exome) and RNA (whole transcriptome) sequencing at Caris Life Sciences (Phoenix, AZ) was queried to identify HPV+ and HPV- HNSCC cohort. Tumor mutational burden (TMB) was measured by totaling all somatic mutations (mt) per tumor (TMB-H: $>$ 10 mt/MB). Real-world overall survival (rwOS) was obtained from insurance claims data, calculated from either time of biopsy (OS) or start of immunotherapy ($_{IO}$OS) to last contact, or time on ICI ($_{IO}$TOT). Mann-Whitney U and X^2/Fisher-Exact tests were applied, with *p*-values adjusted ($p < .05$). **Results:** Compared to HPV- samples, PIK3CA mutation was highly associated with HPV+ primary (28.5% vs 11.4%, p <0.01) and metastatic (23.8% vs 11.2%, $p<0.01$) lesions. The prevalence of TMB-H was significantly higher in both HPV+ (30.7% vs 7.9%, $p<0.01$) and HPV- (30.7% vs 18.2%, $p<0.01$) with PIK3CA mutation compared to WT. HPV- disease showed significantly worse survival as expected (HR = 0.63, $p<0.001$), while PIK3CA mut /wt status was not associated with differences in OS among HPV+ (HR = 1.05, p = 0.78) or HPV- cohorts (HR = 1.11, p = 0.44). However, irrespective of tumor site and metastatic status, mutPIK3CA HPV+ patients' trend towards an increased $_{IO}$OS (HR = 0.64, p =0.176) and increased $_{IO}$TOT compared to wtPIK3CA patients (HR = 0.72, p = 0.073). In contrast, mutPIK3CA HPV- HNSCC showed worse $_{IO}$OS (HR = 1.65, $p<0.001$) and a trend toward decreased $_{IO}$TOT (HR = 1.20, p=0.248) compared to wtPIK3C patients. **Conclusions:** Data from this cohort indicate potential survival association for PIK3CA mutation, with differing impact in HPV+ and HPV- HNSCC. Further research is needed to explore the mechanism underlying these findings and identify other molecular factors that might contribute to the observed outcomes. Research Sponsor: None.

Evaluation of plasma methylated DNA markers for detection HPV-positive oropharyngeal squamous cell carcinoma: A case control study. First Author: Kathryn M. Van Abel, Department of Otorhinolaryngology, Mayo Clinic, Rochester, MN

Background: The incidence rate of human papillomavirus associated oropharyngeal squamous cell carcinoma (HPV(+)OPSCC) has persistently increased over the past decade and is anticipated to rise further over the next decade. Cost effective, accurate, and less invasive screening options for HPV(+)OPSCC have remained stagnant leading to the interrogation of circulating tumor DNA in liquid biopsies such as plasma. We hypothesized that candidate methylated DNA markers (MDMs), previously described by our group, would be present in the plasma of patients with HPV(+)OPSCC and absent in controls. **Methods:** HPV(+)OPSCC cases were enrolled from a high-volume referral practice. Cancer-free control patients were identified from the surrounding 7-county catchment area and frequency matched to cases by age and alcohol use. cfDNA was extracted from 4 mL of plasma and bisulfite converted prior to Target Enrichment Long-probe Quantitative Amplified Signal assays for 15 MDMs. Strand counts for individual MDMs were normalized to a methylated genomic reference marker. An MDM score was derived via random forest modeling of the 15 MDMs. Area under the receiver operator characteristic curve (AUC) for discriminating cases from controls was evaluated for individual markers and for the MDM score. The sensitivity of the MDM score at 95% specificity was also evaluated. **Results:** The study consisted of 96 HPV(+)OPSCC and 100 cancer-free controls. The study population was predominately white (95%) with a median age of 61 yrs (IQR: 52-69 yrs). Eighty-nine percent of the cases were male with cancers affecting either the tonsil in 50 (52%) or base of the tongue in 46 (48%) patients; by design 50% of controls were male. Stage I:II:III:IV disease was present in 66%:22%:9%:3% of the cases. The median (IQR) AUC across the 15 MDMs was 0.83 (0.82-0.85) overall: 0.78 (0.77-0.83) for stage I disease and 0.92 (0.91-0.93) for stage II-IV disease. The MDM score for the combined panel of 15 MDMs achieved a cross-validated AUC of 0.93 (CI: 0.89-0.97) overall: 0.90 (CI: 0.84-0.96) for stage I disease and 0.98 (CI: 0.97-1.00) for stage II-IV disease. At 95% specificity, the cross-validated sensitivity of the MDM score for HPV(+)OPSCC was 80% (CI: 71-87%) overall: 73% (CI: 60-83%) for stage I disease and 94% (CI: 78-99%) for stage II-IV disease. **Conclusions:** We validated a set of previously discovered MDM markers in HPV(+)OPSCC in a robust case control cohort using plasma. The MDMs were detected in both early and late-stage disease. Additional prospective studies in larger intended use cohorts are needed to validate our results for clinical use. Research Sponsor: None.

Evidence of a role for oropharyngeal cancer cells with low HPV gene expression in treatment failure. First Author: Devraj Basu, University of Pennsylvania, Philadelphia, PA

Background: A subset of tumor cells with reduced HPV gene expression, here termed HPV-lo cells, are proposed contribute to therapy resistance in HPV+ oropharyngeal cancers (OPCs). However, the biologic and clinical significance of this cell state is unclear because it has been analyzed in relatively few HPV+ OPCs and total tumor cells and remains to be directly linked to therapy resistance and recurrence. We aimed to evaluate HPV-lo cells for their biologic traits, cytotoxic drug responses, and association with recurrence. **Methods:** Single cell mRNA sequencing (scRNAseq) was performed on 64,822 tumor cells from five HPV+ OPC PDXs, and HPV-lo cells were defined by presence of $<$1.0 normalized HPV mRNA reads. Expression profiles distinguishing HPV-lo cells were assessed by gene set enrichment analysis. Changes in HPV-lo cell frequency and gene expression were examined by scRNAseq after two weeks of *in vivo* cisplatin treatment in NSG mice. To test for association of HPV-lo cells with recurrence, a single institution cohort of 851 therapy-naïve p16+ OPC patients receiving primary surgery was used to curate 50 pT1/2 tumors that later recurred (cases) and match 50 tumors that were cured (controls) for pathologic stage, smoking history, and adjuvant therapy. A clinical *in situ* hybridization (ISH) assay was used to probe for HPV E6/E7 in the case-control cohort. Digital image analysis segmented the ISH(+) vs. ISH(-) cells in tumor regions plus the subset of ISH(-) cells comprised of CD45-IHC(+) tumor infiltrating leukocytes (TILs). The ISH(-) tumor cell fraction was estimated by calculating total % ISH(-) cells - %TILs. **Results:** Content of HPV-lo cells in PDXs ranged from 32% to 65%. These cells showed significant downregulation of E2F target genes and upregulation of p53 target genes, supporting presence of reduced HPV E6/E7 activity. Their relative quiescence was further supported by transcriptional inference of fewer cells in the $S/G_2/M$ cell cycle fractions. HPV-lo cell content in the PDXs negatively correlated with cisplatin response measured by T/C ratio (r=-0.96, p=0.007), and the size and gene expression profile of this fraction were largely unaltered by cisplatin. In the case-control cohort, the HPV ISH(-) tumor cell fraction was larger in cases ($p<0.001$), which often contained large tumor regions devoid of ISH(+) cells. The %ISH(-) tumor cells provided favorable discrimination of cases vs. controls based on an area under the ROC curve of 0.77 ($p<0.001$, OR=66, 95% CI=11-547). **Conclusions:** HPV+ OPCs contain a subset of tumor cells with reduced HPV gene expression and a relatively quiescent phenotype, and increased size of this cell fraction appears predictive of recurrence. Cell state dynamics maintaining this fraction during cytotoxic therapy may contribute treatment failure. Thus, HPV-lo cells merit evaluation for generalizability as a biomarker and mechanistic interrogation as an etiology for tumor recurrence. Research Sponsor: None.

Risk factors for aspiration pneumonia related to postoperative chemoradiotherapy for high-risk head and neck cancer: A supplementary analysis of a phase II/III JCOG1008 trial. First Author: Tomoya Yokota, Shizuoka Cancer Center, Shizuoka, Japan

Background: A randomized phase II/III trial (JCOG1008) suggested that postoperative chemoradiotherapy (POCRT) with weekly cisplatin is a treatment option for patients with postoperative high-risk locally advanced squamous cell carcinoma of the head and neck (LA-SCCHN). Aspiration pneumonia (AP) is one of the most important toxicities associated with CRT. This study investigated the clinical risk factors for AP during and after POCRT. **Methods:** Patients enrolled in JCOG1008 were analyzed to evaluate the incidence of AP, to identify the clinical risk factors for AP during and after POCRT, and to assess the influence of AP on treatment outcomes. AP was defined as a clinical condition meeting all of the following criteria: (i) patients had both subjective and objective symptoms suggesting pneumonia, (ii) the presence of aspiration was suspected clinically or by endoscopic or video-fluorographic examinations, (iii) no evidence of micro-organisms that cause atypical pneumonia. Analyses were performed by logistic regression model. **Results:** Of 251 patients who underwent POCRT, 100 patients who underwent laryngectomy was excluded. Among the 151 patients who received POCRT, 93 (61.6%), 85 (56.3%), and 113 (74.8%) developed AP during, after, and overall period of POCRT, respectively. The multivariable analyses identified two independent risk factors for AP occurring during or after POCRT: PS 1 [vs. PS 0; odds ratio (OR) 3.416, 95% CI (1.192-9.789), p = 0.0222] and dysphagia $\geq$grade 3 (vs. grade 1-2; OR 46.333, 95% CI (2.901-740.080), p = 0.0067). The multivariable analyses also identified two independent risk factors for AP occurring after POCRT: dysphagia $\geq$grade 3 (OR 3.995, 95% CI (1.538-10.375), p = 0.0045) and reconstruction surgery (OR 3.452, 95% CI (1.616-7.374), p = 0.0014). Charlson comorbidity score $\geq$4 and the use of sleeping pills at the end of POCRT were marginally associated with the onset of AP after POCRT (OR 2.699, 95% CI (0.919-7.926), p = 0.0708, OR 2.107, 95% CI (0.918-4.837), p = 0.0788, respectively). The occurrence of AP was not significantly associated with overall survival, relapse-free survival, and local relapse-free survival. **Conclusions:** PS 1, dysphagia $\geq$grade 3, and prior reconstruction surgery were associated with the onset of POCRT-related AP. Careful attention should be paid to these risk factors for AP in patients with LA-SCCHN undergoing POCRT. Clinical trial information: jRCTs031180135. Research Sponsor: National Cancer Center Research and Development Funds; Grant-in-Aid for Clinical Cancer Research; The Japan Agency for Medical Research and Development.

Anti-programmed death-1 inhibitors and nimotuzumab in combination with induction chemotherapy for locoregionally advanced nasopharyngeal carcinoma: A propensity score-matched analysis. First Author: Chunyan Chen, Department of Radiation Oncology, Sun Yat-sen University Cancer Center, State Key Laboratory of Oncology in South China, Guangdong Key Laboratory of Nasopharyngeal Carcinoma Diagnosis and Therapy, Guangdong Provincial Clinical Research Center for Cancer, Guangzhou, China

Background: The poor prognosis of locoregionally advanced nasopharyngeal carcinoma (LANPC) due to the high incidence of metastasis necessitates effective treatment strategies. Synergistic effects have been observed when anti-programmed death-1 (anti-PD-1) inhibitors are combined with chemotherapy or targeted therapy. **Methods:** In total, 319 patients with LANPC were retrospectively enrolled between December 2017 and November 2022. The primary endpoint was progression-free survival. Propensity score matching was performed to adjust for potential confounders. **Results:** Overall, 150 patients were included after propensity score matching. The immunotherapy + nimotuzumab + chemotherapy (INC) group (n=50) had a higher 3-year progression-free survival rate (96.6% [95% confidence interval (CI): 93.2–100.0]) than the nimotuzumab + chemotherapy (NC) group (n=100) (79.8% [95% CI: 75.6–84.0]). The INC group had a hazard ratio of 0.16 (95% CI: 0.02–1.22; P=0.04). The objective response rates were 100% and 99% for the INC and NC groups, respectively. Grade $\geq$3 treatment-related adverse events were reported in eight (5.3%) patients, and hyponatremia (2.0%) was the most common. Grade $\geq$3 immune-related adverse events (rash and reactive capillary proliferation) were reported in two (4.0%) patients. **Conclusions:** Neoadjuvant therapy with anti-PD-1 inhibitors and nimotuzumab combined with chemotherapy demonstrates promising anti-tumor activity with acceptable safety for LANPC. More well-designed randomized trials with larger patient cohorts are needed to confirm long-term efficacy. Research Sponsor: None.

Short-term efficacy of three months after the end of treatment.

Response evaluation	INC group [n = 50 (%)]	NC group [n = 100 (%)]
CR	38 (76.0)	19 (19.0)
PR	12 (24.0)	80 (80.0)
SD	0	1 (1.0)
PD	0	0
ORR (95% CI)	100% (92.9%, 100%)	99% (94.6%, 100%)
DCR (95% CI)	100% (92.9%, 100%)	100% (96.4%, 100%)

CI, confidence interval; CR, complete response; DCR, disease control rate; IC, induction chemotherapy; ORR, objective response rate; PD, progressive disease; PR, partial response; SD, stable disease.

Initial results of MC200710 investigating therapeutic vaccine (PDS0101) alone or with pembrolizumab prior to surgery or radiation therapy for locally advanced HPV associated oropharyngeal carcinoma, a phase 2 window of opportunity trial. First Author: David M. Routman, Department of Radiation Oncology, Mayo Clinic, Rochester, MN

Background: PDS0101 is a T cell stimulating immunotherapy (therapeutic vaccine) targeting HPV16. The combination of PDS0101 + pembrolizumab (5 cycles) has shown durable clinical responses in HPV-positive recurrent/metastatic HNSCC. MC200710 is a window of opportunity study in patients with HPV-associated oropharyngeal squamous cell carcinoma (HPV+ OPSCC). This prospective phase II trial utilized 2 cycles of neoadjuvant PDS0101 aloneor in combination with pembrolizumab prior to surgical resection or chemoradiotherapy (CRT). Herein, we report the initial results, including primary endpoint of ctDNA response. **Methods:** Between June 2022 and September 2024, 20 patients (10 per Arm) with locally advanced HPV+ OPSCC were enrolled in a sequential alternating design. Arm A received 2 cycles of PDS0101 and Arm B received 2 cycles of PDS0101 and pembrolizumab with all patients undergoing subsequent surgery or CRT. Assessments were done at baseline, post cycle 1, and post cycle 2 (prior to surgery or CRT). The coprimary endpoint of ctDNA response was defined as a $\geq$50% decline in ctDNA post cycle 2 compared to baseline as quantified using NavDx (TTMV fragments/mL). Radiologic objective response rate (ORR) was assessed as per RECIST 1.1. Toxicity through the neoadjuvant period was assessed using CTCAE criteria and recurrence rates following surgery or CRT are reported. **Results:** Patients were similar between arms: male 90%, median age 61 years, cT1/T2 70%, cN1 65%, and no smoking history 65%. All patients completed both cycles of therapy with 13 (65%) undergoing primary operative management and 7 CRT (35%). The most common toxicity was injection site reaction 85% grade 1, 15% grade 2, 0% grade 3, consistent with prior studies. One patient experienced grade 2 pneumonitis during the neoadjuvant window (Arm B). There was one grade 3 toxicity (5%) possibly attributable to study intervention with one patient experiencing transient hepatitis requiring hospitalization (Arm A). Zero of 10 patients in Arm A had a $\geq$50% decline in ctDNA from baseline while 5 of 10 patients (50%) met this primary endpoint in ARM B (p=0.03). After Cycle 2, based on RECIST 1.1, no Arm A patients had a partial response (PR), with 7 having stable disease (SD); Arm B had 2 patients with PR and 8 with SD. With median follow up of 6 months, 2 patients in Arm A recurred and 0 patients in Arm B. **Conclusions:** The combination of PDS0101 and pembrolizumab met the trial's primary endpoint of ctDNA response and shows promise for further evaluation. ctDNA can be used to assess early response and future studies could use ctDNA to adapt neoadjuvant therapy. Based on these findings, a neoadjuvant dose optimization study in HPV16+ oropharyngeal carcinoma is warranted and evaluation of PDS0101 and pembrolizumab in comparison to pembrolizumab alone. Clinical trial information: NCT05232851. Research Sponsor: PDS Biosciences.

6062 Poster Session

Efficacy of definitive radiotherapy with concurrent and adjuvant immune checkpoint inhibitors in patients with locally advanced head and neck squamous cell carcinoma (LA HNSCC). First Author: Hazem Aboaid, Department of Internal Medicine, Kirk Kerkorian School of Medicine at UNLV, Las Vegas, NV

Background: Head and neck squamous cell carcinoma (HNSCC) is the most common type of head and neck cancers, associated with a high incidence and mortality. In 2019, the FDA approved pembrolizumab for the treatment of recurrent/metastatic (RM) HNSCC. While many promising results were noted in the RM setting, unfortunately this was not the case for locally advanced HNSCC (LA HNSCC). Multiple studies have yielded negative results. This meta-analysis aims to further explore the efficacy of immune checkpoint inhibitors (ICIs) in the treatment of LA HNSCC. **Methods:** MEDLINE and EMBASE databases were systematically searched up to December 31, 2024. Randomized controlled trials (RCTs) evaluating ICIs in patients with LA HNSCC were included. The primary outcome was 2-year progression-free survival (PFS). A generic inverse variance method was used to calculate the estimated pooled hazard ratio (HR) for PFS with 95% confidence interval (CI). Heterogeneity was assessed with Cochran's Q test. Fixed effects model was applied. **Results:** A total of 1,687 patients from 2 phase III RCTs (KEYNOTE-412, JAVELIN Head and Neck 100) and 1 phase II/III RCT (NRG-HN004) were analyzed. NRG-HN004 compared durvalumab + radiotherapy (RT) vs cetuximab + RT, while KEYNOTE-412 and JAVELIN Head and Neck 100 compared pembrolizumab or avelumab + chemoradiotherapy (CRT) vs CRT alone, respectively. In PD-L1 positive cohort, longer PFS was noted in the ICIs arm (HR 0.81; 95% CI: 0.67-0.99; P=0.04), while in PD-L1 negative cohort, we noted the opposite with a shorter PFS in the ICIs arm (HR 1.34; 95% CI: 1.02-1.76; P=0.03). PFS was not different between the two treatment arms in the overall population and all the other subgroups, including HPV negative, HPV positive, males, and females. We conducted a subset analysis of cisplatin-eligible (CE) LA HNSCC including KEYNOTE-412 and JAVELIN Head and Neck 100 trials to assess the addition of ICIs to definitive CRT. We also noted increased PFS in PD-L1 positive cohort in the ICIs arm (HR 0.78; 95% CI: 0.63-0.97; P=0.02). However, in PD-L1 negative cohort, PFS was near significant to be decreased in the ICIs arm (HR 1.31; 95% CI: 0.99-1.75; P=0.06). **Conclusions:** This study showed that definitive radiotherapy with concurrent and adjuvant ICIs in LA HNSCC was associated with increased PFS in the PD-L1 positive group but decreased PFS in the PD-L1 negative arm. NRG-HN004 trial demonstrated that immunoradiotherapy was inferior to radiation plus cetuximab in cisplatin-ineligible LA HNSCC. In the subset analysis of CE LA HNSCC, addition of ICIs to standard CRT has more pronounced significant PFS in the PD-L1 positive cohort, while there is a trend towards decreasing PFS in the PD-L1 negative cohort. Further studies are needed in the future to evaluate the efficacy of ICIs addition to standard definitive CRT in PD-L1 positive or high LA HNSCC. Research Sponsor: None.

Prognostic impact of preoperative imaging-detected extranodal extension in head and neck squamous cell carcinoma treated with postoperative chemoradiotherapy. First Author: Yuta Hoshi, Department of Head and Neck Medical Oncology, National Cancer Center Hospital East, Kashiwa, Japan

Background: In 2024, the Head and Neck Cancer International Group (HNCIG) newly defined imaging-detected and pathological extranodal extension (iENE/pENE). We previously reported the utility of iENE in induction chemotherapy followed by definitive chemoradiotherapy (Onaga R, et al. ASCO Annual Meeting, 2024). However, the significance of iENE in surgically treated head and neck squamous cell carcinoma (HNSCC) remains unclear, particularly in high-risk populations with positive pENE. We aimed to investigate the prognostic value of iENE in patients treated with completed surgery and postoperative chemoradiotherapy (poCRT) due to pENE-positivity. **Methods:** We retrospectively analyzed patients with HNSCC (oral cavity, oropharynx, hypopharynx, or larynx) who underwent surgical resection between 2013 and 2023 at our hospital. pENE-positive patients who received poCRT (cisplatin $\geq$ 200 mg/m² and radiation therapy $\geq$ 60 Gy) were included, excluding those with positive surgical margins of the primary site. iENE grading on preoperative CT or MRI and pENE assessment in surgical specimens were re-evaluated according to HNCIG consensus recommendations. Relapse-free survival (RFS) and Overall survival (OS) were analyzed using the log-rank test. **Results:** We identified 95 patients with a median age of 62 years (range: 16-76). The primary tumor sites included oral cavity (58 patients), hypopharynx (29), larynx (5), and oropharynx (3). iENE grades were 0/1/2/3 in 24/29/13/29 patients, and pENE was categorized as minor ENE/major ENE/soft tissue metastasis (STM) in 40/20/35 patients. With a median follow-up of 42.1 months, 43 patients developed recurrence (local/regional/distant/regional and distant: 1/7/30/5). In the iENE classification, the 5-year RFS for iENE Grades 0/1/2/3 was 77.8%, 60.3%, 35.9%, and 33.4% (p=0.003), and the 5-year OS was 88.8%, 70.5%, 37.8%, and 63.0% (p=0.021), respectively. When iENE grades were grouped into Grade 0/1 and Grade 2/3, the latter group had significantly shorter RFS (5-year RFS: 68.0% vs. 34.2%, $p < 0.001$) and OS (5-year OS: 78.3% vs. 55.9%, p = 0.008). In the pENE classification, no significant differences in RFS and OS were observed among minor ENE, major ENE, and STM (p=0.380 for RFS, p=0.617 for OS). **Conclusions:** Our study revealed for the first time that preoperative iENE was a significant prognostic factor for pENE-positive patients treated with poCRT. Specifically, patients with iENE grade 2/3 exhibited a poor prognosis, emphasizing the need for additional treatment strategies tailored to this very high-risk group. Research Sponsor: None.

Prognosis based on iENE grades and pENE category.

		N=95	5-year RFS	p-value	5-year OS	p-value
iENE	Grade 0	24	77.8%	0.003	88.8%	0.021
	Grade 1	29	60.3%		70.5%	
	Grade 2	13	35.9%		37.8%	
	Grade 3	29	33.4%		63.0%	
pENE	Minor ENE	40	60.9%	0.380	70.6%	0.617
	Major ENE	20	56.4%		70.1%	
	Soft tissue metastasis	35	45.1%		66.6%

Concurrent chemoradiotherapy with or without nimotuzumab in induction chemotherapy resistant locoregionally advanced nasopharyngeal carcinoma: An open-label randomised, controlled, phase 2 trial. First Author: Li-Ting Liu, Department of Nasopharyngeal Carcinoma, Sun Yat-Sen University Cancer Centre, Guangzhou, China

Background: Induction chemotherapy (IC) followed by concurrent chemoradiotherapy (CCRT) is the current standard of care for locoregionally advanced nasopharyngeal carcinoma (LA-NPC). Patients resistant to IC have a high risk of treatment failure. Nimotuzumab, a humanized anti-epidermal growth factor receptor (EGFR) antibody, has shown potential efficacy in combination with CCRT. This randomized phase 2 trial aimed to evaluate the efficacy and safety of nimotuzumab plus CCRT compared to CCRT alone in IC-resistant LA-NPC. **Methods:** We conducted an open-label, randomized phase 2 trial at Sun Yat-sen University Cancer Center, Guangzhou, China. Eligible patients (aged 18–70) had untreated, non-keratinizing, IC-resistant stage II–IVa (the 8th edition of the American Joint Committee on Cancer classification system) LA-NPC, defined as detectable plasma Epstein-Barr virus (EBV) DNA and/or stable/progressive disease after two cycles of IC. Other inclusion criteria were ECOG performance status of 0–1, positive EGFR expression and adequate organ function. Patients were randomized (1:1) to receive CCRT plus nimotuzumab or CCRT alone. Cisplatin (100 mg/m²) was given on days 1, 22, and 43 of intensity-modulated radiotherapy in both groups. In the experimental group, nimotuzumab (200 mg) was administered weekly during CCRT. Randomization was done using a computer-generated code random number code with a block size of six, stratified by disease stage. The primary endpoint was 2-year progression-free survival (PFS) in the intention-to-treat population. Safety was assessed in all participants who received at least one dose of the assigned treatment. The study was registered at ClinicalTrials.gov (NCT04223024), and patients are under follow-up. **Results:** Two hundred forty-six patients were enrolled and randomized (121 to CCRT plus nimotuzumab, 125 to CCRT alone). At a median follow-up of 47 months (IQR 44–50), the 2-year PFS was 81.0% (95% CI 72.8–86.9) in the CCRT plus nimotuzumab group and 80.8% (95% CI 72.7–86.7) in the CCRT group (stratified HR 0.93 [95% CI 0.59–1.47], p=0.70). The most frequent grade 3–4 adverse events were mucositis (24 [20.2%] vs 22 [17.6%]), leukopenia (23 [19.3%] vs 21 [17.2%]), and nausea (14 [11.8%] vs 16 [13.8%]) in the CCRT plus nimotuzumab group compared with CCRT group. A higher frequency of grades 1–2 rash was observed in the CCRT plus nimotuzumab group (15 [12.6%] vs 6 [4.9%]). Late adverse events were predominantly mild, with no grade 4 events reported in either group. No treatment-related deaths occurred in either group. **Conclusions:** In IC-resistant LA-NPC, the addition of nimotuzumab to CCRT did not provide a significant survival benefit. Further research into predictive biomarkers and novel combinations is needed to optimize treatment for high-risk populations. Clinical trial information: NCT04223024. Research Sponsor: None.

Patient-reported outcomes (PROs) in the C-POST trial of adjuvant cemiplimab (cemi) vs placebo (pbo) for high-risk cutaneous squamous cell carcinoma (CSCC). First Author: Annette May Ling Lim, Peter MacCallum Cancer Centre, Melbourne, Australia

Background: C-POST is a phase 3, double-blind, pbo-controlled trial (NCT03969004) of adjuvant cemi for treatment of patients (pts) with CSCC at high risk of recurrence after surgery and radiation therapy. Positive results for the primary endpoint of disease-free survival (DFS) at interim analysis 1 are reported in a separate ASCO abstract. Here we evaluate adjuvant cemi vs pbo on PROs as exploratory endpoints. **Methods:** Pts (N=415) were randomized 1:1 to adjuvant cemi or pbo for up to 48 weeks (4 cycles). The European Organisation for Research and Treatment of Cancer Quality of Life Questionnaire Core 30 (QLQ-C30) was administered at Day 1 of every cycle, end of treatment, and during follow-up. The pre-specified PRO analysis focused on 6 QLQ-C30 scales of global health status (GHS)/QoL; 3 functional scales (physical [PF], role [RF], emotional [EF]); and 2 symptom scales (fatigue [FA], pain [PA]). Overall changes from baseline across treatment cycles were analyzed using mixed effects models for repeated measures; if 95% CIs did not cross zero, differences were considered of nominal statistical significance (α=0.05) as no adjustment was made for multiplicity. PRO responder analysis used a published threshold of 10 points for clinically meaningful change across scales; median time to first deterioration was determined using Kaplan–Meier analyses. **Results:** QLQ-C30 completion rates from baseline through all cycles were >88% in both arms. Baseline scores showed moderate-to-high GHS/QoL and functioning and low symptom burden (Table). Overall changes from baseline on QLQ-C30 GHS/QoL, functioning, and symptom scores were small and similar between arms (Table). In the PRO responder analysis, most pts in both arms reported maintenance or clinically meaningful improvement in QoL in all scales across all cycles (cemi: 55.9–86.8%; pbo: 55.5–88.2%). Median time to first deterioration was also similar between arms in all scales (cemi: 5.3–25.6 months; pbo: 8.3–22.2 months). **Conclusions:** QoL was maintained during treatment with adjuvant cemi, with no clinically meaningful worsening vs pbo. These PRO results complement the observed improvement in DFS and support the favorable risk profile of adjuvant cemi for pts with high-risk CSCC. Clinical trial information: NCT03969004. Research Sponsor: Regeneron Pharmaceuticals, Inc.

	Baseline mean (SD)		Overall LS mean change from baseline (95% CI)		
QLQ-C30 scale	Cemi (n=209)	Pbo (n=206)	Cemi (n=209)	Pbo (n=206)	Difference (95% CI)

Osteoradionecrosis as a complication following intensity-modulated radiation therapy or proton therapy in the treatment of oropharyngeal carcinoma. First Author: Edward Christopher Dee, Department of Radiation Oncology, Memorial Sloan Kettering Cancer Center, New York, NY

Background: Osteoradionecrosis (ORN) is a late complication of head and neck radiotherapy (RT) that negatively impacts survivorship. Although there is an abundance of literature reporting on ORN for photon-based RT, few studies have investigated the correlation between proton therapy and ORN; also, the current literature on ORN incorporates a broad mix of head and neck subsites. Therefore, we report our 10-year institutional experience to assess rates of ORN in a homogenous and consecutive cohort of patients with oropharyngeal squamous cell carcinoma (OPSCC) treated with curative-intent radiotherapy, representing the largest available institutional series. **Methods:** A consecutive cohort of 1564 OPSCC patients (1344 definitive, 220 post-operative) who received at least 50Gy were treated at our institution between 2013 and 2023 were included in this study. Patients were treated with either IMRT or proton therapy. CTCAE version 5 was used for ORN grading. **Results:** Overall ORN rate was 4.35%. Of 1389 patients who underwent IMRT, 56 (4.03%) developed ORN, vs 12/175 (6.86%) treated with proton therapy (hazard ratio [HR] 2.62, 95%CI 1.39–4.93, P=0.003). Median time to ORN in the IMRT arm was 25mo (range, 2mo–91mo). Median time to ORN in the proton arm was 23.5mo (2mo–45mo). Post-operative vs definitive treatment setting was not associated with the rate of ORN (univariate Cox HR 1.00, 95% CI 0.51–1.95, P=0.99). On subset analysis of the 1344 patients treated in the definitive setting, 47/1210 (3.88%) patients treated definitively with IMRT developed ORN as compared to 11/134 (8.21%) patients treated definitively with protons (univariable Cox HR 3.62, 95% CI 1.85–7.09, P<0.001). On multivariable analysis including treatment modality and use of chemotherapy, proton therapy was associated with increased hazard of ORN (HR 2.75, 95%CI 1.46–5.19, P=0.002). Concurrent chemotherapy was also independently associated with increased hazard of ORN (HR 3.34, 95%CI 1.05–10.65, P=0.041). A total of 10 out of 1564 (0.64%) patients developed CTCAE grade 3 ORN. The rates of grade 3 ORN were 2/175 (1.14%) in the proton cohort and 8/1389 (0.58%) in the IMRT cohort. This difference was not statistically significant on univariable Cox analysis (HR 2.44, 95%CI 0.51–11.60, P=0.26). **Conclusions:** The overall prevalence of ORN was 4.35%; the prevalence of >/= grade 3 ORNs was 0.64% in this consecutive cohort of patients with OPSCC treated with either IMRT or proton therapy. The overall prevalence of ORN of any grade was statistically higher for protons versus IMRT, a difference that was more pronounced in the definitive setting. Given the uncertainties with relative biological effectiveness calculations in proton therapy, avoidance of hot-spots, frequent replanning, and use of empirical proton-specific normal tissue constraints may help to reduce rates of ORN. Future work should explore the role of combination proton and photon treatment, especially in the definitive setting. Research Sponsor: National Cancer Institute/U.S. National Institutes of Health; P30 CA008748.

6067 Poster Session

Efficacy analysis of neoadjuvant PD-1 inhibitor combined with chemotherapy in various subanatomical sites of locally advanced and recurrent resectable head and neck squamous cell carcinoma: A retrospective real-world study. First Author: Haolei Tan, Head and Neck Surgery Department I, Hunan Cancer Hospital and The Affiliated Cancer Hospital of Xiangya School of Medicine, Central South University, Changsha, China

Background: Clinical research on Head and Neck Squamous Cell Carcinoma (HNSCC) often considers the disease as a whole. However, the therapeutic outcomes may vary significantly across different subanatomical sites, as well as between locally advanced (LA) and recurrent resectable (RR) HNSCC. Therefore, we stratified HNSCC according to specific anatomical sites and initial diagnosed versus recurrent tumors, and analyzed the efficacy of neoadjuvant PD-1 inhibitor + chemotherapy. **Methods:** Retrospectively analyzed patients with LA and RR HNSCC admitted to Hunan Cancer Hospital from October 2021 to December 2024, who received neoadjuvant PD-1 inhibitor and chemotherapy. Post-treatment efficacy was evaluated using imaging, endoscopy, or pathology. Differences in efficacy outcomes between different subanatomical sites and between LA and RR tumors were classified and statistically analyzed. **Results:** 1) A total of 482 patients were included: 434 with LA HNSCC(90.04%) and 48 with RR HNSCC (9.96%), 453 males (93.98%) and 29 females (6.02%). Patient ages ranged from 17 to 77 years, with a mean age of 52.43 $\pm$ 9.83 years. 2)The top three types of LAHNSCC that underwent neoadjuvant therapy were: tongue (N=157, 36.180%), buccal oris (N=105, 24.19%),and hypopharynx (N=92, 21.20%). 3)The objective response rates (ORR) following neoadjuvant therapy were as follows: 90.32% for oropharyngx, 83.33% for gingiva, 80.25% for tongue, 79.35% for hypopharynx, 68.57% for buccal oris, and 56.25% for RR HNSCC. The highest pathological deep response rates (pCR+MPR) was observed in tongue (34.40%), followed by oropharynx (29.04%), gingiva (26.67%), and only 33% for RR HNSCC. **Conclusions:** There are significant variations in the sensitivity of HNSCC to neoadjuvant immunotherapy + chemotherapy across different subanatomical sites. Oropharynx exhibits the highest response to this regimen, whereas RR cases demonstrate relatively poor responsiveness. In terms of pathological deep response, tongue, oropharynx, and gingiva show favorable response rates, while RR cases exhibit significantly lower response rates. Functional and survival outcomes in HPV positive oropharyngeal squamous cell cancer treated with response-adaptive de-escalation: A pooled analysis. First Author: Faith Abodunrin, Section of Hematology and Oncology, Department of Medicine, University of Chicago, Chicago, IL

Background: Human papillomavirus (HPV) positive OPSCC is known to have a favorable prognosis compared to its HPV negative counterparts. It is thus important to limit treatment-related toxicity while preserving functional and survival outcomes. In this pooled study, we report functional and survival outcomes across prospective cohorts treated with chemotherapy-response-adaptive dose and volume de-escalation of radiation. **Methods:** Patients with non-metastatic HPV positive OPSCC were sequentially treated at an academic center on either an interventional de-escalation trial: OPTIMA 1 (NCT02258659); OPTIMA II (NCT03107182); (NCT04572100) or off-protocol in a prospective registry. Eligible patients had N1-3 or T3-4 (AJCC 8th edition) disease. Very low-risk patients T0-2N0-1 (single lymph node <3cm) were excluded. Patients were stratified as low risk (LR) or high risk (HR) according to T/N stage and smoking history. Following chemotherapy (carboplatin and paclitaxel or *nab*-paclitaxel) with or without nivolumab, patients received de-escalated treatment with low dose arm (LDA; radiation [RT] alone to 50Gy or transoral robotic surgery), intermediate dose arm (IDA; chemoRT [CRT] to 45-50Gy) or regular dose arm (CRT to 70-75Gy). To analyze functional outcomes, we compared swallowing performance scores (SPS), trismus, percutaneous endoscopic gastrostomy (PEG) tube placement obtained from pre- and post-(C)RT. Comparisons across risk categories and treatment arms using Chi-square, Fisher, and Student t-tests. Survival outcomes were compared using log-rank statistic. **Results:** Eligible patients (n=242) started treatment between 2014 and 2024: 116 LR and 126 HR patients; 83% received de-escalated treatment (LDA/IDA) and 17% received standard dose (RDA). Post-treatment SPS (p=0.0002) and trismus scores (p=0.0013) was better among de-escalated versus non-de-escalated patients. Lower PEG placement rates were observed among de-escalated patients 33/196 (16.8%) vs 27/39 (69.2%) (p<.0001). With median follow-up of 48 months, no statistically significant differences in overall survival or progression free survival were observed between treatment arms. OS (95.1% (95% CI 90.8%-97.4%) vs 93.7%(95% CI 77.72%- 98.4%), P=0.185) and PFS (92.2% (95% CI 87.1%-95.2%) vs 90.7% (95% CI 73.9% - 96.9%, p=0.202) were similar in deescalated and non-deescalated patients at 3 years. Low risk individuals also had better OS (97.1% vs 92.1%, p=0.01) and PFS (96.1% vs 88.3%, p=0.004) at three years. **Conclusions:** Improved functional outcomes including posttreatment swallowing function, trismus, and lower PEG placement rates were observed with chemotherapy-response-adaptive radiation de-escalation with excellent survival in the largest prospective cohort reported to date. Response-adaptive de-escalation warrants further comparative study. Research Sponsor: Chicago Institute of Translational Medicine.

Neoadjuvant chemoimmunotherapy with afatinib for locally advanced head and neck squamous cell carcinoma (neoCHANCE-2): An open-label, single-arm, phase 2 study. First Author: Zhigong Wei, Department of Biotherapy, Cancer Center, West China Hospital, Sichuan University, Chengdu, China

Background: Neoadjuvant chemoimmunotherapy has been an emerging hotspot for the treatment of locally advanced head and neck squamous cell carcinoma (LA-HNSCC), but the treatment response still requires improvement. Given the potential synergistic anti-tumor effects of dual inhibition of the PD-1/L1 and EGFR pathways, we proposed a novel neoadjuvant treatment regimen combining chemoimmunotherapy with EGFR-TKI, followed by adjuvant immunotherapy treatment, and evaluated the efficacy and safety of this approach. **Methods:** This open-label, single-arm, phase 2 trial was done at a tertiary hospital in China. Patients were eligible if they were aged at least 18 years old; had pathologically confirmed HNSCC with locally advanced disease according to the AJCC 8th Edition; had an ECOG performance status of 0−1; had at least one measurable target lesion according to RECIST 1.1 criteria; and had sufficient organ function. Patients with LA-HNSCC received two cycles of tislelizumab (200mg) and TP (nab-paclitaxel and cisplatin) chemotherapy, administrated on day one of each three-week cycle, along with afatinib (30mg) during the intermittent period between chemoimmunotherapy cycles, followed by 15 cycles of adjuvant tislelizumab treatment. The primary endpoint was the complete pathologic response (pCR) rate, defined as the percentage of patients with no detectable RVT cells in the resected primary tumor. **Results:** A total of 40 patients were enrolled and received neoadjuvant treatment, 32 of whom proceeded to surgical resection and achieved a pCR rate of 40.6% (95% CI: 23.7−59.4%). The overall response rate (ORR) was 82.5% (95% CI: 67.2−92.7%). The median follow-up time was 14.4 months (range: 2.4−27.6 months) . The estimated 1-year overall survival (OS) was 96.7% (95%CI: 90.5%−100%). No deaths occurred among patients who achieved pCR/MPR. The most common treatment-related adverse events (TRAEs) of any grade were alopecia (100%), followed by nausea (62.5%), lymphopenia (57.5%), diarrhea (55%), and rash (55%). The most common TRAE of grade 3−4 was lymphopenia (5/40, 12.5%). No treatment-related surgical delays were observed. Neoadjuvant treatment induced a significant increase in the proportion of peripheral CD8+ T cells, along with a reduction in B cells. TP53 wild-type patients were more likely to achieve a more favorable pathologic response compared to those with a TP53 mutation. A significant difference in oral microbial composition was found between patients with different pathologic responses. **Conclusions:** This study firstly reported the promising efficacy and acceptable safety profile of neoadjuvant chemoimmunotherapy combined with apatinib in the treatment of patients with LA-HNSCC. Further evaluation in large-scale clinical trials with longer follow-up periods is needed. Clinical trial information: NCT05516589. Research Sponsor: None.

Induction pembrolizumab plus cisplatin and 5-FU chemotherapy followed by chemoradiotherapy in locally advanced squamous cell cancer of oropharynx, hypopharynx or larynx: Results of multicenter prospective phase II study. First Author: Ilya Pokataev, Moscow City Oncological Hospital No. 1 Named After S.S. Yudin, Moscow, Russian Federation

Background: Chemoradiation with cisplatin or induction chemotherapy with docetaxel, platinum agent and 5-FU are associated with high toxicity. We hypothesized that immunochemotherapy with pembrolizumab and platinum-based chemotherapy followed by chemoradiotherapy (CRT) might be associated with higher clinical efficacy along with a lower likelihood of adverse effects (AE). **Methods:** We conducted the multicenter single-arm phase II study (NCT05551767), including patients (pts) with stage III-IV, PD-L1 positive (CPS≥1), squamous cell carcinoma of larynx, oropharynx or hypopharynx. Pts with ECOG > 2 were excluded. All enrolled pts received 3 cycles of induction therapy with pembrolizumab 200 mg on day (d) 1, cisplatin 100 mg/m^2 on d1 and 96-hour infusion of 5-FU 1000 mg/m^2/d followed by CRT. We aimed to evaluate response rate, survival, safety and incomplete CRT rate after induction therapy. **Results:** Since 2022 to August 2024 120 pts were enrolled, including 82 (72.5%) with oropharyngeal, 21 (17.5%) hypopharyngeal and 12 (10%) laryngeal cancer. The median age was 60 (range 35 - 75), most patients were male (87.5%) and 108 (90%) had ECOG 0-1. Objective response rate (ORR) by RECIST 1.1 was assessed after induction therapy in 116 of 120 pts: 73 (62.9%) pts had response including 19 pts (16.4%) with complete responses (CR). The median change of target lesions was -55% (from -100% to 65%). ORR after CRT was assessed in 102 pts: 84 (82.4%) responders were identified with a 71.6% CR rate. Only 8 (6.7%) pts did not start CRT after induction therapy. Among other 112 pts 92.9% received radiation dose ≥66Gy. With a median follow-up 16.6 months 1-year progression-free survival was 73.5% and 1-year overall survival was 80%. There were no treatment-related deaths on induction therapy although 6 (5%) pts required hospital readmission due to adverse events (AE). The incidence of grade 3-4 AE by CTC AE v.5.0 was 30.8% with asymptomatic neutropenia grade 3-4 being the most frequent AE (23.3%). **Conclusions:** The study demonstrated promising ORR, progression-free survival rate and acceptable safety profile of induction therapy with pembrolizumab, cisplatin and 5-FU in head and neck cancer. High response rate to induction therapy was associated with a high number of CRT completion. Clinical trial information: NCT05551767. Research Sponsor: Moscow Center For Healthcare Innovations.; #2112-10/22.

Primary results from IChoice-02, a phase 2 trial of induction chemoimmunotherapy followed by response-adapted de-escalation of chemoradiation in HPV-associated oropharyngeal cancer. First Author: Xueguan Lu, Department of Radiation Oncology, Fudan University Shanghai Cancer Center, Shanghai, China

Background: Despite multiple attempts to de-intensify treatments in HPV-associated oropharyngeal cancer (OPC), data with incorporation of immunotherapy remain scarce. Neoadjuvant platinum-based chemotherapy and anti-PD-1 therapy has shown promising pathological response after radical surgery. In IChoice-02 trial, we evaluated the efficacy of induction chemoimmunotherapy followed by response-adapted de-escalation of radiotherapy and omission of concurrent chemotherapy in HPV-associated OPC. **Methods:** IChoice-02 trial enrolled T1-2/N1-3M0 (excluding T1N1M0 patients with single and≤3cm lymph node) or T3-4N0-3M0 (UICC/AJCC 8th staging system) HPV+ OPC. Following two cycles of induction toripalimab (240mg), docetaxel (75mg/m2) and cisplatin (75mg/m2) every 3 weeks, patients with deep response (CR or ≥50% PR per RECIST in both oropharynx and nodes) were subjected to de-intensified radiotherapy (60Gy) alone with no concurrent chemotherapy, while those otherwise received standard-dose radiation to 70Gy with two cycles of concurrent cisplatin (80mg/m2 every three weeks). The primary endpoint was 2-year progression-free survival (PFS). **Results:** 97 patients were enrolled from March 2021 until July 2024, including 44 (45.3%) stage I, 28 (28.9%) stage II and 25 (25.8%) stage III. Following induction chemoimmunotherapy, 60.8% (59/97) achieved radiological deep response. 53/73 (72.6%) of stage I-II and only 6/25 (24%) of stage III patients underwent subsequent de-escalation. With 16.5 months median follow-up, 2/59 patients had loco-regional relapse (both in-field) in the de-escalation arm, and 6/38 in the standard arm experienced treatment failure (3 locoregional, 2 distant and 1 with both). 1-year PFS was 92.9%, 96.1% and 87.8% in the full cohort, de-escalation arm and standard arm, respectively. 1-year overall survival (OS) was all 100%. There were no treatment-related deaths. Unexpectedly, two cases of second primary malignancy (one with intracranial lymphoma and the other with melanoma) were observed within 4 months after treatment completion. **Conclusions:** Induction toripalimab in combination with platinum-based doublet chemotherapy followed by de-escalation of chemoradiation to lower radiation dose with omitted concurrent chemotherapy yielded outstanding 1-year survival. Long-term survival is awaited with further follow-up. Clinical trial information: NCT04867330. Research Sponsor: Shanghai Junshi Biosciences.

Preoperative steroid for enhancing patients' recovery after head and neck cancer surgery with free tissue transfer reconstruction: Phase III, placebo-controlled, randomized, double-blind study (J-SUPPORT 2022, PreSte-HN Study). First Author: Kohtaro Eguchi, Department of Head and Neck Surgery, National Cancer Center Hospital, Chuo-Ku, Japan

Background: The enhanced recovery after surgery (ERAS) pathway integrates evidence-based protocols to optimize recovery during the perioperative period. It has recently been applied to head and neck cancer surgery with free tissue transfer reconstruction (HNS-FTR). While preoperative corticosteroid administration has shown benefits in reducing postoperative pain and nausea/vomiting in certain surgeries, its role in the ERAS pathway for HNS-FTR remains unclear. This study aimed to assess the impact of adding preoperative corticosteroid administration on the quality of postoperative recovery within the ERAS pathway for HNS-FTR. **Methods:** This phase III, placebo-controlled, randomized, double-blind trial included 180 patients undergoing HNS-FTR. Patients were randomly assigned (1:1) to receive either 8.0 mg of dexamethasone phosphate in 100 mL of saline or placebo (100 mL of saline) as a single intravenous dose preoperatively. All patients received standardized perioperative care under the multicenter ERAS pathway for HNS-FTR. The primary endpoint was the quality of postoperative recovery, assessed by the area under the curve (AUC) for the total scores of the Japanese version of the Quality of Recovery Score (QOR-40J) on postoperative days 2 and 4. Key secondary endpoints included the AUC of visual analog scale (VAS) scores for pain and nausea on postoperative days 1 to 3. Complications were analyzed using the Clavien-Dindo classification. **Results:** Data from 87 and 91 patients in the dexamethasone and placebo groups, respectively, were evaluated. ERAS pathway completion rates were 97.7% and 97.8% for the dexamethasone and placebo groups, respectively. The estimated AUC for QOR-40J total scores on postoperative days 2 and 4 was 295.7 in the dexamethasone group and 299.8 in the placebo group, with no significant difference (p = 0.665). Similarly, no significant differences were observed in VAS scores for pain (p = 0.829) and nausea (p = 0.649). While there were no significant differences in complications of Grade 2 or higher (p = 0.584) or wound-related complications (p = 0.938), a significant difference was found in postoperative bleeding, with no cases observed in the placebo group (p = 0.039). **Conclusions:** Preoperative corticosteroid administration in the ERAS pathway for HNS-FTR did not yield clinically significant benefits. Ensuring the successful implementation of the ERAS pathway is crucial. Clinical trial information: jRCTs031210593. Research Sponsor: AMED.

Association of AI-informed biomarkers of spatial organization of tumor-infiltrating lymphocytes with loco-regional recurrence in laryngeal squamous cell cancer. First Author: Sahil Hasit Patel, Case Western Reserve University, Cleveland, OH

Background: Laryngeal Squamous Cell Carcinoma (LaSCC) has varying outcomes based on the stage of cancer patients present with. Currently, a high proportion of patients are diagnosed with advanced-stage LaSCC complicating the treatment landscape and over-treating low risk patients. Risk stratification of LaSCC can help tailor treatment plans. Numerous studies have identified spatial architecture of tumor-infiltrating lymphocytes (TILs) as a prognostic biomarker in oral cavity and oropharyngeal SCC. In this work, we evaluate the prognostic value of an artificial intelligence (AI)-leveraged approach that characterizes the spatial architecture of TILs on digitized hematoxylin and eosin (H&E)-stained slides from patients with LaSCC. **Methods:** H&E slides from 192 patients with LaSCC were collected from Baylor Medical Center. This dataset was randomly divided into two equal cohorts, A and B. The slides were digitized as whole slide images at 40x magnification. The nuclei of all cells were automatically segmented using a deep-learning model (Hover-Net). Each nucleus was then classified as TIL or non-TIL based on morphological features. TILs and non-TILs were clustered based on proximity, and features related to the density and spatial distribution were extracted. The top features, determined by the least absolute shrinkage and selection operator, were used to train a Cox Proportional Hazards regression model that assigned a risk score for recurrence of cancer to each patient in cohort A. For validation, the model was applied to patients in cohort B. The 25th percentile training risk score was used as a cutoff for classifying patients as high or low risk. The performance of the model in prognosticating loco-regional recurrence (LRR) was evaluated using survival analysis. **Results:** Patients in Cohort B identified as "high risk" by the model based on spatial organization of TILs had a significantly shorter survival time. Univariate survival analysis showed this model was prognostic for DFS with a hazard ratio of 2.57 (95% Confidence Interval: 1.12-5.89, p-value=0.048), meaning that patients classified as "high risk" are approximately 2.5 times more likely to develop LLR. **Conclusions:** We used computational pathology to characterize the architecture of TILs and develop a model to predict risk of LLR in LaSCC. With additional validation, this approach can be used to assist clinicians with making clinical decisions. Research Sponsor: None.

Multivariate analysis.

Variable	Reference vs Comparison	Pr(>|z|)	HR (95% CI)
Race	Black vs Caucasian	0.93	0.92 (0.40 - 2.31)
N	N0 vs N+	0.67	1.80 (0.12 - 26.06)
T	1-2 vs 3-4	0.83	1.28 (0.13 - 12.38)
Chemo	Yes vs No	0.38	3.49 (0.21 - 56.90)
Tobacco	Yes vs No	0.26	2.08 (0.58 - 7.47)
Alcohol	Yes vs No	0.43	1.53 (0.54 - 4.35)

Decision analysis of PD-1 inhibitor combined with chemotherapy in neoadjuvant therapy of resectable locally advanced head and neck squamous cell carcinoma (LA HNSCC). First Author: Xiaohong Chen, Beijingshijitan hospital Capital medical university, Beijing, China

Background: Neoadjuvant therapy (NAT) with PD-1 inhibitors plus chemotherapy has been shown to have a high pathological response rate in LA HNSCC, but there is controversy over factors such as the number of treatment cycles and biomarkers. This trial explored multiple factors that may affect NAT and provided patients with an individualized treatment strategy. **Methods:** Untreated pts with AJCC 8th edition stage III-IVB (HPV-positive oropharyngeal : stage II-III) LA HNSCC were selected between 2021 and 2024. After enrollment, pts received 2 cycles of PD-1 inhibitors combined with chemotherapy, and RT was used when CR was achieved on imaging. If PR, SD or PD was achieved, direct surgery or RT could be chosen, or 1-2 cycles of PD-1 inhibitors plus chemotherapy could be received again before curative treatment. The primary endpoint was 1y-DFS. The sample size was N=80, which provided 0.8 power based on Exact Test at One-Sided alpha level of 0.05. **Results:** A total of 82 pts were included. Median age was 59 yrs (23-76), and 81 (98.8%) were male. Location: oropharyngeal was 22 (26.8%) (HPV-positive was 61.9%), laryngeal was 10 (12.2%), hypopharynx was 48 (58.5%), nasal cavity and sinuses was 2 (2.4%). T3 +T4 was 55.3%, N2+N3 was 44.7%. CPS of pts who underwent testing was 89.0% (73/82), and 48.0% pts were CPS$\geq$20. Pts received 2 cycle (45.1%), 3cycle (50%), 4 cycle (4.8%) NAT. Median follow-up time was 15.9 months, 1y-PFS was 95.9% and 1y-OS was 98.4%. The PFS of pts with pCR or (CR+PR) were both significantly higher than that of pts with non-pCR or (SD+PD)(p=0.049 and p=0.024). The ORR was 84.1%, and ORR of 2-cycle was lower than muti-cycle (81.1% vs 86.7%,p=0.544) . 49.1% pts achieved pCR of primary lesion. pCR of 2-cycle was little higher than muti-cycle (53.3% vs 44.4%, p=0.867). However, the T3-4 in the 2-cycle group was significantly lower than that in the multi-cycle group (43.2% vs 68.9%, p=0.037). In T3-4 pts, pCR in multiple cycles was higher than that in 2 cycles (56.3% vs 38.5%, p=0.339). In addition, pCR of CPS $\geq$ 20 was significantly higher than that of CPS $<$ 20 (66.7% vs 34.6%, p=0.028). In T1-2 population, pCR of CPS$\geq$20 vs $<$20 was 81.8% vs 28.6% (p=0.006), while no significant different in T3-4 population. Poorly differentiated patients with CPS $\geq$ 20 vs. moderately/highly differentiated pts was 85% and 30.6% ($p<0.001$). 1y - laryngeal function preservation rate was 98.3% (1/58). The overall TRAEs incidence rate was 72%, the most common Grade 3-4 TRAEs were myelosuppression (8.9%). **Conclusions:** Increasing the number of cycles may be beneficial for T3-4 pts. In addition, CPS$\geq$20 pts can achieve higher pCR, especially in T1-2 pts. CPS is also associated with worse pathological differentiation type. Clinical studies (NCT06100497) are currently underway to further explore the efficacy and safety of PD-1 inhibitors combined with chemotherapy in poorly differentiated LA HNSCC. Efficacy and safety of Sapylin versus dexamethasone atomized inhalation for CCRT-induced oral mucositis in patients with nasopharyngeal carcinoma: A randomized, parallel design, and non-inferiority clinical trial. First Author: Haiqing Luo, Affiliated Hospital of Guangdong Medical University, Zhanjiang, China

Background: Radiation-induced oral mucositis (RIOM) is a common adverse reaction to radiotherapy and chemotherapy in patients with nasopharyngeal carcinoma (NPC). Sapylin is an immune adjuvant with anti-tumor effects in multiple malignancies. This study investigated the efficacy and safety of Sapylin versus dexamethasone for treating RIOM in patients with NPC. **Methods:** This prospective, parallel-design, non-inferiority randomized study aims to investigate the effects of inhaling atomized Sapylin versus dexamethasone on the incidence and severity of RIOM in patients with NPC undergoing concurrent chemoradiotherapy (CCRT). A total of 100 patients were enrolled and randomized in a 1:1 ratio into the intervention (Sapylin) and control (dexamethasone) groups. Both groups received cisplatin-based CCRT. The Sapylin and dexamethasone groups received Sapylin (1 KE) and dexamethasone (10 mg), respectively, both via atomized inhalation once daily. Both treatments commenced on the first day of CCRT and continue until the conclusion of radiotherapy. **Results:** Comparisons among groups showed no statistically significant differences in patient characteristics after randomization of patients. Compared to the dexamethasone group, the Sapylin group demonstrated a lower incidence of RIOM (78.9% vs. 83.6%, $P < 0.05$) and a significantly reduced incidence of severe RIOM (grades III-IV) (37.1% vs. 42.5%, $P < 0.05$). The onset times for grades I, II, III, and IV RIOM in the Sapylin group were later than those observed in the dexamethasone group ($P < 0.05$). From baseline to the conclusion of radiotherapy (RT), the changes in Body Mass Index (BMI) in both groups were statistically significant ($P < 0.001$). During RT, the decrease in BMI was less pronounced in the Sapylin group, with a mean change of 0.97 ± 0.76 (mean $\pm$ SD), compared to a larger decrease in the dexamethasone group, which had a mean reduction of 2.02 ± 0.81 (mean $\pm$ SD). A significant positive correlation was found between changes in BMI and the severity of RIOM ($r = 0.671$, $p < 0.003$). No significant difference in the incidence of adverse reactions was observed between the two groups ($P > 0.05$). **Conclusions:** Compared to dexamethasone group, Sapylin group resulted in a decrease in the incidence and severity of RIOM in patients with NPC without obvious side effects. The use of Sapylin atomized inhalation regimen is both safe and effective, and it positively influences the improvement of nutritional status. Clinical trial information: ChiCTR2200064576. Use of early EBV DNA clearance to select optimal induction chemotherapy cycles for locoregional advanced nasopharyngeal carcinoma. First Author: Wanping Guo, Sun Yat-sen University Cancer Cener, Guangzhou, China

Background: Based on 3 cycles of induction chemotherapy (IC) followed by concurrent chemoradiotherapy (CCRT) is the standard treatment for locoregional advanced nasopharyngeal carcinoma (LA-NPC). However, it remains unclear whether all patients benefit from 3 cycles of IC. Epstein-Barr virus (EBV) DNA is a key biomarker for NPC, and changes of cell-free EBV DNA (cfEBV DNA) may reflect tumor dynamics. This study aims to use early cfEBV DNA clearance to guide optimal IC cycle selection for LA-NPC patients. **Methods:** We included 1541 LA-NPC patients treated with IC+CCRT between 2010 and 2023, all with early cfEBV DNA data (pre-treatment, and after 1st IC cycle). Independent prognostic factors were identified by COX regression, and predictive accuracy was assessed using receiver operating characteristic (ROC) curves. Propensity score matching (PSM) balanced covariates between groups receiving different IC cycles. The primary outcome, progression-free survival (PFS) was analyzed using Kaplan-Meier and log-rank tests. **Results:** After the 1st IC cycle, 693 (44.97%) patients had undetectable cfEBV DNA. cfEBV DNA after the 1st IC (p=0.014) and N stage (p=0.048) were significant predictors of PFS. The combination of N stage and cfEBV DNA after the 1st IC cycle had a higher AUC for 5-year PFS (0.610) compared to N stage, cfEBV DNA after 1st IC, or TNM stage alone (0.543, 0.588, 0.557). Based on these two factors, patients were divided into high-risk (N2-3 and detectable cfEBV DNA after 1st IC) and low-risk (N0-1 or undetectable cfEBV DNA after 1st IC) groups. The 5-year PFS for low-risk and high-risk groups was 81.2% vs. 65.1% ($p<0.001$). After PSM, low-risk patients receiving 3 cycles of IC showed significantly better PFS compared to those receiving 2 cycles (5-year PFS: 86.0% vs. 72.5%, $p<0.001$). However, high-risk patients showed similar PFS regardless of IC cycles (5-year PFS: 66.1% vs. 63.7%, p=0.306). **Conclusions:** EBV DNA clearance after the first cycle of IC is a sensitive predictor of outcomes in LA-NPC. Low-risk patients may benefit from an additional cycle of IC, while high-risk patients require alternative strategies such as immunotherapy or earlier initiation of CCRT. Induction chemotherapy with or without toripalimab followed by concurrent chemoradiotherapy for locoregionally advanced nasopharyngeal carcinoma: A multicenter, open-label, randomized, controlled, phase 2 trial. First Author: Kai Hu, Department of Radiation Oncology, the First Affiliated Hospital of Guangxi Medical University, Nanning, Guangxi, China

Background: Although nasopharyngeal carcinoma (NPC) treatment has entered the era of immunotherapy, the optimal treatment model for locoregionally advanced nasopharyngeal carcinoma (LANPC) remains unclear. This trial aimed to evaluate the efficacy and safety of adding toripalimab to induction chemotherapy (IC) in patients with LANPC. **Methods:** Patients with LANPC (T4NanyM0 or TanyN2/N3M0, AJCC 8th edition) were enrolled at 8 centers across China and randomized (1:1) into two arms: the standard arm (gemcitabine and cisplatin IC followed by cisplatin concurrent chemoradiotherapy [CCRT]) and the toripalimab arm (toripalimab plus IC followed by CCRT). Both arms received intravenous gemcitabine (1g/m²) on days 1 and 8, and cisplatin (80 mg/m²) on day 1, every 3 weeks for 3 cycles, followed by standard CCRT (cisplatin 100 mg/m² every 3 weeks for 3 cycles). In the toripalimab arm, patients also received intravenous toripalimab (240 mg) on day 1 every 3 weeks for 3 induction cycles. The primary endpoint was failure-free survival (FFS). Secondary endpoints included complete response (CR) rate after neoadjuvant treatment, locoregional failure-free survival (LRRFS), distant metastasis-free survival (DMFS), overall survival (OS), and toxicity. Response evaluation was conducted according to RECIST 1.1, and adverse events (AEs) were assessed by CTCAE v5.0. This study is registered with ClinicalTrials.gov (NCT05340270), and follow-up is ongoing. **Results:** Between July 2022 and March 2024, 150 patients (mean age 47 years, 72% male) were randomized to the toripalimab arm (n = 75) and the standard arm (n = 75). As of November 30, 2024, the median follow-up duration was 23.4 months, and 15 patients had reached the primary endpoint. Long-term efficacy data are still awaited. The CR rate after neoadjuvant treatment was 36.0% (27 of 75) in the toripalimab arm and 13.3% (10 of 75) in the standard arm (P= 0.001). The overall response rate (ORR) after neoadjuvant treatment was 94.7% (71 of 75) in the toripalimab arm and 85.3% (64 of 75) in the standard arm (P= 0.042). Grade 3-4 acute treatment-related adverse events (trAEs) occurred in 50 (66.7%) patients in the toripalimab arm and46 (61.3%) patients in the standard arm (P= 0.496), with immune-related AEs (irAEs) reported in 5 (6.7%) patients in the toripalimab arm and none (0.0%) in the standard arm (P= 0.058). All grade 3-4 irAEs were manifested as rashes and pruritus. **Conclusions:** Adding toripalimab to standard IC followed by CCRT resulted in a superior CR rate and ORR compared to IC-CCRT alone, with manageable toxicity profiles in patients with LANPC. Further follow-up is needed to confirm long-term efficacy, and this combination may offer an optimal, cost-effective therapeutic model for LANPC. Clinical trial information: NCT05340270. Research Sponsor: None.

Radiotherapy plus nimotuzumab versus cisplatin in low-risk locoregionally advanced nasopharyngeal carcinoma who had favorable response to induction chemotherapy: A randomised, phase III, non-inferiority trial. First Author: Hai-Qiang Mai, Department of Nasopharyngeal Carcinoma, Sun Yat-Sen University Cancer Centre, Guangzhou, China

Background: Patients with low-risk locoregionally advanced nasopharyngeal carcinoma (LA-NPC) have high survival when treated with radiotherapy (RT) plus cisplatin after induction chemotherapy (IC). Whether replacement of cisplatin with nimotuzumab—a humanized antibody against the epidermal growth factor receptor (EGFR)—can preserve high survival and reduce treatment toxicity is unknown for patients with good response to IC. Therefore, we assessed whether nimotuzumab plus RT was non-inferior to cisplatin plus RT in low-risk LA-NPC with favorable response to IC. **Methods:** The study was a randomised, non-inferiority, phase 3 trial at Sun Yat-sen University Cancer Centre, China. Adult patients (aged 18–70 years) with non-keratinizing stage II-IVA (except N3 category; the eighth edition of the American Joint Committee on Cancer classification system) NPC, with pre-treatment plasma EBV DNA$<$1500 copies/mL, positive EGFR expression and an Eastern Cooperative Oncology Group performance status of 0–1, were treated with 2 cycles of paclitaxel-cisplatin-fluorouracil IC, those achieved CR/PR with undetectable EBV DNA were randomly assigned (1:1) to receive either intravenous nimotuzumab at a dose of 200 mg weekly or cisplatin 100 mg/m² on days 1, 22 and 43 of intensity-modulated radiotherapy. Randomization was done using a computer-generated code random number code with a block size of six, stratified by overall stage. The primary endpoint was 2-year progression-free survival (PFS) in the intention-to-treat population. Safety was assessed in all participants who received at least one dose of the assigned treatment. This study is registered with ClinicalTrials.gov, number NCT 04456322. **Results:** Of the 381 patients who underwent randomization, 191 were assigned to RT plus nimotuzumab and 190 to RT plus cisplatin. After median follow-up duration of 39.5 months, in the evaluation of 2-year PFS, RT plus nimotuzumab was noninferior to RT plus cisplatin (94.2% and 95.8%, respectively; absolute difference, 1.6 percentage points; 95% CI, −2.8 to 6.0, [noninferiority margin, -10 percentage points], $P_{noninferiority}$=0.0001). The most common grade 3-4 acute toxicities were leucopenia (37 [19.5%] of 190 patients in the cisplatin group vs. 2 [1.1%] of 189 patients in the nimotuzumab group), mucositis (36 [18.9%] vs. 28 [14.8%]), and vomiting (21 [11.1%] vs. 0). No patients died during treatment. Patients in the cisplatin group also showed more grade 1-2 auditory or hearing loss and peripheral neuropathy in late adverse events, and impaired long-term quality of life. **Conclusions:** Our findings show that nimotuzumab plus RT represents an alternative concurrent treatment strategy for patients with low-risk LA-NPC with a favorable response to IC. Clinical trial information: NCT04456322. Research Sponsor: None.

5-year survival outcomes after perioperative pembrolizumab (pembro) in patients with human papillomavirus (HPV)-unrelated, locally advanced head and neck squamous cell carcinoma (LA-HNSCC): A multi-center, two-cohort, phase 2 trial. First Author: Edward S. Sim, Dana-Farber and Brigham and Women's Cancer Center, Boston, MA

Background: A phase 2 trial (NCT02296684) demonstrated that perioperative pembro added to standard of care (SOC) surgery/adjuvant radiation-based therapy resulted in frequent pathologic tumor responses (pTR) and favorable 2-year survival relative to historical rates in patients with HPV-unrelated, LA-HNSCC (Uppaluri et al., CCR 2020; Oliveira et al., Sci Immunol 2023). The early results of this institutional phase 2 trial provided necessary rationale for the Merck-sponsored, KEYNOTE-689 phase 3 trial that compared perioperative pembro with SOC versus SOC in patients with resectable LA-HNSCC. Here, we report 5-year survival outcomes from the phase 2 trial. We also evaluated the effect of two pembro dosing schedules and the presence or absence of pTR at the primary tumor site on long-term survival outcomes. **Methods:** Cohort 1 received one dose of neoadjuvant pembro (200 mg IV) and, in patients with high-risk pathology, six doses of adjuvant pembro. Cohort 2 received two doses of neoadjuvant but no adjuvant pembro. $pTR_{primary}$ was defined as the proportion of the resected primary site tumor bed that exhibited pathologic response: 0 ($<$10%), 1 (10%-49%), and 2 ($\geq$50%). Event-free survival (EFS), defined as the time from surgery to disease progression, recurrence, or death, and overall survival (OS) was analyzed by the Kaplan-Meier method with log-rank testing for significance. **Results:** Sixty-five patients enrolled (36 in cohort 1 and 29 in cohort 2). The median follow-up was 48.4 months (IQR: 30.1-60.9). The 5-year OS for all patients was 73% (95% CI: 62-85%) and the EFS was 71% (95% CI: 61-83%). A comparison of patients in cohort 2 versus 1 showed no significant differences in OS (HR = 0.39; 95% CI: 0.12-1.20; p = 0.09) or EFS (HR = 0.72; 95% CI: 0.28-1.84; p = 0.48). For all patients, those with $pTR_{primary}$ 1 or 2 versus 0 had significantly better EFS (HR = 0.34; 95% CI: 0.11-1.02; p = 0.04), but not OS (HR = 0.42; 95% CI: 0.14-1.3; p = 0.10). **Conclusions:** Among patients with HPV-unrelated, LA-HNSCC treated with perioperative pembro and SOC, the 5-year OS and EFS were favorable relative to historical results (~40-50% 5-year OS and EFS) with SOC alone. While OS was numerically better in cohort 2 compared to cohort 1, and among patients with $pTR_{primary}$1 or 2 compared $pTR_{primary}$ 0, the differences did not reach statistical significance, possibly due to the small sample size. $pTR_{primary}$ after neoadjuvant pembro was significantly associated with better EFS, suggesting its potential utility as an early surrogate marker for EFS. Clinical trial information: NCT02296684. Research Sponsor: "Merck Sharp & Dohme LLC, a subsidiary of Merck & Co., Inc., Rahway, NJ, USA provided pembrolizumab and financial support for the study".

AI-based classification of laryngeal dysplasia and lymphocytic activity quantification from routine histology. First Author: Adam Shephard, University of Warwick, Coventry, West Midlands, United Kingdom

Background: Laryngeal Dysplasia (LD) is a premalignant condition arising in the lining of the larynx. It is graded based on cytological and architectural features present in the epithelium of H&E-stained histology images. However, LD grading suffers from high inter- and intra-rater variability and is not always predictive of malignant transformation. Additionally, distinguishing LD from other laryngeal lesions, such as squamous cell carcinoma (SCC) or benign polyps, remains challenging. Artificial intelligence (AI) offers a solution by enabling objective classification of lesion types, whilst identifying key features associated with LD progression, including lymphocytic infiltration. We propose an AI model using weakly-supervised deep learning to classify LD and highlight potential diagnostic features. **Methods:** We used 109 H&E-stained whole slide images (WSIs) from 82 cases (UHCW and Dundee) scanned at 40$\times$ magnification (0.12 microns-per-pixel, mpp) using a Pannoramic 250 whole-slide scanner. The dataset comprised 50 LD cases (65 WSIs), 20 laryngeal SCC cases (28 WSIs), and 12 benign polyp cases (16 WSIs). Using a pre-trained H-optimus-0 model, we extracted patch-level (224$\times$224 pixels) features from the slides (20$\times$ magnification, 0.5 mpp), with a TransMIL aggregator predicting slide-level classifications for dysplasia, SCC, and polyps. Additionally, we derived slide-level intra-epithelial lymphocyte (IEL) and peri-epithelial lymphocyte (PEL) scores using HoVer-NeXt based lymphocyte segmentation, in and around the epithelium (segmented by HoVer-Net+) in LD cases, and compared these scores across WHO LD grades using Mann-Whitney U tests. **Results:** In Monte Carlo cross-validation experiments (10 repeats), the model achieved an average one-versus-all AUROC of 0.85 and AUPRC of 0.73 for lesion classification (dysplasia vs SCC vs polyp). In LD cases, both IEL and PEL scores were significantly higher in severe dysplasia cases compared to moderate (IEL: r_{rb} = 0.09, p = 0.02; PEL: r_{rb} = 0.36, p = 0.02) and mild dysplasia (IEL: r_{rb} = 0.09, p = 0.01; PEL: r_{rb} = 0.36, p = 0.003). This suggests a potential link between increased lymphocyte presence (activity) and higher grades of dysplasia. **Conclusions:** We present a novel AI model for classifying laryngeal lesions and quantifying lymphocytic activity in LD. Our findings suggest the diagnostic potential of AI in identifying LD, whilst highlighting peri- and intra-epithelial lymphocyte density as a potential biomarker, which has not been previously linked to dysplasia grade. Further validation in large, multi-centric datasets is required. Research Sponsor: None.

Examining age-specific trends in the incidence of human papillomavirus-associated oropharyngeal cancer in the United States. First Author: Joshua Elbridge Chan, Stanford University School of Medicine, Stanford, CA

Background: The incidence of human papillomavirus (HPV) infection-associated oropharyngeal cancer (OPC) has been steadily rising in the United States, with HPV surpassing behavioral risk factors like tobacco and alcohol use as the leading cause of OPC, particularly in men. We examined the impact of the HPV vaccine on the incidence of OPC, accounting for age, gender, and lifestyle behavior. **Methods:** Cancer incidence was extracted from the United States Cancer Statistics Public Use Database (USCS). Data on alcohol and tobacco consumption were obtained from the Substance Abuse and Mental Health Services Administration (SAMHSA). The Behavioral Risk Factor Surveillance System (BRFSS) was employed to collect HPV vaccination and screening information. Information on HPV infection and number of sexual partners was provided by the National Health and Nutrition Examination Survey (NHANES). The Joinpoint Regression Program (National Cancer Institute) and Pearson correlation coefficients were used for statistical analyses. **Results:** Between 2001 and 2021, oropharyngeal cancer (OPC) incidence rates increased in males by 2.3% ($p<0.001$) compared to a 0.74% annual increase in females (p=0.002). Compared to the rising incidence of OPC in older men, the younger cohort showed a significant decrease in the incidence of OPC. Specifically, younger males 35-39 years old and 40-44 years old had a 1.86% decrease (p=0.004) and 1.37% decrease (p=0.005) in OPC incidence per year, compared to a rising incidence of 1.66% ($p<0.001$) and 2.56% ($p<0.001$) annually among males 60-64 years old and 65-69 years old, respectively. With the 2009 approval of the HPV vaccine for young men, we investigated whether this was associated with decreased OPC incidence. Indeed, HPV vaccination showed a significant negative correlation with OPC incidence in men younger than 45 (r=-0.818; p=0.001). We then evaluated whether substance use and sexual practices, both risk factors for OPC, have changed during this time. Among 18-25 year olds surveyed in SAMHSA from 2003 to 2021, we found that overall consumption of alcohol decreased by 11.0% ($p<0.05$) and tobacco use decreased by 22.8% ($p<0.05$), even though alcohol and tobacco use were initiated at higher rates in this younger age cohort. Using the NHANES database from 2009-2016, we found that the rate of oral HPV infection, assessed via oral cavity rinses, has not significantly changed (7.6% to 7.2%; p=0.896). Similarly, there was no change in the proportion of people with more than four lifetime oral sex partners (36.0% to 39.0%; p=0.684). **Conclusions:** This study reveals a strong inverse relationship between HPV vaccination rates and OPC incidence in men under 45 years, suggesting that vaccination efforts may be effectively reducing cancer risk in this group. The decreasing rate of alcohol and tobacco consumption in this age group may also contribute to our findings. Research Sponsor: None.

AI-driven reflectance confocal microscopy for noninvasive diagnosis and accurate surgical margin assessment intra-operatively in oral cavity squamous cell carcinoma. First Author: Farideh Hosseinzadeh, Department of Surgery, Head and Neck Service, Memorial Sloan Kettering Cancer Center, New York, NY

Background: Oral cavity squamous cell carcinoma (SCC) remains a common malignancy in the head and neck region, with challenges in tumor resection and recurrence prevention. Traditional methods like frozen-section analysis are limited by time delays, sampling errors, and tissue distortion. Reflectance Confocal Microscopy (RCM) provides a noninvasive alternative for real-time, high-resolution imaging, but interpreting RCM images accurately requires expert knowledge. Integrating artificial intelligence (AI) could improve the accuracy and reliability of RCM image interpretation for diagnosing SCC and assessing surgical margins. The integration of machine learning and artificial intelligence (AI) has the potential to enhance the accuracy and reliability of RCM image interpretation, providing a more efficient tool for diagnosing oral cavity SCC and assessing surgical margins in real-time during surgery. **Methods:** We developed an AI model using Google Cloud's AutoML platform to classify RCM images for diagnosing oral cavity SCC and evaluating tumor margins. The dataset comprised 4,090 RCM images from 83 patients, including 1,998 images of benign tissue and 2,092 images of malignant tissue. The dataset was divided into training (80%), validation (10%), and test (10%) sets. A single-label classification approach was employed to differentiate benign and malignant tissue. Model performance was evaluated using sensitivity, specificity, accuracy, F1 score, and negative predictive value. **Results:** The AI model achieved an area under the curve (AUC) of 0.99, sensitivity of 98.09%, specificity of 95.00%, accuracy of 96.58%, and an F1 score of 96.70%. In comparison, expert human readers in our prior study achieved accuracies of 90.91% for normal tissue and 81.7% for tumor detection, highlighting the accuracy of the AI model's diagnostic performance. **Conclusions:** The combination of RCM imaging with AI-powered analysis provides an accurate, noninvasive method for real-time diagnosis and surgical margin assessment in oral cavity SCC. The AI-driven model has excellent sensitivity, specificity, and overall accuracy, offering a potentially efficient and reliable modality for the real-time evaluation of digital RCM images. This approach can reduce the time required for intraoperative margin assessment, minimize patient anesthesia time, and overcome challenges related to conventional histopathology, ultimately improving surgical outcomes in patients with oral cavity SCC. Artificial intelligence-powered real-time model for predicting recurrence and survival in head and neck squamous cell carcinoma after curative intent surgery. First Author: Hyun Ae Jung, Division of Hematology-Oncology, Department of Medicine, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, South Korea

Background: Head and neck squamous cell carcinoma (HNSCC) accounts for approximately 5.3% of cancer-related mortality worldwide, with an estimated 660,000 new diagnoses and 325,000 deaths annually. Curative-intent surgery or definitive chemoradiotherapy remain the only two curative treatment modalities for patients with HNSCC but recurrence rates vary from 10-50% and survival is still limited for some patients emphasizing the need for accurate predictive and prognostic models. This study developed and validated an AI model that integrates clinical, pathological, laboratory, and radiologic data to predict recurrence and survival in HNSCC, aiming to optimize patient outcomes and personalize treatment strategies. **Methods:** The model was developed using XGBoost and Cox regression, internally validated, and tested using data from Samsung Medical Center (SMC). Data in the model included baseline data collected at the time of surgery and longitudinal laboratory data gathered during surveillance. An 80/20 ratio was applied to randomly allocate patients to the developing set and internal validation sets from the SMC dataset. The dataset included patients with HNSCC who underwent curative intent surgery between January 2008 and August 2024. Two models were developed: one to predict progression-free survival (PFS) and overall survival (OS) within 12 months after the surgery, and another to predict PFS and OS within 12 months of the surveillance monitoring point, thus creating a real-time prediction model. External validation was conducted using data from Massachusetts General Hospital (MGH). **Results:** A total of 1,062 patients with HNSCC (oral cavity cancer, oropharyngeal cancer, and laryngeal cancer) were included in the study. The AUC for predicting 12-month PFS after surgery was 0.804 (sensitivity: 82.4%, specificity: 77.3%), with a C-index of 0.802 for RFS. For predicting OS at 12 months after surgery, the AUC was 0.875 (sensitivity: 100%, specificity: 73.1%), with a C-index of 0.862 for RFS. For external validation using MGH data, the AUC for predicting 12-month PFS was 0.875, with a C-index of 0.793 for RFS. The C-index for OS in the MGH dataset was 0.75. In the longitudinal surveillance model, the AUC for predicting 12-month PFS at each monitoring point was 0.883, while the AUC for 12-month OS was 0.902. **Conclusions:** This study successfully developed and validated an AI-powered model for predicting RFS and OS in HNSCC patients, achieving strong performance in both internal and external validations. These findings highlight the potential of AI-based approaches to support personalized treatment strategies and improve prognostic accuracy in HNSCC. Research Sponsor: None.

Pathologic response to neoadjuvant sequenced, lymphatic-sparing SBRT plus pembrolizumab in HPV-negative head and neck squamous cell carcinoma. First Author: Richard Bryan Bell, Providence Cancer Institute, Portland, OR

Background: The Neoadjuvant Immuno-Radiotherapy Trial (NIRT-2) is a phase II study, conducted at 2 institutions, that evaluated in patients (pts) with locoregionally advanced HPV-negative head and neck squamous cell carcinoma (HNSCC) whether the combination of neoadjuvant sequenced, lymphatic sparing stereotactic body radiation therapy (SBRT) delivered to gross tumor volume (GTV) plus pembrolizumab is effective in enhancing major pathologic response (MPR) compared to historical controls of anti-PD-1 alone. **Methods:** 27 pts with resectable clinical stage III-IVA HPV-negative HNSCC who would warrant adjuvant RT per the investigators were enrolled. Neoadjuvant therapy consisted of SBRT 8Gy X 3 delivered over 1 week (GTV +/-3mm) followed by 3 cycles of pembrolizumab (200mg) prior to definitive surgical resection + neck dissection at week 7. Standard of care adjuvant RT +/- chemotherapy was administered based on pathologic staging, followed by adjuvant pembrolizumab for 6 months (14 doses). The primary endpoint was MPR (defined as $</=10\%$ viable tumor cells), assessed using a single-arm Simon Two-stage design to test the hypothesis that SBRT would improve MPR to pembrolizumab from 22%, rejecting the null hypothesis if 10 or more responses (37%) are observed in 27 pts (Type 1 error 5%, 90% power, alternative rate 50%). Secondary endpoints included pathologic down-staging allowing for surgical de-escalation and omission of adjuvant RT. **Results:** The study completed enrollment (N=27) on January 17, 2025, at which time 22 pts had completed surgery. 22/27 (81%) pts enrolled were clinically staged as T3/T4 and 8/27 (30%) were N2b/c (AJCC 8th Ed). Pathologic down-staging was observed in 16/22 (73%) pts, which permitted surgical de-escalation (no tracheostomy or free flap, $>50\%$ organ preservation) in 11 pts (50%). 16/22 (73%, one-sided 95% CI =53%-100%, $p<.0001$) had a MPR, of which 6 had a pathologic complete response (pCR), thus meeting the study's primary endpoint of 10 MPR. Adjuvant RT was omitted in 17/22 (77%) pts. All pts remain disease-free at a median follow-up of 8.5 months (IQR=3.9, 21.2; range=0-32). **Conclusions:** Neoadjuvant sequenced, lymphatic sparing SBRT followed by pembrolizumab led to notable pathologic down-staging allowing for surgical de-escalation and omission of adjuvant RT. Clinical trial information: NCT04938609. Research Sponsor: Providence Portland Medical Center Foundation.

Omission of concurrent chemotherapy in and out of a phase III randomized controlled trial for stage II nasopharyngeal carcinoma. First Author: Yuting Wang, Department of Radiation Oncology, Sun Yat-sen University Cancer Center, State Key Laboratory of Oncology in South China, Guangdong Key Laboratory of Nasopharyngeal Carcinoma Diagnosis and Therapy, Guangdong Provincial Clinical Research Center for Cancer, Guangzhou, China

Background: In the era of intensity-modulated radiotherapy (IMRT), the precision of radiotherapy has been greatly enhanced, allowing for more precise targeting of tumor tissue while minimizing damage to surrounding normal tissues. Therefore, whether radiotherapy alone can replace the traditional chemoradiotherapy regimen, which may cause substantial side effects, particularly hematologic toxicity, gastrointestinal adverse reactions, and immune suppression, has become a key focus of current clinical research. This investigation explores the potential benefits of IMRT as a standalone treatment, particularly its ability to offer similar efficacy in terms of overall survival and disease control while sparing patients from the added toxicities associated with chemotherapy. **Methods:** In a parallel-group, multicenter, randomized, controlled phase III trial, we compared cisplatin-based concurrent chemoradiotherapy with radiotherapy alone. Stage II NPC patients (2010 UICC staging) were randomly assigned in a 1:1 ratio to receive concurrent chemoradiotherapy (IMRT combined with cisplatin, 100 mg/m² every 3 weeks for 3 cycles) or IMRT alone. The primary endpoint was overall survival in the intention-to-treat population. Secondary endpoints included progression-free survival, locoregional relapse-free survival, distant metastasis-free survival, and safety. **Results:** A total of 211 patients were enrolled (106 in the IMRT alone group, 105 in the concurrent chemoradiotherapy group). The median follow-up time was 37 months. The 3-year overall survival rate was 96.3% for the IMRT alone group and 98.2% for the concurrent chemoradiotherapy group (HR = 0.650, 95% CI: 0.109-3.889; p-value = 0.637). No significant differences were observed between the groups in progression-free survival, locoregional recurrence, or distant metastasis (all p-values $>$ 0.05). The incidence of grade 3-4 adverse events was significantly lower in the IMRT alone group (p-value $<$ 0.05), including hematologic toxicity (leukopenia) and non-hematologic toxicity (hypokalemia). **Conclusions:** In stage II NPC patients, IMRT alone can achieve comparable 3-year overall survival to concurrent chemoradiotherapy, while significantly reducing side effects, which may provide a feasible treatment option for these patients, particularly for those with early-stage II nasopharyngeal carcinoma, where radiotherapy alone offers high therapeutic potential and lower treatment risks. Clinical trial information: NCT02610010. Research Sponsor: Sun Yat-sen University Clinical Medical Research 5010 Program.

The use of docetaxel as a radiosensitizer in patients with head and neck cancer unsuitable for cisplatin based chemoradiation: Landmark 3-year survival analysis of a randomized phase III trial (DHANUSH). First Author: Sneha Dhar, Tata Memorial Hospital, Mumbai, India

Background: Patients with cisplatin-ineligible locally advanced head and neck squamous cell carcinoma (LA-HNSCC) have limited guideline-recommended treatment options. DHANUSH (CTRI/2017/05/008700), an open-label, phase II/III randomized controlled trial, was among the first studies to demonstrate superior disease-free survival (DFS) and overall survival (OS) in this patient population. Here, we present the 3-year landmark survival analysis update of our study cohort. **Methods:** This was a single-centre, open-label, randomized controlled phase II/III study conducted at our institute between July 2017 and May 2021. Cisplatin-ineligible patients with LA-HNSCC who were planned for definitive or adjuvant chemoradiation in the multidisciplinary joint clinic were enrolled. Patients were randomly assigned in a 1:1 ratio to receive either radiation therapy alone or concurrent weekly docetaxel (15 mg/m²) for up to seven cycles. The primary endpoint of the study was 2-year disease-free survival (DFS). Here, we present the 3-year landmark survival update, including disease-free (DFS) and overall survival (OS), as of January 25, 2025. **Results:** The study recruited 356 patients, with 179 receiving concurrent docetaxel and 177 receiving radiation therapy alone. The median follow-up for the entire cohort was 67.9 months (95% CI, 65.7–70.3). At the time of the median follow-up, 123 deaths occurred in the concurrent docetaxel arm compared to 136 deaths in the radiation therapy alone arm. The median DFS in the concurrent docetaxel arm was 11.9 months (95% CI, 8.3–21.7) compared to 5.9 months (95% CI, 4.9–8.2) in the radiation therapy alone arm (p = 0.003). Similarly, the median OS was 23.1 months (95% CI, 17.4–30.6) in the concurrent docetaxel arm versus 15.3 months (95% CI, 13.9–22.3) in the radiation therapy alone arm (p = 0.048). The 3-year DFS was 36.3% (95% CI, 29.9–44.1) in the concurrent docetaxel arm versus 23.2% (95% CI, 17.7–30.3) in the radiation therapy alone arm. Similarly, the 3-year OS was 40.2% (95% CI, 33.7–48.1) in the concurrent docetaxel arm compared to 28.8% (95% CI, 22.9–36.3) in the radiation therapy alone arm. **Conclusions:** The addition of concurrent docetaxel to radiation therapy significantly improved survival outcomes (DFS and OS) in cisplatin-ineligible LA-HNSCC patients at the 3-year survival landmark. Clinical trial information: CTRI/2017/05/008700. Research Sponsor: None.

Neoadjuvant APG-157 monotherapy in patients with locally advanced squamous cell carcinoma of head and neck: A phase IIA, single arm trial. First Author: Marilene Beth Wang, Department of Head and Neck Surgery, David Geffen School of Medicine at UCLA, Los Angeles, CA

Background: Newly diagnosed, locally advanced squamous cell carcinoma of the head and neck (SCCHN) poses significant treatment challenges due to its infiltrative nature, and high recurrence risk. From diagnosis to definitive curative-intent therapy, patients may experience rapid disease progression leading to a poor prognosis. A safe and effective therapy to halt tumor growth during this period is critical to improve patient outcomes. **Methods:** APG-157, a first-in-class immuno-oncology drug was evaluated in Phase 2A trial (NCT05312710) of 24 patients with stage I–IVA SCCHN in oral cavity (54.2%) and oropharynx (45.8%). Fifty percent had stage III & IVA disease. 91% of oropharyngeal cases were HPV+. APG-157 was administered orally as a soft lozenge - 200 mg, 3X a day before meals - for 4-6 weeks between initial diagnosis and definitive therapy. The primary and secondary endpoints included overall response rate (ORR) using RECIST v1.1 and safety, respectively. The exploratory endpoints included changes in tissue biomarkers, circulating tumor DNA (ctDNA), salivary cytokines, and post-hoc analysis of Event-Free Survival (EFS). **Results:** APG-157 was well tolerated with no treatment-related Grade 3 or 4 adverse events. There was no delay in subsequent definitive therapy. Of 13 oral cavity patients, 10 completed surgery, 3 had post-operative radiotherapy, and all achieved R0 resection. 11 patients with oropharyngeal cancer had chemoradiation (n=10) or radiation alone (n=1). APG-157 showed antitumor activity as 77% of the subjects achieved pathological responses (23% near-complete, 23% major, 31% partial), while 15% had stable disease and 8% showed progression. Among the patients undergoing surgery as definitive therapy, 46% demonstrated clinical-to-pathological downstaging, while 8% experienced upstaging. The (ORR) was 16.7% (n=24), with tumor reduction observed in 45% of the patients. No primary tumor progression occurred, achieving a 100% disease control rate (DCR) with 2 complete responses (CRs), 2 partial responses (PRs), and 20 cases of stable disease (SD). Median EFS was not reached at 2 years. All patients remain alive with no recurrence except one subject who died from a non-cancer-related cause. Pre- and post-treatment multiplex IHC analysis showed APG-157 reduced Ki-67+ tumor cells, increased CD8+ infiltration, and reprogrammed macrophages to the M1 phenotype. Post-treatment ctDNA clearance correlated with complete (30%) and partial (70%) disease control, resulting in ORR of 100% (Gouda MA, et al. Liquid Biopsy Response Evaluation Criteria in Solid Tumors (LB-RECIST). Ann Oncol. 2024 Mar;35(3):267-275). **Conclusions:** APG-157 is a safe and effective oral therapy addressing a critical unmet need in SSCHN. It is a convenient neoadjuvant treatment option with a strong safety profile and durable long-term outcomes after curative-intent therapy. Clinical trial information: NCT05312710. Research Sponsor: Aveta Biomics, Inc.

Induction chemotherapy (IC) followed by concomitant radiotherapy and weekly cisplatin (CCRT) versus CCRT alone in patients with locally advanced (LA) nasopharyngeal carcinoma (NPC): Twenty-year follow-up of a randomized phase II study conducted by the Hellenic Cooperative Oncology Group (HeCOG) with biomarker evaluation. First Author: Amanda Psyrri, National and Kapodistrian University of Athens, Athens, Attiki, Greece

Background: Non-endemic NPC is associated with inferior outcomes compared to the endemic form. HeCOG conducted a randomized phase II study to compare IC followed by CCRT with CCRT alone in patients with LA NPC. Here, we report the 20-year follow-up data with biomarker analysis. **Methods:** Patients were randomly allocated 1:1 to CCRT alone or 3 cycles of IC with Epirubicin, Paclitaxel, and Cisplatin followed by CCRT. Random assignment was stratified by histology (type I versus type II+III) and stage (IIB+III versus IV). The primary objective of this analysis was to identify clinical and molecular features associated with PFS and OS. Clinical (141 cases /72 Group A, 69 Group B) and biomarker data (IHC / CISH: 109 Cases, NGS: 61 Cases / 29 Group A; 32 Group B) were analyzed using descriptive statistics, traditional survival Analysis techniques (Kaplan-Meier, Cox) and machine learning approaches (random survival forest). **Results:** Regarding the clinicopathological characteristics, only age at the beginning of the study (HR=1.05, 95%CI=(1.03, 1.06), p$<$0.001) and the CCRT response was associated with OS (PD: HR=20.03, 95%CI=(9.02, 44.48), p$<$0.001; SD: HR=5.17, 95%CI=(2.01, 13.32), p=0.001, respectively). For NGS mutational status, irrespective of effect, only *MSH2* (HR=3.37, 95%CI=(1.27, 8.92), p=0.015) and *PIK3CA* (HR=2.71, 95% CI=(1.03, 7.12), p=0.043) displayed significant association with OS, while random survival forest additionally yielded significant associations for *BRCA1*, *CD274*, *TSC1*, *KRAS* and *KIT*. Considering pathogenic mutations only, *CD8B*, *KDM4A, MLH1*, *MSH6*, and *RANBP2* displayed significant association with OS. Concerning IHC, ECADH (HR=1.16, 95%CI=(1.03, 1.32), p=0.018), GSK3B (HR=1.21, 95%CI=(1.01, 1.44), p=0.036) and AE1AE3 (HR=0.13, 95%CI=(0.02, 0.96), p=0.018), displayed significant association with OS, with higher values of ECADH and GSK3B indicating worse outcome, whereas AE1AE3 expression indicates better outcome. **Conclusions:** Age at diagnosis and response to CCRT emerge as the most important clinical factors forlong-term survival in LA non-endemic NPC.We identified potential molecular correlates for long-term outcomes to be validated in prospective studies. Clinical trial information: ACTRN 12609000730202. Research Sponsor: None.

6089 Poster Session

Transoral robotic surgery (TORS) and de-escalated adjuvant therapy for human papillomavirus-related oropharyngeal carcinoma (HPVOPC): Long-term follow up of the Sinai Robotic Surgery (SIRS) trial (NCT02072148). First Author: Marshall R. Posner, Tampa General Hospital Cancer Institute/Cancer Center of South Florida, Palm Springs, FL

Background: De-escalation therapy for HPVOPC remains undefined and controversial. Definitive and postoperative chemoradiation are associated with significant toxicity. Efforts to de-intensify treatment with CRT only, such as HN002 and HN005, were unsuccessful. A previous investigation by this group (SIRS 1.0) and E3311 have highlighted the potential value of TORS with pathological risk stratification of patients for de-escalated adjuvant therapy. Our early work demonstrated that TORS, in combination with reduced-dosed adjuvant therapy for early and intermediate HPVOPC, resulted in equivalent progression-free survival (PFS) and overall survival (OS) while reducing toxicity in the first two years of treatment. Here we report the 5-year results for SIRS. **Methods:** This is a nonrandomized phase II trial for early-stage molecularly confirmed HPVOPC patients (n=63) treated with TORS followed by reduced-dose adjuvant therapy based on pathological risk-stratification into one of three groups: Group 1 (n=31) with no adjuvant therapy, Group 2 (n=15) with 50-Gy radiotherapy, and Group 3 (n=17) with 56-Gy chemoradiotherapy concurrent with weekly cisplatin. Patient demographics, baseline tumor characteristics, clinical outcomes, and adverse events during treatment and surveillance were recorded across the full 5-year study period. **Results:** Among the 63 total patients, median follow-up is 58 months (IQR 43—76 months). In the first two years following TORS, 5 patients experienced locoregional recurrence (7.9%); of these, one later had distant metastasis and one had a second HPV+ recurrence in the ipsilateral neck. All were salvaged by TORS, neck dissection, and/or chemoradiation. No patients had an HPVOPC recurrence between years 2 to 5 of follow-up. Two patients, one each from Group 1 and Group 2, developed a molecularly proven HPV+ contralateral second primary tumor at the tonsils approximately 5 years following TORS. Both patients were successfully salvaged and remain disease-free. Two patients (one each in Group 2 and 3) died from causes unrelated to cancer. The five-year OS is 96.8% (61/63) and the disease-specific survival (DSS) is 100% (63/63). Five-year PFS is 87.1% (27/31) for Group 1, 86.7% (13/15) for Group 2, 94.1% (16/17) for Group 3, and 88.9% (56/63) for the full cohort. **Conclusions:** Long-term follow-up of SIRS demonstrates de-escalation TORS and pathologic risk stratification is safe and effective in molecularly proven HPVOPC and reduces the lethal and morbid long-term side effects of full dose radiation and CRT. All recurrences occurred in the first two years postoperatively and were salvaged. Multidisciplinary decision-making utilizes the benefits of each specialty to optimize outcomes in de-escalation. Clinical trial information: NCT02072148. Research Sponsor: None.

Which systemic regimen to choose in cisplatin-ineligible patients with concurrent radiation therapy for head and neck cancers: carboplatin/5-flurouracil or carboplatin/paclitaxel? First Author: Parth J. Sampat, SUNY Upstate Medical University, Syracuse, NY

Background: For locally advanced head and neck cancer, concurrent chemotherapy-radiation therapy (ChemoRT) is mainstay of treatment. Carboplatin and 5-Flurouracil (CF) is category 1 recommendation per NCCN guidelines and used mainly in Cisplatin ineligible patients. In this study we aim to compare the outcomes of concurrent radiation therapy with either CF or Carboplatin/Paclitaxel (CP). **Methods:** TrinetX, a global federated research network that provides a dataset of electronic medical records from different healthcare organizations (HCOs), was utilized. Initial query was made to isolate patients who had head and neck cancer (ICD 10 codes C02, C03, C04, C05, C06, C09, C10, C12, C13, C14, C32) and received radiation therapy, concurrently either with CP or CF. Further, propensity score matching (PSM) was carried out to match age, sex, and race. Outcomes of all-cause mortality (ACM), sepsis, septic shock, neutropenia, nausea/vomiting (NV), diarrhea were evaluated. **Results:** 8,310 cases were identified who received ChemoRT, of whom 26% (2,160) received CF. Caucasians were the predominant race in both groups, but Asians received more CF (14% vs 4%, $p<0.0001$). Patients receiving CF were younger (61.4 $\pm$ 9.87 vs 63.5 $\pm$ 10.4, $p<0.0001$). It was seen that patients who received CF had higher ACM rate (51.54% vs 48.52%, p=0.0163; median overall survival (OS) 571 days vs 781 days, p=0.0007). Risk of sepsis (21.24% vs 17.05%, $p<0.0001$), septic shock (7.11% vs 5.24%, p=0.0014), neutropenia (21.98% vs 17.05%, $p<0.0001$), NV (32.79% vs 28.58%, p=0.0003) was more with CF compared to CP, while no difference in neuropathy and diarrhea. After PSM, though elevated but no statistical difference was seen in ACM (50.95% vs 48.75%, p=0.1593), septic shock (7.09% vs 5.77%, p=0.0852), and neutropenia (22.10% vs 19.66%, p=0.0544), while there was still difference in sepsis (21.17% vs 17.8%, p=0.0065), and NV (33.74% vs 29.73%, p=0.0059). **Conclusions:** Concurrent chemoRT with CP offers similar efficacy compared to CF, with less toxicity and can be established as to go chemotherapy regimen with radiation therapy in patients who are ineligible for Cisplatin. Research Sponsor: None.

Circulating tumor HPV-DNA dynamics and neoadjuvant chemotherapy with or without nivolumab in viral-mediated oropharyngeal cancer. First Author: Maha AT Elsebaie, University of Chicago, Department of Hematology/Oncology, Chicago, IL

Background: Human papillomavirus-associated (HPV+) oropharyngeal carcinoma (OPC) is linked to favorable survival outcomes, prompting efforts to de-intensify treatment strategies. Circulating tumor HPV-DNA (ctHPV-DNA) is a promising biomarker for assessing treatment response and guiding de-escalation strategies. This study evaluates how patient characteristics influence ctHPV-DNA dynamics during neoadjuvant therapy across two de-escalation clinical trials. **Methods:** Patients with non-metastatic HPV+ OPC enrolled across two trials of neoadjuvant carboplatin/paclitaxel (NCT04572100) or carboplatin/*nab*-paclitaxel/nivolumab (OPTIMA II, NCT03107182), with ctHPV-DNA available at baseline and post-neoadjuvant, were eligible. All participants received three cycles of neoadjuvant therapy followed by response-adapted de-escalated locoregional treatment. ctHPV-DNA values (copies per ml plasma) were measured at baseline and after 2-3 cycles of neoadjuvant therapy, and percentage reductions were calculated. We defined "ctHPV-DNA clearance" as $\geq$ 95% reduction from baseline and compared data distribution between patients who achieved clearance and those who did not using Kruskal-Wallis, Pearson's $\chi 2$, or Fisher's exact tests. Overall survival (OS) and progression free survival (PFS) probabilities were compared using log-rank test. **Results:** The study included 84 patients. The mean age was 60.9 years. 93% of patients with neoadjuvant nivolumab/chemotherapy achieved ctHPV-DNA clearance compared to 82% with chemotherapy alone, p=0.298. Patients with T1-T2 tumors (AJCC 8th edition) were significantly more likely to achieve ctHPV-DNA clearance compared to those with T3-T4 tumors (p=0.0254). Age, race/ethnicity, smoking history, tumor site (e.g., tonsil), and risk group were not significantly associated with ctHPV-DNA clearance rates. ctHPV-DNA clearance by cycle 2-3 of neoadjuvant therapy predicted radiographic response per RECIST v1.1 (p=0.001), and significantly improved OS (p=0.025) and PFS ($p<0.001$). Survival outcomes were similar across OPTIMA II and NCT04572100 as previously reported. **Conclusions:** Earlier T-stage tumors were associated with rapid ctHPV-DNA clearance by cycle 2 with a trend towards higher clearance rate with neoadjuvant nivolumab/chemotherapy. Rapid clearance predicts radiographic response, OS, and PFS, supporting ctHPV-DNA as a useful biomarker for treatment monitoring with neoadjuvant treatment in HPV+ OPC. Clinical trial information: NCT03107182. Research Sponsor: American Cancer Society; University of Chicago Cancer Center.

Evolving beyond the "unknown primary": Investigating histopathology after diagnostic transoral robotic surgery for microscopic HPV-associated oropharyngeal carcinoma. First Author: Nikita Bedi, Division of Head and Neck Surgery, Department of Otolaryngology, Stanford University, Palo Alto, CA

Background: Squamous cell carcinoma metastatic to the head and neck arising from an unknown primary tumor (hnSCCUP) is a common presentation for HPV-associated oropharyngeal carcinoma. Previously, with traditional approaches, rates of primary site identification for hnSCCUP were low. Using diagnostic transoral robotic surgery (TORS), primary tumors are now routinely found. In this report, we evaluate the histopathology and oncologic outcomes of these tumors. **Methods:** A retrospective review was conducted on 100 patients referred to Stanford University for hnSCCUP evaluation between October 2013 and April 2022. A final cohort of 80 patients who remained classified as hnSCCUP after comprehensive multidisciplinary review was analyzed. Surgical excision followed a standardized protocol targeting oropharyngeal subsites, and specimens were meticulously analyzed by three H&N pathologists. **Results:** The primary site was identified in 66 of 80 patients (83%), with a mean tumor size of 6 mm (range: 2–20 mm). Among the identified tumors, 97% were staged as T1, and 71% measured $\leq$1 cm, confirming their predominantly microscopic nature. The most common tumor locations were the palatine tonsil (26%), lateral tongue base (24%), glossopharyngeal sulcus (21%), and midline tongue base (18%). Histologically, most tumors exhibited a pushing pattern embedded within lymphoid stroma, while 29% demonstrated a pagetoid growth pattern, spreading in a ribbon-like distribution along the superficial lymphoepithelium. Following diagnostic TORS, 23 patients (29%) underwent further surgery, including 10 with surgery alone and 13 with adjuvant therapy. Radiation alone was administered to 15 patients (19%), while 42 patients (53%) underwent chemoradiation. At a median follow-up of 38 months (range: 12–101 months), 77 patients (97%) were alive with no locoregional tumor recurrence. Two patients (2.5%) developed distant metastases, with one death, and one patient (1.2%) experienced persistent regional disease after chemoradiation. Functional swallowing outcomes declined temporarily across all treatment groups. At six months, patients who underwent surgery alone had the least decline in Functional Oral Intake Scale (FOIS) scores, while those receiving chemoradiation experienced the greatest impact. By one year, all patients showed significant recovery, with no long-term feeding tube dependence. **Conclusions:** With a systematic surgical technique for p16+ oropharyngeal carcinoma, diagnostic TORS has revealed a unique pattern of small-volume, often microscopic primary tumors often initially mistaken as hnSCCUP. In many cases, it seems the unknown primary represents a T1-microscopic tumor measuring $<$ 1 cm in maximum diameter with a prominent pattern of submucosal spread. Dabrafenib and trametinib in the treatment of BRAF-mutated anaplastic thyroid cancers (ATC). First Author: Irini Yacoub, New York Proton Center/Memorial Sloan Kettering Cancer Center, New York, NY

Background: ATCs are rare, aggressive tumors with poor median overall survival (OS). Approximately 45% harbor BRAF V600 mutations driving tumor progression. We evaluated the outcomes of BRAF-V600E-mutated ATC treated with dabrafenib and trametinib (D/T), with or without local therapy. **Methods:** Consecutive ATC patients with BRAF-V600E mutations treated at our institution from 2016-2024 that received D (150 mg twice daily) and T (2 mg once daily) as a component of their multiple lines of therapies were included. Locoregional therapies included surgery alone, surgery and radiation, or radiation alone. We reported the OS of these patients. **Results:** Out of 82 BRAFV600E mutated ATC patients, 61 pts. (74%) were metastatic at the time of D/T initiation. Median age was 71 years (range 47-86 yrs). Locoregional therapies given: surgery only (n=8); surgery and RT (n=24); RT only (n=23). Median follow-up for all patients is 10 months, and 19 months for alive patients. Median OS for all patients is 14 months. Among those who had surgery only (n=8), the median OS was not reached. Patients who had surgery and radiation had a median OS of 22 months. Lastly, the patients who had RT only as local therapy had a median OS of 14 months. Patients without residual ATC after surgery had a median OS of 39 months versus 21 months for those with residual neck disease. 14 patients who received D/T prior to surgery had a median OS of 39 mo. Table 1 provides details of outcomes by metastatic status. **Conclusions:** This is the largest study to date reporting on outcomes of patients with BRAF V600 mutated ATC receiving D/T. This regimen demonstrates highly favorable results. Our data suggests that patients should undergo surgery when feasible and that D/T should be given prior to surgical intervention. However, the optimal timing, integration as well as the types of local therapy should be prospectively evaluated. Research Sponsor: None.

Efficacy and safety of larotrectinib in patients with TRK fusion thyroid carcinoma: An updated analysis. First Author: Marcia S. Brose, Department of Medical Oncology, Sidney Kimmel Cancer Center, Thomas Jefferson University Hospital, Philadelphia, PA

Background: *NTRK* gene fusions are oncogenic drivers in various tumor types, including thyroid carcinoma (TC). Larotrectinib (laro) is the first-in-class, highly selective, central nervous system-active TRK inhibitor, approved for tumor-agnostic use in patients (pts) with TRK fusion cancer. Here, we report updated long-term efficacy and safety data in pts with TRK fusion TC treated with laro. **Methods:** Pts with TRK fusion TC enrolled in 3 laro clinical trials (NCT02576431, NCT02122913, NCT02637687) were included. Laro was administered at 100 mg twice daily (BID) to adults; 2 pediatric pts received 100 mg/m^2 BID (maximum dose 100 mg BID). Responses were independent review committee-assessed per RECIST v1.1. Data cutoff: July 20, 2024. **Results:** At data cutoff, 31 pts were enrolled; 24 (77%) had differentiated TC (DTC) and 7 (23%) had anaplastic TC (ATC). Median age was 60 years (range 6–80). Median time since initial cancer diagnosis was 5 years (range 0–46). Seventeen pts (55%) were systemic treatment-naïve in the metastatic/unresectable setting, 6 (19%) received 2 or more prior therapies, and 24 (77%) received prior radioiodine. All *NTRK* gene fusions were identified by next-generation sequencing. Overall response rate (ORR) was 65% (95% confidence interval [CI] 45–81): 3 (10%) complete responses, 17 (55%) partial responses (PR), 5 (16%) stable disease (SD), 4 (13%) progressive disease (PD), and 2 (6%) not evaluable. For pts classified as DTC, ORR was 79% (95% CI 58–93). For pts classified as ATC, ORR was 14% (95% CI 0–58). Three (10%) pts had poorly differentiated TC, 1 classified as DTC (PR) and 2 as ATC (1 SD for $>$36 months and 1 PD). Median time to response for all pts was 1.9 months (range 1.6–16.2). Median duration of response, progression-free survival, and overall survival (OS) were 35 months (95% CI 19–not estimable [NE]), 39 months (95% CI 17–NE), and not reached (NR; 95% CI 28–NE), respectively, at median follow-ups of 48, 42, and 68 months. Median OS was NR (95% CI 56–NE) in DTC and 9 months (95% CI 3–NE) in ATC. The 6-year OS rate for all pts was 60% (95% CI 41–79). The 6-year OS rate was 71% (95% CI 50–91) for pts with DTC and 17% (95% CI 0–46) for pts with ATC. Median duration of treatment was 31 months (range 1–88). At data cutoff, 7 (23%) pts remained on treatment, 5 of whom had disease control. Treatment-related adverse events (TRAEs) were predominantly Grade 1/2. Grade 3/4 TRAEs were reported in 5 (16%) pts. There were no discontinuations due to TRAEs. **Conclusions:** Laro demonstrates rapid and durable responses, extended survival, and a favorable safety profile in pts with TRK fusion DTC. Limited single-agent activity is observed in pts with ATC. This supports the use of a TRK inhibitor to treat TRK fusion DTC and the importance of testing for *NTRK* gene fusions in patients with advanced TC needing systemic therapy. Clinical trial information: NCT02576431, NCT02122913, NCT02637687. Research Sponsor: These studies were funded by Bayer HealthCare Pharmaceuticals, Inc.

6095 Poster Session

Comparative transcriptomic analysis to identify similarities and therapeutic vulnerabilities in olfactory neuroblastoma (ONB), sinonasal neuroendocrine carcinoma (SNEC) and sinonasal undifferentiated carcinoma (SNUC). First Author: Elisabetta Xue, Center for Immuno-Oncology, Center for Cancer Research, National Cancer Institute, Bethesda, MD

Background: ONB, SNEC and SNUC are rare sinonasal epithelial/neuroepithelial tumors, underserved by clinical trials, with few treatments available despite novel therapeutic agents against surface targets approved or in clinical development. Transcriptomic similarities of ONB with small cell lung cancer (SCLC), pheochromocytoma (PH), paraganglioma (PG), glioblastoma (GB) and low-grade glioma (LGG) are reported, but not for SNUC or SNEC. We examined the transcriptome of ONB, SNUC, SNEC, neuroendocrine (NE) and central nervous system tumors from a real-world (RW) patient cohort to identify similarities and uncover therapeutic vulnerabilities. **Methods:** Tumor specimens (pathology per referring clinician) tested (Caris Life Sciences, Phoenix, AZ) included ONB (n = 26), SNUC (n = 9), SNEC (n = 6), SCLC (n=1751), pancreatic NE tumors (PNET, n=16), PH (n=23), PG (n=50), LGG (n=657), GB (n=4524) and neuroblastoma (NB, n=47). RNA sequencing data were processed to obtain transcripts per million (TPM) values. Clustering was performed with a random subset of 50 samples for tumor types with n$>$100. ONBs were subtyped to neural and basal (Classe *et al.* 2018). RW overall survival (rwOS) was calculated from insurance claims (tissue collection to last contact), compared with log-rank test; Cox proportional hazard model was used for hazard ratio (HR). Selected genes encoding surface targets included *DLL3*, *PMEL*, *PVRL4*, *TACSTD2*, *ERBB2*, *F3*, *CLDN18*, *EGFR*, *ERBB3*, *MET*, *GPC3*, *CD276*, *VTCN1* and *FOSL1*. Median TPM values for genes of interest in ONB, SNUC and SNEC were examined. **Results:** There were 5 transcriptomic clusters (C1-5) (Table). Across clusters, median rwOS was worse for C1 (11.6 mo) and C3 (16.6 mo) vs. C2, C4, and C5 (all not reached), (p = 0.0) and was numerically better in neural (C4) vs. basal ONB (C0) (HR = 0.388, p=0.199). Highest expression for *F3* (34.5), *CD276* (15.6), *GPC3* (7.2) and *CLDN18* (1.1) was in ONB; *ERBB2* (16.4), *TACSTD2* (13.9), *EGFR* (9.2), *PVRL4* (6.2), *PMEL* (2.0) and *FOLR1* (1.5) in *SNUC*; *ERBB3* (83.3), *MET* (32.4), *DLL3* (3.5) and *VTCN1* (1.7) in SNEC. **Conclusions:** We show that neural ONBs cluster independently and basal ONBs co-cluster with SCLC and PNET, joined also by SNUC and SNEC. In our dataset, this cluster is associated with worse rwOS. We also show expression of surface target genes in ONB, SNUC and SNEC, indicating the presence of actionable subsets with existing drugs approved in other tumor types. Our findings provide targets for protein expression validation and expansion of therapeutic options for patients with these rare tumors. Research Sponsor: None.

Efficacy and safety of anlotinib in neoadjuvant treatment of locally advanced differentiated thyroid cancer (DTC): A multicenter, single-arm, phase II study. First Author: Dapeng Li, Department of Thyroid and Neck Oncology, Tianjin Medical University Cancer Institute and Hospital, Tianjin, Tianjin, China

Background: Neoadjuvant therapy is often necessary for patients with locally advanced inoperable or locally recurrent thyroid cancer without chance of surgery. Anlotinib is a small molecule multi-targeted tyrosine kinase inhibitor that can inhibit tumor angiogenesis while simultaneously inhibiting tumor growth, and has demonstrated significant benefit in radioiodine (RAI)-refractory differentiated thyroid cancer (DTC). Our study aims to evaluate the efficacy and safety of anlotinib in the preoperative neoadjuvant therapy with unresectable DTC. **Methods:** The study (ChiCTR2100048077) was a single-arm, open-label, multicenter phase II study. Eligible patients were between 18-75 years old with histopathological confirmed locally advanced differentiated thyroid cancer at high surgical risk and susceptible to postoperative recurrence. Patients with locally advanced DTC with distant metastasis and potential for local resection were also included. Patients received 12mg of anlotinib once daily on a schedule of 2 weeks on and 1 week off until surgery or disease progression and treatment discontinuation. The primary endpoint was objective response rate (ORR). The secondary endpoints included time to response (TTR), disease control rate (DCR), actual surgery rate, rate of R0 resection and safety. The objective response was evaluated according to RECIST 1.1. Here we report the results of this study. **Results:** 50 patients (20 males vs. 30 females) were enrolled from 3/2022 to 12/2023, with a median age was 56.5 (range: 26.0-74.0), 52% of patients had undergone previous surgery and 14% of patients had received radioiodine (iodine-131) treatment. At the cutoff date (November 30th, 2024), out of 43 patients with assessable efficacy, no CR occurred, 18 patients achieved PR, 24 patients achieved SD and 1 patients had PD.ORR and DCR was 41.86% (95%CI:27.01-57.87) and 97.67% (95%CI: 87.71-99.94) respectively. 21 patients underwent surgery, 57.1% (12/21) achieved R0 resection. Median time to response was 2.84 months (range: 1.31-5.16 months). In patients who did not undergo surgical treatment, the median progression-free survival (mPFS) had not yet reached. The 6-month progression-free survival rate (PFS rate) was 95.83% (95%CI:73.92-99.40). 76%(38/50) of patients had experienced anlotinib treatment-related adverse events (TRAEs), Grade 3+ TRAEs were observed in 9 patients (18%, most common hypertension). 16% (8/50) of patients were discontinued due to TRAEs. No deaths attributable to adverse events (AEs) were observed. **Conclusions:** The study indicated that anlotinib was safe and effective as a neoadjuvant therapy for patients with locally advanced DTC. Clinical trial information: ChiCTR2100048077. Research Sponsor: None.

Updated efficacy, safety and biomarker analysis of a phase 2 study of LBL-007 (alcestobart, an anti-LAG-3 mAb) combined with tislelizumab (an anti–PD-1 mAb) and chemotherapy in previously untreated recurrent or metastatic nasopharyngeal carcinoma (R/M NPC). First Author: Dongchen Sun, Department of Medical Oncology, State Key Laboratory of Oncology in South China, Guangdong Key Laboratory of Nasopharyngeal Carcinoma Diagnosis and Therapy, Guangdong Provincial Clinical Research Center for Cancer, Sun Yat-Sen University Cancer Center, Guangzhou, China

Background: For the first time weevaluated LBL-007 in combination with tislelizumab and chemotherapy in previously untreated R/M NPC in a prospective, multi-center phase 2 study. Preliminary findings indicated this combination had encouraging ORR in this patient population (2024 ASCO, abstr 6033). Here we present the updated efficacy, safety and biomarker analysis of this study focusing on previously untreated R/M NPC (NCT05516914). **Methods:** Untreated R/M NPC patients received gemcitabine at 1 g/m² on days 1 and 8, cisplatin at 80 mg/m² on day 1 (GP) in combination with LBL-007 600 mg and tislelizumab 200 mg on day 1 of every 3 weeks, the chemotherapy was up to 6 cycles, followed by LBL-007 and tislelizumab on day 1 of every 3 weeks as maintenance therapy. The primary endpoint was efficacy, and the secondary endpoints included safety and biomarker analysis. **Results:** As of January 13, 2025, 42 patients with NPC were enrolled and received LBL-007 in combination with tislelizumab plus chemotherapy as first-line treatment. The median follow-up was 17.1 months. Out of 41 efficacy evaluable patients, the ORR and DCR were 85.4% and 100%, the mPFS was 15.0 months and the mDoR was 14.7 months. mOS is not mature. A favorable trend of improved efficacy with LBL-007 combined with tislelizumab plus chemotherapy was observed compared to tislelizumab plus chemotherapy (mPFS 9.6 months, mDoR 8.5 months; NCT03924986). All-grade TRAEs occurred in 39 patients (92.9%), with grade ≥3 TRAEs in 29/42 patients (69.0%). Treatment permanent discontinuance due to LBL-007 TRAEs occurred in 2 (4.8%) patients. 16 patients (38.1%) experienced LBL-007 treatment related SAEs. TRAEs leading to death occurred in 1 patient and infusion-related reaction happened in 4 patients. No new safety signal was observed. Patients with LAG-3 expression ≥5% potentially had improved efficacy compared to those with <5% (Table 1). **Conclusions:** LBL-007/tislelizumab combined with GP chemotherapy has shown encouraging ORR, PFS and DoR in R/M NPC as first-line treatment with favorable safety profiles. These findings support a pivotal phase III study comparing LBL-007/tislelizumab plus GP with tislelizumab plus GP in R/M NPC in 1L setting. The correlation between higher LAG-3 expression and improved efficacy was observed, which warranted further validation in larger population. Clinical trial information: NCT05516914. Research Sponsor: Nanjing Leads Biolabs Co., Ltd.

Results from a phase I study of KL590586 in patients with advanced RET-mutant medullary thyroid cancer. First Author: Xiangqian Zheng, Tianjin Medical University Cancer Institute and Hospital, Tianjin, China

Background: *RET* mutations occur in 70% of medullary thyroid cancers (MTC). KL590586 (A400/EP0031) is a potent next-generation brain-penetrant selective RET inhibitor (SRI) with activity against acquired resistance mutations to first-generation SRIs (Zhou et al. 2023, Garralda et al. 2024). Here we present the preliminary safety and efficacy data of KL590586 in patients (pts) with advanced RET-mutant MTC from the phase I part of a phase I/II study completed in China (KL400-I/II-01, NCT05265091). **Methods:** The phase I part, comprising a dose-escalation phase and a dose-expansion phase, was conducted to evaluate the safety, pharmacokinetics, and efficacy of KL590586 in pts with RET-altered solid tumors. Eligible pts with advanced RET-mutant MTC were enrolled to receive KL590586 once a day (QD) until disease progression or unacceptable toxicity. Tumor assessments were performed every 8 weeks as per RECIST v1.1. **Results:** As of September 20, 2024, 27 advanced RET-mutant MTC pts without prior SRIs were enrolled and treated in the phase I part across 4 dose levels (20 to 90 mg QD). The median age was 49 years, and 66.7% of pts were male. Among these 27 pts, 8 were treatment-naïve, and 19 had received previous systemic treatment, with 84.2% of them treated with multikinase inhibitors (MKIs). The median follow-up was 19.0 months. Adverse events were reported for all pts. The most common adverse events considered treatment related (TRAEs, ≥ 35%) were increased ALT (77.8%), increased AST (70.4%), headache (48.1%), increased blood creatine phosphokinase (40.7%), increased blood lactate dehydrogenase (37.0%), and hyperuricaemia (37.0%), with grade ≥3 TRAEs occurring in 22.2% of pts. The most frequent grade ≥ 3 TRAEs (≥ 5%) were increased ALT (7.4%) and increased GGT (7.4%). No TRAEs led to treatment discontinuation or death. At data cut-off, the confirmed objective response rate (cORR) was 63.0% (17/27) and the disease control rate was 100% for overall population. The cORR was 56.3% (9/16) and 62.5% (5/8) in pts with prior MKI or treatment naïve, respectively. Median duration of response was not reached (95% CI, 7.4 to NE), with the longest duration still ongoing at 25.8 months. Similarly, median progression-free survival (PFS) was not reached, with the 24-month PFS rate of 77.8%. **Conclusions:** KL590586 was well tolerated in pts with advanced RET-mutant MTC, exhibiting a safety profile consistent with that previously reported in NSCLC (Zhou et al. 2023). In MTC pts with or without previous MKIs, KL590586 demonstrated robust clinical activity with durable responses. The findings support further investigation of KL590586 as a potential therapeutic alternative for this patient population. Phase II trials are evaluating KL590586/EP0031 in China and US/Europe/UAE. Clinical trial information: NCT05265091. Research Sponsor: Sichuan Kelun-Biotech Biopharmaceutical Co., Ltd.

***BRAF*-V600E papillary thyroid cancer: Updated analysis of real-world patient data.** First Author: Martina Chirra, University of Cincinnati Medical Center, Cincinnati, OH

Background: Papillary thyroid cancer (PTC) is the most common type of thyroid cancer, usually characterized by a good prognosis after surgery with or without radioactive iodine therapy (RAI). However, ~5-15% of patients become RAI refractory, and some require systemic therapy, often with multi tyrosine kinase inhibitors (mTKIs).*BRAF*-V600E, the most common mutation in PTC (~60% of patients), is associated with poor outcomes. The effectiveness of mTKIs compared to BRAF-targeted therapy (BRAF/MEKi) and immunotherapy (IO) remains unclear in the *BRAF*-V600E mutant (*BRAF*-m) population. Therefore, we conducted an updated analysis comparing real-world (rw) survival and molecular/transcriptional signatures in patients with *BRAF*-m and *BRAF*-wildtype (WT) PTC. **Methods:** Differentiated thyroid cancer (DTC) tumor samples underwent DNA/RNA next-gen sequencing at Caris Life Sciences. Tumor microenvironment (TME) cell fractions were estimated by RNA deconvolution using QuanTIseq. A transcriptional IFNγ signature score associated with response to IO was calculated. PD-L1$^+$ (SP142) was defined as ≥2$^+$ in stain intensity and ≥5% of tumor cells stained. Insurance claims data was used to infer rw overall survival (rwOS) from the time of initial diagnosis to death/last contact, and time on treatment (TOT) was assessed from the first to last date of treatment, with hazard ratios (HR) and p-values calculated using the Cox proportional hazards model and log-rank test, respectively. **Results:** A total of 1,348 patients with DTC were identified, of which 82% (n=1,102) were PTC and 18% (n=246) were follicular thyroid cancer (FTC). The majority (95%) of PTC patients were naïve to mTKIs or BRAF/MEKi. *BRAF*-V600E mutations were present in 68% (n=754) PTC patients and only 0.8% (n=2) FTC patients. *TERT* promoter mutations were the most common mutation overall in PTC (72%), more prevalent in *BRAF*-m *vs* *BRAF*-WT PTC (79% *vs* 54%, p<0.001). Mutations in *NRAS*, *HRAS* and *KRAS* were largely exclusive to *BRAF*-WT PTC (22%, 9% and 6% *vs* 0.1%, 0% and 0% in *BRAF*-m PTC, p<0.001), as were *RET*, *BRAF*, and *ETV6* gene fusions (24%, 5% and 5% *vs* 0%, 0.4% and 0% in *BRAF*-m PTC, p<0.01). *BRAF*-m PTC were more often PD-L1$^+$ (33% *vs* 18%, p<0.001), consistent with higher IFNγ scores. This was accompanied by higher Treg and M1 macrophage TME fractions, and lower M2 macrophage, T cell (CD4$^+$ and CD8$^+$), NK cell, monocyte and myeloid dendritic TME fractions compared to *BRAF*-WT PTC (p<0.05). There was no difference in rwOS between *BRAF*-m and *BRAF*-WT PTC (HR=0.845, 95% CI 0.654-1.092, p=0.197), nor per treatment received in *BRAF*-m PTC (BRAF/MEKi *vs* mTKIs, BRAF/MEKi *vs* IO, IO *vs* mTKIs). Similarly, TOT for BRAF/MEKi, mTKIs and IO were similar between *BRAF*-m and *BRAF*-WT PTC. **Conclusions:** *BRAF*-m PTC is associated with a more pro-inflammatory TME milieu compared to *BRAF*-WT PTC. However, in this limited data set, treatment choice was not associated with differences in overall survival in *BRAF*-m PTC. Research Sponsor: CARIS Life Sciences.

Anti-TROP2 ADC ESG401 in a master protocol clinical trial for salivary gland cancer based on molecular typing. First Author: Xiaojuan Zheng, National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, Beijing, China

Background: Salivary gland carcinomas (SGC) are rare, with limited prospective clinical outcome data. There is no standard of care or FDA-approved systemic therapy for recurrent and/or metastatic (R/M) disease. Precision therapy targeting specific gene alterations is emerging as a promising approach for SGC. We designed a single-center, open-label, master protocol clinical trial evaluating the efficacy and safety of molecular subtype-guided precision neoadjuvant/transformative or rescue therapy for SGC. This report focuses on the preliminary results of the TROP2-targeted group. **Methods:** Pts with locally advanced/recurrent SGC received neoadjuvant/transformative therapy, while pts with locally advanced/recurrent who could not tolerate or refused surgery/radiotherapy and pts with symptomatic, rapidly progressive metastatic SGC received rescue therapy. Pts were divided into molecular subtypes (HER2, NTRK, AR, TROP2) or assigned to chemotherapy if no molecular alterations were detected. Trop2-positive pts were assigned to the TROP2 group and treated with ESG401 (16 mg/kg i.v. on days 1, 8, and 15 of each 28-day cycle). The primary endpoint was ORR per RECIST1.1; secondary endpoints included AEs, DCR, PFS, and OS. **Results:** As of Jan 22, 2025, 14 Trop2-positive pts were enrolled, including 4 receiving neoadjuvant/transformative therapy and 10 receiving rescue therapy. Among the 12 efficacy-evaluable pts, pathological types included salivary duct carcinoma (n=3), adenoid cystic carcinoma (n=5), and others (n=4). Safety findings were consistent with the ESG401-101 study, with no new safety signals observed. Among 4 pts receiving neoadjuvant/transformative therapy, 2 achieved decreased SD, though not meeting PR criteria. Among 8 pts receiving rescue therapy, 4 achieved PR with ORR was 50% (4/8). For 12 efficacy-evaluable pts, DCR was 100% (12/12). Three pts with brain metastases achieved IC-PR/CR, yielding an IC-ORR of 100%. **Conclusions:** ESG401 demonstrated promising efficacy in Trop2-positive SGC, providing a rationale for molecular subtype-based targeted therapy in this population and warranting further investigation in larger studies. Clinical trial information: NCT06145308. Research Sponsor: None.

6101 Poster Session

Amivantamab for recurrent/metastatic adenoid cystic carcinoma: A multicenter, single-arm, phase 2 clinical trial. First Author: Olga Zamulko, University of Cincinnati Cancer Center, Cincinnati, OH

Background: Adenoid cystic carcinoma (ACC) is a rare salivary gland cancer with heterogenous clinical behavior. ACC typically presents with locoregional disease and is treated with curative intent surgery and adjuvant radiation, but many patients develop locally recurrent/metastatic (R/M) disease even years later. Two recognized molecular subtypes exist: ACC 1 (37%), characterized by *MYC* amplification and *NOTCH*-activating mutations and a poor prognosis, and ACC 2 (63%), which demonstrates P63 expression and upregulated EGFR and MET and a better prognosis. There is no standard treatment for R/M ACC, but multi-targeted tyrosine kinase inhibitors are a mainstay of treatment despite their limited efficacy. Amivantamab is a bispecific antibody that binds to the extracellular domains of EGFR and MET, causing immune-directed destruction of cancer cells. Since MET expression renders EGFR inhibitors ineffective, we hypothesized that amivantamab would overcome resistance especially in the ACC 2 subtype. This multicenter, single arm, Phase 2 clinical trial (NCT05074940) evaluated the efficacy of amivantamab in patients with R/M ACC supported by Janssen Pharmaceuticals. **Methods:** Eligible patients were ≥18 years of age with R/M ACC and had progressive disease (PD) within 6 months of enrollment, ECOG ≤1, with adequate organ and marrow function. Patients received amivantamab 1050 mg or 1400 mg (≥80kg) IV weekly for 4 weeks then Q2 weeks until PD or unacceptable toxicity. The primary end point was overall response rate (ORR) assessed by RECIST 1.1. Among 18 treated patients the lower limit of a one-sided 90% exact binomial CI would be >14% if ≥5 patients respond. Adverse events (AEs) were assessed by CTCAE v5. Secondary end points included progression- free survival (PFS) and overall survival (OS). Key exploratory end points were P63 and MYC expression. **Results:** We enrolled 21 patients with 17 evaluable for response at time of submission. Most were male (14, 67%) non-Hispanic (20, 95%), and White (19, 90%) with a median age of 61 (range, 36-76) years. The majority received prior treatment. The best ORR was 6% (1 partial response), while 9 (53%) had stable disease (SD) and 7 (41%) PD. Median duration of SD was 5.4 months. The most common treatment-related AEs (TRAEs) were acneiform rash (17, 81%), infusion related reaction (16, 76%), and fatigue (15,71%). Grade 3 TRAEs occurred in 3 patients (14%) including acneiform rash, oral mucositis, and elevated alkaline phosphatase with no Grade ≥4 TRAEs. Median PFS and OS were 4.8 (95% CI, 1.84-7.64) and 10.4 months (95% CI, 5.48-NR), respectively. There was no correlation between tumor P63 or MYC levels and clinical benefit (PR+SD). **Conclusions:** While amivantamab did not achieve the target ORR, the safety profile was manageable and clinical benefit was observed in 59% of patients. Clinical trial information: NCT05074940. Research Sponsor: Janssen Pharmaceuticals.

6102 Poster Session

A phase 2 study of novel MDM2 inhibitor alrizomadlin (APG-115) with or without toripalimab in patients (pts) with advanced adenoid cystic carcinoma (ACC) or other solid tumors. First Author: Ye Guo, Department of Medical Oncology, Shanghai East Hospital, School of Medicine, Tongji University, Shanghai, China

Background: Alrizomadlin, an investigational MDM2 inhibitor, has shown a manageable safety profile with preliminary efficacy in liposarcoma (LPS) and ACC and in combination with a PD-1/PD-L1 inhibitor in advanced solid tumors. **Methods:** This multicenter trial (APG115XC102) assessed alrizomadlin (± toripalimab) in pts with advanced ACC, malignant peripheral nerve sheath tumor (MPNST), LPS, biliary-tract cancer (BTC), or other solid tumors in China. Enrolled pts had an ECOG PS 0-1 and were without central nervous system metastases. Alrizomadlin was administered orally at 50, 100, or 150 mg every other day for 2 weeks, with 1 week off, in repeated 21-day cycles, and combined with toripalimab 240 mg IV for 30 minutes on Day 1 of repeated 21-day cycles until disease progression or unacceptable toxicity. The primary endpoint was RP2D for the combination. ORR was assessed per RECIST v1.1. **Results:** As of January 5, 2025, 54 pts were enrolled. In the monotherapy arm, 22 pts were treated with alrizomadlin 150 mg; common treatment-related adverse events (TRAEs) included nausea (68.2%), decreased appetite (45.5%), thrombocytopenia (40.9%), white blood cell count decreased (40.9%), neutropenia (36.4%), and hypoalbuminemia (22.7%). Grade ≥ 3 TRAEs included neutropenia (13.6%) and thrombocytopenia (9.1%). No treatment-related serious adverse events (SAEs) were reported. In the combination arm, 32 pts were treated with alrizomadlin at 50 (n = 3), 100 (n = 3), or 150 mg (n = 26). No DLT was observed; the expansion dose was 150 mg plus toripalimab. Common TRAEs at 150 mg included nausea (73.1%), thrombocytopenia (65.4%), neutropenia (50.0%), decreased appetite (42.3%), and anemia (38.5%). Grade ≥ 3 TRAEs included thrombocytopenia (38.5%) and neutropenia (34.6%). Treatment-related SAEs were reported in 8 pts, including 6 thrombocytopenia, 1 neutropenia, 1 intestinal fistula, and 1 peptic ulcer. One pt (3.8%) discontinued treatment because of grade 4 thrombocytopenia; no treatment-related death was reported. Regarding efficacy, in the monotherapy arm, 14 pts were evaluable, with 2 unconfirmed partial responses (PRs) in 9 pts with ACC (ORR 22.2%, DCR 100%). All 5 pts with MPNST achieved SD (DCR 100%). In the combination arm, 28 pts were evaluable: 1 of 5 pts with BTC had a confirmed PR, and the ORR (CR + PR) was 20% and DCR 80%; 1 unconfirmed PR was reported in 6 pts with LPS, for an ORR of 16.7% and DCR of 66.7%. Pts with MPNST had an ORR of 14.3% and a DCR of 53.6%, and 2 pts with MPNST had confirmed PRs with prolonged PFS (1 pt > 60 weeks, 1 > 96 weeks). **Conclusions:** Alrizomadlin monotherapy showed promising antitumor activity in pts with advanced ACC or MPNST. Alrizomadlin combined with toripalimab was also well tolerated, showing antitumor activity in MPNST, BTC, and LPS and an acceptable safety profile (NCT04785196). Clinical trial information: NCT04785196. Research Sponsor: Ascentage Pharma Group Corp Ltd. (Hong Kong).

6103 Poster Session

A phase II study of lenvatinib plus pembrolizumab in patients with recurrent/metastatic salivary gland cancers. First Author: Alan Loh Ho, Memorial Sloan Kettering Cancer Center, New York, NY

Background: Recurrent/metastatic (R/M) salivary gland cancers (SGCs) are rare diseases without standard therapies. Based on the hypothesis that VEGFR inhibition can enhance immune checkpoint-induced responses against SGCs, we conducted a phase II trial of the multikinase inhibitor lenvatinib (len) plus the programmed death-1 (PD-1) inhibitor pembrolizumab (pem) in two R/M SGC cohorts: adenoid cystic carcinoma (ACC) and non-ACC histologies. Here we report results from the completed non-ACC cohort. **Methods:** Patients (Pts) with R/M SGC (except ACC) were enrolled. RECIST v1.1 measurable disease was required; prior therapies were allowed. Pts with acinic cell carcinoma (AcCC) were required to have progression of disease (PD) or worsening disease-related symptoms. Len 20 mg oral daily and pem 200 mg intravenously every 3 weeks was given. The primary endpoint was best overall response (BOR) rate using a minimax Simon two-stage design. In the first stage, >1 confirmed complete and/or partial responses (CRs, PRs) was required among 18 pts to enroll 14 more pts. >4 responses among 32 pts would be considered positive (BOR 5% vs 20%, 1-sided alpha 0.1, power 0.9). Secondary objectives were progression-free survival (PFS) and safety/tolerability per CTCAE v5.0. **Results:** 27 pts with R/M SGC pts were enrolled; 26 evaluable for the study endpoints. Among evaluable pts, the median age was 62 and 15 were men. SGC histologies included 9 AcCC, 8 salivary duct carcinoma (SDC), 4 myoepithelial carcinoma, 2 mucoepidermoid carcinoma, and 1 each of polymorphous adenocarcinoma, epithelial-myoepithelial carcinoma, and mucinous adenocarcinoma. 5/26 (19.2%) had confirmed PR. 18 pts had stable disease (SD), 1 PD as best response; 2 evaluable pts did not reach first scan assessment. As of 1/20/25, median PFS was 47 weeks. Among the 9 AcCC pts, 4 (44.4%) had PR and 5 SD; 8/9 pts had tumor regression in target lesions. For the 8 SDC pts, 1/8 (12.5%) had PR. Per protocol, 2 pts (AcCC and SDC) stopped treatment after 2 years; both resumed treatment when PD occurred, achieving SD and PR, respectively. Six deaths were observed, 4 possibly related to treatment: 3 SDC (respiratory failure due to pneumonitis vs. cancer progression [1]; cardiac arrest after polymyositis/myocarditis/aspiration pneumonia [1]; stroke [1]) and 1 myoepithelial carcinoma (respiratory failure due to pneumonitis vs. infection [1]). **Conclusions:** Trial enrollment was completed after 26 evaluable pts given the study was positive for the primary BOR endpoint and the grade 5 events observed. Len+pembro may be active and safe among pts with AcCC, though further study is needed. This combination may be less promising for SDC given the grade 5 events and low response rate observed. (Merck Sharp & Dohme LLC, a subsidiary of Merck & Co., Inc., Rahway, NJ, USA provided lenvatinib and pembrolizumab for the study.) Clinical trial information: NCT04209660. Research Sponsor: Merck; U.S. National Institutes of Health.

Trop2-targeted PET/CT with ^{68}Ga-MY6349 for detecting metastatic lesions in metastatic thyroid cancer: Prospective comparison of diagnostic accuracy with ^{18}F-FDG PET/CT. First Author: Hao Fu, The First Affiliated Hospital of Xiamen University, Xiamen, Fujian, China

Background: Trophoblast cell surface antigen 2 (Trop2) targeted molecular imaging with ^{68}Ga-MY6349 has been proposed as a potential modality for visualizing cancerous lesions, but its utility for identifying metastatic thyroid cancer (TC) is not well-established in the literature. This study aims to evaluate the clinical utility of ^{68}Ga-MY6349 PET/CT for detecting metastatic TC and to compare the results with those of ^{18}F-fluorodeoxyglucose (FDG) PET/CT. **Methods:** This was a prospective, single-center, open-labeled, single-arm comparative imaging trial. Patients with clinically suspected or confirmed metastatic TC were prospectively enrolled and underwent paired ^{68}Ga-MY6349 and ^{18}F-FDG PET/CT from November 2023 to January 2024. Histopathology and clinical follow-up (mean 12 months ± 0.7 [standard deviation] (range: 11-13 months) were used as reference standards for the final diagnosis. ^{18}F-FDG and ^{68}Ga-MY6349 uptake were compared by using the Wilcoxon signed-rank test. The McNemar test was used to compare the diagnostic efficacy of the two techniques, and the influence of various clinicopathological characteristics on ^{18}F-FDG and ^{68}Ga-MY6349 uptake was evaluated by Mann-Whitney and Kruskal-Wallis tests. **Results:** In total, 55 participants (median age, 51 years [interquartile range, 35-61 years]; 17 men) were evaluated. In all 55 participants, the ^{68}Ga-MY6349-derived SUV_{max} was higher than the ^{18}F-FDG-derived SUV_{max} in the local recurrence (24.9 vs. 10.7, P = .026), metastatic central compartment (12.7 vs. 4.9, P < .001), metastatic lateral compartment (11.0 vs. 5.4, P < .001), and mediastinal lymph nodes (LNs) (9.5 vs. 4.6, P = .012). ^{68}Ga-MY6349 PET/CT had a higher sensitivity than ^{18}F-FDG PET/CT for detecting neck lesions (88% vs. 56%; P < .001). **Conclusions:** ^{68}Ga-MY6349 PET/CT was superior to ^{18}F-FDG PET/CT for detecting metastatic TC, especially in local recurrence and LNs metastases. Clinical trial information: NCT06465017. Research Sponsor: None.

Comparison of ^{18}F-FDG and ^{68}Ga-MY6349 uptake in metastatic thyroid cancer.

Site of Disease	^{18}F-FDG Uptake (SUV max)	^{68}Ga-MY6349 Uptake (SUV max)	*P* value
Local recurrence	10.7±7.6	24.9±23.7	0.026
Central compartment LNs	4.9±4.6	12.7±10.9	<0.001
Lateral compartment LNs	5.4±6.4	11.0±10.23	<0.001
Mediastinal LNs	4.6±2.8	9.5±7.5	0.012
Pulmonary metastases	2.4±0.7	3.4±1.5	0.175
Other sites*	8.5±3.8	14.2±17.1	0.691

LNs, lymph nodes; Other sites include bone and subcutaneous metastasis.

Dual immune checkpoint inhibition in advanced incurable radioiodine-refractory differentiated thyroid carcinoma (RAIR DTC), anaplastic (ATC), and medullary thyroid carcinoma (MTC): Long-term survival results from phase II clinical trial. First Author: Kartik Sehgal, Dana-Farber Cancer Institute, Boston, MA

Background: Immunoprofiling and preclinical studies with patient derived organotypic tumor spheroids supported therapeutic targeting of programmed death (PD)-1 and cytotoxic T lymphocyte antigen (CTLA)-4 pathways in thyroid tumors. We previously presented initial results of a phase 2 clinical trial evaluating dual immune checkpoint inhibition with nivolumab (N) and ipilimumab (I) in advanced incurable thyroid carcinoma (TC) (ASCO 2020, PMID: 39446365) with data cutoff at 24 months (mo) follow up. **Methods:** This nonrandomized phase 2 clinical trial evaluated N (3 mg/kg every 2 weeks) + I (1 mg/kg every 6 weeks) in the primary patient population of RAIR DTC, with exploratory cohorts in ATC and MTC. Primary endpoints were objective response rate (ORR), with secondary endpoints of safety, progression-free survival (PFS), and overall survival (OS). Here, we present long term results (data cutoff 12/27/24), with median follow up of 75.3 mo for the overall population. **Results:** 49 patients (32 RAIR DTC, 10 ATC, and 7 MTC) were evaluable, 51% female, with median age of 65 years (range 30-88). Median duration of follow up (by cohorts) for this analysis was 74.9 mo (range 12.7 - 82.1) for RAIR DTC, 67.6 mo (29.9 - 84.4) for ATC and 81.1 mo (75 - 82.1) for MTC. ORR was 9.4% (in RAIR DTC), 30% (ATC), and 0% (MTC), all partial responses. Previously unreported, median duration of response (DoR) was 30 mo (range: 18.1 – 69.7) for RAIR DTC, and 23.2 mo (9.1 - 73.1) for ATC. Updated median PFS was 4.9 mo (95% CI 2.1, 17.0) for RAIR DTC, 4.3 mo (0.5, NA) for ATC, and 2.1 mo (0.9, 4.0) for MTC. 5-year PFS rates were 14.6% (95% CI 4.3%, 30.9%) for RAIR DTC, and 26.7% (4.8%, 56.3%) for ATC. Updated median OS was 44.6 mo (95% CI 24.6, NA) for RAIR DTC, 13.8 mo (1.2, NA) for ATC, and 46.1 mo (12.2, NA) for MTC. 5-year OS rates were 39.0% (95% CI 22.2%, 55.4%) for RAIR DTC, 30.0% (7.1%, 57.8%) for ATC, and 42.9% (9.8%, 73.4%) for MTC. **Conclusions:** Exceptionally durable responses were observed in the exploratory cohort of ATC (median DoR: 23.2 mo). To the best of our knowledge, this is the longest follow up reported for patients with aggressive thyroid carcinoma treated with immunotherapy. 5-year OS rate of 30% in incurable ATC is congruent with one prior report of 25.7% at another large volume cancer center (PMID: 3597734), but compares favorably with the historical rates reported for ATC in the SEER database (8% for all stages and 4% for distant metastatic disease). Biomarker studies are currently underway to identify exceptional responders and long-term survivors. Clinical trial information: NCT03246958. Research Sponsor: Bristol Myers Squibb.

	RAIR DTC (N=32)	ATC (N=10)
Median PFS (95% CI), mo	4.9 (2.1, 17.0)	4.3 (0.5, NA)
5 year PFS (95% CI)	14.6% (4.3%, 30.9%)	26.7% (4.8%, 56.3%)
Median OS (95% CI), mo	44.6 (24.6, NA)	13.8 (1.2, NA)
5 year OS (95% CI)	39.0% (22.2%, 55.4%)	30.0% (7.1%, 57.8%)

6106 Poster Session

A phase II study of pemetrexed and pembrolizumab in patients (pts) with recurrent and/or metastatic (R/M) salivary gland cancer (SGC): Results from non-adenoid cystic cohort. First Author: Katharine Andress Rowe Price, Department of Oncology, Mayo Clinic, Rochester, MN

Background: Treatment options for pts with R/M SGC are limited. Responses to chemotherapy (CT) are low with high toxicity and responses to immune checkpoint inhibition (ICI) are $<$10%. Pemetrexed (PTX) is safe and tolerable with responses reported in pts with R/M SGC.[1] Given enhanced responses with PTX and pembrolizumab (PMB) for lung cancer, we hypothesized that PTX and PMB will have activity for SGC. Herein we present the efficacy results in pts with non-adenoid cystic carcinoma (ACC). **Methods:** MC200708 is a single arm phase II study of PTX and PMB in pts with R/M SGC (NCT04895735). Pts were treated in 2 cohorts: ACC (cohort A) and non-ACC (cohort B). Key eligibility criteria: $\geq$18 years, ECOG 0-1, measurable disease. Prior ICI and/or PTX was allowed. Key exclusion criteria: serious comorbidities, autoimmune disease, and brain metastases. Simon's 2-stage design was used for each cohort. Primary endpoint was overall response rate (ORR). Secondary endpoints: progression free survival (PFS), overall survival (OS), and toxicity. All pts received PTX 500 mg/m2 IV + PMB 200 mg IV q3 weeks until progression or treatment intolerance. Imaging was q3 cycles. **Results:** 25 pts were enrolled Aug 2021-Feb 2024; 1 cancelled prior to treatment. Of 24 eligible and treated pts, median age was 59.5 years (46-77), 66.7% male, performance status 0 (62.5%) or 1 (37.5%). Histologies were salivary duct carcinoma (SDC, 11), acinic cell carcinoma (8), mucoepidermoid carcinoma (MEC, 3), myoepithelial carcinoma (1), and carcinoma NOS (1). 7 pts had no prior therapies (29.2%). The remaining pts had 1 (33.3%), 2 (29.2%), or $\geq$ 3 lines of therapy (8.3%). 83.3% of pts had no prior ICI. Median cycles of treatment was 8 (2-34), and duration of response was 12.5 months (4.1-20.6). 9 of 24 pts had a confirmed partial response (PR) for ORR of 37.5% (CI: 18.8-59.4). PRs were seen in 7 pts with SDC (7 of 11, 63.6% PR), 1 with MEC, and 1 with acinic cell. Stable disease (SD) was seen in 5 (20.8%), progressive disease in 8 (33.3%), and 2 didn't have post-baseline imaging, but were considered non-responders per protocol. Clinical benefit rate was 58.3% (CI: 36.6-77.9). With median follow-up of 12.0 months (2-34.7), median OS is 20.7 months (CI: 17.3-not reached) and median PFS is 6.2 months (CI: 2.1-17.3). 1-year OS and PFS rate is 76.3% (95% CI: 59.9-97.2) and 36.1% (CI: 21.01-62.2), respectively. Common toxicities were grade 1 fatigue and nausea. 6 pts (25.0%) had $\geq$1 grade 3-4 toxicity possibly related to treatment, mostly hematologic. The 4 pts with grade 3-4 non-heme toxicity had grade 3 fatigue, rash, and heart failure, and 1 grade 4 hypokalemia. Correlative studies investigating biomarkers of response are underway. **Conclusions:** PTX and PMB has activity in pts with R/M SGC, with promising responses in pts with SDC and median response duration of 1 year. A multisite randomized trial of an advanced pneumatic compression device vs usual care for head and neck cancer related lymphedema: Short-term results. First Author: Barbara Murphy, Vanderbilt University Medical Center, Nashville, TN

Background: Lymphedema is common in head and neck cancer survivors (HNCS). Published data indicate that an Advanced Pneumatic Compression Device (APCD) is an effective intervention for lymphedema refractory to Therapist Guided Lymphedema Treatment (TGLT). It may also address barriers to TGLT. We therefore conducted a study in which HNCS with previously untreated lymphedema were randomized to APCD or Usual Care. We report short-term, two-month outcomes. **Methods:** This was a six-month, multi-site (community/academic), stratified, randomized effectiveness trial. Eligible patients were lymphedema therapy naïve HNCS with internal or external lymphedema on exam or imaging and at least 1 moderate ($\geq$ 4/10) lymphedema associated symptom. Participants were randomized (1:1) to APCD or Usual Care. Those randomized to APCD were to use the device for 32 minutes per day. Participants randomized to Usual Care were referred for lymphedema therapy per institutional standards. The primary outcome was improvement in lymphedema associated symptom severity. Additional outcomes included anatomical measures, patient reported biopsychosocial outcomes, barriers to care, and patient satisfaction. **Results:** 236 participants were enrolled (119 APCD group, 117 Usual Care group). At two-months there was a similar decrease in lymphedema associated symptom burden and internal soft tissue swelling in both groups. We demonstrated a statistically significant external soft tissue swelling benefit favoring the APCD group as measured by the Head and Neck Cancer Related Lymphedema and Fibrosis Grading score (p=0.016). Digital photography identified a reduction in number of grids with swelling (p=$<$0.001) in the APCD group only. No reduction of internal swelling was noted in either group by imaging measures. 95% of APCD participants and 71% of Usual Care participants received assigned therapy. Time to therapy initiation was 29.8 days (SD 23.5) for Usual Care and 17.86 days (SD 10.53) for APCD. **Conclusions:** We demonstrated that APCD therapy is an effective treatment modality in lymphedema therapy naïve HNCS. Furthermore, participants experienced significant barriers to TGLT which may be effectively addressed with use of the APCD. A hybrid multi-modal approach to treatment associated lymphedema may further optimize patient outcomes. Clinical trial information: NCT04797390. Research Sponsor: Tactile.

Outcomes with 177 lutetium-dotatate (177Lu-dotatate) in olfactory neuroblastoma (ONB): A case series. First Author: Mateus Trinconi Cunha, Department of Thoracic/Head and Neck Medical Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Olfactory neuroblastoma (ONB) is a rare malignant tumor of the nasal cavity with a high recurrence rate after local therapy. Effective treatments for recurrent/metastatic (R/M) ONB are lacking. ONB frequently expresses somatostatin receptor (SSTR). Radionuclide bound to somatostatin analogues is an established treatment for SSTR-expressing gastrointestinal and pancreatic neuroendocrine tumors. This study reports the efficacy and survival outcomes of ONB patients treated with 177Lu-dotatate at a comprehensive cancer center. **Methods:** We conducted a retrospective analysis of ONB patients treated with 177Lu-dotatate at MD Anderson Cancer Center through NOV 1 2024, with a follow-up cutoff date of DEC 1 2024. Time-to-event outcomes were estimated with the Kaplan-Meier method, and comparisons of survival were done with the log-rank test. Objective response rate (ORR) to 177Lu-dotatate was assessed by RECIST v1.1 and PERCIST criteria adapted to Ga-60 Dotatate PET-CT. The magnitude of effect was estimated with Cox proportional hazards model, with statistical significance set at p$<$ 0.05. **Results:** Thirteen R/M ONB patients were identified, 8 were female, and the median age at first dose of 177Lu-dotatate was 54 years. Overall, 6 (46%) ONB tumors were Hyams grade 2, 5 (38%) were grade 2-3, 1 (8%) grade 3, and 1 (8%) grade 4. All patients had distant metastasis prior to 177Lu-dotatate treatment, with the most common sites being bone (76%), and dura (38%), while 6 (46%) also had locoregional disease. Six (46%) patients received 177Lu-dotatate as first line therapy, 4 (31%) as second line, and the remaining 3 (23%) in later lines. Prior therapies included somatostatin analogues (n=4), chemotherapy plus PD-L1 inhibitor (n=1), Lenvatinib (n=1), and clinical trials with experimental drugs (n=3). Among 10 patients with post-treatment restaging scans, PERCIST showed partial response in 7 (70%) and stable disease in 3 (30%). Of these pts, 7 were evaluable per RECIST, demonstrating partial responses in 4 (57%) and stable disease in 3 (43%). At a median follow-up of 19.8 months from starting 177Lu-dotatate, the median progression-free survival (PFS) was 17.43 mo. (95%CI 8.29-NE). For patients treated with 177Lu-dotate in second-line or beyond, the median PFS significantly shorter at 4.18 mo. (95%CI 1.35-NE); hazard ratio (HR) 0.22 (95%CI 0.08-0.60; p = 0.001). Median time-to-progression for 177Lu-dotatate was not achieved. There was no statistical difference in PFS between first or later lines 177Lu-dotatate use (HR 1.74; 95%CI 0.38-7.86; p = 0.47). **Conclusions:** 177Lu-dotate demonstrates activity in R/M ONB, with a favorable PFS compared to previously administered lines of systemic therapy. This case series, the largest reported to date to our knowledge, supports the growing evidence supporting for the use of 177Lu-dotate in this orphan disease. Research Sponsor: None.

TPS6109 **Poster Session**

HexAgon-HN: Phase 2/3, randomized study of the hexavalent OX40 agonist INBRX-106 in combination with pembrolizumab vs pembrolizumab alone as first-line treatment for recurrent/metastatic head and neck cancer with a PD-L1 combined positive score of ≥20. First Author: Jong Chul Park, Massachusetts General Hospital, Boston, MA

Background: Pembrolizumab (pembro) ± chemotherapy is a standard-of-care first-line treatment option for recurrent/metastatic (R/M) head and neck squamous cell carcinoma (HNSCC). Pembro monotherapy is commonly used in patients with a PD-L1 combined positive score (CPS) of ≥20, with an objective response rate (ORR) of <25% and median overall survival (OS) of <15 months.[1] Therefore, a high unmet need exists for more effective, non–chemotherapy-based treatment options. INBRX-106 is a novel, hexavalent OX40 agonist designed to promote higher-order clustering of the costimulatory receptor OX40, leading to more potent agonism than the bivalent first generation of OX40 agonists. Combining INBRX-106 with pembro may amplify and prolong the antitumor immune response. In an ongoing phase 1/2 study (NCT04198766), INBRX-106 + pembro has demonstrated robust pharmacodynamics, a favorable safety profile, and promising clinical activity in multiple tumor types, including R/M HNSCC. These findings supported the initiation of HexAgon-HN (NCT06295731), a phase 2/3, randomized study evaluating INBRX-106 + pembro vs pembro alone as first-line treatment for R/M HNSCC with a PD-L1 CPS of ≥20. **Methods:** Eligible patients must have biopsy-confirmed R/M HNSCC that is considered incurable; a primary tumor in the oral cavity, oropharynx, hypopharynx, or larynx; no previous receipt of therapy for R/M disease; a centrally confirmed PD-L1 CPS of ≥20; measurable disease per RECIST 1.1; and an Eastern Cooperative Oncology Group performance status (ECOG PS) of 0 or 1. Prior curative-intent treatment for locoregionally advanced HNSCC is allowed if progressive disease occurred ≥6 months (≥12 months if immunotherapy) after completion of treatment. Up to 410 patients will be randomized 1:1 (stratified by locoregional advanced vs distant metastatic disease, HPV status, and ECOG PS) to INBRX-106 + pembro 200 mg every 3 weeks or pembro (alone in the open-label, phase 2 part or in combination with placebo in the double-blind, phase 3 part). If the phase 2 part (N≈60) shows favorable results for the primary efficacy endpoint (ORR) and secondary safety and efficacy endpoints (eg, duration of response [DOR], progression-free survival [PFS] rate at 6 months, and clinical benefit rate [CBR]), the study can seamlessly proceed to the phase 3 part. The phase 3 part (N≈350) has dual primary efficacy endpoints of PFS and OS; secondary endpoints include ORR, DOR, CBR, time to chemotherapy, safety, and patient-reported quality of life. This study is currently enrolling in the US (30 sites), Europe (40 sites), and Asia-Pacific region (15 sites). 1. Burtness B, et al. *Lancet*. 2019;394:1915-1928. Clinical trial information: NCT06295731. Research Sponsor: Inhibrx Biosciences, Inc.

TPS6110 **Poster Session**

A phase II study of ACR-368 and low dose gemcitabine combination therapy in patients with recurrent and/or metastatic head and neck squamous cell carcinoma. First Author: Robin Park, Department of Head and Neck-Endocrine Oncology, Moffitt Cancer Center, Tampa, FL

Background: Safe and efficacious therapeutic options for patients with recurrent and/or metastatic head and neck squamous cell carcinoma (R/M HNSCC) beyond the 1st line palliative treatment, for which the standard of care is PD-1 inhibitor with/without chemotherapy, are limited. Therefore, developing novel therapeutic strategies in this setting remains a critical unmet need. ACR-368 (prexasertib) is a potent, selective CHK1/2 inhibitor which impairs DNA damage repair (DDR) and induces cancer cell apoptosis. ACR-368 has shown single agent activity in a phase Ib trial of patients with advanced squamous cell carcinomas including heavily treated R/M HNSCC. Pre-clinical studies suggest down-regulation of DDR pathways downstream to CHK1/2 is a major resistance mechanism to ACR-368 that can be overcome with low doses of nucleoside analogs that increase replication stress. Work conducted at Acrivon Therapeutics using their AP3 platform uncovered protein signaling features linked to ACR-368 resistance that demonstrated low-dose gemcitabine (LDG) may sensitize cancer cells to ACR-368 treatment. Furthermore, combining LDG with ACR-368 induces synergistic cancer cell regression in *in vitro* and *in vivo* models of HNSCC. Therefore, combined ACR-368 and LDG warrant further evaluation. **Methods:** This is a multi-center, parallel-arm, open-label, phase II trial evaluating combined ACR-368 with LDG in patients with R/M HNSCC. Eligible patients must have been treated with 1 prior line of PD-1/L1 inhibitor with/without chemotherapy with no limitation on the number of prior therapies received in the R/M setting. Patients must agree to a biopsy after the lead-in LDG infusion and at disease progression or end of treatment. OncoSignature is a proprietary predictive biomarker designed to predict response from ACR-368 that will be evaluated as a companion diagnostic. Lead-in LDG 10 mg/m2 IV will be administered before Cycle 1 only followed by ACR-368 105 mg/m2 IV Q2W and LDG 10 mg/m2 Q2W until discontinuation due to disease progression, intolerance, or consent withdrawal. Patients with HPV-unrelated R/M HNSCC will be assigned to Cohort A and patients with HPV-related R/M HNSCC to Cohort B. Primary objective is to determine objective response rates (ORR) in Cohort A and Cohort B, respectively. Study will enroll 14 patients in Cohort A and 29 patients in Cohort B to detect an increase in ORR from 0 to 19% and 5 to 22%, in respective cohorts (type I, II errors, both 10%). Secondary objectives include safety, duration of response, progression-free survival, and overall survival. Exploratory objectives include evaluating potential predictive biomarkers and the effect of lead-in LDG on OncoSignature by comparing pre- and post-LDG tumors. Since recruitment began 09-25-2024, 5 of planned 43 patients have been enrolled as of 01-22-2025. Clinical trial information: NCT06597565. Research Sponsor: Acrivon.

TPS6111 **Poster Session**

VERSATILE-003: A phase 3, randomized, open-label trial of PDS0101 and pembrolizumab compared with pembrolizumab for first-line treatment of patients with HPV16-positive recurrent/metastatic head and neck squamous cell carcinoma. First Author: Katharine Andress Rowe Price, Mayo Clinic, Rochester, MN

Background: Human papillomavirus (HPV)-related head and neck squamous cell carcinoma (HNSCC) has surpassed cervical cancer as the most common HPV-related cancer in the US, with the majority being caused by HPV16. Persistent expression of HPV16 oncoproteins E6 and E7 by host genome may promote HNSCC. HPV16-positive HNSCC may be associated with poor clinical outcomes in the recurrent/metastatic (R/M) setting. PDS0101 (Versamune HPV) is an HPV16-immunotherapy that generates a potent, targeted T cell attack against HPV16 E6 & E7. In a Phase 2 study, PDS0101 plus pembrolizumab has shown encouraging safety and survival benefit in patients with HPV16-positive R/M HNSCC. (Weiss J et al. ESMO 2024. Poster 879P. NCT04260126). **Methods:** VERSATILE-003 is a global Phase 3, randomized, controlled, open-label study evaluating PDS0101 plus pembrolizumab vs. pembrolizumab in patients with HPV16-positive R/M HNSCC with PD-L1 positive disease (CPS ≥1). Key eligibility criteria include age ≥18-years-old, histologically- or cytologically-confirmed diagnosis of R/M HNSCC with primary tumor location of oropharynx, oral cavity, hypopharynx, or larynx and no prior systemic anticancer treatment in the R/M setting, HPV16 tumor positivity (centrally tested), PD-L1 positivity defined as CPS ≥ 1 using FDA-approved PD-L1 IHC 22C3 pharmDx kit, and measurable disease based on RECIST 1.1 confirmed by blinded independent central review (BICR). Patients will be randomized 2:1 to receive pembrolizumab 200 mg IV Q3W with PDS0101 1 mL SC administered concurrently during Cycles 1, 2, 3, 4, and 12 (investigational arm), or pembrolizumab 200 mg IV Q3W alone (control arm). The primary objective is to compare overall survival (OS) between the investigational and control arms. Secondary objectives include objective response rate (ORR), disease control rate (DCR), duration of response (DOR), and progression-free survival (PFS) using RECIST 1.1 and assessed by BICR. Exploratory objectives include tumor response assessed by investigator and by irRECIST, PFS2, quality of life as assessed by EQ-5D, QLQ-C30, and QLQ H&N35, and assessment of ctHPVDNA. Updated enrollment data will be provided. Clinical trial information: NCT06790966. Research Sponsor: PDS Biotechnology Corporation.

TPS6112 **Poster Session**

A phase 2 study of fianlimab (anti–LAG-3) plus cemiplimab (anti–PD-1) versus cemiplimab plus placebo in patients with recurrent/metastatic head and neck squamous cell carcinoma (HNSCC) with positive PD-L1 expression. First Author: Danny Rischin, Peter MacCallum Cancer Centre, Melbourne, Australia

Background: Concurrent blockade of lymphocyte activation gene 3 (LAG-3) may enhance the efficacy of anti–programmed cell death-1 (PD-1) therapies. In a multicohort study, fianlimab (anti–LAG-3) plus cemiplimab (anti–PD-1) showed signs of clinical activity with durable responses and a generally manageable safety profile in patients with recurrent/metastatic (R/M) head and neck squamous cell carcinoma (HNSCC) warranting further investigation. **Methods:** This randomized, multicenter, Phase 2 study (NCT06769698) will investigate fianlimab (anti–LAG-3) plus cemiplimab (anti–PD-1) versus cemiplimab plus placebo in patients with R/M HNSCC with positive programmed cell death-ligand 1 (PD-L1) expression. The primary objective is to evaluate investigator-assessed objective response rate (ORR) with combination therapy (fianlimab + cemiplimab) versus cemiplimab monotherapy (cemiplimab + placebo). Key inclusion criteria: (1) aged ≥18 years; (2) histologically confirmed R/M HNSCC; (3) primary tumor location of oral cavity, oropharynx, larynx, or hypopharynx; (4) confirmed positive PD-L1 expression status with a Combined Positive Score of ≥1 based on a previous immunohistochemistry (IHC) test performed on a surgical/core biopsy specimen; (5) for patients with oropharynx disease, human papillomavirus (HPV) status must be established by p16 IHC or HPV DNA or RNA *in situ* hybridization (ISH) test; biopsy can be from primary tumor or nodal/distant metastasis; (6) for patients with squamous cell carcinoma of neck node with occult primary, a positive HPV DNA or RNA ISH test; (7) measurable disease per Response Evaluation Criteria in Solid Tumors version 1.1; (8) Eastern Cooperative Oncology Group performance status of ≤1; (9) adequate bone marrow, hepatic, and renal function. Key exclusion criteria: (1) patients who have progressive disease within 6 months of completion of curatively intended systemic treatment for locoregionally advanced HNSCC; (2) patients who have received prior systemic anticancer therapy in the R/M HNSCC setting. Approximately 120 patients will be enrolled across two cohorts. Patients will receive fianlimab + cemiplimab intravenously (IV) every 3 weeks (Q3W) or cemiplimab (350 mg) + placebo IV Q3W. Cohort 1 (n=60, HPV positive HNSCC) will be randomized 1:1 to receive: a) fianlimab + cemiplimab, b) placebo + cemiplimab. Cohort 2 (n=60, HPV negative HNSCC) will be randomized 1:1 to receive: a) fianlimab + cemiplimab, b) placebo + cemiplimab. The primary endpoint is ORR per investigator assessment. The secondary endpoints are progression-free survival, disease control rate, duration of response, safety, pharmacokinetics, and immunogenicity. Clinical trial information: NCT06769698. Research Sponsor: Regeneron Pharmaceuticals, Inc.

TPS6113 **Poster Session**

A multicenter, randomized, double-blind, phase 2/3 study of ficerafusp alfa (BCA101) or placebo in combination with pembrolizumab for first-line treatment of PD-L1-positive, recurrent or metastatic head and neck squamous cell carcinoma: The FORTIFI-HN01 study. First Author: Renata Ferrarotto, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: HPV-negative head and neck squamous cell carcinoma (HNSCC) is an aggressive disease characterized by high rates of recurrence, metastasis, and resistance to standard treatments. Over 80% of HPV-negative HNSCC cases overexpress TGF-β, a key driver of poor survival and treatment resistance. Ficerafusp alfa, a first-in-class bifunctional antibody, targets epidermal growth factor receptor (EGFR) while neutralizing TGF-β in the tumor microenvironment. In a Phase 1/1b trial (NCT04429542), ficerafusp alfa demonstrated promising efficacy and a manageable safety profile in first-line recurrent/metastatic (R/M) HNSCC. The ongoing FORTIFI-HN01 study (NCT06788990) is a randomized, double-blind, placebo-controlled Phase 2/3 trial designed to assess the efficacy and safety of ficerafusp alfa combined with pembrolizumab versus placebo plus pembrolizumab in patients with PD-L1 positive first-line R/M HPV-negative HNSCC. **Methods:** Eligible patients must have histologically confirmed R/M HNSCC with primary lesions in the oral cavity, larynx, or hypopharynx, or OPSCC, excluding HPV-positive OPSCC confirmed by central laboratory testing. Additional criteria include no prior systemic therapy for R/M disease, PD-L1 positive tumors (CPS $\geq$1), measurable disease per RECIST v1.1 assessed by BICR, and ECOG performance status of 0 or 1. The Phase 2 objective is to determine the optimal biological dose (OBD) of ficerafusp alfa through an integrated analysis of safety, tolerability, PK, PD, and efficacy. Subjects will be randomized 1:1:1 to receive high-dose ficerafusp alfa, low-dose ficerafusp alfa, or placebo, each combined with pembrolizumab. Randomization is stratified by PD-L1 CPS (1-19 vs. $\geq$20) and disease extent (local/regional recurrence only, distant metastasis only, or both). After OBD determination, the trial will transition seamlessly into Phase 3 with a 2:1 randomization (OBD vs. control).Patients will receive pembrolizumab (200 mg i.v. every 3 weeks for up to 35 cycles) and either ficerafusp alfa (1500 mg or 750 mg) or placebo weekly until disease progression or unacceptable toxicity. Tumor imaging will occur every 6 weeks during the first year and every 9 weeks thereafter. The primary endpoints are objective response rate (ORR) per RECIST v1.1 (BICR) and overall survival (OS). Secondary endpoints include safety, additional efficacy measures, and patient-reported outcomes (PROs). The trial is actively recruiting, with a planned enrollment of (NCT06788990). Clinical trial information: NCT06788990. Research Sponsor: Study funded by Bicara Therapeutics Inc.

TPS6114 **Poster Session**

A phase II study of AK117 combined with cetuximab or AK104 in the treatment of recurrent or metastatic head and neck squamous cell carcinoma after the failure of PD-1 (L1) inhibitors and/or platinum-based therapy. First Author: Jun Wang, Division of Head & Neck Tumor Multimodality Treatment, Cancer Center, West China Hospital, Sichuan University, Chengdu, China

Background: The administration of first-line pembrolizumab monotherapy or pembrolizumab combined chemotherapy has been shown to improve survival among patients with recurrent or metastatic head and neck squamous cell carcinoma (R/M HNSCC). However, over 80% of the patients still experience disease progression within a year. Upon progression, treatment options are notably limited. Therefore, there is a dearth of a standardized treatment for R/M HNSCC after the failure of PD-1 (L1) inhibitors and/or platinum-based therapy. This study aims to assess the safety and efficacy of AK117 (anti-CD47) combined with Cetuximab or AK104 (PD-1/CTLA-4 Bispecial Antibody) in this patient subset. **Methods:** This is a non-randomized, two-group, phase II study. The inclusion criteria include: 1) Pathological or radiological diagnosis of R/M HNSCC (including oral cavity, oropharynx, larynx, and pharynx) and cannot be cured by local treatment; 2) Failure of PD-1 (L1) inhibitors and/or platinum-based therapy; 3) Eastern Cooperative Oncology Group (ECOG) Performance Status (PS) 0-1 and expected survival $\geq$3 months. Key exclusion criteria are active autoimmune diseases, use of immunosuppressive drugs, or any severe or uncontrolled systemic disease. We group the patients based on the duration of first-line PD-1 (L1) inhibitors from start to failure (Group 1: the duration $\leq$ 3 months; Group 2: the duration $>$ 3 months). Group 1 patients receive AK117 (45mg/kg, day 1, every 3 weeks) in combination with Cetuximab (initial dose 400mg/m^2, subsequent doses of 250mg/m^2, day 1, every week) maintained for one year or until progression or intolerable toxicity occurred. Group 2 patients are treated with AK117 (45mg/kg, day 1, every 3 weeks) in combination with AK104 (10mg/kg, day 1, every 3 weeks) maintained for one year or until progression or intolerable toxicity occurred. The primary endpoints are incidence of adverse events and overall survival. Secondary endpoints are objective response rate, progression free survival, disease control rate, and duration of response. Clinical trial information: NCT06508606. Research Sponsor: Akeso, Inc.

TPS6115 **Poster Session**

FIERCE-HN: A multicenter, randomized, double-blind, placebo-controlled, phase 3 study of ficlatuzumab (HGF/cMET MAb) in combination with cetuximab in participants with recurrent or metastatic (R/M) HPV negative head and neck squamous cell carcinoma (HNSCC). First Author: Julie E. Bauman, GW Cancer Center, George Washington University, Washington, DC

Background: Patients with HPV-negative R/M HNSCC have a worse median overall survival (OS) than HPV-positive patients and current treatments options are limited.[1] Ficlatuzumab is a humanized IgG1 MAb that binds HGF, the ligand for the c-MET tyrosine kinase receptor. HGF/c-MET pathway dysregulation is frequently observed in HPV-negative HNSCC, and has been linked to EGFR inhibitor resistance, limiting the potential efficacy of EGFR-targeting drugs like cetuximab. In a phase 2 study, both pathways were targeted using ficlatuzumab plus cetuximab in patients with HPV-negative R/M HNSCC resistant to cetuximab, platinum, and anti-PD1 immune checkpoint inhibitors (ICI) who have a very poor historical prognosis. A PFS of 4.1 months, median OS of 7.4 months, and overall response rate (ORR) of 38% (6/16; 2 CR, 4 PR) was observed.[2] FIERCE-HN compares the efficacy/safety of ficlatuzumab+cetuximab vs placebo+cetuximab in patients with R/M HPV-negative HNSCC. **Methods:** This is an international, multicenter, randomized, double-blind, placebo-controlled phase 3 study. Major enrollment criteria include confirmed diagnosis of R/M HNSCC primary tumors of the oropharynx (p-16 negative only), oral cavity, hypopharynx, or larynx. Participants must have progressed on, or be intolerant to, previous anti-PD-1/PD-L1 ICI and platinum-based chemotherapy; have 2 or fewer prior lines of anticancer therapy; and have no prior treatment with cetuximab/alternative EGFR inhibitors in the R/M setting. Patients with feeding tubes are eligible. The primary endpoint is OS; key secondary endpoints include PFS and ORR. Other secondary endpoints are DCR, DoR, safety, PK, immunogenicity and QoL. Patients will receive cetuximab 500mg/m2 and are randomized 1:1:1 to Arm A: ficlatuzumab 10mg/kg, Arm B: ficlatuzumab 20mg/kg, or Arm C: placebo. Treatments will be on Days 1 and 15 of a 28-day cycle. This is an adaptive study with two interim analyses (IAs). IA 1 will be conducted after 70 OS events, when futility and optimal dose assessments will be performed. Participants enrolled after IA 1 will be randomized 1:1 to the optimal ficlatuzumab dose or placebo, plus cetuximab. IA 2 will be conducted after 163 OS events to assess whether an event count re-estimation is needed. The final analysis will occur after 232 (or up to 279) OS events, depending on the re-estimation outcome. The study has statistical power of 80%, assuming a true OS hazard ratio of 0.667. Between 410 to 500 patients will be enrolled. The study is ongoing and actively recruiting in North America, Europe, United Kingdom, and Asia-Pacific. Clinical trial information: NCT06064877 (collaborator Eli Lilly provided cetuximab). 1. Cohen E et al., JITC. 2019;7:184. 2. Bauman JE et al., JCO. 2023. 41:3851. Clinical trial information: NCT06064877. Research Sponsor: AVEO Oncology.

TPS6116 **Poster Session**

Reduction of postoperative radiotherapy in head and neck squamous cell carcinoma: A single-arm, phase II trial (REPORT-HNSCC study). First Author: Chunyan Chen, Department of Radiation Oncology, Sun Yat-sen University Cancer Center, State Key Laboratory of Oncology in South China, Guangdong Key Laboratory of Nasopharyngeal Carcinoma Diagnosis and Therapy, Guangdong Provincial Clinical Research Center for Cancer, Guangzhou, China

Background: Postoperative radiotherapy (PORT) significantly enhances the prognosis for high-risk patients with locally advanced squamous cell carcinoma of the head and neck (LA HNSCC). However, elective nodal irradiation (ENI) in low-risk areas can lead to serious acute and long-term toxicities, which negatively impact quality of life. In a study by Contreras (NCT00593840), 72 patients with LA HNSCC experienced a remarkable 97% regional control rate at five years after eliminating PORT to the pathologically negative (pN0) neck. Additionally, patients who responded well to neoadjuvant therapy showed better local control rates, suggesting a possible reduction in the need for radiotherapy. The RAVD study (NCT01133678) demonstrated that the elimination of ENI in patients with good response to neoadjuvant chemotherapy did not appear to compromise outcomes and resulted in significantly decreased late toxicity. Preclinical studies have also suggested that the elimination of ENI may preserve beneficial T cells in normally draining lymph nodes, enhancing the efficacy of radioimmunotherapy. The study was designed to evaluate regional control rates and quality of life in LA HNSCC patients undergoing sequential elimination of ENI to the pN0 neck by neoadjuvant chemo-immunotherapy. **Methods:** REPORT-HNSCC is a phase 2, single-arm, single-center trial assessing patients with newly diagnosed LA HNSCC. Patients receive neoadjuvant chemo-immunotherapy (flexibility in regimens and cycles). This trial targets patients with an ipsilateral and/or bilateral pN0 neck, while surgical resection will be guided by the surgeon's discretion. Key treatment components include 60 to 66 Gy to the primary tumor bed (CTVtb), 60 Gy to CTV1, and 54 to 60 Gy to CTV2, with appropriate expansion margins to optimize target volume. Eliminating ENI (that is, CTV2) to the pN0 neck. A symmetric 0.3-cm expansion around the CTV defined the corresponding planning target volume (PTV). Radiation doses were prescribed to the PTV. Intensity-modulated radiotherapy (IMRT) will be administered to all patients, while select patients with positive surgical margins or extranodal extension receive concurrent chemotherapy. The primary endpoint is 2-year region-free recurrence survival rate. Secondary endpoints include 2-year PFS, 2-year OS, 2-year DMFS, 2-year LRFS, acute and late toxicities, and quality of life. We will also explore predictive biomarkers for better understanding of responses and survival. As of January 2025, we have enrolled 14 of the planned 50 patients since the study began in October 2024, with results expected by December 2029. Clinical trial information: NCT06630780. Research Sponsor: None.

TPS6117 **Poster Session**

Phase II trial of neoadjuvant chemotherapy (NAC) docetaxel-cisplatin alone (DC) or with anti-human papillomavirus (HPV) gene therapy PRGN-2009 (DCP) followed by surgery in patients (pts) with newly diagnosed HPV-associated oropharyngeal cancer (HPV-OPC). First Author: Charalampos S. Floudas, Center for Immuno-Oncology, Center for Cancer Research, National Cancer Institute, National Institutes of Health, Bethesda, MD

Background: HPV-OPC is caused primarily by HPV16. Prognosis following standard-of-care (SOC) treatment, (surgery followed by adjuvant radiotherapy (RT), or concurrent chemoRT (CRT)) is favorable, with >80% 5-year recurrence-free survival (RFS). However, RT toxicity including tissue fibrosis results in long-term swallowing dysfunction and impacts quality of life (QOL). NAC treatment (DC) followed by surgery has resulted in clinical-to-pathologic downstaging or pathologic complete response (pCR) and avoidance of RT in most pts, with >90% 5-year survival, and induces HPV-specific T cell immunity. PRGN-2009 is a gorilla adenoviral vector based gene therapy harboring a DNA payload designed to induce HPV specific T-cell responses. This trial will evaluate the rate of pCR with NAC (DC) alone or combined with PRGN-2009 (DCP) in pts with newly diagnosed HPV-OPC. **Methods:** This is an investigator-initiated, single-center, randomized controlled phase II trial. Newly diagnosed HPV-positive OPC pts of stage I (cT1-2, N0-1) or II (T1-3, N0-2), M0 (AJCC Cancer Staging Manual, 8th ed.) planned for SOC surgery will be randomized to 2 treatment arms of 30 patients each, DC and DCP, to evaluate if PRGN-2009 may be associated with an increased rate of pathological CR (pCR) following neoadjuvant chemotherapy. DC consists of 3 cycles of intravenous cisplatin 75 mg/m^2 and docetaxel 75 mg/m^2 every 21 days (dose reductions allowed). DCP also includes PRGN-2009 induction dose pre-cycle 1, and one dose after each DC cycle (total 4 doses). Supportive measures include pre-infusion dexamethasone, antiemetics, neutropenia primary prophylaxis. Imaging (FDG PET, CT) will be performed at baseline. Research blood samples will be collected longitudinally. Mandatory research primary tumor biopsy will be performed at baseline and post-treatment tumor/tumor bed biopsy will be at the time of surgical resection. On-treatment tumor biopsies will be offered (optional). Study treatment and procedures will be performed at the NIH Clinical Center (Bethesda, MD). After treatment completion, pts will have surgery at their primary institution; adjuvant treatment determined per established risk factors. Primary endpoint is the rate of pCR in each arm. Secondary endpoints include safety and 2-year RFS in each arm. Exploratory objectives include assessment of changes in hearing (audiograms baseline/post-treatment), swallowing function (MD Anderson Dysphagia Inventory) and QOL (Functional Assessment of Cancer Therapy – Head & Neck); associations between changes in imaging, pathologic response, and circulating cell-free HPV DNA; changes in the tumor microenvironment and in HPV-specific T cell immunity. 8 of 60 pts planned have been enrolled. Clinical trial information: NCT06223568. Research Sponsor: NCI, NIH.

TPS6118 **Poster Session**

A phase III randomized controlled trial comparing palliative stereotactic body radiotherapy vs. palliative standard radiotherapy in patients with advanced head and neck cancer (NCT06641791). First Author: Ian Poon, Sunnybrook Health Sciences Centre, Toronto, ON, Canada

Background: The optimal radiotherapy (RT) treatment regimen for patients with advanced head and neck cancer (AHNC) unsuitable to receive curative intent RT is undefined. Stereotactic body radiotherapy (SBRT) is a promising technique but rigorous multicentre evaluation is required prior to adoption. **Methods:** This is a Phase III randomized controlled trial comparing palliative SBRT to palliative standard RT (SRT) in participants with advanced mucosal, squamous cell head and neck cancer unable to tolerate curative intent RT. Key eligibility criteria: Unsuitable for curative intent therapy, no evidence of metastatic disease, stages TX or T0-T4/N0-N3, geriatric 8 score [1] ≤14. Treatment arms: (Experimental) SBRT 4500 cGy/ 5fr (twice a week to primary and nodal GTV (BED_{10}85) OR 4000 cGy /5 fr twice a week if organs at risk (BED_{10}-72) versus (standard) 2400 cGy/ 3fr (day 0/7/21 (BED_{10}43) or 2500 cGy/ 5fr over 1 week (BED_{10}38). Primary objective: To compare OS between arms. Secondary objectives evaluate progression-free survival (PFS), locoregional failure-free survival, distant metastases-free survival, response rates, acute and long-term toxicity (CTCAE v5.0), treatment compliance, patient-reported outcomes (PRO-CTCAE, FACT-HN), resource utilization, and health utilities. Statistical design: The trial aims to enroll 196 patients with a 2:1 randomization ratio (SBRT:SRT). The study is powered at 80% with a two-sided alpha of 0.05 to detect a difference in 1-year OS of 40.3% vs. 22% (HR = 0.6), assuming a 15% drop-out/lost to follow-up rate. Conduct to Date: This trial was activated on October 31, 2024. Supported by CCS grant #707213; CIHR #175014. [1] Takahashi M, Takahashi M, Komine K, Yamada H, Kasahara Y, Chikamatsu S, et al. TPS6119 **Poster Session**

TRENT-002: A prospective, multicenter, randomized controlled phase II study to evaluate the efficacy and safety of salvage preoperative PD-1 inhibitor combined with chemotherapy neoadjuvant therapy in recurrent laryngeal/hypopharyngeal squamous cell carcinoma (L/HPSCC). First Author: Xiaohong Chen, Beijing Tongren Hospital, Capital Medical University, Beijing, China

Background: Salvage surgery is considered the standard of care for patients with resectable recurrent L/HPSCC. However, salvage surgery achieves durable disease control in only 20% to 50% of patients. The PATHWay study showed that the subgroup that received salvage therapy indicated that adjuvant pembrolizumab could significantly improve PFS compared with placebo, but there is no OS data. This muti-center, prospective, randomized controlled phase II study will evaluate efficacy and safety of PD-1 inhibitors plus chemotherapy as neoadjuvant therapy in recurrent L/HPSCC. **Methods:** Patients who meet the inclusion criteria will be divided into groups according to whether they had received radiotherapy in the past. Arm 1 and Arm 2 are the groups that had not received radiotherapy in the past (N=100), and Arm 3 and Arm 4 are the groups that had received radiotherapy (N=160). Arm 1 and Arm 2 will be randomly assigned at a 1:1 ratio. Arm 1 will receive 3 cycles of pembrolizumab + nab-paclitaxel + cisplatin, followed by surgery. After surgery, patients will be stratified according to the presence or absence of high-risk factors (extranodal extension or positive margins). The high-risk group will receive concurrent chemoradiotherapy + pembrolizumab maintenance therapy (up to 15 cycles), and the low-risk group will receive radiotherapy + pembrolizumab maintenance therapy (up to 15 cycles). Arm 2 will undergo surgery directly, followed by concurrent chemoradiotherapy/radiotherapy. The total radiation dose is 60-66 Gy, 2.0 Gy/fraction for high-risk group and 44-50 Gy, 2.0 Gy/fraction for low-risk group. Similarly, Arm3 and Arm4 will be randomly assigned in a 1:1 ratio. Arm 3 will receive 3 cycles of pembrolizumab + nab-paclitaxel + cisplatin, followed by surgery, and pembrolizumab maintenance treatment after surgery. Arm 4 will be directly given surgery, and after surgery, the doctor will choose observation / re-radiotherapy or chemoradiotherapy. Eligibility criteria will include patients with squamous cell carcinoma of the larynx and hypopharynx confirmed by histology and/or cytology; patients with recurrence of primary tumor or second primary tumor after receiving curative treatment; At least 6 months after the last platinum-containing treatment; ECOG performance status 0-1. Primary end points is 2y-PFS. Secondary end points include ORR, pCR, 3y-OS, safety. Recruitment is ongoing and will continue until 260 patients are enrolled. Clinical trial information: NCT06793761. Research Sponsor: None.

TPS6120 **Poster Session**

A phase II randomized trial of nano-crystalline megestrol acetate for nutritional improvement in postoperative head and neck squamous cell carcinoma undergoing radiotherapy. First Author: Lei Liu, Division of Head & Neck Tumor Multimodality Treatment, Cancer Center, West China Hospital, Sichuan University, Chengdu, China

Background: Head and neck squamous cell carcinoma (HNSCC) patients frequently experience malnutrition and weight loss, exacerbated by cancer cachexia and treatment-related side effects during concurrent radiotherapy. Nano-crystalline megestrol acetate (NMA) improves bioavailability and efficacy compared to conventional formulations, demonstrating enhanced appetite, weight gain, and quality of life (QoL) in cancer cachexia. **Methods:** This randomized, parallel-controlled Phase II trial evaluates the efficacy and safety of NMA in improving nutritional outcomes in HNSCC patients undergoing postoperative CCRT. The study enrolls 96 HNSCC post-surgery patients. Participants are stratified by pre-treatment weight loss (>5% vs. ≤5%) and standard treatment regimen (radiotherapy vs. concurrent chemoradiotherapy), then randomized 1:1 to receive NMA (625 mg/day) plus standard treatment or standard treatment alone. The novel aspects of this design include the use of a nano-crystalline formulation to overcome absorption challenges, allowing effective drug delivery in fasting states. Additionally, comprehensive endpoints assess appetite status (A/CS-12 score), weight changes, lean body mass, inflammatory and nutritional markers, and QoL, providing an integrated evaluation of nutritional and clinical benefits. 12 of planned 96 patients have been enrolled. Clinical trial information: NCT06772428. Research Sponsor: None.

TPS6121 **Poster Session**

A phase 2 clinical trial of preoperative pembrolizumab and chemotherapy followed by adjuvant pembrolizumab in resectable locoregionally recurrent head and neck squamous cell carcinoma. First Author: Kartik Sehgal, Dana-Farber Cancer Institute, Boston, MA

Background: Locoregional recurrence is a major cause of death in squamous cell carcinoma of head & neck (HNSCC) initially treated with curative intent approaches. While salvage surgery may still provide a chance for cure, disease-free survival (DFS) and overall survival (OS) rates remain low for this high-risk population. Neoadjuvant programmed death (PD)-1 inhibitor based approaches have shown promising clinical outcomes compared to upfront surgery in multiple cancer types, e.g. melanoma and non-small cell lung cancer. Recently, a randomized placebo-controlled phase III (KEYNOTE-689) trial evaluating perioperative pembrolizumab in treatment-naïve locally advanced HNSCC met its primary endpoint of event-free survival. Since our trial is targeted at a higher risk patient (pt) population of locoregionally recurrent resectable HNSCC (already managed with curative intent once), we are evaluating the combination of pembrolizumab with chemotherapy in the neoadjuvant setting followed by adjuvant pembrolizumab therapy. **Methods:** This investigator-initiated non-randomized open-label phase 2 clinical trial is enrolling pts with resectable locoregionally recurrent HNSCC, with primary sites in oral cavity, oropharynx, larynx or hypopharynx. Pts must have documented duration of $\geq$6 months from completion of prior curative intent treatment for HNSCC (surgery and/or radiation therapy with/without platinum chemotherapy or cetuximab targeted therapy) to diagnosis of local or locoregional recurrence, and must have resectable disease. Study treatment plan consists of three phases: pre-operative phase, curative intent surgery, and adjuvant phase. In the pre-operative phase, pembrolizumab, cisplatin (or carboplatin) and docetaxel will be administered every 3 weeks for 2 treatment cycles. This will be followed by surgery within 6 weeks of cycle 2 day 1 in pre-operative phase. Adjuvant phase consists of pembrolizumab every 3 weeks until total of 15 cycles, disease recurrence, or intolerable adverse events. The primary endpoint of the trial is major pathological response (mPR) in surgical specimens after pre-operative treatment, defined as $\leq$ 10% residual invasive SCC within the resected primary tumor specimen and all sampled regional lymph nodes. Key secondary endpoints include safety, DFS, and OS. Correlative biomarker analyses are planned as exploratory endpoints. We hypothesize that treatment with pre-operative pembrolizumab and chemotherapy will lead to mPR rate of 15% compared to null hypothesis of 2%. If we find $\geq$2 pts with disease in mPR among 25 evaluable pts, the Simon two-stage design (14 pts in first stage) will have a power of 85.5% with a type I error rate of 7.4%. Safety rule is built in to monitor delays in surgery. 12 of planned 28 pts have been enrolled as of January 2025 (ClinicalTrials.gov NCT05726370). Clinical trial information: NCT05726370. Research Sponsor: Merck.

TPS6122 **Poster Session**

A phase 3 randomized study of ASP-1929 photoimmunotherapy in combination with pembrolizumab versus standard of care in locoregional recurrent head and neck squamous cell carcinoma (HNSCC). First Author: Anastasios Maniakas, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Recurrent (r) HNSCC carries a poor prognosis and a low survival rate. Locoregional (LR) progression significantly contributes to both morbidity and mortality in these patients, underscoring the importance of LR disease control. The approval of anti-PD-1 inhibitors (pembrolizumab, nivolumab) has expanded treatment options for rHNSCC, but response rates with monotherapy remain low. ASP-1929 photoimmunotherapy (PIT), a novel drug-device treatment, combines cetuximab with a light-activatable dye (IR700) to selectively target EGFR-expressing cancer cells and cause cell membrane destruction and rapid tumor necrosis after activation with local light illumination. Preclinical data have demonstrated that ASP-1929 PIT-mediated tumor necrosis and immunogenic cell death induces antitumor immunity and when combined with anti-PD-1 therapy, synergistically enhances anticancer activity. In an interim evaluation of a multicenter, phase 1/2a, open-label study of 19 patients with metastatic and/or rHNSCC, the combination of ASP-1929 PIT and pembrolizumab showed promising efficacy with a manageable safety profile.[1] The objective of this pivotal phase 3 study is to further evaluate the efficacy and safety of ASP-1929 PIT in combination with pembrolizumab in rHNSCC. **Methods:** The ASP-1929-381is a global phase 3, multi-center, randomized, open-label, controlled study of ASP-1929 PIT in combination with pembrolizumab vs pembrolizumab-based standard of care (SOC) in the first line treatment of LR rHNSCC with no distant metastases. Key inclusion criteria: rHNSCC patients without distant metastases who are candidates for SOC first-line treatment with pembrolizumab + chemotherapy; anti-PD-1 and anti-PD-L1-treatment naïve; at least one lesion accessible for PIT light treatment and RECIST 1.1 measurable; age $\geq$18 years; ECOG score 0 or 1. Key exclusion criteria: diagnosis and/or treatment of additional malignancy within 2 years of randomization; history of $\geq$ grade 3 cetuximab infusion reactions; prior allogeneic tissue/solid organ transplant; life expectancy $<$3 months. The study will enroll ~408 patients and begin with a 2:2:1 randomization into three arms (ASP-1929 PIT 320 mg/m^2 plus pembrolizumab vs ASP-1929 PIT 640 mg/m^2 plus pembrolizumab vs physicians' choice pembrolizumab-based SOC regimen). The SOC arm will include pembrolizumab monotherapy, or pembrolizumab in combination with platinum (cisplatin or carboplatin) + 5-fluorouracil or taxane (paclitaxel or docetaxel). The primary endpoint is overall survival (OS). Key secondary endpoints include complete response rate (CRR) and overall response rate (ORR). The study is currently enrolling in the US, with plans to expand to Taiwan, Japan, and other territories (NCT06699212). 1. Cognetti et al. J Clin Oncol 42, 2024 (suppl 16; abstr 6083). Clinical trial information: NCT06699212. Research Sponsor: Rakuten Medical, Inc.

TPS6123 **Poster Session**

RIBBON-UM: Treatment individualisation by EBV stratification in nasopharyngeal carcinoma (NPC): A phase 2, multi-arm umbrella platform trial. First Author: Melvin L.K. Chua, National Cancer Centre Singapore, Duke-NUS Medical School, Singapore, Singapore

Background: Induction chemotherapy (IC) and chemoradiotherapy (CRT) is the current standard of care (SOC) for locoregionally advanced NPC (LA-NPC). However, CRT alone or CRT and adjuvant chemotherapy (AC) are also first-line SOC options. Plasma Epstein-Barr virus (EBV) DNA is an archetypal biomarker for endemic NPC, and has been assessed for pre-and on-treatment clinical stratification. RIBBON-UM is a phase 2, multi-arm umbrella trial investigating pre- and on-treatment plasma EBV DNA assessment to individualise treatment of patients with LA-NPC. **Methods:** Patients who are newly-diagnosed, biopsy-proven NPC of TNM-stage III-IVA by AJCC/UICC 8th ed and have DETECTABLE EBV DNA pre-treatment are eligible. RIBBON-UM incorporates a 2-tier stratification by TN-status and EBV DNA levels – (1) First, patients will be stratified into low- (LR) and high-risk (HR) based on pre-treatment EBV DNA cut-off 4000 copies/mL AND/OR T4N+ or N2-3 disease; (2) Second, for the HR patients who are assigned to IC (gemcitabine-cisplatin), patients will be further stratified into HR and very-high risk (VHR) depending on their EBV DNA clearance post-3 cycles of IC. RIBBON-UM consists of 3 treatment arms (NCT05517135): Arm I will enroll LR patients (T3N0-1, T4N0 AND EBV DNA $<$4000 copies/mL) to upfront CRT (cisplatin/carboplatin) $\pm$ AC (cisplatin and 5-fluorouracil or capecitabine based on physician's discretion). HR patients (T4N+ OR N2-3 OR EBV DNA $\geq$4,000 copies/mL) will receive upfront IC, and if UNDETECTABLE EBV DNA post-IC, they will be assigned to Arm II – CRT $\pm$ AC. For patients with a DETECTABLE EBV DNA post-IC (VHR), these patients are assigned to Arm III – a single-arm, phase 2 trial investigating experimental AC (NCT06093061), embedded within the RIBBON-UM protocol. Currently, VHR patients enrolled into Arm III will receive CRT + 1-y combined tislelizumab (200 mg IV 3-weekly) and metronomic capecitabine at 650 mg/m^2 bidaily (RIBBON-LA-01, NCT06093061) or 1-y metronomic capecitabine (if they decline). Statistical plan of RIBBON-UM consists of 2 analyses: (1) we will evaluate if our risk-stratification strategy by TN-status and pre- and on-treatment EBV DNA levels improves 2-y disease-free survival (DFS) rate of patients with LA-NPC from 65% (historical) to 75% for the modular platform trial; (2) we hypothesise that AC intensification (Arm III) will improve 2-y DFS of the VHR cohort from 60% (historical) to 75%. 133 and 62 patients are required to test these hypotheses at 5% 1-sided significance level with 80% power, respectively. The risk-stratified treatment individualisation and AC intensification strategies will be deemed successful if 96 of 133 (from Arms I-III) and 44 of 62 patients (Arm III) remain disease-free at 2 y. From Nov 2022 to Jan 2025, we have enrolled 93 and 51 patients into RIBBON-UM and RIBBON-LA-01, respectively. We expect enrolment to RIBBON-UM to complete by Jun 2025. Clinical trial information: NCT05517135, NCT06093061. Research Sponsor: BeiGene; NMRC Singapore Open-Fund Large Collaborative Grant; NMRC Singapore Clinical Trials Grant.

TPS6124 **Poster Session**

A phase 2 clinical trial of adjuvant ado-trastuzumab emtansine (T-DM1) for patients with HER2-positive salivary gland cancer. First Author: Glenn J. Hanna, Department of Medical Oncology, Dana-Farber Cancer Institute, Boston, MA

Background: Salivary gland carcinomas (SGCs) represent a rare, but unique group of histologically and molecularly distinct head and neck cancers. Despite aggressive locoregional management with surgery and adjuvant (chemo)radiation, distant metastatic spread is not infrequent, particularly among high-risk subtypes like salivary duct carcinoma. Strong surface expression of HER2 has been observed in 60-80% of high-risk SGCs. This is the first clinical trial exploring the early addition of concurrent and adjuvant HER2-directed therapy to improve both locoregional and distant disease control rates in a HER2-overexpressing high-risk SGC population. **Methods:** This phase 2 open-label, clinical trial (NCT04620187) is enrolling patients (pts) with newly diagnosed SGC of any histology arising in the head and neck whose tumor overexpresses HER2 (2-3+ by IHC expression or *ERBB2* amplification/select mutations) treated with upfront definitive surgery. Pts must have adequate organ and cardiac function, with stage II-IVB (AJCC 2017 8th ed.) disease (stage II requires positive margins). Enrollment following surgery is permitted. Once registered post-op, adjuvant T-DM1 (3.6 mg/kg IV every 21-days) starts within 3-7 weeks of surgery prior to radiation (RT). Four to 8 weeks post-op pts receive standard RT (photon or particle) with concurrent weekly cisplatin (40 mg/m^2) for 6-weeks. T-DM1 continues every 3-weeks during RT and up to 1-year following surgery. The primary endpoint is 2-year disease-free survival (DFS). Secondary endpoints include safety and tolerability, overall survival, distant metastatic-free survival, and correlation between HER2 expression and outcomes. We hypothesize that treatment with adjuvant T-DM1 will improve historical 2-year DFS from 60 to 72%. When 24 DFS events are observed among N=47 pts who are eligible and receive protocol treatment, the design has 80% power to detect a 35% reduction in the DFS hazard to 0.1660 (using a one-sided 10% type I error rate; Wald's test). The study opened to accrual in October 2020 and is now accruing at four academic medical centers throughout the U.S. Sixteen of 47 planned subjects have been enrolled as of December 2024. Clinical trial information: NCT04620187. Research Sponsor: Genentech.

6500 Oral Abstract Session

Ropeginterferon alfa-2b versus anagrelide for the treatment of essential thrombocythemia: Topline results of the phase 3 SURPASS-ET trial. First Author: Ruben A. Mesa, Atrium Health Wake Forest Baptist Comprehensive Cancer Center, Wake Forest University School of Medicine, Winston-Salem, NC

Background: *BCR::ABL1*-negative myeloproliferative neoplasms (MPNs), including essential thrombocythemia (ET), polycythemia vera (PV) and myelofibrosis (MF). No new treatments have been approved for ET in the US since anagrelide in 1997. Ropeginterferon alfa-2b (ropeg) is an anti-clonal interferon-based therapy approved by the FDA and globally for PV, providing the rationale for evaluation in ET and other MPNs. **Methods:** SURPASS ET is an open-label, multicenter, Phase III trial comparing ropeg with anagrelide over 12 months in patients with ET who were hydroxyurea-resistant or-intolerant. A total of 174 patients were randomized in a 1:1 ratio to receive ropeg or anagrelide. Ropeg was administered at 250 mcg at Week 0 titrating to 350 mcg at Week 2 and 500 mcg from Week 4 if tolerated. The primary endpoint was the rate of response, as defined by the Modified European LeukemiaNet response criteria, at both Months 9 and 12. Secondary endpoint assessments included *JAK2*V617F allele burden, MPN-associated symptoms, thromboembolic events, spleen size, and safety. **Results:** Baseline patient characteristics were balanced across treatment arms (Table 1). The primary endpoint was achieved in 42.9% of patients in the ropeg arm versus 6.0% in the anagrelide arm (p=0.0001). Ropeg showed response improvements by each parameter: 1) Platelets $\leq 400 \times 10^9$/L and white blood cells $< 9.5 \times 10^9$/L: 56.0% vs. 6.0%. 2) Improvement or stabilization of splenomegaly: 87.9% vs. 54.2%. 3) Symptom improvement or stabilization: 71.4% vs. 33.7%. 4) Absence of hemorrhagic/thrombotic events: 84.6% vs. 51.8%. ET-related major thrombotic and cardiovascular events occurred in 1 (1.1%), and 0 patients in the ropeg arm vs. 7 (8.8%) and 6 (7.5%) patients, respectively, in the anagrelide arm. Mean *JAK2*V617F allelic burden decreased from 33.7% at baseline to 25.3% at 12 months (ropeg arm) vs. 39.7% to 37.3% (anagrelide arm). Ropeg showed lower rate of adverse event (AE)-related discontinuation (5.5% vs.18.8%) and treatment-related serious AEs (2.2% vs. 10.0%). **Conclusions:** Ropeg showed superior efficacy and safety compared to anagrelide as second-line therapy for ET. It represents a potential new therapeutic option for ET. Clinical trial information: NCT04285086. Research Sponsor: PharmaEssentia Corporation.

6501 Oral Abstract Session

Primary endpoint results of the phase 3b ASC4START trial of asciminib (ASC) vs nilotinib (NIL) in newly diagnosed chronic phase chronic myeloid leukemia (CML-CP): Time to treatment discontinuation due to adverse events (TTDAE). First Author: Andreas Hochhaus, Klinik für Innere Medizin II, Universitätsklinikum Jena, Jena, Germany

Background: ASC, the first BCR::ABL1 inhibitor to Specifically Target the ABL Myristoyl Pocket, recently received FDA Accelerated Approval for newly diagnosed CML-CP based on major molecular response (MMR) rates in the ASC4FIRST trial (NCT04971226). We present results from ASC4START (NCT05456191), with the primary objective of assessing the tolerability of ASC vs second-generation tyrosine kinase inhibitor NIL in patients (pts) with newly diagnosed CML-CP. **Methods:** Adults were randomized 1:1 to receive ASC 80 mg once daily or NIL 300 mg twice daily, stratified by ELTS risk category. The primary endpoint is TTDAE. Events included AEs leading to treatment (tx) discontinuation and deaths due to AEs. Secondary endpoints include molecular response and safety. **Results:** Pts were recruited by 120 participating sites across 24 countries and randomized to ASC (n=284) or NIL (n=284). Two pts who did not receive NIL were excluded from safety analyses. Median follow-up was 9.7 mo. At cutoff (Sep 3, 2024), 10.9% and 17.3% of pts discontinued ASC and NIL, respectively, most commonly due AEs (4.9% vs 11.6%) and unsatisfactory therapeutic effect (2.5% vs 2.8%). The study met its primary endpoint, showing statistically significant difference in TTDAE in favor of ASC with a cause-specific hazard ratio of 0.45 (95% CI, 0.25-0.81; *P*=.004). Fewer pts discontinued due to AEs with ASC (16/284 [5.6%]) vs NIL (34/282 [12.1%]). There were 3 deaths on study due to AEs (ASC: cardiac arrest and suicide, n=1 each; NIL: cardiac arrest, n=1). Median duration of exposure was 39.1 wk with ASC vs 38.0 wk with NIL. Mean relative dose intensity was 94.8% vs 92.6%, respectively. Any-grade AEs occurred in 80.3% of pts with ASC vs 86.5% with NIL. Grade $\geq$3 AEs occurred in 25.0% and 31.9% of pts, respectively. AEs leading to dose adjustment/interruption occurred in 24.3% of pts with ASC vs 30.1% with NIL. Most frequent any-grade AEs ($\geq$10%) with ASC vs NIL were thrombocytopenia (15.1% vs 13.8%), headache (10.2% vs 13.1%), myalgia (10.2% vs 8.2%), rash (8.5% vs 16.3%) and increased alanine aminotransferase (3.2% vs 12.4%). AEs of special interest included arterial occlusive events (0.7% vs 2.1%), acute pancreatitis (clinical events; 0.4% vs 2.5%), and hepatotoxicity (including laboratory terms; 8.1% vs 24.8%). *BCR::ABL1*^{IS} $\leq$10% (89.8% vs 82.0%), *BCR::ABL1*^{IS} $\leq$1% (69.0% vs 52.5%), MMR (22.9% vs 10.2%), MR^4 (4.6% vs 1.1%), and MR$^{4.5}$ (2.5% vs 0.4%) rates by wk 12 were higher with ASC vs NIL. **Conclusions:** The study met the primary endpoint with ASC showing significantly superior tolerability vs NIL based on TTDAE. The study is ongoing with additional analyses planned for tolerability and efficacy. The findings further support the potential for ASC to be a preferred therapy for newly diagnosed CML-CP, allowing more pts to meet tx goals without requiring tx switch. Clinical trial information: NCT05456191. Research Sponsor: Novartis Pharma AG.

6502 Oral Abstract Session

Efficacy and safety of pivekimab sunirine (PVEK) in patients (pts) with blastic plasmacytoid dendritic cell neoplasm (BPDCN) in the CADENZA study. First Author: Naveen Pemmaraju, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: BPDCN is a rare, clinically aggressive hematological malignancy primarily involving the skin, bone marrow, and lymph nodes. CD123 (IL-3Rα) is highly overexpressed on the surface of all BPDCN blasts making it an ideal target for novel immunochemotherapy. PVEK is a first-in-class antibody-drug conjugate comprising a high-affinity CD123 antibody, cleavable linker, and an indolinobenzodiazepine pseudodimer payload. Here, we present the primary analysis of efficacy and safety from CADENZA. **Methods:** In the open-label, multicenter, phase 1/2 CADENZA study, adults with BPDCN received PVEK monotherapy intravenously on day 1 of a 21-day cycle, as a <30-min outpatient infusion. Primary endpoint was the rate of composite complete response, defined as complete response (CR) + clinical CR (CR with minimal skin abnormality [CRc]) in frontline (1L) pts. Key secondary endpoints were duration of CR + CRc, median overall survival (OS), overall response rate (ORR), % of pts who were bridged to stem cell transplantation (SCT) after PVEK, and safety and tolerability. **Results:** At primary analysis (data cutoff: October 2, 2024), CADENZA enrolled 84 pts with CD123-positive BPDCN who received PVEK at the recommended phase 2 dose (RP2D) of 0.045 mg/kg every 21 days, including 33 pts with 1L BPDCN (median age, 73.0 [range, 48-84]; $\geq$65 years, 91%; male, 82%) and 51 pts with relapsed/refractory (R/R) BPDCN (median age, 69.0 [range, 19-85]; $\geq$65 years, 59%; male, 82%). Pts with R/R BPDCN had received 1-3 prior systemic therapies; 57% had prior tagraxofusp. Median follow-up was 21.5 mo for 1L pts and 24.1 mo for the R/R group. Among 1L pts, CR + CRc was 70% (95% CI, 51.3-84.4) and median duration of CR + CRc was 9.8 months (mo) (95% CI, 4.6-Not Reached [NR]); ORR was 85%. Median OS was 16.6 mo (95% CI, 11.4-NR). Among 13 (39%) 1L pts bridged to SCT, CR + CRc was 92% (95% CI, 64.0-99.8) and median OS was NR. In the R/R group, CR + CRc was 14% and median duration of CR + CRc was 9.2 mo (95% CI, 2.4-NR); ORR was 35%. Median OS was 5.8 mo (95% CI, 3.9-8.4) and 12% of pts bridged to SCT. Median (IQR) PVEK treatment exposure was 5 (4-9) cycles for the 1L group and 3 (2-5) cycles for the R/R group. Safety was assessed in all 84 pts. The most common treatment-emergent adverse event (TEAE) was peripheral edema (any grade, 54%; grade $\geq$3, 12%). TEAEs led to discontinuation in 9% and 7% of pts with 1L and R/R BPDCN, respectively. No capillary leak syndrome (CLS) events or treatment-related deaths were reported, and 2 (2%) pts experienced veno-occlusive disease of grades 2 and 3 after cycles 4 and 8, respectively, which resolved. **Conclusions:** PVEK treatment demonstrated promising efficacy, with high and durable CR + CRc responses. PVEK was tolerable at the RP2D. The safety profile was manageable, with no CLS events. These results support PVEK as a potential new treatment option for adult pts with BPDCN. Clinical trial information: NCT03386513. Research Sponsor: AbbVie.

6503 Oral Abstract Session

Phase II study of cladribine, low-dose cytarabine, and venetoclax, alternating with azacitidine and venetoclax, in higher-risk chronic myelomonocytic leukemia and myelodysplastic syndromes. First Author: Guillermo Montalban-Bravo, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Responses to hypomethylating agents (HMAs) in patients (pts) with higher-risk myelodysplastic syndromes (HR-MDS) and chronic myelomonocytic leukemia (CMML) are short-lived, with a high risk of transformation to acute myeloid leukemia (AML). Cladribine (CDA) induces monocyte apoptosis and is active in AML when combined with low dose cytarabine (LDAC) and venetoclax (VEN). We aimed to evaluate the safety and activity of CDA, LDAC and VEN in HR-MDS and CMML. **Methods:** We designed a phase II clinical trial (NCT05365035) for pts with newly diagnosed (ND) or relapsed/refractory (R/R) HR-MDS or CMML. Induction consisted of CDA 5 mg/m^2 daily IV on days 1-3, LDAC 20 mg s.c bid days 1-5 and VEN 400 mg daily days 1-5 followed by azacitidine 75 mg/m^2 daily days 1-7 with VEN 400 mg daily days 1-7 or CDA 5 mg/m^2 days 1-3, LDAC 20 mg s.c bid days 1-5 and VEN 400 mg days 1-5 alternating every 2 cycles. The primary end point was to evaluate safety and efficacy of the combination. **Results:** Between 10/2022 and 01/2025, 50 pts have been treated (19 [38%] ND and 31 [62%] R/R). Thirty pts (60%) had MDS, and 20 (40%) had CMML. Thirty-seven (74%) pts had high/very high IPSS-Molecular risk and 5 (10%, 4 R/R, 1 ND) pts had biallelic *TP53* (*biTP53*) loss. The median age was 75 years (range 52-83). Among R/R pts, the median number of prior therapies was 1 (range 1-4) with 6 (19%) having received prior VEN treatment and 2 (4%) having undergone allogeneic stem cell transplant (SCT). The median number of cycles received was 2 (range 1-15). The 4- and 8-week mortality was 2% and 4%, respectively. Overall, the combination was well tolerated with thrombocytopenia (n=17, 35%), febrile neutropenia (n=6, 13%) and neutropenia (n=5, 10%) being the most common grade $\geq$3 adverse events. Among the 48 pts with evaluable responses, the overall response rate (ORR) based on the IWG 2006 response criteria was 43% (complete response [CR] rate of 13% [n=4]) in R/R pts and 72% (CR rate of 39% [n=7]) in ND pts. Based on the IWG 2023 response criteria, the ORR was 40% (n=12, CR: 5 [17%]) and 72% (n=13, CR: 10 [56%]) in R/R and ND pts, respectively. Median number of cycles to best response was 1 (range 1-5). Among responders, 85% and 73% of pts demonstrated neutrophil ($>1 \times 10^9$/L) and platelet ($>100 \times 10^9$/L) recovery after cycle 1 after a median of 27 and 21 days, respectively. Eight (16%) pts required dose reductions due to cytopenias. Fifteen (30%) pts underwent subsequent SCT. After a median follow up of 15.1 months, the median overall survival (OS) was 5.8 months and not reached in R/R and ND pts, respectively. The median leukemia-free survival was 4.1 months and not reached in R/R and ND pts, respectively. Among R/R pts, *biTP53* was associated with shorter OS (3.1 vs 12.3 months, p=0.0344). **Conclusions:** CDA, LDAC and VEN is safe in pts with HR-MDS and CMML, demonstrating promising results in ND pts. Clinical trial information: NCT05365035. Research Sponsor: None.

6504 Oral Abstract Session

An all-oral regimen of decitabine-cedazuridine (DEC-C) plus venetoclax (VEN) in patients (pts) with newly diagnosed acute myeloid leukemia (AML) ineligible for intensive induction chemotherapy: Results from a phase 2 cohort of 101 pts. First Author: Amer Methqal Zeidan, Yale University School of Medicine, New Haven, CT

Background: In pts with AML aged ≥75 years and ineligible for induction chemotherapy, the combination of the Bcl-2 inhibitor VEN plus azacitidine (AZA) was approved based on the Phase 3 VIALE-A trial (complete remission [CR] rate, 36.7%; median CR duration, 17.5 months; median overall survival [OS], 14.7 months). However, monthly seven-day clinic injections of parenteral AZA until progression impose a significant burden on pts. Further, multiple adjusted comparisons have demonstrated similar clinical efficacy between AZA and decitabine. Oral DEC-C (decitabine 35 mg and cedazuridine 100 mg) has equivalent pharmacokinetic (PK) area under the curve exposure to intravenous decitabine. This Phase 1/2 trial was designed to evaluate the all-oral regimen of DEC-C plus VEN in pts with AML aged ≥75 years or with comorbidities precluding first-line intensive induction chemotherapy (NCT04657081). Here, we report results from the pivotal Phase 2 part of the trial. **Methods:** Eligible pts received oral DEC-C on Days 1–5 plus VEN 400 mg daily in 28-day cycles after Cycle 1 VEN ramp up (100 mg Day 1, 200 mg Day 2, 400 mg Day ≥3). Bone marrow examination during Cycle 1 was optional, with VEN and/or DEC-C dose adjustments based on response and count recovery. The primary endpoint was CR rate, based on European LeukemiaNet (ELN) 2017 response criteria. The sample size was calculated based on the lower limit of the 95% confidence interval (CI) of the target CR rate exceeding the clinically meaningful historical rate of 17.9%, with a one-sided α of 0.025, which required ~100 pts to ensure ≥95% power. **Results:** As of September 30, 2024, 101 pts were enrolled and had completed a median of 4 (range, 1–15) cycles. Median age was 78 years. ELN 2017 classification was favorable, intermediate, and adverse in 31.7%, 33.7%, and 29.7% of pts, respectively. Median follow-up was 11.2 months. The CR and CR/CR with incomplete hematologic recovery rates were 46.5% (95% CI, 36.5%–56.7%) and 63.4% (95% CI, 53.2%–72.7%), respectively. Median time to CR was 2.4 months. Median CR duration was not reached; among pts who achieved CR, 80.0% remained so at 6 months and 75.3% at 12 months. Median OS was 15.5 (95% CI, 7.6–not estimable) months. Grade ≥3 treatment-emergent adverse events were reported in 98.0% of pts, most commonly febrile neutropenia (49.5%), anemia (38.6%), and neutropenia (35.6%). The 30- and 60-day mortality rates were 3.0% and 9.9%, respectively. PK data confirmed no drug-drug interactions between oral DEC-C and VEN. **Conclusions:** The all-oral regimen of DEC-C plus VEN resulted in comparable safety, response, and survival rates to parenteral AZA plus VEN in pts with newly diagnosed AML ineligible for intensive induction chemotherapy. These data support the potential use of DEC-C plus VEN as a treatment option for these pts. Clinical trial information: NCT04657081. Research Sponsor: Taiho Oncology, Inc.

6505 Oral Abstract Session

Phase 1b/2 study of lisaftoclax (APG-2575) combined with azacitidine (AZA) in patients (pts) with treatment-naïve (TN) or prior venetoclax (VEN)-exposed myeloid malignancies. First Author: Michael Francis Leahy, Royal Perth Hospital, Perth, Western Australia, Australia

Background: Lisaftoclax (LISA), an investigational, orally active small molecule BCL-2 inhibitor, has shown enhanced treatment responses when combined with AZA in preclinical and clinical studies. We evaluated the safety and efficacy of LISA plus AZA in pts with myeloid malignancies. **Methods:** This open-label, multicenter study enrolled pts with TN or relapsed/refractory (R/R) AML/MPAL or high-risk (HR) MDS/CMML. Prior VEN treatment was permitted. In Part 1, LISA was administered at escalating doses (200, 400, 600, or 800 mg once daily [QD]) and combined with AZA to assess DLTs and determine the MTD. Part 2 evaluated the safety and efficacy of LISA 200, 400, or 600 mg QD over 28 or 14 days of 28-day cycles, combined with AZA at the standard dose (75 mg/m^2 on days 1-7 or 1-5 and 8-9 of each cycle). Safety and efficacy assessments were conducted for all pts receiving at least one dose of LISA. **Results:** As of January 6, 2025, 97 pts were enrolled, with a median treatment duration of 2 (0-16) cycles. Pt distribution included: 49 R/R AML; 20 R/R HR-MDS; 14 TN HR-MDS; 7 TN AML; 4 R/R CMML; 2 R/R MPAL; and 1 TN CMML. The median (range) age was 71 (23-89) years, with 59.8% of pts being male and 73.2% having an ECOG PS ≥ 1. Pts with R/R AML/MPAL D1-28, D1-14, and MDS/CMML had median prior therapies of 2.0 (1.0-8.0), 1.0 (1.0-3.0), and 1.0 (1.0-2.0), respectively, with prior VEN exposure in 46.2% (12/26), 50.0% (5/10), and 14.3% (2/14), respectively. There were no DLTs, and the MTD was not reached. The RP2D for TN HR-MDS was AZA (standard dose) + LISA 600 mg on days 1-14; for TN AML, it was AZA (standard dose) + LISA 600 mg on days 1-28. Common grade 3/4 TEAEs included neutropenia (40%), febrile neutropenia (31%), and thrombocytopenia (22%). Others included sepsis (9%), pneumonia (7%), and lower-respiratory-tract infections (3%). Febrile neutropenia was the most frequently reported SAE (26.8%). Only 3% of pts had neutropenia leading to a dose reduction of LISA, with no 60-day mortality reported. In 14 efficacy-evaluable pts with TN-MDS/CMML, the ORR was 64%, with CR and marrow CR achieved by 29% and 36% of pts, respectively; no PRs were observed. In pts with R/R AML treated with LISA for either 28 (n = 18) or 14 days (n = 8) of repeated 28-day cycles, the ORRs were 39% and 50%, respectively, including CR rates of 28% and 37.5%, respectively. In 20 pts refractory to VEN, the ORR was 17% (3/18) in pts with AML/MPAL and 50% (1/2) in pts with HR-MDS; 11% of pts with AML/MPAL and 50% with MDS had bone marrow blasts < 5%. **Conclusions:** LISA at different dose regimens combined with AZA provides promising treatment options for pts with HR-MDS or AML. No DLTs occurred. The MTD was not reached. The combination was efficacious and well tolerated, with few dose modifications and low infection rates, supporting further clinical development of this regimen in these populations (APG2575AU101; NCT04964518). Clinical trial information: NCT04964518. Research Sponsor: Ascentage Pharma Group Corp Ltd. (Hong Kong).

6506 Oral Abstract Session

Ziftomenib in relapsed/refractory (R/R) *NPM1*-mutant acute myeloid leukemia (AML): Phase 1b/2 clinical activity and safety results from the pivotal KOMET-001 study. First Author: Eunice S. Wang, Roswell Park Comprehensive Cancer Center, Buffalo, NY

Background: *NPM1*-m drives leukemogenesis in ~30% of AML. Despite current risk stratification, nearly half will have R/R disease within a year, after which outcomes are poor with <10% complete response following chemotherapy. Ziftomenib – a potent, highly selective, oral, investigational menin inhibitor – has shown clinical activity as monotherapy and in combination for adults with R/R *NPM1*-m and *KMT2A*-r AML, with 600 mg once-daily (QD) as the recommended phase 2 monotherapy dose for *NPM1*-m. Here we present the primary analysis for *NPM1*-m patients (pts) treated with ziftomenib 600 mg QD in the pivotal KOMET-001 study. **Methods:** KOMET-001 (NCT04067336) is a multicenter, open-label phase 1/2 study of ziftomenib in adults with R/R AML. In phase 2, pts with *NPM1*-m R/R AML received ziftomenib 600 mg QD. Phase 2 primary endpoint: complete remission with full/partial hematologic recovery (CR/CRh); key secondary endpoints: composite complete remission (CRc), durations of CR/CRh and CRc, and safety. The analyses below include *NPM1*-m pts pooled from phase 1b/2. **Results:** The phase 2 primary endpoint was met (p=0.0058). As of 20 Dec 2024, 112 pts were enrolled (51% US/Canada, 49% Europe/UK) in phase 1b/2 and treated with ziftomenib 600 mg QD, with a median follow-up of 4.2 months. Median age was 69 yrs (range 22–86), 56% female, 83% ECOG PS 0–1, median of 2 prior therapies (range 1–7), including 60% prior venetoclax (VEN) and 23% prior transplant. CR/CRh rate in all phase 1b/2 pts was 25% (28/112; 95% CI 17–34) and overall response rate was 35% (39/112; 95% CI 26–44). In phase 2 pts, 23% (21/92; 95% CI 15–33) achieved CR/CRh (Table), with 67% (10/15) MRD negativity among CR/CRh responders tested (local). Comparable CR/CRh rates were observed in both VEN-naïve and exposed pts (21% vs. 24%). Ziftomenib was well tolerated with 3% (3/112) discontinuing due to treatment-related adverse events (TRAEs). 40% (45/112) of pts had Grade (Gr) ≥3 TRAEs, including 13% differentiation syndrome (all Gr3), ≤5% each anemia, febrile neutropenia and thrombocytopenia, and 2% QTc prolongation (Gr3). Updated clinical activity and safety data will be presented. **Conclusions:** In the pivotal KOMET-001, the phase 2 primary endpoint was met: Ziftomenib achieved deep and durable responses in R/R *NPM1*-m AML, regardless of prior VEN. Ziftomenib was well tolerated with limited myelosuppression and only 3% ziftomenib-related discontinuations. Taken together, these data support the potential use of ziftomenib monotherapy as a new treatment option for R/R *NPM1*-m AML. Clinical trial information: NCT04067336. Research Sponsor: Kura Oncology, Inc.

γ9δ2 T-cell activation (γδTCA) with ICT01 combined with azacitidine-venetoclax (AV) for older/unfit adults with newly diagnosed (ND) AML: Preliminary efficacy and dose selection in phase 1/2 study EVICTION. First Author: Pierre Yves Dumas, CHU, Bordeaux, France

Background: AML impairs immunosurveillance bypassing target recognition and subsequent cytotoxic T cell responses. Immunomodulatory and cytotoxic effects of AV and γδTCA with ICT01 have shown synergistic efficacy in an in-vivo AML model with adoptive γδTC transfer. ICT01 is a first-in-class humanized, Fc-disabled anti-butyrophilin 3A mAb selectively inducing γδTCA for direct anti-leukemic cytotoxicity and IFNγ/TNFα release. γδTC are known to drive anti-leukemic efficacy in the post-transplant setting and intratumor presence of γδTCs is prognostic. γδTCA by ICT01 was dose dependent, safe, and tolerable. Here, ICT01-mediated γδTCA added to AV has been investigated in a dose-optimization Phase 1/2 study. **Methods:** ND-AML pts ≥ 75 years old or unfit to receive intensive chemotherapy were randomized 1:1 to AV plus either 10 mg (ICT01^{LOW}) or 75 mg ICT01 (ICT01^{HIGH}) Q4W. We assessed cytogenetics, NGS, pharmacodynamics (PD) in peripheral blood (PB) and bone marrow (BM), safety, and anti-tumor efficacy. **Results:** Of 45 pts randomized, 33 had conclusive disease assessments as of 20-Jan-2025, median age was 75 yrs (range 51–87), the minority (30%) had favorable risk (ELN 2024) and 55% had abnormalities of uncertain risk, some of which are suggestive of a poor response to AV. Median number of BM blasts at diagnosis was 38% (range 5–98%). No DLT was reported, and all pts had at least one adverse event; 30-day mortality was 3%. Grade 3/4 febrile neutropenia was seen in 19 (42%) and neutropenia in 32 pts (71%). ICT01 reproducibly induced rapid γδTCA in PB and BM, followed by increased serum IFNγ/TNFα reflective of downstream immune-cell effects. γδTC counts rapidly dropped in both PB and BM upon first ICT01 dosing and returned to near baseline values during ICT01^{LOW} dosing but became almost undetectable during continued ICT01^{HIGH} dosing. ICT01^{LOW} exhibited a favorable benefit–risk profile with 90% CR/CRi (71% CR, 19% CRi) and lower rates of neutropenia/febrile neutropenia than both ICT01^{HIGH} and published data, while PD effects seen with ICT01^{HIGH} suggestive of activation-induced γδTC death upon repeated dosing were associated with less efficacy (75% CR/CRi [42% CR, 33% CRi]). Notably, response rates were high (particularly with ICT01^{LOW}) both in pts with adverse (CR 40% / CR/CRi 60% for *TP53/CK*; N=10), intermediate/uncertain (CR 47% / CR/CRi 95% for *MECOMr, NRAS, ASXL1*, *JAK2*, *DNMT3A*, *SF3B1*, *U2AF1*, *SRSF2*, *RUNX1*, *STAG2*; N=19) and favorable (CR 80% / CR/CRi 90% for *NPM1*, *IDH1/2*; N=10) risk mutations per ELN 2024. **Conclusions:** For AV combination, the recommended Phase 2 dose is 10 mg ICT01 Q4W. Both ICT01 regimens were safe and very well tolerated and generated very high CR and CR/CRi rates in older/unfit ND-AML pts. The high response rates seen in adverse risk pts warrant further clinical investigation. Clinical trial information: NCT04243499. Research Sponsor: ImCheck Therapeutics.

6508 Oral Abstract Session

Long-term outcomes of patients surviving beyond 2 years post–allogeneic stem cell transplantation. First Author: Nihar Desai, Princess Margaret Hospital, Toronto, ON, Canada

Background: Advances in hematopoietic stem cell transplantation (HSCT) have been driven by progress in supportive care, conditioning regimens, and graft-versus-host disease (GvHD) prophylaxis. Post-transplant morbidity and mortality are most pronounced in the first two years after HCT. Long-term outcomes have been previously described in a CIBMTR study, which reported a 10-year survival of 85% for those who survived the first two years. Post-transplant cyclophosphamide (PTCy) has revolutionized transplant outcomes. However, its impact on long-term survival remains unclear. **Methods:** We included patients undergoing HSCT from Jan 2015 to Dec 2023 who were alive and without relapse two years after HSCT. We aimed to compare long-term outcomes in patients receiving PTCy-based GvHD prophylaxis to previous conventional GvHD prophylaxis strategies. Overall survival (OS) was calculated using the Kaplan–Meier method. The incidence of non-relapse mortality (NRM) and relapse were estimated using Fine & Gray's competing risk analysis. **Results:** Of the 1,401 patients, we included 571 patients alive and relapse-free two years after HCT (Table 1). The median follow-up post-HSCT was 4.8 years (3-5.9). The 5-year OS was 91% (95% CI: 88 – 94). The causes of death were: disease recurrence (17, 3%), infection (8, 1.4%), GvHD (4, 0.7%), second primary malignancies (3, 0.5%), and cardiac complications (3, 0.5%). The use of PTCy was associated with improved OS, 91.7% (95% CI: 88 – 95) vs. 88.7% (95% CI: 81 – 93), p=0.05. NRM at 5 years was 4.9% (95% CI: 3 – 7) and was significantly lower in patients receiving PTCy (2.9 % vs. 10.4%, p<0.001). Relapse risk at 5 years was 9.2% (7 – 13) and was not significantly different between the groups, 10.6% in recipients of PTCy vs. 5.6%, p=0.06. On MVA accounting for confounding variables, PTCy was independently associated with improved OS [HR: 0.46 (0.2 – 0.8), p=0.01], and NRM [HR: 0.23 (0.1 – 0.5), p<0.001]. Age >60 years at HSCT was associated with increased mortality [HR: 2.8 (1.5 – 5.3), p=0.001]. The development of chronic GvHD was protective against relapse [HR: 0.5 (0.3 – 0.9), p=0.04] (Table 1). **Conclusions:** The long-term outcomes for patients alive and relapse-free 2 years after HSCT are excellent. Relapse remained the most common cause of death even after 2 years. PTCy-based GvHD prophylaxis was associated with improved NRM and OS without an impact on disease relapse. Research Sponsor: None.

6509 Rapid Oral Abstract Session

A phase I study of asciminib in combination with dasatinib, prednisone, and blinatumomab for Ph-positive acute leukemia in adults. First Author: Marlise R. Luskin, Dana-Farber Cancer Institute, Boston, MA

Background: Treatment of Ph+ acute lymphoblastic leukemia (ALL) requires potent BCR:ABL1 inhibition. Acquired resistance to the ATP-competitive ABL1 inhibitor dasatinib (DAS) justifies combination with the allosteric inhibitor asciminib (ASC) to deepen responses and prevent mutational resistance. Our phase 1 study (NCT03595917) confirmed the safety and preliminary efficacy of DAS 140 mg/day(d) and ASC 80 mg/d (Luskin *Blood* 2024). Blinatumomab (blin), a bispecific CD19-CD3 T-cell engager, is effective consolidation for Ph+ ALL. Here we report a 15-patient (pt) expansion cohort testing the safety of DAS, ASC and blin. **Methods:** Pts ≥18 years (yrs) with Ph+ ALL or chronic myeloid leukemia (CML) blast crisis, no prior DAS or ASC treatment or ABL1 T315I were eligible. Induction: DAS 140 mg/day (d), ASC 80 mg/d and prednisone 60 mg/m^2/d (max 120) 1-24 (tapered d 25-32). Consolidation: DAS 140 mg/d, ASC 80 mg/d, and blin (28 mcg/d d1-28 of a 42-d cycle) for 5 cycles. DAS and ASC are administered indefinitely. Dose-limiting toxicity (DLT) was CTCAEv5 non-heme toxicity grade (gr) 3+ during the first DAS, ASC, and blin combination cycle. **Results:** The 15-pt (9 male, 6 female) cohort accrued 08/2023-09/2024 (data cut 11/15/24). Median age was 62 yrs (range 25 – 83; 87% [13] ≥60). All pts were newly diagnosed: median WBC 11.1x10^3/μL (20% [3] ≥50), transcript type p190 (11, 73%) vs p210 (4, 27%), *IKZF1*^{plus} in 36% (5/14). Most (87%, 13/15) were trackable by clonoSEQ. Median time to blin was 33 days (range 28 – 77). There were no DLTs during the 6-pt safety run-in so 9 additional pts enrolled with all completing at least 1 cycle of ASC, DAS, plus blin. DAS dose reductions were common (n=7) for pleural effusion (n=3), transaminitis (n=1), and other (n=3). ASC dose reduction to 40 mg/d was required in 1 pt (asymptomatic gr3 lipase increase). One pt (age 81) discontinued protocol after 1 blin cycle due to general health decline. Five pts were transplanted per physician discretion after 2 (n=2), 3 (n=2), or 4 (n=1) blin cycles (suspected CML n=2; high-risk genetics n=2; persistent *BCR::ABL1* n=1). All others (n=9) have completed 4 or 5 blin cycles, or blin is ongoing. Responses deepened after the first cycle of blin (Table). No pt has progressed (median follow-up 238 days, 95% CI 112-420). **Conclusions:** Dual ABL1 inhibition with ASC and DAS can be safely combined with blin in Ph+ acute leukemia. An additional 25-pt cohort is planned with blin in combination with DAS and ASC at optimized doses. Clinical trial information: NCT03595917. Research Sponsor: Novartis.

6510 Rapid Oral Abstract Session

MRD negativity after end of induction in the phase 3 PhALLCON trial: A post hoc analysis. First Author: Ibrahim Aldoss, City of Hope – Duarte, Duarte, CA

Background: The phase 3 PhALLCON trial (NCT03589326) in adults with newly diagnosed Ph+ ALL met its primary endpoint, showing a significantly higher rate of minimal residual disease negativity (MRDneg; *BCR::ABL1*^{IS} ≤0.01%) with complete remission (CR) at end of induction (EOI) with ponatinib (PON) vs imatinib (IMA; 34.4% vs 16.7%; *P*=0.002) and safety comparable to IMA. We report post hoc analyses of patients (pts) who did not reach MRDneg by EOI. **Methods:** Pts were randomized 2:1 to PON (30 mg QD reduced to 15 mg upon MRDneg CR at EOI) or IMA (600 mg QD) plus 20 cycles (C) of reduced-intensity chemotherapy (induction C1–3; consolidation C4–9; maintenance combination C10–20) then PON/IMA monotherapy until disease progression or unacceptable toxicity. Cumulative molecular response rates, event-free survival (EFS; defined as any-cause death, no CR by EOI, or relapse from CR), and safety were evaluated in pts with *BCR::ABL1* p190/p210 confirmed by central lab at baseline who did not reach MRDneg by EOI and those achieving MRDneg post-cycle 4 day 1 (C4D1). Data cutoff: Aug 12, 2022. **Results:** Of 232 pts (PON/IMA: n=154/78) with p190/p210, 140 (86 [56%]/54 [69%]) did not have MRDneg by EOI (median age: 54 y; ≥60 y: 37%; female: 55%; ECOG 0/1: 44%/49%; p190/p210: 66%/34%). Of these, 113 pts (PON/IMA: 73/40) continued treatment after EOI, 48 of whom (35 [48%]/13 [33%]) reached MRDneg (MR4 or better) post-C4D1 (Table). Of those 48 pts (median age: 54 y; ≥60 y: 33%; female: 60%; ECOG 0/1: 46%/54%; p190/p210: 71%/29%), median duration of MRDneg (95% CI) was not reached (NR; 13.0 mo–NR) with PON and 3.8 mo (2.3–NR) with IMA; 16 pts (PON/IMA: 10/6) had HSCT. In the 140 pts without MRDneg by EOI, median EFS (mEFS; 95% CI) was NR (NR–NR) with PON and 24.8 mo (21.3–NR) with IMA; 2-y EFS (95% CI) was 82% (69–90) and 62% (41–77), respectively. In the 48 pts with MRDneg post-C4D1, mEFS was NR (NR–NR) and NR (21.3 mo–NR); 2-y EFS was 88% (68–96) and 80% (20–97), respectively. In the 140 pts without MRDneg by EOI, treatment-emergent adverse event (TEAE) rates with PON/IMA were 100%/98% (gr ≥3: 91%/94%); dose modification due to TEAEs: 71%/54% (discontinuation: 15%/9%; reduction: 16%/28%; interruption: 66%/41%). In the 48 pts with MRDneg post-C4D1, TEAE rates with PON/IMA were 100%/100% (gr ≥3: 91%/100%); dose modification due to TEAEs: 69%/62% (discontinuation: 6%/0%; reduction: 11%/46%; interruption: 69%/38%). **Conclusions:** Among pts without MRDneg by EOI, more pts who continued the study achieved deep and durable molecular response after C4D1, and 2-y EFS appeared to be better with PON than IMA. These data support the clinical benefit and tolerability of continuing PON in pts without MRDneg by EOI. Clinical trial information: NCT03589326. Research Sponsor: Takeda Development Center Americas, Inc.

6511 Rapid Oral Abstract Session

Reduced dose PTCy in patients with acute myeloid leukemia receiving matched unrelated donor allogeneic hematopoietic stem cell transplantation. First Author: Nihar Desai, Princess Margaret Hospital, Toronto, ON, Canada

Background: Post-transplant cyclophosphamide (PTCy) at 50 mg/kg on D+3 & +4 after allogeneic hematopoietic cell transplantation (HCT) is established for graft-versus-host disease (GvHD) prophylaxis. PTCy causes significant toxicities, including bloodstream infections (BSI), delayed engraftment, viral reactivations, hemorrhagic cystitis (HC), cardiotoxicity, and fluid overload (FO), contributing to increased non-relapse mortality (NRM). **Methods:** In July 2024, we initiated a pilot to evaluate reduced (35 mg/kg on D+3 & +4) PTCy dosing (PTCy70). We included patients with AML receiving 10/10 matched unrelated donor peripheral blood grafts. All patients received fludarabine and busulfan conditioning. GvHD prophylaxis included anti-thymocyte globulin (ATG 2 mg/kg), a calcineurin inhibitor, & PTCy70. Outcomes were compared with a contemporary cohort receiving PTCy 100. **Results:** From July-Dec 2024, 30 patients received PTCy70. Baseline characteristics were comparable except for conditioning intensity (Table 1). Median follow up was 497 days (316 – 733) & 80 days (56 – 119) for PTCy100 & PTCy70, respectively. No graft failure occurred in PTCy70 group vs one in PTCy100 group. Median time to neutrophil engraftment was comparable, 20 days (19–21). Median time to platelet engraftment was shorter in the PTCy70 group (14 vs. 16 days, p=0.01). At D+30, the incidence of platelet engraftment was significantly higher in the PTCy70 group (87% vs. 81%, p=0.01).D+30 incidence of BSI was much lower in the PTCy70 group (30% vs. 59%, p=0.005). Most BSIs in both groups were caused by gram-positive organisms (71% vs. 77%, p=0.7). CMV at D+100 was 7.2% (95% CI: 1.2 – 21) in PTCy70 and 18.7% (95% CI: 12 – 27) in the PTCy100 group (p=0.14). None of the patients receiving PTCy70 developed HC vs. 11 in the PTCy100 group. FO occurred in 16 (53%) patients (grade 1: 12; grade 2: 4) receiving PTCy70, with none developing >grade 2 FO. There was no difference in the median duration of admission (31 days, p=0.9).Six patients receiving PTCy70 developed grade II-IV aGvHD. Four had grade II skin GvHD & responded to topical steroids. At D+100, there was no significant difference in grade II-IV (18.7% vs. 29%, p=0.29), grade III-IV acute GvHD (4.8% vs. 3.3%, p=0.80), and NRM (5.3% vs 1.8%, p=0.62). **Conclusions:** PTCy70 is associated with faster platelet engraftment & lower BSI, with no increase in aGVHD. PTCy70 also seems to reduce HC and viral reactivation. Extended follow-up is necessary to examine longer term outcomes. Research Sponsor: None.

6512 Rapid Oral Abstract Session

Overall survival (OS) and duration of response for transfusion independence (TI) in erythropoiesis stimulating agent (ESA)–naive patients (pts) with very low-, low-, or intermediate-risk myelodysplastic syndromes (MDS) treated with luspatercept (LUSPA) vs epoetin alfa (EA) in the COMMANDS trial. First Author: Guillermo Garcia-Manero, University of Texas MD Anderson Cancer Center, Houston, TX

Background: In the phase 3 COMMANDS trial (NCT03682536), LUSPA was superior in improving red blood cell (RBC)-TI ≥12 wks with concurrent hemoglobin increase ≥1.5 g/dL in Wks 1 to 24 vs EA and had durable clinical benefit in pts with ESA-naive transfusion-dependent (TD) lower-risk MDS (LR-MDS; Della Porta MG, et al. *Lancet Haematol*. 2024; Garcia-Manero G, et al. *ASH*. 2024). Here, we report updated results including OS and duration of response. **Methods:** Eligible pts (≥18 yrs; ESA-naive; RBC TD; very low/low/intermediate-risk MDS) were randomized 1:1 (stratified by baseline [BL] RBC transfusion burden [TB], serum erythropoietin [EPO] level, and ring sideroblast [RS] status) to receive LUSPA (1.0-1.75 mg/kg) SC Q3W or EA (450-1050 IU/kg; max dose 80,000 IU) SC QW for ≥24 wks. Secondary endpoints included OS, duration of RBC-TI ≥12 wks, and safety. **Results:** As of Nov 4, 2024, median follow up (FU) was 29.0 and 27.1 mos for the LUSPA (n=182) and EA (n=181) groups, respectively. Median OS for LUSPA was not reached (NR) and was 46.7 mos for EA (HR, 0.86; 95% CI, 0.60-1.24); 3-yr OS rates were 63.8% and 62.2%, respectively, and 5-yr OS rates were 54.0% and 41.8%. In subgroups, similar OS trends were observed (Table). Overall, RBC-TI ≥12 wks (Wk 1 to end of treatment [EOT]) was reached by 76.4% (139/182) of pts in the LUSPA group and 55.8% (101/181) in the EA group. Median cumulative duration (95% CI) of RBC-TI ≥12 wks (sum of all durations of RBC-TI ≥12 wks episodes from Wk 1 to EOT) was 187.3 (119.6-NE) wks for LUSPA vs 94.9 (73.1-179.0) wks for EA (HR, 0.51; 95% CI, 0.34-0.77). Median duration (95% CI) of longest RBC-TI ≥12 wks period (from Wk 1 to EOT) was 126.6 (81.0-184.4) vs 86.7 (55.9-111.1) wks (HR, 0.64; 95% CI, 0.44-0.93). At cutoff, 24.7% of LUSPA pts and 11.2% of EA pts were on treatment; 84.6% and 82.7%, respectively, had ≥1 dose escalation. With longer FU, no new safety concerns emerged. Deaths occurred in both groups on- (10.4% vs 9.5%) and post-treatment (20.9% vs 26.3%). Progression to acute myeloid leukemia was comparable between groups (3.8% vs 4.4%). **Conclusions:** LUSPA led to improvements in response rate and duration, with a positive OS trend requiring further evaluation through more extended follow up. LUSPA signifies a new standard of care for anemia in first-line LR-MDS. Clinical trial information: NCT03682536. Research Sponsor: Bristol Myers Squibb.

6513 Rapid Oral Abstract Session

Efficacy of macrophage checkpoint Clever-1 inhibition with bexmarilimab plus azacitidine in myelodysplastic syndrome: Results from the ph1/2 BEXMAB study. First Author: Naval Guastad Daver, Department of Leukemia, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Treatment of higher-risk (HR) myelodysplastic syndrome (MDS) represents an unmet medical need. Hypomethylating (HMA) agents, including azacitidine, are used in the frontline setting for HR MDS patients with complete remission rate reported as 16% (Hasegawa et al., 2023) After HMA-failure, including primary refractory disease or relapse after frontline treatment (r/r MDS), the reported median overall survival (mOS) is <6 months (Prébet et al., 2011). Bexmarilimab, a first-in-class macrophage checkpoint inhibitor, blocks Common lymphatic and vascular endothelial receptor-1 (Clever-1) to enhance macrophage antigen presentation and T cell activation. In the MDS bone marrow (BM), Clever-1 is also abundant on malignant blasts. Translational data suggest that by inhibiting blast Clever-1, bexmarilimab hampers the energy production of the malignant cells. Thus, bexmarilimab may alter the BM immune microenvironment and make the blasts susceptible to other cytotoxic agents, such as HMAs, thereby enhancing their effectiveness in patients with HR MDS, both in frontline and r/r setting. **Methods:** The Phase 1/2 (Ph1/2) BEXMAB study investigates safety, tolerability and preliminary efficacy of bexmarilimab in combination with standard-of-care, azacitidine, in HR MDS. Key inclusion criteria include indication for azacitidine treatment with a risk score of >3 based on the revised International Prognostic Scoring System (IPSS-R) and for r/r MDS, failure to achieve response to or disease progression during treatment with HMA or HMA containing regimen. In Ph1, Bayesian optimal interval (BOIN) design was used for dose escalation to identify recommended dose for expansion (RDE). Ph1 studied 1, 3 and 6mg/kg bexmarilimab, administrated weekly in 28-day cycles, in combination with a standard regimen of azacitidine (75 mg/m^2 D1-7 each cycle). r/r MDS was selected as the first population for Ph2 dose optimization and expansion following a Simon's 2-stage design, with subjects randomized to RDE (6mg/kg) and RDE-1 (3mg/kg). After dose escalation, Ph1 expansion cohorts were used to enrich frontline MDS population at RDE and RDE-1. **Results:** Safety and efficacy data from 20 frontline HR MDS and 35 r/r MDS patients, comparing bexmarilimab dose levels, will be reported. Previous analysis per IWG2006 criteria indicated an overall response rate (ORR) of 100% in 5 frontline MDS patients and 80% in 20 r/r MDS patients (65% per IWG2023). Simultaneously, a median overall survival estimate of 13.4 months, was reported for the r/r MDS population. During dose escalation, no dose limiting toxicities (DLT) were reported during the 28-day DLT period. Ongoing safety follow-up indicates a total of 277 treatment-emergent adverse events, of which 38 (13.7%) are considered bexmarilimab-related. **Conclusions:** Enrolment for both dose finding and randomized dose optimization parts (n=55) of the BEXMAB Phase 1/2 study has been completed. Safety and efficacy results for both populations will be reported for the first time. Clinical trial information: NCT05428969. Research Sponsor: Faron Pharmaceuticals.

6514 Rapid Oral Abstract Session

Dosing decitabine and venetoclax for terminal differentiation to improve outcomes in TP53 mutant MDS and AML. First Author: Bradley Rockwell, Montefiore Einstein Comprehensive Cancer Center, Bronx, NY

Background: Mutations in the tumor suppressor TP53 gene are common in elderly patients with myelodysplastic syndrome (MDS) and acute myeloid leukemia (AML) and confer resistance to conventional chemotherapeutic DNA damaging agents. Venetoclax (Ven) added to the hypomethylating agents (HMA) of Decitabine or Azacitidine is the current standard of care for elderly patients with AML and is frequently used in high-risk MDS (HR-MDS). Currently approved dosing schedules of HMA/Ven rely on cytotoxicity and have not improved outcomes in the TP53 mutant population. The efficacy and tolerability of metronomic weekly dosing of Decitabine and Ven in HR-MDS and AML were previously described (Goldfinger et al, Blood 2024). Mechanistically, metronomic dosing relies on terminal differentiation, rather than cytotoxicity making it an attractive regimen for TP53 mutant MDS/AML. **Methods:** Patients with histologically confirmed AML or MDS and a TP53 mutation received a once-weekly dose of decitabine 0.2 mg/kg subcutaneously and one dose of Ven 400 mg on days 1, 8, 15 and 22 of a 28-day cycle. **Results:** Between April 2020 and January 2025, 40 patients with TP53 mutated myeloid malignancies were treated with metronomic weekly low-dose Decitabine/Ven (14 AML, 26 MDS). Twenty-four patients were followed prospectively as part of a clinical trial (NCT05184842), and 16 were treated off-trial and had data collected retrospectively. Median age at diagnosis was 76.5 years, 13 (32%) were from minority backgrounds, 28 (70%) had complex cytogenetics and 31 (82%) had biallelic TP53 mutations (median VAF 36%). All AML patients were ELN-poor risk, 21 MDS patients (82%) were R-IPSS high or very high risk. The median time on therapy was 5.8 months, with 10 (25%) patients still on therapy at time of data cut-off. Four patients in the AML and five in the MDS cohorts were not evaluable (2 withdrew consent, 1 lost to follow-up and 6 did not have a BM biopsy for evaluation). Of the evaluable AML patients, 7 (70%) achieved a complete remission (CR), 3 (30%) did not respond. In the evaluable MDS patients, 9 (43%) achieved a CR and 3 (15%) a marrow CR, 4 (19%) with stable disease, 5 (24%) with no response. Of the 26 patients who were transfusion-dependent at the start of therapy, 15 (58%) became transfusion-independent. For the entire cohort (n=40), the median overall survival (OS) was 11.3 months. For the AML and MDS cohorts, the OS was 11.6 and 9.9 months, respectively. In patients who underwent allogeneic stem cell transplant (n=6), OS was 16 months. Non-heme therapy-related adverse events of ≥ grade 3 was seen in 13 (54%) of patients. **Conclusions:** In this cohort, of elderly patients with poor risk TP53 mutated MDS and AML the use of a non-cytotoxic dosing schedule of Decitabine and Ven resulted in over half the patients achieving a CR and transfusion independence. The median OS of 11.3 months compares favorably to currently approved cytotoxic dosing of HMA/Ven. Clinical trial information: NCT05184842. Research Sponsor: None.

6515 Rapid Oral Abstract Session

IMproveMF update: Phase 1/1B trial of imetelstat (IME)+ruxolitinib (RUX) in patients (pts) with intermediate (INT)-1, INT-2, or high-risk (HR) myelofibrosis (MF). First Author: John Mascarenhas, Tisch Cancer Institute, Icahn School of Medicine at Mount Sinai, New York, NY

Background: IME, a first-in-class, direct, and competitive inhibitor of telomerase activity, showed potential survival improvements and disease-modifying activity in the phase 2 IMbark MF trial (NCT02426086). Preclinical evidence demonstrated IME+RUX reduced disease burden better than either agent alone. IMproveMF (NCT05371964) aims to evaluate IME+RUX in pts with INT-1/INT-2/HR MF. **Methods:** IMproveMF is an open-label, single-arm, phase 1/1b trial (part 1: dose escalation; part 2: dose confirmation and expansion) of IME+RUX in adults with DIPSS INT-1, INT-2, or HR MF. In part 1 (up to 21 pts), RUX was required for ≥12 wk with a stable dose for ≥4 wk immediately before adding IME; pts received IME via intravenous infusion at each dose level cohort (4.7, 6.0, 7.5, and 9.4 mg/kg IME sodium; equivalent to 4.4, 5.6, 7.1, and 8.9 mg/kg active dose, respectively) every 28 d based on Bayesian Optimal Interval design to identify the recommended part 2 dose (RP2D). Pts in part 1 were dose adjusted to the RP2D as needed in part 2, with 2 dose reductions allowed. Part 2 of the trial will enroll pts who are RUX naive. Primary endpoints are adverse events (AE), including dose-limiting toxicity (DLT), in part 1 and AEs and 24-wk response rate (≥50% reduction in MF total symptom score [TSS]) in part 2. Secondary endpoints include pharmacokinetics (PK) and clinical activity. Total planned enrollment is ≈41 pts. **Results:** As of 11/04/2024, 17 pts were enrolled in part 1 with a median age of 67 y (71% aged ≥65 y); 7 had INT-1, 9 INT-2, and 1 HR MF. Respective to the dose levels in the Methods, 3, 3, 4, and 7 pts received the corresponding IME dose level. No DLTs were reported for IME; 2 pts had dose reductions due to neutropenia. Five pts discontinued IME (none due to AEs). Four pts had RUX dose reductions (due to AEs and other, n=2 each). AEs were experienced by 15 pts; 8 experienced grade 3 events of anemia (n=4), neutropenia (n=3), leukopenia (n=2), abdominal pain, fatigue, epistaxis, and pneumonia (n=1 each; the latter 2 and 1 anemia event were considered serious AEs). There were no grade 4/5 AEs. There was an overall reduction in TSS from baseline (median, −5 points in maximum absolute reduction up to wk 24) with IME regardless of dosing, and a trend of dose-dependent spleen volume decrease. A reduction in variant allele frequency of several driver mutations was also observed. Hematologic, PK, and additional mutational data will be included in the presentation, as available. **Conclusions:** In part 1 of IMproveMF, no DLTs were observed and the RP2D dose of 9.4 mg/kg IME was determined. AEs were consistent with those observed in other IME clinical trials, and preliminary efficacy was positive, demonstrating the potential of IME+RUX in this pt population with high unmet needs. Part 2 of this trial is ongoing across the US at 6 sites. Clinical trial information: NCT05371964. Research Sponsor: This study was funded by the Geron Corporation. All authors contributed to and approved the abstract; writing and editorial support were provided by Jeremy J. Henriques, PhD, CMPP, of The Lockwood Group (Stamford, CT, USA), funded by the Geron Corporation.

6516 **Rapid Oral Abstract Session**

Efficacy and safety of asciminib (ASC) in patients (pts) with chronic-phase chronic myeloid leukemia (CML-CP) after 1 tyrosine kinase inhibitor (TKI): Interim analysis (IA) of the phase 2 ASC2ESCALATE trial. First Author: David Jacob Andorsky, Rocky Mountain Cancer Centers, US Oncology Research, Boulder, CO

Background: ASC2ESCALATE (NCT05384587) is the first prospective trial of ASC in CML-CP after 1 TKI (2L) with dose escalation for pts with suboptimal response; ASC is also being assessed in a separate newly diagnosed (1L) cohort. A previous IA of the 2L cohort reported ASC's safety (n=71) and wk 24 efficacy (n=28; *BCR::ABL1*^{IS} ≤1%, 85.7%; major molecular response [MMR], 42.9%). We report updated safety (n=101) and wk 24 efficacy (n=63) results. **Methods:** ASC2ESCALATE is a phase 2, single-arm, open-label US study of ASC in adults with 1L or 2L CML-CP without the T315I mutation. In the 2L cohort, eligible pts had discontinued their prior TKI due to warning or failure per ELN2020 or intolerance with *BCR::ABL1*^{IS} >0.1% at screening. Pts received ASC 80 mg once daily (QD). If *BCR::ABL1*^{IS} >1% at wk 24, dose was increased to 200 mg QD. If *BCR::ABL1*^{IS} >0.1% at wk 48, dose was increased from 80 to 200 mg QD or from 200 mg QD to 200 mg twice daily, or pts could be taken off study. If pts had any grade 3/4 or persistent grade 2 toxicity refractory to optimal management, they were ineligible for dose escalation at wk 24 and/or 48 and continued the same dose. **Results:** This IA included all 101 pts enrolled with 2L CML-CP; all pts had received ≥1 ASC dose by the cutoff (Nov 15, 2024). Prior treatment (Tx) included dasatinib (44.6%), imatinib (42.6%), nilotinib (9.9%), or bosutinib (5.0%); 66.3% of pts had received prior Tx for ≥12 mo. Pts discontinued prior Tx due to lack of efficacy (56.4%) or intolerance (43.6%). By the cutoff, 92 pts (91.1%) remained on ASC; 9 pts (8.9%) discontinued ASC, mostly due to adverse events (AEs; n=4) and pt decision (n=3). Median duration of ASC exposure was 26.1 (range, 6-100) wk. Pts evaluable for all efficacy analyses completed assessments for the respective timepoint or discontinued earlier (wk 4, n=94; wk 12, n=86; wk 24, n= 63). At wk 4, 12, and 24, 46.8%, 84.9%, and 82.5% pts, respectively, had *BCR::ABL1*^{IS} ≤1%. Deeper responses were also achieved at wk 12 (MMR, 39.5%; MR^4, 11.6%; MR$^{4.5}$, 2.3%) and 24 (MMR, 44.4%; MR^4, 25.4%; MR$^{4.5}$, 9.5%). Seven pts had dose escalation from 80 to 200 mg QD per their response level at wk 24 (n=3) and 48 (n=4). All-grade AEs ≥20% were headache (22.8%) and nausea (20.8%). Grade ≥3 AEs ≥5% were hypertension (8.9 %), thrombocytopenia (6.9%), and neutropenia (5.9%). AEs led to dose adjustment/interruption in 27 pts (26.7%). AEs led to discontinuation in 4 pts; 1 of these AEs occurred >30 d after last ASC dose. No arterial-occlusive events or on-Tx deaths occurred. **Conclusions:** 2L ASC demonstrated high molecular response rates at wk 24 and safety consistent with previously established ASC data across Tx lines; no new or worsening safety signals arose. ASC was tolerable with few AEs leading to discontinuation. These IA results support ASC as a Tx option in 2L CML-CP. The impact of dose escalation continues to be explored. Clinical trial information: NCT05384587. Research Sponsor: Novartis Pharmaceuticals Corporation.

Age-related macular degeneration in individuals with clonal hematopoiesis. First Author: Keishla Marie Arce-Ruiz, McGraw/Patterson Center for Population Sciences, Dana-Farber Cancer Institute, Boston, MA

Background: Clonal hematopoiesis (CH), an age-related condition involving somatic mutations in blood stem cells, increases the risk of myelodysplastic syndrome (MDS), blood cancers and cardiovascular disease through inflammatory pathways. Age-related macular degeneration (AMD), the leading cause of blindness in the developed world, is also characterized by chronic inflammation. An increased prevalence of AMD has been observed in older adults with MDS, but the association between CH and AMD remains unexplored. Understanding this relationship could reveal shared inflammatory mechanisms in age-related diseases and guide prevention strategies. **Methods:** This retrospective cohort study used exome sequencing and electronic medical records (EMRs) from 467,200 adults ≥40 years of age in the UK Biobank (UKB), recruited between 2006–2010 and followed until 2020. Participants with prevalent blood cancer, AMD, or with missing AMD diagnosis dates were excluded. CH was defined as pathogenic somatic mutations with a variant allele fraction (VAF) ≥0.02. Incident AMD was identified using ICD-10 codes (H35.3). Kaplan-Meier estimates and log-rank tests assessed cumulative incidence, while Cox regression models calculated hazard ratios (HRs), adjusted for age, sex, smoking and hypertension. A separate cohort of 4,079 patients from Dana-Farber Cancer Institute (DFCI) validated findings and enabled granular clinical data abstraction from EMRs. **Results:** CH was detected in 29,550 (6.8%) individuals of the UKB. The 12-year cumulative incidence (C.I.) of AMD was higher in individuals with CH (n=671, C.I. 2.45%) compared to those without (n=6,728, 1.61%; p<2x10-16). In unadjusted Cox models, individuals with CH had a 51% higher risk of AMD compared to those without (HR =1.51 (95% CI: 1.39–1.63; $p < 2\times10^{-16}$), remaining significant after adjusting for covariates (p=0.023). CH genotypes most associated with AMD risk included *ASXL1* (HR: 1.32; p = 0.0146) and splicing factors (HR: 1.54; p = 0.0345). Individuals with CH and AMD had a 33% higher risk of progressing to blindness compared to those without CH, though this was not statistically significant (p = 0.242). In the DFCI cohort (n= 4,079), CH was present in 1,028 (25.2%) individuals. 86 (8.37%) individuals with CH had AMD diagnoses compared to those without CH (n= 86, 3.21%; $p = 2.53\times10^{-10}$), with exudative AMD, a more severe subtype, being more prevalent in CH patients (n=11; $p = 1.1\times10^{-5}$). **Conclusions:** There is a significant association between CH and AMD, suggesting that AMD prevalent in individuals with MDS is related to presence of CH in the pre-MDS state. Real world data support these findings, highlighting a trend towards severe AMD subtypes in individuals with CH. The identification of specific genes linked to AMD incidence suggests that certain CH genotypes may confer a higher risk for AMD, highlighting the role of AMD screening in individuals with myeloid malignancy precursor conditions. Outcomes in patients (pts) younger than 50 years old (yo) with treatment-naïve blastic plasmacytoid dendritic cell neoplasm (BPDCN) treated with tagraxofusp (TAG): Subanalysis of a phase 1/2 trial. First Author: Anthony Selwyn Stein, City of Hope, Duarte, CA

Background: BPDCN is an aggressive, orphan hematologic malignancy characterized by cells expressing CD123 and other markers. In BPDCN pts <50 yo, including in the adolescent and young adult (AYA) population (ie, pts 15-39 yo), data are limited. TAG, a first-in-class CD123-targeted therapy, is the only drug approved for adults (US/EU) and pediatric pts aged ≥2 yo (US only) with BPDCN. TAG has a well-characterized and manageable safety profile, with transient adverse events (AEs) occurring mostly in cycle 1, no cumulative long-term toxicity, and no myelosuppression. While not approved, multi-agent chemotherapy is used in AYAs, resulting in short- and long-term toxicity, including myelosuppression. Here we report the safety and efficacy of 1L TAG treatment, with prespecified/multi-system response criteria, for BPDCN pts <50 yo from a subgroup analysis of the phase 1/2 TAG monotherapy study (NCT02113982). **Methods:** We analyzed outcomes in treatment-naïve pts <50 yo who received 1L TAG 12 μg/kg intravenously on days 1-5 of a 21-day cycle. Assessed outcomes included best response, time to best response, duration of response (DOR), overall survival (OS), treatment-related adverse events (TRAEs), and capillary leak syndrome (CLS). **Results:** Ten pts (median age of 31.5 yo [range 22-45]) were included in this analysis, including 6 AYA pts. All pts had ECOG PS of 0-1, 20% had bone marrow involvement, and 60% had ≥2 sites of BPDCN disease. Pts received a median of 4 cycles (range 2-7) of TAG. In cycle 1, pts received a median of 5 TAG doses (range 3-5) in line with the USPI dosing. At a median follow-up of 34 months, the CR/CRc rate was 70%, with a 41-day median time to CR/CRc. DOR was not reached (range 8.4-51.8 months); median OS was 38.4 months. All pts were bridged to stem cell transplantation (SCT), including 2 autologous SCTs: 7 pts with CR/CRc following TAG treatment (median time from last TAG dose to SCT, 38 days) and 3 pts with PR or SD were bridged to SCT following subsequent multi-agent chemotherapy. Most common Grade 3-4 TRAEs were thrombocytopenia and ALT/AST elevation; the majority of TRAEs resolved with resolution in the same cycle; no grade 5 TRAEs occurred. No pts had a dose reduction or discontinuation due to a TRAE. No investigator-assessed CLS was reported, although some pts required dose interruption due to weight gain or hypoalbuminemia. **Conclusions:** In treatment-naïve BPDCN pts <50 yo, including AYAs, TAG, a chemotherapy-free option, induced high rates of CR/CRc (70%) and allowed all pts who achieved CR/CRc to bridge to SCT. TAG was well tolerated with no cumulative AEs or cumulative myelosuppression. No investigator-assessed CLS was observed in these younger pts. Overall, TAG is an effective front-line therapy, including in pts <50, with durable (median not reached) responses and prolonged survival. Clinical trial information: NCT02113982. Research Sponsor: Menarini Group.

Decoding immune dysregulation in AML: Insights from integrated genomic and transcriptomic analysis. First Author: Harsh Goel, All India Institute of Medical Science (AIIMS), New Delhi, India

Background: Acute Myeloid Leukemia (AML) is an aggressive hematologic malignancy marked by abnormal proliferation of myeloid progenitor cells, often leading to poor outcomes and high relapse rates. While the genetic underpinnings of AML are well-documented, the role of immune dysregulation in its progression remains underexplored. This study integrates whole exome sequencing (WES) and transcriptome analysis to identify genetic mutations, transcriptional alterations, and immune regulatory disruptions, with a focus on their contributions to hematopoiesis and immune dysfunction. **Methods:** WES and RNA sequencing were performed on 10 AML patient samples to investigate somatic mutations, differential gene expression, and immune-related pathways. WES data were analyzed to detect mutations in AML-associated genes, while transcriptomic analysis compared gene expression profiles between AML cells and normal hematopoietic stem cells (HSCs). Bioinformatic tools, including differential expression analysis, Gene Set Enrichment Analysis (GSEA), and pathway mapping, were employed to identify key regulatory networks. Single-cell RNA sequencing (scRNA-seq) was conducted to assess cellular heterogeneity and differentiation dynamics, with a focus on immune cell subsets and pathways involved in immune evasion. **Results:** Analysis revealed recurrent mutations and dysregulation in genes critical to hematopoiesis, apoptosis, and immune regulation, including *RUNX1, FLT3, CEBPA, TP53, WT1, GATA2,* and *TET2*. Transcriptomic profiling highlighted distinct gene expression patterns in AML cells, with significant disruption in cell cycle control, differentiation, and apoptosis. Dysregulated immune pathways, such as IL-7R and PD-1, were identified as key contributors to immune cell activation impairment and immune tolerance. scRNA-seq data provided insights into the cellular heterogeneity of AML, uncovering altered lineage differentiation and immune subset composition, which may facilitate immune evasion and disease progression. **Conclusions:** This integrative analysis illuminates the interplay between genetic mutations, transcriptional dysregulation, and immune dysfunction in AML. The findings underscore the pivotal role of immune pathways, such as IL-7R and PD-1, in AML pathogenesis, presenting them as potential therapeutic targets. By linking genetic and immune alterations, this study advances our understanding of AML biology and highlights the need for therapies addressing both genetic and immune dysfunctions to improve clinical outcomes. V-RULES: Real-world effectiveness and safety of CPX-351 in patients with secondary acute myeloid leukemia (AML). First Author: Thomas William LeBlanc, Department of Medicine, Duke University School of Medicine, Durham, NC

Background: CPX-351 was approved for newly diagnosed (ND) therapy-related AML (t-AML) or AML with myelodysplasia-related changes (AML-MRC) following the pivotal phase 3 trial, which demonstrated improved CR/CRi (47.7% vs 33.3%) and median OS (9.56 vs 5.95 months [mo]), and comparable safety vs conventional 7+3 in adults aged 60-75 years. The Vyxeos Real-world US Long-term Effectiveness and Safety Study (V-RULES) evaluated real-world (RW) clinical outcomes and safety of CPX-351 in US patients with ND t-AML or AML-MRC. **Methods:** V-RULES is a retrospective, multicenter, single-arm study based on medical records of patients with ND t-AML or AML-MRC who were treated with CPX-351 since its FDA approval in August 2017. Primary endpoints were CR/CRi/CRh and OS. **Results:** Overall, 161 patients (t-AML, n=47; AML-MRC, n=114) received $\geq$ 1 induction of CPX-351 (1 cycle, n=142; 2 cycles, n=19) and 50 patients received consolidation (1 cycle, n=40; 2 cycles, n=10). Median age at AML diagnosis was 60 years (range: 21-78); 78 (48%) patients were aged $<$60 years. Of patients with available cytogenetic data, 88/154 (57%) were classified as adverse-risk per Grimwade 2010 and 49/155 (32%) had complex karyotype. Notably, 33/134 patients (25%) had *TP53* mutations (*TP53*m) and 57/91 patients (63%) had myelodysplasia-related gene mutations (MRm). Median follow-up time (IQR) was 9.7 mo (4.1, 27.8). CR (including minimal residual disease negativity)/CRi/CRh at any time was 63% in 149 evaluable patients (t-AML, 85%; AML-MRC, 53%). Median OS was 12.9 mo (95% CI: 8.9, 19.7) and estimated 4-year OS was 29% (95% CI: 21%, 38%). Survival was longer in patients aged $<$60 vs $\geq$ 60 years: median OS was 17.8 (95% CI: 9.6, 45.4) vs 10.6 mo (95% CI: 6.7, 13.8) and estimated 4-year OS was 37% (95% CI: 24%, 49%) vs 22% (95% CI: 12%, 34%). Compared with the overall population, median OS was shorter in patients with *TP53*m (5.3 mo [95% CI: 2.3, 7.4]) and longer in patients with MRm (17.8 mo [95% CI: 11.4, 38]). Patients who underwent hematopoietic cell transplantation (HCT) after CPX-351 treatment (38%) had a median OS post-HCT of 45.6 mo (95% CI: 24.9, not estimated). In patients with CR/CRh/CRi, median time to neutrophil ($\geq$ 500/μL) and platelet ($\geq$ 50,000/μL) recovery in induction 1 was 35 days (n=76) and 36 days (n=72), respectively. Infection (52%) and febrile neutropenia (42%) were the most common grade $\geq$ 3 adverse events (AEs); 2 patients had a serious AE of cardiac events. **Conclusions:** These results highlight the effectiveness and safety of CPX-351 for the treatment of t-AML and AML-MRC in the US RW setting, consistent with the pivotal trial and published RW data. Notably, this study demonstrated favorable outcomes for younger patients ($<$60 years) who were not included in the pivotal trial. Patients who received HCT also had improved outcomes, as did those with MRm. These results support the continued use of CPX-351 as the standard of care for ND t-AML or AML-MRC. Venetoclax as cytoreductive therapy in high-risk acute promyelocytic leukemia: A potential alternative to anthracyclines. First Author: Ravi Teja Banda, Continental Hospitals, Hyderabad, India

Background: High-risk acute promyelocytic leukemia (APL) presents a significant mortality risk during induction therapy, primarily due to complications like disseminated intravascular coagulation (DIC) and treatment-related toxicities. Anthracyclines, traditionally used for cytoreduction, can cause cardiotoxicity, increase DIC risk, and induce severe neutropenia. Venetoclax has demonstrated efficacy in relapsed/refractory APL. This study explored the feasibility of using venetoclax for cytoreduction in high-risk APL patients, particularly those contraindicated for anthracyclines (cardiac issues, advanced age and in select patients based on physician discretion). **Methods:** We evaluated the safety and efficacy of venetoclax in high-risk APL patients unsuitable for anthracycline-based induction therapy. Venetoclax was initiated at 100 mg and gradually increased to 400 mg over a week. Treatment duration was determined by the patient's leukocyte count, with the goal of achieving a count below 4000/mm^3. All patients received standard ATRA (All-Trans Retinoic Acid) + ATO (Arsenic Trioxide) induction. **Results:** Ten patients received venetoclax for cytoreduction. The median age was 45 years (range: 26-70). The median duration of venetoclax therapy was 8 days (range:6-12). All patients achieved complete hematological remission within 31 days of induction and molecular remission by 28 days of the first consolidation cycle. Two patients experienced laboratory tumor lysis syndrome, and one developed differentiation syndrome which was effectively managed with continued venetoclax therapy. No patients required interruption of ATRA or ATO. Notably, no patients experienced prolonged neutropenia ($>$ 28 days), severe mucositis (Grade 3 or 4), cardiotoxicity, or DIC. **Conclusions:** This study demonstrates the feasibility of using venetoclax for cytoreduction in high-risk APL patients. Venetoclax effectively reduced tumor burden while minimizing the risks associated with anthracyclines. These encouraging results warrant further investigation into the potential role of venetoclax in high-risk APL to improve patient outcomes and mitigate treatment-related toxicities. Use of BAFFR CAR-T to treat B cell leukemia/lymphoma and auto-immune diseases. First Author: Min Luo, Guangzhou Bio-gene Technology Co., Ltd., Guangzhou, China

Background: BAFFR (B-cell Activating Factor Receptor) is a member of the tumor necrosis factor (TNF) receptor superfamily and is almost exclusively expressed on B cells. Meanwhile, BAFFR is found to be highly expressed on the surface of lymphoma cells. In addition, blocking the BAFF/BAFFR interaction can inhibit the maturation of B cells, which is beneficial for alleviating autoimmune diseases, such as psoriasis, inflammatory bowel disease, multiple sclerosis, and rheumatoid arthritis. These characteristics make BAFFR a promising target for B-cell malignancies and autoimmune diseases. It has been reported that BAFFR CAR-T (PMB-CT01) treated six non-Hodgkin lymphoma (NHL) patients, and all of these patients achieved CR and showed tolerable safety profile. **Methods:** In the current study, we screened out three different BAFFR antibodies (1312, 1313, and 1315) and constructed them into second-generation CARs, consisting of BAFFR scFv, 4-1BB co-stimulatory domain and CD3ζ. The preclinical efficacy of BAFFR CAR-T cells was evaluated *in vitro* and *in vivo*. **Results:** *In vitro* experiments showed that all three CAR-T cells effectively killed Raji tumor cells, with 1312-CAR-T demonstrating the strongest cytokine release and cytotoxicity. *In vivo* tumor-bearing mouse experiments using Raji cells showed that 1312-CAR-T could effectively clear tumor cells in the mice. While the control group all mice died by day 33, and the experimental group remained fully alive. In addition, SLE model using MRL/MpJ-Fas^{lpr} mice showed that BAFFR CAR-T cells could decrease the dsDNA-IgG levels in the serum. **Conclusions:** The results of this study suggest that BAFFR is an active and promising immunotherapeutic target for B-cell malignancies and auto-immune diseases. In the future, BAFFR CAR-T clinical trials will be conducted to treat B-ALL, lymphoma, and autoimmune diseases. It would be interesting to see whether BAFFR CAR-T can achieve similar or even better results than CD19 CAR-T in treating these diseases. Research Sponsor: National Natural Science Foundation of China; No. 82202034.

The IRAK4 long isoform as widely upregulated in non-splicesome mutated acute myeloid leukemia and as altered by hypomethylating agent therapy. First Author: Eric J. Vick, University of Cincinnati, Cincinnati, OH

Background: IRAK4, a kinase effector of MyD88 signaling downstream of Toll-Like Receptor and IL-1 receptor pathways, has recently been shown to function independently of MyD88 in Myelodysplastic Syndrome (MDS) and AML leukemic cells. Our previous research demonstrated that AML leukemic stem and progenitor cells (LSPC) rely on signaling through IRAK4. Notably, AML LSPCs express a hypermorphic long splice isoform of IRAK4 (IRAK4-L) resulting from the inclusion of exon 4. IRAK4 inhibitors, currently in clinical trials for the treatment of MDS and AML, show improved efficacy in spliceosome mutants, which preferentially express IRAK4-L. However, in patients without known spliceosome mutations, the extent of IRAK4-L expression remains unclear. Additionally, the impact of IRAK4-L levels in Venetoclax and Azacitidine treatment is unknown in refractory or unfit AML. **Methods:** Umbilical cord vein blood stem cells expressing MLL-AF9 and NRAS^{G12D} (CD34+MA9.NRAS) were maintained in vitro using supplemented media. Venetoclax and Azacitidine doses were incrementally increased in combination until cells tolerated co-treatment with up to 1 μM of each compound with minimal cell death. Patient-derived xenograft (PDX) samples were obtained from the Cincinnati Children's Biobank and included AML samples from diverse genetic backgrounds, relapsed/refractory cases, and pediatric populations (ages 1-20). Cell lysates were normalized to total protein and analyzed using a chemiluminescent capillary-based immunoblotting system, which requires minimal lysate quantities. An IRAK4 C-terminus antibody was used to detect both the shorter and longer IRAK4 protein isoform. RNA sequencing was performed, and transcripts were normalized per million counts. IRAK4 transcript ratios were calculated by dividing the total long isoform transcripts by the short isoform transcript for each condition in duplicate. **Results:** Analysis of PDX and human AML cell lines revealed that 8/9 PDX preferentially expressed the IRAK4-L isoform ($>$70% of IRAK4-L), with 4/9 PDX samples and 5/6 previously uncharacterized cell lines producing it almost exclusively ($>$95% IRAK4-L). MA9.NRAS cells predominantly express IRAK4-L, but transiently shifted to IRAK4-S during treatment with AZA/VEN (27% IRAK4-S), an effect reversed upon recovery from treatment. **Conclusions:** IRAK4-L is widely expressed in AML patient-derived samples, including those with complex karyotypes and TP53 mutations, suggesting that IRAK4 inhibitors may be useful beyond splicing factor-mutant MDS/AML. Our models demonstrate that changes in IRAK4-L expression during treatment with hypomethylating agents may be useful as a biomarker to guide therapy strategies. Further research is needed to understand how prolonged treatment and other standard of care therapies affect IRAK4-L expression and sensitivity to IRAK4 inhibitors. A phase I study of allogeneic anti-CD19 CAR-T therapy for patients with CD19+ relapsed/refractory acute B-lymphoblastic leukemia. First Author: Sun Guangyu, The First Affiliated Hospital of University of Science and Technology of China, Hefei, China

Background: Acute B-lymphoblastic leukemia (B-ALL), characterized by CD19 expression, responds well to CD19-targeted CAR-T therapy. However, autologous CAR-T is limited by cost and accessibility. We've developed RD06-03, an allogeneic CAR-T product engineered with TCR/Gene-X knockout and NK inhibitory molecule overexpression, exhibiting resistance to allogeneic rejection and enhanced anti-tumor effects without inducing graft-versus-host disease (GvHD). Our phase 1 trial (NCT06307600) aims to assess the safety and efficacy of RD06-03 in R/R B-ALL patients, offering a novel "off-the-shelf" solution. **Methods:** Patients aged 3-70 years with CD19+ R/R B-ALL were eligible and enrolled in a dose escalation study with dosing groups (CAR+ T cells/kg) of DL1: 1×10^5, DL2: 3×10^5, DL3: 5×10^5 and EDL (exploratory dose level): 6.5×10^5. All patients received lymphodepletion with fludarabine (30mg/m^2/day) and cyclophosphamide (500mg/m^2/day) for 3 days before CAR-T infusion. Dose-limiting toxicity (DLT) and the maximum tolerated dose (MTD) were evaluated using accelerated titration and "3+3" escalation, followed by case expansion at the appropriate dose. **Results:** As of December 15, 2024, six R/R B-ALL patients were enrolled (DL1: 1, DL2: 3, DL3: 1 and EDL: 1) with a median age of 37.5 years (range, 18-63) and a median of 3 prior therapies (range, 2-8+). One patient relapsed after unrelated umbilical cord blood transplantation. Baseline median bone marrow blasts were 41.9% (range, 10%-88.5%). RD06-03 was well tolerated with no DLT, neurotoxicity or GvHD observed. CRS occurred in 4 of 6 patients (66.7%, all Grade 1) with a median duration of 2.5 days (range, 1-4). For doses above DL2, all 5 patients achieved CR/CRi (100%) with undetectable MRD, indicating a deep remission. The majority of responders remain in remission, with the longest remission duration reaching 147 days and a median follow-up of 128 days (range, 60-175). Robust expansion was observed in all patients receiving doses above DL2, with rapid expansion occurring at a median of 4 days post-infusion. The median peak expansion exceeded 1 million copies/μg DNA, with a median persistence of 28 days and the longest persistence surpassing 3 months. **Conclusions:** The phase I trial of RD06-03 confirms its safety and efficacy in patients with R/R B-ALL. Notably, RD06-03's engineered TCR/Gene-X and NK inhibitory molecules enhance its resistance to rejection and antileukemic activity without GvHD. RD06-03 demonstrates robust persistence, achieving a 100% CR/CRi rate in medium- to high-dose groups, which is even lower than that of autologous CAR-T, while maintaining a manageable safety profile under standard lymphodepletion. This aligns with its genetic modifications designed for optimal immune rejection resistance. Further studies are essential to solidify these findings and explore RD06-03's therapeutic potential. Clinical trial information: NCT06307600. Research Sponsor: None.

TLR9 agonists as a potential therapeutic option for B-ALL patients with low P53 expression. First Author: Ling Bai, First Affiliated Hospital of Jilin University, Changchun, China

Background: B-cell acute lymphoblastic leukemia (B-ALL) is a highly malignant hematologic cancer with poor prognosis, especially in relapsed or refractory cases. Abnormal P53 expression is more prevalent in relapsed/refractory B-ALL and is associated with increased drug resistance. B-ALL cells in the bone marrow (BM) promote the survival of malignant cells by suppressing P53 accumulation. Therefore, identifying drugs that can reactivate P53 signaling may provide novel therapeutic strategies for patients with low P53 expression, particularly by targeting BM-resident B-ALL cells. **Methods:** Building on our previous findings that TLR9 agonists can activate the P53 signaling pathway and preferentially eliminate BM-resident B-ALL cells over peripheral B-ALL cells, we investigated the mechanisms by which TLR9 agonists regulate glucose metabolism through P53 to induce B-ALL apoptosis. We constructed P53 knockdown cell lines, conducted seahorse assays to analyze glucose metabolism, and performed RNA sequencing to identify key molecules. Mechanistic studies focused on the regulation of glucose metabolism and its P53-dependent pathways. Furthermore, we elucidated the role of glucose metabolism in TLR9 agonist-induced reactive oxygen species (ROS) production and mitochondrial apoptosis. **Results:** TLR9 agonists preferentially eliminate BM-resident B-ALL cells via P53-dependent pathways. Specifically, TLR9 agonists suppress glycolysis while enhancing oxidative phosphorylation and ROS generation through the P38-P53-TIGAR signaling axis. Elevated ROS levels further facilitate the formation of the BAX/BAK/TOM20 complex, promote TOM20 oxidation and accumulation, and activate BAX. The P53-TIGAR-ROS-MOMP axis was identified as the critical mechanism underlying TLR9 agonist-induced apoptosis in B-ALL. Additionally, patient-derived xenograft models confirmed that ROS generation is key to the efficient clearance of BM-resident B-ALL cells by TLR9 agonists. **Conclusions:** As P53-reactivating agents, TLR9 agonists selectively eliminate B-ALL cells while preserving immune cell anti-tumor function. This study highlights the role of glucose metabolism in the TLR9 agonist-mediated clearance of BM-residual B-ALL cells, providing a potential maintenance or combination therapy strategy for relapsed/refractory B-ALL patients, particularly those with low P53 expression. Real-world patient management practices in responders to venetoclax for newly diagnosed acute myeloid leukemia. First Author: Ofir Wolach, Rabin Medical Center, Petach Tikva, Israel

Background: Venetoclax (VEN) is approved for adult patients (pts) with newly diagnosed (ND) acute myeloid leukemia (AML) in combination with hypomethylating agents (HMAs) or low dose cytarabine. This abstract describes real-world pt management practices among pts with ND AML who respond to VEN+HMA. **Methods:** The AML Real world evidenCe (ARC) Initiative is a multicenter chart review study of adults with ND AML treated with VEN at 17 academic sites in the US, Israel, and Canada. Pts ineligible for intensive chemotherapy (IC; ie, aged ≥75 years or ≥1 Ferrara criteria comorbidity) who initiated VEN+HMA on or after April 2016 were included (ie, before and after release of product label). Pt management practices in first-line VEN treatment and related impact on duration of response (DoR; assessed with Kaplan-Meier analyses) were examined among pts achieving composite complete remission (CRc; ie, CR or CR with partial hematologic recovery or incomplete count recovery). **Results:** Among IC-ineligible VEN-treated pts, 116 (60.4%) achieved CRc (median age 73.0 years, 37.9% female, 53.4% European LeukemiaNet 2017 adverse risk, 24.2% Eastern Cooperative Oncology Group grade ≥2). Median DoR was 11.0 months (95% confidence interval: 8.8; 15.2). Most pts (75.9%) received VEN + azacitidine. Median observed VEN treatment duration was 5.8 months and 31.9% remained on VEN as of data entry; 12.1% received hematopoietic stem cell transplant post-VEN. Almost all pts (93.6%) had ≥1 marrow assessment post-VEN initiation, usually in cycle 1 (68.0%) or 2 (19.4%). During VEN treatment, 44.8% received granulocyte colony stimulating factor. Antifungals were used in cycle 1 by 68.1% (83.5% prophylactic; 63.3% strong CYP3A4 inhibitor); DoR did not differ by antifungal use. Most pts (68.1%) had VEN dose ramp-up, from a median of 100 mg to 400 mg daily over 3 days. In cycle 1, 59.5% started with 28 VEN dosing days; this proportion declined in subsequent cycles. Among pts still treated, 48.6% and 54.8% had ≤21 dosing days in cycles 2 and 3, respectively. Most pts achieved CRc in cycle 1 (58.6%) or 2 (21.6%); median DoR did not differ significantly between these pts vs later responders. Among 93 pts treated for ≥1 cycle post-response, most (87.1%) had a dose hold before initiating the next cycle; 51.6% of these 93 pts had a dose hold up to 14 days. Of 50 pts remaining on 28 dosing days until CRc, 26.0% reduced to ≤21 dosing days in the next cycle. Neither postremission dosing days modifications nor between-cycle dose holds significantly impacted DoR. **Conclusions:** Among VEN-treated ND pts with AML achieving CRc in real-world academic settings, most achieved CRc by the end of cycle 2, consistent with clinical trial results. Nevertheless, timing of response did not appear to affect DoR. Postremission dosing days modifications and between-cycle dose holds were common in clinical practice and did not appear to impact DoR. Research Sponsor: AbbVie; Genentech.

Nucleophosmin (*NPM1*) genomic alterations (GA) in acute myeloid leukemia (AML): A genomic landscape study. First Author: Osama Batayneh, SUNY Upstate Medical University, Syracuse, NY

Background: *NPM1* GA characterize a clinically important subset of AML cases which relapse in more than 50% of treated patients despite being generally sensitive to conventional chemotherapy regimens. In AML, the interactions between GA in *NPM1*, *KMT2A* and menin protein have been linked to leukemogenesis and represent new potential targets for anti-tumor therapies. **Methods:** 4,206 cases of AML underwent comprehensive genomic profiling from 2019 through 2024, using the FoundationOne Heme combined hybrid capture based DNA and RNA sequencing assay. All classes of relevant GA were evaluated. The tumor mutation burden (TMB), homologous recombination deficiency signature (HRDsig) and microsatellite Stability (MSS) status were determined from the sequenced data. **Results:** 633 (15.1%) of the 4,206 AML featured *NPM1* GA (NPM1mut). Short variant mutations were found in >99% of the NPM1mut AML with the W288fs*12 frameshift base substitution accounting for 92.4% of cases. An *NPM1 - MLF1* fusion was identified in 1.3% of NPM1mut cases. The NPM1mut+ were more frequently associated with female patients (53.4% vs 41.5%; p<.0001) and had a slightly higher median age compared to the NPM1 wild type (NPM1wt) AML patients (62yrs vs 60yrs; p<.0001). Majority of patients (>60%) were from European decent. There were greater NPM1 GA in patients with European (77.1% vs 68.5%; p<.0001) and lower with African ancestry (9.2% vs 10.2%; p<.0001). MSI High (0% in both groups) status, HRDsig+ (0–0.1%) and elevated TMB (median < 1 mutation/Mb) were extremely uncommon in both groups. GA more frequent in NPM1mut AML compared to the NPM1wt AML cohort included *DNMT3A* (39.2% vs 12.6%; p<.0001), *FLT3* (54.5% vs 14.7%; p<.0001), *IDH1* (16.1% vs 5.6%; p<.0001), *IDH2* (19.0% vs 9.0%; p<.0001), *TET2* (23.4% vs 13.5%; p<.0001) and *WT1* (12.5% vs 9.4% p=.02). GA more frequent in NPM1wt AML included *ASXL1* (17.1% vs 3.6%; p,.0001), *BCOR* (7.5% vs 1.6%; p<.0001), *KMT2A* (14.7% vs 0.2%; p<.0001), *RUNX1* (22.5% vs 1.9%; p-,.0001), *STAG2* (6.9% vs 1.6%; p<.0001) and *TP53* (19.1% vs 4.1%; p<.0001). **Conclusions:** The development of menin inhibitors has recently identified GA in *NPM1* as a promising target of therapy for AML patients. Other therapy targets in AML such as *FLT3* and *IDH1/2* are more frequently identified in NPM1mut than NPM1wt AML, while *KMT2A* is more frequently identified in NPM1wt AML. This genomic landscape study reveals significant differences in important GA associated with AML in NPM1mut and NPM1wt cases which may enrich our understanding of the molecular profile in AML and identify additional targets for therapy. Research Sponsor: None.

Real-world outcomes of inaticabtagene autoleucel in Chinese patients with B-ALL. First Author: Hongsheng Zhou, Southern Medical University Southern Hospital, Guangzhou, China

Background: Inaticabtagene autoleucel (Inati-cel) is a CD19-specific chimeric antigen receptor (CAR) T-cell product, featuring a CD19 scFv derived from the clone HI19α and a 4-1BB/CD3-ζ costimulatory domain, which was approved in China for adult patients with relapsed or refractory B-acute lymphoblastic leukemia (r/r B-ALL) in November 2023. **Methods:** We conducted the multi-center, non-interventional real-world study (NCT06450067) to evaluate Inati-cel for adult B-ALL patients. Between November 20, 2023, and November 13, 2024, 62 patients received Inati-cel and were evaluable. The median age was 37.5 (range, 14-76) years, with 13 patients aged≥60 years. At screening, 16 cases relapsed after hematopoietic stem cell transplantation (HSCT), 4 cases were primary refractory, and over 70% of patients carried high-risk genetic abnormity. The median infusion dose was 0.60 (range: 0.46-0.9) $\times 10^8$CAR-T live cells. **Results:** The data as of December 30, 2024, with a median follow-up of 3.8 months (range: 0.5–12.4 months), 89.5% achieved MRD-negative ORR after Inati-cel in r/r patients, including 31 with CR and 3 with CRi (table1). Nine patients with MRD-positive at screening, the MRD-negativity rate reached 100% after Inati-cel. After Inati-cel, 26 patients had MRD results detected by q-PCR, and 92.3% obtained negative results. After achieving CR/CRi, 4 patients subsequently underwent allo-HSCT in remission. The median DOR, OS and RFS have not been reached with and without censoring patients at subsequent allo-HSCT. Among the evaluable patients, the 1-year RFS and DOR rates were 76.2% and 74.1%, respectively. Seven patients experienced relapses, including 3 CD19+ relapses, 2 CD19- relapses, and 2 with unclear CD19 status. It is worth noting that in 6 cases of extramedullary disease, 4 cases were effective, but 2 cases relapsed within 3 months after Inati-cel. All patients who received the Inati-cel infusion were alive, except for one death from disease progression. The most common adverse events (AEs) of special interest were cytokine release syndrome (CRS) and immune effector cell-associated neurotoxicity syndrome (ICANS). Fifty-one percent of patients developed CRS, but grade 3 or higher CRS and ICANS only occurred in 3.2% and 1.6% of patients, respectively; all patients recovering without sequelae, no AE-related deaths. **Conclusions:** The real-world use of Inati-cel demonstrates a high MRD-negative ORR in adult B-ALL. The safety profile was manageable, with a low incidence of grade ≥3 CRS and ICANS in the real-world setting. Longer follow-up data will be presented. Clinical trial information: NCT06450067. Research Sponsor: None.

Comparable efficacy of venetoclax 50mg with posaconazole versus venetoclax 400mg in newly diagnosed AML patients: A prospective study of pharmacokinetics, toxicity, and clinical outcomes. First Author: Gaurav Prakash, PGIMER, Chandigarh, Nehru Hospital, Chandigarh, India

Background: Metabolism of Venetoclax(VEN) by CYP3A enzymes gives a unique opportunity to administer it at a lower dose with a CYP3A inhibitor. Azoles are strong CYP3A inhibitors & they are commonly used for antifungal prophylaxis during AML induction. Current data suggest that VEN 100mg with posaconazole achieves comparable clinical efficacy but is associated with higher myelotoxicity. We prospectively explored further dose reduction of VEN to 50 mg with posaconazole & compared it with VEN 400 mg with respect to pharmacokinetics, response rates & toxicity. **Methods:** We conducted an open-label, prospective study & enrolled 31 AML patients unfit for intensive chemotherapy. Patients received either VEN 50 mg with posaconazole (VEN50 cohort, n=20) or VEN 400 mg without posaconazole (VEN400 cohort, n=11). Pharmacokinetic parameters, including C0, Cmax, & AUC(0–24), were assessed using high-performance liquid chromatography. Clinical outcomes: overall response rate (ORR), composite complete response (CRc), measurable residual disease (MRD), & hematological recovery time-were analysed. **Results:** The median age of patients was 50 years (IQR: 35.5–60). Under the ELN2024 model, 74% of VEN50 patients & 63.6% of VEN400 patients were favourable-risk, while 26% & 36.4% were intermediate-risk, respectively. The ORR was 80% in the VEN50 cohort & 81.8% in the VEN400 cohort. CRc rates were comparable between the VEN50 (60%) & VEN400 (63.6%) cohorts, with similar MRD negativity rates (30% vs. 36.3%). Pharmacokinetic analysis revealed significantly lower systemic drug exposure in the VEN50 cohort [AUC(0–24):17.88 μg·h/mL vs. 48.05 μg·h/mL, p=0.002] with C0 levels of 0.42 μg/mL vs. 1.08 μg/mL (p=0.004) & Cmax levels of 1.435 μg/mL vs. 3.63 μg/mL (p=0.002). Patients in VEN50 cohort experienced shorter neutropenic phase (17.5 vs. 24 days). Adverse events, including febrile neutropenia (60% vs. 72.7%, p=0.501) & culture-positive infections (20% vs. 27.2%, p=0.569), were comparable between the two cohorts. No treatment-related death occurred in either of the group. **Conclusions:** Our findings suggest that lower plasma levels achieved with VEN50 can lead to comparable CR rate & MRD negative rate in comparison with VEN400 with lesser myelotoxicity. Research Sponsor: None.

Comparison of baseline characteristics and outcomes.

Subgroup analysis by fitness criteria of patients (pts) with blastic plasmacytoid dendritic cell neoplasm (BPDCN) treated with first-line (1L) tagraxofusp (TAG). First Author: Naveen Pemmaraju, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: BPDCN, an aggressive orphan hematologic neoplasm, expresses CD123 and presents in skin, bone marrow, blood, and viscera. For pts eligible to undergo hematopoietic cell transplantation (HCT), the 1L treatment goal is to rapidly induce a durable complete response (CR) before HCT. TAG is a first-in-class CD123-targeted therapy with a well-characterized and manageable safety profile without cumulative myelosuppression and the only drug approved to treat BPDCN. In 1L pts with a median age of 68 yrs, TAG has demonstrated, in a phase 1/2 pivotal trial with prespecified/multisystem response criteria, a 75% overall response rate, 24.9-month (mo) median duration of CR/clinical CR (CRc), and the ability to bridge 51% of pts with CR/CRc to HCT (Pemmaraju, JCO 2022). Notably, multi-agent intensive chemotherapy (IC) prior to HCT is still used, particularly in young fit pts, despite short- and long-term toxicity/myelosuppression and despite short durations of response (DOR). Also, many pts with BPDCN are ineligible for IC before HCT. We assess outcomes, based on pretreatment comorbidity burden, across HCT-specific comorbidity index (HCT-CI; Sorror, JCO 2007) fitness groups for pts who received 1L TAG for BPDCN in the pivotal trial (NCT02113982). **Methods:** Pts who received 1L TAG 12 μg/kg IV on days 1-5 of a 21-day cycle (C) were retrospectively assigned to categories by HCT-CI score (0 [low], 1-2 [intermediate; int] and 3+ [high]) per baseline medical history, concomitant medications, and labs. Outcomes included best response, time to response (TTR), DOR, overall survival (OS), HCT rate, treatment-related adverse events (TRAEs), and capillary leak syndrome (CLS). **Results:** 65 pts were scored as HCT-CI low (n=15), int (n=22), or high (n=28). Median age was 61, 67.5, and 70 yrs, respectively; disease was more extensive in high-risk pts. Objective responses (80%, 68%, 79%) were high regardless of HCT-CI group, with CR/CRc rates of 73%, 59%, and 46%. Median TTR was similar; median DOR was longer in low and int (24.9 mo/not reached [NR]) vs high (3.9 mo). HCT rates were 33%, 45%, and 21%; pre-transplant CR/CRc rates were 100%, 90%, and 83% with median DOR NR. Median OS in HCT pts was 38.4 mo, NR, and NR. In each group, most common Grade 3-4 TRAEs were thrombocytopenia and increased ALT/AST; most were in C1 and transient. Two deaths due to CLS occurred in int pts. Grade 3-4 CLS occurred in 0%, 9%, and 4% of pts; all CLS events were in C1 and all grade 1-4 CLS events resolved. **Conclusions:** 1L TAG BPDCN treatment yielded high response rates regardless of HCT-CI fitness, with a similar safety profile across HCT-CI groups. TAG enabled bridge to HCT across all fitness groups, including pts with high risk possibly ineligible for IC, as TAG is not associated with prolonged myelosuppression seen with IC. These results affirm TAG as the SOC in 1L treatment for the majority of pts with BPDCN. Clinical trial information: NCT02113982. Research Sponsor: Menarini Group.

Detection of KMT2A partial tandem duplication (PTD) in AML by whole genome sequencing (WGS): Addressing limitations of traditional techniques in the era of revumenib approval. First Author: Robert Huether, Tempus AI, Inc., Chicago, IL

Background: The menin inhibitor revumenib was recently FDA approved for treating patients with relapsed or refractory KMT2A-rearranged (rKMT2A) acute leukemias. Cytogenetics, FISH, and targeted next-generation sequencing (NGS) frequently miss KMT2A 11q23 partial tandem duplications (KMT2A-PTD)). Although KMT2A-PTDs have expression signatures similar to rKMT2A, they were excluded from revumenib's registration trial. Preclinical models have shown that menin inhibitors may also be effective for KMT2A-PTD, highlighting the need for precise breakpoint and KMT2A fusion product detection. Here, we evaluated the effectiveness of high-resolution WGS to identify a diverse array of KMT2A-PTD. **Methods:** Using a WGS assay (Tempus xH) optimized for comprehensive profiling of myeloid neoplasms, we capture the entire KMT2A locus at base pair resolution. DNA was extracted from blood or bone marrow aspirates and was used to construct paired-end libraries via tagmentation. Sequencing was performed on the Illumina NovaSeq-X platform, achieving a mean coverage of 80X. Data were analyzed using the DRAGEN Platform with custom post-processing filters. Exon copy number calls from a targeted NGS assay and exon capture RNAseq NGS assay (Tempus xT and xR, respectively) were used for verification. **Results:** WGS from 230 hematopoietic neoplasms (68% AML, 18% MDS, 12% CML, and 2% others) identified 13 specimens (5.6%) containing a KTM2A-PTD, with variant allele frequencies (VAFs) between 9-66%. All PTDs contained breakpoints within known intron boundaries: one breakpoint in intron 1 (13/13) with terminal breakpoints located in intron 8 (6/13) or intron 10 (7/13). RNA data was available for 11 of 13 specimens and contained direct support for the presence of all the KMT2A-PTDs (100%). Using an NGS-targeted panel, exon-level copy calls were assessed for all 13 specimens with PTDs. Although unvalidated, we observed exon level gains in 9 of the 13 specimens (69%). As shown in prior studies, KMT2A-PTDs were mutually exclusive to other translocations, including rKMT2A. However, other high-frequency mutations for myeloid disease were present in select samples including mutations in IDH1, DNTM3A, WT1, and RUNX1. **Conclusions:** WGS is an effective tool for detecting KMT2A alterations that may be missed by traditional techniques such as NGS targeted capture, FISH or cytogenetics. 100% concordance was observed between WGS and RNAseq for KMT2A-PTDs, supporting the reliability of WGS. The FDA approval of menin inhibitors for KMT2A-rearranged AML/ALL suggests potential clinical opportunities for broad tests (WGS) to identify other rearrangements, including KMT2A-PTDs, highlighting the need for further research into targeted anti-leukemia therapies. Research Sponsor: Tempus AI, Inc.

Mitoxantrone hydrochloride liposome combined with cytarabine (MA) for patients with newly diagnosed secondary acute myeloid leukemia. First Author: Stephen Yang Liang, Department of Hematologic Oncology, State Key Laboratory of Oncology in South China, Guangdong Provincial Clinical Research Center for Cancer, Sun Yat-Sen University Cancer Center, Guangzhou, China

Background: Secondary acute myeloid leukemia (sAML) is an aggressive subset typically characterized by unfavorable biological features. CPX-351, a dual-drug liposomal formulation of cytarabine and daunorubicin, has demonstrated improved remission rates and overall survival (OS) in sAML; however, its use remains limited in China. Mitoxantrone hydrochloride liposome (Lipo-MIT), a pegylated liposomal formulation of mitoxantrone, provides enhanced anti-tumor efficacy and reduced toxicity. Here we report the outcomes of a novel regimen combining Lipo-MIT and cytarabine (MA) for patients (pts) with newly diagnosed sAML. **Methods:** This is a single-arm, prospective, exploratory study. Eligible pts were aged 18 to 75 years and had newly diagnosed therapy-related AML, AML with antecedent myelodysplastic syndrome (MDS) or chronic myelomonocytic leukemia (CMML), or de novo AML with MDS-related cytogenetic abnormalities. Patients received MA regimen consisting of Lipo-MIT (24mg/m^2 on day 1) and cytarabine (100mg/m^2/d from days 1 to 7) every four weeks for up to 2 cycles. The primary endpoint was CRc (complete remission (CR)+CR with incomplete neutrophil or platelet recovery (CRi)). The secondary endpoints included the rate of CRc with negative minimal residual disease (MRD), overall response rate (ORR), overall survival (OS) and safety. **Results:** As of January 20, 2025, a total of 13 pts were enrolled with a median age of 53 years (range, 24.0-65.0), including 8 with therapy-related AML and 5 with AML arising from antecedent MDS. According to the 2022 edition of the European Leukemia Network recommendations, 2 (15.4%) pts were classified as a favorable prognosis, 2 (15.4%) as intermediate, 8 (61.5%) as adverse, and 1 (7.7%) as unknown. The most commonly mutated gene and abnormality karyotype was TP53 and del(7q), respectively, both occurring in 23.1% (3/13). Of 13 pts, 5 were assessed as CR, 3 as CRi and 1 as PR. The CRc rate was 61.5% (8/13) and the ORR was 69.2% (9/13). Among 8 pts who achieved CRc, the rate of negative MRD was 75% (6/8). With a median follow-up of 3.4 months, the 1-year OS rate was 88.9% (95% CI, 43.3-98.4) while the median OS was not reached. The median duration of absolute neutrophil count $<$500 cells/μL was 21.0 days (range, 7.0-29.0) and platelet count $<$50000 platelets/μL was 20.0 days (range, 14.0-61.0) in pts who achieved CRc after initial induction. The non-hematological treatment-emergent adverse events (TEAEs) graded at 3 were febrile neutropenia (46.2%), fever (7.7%), sepsis (7.7%), pulmonary infection (7.7%), oral mucositis (7.7%), anaphylaxis (7.7%) and pruritus (7.7%). No non-hematological TEAEs of grade 4 or worse were observed and the 60-day mortality rate was 0%. **Conclusions:** The MA regimen demonstrated encouraging remission rates and a superior safety profile, indicating its potential as a treatment option for newly diagnosed sAML. Clinical trial information: ChiCTR2300076618. Research Sponsor: None.

Co-mutational landscape of Indian core binding AML: An answer to the unfavorable outcome in a favorable AML? First Author: Rahul Bhargava, Fortis Memorial Research Institute, Gurugram, India

Background: Core binding factor AML, which encompasses RUNX1/RUNX1T1 and CBFB/MYH11, comprise 10-15% of all AML, currently classified as favorable risk in the 2022 European LeukemiaNet Risk Stratification. The Indian CBF AML cohort as reported in earlier studies tends to be younger, with extramedullary disease and with higher number of co-mutations. Also due to unavailability of the anti CD33 gemtuzumab ozogamicin in India, the outcomes to standard therapies tend to be dismal when compared to the West. This raises a dilemma for the ELN risk stratification of this entity as a favorable risk. **Methods:** 165 patients of CBF AML were accrued, from two different centers. Non-disclosure consents from the participating centers were obtained. Patients with documented CBF AML who have undergone NGS based testing were included. Descriptive statistical analysis was done for continuous and ordinal data. The analysis was done using SPSS version 24. A two tailed p value of $<$5% was considered significant. The data from TCGA studies was compared which was accessed through www.cbioportal.org and all studies of AML were included. **Results:** A total of 165 patients of CBF AML were included in the study. Median age was 33.4 years (range 16-45) with a clear male predilection (male to female ratio of 3.1:1).RUNX1/RUNX1T1 rearrangement was detected in 70% (116) cases and 49 (30%) cases harbored the CBFB/MYH11 gene rearrangement. At least one additional mutation was detected in 70% cases with RUNX1/RUNX1T1 rearrangement and 80% cases of CBFB/MYH11.The most frequent co-occurring alteration was NRAS (32% cases across both subtypes, more common in CBFB/MYH11). Another statistically significant finding was patients with inv(16) manifested a significantly higher frequency of Spliceosome mutations (p = 0.028) and WT1 mutations (p = 0.021) compared to t(8;21). Two patients harbored concomitant TP53 mutations predicted to be pathogenic based on ClinVar database as well as IARC TP53 database. Both these patients also had a complex karyotype along with RUNX1/RUNX1T1 fusion. Mutation in DNA methylation genes occurred more in CBFB/MYH11 vs RUNX1/RUNX1T1 cases ($p<0.06$). The patients with CBFB/MYH11 also depicted a higher prevalence of mutations in the polycomb repressor genes ASXL1 and ASXL2 when compared to RUNX1/RUNX1T1($p<0.06$).Another feature was higher prevalence of cohesin complex gene mutations involving SMC1A and SMC3 which were seen in 20% cases overall. The inv(16) group showed a lower predilection compared to the t(8;21) group ($p<0.061$). **Conclusions:** The presence of higher number of additional mutations in the Indian cohort underscores the need of larger studies/controlled trials of this subset, which otherwise has been stratified as favorable. The access to standard of care like GO is a necessity and there is a need to formulate national/regional guidelines for the Indian subset. Research Sponsor: None.

Outcomes of Ph-like B-lineage acute lymphoblastic leukemia in the era of novel therapies. First Author: Hamed Rahmani Youshanlouei, University of Chicago, Chicago, IL

Background: Ph-likeALL) is a high-risk subset of B-ALL with poor treatment response and high relapse rates. We examined outcomes of Ph-like B-ALL pts (pts) treated at a large academic center in the current era of novel therapies. **Methods:** We retrospectively analyzed 68 adults with Ph-like B-ALL treated at the University of Chicago (2014-2023). Ph-like status was classified per WHO 2022 criteria using FISH, DNA and RNA sequencing. **Results:** Median age at diagnosis was 34 years (range, 18-74), 68% were male. We found CRLF2 rearrangements (CRLF2-r) in 75%, JAK2-r in 10%, ABL1-r in 6%, FGFR-r in 3%, and rearrangements in ABL2, CSF1R, PDGFR and ROS1 at 1.5% each. Most common co-occurring somatic gene mutations involved IKZF1 (41%), CDKN2A (37%), JAK2 (37%), KRAS (16%), PAX5 (12%) and NRAS (10%). First-line therapy was chemo alone in 80% of pts with the following distribution: CALGB 10403 in 43%, hyper-CVAD in 28% and other chemo in 9%. The remaining 20% of pts received novel therapies in first-line setting, including C10403 + inotuzumab (InO) in 7%, ino + blinatumomab (blin) in 6%, hyperCVD + venetoclax in 4% and C10403 + imatinib in 3%. Post-induction flow cytometry-based measurable residual disease (MRD) negativity rate was significantly higher in pts who received novel therapies upfront vs pts who received standard chemo (55% vs 20%, p= 0.02). This is lower than our non-Ph-like B-ALL pts, for whom the MRD-negative CR rate after chemo induction was 62% ($p< 0.01$). We also observed higher 5-year relapse-free survival (RFS) rate for pts who received novel therapies upfront vs standard chemo alone (65% vs 20%, $p< 0.01$). We did not detect a significant difference in overall survival (OS) for pts treated with novel therapies vs standard of care (p= 0.52), which is likely due to the utilization of novel therapies as salvage regimens after relapse. Of note, 5 pts received kinase inhibitors (ruxolutinib, dasatinib, imatinib) in salvage setting, but did not achieve remission. There were no differences in OS or RFS outcomes when pts were stratified based on CRLF2-r vs non-CRLF2-r. Among co-occurring gene alterations, we observed higher risk for relapse in cases with KRAS mutations (HR= 4.29, 95% CI= 1.3-13.4), which was independent from the type of first-line therapy. 7% received anti-CD19 CAR-T cell therapy. 32% had allogeneic transplant (HCT), which was done in CR1 in 31%, while 69% received HCT after salvage (CR2 or CR3). 64% received myeloablative conditioning (TBI-based regimens) with the following distribution of donors: 46% matched unrelated, 27% mismatched unrelated, 18% matched related, 9% haplo-cord. Median OS after HCT was 10 months. **Conclusions:** Ph-like B-ALL pts treated with standard chemo have lower CR and RFS rates. Adding novel agents (InO, blin, venetoclax) to upfront regimens may improve outcomes. Future studies should focus on optimal first-line combinations and higher-risk groups such as KRAS-mutated Ph-like B-ALL. Research Sponsor: None.

Potential benefits of using a different donor for transplantation consolidation after donor-derived CD7 CAR T. First Author: Jing Pan, State Key Laboratory of Experimental Hematology, Boren Clinical Translational Center, Department of Hematology, Beijing Gobroad Boren Hospital, Beijing, Beijing, China

Background: Stem cell transplantation (SCT) is often used in patients with relapsed or refractory T-cell acute lymphoblastic leukemia (r/r T-ALL) after CD7 CAR T therapy, in order to consolidate efficacy or promote immune reconstitution to reduce the risk of infection. Previous studies have shown that consolidatory SCT may be able to prolong the survival of patients after CD7 CAR T. However, infections after SCT raise concerns. Here, we explored optimization strategies for SCT consolidation after newly HLA-matched donor-derived CD7 CAR T therapy in r/r T-ALL patients. **Methods:** This is a retrospective analysis of SCT consolidation following donor-derived CD7 CAR T therapy, based on a phase 1 trial (ChiCTR2000034762) and a phase 2 trial (NCT04689659) approved by the Institutional Review Board (IRB) of Beijing Goboard Boren Hospital, and a phase 1/2 trial (NCT06316427) approved by the IRB of Beijing Goboard Hospital. The analysis was aimed to evaluate the impact of using different donors for CAR T therapy and the subsequent SCT, compared to using the same donor. **Results:** A total of 19 patients were included in this analysis, including four from the phase 1/2 trial who used different donors for CAR T therapy and SCT consolidation (Group A), and 15 patients who used the same donor for CAR T therapy and SCT consolidation (Group B, 7 from the phase 1 trial and 8 from the phase 2 trial). The median age of the 19 patients was 11 (range 2-43). 16 patients (84%) were male, and three (16%) were female. The median interval from CAR T cell infusion to stem cell infusion was 32 days (range, 26-34) for group A, and 39 days (range 32-48) for group B. After stem cell infusion, all patients in group A had no detectable CAR T cells in the peripheral blood. However, in group B, six of the 13 patients evaluated had detectable CAR T cells in the peripheral blood, whereas the other seven did not. Within three months after stem-cell infusion, no patients in group A had CMV or EBV activation, while nine patients (60%) in group B had CMV or EBV activation. Two patients (50%) in group A and 10 patients (67%) in group B had any type of viral activation. Compared to group B, patients in group A tended to have a higher chimerism rate in the peripheral blood at two months and in the bone marrow at three months after stem cell infusion. **Conclusions:** In post-CD7-CAR patients, the risk of viral activation (especially CMV/EBV activation) after SCT using the same donor as CAR T was high. This may be partly related to the persistence of CAR T cells after SCT. The results showed that using a different donor from CD7 CAR T for subsequent SCT may contribute to the timely clearance of CAR T cells from patients and simultaneously reduce the rate of CMV/EBV activation after stem cell infusion. In addition, the chimerism rate was slightly increased at some time points. These results will be further evaluated in an ongoing phase 1/2 study at our center. Clinical trial information: NCT04689659, NCT06316427, ChiCTR2000034762. Research Sponsor: None.

Overcoming acquired venetoclax resistance in acute myeloid leukemia through cell metabolism targeting. First Author: João Agostinho Machado-Neto, Department of Pharmacology, Institute of Biomedical Sciences, University of São Paulo, São Paulo, Brazil

Background: Venetoclax is a selective inhibitor of the anti-apoptotic protein BCL2, often overexpressed in acute myeloid leukemia (AML), contributing to cell survival and resistance to standard therapies. It has expanded treatment options, especially for elderly or chemotherapy-ineligible patients. However, acquired resistance to venetoclax is a significant challenge, limiting long-term effectiveness. Understanding the mechanisms of resistance is crucial for improving therapeutic strategies and identifying biomarkers for personalized treatment. This study investigates these mechanisms by analyzing cellular phenotype, metabolic changes, BCL2 family gene/protein expression, and signaling pathways in venetoclax-resistant AML cell lines. **Methods:** Venetoclax-sensitive AML cell lines, MOLM-13 and MV4-11, were exposed intermittently to increasing concentrations of the drug to induce resistance. Cell viability was assessed using MTT assays, clonogenicity by colony formation, and apoptosis, mitochondrial damage, and DNA content by flow cytometry. Metabolic profiles were analyzed with Seahorse XF96, and signaling pathways were studied by Western blotting, qPCR, and global proteomics. Synergy assays were conducted with metformin (mitochondrial complex I inhibitor) and KPT-9274 (NAMPT inhibitor). **Results:** Intermittent exposure to venetoclax selected for resistant clones, MV4-11VR (IC_{50} > 1000 nM; parental cells IC_{50} = 2.5 nM) and MOLM-13VR (IC_{50} = 723 nM; parental cells IC_{50} = 3.3 nM). Venetoclax-induced apoptosis, mitochondrial damage, and DNA fragmentation were absent in resistant cells. Metabolic analysis showed increased mitochondrial metabolism in MOLM-13VR cells and enhanced glycolysis in MV4-11VR cells. Molecularly, MV4-11VR cells exhibited downregulation of BCL2L10, BAX, BCL2L11, BBC3, BIK, and BNIP3, while MOLM-13VR cells showed reduced BID, PMAIP1, BAD, BMF, and BECN1, along with increased MCL1. MOLM-13VR cells displayed enhanced MAPK signaling, and both resistant models had activation of the PI3K/AKT/mTOR pathway and upregulation of BCL-XL. Proteomic analysis revealed enhanced metabolic activity, with MV4-11VR cells enriched in fatty acid biosynthesis and carbohydrate metabolism pathways, while MOLM-13VR cells showed upregulation of aerobic respiration and ATP metabolism. Both parental and resistant cells exhibited comparable sensitivity to metformin and KPT-9274. The combination of these inhibitors with venetoclax resulted in synergistic effects, with KPT-9472 and venetoclax eliminating over 95% of resistant cells. **Conclusions:** This study provides key insights into the mechanisms of venetoclax resistance in AML. Targeting cellular metabolism with metformin or KPT-9274, combined with venetoclax, offers promising synergistic effects and potential strategies to overcome resistance, improving treatment outcomes in resistant AML cases. Should we treat TP53-mutated high-risk myeloid neoplasms in older patients? First Author: Talha Badar, Mayo Clinic, Jacksonville, FL

Background: *TP53* mutated (*TP53*^{mt}) high-risk myeloid neoplasm (HR-MN) confers a dismal prognosis in the contemporary era with only a subset of eligible patients (pts) able to achieve long-term remission with allogeneic stem cell transplantation (allo-HCT). Owing to poor outcomes, many physicians believe it is futile to treat older pts with disease-directed therapy, since curative intent allo-HCT cannot be offered. We sought to describe the outcomes of older pts with *TP53*^{mt} HR-MN receiving disease directed treatment. **Methods:** We conducted a multicenter observational study in collaboration with 11 U.S. academic centers under the COMMAND consortium. We reviewed the data of 451 older (≥ 60 years [yrs]) *TP53*^{mt} HR-MN (n= 282 acute myeloid leukemia [AML], n= 91 MDS transformed AML, n= 50 myeloproliferative neoplasm blast phase (MPN-BP) and n= 28 high-risk myelodysplastic syndromes [HR-MDS]) pts to analyze their outcome with disease directed treatment. **Results:** The median age was 70 yrs (range [R],60-90) and 58% were male. Proportions of pts with age ≥ 70 yrs were 47.5%. Eastern Cooperative Oncology Group Performance Status (ECOG-PS) was available in 68% (n= 306) of pts; 10.5%, 49%, 32% and 8.5% had ECOG-PS 0-3, respectively. The median bone marrow (BM) blast % was 32 (R, 5-99) and *TP53* variant allele frequency (VAF) was 45% (R, 2-97). The proportion of pts with multi-hit (MH) *TP53*^{mt} and complex cytogenetics (CG) was 83% and 82%, respectively. 43 %, 31%, 20% and 6% received hypomethylating agent (HMA) + venetoclax, intensive chemotherapy, HMA and other low-intensity therapy, respectively. The complete remission rate with or without count recovery (CR/CRi) amongst evaluable patients (n= 356) was 37%. The median duration of response was 6.7 months (mo) (R, 5.9-7.5). Amongst 56 (12%) pts who underwent allo-HCT, the median overall survival (mOS) from time of allo-HCT was 21.9 mo. The mOS among pts ≥ 70 yrs was 6.5 mo. The mOS in mo was better in HR-MDS (16.4), compared to *de novo* AML (6.5), MDS transformed AML (7.1) and MPN-BP (5.27), p= 0.003. We conducted multivariable analysis for OS using baseline variables that were significant/ showed trend towards significance, on univariate analysis (p<0.1). HR-MDS (HR; 0.43, 95% CI: 0.23-0.82, p= 0.01), CR/CRi (HR; 0.55, 95% CI: 0.39-0.77, p= <0.001) and allo-HCT (HR; 0.28, 95% CI: 0.16-0.47, p= <0.001) positively impacted OS. Whereas age ≥ 70 yrs showed trends towards inferior OS (HR; 1.31, 95% CI: 0.95-1.80, p=0.09). Complex CG (HR; 1.63, 95% CI: 0.83-3.21, p=0.15) and MH*TP53*^{mut} (HR; 1.30, 95% CI: 0.67-2.52, p= 0.42) did not retain significance for OS. **Conclusions:** Our multicenter study suggests that disease directed treatment in older *TP53*^{mt} HR-MN leads to modest response rates with short durations of response in the absence of allo-HCT. 12% of pts were able to receive allo-HCT with improvement in OS close to 2 yrs. The decision to treat this poor risk gp of pts should be based on individual pt characteristics and desires. Research Sponsor: None.

Cytomolecular mechanisms of relapse after frontline FLT3 inhibitor (FLT3i)-based therapy in FLT3-mutated (mut) acute myeloid leukemia (AML). First Author: Sankalp Arora, Division of Cancer Medicine, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Data regarding the mechanisms of relapse and outcomes with salvage therapies in patients (pts) with *FLT3* mut AML after frontline FLT3i-based therapy are limited. **Methods:** This is a retrospective study of pts with *FLT3* mut AML who received frontline FLT3i-based therapy at our institution. Molecular and cytogenetic (CG) testing was compared between diagnosis and relapse. **Results:** 272 pts received frontline treatment with FLT3i from 9/2013-7/2024: 214 *FLT3*^{ITD}, 27 *FLT3*$^{ITD+TKD}$ and 31 *FLT3*^{TKD}. Induction therapy was intensive chemotherapy (IC) in 107 pts and low intensity therapy (LIT) in 165 pts [including HMA+venetoclax(VEN)+FLT3i in 93 pts]. FLT3i's used were gilteritinib (n=105), sorafenib (n=96), quizartinib (n=54), midostaurin (n=16), and crenolanib (n=1). Composite complete remission (CRc = CR + CRi) was attained in 203 pts (75%). 97 pts (36%) underwent allogenic stem cell transplant (ASCT) in 1st remission. After a median (med) follow-up of 46 months (mos), 80 pts (35% of responders) relapsed. Post-ASCT relapses occurred in 22/97 pts (23%). Relapse rates in pts receiving IC+FLT3i, HMA+VEN+FLT3i, and LIT+FLT3i (no VEN) were 23% (p<0.01), 31% (p<0.01), and 65% (ref), respectively. At relapse, loss of a *FLT3* mut (ITD and/or TKD) was noted in 34/72 tested pts (47%), with similar rates among transplanted and non-transplanted pts. *FLT3* loss at relapse was more common in pts who received IC+FLT3i or HMA+VEN+FLT3i *vs* LIT+FLT3i (no VEN): 57% vs 32% (p=0.05). Among 55 pts with comprehensive molecular testing at relapse, 24 (44%) had a newly detectable non-*FLT3* mut, most commonly *RAS* pathway (8, 15%), *WT1* (7, 13%), *TET2* (4, 7%), and *IDH1/2* (4, 7%). New mutations at relapse were less common in post-ASCT pts (19% vs 59%; p<0.01). Among *FLT3*^{ITD} pts, new *FLT3*^{TKD} mut at relapse occurred in 8/58 tested pts (14%): 7 had received frontline type 2 FLT3i. New CG abnormalities at relapse occurred in 27/65 tested pts (42%), most commonly trisomy in 11 pts (17%). No *BCR::ABL1* was observed at relapse. 51 pts received 1st salvage therapy after relapse (22 *FLT3*^{wt} and 29 *FLT3*^{mut} relapses). *FLT3*^{wt} relapses had higher CRc rates (41% vs 10%, p=0.02), and a trend to higher med OS (8.6 mos vs 5.7 mos, p=0.13) with salvage therapy compared with *FLT3*^{mut} relapses. **Conclusions:** Loss of *FLT3* mut at relapse occurred in almost 50% of pts receiving frontline FLT3i and was more common in pts receiving IC+FLT3i or HMA+VEN+FLT3i. Common mechanisms of clonal evolution included emergent mutations in *RAS* pathway, *WT1*, and DNA methylation genes (*TET2*, *IDH1/2*). Mutational clonal evolution was less frequent in post-ASCT relapses. Persistent *FLT3* mut at relapse was associated with a worse prognosis. Initial results from a phase II study of dose-adjusted etoposide, prednisone, vincristine, cyclophosphamide, and doxorubicin (DA-EPOCH) ± rituximab (R) + tafasitamab (tafa) for adults with newly-diagnosed (ND) Philadelphia chromosome negative (Ph-) B lymphoblastic leukemia (B-ALL). First Author: Noam Edward Kopmar, Fred Hutchinson Cancer Center, Seattle, WA

Background: For adults with ND Ph- B-ALL, treatment consists of intense multiagent chemotherapy, with outcomes linked to early measurable residual disease negativity (MRD-). The addition of blinatumomab to frontline chemotherapy improves survival, but regimens used are limited by toxicity and complexity. DA-EPOCH ± R is well-tolerated, effective (32% MRD- after cycle [C]1), and relatively simple to administer for ND B-ALL. Tafa is a CD19 monoclonal antibody with activity in B-cell lymphomas. We hypothesized that adding tafa to DA-EPOCH ± R in adults with ND Ph- B-ALL would improve rates of early MRD- without an increase in toxicity. **Methods:** This is a phase II investigator-initiated trial of DA-EPOCH ± R + tafa in adults with ND CD19+ Ph- B-ALL who are not candidates for pediatric-inspired therapy: age >40, unable to receive all care in specialized center, etc. (NCT05453500). The primary endpoint is MRD- (<0.01%) by multiparameter flow cytometry (MFC) after C1; secondary endpoints include rates of MRD- by C4, incidence of grade 3+ non-hematologic adverse events (AEs) by CTCAE v5, and event-free (EFS) and overall survival (OS). Exploratory endpoints include high-throughput sequencing (HTS)-based MRD detection in marrow and cerebrospinal fluid (CSF) by clonoSEQ. DA-EPOCH (+ R if CD20+) with intrathecal chemo given on days (D) 1-5 every 21 D for up to C8 (Cassaday, et al. *Leuk Lymphoma*, 2023). Tafa is given at 12 mg/kg IV on D 1, 8, and 15 in each C. Risk and response are assigned per NCCN. We used a Simon 2-stage design based on results with DA-EPOCH alone: if ≥5/15 pts (33%) achieved MRD- after C1, we would enroll up to 30 pts. **Results:** From 3/2023 to 1/2025, 17 pts have enrolled: 15 are evaluable (2 on treatment without sufficient time to categorize response), with 1 pt removed during C1 for AE (grade 4 AST elevation). Median age was 67 (range: 44-84), and 67% (12/16) had poor-risk cytogenetics. Six pts (38%) received R. In those with sufficient follow-up (f/u), complete response rate was 80% (12/15); MRD- by MFC after C1 was 40% (6/15) and 71% (10/14) by C4. In pts MRD- by MFC, 56% (5/9) were MRD- by HTS. Initial CSF evaluation demonstrated disease by MFC in 3 pts; HTS on CSF was positive in those pts, plus 3 more (6 total). There were 2 grade 4 AEs (reported as serious AEs): sepsis and intracranial hemorrhage. Grade 3 AEs seen in > 1 pt were fibrinogen decreased (5), infections (5), febrile neutropenia (4), hypotension (3), and syncope (2). With the longest f/u at 21 mo (range 0.6-21), 0 pts have relapsed. Four pts have died: 3 from non-relapse mortality unrelated to study treatment (2 following allogeneic transplantation) and 1 from refractory ALL. **Conclusions:** In a cohort of ND Ph- B-ALL, the addition of tafa to DA-EPOCH ± R led to rates of MRD- that are higher than historical rates, with similar toxicity. Since the target C1 MRD- rate was reached in part 1 of the 2-stage design, the trial is proceeding to part 2 and accrual will be completed. While f/u is short, no relapses have been seen. HTS is feasible on CSF and extends the level of detection beyond MFC. Clinical trial information: NCT05453500. Research Sponsor: Incyte.

Outcomes in patients with B-cell precursor acute lymphoblastic leukemia receiving inotuzumab ozogamicin stratified by body mass index. First Author: Wendy Stock, University of Chicago, Chicago, IL

Background: Inotuzumab ozogamicin (InO) is approved for the treatment of adults for relapsed/refractory B-cell precursor acute lymphoblastic leukemia (R/R B-ALL). In previous studies, elevated body mass index (BMI) has been associated with worse outcomes in adult patients treated for ALL. We report the efficacy and safety of InO in adult patients with R/R B-ALL, stratified by BMI. **Methods:** Data from three previous studies, NCT01363297/B1931010 (InO: 0.8–1.8 mg/m^2/cycle [Ph1], 1.6–1.8 mg/m^2/cycle [Ph2]) NCT01564784/B1931022 (InO: 1.5–1.8 mg/m^2/cycle) and, NCT03677596/B1931030 (InO: 0.9–1.2mg/m^2 or 1.5–1.8mg/m^2 per cycle) were pooled, participants (pts) were grouped by formal BMI definitions: <25 kg/m^2 (healthy), 25–30 kg/m^2 (overweight) and >30 kg/m^2 (obese). Data presented as descriptive statistics only. A genAI tool was used with author review to develop the first draft (8 Jan 2025; Pfizer; GPT-4o); authors take full responsibility for the content. **Results:** Data from 338 pts (18–79 years; median age 44, 41% female) were analyzed, with 155 pts in the <25 kg/m^2 group, 116 pts in the 25–30 kg/m^2 group and 67 pts in the >30 kg/m^2 group. Across the <25, 25–30 and >30 kg/m^2 BMI groups, CR/CRi was achieved in 108 (70%), 88 (76%) and 46 (69%) of pts, and MRD negativity observed in 87 (56%), 73 (63%) and 35 (52%) of pts, respectively. At 24 months, the probability of progression-free survival (95% CI) was 19.9% (13.2, 27.5), 12.8% (7.2, 20.1) and 10.9% (4.2, 21.1), and the probability of survival (95% CI) was 28.1% (21.0, 35.6), 22.1% (14.8, 30.3) and 17.5% (9.2, 27.8) in the <25, 25–30 and >30 kg/m^2 BMI groups, respectively. Most pts experienced TEAEs, and incidence was similar across BMI groups (97%–99%). Common hepatic Grade ≥3 TEAEs were sinusoidal obstruction syndrome (SOS) (10 %, <25 kg/m^2; 6%, 25–30 kg/m^2; 9%, >30 kg/m^2) and GGT increase (7 %, <25 kg/m^2; 5%, 25–30 kg/m^2; 5%, >30 kg/m^2). Overall, 143 pts (42%) proceeded to hematopoietic stem cell transplantation (HSCT) after InO treatment, sixty-seven (43%) in the <25 kg/m^2 group, 49 (42%) in the 25–30 kg/m^2 group, and 27 (40%) in the >30 kg/m^2 group. Post-HSCT, non-relapse mortality within 100 days was estimated to be 22% in the <25 kg/m^2 group, 22% in the 25–30 kg/m^2 group and 19% in the >30 kg/m^2 group. Post-HSCT SOS was observed in 18 pts (27%) in the <25 kg/m^2 group, 7 pts (14%) in the 25–30 kg/m^2 group and 6 pts (22%) in the >30 kg/m^2 group, with grade 3–4 SOS observed in 10 (15%), 7 (14%) and 5 pts (19%), respectively. **Conclusions:** In this pooled analysis of pts treated with InO for R/R B-ALL, efficacy and safety outcomes were broadly consistent across BMI groups. However, lower PFS and OS rates at 24 months were noted in pts with higher BMI. Research Sponsor: Pfizer.

Summary of outcomes.

%	<25 kg/m^2 (N=155)	25–30 kg/m^2 (N=116)	>30 kg/m^2 (N=67)
CR/CRi	70	76	69
CR	33	36	40
CRi	37	40	28
MRD-negativity	56	63	52
PFS (24 months)	20	13	11
OS (24 months)	28	22	18

Novel potent and selective inhibitors targeting FLT3 for AML therapy. First Author: Gauthier Errasti, PMC Isochem, Paris, France

Background: Acute Myeloid Leukemia (AML) is a malignancy frequently driven by mutations in the FMS-like tyrosine kinase 3 (FLT3) gene. The FLT3 internal tandem duplication (ITD) and tyrosine kinase domain (TKD) mutations, particularly D835 and F691, appear in approximately 30% of AML patients, often leading to poor prognosis and resistance to existing therapies. Gilteritinib and Quizartinib are two FDA-approved FLT3 inhibitors, with the former approved only for relapsed/refractory AML and the latter approved only for newly diagnosed AML. Quizartinib does not target TKD resistance mutations, whereas Gilteritinib's efficacy on FLT3-ITD-D835Y is limited and it is not effective against FLT3-ITD-F691L. Consequently, there is a critical need for next-generation FLT3 inhibitors that can address all of these mutations. **Methods:** We have characterized efficacy of two novel FLT3 inhibitors, CCM-405 and CCM-445. *In vitro* enzymatic binding affinities were determined by the KdELECT assay, and cellular IC_{50}s were determined by the Cell-Titer Glo assay. *In vivo* antitumor activity of CCM-405 / 445 was evaluated in mutant cell line-derived xenograft (CDX) models of AML. Tumor growth inhibition (TGI) was measured in the FLT3-ITD luciferase-expressing MV4-11 (MV4-11-luc) systemic xenograft model as well as subcutaneous xenograft models of FLT3-ITD F691L and D835Y mutants. Efficacy of novel inhibitors was compared with Gilteritinib. *In vitro* efficacy was compared with experimental FLT3 TKD mutant inhibitor Luxeptinib. **Results:** Enzymatically, CCM-405 / 445 inhibit FLT3-ITD, FLT3-ITD-D835V and FLT3-ITD-F691L with K_ds of 12 nM / 4.1 nM, 1.9 nM / 0.39 nM and 1.6 nM / 0.4 nM, respectively (Luxeptinib K_ds: ITD-D835V: 550 nM; ITD-F691L: 97 nM). CCM-405 / 445 inhibit the proliferation of Ba/F3 FLT3-ITD and FLT3-ITD D835Y cell lines with potency comparable to Gilteritinib, and FLT3-ITD F691L with potency superior to Gilteritinib, and are significantly less toxic to Ba/F3 FLT3 WT than to the mutants (Luxeptinib: negligible cellular mutant/WT selectivity). CCM-405 / 445 are also potent against human AML cell lines MV4-11 and MOLM-13. *In vivo*, in the systemic FLT3-ITD model, CCM-405 induced ~90% tumor regression (> 100% TGI) and was significantly more effective than Gilteritinib ($p < 0.001$), which did not regress the tumor, when these agents were administered orally at doses corresponding to equal fractions of their maximum tolerated doses (MTDs). In both FLT3-ITD-F691L and FLT3-ITD-D835Y CDX models, CCM-405 induced almost complete tumor regression (>100% TGI). Both novel inhibitors were significantly more efficacious than Gilteritinib (45% and 4% TGI, respectively). **Conclusions:** Novel FLT3 inhibitors have been developed that can both target FLT3-ITD and potentially overcome mutational resistance to FDA-approved FLT3 inhibitors. These agents are significantly more effective than Gilteritinib and have potential clinical applications. Research Sponsor: CCM Biosciences.

Brexucabtagene autoleucel (Brexu-cel) as consolidation treatment in adults with B-cell acute lymphoblastic leukemia. First Author: Niranjan Khaire, University of Texas MD Anderson Cancer Center, Houston, TX

Background: Brexu-cel is a CD19 CAR T cell approved for adult patients with R/R B-cell ALL. We aimed to evaluate toxicity/efficacy in adult pts with marrow blasts <5%. **Methods:** We retrospectively analyzed pts (≥18y) with B-ALL who received brexu-cel (not on clinical trials) at MDACC, Houston. Pts were included if they had marrow blasts <5% and without any clinical (and imaging) evidence of extra-medullary disease (EMD) at the time of LD. CAR T levels were monitored post infusion in PB using flow cytometry. **Results:** 46 pts received Brexu-cel from Feb 2022 to Dec 2024. Baseline characteristics are as in table 1. 36/46 pts were NGS MRD negative (30 had undetectable disease at 10^{-6} sensitivity and 6 had disease detectable < LLOD of the assay; clonoSEQ). 10/36 pts were positive at values ranging from 3-3283 cells/million. Post infusion peak CAR T expansion was noted at a median of 8 days from infusion and the median peak expansion was 13.5 cells/μL [range <1-2222]. A peak CAR T expansion threshold of 15 cells/μL was identified as an optimal predictor for RFS with a neg predictive value of 97%. 23/46 (50%) pts of the whole cohort had a peak CAR T expansion of ≥15 cells/μL. Amongst the 10 pts who were NGS MRD positive at the time of CAR T infusion, the median peak CAR T expansion was 77.5 cells/μL [range 3-573] and 7/10 (70%) had a peak expansion of ≥15 cells/μL. Amongst those (n=36) who were NGS MRD negative at the time of CAR T infusion, the median peak CAR T expansion was 10 cells/μL [range <1-2222] and 16/36 (44%) had a peak expansion of ≥15 cells/μL.Among the 23 pts who had a peak expansion of ≥15 cells/μL, 1 had a relapse, 1 died while in MRD negative remission and the remaining 21 (91%) are alive in remission. In contrast, among the 23 pts with a peak expansion of <15 cells/μL, 8 pts had a molecular/clinical relapse while 15/23 (65%) were alive in remission. With a median follow-up of 12.8 mos (range 1-27), the 12-mo RFS is 71% for the whole cohort (86% in the CAR T expansion ≥15 cells/μL; 58% in the peak CART expansion <15 cells/μL). The 12-mo OS is 94% for all pts. 6 pts had a subsequent allo-SCT after the CAR T infusion at the treating physician's discretion at a median of 3.6 mos (range 2.8-8.8) from the cell infusion. Among the 3 pts with G3-4 CRS/ICANS, (table1) the peak CAR T expansion was 102, 1270 and 2222 cells/μL. **Conclusions:** Brexu-cel CAR T expansion was observed even in pts with no morphologic disease. CAR T expansion threshold of ≥15 cells/μL could identify pts with durable RFS. Rates of G3-4 CRS/ICANS were low when brexu-cel was used as consolidation. Research Sponsor: None.

Impact of *TP53* mutations and variant allelic frequency on survival in adults with newly diagnosed acute lymphoblastic leukemia. First Author: Roberta Santos Azevedo, Department of Leukemia, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: *TP53* mutations are associated with poor outcomes in acute lymphoblastic leukemia (ALL); however, a variant allele frequency (VAF) cutoff (mutation burden) which may more accurately predict overall survival (OS) has not been identified. **Methods:** We retrospectively analyzed adult patients (pts) with newly diagnosed ALL with *TP53* mutation status tested at diagnosis. The maximum log-rank test was used to evaluate the impact of *TP53* VAF. **Results:** Among 654 pts, 115 (18%) harbored *TP53* mutations. *TP53* mutations were more common in B-cell ALL (19% vs. 6% in T-cell ALL, p=0.003), older age (61 vs. 45 years, p<0.001), low hypodiploid/near-triploid (Ho-Tr) karyotype (98% vs. 10%, p<0.001), and therapy-related ALL (20% vs. 9%, p<0.001). 11 pts (10%) harbored ≥2 *TP53* mutations. The median *TP53* VAF was 42% (range, 1-94%) and was higher in pts with Ho-Tr karyotype (54%) compared to diploid karyotype (41%, p=0.02). *TP53*-mutated ALL was associated with significantly inferior OS in pts ≥60 years of age (2-year OS 55% vs. 69%; p=0.03). In the older pts, *TP53* VAF was associated with worse OS and the optimal cutoff was 45%. Among pts ≥60 years, *TP53* VAF ≥45% had a 2-year OS of 37% compared to 71% for those with VAF <45% (p=0.01), which was driven by higher rates of both relapse and non-relapse mortality. In older pts who received frontline inotuzumab ozogamicin (InO) and/or blinatumumab (Blina), *TP53* VAF ≥45% remained a strong predictor of OS (2-year OS 37% vs. 75% for VAF <45%; p=0.04). By multivariate analysis (MVA) in pts aged ≥60 years, *TP53* VAF ≥45% (HR 1.8, 95% CI 1.0-3.2, p=0.03) and complex karyotype (HR 2.9, 95% CI 1.2-7.3, p=0.02) were associated with inferior OS, while frontline InO and/or Blina trended toward improved OS (HR 0.6, 95% CI 0.3-1.0, p=0.07). *TP53*-mutated ALL was associated with a trend towards inferior OS in pts <60 years of age (2-year OS 66% vs. 88%; p=0.06), despite higher rates of allo-SCT in pts with *TP53*-mutated ALL (47% vs. 22% for *TP53* wild type; p<0.001). In these younger pts, *TP53* VAF was not prognostic (2-year OS 72% vs. 61% for VAF ≥45% vs. <45%; p=0.6). Outcomes were similar in younger pts with *TP53* VAF≥45%, irrespective of allo-SCT status (2-year OS of 68% vs. 74% for those with VAF≥45% who underwent allo-SCT vs. those who did not; p=1.0). By MVA in younger pts, Ph-like was associated with worse OS (HR 2.1, 95% CI 1.3–3.1, p=0.002), while frontline InO and/or Blina significantly improved outcomes (HR 0.5, 95% CI 0.3–0.7, p<0.001). Neither *TP53* mutation status nor VAF impacted OS on MVA. **Conclusions:** *TP53* mutations were associated with worse outcomes in both younger and older adults with ALL. VAF ≥45% can risk stratify pts aged ≥60 years but did not impact OS in younger pts. Incorporating frontline InO and/or Blina into therapy might improve outcomes of *TP53*-mutated ALL. A phase 2 study of olutasidenib in relapsed/refractory acute myeloid leukemia: Outcomes by number of prior treatment regimens. First Author: Eunice S. Wang, Roswell Park Comprehensive Cancer Center, Buffalo, NY

Background: A subset of patients (7-14%) with acute myeloid leukemia (AML) have mutations in the isocitrate dehydrogenase 1 gene (m*IDH1*). Olutasidenib (OLU), a selective, potent, oral inhibitor of mIDH1, is approved for treatment of relapsed/refractory (R/R) m*IDH1* AML. Results from the phase 2 pivotal cohort (NCT02719574) demonstrated clinical efficacy and tolerability of OLU, with a complete remission/complete remission with partial hematological recovery (CR/CRh) rate of 35% for a median duration of 25.9 months. Here we evaluated the efficacy and safety of OLU in patients with R/R AML grouped by the number of prior regimens. **Methods:** The pivotal cohort of the phase 2 study assessed OLU 150 mg BID in adult patients and included efficacy endpoints of CR/CRh, overall response rate (ORR), duration of response (DOR), and overall survival (OS). This post hoc analysis evaluated outcomes based on when patients received OLU: after 1-2 or ≥3 prior lines of therapy. **Results:** There were 147 patients in the efficacy evaluable analysis set (1-2 prior regimens, n=93; ≥3 prior regimens, n=54). Median age was 72 years in patients with 1-2 prior regimens and 66.5 years in those with ≥3 prior regimens. Forty-three percent and 33% of patients had prior treatment with a hypomethylating agent, and 11% and 4% received prior venetoclax therapy (1-2 and ≥3 prior regimens groups, respectively). In patients with ≥3 prior regimens, 31% had prior hematopoietic stem cell transplantation vs none in those with 1-2 prior regimens. Those in the 1-2 prior regimens group had a higher ORR and CR/CRh rate and longer median OS, with a larger percentage of patients achieving CR, than those in the ≥3 prior regimens group (Table 1). All patients experienced ≥1 treatment-emergent adverse event (TEAE). Serious TEAEs were reported in 73% (68/93) and 77.8% (42/54) of patients in the 1-2 and ≥3 prior regimens groups, respectively, and TEAEs ≥grade 3 occurred in 89.2% (83/93) and 90.7% (49/54). The most common TEAEs included nausea, decreased red blood cell count, and fatigue. No new safety signals were identified. **Conclusions:** Higher response rates (including CR and CRh) and greater survival were observed in patients receiving OLU following 1-2 versus ≥3 prior treatment regimens, providing rationale for initiating OLU earlier in the R/R treatment paradigm. Clinical trial information: NCT02719574. Research Sponsor: Forma Therapeutics, Inc; Rigel Pharmaceuticals, Inc.

Matching-adjusted indirect comparison (MAIC) of olutasidenib (OLU) and ivosidenib (IVO) in isocitrate dehydrogenase 1 (IDH1)-mutated relapsed/refractory (R/R) acute myeloid leukemia (AML). First Author: Justin M. Watts, University of Miami, Sylvester Comprehensive Cancer Center, Miami, FL

Background: OLU and IVO are allosteric type II IDH1 inhibitors approved by the FDA and recommended by NCCN for *IDH1*^{mut} R/R AML patients based on single-arm trials. In the absence of a head-to-head trial, a MAIC was performed to estimate relative treatment effects of OLU vs. IVO in *IDH1*^{mut} R/R AML. **Methods:** Analyses used registrational data for OLU (Study 2102-HEM-101; N=147; individual-level data) and IVO (AG120-C-001; N=174; study-level data). A logistic propensity score model was used to estimate weights based on the first moment for Study 2102-HEM-101 patients to match AG120-C-001, including the following characteristics identified from a literature review, validated by clinical experts: number of prior systemic therapies, age, prior stem cell transplant, AML type, relapse type, cytogenetic risk, ECOG PS, and *IDH1* mutation. Complete remission (CR) and CR + CR with partial hematological recovery (CRh) were summarized as odds ratios (ORs) and 95% confidence intervals (CIs). Duration of CR (DoCR), duration of CR+CRh, and OS were summarized in terms of difference in medians and 95% CIs. OS was also summarized in terms of hazard ratios (HRs) and restricted mean survival time (RMST). A simulated treatment comparison (STC) was performed as a sensitivity analysis. **Results:** Table 1 summarizes MAIC-adjusted estimates. Naïve and adjusted rates of CR and CR+CRh for OLU vs. IVO were comparable, but point estimates favored OLU for CR. Differences in median DoCR were not statistically significant but favored OLU over IVO. OLU had a significantly longer duration of CR+CRh than IVO. For OS, the naïve comparison suggested OLU was better than IVO (HR=0.72; 95% CI 0.55, 0.92), whereas the MAIC was uncertain but favored OLU. STC results were consistent with the MAIC. **Conclusions:** Naïve and adjusted rates of response for OLU vs. IVO were comparable (adjusted point estimate favored OLU for CR and IVO for CR+CRh), while a longer duration of CR+CRh was observed with OLU. Adjusted OS was similar between the two groups, although the HR favored OLU, and could not be estimated by response category given lack of patient characteristics and reduction in effective sample size (ESS). Results rely on the assumption of no unmeasured confounders which reflects a limitation of the methodology. Research Sponsor: Rigel Pharmaceuticals, Inc.

Investigating age of onset and prognosis of p53 mutant myeloid malignancies in African Americans. First Author: Brendon Fusco, Montefiore Einstein Comprehensive Cancer Center, Bronx, NY

Background: TP53 mutations drive poor outcomes in Myelodysplastic Syndrome (MDS) and Acute Myeloid Leukemia (AML), aggressive hematologic malignancies characterized by clonal abnormalities in myeloid hematopoiesis. Prognostic scoring systems incorporate cytogenetic and molecular abnormalities based on data from majority White populations and have limited applicability to minorities. Racial disparities in survival are well-known, with Black patients experiencing worse outcomes. While TP53 mutations are associated with poor outcomes, there is limited data about their implications in minority populations. Objective: To study TP53 mutation status, variant allele frequency (VAF), and co-mutations on outcomes in MDS and AML between White and minority populations in the Bronx, a racially diverse region. **Methods:** This retrospective cohort study analyzed 84 patients diagnosed with TP53 mutated AML and MDS between 2014 and 2024 at Montefiore Medical Center. Data included race/ethnicity (Black, White, Hispanic), age, age at diagnosis, gender, diagnosis, first-line chemotherapy, and bone marrow blast percentage. Molecular data included TP53 mutation status (bi- vs. mono-allelic), variant allele frequency (VAF), and co-mutations. Co-mutation patterns will be presented at the meeting. Comparisons were made using descriptive statistics, and survival outcomes were analyzed using Cox proportional hazards models adjusted for age and gender. **Results:** Black patients were diagnosed at a younger age than White or Hispanic patients (mean: 63.7 vs. 72.6 vs. 65.9 years, p = 0.029) and had shorter median overall survival (3.9 vs. 16.4 vs. 10 months, p = 0.014). Black patients had higher mean VAF (48.1 vs. 31.9 vs. 38.2, p = 0.047) and were more likely to have co-mutations than isolated TP53 mutations, though this was not significant (OR 4.21, p = 0.06). Patients with VAF above the median had a threefold increased risk of death (aOR 3.14, p = 0.019), independent of age or gender. **Conclusions:** Black patients with TP53 mutant MDS and AML present younger and have worse outcomes than White patients, associated with a higher TP53 VAF and more frequent co-mutations. This is to our knowledge the largest dataset of TP53 in minorities with MDS and AML; highlighting the need for personalized prognostic models that incorporate minorities to overcome racial disparities in myeloid malignancies. Research Sponsor: None.

Socioeconomic and clinical predictors of 30-day readmissions in AML patients undergoing allogeneic stem cell transplantation. First Author: Aditi Sharma, Barbara Ann Karmanos Cancer Institute, Detroit, MI

Background: 30-day readmissions among acute myeloid leukemia (AML) undergoing allogeneic hematopoietic stem cell transplantation (allo-HCT) are a key quality metric, contributing to morbidity, mortality, and healthcare costs. We analyzed age-specific characteristics and factors associated with readmissions. **Methods:** Using the 2016–2021 National Readmissions Database, we identified adult AML hospitalizations for allo-HCT, stratified into <45, 45–65, and >65 years. Patient demographics, hospital factors, comorbidities, complications and outcomes were analyzed. Multivariable Cox regression determined adjusted hazard ratios for 30-day readmissions. **Results:** Of 15,757 admissions, 3,743 were <45, 8,169 were 45–65, and 3,844 were >65 years. The younger cohort had a higher proportion of females (53% vs. 47% vs. 39%, p<0.001). Overall infection rates, acute graft-versus-host disease, and use of total body irradiation were similar across groups (p>0.05). Mean LOS was 29 vs. 32 days for >65 and <45 years (p<0.001). Inpatient mortality was 4%, 5% and 6% in young, middle-aged and older group (p=0.02), while readmission rates (27% vs. 27% vs. 30%, p=0.16) and mortality during readmission (5% vs. 7% vs. 7%, p=0.42) were comparable. Mean time to readmission was 12 days, primarily driven by infections (34%), GI/hepatobiliary complications (10%), active AML (5%), & kidney dysfunction (5%). Lower-income quartiles vs. wealthiest and Medicare vs. private insurance were linked to higher readmission risk. Depression further elevated risk, whereas home-health care lowered it. Among clinical variables, GVHD, chronic kidney disease, and acute respiratory failure each predicted higher readmission (see Table). **Conclusions:** Our findings highlight disparities in 30-day readmissions after allo-HCT for AML, driven by socioeconomic, clinical, and mental health factors. Targeted interventions, such as optimizing post-discharge care and providing psychosocial support, may help reduce the readmission burden in high-risk patients. Research Sponsor: None.

Outcomes of therapy-related AML (T-AML) with venetoclax-based therapies. First Author: Jennifer Croden, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: T-AML refers to AML in patients (pts) with prior exposure to cytotoxic chemotherapy (CT) and/or radiotherapy (RT) and is often associated with adverse risk (AR) genomics. Evaluation of outcomes of T-AML with respect to type of prior therapy exposure, AML genomics, and contemporary AML therapy, especially with venetoclax (VEN), is warranted. **Methods:** We retrospectively analyzed pts aged ≥18 years with newly diagnosed T-AML. Pts with an antecedent myeloid disorder (MDS/CMML) prior to AML diagnosis were excluded; thus, including only pure T-AML. Composite complete response (CRc) included CR and CRi and overall response (OR) included CRc + morphologic leukemia free state. **Results:** From 1/2012 to 12/2023, 317 pts were included; median (med) age was 69 years (range 21-92). Overall, 120 (38%) received prior CT alone, 77 (24%) received prior RT alone (RT), and 114 (36%) received both (CRT). The most common prior malignancy was non-Hodgkin lymphoma (37%) in the CT group, prostate cancer (60%) in the RT group, and breast cancer (45%) in the CRT group.Among 286 pts with complete cytogenetic data, 180 (63%) were adverse, of whom 132 (46%) had complex karyotype (CK; 42% of CT, 48% of RT, and 61% of CRT groups). *TP53* was mutated in 113/286 patients (40%) tested (36% of CT, 35% of RT, and 47% of CRT groups). Stratified by type of CT received, CK and *TP53* mutation were seen in 5/5 (100%) and 3/5 (60%) of PARP inhibitor-exposed, 98/184 (53%) and 78/183 (43%) of alkylator-exposed, and 21/36 (58%) and 16/37 (43%) of topoisomerase inhibitor-exposed. Overall, 217/304 (71%) were ELN 2017 AR. In total, 251 pts (79%) received low-intensity AML therapy (LIT). CRc and OR was achieved in 122 (49%) and 146 (58%) pts treated with LIT (vs 58% and 65% with LIT+VEN). In pts treated with intensive chemotherapy (IC), the CRc and OR rate was 64% and 68% (vs 68% and 73% with IC+VEN). Overall, med RFS was 7.2 months (mos; 95% CI 5.6-8.9), and med OS was 11.8 mos (10.0-13.7). Med OS was 5.7 vs 9.0 mos (p=0.02) with LIT and LIT+VEN, respectively (resp), and med OS was 10.9 vs 48.9 mos (p=0.03) for IC vs IC+VEN, resp. Among pts treated with LIT+VEN, med OS was 14.0, 12.4, and 9.6 mos in those who had received prior CT, RT and CRT, resp; when stratified by ELN 2017 criteria, med OS was 24.6, 9.4 and 4.8 mos in the favorable, intermediate and AR groups, resp. Sixty-seven (21%) pts underwent HSCT with a landmarked comparison showing improved OS with HSCT (28.5 months vs 9.4, p<0.001). On multivariate Cox analysis in the LIT+VEN group, with forward model selection, using variables age </≥ 60, adverse cytogenetics, *ASXL1, IDH1/2, FLT3-ITD, RAS, RUNX1, TP53* status, HSCT, and prior therapy group, HSCT was favorable (HR=0.19, 95% CI 0.01-0.37), along with *IDH2* and *NPM1* mut, while *RAS* and *TP53* mut was associated with higher hazards of death. Other factors were not significant. **Conclusions:** Venetoclax improves outcomes in T-AML. In LIT+VEN treated patients, ELN 2024 risk stratification is prognostic. Research Sponsor: None.

Impact of clinical trial treatment and area deprivation index in the outcomes of adolescent and young adult patients with acute myeloid leukemia. First Author: James Wesley Hill, Department of Internal Medicine, McGovern Medical School, The University of Texas Health Science Center at Houston (UTHealth Houston), Houston, TX

Background: Socioeconomic status (SES) is an independent prognostic factor in patients (pts) with acute myeloid leukemia (AML). Adolescent and young adult (AYA, age 15-39) pts with AML traditionally have better outcomes than older adult pts. Prior studies have shown that SES adversely impacts outcomes in AYA pts. Area Deprivation Index (ADI) is one of the most advanced SE tools, incorporating 17 SE factors to rank neighborhoods based on disadvantaged status. Higher ADI score corresponds to more disadvantaged neighborhoods. Here, we report the largest cohort of AYA pts with AML treated at a single institution with molecular, cytogenetic (CG) and ADI data. **Methods:** AYA pts with AML treated at MD Anderson Cancer Center from 3/2013 to 3/2023 were included. ADI data was downloaded from https://www.neighborhoodatlas.medicine.wisc.edu. Backward elimination was applied to the multivariable model, removing variables sequentially until only variables with p<0.1 remained. **Results:** 190 AYA pts were included (non-Hispanic White, NHW-139, non-Hispanic Black-24, Hispanic-16, Asian-11). Median age was 31 years (17-39). 81 pts (43%) had adverse risk by ELN 2022 and 135 (71%) were treated in clinical trials. Both median overall survival (OS) and relapse-free survival (RFS, not censored for transplant (SCT)) was 85.4 months, respectively. ADI national rank 61-100 (HR 1.906, 1.069-3.396, p=0.029), complex CG (HR 2.854, 1.530-5.324, p=0.001), intermediate risk (HR 2.514, 1.160-5.449, p=0.020), and adverse risk (HR 4.257, 1.975-9.177, p<0.001) adversely affected OS. Notably, treatment in clinical trials (HR 0.499, 0.309-0.806, p=0.005) and SCT (HR 0.499, 0.288-0.862, p=0.013) led to longer OS. Only complex CG and adverse risk negatively impacted RFS. **Conclusions:** AYA pts from disadvantaged neighborhoods (ADI national rank 61-100) had an inferior OS. Our data showed that treatment in clinical trials and SCT led to longer OS. These results underscore the importance of treatment in clinical trials and SCT for improving OS in AYA, particularly for AYA pts from disadvantaged neighborhoods. Efforts to improve access to clinical trials and SCT, especially for AYA pts from disadvantaged neighborhoods are needed. Research Sponsor: None.

Phase II trial of 10-day ASTX727 (decitabine/cedazuridine) in combination with venetoclax for relapsed or refractory acute myeloid leukemia. First Author: Mehmet Uyanik, Department of Leukemia, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: The disease outcomes in relapsed refractory acute myeloblastic leukemia (R/R AML) remain dismal. We previously demonstrated safety and encouraging activity of 10-day regimen of IV decitabine with venetoclax (VEN) in R/R AML. In this prospective clinical trial, we investigate the efficacy of a novel 10-day induction regimen with fully oral combination therapy for pts with R/R AML. **Methods:** We conducted a phase II trial in pts with R/R aged ≥18 y with ECOG performance status ≤2 was eligible for enrollment. Exclusion criteria included GI conditions affecting absorption of the drugs, active GvHD, and APL. For induction, pts received oral ASTX727 (100mg/35mg) D1-10 and VEN 400mg D1-28. In subsequent cycles, ASTX727 was reduced to D1-5 in pts achieving CR/Cri (NCT04975919). **Results:** Between December 2021 and March 2024, 20 were enrolled on this trial. The median age was 65 (39-76), 25% of pts (n=5) had therapy-related AML. 60% pts (n= 12) had prior VEN exposure. Eighty-five percent of the pts were either and/or harbored complex karyotype. Median duration of the treatment was 1.7 m (0.5-9.5) and median no of cycles was 1 (range 1-6). The composite CR/CRi/MLFS rate was 40% (n=8), with best response achieved at median 1.3 m. Duration of response in responders was 8.5 m (2.9-30.8). MRD was negative in 25% (2/8) of responding pts, and 3 pts (15%) proceeded to stem cell transplantation (SCT). Two transplanted patients (67%) were in CR before SCT, while 1 patient (33%) was in MLFS. The median OS was 8.6 m. VEN-naive pts showed longer OS (10.5m vs 4.4m with prior VEN, p=0.12). Responding pts who could be bridged to SCT had better OS benefit (not reached vs 6.6m, p=0.01). The median OS of pts with $TP53^{mut}$ was 3.1 m vs 8.6 m in pts who were $TP53^{WT}$ (p=0.60). The 4-week mortality rate was 6%, and the 8-week mortality rate was 17%. Treatment-emergent adverse events of Gr 3/4 were observed in 81% of pts (17), with infections and febrile neutropenia being the most frequent complications (35% each). After a median follow up of 8.7 m (0.5-30.8), 80% of pts (16) died. Among the deaths, 40% were attributed to disease progression, and 25% to bacterial infections. None of the deaths were associated with bacterial infections occurred in patients with CR. **Conclusions:** The 10-day ASTX727-VEN combination showed safety profile comparable to other HMA-VEN regimens in salvage setting. TP53 wild type, VEN-naïve pts and those who could be bridged to SCT had better outcomes. Novel therapies are needed to improve outcomes in R/R AML. Clinical trial information: NCT04975919. Research Sponsor: MD Anderson Cancer Center.

Factors associated with frailty in vulnerable hematopoietic cell transplantation candidates. First Author: Hyunhae Lee, University of Washington, Seattle, WA

Background: Allogenic hematopoietic cell transplantation (allo-HCT) is increasingly offered to older patients and those with comorbidities. Frailty, characterized by reduced muscle strength and functional decline, is associated with lower quality of life, increased mortality, and higher hospitalization after allo-HCT. However, frailty prior to allo-HCT remains understudied. The study investigated factors associated with frailty in allo-HCT candidates prior to transplant. **Methods:** This cross-sectional analysis utilized data from the ACE-BMT study, an ongoing longitudinal, unblinded, randomized seamless phase II/III trial, that enrolled adult patients allo-HCT candidates either age of ≥65 years, with HCT comorbidity index (HCI-CI) score of ≥3, or 4-meter walk speed test <0.8 m/s. We classified frailty in participants at baseline using the Fried frailty phenotype: 1) unintentional weight loss, 2) low energy (Patient Health Questionnaire 9-item [PHQ-9]), 3) grip strength or stand-up time below standard, 4) 4-meter walk test < 0.8m/s, and 5) the lowest 20% of physical functioning (Medical Outcomes Study Physical Health). Participants were classified as frail (≥3), pre-frail (1-2), or not frail (0). We assessed pre-HCT variables including demographics, comorbidities, and self-reported social support (ENRICHED Social Support Instrument), symptom severity and interference with daily life (MD Anderson Symptom Inventory), depression (PHQ-9), cognitive impairment (Bless Orientation Memory Concentration), quality of life (Euro Quality of Life 5-Dimensions), and functional status (Karnofsky Performance Status). We compared baseline characteristics based on frailty status and conducted a multivariable logistic regression to identify the factors associated with frailty. **Results:** Among 381 patients (mean age 65.49, 38.32% female) included in the analysis, 81.7% were pre-frail and frail at baseline. Compared to non-frail, participants as frail were younger (mean age 66.49 vs 61.49), more likely to be female (35.7% vs. 48.7%), to have cardiovascular disease (1.3% vs. 9.2%) and diabetes (9.8% vs. 23.7%), and a HCT-CI score ≥3 (39.3% vs. 61.8%). They also self-reported greater depression, symptom severity and interference, cognitive impairment, and poorer quality of life. In a multivariable logistic regression model, older age (OR: 0.98, 95% CI: 0.95, 1.00), higher symptom interference (OR: 1.04, 95% CI: 1.01-1.08), and depression (OR: 1.14, 95% CI: 1.03-1.27) were significantly associated with frailty. **Conclusions:** Frailty prior to allo-HCT is associated with symptom burden and depression, underscoring the importance of addressing these factors pre-HCT. These findings provide preliminary support for psychological screening and symptom-focused interventions. Future analyses will examine the incidence and risk factors of post-HCT frailty and its association with clinical outcomes. Research Sponsor: NIH, NCI; R01CA227092.

Allogeneic hematopoietic cell transplantation for acute leukemia patients not in complete remission. First Author: Shlomo Elias, Hadassah University Hospital Jerusalem Israel, Jerusalem, Israel

Background: Current guidelines support allogeneic hematopoietic cell transplantation (allo-HCT) in patients with acute leukemia who achieve complete remission (CR) and are at high risk for relapse. Patients with primary refractory disease or those refractory to re-induction therapy after relapse have a poor prognosis without allo-HCT. While several studies have explored the role of allo-HCT in this setting, most have focused on patients receiving myeloablative conditioning (MAC) and have not included contemporary transplant patients or accounted for the impact of molecular genetic risk factors. Consequently, the benefit of allo-HCT in this patient population remains unclear. **Methods:** This study evaluated the outcomes of patients with acute leukemia from two centers who underwent allo-HCT between 2009 and 2020 while not in CR at the time of transplant, receiving either myeloablative conditioning (MAC) or reduced-intensity conditioning (RIC) regimens. **Results:** Our cohort included 196 patients who underwent transplantation between 2009 and 2020, with the majority (86%) diagnosed with acute myeloid leukemia (AML). At 36 months post-transplant, the probability of overall survival (OS) was 24% (95% CI: 19-31). In multivariable analysis, the presence of circulating blasts, recipient CMV seropositivity, and low pre-transplant albumin levels were associated with reduced OS. The cumulative incidence of relapse was 54% (95% CI: 47-61) at 36 months, with the presence of circulating blasts being significantly associated with an increased incidence of relapse. Among AML patients, the presence of at least one high-risk mutation (TP53, RUNX1, ASXL1, or FLT3-ITD, historically considered high-risk per National Comprehensive Cancer Network [NCCN] criteria version 3.2021) was also associated with an increased incidence of relapse. **Conclusions:** Allo-HCT provides a durable remission in a select group of patients with relapsed or refractory acute leukemia, with an overall survival of 24% at 36 months. The presence of circulating blasts, CMV seropositivity, and low albumin levels at the time of allo-HCT were associated with increased relapse and inferior OS in this retrospective analysis. The impact of these factors should be further investigated in larger, prospective cohorts to better identify patients with acute leukemia not in CR who would benefit from allo-HSCT. Exploratory analyses of immune reconstitution biomarkers from a Ph1b study of an investigational, oral, live biotherapeutic, SER-155, in adult allo-HCT. First Author: Emily Walsh, Seres Therapeutics, Cambridge, MA

Background: SER-155 is an investigational, oral, live biotherapeutic product (LBP) comprised of 16 bacterial strains designed to decolonize gastrointestinal (GI) pathogens, improve epithelial barrier integrity, and modulate immune responses to prevent bloodstream infections (BSI). In the placebo-controlled cohort 2 of the phase 1b study, SER-155-001 (NCT04995653), SER-155 was generally well tolerated with a safety profile similar to placebo and the incidence of BSIs, a secondary endpoint, was significantly lower after treatment with SER-155 when compared to placebo. We report exploratory analyses of biomarkers of T cell expansion relevant for immune reconstitution after HCT. **Methods:** Participants were randomized 1:1 to receive 4 days of oral vancomycin (for microbiome conditioning) and 10 days of SER-155 or placebo/placebo administered pre-HCT (course 1) and post-neutrophil engraftment (course 2). Primary endpoints were safety and SER-155 strain engraftment (PK). Exploratory endpoints included plasma cytokine concentrations measured by ELISA and analysis of peripheral blood mononuclear cells (PBMCs) by flow cytometry. **Results:** Demographics were comparable across treatment arms. 34 of 45 randomized participants were treated and received allo-HCT (SER-155, 20; placebo, 14); 28 received course 2 (SER-155, 19; placebo, 9). SER-155 strain engraftment was observed in the peri-transplant period (median 11.5 strains after course 1) and post-HCT (median 11 strains after course 2 and HCT Day 100). Significant differences and trends in cytokines of systemic inflammation and immune homeostasis were observed relative to placebo prior to HCT Day 0 and post-HCT. On HCT Day 0, both arms had similar concentrations of IL7 and IL15 (Table 1). However, after course 2, and at HCT Day 100, significantly higher concentrations of IL7 were observed in the SER-155 arm relative to placebo (p=0.02, and p=0.003, respectively). In a preliminary analysis of PBMCs from a subset of participants, a high frequency of CD4+ T cells were observed in the SER-155 arm at the same timepoints. For homeostatic cytokine IL15, no significant differences were observed between arms. **Conclusions:** The significantly higher concentrations of IL7 with SER-155 treatment and observed frequency of CD4+ T cells support the potential role of the GI microbiome in promoting homeostatic expansion of peripheral T cells and immune reconstitution important for successful HCT. Clinical trial information: NCT04995653. Research Sponsor: Seres Therapeutics.

Median plasma IL7 and IL15 (pg/mL), SER-155 vs. placebo (generalized linear model).

HCT Day or event	SER-155 IL7	Placebo IL7	SER-155 IL15	Placebo IL15
D0	13.8	13.0	31.9	30.4

Peripheral blood cell-free DNA testing as a predictor for relapse post-allogeneic stem cell transplant for AML. First Author: Vanisha Patel, Hackensack University Medical Center, Hackensack, NJ

Background: Allogeneic stem cell transplantation (allo-SCT) is a curative option for acute myelogenous leukemia (AML), but relapse is a challenge. Monitoring minimal residual disease post-transplant through tumor-derived circulating cell-free DNA (cfDNA) in peripheral blood (PB) and bone marrow is an emerging strategy. Persistent mutations in cfDNA may be prognostic indicators of relapse. **Methods:** This single-center retrospective study included 120 AML patients who received allo-SCT from 2018 to 2022, with PB cfDNA collected between Days 30-200. Samples were analyzed by commercial assays (Liquid Trace or Hematology Profile Plus), that use next generation sequencing, Sanger Sequencing, and fragment length analysis to identify molecular abnormalities in DNA of 179 genes associated with hematologic neoplasms. cfDNA positivity was determined by identifying gene amplifications, deletions, single nucleotide variations and indels, including reported variant allele frequency (VAF) above 0. cfDNA negativity was defined by absence of genomic alterations. The primary endpoints were the association of cfDNA presence with overall survival (OS) and relapse-free survival (RFS). A secondary endpoint was the association of mutation risk (adverse/intermediate) with OS and RFS. **Results:** Patients were grouped by cfDNA presence at Day 45 ± 15 (n=30, median survival time 1.173 years) and Day 150 ± 50 (n=90, median survival time 1.4822 years). Kaplan-Meier analysis revealed that patients positive for PB cfDNA at Day 150 ± 50 had significantly worse OS ($p<0.0001$) and RFS ($p<0.0001$) compared to cfDNA negative. Similarly, cfDNA positivity at Day 45 ± 15 also correlated with worse OS ($p<0.01$) and RFS ($p<0.0007$). Regarding mutation risk, adverse mutations at Day 150 ± 50 were linked to worse OS ($p<0.0001$) and RFS ($p<0.0001$). Multivariate analysis revealed that adverse-risk mutations were significantly associated with relapse (odds ratio [OR] 29.48, 95% CI 4.306-350.4, $p<0.002$), RFS (hazard ratio [HR] 12.62, 95% CI 3.541-44.35, $p<0.0001$), and OS (HR 19.24, 95% CI 5.242-75.73, $p<0.0001$). Intermediate-risk mutations also correlated with relapse (OR 13.27, 95% CI 2.818-89.91, $p<0.002$), RFS (HR 9.325, 95% CI 2.748-35.25, $p<0.0005$), and OS (HR 11.48, 95% CI 3.279-45.61, $p<0.0002$). Transplant age, donor type, CMV status, and GvHD regimen were not statistically significant. **Conclusions:** This study demonstrates that cfDNA detection in PB post-allo-HSCT is strongly associated with increased relapse and mortality in AML patients. Persistent high-risk mutations correlate with increased risk of relapse and poor survival outcomes. These findings highlight the potential of PB cfDNA as a predictive marker, potentially enabling earlier intervention to alter post-transplant treatment strategies. Research Sponsor: None.

6557 Poster Session

The impact of the use of hypomethylating agents prior to reduced intensity conditioning allogeneic bone marrow transplant among patients with MDS. First Author: Yanal Mufeed Alnimer, University of Kentucky, Lexington, KY

Background: Allogeneic transplantation is the only potential cure for patients with myelodysplastic syndrome (MDS). It is unclear whether cytoreduction with hypomethylating agents (HMAs) prior to reduced intensity conditioning (RIC) transplantation in patients with 5–10% bone marrow blasts impact transplant outcomes. **Methods:** We utilized the publicly available CIBMTR dataset from the publication *"Alternative Donor Transplantation for Myelodysplastic Syndrome: Haploidentical Relative and Matched Unrelated Donor"* to evaluate the differences in relapse-free survival (RFS), transplant-related mortality (TRM), and overall survival (OS) between recipients and non-recipients of pretransplant HMAs among MDS patients undergoing RIC Allo-SCT. The two groups were matched on confounding variables, including donor type, blast percentage at diagnosis and at the time of transplant, age, sex, race, IPSS-R score, CMV donor status, conditioning regimen, time to transplant, and year of diagnosis. Matching was performed using the inverse probability of treatment weights (IPTW) method. Weighted Kaplan-Meier curves were used to evaluate OS, RFS, and TRM between the two groups. Additionally, a doubly robust Cox regression model was constructed to estimate hazard ratios (HR) for the effect of pretransplant HMA use on OS and RFS. **Results:** A total of 603 patients were included in our analysis. The median age was 67.1 years (IQR 63.1–70.5), and the median follow-up was 21.8 months (0.95 CI 13.1–NR). In the weighted data. The 0.75 quantile for RFS was 7.57 months (0.95 CI 6-NR months) for the non-HMA group versus 5.79 months (0.95 CI 4.14–6 months) for the HMA group (P = 0.027). Similarly, the 0.75 quantile for OS was 9.54 months (0.95 CI 7.96–NR) for the non-HMA group versus 5.79 months (0.95 CI 4.38–7.43 months) for the HMA group (P = 0.005). There was no significant difference in the incidence of acute or chronic GVHD or TRM. In doubly robust Cox regression model. Pretransplant HMA was associated with worse RFS and OS with a HR of 0.66 (0.95 CI 0.44-0.97, P value =0.035) and HR of 0.60 (0.95 CI 0.42-0.90, P value< 0.01) respectively. **Conclusions:** Pretransplant use of HMA in MDS patients with less than 10% bone marrow blasts is associated with worse RFS and OS following allogeneic SCT with RIC. Notably, this detrimental impact is most pronounced in patients with less than 5% blasts, raising critical questions about the role of pretransplant HMA in this low-risk subgroup and emphasizing the need for refined treatment strategies. Research Sponsor: None.

Doubly robust (weighted) Cox-regression model on RFS.

Variable	Estimate	Lower .95 CI	Upper .95 CI	P-Value
No-Hypomethylating agents before Transplant (Reference=HMA pretransplant)	0.66	0.44	0.97	**0.035**
Sex (Reference=Male)	1.27	0.89	1.80	0.186

Allogeneic stem cell transplantation in chronic myelomonocytic leukemia: Analysis of post-transplant survival and risk factors in 138 Mayo Clinic patients. First Author: Ali Alsugair, Mayo Clinic, Rochester, MN

Background: Allogeneic stem cell transplantation (ASCT) is currently the only curative therapy in chronic myelomonocytic leukemia (CMML). **Methods:** A Mayo Clinic enterprise-wide database search identified 138 CMML cases who underwent ASCT. Conventional statistical methods were used for analyses. **Results:** 138 CMML patients (transplanted between 1995-2024) were included (median age 63 years; males 62%);104 (group A) received ASCT before and 34 (group B) after blast transformation (BT). At initial diagnosis, CMML-1/CMML-2 and dysplastic/proliferative representations were 78%/22% and 54%/46%; 31% displayed abnormal karyotype and most frequent mutations were *ASXL1* (56%), *TET2* (44%) and *SRSF2* (38%). At time of initial diagnosis, CPSS-Mol risk categories were low (17%), intermediate-1 (11%), intermediate-2 (40%), and high (32%). Median time from diagnosis to ASCT was 11 months (range 0-201). Median overall survival (OS) from the time of initial diagnosis was 67 months (range 4-239) and from the time of ASCT 54 (range 0-212) months. Occurrence of BT before ASCT was associated lower post-transplant survival (PTS; 16 vs 95 months, P=0.01, HR 1.9, 95%CI 1.2-3.2). Bone marrow (BM) blasts, at the time of ASCT, $<$5%, 5-9%, and 10-19% correlated with median OS of 171, 81, and 18 months in group A (p=0.01) and 50, 25, and 13 months in group B (P=0.07), respectively. Pre-ASCT hypomethylating agent exposure was associated with lower PTS in group A (P=0.02). PTS was also adversely affected by *DNMT3A* and *SETBP1* mutations. In group A, PTS was the longest with myeloablative busulfan-based (median not reached) and the shortest (median 22 months) with Cy-TBI-based conditioning (p=0.1). Donor type did not impact PTS: matched unrelated (63%), matched sibling (23%), mismatched unrelated (7%), or haploidentical (7%). Post-transplant cyclophosphamide was associated with a numerically lower median PTS (22 months), compared to other forms of GVHD prophylaxis (107 months; p=0.1) and significantly higher non-relapse mortality (p=0.02). Documentation of morphologic CR at day 100 was associated with significantly longer PTS in both groups A (92%,164 vs. 18 months; p=0.01) and B (84%, 42 vs. 11 months; p=0.01). The presence of abnormal karyotype at day 100 was associated with shorter PTS in group A (p=0.01). Grade $\geq$3 acute and moderate to severe chronic GVHD occurred in 20% and 34%, respectively, in group A patients and in 26% and 44% in group B. GRFS at 1/3 years were 42/21% in group A and 31/16% in group B. At last follow up, 44% in group A and 65% in group B were dead. Causes of death were relapse/non-relapse related in 36/64% in group A and 39/61% in group B. **Conclusions:** ASCT is effective in securing long-term survival in CMML, especially when the procedure is performed prior to BT and in the setting of $<$5% BM blasts/promonocytes. Response assessment at day 100 was highly informative of outcome. Research Sponsor: None.

6559 **Poster Session**

Allogeneic hematopoietic stem cell transplantation in T-cell acute lymphoblastic leukemia adults in complete remission: A systematic review and meta-analysis. First Author: Muhammad Umair Mushtaq, Division of Hematologic Malignancies & Cellular Therapies, University of Kansas Medical Center, Kansas City, KS

Background: There is limited data on the outcomes of allogeneic hematopoietic stem cell transplantation (allo-HCT) in T-cell acute Lymphoblastic Leukemia (T-ALL) patients. This study aims to assess complications, recurrence rates, and survival outcomes in T-ALL patients in clinical remission receiving allo-HCT. **Methods:** Following PRISMA guidelines, a comprehensive literature search was conducted across PubMed, Embase, Cochrane, and the clinicaltrials.gov registry from inception to December 2024 using keywords related to T-ALL and allo-HCT. Out of 1161 identified search results, 8 studies were included in this meta-analysis. Data was analyzed for outcomes including overall survival (OS), leukemia-free survival (LFS), relapse rates, non-relapse mortality (NRM), and graft-versus-host disease (GVHD) of Allo-HSCT in adult T-ALL patients in clinical remission. R version 4.4.2 was used to conduct a proportional meta-analysis using an inverse variance, random effects model. **Results:** This study included eight retrospective studies involving 3,280 T-ALL patients undergoing allo-HCT, with a median age of 32 years (range: 17–49) and a median follow-up of 37 months (range: 28–44). Seventy-one percent of the patients were male. Donor types included matched sibling (48.3%), matched unrelated (33.7%), haploidentical (10.2%), and mismatched unrelated (7%). Most grafts were from peripheral blood (75.8%), with the remainder from bone marrow. A myeloablative conditioning regimen was used in 86% of patients. At the time of HSCT, 92.16% of patients were in clinical remission. The pooled 2-year overall survival (OS) for patients in clinical remission was 63.2% (95% CI: 47.2–79.2; p$<$0.0001; I^2 = 89.4%), and 53.5% at 5 years (95% CI: 25.9–81.1; p$<$0.0001; I^2 = 93.7%). Similarly, the pooled leukemia-free survival (LFS) was 64.5% at 2 years (95% CI: 51.9–77.1; p$<$0.0213; I^2 = 74%) and 62.7% at 5 years (95% CI: 26.9–99.4; p$<$0.0003; I^2 = 92.5%). The pooled relapse rate was 23.4% at 2 years (95% CI: 9.6–37.2; p$<$0.0001; I^2 = 89.4%) and 53.3% at 4 years (95% CI: 0.0–100; p$<$0.0001; I^2 = 98.5%). The pooled non-relapse mortality (NRM) rate was 14.5% at 1 year (95% CI: 9.1–19.6; p = 0.0695; I^2 = 69.6%), 20.8% at 4 years (95% CI: 17.9–23.8; p = 0.4907; I^2 = 0%), and 26% at 5 years (95% CI: 18.6–29.9; I^2 = 0%). The pooled incidence of chronic graft-versus-host disease (cGVHD) was 34.3% (95% CI: 27.0–41.5; p = 0.6564; I^2 = 75.8%). **Conclusions:** T-ALL patients in clinical remission at allo-HCT showed favorable survival outcomes, though relapse remains a significant concern, particularly over time. Non-relapse mortality stabilizes after the first year but continues to pose a challenge. Chronic graft-versus-host disease prevalence remains high, underscoring the importance of long-term management strategies. Research Sponsor: None.

Factors associated with outcomes following reduced intensity conditioning haploidentical hematopoietic cell transplantation in acute myeloid leukemia. First Author: Muhammad Umair Mushtaq, Division of Hematologic Malignancies & Cellular Therapies, University of Kansas Medical Center, Kansas City, KS

Background: Allogeneic hematopoietic cell transplantation (HCT) is a curative therapy for high-risk acute myeloid leukemia (AML). Elderly patients can undergo HCT using a reduced-intensity conditioning (RIC) regimen. When HLA-matched donors are unavailable, haploidentical (Haplo) family donors can be used, offering outcomes similar to those with matched donors. This study investigates factors influencing outcomes following RIC haplo HCT with posttransplant cyclophosphamide (PT-Cy)-based GVHD prophylaxis. **Methods:** A retrospective multicenter study was conducted using the CIBMTR registry (2012-2017, P-5737 dataset, Ustun et al.) to assess AML patients undergoing first RIC haplo-HCT. Outcomes included overall survival (OS), disease-free survival (DFS), relapse, non-relapse mortality (NRM), acute and chronic GVHD, GVHD-free relapse-free survival (GRFS), and engraftment. Patient- and transplant-related factors were analyzed with Chi-square and Wilcoxon tests. Kaplan-Meier and univariate and multivariate Cox regression analyses were conducted. Hazard ratios (HR) with 95% confidence intervals (CI) were calculated. Statistical significance was defined as p$<$0.05. **Results:** We included 185 AML patients undergoing the first RIC haplo-HCT with PT-Cy-based GVHD prophylaxis. The median age was 63.8 years, 58% were male, and 70% were Caucasians. Graft sources were peripheral blood (55%) and bone marrow (45%), with a graft cell dose of$>$2 million CD34 cells/kg in 82% of patients. HCT-Comorbidity index (CI) was three or higher in 45% of patients, and Karnofsky's performance status was $<$90% in 53% of patients. The median follow-up was 4 years, and 36% were alive at the last follow-up. The median OS, DFS, and GRFS were 1.59, 0.76, and 0.31 years, respectively. Primary disease (33.5%), organ failure (9%), and infection (8%) were the leading causes of death. Relapse, acute (grade II-IV), chronic GVHD, and NRM occurred in 52%, 36%, 30%, and 20.5% of patients, respectively. Neutrophil engraftment occurred over a median of 17 days. In multivariate analyses, high disease risk independently predicted inferior OS (HR 1.72, p=0.012), inferior DFS (HR 1.49, p=0.136), higher relapse (HR 1.88, p=0.028), and higher NRM (HR 2.12, p=0.011). Higher HCT-CI predicted inferior OS (HR 1.88, p=0.041), higher NRM (HR 5.21, p=0.043), and delayed neutrophil engraftment (HR 0.37, p$<$0.001). Asians, compared to Caucasians, had superior GRFS (HR 0.46, p=0.040). **Conclusions:** In AML patients undergoing RIC haploidentical HCT, favorable outcomes were observed, and key determinants were high disease risk and comorbidities. Relapse remains the leading cause of treatment failure. These findings suggest pre-transplant assessments and post-transplant strategies to mitigate relapse risk for optimizing outcomes in this patient population. Research Sponsor: None.

Myeloablative fractionated busulfan conditioning regimen with sorafenib for allogeneic stem cell transplant in AML: Results of a phase 1/2 study. First Author: Uday R. Popat, Department of Stem Cell Transplantation and Cellular Therapy, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Myeloablative conditioning for allogeneic stem cell transplant (allo-SCT) can be given safely to older patients by extending the duration of busulfan (Bu) administration. This allows the addition of agents like sorafenib for a 3-week period to synergize with the conditioning. Here, we studied 4 doses of sorafenib with myeloablative fludarabine and fractionated Bu (f-Bu) in a phase 1/2 study (NCT03247088). **Methods:** From 3/2018-9/2023, 59 AML patients 18-70 years old with 8/8-HLA matched donors were enrolled prospectively. Sorafenib dose finding was done in phase 1 with a Bayesian Model Averaging Continual Reassessment Method with target toxicity probability .30 and cohort size 3, with DLT defined as grade $>$3 regimen-related toxicity occurring on days -24 to 30. Subsample sizes were 3 patients at 200, 400, and 600mg, and 50 patients at the highest tolerated dose of 800mg (400mg bid), given daily on days -24 to -5. The f-Bu dose targeted an area under the concentration vs time curve of 20,000 $\pm$ 12% μmol.min, given over 3 weeks. The first 2 doses (80 mg/m2 each) were given outpatient on days -20 and -13. The last 4 pharmacokinetically guided doses were given inpatient after Flu 40mg/m2 on days -6 to -3. GVHD prophylaxis was cyclophosphamide 50mg/kg on days 3-4 and tacrolimus. Unrelated donor graft recipients also received MMF. All patients were eligible for sorafenib maintenance for 1 year post-transplant. 30 (51%) patients began this maintenance and 13 (21%) completed 1 year. **Results:** Median age was 53 years (range, 24-70). Disease status at SCT was CR1 in 42 (71%) patients, CRi in 6 (10%), and advanced disease in 11 (19%). 34 (58%) had ELN22 adverse risk disease, 31 (53%) were MRD+, 17 (29%) had FLT3 ITD, donor was unrelated in 37 (63%), and peripheral blood was the graft source in 53 (90%). The cohort's 2-year overall survival (OS) was 74.9% (95% credible interval (CrI) 61.8-84.8%), with a median follow-up in 43 surviving patients of 2.2 years. A fitted Bayesian Weibull regression model for OS showed a higher risk of death with MRD+ disease (posterior mean HR = 3.13, 95% CrI 1.01–12.03) and age $>$ 60 (posterior mean HR = 2.22, 95% CrI 0.76–6.91). No association was seen with OS or PFS and comorbidity score, remission status, or ELN22 risk group. Outcomes were similar in FLT3 ITD and wild type patients. **Conclusions:** The f-Bu regimen with sorafenib results in promising outcomes for AML patients. Clinical trial information: NCT03247088. Research Sponsor: National Cancer Institute.

Association between pre-transplant biological aging markers and clinical outcomes in allogeneic hematopoietic cell transplant recipients. First Author: Kelly E. Rentscher, Medical College of Wisconsin, Milwaukee, WI

Background: Cancer and its treatments can accelerate the aging process, placing survivors at increased risk for poor outcomes. Hematopoietic cell transplant (HCT) recipients may show variations in biological aging before HCT due to previous treatment exposures; however, pre-transplant transcriptomic markers of biological aging have not yet been investigated as predictors of clinical outcomes. We used data from the Center for International Blood and Marrow Transplant Research (CIBMTR) to examine the hypothesis that recipients with greater pre-transplant expression of molecular processes in the cellular senescence pathway—a fundamental mechanism of aging—would have worse clinical outcomes. **Methods:** Participants included 261 adults (M_{age}=41.3 years) that received an HLA-matched unrelated donor myeloablative HCT between 1995–2005 for acute myelogenous leukemia (AML) in complete remission and had pre-transplant blood samples available in the CIBMTR Repository. Whole-genome RNA sequencing of recipient peripheral blood mononuclear cells (PBMCs) was used to derive molecular senescence markers, including the DNA damage response (DDR; 29-gene composite), cellular senescence signals $p16^{INK4a}$ and p21 (*CDKN2A* and *CDKN1A*, respectively), the pro-inflammatory senescence-associated secretory phenotype (SASP; 60-gene composite) and the SenMayo senescence gene set (125-gene composite). We examined acute and chronic graft-versus-host disease (GVHD), transplant-related mortality (TRM), relapse, leukemia-free survival (LFS), and overall survival (OS) as clinical outcomes. **Results:** Transcriptomic composites were examined as continuous variables. Cox proportional hazard models adjusting for patient, disease, and transplant characteristics and major cell subsets in the PBMC pool revealed that elevated SASP and SenMayo expression were associated with increased risk of TRM (*HR*=3.56, *p*=.005 and *HR*=6.88, *p*=.002, respectively) and OS (*HR*=2.31, *p*=.03 and *HR*=4.50, *p*=.004, respectively). However, enhanced expression of senescence signal p21 was associated with decreased risk of relapse (*HR*=0.52, *p*=.01) and LFS (*HR*=0.70, *p*=.03). The DDR and senescence signal $p16^{INK4a}$ did not significantly relate to clinical outcomes. **Conclusions:** Transcriptomic markers of biological aging assessed in allogeneic HCT recipients before transplant are predictive of relapse and survival outcomes. Specifically, findings suggest that enhanced expression of pro-inflammatory SASP and SenMayo genes may represent a pre-transplant molecular risk profile, whereas elevated expression of p21 may serve as a protective prognostic indicator in the HCT setting. Given the heterogeneous nature of senescent cells, research that examines these transcriptomic markers following HCT as well as how recipient and donor profiles may interact to influence outcomes is warranted. Pre-transplant measures of geriatric assessment domains and outcomes of allogeneic hematopoietic cell transplantation in adults aged 75 and older. First Author: Amar Harry Kelkar, Dana-Farber Cancer Institute, Boston, MA

Background: The upper age limit for allogeneic hematopoietic cell transplantation (HCT) has risen over time, yet prior studies indicate worse outcomes—particularly non-relapse mortality (NRM)—in patients over 70 compared to younger patients (Shahzad, *Transplant Cell Ther* 2025). As the population ages, we expect the transplant-eligible age range to extend, underscoring the need to identify reliable predictors of outcomes in older adults. **Methods:** We conducted a retrospective study of all adults aged ≥75 who underwent HCT at Dana-Farber Cancer Institute from January 2008 to August 2024. We evaluated overall survival (OS), progression-free survival (PFS), NRM, and cumulative incidence of relapse (CIR). Guided by geriatric assessment (GA) domains, clinical health data were collected from pre-HCT consent session notes. Log-rank (OS, PFS) and Gray's tests (NRM, relapse) were used for group comparison; Cox (OS, PFS) and Fine-Gray (NRM, relapse) models were used for multivariable analysis. **Results:** Sixty-seven patients (median age 76 years, range 75-80) were analyzed; 73.1% were male and 86.6% were White. Acute myeloid leukemia (46.3%) and myelodysplastic syndromes (35.8%) were the most common HCT indications. Neutrophil engraftment occurred in 94% of patients by a median of 15 days (range 3-40). Median follow-up for survivors was 21 months (range 11-125), and median OS was 33 months (95% CI: 18-55). At 18 months, OS was 61% (95% CI: 48-72%), PFS 54% (95% CI: 41-66%), NRM 11% (95% CI: 4.9-21%), and CIR 34% (95% CI: 23-46%). In univariable analysis, age ≥77 (p=0.0095), number of medications ≥15 at HCT consent (p=0.0078), and post-HCT bacterial or fungal infection (p=0.039) were associated with worse OS; similar factors affected PFS (e.g., for patients with bacterial or fungal infection, p=0.049). Diabetes (p=0.0001) and ≥15 medications at time of HCT consent (p=0.001) correlated with higher NRM. On multivariable analysis, age ≥77 (HR 2.44; p=0.028) and ≥15 medications (HR 2.68; p=0.019) significantly predicted worse OS; both factors also predicted inferior PFS. **Conclusions:** In this relatively large cohort of the oldest HCT recipients, older age, polypharmacy, and comorbidities emerged as likely predictors of worse clinical outcomes. Interestingly, relapse—rather than NRM—was the primary cause of treatment failure, aligning with established links between advanced age and the biology of myeloid malignancies. While the expanding upper age limit for HCT is a promising development for patients ≥75, our data are vital to facilitate informed consent discussions. These findings also underscore the need for robust pre-HCT evaluations, such as assessment of other GA domains via dedicated functional assessments (e.g., IADLs and gait speed) to improve risk stratification. Investigation in a larger cohort (≥70 years) is underway to further explore these results. Research Sponsor: None.

Assessment of long-term toxicities of imatinib in CML: Experience from a tertiary care cancer centre in south India. First Author: Akhil Santhosh, MVR Cancer Centre & Research Institute, Calicut, India

Background: Imatinib has been the standard 1st line drug for chronic myeloid leukemia (CML) in chronic phase for decades. Literature is replete with data regarding acute toxicities of imatinib, but chronic long-term effects of the drug on cardiac, renal, endocrine, skin and bone health are less explored. In rare cases, imatinib has been postulated to cause left ventricular dysfunction, impairment in bone mineral density, thyroid hormone abnormalities and sensorineural hearing loss. **Methods:** We conducted a prospective study on CML patients aged 18 and above who had taken Imatinib for a minimum duration of 10 years. All patients were subjected to a detailed skin examination, laboratory tests including complete blood count, liver/renal function tests, thyroid profile, 2D echo, bone densitometry and pure tone audiometry. All tests were organized in accordance with a camp conducted for CML patients in our center. Children, pregnant women, patients who had not achieved major molecular remission and patients in accelerated phase/blast crisis were excluded. **Results:** 100 patients (males n=60, females, n=40) participated in the study. Median age was 45years (IQR 30-60). All patients were in major molecular remission with excellent drug compliance. Regarding the rarer side effects, 2D echo revealed left ventricular dysfunction in 4 patients (4%, n=1 moderate, n=3 mild). After interruption of drug, ejection fraction improved in all 3 patients with mild LV dysfunction (repeat 2d echo after 3 months). Pure tone audiometry revealed bilateral sensorineural hearing loss in 5 patients (5%, moderate n=3, severe n=2). Repeat testing done after 3 months post drug discontinuation showed improvement for 2 out of 3 patients with moderate sensorineural hearing loss (conversion to mild degree). 10 patients had osteopenia and 2 patients had osteoporosis in bone densitometry scans. Drug was not discontinued for the same. Patients were started on calcium+ vitamin D supplementation for osteopenia and 6 monthly zoledronic acid injections for osteoporosis. Cutaneous side effects were reported in 43%(N=43). Hyperpigmentation was the most common, seen in 30%(n=30) followed by hypopigmentation in 11% and chronic malar flush in 2%. Menstrual irregularities were reported in 10 females (n=10, 25%), most common being oligomenorrhea(n=7). 4 males (6.66%) had gynecomastia on examination. Anemia was seen in 25% (n=25,10 males and 15 females). Hypophosphatemia and elevated TSH were seen in 12 (12%) and 7 patients (7%) respectively. **Conclusions:** CML is now equated to a chronic disease with patients attaining a near normal life expectancy which makes it very important for clinicians to be well versed with both acute and chronic toxicities of imatinib. Through our study, we were able to highlight certain rare toxicities like ejection fraction abnormalities, hearing loss and bone mineral density changes that may be seen with imatinib. Early predictors of treatment-free remission in chronic myeloid leukemia. First Author: Aziz Farhat, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Tyrosine kinase inhibitors (TKIs) have significantly improved outcomes for chronic myeloid leukemia (CML), allowing most patients to achieve near-normal life expectancy. This has shifted treatment goals toward achieving treatment-free remission (TFR), particularly important for younger patients. Current criteria for TFR rely on sustained deep molecular remission after years of therapy, but early predictors are lacking. We aimed to identify factors predictive of TFR eligibility. **Methods:** We screened 780 patients with newly diagnosed chronic phase CML treated at The University of Texas MD Anderson Cancer Center from January 2012 to December 2023. Among them, 412 patients (53%) met the NCCN criteria for TFR (sustained MR4.5 for 2 years following 3 years of therapy). Thirty patients (4%) were excluded due to insufficient treatment duration. The remaining 338 patients (43%) formed the control cohort. We compared these cohorts and evaluated predictive factors for TFR eligibility using univariate and multivariate logistic regression, including factors with $P < 0.1$ in the multivariate model. **Results:** Patients in the TFR cohort were older (median age 51 vs. 46 years, P = 0.007) and had a different distribution of Sokal risk categories (P = 0.037): 67% low risk, 27% intermediate, and 6% high risk, compared to 64%, 25%, and 11% in the control group. TKI usage also differed (P = 0.01), with 32% vs. 41% receiving imatinib, 43% vs. 33% dasatinib, 19% receiving nilotinib in both groups, and 6% vs. 8% receiving ponatinib. *BCR::ABL* transcript distribution was significantly different ($P < 0.001$). The e13a2 transcript was more common in the control group (51% vs. 33%), while the e14a2 transcript predominated in the TFR group (46% vs. 32%). Co-occurrence of both transcripts was similar (21% vs. 16%), but other variants were rare and only observed in the control group (1% vs. 0%). Resistance mutations in the ABL gene were exclusively detected in the control group (13%, 44 patients). Univariate analysis identified older age (OR: 1.02; P = 0.001), BCR::ABL halving-time <30 days (OR: 4; $P < 0.001$), and achieving molecular milestones—transcript levels <10% IS at 3 months (OR: 11.4; $P < 0.001$), <1% IS at 6 months (OR: 10.5; $P < 0.001$), and <0.1% IS (MMR) at 1 year (OR: 6.5; $P < 0.001$)—as predictive factors for TFR eligibility. The e14a2 transcript (OR: 2.2; $P < 0.001$), co-occurrence of both transcripts (OR: 1.9; P = 0.001), and treatment with newer-generation TKIs vs. imatinib (OR: 1.5; P = 0.008) were also significant predictors. Multivariate analysis confirmed that older age (OR: 1.2; P = 0.045), halving-time <30 days (OR: 2; P = 0.041), achieving MMR at 1 year (OR: 5.6; $P < 0.001$), and the e14a2 transcript (OR: 1.6; P = 0.049) were independent predictors. **Conclusions:** Early predictors of TFR eligibility include older age, halving-time <30 days, MMR at 1 year, and the e14a2 transcript. These factors could guide prospective trial designs as early surrogates for TFR. Research Sponsor: None.

Long-term follow-up of treatment-free remission in chronic myeloid leukemia after discontinuation of tyrosine kinase inhibitor therapy. First Author: Mehmet Uyanik, Department of Leukemia, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Treatment-free remission (TFR) is an important goal of therapy in patients (pts) with chronic myeloid leukemia in chronic phase (CML-CP). Here, we report our TFR experience in pts with CML-CP after a longer follow-up. **Methods:** Pts with CML-CP who were treated with tyrosine kinase inhibitors (TKIs) and subsequently discontinued therapy between October 2011 and January 2024 were included in this analysis. Molecular responses were assessed by qPCR (MMR, MR4, and MR4.5 defined as *BCR::ABL1* transcripts ≤0.1%, ≤0.01%, and ≤0.0032% on the international scale, respectively). The Kaplan Meier method was used to estimate the probability of TFR. **Results:** A total of 351 pts with CML-CP discontinued TKI therapy after a median treatment duration of 118.5 mo (range, 15.8-303.2). Most of the pts opted for elective discontinuation (70.2%) or discontinued therapy due to adverse events (24.3%). The median duration of sustained MR4.5 before TKI discontinuation was 61.8. mo (range, 1.0-206.8), and the median duration of sustained MR4 before TKI discontinuation was 76.5 mo (range, 1.37-215.1). With a median follow-up of 66.8 mo (range, 4.7-211.4) after TKI discontinuation, 93 pts (26.5%) lost MMR after a median of 7.2 mo (range, 1.2-124.9) from stopping therapy. 88 (93%) pts regained MMR after resuming therapy after a median of 3.6 mo (range, 0.4-36.5). The median TFR duration was not reached, with a 5-year TFR rate of 72.2%. The 5-year TFR rates were 63.0% and 79.2% in pts with a MR4.5 duration of <5 years, and ≥5 years before cessation of the TKI, respectively. The 5-year TFR rates were 54.5%, and 80.4% in pts with a MR4 duration of <5 years, and ≥5 years before cessation of the TKI, respectively. There was no significant difference in the rates of 5-year TFR between pts who received frontline first- or second-generation TKIs (P=0.79). Five-year TFR rates were similar between pts who were treated at standard TKI dose and those treated with TKIs at reducing dosing (p=0.52). There was no significant difference in the TFR rates according to the *BCR::ABL1* transcripts subtypes (p=0.1). **Conclusions:** The long-term follow-up results continue to demonstrate improved TFR rates of approximately 80% in patients who achieve a deep molecular response (MR4 or deeper response) sustained for 5 years or more. Research Sponsor: None.

Allogeneic stem cell transplantation-related outcomes in myelodysplastic syndromes. First Author: Alexandre Bazinet, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Allogeneic stem cell transplantation (SCT) is the only known curative modality in myelodysplastic syndromes (MDS). Its use has historically been limited due to older patient age and comorbidity burden. Recent advances in reduced-intensity conditioning (RIC) have expanded the use of SCT in MDS. **Methods:** This was a retrospective single center database review study to evaluate contemporary outcomes in SCT-treated MDS. We identified all patients with newly diagnosed MDS presenting to our center between Jan 2000 and Mar 2023 and stratified them by receipt of SCT. Biallelic *TP53*-mutated status was defined as 2 *TP53* mutations, VAF ≥ 50%, or concomitant del(17p). Landmark analyses were performed to compare outcomes with or without SCT (median time from diagnosis to SCT as landmark). **Results:** 3649 patients with newly-diagnosed MDS were included. 573 (16%) underwent SCT. 4-week, 8-week, and 100-day mortality were 3%, 6%, and 14%, respectively. Acute GVHD occurred in 64% of patients (14% grade 3/4). Chronic GVHD occurred in 33%. Patients undergoing SCT (ages 18-77) had a median OS of 25 m from SCT day 0. The 5-year cumulative incidences of death and relapse were 21% and 31% with myeloablative conditioning (MAC) and 27% and 36% with reduced-intensity conditioning (RIC). Stratified by IPSS-R, the median OS post-SCT was 136, 40, 92, 103, and 8 m in Very Low, Low, Intermediate, High, and Very High risk. Patients with *TP53*wt, *TP53*mut monoallelic, and *TP53*mut biallelic had a median OS of not reached (NR), 9 m, and 7 m. Patients with non-complex, complex (3 abn), and very complex (> 3 abn) CG had a median OS of 96 m, 14 m, and 7 m. Transplanted patients without *TP53* mutations had 5-year OS of 59% and those without complex CG had 5-year OS of 54%. Immediate pre-SCT blasts <5% and 5-9% were associated with similar post SCT OS (median 29 and 30 m) whereas patients with 10-19% (8 m) and > 20% (12 m) had inferior survival. Multivariate analysis identified bone marrow ring sideroblast %, *TP53* mutations, haplo donor, pre-SCT transformation to AML, and increasing donor age as associated with worse post-SCT OS while receipt of venetoclax pre-SCT and higher Karnofsky score were favorable. By landmark analyses, SCT was associated with improved OS across IPSS-R risk categories. Median OS was 185 m with SCT vs 82 m without SCT in Very Low risk (p<0.01), 107 vs 58 m in Low risk (p<0.01), 103 vs 31 m in Intermediate risk (p<0.01), 108 vs 18 m in High risk (p<0.01), and 16 vs 13 m in Very High risk (p<0.01). No significant benefit of SCT was noted in patients with *TP53* mutations. The median OS was 27 m with SCT vs 17 m without SCT in *TP53*mut monoallelic (p=0.10) and 14 vs 13 m in *TP53*mut biallelic (p=0.16). **Conclusions:** SCT is curative in 50-60% of patients with MDS without *TP53* mutations or complex CG. Efforts should be made to improve accessibility of SCT in this population. Alternative therapies are urgently needed in patients with *TP53* mutations or complex CG. Research Sponsor: University of Texas MD Anderson Cancer Center Support Grant; CA016672.

Impact of static and dynamic risk assessment in HMA-treated MDS patients undergoing stem cell transplantation. First Author: Luis E. Aguirre, Dana-Farber Cancer Institute, Boston, MA

Background: MDS risk assessed by the IPSS-R and IPSS-M at diagnosis impacts outcomes post-hematopoietic stem cell transplant (HSCT). Recent EBMT data showed no post-HSCT survival benefit from downstaging IPSS-R scores with hypomethylating agent (HMA) therapy. However, the lack of mutational data precluded evaluating dynamic IPSS-M changes. This study aimed to determine whether evaluating IPSS-M at diagnosis or pre-HSCT more accurately predicts post-HSCT outcomes in pts treated with HMA. Additionally, in the absence of consensus on the role of cytoreductive therapy in the pre-HSCT setting for pts with higher-risk MDS, we investigated whether the dynamic application of IPSS-M offers any advantages for such therapy. **Methods:** We analyzed 176 paired samples from higher-risk MDS pts treated with HMA followed by HSCT at Dana-Farber (n=91) and Moffitt (n=85). Disease risk was assessed by IPSS-M at diagnosis and after HMA therapy pre-HCT. Dynamic assessment was categorized as decrease (improvement), no change, or increase (progression) in IPSS-M risk category from diagnosis to HSCT. The primary outcome was post-HSCT progression-free survival (PFS). **Results:** In the cohort, 60% were male, with a median age of 66 yrs (range 26-79). At diagnosis, 87.5% had MDS with increased blasts and 9.7% had MDS with low blasts. Pts received a median of 4 cycles of HMA prior to HSCT, with 63.1% having MUD donors and 84.1% receiving RIC. At diagnosis, 80% were higher-risk (MH/H/VH) per IPSS-M. Post-HMA, 61.4% improved in IPSS-M, while 24.4% had no change and 14.2% progressed. The 4y PFS for the cohort was 47%, with no significant differences between centers (48% vs 47%, p=0.75). In MVA, there was no difference in prognostic accuracy between IPSS-M estimated at diagnosis and pre-HSCT (c-index: 0.635 vs. 0.645). Dynamic assessment showed a 4y PFS of 50% for both improved/unchanged IPSS-M vs 31% for progressive IPSS-M (c-index: 0.647, p=0.09). Substantial improvement in IPSS-M (≥2.5 score change) yielded a 4y PFS of 38%, comparable to those with progression (23%) and much worse than those with discreet/evident improvement (53%/56%). Pts with substantial improvement in IPSS-M had a higher proportion of VH risk MDS at diagnosis than those with discreet/evident improvement (77% vs. 28%), indicating that adverse disease biology at diagnosis negatively affected outcomes despite favorable response to HMA. **Conclusions:** Pre-HSCT IPSS-M assessment did not enhance post-HSCT outcome predictions compared to evaluation at diagnosis. Worsening IPSS-M correlated with worse outcomes, while improvement did not yield better results than unchanged risk. For those with high-risk disease, improvement in IPSS-M achieved through HMA does not appear to mitigate the adverse risk established at diagnosis. Thus, in HMA-treated pts, downstaging of IPSS-M pre-HSCT should not be a therapeutic goal or an endpoint for response evaluation in MDS trials. Research Sponsor: None.

6569 **Poster Session**

Effect of prior treatment (tx) on the clinical activity of imetelstat (IME) in transfusion-dependent (TD) patients (pts) with erythropoiesis-stimulating agent (ESA), relapsed or refractory (R/R)/ineligible lower-risk myelodysplastic syndromes (LR-MDS). First Author: Rami S. Komrokji, H. Lee Moffitt Cancer Center and Research Institute, Tampa, FL

Background: IME, a first-in-class, direct, and competitive inhibitor of telomerase activity, was approved in the US for the tx of red blood cell (RBC)-TD LR-MDS in pts who are R/R or ineligible for ESA based on the results of the pivotal IMerge trial (NCT02598661). IMerge demonstrated significant and durable efficacy of IME (n=118) versus placebo (n=60) for ≥8-week, ≥24-week, and ≥1-year RBC-transfusion independence (TI), with a generally manageable safety profile in this pt population. Here, we pooled data from the 3 parts of the IMerge trial (phase 2, phase 3, and QTc substudy) to investigate the effect of prior txs on the clinical activity of IME. **Methods:** In IMerge, pts received IME intravenously every 4 weeks at 7.1 mg/kg active dose (7.5 mg/kg IME sodium equivalent). Prior lenalidomide (LEN) and prior hypomethylating agent (HMA) use were exclusion criteria in phase 3 only. In this analysis, pooled data from IME-treated pts (phase 2, phase 3, and QTc substudy) were analyzed by prior tx: ± ESA, luspatercept (LUSP), LEN, and HMA; pts may have received >1 prior tx. Outcomes included ≥8-week, ≥24-week, and ≥1-year RBC-TI, rates of hematologic improvement-erythroid (HI-E) based on the revised International Working Group (IWG) 2018 criteria, transfusion reduction of ≥4 U/8 weeks, and a hemoglobin (Hb) rise of ≥1.5 g/dL for ≥8 weeks. **Results:** The data cutoff dates were 10/13/2023 (phase 2/3) and 10/13/2024 (QTc substudy). A total of 226 IME-treated pts pooled in IMerge were included in this analysis; most pts (n=188) had a high transfusion burden (TB) per revised IWG 2018 at baseline (vs low TB [n=38]; Table). Of all pts, 39% achieved ≥8-week RBC-TI (median duration of response, 55 weeks), and 28% and 18% achieved ≥24-week and ≥1-year RBC-TI, respectively. Among all IME-treated pts, 204 had prior tx with an ESA and 22 were ineligible for ESAs; 36 had prior LUSP, 26 had prior LEN, and 22 had prior HMA. Pt characteristics and efficacy by prior tx are shown in the table. **Conclusions:** Pts who were ESA ineligible or who had prior tx with LUSP, LEN, or HMA, and were largely high TB, in IMerge experienced clinical benefit from IME tx, though the number of pts was small. Given the limited efficacy data available in later lines of tx for LR-MDS, these results have important clinical implications, suggesting that IME has clinical activity regardless of prior txs. Clinical trial information: NCT02598661. Research Sponsor: This study was funded by the Geron Corporation. All authors contributed to and approved the abstract; writing and editorial support were provided by Casandra Monzon, PhD, CMPP, of The Lockwood Group (Stamford, CT, USA), funded by the Geron Corporation.

Real-world (RW) outcomes of patients (pts) with lower-risk myelodysplastic syndrome (LR-MDS) receiving first-line (1L) luspatercept (LUSPA) or 1L erythropoiesis-stimulating agents (ESA) in the US. First Author: Idoroenyi Usua Amanam, City of Hope Cancer Center, Duarte, CA

Background: LR-MDS pts receiving ESAs for anemia often experience treatment (tx) resistance or relapse. Evidence from the COMMANDS trial led to LUSPA's US FDA approval in August 2023 as 1L tx for anemia in pts with LR-MDS. This is the first study assessing RW characteristics and outcomes in pts with LR-MDS receiving 1L LUSPA or ESA after 1L LUSPA approval. **Methods:** Interim data from an ongoing, retrospective medical records review of pts with LR-MDS receiving 1L LUSPA or ESA was collected (17 Oct 2024-19 Dec 2024; target sample size = 200 pts per cohort). Eligible adult pts had IPSS/IPSS-R-defined diagnosis of LR-MDS and initiated 1L LUSPA or ESA between 28 Aug 2023-31 Jul 2024 (tx initiation date = index date). Outcomes were descriptively analyzed; pt characteristics and changes in hemoglobin (Hb) and red blood cell (RBC) transfusion requirements during the first 6 months (mos) of 1L anemia tx are reported. **Results:** 103 pts (1L LUSPA: 46; 1L ESA: 57) were included in the interim data.In the LUSPA and ESA cohorts, respectively,median age at index was 67.7 and 62.9 yrs; 63.0% and 66.7% were White; 54.3% and 40.4% were female; 28.3% and 10.5% had *SF3B1* mutation; 93.5% and 68.4% had ECOG 0/1; and median follow-up was 7.9 and 8.4 mos. IPSS/IPSS-R risk status was intermediate-1/intermediate for 21.7% of LUSPA pts and 8.8% of ESA pts. Of pts with known ring sideroblast (RS) level, 62.2% (23/37) of LUSPA pts and 71.8% (28/39) of ESA pts were RS negative. Baseline (BL) sEPO was $<$200 IU/L for 30.6% (11/36) of LUSPA pts and 78.9% (30/38) of ESA pts. Most ptsreceiving 1L LUSPA achieved Hb increase of $\geq$1.5 g/dL (LUSPA: 89.1%; ESA: 56.1%) in the first 6 mos of tx. Of pts who were RBC transfusion-dependent (RBC-TD) at BL, a greater proportion of LUSPA pts became RBC transfusion-independent (RBC-TI) vs ESA pts (91.7% vs 71.4%) in the first 3 mos (Table). Updated results for the full cohort to be presented at the meeting. **Conclusions:** During the first 6 mos of tx,a higher proportion of ptsreceiving 1L LUSPA showed improvement in Hb and a reduced need for RBC compared to those receiving 1L ESA. This analysis corroborates the results of the COMMANDS trial and demonstrates the favorable RW effectiveness of 1L LUSPA vs 1L ESA for anemia treatment in LR-MDS. Research Sponsor: Bristol Myers Squibb.

An exploratory analysis of myelofibrosis (MF) patient subgroups by baseline hemoglobin levels in the gecacitinib phase 3 trial. First Author: Yi Zhang, The First Affiliated Hospital, Zhejiang University School of Medicine, Hangzhou, China

Background: Anemia is a key prognostic indicator of MF. In the double-blind, randomized phase 3 ZGJAK016 trial, gecacitinib (GCA), a dual JAK/ACVR1 inhibitor, demonstrated superior spleen response over hydroxyurea, and a trend toward improvement in constitutional symptom and anemia associated with MF in JAK inhibitor-naive patients (pts). To further elucidate the impact of GCA on anemia, we conducted a post-hoc analysis of the data from this trial, examining outcomes in relation to the severity of anemia. **Methods:** Pts in the GCA group were categorized post subgroups based on their baseline hemoglobin (Hb) levels: less than 100 g/L (moderate to severe anemia), 100 g/L to lower limit of the normal (LLN) (mild anemia), LLN to upper limit of the normal (ULN) (normal), and more than ULN for (Hb elevated). The primary endpoint was the proportion of pts with a spleen volume reduction of $\geq$ 35% from baseline (SVR35) at week (wk) 24. Secondary endpoints included the proportion of pts with a $\geq$ 50% reduction in Total Symptom Score (TSS50), and transfusion independence (TI) rate at wk 24 (no red blood cell transfusions and no Hb levels of $<$80 g/L in the last 12 wks before wk 24). **Results:** Of all the 71 pts randomly assigned to GCA in the intent-to-treat (ITT) population, 47 (66.2%) were moderately/severely anemic at baseline (including 16 pts [22.5%] with severe anemia [Hb levels of $<$ 80 g/L]), 11 (15.5%) were mildly anemic and 13 (18.3%) were non-anemic (including three pts [3.8%] with Hb levels of $>$ ULN). In the moderately/severely anemic subgroup, a higher proportion of pts were classified as DIPSS high risk, transfusion dependent, and had a diagnosis with primary MF at baseline. Most pts in the mildly anemic group were TI, as were all in the nonanemic subgroup. The three pts with elevated Hb all had post- polycythemia vera MF. Mean Hb levels increased by wk 2 across all GCA subgroups, then remained stable in the anemic subgroups, or slightly decreased but still $>$ 110 g/L in the normal subgroup and markedly decreased in the Hb elevated subgroup. Mean platelet counts decreased by wk 2 except in the Hb elevated subgroup and then maintained stability. In the moderately/severely and mild anemic subgroup, 24 of 36 (66.7%) pts who were TI at baseline maintained this status at wk 24 and 8 of 22 (36.4%) who were non-TI at baseline achieved TI at wk 24. The SVR35 rates and TSS50 rates at wk 24 were comparable across subgroups and consistent with those observed in the ITT population. **Conclusions:** In summary, GCA delivers a threefold benefit in terms of spleen and symptom management, as well as anemia, to JAK inhibitor-naive pts with MF who have mild, moderate/severe, or no anemia at baseline, particularly those with Hb levels below LLN. Clinical trial information: NCT04617028. Research Sponsor: Suzhou Zelgen Biopharmaceuticals Co, Ltd.

	ITT (n =71)	Hb <100 g/L (n =47)	Hb ≥100 g/L to LLN (n =11)	LLN to ULN (n =10)	>ULN (n =3)
SVR35 rate at wk 24	64.8%	59.6%	81.8%	70.0%	66.7%
TSS50 rate at wk 24	62.0%	57.4%	90.9%	50.0%	66.7%

Efficacy of BTI615 on malignant cells expansion and bone marrow fibrosis in a myelofibrosis mice model. First Author: Xiaomei Li, Chengdu Brilliant Inspiration Biotherapeutics Co., Ltd., Chengdu, Sichuan, China

Background: Due to the limitation of Janus kinase inhibitors and allogeneic transplant, critical unmet needs are remained in myelofibrosis (MF) patients, particularly for those with cytopenias, non-response or intolerance issues. Novel therapeutic avenues could arise from promoting bone marrow regeneration, which is dysregulated by pro-tumorigenic, fibrotic niche networked by vicious cycle of transforming growth factor β (TGF-β) signaling. Here we verified that BTI615, a synthetic active TGF-β modulating peptide, rescued malignant cells expansion and bone marrow fibrosis to restore hematopoiesis in a romiplostim-induced MF model. **Methods:** Mice (5-6 weeks old C57BL/6J, male) were treated with romiplostim (s.c., 90 μg/kg, Q3D), and simultaneously dosed with BTI615 (i.v., 30 or 120 mg/kg, TIW) for 4 weeks. The bloods, femurs, and spleens were collected for cell counting, Hematoxylin and Eosin staining, Gordon & Sweet's silver staining, immunofluorescence imaging and cytokines quantification. **Results:** In blood, BTI615 restored the declined peripheral red blood cells and hemoglobin, and suppressed inflammatory increase of white blood cells (incl. monocytes and granulocytes). Histological examination of bone marrow and spleen revealed that BTI615 remarkably suppressed megakaryocytes hyperplasia and atypia. Moreover, there was a significant reduction in the deposition of reticular fibers, fibronectin and collagen IV over the femurs by BTI615. Notably, in BTI615 treated bone marrow, the specialized niches erythroblastic islands and total Ter-119 positive cells markedly increased, accompanied by declining trends of splenomegaly. Aligned with those symptom relieves, BTI615 decreased the amount of active TGF-β_1 and the intensity of phospho-Smad2, as well as the expression of interleukin (IL)-1α and monocyte chemoattractant protein (MCP)-1 in bone marrow. **Conclusions:** Given its effective suppression on hyperplasia of atypical megakaryocytes, inflammation, marrow fibrosis and the ultimate recovery of hematopoietic function via modulating TGF-β signaling, BTI615 has a great potential to be the next generation therapeutic approach for MF. Research Sponsor: None.

Ropeginterferon alfa-2b for pre-fibrotic primary myelofibrosis and DIPSS low/intermediate-risk myelofibrosis. First Author: Harinder Gill, Department of Medicine, School of Clinical Medicine, LKS Faculty of Medicine, the University of Hong Kong, Hong Kong, China

Background: There is currently no consensus on the optimal treatment for primary myelofibrosis (PMF) in pre-/early fibrotic stage (pre-PMF) and DIPPS low/intermediate-1 risk MF. Ropeginterferon alfa 2b (Ropeg-IFN-α2b) is a next-generation monopegylated interferon alfa-2b developed specifically to treat myeloproliferative neoplasms (MPN). **Methods:** Key eligibility included morphologically confirmed pre-PMF, and DIPSS low/intermediate-1 risk overt PMF, post-polycythemia vera MF (PPV-MF), and post-essential thrombocythemia MF (PET-MF) in patients requiring cytoreduction. The primary endpoints were responses in hemoglobin (from 10 g/dL to upper reference range), white blood cell (to $<$ 10 x 10^9/L) and platelet (to $\leq$ 400 x 10^9/L) at 24 and 52 weeks. Secondary endpoints included safety (adverse events, AEs), reductions in variant allele frequencies (VAF) of driver and non-driver genes, spleen length by palpation, Myeloproliferative Neoplasm Symptom Assessment Form Total Symptom Score (MPNSAF-TSS), and bone marrow fibrosis. Patients received Ropeg-IFN-α2b at a dose of 250 mcg at Week 0, followed by 350 mcg at Week 2 and 500 mcg every 2 weeks from Week 4 onwards. **Results:** At the data cut-off of 30 June 2024, 71 patients (40 men and 31 women) with a median age of 60 (range: 31-86) years were enrolled. At a median follow up of 119 (10-131) weeks, responses in hemoglobin, white blood cell and platelet counts were 73.9%, 82.6% and 100% at Week 24; and 76.2%, 79.4% and 100% at Week 52, respectively. Reduction in *JAK2*V617F VAF was found in 16 of 47 evaluable patients (34%) at Week 24, and 20 of 41 evaluable patients (44%) at Week 52. Reduction in *CALR* VAF was found in 10 of 19 evaluable patients (53%) at Week 24, and 6 of 14 evaluable patients (43%) at Week 52. Reduction of spleen size was found in 9 of 19 patients (47%) at Week 24, and 9 of 17 patients (53%) at Week 52. Reduction in MPNSAF-TSS of $\geq$50% was found in 27 of 63 evaluable patients (42.9%) at Week 24, and 23 of 57 patients (42.1%) at Week 52. The most common non-hematologic AEs included transaminitis (grade 1-2, N=35, 49.2%); malaise (grade 1-2, N=29, 40.8%; grade 3-4, N=1, 1.4%), and hair loss (grade 1-2, N=24, 33.8%). The most common hematologic AEs were anemia (grade 1-2, N=15, 21.1%; grade 3-4, N=6, 8.5%), neutropenia (grade 1-2, N=15, 21.1%; grade 3-4, N=4, 5.6%) and thrombocytopenia (grade 1-2, N=8, 11.2%; grade 3-4, N=3, 4.2%). Thrombohemorrhagic events or progression to blast-phase MF was not observed during the study. **Conclusions:** Ropeg-IFN-α2b was well-tolerated and induced clinical, hematologic and molecular responses in patients with pre-PMF and low/intermediate-1-risk MF. Clinical trial information: NCT04988815. Research Sponsor: Health and Medical Research Fund (HMRF); 09201046.

Safety and efficacy of bromodomain and extra-terminal (BET) inhibitor INCB057643 in patients (pts) with relapsed or refractory myelofibrosis (r/r-MF) and other advanced myeloid neoplasms: A phase (Ph) 1 study. First Author: Justin M. Watts, Sylvester Cancer Center, University of Miami, Miami, FL

Background: BET proteins are epigenetic readers that regulate expression of oncoproteins involved in hematologic malignancies, including MF. The oral, small-molecule BET inhibitor INCB057643 had favorable tolerability and encouraging clinical activity in pts with advanced MF in a previous Ph 1/2 trial. **Methods:** This ongoing Ph 1, open-label 3+3 dose-escalation/expansion study (NCT04279847) is evaluating INCB057643 monotherapy (mono; part 1; 4 mg→12 mg once daily [qd]) in adults with r/r-MF, essential thrombocythemia (ET), myelodysplastic syndrome (MDS), or MDS/myeloproliferative neoplasm (MPN) overlap syndrome, or combination therapy (combo; part 2; 4 mg qd→part 1 maximum tolerated dose) with ruxolitinib (RUX) in adults with MF and suboptimal response to RUX or who were Janus kinase inhibitor (JAKi) naive. Primary endpoint is safety/tolerability. Secondary endpoints: spleen volume (SV) response (≥35% reduction from baseline [BL; SVR35] at Week [Wk] 24), symptom response (≥50% reduction from BL in MPN-Symptom Assessment Form total symptom score [TSS50] at Wk 24), and anemia response (sustained hemoglobin increase ≥1.5 g/dL from BL [if transfusion (TF) independent at BL] or TF independence [if dependent at BL] for ≥12 wks). **Results:** As of 9Sep2024, 18 pts were treated in mono dose escalation, 20 in mono dose expansion, and 23 in combo dose escalation. 48 (79%) pts had MF, 5 (8%) MDS or MDS/MPN, and 8 (13%) ET. Median (range) INCB057643 exposure was 196 (15–812) days (d) in mono dose escalation, 155 (14–341) d in mono dose expansion, and 176 (25–560) d in combo dose escalation. The most common treatment (tx)-emergent adverse event (TEAE) was thrombocytopenia (TCP; 46%). Grade ≥3 TEAEs occurred in 57%, most commonly TCP (26%) and anemia (20%). Serious TEAEs occurred in 31%; 3 (5%) were tx related. No fatal events were tx related. 9 TEAEs lead to discontinuation. 2 dose-limiting toxicities occurred with mono (12 mg, TCP, hyperbilirubinemia) and 1 with combo (6 mg, TCP). 3 pts had acute myeloid leukemia transformation (4-mg mono MDS/MPN, 10-mg mono MDS, 4-mg combo MF). Wk 24 SVR35 was achieved by 3/20 evaluable MF pts treated with any mono dose (3/7 receiving ≥10 mg) and by 4/17 treated with any combo dose. Wk 24 TSS50 was achieved by 7/19 evaluable MF pts treated with any mono dose (5/8 receiving ≥10 mg) and by 8/16 treated with any combo dose. Durable anemia response occurred in 6/22 evaluable mono pts (2 TF-dependent at BL) and 4/20 combo pts. **Conclusions:** INCB057643 mono or combo with RUX was generally well tolerated, with no tx-related fatal events. Improvements in anemia, spleen size, and symptom burden were observed with mono and combo. Dose expansion is ongoing for 6- and 10-mg mono and 4- and 8-mg combo groups (add-on and JAKi naive). A Ph 3 study of INCB057643 mono in advanced post-JAKi MF pts is being initiated. Clinical trial information: NCT04279847. Research Sponsor: Incyte Corporation.

A simplified scoring system to predict in-hospital mortality of leukapheresis in patients with leukemia. First Author: Barath Prashanth Sivasubramanian, Northeast Georgia Medical Center, Gainesville, GA

Background: The 2019 consensus guidelines from the American Society for Apheresis recommend leukapheresis as a category II recommendation (acceptable second-line therapy) for patients with symptomatic hyperleukocytosis or leukostasis. Mortality in these patients has been reported to vary between 8-29%. However, no tool is currently available to assess the mortality risk following the procedure. **Methods:** The National Inpatient Sample Database (2016-2021) and ICD-10 coding were utilized to identify adults (age ≥18 years) with leukemia who underwent leukapheresisprocedure. Different types of leukemia were identified along with various demographic and clinical characteristics of patients including symptoms of leucostasis such as acute encephalopathy, respiratory failure, cardiac failure, and renal failure using ICD-10 codes. Also included were complications associated with leukapheresissuch as hemorrhage. Multivariate logistic regression models were constructed to identify independent factors associated with mortality. A scoring system was constructed to identify the risks of mortality using the variables in the model and their associated odds ratio (OR). Splines were used to identify the knots which were used as cutoff values. The cumulative risk score was divided into three strata: low (mortality < 10%), intermediate (10-40%), and high risk (>40%). **Results:** Of the estimated 4,705 patients who underwent leukapheresis, 14.2% had lymphoid leukemia, 6.2% had monocytic leukemia, 52.2% had myeloid leukemia, and 3.6% had other types of leukemia. The overall in-hospital mortality was 24.2% and the median length of hospital stay was 10 days (IQR 5-24). 71.3% received leukapheresiswithin the first 48 hours of hospitalization. Variables identified as significantly associated with mortality included the type of leukemia: monocytic leukemia (OR 3.1), myeloid leukemia (OR 2.6), lymphoid leukemia (OR 1.8) other types of leukemia (OR 3.8). Organ failure associated with hospital mortality included acute respiratory failure (OR 12.7), acute renal failure (OR 2.3), cardiogenic shock (OR 8), acute encephalopathy (OR 2.2), and disseminated intravascular coagulation (OR 1.8). The cumulative mortality score ranged from 0 to 33, categorizing patients into high risk (score ≥ 5), intermediate risk (score 2-4) and low risk (score 0-1). The risk score demonstrated a performance with an area under the curve of 0.79. of note, age, gender, and race were non-contributory in this scoring system. **Conclusions:** A novel simplified scoring tool to predict in-hospital mortality in leukemia patients requiring leukapheresis is proposed. This tool can assist in preprocedural risk assessment and help guide management planning along with consideration for the role of other treatment modalities. Research Sponsor: None.

Efficacy and safety outcomes of obecabtagene autoleucel (obe-cel) stratified by age in patients (pts) with relapsed/refractory B-cell acute lymphoblastic leukemia (R/R B-ALL). First Author: Bijal D. Shah, Moffitt Cancer Center, Tampa, FL

Background: CD19 chimeric antigen receptor T-cell therapy (CAR T) exhibits good efficacy in adults with R/R B-ALL but is associated with higher toxicity with increasing age. Obe-cel, an autologous anti-CD19 CAR T, has shown high and durable response rates with low incidence of immunotoxicity in adult R/R B-ALL, and was recently approved by the US FDA. Here, we report a post-hoc analysis of the Phase Ib/II FELIX trial (NCT04404660) evaluating efficacy, safety, and persistence outcomes with obe-cel stratified by pt age. **Methods:** Adult R/R B-ALL pts received obe-cel using a tumor burden-guided dosing strategy to minimize toxicity. Overall remission rate (ORR; complete remission [CR]/CR with incomplete hematologic recovery), event-free survival (EFS), safety, and persistence are reported for pts aged <55 and ≥55 years (yrs; data cut-off: 7 Feb 2024). **Results:** Of 127 obe-cel infused pts, 79 (62.2%) were aged <55 yrs (median 36.0 [range: 20–54]) and 48 (37.8%) were aged ≥55 yrs (median 65.0 [range: 55–81]). A higher proportion of pts aged <55 yrs were Hispanic/Latino (36.7% vs 18.8%), had extramedullary disease at lymphodepletion (LD; 29.1% vs 8.3%), received prior blinatumomab (53.2% vs 22.9%), and prior inotuzumab ozogamicin (35.4% vs 25.0%) than those ≥55 yrs, while a higher proportion of pts aged ≥55 yrs had Philadelphia chromosome-positive disease (47.9% vs 16.5%). Median bone marrow blast burden at LD was higher in pts aged ≥55 yrs (45.5%) vs <55 yrs (30.0%). At 21.5 months' (mos) median follow-up (range: 8.6–41.4), the ORR (95% CI) was 72.2% (60.9–81.7) in pts aged <55 yrs vs 87.5% (74.8–95.3) in pts aged ≥55 yrs. In responders, 84.2% of pts <55 yrs and 83.3% ≥55 yrs with ≥1 post-infusion next-generation sequencing result achieved measurable residual disease-negative remission to 10^{-6} leukemic cells by Month 3. Durable remission at 1 yr post infusion was observed in 68.3% and 51.8% of pts aged <55 and ≥55 yrs, respectively. EFS was comparable in pts aged <55 and ≥55 yrs: median (95% CI) 14.3 mos (6.0–not estimable [NE]) vs 11.7 mos (6.6–NE), respectively. While in remission, 29.8% of pts aged <55 yrs and 2.4% aged ≥55 yrs proceeded to consolidative stem cell transplant (SCT). Incidence of Grade ≥3 cytokine release syndrome (CRS; 2.5% vs 2.1%) and immune effector cell-associated neurotoxicity syndrome (ICANS; 5.1% vs 10.4%) were low for pts aged <55 and ≥55 yrs, respectively. Treatment-related mortality within 3 mos post obe-cel infusion was 0% in pts aged <55 yrs vs 4.2% in pts aged ≥55 yrs. CAR T-cell persistence was similar in both age groups. **Conclusions:** Obe-cel treatment resulted in favorable ORR and EFS with low Grade ≥3 CRS/ICANS incidence in both age groups. These findings indicate that obe-cel is effective and has a positive benefit/risk profile regardless of age, including in older adults with R/R B-ALL despite few receiving consolidative SCT. Clinical trial information: NCT04404660. Research Sponsor: Autolus Therapeutics PLC. Third-party medical writing assistance, under the direction of the authors, was provided by Michaella Hulley, PhD, of Ashfield MedComms, an Inizio company, funded by Autolus Therapeutics PLC.

Updated results of a phase 2 study: Timdarpacept (IMM01) combined with azacitidine (AZA) as the first-line treatment in adults with chronic myelomonocytic leukemia (CMML). First Author: Hongyan Tong, The First Affiliated Hospital of Zhejiang University School of Medicine, Hangzhou, Zhejiang, China

Background: Timdarpacept is a recombinant signal regulatory protein α (SIRPα) IgG1 fusion protein that exerts anti-tumor activity via blocking "Don't eat me" signal and activating the "Eat me" signal to induce strong antibody-dependent cellular phagocytosis (ADCP). **Methods:** The study (NCT05140811) assessed the safety and efficacy of Timdarpacept combined with AZA as first-line treatment for newly diagnosed CMML patients. Timdarpacept was administered intravenously at a dosage of 2.0mg/kg/week, while subcutaneous AZA was given at a dosage of 75 mg/m^2 on D1-7 per 28-day cycle. **Results:** At the cut-off date on Dec 31, 2024, 24 patients, with a median age of 62, males 62.5%, and 75.0% ECOG≥1, were enrolled. 33.3% and 66.7% patients were and high risk (HR), respectively. Majority of patients had poor baseline of hematologic conditions with a median hemoglobin (Hb) level of 69.5 (32-132) g/L and a median platelet (PLT) count of 73.5 (5-667)×10^9/L. The median duration of follow-up was 21.0 months (95% CI, 19.3-23.3). Among 22 efficacy evaluable patients, overall response rate (ORR) was 72.7%, including 27.3% complete response (CR), 13.6% marrow CR (mCR) with hematologic improvement (HI), 4.5% HI and 27.3% mCR alone. The median time to response (TTR) was 1.8 months and the median duration of response (DoR) was 16.9 months (95%CI, 5.1-not reached [NR]). The median time to CR (TTCR) was 3.7 months and the median duration of CR (DoCR) was 13.6 months (95%CI, 5.7-NR). The median of progression-free survival (PFS) was 17.8 months (95%CI, 5.3-NR), with an estimated 12-month PFS of 59.0% (95%CI, 33.4-77.6). Median OS has not been reached yet. The most common ≥Grade 3 TRAEs (≥10%) included lymphopenia (66.7%), leukopenia (62.5%), neutropenia (58.3%), thrombocytopenia (50.0%), anemia (29.2%) and pneumonia (16.7%). Without using of a low dose priming regimen, Grade ≥3 hemolysis occurred in 1 patient (4.2%). **Conclusions:** Timdarpacept, without a low-dose priming, combined with AZA, was well tolerated in 1L CMML. The combination, when compared to the historical data of AZA monotherapy, showed promising efficacy results for patients with treatment-naive CMML-1 and -2. Clinical trial information: NCT05140811. Research Sponsor: ImmuneOnco Biopharmaceuticals (Shanghai) Inc., Shanghai, China.

Maintenance therapy with azacitidine and valproic acid after allogeneic stem cell transplant in patients with high-risk myelodysplastic syndrome and acute myelogenous leukemia. First Author: Timothy Edward O'Connor, Loyola University Medical Center, Maywood, IL

Background: Relapse is a major cause of death after allogeneic stem cell transplant (allo-SCT) in patients with high-risk myelodysplastic syndrome (MDS) and acute myelogenous leukemia (AML). Chemotherapy maintenance to prevent relapse has had limited success to date, with a phase 3 hypomethylating agent (HMA) study showing no improvement in relapse rate or survival (Oran et al.). A subgroup analysis, however, showed that high-risk patients may indeed benefit (Pasvolsky et al.). We tested a combination of an HMA [azacitidine (AZA)] and a histone deacetylase (HDAC) inhibitor [valproic acid (VPA)] as a novel maintenance following allo-SCT for high-risk AML and MDS patients based on previously reported in vitro synergism between these agents. **Methods:** This investigator-initiated, single-center, phase II trial included only patients with high-risk MDS and AML who were enrolled following day+40 of allo-SCT to receive AZA and VPA for 4, 28 day cycles. Exclusions included no grade 3-4 acute GVHD, active infection, low risk AML in CR1, a neutrophil count $<$ 1500/μl, or platelets $<$ 50 000/μl. Risk was assessed via DRI at time of transplant. AZA was administered at 40 mg/m2 daily for 5 days SQ with daily oral VPA starting at 15 mg/kg and dose-adjusted to achieve a trough level of bound VPA of 100 μg/mL. Tacrolimus and methotrexate were used as GVHD prophylaxis. The primary endpoints were 1-year relapse rate, overall (OS), and progression-free (PFS) survival. **Results:** Fifty patients were enrolled. The median age was 52 with 28 (56%) male. The median hematopoietic cell transplantation-specific comorbidity index was 2. Graft types: 21 (42%) matched related, 21 (42%) matched unrelated, and 8 (12%) cord blood. Thirty grafts were from peripheral blood and 12 marrow. Myeloablative conditioning was used in 36 (72%) and reduced intensity conditioning in 14 (28%). At time of transplant for AML patients, 21 (46%) were in CR1, 5 (11%) in CR2, 2 (4%) in CRi, and 18 (39%) were relapsed/refractory. Four had high grade MDS. Baseline DRI: 42 (84%) were very high risk or high risk and 8 (16%) were intermediate risk. Eight (16%) patients did not receive all four cycles: 5 (10%) due to progression of disease, 1 (2%) due to acute GVHD, 1 each (2%) due to fatigue and cytopenias. One-year PFS and OS were 80% and 86% and 5-year PFS and OS were 47% and 61%, respectively. The one-year relapse rate was 18%. Most toxicities were grade I or II: fatigue, cytopenias, and acute kidney injury. **Conclusions:** The co-administration of AZA and VPA as a short-term maintenance strategy following allo-SCT in patients with high risk MDS and AML is safe and feasible. While a comparative trial is warranted, the use of this HMA+HDAC regimen seems to validate prior data that HMA-based maintenance may improve the outcomes of high-risk MDS and AML patients. Clinical trial information: NCT02124174. Research Sponsor: None.

Hydroxyurea vs. hypomethylating vs. other agents in chronic myelomonocytic leukemia: A retrospective inspection of treatment strategies among 457 Mayo Clinic patients. First Author: Muhammad Yousuf, Mayo Clinic, Rochester, MN

Background: Treatment strategies in chronic myelomonocytic leukemia (CMML) are not standardized and include hydroxyurea (HU) and hypomethylating agents (HMA). In a phase 3 study comparing HU and decitabine, in proliferative CMML, response rates were higher for decitabine (56% vs 31%; p$<$0.01) but overall survival was similar (p=0.67) between the two groups (Itzykson, R. JCO, 2023. 41:1888). In the current retrospective study, we examined the survival impact of different treatment strategies among 457 Mayo Clinic patients with CMML. **Methods:** The current study was conducted under institutional review board approved minimum risk protocols allowing retrospective patient data collection and analysis. Diagnostic criteria were according to the International Consensus Classification (Arber et al. Blood 2022. 140:1200). All statistical analyses were conducted using JMP 17 software. For survival analysis, patients were censored at time of allogeneic stem cell transplant (ASCT). **Results:** A total of 457 patients were considered (median age 72 years; 68% males). 209 patients received CMML-directed therapy: HU (N=102), HMA (N=78; azacitidine 32 and decitabine 46). Responses were adjudicated separately for leukocytosis and anemia; normalization of leukocyte count was achieved in 21% vs. 16 % (p$<$0.01) for HU vs. HMA and overall response in anemia in 1% vs. 9% (p=0.02), respectively. Overall survival did not appear to be impacted by different treatment strategies at any stage of CMML; (i) treated vs. untreated (p=0.3), (ii) HU vs. HMA for first-line therapy (p=0.3), and (iii) HU/HMAs vs. other drugs as first-line therapy (p=0.1). Blast transformation-free survival (BTFS) was also similar between HU vs. HMA as well as HU/HMA vs. other drugs. In univariate analysis, BTFS was inferior in patients receiving CMML-directed therapy (p$<$0.01); the particular association (HR 2; 95% CI 1.2-3.3) retained its significance in multivariable analysis that also included other risk factors for BTFS: bone marrow blast $\geq$10% (HR 4.3), circulating blast $\geq$2% (HR 2.7), WBC $\geq$13 x 10^9/L (HR 1.8), and ASXL1 mutation (HR 1.7). **Conclusions:** In the current retrospective study that included a large number of patients with CMML, chemotherapy with HU or HMA did not appear to affect overall survival but might have increased the risk of blast transformation. The study also suggests superiority of HU for the treatment of leukocytosis and HMA for anemia. Research Sponsor: None.

Predictors of blast transformation-free survival (BTFS) in 457 patients diagnosed with chronic myelomonocytic leukemia (CMML).

BTFS	Univariable analysis *p-value* (HR)	Multivariable analysis *p-value* (HR)
CMML-directed therapy	**<0.01** (2.9; 1.8-4.7)	**<0.01** (2; 1.2-3.3)
Bone marrow blasts ≥10%	**<0.01** (12.4)	**0.01** (4.3)
Circulating blasts ≥2%	**<0.01** (5.2)	**<0.01** (2.7)
WBC ≥13 x 10^9/L	**<0.01** (2.9)	**0.02** (1.8)
ASXL1mut	**<0.01** (2.1)	**0.02** (1.7)

TPS6580 **Poster Session**

QuANTUM-Wild: A phase 3, randomized, double-blind, placebo-controlled trial of quizartinib in combination with chemotherapy and as single-agent maintenance in *FLT3*-ITD–negative acute myeloid leukemia (AML). First Author: Pau Montesinos, Hematology, Hospital Universitari I Politécnic La Fe and Programa Español de Tratamientos en Hematología (PETHEMA) Group, Valencia, Spain

Background: Quizartinib (Quiz) is an oral, selective, type-II FLT3 inhibitor with potent activity against wild-type (wt) FLT3, FLT3-ITDs, and other kinase domain variants. Quiz is approved for patients (pts) with *FLT3*-ITD+ newly diagnosed (ND) AML based on results from the QuANTUM-First trial (NCT02668653). Mutations in the *FLT3* gene are observed in ~30% of AML cases, most commonly as ITDs, but they are not the only mechanism affecting FLT3 activation. Elevated expression of the FLT3 receptor is observed in nearly all cases of AML, and high levels of *FLT3* gene expression are detected in 70–100% of AML blasts, independent of the presence of *FLT3* gene mutations, potentially contributing to leukemic cell survival and proliferation. Evidence from preclinical and clinical studies supports Quiz activity in *FLT3*-ITD–negative (*FLT3*-ITDneg) AML. In the phase 2 QUIWI trial, the addition of Quiz to standard chemotherapy and as single-agent maintenance significantly prolonged overall survival (OS) vs placebo (Pbo) in ND *FLT3*-ITDneg AML. QuANTUM-Wild is a global, phase 3, double-blind, Pbo-controlled trial evaluating Quiz with standard induction/consolidation chemotherapy and as maintenance in ND *FLT3*-ITDneg AML (NCT06578247). **Methods:** Eligible pts are aged 18–70 years with *FLT3*-ITD allelic frequency $<$ 5%. Treatment includes standard induction with cytarabine and an anthracycline plus Quiz/Pbo, followed by up to 4 cycles of consolidation (+/− allo-HSCT) with high-dose cytarabine and Quiz/Pbo, and then single-agent maintenance with Quiz/Pbo in 28d cycles for up to 36 cycles. Pts are randomized 2:2:1 into 3 arms: Arm A (Quiz in all phases), Arm B (Pbo in all phases), or Arm C (Quiz in induction/consolidation and Pbo in maintenance). Quiz is administered at 60 mg/day, reduced to 30 mg if combined with strong CYP3A inhibitors. The primary endpoint is OS, and secondary endpoints include event-free survival (EFS), relapse-free survival (RFS), complete remission (CR) rate and duration, measurable residual disease (by *FLT3*-ITD in all pts and by *NPM1* and *CBF* if present), and safety. Planned enrollment is ~700 pts, with 280 each in Arms A and B, and 140 pts in Arm C. The primary OS analysis compares Arms A and B, while Arm C is descriptive. Enrollment is expected to continue through 2028. Clinical trial information: 2023-507936-20-00; NCT06578247. Research Sponsor: Daiichi Sankyo.

TPS6581 **Poster Session**

First-in-human study of autologous chimeric engulfment receptor T-cell CER-1236 targeting TIM-4-I in acute myeloid leukemia (CertainT-1). First Author: Abhishek Maiti, Division of Cancer Medicine, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Acute myeloid leukemia (AML) is the most common adult acute leukemia. Patients with relapsed or refractory (R/R) disease have dismal outcomes with complete remission (CR) rates of 5%- 15% and median overall survival of 3 to 6 months with best available therapies. In addition, patients in remission with measurable residual disease (MRD) have poor outcomes with no approved therapies. CER-1236 is an autologous chimeric engulfment receptor T cell (CER-T) which fuses external domain of TIM-4 with intracellular domains from T cells and innate immune cells including Toll-like receptor 2 (TLR2), CD28 and CD3ζ. This receptor binds TIM-4-ligand (phosphatidylserine) on tumor cells leading to phagocytosis and lysis of target cells followed by tumor antigen processing and cross-presentation to induce an adaptive immune response. CER-1236 was shown to eliminate AML cell in vitro, and in vivo in a xenograft model. TIM-4 is the key receptor which binds to TIM-4-L and leads to target cell engulfment. TIM-4-L is expressed in 88% of primary patient AML samples, across TP53 mutated and other mutational subgroups, with significantly higher expression than bone marrow from healthy donors. **Methods:** This is an open label phase I study to evaluate the safety and preliminary activity of CER-1236 in patients with R/R AML. We will evaluate 3 doses levels from 1 to 5 x10^6/kg CER+ T cells using a BOIN dose escalation design. Subsequently we will evaluate patients in 3 expansion cohorts including R/R AML, TP53 mutated AML, and AML in composite CR (cCR), i.e., CR/CRi/CRh with positive MRD. For the dose escalation study we will enroll adults with R/R AML or myelodysplastic syndrome (MDS)/AML per ICC 2022 criteria who have exhausted standard therapeutic options and patients with treated secondary AML who have progressed to AML after receiving AML directed therapy for antecedent hematological disorder, e.g, MDS. Patients will need an ECOG performance status of 0 to 1 and adequate end organ function. We will exclude patients with t(15;17), proliferative disease or active infections. For the MRD dose expansion cohorts we will enroll patients with cCR with MRD $\geq$0.1% by validated multi-parametric flow cytometry. Study treatment: Patients will receive lymphodepleting chemotherapy (LDC) with fludarabine 30 mg/m^2/d and cyclophosphamide 400 mg/m^2/d for 3 days followed by a single infusion of CER-1236 2 days later. Patients may receive standard treatments as bridging therapy after apheresis and prior to LDC. The primary objective of the study is the safety of CER-1236 in terms of dose-limiting toxicities, cytokine release syndrome, and Immune effector cell-associated neurotoxicity syndrome. Secondary objectives are to measure objective response rate per the ELN 2022 criteria including CR+CRh+CRi+MLFS, cCR, MRD negativity by flow cytometry, and PK/PD profile and biomarkers of response. Research Sponsor: None.

TPS6582 **Poster Session**

Tagraxofusp and low-intensity chemotherapy for the treatment of CD123-positive relapsed or refractory acute myeloid leukemia. First Author: Wooin Cho, Stanford Cancer Institute, Clinical Trial Office, Stanford University School of Medicine, Palo Alto, CA

Background: The combination of venetoclax and a hypomethylating agent (Ven/HMA) is the standard frontline (1L) therapy for patients with acute myeloid leukemia (AML) who are ineligible for intensive chemotherapy (IC). However, outcomes after Ven/HMA failure are poor, with a median overall survival of only 2-3 months. Cladribine (CLAD) with LDAC has previously been shown to be well-tolerated and effective in IC-ineligible patients with newly diagnosed AML. Resistance to Ven/HMA is commonly driven by mutations in the RAS/MAPK pathway and the presence of monocytic subclones that are less dependent on BCL2, both of which may retain sensitivity to cladribine-based therapy following 1L Ven/HMA. Tagraxofusp (TAG), a CD-123 targeted therapy, selectively induces apoptosis in CD123-expressing cells by irreversibly inhibiting protein synthesis through EF-2 inactivation. CD123 is highly expressed on AML blasts and leukemia stem cells compared to normal hematopoietic stem cells in the majority of AML patients. TAG in combination with Ven/HMA has shown efficacy in 1L adverse-risk AML. With its minimal additive myelosuppression and targeted specificity, TAG represents an ideal partner to combine with traditional cytotoxic chemotherapies such as CLAD and LDAC. This investigator-initiated study aims to determine the safety and tolerability of TAG in combination with CLAD and LDAC for IC-ineligible patients with relapsed or refractory (R/R) CD123 positive AML after 1L treatment with Ven/HMA. **Methods:** This single-center, open-label Phase 1b/2 trial will enroll up to 20 patients. Key inclusion criteria are: age$\geq$18 years, R/R AML after 1L Ven/HMA with no prior salvage therapies with the exception of monotherapy with targeted inhibitors, ECOG 0-2; serum albumin$\geq$3.2g/dL; and adequate cardiac, renal, and liver function. The phase 1b dose-exploration will determine the safety and tolerability of CLAD, LDAC, and TAG. The first 3 patients will all be treated at Dose Level 1, consisting of CLAD 5mg/m2 IV daily on days 1-3, LDAC 20mg/m2 IV daily days 1-5, TAG 12mcg/kg IV daily days 4-6. Dose escalation will proceed as tolerated to a target dose level of Dose Level 3, consisting of CLAD 5mg/m2 IV daily on days 1-5, LDAC 20mg/m2 IV daily days 1-10, TAG 12mcg/kg IV daily days 4-6. Dose-escalation and de-escalation will be determined by the BOIN design. The primary objective is determination of the RP2D based on the safety of TAG+CLAD+LDAC, as assessed by DLT evaluation. Secondary objectives include ORR, CR, composite CR (CR+CRi+CRh), and rate of MRD negativity in responders. Duration of RFS, OS, and responses according to mutational profile, karyotype, CD123 expression, and patient demographics will be reported. Once the RP2D is determined, a dose expansion cohort will begin enrolling. The study began enrolling patients in January 2025 and is actively recruiting. Clinical trial information: NCT06561152. Research Sponsor: None.

TPS6583 **Poster Session**

A phase II open-label study of olutasidenib post-transplant maintenance therapy for patients with IDH1-mutated myeloid malignancies. First Author: Jeremy L. Ramdial, Department of Stem Cell Transplantation and Cellular Therapy, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Allogeneic hematopoietic stem cell transplantation (alloSCT) remains one of the most effective treatments for patients with myeloid malignancies. Much of the benefit is due to the immune-mediated graft-versus-leukemia effect to prevent relapse. Nevertheless, despite advances in conditioning therapy, disease relapse remains the most important cause of treatment failure after alloSCT. Maintenance therapy post alloSCT aims to reduce relapse incidence and strengthen the potential for cure. With modern treatment regimens, expected complete remission (CR) rates for newly diagnosed AML patients are 60-70%, however, long-term cure rates are only ~30% and improved treatments are needed. IDH1 mutations occur in $>$7% of older patients with AML and up to 4% of patients with high-risk CMML or MDS. A multicenter phase I trial of another IDH1 inhibitor used as maintenance treatment following alloSCT for IDH1-mutated AML demonstrated a two-year progression-free survival (PFS) of 81%, and two-year overall survival (OS) of 88%. The 2-year cumulative incidence of disease relapse was 19% (95% CI, 4%–41%) and the 2-year cumulative incidence of non-relapse mortality (NRM) was 0%. Olutasidenib is a well-tolerated, highly selective, non-cytotoxic, and potent FDA-approved oral inhibitor of mutant IDH1, with an overall response rate in relapsed/refractory AML of 48%. **Methods:** In our single center, investigator-initiated study under the MDACC-Rigel Research Alliance we aim to determine the safety and tolerability of olutasidenib as maintenance post-allo-SCT and to determine the rate of progression-free survival (PFS). Eligibility includes patients 18-75 years old with IDH1 mutation presence at diagnosis with acceptable organ function. Patients must also have a diagnosis of AML, MDS, MPN, or CMML according to World Health Organization (WHO) classification that underwent first or second alloSCT with either peripheral blood or bone marrow hematopoietic stem cell source, regardless of donor type/match, conditioning regimen, or GVHD prophylaxis and is at least 30 days post stem cell transplant until day 120. A safety lead-in phase will be given for the first 6 patients to investigate whether the starting dose of 150 mg BID is safe and tolerable. After the safety lead-in phase, the remaining patients will be enrolled at the same dose and the safety and tolerability will be monitored. We also would like to determine response rate, overall survival (OS), cumulative incidence of relapse, NRM, GVHD relapse-free survival (GRFS), rate and grading of aGVHD grade 2-4 and 3-4 at day 100, incidence and grading chronic GVHD (cGVHD) all grades. The goal enrollment is 25 total patients. The study was activated and enrollment began in December 2024. Clinical trial information: NCT06668584. Research Sponsor: None.

TPS6584 **Poster Session**

Phase 3 study of either ivosidenib monotherapy or azacitidine monotherapy in patients with IDH1-mutant myelodysplastic syndromes who are hypomethylating agent naive (PyramIDH). First Author: Valeria Santini, DMSC, Azienda Ospedaliero-Universitaria Careggi, University of Florence, Florence, Italy

Background: Myelodysplastic syndromes (MDS) are a heterogeneous group of clonal myeloid disorders that occur predominantly in older patients with variable risk of progression to acute myeloid leukemia (AML). According to International Prognostic Scoring Systems, patients with lower-risk MDS (LR-MDS) and cytopenias can be treated with different drugs and in some cases hypomethylating agents (HMAs). However, in higher-risk MDS (HR-MDS), HMAs are the only available standard of care therapy. The complete response (CR) + partial response (PR) rate of azacitidine in treatment-naive MDS ranges between 16% and 22%. These low response rates, combined with the short duration of responses observed with these approaches highlight an unmet medical need for this population. Ivosidenib (IVO) is an oral, targeted small molecule inhibitor of mutant IDH1 that is currently FDA approved in relapsed/refractory MDS with a complete remission (CR) + partial remission (PR) rate of 38.9% (95% CI: 17.3%, 64.3%) with all responses being CR. In the phase 2 IDIOME study, 72% of patients with previously untreated *mIDH1* HR-MDS obtained CR+PR with IVO monotherapy; median OS and DOR were not reached after median follow-up of 25.2 months. The aim of PyramIDH is to confirm the safety and clinical activity of IVO monotherapy in HMA–naive *mIDH1* MDS in a larger cohort. **Methods:** PyramIDH (NCT06465953) is a phase 3, multicenter, open-label, randomized, non-comparative two-arm study of IVO or azacitidine (AZA) monotherapy in patients with HMA-naive *mIDH1* MDS. Key eligibility criteria include diagnosis of HMA-naive *IDH1 R132* mutated MDS. HR-MDS (moderate high-, high- and very-high-risk MDS per IPSS-Molecular (IPSS-M) score), will be eligible if the bone marrow blast count is $<$20% regardless of blood cell counts. LR-MDS (low- and moderate-low-risk MDS per IPSS-M score), must have cytopenias related to MDS, defined as: $<$100 platelets/μL, or absolute neutrophil count (ANC) $<$1000/mm^3, or hemoglobin $<$10g/dL, have a blast count between 5% and 19%, and be eligible for HMA therapy. Very-low-risk MDS per IPSS-M will not be eligible for enrollment. Enrolled patients (n=~48) will be randomized (2:1) to IVO or AZA monotherapy and they will be stratified by IPSS-M risk status (HR versus LR). The primary endpoint is CR+PR at 4 months as per IWG 2006 criteria. Key secondary endpoints include duration of CR+PR per IWG 2006 criteria, time to CR+PR per IWG 2006 criteria, transfusion independence rate, AML transformation rate, and number of patients going to transplant. Other secondary endpoints are CR+PR at 6 months per IWG 2006 criteria; CR+PR at 4 and 6 months per IWG 2023 criteria; overall response rate per IWG 2023 criteria, duration of response, EFS, OS, duration of transfusion independence (TI), time to TI, AML transformation, quality of life, PK/PD, and safety. Clinical trial information: NCT06465953. Research Sponsor: Servier.

TPS6585 **Poster Session**

Phase II study evaluating olutasidenib in patients with *IDH1*-mutated clonal cytopenia of undetermined significance or lower-risk myelodysplastic syndromes/chronic myelomonocytic leukemia. First Author: Kelly Sharon Chien, Department of Leukemia, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Observational studies have demonstrated that individuals with clonal cytopenia of undetermined significance (CCUS) involving high-risk mutations, such as *IDH1*, are more likely to transform to acute myeloid leukemia (AML), with one study showing a progression rate of 100% in *IDH1/2*-mutated patients after 5 years of follow-up. However, there are no Food and Drug Administration (FDA)-approved strategies for the prevention of hematologic malignancies in the setting of CCUS. *IDH1* mutations are detected in 3-4% of patients with myelodysplastic syndromes (MDS) or chronic myelomonocytic leukemia (CMML). Despite the safety and efficacy of IDH1 inhibitors in acute myeloid leukemia and the recent FDA approval of ivosidenib for relapsed/refractory *IDH1*-mutated MDS, no IDH1-directed therapies are approved in lower-risk, treatment-naïve MDS/CMML. Olutasidenib, an FDA-approved oral, highly selective, potent inhibitor of mutant IDH1, is well-tolerated, non-cytotoxic and effective, with overall response rates in relapsed/refractory AML of 48% as monotherapy. We consequently hypothesize olutasidenib to be effective in both improving hematologic parameters and decreasing the risk of progression to high-risk MDS/CMML and AML in *IDH1*-mutated patients. **Methods:** This multicenter investigator-initiated study under the MDACC-Rigel Research Alliance is a phase II single-arm study evaluating the efficacy of olutasidenib monotherapy in patients with *IDH1*-mutated CCUS or lower-risk MDS/CMML. Eligibility includes adult patients with acceptable organ function and confirmed *IDH1* mutation with CCUS (by World Health Organization criteria) or lower-risk MDS/CMML (by Revised International Prognostic Scoring System [IPSS-R] and Molecular International Prognostic Scoring System [IPSS-M] criteria). The primary objective of the study is to determine the response rate by International Working Group 2018 criteria. Secondary objectives include rates of transfusion independence, safety and tolerability, overall survival, progression-free survival, duration of response, rates of leukemic transformation, and changes in *IDH1* clone size. All patients will receive olutasidenib 150 mg orally twice daily. CCUS patients will receive up to 18 months of olutasidenib, while lower-risk MDS/CMML patients can receive olutasidenib indefinitely. Response assessments will be performed approximately every 3 months for the first year, then yearly thereafter. Once off treatment, survival follow-up will occur every 3 months for 3 years. The goal enrollment is 15 total patients with at least 8 CCUS patients across 5-6 centers in the United States. The study was activated and enrollment began in December 2024. Clinical trial information: NCT06566742. Research Sponsor: None.

TPS6586 **Poster Session**

Phase II study evaluating olutasidenib and azacitidine in patients with *IDH1*-mutated higher-risk myelodysplastic syndromes, chronic myelomonocytic leukemia, or advanced myeloproliferative neoplasms. First Author: Kelly Sharon Chien, Department of Leukemia, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: *IDH1* mutations are detected in 3-4% of patients with myelodysplastic syndromes (MDS) or chronic myelomonocytic leukemia (CMML) and approximately 9% of patients with myeloproliferative neoplasms (MPN). *IDH1* mutations have been associated with shortened survival and increased rates of transformation to acute myeloid leukemia (AML). Despite the use of IDH1 inhibitors in AML and the recent FDA approval of ivosidenib for relapsed/refractory *IDH1*-mutated MDS, no IDH1-directed therapies are approved in MPN or treatment-naïve MDS/CMML, and no combination treatment regimens are commercially available. Olutasidenib, an FDA-approved oral, highly selective, potent inhibitor of mutant IDH1, is well-tolerated, non-cytotoxic and effective, with overall response rates in relapsed/refractory AML of 51% in combination with azacitidine. Olutasidenib alone or with azacitidine demonstrated overall response rates of 86% in treatment-naïve and 47% in relapsed/refractory MDS. We consequently hypothesize olutasidenib to be effective in patients with *IDH1*-mutated higher-risk MDS/CMML or advanced MPN. **Methods:** This multicenter investigator-initiated study under the MDACC-Rigel Research Alliance is a phase II non-randomized study evaluating the efficacy of olutasidenib in combination with azacitidine in patients with *IDH1*-mutated higher-risk MDS/CMML or advanced MPN. Patients will be divided into 2 arms: treatment naïve and previously treated. Eligibility includes adult patients with acceptable organ function and confirmed *IDH1* mutation with higher-risk MDS/CMML (by International Prognostic Scoring System [IPSS], Revised IPSS [IPSS-R], or Molecular IPSS [IPSS-M] criteria) or advanced MPN (with bone marrow blast percentage $\geq$ 10%). The primary objective of the study is to determine the overall response rate by International Working Group 2023 criteria (MDS), 2015 MDS/MPN uniform response criteria (CML), and European Leukemia Network 2017 AML criteria (advanced MPN). Secondary objectives include rates of complete remission, safety and tolerability, overall survival, progression-free survival, duration of response, and changes in *IDH1* clone size. All patients will receive azacitidine 75 mg/m^2 intravenously or subcutaneously daily on days 1-7 of each treatment cycle and olutasidenib 150 mg orally twice daily. Response assessments will be performed after cycle 1, then every 3 cycles up through cycle 12, then every 12 cycles thereafter. Once off treatment, survival follow-up will occur every 3 months for 3 years. The goal enrollment is 45 patients (25 treatment-naïve and 20 previously-treated with no more than 5 MPN patients in each arm) across 5-6 centers in the United States. The study was activated and enrollment began in January 2025. Clinical trial information: NCT06597734. Research Sponsor: None.

TPS6587 **Poster Session**

Shorespan-007: Phase 3 study of bomedemstat versus hydroxyurea in essential thrombocythemia naive to cytoreductive therapy. First Author: Kristen M. Pettit, University of Michigan, Ann Arbor, MI

Background: Lysine-specific demethylase 1 (LSD1) is an enzyme that regulates hematopoietic stem and progenitor cell proliferation and maturation. Bomedemstat (MK-3543) is an LSD1 inhibitor shown to have manageable safety and improve symptoms, durably reduce platelet and white blood cell (WBC) count, and reduce mutation burden in patients with essential thrombocythemia (ET) in a phase 2 study. Here, we describe the methodology of the randomized, double-blind, phase 3 Shorespan-007 study (NCT06456346), which has been designed to evaluate the efficacy and safety of bomedemstat compared with hydroxyurea in participants with ET naive to cytoreductive therapy. **Methods:** Key eligibility criteria include patients aged $\geq$18 years with an ET diagnosis per WHO diagnostic criteria for myeloproliferative neoplasms, an indication for cytoreductive therapy, no prior cytoreductive therapy, a bone marrow fibrosis score of 0 or 1, a platelet count of $>450 \times 10^9$/L, and an absolute neutrophil count of $\geq 0.75 \times 10^9$/L. Key exclusion criteria include a documented increased risk of bleeding or an active infection necessitating systemic therapy. Approximately 300 participants will be enrolled. Participants will be randomly assigned 1:1 to bomedemstat at a starting dose of 50 mg/day by mouth titrated to a target platelet count of $\geq 150 \times 10^9$/L to $\leq 350 \times 10^9$/L or hydroxyurea at a starting dose of 500 mg/day by mouth titrated per the approved product labeling. The primary end point is durable clinicohematologic response, defined as the following: a confirmed reduction of platelet count to $\leq 400 \times 10^9$/L; absence of a WBC count elevation to $>10 \times 10^9$/L locally assessed to be due to ET; and, if WBC count is elevated to $>10 \times 10^9$/L at screening, a reduction of WBC count to $\leq 10 \times 10^9$/L (confirmed by first subsequent visit a minimum of 2 weeks apart, starting by week 24 and maintained for $\geq$24 weeks to at least week 48; absence of any thrombotic or major hemorrhagic events or disease progression to myelofibrosis [MF] or myelodysplastic syndrome [MDS]/acute myeloid leukemia (AML) by week 52). Secondary end points include change in fatigue from baseline per the MFSAF v4.0, change in total fatigue score from baseline per the PROMIS Fatigue SF-7a scale, change in total symptom score from baseline per the MFSAF v4.0, duration of clinicohematologic response, duration of hematologic remission, incidence of thrombotic events, incidence of major hemorrhagic events, transformation to post-ET MF or MDS/AML, and safety and tolerability. Clinic visits will occur every 2 weeks for the first 12 weeks and every 4 weeks thereafter. Adverse events will be monitored throughout the study and for $\leq$30 days after treatment end and will be graded per NCI CTCAE v5.0. Recruitment for Shorespan-007 is ongoing or planned in sites in Asia, Australia, Europe, North America, and South America. Clinical trial information: NCT06456346. TPS6588 **Poster Session**

IMpactMF, randomized, open-label, phase 3 trial of imetelstat (IME) versus best available therapy (BAT) in patients (pts) with intermediate-2 (INT-2) or high-risk (HR) myelofibrosis (MF) relapsed or refractory (R/R) to Janus kinase inhibitors (JAKi). First Author: John Mascarenhas, Tisch Cancer Institute, Icahn School of Medicine at Mount Sinai, New York, NY

Background: IME is a first-in-class telomerase inhibitor approved in 2024 for pts with transfusion-dependent lower-risk myelodysplastic syndromes who are R/R or ineligible for erythropoiesis-stimulating agents. In the phase 2 IMbark trial (NCT02426086) in pts with MF, IME (9.4 mg/kg every 3 weeks [q3w]; N=59) at wk 24 showed median overall survival (OS) of 29.9 mo (median follow-up, 27.4 mo), total symptom score reduction $\geq$50% in 32% of pts, and spleen volume reduction $\geq$35% in 10% of pts. IME treatment dose-dependently improved bone marrow (BM) fibrosis and reduced MF driver mutation variant allele frequency, which correlated with improved OS. The most common grade $\geq$3 adverse events were thrombocytopenia, anemia, and neutropenia; cytopenias were generally manageable, short-lived, and resolved to grade $\leq$2 in $<$4 wks. These data support further evaluation of IME. **Methods:** IMpactMF (MYF3001; NCT04576156) is a phase 3, open-label, randomized (2:1) trial of IME versus BAT in ≈320 adults with INT-2 or HR MF R/R to JAKi or ineligible for allogeneic stem cell transplantation or further JAKi. Randomization is to IME sodium 9.4 mg/kg (8.9 mg/kg active dose) intravenously q3w or investigator-selected BAT (eg, hypomethylating agents, hydroxyurea, interferon, thalidomide, danazol, chemotherapy, or other non–JAKi-containing therapy, but not hematopoietic stem cell transplantation or splenectomy). Eligibility criteria include peripheral blood and marrow blast counts $<$10% and Eastern Cooperative Oncology Group performance status $\leq$2. Chronic liver disease unrelated to underlying MF, active systemic hepatitis infection, or clinically significant cardiovascular disease are not allowed. Pts are stratified at randomization based on INT-2 or HR MF per the Dynamic International Prognostic Scoring System and baseline platelet count. Crossover to IME may be permitted for pts who meet progressive disease criteria ($\geq$25% increase in spleen volume from baseline) or a palpable increase in splenomegaly after 6 mo of BAT. IMpactMF is the first MF phase 3 trial evaluating OS as the primary endpoint. Secondary endpoints include wk 24 symptom and spleen response rates, progression-free survival, clinical response assessments per modified 2013 International Working Group-Myeloproliferative Neoplasms Research and Treatment criteria, time to and duration of response, reduction in BM fibrosis, safety, pharmacokinetics, and pt-reported outcomes. Biomarkers and mutation analyses will be performed. As of December 2024, 172 sites in North and South America, Europe, Middle East, Australia, and Asia have enrolled ≈75% of pts. The planned interim analysis (when ≈35% of pts planned to be enrolled have died) is expected in early 2026 and final analysis is expected in early 2027. Clinical trial information: NCT04576156. Research Sponsor: This study was funded by the Geron Corporation; writing and editorial support were provided by Meredith Rogers, MS, CMPP, of The Lockwood Group (Stamford, CT, USA), funded by the Geron Corporation.

TPS6589 **Poster Session**

Anti-tumor activity of CoREST inhibitor, JBI-802 (dual epigenetic modifier of LSD1/HDAC6): An opportunity to treat essential thrombocythemia and MPN/MDS patients with thrombocytosis in ongoing phase 1/2 clinical trial. First Author: Melda S. Dolan, Jubilant Therapeutics and Jubilant Radiopharmaceuticals, Yardley, NJ

Background: Lysine specific demethylase 1 (LSD1) and histone deacetylase 6 (HDAC6) are epigenetic proteins associated with several diseases, including cancer. JBI-802 is a highly potent CoREST inhibitor with LSD1/HDAC6 selective dual inhibition that shows superior anti-tumor activity in several pre-clinical models with significant modulation of PD biomarkers that include CD11b, CD86 and acetylated alpha-tubulin. JBI-802 in first-in-human phase I clinical trial (NCT05268666) demonstrated a dose-proportional increase in exposure across cohorts and its correlation with on-target effects in therapy resistant advanced lung cancers patients. 2/2 immunotherapy resistant NSCLC patients displayed improvement in tumor-related symptoms with confirmed partial response (PR) in one NSCLC patient at 10 mg dose. Overall, JBI-802 was well tolerated and showed remarkable safety profile without affecting hemoglobin, with grade 3/4 thrombocytopenia as the only adverse event observed in 38% of patients at the higher dose. Dose-dependent decrease in platelets as a part of MOA of LSD1 and HDAC6 inhibition demonstrated that JBI-802 is pharmacologically active and provided an opportunity to treat patients with hematological malignancies like essential thrombocythemia (ET) and other myelodysplastic/myeloproliferative neoplasms (MDS/MPN) characterized by thrombocytosis. **Methods:** The ongoing phase 1/2 clinical trial will assess the safety and preliminary efficacy of orally administered JBI-802 in ET and MDS/MPN patients with thrombocytosis (ACTRN12624000478516) in a standard 3+3 design in 30 patients in two phases. Part 1: Dose Escalation Phase - Primary objective is to determine the recommended phase 2 dose (RP2D) of JBI-802 and safety in subjects with ET and MDS/MPN neoplasms with thrombocytosis, with dose-limiting toxicity as the primary endpoint during the monitoring period. Secondary objective is to evaluate the overall safety and tolerability, and to determine the preliminary antitumor activity along with characterization of pharmacokinetic (PK) profile of JBI-802 and its metabolites as well as clinical and hematologic responses. Part 2: Dose Expansion Phase – The objective is to obtain preliminary evidence of efficacy as defined by MDS/MPN IWG response criteria, which includes platelet count reduction, and response assessments of spleen size and volume, evaluation of hematology parameters and bone marrow aspiration/biopsy, and to further evaluate the overall safety and tolerability of JBI-802, along with characterization of PK and PD profile and changes in mutant allele frequencies. Study results will provide insights into the clinical potential of JBI-802 in treating ET and MDS/MPN patients relapsed and/or refractory to standard of care therapies. Clinical trial information: ACTRN12624000478516. Research Sponsor: None.

7000 Oral Abstract Session

Prospective validation of end of treatment ctDNA-MRD by PhasED-Seq in DLBCL patients from a national trial. First Author: Steven Wang, Amsterdam UMC Location Vrije Universiteit, Amsterdam, Netherlands

Background: The prognostic utility of circulating tumor DNA measurable residual disease (ctDNA-MRD) detection at end of treatment (EOT) using phased variant (PV) enrichment and detection sequencing (PhasED-Seq) has been demonstrated in patients with diffuse large B-cell lymphoma (DLBCL) receiving first-line (1L) therapy. Prior studies are limited by treatment, patient, and sample heterogeneity. Here, we independently validate the prognostic value of PhasED-Seq in a national, multi-center study of uniformly treated 1L DLBCL patients. **Methods:** ctDNA-MRD was assessed using Foresight CLARITY in LBCL patients enrolled on HOVON-902 from >50 centers in the Netherlands and Belgium. Patients were treated with curative-intent 1L therapy (R-CHOP or DA-EPOCH-R). We evaluated the prognostic significance of MRD status [positive (+), negative (-)] on progression-free survival (PFS) and overall survival (OS). PVs were identified from pretreatment biopsies or plasma with matched normal DNA. EOT plasma samples were used for ctDNA-MRD detection. **Results:** A total of 150 of 156 (96%) eligible patients had successful PV identification. Of included patients, 90%, 9%, and 1% had DLBCL, HGBL, and PBMCL, respectively. IPI distribution was 22% low, 29% low-intermediate, 27% high-intermediate, and 22% high risk; median age was 67.5. The 24-month PFS and OS in this cohort were 74% and 86%, respectively, with 31 months of median follow-up. At the EOT, 76% of patients were MRD- and 24% were MRD+. MRD+ status significantly predicted inferior PFS (2 yr PFS 88 vs 28%; HR 9.7, 95% CI 4.2-22.3, p<0.0001) and OS (2 yr OS 97 vs 50%; HR 10.6, 95% CI 4.1-27.7, p<0.0001). Moreover, in patients without complete response, MRD+ was significantly prognostic for PFS, suggesting an ability to adjudicate imaging results (HR for PFS 7.6, 95% CI 3.6-16.3, p < 0.0001). Among patients who were MRD- and achieved CMR at EOT, 2-year PFS and OS were 91% and 99%, respectively. All patients who failed to achieve CMR and remained MRD+ experienced relapse. ctDNA-MRD was prognostic for outcomes in all subgroups considered, including source of baseline sample (tumor versus plasma), best clinical response, IPI, sex, lactate dehydrogenase, stage, or extranodal disease. In multivariate analysis including ctDNA-MRD, IPI, and best overall response, ctDNA-MRD was significantly and independently prognostic for both PFS [HR for ctDNA: 7.1, 95% CI 3.5-14.3, p<0.0001] and OS [HR for ctDNA: 5.1, 95% CI 2.2-11.9, p=0.00018]. **Conclusions:** We validated the prognostic value of PhasED-Seq-based ctDNA-MRD in a real-world multicenter 1L DLBCL cohort. This highlights the utility of ctDNA-MRD to confirm residual disease in patients without complete response by imaging, as well as the potential to identify patients who may benefit from consolidation therapy. These results support the integration of MRD as a standard component of response evaluation in 1L DLBCL treatment. Research Sponsor: None.

7001 Oral Abstract Session

Revision of staging system for natural killer T-cell lymphoma: A multicenter study from the Chinese Southwest Oncology Group and Asia Lymphoma Study Group. First Author: Tongyu Lin, Phase I Clinical Trial Ward of Medical Oncology Center, Sichuan Clinical Research Center for Cancer, Sichuan Cancer Hospital & Institute, Sichuan Cancer Center, Affiliated Cancer Hospital of University of Electronic Science and Technology of China, Chengdu, China

Background: Natural killer T-cell lymphoma (NKTCL), characterized by extranodal involvement, challenges the efficacy of the Ann-Arbor staging system (AASS) in its precise prognostic stratification. A revised staging system is warranted for precise prognosis prediction in the modern chemotherapy era. **Methods:** A training cohort of patients with newly diagnosed NKTCL was assessed to revise the AASS in the context of the modern chemotherapy era. The results were validated in an independent international cohort that received asparaginase-based chemotherapy. **Results:** Our analysis of 2017 newly diagnosed NKTCL patients from 19 centers across two countries highlights the limitations of the AASS, which demonstrates an uneven patient distribution and insufficient differentiation of outcomes, particularly between stages III and IV. We proposed a revised staging system in which AASS stage I patients with nasal-type disease only were classified as stage I, whereas those with local invasion or limited non-nasal-type disease were reclassified as stage II. AASS stage II patients with regional lymph node involvement were assigned to stage III. Additionally, patients with distant lymph node involvement or extensive skin/subcutaneous soft tissue involvement were classified as stage IVA, those with extensive visceral organ invasion were classified as stage IVB, and those with bone marrow infiltration or hemophagocytic lymphohistiocytosis were classified as stage IVC. This proposal better distinguishes clinical outcomes across different stages, achieves a more equitable distribution of patients, and demonstrates multiple advancements over the AASS. **Conclusions:** The revised staging system is promising for the staging of NKTCL patients with different prognoses and could be useful for decisions regarding the treatment strategy and future clinical trial designs. 7002 Oral Abstract Session

Molecular landscape of distinct follicular lymphoma histologic grades: Insights from genomic and transcriptome analyses. First Author: Cong Sun, Department of Lymphoma, Tianjin Medical University Cancer Institute and Hospital, Tianjin, China

Background: The 2022 *World Health Organization Classification of Hematologic Malignancies* classifies follicular lymphoma grades 1-2 (FL1-2) and grade 3A (FL3A) as classical follicular lymphoma (cFL) and reclassifies grade 3B (FL3B) as follicular large B-cell lymphoma (FLBL), without addressing cases of patients with concurrent FL and DLBCL. However, genetic information of FL histologic grading remains limited, and the latest classification lacks sufficient evidence to resolve whether these subgroups represent single or multiple distinct biological entities. **Methods:** This study analyzed clinical data from 831 patients, whole-exome sequencing (WES) from 149 patients, and transcriptome sequencing from 63 patients to explore differences among FL1-2, FL3A, FL3B, and FL/DLBCL. **Results:** A total of 1006 patients were initially identified. After excluding those under 18 years of age, those with histological transformation, and those with incomplete clinical information, 831 patients remained. Among them, 588 (71%) had FL1-2, 84 (10%) had FL3A, 67 (8%) had FL3B, and 92 (11%) had FL/DLBCL. Baseline clinical and tumor characteristics are summarised in table. The Kaplan-Meier survival analysis was performed on 477 FL patients who received R-CHOP treatment. Age > 60, spleen involved, elevated serum LDH, elevated β2-MG and grade 3B were associated with inferior PFS and OS; while ECOG 3-4 and Ann Arbor stage III/IV disease were associated with inferior PFS. Factors that retained significance on multivariable analysis for PFS were grade 3B (HR 2.08, 95% CI 1.22-3.56, p = 0.0076) , ECOG 3-4 (HR 2.49, 95% CI 0.98-6.32, p = 0.05) and elevated serum LDH (HR 1.68, 95% CI 1.05-2.69, p = 0.03), while for OS, it was only grade 3B (HR 4.67, 95% CI 1.95-11.15, p < 0.001). Genomics showed that FL3B and FL/DLBCL lack mutations in epigenetic regulators CREBBP and KMT2D but exhibit additional copy number variations, such as 1p36.32 losses and 3p21.1 gains, which are linked to poor prognosis. Transcriptomics revealed that with increasing histologic grade, immune-related pathway activity decreases, whereas metabolic pathway activity increases, which may be associated with the upregulation of MYC, IRF4, and BATF expression. **Conclusions:** In summary, these findings define FL3B and FL/DLBCL as biologically and clinically distinct B-cell lymphomas, differing from traditional FL. FL1-2 and FL3A differ in their tumor microenvironments rather than genetic profiles. Research Sponsor: None.

7003 Oral Abstract Session

A phase 1 study of KITE-363 anti-CD19/CD20 chimeric antigen receptor (CAR) T-cell therapy in patients (pts) with relapsed/refractory (R/R) B-cell lymphoma (BCL). First Author: Saurabh Dahiya, Stanford University School of Medicine, Stanford, CA

Background: Approximately 30% of pts with R/R LBCL who relapse after CAR T-cell therapy experience CD19 antigen escape (Spiegel et al. *Blood.* 2021).KITE-363 is a bicistronic, autologous CAR T-cell therapy that can potentially prevent CD19 escape through upfront dual targeting of CD19 and CD20. Here we report safety and preliminary efficacy from an open-label, multicenter Phase 1 study of KITE-363 in R/R BCL. **Methods:** Eligible adults had LBCL, indolent NHL, nodular lymphocyte-predominant Hodgkin lymphoma (NLPHL), or mediastinal gray zone lymphoma R/R after ≥2 lines of therapy (LoT). Pts with LBCL may have had primary refractory disease after ≥1 LoT. Study included dose escalation (1A) and expansion (1B; LBCL only) cohorts. After lymphodepleting chemotherapy, pts received KITE-363 at dose levels (DLs) 1, 2, or 3 (0.5×10^6, 1×10^6, or 2×10^6 CAR T cells/kg, respectively). Primary endpoints were incidence of dose-limiting toxicities (DLTs; Phase 1A) and investigator-assessed objective response rate (ORR per Lugano; Phase 1B). **Results:** As of 10/14/2024, 41 pts enrolled and 37 received KITE-363 (see table). For pts with LBCL (n = 34), 50% were primary refractory and 44% had IPI 3-4. No DLTs occurred. Grade ≥3 adverse events (AEs) occurred in 76% of treated pts and serious AEs in 49%. Grade 3 cytokine release syndrome (CRS; per Lee et al. 2014) occurred in 1 pt (3%; NLPHL; DL 3); Grade 3 immune effector cell-associated neurotoxicity syndrome (ICANS) occurred in 3 pts (8%; 1 DL 2; 2 DL 3); no Grade ≥4 CRS/ICANS occurred. Median onset of ICANS was 6 d with median duration of 5 d, and median onset of CRS was 4 d with median duration of 5 d. Six pts died (5 to progression; 1 to myelodysplastic syndrome concurrent with LBCL relapse, unrelated to KITE-363). At 7.3 months median follow-up, ORR in CAR-naive pts at DL 3 was 87%; complete response (CR) rate was 78%. Among those, all 7 pts with LBCL who were CAR-naive after ≥2 LoT had a CR. Those in DL 3 who were primary refractory (n = 15) had an 80% ORR (CR rate, 67%). Median duration of response was not reached. In all pts at DL 3 (n = 26), median CAR T-cell expansion peak, area under the curve (AUC), and time to peak were 121.5 cells/μL, 711.1 cells/μL×d, and 10 d, respectively. For CAR-naive pts in DL 3, median peak and AUC were 132.2 cells/μL and 819.2 cells/μL×d; medians in those with prior CAR T-cell therapy (n = 3) were 5.7 cells/μL and 85.7 cells/μL×d, respectively. **Conclusions:** No DLTs occurred in Phase 1A. Safety profile of KITE-363 was tolerable, with no Grade ≥3 CRS in pts with LBCL and 2 cases of Grade 3 ICANS at the highest DL. KITE-363 demonstrated high responses in pts with highly refractory BCL, including those with primary refractory disease. Clinical trial information: NCT04989803. Multi-virus specific T cells to enhance the activity of bispecific antibodies in lymphoma. First Author: Akiva Diamond, Department of Medicine, Section of Hematology-Oncology, Baylor College of Medicine; Baylor St.Luke's Medical Center; Dan L Duncan Comprehensive Cancer Center, Houston, TX

Background: Although Bispecific Antibodies (BsAbs) have the advantage of an "off the shelf" immune approach, their clinical activity relies on the patients' native T-cell population that is impaired by prior chemotherapy and tumor-induced T cell exhaustion. T-cell dysfunction within the TME is one potential mechanism of BsAb resistance (Falchi, L. et. al. Blood), while continuous exposure to bispecific molecules also induces T-cell exhaustion (Phillipp, N. et. al. Blood). A higher frequency of regulatory T cells and increased markers of T cell exhaustion were seen in BsAb non-responders (Cortes-Selva, D. et. al. Blood). Banks of multi-virus specific T cells (MVSTs) have safely controlled viral infections in allogeneic hematopoietic stem-cell transplantation recipients (Tzannou, et. al JCO). Expanded MVSTs have a differentiated phenotype, exhibit immediate effector functions (cytotoxicity and cytokine secretion) and have not produced severe graft versus host disease in hundreds of recipients. We hypothesized that MVSTs would enhance the antitumor activity of BsAbs. **Methods:** To compare the anti-tumor activity of PBMCs and MVSTs, we cocultured GFP-labeled CD20+ BJAB lymphoma cells alone or with healthy donor PBMCs or MVST at a 1:1 ratio, in the presence or absence of CD3xCD20 BsAb. We evaluated T-cell activation using CD69 and CD25 antibodies using quantitative flow cytometry and tumor cell killing by assessing tumor survival at 24 and 48 hours. **Results:** While the addition of both MVSTs and PBMCs alone reduced tumor cell numbers, PBMCs + BsAbs reduced tumor cells to less than 50% of the cultures at 24 hours but the subsequent increase tumor cell numbers indicated lack of effective control. By contrast, MVSTs reduced the frequency of tumor cells from 42.5% at 24 hours and less than 2% by 48 hours. The number of T-cells in PBMCs decreased by 0.88-fold after 48-hours, while MVSTs increased by 2.16-fold in the presence of 1ng/ml BsAb. The number of T cells expressing CD25 increased 6.25-fold with PBMCs and 456.68-fold with MVST in the presence of BsAb. **Conclusions:** We have demonstrated that in combination with BsAb, MVSTs exhibit more rapid effector function and expansion than similarly cultured PBMCs, suggesting they could enhance tumor response depth. Despite using healthy donor PBMCs, which showed a 6-fold increase in activated T cells with BsAb, MVSTs induced 456-fold increase. This significant boost in T cell activation highlights MVSTs' potential to overcome endogenous T cell exhaustion and enhance BsAb therapy. Research Sponsor: National Cancer Institute; 5 P50 CA126752-12 (Heslop).

Tumor cell and T cell numbers after co-culture with PBMC or MVST +/- BsAb.

	Tumor cell numbers		CD3+ T-cell numbers	CD25+ Activated T-cells
	24 hours	48 hours	48 hours	48 hours
BJAB Alone	104,345	101,992		
+ PBMC	104,632	57,094	30,458	5,058
+ PBMC + BsAb 1ng	17,350	37,621	26,665	31,621
BJAB Alone	51,633	69,183		
+ MVST	52,815	19,858	86,545	419

WaveLINE-003: Phase 2/3 trial of zilovertamab vedotin plus standard of care in relapsed/refractory diffuse large B-cell lymphoma. First Author: Philippe Armand, Dana-Farber Cancer Institute, Boston, MA

Background: Outcomes for patients relapsed/refractory (R/R) diffuse large B cell lymphoma (DLBCL) remain poor. Zilovertamab vedotin (ZV) is a novel ROR1-targeting antibody-drug conjugate that has shown promising efficacy in patients with DLBCL. Here we present results of the dose confirmation part of the waveLINE-003 (NCT05139017) trial evaluating ZV plus rituximab and gemcitabine-oxaliplatin (R-GemOx) in pts with R/R DLBCL. **Methods:** The phase2/3 trialwaveLINE-003 enrolled adult participants (pts) with confirmed R/R DLBCL after ≥1 lines of therapy (LOT) who were ineligible for chimeric antigen receptor T-cell therapy (CAR-T), autologous stem-cell transplant (ASCT), or failed such therapies (cohort A). In the dose confirmation phase, eligible pts received ZV (1.5, 1.75, or 2.0 mg/kg) plus R-GemOx Q3W for ≥6 cycles. Primary endpoints were safety and recommended phase 2 dose (RP2D). Secondary endpoints were objective response rate (ORR) and duration of response (DOR) per Lugano 2014 response criteria by central review, and overall survival. **Results:** At data cut-off date (August 1, 2024),40 pts had been enrolled in cohort A to receive R-GemOx plus ZV 1.5 mg/kg (n=17), 1.75 mg/kg (n=16), or 2.0 mg/kg (n=7); 22 (55%) were ≥65 years old, and 8 (20%) relapsed >12 mo. Median number of prior LOTs was 2.0 with 7 (18%) pts receiving prior CAR-T, and 7 (18%) receiving prior ASCT. Median follow-up was 9.8 months (mo). Seven DLTs (1 for ZV [1.5 mg/kg], 2 for ZV [1.75 mg/kg], and 4 for ZV [2.0 mg/kg]) were reported. Treatment-related adverse events (AE) were reported in 39 (98%) pts; the most common being diarrhea (n=18 [45%]), nausea (n=15 [38%]), anemia (n=11 [28%]), and platelet count decrease (n=11 [28%]). Grade ≥3 treatment-related AEs were reported in 26 (65%) pts, the most common being neutropenia (n=9 [23%]), neutrophil count decreased (n=9 [23%]), platelet count decreased (n=9 [23%]), and anemia (n=8 [20%]). Two pts discontinued due to AE (sepsis and respiratory failure, both treatment-related), and 1 pt died due to sepsis (treatment related), all in the 2.0 mg/kg dose cohort. The RP2D was determined to be 1.75 mg/kg. ORR was 27% (3 CR, 1 PR [ZV 1.5 mg/kg]), 56% (8 CR, 1 PR [ZV 1.75 mg/kg]), and 57% (3 CR, 1 PR [ZV 2.0 mg/kg]), with median DOR of 14.4 mo, 8.7 mo and not reached (NR), respectively. Median overall survival was 11.5 mo (ZV 1.5 mg/kg), NR (ZV 1.75 mg/kg), and 7.4 mo (ZV 2.0 mg/kg), with 6-month OS rate of 70.0%, 78.8%, and 68.6%, respectively. **Conclusions:** Zilovertamab vedotin in combination with R-GemOx demonstrated promising efficacy and acceptable safety in R/R DLBCL at the RP2D of ZV of 1.75 mg/kg plus R-GemOx. The study is proceeding to the phase 3 portion randomizing patients to ZV-RGemOx versus RGemOx. Clinical trial information: NCT05139017. Research Sponsor: Merck Sharp & Dohme LLC, a subsidiary of Merck & Co., Inc., Rahway, NJ, USA; N/A.

7006 **Oral Abstract Session**

Sintilimab (anti-PD-1 antibody) combined with chidamide (an oral subtype-selective HDACi) followed by P-GemOx regimen in patients with treatment-naïve extranodal natural killer/T cell lymphoma (TN-ENKTL): A multicenter, open-label, single-arm, phase II study (SCENT-2 trial). First Author: Huiqiang Huang, Sun Yat-sen University Cancer Center, Guangdong, China

Background: ENKTL is a highly aggressive NHL with a higher incidence in Asia. P-GemOx regimen is one of standard first-line treatment with mildly toxicities. We confirmed that Sintilimab plus Chidamide (SC) is safe and efficacious in patients(pts) with relapsed or refractory (r/r) ENKTL in previous study (SCENT trial). Initiation of SC prior to r/r might further optimize pts outcomes. Therefore, we conducted a prospective study to investigate the efficacy and safety of SC followed by P-GemOx for TN-ENKTL (NCT04994210). Here we present the preliminary results of pts with early stage. **Methods:** This is an investigator-initiated study,eligible pts were aged 18-80 years with histologically confirmed TN-ENKTL. Pts received 2 cycles of SC (SC×2) with standard doses (part A). Once pts had a CR or PR, 2 cycles of P-GemOx (P-GemOx×2) were administered (part B). If they got SD or PR, pts received P-GemOx×4. All pts accepted involved field radiotherapy (IFRT) after part B. The primary endpoint is the CR rate (CRR) of part A+B. Key secondary endpoints include CRR of part A, duration of CR (DoCR), PFS, OS and safety. According to historical data of P-GemOx, we expected a CRR of 80% and a minimum CRR of 60% after part A + B. A sample size of 47 was required. Pretreatment FFPE tumor and blood samples were analyzed by capture-based NGS targeting lymphoma relevant genes. **Results:** From Aug 2022 to Dec 2024, 47 eligible pts were enrolled from 3 centers in China. Two pts remained on treatment. All pts underwent PET/CT for efficacy evaluation. Across the 46 efficacy-evaluable pts after SC×2, 36 (78.2%) achieved response, including 29(60.3%) CR pts. Median cycles of P-GemOx were 2(1-4). After part B, among the 42 response-evaluable pts, the CRR was 95.2% (40/42), and the ORR was 97.6% (41/42). The median follow-up time was 12.4 (0.2-23.7) months. The 1-year DoCR, PFS, OS rates were 96.2% (95%CI, 75.7-99.5), 97.5% (95%CI, 83.6-99.6), 95.3% (95%CI, 82.2-98.8), respectively. The most common myelotoxicities were neutropenia (97.8%), lymphopenia (89.4%), anemia (74.5%), thrombocytopenia (58.7%), and non-myelotoxicities including appetite (38.3%), nausea (38.3%), lipase increased (31.9%). Most toxicities came from P-GemOx. Three patients died, 2 due to disease progression and 1 due to accident. Tumor DNA data in relation to efficacy will be presented at the meeting. **Conclusions:** Preliminary results from SCENT-2 trial exceeded expected efficacy. It may be a promising chemo-reduced therapeutic and manageable toxicities for this population. Further investigation is needed. Clinical trial information: NCT04994210. Research Sponsor: None.

7007 **Oral Abstract Session**

Sintilimab (anti-PD-1) plus ifosfamide, carboplatin, and etoposide (ICE) in second-line classical Hodgkin lymphoma (cHL): Results of a multicenter, randomized, controlled, double-blind phase 3 study (ORIENT-21). First Author: Peng Liu, National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College, Beijing Key Laboratory of Clinical Study on Anticancer Molecular Targeted Drugs, Beijing, China

Background: Sintilimab monotherapy for cHL in third-line setting and beyond has been evaluated in a single-arm, phase 2 study ORIENT-1. Here, we present results of the phase 3 study ORIENT-21 evaluating sintilimab plus ICE versus placebo plus ICE as the second-line treatment for cHL. **Methods:** This study enrolled cHL pts who have failed first-line standard chemotherapy. The study has a safety run-in phase to enroll pts receiving sintilimab plus ICE, followed by a randomized phase in which pts were assigned in a 1:1 ratio to receive either sintilimab plus ICE (experimental arm) or placebo plus ICE (control arm) for 6 cycles. Patients without disease progression continued either sintilimab or placebo monotherapy. Stratification factors were age (<50 vs ≥50), disease status (relapsed vs refractory), and international prognostic score (IPS, <3 vs ≥3). Primary endpoint was complete remission rate (CRR) assessed by investigators according to Lugano 2014 criteria. Secondary endpoints included progression-free survival (PFS), duration of complete remission (DoCR) and safety. **Results:** As of Nov 21, 2024, 81 pts (ITT set: 10 in safety run-in, 34 in experimental arm, 37 in control arm) were enrolled (age≥50: 12.3%, IPS≥3: 18.5%, relapsed: 56.8%, refractory: 43.2%) with a median follow-up of 38.4 months (range: 0-58). In mITT set (randomized pts, n=71), significant higher CRR was observed in the experimental arm than the control arm (61.8% vs 32.4%, p=0.0295). Consistent results were also observed in ITT set (CRR: 61.4% vs 32.4%, p=0.0105). In mITT and ITT sets, median DoCR was not reached in sintilimab plus ICE (events in 28.6% and 22.2% pts), and was 20.7 months in placebo plus ICE. There were 16 pts in control arm switching to sintilimab monotherapy after disease progression. In ITT set, median PFS was not reached in sintilimab plus ICE (events in 34.1% pts), and was 9.0 months in placebo plus ICE (HR: 0.48, 95% CI: 0.23-1.00). Favorable PFS was observed in CR pts than non-CR pts with either sintilimab plus ICE (HR: 0.22, 95% CI: 0.08-0.63) or placebo plus ICE (HR: 0.15, 95% CI: 0.04-0.52). In safety set (n=80), all pts had treatment-emergent adverse events (TEAEs) while ≥grade 3 TEAEs occurred in 81.4% pts with sintilimab plus ICE (n=43) and in 97.3% pts with placebo plus ICE (n=37). Most common ≥grade 3 TEAEs were neutrophil count decreased (62.8% vs 70.3%), white blood cell count decreased (53.5% vs 64.9%) and platelet count decreased (51.2% vs 67.6%). TEAEs led to treatment discontinuation in both arms (18.6% vs 13.5%). No TEAE led to death. **Conclusions:** Sintilimab plus ICE significantly improved CRR and showed a trend of favorable PFS compared with placebo plus ICE. The safety profiles were manageable and no new safety signal was observed. Clinical trial information: NCT04044222. Research Sponsor: Innovent Biologics (Suzhou) Co., Ltd.

7008 Oral Abstract Session

Results from the completed dose-finding part of phase 2 study of the innate cell engager acimtamig (AFM13) in combination with AlloNK (AB-101) in relapsed or refractory classical Hodgkin lymphoma (LuminICE-203). First Author: Joseph E. Maakaron, Division of Hematology, Oncology and Transplantation, Department of Medicine, Masonic Cancer Center, University of Minnesota, Minneapolis, MN

Background: There is an unmet need for new treatment approaches for patients (pts) with relapsed or refractory (R/R) classical Hodgkin lymphoma (HL) who progress following standard systemic therapies. Combining acimtamig (AFM13), a tetravalent bispecific CD30/CD16A innate cell engager (ICE), with AlloNK (AB-101), a cryopreserved, off-the-shelf, cord blood-derived NK cell product, induces antibody-dependent cellular cytotoxicity against CD30+ lymphoma cells. **Methods:** This Phase 2, open-label, multi-center, multi-cohort study (LuminICE-203; NCT05883449) is evaluating the efficacy and safety of acimtamig in combination with AlloNK in pts with R/R HL. An initial dose-finding part with 4 cohorts is investigating 2 doses of acimtamig (200 mg or 300 mg weekly flat dosing for 6 weeks) in combination with AlloNK (dose level 1 [DL1]: 3 doses of 2×10^9 cells on Days 1, 8 and 15; or dose level 2 [DL2]: 1 dose of 4×10^9 on Day 1, followed by 2 doses of 2×10^9 cells on Days 8 and 15), after a standard lymphodepletion up to 3 cycles, followed by a randomized part using a Simon's 2-stage design. The primary endpoint is objective response rate (ORR) assessed by an Independent Radiology Committee (IRC) based on PET-CT per Lugano classification criteria. **Results:** As of 16 December 2024, 24 pts with R/R HL were treated in the initial dose-finding part of the study and were assessed by the IRC for metabolic response. Median (range) age was 42.5 (23–80) years; 16 (67%) were male. All pts in the study were heavily pretreated with chemotherapy, brentuximab vedotin and PD-1 inhibitors; median (range) prior treatment lines was 4.5 (2–13), including previous stem cell transplant in 14 (58%) pts. An ORR of 88% was achieved with 14 (58%) complete responses (CR) (Table). The safety profile was in line with that previously reported, with mostly mild to moderate infusion related reactions as the most common reported treatment-related adverse event (TRAE) in 50% of patients; no fatal TRAEs and no stopping criteria have been observed. The study is ongoing and updated safety and efficacy results, including pharmacokinetic / pharmacodynamic analyses and preliminary results on duration of response will be presented. **Conclusions:** Acimtamig in combination with AlloNK shows promising efficacy with a well-managed safety profile with the potential to address an unmet need in pts with R/R HL who have exhausted standard-of-care treatment options. Clinical trial information: NCT05883449. Research Sponsor: Affimed GmbH and Artiva Biotherapeutics Inc.

Efficacy results of acimtamig plus AlloNK in pts with R/R HL.

7009 Rapid Oral Abstract Session

Combination of zanubrutinib (zanu) + venetoclax (ven) for treatment-naive (TN) CLL/SLL: Results in SEQUOIA arm D. First Author: Mazyar Shadman, Fred Hutchinson Cancer Center and University of Washington, Seattle, WA

Background: Zanu monotherapy demonstrated superior progression-free survival (PFS) compared with bendamustine + rituximab in patients (pts) without del(17p) at 26.2-month follow-up and sustained PFS benefit at 5-year follow-up. In a single-arm cohort, zanu monotherapy was also shown to be effective in pts with del(17p). Several CLL studies have demonstrated promising efficacy with the combination of B-cell lymphoma 2 + Bruton tyrosine kinase inhibitors; however, pts with del(17p)/*TP53* mutation comprised a small percentage of or were excluded from study populations. Here, we present results in SEQUOIA (NCT03336333) arm D with zanu + ven in pts with or without del(17p) and/or *TP53* mutation. **Methods:** Arm D is a nonrandomized cohort of the SEQUOIA study in pts aged ≥65 years (or 18-64 years with comorbidities). Pts received zanu (160 mg twice daily) + ven (ramp-up to 400 mg once daily) from cycle 4 to cycle 28, followed by continuous zanu monotherapy until progressive disease (PD), unacceptable toxicity, or meeting undetectable minimal residual disease (uMRD)–guided early zanu or ven stopping rules (CR/CRi and uMRD [$<1\times10^{-4}$ by flow cytometry] in peripheral blood [PB] and bone marrow on 2 consecutive tests ≥12 weeks apart). Efficacy responses were assessed by investigator every 3 cycles until cycle 28, then every 6 cycles with PB MRD assessment. **Results:** Between Nov 2019 and Jul 2022, 114 pts were enrolled: 66 (58%) with del(17p) and/or *TP53* mutation, 47 (41%) without del(17p) and *TP53* mutation, and 1 with missing *TP53* results. In all pts, median age was 67 years (range, 26-87), 64 (56%) were male, 86 (75%) had unmutated IGHV, and 47 (41%) had complex karyotype (≥3 abnormalities). As of Sept 16, 2024, 85 (75%) remained on treatment. The most common reasons for early discontinuation were reaching the uMRD-guided early stopping rules (zanu: 7%; ven: 7%), adverse events (AEs) (zanu: 8%; ven: 6%), and PD (zanu: 5%; ven: 4%). Six pts died (5 due to non–treatment-related AEs; 1 due to PD). Pts with or without del(17p)/*TP53* mutation achieved similar efficacy responses and best PB uMRD (Table). The most common any-grade treatment-emergent AEs (TEAEs) were COVID-19 (54%), diarrhea (41%), contusion (32%), and nausea (30%). The most common grade ≥3 TEAEs were neutropenia (17%), hypertension (10%), diarrhea (6%), and neutrophil count decreased (6%). **Conclusions:** SEQUOIA arm D data demonstrate promising efficacy and tolerability of zanu + ven combination treatment in TN CLL/SLL, regardless of del(17p) and/or *TP53* mutation status. The safety profile of zanu + ven was consistent with results of prior zanu studies, and no new safety signals were identified. Clinical trial information: NCT03336333. Research Sponsor: BeiGene.

7010 Rapid Oral Abstract Session

Phase 1/2 studies of DZD8586 in CLL/SLL patients after covalent or non-covalent BTK inhibitors and BTK degraders. First Author: Jianyong Li, Department of Hematology, the First Affiliated Hospital of Nanjing Medical University, Jiangsu Province Hospital, Nanjing, China

Background: New therapies are needed for patients with relapsed or refractory (r/r) CLL/SLL following covalent and/or non-covalent BTK inhibitors. While early clinical data showed encouraging anti-tumor activities from BTK degraders in these patients, resistance mutations to both BTK inhibitors and degraders have already been reported. In addition, concerns with emerging clinical safety signals from these degraders may limit their longer-term clinical use. DZD8586 is a rationally designed LYN/BTK dual inhibitor with high selectivity against other TEC family members. Here we report results from ongoing phase 1/2 clinical studies of DZD8586 in r/r CLL/SLL patients with prior treatment of covalent and/or non-covalent BTK inhibitors as well as BTK degraders. **Methods:** The data from two clinical studies, TAI-SHAN5 (NCT05824585) and TAI-SHAN8 (NCT06539182, CTR20240120), were pooled for the safety and efficacy analysis in patients with CLL/SLL. Modulation of PD biomarkers was evaluated at doses tested. Tumor response was assessed by investigators per iwCLL 2018 or Lugano 2014 criteria as appropriate. **Results:** As of January 3, 2025, a total of 40 patients with r/r CLL/SLL have been enrolled and received DZD8586 at doses ranging from 25 mg to 100 mg once daily (QD). The median age was 64.5 years, 62.5% were male, and 60% had ECOG score of 1 or 2. A total of 30 patients were evaluable for efficacy analysis. The median number of prior therapies was 2 (range 1-8). Most common prior CLL/SLL therapies included BTK inhibitor (76.7%), and Bcl-2 inhibitor (43.3%). Patients previously treated by non-covalent BTK inhibitor (13.3%) and BTK degrader (13.3%) were also reported. Across all dose levels, 15 out of 30 patients achieved tumor response, with objective response rate (ORR) of 50%. At the recommended phase 2 dose (RP2D) of 50 mg QD, 9 out of 14 patients achieved tumor response, with ORR of 64.3%. Efficacy was observed in patients with prior BTK inhibitor treatment (ORR 52.2%), and Bcl-2 inhibitor treatment (ORR 46.2%). Seventy five percent patients who received prior BTK degrader treatment achieved partial response. As of the data cut-off date, the longest responder was on therapy for 12.1 months. Deepening response was observed with longer treatment time. DZD8586 was well tolerated across the doses investigated. At the RP2D, the most common ≥grade 3 TEAEs were neutropenia (15%) and pneumonia (10%). No major bleeding or atrial fibrillation was reported. No grade 4/5 AEs reported. **Conclusions:** DZD8586 showed encouraging anti-tumor activity with a well tolerated and manageable safety profile in heavily pre-treated CLL/SLL patients, including patients with prior covalent BTKi, non-covalent BTKi, BTK degrader and Bcl-2 inhibitor treatment. PK/PD results confirmed dose/exposure-dependent pathway inhibition by DZD8586. The updated data will be presented at the meeting. Clinical trial information: NCT06539182, NCT05824585. Research Sponsor: None.

7011 Rapid Oral Abstract Session

SEQUOIA 5-year follow-up in arm C: Frontline zanubrutinib monotherapy in patients with del(17p) and treatment-naive chronic lymphocytic leukemia/small lymphocytic lymphoma (CLL/SLL). First Author: Constantine Si Lun Tam, Alfred Hospital and Monash University, Melbourne, VIC, Australia

Background: Zanubrutinib (zanu) is a next-generation Bruton tyrosine kinase inhibitor that is approved for 5 indications, including CLL/SLL. Initial results from the SEQUOIA study (NCT03336333), at a median follow-up of 26.2 mo, demonstrated superior progression-free survival (PFS) by independent review with zanu vs bendamustine + rituximab (arms A and B) in patients (pts) with treatment-naive (TN) CLL/SLL without del(17p) as well as high overall response rate (ORR) and PFS benefit in pts with del(17p) (arm C). Additionally, the 5-y follow-up in arm A demonstrated durable PFS benefit, with estimated 54- and 60-mo PFS rates of 80% and 76%, respectively. Here we report updated results in SEQUOIA arm C, in pts with del(17p), after approximately 5 y of follow-up (data cutoff: Apr 30, 2024). **Methods:** Arm C is a nonrandomized cohort of SEQUOIA pts with del(17p) that received zanu monotherapy. Investigator-assessed PFS, overall survival (OS), ORR, and safety/tolerability were evaluated. Adverse events (AEs) were recorded until disease progression or start of next-line therapy. **Results:** Between Feb 2018 and Mar 2019, 111 TN ptswith del(17p) were enrolled to receive zanu. The median age was 71 y (range, 42-87 y), 79 (71%) were male, 67 (60%) were IGHV unmutated, and 47 (42%) had both del(17p) and *TP53* mutation. At a median follow-up of 65.8 mo (range, 5-75 mo), median PFS was not reached. The estimated 60-mo PFS rate was 72.2% (62.4%-79.8%), or 73.0% (63.3%-80.6%) when adjusted for COVID-19. Median OS was also not reached. The estimated 60-mo OS rate was 85.1% (76.9%-90.6%), or 87.0% (79.0%-92.1%) when adjusted for COVID-19. The ORR was 97.3%, and the complete response/complete response with incomplete hematologic recovery rate was 18.2%. Zanu treatment was ongoing in 62.2% of pts. The most common causes for treatment discontinuation were AEs and progressive disease (in 17.1% and 15.3%, respectively). Key AEs of interest (AEI) included any-grade infection (82%), bleeding (60%), neutropenia (19%), hypertension (18%), anemia (9%), thrombocytopenia (8%), and atrial fibrillation/flutter (7%). Grade ≥3 AEI included infection (33%), neutropenia (16%), hypertension (8%), bleeding (6%), atrial fibrillation/flutter (5%), and thrombocytopenia (2%). **Conclusions:** With this 5-y follow-up in SEQUOIA, the efficacy of zanu in TN higher-risk pts with del(17p) was maintained, and pts continue to demonstrate PFS benefits consistent with the randomized cohort of pts without del(17p) (arm A). Additionally, with longer-term follow-up, no new safety signals were identified. This update, in the largest cohort of uniformly treated pts with del(17p), suggests that zanu remains a valuable frontline treatment option for patients with or without del(17p) CLL/SLL. Clinical trial information: NCT03336333. Research Sponsor: BeiGene.

7012 Rapid Oral Abstract Session

A phase 1/2 study to evaluate the safety and efficacy of XNW5004, a selective EZH2 inhibitor, in subjects with relapsed/refractory non-Hodgkin lymphoma. First Author: Lugui Qiu, State Key Laboratory of Experimental Hematology, Institute of Hematology & Blood Diseases Hospital, Chinese Academy of Medical Science & Peking Union Medical College, Tianjin, China

Background: Prognosis of relapsed/refractory (R/R) non-Hodgkin Lymphoma (NHL) which has progressed on standard therapy remains poor. EZH2 is a methyltransferase playing crucial roles in gene regulation and epigenetic modifications. Gain-of-function mutations/overexpression of EZH2 has been found in NHL and correlates with disease progression. XNW5004 is a small molecule, highly selective inhibitor of EZH2. Here, we report the safety and efficacy of XNW5004 in subjects with R/R NHL from a phase 1/2 study. **Methods:** Subjects with histologically confirmed, R/R NHL who has received ≥ 2 lines of systemic therapies were eligible to enroll in this multicenter, open label, dose escalation and dose expansion study in China. Standard 3+3 design with accelerated titration was used for dose escalation in 6 doses of XNW5004 from 100mg to 2000mg, PO, BID. 800mg BID and 1200mg BID were selected for dose expansion in subjects with follicular lymphoma (FL) and peripheral T cell lymphoma (PTCL). **Results:** As of Dec 18, 2024, 120 subjects were enrolled (escalation:19, expansion: 101) including 51 FL and 58 PTCL. Median follow-up was 17.4 months (mos). 87.4% of the subjects had an Ann Arbor Stage of III-IV at baseline. The median lines of prior systemic therapy were 3. 93.8% of the FL subjects received anti-CD20 antibody, 68.8% were POD24 (progression of disease within 24 months of diagnosis). 91.7% of the PTCL subjects received HDAC inhibitor prior to enrollment. Any grade treatment-emergent adverse events (TEAEs) in ≥10% subjects included diarrhea, anemia, WBC count decreased, platelet count decreased, vomiting, nausea, and neutrophil count decreased. No DLT was observed. In dose escalation phase, ORR and DCR of the 16 evaluable subjects across doses was 56.3% and 87.5%, respectively. Median progression-free survival (mPFS) was 9.2 mos. Median duration of response (mDOR) and median overall survival (mOS) were not reached. In dose expansion phase, 1200mg BID was selected as RP2D. At 1200 mg BID, ORR in all FL, EZH2 wild type FL, and EZH2 mutant FL was 66.7%, 63.2%, and 70%, respectively. mPFS and mDOR in all FL was 10.8 mos and 7.4 mos, respectively. mOS was not reached. ORR in FL with POD24 was 56.5%. ORR in FL previously treated with CAR-T was 66.7%. ORR in FL previously received autologous stem cell transplantation was 100%. At 1200 mg BID, ORR in all PTCL, PTCL-NOS, and PTCL-AITL was 70.3%, 72%, and 68.2%, respectively. In all PTCL, mPFS was 15.7 mos and mDOR was 13.9 mos. mOS was not reached. **Conclusions:** XNW5004 has shown a well-tolerated safety profile and promising efficacy in different types of NHL. Pivotal studies of XNW5004 monotherapy in PTCL are ongoing. Clinical trial information: NCT06558513. Research Sponsor: Evopoint Biosciences, Co. Ltd.

7013 Rapid Oral Abstract Session

CD79b-targeted antibody-drug conjugate (ADC) SHR-A1912 in combination with rituximab, gemcitabine, and oxaliplatin (R-GemOx) in relapsed or refractory (r/r) diffuse large B-cell lymphoma (DLBCL): Data from a phase 1b/2 study. First Author: Yajun Li, Department of Lymphoma and Hematology, The Affiliated Cancer Hospital of Xiangya School of Medicine, Central South University/Hunan Cancer Hospital, Changsha, China

Background: Patients (pts) with transplant-ineligible r/r DLBCL have an unmet need, with an objective response rate (ORR) of around 40%. CD79b, a key component of the B-cell receptor and expressed in a majority of mature malignancies of B-cell origin, is an attractive therapeutic target for DLBCL. We initiated a phase 1b/2 study to assess the safety and efficacy of SHR-A1912, a novel CD79b-targeted ADC, in combination with chemotherapy in pts with r/r or treatment-naive DLBCL. Here, we report the findings of SHR-A1912 plus R-GemOx regimen in the r/r DLBCL cohort. **Methods:** The study comprised a dose-escalation (D-ESC) and dose-expansion (D-EXP) phase 1b part and an efficacy-expansion phase 2 part. For the r/r DLBCL cohort, pts who had failed to respond to or had progressed after ≥1 prior anti-cancer therapy were enrolled to receive SHR-A1912 plus R-GemOx (Q3W, IV) for up to 8 cycles, followed by maintenance therapy with SHR-A1912 until disease progression, intolerable toxicity, or investigator decision. The primary endpoints were safety and recommended phase 2 dose (RP2D) in the phase 1b part and ORR in the phase 2 part. **Results:** As of cutoff date on Nov 19, 2024, 41 pts were enrolled (n=7, 8, and 26 in D-ESC, D-EXP, and phase 2 parts). During D-ESC, DLTs were observed in 2 of the 4 pts receiving 2.7 mg/kg of SHR-A1912 plus R-GemOx (1 with grade 4 decreased platelet count and 1 with grade 3 asthenia and grade 3 decreased appetite); subsequently, 3 pts were given 1.8 mg/kg of SHR-A1912 plus R-GemOx, and no DLTs occurred. 1.8 mg/kg was determined to be the RP2D of SHR-A1912 when combined with R-GemOx. Totally, 37 r/r DLBCL pts received 1.8 mg/kg of SHR-A1912 plus R-GemOx in the study. Grade ≥3 treatment-emergent adverse events occurred in 21 (56.8%) out of the 37 pts, with the most common being hematological toxicities (decreased platelet count, 29.7%; decreased white blood cell count, 24.3%; decreased neutrophil count, 21.6%; anemia, 13.5%; decreased lymphocyte count, 10.8%). Among the 37 pts, 19 achieved a complete response (CR), and 8 achieved a partial response. The ORR was 73.0% (95% CI, 55.9–86.2), and the CR rate was 51.4% (95% CI, 34.4–68.1). 23 (85.2%) of the 27 responders showed an objective response at their first anti-tumor assessment, with a time to response of 1.4 mo (95% CI, 1.2–3.5). All responses were ongoing as of the cutoff date. **Conclusions:** Inpts with r/r DLBCL, SHR-A1912 at 1.8 mg/kg in combination with R-GemOx was tolerable and demonstrated a safety profile consistent with its individual components. This combination exhibited potent anti-tumor activity, as well as rapid and durable responses. Clinical trial information: NCT06104553. Research Sponsor: Jiangsu Hengrui Pharmaceuticals.

7014 Rapid Oral Abstract Session

Fixed duration subcutaneous (SC) mosunetuzumab (Mosun) in patients with previously untreated high-tumor burden follicular lymphoma (FL): Interim results from the phase II MorningSun study. First Author: Ian W. Flinn, Tennessee Oncology and OneOncology, Nashville, TN

Background: Mosun is a CD20xCD3 bispecific antibody that can be administered in the outpatient setting for a fixed duration. Intravenous Mosun is approved for the treatment of relapsed/refractory FL after ≥2 prior lines of therapy. Mosun SC achieved high response rates with manageable safety in patients with 3L+ FL in a pivotal Phase II study (Bartlett et al. ASH 2024). We report the efficacy and safety of Mosun SC in patients with previously untreated high-tumor burden FL in the Phase II MorningSun study (NCT05207670). **Methods:** Patients with previously untreated high-tumor burden FL, per GELF criteria, were enrolled into this cohort. Mosun SC was administered with step-up dosing in Cycle (C)1 (Day [D]1, 5mg; D8, 45mg; D15, 45mg) then 45mg on D1 for up to 17 cycles (1 year; 21-day cycles). Patients with a partial or complete metabolic response (CMR) after C17 could receive additional Mosun maintenance therapy (45mg every 8 weeks for up to 1 year). Corticosteroid prophylaxis to reduce the risk of cytokine release syndrome (CRS) was mandatory in C1–2 and optional thereafter. The primary endpoint was progression-free survival (PFS) rate at 24 months. Key secondary endpoints included objective response rate (ORR), time to response (TTR), and safety. **Results:** As of May 29, 2024, 102 patients were enrolled; 55 patients had completed initial treatment (17 cycles), 31 had discontinued (most commonly due to progressive disease [n=19] and adverse events [AEs; n=4]), and 16 were ongoing initial treatment. Forty-two patients received maintenance treatment, and this was ongoing in 38 patients. Median age was 65 years (range: 24–86); 52.0% of patients were female. Most patients had Ann Arbor stage III/IV (91.2%) and a FLIPI score ≥2 (78.4%). Median duration of follow-up was 13.9 months. The 12-month PFS rate was 82.8% (95% confidence interval [CI]: 73.0–89.3). ORR was 87.3%; 60.8% of patients had a CMR. Among the 89 patients with a response, the median TTR was 2.7 months (range: 1.2–5.8). The most common AEs (≥30%) were injection-site reaction (57.8%), fatigue (42.2%), CRS (34.3%), headache (31.4%), and nausea (30.4%). Grade ≥3 AEs and serious AEs (SAEs) were reported in 44.1% and 29.4% of patients, respectively. CRS events were all Grade 1/2 and SAE of CRS occurred in 10.8% of patients (Table); all events resolved. **Conclusions:** Mosun SC demonstrated promising efficacy in patients with previously untreated high-tumor burden FL. The manageable safety profile, including rate of CRS, supports the administration of fixed duration Mosun SC in an outpatient setting. Additional data, including cytokine profiling and T/B/NK dynamics, will be presented. Clinical trial information: NCT05207670. Research Sponsor: Genentech, Inc.

7015 Rapid Oral Abstract Session

Glofitamab plus gemcitabine and oxaliplatin (Glofit-GemOx) in patients (pts) with relapsed/refractory (R/R) diffuse large B-cell lymphoma (DLBCL): 2-year (yr) follow-up of STARGLO. First Author: Jeremy S. Abramson, Massachusetts General Hospital Cancer Center, Boston, MA

Background: Glofitamab, a CD20:CD3 bispecific antibody, has shown durable responses as fixed duration monotherapy in R/R DLBCL after ≥2 prior lines of therapy (LOT; Dickinson et al. NEJM 2022). When combined with GemOx, glofitamab has shown overall survival (OS) and progression-free survival (PFS) benefits in autologous stem cell transplant (ASCT)-ineligible R/R DLBCL (Abramson et al. Lancet 2024). We present updated efficacy and safety of Glofit-GemOx vs rituximab (R)-GemOx in pts with R/R DLBCL after ≥1 LOT from the Phase 3 STARGLO trial (NCT04408638), including landmark analyses of pts in complete remission (CR). **Methods:** Pts were randomized 2:1 to Glofit-GemOx (8 cycles plus 4 cycles glofitamab monotherapy) or R-GemOx (8 cycles) and stratified by no. of prior LOT (1 vs ≥2) and refractoriness to last therapy. After obinutuzumab pretreatment, glofitamab was given in Cycle (C) 1 as weekly step-up doses (2.5/10mg) then 30mg target dose every 21 days from C2 Day 1. Pts with only 1 prior LOT must have been ASCT-ineligible. Primary endpoint was OS. Secondary endpoints included independent review committee (IRC)-assessed PFS and CR rate. A landmark analysis of pts in CR at end of treatment (EOT) was performed. **Results:** Of 274 pts (Glofit-GemOx, n=183; R-GemOx, n=91), 172 (62.8%) had 1 prior LOT, 102 (37.2%) had ≥2 prior LOT, 153 (55.8%) were primary refractory, and 166 (60.6%) were refractory to last therapy. Baseline characteristics were unchanged and balanced across arms. With 2 yrs follow-up (data cut off: June 17, 2024; median follow-up: 24.7 months [mo]), Glofit-GemOx continued to confer superior OS benefits (median: not evaluable [NE] vs 13.5 mo; HR 0.60, 95% CI: 0.42–0.85), median IRC-assessed PFS (13.8 vs 3.6 mo; HR 0.41, 95% CI: 0.29–0.58), and CR rate (58.5 vs 25.3%) vs R-GemOx. For Glofit-GemOx-treated pts in CR (n=107), median duration of CR was not reached (95% CI: 27.2–NE; median CR follow-up, 18.2 mo [range: 15.2–19.3]). In pts with a CR at EOT (n=82), the OS and PFS rates 1 yr after EOT were 89.3% and 82.4%, respectively. The Glofit-GemOx safety profile was unchanged. Cytokine release syndrome (CRS) was the most common adverse event in glofitamab-exposed pts (Grade [Gr] 1, 32.0%; Gr 2, 10.5%; Gr 3, 2.3%). Events consistent with immune effector cell-associated neurotoxicity syndrome occurred in 4 pts (all concurrent with CRS; most Gr 1–2 [n=3]). Exploratory biomarker and immune recovery data will be presented. **Conclusions:** With 2 yrs follow-up, Glofit-GemOx sustained a clinically meaningful benefit in OS and PFS vs R-GemOx in ASCT-ineligible pts with R/R DLBCL, with most (82%) pts in CR at EOT still in remission. The safety profile was consistent with known risks of each drug. The updated analyses support the long-lasting remissions and maintained OS benefit in pts with R/R DLBCL treated with fixed duration Glofit-GemOx. Clinical trial information: NCT04408638. Research Sponsor: F. Hoffmann-La Roche Ltd; N/A.

7016 **Rapid Oral Abstract Session**

Worldwide experience of chronic active EBV infection: Retrospective cohort study. First Author: Xinran Wang, Department of Hematology, Tongji Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, China

Background: Chronic active Epstein-Barr virus disease (CAEBV) is a rare, life-threatening disorder characterized by systemic inflammation and clonal proliferation of EBV-infected T or NK cells. The disease exhibits clinical variability, ranging from mild to rapidly progressive and fatal forms. Despite advances in understanding its features, most studies are based on small cohorts or case reports, with no standardized diagnostic or therapeutic guidelines. Regional differences in age distribution, clinical characteristics, and treatment strategies exist. This study analyzed 763 CAEBV cases to summarize global experiences and propose a new classification and risk stratification model. **Methods:** This retrospective cohort study analyzed 763 CAEBV cases from 57 centers across 9 countries, including data from a systematic review and institutional data from Tongji Hospital, Wuhan, China. A novel classification system and risk stratification model were developed based on clinical and pathological data. Treatment outcomes, including allo-HSCT, anti-PD-1 therapy, and chemotherapy, were evaluated using survival analysis and multivariate Cox regression. **Results:** Among the 763 cases, 98.1% were from East Asia (China 53%, Japan 41%, Korea 4%), with smaller contributions from America (2%) and other countries. The median age at diagnosis was 18 years, with 53.7% of cases in those under 20. EBV-infected T cells were seen in 52% of cases, NK cells in 38%, and mixed infections in 10%. A new classification system divided systemic CAEBV (sCAEBV) into four subtypes: cutaneous (10%), gastrointestinal (4.6%), vascular (3.2%), and not otherwise specified (82.2%). Gastrointestinal involvement was associated with the poorest prognosis, necessitating early intervention. Treatment data from 399 patients showed that allo-HSCT is the only curative option, significantly improving survival rates. For high-risk patients unable to undergo allo-HSCT, anti-PD-1 therapy showed potential as an adjunctive treatment. A risk stratification model categorized patients into low-risk, high-risk, and very high-risk groups. Low-risk patients were monitored and treated with anti-PD-1 therapy, high-risk patients received either anti-PD-1 therapy or allo-HSCT, and very high-risk patients were advised to undergo allo-HSCT. **Conclusions:** This study represents the largest global cohort of CAEBV cases, with 763 cases from 9 countries. A novel classification system for sCAEBV was proposed, highlighting gastrointestinal involvement as a poor prognostic factor. Based on clinical symptoms and laboratory findings, a new risk stratification model was developed, guiding personalized treatment. Allo-HSCT remains the only curative treatment, significantly improving survival, while anti-PD-1 therapy offers potential as an adjunctive treatment for high-risk patients who cannot undergo allo-HSCT. Research Sponsor: This study was supported by the National Natural Science Foundation of China, the Natural Science Foundation of Hubei Province.

Efficacy and safety of first-line ibrutinib plus venetoclax in patients with mantle cell lymphoma (MCL) who were older or had *TP53* mutations in the SYMPATICO study. First Author: Michael Wang, Department of Lymphoma and Myeloma, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: The phase 3 SYMPATICO study evaluated ibrutinib (Ibr) combined with venetoclax (Ven) in 3 cohorts of patients (pts) with MCL: an open-label safety run-in phase to evaluate concurrent initiation of Ibr+Ven in relapsed/refractory (R/R) MCL; a randomized phase to evaluate Ibr+Ven vs Ibr+placebo (Pbo) in R/R MCL; and an open-label cohort to evaluate first-line Ibr+Ven in treatment-naive (TN) MCL. Primary analysis of the randomized phase showed superior PFS with Ibr+Ven vs Ibr+Pbo in pts with R/R MCL (Wang M et al, *Lancet Oncol*, in press). Here, we report efficacy and safety of Ibr+Ven in pts with TN MCL in older pts (≥65 y) or younger pts with a *TP53* mutation (*TP53*mut) (≥18 y) who are in need of novel and better tolerated treatment options. **Methods:** Older pts (≥65 y) or pts with a *TP53*mut with TN MCL received oral Ibr 560 mg once daily and Ven (5-wk ramp-up to 400 mg once daily) for 2 y, then single-agent Ibr 560 mg until PD or unacceptable toxicity. Primary endpoint was complete response (CR) rate assessed by investigator per Lugano. Key secondary endpoints included overall response rate (ORR), duration of response (DOR), PFS, OS, and time to next treatment. Subgroup analyses were performed according to *TP53*mut status and age. **Results:** In total, 78 TN MCL pts were enrolled. At baseline, 83% of pts were ≥65 y, 97% had ECOG PS of 0–1, 45% had high-risk simplified MIPI score, 31% had bulky disease (≥5 cm), 78% had bone marrow involvement, 46% had splenomegaly, and 37% had *TP53*mut. Median time on study was 40.5 mo (range, 0.6+–46.9). CR rate was 69% (95% CI, 58–79), and ORR was 95% (95% CI, 87–99). Median DOR was 37.1 mo (95% CI, 30.3–NE). Median PFS was 40.2 mo, and 3-y OS was 79%. CR rate was 76% in pts ≥65 y without *TP53*mut, 44% in pts ≥65 y with *TP53*mut, and 73% in pts <65 y with *TP53*mut; median PFS was 40.2, 22.0, and 15.4 mo, and 3-y OS was 85%, 66%, and 73%, respectively (Table). Median duration of treatment was 24.0 mo (range, 0.3–46.9). Most common AEs were diarrhea (49%), fatigue (37%), neutropenia (35%), and COVID-19 (32%). Most common grade ≥3 AE was neutropenia (29%). **Conclusions:** First-line Ibr+Ven showed promising efficacy with high CR rates and durable remissions in pts with TN MCL with and without *TP53*mut. Safety was acceptable and trended better in younger pts. Ibr+Ven may be an option for older pts with TN MCL or pts of any age with *TP53*mut. Clinical trial information: NCT03112174. Incidence of infections, cardiac events, neurological toxicity and cytokine response syndrome (CRS) in patients treated with chimeric antigen receptor (CAR) T cell therapy: A 3-year nationwide analysis. First Author: Himil Mahadevia, University of Missouri - Kansas City, Kansas City, MO

Background: CAR-T cell therapy represents a notable advancement in treating relapsed/refractory (R/R) hematological malignancies. Adverse events include CRS, infections, and neurological and cardiac complications. While there are reports from major academic institutions on the adverse effects of CAR-T therapy, we used data from the National Inpatient Sample (NIS) to gather national estimates of complications related to CAR-T therapy. **Methods:** A retrospective study was conducted to analyze patients who underwent CAR-T cell therapy by utilizing appropriate ICD-10-PCS procedure codes (XW033C3, XW043C3, XW23346, XW24346, XW23376, and XW24376) from NIS 2019 to 2021. Data regarding infections, toxic encephalopathy (a surrogate for neurological toxicity), and adverse cardiac events were extracted using relevant ICD-10-CM diagnostic codes. Patients experiencing various grades of CRS were identified through specific ICD-10 codes available in 2021 (Grades 1-5: D89.831-D89.835). **Results:** This study analyzed 6515 patients who underwent CAR-T cell therapy from January 2019 to December 2021. Among them, 60.7% were male. 74.6% were Caucasian, 11.7% were Asian and 6.7% were African American. 49.8% of patients had private insurance, 36.2% had Medicare, and 8.6% had Medicaid. 6.8% of patients were diagnosed with pneumonia, while sepsis occurred in 7.4% of patients and 3% experienced septic shock. 19.4% of patients experienced cardiac arrhythmias, and major cardiovascular events were recorded in 4.7% of the cohort. Acute myocardial infarction and stroke were documented in 0.6 and 1.2% of patients, respectively. Toxic encephalopathy was reported in 19.7% of patients. Among 2235 patients identified to have received CAR-T in 2021, 59.7% developed CRS. Grade 1 and grade 2 CRS were reported in 32% and 21% of patients, respectively, while grade 3 and grade 4 reactions were noted in 4.7% and 2% of patients, with no cases of grade 5 identified. The mean total cost of hospitalization was 308,364$, and the mean length of hospital stay was 19.5 days. The overall in-hospital mortality rate was 3.4%. **Conclusions:** Our study describes real-world outcomes from a large dataset of CAR-T patients. Infections pose a significant challenge with CAR-T therapy, highlighting the importance of early detection and timely antimicrobial treatment. CRS is common, with a 60% incidence, similar to previous clinical trials (55%). Immediate management is crucial for addressing CRS toxicity. Adverse neurological and cardiovascular incidents are often reported, emphasizing the need for meticulous monitoring and coordinating multidisciplinary care plans. The financial burdens also bear mentioning: CAR-T therapy costs significantly higher than autologous stem cell transplants. Further studies to address these issues are warranted. Association of enrichment of CD7$^+$CXCR3$^+$ CAR T cells in infusion products with remission in relapsed or refractory diffuse large B-cell lymphoma. First Author: Michel Obeid, CHUV, LCIT Center, Lausanne, Switzerland

Background: Chimeric antigen receptor (CAR) T-cell therapy is the standard of care for relapsed or refractory diffuse large B-cell lymphoma (R/R DLBCL), yet more than half of patients do not achieve durable remission. Identifying predictive biomarkers in CAR T-cell infusion products (IPs) could guide strategies to improve outcomes. **Methods:** This was a single-centre observational study conducted at Lausanne University Hospital (CHUV), Switzerland. IPs from 13 patients with R/R DLBCL who underwent CAR T-cell therapy were analyzed using a 39-marker mass cytometry panel. We compared phenotypic and functional markers between long-term responders (R) and non-responders (NR). Both unsupervised and supervised analyses were performed. Additionally, longitudinal blood samples collected over 30 days after infusion were examined to track CAR T-cell subpopulation dynamics. **Results:** At a median follow-up of 13.5 months, median progression-free survival (PFS) was 13.3 months (95% CI 9.7–24.3) in R (n=8) versus 3.5 months (95% CI 0.5–5.4) in NR (n=5) (hazard ratio 56.67 [95% CI 7.3–439.3]; p=0.0001). A subset of CD3$^+$CXCR3$^+$CD7$^+$ CAR T-cells—present within both CD4$^+$ and CD8$^+$ subsets—was significantly enriched in R. These cells showed increased expression of perforin, granzyme B, and NKG2D (restricted to CD8$^+$ cells). In contrast, NR had a higher frequency of CXCR3$^+$CD7$^+$LAG3$^+$ CAR T-cells. Surface expression levels of CD3, CD7, CXCR3, and NKG2D were higher in R, whereas LAG3, Ki67, and CD71 were elevated in NR. A predictive cut-off ratio of CD3$^+$CXCR3$^+$CD7$^+$LAG3$^+$CAR$^+$ T-cells <0.83 and CD3$^+$CXCR3$^+$CD7$^+$NKG2D$^+$CAR$^+$ T-cells >1.034 yielded a predictive accuracy of 0·92. Serum CXCL9 and CXCL10 concentrations did not differ between groups. **Conclusions:** The enrichment of CD7$^+$CXCR3$^+$ CAR T-cells and expression of NKG2D in R, as opposed to elevated LAG3 and CD71 in NR, emerged as robust correlates of therapeutic outcome. These findings could inform the development of biomarker-driven strategies to optimize CAR T-cell products and enhance the likelihood of sustained remission. Research Sponsor: CHUV pôle prioritaire.

7021 Poster Session

Clinical outcomes of cytomegalovirus infection among patients receiving chimeric antigen receptor T cell therapy. First Author: Muhammad Atif Khan, University of Kansas Medical Center, Collaborative Opportunities for Research, Training, And Excellence in Innovation (CORTEX), Kansas City, KS

Background: Chimeric antigen receptor T (CAR-T) cell therapy is a transformative treatment for hematologic malignancies, including multiple myeloma (MM), non-Hodgkin lymphoma (NHL), and acute leukemia (AL). Despite its success, CAR-T therapy is associated with significant toxicities and an increased risk of infections, particularly cytomegalovirus (CMV) infection. CMV infection in CAR-T recipients has been linked to increased non-relapse mortality (NRM) and prolonged hospital stays; however, comprehensive data on its clinical impact remains limited. This study aimed to evaluate the clinical impact of CMV infection on outcomes in CAR-T therapy recipients. **Methods:** This retrospective cohort study utilized the HCUP-National Readmission Database (NRD) 2021 database to analyze adult hospitalized patients (≥18 years) who underwent CAR-T cell therapy for MM, NHL, or AL in the USA. Patients with a prior CMV diagnosis or discharged in the last three months of 2021 were excluded. Propensity score matching (PSM) was applied to balance baseline characteristics, and weighted estimates were used for outcome analysis. The primary outcome was all-cause mortality within three months post-discharge. Secondary outcomes included length of hospital stay (LOS) and CAR-T-related complications. **Results:** A total of 1806 hospitalizations met the inclusion criteria. The mean age was 61.9 years, with a male majority of 64.4%. The underlying disorders were NHL (73.7%), MM (21.6%), and AL (4.7%). The incidence of CMV infection during the index hospitalization was 2.2%, increasing to 4.2% within three months post-CAR-T therapy. Matched analysis showed higher three-month mortality in CMV-infected patients (15.8%) compared to non-CMV patients (2.5%) (risk ratio 6.32, 95% CI: 1.46-27.30, p=0.004). CMV-infected patients had a significantly longer mean LOS (41.5 vs. 15.9 days, adjusted mean difference 15.5 days, 95% CI: 6.7-24.2, p=0.001). CMV infection was significantly associated with encephalopathy (risk ratio 13.21, 95% CI: 1.66-105.2, p=0.015), while other complications such as cytokine release syndrome (CRS), AKI, and transaminitis did not show a statistically significant association. **Conclusions:** CMV infection in CAR-T cell therapy recipients is associated with increased mortality, prolonged hospitalization, and risk of encephalopathy. These findings underscore the need for vigilant CMV surveillance and targeted management strategies to improve patient outcomes. Research Sponsor: None.

7022 Poster Session

Characterization of mechanisms driving CD20 loss in patients with relapsed or refractory large B-cell lymphoma treated with glofitamab. First Author: Linlin Cao, Roche Innovation Center Zurich, Schlieren, ZH, Switzerland

Background: Glofitamab is a CD20xCD3 T-cell engaging bispecific monoclonal antibody that redirects T cells to eliminate malignant B cells in patients (pts) with relapsed or refractory non-Hodgkin Lymphoma. We characterized mechanisms driving CD20 loss in pts from a Phase I/II trial (NP30179) receiving Glofitamab monotherapy for Relapsed/Refractory Large B-cell lymphoma (R/R LBCL). **Methods:** Pts with LBCL and ≥2 prior therapies received obinutuzumab pretreatment followed by fixed-duration Glofitamab at the approved dose in phase I/II trial NP30179 (NCT03075696) (Dickinson, et al. N Engl J Med 2022). Tumor biopsies were collected prior to treatment (Baseline, BL) in 128 pts, during treatment (tx) or at progression (PD) in 11 pts. The proportion of CD20+ tumor cells was determined by immunohistochemistry (IHC) using a dual CD20+ PAX5+ assay. Expression of *MS4A1*, the gene encoding CD20, was measured by RNA-sequencing (RNA-seq) in 105/139 biopsies. *MS4A1* mutation profiling was performed by next-generation sequencing on Cell-free circulating tumor DNA (ctDNA) from 133 pts. We subsequently characterized the functional consequences of identified mutations in vitro. **Results:** CD20 levels evaluated by IHC were high (>75% CD20+ tumor cells) in 110/128 BL biopsies. At BL, CD20 loss (<5% CD20+ tumor cells) was seen in 4/128 (3.1 %) biopsies. For 11 pts with BL and on-tx or at-PD biopsies, 7/11 (63.6%) pts presented CD20 loss on-tx/at-PD and 4/11 (36.4%) did not. Evaluation of gene expression profile showed a good correlation between CD20 gene and protein expression. Among the 7 pts with CD20 loss on-tx/at-PD biopsies, there were 4 biopsies with available gene expression data, and decreased CD20 expression was identified in 2/4. Evaluation of CD20 mutation revealed 11/134 (8.2%) pts harbored 16 *MS4A1* mutations at BL or on-tx/at-PD. IHC data were available for 8/11 pts at BL where 2/8 presented CD20 loss (<5% CD20+ tumor cells), and for 1 pt at-PD who presented CD20 loss. 12/16 mutations were not previously reported. We characterized 14 mutations in vitro and subsequently demonstrated that 8 frameshift or deletion mutations lead to truncation of the protein, and 4 missense mutations lead to disruption in the transmembrane domain of CD20. These 12 mutations lead to loss of intracellular and extracellular CD20 expression, and abrogation of Glofitamab-mediated cytotoxicity in vitro. **Conclusions:** In pts with R/R LBCL treated with Glofitamab, loss of tumor antigen CD20 expression is one resistance mechanism to Glofitamab. Genetic alterations (fs, del or missense mutations) and transcriptional downregulation can contribute to loss of CD20 expression and they were both observed in pts treated with Glofitamab. 7023 Poster Session

Trends and outcomes by inpatient and outpatient infusion of axicabtagene ciloleucel (axi-cel) in the US for patients (pts) with relapsed/refractory large B-cell lymphoma (R/R LBCL). First Author: Fateeha Furqan, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Axi-cel is an autologous chimeric antigen receptor (CAR) T-cell therapy approved for adults with R/R LBCL after ≥ 1 prior line of therapy (LoT). Adverse events, such as cytokine release syndrome (CRS) and neurologic events (NEs), may deter centers from using axi-cel in an outpatient (OPT) setting, though individual centers have observed comparable safety and effectiveness in OPT and inpatient (IPT) care (Furqan et al. *Blood Adv*. 2024). Here, we present safety and effectiveness outcomes of axi-cel by intention to treat in OPT and IPT settings in a multicenter real-world dataset. **Methods:** Pts receiving axi-cel for R/R LBCL in the US from 01/2021-07/2023 with data in the Center for International Blood and Marrow Transplant Research (CIBMTR) registry were eligible for analysis. Pts with prior allogeneic transplant or unknown intended care setting were excluded. Of potential pts, 119 OPT pts were identified from 29 centers where an increasing trend was seen (9.6% of pts in 2021 were OPT, 13.5% in 2022, 22.8% in 2023). Pts were matched to 119 IPT pts by propensity score matching on age, sex, comorbidities, lactate dehydrogenase (LDH), bulky disease, prior LoT, chemosensitivity, and infusion year (see table). **Results:** OPT pts had median age of 63 y (25% ≥ 70), 66% were male, and 67% had ≥ 1 comorbidity. Half (50%) had elevated LDH and 73% had 1 prior LoT. Bulky disease was reported in 3%, and 60% had chemo-resistant disease. Outcomes were analyzed at median follow-up of 12 mo. Safety and effectiveness outcomes were similar between OPT and IPT pts (see table). In multivariate analyses, no differences were found between intended care setting and CRS (odds ratio [OR] 1.09 [95% CI 0.51-2.35]), CRS Gr ≥ 3 (OR 0.57 [0.12-2.60]), NEs (OR 1.14 [0.65-2.00]), or NEs Gr ≥ 3 (OR 0.98 [0.48-2.00]). Among OPT pts, 24% and 50% did not require hospital admission within 30 d and 3 d, respectively. In pts aged ≥ 70 y, only any Gr NEs were higher in the OPT group. **Conclusions:** After matching on key factors that may be used to select pts for OPT infusion, outcomes were comparable between intended care settings. These findings corroborate prior results and support the consideration of axi-cel in appropriate OPT care settings. Research Sponsor: Kite, a Gilead Company.

Outcomes between matched pts with R/R LBCL receiving axi-cel intended for OPT or IPT.

	OPT (n=119)[a]	IPT (n=119)[a]
CRS any Gr / Gr ≥ 3	83 (75–89) / 3 (<1–7)	83 (74–89) / 4 (1–10)
NE any Gr / Gr ≥ 3	47 (38–57) / 19 (12–27)	46 (37–56) / 21 (14–30)
Overall / complete response rates	78 (69–85) / 68 (59–76)	76 (67–83) / 62 (52-70)

Real-world outcomes of axicabtagene ciloleucel (axi-cel) for the treatment of relapsed/refractory (R/R) secondary central nervous system lymphoma (SCNSL). First Author: Narendranath Epperla, Huntsman Cancer Institute, University of Utah, Salt Lake City, UT

Background: Axi-cel is an autologous anti-CD19 CAR T-cell therapy that demonstrated durable, long-term efficacy and manageable safety in R/R LBCL. However, there is paucity of data using axi-cel in SCNSL, a subset associated with poor clinical outcomes. Here, we describe effectiveness and safety outcomes of axi-cel in R/R SCNSL. **Methods:** Patients (pts) receiving commercial axi-cel for R/R active SCNSL from 2018-2023 were selected from the CIBMTR database. Pts with primary CNS lymphoma and diseases other than LBCL were excluded. Outcomes included overall response rate (ORR), complete response (CR) rate, cumulative incidence of relapse (CIR), duration of response (DOR), progression-free and overall survival (PFS and OS), cytokine release syndrome (CRS) and immune effector cell-associated neurotoxicity syndrome (ICANS) per ASTCT consensus grading, other adverse events, and non-relapse mortality (NRM). Outcomes were analyzed descriptively. **Results:** At May 2024 data cutoff, 65 pts from 28 centers were identified. Median age at infusion was 63 y (range, 21-79) with 66% male and 81% white. Few pts (9/58, 16%) had ECOG PS ≥2; 52/65 (80%) had clinically significant comorbidities. Double-/triple-hit lymphoma was seen in 12/50 pts (24%), and 51/58 (88%) had Stage III/IV disease. CNS sites involved preinfusion were brain (51%), cerebrospinal fluid (12%), epidural space (15%), leptomeninges (11%), eyes (9%), and spinal cord (5%). Median number of prior lines of therapy was 4 (IQR, 3-5); 12/65 pts (18%) had prior autologous stem cell transplantation. Median time from leukapheresis to infusion was 28 days (IQR, 26-34). Bridging therapy was given to 47/65 pts (75%; systemic, 40 [63%]; intrathecal, 12 [19%]; radiation, 17 [27%]). At 48.2-mo median follow-up, ORR was 72% (95% CI, 60-83); CR rate was 51% (95% CI, 38-63). Median (95% CI) DOR, PFS, and OS were 4.0 (2.3-NE), 3.6 (2.2-4.9), and 8.4 mo (6.6-18.2), respectively. CIR was 66% (95% CI, 51-77) at 1 and 2 y. At 2 y and 3 y, PFS (95% CI) was 26% (16-38) and 23% (13-35), respectively, and OS (95% CI) was 36% (24-49) and 32% (20-44). Among pts without progression at 1 y, PFS was 100% and 90% (47-99) at 2 y and 3 y, respectively; OS was 82% (59-93) and 72% (48-86). Grade ≥3 CRS and ICANS occurred in 14% and 37% of pts, respectively (any grade, 81% and 62%). Of 56 pts with CRS and/or ICANS, tocilizumab, corticosteroids, and anakinra were used in 68%, 73%, and 7% of pts, respectively. Prolonged cytopenia (by Day 30) was reported in 25/63 pts (40%; thrombocytopenia, 37%; neutropenia, 11%), and 39/65 (60%) had clinically significant infections. Subsequent cancers were found in 3/39 pts (8%); 2 were myeloid. NRM at 3 y was 12%. **Conclusions:** With 4-y median follow-up, this real-world study highlights the potential use of axi-cel as an option to treat this challenging group of pts. Further studies are needed to improve response durability. Research Sponsor: U.S. National Institutes of Health; Kite, a Gilead Company.

Social vulnerability by neighborhood of association correlates with CAR T referrals. First Author: Clare E. Anderson, Durham VA Health Care System and Duke University, Durham, NC

Background: Chimeric antigen receptor T (CAR T) cell therapies are effective for relapsed/refractory (R/R) diffuse large B-cell lymphoma (DLBCL) and multiple myeloma (MM). However, factors influencing referrals remain unclear, particularly among the denominator of all eligible candidates. This study examines patterns of CAR T referral in the VA health system. **Methods:** A retrospective review identified veterans with R/R DLBCL or MM eligible for CAR T per FDA label during approval periods. Multivariable logistic regression assessed associations of CAR T referral with demographics, comorbidities, and social deprivation index (SDI). SDI is a composite social determinants of health measure at the zip code level, with higher SDI (range: 0-100) indicating greater social disadvantage. **Results:** Of 1,474 eligible patients across 112 VA hospitals, 25% (153/606) of DLBCL and 7.5% (65/868) of MM patients were referred for CAR T. Multivariable analysis showed that higher SDI (OR 0.90 per 10 points, 95% CI 0.84-0.96, p = 0.001) and older age (OR 0.58 per 10 years, 95% CI 0.49-0.69, p $<$ 0.0001) were associated with a lower chance of referral, while DLBCL diagnosis (OR 3.22, 95% CI 2.28-4.59, p $<$ 0.0001) and Hispanic ethnicity (OR 1.964, 95% 1.09-3.45, p = 0.02) were more likely to have referrals. Marital status, sex, race, psychiatric history, substance abuse, heart disease, kidney disease, cirrhosis, and rural/urban residence were not significant. Among referred patients, older age (OR 0.98, 95% CI 0.95-0.99) and substance abuse (OR 0.42, 95% CI 0.19-0.88) were linked to lower CAR T administration. Median lines of therapy for CAR T were 4 (range: 2-6) for DLBCL and 7 (range: 5-10) for MM. Common reasons for not receiving CAR T included death (23%), age/performance status (21%), alternative therapies (18%), adequate disease control (13%), comorbidities (8%), and patient preference (5%). **Conclusions:** Social vulnerability by neighborhood of association is associated with fewer CAR T referrals. Once referred, most variables minimally impacted CAR T administration. Efforts should focus on improving referral rates and addressing access barriers across all patients. Research Sponsor: None.

Optimizing post–chimeric antigen receptor (CAR) T cell monitoring: Evidence across lisocabtagene maraleucel (liso-cel) pivotal clinical trials and real-world experience. First Author: Manali Kirtikumar Kamdar, University of Colorado Cancer Center, Aurora, CO

Background: CAR T cell therapies have shown remarkable efficacy in B-cell NHL. Here, we report CRS and ICANS timing in 1579 patients (pt) treated with liso-cel in clinical trials across indications or in the standard of care (SOC) setting to inform safety monitoring requirements. **Methods:** Data from pivotal trials (TRANSCEND NHL 001, TRANSCEND CLL 004, TRANSFORM, PILOT, TRANSCEND FL) included pts treated with liso-cel for R/R LBCL, CLL/SLL, MCL, and FL; data from the Center for International Blood and Marrow Transplant Research (CIBMTR) Registry included pts who received commercial liso-cel for R/R LBCL and had $\geq$ 1 assessment after infusion. Outcomes were incidence, onset, grade (gr), and duration of CRS and ICANS from pivotal trials and the CIBMTR Registry. **Results:** Of 702 pts treated with liso-cel in 5 clinical trials, 46% had no CRS, 54% had any-gr CRS (gr $\geq$ 3 at onset, 1%); 98% of events had onset $\leq$ 2 wk after infusion and median duration was 5 d (Table). Of 7 pts with CRS onset $>$ Day 15 (gr 1, n = 5; gr 2, n = 2), all resolved. Most (69%) pts had no ICANS, 31% had any-gr ICANS (gr $\geq$ 3 at onset, 5%); 88% of events had onset $\leq$ 2 wk after infusion and median duration was 7 d (Table). Of 27 pts with ICANS onset $>$ Day 15 (gr 1, n = 20; gr 2, n = 6; gr 3, n = 1), all resolved except 1 pt with gr 2 leukoencephalopathy. Of 877 liso-cel–treated pts from the CIBMTR Registry, 51% had no CRS, 49% had any-gr CRS (gr $\geq$ 3, 3%); 97% of events had onset $\leq$ 2 wk after infusion and median duration was 4 d (Table). Of 15 pts with CRS onset $>$ Day 15 (gr 1, n = 9; gr 2, n = 2; gr 3, n = 1; unknown, n = 3), 13 resolved (missing, n = 2). Most (73%) pts had no ICANS, 27% had any-gr ICANS (gr $\geq$ 3, 7%). Of 150 pts with reported onset date, 95% had onset $\leq$ 2 wk after infusion and median duration was 5.5 d. Of 8 pts with ICANS onset $>$ Day 15 (gr 1, n = 5; gr 2, n = 1; gr 4, n = 2), 5 resolved (missing, n = 3). Further characterization/management of CRS/ICANS events will be presented. **Conclusions:** Data from the liso-cel pivotal clinical trials and SOC setting from the CIBMTR Registry demonstrated that most CRS/ICANS events occurred $\leq$ 2 wk after infusion and were not severe. For the few pts who experienced onset of CRS/ICANS after Day 15, most events were low grade and resolved. Clinical trial information: NCT02631044, NCT03331198, NCT03483103, NCT03575351, NCT04245839. Research Sponsor: This study was funded by Bristol Myers Squibb. Writing and editorial assistance were provided by Amy Agbonbhase, PhD, CMPP, of The Lockwood Group (Stamford, CT, USA), funded by Bristol Myers Squibb.

CRS and ICANS in liso-cel–treated pts.

	Pivotal clinical trials (N = 702)		CIBMTR Registry (N = 877)	
	CRS	ICANS	CRS	ICANS
Any gr, n (%)	381 (54)	220 (31)	430 (49)[a]	234[a,b] (27)
Gr 3/4/5,[c] n (%)	4 (0.6)/3 (0.4)/0	29 (4)/3 (0.4)/0	4 (0.5)/13 (1)/7[d] (0.8)	43 (5)/17 (2)/5 (0.6)
Median (range) time to onset, d	5 (1–63)	8 (1–63)	4 (IQR, 3–6)	6 (IQR, 4–9)
Median (range) duration from onset, d	5 (1–37)	7 (1–119)	4 (IQR, 2–6)	5.5 (IQR, 2–11)
Onset > Day 15, n/N (%)	7/381 (2)	27/220 (12)	15/430 (3)	8/150 (5)

[a]Gr was to be determined for 3 pts; [b]A total of 150/234 had a reported onset date; [c]Gr at onset for clinical trials; maximum gr during reporting period for CIBMTR; [d]Three pts had PD and 1 had ICANS reported as primary cause of death.

Comprehensive precise CAR-T bridging therapy for diffuse large B-cell lymphoma: A multicenter study from the Chinese Southwest Study Group. First Author: Tongyu Lin, Sichuan Cancer Hospital and Institute, Sichuan Cancer Center, School of Medicine, University of Electronic Science and Technology of China, Chengdu, China

Background: Chimeric antigen receptor T-cell (CAR-T) therapy has showed substantial efficacy in relapsed/refractory diffuse large B-cell lymphoma (r/r DLBCL). However, over 50-60% of patients fail to respond or relapse following CAR T-cell treatment, underscoring the need for strategies to enhance its efficacy. **Methods:** We prospectively evaluated the efficacy of the Chinese Southwest Oncology Group (CSWOG) regimen, a precise bridging strategy, in patients with r/r DLBCL who received commercial CAR-T therapy. All patients underwent re-biopsy to assess the expression of biomarkers including CD19, CD20, CD22, CD30, CD38, CD79b, ALK, BCL2, PD-L1, and Ki-67 to identify potential treatment targets. Only patients with positive CD19 expression were eligible for inclusion. Patients received a precise salvage therapy consisting of non-cross-resistant chemotherapy and targeted immunotherapy guided by the re-biopsy results. Only those who responded to salvage therapy proceeded to leukapheresis and received an additional cycle of salvage immunochemotherapy. Non-responders were switched to an alternative precise regimen. Based on our previous findings that low-dose radiation enhances CAR-T cell recruitment and increases antigen exposure, all patients received involved-field low-dose radiation prior to CAR-T cell infusion. Patients treated with axicabtagene ciloleucel (axi-cel) in a real-world setting served as the control group. **Results:** Seventy-one patients with r/r DLBCL received the CSWOG bridging regimen, while 101 Chinese patients treated with axi-cel in a real-world setting served as the control group. In the CSWOG group, 63 patients (88.7%) responded to salvage precise immunochemotherapy, while 8 patients (11.3%) who did not respond were switched to alternative immunochemotherapy regimen. All patients in the CSWOG group received a median dose of 24.0 Gy involved-field radiation. After CAR-T infusion, the best overall response (BOR) rate was 84.5% in CSWOG group, with 74.6% achieving complete response (CR) and 9.9% partial response (PR). The BOR rate in control group was 83.2%, with 58.4% achieving CR and 24.8% achieving PR. After a median follow-up of 15.3 months, the 2 - year overall survival (OS) and progression-free survival (PFS) rates were 84.1% and 75.2%, respectively, in the CSWOG group, compared to 70.0% and 49.8% in the control group. Grade 3 or higher cytokine release syndrome occurred in 9.8% of the CSWOG group and 15.2% of the control group. Neurologic events of any grade were observed in 12.8% of the CSWOG group and 16.2% of the control group. Among the 4 CSWOG patients with neurologic events, all were managed with steroids and resolved; however, all 4 relapsed. **Conclusions:** Our results show that combining precise immunochemotherapy with low-dose radiation optimizes CAR-T therapy, supporting its global implementation. Clinical trial information: ChiCTR2100043613. Research Sponsor: National Natural Science Foundation of China; 82470237.

Postmarketing safety profile of chimeric antigen receptor (CAR) T cell therapies in diffuse large B-cell lymphoma (DLBCL): Analysis of real-world (RW) AE reporting from the FDA Adverse Event Reporting System (FAERS). First Author: Matthew Alexander Lunning, University of Nebraska Medical Center, Omaha, NE

Background: CAR T cell therapies have emerged as effective treatment options with deep and durable responses in patients (pt) with DLBCL. Although efficacy and safety data from clinical trials are usually used for drug approval, potentially relevant AEs may not be captured due to limited study follow-up and population. Surveillance databases like FAERS can further characterize safety of therapeutic biologics by capturing RW AEs. We aimed to characterize the safety profile of CAR T cell therapies in the DLBCL population using FAERS. **Methods:** FAERS was used to identify AEs in pt with DLBCL treated with 2 commercially available CAR T cell therapies, lisocabtagene maraleucel (liso-cel) or axicabtagene ciloleucel (axi-cel). AEs of interest were cytokine release syndrome (CRS), neurological events (NE), hemophagocytic lymphohistiocytosis (HLH), cytopenia, and infections. The primary analysis examined all case reports from Q4 2017 to Q3 2024, the latest available quarterly release. Two sensitivity analyses adjusting for differences in follow-up after FDA approvals were performed: (1) AEs reported any time after liso-cel FDA approval (02/05/2021), which is later, and (2) AEs reported within 2 years of FDA approval for each CAR T cell therapy. Disproportionality analysis compared relative frequency of AEs. Reporting odds ratios (ROR) and 95% CIs were used to identify significant differences in AEs between treatments (ie, 95% CI did not cross 1). An ROR $>$ 1 indicated higher event frequency for axi-cel vs liso-cel. **Results:** From Q4 2017 to Q3 2024, 3251 AE reports in pt with DLBCL were associated with liso-cel (n = 232) or axi-cel (n = 3019). In disproportionality analysis, axi-cel had significantly higher ROR for CRS (1.48; 95% CI, 1.13–1.93), NE (1.61; 1.23–2.11), and cytopenia (2.45; 1.41–4.24) than liso-cel. Considering limitations of underreporting and incomplete information inherent in FAERS, no statistically significant difference can be inferred for infections (1.36; 95% CI, 0.75–2.48), seizures (1.36; 0.42–4.40), and HLH (1.18; 0.36–3.83). Observed trends were consistent in both sensitivity analyses, where reporting frequencies remained significantly higher with axi-cel vs liso-cel for CRS (1.60; 95% CI, 1.17–2.17 and 2.02; 1.37–2.98), NE (1.59; 1.18–2.15 and 2.04; 1.39–3.00), and cytopenia (2.00; 1.11–3.60 and 2.60; 1.24–5.46), after adjusting for differences in follow-up durations. **Conclusions:** This retrospective analysis of FAERS, using spontaneous safety reporting data after approval and broader population beyond clinical trials, demonstrated a favorable RW safety profile for liso-cel vs axi-cel for CRS, NE, and cytopenia. These findings provide valuable insights into the safety profile of CAR T cell therapies in DLBCL to inform clinical decision-making and pt management. Research Sponsor: This study was funded by Bristol Myers Squibb. Writing and editorial assistance were provided by Emily Burke, PhD, CMPP, of The Lockwood Group (Stamford, CT, USA), funded by Bristol Myers Squibb.

Pregnancy and infant outcomes post–CD19-directed CAR-T therapy: Tisagenlecleucel (tisa-cel) and/or huCAR19 (CTL119). First Author: Stephan A. Grupp, Division of Oncology, Children's Hospital of Philadelphia, Philadelphia, PA

Background: Data on pregnancy post–CD19-directed CAR-T therapy for B-cell malignancies are limited (Ligon et al). There is a theoretical risk of cross-placental transmission of CAR-T cells in female patients (pts) during pregnancy. The impact of CAR-T on fertility, conception or pregnancy in pts is uncertain. High-dose chemotherapy/radiation has a high infertility risk (Lowe et al). Early use of CAR-T may increase the chance of fertility preservation. **Methods:** In this retrospective cohort analysis, a cumulative search in the Novartis Global Safety database for all CAR-T products, up to Jan 2025 was conducted using the Standard MedDRA Query: Pregnancy and neonatal topics (narrow). Transgene levels were monitored in clinical trial pts for all indications. Ongoing B-cell aplasia (BCA)/deficiency or intravenous immunoglobulin (IVIG) utilization was used as a surrogate marker for persistence of tisa-cel in pts with acute lymphoblastic leukemia (ALL). Pregnancy outcomes were collected via pregnancy and infant forms at birth and 3 and 12 month (mo), subject to reporter and/or patient consent. **Results:** Sixteen events of tisa-cel or CTL119 exposure during pregnancy were reported. Elective termination of pregnancy was noted in 2 cases. Pathology review of placental/fetal parts in one of these cases was unremarkable. One case did not have consent for follow-up (FU) and another one did not have newborn status. One pregnancy was ongoing with normal pregnancy to date and delivery expected in Q2 2025 (commercial tisa-cel). Eleven pregnancies resulted in live birth of 12 healthy infants (1 pregnancy with twins). Further details on these 11 pregnancies are provided in Table 1. Persistent CAR transgene levels in the clinical trial pts with ALL have shown concordance with the use of IVIG/ongoing BCA/deficiency (data not shown). One infant was enrolled to long-term FU and tested negative for huCAR19 transgene on day 7, though the number of B cells (80 cells/μL) and IgG levels were slightly low at birth. Among 3 commercial tisa-cel pts with reported pregnancies, 2 had ongoing IVIG during pregnancy and 1 at the time of delivery. **Conclusions:** Pregnancy and delivery of a healthy infant after CAR-T therapy is possible. The use of CAR-T therapy may improve chances of healthy pregnancy by avoiding the risks for infertility associated with high-dose chemotherapy and/or radiation. Capturing data on all pregnancies post CAR-T remains an important goal. Research Sponsor: Novartis Pharma AG.

7030 Poster Session

Effect of prophylactic corticosteroids on toxicities and outcomes in CAR T-cell therapy: A cohort study. First Author: Anuja Vidyadhar Abhyankar, Roswell Park Comprehensive Cancer Center, Buffalo, NY

Background: Common toxicities associated with infusion of Chimeric antigen receptor T-Cell (CAR T-cell) therapy include cytokine release syndrome (CRS) and immune-effector-cell-associated neurotoxicity syndrome (ICANS). While early steroid use has correlated with a reduced risk of high-grade CRS and ICANS, there is conflicting data regarding its impact on CAR-T efficacy. We aim to study the impact of prophylactic steroid use on toxicities and outcomes at our institution. **Methods:** We performed a single-center comparative analysis between two patient cohorts at higher risk of CRS and ICANS based on elevated inflammatory markers, (ferritin $\geq$400 ng/mL and CRP $\geq$4 mg/dL). One cohort received prophylactic dexamethasone 10 mg on days 0,1, and 2. Univariate statistics were calculated using X2, Fisher's exact tests, and ANOVAs, where appropriate. Kaplan Meier was used to estimate overall survival (OS) and progression-free survival (PFS) and compared using the log-rank test. **Results:** Out of 63 patients with high ferritin and CRP, 10 patients received prophylactic steroids (Group PS) and 53 patients did not (Group NPS). In the NPS group, 46 patients had a primary diagnosis of non-Hodgkin lymphoma and 7 had a diagnosis of multiple myeloma. In the PS group, 9 had non-Hodgkin lymphoma and 1 had multiple myeloma. The median age at CAR-T was 58 years in PS and 64 years in NPS group (p=0.48). The rate of CRS grade $\geq$3 was higher in the NPS group compared to the PS group, (47.2 vs 20%, p=0.26) whereas ICANS grade $\geq$3 was similar (32% in NPS and 30% in PS group). More patients achieved a complete response in the PS group (60%) compared to the NPS group (30.2%). The1-year PFS was higher in PS group compared to NPS (60% vs 28%,p=0.08) which was also reflected in the 1-year OS (70% vs 38%, p=0.10). At a median follow-up of 22 months, 70% patients were alive in the PS group compared to 28.3% patients in the NPS group. **Conclusions:** Our study shows lower rates of CRS and a pattern towards higher rates of complete remission and survival benefit in patients undergoing CAR T-cell therapy receiving prophylactic steroids. The data must be interpreted with caution given the small sample size, but it warrants the need for future studies. Research Sponsor: None.

Phase I study to evaluate the safety and efficacy of switchable CAR-T cell therapy with FY001 and CART001 in patients with refractory CD20-positive B-cell non-Hodgkin lymphoma (EPOC1803). First Author: Junichiro Yuda, Department of Hematology and Experimental Therapeutics, National Cancer Center Hospital East, Kashiwa, Japan

Background: CD19-targeted CAR-T cell therapy has shown remarkable efficacy against relapsed/refractory B-cell non-Hodgkin lymphoma (r/r B-NHL). However, clinical challenges persist, including relapse due to CD19 antigen loss and severe immune-related adverse events such as cytokine release syndrome (CRS) and immune effector cell-associated neurotoxicity syndrome (ICANS). We developed a combination therapy using FITC-labeled rituximab (FY001) with FITC-recognizing CAR-T cells (CART001). FY001 binds to CD20 on lymphoma cells, and CART001 activation occurs exclusively through FY001, enabling fine-tuning of anti-tumor activity while minimizing adverse events. This switchable CAR-T can be applied to broader r/r B-NHL cases, including elderly or frail patients. In addition, for patients with target antigen loss, FITC-labeled antibodies targeting different antigens can activate residual CART001 to combat relapsed lymphoma cells. We conducted a phase I trial to assess the safety and efficacy of the switchable CAR-T. **Methods:** This investigator-initiated phase I trial enrolled patients with r/r B-NHL, to evaluate adverse event, including dose-limiting toxicities (DLTs), as the primary endpoint. The trial design specified evaluating DLTs in 3 initial participants; zero DLTs prompted the addition of 3 expansion cohort participants; one DLT necessitated 3 additional participants for DLT evaluation; two or more DLTs led to enrollment discontinuation. Participants underwent lymphocyte-depleting chemotherapy (LDC) until the day before FY001 administration. Following LDC, participants received intravenous FY001 administration at 2 mg/kg, and CART001 infusion at 1×10^6 cells/kg on the subsequent day. **Results:** Between March 2020 and March 2022, 6 participants received FY001 and CART001 treatment, in DLT evaluation (n=3) and expansion (n=3) cohorts. Participant ages ranged from 68-79 years, with 2-8 prior therapy lines; five had diffuse large B-cell lymphoma and one had follicular lymphoma. In all cases, no DLTs occurred. Observed adverse events, none of which were determined to be causally related to FY001 or CART001, included 1 case of Grade 4 blood creatine phosphokinase elevation (16.7%) and 1 case of Grade 3 anemia (16.7%). Notably, no CRS or ICANS cases were reported. The best overall response rate reached 100% (95% CI: 54.1%-100%), comprising 4 complete responses (CR) and 2 partial responses (PR). As of January 2025, 2 patients continue maintaining CR (57 and 47 months). **Conclusions:** The switchable CAR-T demonstrated excellent tolerability and 100% response rate with long-term remission in r/r B-NHL patients. These promising results warrant further clinical development of this therapy. Clinical trial information: jRCT1080224690. 7032 Poster Session

Impact of pre-lymphodepletion (pre LD) and day 30 (M1) immune cell counts on outcomes of CAR T therapy in patients with relapsed/refractory (R/R) large B-cell lymphoma (LBCL). First Author: Suheil Albert Atallah-Yunes, Division of Hematology, Mayo Clinic, Rochester, MN

Background: The impact of immune cell counts pre LD and during immune reconstitution on CAR T therapy outcomes is poorly understood. We investigated the association between CD4, CD8 and NK cell counts and CAR T therapy outcomes in patients with LBCL. **Methods:** Retrospective study of R/R LBCL patients who received CAR T cells between 2016-24 at Mayo Clinic, Rochester, were included in this analysis. Peripheral blood CD4, CD8 and NK counts were measured pre LD and at M1 post CAR T infusion. The receiver operating characteristic (ROC) curve was used to determine the optimal cutoff for pre LD and M1 immune cells to predict patients who were alive and in remission at 6 months (M6) post CAR T infusion. Patients who progressed or were lost to follow up prior to day 30 were excluded from M1 ROC analysis. **Results:** Of 140 patients, 81 were alive and in remission at M6 (Group A), while 59 had relapse or death (Group B). Axicabtagene ciloleucel was the CAR T product given in 81% of patients (114/140). Median pre LD CD4 counts were significantly lower in Group B compared to group A (143 vs 280 cells/μL, p = 0.001). No significant difference was observed in median pre LD CD8 counts (205 vs 221 cells/μL, p = 0.8). ROC analysis identified an optimal pre LD CD4 count of 124.5 cells/μL for M6 alive+remission. Lower pre LD CD4 counts ($<$124.5) predicted worse progression free survival (PFS) in univariate (HR = 3.02, 95% confidence interval [CI]: 1.73–5.27, p$<$ 0.01) and multivariable analysis (MVA) adjusted for IPI and the number of prior lines (aHR = 2.54, 95% CI: 1.39–4.62, p$<$ 0.01).Lower pre LD CD4 counts also predicted inferior overall survival (OS) in MVA (aHR = 2.27, 95% CI: 1.08–4.77, p = 0.03). (Table 1) On day 30 landmark analysis, ROC identified M1 optimal CD4 count of $\geq$ 99.5 cells/μL to be associated with a trend toward superior PFS (P=0.09), but not OS (p=0.90) in MVA. Median pre LD NK cell counts were significantly lower in Group B (73 vs 98 cells/μL, p = 0.04). ROC analysis identified an optimal pre LD NK count of 151 cells/μL for M6 alive + remission. Lower pre LD NK counts ($<$151) predicted worse PFS, both on univariate (HR = 4.17, 95% CI: 1.29–13.47, p = 0.02) and MVA (aHR = 4.64, p$<$ 0.01). The lower pre LD NK cell count group had worse OS in MVA (aHR = 5.69, 95% CI: 1.16–28.1, p = 0.01). (Table 1) On D30 landmark analysis, M1 NK cell count of $\geq$ 128.5 cells/μL was associated with a trend toward superior PFS (P=0.08), but not OS (p=0.30) in MVA. **Conclusions:** Pre LD CD4 and NK cell counts are significantly associated with PFS and OS post CAR T therapy in patients with R/R LBCL. Pre-treatment immune subset levels may identify patients at higher risk of relapse or death after CAR-T therapy. Research Sponsor: None.

Groups	Median PFS	2 Year PFS	Median OS	2 Year OS
CD4 $\geq$124.5 cells/μL (N=75)	NR	58%	3.31 years	67%
CD4 <124.5 cells/μL (N=30)	2.2 months	22%	1.59 years	45%
NK $\geq$151 cells/μL (N=17)	NR	77%	NR	84%
NK <151 cells/μL (N=82)	10.6 months	44%	3.31 years	62%

Influence of pre-existing autoimmune disease on outcomes in patients treated with CD-19 targeting CAR-t cell therapy for lymphoma: A retrospective propensity score matched study utilizing TriNetX. First Author: Shanawar Ali Waris, West Virginia University, Department of Internal Medicine, Morgantown, WV

Background: There is a lack of studies in the literature about the impact of baseline autoimmune diseases (AD) on outcomes in patients with lymphoma treated with CD-19 targeting-chimeric antigen receptor T-cell (CAR-T) therapy. This retrospective propensity score matched study aims to provide real-world evidence to understand the impact of pre-existing AD on outcomes in this population. **Methods:** This multicenter retrospective study included 504 patients with pre-existing AD diagnoses prior to receiving treatment with CD-19 targeting CAR-T therapy for lymphoma and 504, 1:1 propensity-score matched controls, without pre-existing AD, in the TriNetX Network. The outcomes analyzed were 5-year mortality, development of cytokine release syndrome (CRS), development of immune effector cell-associated neurotoxicity syndrome (ICANS), all cause hospitalization, ICU level care, risk of infection, and steroid use. Kaplan-Meier analysis, hazard ratios (HR), risk ratios (RR), and 95% confidence intervals (CI) were used to assess the primary outcomes. **Results:** Patients with pre-existing AD diagnosis were not at a statistically significant increased risk of mortality when compared to non-AD patients (HR = 1.10 [95% CI, 0.90-1.36]; P= 0.081). Both all-cause hospitalization (RR, 1.07 [95% CI, 1.03-1.10]) and ICU level of care (RR, 1.49 [95% CI, 1.19-1.84]) were higher in the pre-existing AD group when compared to non-AD patients. There was an increased risk for development of CRS in the AD group when compared to the non-AD group (RR, 1.17 [95% CI, 1.06-1.28]). There was no significant difference in the development of ICANs between the AD and non-AD group (RR, 1.10 [95% CI, 0.88-1.37]). There was an increased risk of infection amongst the AD group when compared to the non-AD group (RR, 1.48 [95% CI, 1.32-1.66]). Steroid use was higher in the pre-existing AD group (RR, 1.22 [95% CI, 1.09-1.38]). There was no statistically significant difference in rates of subsequent bone marrow transplant in patients with the pre-existing AD compared to the non-AD group (RR, 1.17 [95% CI, 0.93 -1.47]). **Conclusions:** CD19 CAR T- therapy has emerged as a promising therapeutic option for patients with AD, given its capacity to target and eliminate B-cells, which are vital in the pathogenesis of many AD. To our knowledge, this study represents the largest examination of the real-world impact of a baseline AD on clinical outcomes in patients undergoing CD19-targeted CAR T-cell therapy for lymphoma. Our findings indicate that pre-existing AD is associated with an increased risk of hospitalization, ICU level of care, CRS, and infections, without significantly affecting survival probability. Clinical trials are ongoing to evaluate the efficacy and safety of CAR T therapy in patients with AD. Research Sponsor: None.

Comparing outcomes of lymphoma-directed CAR T-cell therapy in patients with and without HIV: A retrospective cohort study from a global health research network. First Author: Cassandra Reimonn, UMass Chan Medical School, Department of Internal Medicine, Worcester, MA

Background: Since its introduction into the world of oncology, chimeric antigen receptor (CAR) T-cell therapy has revolutionized the treatment of relapsed and refractory lymphomas. However, patients with HIV (PWH) have historically been excluded from CAR T-cell studies. This is likely due to assumed decreased efficacy and increased infection-related morbidity and mortality due to their immunocompromised status. This lack of understanding contributes to healthcare disparities, resulting in fewer individuals from this vulnerable population receiving this innovative treatment. Thus, this study aims to compare the 1-year survival and safety outcomes of CAR T-cell therapy for Hodgkin and Non-Hodgkin lymphomas in adult patients with and without HIV. **Methods:** Using TriNetX global health research network, we identified 35 PWH who received lymphoma-directed CAR T-cell therapy. For the control group, we identified 2,575 patients without HIV who received lymphoma-directed CAR T-cell therapy. We then conducted a log-rank test and calculated relative risks (RR) to compare outcomes in 1-year overall survival (OS) and incidence of cytokine release syndrome (CRS), immune effector cell-associated neurotoxicity syndrome (ICANS), bacteremia and sepsis. **Results:** In our group of PWH, we observed a mean age of 56.1+/-12.6 years at time of CAR T-cell therapy, compared to a mean age of 63.0+/-13.0 years in our group of patients without HIV. RR analysis demonstrated significantly increased 1-year risk for development of sepsis (RR=1.75, 95%CI 1.03, 2.97) and bacteremia (RR=2.41, 95%CI 1.41, 4.12) in our group of PWH. However, it showed no statistically significant differences in risk for development of CRS (RR=1.11, 95%CI 0.788, 1.57), ICANS (RR=1.23, 95%CI 0.723, 2.08), or death from any cause (RR=1.43, 95%CI 0.873, 2.35). Log rank test revealed no significant differences in 1-year OS (p=0.208) or incidence of CRS (p=0.567), ICANS (p=0.223), bacteremia (p=0.561) or sepsis (p=0.225). Median OS was not reached in either group. **Conclusions:** This data supports that PWH may be at increased risk of infectious complications, but not increased mortality, following lymphoma-directed CAR T-cell therapy. While this study is limited by a small cohort size, its results support the need to include PWH in future clinical trials to better understand the effect of HIV infection on CAR T-cell treatment outcomes. Research Sponsor: None.

Risk of invasive fungal infections in patients with chronic lymphocytic leukemia treated with Bruton tyrosine kinase inhibitors: A TriNetX-based retrospective cohort study from 2000-2025. First Author: Raza Aslam, Nishtar Medical University, Multan, Pakistan

Background: Chronic lymphocytic leukemia (CLL) is associated with immunosuppression, and Bruton tyrosine kinase inhibitors (BTKis) may further increase the risk of invasive fungal infections (IFIs). This retrospective study evaluates the trends in BTKi use and the associated risk of IFIs among CLL patients in a real-world setting. **Methods:** We conducted a retrospective cohort study using the TriNetX database, analyzing U.S. CLL patients diagnosed between January 2000 and January 2025. Propensity score matching (1:1) by age, comorbidities, and immunosuppressive therapy was performed. Outcomes included invasive fungal infections (candidiasis, aspergillosis, cryptococcosis, and pneumocystis jirovecii pneumonia), assessed using Kaplan-Meier survival analysis and risk measures. **Results:** Among 10,736 patients treated with BTK inhibitors and 80,446 controls, the median follow-up was 881 and 868 days, respectively. Patients in the BTK cohort had a mean age of 75 ± 10 years, predominantly male (62.21%) and primarily White (76.24%). In contrast, the control cohort had a mean age of 76 ± 12 years, with 55.87% male patients and 73.12% identified as White. On the other hand, the risk of invasive candidiasis was significantly lower in the BTK cohort (RR: 0.364, 95% CI: 0.193–0.686), as was the risk of invasive aspergillosis (RR: 0.532, 95% CI: 0.289–0.98). Pneumocystis jirovecii pneumonia (PJP) rates were comparable between the cohorts (RR: 0.961, 95% CI: 0.497–1.855). Cryptococcosis was detected in 0.001% of the BTKi group but did not occur in the control cohort; this variation, however, did not reach statistical significance (P = 0.823). **Conclusions:** This retrospective study reveals the complex infection profile associated with BTK inhibitor use in CLL patients. Treatment with BTK inhibitors was linked to a significant decrease in the occurrence of invasive candidiasis and aspergillosis in the BTK cohort, and rates of Pneumocystis jirovecii pneumonia (PJP) and Cryptococcus were similar between groups. Although the absolute rates of fungal infections remain low, these findings underscore the importance of identifying at-risk patients to guide preventive and cost-effective interventions. Further research is needed to differentiate infection risks across specific BTK inhibitors and develop tailored management strategies to optimize patient outcomes. Research Sponsor: None.

Final analysis of fixed-duration ibrutinib + venetoclax for chronic lymphocytic leukemia (CLL)/small lymphocytic lymphoma (SLL) in the phase 2 CAPTIVATE study. First Author: Paolo Ghia, Università Vita-Salute San Raffaele and IRCCS Ospedale San Raffaele, Milano, Italy

Background: First-line ibrutinib (Ibr) + venetoclax (Ven) treatment for CLL/SLL was tested in the phase 2 CAPTIVATE study, including minimal residual disease (MRD)–guided randomized discontinuation (MRD cohort) and Fixed Duration (FD) cohorts. We report final analysis results for patients (pts) treated with FD Ibr+Ven in the FD cohort and MRD cohort placebo arm. **Methods:** Pts $\leq$70 y with previously untreated CLL/SLL received 3 cycles of Ibr, then 12 cycles of Ibr+Ven (Ibr, 420 mg/d orally; Ven, 5-wk ramp up to 400 mg/d orally), up to 13 cycles in the MRD cohort placebo arm. On-study retreatment included single-agent Ibr; FD cohort pts with progressive disease (PD) $>$2 y after end of treatment (EOT) could be retreated with FD Ibr+Ven. **Results:** 202 pts completed FD Ibr+Ven (FD cohort, n=159; MRD cohort placebo arm, n=43). With median follow-up of 68.9 mo (range, 0.8–83.9), 5.5-y PFS and OS rates (95% CI) were 66% (58–72) and 97% (93–99), respectively. 5.5-y PFS rates (95% CI) in pts without and with del(17p)/mutated *TP53* were 70% (62–76) and 36% (17–55), respectively. In pts with unmutated IGHV, 5.5-y PFS was 55% (45–64): 63% (49–74) in pts without, and 44% (28–60) in pts with, concomitant del(17p)/mutated *TP53*/complex karyotype. The corresponding rates for pts with mutated IGHV were 79% (68–87), 85% (71–93), and 62% (34–81). Undetectable MRD (uMRD4; $<10^{-4}$ by flow cytometry) was achieved in peripheral blood (PB) in 54% of pts at C7 and 69% at EOT, and in bone marrow in 69% of pts at EOT. 5.5-y PFS rates (95% CI) were higher in pts with uMRD4 in PB at EOT (75% [67–82]) vs those with MRD (47% [33–59]). 64 pts had PD after completion of FD Ibr+Ven. 5.5-y freedom from next-line treatment was 73% (95% CI 66–79). Of 40 pts with available samples at PD to date, 1 had an acquired subclonal mutation in *BCL2* of unclear significance (A113G, VAF 8.3%); none had acquired resistance-associated mutations in *BTK* or *PLCG2*. 36 pts initiated retreatment with Ibr (n=25) or Ibr+Ven (n=11). With 28.4 mo median follow-up on Ibr retreatment (range, 3.7–59.1), ORR was 76% (best response: 1 CR; 1 nodular PR; 17 PR; 4 SD; 1 PD [Richter transformation]; 1 no assessment); 2-y PFS and OS rates from the start of retreatment were 91% and 96%, respectively. With 15.2 mo median follow-up on Ibr+Ven retreatment (range, 7.4–29.3), ORR was 82% (best response: 1 CR; 8 PR; 2 SD); 1-y PFS and OS rates from the start of retreatment were both 100%. Second malignancies occurred in 24 pts across the entire study period, including 12 initial treatment and 4 retreatment TEAEs. **Conclusions:** Ibr+Ven is an all-oral, once-daily, chemotherapy-free FD regimen for first-line treatment of CLL/SLL that continues to provide durable PFS and OS with long-term follow-up, including in pts with high-risk genomic features. Ibr-based retreatment provided durable responses in pts needing subsequent therapy after completion of FD Ibr+Ven. Clinical trial information: NCT02910583. Research Sponsor: Pharmacyclics LLC, an AbbVie Company.

Propensity score (PS) comparison between lisocabtagene maraleucel (liso-cel) plus ibrutinib combination therapy (combo) and liso-cel monotherapy (mono) cohorts from TRANSCEND CLL. First Author: William G. Wierda, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: TRANSCEND CLL 004 (NCT03331198) is a phase 1/2, open-label, nonrandomized, multicohort study in adult patients (pt) with R/R chronic lymphocytic leukemia/small lymphocytic lymphoma with liso-cel mono and liso-cel + ibrutinib combo cohorts. Given the study design, we performed PS matching/weighting to adjust for differences in key covariates between cohorts to compare efficacy and safety. **Methods:** Here, PS is the probability of receiving combo given the covariates and estimated by logistic regression. Covariates were hemoglobin, LDH, number of prior therapies, platelets, prior BTKi + venetoclax exposure, R/R on prior BTKi, and bulky disease for efficacy; and ALC, bulky disease, CRP, ferritin, and number of prior therapies for safety. PS balancing methods were optimal 1:1 matching, average treatment effect for treated pts (ATT) full matching, and ATT inverse probability of treatment weighting (IPTW). Efficacy endpoints were response (CR rate, ORR) and time to event endpoints (DOR, PFS, OS). Safety endpoints were proportions of pts with any-grade (gr)/gr $\geq$ 3 cytokine release syndrome (CRS) and investigator-identified neurological events (NE). **Results:** Fifty-one and 88 efficacy-evaluable pts were treated at dose level 2 (100×10^6 CAR$^+$ T cells) in the combo and mono cohorts, respectively. Before matching/weighting on PS, odds of achieving CR and overall response were statistically significantly higher for combo (Table). DOR did not differ between cohorts. For PFS and OS, HRs were lower with combo vs mono (not statistically significant [NS]). Odds of gr $\geq$ 3 CRS/NE were lower with combo vs mono (NS). After matching/weighting, odds of CR (except IPTW ATT) and overall response remained statistically significantly higher in combo. HRs for PFS and OS and ORs for gr $\geq$ 3 CRS/NE were numerically lower with combo vs mono (NS, except IPTW ATT for PFS). HRs for DOR were less but close to HR of 1. **Conclusions:** The liso-cel + ibrutinib combo demonstrated a trend for better efficacy and safety vs liso-cel mono, with statistically significant differences for CR rate and ORR. Clinical trial information: NCT03331198. Research Sponsor: This study was funded by Bristol Myers Squibb. Writing and editorial assistance were provided by Nikola Vojtov, PhD, of The Lockwood Group (Stamford, CT, USA), funded by Bristol Myers Squibb.

Efficacy and safety outcomes: combo vs mono.

	No adjustment	ATT optimal 1:1	IPTW - ATT

Preliminary safety and efficacy data of ICP-248, a novel BCL2 inhibitor, in patients with relapsed or refractory B-cell malignancies. First Author: Shuhua YI, Institute of Hematology and Blood Diseases Hospital, Chinese Academy of Medical Sciences, Tianjin, China

Background: BCL2, a critical protein regulator of the apoptotic pathway, highly expressed in various malignancies, including B-cell non-Hodgkin lymphomas (B-NHLs). The only approved BCL2 inhibitor, Venetoclax, has been approved for the treatment of chronic lymphocytic leukemia/small cell lymphoma (CLL/SLL) or acute myeloid leukemia (AML). However, hematologic toxicities and tumor lysis syndrome (TLS) remain as safety challenges in clinical practice. ICP-248 was developed as a potent and highly selective BCL2 inhibitor. Preclinical studies have demonstrated favorable pharmacokinetics profile and excellent safety profile. **Methods:** ICP-CL-01201 is an ongoing phase I study (NCT05728658) including dose escalation and dose expansion parts. Safety and tolerability of ICP-248 was evaluated from target doses of 50 mg to 200 mg. Patients receive oral treatment every day until disease progression or intolerable toxicities. Eligible patients include those aged 18-80 years, diagnosed with CLL/SLL and B-NHLs who are in relapsed or refractory disease. Key exclusion criteria include CNS involvement, resistance to BCL2 inhibitors and clinically significant cardiovascular disease. Efficacy was evaluated according to the Lugano 2014 or iwCLL 2018 criteria. **Results:** As of 12 Dec 2024, 55 patients were enrolled in the study: 18 in dose escalation and 37 in dose expansion. 24 patients were CLL/SLL, 26 patients were mantle cell lymphoma (MCL), 5 patients were other B-NHLs. The median age was 65 years, and 72.7% of patients were refractory disease and 56.4% of the patients were previously treated with BTK inhibitors. The median prior therapeutic line was 2 (1-8). ICP-248 was well tolerated through all dose levels, with no dose-limiting toxicities (DLTs) observed, and maximum tolerated dose (MTD) not reached. Toxicity leading to drug discontinuation and death was not observed. Most of TEAEs were in grade 1-2. The most frequent TEAEs were hematologic AEs including neutropenia, leukopenia, and thrombocytopenia. Serious adverse events (SAEs) were reported in 16.4% patients. As cutoff date, 20 CLL/SLL and 19 MCL patients treated with ICP-248 dose ≥100 mg had at least one response assessment: ORR was 80% and CRR was 15% in r/r CLL/SLL patients, while those for r/r MCL patients were 78.9% and 42.1% respectively. uMRD was reported in 10% CLL/SLL and 15.8% MCL patients. In 10 patients with previous BTK inhibitor refractory MCL patients (2 blastoid or pleomorphic subtype and median 3.5 prior treatment lines), the ORR was 80% and CRR was 30%; in 11 patients with previous BTK inhibitor failure CLL/SLL, the ORR was 81.8% and CRR was 18.2%. **Conclusions:** The preliminary results of ICP-248 monotherapy suggests a well-tolerated safety profile and an exciting efficacy with dose-dependent effect in BTK failed, heavily treated, relapsed or refractory B-cell malignancies. Clinical trial information: NCT05728658. Research Sponsor: None.

7039 Poster Session

Comparison of outcomes for patients (pts) with R/R chronic lymphocytic leukemia (CLL)/small lymphocytic lymphoma (SLL) previously treated with Bruton tyrosine kinase inhibitor (BTKi) and venetoclax from the TRANSCEND CLL 004 study versus a matched cohort of real-world (RW) pts. First Author: William G. Wierda, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Pts with R/R CLL/SLL who failed BTKi and venetoclax have limited treatment (tx) options and poor prognoses. FDA approval of lisocabtagene maraleucel (liso-cel) for R/R CLL/SLL was based on positive results from TRANSCEND CLL 004 (NCT03331198), a single-arm trial. We assessed relative efficacy of liso-cel vs standard of care (SOC) by identifying (or assembling) an external comparator cohort of pts treated in a RW setting. **Methods:** Pts from TRANSCEND CLL 004 and a matched RW cohort were analyzed. Eligible pts were ≥ 18 y with CLL/SLL, had ≥ 2 prior lines of therapy (pLoT), including a BTKi and venetoclax, and started subsequent tx for CLL/SLL. SOC pts were selected from de-identified datasets (Flatiron [1993–2023], COTA [2000–2023], and ConcertAI [1997–2022]). TRANSCEND CLL 004 eligibility criteria were applied as applicable. Liso-cel pts were eligible trial participants treated with liso-cel and efficacy-evaluable. Endpoints were ORR, PFS, and OS. Inverse probability of tx weighting (IPTW) and regression model were used to balance pt characteristics between cohorts, including age, sex, race, time from initial diagnosis, Rai stage, bulky disease, ECOG PS, high-risk cytogenetics, pLOT, prior chemoimmunotherapy and phosphatidylinositol 3-kinase inhibitor (PI3Ki), and refractoriness to BTKi and venetoclax. **Results:** Analysis included 278 pts (SOC, n = 212; liso-cel, n = 66). SOC regimens included chemotherapy, immunotherapy (excluding CAR T cell therapy), BTKi, venetoclax, PI3Ki, and combinations. Median follow-up was 17.2 mo for SOC and 35.4 mo for liso-cel. Most pt characteristics were balanced after IPTW (Table) with imbalance adjusted by regression. After adjustment, ORR (95% CI) was 19.2% (14.1–26.1) for SOC vs 52.5% (34.8–79.2) for liso-cel. Median (95% CI) PFS was 4.4 mo (3.2–5.5) for SOC vs 12.0 mo (10.8–13.2) for liso-cel (HR, 0.40; 95% CI, 0.24–0.68). PFS probabilities at 24 and 36 mo were 11.5% and 5.1% for SOC vs 46.3% and 30.3% for liso-cel. Median (95% CI) OS was 14.8 mo (9.4–20.1) for SOC vs 33.6 mo (31.7–35.5) for liso-cel (HR, 0.47; 95% CI, 0.28–0.79). OS probabilities at 24 and 36 mo were 35.1% and 29.7% for SOC vs 73.4% and 42.6% for liso-cel. **Conclusions:** Liso-cel was associated with significantly improved response, delayed progression, and prolonged survival vs SOC in pts with R/R CLL/SLL after ≥ 2 pLOTs, including a BTKi and venetoclax. Clinical trial information: NCT03331198. Research Sponsor: This analysis was funded by Bristol Myers Squibb. Writing and editorial assistance were provided by Nikola Vojtov, PhD, of The Lockwood Group (Stamford, CT, USA), funded by Bristol Myers Squibb.

Characteristics before/after IPTW.

	SOC (before)	Liso-cel (before)	SOC (after)	Liso-cel (after)
Mean age, y	70.5	65.4	68.7	69.3

7040 Poster Session

Circulating tumor DNA assessment in patients with early-stage classical Hodgkin lymphoma treated with combination of brentuximab vedotin and nivolumab. First Author: Ryan C. Lynch, Fred Hutchinson Cancer Center, University of Washington, Seattle, WA

Background: Recent data suggest circulating tumor DNA (ctDNA) can be detected in patients with classical Hodgkin lymphoma (cHL), with molecular response potentially complementing imaging assessments. We report on the use of an ultra-sensitive assay for ctDNA detection in patients with early-stage cHL to explore its utility in this population. **Methods:** In SGN35-027 (NCT03646123) Part C study, patients with stage I or II cHL without bulky disease (N=154) received brentuximab vedotin, nivolumab, doxorubicin, and dacarbazine (AN+AD) intravenously on days 1 and 15 of each 28-day cycle. Responses were assessed by PET/CT according to Lugano Classification with LYRIC at cycle (C) 2 day (D) 25-28 and end of treatment (EOT). 36 of 154 patients (23%) had plasma samples (collected at baseline, prior to C2D1 and C4D1, and EOT) analyzed for ctDNA using the PhasEDseq MRD assay. PET/CT results were compared with ctDNA dynamic changes in those with detectable baseline ctDNA. A genAI tool (12/19/24; Pfizer; GPT-4o) developed the 1st draft; authors assume content responsibility. **Results:** Baseline ctDNA was detectable in 34 of 36 patients (94%) and was higher in patients with greater disease burden (indicated by baseline stage/risk status [P=0.015] and International Prognostic Score [P=0.014]). At C2D1, ctDNA was undetectable in 27 of 33 patients (82%). ctDNA levels decreased in all patients after 1 cycle of treatment. At C2 interim PET/CT, 18 of 34 patients (53%) achieved complete metabolic response (CMR); of these, 17 patients had ctDNA samples evaluable with 16 patients having undetectable ctDNA. The remaining 16 patients achieved partial metabolic response (PMR); of these, 5 patients had detectable ctDNA and 11 had undetectable ctDNA (all 11 patients with undetectable ctDNA achieved CMR at later time points). At C4D1, only 1 patient continued to have detectable ctDNA. At EOT, PET/CT showed that 26 of 34 patients (76%) achieved CMR, 5 achieved PMR, and 3 achieved indeterminate response (IR); none had detectable ctDNA at EOT. In long-term follow up (LTFU), 4 of the 5 PMRs eventually converted to CMR; 1 patient developed a second primary malignancy (mantle cell lymphoma). Follow up assessments during LTFU confirmed that 2 IRs converted to CMR and 1 converted to PMR. **Conclusions:** ctDNA was detectable in majority of patients with early-stage cHL at baseline, and higher levels are associated with increased disease burden. Treatment with AN+AD reduced ctDNA levels, with ctDNA becoming undetectable by EOT in all patients. In some patients, decline in ctDNA levels was observed earlier than responses observed through imaging, suggesting that ctDNA clearance may be an early indicator of treatment response. The potential value of ctDNA as a biomarker for early detection and monitoring of treatment response in early-stage cHL should be further investigated. Clinical trial information: NCT03646123. Research Sponsor: Pfizer Inc.

Updated efficacy and safety results from the phase 2 study of timdarpacept in combination with tislelizumab in patients with classical Hodgkin lymphoma for whom prior anti–PD-1 therapy failed. First Author: Ke-Shu Zhou, Department of Hematology, Henan Cancer Hospital, Zhengzhou, China

Background: Timdarpacept (IMM01), a recombinant SIRPa-Fc fusion protein, can activate macrophages to enhance anti-tumor activity by blocking CD47-SIRPa interaction. Timdarpacept showed unique property of weak human erythrocyte binding in preclinical studies, and low incidence of anemia in early clinical trials with no need for a priming dose. **Methods:** Eligible patients (pts) with R/R classical Hodgkin lymphoma (cHL) who had failed prior anti-PD-1 treatment were enrolled in this study (NCT05833984). Timdarpacept (2.0mg/kg, QW) and tislelizumab (200mg, Q3W) were intravenously administered in 3-week treatment cycle until disease progression or intolerable toxicity. Objective response rate (ORR) by Lugano 2014 was the primary endpoint and secondary endpoints include tolerability, disease control rate (DCR), duration of response (DoR), progression free survival (PFS) and time to response (TTR). **Results:** As of 18 Oct 2024, 33 cHL pts were enrolled with 19 refractory to anti PD-(L) 1 therapy (best objective response was SD/PD or CR/PR and progressed within 12 weeks of last dose). The median age was 35 years with 23 (69.7%) male pts. The median prior lines of therapy were 4. In all 33 efficacy-evaluable pts with median follow up of 13.83 months, the ORR, complete response (CR) rate and DCR were 69.7%, 24.2% and 93.9%, respectively. For PD-(L) 1 refractory pts, the ORR was 68.4%, and 1 pt achieved CR. The median TTR was 1.6 months. The median DoR was not reached. Further analysis indicated that pts could benefit from timdarpacept combined with tislelizumab treatment regardless of being relapsed or refractory to anti-PD-1 treatment, or having had prior CD30-ADC treatment or not. All pts experienced treatment-related adverse events (TRAEs), 17 (48.5%) of whom experienced grade 3/4 TRAE. The most common TRAEs were WBC decreased (57.6%), PLT decreased (42.4%), anemia (39.4%), ANC decreased (39.4%), lymphocyte decreased (30.3%). Six (18.2%) pts had treatment related SAE. Three pts (9.1%) had an IMM01 dose reduction. One pt (3.0%) experienced permanent discontinuation of IMM01. No TRAEs led to death. **Conclusions:** Timdarpacept in combination with tislelizumab showed promising therapeutic efficacy and a well-tolerated safety profile in cHL patients for whom anti-PD-1 failed, providing evidence for future investigation. Clinical trial information: NCT05833984. Research Sponsor: None.

Longitudinal assessment from liquid biopsy of mutations in CD20: A pilot study using a PETE enrichment strategy. First Author: Tyler Landrith, Roche Molecular Systems, Pleasanton, CA

Background: In recent years, bispecific T cell Engagers (BsTCE) targeting CD3 and CD20 have emerged as a potent new class of therapeutics for NHL; however, a subset of patients still experience relapsed or refractory disease. Patients undergoing treatment with BsTCEs could benefit from longitudinal screening via liquid biopsy to identify baseline (primary) and treatment-induced (acquired) resistance mutations and tailor treatment accordingly. Here we present the results from a pilot study screening patients treated with Glofitamab (CD20xCD3) using a single gene Primer Extension Target Enrichment (PETE) strategy for *MS4A1* (CD20 gene) in liquid biopsies. **Methods:** Our pilot study was conducted using libraries from the plasma of 134/155 patients with relapsed or refractory large B cell lymphoma (r/r LBCL) who underwent Glofitamab treatment at approved dose in the phase I/II trial NP30179 (NCT03075696) (Dickinson, et al. N Engl J Med 2022), and paired PBMC/PDB available in 91 cases. Primers were designed against the coding regions of the *MS4A1* gene. Enrichment was performed using a workflow optimized for the detection of somatic variants in cell-free DNA isolated from plasma. Results were analyzed using a modified AVENIO circulating tumor (ct) DNA (Roche; For Research Use Only) analysis workflow. Variants detected by the analysis pipeline were further filtered based on inclusion criteria: allele fraction $>$ 0.1%, rarity in the cohort, impact on protein function *in silico*, and if sample was available, absence in germline. Tumor burden as assessed by ctDNA was obtained from retrospective sequencing data. Response to treatment was assessed by PET/CT using the Lugano Criteria. **Results:** Using inclusion criteria a total of 11/134 (8.2%) patients were identified with a total of 16 unique *MS4A1* candidate mutations at baseline or during treatment. The Best Overall Investigator Response (BOR) was progressive disease (PD) for 7 patients and partial metabolic response (PR) for 4 patients. All patients with BOR PR experienced disease progression before treatment completion. Sufficient samples were available to demonstrate expansion of the candidate mutation by the end of treatment (EOT) timepoint for 5 patients. Four of the identified mutations were previously reported in the literature, the remaining mutations were novel, and *in vitro* characterization demonstrated their functional impact. **Conclusions:** This work identifies known and novel mutations in CD20 in plasma samples as a potential contributing mechanism to relapsed or refractory cases of NHL. Although the prevalence appears to be low, this is consistent with previous reports and supports investigation of the clinical utility, including utility as a potential predictive biomarker, of sequencing this gene during treatment with CD20xCD3 BsTCE. Future and ongoing work will screen additional cohorts and therapy combinations. Research Sponsor: The NCT03075696 study was sponsored by F. Hoffman LaRoche Ltd.

Novel analysis of 3-y results from the pivotal EPCORE NHL-1 study: Outcomes in patients (pts) with relapsed/refractory large B-cell lymphoma (R/R LBCL) and complete response (CR) at 2 y with epcoritamab (epcor) monotherapy. First Author: Yasmin Karimi, University of Michigan Division of Hematology/Oncology, Ann Arbor, MI

Background: Depth and duration of CR correlate with long-term outcomes in LBCL. Epcor is a subcutaneous (SC) CD3xCD20 bispecific antibody approved for the treatment (tx) of pts with DLBCL or high-grade BCL after $\geq$2 lines of tx (LOT). In the 3-y follow-up from the NHL-1 trial, epcor monotherapy led to durable CRs, with a 36-mo median CR duration (mDOCR), 37-mo median progression-free survival (mPFS), and not reached (NR) median overall survival (mOS) in pts with R/R LBCL who had CR. We report long-term outcomes from a post-hoc analysis of the NHL-1 trial in pts who were in CR 2 y after starting tx, referred to herein as pts in CR at 2 y. **Methods:** Pts with R/R CD20$^+$ LBCL and $\geq$2 prior LOT received epcor SC in 28-d cycles (C; 0.16- and 0.8-mg step-up doses in C1; 48-mg full dose thereafter; once weekly [QW], C1–3; Q2W, C4–9; Q4W, C$\geq$10) until progressive disease (PD) or unacceptable toxicity. The primary endpoint was overall response rate. **Results:** As of the May 3, 2024 data cutoff, 41% (65/157) of pts had CR, of whom 49% (n=32) remained in CR at 2 y. Among the 32 pts in CR at 2 y, median age was 63 y, 47% were male, and 66% were refractory to $\geq$2 consecutive prior LOT. Pts in CR at 2 y vs pts without CR at 2 y had lower tumor burden at baseline (bulky disease $>$7 cm 19% vs 34%; LDH 294 vs 501 U/L); pts in CR at 2 y had lower baseline ferritin levels (383 vs 856 μg/L) and similar CAR T exposure (38% vs 39%). At data cutoff, median follow-up for pts in CR at 2 y was 37 mo (range 32−46). All but 1 had a response (CR or partial response) by the 2nd assessment at wk 12. mDOCR was NR, and ~96% of pts remained in CR at 3 y. At the data cutoff, the longest ongoing CR was $>$43 mo. mPFS and mOS were NR. The overall epcor safety profile in pts in CR at 2 y was consistent with that of the intention-to-treat population. Median tx duration was 35 mo (range 8–43); 81% (26/32) of pts remained on tx at 2 y. 19% (5/26) pts still on tx at 2 y had $\geq$1 serious infection after 2 y, most commonly pneumonia (n=4). Two pts had a fatal infection (COVID-19 pneumonia, pneumonia) after 2 y. At data cutoff, 19/32 (59%) pts with CR at 2 y were still on tx. One pt discontinued (D/C) due to PD; 12 D/C for reasons other than PD, most commonly adverse events (n=6, including the 2 pts with fatal infections above). In 12 pts who D/C due to reasons other than PD, CR was maintained for a median of 14 mo (range 2−28) after tx D/C. **Conclusions:** This novel subgroup analysis of pts with R/R LBCL in CR at 2 y after starting epcor highlights long-term disease remission, overall survival, and potential for cure with epcor in some pts. Long-term safety remained manageable. These results underscore the benefits of epcor in the 3L+ setting and may inform personalized tx strategies. Additional data to further characterize pts with R/R LBCL and a prolonged CR with epcor monotherapy will be presented. Clinical trial information: NCT03625037. Research Sponsor: Genmab.

Ibrutinib, venetoclax plus CD20 monoclonal Ab: Initial results of OASIS II, a prospective randomized phase 2 trial in previously untreated mantle cell lymphoma patients. First Author: Steven Le Gouill, Institut Curie, Paris, France

Background: Ibrutinib is approved in R/R MCL. Enrich trial (Lewis, ASH 2024, abst 235) showed that Ibrutnib/CD20mAb outperforms chemotherapy front-line. We demonstrated that Ibrutnib/CD20mAb plus Venetoclax has a good safety profile in R/R and untreated MCL (Le Gouill, Blood 2021). Whether or not Ibrutnib/CD20mAb is superior to Ibrutnib/CD20/Venetoclax front-line is a key question. OASIS 2 (NCT04802590) is a phase 2 prospective randomized international trial that investigates Ibrutinib/CD20mAb (Arm A) plus Venetoclax (Arm B) in untreated MCL. **Methods:** Patients were stratified by country, age ($<$ / $>$=66 years) and MIPI. All patients (18-80y) with untreated MCL, stage II-IV and nodal disease were eligible. Treatment consisted of Ibrutinib (560 mg/d, C1-24) and anti-CD20mAb (C1-6), then 2 monthly (C7-42). In Arm B, Venetoclax was added for a fixed duration of 2y (400 mg/d). The study uses a two-stage Simon's design. A preplanned interim futility analysis occurred after 39 pts with informative MRD were randomized in each arm. The primary endpoint of the futility analysis is the measurable residual disease (MRD) negativity rate assessed by digital-droplet PCR technique at the end of C6. Each treatment arm was to be considered effective if the 80% upper CI MRD negativity percentage was $\geq$ 64%. The interim analysis result was mandatory to re-open the trial (only for effective arms) for the second phase of recruitment. Herein, we present the results of the futility pre-planed interim analysis. **Results:** 102 pts were randomized (51 in each arm, 78 were MRD informative). Pts' characteristics were comparable between the two arms. One patient in arm B withdrew consent before any treatment. 46 in arm A and 45 in arm B completed the first 6 cycles. The median dose intensity for CD20mAb was 100%, 96% for Ibrutinib in arm A and 90% in Arm B, 91% for Venetoclax. At least one dose adjustment of Ibrutinib was more frequent in Arm B (28% vs 15.7%). At least one Venetoclax dose reduction was needed in 24% of patients in Arm B. AE, AESI, AE grade $\geq$ 3 were more frequent in Arm B (92% vs 82.4%; 82% vs 52.9%; 64% vs 47.1%) but not for SAE grade $\geq$ 3 (32% vs 31.4%). The most frequent grade 3 AE was neutropenia (11.8% vs 34%). MRD negativity was obtained in 53.8% (CI 80% 42.4% - 65%) in Arm A and 82.1% (CI 80% 71.7% - 89.7%) in Arm B. According to Lugano criteria at the end of C6, 21 out of 39 (54%) pts were in a complete metabolic remission in Arm A vs 27 out of 39 (69%) in Arm B. The export in Oct 2024 showed that the 2-y PFS and OS were 87.9% (95%CI, 79.7-92.9) and 91.9% (95% CI, 84.5-95.9). **Conclusions:** Ibrutinib/CD20mAb /Venetoclax frontline provides very high MRD negativity rate. According to the statistical analysis plan, both arms were thus re-opened for inclusion on 02APR24 and 102 new patients have been included (end of inclusion DEC 2024). Clinical trial information: NCT04802590. Research Sponsor: None.

Survival outcomes of Epstein-Barr virus-positive diffuse large B-cell lymphoma, not otherwise specified: Results from Latin American and United States cohorts. First Author: Jose Concepcion-Holguin, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Epstein-Barr virus-positive diffuse large B-cell lymphoma (EBV+ DLBCL), not otherwise specified, is rare in North America and Europe (2–4%) but prevalent in Latin America (LATAM, 7–14%). Most studies are limited by single-center designs, small cohorts, short follow-up, and infrequent rituximab use. Prognostic systems like the International Prognostic Index (IPI) are widely used, yet their predictive power in EBV+ DLBCL remains unclear. Additionally, the optimal threshold for EBV-encoded RNA (EBER) positivity remains controversial, with cutoffs ranging from ≥20% to ≥80%. This study aimed to characterize clinical outcomes and evaluate prognostic scores and EBER thresholds in LATAM patients treated with chemoimmunotherapy, contrasted with a U.S.-based cohort. **Methods:** This multicenter retrospective cohort study included patients diagnosed with EBV+ DLBCL from 2002–2020 in five LATAM countries (GELL registry) and a two U.S. centers (2008–2023). EBV positivity was defined per institutional EBER standards. Patients managed without anti-CD20 antibodies were excluded. Outcomes (overall survival [OS] and progression-free survival [PFS]) were assessed using Kaplan-Meier analysis, log-rank tests, and Cox regression. Prognostic systems (IPI, NCCN-IPI, R-IPI, Oyama score) were evaluated using C-indices. **Results:** In the LATAM cohort (n=139), median age was 58 years, 71% had advanced-stage (stage III-IV) disease, and 90% received R-CHOP. In the U.S. cohort (n=136), median age was 67 years, 74% had advanced-stage disease, and 74% received R-CHOP. In the LATAM cohort, with a median follow-up of 61 months (95% CI=53-68), 43 deaths were observed. The 5-year OS and PFS rates were 63% (95% CI=54-73%) and 50% (95% CI=41-60%), respectively. In the US cohort, with a median follow-up of 54 months (95% CI=45-66), 52 deaths were observed. The 5-year OS and PFS rates was 54% (95% CI=45-65%), and 41% (95% CI=32-52%), respectively. All evaluated prognostic scores had a similar performance in the LATAM (OS: C-index range 0.595-0.674; PFS: C-index range 0.553-0.633) and US (OS: C-index range 0.679-0.744; PFS: C-index range 0.701-0.782) cohorts. EBER test ≥80% was associated with mortality in the US cohort (adjusted HR=2.76, 95% CI=1.53-5.00). **Conclusions:** To the best of our knowledge this is one of the largest studies on EBV+ DLBCL. This study highlights comparable survival outcomes for EBV+ DLBCL in LATAM and the U.S. with chemoimmunotherapy, supporting its use in the management of this rare entity. Prognostic systems show variable performance across regions, emphasizing the need for further validation in EBV+ DLBCL populations. Variability in EBER thresholds underscores the need for standardized diagnostic criteria to optimize prognostication and treatment. Research Sponsor: None.

Safety and efficacy of AZD0486, a CD19xCD3 T-cell engager, in relapsed or refractory diffuse large B-cell lymphoma. First Author: Tae Min Kim, Seoul National University Hospital, Seoul, South Korea

Background: Treating relapsed/refractory (R/R) diffuse large B-cell lymphoma (DLBCL) is challenging despite advances. AZD0486, a novel IgG4 fully human CD19xCD3 bispecific T-cell engager, showed promising safety and efficacy in patients (pts) with heavily pretreated follicular lymphoma with an overall response rate (ORR) and complete response (CR) rate of 95% and 85%, respectively, at target doses (TD) ≥2.4 mg (Hou JZ, et al. *Blood.* 2024). We present results from an ongoing phase 1 trial in pts with R/R DLBCL (NCT04594642). **Methods:** Eligible pts with R/R CD19+ B-cell lymphoma and ≥2 prior lines of therapy (pLOT) received fixed-duration AZD0486 intravenously for 2 years. Initially, pts received either no or 1 step-up dose (SUD). Subsequently, 2SUD on D1/D8 was implemented with TD on D15. TDs were given every 2 weeks in 28-day cycles. After 2 consecutive CRs, pts could receive dosing every 4 weeks. Primary objectives are safety, tolerability, pharmacokinetics, and determining the maximum tolerated dose (MTD). RECIL-based response assessment is performed by central imaging review. Measurable residual disease (MRD) in plasma ctDNA is assessed by PhasED-seq CLARITY assay. CTCAE v5.0 and ASTCT criteria are used to grade adverse events (AEs). **Results:** As of Sept 29, 2024, 70 pts with R/R DLBCL received AZD0486 at TDs ≤0.8 mg (n=2), 2.4 mg (n=18), 7.2 mg (n=22), 15 mg (n=25), and 25 mg (n=3). Median pLOT was 3 (range, 1–12) and 34 (49%) pts received prior CD19-directed CAR-T therapy. In 61 evaluable pts who received TDs ≥2.4 mg, ORR and CR rate were 46% and 33%, respectively. ORR/CR rates tended to be higher with higher doses (39%/22% at 2.4 mg, 43%/33% at 7.2 mg, and 55%/41% at 15 mg, respectively). ORR/CR rates were higher in pts without prior CAR-T vs CAR-T–exposed pts (57%/39% vs 36%/27%). For pts who received 7.2 mg or 15 mg (median follow-up 8.8 months and 5.3 months, respectively), median duration of response (DOR) was not reached; 12-mo estimated DOR was 64%. One pt who achieved CR progressed. Of the 15 pts who achieved CR and were evaluable for MRD in the 7.2-mg and 15-mg cohorts, 87% (13/15) achieved undetectable MRD. In the overall population (N=70), infections occurred in 37% of pts, with 9% grade [G] ≥3; COVID-19 occurred in 13% of pts. Febrile neutropenia occurred in 3% of pts. Neutropenia ≥G3 occurred in 23% of pts, while anemia ≥G3 occurred in 14%. In pts who received 2SUD (n=54), CRS occurred in 44% of pts, all low grade (G1/G2, 41%/4%), and 20% received tocilizumab; ICANS occurred in 17% of pts (G3, 3%). All CRS and ICANS events in the 2SUD cohort occurred in C1 (except for 1 CRS event on C2D1), were transient, and did not require treatment discontinuation. No AZD0486-related deaths or AEs leading to discontinuation occurred. **Conclusions:** AZD0486 at TDs ≥2.4 mg showed promising efficacy and manageable safety in pts with R/R DLBCL. Target doses up to 25 mg have been tested without exceeding MTD. Dose escalation is ongoing. Clinical trial information: NCT04594642. Research Sponsor: AstraZeneca.

High HDAC I/IIb selective inhibitor purinostat mesylate in relapsed and refractory diffuse large B-cell lymphoma: A single agent phase IIb study. First Author: Lijuan Chen, Department of Hematology, State Key Laboratory of Biotherapy and Cancer Center, West China Hospital, Sichuan University, Chengdu, China

Background: Relapsed/refractory diffuse large B-cell lymphoma (r/r DLBCL) has a poor prognosis. Purinostat Mesylate (PM) is a high selective HDAC I/IIb inhibitor. PM has demonstrated its safety and efficacy in r/r DLBCL in previous studies. Based on results of phase IIa, 11.2mg/m^2 was chosen to be the RP2D. The efficacy and safety of PM monotherapy in r/r DLBCL patients are evaluated in phase IIb study (NCT05563844). **Methods:** This multicenter, single-arm, phase IIb study is conducted in 37 sites in China. Key eligibilities include r/r DLBCL 2~5 lines; prior therapies include anti-CD20 monoclonal antibody and anthracycline-based chemotherapy; ECOG≤2. The IIb study plans to enroll 90 patients to receive IV of PM at 11.2mg/m^2 on day 1, 4, 8, 11 of 21-day cycle. Patients continue to receive PM until disease progression or unacceptable toxicity. Primary outcome is ORR. Secondary outcomes include PFS, OS and safety. **Results:** As of2025.1.18, 44 r/r DLBCL patients had been enrolled (median age 62.5 years, 45.5% female) with a median of 2 lines of prior therapy. 43 patients have at least one response evaluation. After a median follow-up of 6.0 months, the ORR is 60.5% (26/43) with 9 complete response (CR) and 17 partial response (PR). Most response (19/26) occurred at early cycle with median TTR of 1.3 months (95% CI, 1.25-2.00), and the mDOR is 8.6 months (95% CI, 4.24- NR). Among 26 patients with response, 16 patients remain on treatment and the longest treatment has lasted for 22 cycles (still CR at cycle 21). The mPFS is 6.2 months (95% CI, 3.22-NR) and the mOS is immature. In subgroup analysis, 16 double-expressor DLBCL patients obtained 56.3% (9/16) ORR and 32 patients with TP53 mutation by NGS/FISH test achieved 62.5% (20/32) ORR. The most common grade ≥3 treatment emergent adverse events include thrombocytopenia (81.8%), neutropenia (79.5%), leukocytopenia (47.7%), lymphocytopenia (27.3%), hypokalemia (11.4%), anemia (9.1%) and hypertriglyceridemia (9.1%). No PM-related death was reported. **Conclusion:** This ongoing study showed 11.2mg/m^2 PM in 21-day-cycle achieved remarkable efficacy in r/r DLBCL and acceptable safety profile. The strategy for pivotal study of PM in r/r DLBCL is discussed with NMPA. Clinical trial information: NCT05563844. Combination of mitoxantrone hydrochloride liposome with cyclophosphamide, vincristine, and prednisone (CMOP) for patients with treatment-naïve peripheral T-cell lymphomas (PTCLs): Extended follow-up analysis of a multicenter, open-label, single-arm, phase Ib study. First Author: Huiqiang Huang, Sun Yat-sen University Cancer Center, Guangdong, China

Background: PTCLs represent a heterogeneous group of lymphomas generally majority of patients (pts) associated with a poor prognosis when treated with CHOP based therapy. Mitoxantrone hydrochloride liposome (Lipo-MIT) has demonstrated efficacy in relapsed/refractory PTCLs in our previous study. This study previously reported that CMOP regimen exhibits encouraging efficacy in treatment-naïve (TN) PTCLs. Here we present extended follow-up data of the final dose (NCT04548700). **Methods:** Eligible pts were aged 18-70 years with histologically confirmed TN PTCLs. Pts received Lipo-MIT combined with standard doses of COP regimen every four weeks for six cycles. The study consisted of a 3+3 dose-escalation phase (Lipo-MIT at 12, 15, 18, and 21 mg/m^2) and a specific dose-expansion phase (Lipo-MIT at the recommended phase 2 dose [RP2D]). The primary endpoints were dose-limiting toxicity (DLT) and safety. Secondary endpoints included objective response rate (ORR) assessed by an independent review committee (IRC), duration of CR (DoCR), DoR, PFS, OS, and pharmacokinetics (PK). **Results:** As of November 17, 2022,38 pts were enrolled (26 in the dose-escalation) from 7 centers in China, including 21 (55.3%) AITL, 6 (15.8%) PTCL-NOS, 4 (10.5%) ALK- ALCL, 3 (7.9%) ALK+ PTCL, and 4 (10.5%) other types,16 (42.1%) pts had stage IV disease. No DLTs were observed and a Lipo-MIT dose of 18 mg/m^2 was recommended as the RP2D. The most common treatment-related grade 3/4 adverse events were hematologic toxicities, including neutropenia (76.3%), leukopenia (73.7%), lymphopenia (44.7%), thrombocytopenia (15.8%) and anemia (13.2%). After a median follow-up of 23.8 (range 1.0-42.4) months, among the 35 response-evaluable pts, the IRC-assessed CR rate was 54.3% (95% CI, 36.6-71.2%), and the ORR was 88.6% (95% CI, 73.3-96.8%). According to the investigator assessment, the CR and ORR rate were 51.4% (95% CI, 34.0-68.6%) and 85.7% (95% CI, 69.7-95.2%), respectively. The median DoCR was not reached, while the median DoR were 20.1 (95% CI, 5.2-35.1) months. The median PFS was 20.8 (95% CI, 6.1-35.5) months, and the median OS was not reached with a 2-year OS rate of 93.3% (95% CI, 75.9-98.3%). Moreover, Lipo-MIT exhibited a favorable PK profile, with linear PK characteristics in the 12-18 mg/m^2 dose range. **Conclusions:** The CMOP regimen demonstrates a favorable PK profile, manageable safety profile, and encouraging preliminary anti-tumor activity. These results support further phase 2 and 3 trials clinical studies to confirm activity and assess efficacy in this population. Clinical trial information: NCT04548700. Research Sponsor: CSPC Zhongqi Pharmaceutical Technology Co., Ltd.

Long-term follow-up of the phase 2 ELM-2 study: Odronextamab for patients (pts) with relapsed/refractory (R/R) follicular lymphoma (FL). First Author: Deepa Jagadeesh, Cleveland Clinic, Cleveland, OH

Background: Odronextamab, an investigational off-the-shelf CD20×CD3 bispecific antibody, demonstrated compelling efficacy and a generally manageable safety profile in heavily pretreated pts with R/R FL in the primary analysis of the Phase 2 ELM-2 study (NCT03888105; Kim TM, et al. *Ann Oncol* 2024). We present updated efficacy and safety data for odronextamab in pts with R/R FL from ELM-2 after >2 yrs follow-up. **Methods:** Odronextamab was administered intravenously until disease progression/unacceptable toxicity, with Cycle (C) 1 step-up dosing to help mitigate cytokine release syndrome (CRS) risk, as reported previously. Pts with a complete response (CR) for ≥9 months (mo) switched from maintenance dosing Q2W to Q4W. Primary endpoint: objective response rate (ORR) per Lugano criteria by independent central review (ICR); secondary endpoints: CR rate, duration of response (DOR), progression-free survival (PFS), overall survival (OS). **Results:** At the updated data cutoff (Aug 15, 2024), 157 pts with centrally confirmed R/R FL Grade (Gr) 1–3a were enrolled. Median no. of treatment cycles: 19.0 (range 0.1–117.3); 96.2% (n = 151) and 82.8% (n = 130) of pts completed C1 and C4, respectively. The global cohort comprised 128 pts evaluable for efficacy. At a median efficacy follow-up of 28.3 mo, ORR was 80.5% (n = 103) by ICR and CR rate was 74.2% (n = 95); 92.2% of responders achieved CR. Responses were durable (median DOR, 26.0 mo; median duration of CR, 32.2 mo). ORR was consistent across high-risk subgroups (Follicular Lymphoma International Prognostic Index score 3–5, 78.4%; progression of disease within 2 yrs of frontline therapy, 81.0%). Median PFS was 23.0 mo (estimated 36-mo PFS rate, 37.5%), and median OS was 54.2 mo (estimated 36-mo OS rate, 62.6%). Median PFS was longer in pts who were minimal residual disease (MRD) negative (42.4 mo) versus MRD positive (21.6 mo) at Week 12. Of 47/128 pts who switched to Q4W dosing, 32 remained in CR. The odronextamab long-term safety profile was consistent with the primary analysis. All 157 pts had TEAEs (Gr ≥3, 86.0%), and 15.3% discontinued treatment due to TEAEs (most common: COVID-19 infection, 2.5%). With 0.7/4/20 mg step-up dosing (n = 89), CRS events were mostly low grade (Gr 1, 46.1%; Gr 2, 13.5%; Gr 3, n = 1; Gr ≥4, n = 0), occurred mostly in C1, and resolved in a median of 8.4 hrs. Immune effector cell-associated neurotoxicity syndrome was reported in one pt (Gr 2). Infections were reported in 79.0% of pts (124/157; Gr ≥3, 42.0%). COVID-19-related infections were reported in 38.2% of pts (Gr 5, 5.7%). **Conclusions:** With longer follow-up, odronextamab demonstrated durable responses in heavily pretreated pts with R/R FL from ELM-2, with robust efficacy in those with high-risk features, and a generally manageable safety profile. Overall, these compelling results support odronextamab as a potential off-the-shelf treatment option for pts with R/R FL. Clinical trial information: NCT03888105.
