Efficacy and safety of ifupinostat (BEBT-908) in combination with rituximab for relapsed/refractory diffuse large B-cell lymphoma: Results from an exploratory phase Ib study. First Author: Peng Liu, National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College, Beijing Key Laboratory of Clinical Study on Anticancer Molecular Targeted Drugs, Beijing, China

Background: Ifupinostat is a dual HDAC/PI3Kα inhibitor designed to target tumor cell signaling networks by simultaneously inhibiting HDAC and PI3Kα, thereby disrupting tumor cell proliferation and inducing apoptosis. A single-arm pivotal trial of Ifupinostat in patients who received at least two lines of systemic therapy for relapsed/refractory diffuse large B-cell lymphoma (r/r DLBCL) has been completed, with data currently under NDA review by the NMPA. This exploratory trial evaluates Ifupinostat in combination with rituximab as part of a confirmatory phase 3 trial to further assess its efficacy and safety as a second-line treatment for r/r DLBCL (NCT06164327). **Methods:** This multicenter Phase 1b trial was designed to evaluate the efficacy and safety of Ifupinostat in combination with rituximab (R) with or without standard second-line regimens (R-GemOx or R-ICE). Cohort 3 included 24 r/r DLBCL patients with prior exposure to at least one systemic therapy, all involving anti-CD20 antibody. Among these, 16 patients (66.6%) were primary refractory, 4 patients (16.7%) were refractory to their most recent line of therapy, and 4 patients (16.7%) were relapsed cases. Treatment consisted of Ifupinostat administered intravenously at a dose of 22.5 mg/m² on days 1, 3, 5, 8, 10, and 12 of each 21-day cycle. Rituximab was administered intravenously at a dose of 375 mg/m² on day 1 of each cycle. Tumor assessments were conducted following treatment, and efficacy was evaluated according to the Lugano 2014 criteria. Key endpoints included the objective response rate (ORR) and safety. **Results:** Of the 24 enrolled patients, 21 completed at least one treatment dose and underwent tumor assessment. The ORR was 76.2%, with 10 patients (47.6%) achieving a complete response (CR) and 6 (28.6%) achieving a partial response (PR). The disease control rate (DCR) was 85.7%. Median progression-free survival (PFS) has not yet been reached (>7.7 months). Common grade 3-4 hematological toxicities observed during treatment included thrombocytopenia (34.8%), leukopenia (17.4%), and lymphopenia (13.0%). No unexpected toxicities were observed, and the safety profile was deemed manageable. **Conclusions:** The study results demonstrate promising efficacy and a manageable safety profile for Ifupinostat in combination with rituximab as a second-line treatment for r/r DLBCL. These findings support further investigation in confirmatory phase 3 trials, which are currently underway. Clinical trial information: NCT06164327. Research Sponsor: None.

Phase II safety and preliminary efficacy of amulirafusp alfa (IMM0306) in combination with lenalidomide in patients with relapsed or refractory CD20-positive follicular lymphoma. First Author: Yan Huang, Department of Hematology and Oncology, Jiangxi Cancer Hospital, Nanchang, China

Background: Amulirafusp alfa (IMM0306) consists of anti-CD20 monoclonal antibody fused with the CD47 binding domain of SIRPα. It exerts potent anti-cancer efficacy by activating both macrophages and NK cells via blockading of CD47-SIRPα interaction and FcγR engagement. Lenalidomide was approved for relapsed or refractory (R/R) indolent non-Hodgkin's lymphoma (iNHL). Here, we report results from a Phase II study of 34 patients with R/R CD20-positive follicular lymphoma (FL) (NCT05771883). **Methods:** Eligible patients with grade 1-3a FL received amulirafusp alfa 1.6 mg/kg intravenously once a week with lenalidomide 20 mg orally once a day on Days 1 to 21 in each 28-day cycle until disease progression or intolerable toxicity. Safety was evaluated by CTCAE 5.0, tumor assessments performed every 8 weeks by Lugano 2014. **Results:** Until Dec 26, 2024, 34 patients with R/R FL were enrolled. Median age was 54, 20 (58.8%) were males, and 32 (94.1%) had stage III-IV disease. The median number of prior line therapy was 2. All patients received previous anti-CD20 therapy. Among 22 efficacy-evaluable patients, 10 CR, 8 PR, 2 SD and 2 PD were observed. The CRR and ORR were 45.5% and 81.8%, respectively. Of the 4 efficacy-evaluable patients who did not achieve response, 2 SD patients were both CD20 therapy refractory, 1 PD patient had histologic transformation and 1 PD patient were lenalidomide-resistant (had taken lenalidomide continuously for about 4 years). The most common treatment related adverse events (TRAEs) (≥ 20%) were PLT decreased (70.6%), WBC decreased (58.8%), anemia (52.9%), ANC decreased (52.9%), lymphocyte decreased (52.9%), infusion-related reactions (35.3%) and hypoalbuminaemia (23.5%). Grade ≥3 TRAEs occurred in 22 (64.7%) patients, the most common ≥ grade 3 TRAEs (≥ 10%) were ANC decreased (29.4%), lymphocyte decreased (26.5%), PLT decreased (23.5%) and WBC decreased (11.8%). 5 (14.7%) patients experienced serious TRAE. 1 (2.9%) patient had a dose reduction of amulirafusp alfa, 5 (14.7%) patients had dose reductions of lenalidomide due to TRAEs. 1 (2.9%) patient experienced TRAE leading to the study drug discontinuation (Grade 4 Type I hypersensitivity, recovered with sequelae within 1 month). No patient experienced TRAE leading to death. There were no significant differences between amulirafusp alfa monotherapy and combination with lenalidomide in terms of PK exposure and ADA incidence rate. Pharmacodynamics analysis demonstrated amulirafusp alfa combine lenalidomide effectively depleted $CD19^{+}$B cell in peripheral blood and achieved sustained long-term B cell depletion. **Conclusions:** Amulirafusp alfa in combination with lenalidomide showed a preliminary anti-tumor activity and a well-tolerated safety profile in patients with R/R FL. This phase Ib/II study is still ongoing. Clinical trial information: NCT05771883. Research Sponsor: None.

7052 **Poster Session**

Impact of cell of origin, gene rearrangements, and frontline treatment on incidence of secondary central nervous system lymphoma in newly diagnosed diffuse large B-cell lymphoma. First Author: Ayo Samuel Falade, Department of Medicine, Mayo Clinic, Rochester, MN

Background: Secondary central nervous system lymphoma (SCNSL) is a rare but serious complication that occurs in 2-10% of patients (pts) with diffuse large B-cell lymphoma (DLBCL). The CNS-International Prognostic Index (CNS-IPI) is a validated tool used to assess the risk of CNS relapse. However, with advancements in molecular profiling and treatments, the predictors of SCNSL, including the predictive ability of CNS-IPI combined with other molecular markers and treatment regimens, have become uncertain. This study evaluates new prognostic markers for CNS relapse in DLBCL, focusing on cell-of-origin (COO), gene rearrangements, and treatment types. **Methods:** DLBCL pts enrolled from 2002-2015 in the Mayo Clinic and University of Iowa Lymphoma Molecular Epidemiology Resource were prospectively followed for incidence of CNS relapse. Pts with primary CNS lymphoma or CNS involvement at diagnosis, and pts treated with high-dose methotrexate containing regimens were excluded. COO classification (GCB vs non-GCB) was determined using Hans algorithm and/or NanoString data. Multivariate Cox regression models estimated hazard ratios (HRs) and 95% confidence intervals (CIs) for predictors of SCNSL. Survival analysis was performed from time of DLBCL diagnosis using Cox proportional hazards model. **Results:** Among 1278 newly diagnosed DLBCL pts included (median age: 63 years; 43.6% female), SCNSL occurred in 46 (3.6%) pts. Pts with SCNSL were more likely to have intermediate/high CNS-IPI scores (80.4%) than pts without SCNSL (63.9%, p=0.02). The 3 yr SCNSL incidence was 0.016 (0.008-0.0033) in low CNS-IPI vs 0.043 (0.031-0.0060) in high CNS-IPI. Those with SCNSL were significantly more likely at baseline to have non-GCB COO (56.3% vs. 36.5%, p=0.02), and advanced stage (76.1% vs. 59.9%, p=0.03) compared to those without SCNSL. The incidence of SCNSL was not influenced by MYC, BCL2, or BCL6 rearrangements, nor by treatment with R-CHOP, R-EPOCH, or other immunochemotherapy regimens. MVA showed that intermediate CNS-IPI (HR 2.32, 95% CI 1.09-4.92, p=0.029), high CNS-IPI (HR 3.59, 95% CI 1.49-8.62, p=0.004), and non-GCB COO (HR 2.19, 95% CI 1.08-4.42, p=0.0029) were independently associated with increased SCNSL risk. After a median follow-up of 12 years (IQR 9–15), overall survival (OS) was 52.1% for the cohort, with OS significantly worse for SCNSL pts (17.4% vs. 53.4%, p<0.001). **Conclusions:** This large cohort with extensive follow-up highlights the role of COO as an additional prognostic factor for SCNSL while reinforcing CNS-IPI's prognostic value. Non-GCB COO pts had a higher risk of SCNSL even when adjusted by CNS-IPI risk. Despite advancements in management, SCNSL pts continue to have poor outcomes. Strategies to reduce the incidence of CNS relapse in high-risk pts require further investigation. Research Sponsor: None.

A phase I study of the EZH2 inhibitor TR115 in patients with relapsed/refractory non-Hodgkin's lymphomas and advanced solid tumors. First Author: Jie Jin, The First Affiliated Hospital, Zhejiang University School of Medicine, Hangzhou, China

Background: EZH2 gain-of-function mutations and overexpression lead to aberrant H3K27me3 levels and result in tumorigenesis and metastasis, including several categories of B cell and T cell lymphoid malignancies, and it is associated with poor clinical prognosis and outcomes. TR115, a novel, highly selective, orally administered EZH2 inhibitor, has demonstrated potent anti-tumor activity in preclinical models. This Phase I study aims to evaluate the safety, tolerability, and preliminary efficacy of TR115 in patients with relapsed/refractory non-Hodgkin's lymphomas (NHL) and advanced solid tumors. **Methods:** Dose escalation started at 200mg bid and progressed up to 1600mg bid. Patients received TR115 orally twice daily in 28-day cycles until disease progression, unacceptable toxicity, or patient withdrawal. Adverse events (AEs) were graded according to the National Cancer Institute Common Terminology Criteria for Adverse Events (NCI-CTCAE) version 5.0. Efficacy was evaluated using Lugano 2014 criteria for lymphomas and RECIST v1.1 for solid tumors. **Results:** By January 10, 2025, a total of 20 patients were enrolled, including those with angioimmunoblastic T-cell lymphoma (AITL, n=4), diffuse large B-cell lymphoma (DLBCL, n=4), ovarian cancer (n=4), ALK-negative anaplastic large cell lymphoma (ALCL, n-2), peripheral T-cell lymphoma not otherwise specified (PTCL-NOS, n=2), mycosis fungoides (n=1), follicular lymphoma (FL, n=1), extranodal marginal zone mucosa-associated lymphoid tissue lymphoma (MALT, n=1) and breast cancer (n=1). Median age was 61 (range 37-77) with 10 (50%) males. Most were heavily pretreated with a median of 2 previous lines of therapy. the most common TRAEs (all grades/Grade $\geq$3) included thrombocytopenia (50%/15%), leukopenia (45%/10%) , anemia (40%/15%), neutropenia (35%/10%), hypertriglyceridemia (35%/5%), elevated blood creatinine (35%/0%), elevated lactate dehydrogenase (25%/0%), hypokalemia (25%/5%), hyperbilirubinemia (20%/0%), adynamia (20%/5%), Hypoproteinemia (20%/0%), and upper respiratory tract infection (10%/5%). Of the 11 patients with non-Hodgkin's lymphomas evaluable for response, the overall response rate (ORR) was 63.6%, and the disease control rate (DCR) was 81.8%. 6 patients with PTCL had an ORR of 100%, and 4 continue to receive treatment with the investigational drug. One PTCL-NOS patient achieved a complete response (CR) remaining on treatment at Cycle 16. PK parameters $AUC_{0\text{-}24h}$ and C_{max} were dose proportional with median T_{max} 2 hours. **Conclusions:** In this study, TR115 exhibited a favorable safety profile and promising efficacy in patients with relapsed/refractory non-Hodgkin's lymphoma, especially in relapsed/refractory PTCL patients. Further investigation of TR115 alone or in key therapeutic combinations is warranted. (NCT05650580). Clinical trial information: NCT05650580. Lorlatinib therapy in relapsed/refractory ALK+ lymphomas previously treated with tyrosine kinase inhibitors. First Author: Federica Colombo, Università degli studi Milano Bicocca, Milano, Italy

Background: ALK+ Lymphomas are aggressive diseases with poor prognosis when chemoimmunotherapy (CIT) and Crizotinib fail. Lorlatinib is a 3rd-generation tyrosine kinase inhibitor (TKI), that inhibits all reported ALK kinase domain mutations responsible for resistance to Crizotinib. **Methods:** From 2019 to 2024, we enrolled 8 patients (pts) in a phase 2 open label monocentric study with Lorlatinib in relapse/refractory (r/r) ALK+ lymphomas previously treated with other TKI (EudraCT2016-003970-41). Overall response rate (ORR), the primary endpoint, was evaluated using 18F-FDG PET/CT scans and ALK RT-PCR on peripheral blood and bone marrow samples. Secondary endpoints were progression-free survival (PFS) and overall survival (OS) from the start of Lorlatinib to relapse and/or death. Side effects were classified according to CTCAEv4.03. Our cohort included 4 ALK+ Large B Cell Lymphoma (LBCL) with Clathrin-ALK (CLTC::ALK) rearrangement, 2 ALK+ Anaplastic Large Cell Lymphoma (ALCL) with ATIC::ALK fusion, 1 ALK+ ALCL Lymphoma with NPM::ALK translocation and 1 ALK+ histiocytosis with EML4::ALK rearrangement. **Results:** The median follow-up (fup) was 23 months (1,3- 62), the median age at diagnosis was 23 years (19-57); all pts were in stage IV Ann Arbor and treated with CIT and Crizotinib. 2 pts also received other TKIs (Alectinib and Ceritinib). Lorlatinib was administered daily at a dose of 100 mg. The ORR at one month (M1) was 100% (95% CI: 72-100%): 5 CR and 3 PR. 3 pts (2 ALCL [ATIC::ALK], 1 ALCL [NPM::ALK]), underwent Allogeneic Stem Cell Transplant (ASCT) while in CR and resumed Lorlatinib post-transplant. Due to hepatic GVHD and memory impairment, their Lorlatinib dosage was reduced from 100 mg to 75-50 mg/day. All of them are in CR. 2 pts (LBCL with CLTC::ALK) refused ASCT, maintained CR from M1 through their last fup at 15 and 65 months respectively, continuing with Lorlatinib at 100 mg/day. 2 ALK+ LBCL pts (CLTC::ALK) achieved PR at M1 but relapsed within 3 months and did not benefit from ASCT or salvage treatments. The pt with ALK+ histiocytosis was in PR at M1 and then obtained CR at M3 with Lorlatinib; surgical resection of a residual necrotic lung mass was performed. She has been in CR for $>$40 months. PFS rate at 3 months was 75%, with no additional events reported. OS was 87% at 3 and 12 months, and 72% at 24 months and stabilized thereafter. All ALK+ lymphoma pts in CR at M1 maintained a durable response, whereas those in PR died of disease progression. The type of lymphoma or of ALK translocation did not correlate with outcome. Main adverse effects (all grade I/II) included hyperlipidaemia, weight gain, muscle cramps, gastrointestinal symptoms, thrombocytopenia and memory difficulty. **Conclusions:** Our analysis confirms Lorlatinib's efficacy and safety as salvage therapy. Achieving a CR at M1 was found to be the most important prognostic factor for survival. Adverse events are manageable with dose adjustments. Clinical trial information: EudraCT2016-003970-41. Research Sponsor: None.

Combination of mitoxantrone hydrochloride liposome with tislelizumab in patients with relapsed or refractory NK/T cell lymphoma: A phase Ib/II study. First Author: Qingqing Cai, Department of Medical Oncology, Sun Yat-Sen University Cancer Center, Guangzhou, China

Background: Natural killer/T-cell lymphoma (NKTCL) is a unique subtype of non-Hodgkin lymphoma with aggressive disease course. Mitoxantrone hydrochloride liposome (Lipo-MIT) is a nano-drug that has been approved for relapsed/refractory (r/r) PTCL, and has shown certain efficacy and safety in a pivotal phase II study (Cancer. 2025, e35672). Tislelizumab is a humanized immunoglobulin G4 variant monoclonal antibody against PD-1. This study aims to investigate the safety and efficacy of combining Lipo-MIT with tislelizumab in patients (pts) with r/r NKTCL. **Methods:** Pts with r/r NKTCL and failed asparaginase-based therapy were recruited in this single-arm, multicenter phase Ib/II study (NCT05464433). Phase Ib was 3+3 dose escalation design with two dose levels of Lipo-MIT (16 mg/m^2 and 20 mg/m^2, d1) plus tislelizumab 200 mg (d1, Q4W) induction therapy for up to 6 cycles, then tislelizumab 200 mg (Q3W) maintenance therapy for up to 1 year. Phase II was conducted at the recommended phase II dose (RP2D). The primary endpoints were safety and tolerability, and determination of the maximum tolerated dose (or RP2D) of Lipo-MIT in phase Ib, and the overall response rate (ORR) of phase II. **Results:** As of the data cut-off on January 24, 2025, a total of 40 eligible pts were enrolled (phase Ib, n=6 and phase II, n=34). The median age was 46.5 (range 22-73) years. Among the pts, 62.5% had stage III or IV and 87.5% had nasal type NKTCL. No dose-limiting toxicities (DLT) were observed in the phase Ib study, and the RP2D of Lipo-MIT was determined to be 20 mg/m^2. The ORR and DCR were all of 100.0% (6/6, 95% CI 60.7%-100.0%) and the CR rate was 66.7% (4/6, 95% CI 27.1%-93.7%) in phase Ib. In the ongoing phase II stage, 30 pts were evaluable for efficacy. The ORR, DCR and CR rate were 70.0% (21/30, 95% CI 50.6%-85.3%), 76.7% (23/30, 95% CI 57.7%-90.1%) and 46.7% (14/30, 95% CI 28.3%-65.7%), respectively. Overall, combining data from phase Ib and phase II, the ORR was 75.0% (27/36, 95% CI 57.8%-87.9%) and the CR rate was 50.0 (18/36, 95% CI 32.9%-67.1%). Among the 15 pts who had not used PD-1 before, CR rate was 66.7% and ORR reached 80.0%. The median PFS and OS will be reported with longer follow-up. The most common grade 3/4 treatment-related adverse events (TRAEs) included leucopenia (37.5%), neutropenia (30.0%) and decreased lymphocyte count (27.5%). Notably, no cardiac events occurred during the study. **Conclusions:** Lipo-MIT in combination with tislelizumab demonstrated an encouraging efficacy in r/r NKTCL pts with a manageable safety profile. Clinical trial information: NCT05464433. Research Sponsor: None.

Comparative analysis of survival outcomes in infused versus not-infused patients with aggressive B-cell lymphoma referred for CART. First Author: John Seng Wang, Northwestern University Feinberg School of Medicine, Chicago, IL

Background: Chimeric antigen receptor T-cell therapy (CART) has changed the treatment paradigm for patients (pts) with relapsed/refractory (R/R) aggressive B-Cell Non-Hodgkin's Lymphoma (B-NHL). Yet, not all referrals complete the full process from harvest to re-infusion. This study evaluated a large cohort of pts "referred yet not infused" with CART to identify barriers to care and compare outcomes between pts infused vs non-infused. **Methods:** This is a retrospective analysis of adult pts with R/R B-NHL referred to Northwestern University from 2016-2024 for consideration for CART. Demographics, disease characteristics, and lines of therapy were evaluated. Survival analysis assessed median progression free survival (mPFS) and overall survival (mOS) in months (mo) from 2 starting timepoints (1) date of relapse with last line therapy prior to CART referral, denoted as PFS1 and OS1, and (2) date of treatment with CART or alternative to CART after referral, denoted as PFS2 and OS2. **Results:** Of 196 pts, 157 (80%) received CART (infused) whereas 39 (20%) were referred, but did not proceed to CART (non-infused). Comparison of demographics/disease characteristics demonstrated differences in age and ethnicity (Table 1). For infused pts, median time from apheresis to infusion was 33 days (range 9-86) and 94 pts (60%) received bridging therapy. For non-infused pts, median time from CART referral to alternative treatment was 14.5 days (range 1-80), most commonly rituximab-lenalidomide, rituximab-gemcitabine-based therapy (n=6 for each, 15%), or polatuzumab-based therapy (n=3, 8%). Death from disease progression was the most common reason for non-infusion (n=25, 64.1%). Median follow-up was 19 mo in surviving pts. Infused pts had higher mPFS1 than non-infused pts (5.6 [95% CI 3.7-7.5] vs 1.8 mo [95% CI 1.3-2.3]; p=0.05). Median PFS2 showed no significant difference. Infused pts had a markedly higher mOS1 (45.9 [95% CI 20-72] vs 2.5 mo [95% CI 1.8-3.2]; p=0.001), and mOS2 (32.3 [95% CI 0.1-64.5] vs 2.4 mo [95% CI 1.9-2.9]; p=0.001). **Conclusions:** CART infused vs non-infused pts differed with respect to age and ethnicity. The most common reason for failure to infuse was death due to disease progression. Infused pts demonstrated similar PFS to non-infused pts treated with alternative therapy. However, infused pts had a markedly improved OS. Collectively, our results suggest that survival in R/R B-NHL may be optimized by adopting measures that ensure success of proceeding to CART. Research Sponsor: None.

CD58 alterations and their role in regulating antitumor immune responses in diffuse large B-cell lymphoma. First Author: Yidan Zhang, Tianjin Medical University Cancer Institute and Hospital, Tianjin, China

Background: Recurrent abnormalities of immune surveillance-related genes play a crucial role in DLBCL progression. Prior studies have shown that CD58, a key adhesion molecule that acts as a ligand for the T-cell costimulatory molecule CD2, is frequently mutated or deleted in certain hematological malignancies. Downregulation or loss of CD58 is linked to resistance to ICB therapy in melanoma and CAR-T therapy in B-cell malignancies. Nevertheless, the role of CD58 in cancer is not yet well understood. **Methods:** Comprehensive analysis of the genetic characteristics of *CD58* were performed through targeted deep sequencing (n=176), whole exome sequencing (n=38), and RNA-sequencing (n=162) in patients with de novo DLBCL. To investigate the mechanistic impacts of CD58 alterations on co-inhibitory molecules expression and immune cell function, we performed bulk and single-cell RNA-sequencing analysis of tumor samples and conducted co-IP, flow cytometry and co-culture assays in vitro. **Results:** We identified that *CD58* mutation rate was 9.1%, and the copy number loss rate was 44.7% among all enrolled DLBCL patients. Notably, *CD58* genetic alterations, along with low CD58 expression, significantly correlated with reduced rates of response to R-CHOP therapy and inferior progression-free and overall survival. Single-cell RNA sequencing revealed that CD58 expression in tumor cells was negatively correlated with $CD8^+$ T cell exhaustion/dysfunction status. CD58 inhibited the activity of the JAK2/STAT1 pathway by activating the Lyn/CD22/SHP1 axis, thereby limiting PD-L1 and IDO expression. Elevated PD-L1 and IDO expression in CD58 deficient DLBCL cells led to immune evasion and tumor-intrinsic resistance to CAR T-cell therapy. Direct activation of CD58-CD2 costimulatory signaling in combination with anti-PD-L1 blockade or IDO inhibitor sensitized CD58-deficient DLBCL to CAR T-cell therapy. **Conclusions:** Our study comprehensively characterized *CD58* genetic alterations in DLBCL. We demonstrated that CD58 downregulation or mutation led to upregulation of PD-L1 and IDO expression mainly by regulating the LYN/CD22/SHP1 axis. Our findings provide novel insights for individualized therapy for DLBCL patients with CD58 mutation or deletion. Research Sponsor: None.

Assessing the role of cytarabine-based regimens in mantle cell lymphoma: A real world study. First Author: Yanal Mufeed Alnimer, University of Kentucky, Lexington, KY

Background: Mantle cell lymphoma (MCL) is an aggressive subtype of non-Hodgkin lymphoma. For decades, cytarabine-based regimens have been the cornerstone of MCL treatment, offering substantial efficacy but often at the cost of significant toxicity. More recently, non-cytarabine-based regimens, such as bendamustine combined with rituximab, have emerged as a promising alternative, demonstrating comparable efficacy with more favorable toxicity profile. This study aims to compare the clinical efficacy of cytarabine-based (Ara-C) versus non-cytarabine-based (non-Ara-C) regimens. **Methods:** We conducted a retrospective cohort study for patients diagnosed with MCL between 2010 and 2023 at Allegheny Health Network and Markey Cancer Center. Data pertaining to demographics, MIPIc, Lugano stage and treatments at induction were collected. Patients were divided into two groups based on whether they received cytarabine based regimen during induction (Ara-c) or not (non-Ara-c). Primary outcomes were overall survival (OS) measured from the time of diagnosis to the time of last follow up or death, and relapse free survival (RFS), calculated from the time of diagnosis to the time of relapse, persistent or progressive disease at the last day of follow up. Sensitivity analysis, with censoring on the time of autologous bone marrow transplant (ASCT) was done. RFS and OS were compared between the two groups after weighted propensity score matching (PSM). **Results:** We identified 223 patients diagnosed with MCL. The median age was 67.7 (IQ 60-74.5), Majority of patients were males (71%). The median MIPIc score was 8.1(IQR 7-9.5). 72 patients (31%) were in the Ara-c group while 151 patients (69%) were in the non-Ara-c group. The median follow-up of 5.6 years (0.95CI 4.91-6.32). Median OS was 13 years (0.95 CI 7.24-NR) and median RFS was 4.1 years (0.95 CI 3-4.96) for the entire cohort. Baseline comparison between the two groups is shown in table_1. After PSM, Median RFS for Ara-c group was 4.8 (IQR=1.8-16.2) yrs VS 3.6 (IQR=1.52-7) yrs for non-Ara-c group (P value 0.03). However, after censoring on ASCT, median RFS for Ara-c group was 4.7 (IQR 1.5-16.2) yrs VS 3.3 (IQR 1.5-6.9) yrs (P value 0.16). Median OS for Ara-c group was 16.2 yrs (IQR=4.3-16.2) vs 12.95 yrs (IQR=3.7-17.8) for non-Ara-c group (P value 0.5), which was the same after censoring on ASCT. **Conclusions:** In our cohort, cytarabine use in induction chemotherapy for MCL was associated with longer RFS and OS but it did not reach statistical significance. Larger scale studies are warranted to confirm these results. Of note, older and less fit patients received less cytarabine. Research Sponsor: None.

	Cytarabine	Other	P value
Age	64 (57-69)	69 (63-77)	0.013
Eastern Cooperative group 0,1	96%	84%	0.05
MIPIc	7.56 (6.89-7.92)	8.28 (6.97-9.66)	0.01
Consolidation with ASCT	42%	13%	<0.01

Total metabolic tumor volume for predicting cytokine release syndrome and treatment response in patients receiving bispecific antibodies for B-cell lymphoma. First Author: Xi Yang, Division of Hematology/Oncology, University of Michigan, Ann Arbor, MI

Background: CD20xCD3 bispecific antibodies (BsAb) show high response rates with manageable cytokine release syndrome (CRS) in B-cell non-Hodgkin lymphomas (B-NHLs). While emerging data suggest that total metabolic tumor volume (TMTV) may predict treatment response and CRS, these findings have not yet been validated in real-world settings or across diverse histologic subtypes. **Methods:** We conducted a single center retrospective study evaluating B-NHL patients treated with BsAb. Baseline characteristics, efficacy, and safety outcomes were analyzed. TMTV was calculated from baseline PET scans using a semi-automated method with a threshold of 2x liver SUV_{mean}. Median TMTV separated high/low groups. **Results:** A total of81 patients are included. The baseline characteristics, efficacy outcomes, and CRS outcomes of each histological subtype are summarized in Table 1. There were no Grade 4 CRS events observed. The median TMTV for DLBCL, FL and MCL was 107.1ml, 61.7ml, and 92.2ml, respectively. In DLBCL, patients with high TMTV were more likely to have bulky disease (>7.5cm) and elevated LDH. Other baseline characteristics as outlined in Table 1 were comparable to low TMTV group. High TMTV was associated with increased risk of CRS of any grade (OR 5.0, 95% CI 1.4-18.1, p=0.017) but was not associated with ORR, CR, PFS or OS. While bulky disease and elevated LDH levels were associated with TMTV, these clinical factors were not predictive of CRS. In contrast, TMTV retained its prognostic significance in multivariate analysis. In FL, high TMTV was associated with a higher rate of bulky disease while LDH level and other baseline characteristics did not differ from the low TMTV group. High TMTV correlated with a lower CR rate (OR 0.1, 95% CI 0.0-0.6, p=0.020) but did not influence CRS risk, PFS or OS. In the small cohort of MCL patients, no significant associations between TMTV and CRS or treatment efficacy were observed. TMTV has no correlation with neurotoxicity in all cohorts. **Conclusions:** High TMTV predicts for a higher rate of CRS on multivariate analysis in DLBCL, independent of clinical factors. High TMTV was associated with a lower CR rate in FL and further evaluation in MCL is needed with larger sample sizes. Research Sponsor: None.

DLBCL-associated PIM1 mutation and its impact on ANXA2 localization and lymphomagenesis. First Author: Yaxiao Lu, Tianjin Medical University Cancer Institute and Hospital, Tianjin, China

Background: Diffuse large B-cell lymphoma (DLBCL) is the most common subtype of non-Hodgkin lymphoma and has an overall cure rate of approximately 60%. Previously, we observed high PIM1 mutation rates in DLBCL patients with poor outcome. However, the mechanism whether they lead to enhanced PIM1 kinase activity and contribute to lymphomagenesis is currently unknown. **Methods:** In this study, a multifaceted approach was employed to elucidate the functional consequences of PIM1 gene mutations and their implications in DLBCL. Recurrent PIM1 gene mutations that exhibited high frequencies across various lymphoma cohorts from public databases were screened and patient outcomes were stratified by PIM1 genen mutational sites. Liquid chromatography-mass spectrometry (LC-MS/MS) analysis combined with Co-IP was used to identify proteins interacting with PIM1. Transcriptomics analysis was utilized to identify proteins involved in critical cellular pathways relevant to PIM1 mutation. A high-throughput drug screening platform was leveraged to find potential therapeutic vulnerabilities unique to PIM1 mutant cells. The antiproliferative effects of PIM1 and PI3K inhibitor were evaluated in DLBCL cell lines and further validated in NSG mouse xenograft models. **Results:** We have identified PIM1 mutations, specifically P81S, E135K, L184F, and S97N, as frequently occurring variants, with the former three significantly associated with poor outcome. In particular, the $PIM1^{L184F}$ mutation promoted cell proliferation and inhibited cell apoptosis in vitro and showed faster tumor growth in vivo. Mechanistically, the $PIM1^{L184F}$ mutation was found to interact with the annexin A2 (ANXA2) gene, activating it through phosphorylation of serine 26. The activated ANXA2 gene then translocated from the cytoplasm to the cell membrane, binding with the Toll-like receptor 4 (TLR4) gene and recruiting BCAP to the cell membrane to interact with p85α further activating the PI3K/AKT/mTOR signaling pathway. Additionally, the high-throughput drug screening demonstrated that the $PIM1^{L184F}$ mutated cells were more sensitive to the PI3K inhibitor YY20394. PIM1 inhibitor SMI-4a combined with YY20394 showed synergistic antitumor effects both in vitro and in vivo. **Conclusions:** Taken together, these findings not only shed light on an innovative regulatory mechanism for how $PIM1^{L184F}$ mutation contributes to the pathogenesis of DLBCL but also provide a potential therapeutic strategy for effectively managing DLBCL patients harboring $PIM1^{L184F}$ mutation. Efficacy and safety of polatuzumab vedotin plus rituximab, cyclophosphamide, doxorubicin and prednisone for previously untreated diffuse large B-cell lymphoma: A real-world, multi-center, retrospective cohort study. First Author: Peiqi Zhao, Department of Lymphoma, Tianjin's Clinical Research Center for Cancer, Key Laboratory of Cancer Prevention and Therapy, National Clinical Research Center for Cancer, Tianjin Medical University Cancer Institute and Hospital, Tianjin Medical University, Tianjin, China

Background: In the POLARIX study, Pola-R-CHP showed significant improvement in progression free survival (PFS) in previously untreated DLBCL compared to R-CHOP. However, there are still few reports about the efficacy and safety of Pola-R-CHP in real-world setting in China, leaving some questions about the optimal patient population for Pola-R-CHP. Therefore, we conducted this retrospective observational study to compare the efficacy and safety of Pola-R-CHP with R-CHOP in clinical practice. **Methods:** The Pola-R-CHP group included previously untreated DLBCL patients who received Pola-R-CHP therapy across 6 medical centers in China. The control group included previously untreated DLBCL patients treated with R-CHOP. Patients treated with Pola-R-CHP were matched by propensity scores with those treated with R-CHOP. The primary endpoint was 12-month PFS based on Lugano 2014 criteria. **Results:** A total of 650 eligible patients from 6 centers were identified, 155 receiving Pola-R-CHP and 495 R-CHOP. After 1:2 propensity score matching, 150 pairs were obtained for further survival and prognosis analysis. With a median follow-up of 14.3 months, 12-month progression-free survival (PFS) was numerically higher with Pola-R-CHP versus R-CHOP (90.5% vs 84.8%, P=0.19). Benefits were consistently observed across molecular subgroups, especially advanced stage, ECOG≥2, extranodal involvement ≥2 and non-GCB group. The complete response rate of the Pola-R-CHP group was higher than that of the RCHOP group (87.2% vs 80.1%; P=0.11), but there was no statistical difference. Among 150 patients treated with Pola-R-CHP, 110 underwent gene sequencing analysis: MCD (25.5%), combined subtype (14.5%), ST2 (10.9%), and other/unclassifiable subtype (31.8%). The most common mutations (>25% of cases) were PIM1, TP53, BCL-6, KMT2D, SOCS1, BCL-2. Genetic testing results show the correlation between genotyping, gene mutations in PIM1/TP53 and therapeutic efficacy. Safety was comparable between Pola-R-CHP and R-CHOP, including rates of grade 3 to 4 AE. Prophylactic PEG-G-CSF administration was given in most of the cases. No deaths due to AE were observed. Unexpected adverse events were not observed. **Conclusions:** This large real-world study supports Pola-R-CHP as an effective frontline option for DLBCL, with sustained efficacy versus R-CHOP observed in unselected populations. While 12-month PFS failed to reach statistical significance, subgroup analyses favor Pola-R-CHP. Further research with a wider population, longer follow-up, and screening of advantageous groups are warranted. Research Sponsor: None.

Association between progression-free survival and overall survival in relapsed/refractory diffuse large B-cell lymphoma in the CAR T-cell era: A surrogate endpoint analysis. First Author: Charles J. Milrod, Brown University Health, Providence, RI

Background: In lymphoid malignancies, the strength of association between progression-free survival (PFS) and overall survival (OS) varies by disease aggressiveness. More-indolent malignancies such as multiple myeloma and follicular lymphoma have a weak correlation between PFS and OS, while more aggressive diseases like Hodgkin lymphoma have a stronger association. PFS has been validated as a surrogate for OS in first-line DLBCL, but its utility in R/R DLBCL in the era of CAR T-cell therapy has not been explored. This analysis is the first assessment of PFS as a surrogate endpoint for OS in DLBCL after the introduction of CAR T-cell therapy. **Methods:** A systematic review of ClinicalTrials.gov was conducted to identify phase 3 trials in DLBCL that reported hazard ratios (HR) for both PFS and OS. Trials initiated after 2015 were included to reflect the post-CAR T-cell therapy era, acknowledging that CAR T-cell therapy was approved in 2017 and most patients experience disease progression within two years. First-line trials were excluded from final analysis, resulting in an analysis focused exclusively on R/R DLBCL. Weighted linear regression analysis was performed, with the number of participants as the weighting factor. The strength of the association was evaluated using the coefficient of determination (R^2), with predefined thresholds: $R^2 > 0.80$ indicating a strong association, 0.60–0.80 indicating a moderate association, and $R^2 < 0.60$ indicating a weak association. **Results:** A total of 101 randomized clinical trials were identified. Upon screening, 20 trials reported rates for both PFS and OS. Of these, 4 trials, encompassing 1,139 patients, reported HRs and were included in the final analysis. The weighted regression analysis demonstrated a strong correlation between PFS and OS, with a correlation coefficient (r) of 0.98 and a coefficient of determination (R^2) of 0.98, indicating that 98% of the variance in OS could be explained by PFS (p = 0.012). **Conclusions:** This study provides the first surrogate endpoint analysis of PFS in R/R DLBCL in the post-CAR T-cell therapy era, excluding first-line trials. The findings suggest that PFS remains a strong surrogate for OS in this population. While the analysis is limited by the small number of available trials, the results highlight the need for ongoing surrogate validation as treatment landscapes evolve. Research Sponsor: None.

Immune biomarkers as predictors of response to mosunetuzumab in previously untreated follicular (FL) and marginal zone lymphoma (MZL). First Author: Charles J. Milrod, Brown University Health, Providence, RI

Background: CD3xCD20 bispecific antibodies (BsAbs), including mosunetuzumab, induce high rates of complete response (CR) in indolent B-cell lymphomas. However, predicting the response and understanding systemic immune changes induced by the treatment (Tx) remain unmet needs. We hypothesized that changes in circulating immune biomarkers could predict Tx response in patients (pts) receiving first-line mosunetuzumab for FL and MZL. **Methods:** Immune biomarkers were measured in peripheral blood samples from pts enrolled in BrUOG-401 (NCT04792502), an investigator-initiated phase 2 trial of time-limited (8 cycles [C]) mosunetuzumab Tx for untreated, high-burden FL and MZL. Disease assessments by PET/CT occurred after C4 (MidTx) and C8 (end of Tx, EOTx). Pts without MidTx CR received additional lenalidomide in C4-8 with optional Tx extension up to C12. Samples were collected at baseline (PreTx), C1 day 8 (C1D8), C2 day 1 (C2), at MidTx, and at EOTx. We measured 25 plasma cytokines related to T-cell activation and regulation using a multiplex Luminex assay, and immune cell subsets using flow cytometry. Markers were compared by rank-sum tests or mixed-effects generalized linear models. P values were not corrected for multiplicity in this exploratory study. **Results:** Among 34 pts evaluable for EOTx response, 29 (85%) attained EOTx CR, and 22 (65%) achieved MidTx CR. Baseline cytokine levels were available for 22 pts, of whom 19 had EOTx CR, and 15 MidTx CR. No significant association was found between PreTx cytokine levels and CR at MidTx or EOTx. At C1D8, markers of T cell activation (IL2, IL7, IFNg, GZMA/B) increased overall (all P< 0.05), but only lower CTLA-4 levels significantly predicted MidTx CR (P=0.0031). Persistently lower CTLA-4 at MidTx also correlated with MidTx CR (P=0.008). No cytokine was significantly associated with EOTx CR. Flow cytometry (n=26) showed an overall increase in circulating NK cells on Tx (P<0.05 at all timepoints). Higher PreTx NK cell abundance significantly correlated with MidTx CR (P=0.043), while higher PreTx CD4+CD45RA+ (naïve helper T) cells (P=0.0035) and lower CD4+CD45RO+CD25- (memory helper) T cells (P=0.0061) were associated with EOTx CR. Increased NK (P=0.011) and HLA-DR+ NK cells (P=0.0042) at C2 also correlated with MidTx CR. Although the CD8+CD45RO+CCR7-CD27- effector memory T cell subset increased overall at MidTx (P=0.025), no CD8+ subset was predictive of CR at any timepoint. **Conclusions:** Although CD8+ T cells are the main effector cells engaged by mosunetuzumab, our observations in previously untreated FL/MZL suggest that increased naïve CD4+ helper T cells and NK cells PreTx, along with lower CTLA-4 levels during Tx may better predict CR. These findings suggest that cytokine-driven immune priming could influence response to BsAbs, providing a basis for future investigations of combinations therapies to enhance their efficacy. Descriptive epidemiology of Waldenström macroglobulinemia (WM): Demographics, outcomes, and predictors of survival in the US community oncology setting. First Author: Alisha Monnette Kimble, Ontada, Boston, MA

Background: WM is a rare, indolent subtype of non-Hodgkin lymphoma (NHL), comprising <2% of annual U.S. NHL cases. Natural history studies and registries often lack sufficient patient-level data about treatment patterns and outcomes. This study describes demographics, clinical characteristics, and outcomes of patients with WM treated in the community oncology setting. **Methods:** This retrospective cohort study included adults diagnosed with WM in the U.S. Oncology Network from 2014 to 2022, with follow-up through 2023. Data were sourced from the iKnowMed electronic health record system. Structured data were used to assess patient characteristics and overall survival (OS). Chart abstraction was performed on a random subset (n=200) to evaluate treatment characteristics and outcomes (i.e. OS, time to next treatment (TTNT), and real-world progression-free survival (rwPFS)). Multivariable Cox proportional hazard models evaluated factors associated with these outcomes. **Results:** Among 2,554 patients with WM (mean age: 72.7 years, SD: 10.1), majority were male (58.9%), and White (77.3%), consistent with SEER data reflecting the indolent nature of WM, with 82.1% alive at study conclusion and median OS was not reached. At 5-years, OS probabilities stratified by Modified Staging System for WM (MSS-WM) were 96.4% (low risk, N=135), 87.3% (low-intermediate risk, N=237), 69.2% (intermediate risk, N=267), and 50.9% (high risk, N=278; $p < 0.0001$), aligning with the externally validated MSS-WM model, demonstrating its utility in risk stratification. In the subset of 200 patients, 8.5% (N=17) had smoldering WM, and 23% (N=46) experienced disease progression. MYD88 L265P and CXCR4 mutations were present in 85.4% and 29% of patients, respectively, consistent with reported case series. Most (78%) patients initiated LOT 1 therapy. Treatment patterns aligned with NCCN guidelines, with BTK inhibitors and Rituximab-based regimens comprising 98% of LOT 1 therapies. In the multivariable model, area deprivation index was significantly linked to poorer OS (HR: 12.8, CI: 2.6–63.4), shorter TTNT (HR: 2.2, CI: 1.1–6.3) and worse rwPFS (HR: 4.1, CI: 1.2–14.3). Patients with a Charlson Comorbidity Index score ≥2, were more likely to discontinue treatment (HR: 2.2, CI: 1.3–3.5) and progress to next therapy (HR: 2.2, CI: 1.2–4.0). **Conclusions:** This natural history study of patients with WM treated in the community oncology setting confirms WM's indolent nature, with long survival and effective risk stratification using the MSS-WM. Real-world treatment patterns aligned to guidelines, while area-level socioeconomic factors and comorbidities highlighted disparities impacting outcomes. These findings emphasize the need for tailored, equitable care strategies and provide insights to enhance treatment approaches and address unmet needs in patients with WM. PET metabolic response in Lugano: Comparison of qualitative and quantitative outcome by independent central review. First Author: Danielle Phillippi, Clario, Philadelphia, PA

Background: The 2014 Lugano Criteria is the standard for radiographic assessment in lymphoma clinical trials, emphasizing qualitative evaluation of 18F-FDG PET-CT (PET) metabolic response (MR). In 2017, Van Heertum et al. introduced a quantitative approach defining strict percent change of standard uptake values (SUV) determination of MR, primarily for partial metabolic response (PMR) and progressive metabolic disease (PMD). Both Lugano and Van Heertum compared to baseline for determination of PMD, though industry practice frequently compare PMD to nadir. While both qualitative and quantitative approaches have been utilized in pivotal trials, few studies have compared qualitative and quantitative Lugano radiographic metabolic assessments to date. Thus, this study aims to investigate PET MR timepoint responses (TPRs) from blinded independent central review (BICR) radiologists using qualitative Lugano approach vs quantitatively derived TPRs. **Methods:** 3416 radiologist qualitatively assessed designated (desPET) responses consisting of PET TPR, 5PS, most-FDG avid lesion SUV, and liver SUV were analyzed. For desPET TPRs, radiologists compared MRs to baseline and nadir. We quantitatively derived PET (derPET) TPRs using the Van Heertum et al.,2017 %Δ utilizing SUV and 5PS, comparing to baseline and nadir, defining PMR as ≥25% decrease with a 5-point score (5PS) of 4 or 5; PMD as ≥50% increase with 5PS of 4 or 5; complete metabolic response (CMR) as 5PS of 1–3 without residual disease; and no metabolic response (NMR) as 5PS of 4 or 5, not meeting PMR or PMD criteria. To understand the merit of qualitative PET assessments, the desPET were compared to the derPET TPRs. Then, the desPET TPRs were compared among radiologists who reviewed the same case to determine concordance. **Results:** Results showed desPET differed from the derPET for 1198 TPRs (35.1%). When PMD was the derPET TPR, the desPET TPRs were: 270 PMD (53.9%), 134 NMR (26.8%) and 89 PMR (17.8%). When CMR was the derPET TPR, the desPET TPRs were: 830 CMR (51.7%), 634 PMR (39.5%), and 122 PMD (7.6%). When PMR was derPET TPR, desPET TPRs were: 177 PMR (61.9%), 55 NMR (19.2%), 51 PMD (17.8%). In the instances where desPET TPRs differed from the derPET, radiologists reviewing the same cases had concordance in desPET TPRs for 79.5% of cases. **Conclusions:** Our data show notable differences in PET MR when comparing derPET and desPET TPRs. Almost 20% BICR radiologists assessed a PMR, when our derived values were PMD and in over half the cases BICR radiologists assessed CMR when the derPET was PMR, thus suggesting that the quantitative approach results in more PD and fewer CR cases. When determining reader concordance, nearly 80% of readers aligned in desPET TPR when their TPRs differed from the derPET, suggesting that a qualitative assessment supports medical judgment in determining patient metabolic disease and consistency between readers assessments. Secondary primary malignancies (SPMs) with CAR-T cell therapy in RR-DLBCL from real-world data. First Author: Deevyashali Parekh, SUNY Upstate Medical University, Syracuse, NY

Background: Three CAR-T cell therapies i.e. axicabtagene ciloleucel, tisagenlecleucel and lisocabtagene maraleucel are currently approved for relapsed refractory DLBCL after 2 or more prior lines of treatment. Landmark trials have shown promising efficacy however, a notable concern with CAR-T therapy is the potential development of secondary primary malignancies. **Methods:** A retrospective study was performed using TriNetX, a global research de-identified database with data from 145 health care organisations as of January 2025. ICD-10 codes were used for associated diagnosis and medications. The database was queried to identify RR-DLBCL patients who had received any of axi-cel, tisa-cel or liso-cel. These treatments were set as the index event for outcome analysis. Demographics and prevalence of comorbidities were extracted. Outcome analysis queried for several hematological and solid tumor malignancies. The Measure of Association Analysis was used to calculate Odds Ratio. **Results:** 1842 adult patients with RR-DLBCL received one of the 3 CAR-T cell treatments as listed above and 12,431 patients with RR-DLBCL did not receive any of the 3 treatments. There were 1:1 propensity score matched adjusting for age, race, sex and tobacco use. Final number for both groups was 1842. For both cohorts, 1367 (73.8%) were white, 1055 were male (57%). The cohort had a mean follow up of 497 days, median follow up of 331.5 days. The CAR-T group had higher rates of MDS (3.9% vs 0.8%, p=<0.001) and AML (3.2% vs 1.2%, p=<0.001) in our database review of the US population. It did not show higher rates of other reported SPMs like Mature T/NK cell lymphoma, Hodgkin's lymphoma, multiple myeloma or solid tumours like lung, breast, prostate primary or malignant melanoma. Data on other SPMs is shown in Table 1. **Conclusions:** In our retrospective study of real-world population, RR-DLBCL patients who received CAR-T cell therapy with any of axi-cel, tisa-cel or liso-cel showed higher rates of MDS and AML compared to propensity matched patients with RR-DLBCL who did not receive CAR-T cell therapy while rates of other reported SPMs were not significantly different. Research Sponsor: None.

Frequency of SPMs in CAR-T receiving and no CAR-T receiving patients with RR-DLBCL.

SPM	Received CAR-T cohort (%)	Did not receive CAR-T cohort (%)	Odds Ratio	p-value
MDS	3.9	0.8	4.852 (2.767-8.507)	<0.001
AML	3.2	1.2	2.668 (1.624-4.382)	<0.001
Mature T/NK cell lymphoma	0.7	1.5	0.466 (0.238-0.909)	0.022
Hodgkin's lymphoma	0.9	1.9	0.469 (0.257-0.854)	0.011
Follicular lymphoma	3.8	3.6	1.055 (0.721-1.545)	0.781
Mantle cell lymphoma	1.0	0.5	1.792 (0.825-3.893)	0.135
Multiple Myeloma	1.4	2.4	0.566 (0.341-0.938)	0.025
Primary Lung site	0.7	0.5	1.292 (0.565-2.954)	0.543
Primary Breast site	0.5	0.7	0.815 (0.351-1.892)	0.634
Prostate cancer	0.5	0.6	0.902 (0.382-2.129)	0.814

Distinct outcomes with the detection of endemic Burkitt lymphoma, T-cell receptor (TCR) complementarity determining region-3s (CDR3s) matching known anti-HIV TCR CDR3s. First Author: Taha Huda, HCA Healthcare/USF Morsani College of Medicine GME: Bayonet Point Hospital, Hudson, FL

Background: The adaptive immune response is represented by diverse complementary determining region 3's (CDR3s), which frequently represent antigen contact points and can be obtained from sequencing data. In particular, T-cell receptor (TCR) CDR3s in tumors have added an additional dimension to investigating the role of viruses in tumor development. Further, identifying TCR V- and J-gene segment usage, HLA allele combinations has been shown to represent outcome distinctions in various cancers. Given that endemic Burkitt lymphoma (BL) is well-known to be caused by Epstein-Barr virus (EBV), we aimed to characterize endemic BL adaptive immune features using TCR recombination reads, focusing on anti-HIV CDR3s and the presence of specific TCR V/J, HLA allele combinations. **Methods:** The Cancer Genome Characterization Initiative – Burkitt Lymphoma Genome Sequencing Project provided data available at the Genomic Data Commons website: 160 RNA-seq files from primary tumor that represented 105 cases. Phenotypic data representing these cases included gender, race, age at diagnosis, days to last follow-up, vital status, and Ann Arbor pathologic stage. The RNA-seq files were mined for TCR recombination reads using a high-stringency search algorithm (Chobrutskiy et al. 2020) and for HLA alleles utilizing xHLA (Xie et al. 2017). Anti-HIV CDR3s and specific TCR V/J, HLA allele combinations were then correlated with the progression of endemic BL as measured by overall survival (OS) and staging. **Results:** 47,302 productive TCR CDR3 recombination reads were recovered across all samples. We identified that the 22 cases with anti-HIV *TRA* CDR3s had improved OS as compared to those without an anti-HIV *TRA* recovery (median OS not reached vs. 215 days; log-rank p = 0.0013). Similarly, the 74 cases with anti-EBV *TRA* CDR3s were associated with an improved OS as compared to remaining cases (median OS 437 vs. 164 days; log-rank p = 0.005). Decreased disease progression as measured by lower pathologic stage was also noted in patients with anti-HIV *TRA* and *TRB*s compared to remaining cases (Mann-Whitney U p-value: 0.05, 0.01 respectively). Lastly, we identified five TCR V/J, HLA allele combinations which were associated with survival where the individual V or J gene segment and HLA allele was not associated with survival. An example of this were 33 cases with TRAV12-3 and DQB1*05:01, whose OS did not reach the median compared to the 199-day median OS of all other cases (log-rank p = 0.01). **Conclusions:** Early control of tumor progression via the T-cell response, whether by increased anti-viral T-cell receptors or via effective combination of antigen presentation and TCR antigen binding, appears to impact the progression of BL. Specifically, the success of anti-HIV TCRs indicates that treating co-infection with HIV may be a key factor in slowing disease progression. Research Sponsor: None.

Effect of CD73 on immune escape via tryptophan metabolic reprogramming in diffuse large B-cell lymphoma. First Author: Yingfang Feng, Tianjin Medical University Cancer Institute and Hospital, Tianjin, China

Background: Immunotherapy is playing an increasingly important role in patients with relapsed or refractory DLBCL. Our previous studies have shown that high CD73 expression in DLBCL tumor cells correlates with poor prognosis and mediates immune escape. However, the underlying mechanism of CD73-mediated immune escape in DLBCL remains unclear. **Methods:** We analyzed RNA-Seq data from TCGA and de novo DLBCL patients at our center, comparing CD73 expression levels to identify enriched pathways related to tumor immune escape. These findings were validated in an syngeneic mouse model. To explore the mechanism by which CD73 regulates immune escape in DLBCL, we performed RNA sequencing and targeted tryptophan metabolism sequencing in cell lines. We further conducted co-culture, flow cytometry, Co-IP, ChIP-qPCR in vitro, and generated a mouse subcutaneous xenograft model for in vivo validation. **Results:** The syngeneic mouse model showed that CD73 knockdown significantly reduced tumor size compared to the control group, while increasing the infiltration of $CD8^+$ T cells and effector $CD8^+$ T cells in tumor tissue, and reducing $CD8^+$ T cell depletion. After systemic $CD8^+$ T cell depletion, the anti-tumor effect of CD73 monoclonal antibody was significantly weakened. RNA-seq and targeted tryptophan metabolism sequencing revealed a positive correlation between CD73 expression and tryptophan metabolism. In vitro, CD73 overexpression reduced ERK/c-Jun dephosphorylation by decreasing binding to INPPL1, leading to upregulation of IDO1 and TDO2 expression. Co-culture experiments showed weakened $CD8^+$ T cell proliferation in the CD73OE group compared to controls, while inhibition of IDO1/TDO2 significantly enhanced $CD8^+$ T cell proliferation, a result reversed in the knockdown group. The therapeutic effect of an IDO1/TDO2 inhibitor was assessed in an A20 mouse model, where both the AT-0174-treated vector and CD73 OE groups showed decreased tumor growth and increased $CD8^+$ T cell and effector $CD8^+$ T cell infiltration compared to the untreated group. Finally, we investigated whether combining CD73 monoclonal antibody with IDO1/TDO2 inhibitors could enhance immune cell infiltration in tumor tissues, and found that the combination treatment increased $CD8^+$ T cell infiltration. **Conclusions:** Our study uncovers a novel mechanism by which CD73 regulates immune escape in DLBCL through an adenosine-independent pathway. CD73 overexpression upregulates IDO1 and TDO2 levels by inhibiting ERK/c-Jun dephosphorylation via reduced binding to INPPL1. These findings offer new insights for combination therapies targeting CD73 in DLBCL patients with high CD73 expression. Research Sponsor: None.

Outcomes of patients treated for monomorphic B-cell post-transplant lymphoproliferative disorder: A single-center experience. First Author: Imran Nizamuddin, Washington University School of Medicine, St. Louis, MO

Background: Patients (pts) with monomorphic B-cell post-transplant lymphoproliferative disorder (B-PTLD) have poor outcomes and high treatment-related mortality (TRM). With risk-stratified sequential treatment (RSST), some can be treated with rituximab alone. We sought to evaluate predictors of outcome in newly diagnosed B-PTLD, including involvement of extranodal (EN) sites and allograft. **Methods:** Adults diagnosed at Siteman Cancer Center with confirmed B-PTLD from 1/1/2006–12/31/2024 were identified via electronic health records. Kaplan-Meier and log-rank tests were used to evaluate progression-free survival (PFS) and overall survival (OS). Univariate analyses were done using Fisher's exact and $\chi 2$ tests with a=0.05. **Results:** 106 pts with monomorphic B-PTLD were identified (Table). The most common graft types were kidney (33%), liver (26%), and lung (15%). After diagnosis, immunosuppression was reduced in 93 (88%) pts and 105 pts received systemic therapy. 56 (53%) pts received frontline chemotherapy (chemo), most commonly R-CHOP (68%, n=38) and DA-EPOCH-R (21%, n=12), and overall response rate (ORR) was 66% (complete response [CR] 57%). 49 (46%) pts initially received rituximab monotherapy, including 39 on RSST, with ORR 36% (CR 23%). 28 (72%) were escalated to chemo, including 7 (18%) pts who progressed prior to reimaging. Treatments used were R-CHOP (71%, n=20), Pola-R-CHP (21%, n=6), and DA-EPOCH-R (7%, n=2), with ORR 59% (CR 56%). With median follow up of 58 months (mo), median PFS and OS were 33 and 64 mo, respectively. Pts who did not have CR to rituximab had worse PFS vs responders (12 mo vs 86 mo, p=0.037) and OS (27 mo vs 86 mo, p=0.04). Factors predicting CR to rituximab included early stage (p=0.001) and absence of EN disease (p=0.005). Graft type, involvement of allograft, tumor EBV status, and gene rearrangements were not predictive. Following frontline therapy, 33 (31%) pts developed relapsed/refractory disease. Elevated LDH (p=0.021) and extranodal disease (p=0.032) at diagnosis predicted relapse. 13 (12%) pts experienced graft failure, and 6 (6%) required repeat transplant. Discontinuation of antimetabolites was associated with higher rates of graft failure (p=0.020). 51 (48%) pts died, 8 (16%) due to TRM. **Conclusions:** In a large cohort of B-PTLD, ORR to rituximab on RSST and chemo confirm prior data. Pts with lack of response to rituximab monotherapy, EN disease, and elevated LDH have worse outcomes. Despite advances, TRM remains high in PTLD. Research Sponsor: None.

Demographics and predictors of response to rituximab.

Variable	Median (range)	Variable	n (%)	OR (response to rituximab)	p-value

Clinical and biological subtypes of follicular lymphoma revealed by tumor and immune cell states. First Author: Hengqi Liu, Department of Lymphoma, Tianjin Medical University Cancer Institute and Hospital, Tianjin, China

Background: Follicular lymphoma (FL) exhibits considerable variability in biological features and clinical trajectories, compounded by a complex tumor microenvironment (TME) populated with nonmalignant immune cells. In this study, we comprehensively characterized FL by integrating multi-omics data that considered both tumor cells and microenvironmental components. This analysis revealed four subtypes of FL, each exhibiting distinct biological characteristics and differing clinical behaviors. **Methods:** Our study included 1,203 samples, 53 bulk transcriptomic samples from our center, 1,150 samples from public databases, and five single-cell RNA sequencing (scRNA-seq) cohorts. The Ecotyper algorithm was employed to identify immune cell states. Unsupervised clustering analysis using non-negative matrix factorization (NMF) was performed to identify distinct FL subtypes based on cellular infiltration. **Results:** A total of 30 unique cell states were identified from nine annotated cell populations (B cells, plasma cells, CD4 T cells, CD8 T cells, Tregs, NK cells, Tfh, monocytes/macrophages, and dendritic cells). Validation was performed across three independent scRNA-seq and bulk transcriptomic cohorts to ensure robustness. Four distinct B cell states were identified, each exhibiting unique gene expression profiles and varying prognostic implications. B cell S2 and S3 were associated with adverse outcomes. Notably, PRDM15 in B cell S2 had the most significant prognostic impact, remaining an independent adverse prognostic factor even after adjustment for m7-FLIPI. Mutational profile analysis demonstrated distinct mutation patterns across B cell states: mutations in CCND3, SPEN, and ARID1A were enriched in B cell S1; CREBBP and STAT6 mutations were prominent in B cell S2; and IRF8 and BCL2 mutations were observed in B cell S4, while no significant mutation enrichment was detected in B cell S3. Similarly, immune cells of the same type yet in different states exhibited functional and clinical heterogeneity. Four subtypes of follicular lymphoma characterized by distinct tumor cell states and varying immune infiltration were identified through unsupervised clustering analysis. FLE1 exhibits characteristics of a "cold tumor" with a high abundance of B cell S2. In contrast, FLE2 and FLE3 show moderate immune infiltration, while FLE4 is marked by abundant immune infiltration and elevated expression of immunosuppressive checkpoint molecules, resembling an "inflammatory" tumor phenotype. Prognostic analysis indicates that FLE1 has the most unfavorable prognosis, followed by FLE4. **Conclusions:** Our study stratifies FL patients based on the heterogeneity of tumor cells and the immune microenvironment, proposing an immune-based classification for FL. Targeting CREBBP and PRDM15 may offer promising new strategies for the clinical management of patients exhibiting a "cold tumor" phenotype. Research Sponsor: None.

Clinical outcomes of hemophagocytic lymphohistiocytosis in patients with HIV-related lymphomas: A multicentre observational study. First Author: Alessia Dalla Pria, Department of Oncology and National Centre for HIV Malignancy, Chelsea and Westminster Hospital, London, United Kingdom

Background: Secondary Hemophagocytic Lymphohistiocytosis (HLH) is a rare and potentially fatal inflammatory disorder triggered by infections, malignancies, autoimmune diseases or drug reactions. A very limited body of evidence is available regarding HLH in people living with HIV (PLWH). The aim of this report is to evaluate the frequency, clinical characteristics and outcomes of HLH in a multicentre cohort of patients with HIV-related lymphomas (HRL). **Methods:** We retrospectively reviewed prospectively collected data of HRL patients treated at the National Centre for HIV Malignancy, Chelsea and Westminster Hospital, London (2013- 2024) and at the Department of Infectious Diseases at St. Joseph Hospital Berlin-Tempelhof, Germany (2020-2024). The diagnosis of HLH was based on both the HLH-2004 diagnostic criteria and the H-Score Saint Antoine. Statistical analyses were performed using IBM SPSS software. **Results:** We enrolled 253 patients in this study (17.4% female at birth; median age = 48.6 years, range 21.3 – 82.9). Median CD4 count was 206 cells /μL (range, 3-1.610) with 124 patients (49.2%) having a CD4 cell count $<$200/μL. Mean HIV viral load (VL) was 182.458 cop/mL (range, 0-26.000 .000), with 140 (55.3%) being undetectable at the time of lymphoma diagnosis. 206 (81.4%) had advanced stage disease, III (14.4%) or IV (67%). Median follow-up was 31 months and the 5-year overall survival was 51.3%. At the time of lymphoma diagnosis, 35 patients (13.5%) were diagnosed with HLH with an H-Score $\geq$169 points and/or $\geq$ 5/8 HLH criteria with a median age of 45.7 years (range 22.8-64.2), whereas 24 patients (9.5%) had an H-Score $\geq$ 200 points. HLH was present in 25% of patients with Primary Effusion Lymphoma, followed by 24.2% in Burkitt Lymphoma, 18.7% in Hodgkin´s Lymphoma, 9.5% in Plasmablastic Lymphoma, and 6.6% in Diffuse-large-B-cell Lymphoma. HLH patients were more likely to be diagnosed with HIV and lymphoma simultaneously (*p=0.001*), less likely to have a suppressed HIV-VL (31.4% vs 61%; $p < 0.01$) and had a lower median CD4 count (102 vs. 239 cells/μL; $p < 0.01$). A significant correlation was identified between a lower CD4 count and a higher H-Score in the bivariate analysis. Patients with HLH demonstrated a significantly poorer outcome with 1-, 2-, and 5-year overall survival of 41.2%, 32.4% and 11.8% compared to patients without HLH ($p < 0.01$). **Conclusions:** HLH is considerably more frequent in HRL in comparison to lymphomas affecting the general population. Outcome is poor and comparable to published data in HIV-negative cohorts. The acquired immune disfunction and the complex interplay of HIV and oncogenic viruses such as EBV and HHV8 in this population creates multiple potential triggers for this fatal inflammatory disorder of which the immunopathological basis is yet to be understood. Research Sponsor: None.

Effect of pre-biopsy steroids on diagnostic yield in diffuse large B-cell lymphoma (DLBCL). First Author: Sathwik Madireddy, Brown University Health, Providence, RI

Background: DLBCL is an aggressive lymphoma, and patients (pts) often require urgent steroid administration for symptom relief or organ compromise prevention. Steroids before biopsy are avoided due to concerns about diagnostic accuracy. This supposition remains underexplored, with limited evidence supporting this practice. **Methods:** A retrospective chart review of pts with a diagnosis of DLBCL at Brown University Health between 2015 and 2024 was conducted for baseline demographics, steroid administration within 30 days of first biopsy, type and dose of steroids, markers of disease severity, type of biopsy, and biopsy results. Exclusion criteria included relapsed/refractory DLBCL. Statistical analysis was conducted using Chi-square test, T-test, and logistic regression. **Results:** 365 pts met inclusion criteria, of whom 65 received steroids prior to their first biopsy. Both steroid-treated and steroid-naive pts had similar baseline demographics (age) and markers of disease severity (LDH, "Double HIT" status, IPI score, and Stage), ($p > 0.05$). Both groups had similar rates of diagnostic first biopsies ($p > 0.05$). After initial negative biopsies, similar rates of diagnostic repeat biopsies were observed. Neither group had a significant difference in treatment delay from initial negative biopsy to start of chemotherapy ($p > 0.05$). Logistic regression analysis showed no statistical significance in the relationship between total dose of steroids and the likelihood of a diagnostic biopsy result (p = 0.07). Type of biopsy influenced diagnostic yield: fine needle aspiration (n = 32) was inferior with 28% diagnostic biopsies compared with core needle, excisional or incisional biopsies (n = 284) at 88% ($p < 0.001$). **Conclusions:** No significant differences were observed in biopsy success rates or treatment delays between steroid-treated and steroid-naive patients. These results support the safe use of corticosteroids when clinically indicated. Notably, biopsy type, rather than steroid exposure, was the primary determinant of diagnostic success, with fine needle aspiration yielding significantly lower diagnostic rates. These findings reinforce the importance of biopsy selection and support corticosteroid use without compromising diagnostic accuracy. Research Sponsor: None.

Characteristics	Steroids-treated (n=65)	Steroid-naive (n=283)	P value
Age (years), mean (95% CI)	67 (64 - 70)	67 (65 - 69)	0.805
Advanced Stage, proportion (95% CI)	64.15%	71.48%	0.286
LDH (U/L), mean (95% CI)	392 (297 - 487)	364 (315 - 413)	0.637
Percent "Double Hit"	13.85%	9.54%	0.304
Percent first biopsy diagnostic	86.67%	81.79%	0.219
Percent repeat biopsy diagnostic	87.50%	97.92%	0.116
Days from first negative biopsy to treatment, mean (95% CI)	39.5 (12.6 - 66.4)	50.7 (42.9 - 58.5)	0.327
Total steroid dose in prednisone equivalents (mg), mean (95% CI)	261 (193 - 329)	0	N/A
Total days on steroids, mean (95% CI)	6.8 (4.5 - 9.1)	0	N/A

7073 Poster Session

The optimized HLH inflammatory index: A novel prognostic tool for newly diagnosed patients with diffuse large B-cell lymphoma—Discovery and validation. First Author: Adi Zoref Lorenz, Meir Medical Center, Faculty of Medicine and Health Sciences, Tel Aviv University, Kfar Sava, Israel

Background: The Optimized HLH Inflammatory (OHI) index (Zoref-Lorenz et al., *Blood*, 2022), based on serum soluble CD25 (sCD25) and ferritin, is a prognostic tool identifying inflammation in the hemophagocytic lymphohistiocytosis (HLH) spectrum and early mortality risk. Prior studies were retrospective and enriched with HLH-suspected cases. We hypothesized that the OHI index would predict outcomes in unselected diffuse large B-cell lymphoma (DLBCL). **Methods:** 670 newly diagnosed DLBCL patients from a prospective cohort (2002–2015) were analyzed: 335 for discovery and 335 for validation. Pre-treatment serum sCD25 and ferritin levels were quantified via ELISA, and we evaluated original thresholds (sCD25 $\geq$ 3,900 U/mL; ferritin $\geq$ 1,000 ng/mL) and developed DLBCL-optimized thresholds (using receiver operator curves) for predicting 500-day mortality. We also evaluated event-free survival (EFS), EFS at 24 months (EFS24), and overall survival (OS). **Results:** The median age was 64, and 51% were male. Using original thresholds, 4.2% (n=14) of patients were OHI+, with a 5.6-fold higher risk of 500-day mortality (95% CI 1.6–17; p$<$0.001). Optimized thresholds identified 23.6% (n=78) as OHI+ with a 9.2-fold higher 500-day mortality risk (95% CI 4.0–24; p$<$0.001). Optimized OHI+ also had a higher risk of EFS24 failure and inferior EFS and OS (Table). OHI+ patients had higher rates of B symptoms (35% vs. 20%; p=0.027), elevated LDH (76% vs. 34%; p$<$0.001), worse performance status (ECOG $\geq$2: 38% vs. 12%; p$<$0.001), and advanced-stage disease (Stage IV: 57% vs 38%; p$<$0.001), though IPI scores (3–5) were not significantly different (44% vs 36%; p=0.28). Adjusting for age and IPI, OHI+ independently predicted 500-day mortality (OR=5.0; CI 1.9–13; p=0.001), EFS24 failure (OR=3.2; CI 1.5–6.5; p=0.0018), and inferior long-term EFS (HR=2.2; CI 1.1–4.3; p=0.030) and OS (HR=2.0; CI 1.0–4.0; p=0.040) at a median follow up of 9.8 years in living patients. In validation, optimized OHI predicted 500-day mortality, EFS24 failure, and long-term OS and EFS (Table). Cytokine profiling revealed elevated inflammatory markers in OHI+ patients, including IL1a (p=0.008), CCL2 (p=0.03), CXCL10 (p$<$0.001), and CXCL9 (p$<$0.001), reflecting systemic hyperinflammation. **Conclusions:** The OHI index is a powerful predictor of early and long-term outcomes in DLBCL patients. Optimized thresholds identify a larger OHI+ group, highlighting hyperinflammation's critical role in poor outcomes. These findings support its use in routine management and clinical trial design for novel therapies. Research Sponsor: ASCO-ICRF; Conquer Cancer, the ASCO Foundation; The Varda and Boaz Dotan Research Center for Hemato-Oncology Research.

Odds ratios or hazard ratios and p-values for optimized OHI+ and DLBCL prognosis.

Outcome	Discovery	Validation
OR for 500-day mortality	9.2; p$<$0.001	4.0; p=0.002
OR for EFS24 failure	5.2; p $<$0.001	6.3; p$<$0.001
HR for OS	2.3; p$<$0.001	1.8; p=0.006
HR for EFS	2.4; p$<$0.001	2.5; p$<$0.001

7074 Poster Session

The effect of patient self-reported confidence on psychosocial outcomes in the context of lymphoma and chronic lymphocytic leukaemia. First Author: Steve Kalloger, Lymphoma Coalition, Las Vegas, NV

Background: Adverse psycho-social outcomes (APSO's) are common side effects often underreported which have great impact on the wellbeing of patients with lymphoma or chronic lymphocytic leukemia (CLL). As patient's traverse through their unique cancer journey, relationships with their care team yield varying degrees of confidence. We explored how confidence in both the management of their care and in the doctor coordinating their care was associated with various APSO's. **Methods:** A cross-sectional, anonymous online global survey directed at patients with lymphoma or CLL was deployed in 2024. Two questions asked how confident the patient feels about 1) the management of their care (MOC) and 2) the doctor coordinating their care (DCC). Patients were split into dichotomous groups who were and were not confident. Nominal logistic regression was used to explore how answers to these two questions influenced the prevalence of 19 different APSO's controlling for age and biological sex. Results were expressed in odds ratios with 95% confidence intervals. **Results:** Responses were received from 5,186 patients with 64% female and a median age of 61 [20-96]. Significantly increased incidence of APSO's associated with a lack of confidence in the MOC included: conflicts between beliefs and cancer treatment OR = 2.3 [1.4 – 3.6]; loss of meaning/purpose OR = 1.9 [1.5 – 2.4]; depression OR = 1.7 [1.4 – 1.99]; grief/loss OR = 1.6 [1.3 – 1.96]; loss of interest in usual activities OR = 1.6 [1.3 – 1.9]; post-traumatic stress disorder OR = 1.5 [1.2 – 1.98]; isolation/loneliness OR = 1.5 [1.3 – 1.9]; feelings of worthlessness/being a burden OR = 1.5 [1.2 – 1.9]; loss of self-esteem OR 1.5 [1.2 – 1.8]; anxiety OR = 1.5 [1.2 – 1.7]; fear of incapacitation OR = 1.4 [1.1 – 1.7]; changes in relationships OR = 1.3 [1.1 – 1.6]; worry OR = 1.3 [1.1 – 1.5]. APSO's that significantly increased due to a lack of confidence in DCC included: anger OR = 1.6 [1.2 – 2.0]; isolation/loneliness OR = 1.5 [1.2 – 1.9]; fear of incapacitation OR = 1.5 [1.1 - 1.9]. The remaining APSO's examined failed to produce significant differences regarding patient confidence levels. This analysis illustrates that approximately 73% of the APSO's reviewed in our survey had significant odds of being associated with patients who reported a lack of confidence in their MOC or the DCC. **Conclusions:** These results suggest that patients with low confidence in the management of their care plan and in the doctor coordinating their care may disproportionately experience APSO's. It is important that care teams take time to build relationships with their patients to help reinforce confidence in their care. In doing so the patient might experience fewer APSO's. Going forward, we plan to explore the effect of general practitioner involvement on patient confidence and the effect confidence has on physical side effects experienced by patients with lymphoma and CLL. Clinical characteristics and treatment outcomes of hepatosplenic T-cell lymphoma: Mayo Clinic experience. First Author: Syeda A. Mina, Mayo Clinic, Rochester, MN

Background: Hepatosplenic T-cell lymphoma (HSTCL) is a rare, aggressive peripheral T-cell lymphoma arising primarily from $\gamma\delta$ T-cells. It carries a poor prognosis and resists conventional chemotherapy. Most reports on HSTCL are case-based. This study comprehensively analyzes a large cohort, evaluating treatment strategies and survival outcomes. **Methods:** This retrospective study included patients (pts) with pathologically confirmed HSTCL diagnosed between 2000-2024, consecutively seen at Mayo Clinic MN. Clinical, pathological, genomic, and treatment-related data were extracted when available. Descriptive statistics were used to summarize baseline characteristics. Time-to-event analyses, including Kaplan-Meier estimates, median overall survival (OS), and survival time estimates were conducted from the date of diagnosis. **Results:** A total of 20 patients with newly diagnosed HSTCL were included, with a median age of 57 years (range: 35-71). The cohort was predominantly male (70%) and non-Hispanic (93%). Molecular data was available for five patients, revealing abnormalities in *STAT5B, MLL3 deletion, TP53, EZH2, TERT*, and *NF1 E291D*. The median follow-up was 27.6 months (m) with a median OS of 17.6 m (95% CI: 11.2 - NA). First-line treatment was anthracycline-based in 68% of pts and non-anthracycline-based in 32%, with higher response rates in the latter group (50% vs.83%). Although non-anthracycline regimens showed a trend toward improved 3-year OS (100% vs. 29%) the difference was not statistically significant (p = 0.16). Achieving a complete response to first-line therapy was also associated with a trend towards a better 3-year OS compared to refractory disease (80% vs. 50%, p = 0.17). Most pts (79%) underwent hematopoietic stem cell transplant (HSCT), primarily allogeneic, with only one receiving autologous HSCT. First-line therapy before HSCT was evenly distributed between anthracycline (55%) and non-anthracycline (45%) regimens. HSCT recipients had significantly higher 3-year OS than non-recipients (83% vs. 33%, p = 0.017). Notably, the patient with a TP53 mutation has remained in remission for over a year post-allogeneic HSCT. **Conclusions:** HSTCL predominantly affects younger pts, with nearly half dying within a year. Allogeneic HSCT, rarely used in other NHL subtypes, improved survival. Non-anthracycline regimens and achieving CR trended toward better outcomes. Our study, leveraging a sizable cohort, highlights the need for targeted research and novel therapies to improve HSTCL management. Research Sponsor: None.

Summary of survival outcomes in HSTCL.

Characteristics	Median OS (y)	3-Year OS (95% CI)
	1.48 [0.93- NA]	46% [0.26 - 0.81]
Transplant		
Transplant	NA [NA - NA]	83% [0.58 - 1.00]
No Transplant	1.02 [0.93 - NA]	33% [0.07 - 1.00]
Treatment		
Anthracycline Based	1.02 [0.36 - NA]	29% [0.11 - 0.73]
Non-Anthracycline Based	4.61 [NA- NA]	100% [1.00 - 1.00]

Influence of HIV on outcomes in patients with diffuse large B cell lymphoma treated with CD19 targeting CAR-T cell therapy. First Author: Shanawar Ali Waris, West Virginia University, Department of Internal Medicine, Morgantown, WV

Background: HIV+ patients have an 18-fold increased risk of developing diffuse large B Cell Lymphoma (DLBCL). There is uncertainty in the literature regarding the safety and efficacy of chimeric antigen receptor T-cell (CAR-T) therapy in HIV+ patients. This study aims to evaluate the influence of HIV infection on outcomes in patients treated with CD19 targeting CAR-T therapy. **Methods:** This is a multicenter retrospective cohort study that included patients with co-diagnosis of DLBCL and HIV who received a CD19 targeting CAR-T in the TriNetX Network, a database of deidentified electronic medical records with over 130 million patient records. Outcomes comprised of 5-year mortality, development of cytokine release syndrome (CRS), development of immune effector cell-associated neurotoxicity syndrome (ICANS), risk of infection, hypogammaglobinemia, and treatment with Tocilizumab, G-CSF, or IVIG. **Results:** Eighty-one patients met inclusion criteria. The mean current age was 62 years old, 75.6% were White, 16.3% were Black, 11.6% were Asian, and 73.3% were male. Approximately 72% of patients received Fludarabine/Cyclophosphamide, while 19% received Bendamustine as lymphodepletion chemotherapy. Within the cohort, 42% died within 5 years; 58% developed infection following treatment with CD19 targeting CAR-T therapy. The risks for CRS and ICANS were 65% and 14%, respectively; 53% treated with tocilizumab. Approximately 46% of patients developed hypogammaglobinemia; 31% were treated with IVIG, and 44% were treated with G-CSF. Further analysis to assess effect of development of CRS on outcomes showed no significant difference in survival probability among patients with or without CRS. **Conclusions:** CD19 CAR-T therapies have emerged for patients with refractory or relapsed DLBCL; however, HIV+ patients have been excluded from all registration CAR-T Cell clinical trials. Compared to the general population, our study demonstrates HIV+ patients with DLBCL have a similar mortality and morbidity rates when treated with CD19 targeted CAR-T therapy, indicating that in the future perhaps these patients should not be excluded from clinical trials. Research Sponsor: None.

Outcomes	Patients in Cohort	Patients with Outcome	Risk (%)
Mortality	81	34	42%
CRS	81	53	65.4%
CRS Grade 1 or 2	81	21	25.9%
CRS 3, 4, or 5	81	20	24.7%
ICANS	81	11	13.6%
Overall Infection	81	47	58%
Bacterial Infection	81	24	29.6%
Viral Infections	81	23	28.4%
Treatment with Tocilizumab	81	43	53.1%
Hypogammaglobulinemia	81	37	45.7%
Treatment with IVIG	81	25	30.9%
Treatment with G-CSF	81	36	44.4%

Frontline brentuximab vedotin (BV) and CHP in patients (pts) with peripheral T-cell lymphoma (PTCL) with <10% CD30 expression: Primary analysis results from the phase 2 SGN35-032 study. First Author: Swaminathan P. Iyer, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: BV, an antibody-drug conjugate targeting CD30, has shown single-agent activity in lymphomas with low CD30 expression. The combination of BV plus cyclophosphamide, doxorubicin, and prednisone (A+CHP) was effective in pts with PTCL with CD30 ≥10%. We report primary analysis results of frontline A+CHP in pts with non-systemic anaplastic large cell lymphoma (non-sALCL) PTCL with CD30 <10%. **Methods:** SGN35-032 (NCT04569032) is an open-label, multicenter, phase 2 study. Pts received 21-day cycles of A+CHP (BV 1.8 mg/kg, cyclophosphamide 750 mg/m^2, and doxorubicin 50 mg/m^2 by IV infusion on day 1 of each cycle and prednisone 100 mg by mouth daily [days 1-5]) up to 6-8 cycles. The primary endpoint, objective response rate (ORR), was assessed by blinded independent central review per Cheson 2007. Secondary endpoints included safety and complete response (CR) rate, PFS, OS, and duration of response (DOR). Efficacy endpoints are reported per central CD30 assessment unless otherwise noted. A genAI tool (12/13/24; Pfizer; GPT-4o) developed the 1st draft; authors assume content responsibility. **Results:** As of Jul 22, 2024, 82 pts received ≥1 dose of A+CHP, including 34 in the CD30 <1% cohort and 48 in the CD30 1% to <10% cohort per local CD30 assessment. At data cutoff, all pts were off study treatment. Overall median age was 63.5 y; most pts were male (56%), were White (77%), had an IPI score of 2-3 (66%), and had an ECOG PS ≤1 (90%). The most common (≥10%) disease subtypes were PTCL-not otherwise specified (45%), angioimmunoblastic T-cell lymphoma (32%), and nodal PTCL with T-follicular helper phenotype (10%). Overall median duration of treatment was 18.0 w (range, 3-24). The ORR at treatment completion was 77% (95% CI, 66.2-85.4) with a CR rate of 63% (95% CI, 52.0-73.8). Median (95% CI) PFS and OS were 12.7 mo (9.0-not estimable [NE]) and not reached (NR; 24.4-NE). Median (95% CI) DOR was 15.9 mo (8.3-NE), but NR in either cohort. Other efficacy parameters per cohort are listed in the table. Most pts (95%) had a treatment-emergent adverse event (TEAE), with 59% having a grade ≥3 TEAE. The most common (≥10%) overall grade ≥3 TEAEs were neutropenia (18%), febrile neutropenia (17%), and anemia (10%). Treatment-related grade 5 TEAEs were reported in 2 pts (2%); 19 pts (23%) reported a BV-related serious TEAE. **Conclusions:** As a frontline therapy, A+CHP demonstrated clinically meaningful efficacy in pts with non-sALCL PTCL regardless of CD30 expression, with a safety profile consistent with the label. Clinical trial information: NCT04569032. Research Sponsor: Pfizer.

ALK-positive anaplastic large cell lymphoma: Statistics and survival trends. First Author: Hassan Ali, Mercy Catholic Medical Center, Darby, PA

Background: Anaplastic lymphoma kinase positive anaplastic large cell lymphoma (ALK+ ALCL) is a rare subtype of peripheral T-cell lymphoma, characterized by CD 30+ large pleomorphic lymphoid cells with horseshoe nuclei and abundant cytoplasm. It frequently involves t(2;5) combining ALK with nucleophosmin (NPM1) gene. ALK+ ALCL is chemotherapy responsive, and CHOP, CHOEP (CHOP+etoposide) or BV-CHP (brentuximab instead of vincristine) are the popular drug combinations used. **Methods:** We extracted ALK+ ALCL cases using the ICD Code 9714/3, from Surveillance, Epidemiology and End Result (SEER) database Research Plus Data, 17 Registries, Nov 2023 Sub (2000-2021). The analysis was stratified based on age, sex, race, primary site labelled, laterality, stage, median household income inflation adjusted to 2022, and treatment options utilized. Survival curves were compared using the Log-Rank test (GraphPad Prism). **Results:** Total 3916 cases of ALK+ ALCL were identified, with median age at diagnosis of 53.5 years. Of the cases, 61% were males. Racial distribution was noted as: Caucasians 63.2%, Hispanics 16.1%, Blacks 12.4%, Asian/Pacific Islanders 6.7%, American Indians/Alaskan and unknown race were <1%, each. Overall median of survival (MoS) was 118 months, with 1-year OS of 0.696 (CI 95%, 0.68-0.71), 3-year OS of 0.61 (CI 95%, 0.596-0.63), and 5-year OS of 0.57 (CI 95%, 0.56-0.59). MoS were significant for Age: 0-30 yrs (undefined), 31-60 (233), 60+ yrs (17) (p <0.0001); Gender: males (94) and females (153) (p 0.0011); Race: White (119), Black (49), Hispanics (118), Asian/Pacific Islanders (180), Alaskan/Native Americans (87), and unknown race (undefined) (p <0.0001); Laterality: right (162), left (173), bilateral (144), and unknown side (66) (p <0.0001). Survival based on stage was undefined for loco-regional disease, 67 for distant and 65 months for unknown stage (p <0.0001). Anatomically, analysis revealed higher MoS with connective tissue (179), head/face/neck (72), and lymphoid origin (119); while lower survival with GI (21), thorax (13), and unknown site (7) (p <0.0001). MoS improved with increasing income, <70,000$ (73), 70K-100K (129), and >100K (135) (p <0.0001). Treatment based analysis showed: surgery (151) vs no surgery (100) (p <0.0001), chemotherapy (182) vs no chemo (27) (p <0.0001), radiotherapy (XRT) (173) vs no XRT (108) (p <0.0001). Undefined MoS were likely observed due to insignificant numbers of death in those age categories to calculate 50% survival probability. **Conclusions:** ALK+ ALCL is a rare malignancy that favors male gender, and Caucasian race. Our analysis revealed superior survival outcomes associated with younger age, female sex, Asian/Pacific Islander origin, connective tissue involvement, unilateral and loco-regional disease, and treatment involving either surgery or non-surgical options, specifically chemotherapy. This is the first study to our knowledge to establish association of ALK+ ALCL to income, showing higher survival with increasing income bracket. Research Sponsor: None.

Safety and efficacy of chimeric antigen receptor (CAR)—T cell therapy (BRG01) targeting the Epstein-Barr virus (EBV) envelope protein in EBV+ lymphoproliferative disease patients. First Author: Xinfeng Chen, The First Affiliated Hospital of Zhengzhou University, Zhengzhou, Henan, China

Background: Epstein-Barr virus (EBV) is a type I carcinogen which has infected more than 95% of population. EBV infection is closely associated with infectious mononucleosis and various malignancies. The envelope glycoprotein gp350 is present on EBV-infected host cells and serves as a potential tumor-specific antigen for the treatment of EBV$^+$ solid tumors like nasopharyngeal cancer as reported previously (NCT05864924)[1,2]. Anti-gp350 CAR-T also demonstrated robust inhibition for EBV replication and lymphoproliferation in a humanized mouse EBV infection model[3]. Here we explored the safety and efficacy of anti-gp350 CAR-T (BRG01) against EBV$^+$ T cell lymphoproliferative disease (LPD) in an exploratory pilot trial study. **Methods:** Patients with EBV$^+$ T cell LPD failing at least two lines of standard therapies were enrolled. Other criteria include EBER$^+$ and Gp350$^+$ expression on tumor biopsies. A single dose of EBV CAR-T cells (BRG01) were infused after a lymphodepletion regimen (cyclophosphamide 250-350 mg/m^2/day, fludarabine 25-30 mg/m^2/day for three days). Safety profile, pharmacokinetics (PK), EBV DNA copy number in the peripheral blood and tumor burden were monitored after BRG01 treatment. **Results:** From September 2021 to June 2023, a total of three patients with EBV$^+$ T cell LPD, subject 01, 02 and 03 were treated with 3*10^6/kg, 9*10^6/kg and 1.5*10^7/kg BRG01 respectively. The cells expanded and proliferated well in the patients. The EBV DNA copies in the peripheral blood of subject 01 and 03 decreased significantly post BRG01 infusion and remained at less than 500 copies/ml for subject 02. The disease control rate for the three patients is 100% (3/3) and the overall response rate is 66.7% (2/3) based on Lugano 2014 criteria. One patient showed complete metabolic remission 28 days post 9*10^6/kg BRG01 infusion and remained disease free for over three years. **Conclusions:** BRG01 is well tolerated and expanded in all treated patients. The durabler efficacy in all treated patients supports its further clinical investigation in various subtypes of EBV$^+$ lymphomas and LPD. 1. Second primary malignancy in patients with diffuse large B-cell lymphoma (DLBCL) receiving chimeric antigen receptor T-cell (CAR T) therapy and other systemic anti-cancer therapy: A real-world data analysis. First Author: Matthew Alexander Lunning, University of Nebraska Medical Center, Omaha, NE

Background: CAR T therapy is a recent class of treatment for DLBCL and has been linked to the development of second primary malignancy (SPM), specifically T-cell malignancies. This study compared the risk of SPM in patients (pts) with DLBCL receiving CAR T therapy vs other systemic anti-cancer therapy (SACT). **Methods:** Adult pts with a diagnosis of DLBCL who received CAR T therapy or other SACT as second or higher line of therapy (LoT) were identified from Komodo Health claims data (10/18/2017–1/31/2024). Incident SPM (first diagnosis in pts with no history of that malignancy) was assessed from index treatment initiation through earliest report of death, disenrollment from medical coverage, or data cutoff (4/30/2024). Cumulative incidence of SPM was calculated using the Aalen–Johansen estimator with baseline risk factors, including previous treatments and number of prior LoTs (pts may contribute to multiple LoTs), demographic and lifestyle factors, and comorbidity history balanced between the treatment groups using inverse probability of treatment weighting. **Results:** The study assessed a total of 1079 (CAR T therapy) and 5836 (SACT) LoTs over a median follow-up of 10.6 months (IQR 4.3–24.3). The risk of SPM (95% CI) at 3 years post-index tended to be nominally lower in the CAR T therapy group vs the SACT group for any (37.2% [33.4, 40.7] vs 41.6% [35.5, 48.7]), hematologic (27.4% [23.8, 30.7] vs 28.5% [22.8, 35.0]; excluding DLBCL relapse), solid (14.7% [12.3, 17.1] vs 18.4% [14.8, 23.0]) (Table) and T-cell (2.6% [1.7, 3.8] vs 4.3% [2.8, 5.9]) SPM. A sensitivity analysis identifying SPM using ≥2 ICD-10 codes showed similar associations. In another sensitivity analysis excluding SPMs occurring in the first 3 months of follow-up, the risk in the CAR T therapy group remained nominally lower for any, solid, and T-cell SPMs, and higher for hematologic SPM, compared with the SACT group (Table). **Conclusions:** A large proportion of pts with DLBCL experienced SPMs with current treatment options. At 3 years post-index, there was no evidence of an increased risk of SPM in pts treated with CAR T therapy compared with those receiving SACT. Longer term studies are needed to confirm this observation. Research Sponsor: Regeneron Pharmaceuticals, Inc.

Cumulative incidence (%) and 95% CI of SPM at 3 years post-index.

SPM	Analysis	SACT	CAR T therapy	p-value

A phase I/II trial of high-dose methotrexate (HDMTX) followed by prophylactic glucarpidase in patients with impaired renal function and central nervous system lymphoma (CNSL). First Author: Sven Liebig, Department of Hematology, Oncology and Cancer Immunology (Campus Benjamin Franklin), Charité – Universitätsmedizin Berlin, Corporate Member of Freie Universität and Humboldt-Universität Zu Berlin, Berlin, Germany

Background: HDMTX is a key component of treatment protocols for CNSL patients (pts), but impaired renal function in elderly or comorbid pts limits its use. The recombinant enzyme glucarpidase rapidly hydrolyzes MTX into non-toxic metabolites and is approved for therapeutic use in pts with delayed MTX elimination following HDMTX. We conducted a phase I/II study (NCT04841434) to assess the efficacy of prophylactic glucarpidase in HDMTX-treated pts with renal impairment or a history of delayed MTX elimination. **Methods:** A total of 18 pts with CNSL and pre-existing renal insufficiency (glomerular filtration rate [GFR] 40–80 mL/min) or a history of renal failure post-HDMTX were treated with up to six HDMTX cycles. HDMTX was given as a 4-hour infusion at three dose-escalation levels (3.0, 3.5, and 4.0 g/m²; 6 pts each). Glucarpidase (2000 U IV) was administered in each cycle 24 hours after start of HDMTX. The coprimary endpoints were safety and pharmacological efficacy of glucarpidase. Plasma concentrations of MTX and its metabolites were monitored using combined liquid chromatography-tandem mass spectrometry. **Results:** Overall, 18 pts (63-86 years, median 78) were enrolled with a median baseline GFR of 69.5 mL/min. A median of 3.5 HDMTX treatment cycles was given, with 6 pts completing the maximum allowed 6 cycles. Reasons for protocol-predefined early termination included clinical non-response or radiological disease progression (n=8), investigator decision due to adverse event (AE; n=2), and termination criteria (n=2). Administration of glucarpidase resulted in a median reduction of MTX plasma levels within 15 minutes by 99.2% (95% CI: 98.4-99.1%). Results from serum samples analyses for anti-glucarpidase antibodies were performed and will be available by the meeting, but in pts with more than two HDMTX cycles, there was no statistically significant difference in the reduction of MTX plasma levels between the first and last cycles (p=0.47). Glucarpidase treatment reduced MTX plasma levels to a median of 0.05 μmol/L (range 0.00-0.84) within 15 minutes. MTX plasma levels remained consistently below 0.6 μmol/L across all cycles at 42 hours or later after start of the HDMTX infusion. A single grade III AE potentially related to glucarpidase was recorded: a transient facial flushing with a brief loss of consciousness and rapid and spontaneous full recovery. This event prompted implementation of a premedication (prednisolone, antihistaminic) in all subsequent treatment cycles. No further glucarpidase-related AE's grade >II occurred. **Conclusions:** The repeated prophylactic application of glucarpidase was feasible and safe and facilitated HDMTX treatment in pts at risk for delayed MTX elimination. This approach may enable adequate HDMTX dosing in pts with renal insufficiency and limiting comorbidities, and should be further evaluated. Clinical trial information: NCT04841434. Research Sponsor: Protherics Medicines Development Limited.

Variable response rates across chemotherapy regimens for severe idiopathic multicentric Castleman disease. First Author: Saishravan Shyamsundar, Center for Cytokine Storm Treatment & Laboratory, Department of Medicine, Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA

Background: Idiopathic multicentric Castleman disease (iMCD) is a hematologic disorder treated by oncologists and characterized by diffuse lymphadenopathy and systemic inflammation that can cause multi-organ failure. iMCD subtypes include thrombocytopenia, anasarca, fever, renal dysfunction, and organomegaly (TAFRO) and not otherwise specified. Siltuximab, an interleukin 6 (IL6) antagonist, is the only FDA-approved treatment. For patients with severe disease worsening after siltuximab, consensus guidelines recommend combination chemotherapy though data is limited in guiding chemotherapy selection. **Methods:** The ACCELERATE registry leverages an expert panel who reviewed medical history and lymph node biopsy slides to rigorously confirm the diagnosis for each patient. To achieve a clinical response, the proportion of abnormal clinical and laboratory criteria assessed prior to regimen initiation has to decrease by at least 50% after regimen initiation. Regimens were grouped based on inclusion of cyclophosphamide, etoposide, doxorubicin, and bortezomib. We quantified response rates and times to next treatment for regimens containing these chemotherapies but statistical comparisons were not possible due to overlapping treatments used across these groups. Response rates for chemotherapy ± IL6 inhibition were compared. **Results:** We identified 34 (31%) chemotherapy recipients among 111 diagnosis-confirmed iMCD patients: 71% were male, 91% had iMCD-TAFRO; 35 years median age at diagnosis. All iMCD-TAFRO patients met the criteria for severe disease. We found 52 chemotherapy regimens administered to 34 patients. We observed 33 (64%) of the 52 regimens included cyclophosphamide; 23 (44%) etoposide; 21 (40%) doxorubicin; 15 (29%) bortezomib. Regimens were typically given with more than one agent. Twenty-two (42%) were co-administered with anti-IL6. Nineteen (68%) patients had a response if the regimen included cyclophosphamide; 14 (64%) etoposide, 10 (56%) doxorubicin; and 9 (69%) bortezomib. Response rates for all regimens were 60% with IL6 inhibition compared to 64% without. For cyclophosphamide, etoposide, doxorubicin, and bortezomib regimens, median time to next treatment was 9, 4, 4, 6 months, respectively. **Conclusions:** We found that almost all iMCD patients who received chemotherapy had TAFRO with severe disease. We observed relatively similar response rates across different chemotherapy containing regimens and for patients who received chemotherapy with and without IL6 inhibition. Time to next treatment was longer in the cyclophosphamide group, but this could not be statistically tested. Altogether, we provide the first study of the comparative effectiveness of chemotherapies against iMCD. Research Sponsor: U.S. Food & Drug Administration; R01FD007632.

SOUNDTRACK-E: A phase 1/2, open-label, multicenter study to evaluate the safety and efficacy of AZD0486 monotherapy or combination therapy in patients with mature B-cell malignancies. First Author: Toby Andrew Eyre, Cancer and Haematology Centre, Oxford University Hospitals NHS Foundation Trust, Oxford, United Kingdom

Background: AZD0486 is an IgG4 fully human CD19xCD3 bispecific T-cell engager that binds CD3 with low affinity to potentially reduce cytokine release upon T-cell activation while preserving effective T-cell cytotoxicity against malignant B cells. In a first-in-human phase 1 trial (NCT04594642), AZD0486 was active and well tolerated in patients (pts) with relapsed/refractory (R/R) follicular lymphoma or R/R diffuse large B-cell lymphoma (Gaballa S, et al. *Blood*. 2024;144:868; Hou JZ, et al. *Blood*. 2024;144:341). This study assesses fixed-duration subcutaneous (SC) AZD0486 monotherapy in B-cell malignancies and fixed-duration SC or intravenous AZD0486 in combination with other anticancer agents. This study is the first to evaluate SC AZD0486, and the first to evaluate AZD0486 in chronic lymphocytic leukemia (CLL). **Methods:** SOUNDTRACK-E (NCT06564038) is a phase 1/2 dose-escalation, global, multicenter trial of AZD0486 with 3 substudies. The study is recruiting pts aged ≥18 years with Eastern Cooperative Oncology Group performance status 0–2 and a histologically confirmed diagnosis. Pts with clinically significant central nervous system events (eg, seizure, stroke) or cardiovascular disease are excluded. Substudy 1 evaluates SC AZD0486 in R/R CLL/small lymphocytic lymphoma and includes a monotherapy cohort (1A; ≥2 prior lines of therapy [pLOT] with Bruton tyrosine kinase inhibitor exposure) and a cohort that receives combination with acalabrutinib (1B; ≥1 pLOT). Substudy 2 evaluates SC AZD0486 in R/R mantle cell lymphoma and includes a monotherapy cohort (2A; ≥2 pLOT) and a cohort that receives combination with acalabrutinib (2B; ≥1 pLOT). Substudy 3 evaluates AZD0486 in combination with R-CHOP in pts with untreated large B-cell lymphoma with International Prognostic Index ≥2, or R/R B-cell non-Hodgkin lymphoma with ≥1 pLOT. In each cohort, AZD0486 is administered via a double step-up dosing schedule in cycle 1; the target dose is given every 2 weeks. Treatment is administered for 24 (28-day) cycles in substudy 1, 12 (28-day) cycles in substudy 2, and 17 (21-day) cycles in substudy 3. Pts in cohorts 1B and 2B receive acalabrutinib 100 mg orally BID beginning at cycle 2. In substudy 3, R-CHOP is administered once every 3 weeks for 6 cycles. Dose escalation decisions will be based on a modified probability interval (mTPI-2) design. Approximately 46 pts for each cohort in substudies 1 and 2 and 36 pts in substudy 3 (~200 total pts) will be recruited. Primary objectives are to assess safety and tolerability, and to determine the recommended phase 2 dose for AZD0486 as monotherapy and combination therapy in mature B-cell malignancies. Secondary objectives include efficacy endpoints, pharmacokinetics, and immunogenicity. Enrollment opened in October 2024. Clinical trial information: NCT06564038. Research Sponsor: AstraZeneca.

TPS7084 **Poster Session**

A phase 2 trial to evaluate the efficacy and safety of WZTL-002, a third-generation anti-CD19 CAR T-cell therapy, in patients with relapsed or refractory large B-cell lymphoma (ENABLE-2). First Author: Aine Hurley, Malaghan Institute of Medical Research, Wellington, New Zealand

Background: Autologous chimeric antigen receptor (CAR) T-cells directed against CD19 are a standard of care for relapsed or refractory (r/r) large B-cell lymphoma (LBCL). CAR T-cells incorporating a CD28 costimulatory domain are among the most effective CAR T-cell therapies for LBCL, but are associated with high rates of cytokine release syndrome (CRS) and immune effector cell-associated neurotoxicity syndrome (ICANS). In a phase I dose escalation and expansion study (ENABLE-1, NCT04049513), a new 'third-generation' CAR T-cell incorporating a TLR2 co-stimulatory domain alongside CD28 (WZTL-002) demonstrated low rates of CRS and ICANS and promising efficacy. a recommended phase 2 dose (RP2D) of 0.5 – 1.0×10^6 CAR^+ cells/kg was selected following dose escalation, and outpatient management and automated closed-system WZTL-002 manufacture were implemented within a dose expansion cohort. ENABLE-2 (ClinicalTrials.gov NCT06486051) is a multicentre phase 2 that aims to assess the efficacy and safety of WZTL-002 in patients with r/r LBCL. **Methods:** Eligible participants are age 18 – 75 years with relapsed or refractory LBCL (either de novo or transformed from follicular or marginal zone lymphoma) following 1 or 2 prior lines of therapy, have assessable disease and satisfactory organ function. Leukapheresis is conducted to obtain autologous T-cells, which are transduced *ex vivo* to express a third-generation CD19-directed CAR incorporating CD28, TLR2 and CD3zeta stimulatory domains (1928T2z). Bridging therapy is permitted pending WZTL-002 manufacture and product release. Lymphodepletion comprises intravenous fludarabine (30mg/m^2) and cyclophosphamide (500mg/m^2) daily for 3 days. Two days later a single dose of WZTL-002 is administered at 0.5 – 1.0×10^6 CAR^+ cells/kg (capped at 10^8 CAR^+ cells). Participants undergo daily outpatient assessments for toxicities including CRS and ICANS for the first 11 days after WZTL-002 administration, and at days 14 and 28. Disease response is assessed by PET/CT scans at day 28, 3 months and 6 months, and duration of response by CT scan at months 12 and 24. The co-primary endpoints are complete response rate (Lugano criteria) and ICANS rate (any grade) 3 months after WZTL-002 administration. Secondary outcomes include safety (with CRS, ICANS and cytopenias as adverse events of special interest), and progression-free, event-free and overall survival. The first participant was enrolled on 13 August 2024. Clinical trial information: NCT06486051. Research Sponsor: None.

TPS7085 **Poster Session**

ALPHA3: A pivotal phase 2 study of first-line (1L) consolidation with cemacabtagene ansegedleucel (cema-cel) in patients (pts) with large B-cell lymphoma (LBCL) and minimal residual disease (MRD) after response to standard therapy. First Author: Jason Westin, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: R-CHOP as 1L therapy for LBCL has a cure rate of ~60%. However, ~10% of pts are refractory (Coiffier, *NEJM* 2002) and ~30% of responders relapse within 2 years (Maurer, *J Clin Oncol* 2014). Autologous CAR T cell therapies have revolutionized treatment of relapsed/refractory (R/R) LBCL and are considered standard 2L treatment due to improved overall survival (OS; Westin, *NEJM* 2023) but may not be an option due to aggressive disease, pt comorbidities, access barriers, and/or manufacturing issues/delays. Identifying responders to 1L therapy at high risk of relapse and rapidly administering an off-the-shelf CAR T cell therapy for remission consolidation may improve outcomes. Presence of circulating tumor DNA–based MRD, measured by PhasED-Seq, at the end of 1L therapy is highly prognostic for relapse (Roschewski, *Hematol Oncol* 2023). Cema-cel is an immediately available, off-the-shelf, HLA-unmatched allogeneic CD19 CAR T cell product made using Cellectis technologies. A phase 1 study of cema-cel in pts with R/R LBCL showed safety and efficacy comparable to that of autologous CAR T cell therapies (Locke, *J Clin Oncol* 2023). We describe the design of the pivotal ALPHA3 phase 2 study of cema-cel, the first randomized, open-label study to assess a CAR T cell therapy as a consolidation strategy in pts with detectable MRD measured by PhasED-Seq after standard 1L immunochemotherapy. **Methods:** ALPHA3 (NCT06500273) will evaluate efficacy and safety of cema-cel with 1 of 2 lymphodepletion (LD) regimens compared to standard-of-care (SOC) observation in pts with LBCL who are in response at the end of 1L therapy but test MRD+. Key eligibility criteria include histologically confirmed LBCL, completion of a full course of standard 1L therapy, ECOG PS 0/1, and adequate organ function. The study will consist of a 2-part seamless design. In Part A (currently enrolling), pts will be randomized to SOC observation or to 1 of 2 treatment arms (cema-cel [120×10^6 CAR T cells] following 3-day LD with fludarabine [30 mg/m^2/day] and cyclophosphamide [300 mg/m^2/day] with/without the anti-CD52 monoclonal antibody, ALLO-647 [30 mg/day]). Part A will conclude with an interim analysis to select the optimal LD regimen. Part B will assess efficacy of the selected regimen vs observation. The primary endpoint is event-free survival per independent review committee (IRC), with hierarchical testing of key secondary endpoints of progression-free survival per IRC and OS. Other secondary endpoints include MRD clearance, safety of cema-cel and ALLO-647, and disease outcomes after subsequent therapy. The study will enroll ~240 pts across ~50 sites at academic- and community-based centers. Site activation is ongoing; sites outside the US are being considered. The study was initiated in June 2024 with accrual into 2026. Clinical trial information: NCT06500273. Research Sponsor: Allogene Therapeutics, Inc.

TPS7086 **Poster Session**

A phase 2 study to confirm safety and efficacy of MB-105, an autologous CD5-directed CAR T-cell therapy, in relapsed/refractory T-cell lymphoma (R/R TCL). First Author: Swaminathan P. Iyer, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: R/R TCL presents an unmet clinical need with limited treatment options and 3-year survival $<$ 20%. MB-105 is an autologous CD5-targeting CAR T-cell therapy developed at Baylor College of Medicine that has been designed to address the unique challenge of treating T-cell malignancies by overcoming CAR T-cell fratricide without additional engineering. In the phase 1 trial, 44% (4/9) patients experienced objective responses, including 2/3 complete responses with survival $>$5 years. Mid-trial manufacturing refinements enhanced MB-105 potency and persistence without compromising safety. We have developed an industrialized, 6-day process of manufacturing MB-105 and are conducting a phase 2, multicenter study in the USA to evaluate MB-105 in patients with R/R peripheral and cutaneous TCL (PTCL, CTCL). Durable responses and safety observed across all dose levels in phase 1 guided the dose selection for this trial. **Methods:** The study follows a Simon two-stage design with a safety run-in to confirm tolerability of the recommended phase 2 dose (RP2D) of 50 million cells in 6 patients. This is followed by an efficacy evaluation first in 15 patients then 46 total. Adaptive elements allow the independent data monitoring committee to adjust doses, monitoring schedules, or lymphodepletion regimens without formal protocol amendments Primary objectives are first to confirm tolerability of the recommended dose by CTCAE v5 and ASTCT for cytokine release syndrome and immune effector cell-associated neurotoxicity syndrome (CRS/ICANS) and then evaluate efficacy through central review. Secondary/other objectives include assessing response durability, overall survival, persistence, immune correlates and manufacturing success. Adults with R/R TCL who have failed $\geq$ 1 prior systemic therapy for PTCL or $\geq$ 2 for high-volume CTCL are eligible. Local pathology for CD5 expression is required, later confirmed by central lab. Patients must have adequate organ function, Karnofsky PS $\geq$70%, and no prior cell therapy/transplant within 60 days of leukapheresis. Key exclusions are Sezary syndrome (potential for high circulating tumor cells to affect manufacturing), active CNS involvement, infections, graft-versus-host disease $>$ grade 2, or comorbidities that may interfere with study participation or endpoints. Patients are closely monitored for CRS/ICANS. Safety and efficacy are assessed intensively for the first 3 months and gradually less frequently over the subsequent 21 months. Imaging and post-infusion testing, including CAR-T persistence, immune profiling and biomarkers are conducted throughout. Patients are encouraged to participate in a separate long-term follow-up study. Recruitment is ongoing. Clinical trial information: NCT06534060. Research Sponsor: None.

TPS7087 **Poster Session**

CD5-deleted chimeric antigen receptor cells (Senza5 CART5) to enhance immunotherapy against T-cell non-Hodgkin lymphoma: A first-in-human phase I clinical trial (NCT06420089). First Author: Stefan K. Barta, Lymphoma Program, Abramson Cancer Center, University of Pennsylvania, Philadelphia, PA

Background: Autologous CART options for patients with relapsed or refractory (R/R) T-cell lymphomas (TCL) have faced challenges such as T-cell fratricide during CART manufacture and safety concerns regarding depletion of normal T cells. To overcome these obstacles, we proposed a dual cell population CART product, which contained both autologous 4-1BB costimulated CART cells against CD5 and healthy T-cells, with both populations knocked out for CD5 (CRISPR-Cas9 CD5 short-guide RNA to delete CD5 - Senza5). In vivo experiments using the dual population product of (Senza5 CART5) demonstrated increased CART5 expansion and enhanced antitumor efficacy in TCL xenograft models compared to wild-type (WT) CART5. For clinical use, a novel 5-day manufacturing process was designed to obtain a less differentiated and less exhausted product, with enhanced in vivo expansion and fitness. **Methods:** A human phase I trial was designed to determine the safety, effectiveness and recommended phase 2 dose (RP2D) of Senza5 CART5 cells in participants with R/R TCL with $\geq$50% expression of CD5 on malignant cells, and no circulating CD5+ cells. Participants must have a suitable backup stem cell product or donor identified in the unlikely event of T-cell aplasia. Patients with prior allo HCT are currently excluded. Cohorts of patients are treated with escalating doses of Senza5 CART5 cells ($3x10^6$ to $1.25x10^8$) using a Bayesian Optimal Interval design following lymphodepletion. The study will enroll and treat participants until a maximum of 9 participants are infused and evaluable for dose limiting toxicity (DLT) assessments at a given dose level, or a maximum of 30 DLT-evaluable participants from all dose levels are infused. The RP2D will be determined based on both safety and biological evidence of efficacy. Study objectives include frequency and severity of treatment-related adverse events, as well as efficacy by assessing overall and complete response rates, duration of response, progression-free and overall survival. Manufacturing feasibility will be determined by the frequency of product release failures and occurrence of dose failures (inability to meet targeted dose). Exploratory objectives will evaluate the persistence and trafficking of Senza5 CART5 cells in blood and tumor by characterizing the kinetics of the infused cells by flow cytometry and qPCR gene expression. We will perform profiling of the tumor microenvironment and measure systemic soluble cytokines before and after treatment. We will also assess the impact of CART5 on normal T cells, and the persistence of CD5KO untransduced T cells that are infused as part of the Senza5 CART5 product by multicolor flow cytometry and qPCR. The trial is sponsored by Vittoria Biotherapeutics and is registered at clinicaltrials.gov as NCT06420089. Enrollment in this trial has begun. Clinical trial information: NCT06420089. Research Sponsor: Vittoria Biotherapeutics.

TPS7088 **Poster Session**

Efficacy and safety of nemtabrutinib in relapsed or refractory chronic lymphocytic leukemia/small lymphocytic lymphoma: Cohort J of the phase 2 BELLWAVE-003 study. First Author: Thomas Kipps, UC San Diego, San Diego, CA

Background: Treatment options for patients with relapsed or refractory (R/R) chronic lymphocytic leukemia/small lymphocytic lymphoma (CLL/SLL) can be limited if patients do not respond to both Bruton tyrosine kinase inhibitors (BTKis) and B-cell lymphoma 2 inhibitors (BCL2is). Nemtabrutinib is a once-daily, potent, noncovalent, reversible BTKi with a distinct kinase profile that inhibits BTK and other B-cell receptor relevant kinases. The multicenter, open-label, single-arm, phase 2 BELLWAVE-003 study (NCT04728893) is designed to evaluate nemtabrutinib at the recommended phase 2 dose (RP2D) in participants with R/R CLL/SLL, Richter transformation, mantle cell lymphoma, marginal zone lymphoma, follicular lymphoma, and Waldenström macroglobulinemia. Cohort J will evaluate nemtabrutinib in participants with R/R CLL/SLL who are relapsed/refractory to both a BTKi and BCL2i. **Methods:** Key eligibility criteria for cohort J include participants aged $\geq$18 years with CLL/SLL whose disease is R/R to prior therapy with both a BTKi (covalent or irreversible) and a BCL2i, and an ECOG PS of 0 to 2. Additional use of noncovalent or reversible BTKis is permitted if disease is R/R to such therapy. Participants must have received and not responded to, been intolerant to, or determined by their treating physician to be a poor PI3Ki candidate or ineligible for PI3Ki per local (institution) guidelines. Exclusion criteria include prior exposure to nemtabrutinib, active CNS disease, and prior systemic therapy with a monoclonal antibody within 5 half-lives or 4 weeks before allocation. Overall, the BELLWAVE-003 study comprises a dose escalation and confirmation phase (part 1) to establish the RP2D, and a cohort expansion phase (part 2). Part 1 evaluated nemtabrutinib in $\geq$6 to $\leq$20 participants with R/R CLL/SLL after $\geq$2 prior lines of therapy. The RP2D has been established as nemtabrutinib 65 mg QD. In part 2, ~460 participants will be enrolled across 9 expansion cohorts. Approximately 40 participants will be enrolled in cohort J. Treatment will continue until unacceptable toxicity, disease progression, or withdrawal. Adverse events will be monitored throughout and graded using NCI CTCAE version 5.0. Hematologic toxicities in participants with CLL will be assessed using iwCLL 2018 criteria. CT/MRI and/or PET will be performed every 12 weeks unless needed more frequently. The primary end point for cohort J is ORR per iwCLL 2018 criteria by independent central review (ICR). Additional end points include DOR and PFS per iwCLL 2018 criteria by ICR, OS, and safety and tolerability. Recruitment is ongoing. This is the first clinical trial with a dedicated cohort to assess noncovalent BTKis in patients whose disease has failed to respond to both BTKi and BCL2i. Clinical trial information: NCT04728893. Research Sponsor: Merck Sharp & Dohme LLC, a subsidiary of Merck & Co., Inc., Rahway, NJ, USA.

TPS7090 **Poster Session**

Phase 2 study of MK-3475A in relapsed or refractory classic Hodgkin lymphoma or primary mediastinal large B-cell lymphoma. First Author: Alejandro Berkovits, Immunocel Chile, Providencia, Chile

Background: The PD-1 inhibitor pembrolizumab is approved globally for the treatment of multiple cancers, including relapsed or refractory (R/R) classic Hodgkin lymphoma (cHL) and R/R primary mediastinal large B-cell lymphoma (PMBCL). Pembrolizumab is currently administered as an intravenous infusion. Subcutaneous administration of pembrolizumab offer advantages to patients, providers, and the healthcare system. MK-3475A is pembrolizumab with berahyaluronidase alfa for subcutaneous administration (subcutaneous pembrolizumab). Berahyaluronidase alfa, a human hyaluronidase variant developed and manufactured by Alteogen Inc., is a permeation enhancer that increases dispersion and allows for subcutaneous administration of pembrolizumab in 1 injection for both Q3W and Q6W dosing. Here, we describe the methodology of a single-arm, open-label, phase 2 study (NCT06504394) designed to evaluate subcutaneous pembrolizumab in participants with R/R cHL or R/R PMBCL. **Methods:** Key eligibility criteria include participants aged ≥18 years with a histologically confirmed diagnosis of cHL or PMBCL that is FDG-avid per WHO classification criteria, radiographically measurable disease, and an ECOG performance status of 0 or 1. Participants with cHL must be anti–PD-1 naive and have not responded to or relapsed after ≥1 line of multiagent therapy, did not achieve a complete response (CR) or relapsed after autologous stem cell transplant (auto-SCT), or are ineligible for auto-SCT. Participants with PMBCL must be anti–PD-1 naive and have not responded to or relapsed after ≥2 prior lines of therapy (≥1 rituximab based), or did not achieve a CR or relapsed after auto-SCT or are ineligible for auto-SCT. Key exclusion criteria include clinically significant cardiovascular disease, pericardial effusion or clinically significant pleural effusion, or an additional malignancy that is progressing or has required active treatment within the past 2 years. Approximately 60 participants will be enrolled. All participants will receive subcutaneous pembrolizumab 790 mg every 6 weeks for up to 18 cycles (~2 years), or until disease progression or other discontinuation criteria are met. Primary end points are pharmacokinetics during cycle 1 and objective response rate per Lugano classification criteria by investigator review. Secondary end points are pharmacokinetics at steady state (cycle 3), antidrug antibody levels, safety and tolerability, and duration of response per Lugano classification criteria by investigator review. CT scans will be performed every 12 weeks; PET scans will be performed at week 12, week 24, and to confirm CR. Adverse events (AEs) will be monitored throughout the study and for ≤30 days after treatment end (90 days for serious AEs; or 30 days if new anticancer therapy is initiated) and will be graded per NCI CTCAE v5.0. Recruitment is ongoing. Clinical trial information: NCT06504394. Research Sponsor: Merck Sharp & Dohme LLC., a subsidiary of Merck & Co., Inc., Rahway, NJ, USA.

TPS7091 **Poster Session**

TITANium: An open-label, global multicenter phase 1/2 study of AZD5492, a first-in-class subcutaneous CD8-guided tri-specific T-cell engager (TCE), in patients (pts) with relapsed or refractory (r/r) B-cell malignancies. First Author: Mazyar Shadman, Medical Oncology Division, University of Washington School of Medicine, Seattle, WA

Background: Bispecific CD20 x CD3 TCEs are changing the treatment landscape for pts with r/r non-Hodgkin lymphomas (NHL); however, they are associated with immune-related toxicities, namely cytokine release syndrome (CRS) and immune effector cell-associated neurotoxicity syndrome (ICANS), which limit their use. AZD5492 is a first-in-class, humanized, asymmetric, subcutaneously-administered, trispecific monoclonal IgG1 antibody that harbors two Fab binding domains to CD20, one VHH binding domain to T-cell receptor and one VHH binding domain to a CD8 co-receptor. Preclinical data have shown that AZD5492 drives B-cell killing through preferential engagement of CD8+ T cells, with reduced CD4+ T-cell activation and associated cytokine production. Thus, AZD5492 may have a wider therapeutic index and safety advantage compared with first generation CD20 x CD3 TCEs which equally engage and activate CD4+ and CD8+ T cells. In an in vivo NHL model, AZD5492 showed potent antitumor activity with reduced cytokine release compared with a CD20 x CD3 comparator. TITANium is a global Phase 1/2 multicenter dose escalation (Part A) and expansion (Part B) study (NCT06542250) of AZD5492 in pts with r/r B-cell malignancies. **Methods:** We present the study design of Part A. Eligible pts are aged ≥18 years with histologically documented CD20+ mature B-cell neoplasm, specifically large B-cell lymphoma (LBCL), follicular lymphoma (FL), mantle cell lymphoma (MCL), chronic lymphocytic leukemia (CLL), and small lymphocytic lymphoma (SLL), with ≥1 measurable lesion (except for CLL) and r/r disease after ≥2 prior lines of therapy. Pts with history of Grade ≥3 CRS or ICANS, post-transplant lymphoproliferative disease, Ritcher's transformation, Burkitt's lymphoma or Burkitt-like lymphoma are excluded. Part A will consist of two independent dose escalation groups: Part A1 will enroll pts with MCL or CLL/SLL; Part A2 will enroll pts with LBCL or FL. Dose escalation will start with pts receiving AZD5492 subcutaneously at a fixed dose per dose-level. An immune-related toxicity during Part A will trigger a double step-up strategy. Thereafter, treatment will continue for a limited duration. Each part will continue dose escalation independently, using fixed or step-up dosing. Part A will initially follow an accelerated titration design and will switch to a modified toxicity probability interval-2 design when triggered by emerging data. The primary objective is to assess safety and tolerability of AZD5492. Key secondary objectives are to evaluate preliminary efficacy, pharmacokinetics and immunogenicity of AZD5492. Enrollment began in September 2024 and is currently ongoing. Clinical trial information: NCT06542250. Research Sponsor: AstraZeneca.

TPS7092 **Poster Session**

waveLINE-010: Zilovertamab vedotin plus R-CHP versus R-CHOP in untreated diffuse large B-cell lymphoma. First Author: Russell Patrick Trapletti Gollard, Optum Care Cancer Care, Las Vegas, NV

Background: Despite recent advances in the treatment of diffuse large B-cell lymphoma (DLBCL), 5-year survival rates range between 60% and 80%. Modest improvements have been made over standard-of-care with rituximab plus cyclophosphamide, doxorubicin, vincristine, and prednisone (R-CHOP) immunochemotherapy being used in the first-line setting. Zilovertamab vedotin, an ROR1-targeting antibody-drug conjugate with a monomethyl auristatin E payload, has demonstrated promising efficacy in patients with DLBCL. The randomized, open-label, phase III waveLINE-010 (NCT06717347) study will evaluate the efficacy and safety of zilovertamab vedotin in combination with rituximab plus cyclophosphamide, vincristine, and prednisone (R-CHP) versus R-CHOP in patients with untreated DLBCL. **Methods:** Eligible participants are aged ≥18 years and have histologically confirmed DLBCL per World Health Organization classification of neoplasms of the hematopoietic and lymphoid tissues (including but not limited to: DLBCL, not otherwise specified [NOS] germinal center B-cell type, or activated B-cell type; DLBCL leg-type; Epstein-Barr virus–positive DLBCL, NOS; and T-cell histiocytic-rich DLBCL), positron emission tomography–positive disease at screening (4-5 on the Lugano 5-point scale), no prior treatment for DLBCL, an International Prognostic Index (IPI) score of 2-5, and an ECOG performance status score of 0-2. Approximately 1046 patients will be randomly assigned (1:1) to receive zilovertamab vedotin 1.75 mg/kg plus R-CHP on day 1 of every 3-week cycle for 6 cycles, or R-CHOP on day 1 of every 3-week cycle for 6 cycles. Patients with high-risk DLBCL in both treatment arms will receive rituximab (or biosimilar) for an additional 2 cycles. Randomization will be stratified by 3 geographic regions (Western Europe, the United States, Canada, and Australia vs Asia vs rest of world), IPI score (2 vs 3-5), and bulk (<7.5 cm vs ≥7.5 cm). The primary end point is PFS per Lugano criteria by blinded independent central review (BICR). Secondary end points include complete response rate at end of treatment (EOT) per Lugano criteria by BICR, overall survival, event-free survival per Lugano criteria by BICR, duration of complete response, safety and tolerability, and changes from baseline in health-related quality-of-life assessments. Response assessments will be performed after day 1 of cycle 4 but before day 1 of cycle 5, and then at 12 weeks after cycle 4 scan (EOT assessment). Efficacy follow-up assessments will be completed every 24 weeks for 2 years from EOT assessment, then every year for 3 years (total of 5 years). Adverse events will be graded per NCI CTCAE v5.0. Recruitment is ongoing. Clinical trial information: NCT06717347. Research Sponsor: Merck Sharp & Dohme LLC, a subsidiary of Merck & Co., Inc., Rahway, NJ, USA.

TPS7093 **Poster Session**

A phase 1 first-in-human study evaluating safety, pharmacokinetics, and efficacy of ABBV-291, a CD79b-targeting antibody-drug conjugate, in patients with relapsed/refractory B-cell non-Hodgkin lymphoma. First Author: Dai Maruyama, Department of Hematology Oncology, Cancer Institute Hospital, Japanese Foundation for Cancer Research, Tokyo, Japan

Background: Chemoimmunotherapy successfully treats ~60% of patients (pts) with diffuse large B-cell lymphoma (DLBCL), the most common form of B-cell non-Hodgkin lymphoma (B-NHL). However, pts who are not cured often die from relapsed/refractory (R/R) disease, highlighting the need for new therapies. CD79b is expressed on most major subtypes of B-NHL and is a validated target in DLBCL. ABBV-291 is an antibody-drug conjugate (ADC) comprising the anti-CD79b antibody conjugated to a potent topoisomerase 1 inhibitor payload, and offers potential as a best-in-class treatment in DLBCL. Preclinical data indicate that ABBV-291 has robust antitumor activity, with superior responses compared with other anti-CD79b ADCs. There is also the possibility for lower rates of key adverse events (AEs) such as neuropathy compared with monomethyl auristatin E-payload ADCs. Herein, we describe a first-in-human study evaluating the safety, pharmacokinetics (PK), and efficacy of ABBV-291 monotherapy in pts with R/R B-NHL. **Methods:** This phase 1, open-label, multicenter, dose-expansion study (NCT06667687) is enrolling pts (≥18 years) who have a documented diagnosis of B-NHL (except chronic lymphocytic leukemia), measurable disease, ECOG 0–1, and are R/R to or intolerant of ≥2 prior lines of therapy, with no other available therapies of clinical benefit. Primary objectives are to assess safety/tolerability of ABBV-291 and determine its recommended phase 1 expansion dose (RP1ED). Secondary objectives are to evaluate preliminary efficacy of ABBV-291 in specified subsets of R/R B-NHL (eg DLBCL, follicular lymphoma [FL], mantle cell lymphoma [MCL]) and to characterize its PK. Exploratory objectives include investigating the association between biomarkers, safety, efficacy, and PK. The study consists of 2 parts: dose escalation (up to ~45 pts), and dose expansion and optimization (~120 pts). ABBV-291 is administered intravenously. In the BOIN-guided dose-escalation, ABBV-291 administration for the first 2 pts is staggered by ≥24 hours at the first 2 dose levels (DLs); dose-limiting toxicities (DLTs) are assessed for 35 days from the initial dose. In dose expansion, ABBV-291 is evaluated at the RP1ED in DLBCL and FL; for dose optimization, ABBV-291 is evaluated in ≥2 DLs in MCL. Pts continue treatment until disease progression, intolerable toxicity, or other study discontinuation criteria are met. Safety evaluations include AE monitoring, DLTs, vital signs, ECG, and clinical laboratory parameters. Response evaluations are performed per disease-specific response criteria and include objective response rate, duration of response, and progression-free survival. PK parameters are determined using noncompartmental methods. The study is actively enrolling globally. Clinical trial information: NCT06667687. Research Sponsor: AbbVie, Inc.; n/a.

TPS7094 **Poster Session**

Optimizing frontline therapy for diffuse large B cell lymphoma (DLBCL) in older adults: A glofitamab-based, response-adapted, window-style study (GLORY). First Author: Pallawi Torka, Memorial Sloan Kettering Cancer Center, New York, NY

Background: Older adults (OA) with DLBCL classified as unfit or frail based on simplified geriatric assessment (sGA) do poorly with standard doses of anthracycline based chemotherapy. Bispecific antibodies have a preserved risk-benefit profile in OA and their combination with chemotherapy represents a promising strategy to increase cure rates in DLBCL. Interim PET scans have a high negative predictive value and can be harnessed to guide response adapted therapy in this setting to minimize exposure to chemotherapy for responsive patients. GLORY is a window-style, glofitamab-based, response-adapted study with polatuzumab-rituximab-miniCHP (pola-R-miniCHP) backbone specifically designed for unfit and frail older adults with DLBCL who are being treated with curative intent. The dual goals of this personalized strategy are: 1. To improve cure rates in patients with iPET2 positivity, 2. To reduce chemotherapy dosage and ensuing toxicities in patients with iPET2 negativity while maintaining/improving cure rate. **Methods:** In this Phase II, prospective, open label, single arm, single institution study, OA $\geq$ 65 years of age with newly diagnosed DLBCL, high grade or transformed B-cell lymphoma, classified as unfit or frail by simplified geriatric assessment (sGA) will be included. All patients will receive 2 cycles of glofitamab and polatuzumab followed by an interim PET scan (iPET2). If iPET2 is negative (Deauville 1-3), patients will receive 4 cycles of glofitamab-pola-R-miniCHP. If iPET2 is positive without progression, patients receive 6 cycles of glofitamab-pola-R-miniCHP. All patients undergo end of treatment (EOT) PET and are followed for 5 years. ctDNA and dynamic changes in aging biomarkers [epigenetic aging clock, senescence associated secretory phenotype (SASP)] will be measured at baseline, after cycle 1 (C1), after C2 and at the EOT and correlated with outcomes. On therapy tumor biopsy after cycle 1 of glofitamab+polatuzumab is optional. The trial has been thoughtfully designed to be OA-friendly with pragmatic eligibility criteria and stepwise strategies (eg. prephase) to mitigate the risk of toxicities. The primary endpoints are complete response rate (CRR) after 2 cycles of glofit-pola and CRR after completion of therapy. Key secondary end points include other measures of efficacy such as overall response rate (ORR), progression free survival (PFS) and overall survival (OS) and safety. The target CRR at the end of therapy is 60% with an unacceptably low rate of 40%. Based on these assumptions, a sample size of 42 patients provides a 5% one sided type 1 error and 80% power. This is a single stage design, and the study will be considered positive if 23 of 42 patients achieve a CR at the end of therapy. Additionally, the coprimary endpoint of CR rate after 2 cycles of glofitamab+polatuzumab will be used to stop for futility. Clinical trial information: NCT06765317. Research Sponsor: Genentech; Memorial Sloan Kettering Cancer Center.

TPS7095 **Poster Session**

Sequencing-guided chemotherapy optimization using real-time evaluation in newly diagnosed DLBCL with circulating tumor DNA: SHORTEN-ctDNA (NCT06693830). First Author: Hua-Jay Jeffery Cherng, Columbia University Irving Medical Center, New York, NY

Background: Circulating tumor DNA (ctDNA) is a clinically valid tool for detection of measurable residual disease (MRD) in patients with diffuse large B-cell lymphoma (DLBCL). Phased variant enrichment and detection sequencing (PhasED-seq), which uses multiple somatic mutations on individual DNA fragments, improves upon first-generation single nucleotide variant-based MRD tests with improved sensitivity (Kurtz et al. *Nat Biotech* 2021). To utilize ctDNA-MRD testing in a clinical setting to guide treatment decisions, the ability to test and report in a real-time manner is required. However, the feasibility of real-time MRD testing using the PhasED-seq-based Foresight CLARITY platform to inform treatment decisions has yet to be established. Therapy de-escalation after 4 cycles of standard R-CHOP therapy was non-inferior and less toxic than 6 cycles for patients with DLBCL with no baseline risk factors (Poeschel et al. *Lancet* 2019). Identification of patients who are ideal candidates for de-escalation based on treatment response remains a challenge as radiographic imaging has a high false-negative rate (Le Gouill & Casanovas, *Blood* 2017). ctDNA-MRD has a higher sensitivity and may be a better test to guide dose de-escalation decisions in patients with DLBCL. This feasibility study will have two co-primary objectives: (1) to evaluate the feasibility of ctDNA sequencing for real-time guidance of clinical decision making during frontline therapy for DLBCL; and (2) to determine the outcomes of patients with newly diagnosed DLBCL who become undetectable for ctDNA and demonstrate a radiographic complete response (CR) during standard frontline therapy and discontinue chemotherapy early. **Methods:** This single-center investigator-initiated study began enrolling in November 2024 and is enrolling patients (N=32) with newly diagnosed stage II-IV, CD20+ DLBCL with measurable disease. Patients will receive 4 cycles of standard-of-care therapy (R-CHOP or R-pola-CHP). Positron emission tomography/computed tomography (PET/CT) scans will be performed after cycle four (C4) and at the end of therapy. Additionally, whole blood samples will be drawn on C4 day 1 (C4D1) and shipped to Foresight Diagnostics, Inc. (Boulder, CO) for real-time MRD testing. Patients who experience a CR on iPET4 and have undetectable ctDNA on C4D1 will de-escalate therapy and receive rituximab alone for C5-6. Patients not meeting these response criteria or with unsuccessful real-time MRD testing for any reason will continue standard therapy for the remaining cycles. MRD will also be evaluated in a batched manner at the end of the study at other timepoints to evaluate the kinetics of ctDNA as well as correlation with clinical outcomes. The primary efficacy endpoint is the EOT CR rate on PET/CT performed 10-14 weeks after C6D1 in the patients who receive de-escalated treatment. Clinical trial information: NCT06693830. Research Sponsor: Foresight Diagnostics, Inc.; National Cancer Institute; Conquer Cancer, the ASCO Foundation.

TPS7096 **Poster Session**

A phase 1a/1b trial in relapsed/refractory T-cell non-Hodgkin lymphoma to determine the safety profile, pharmacology, and maximum tolerated dose of ST-001, an intravenous fenretinide phospholipid suspension (12.5 mg/mL). First Author: Oleg Akilov, University of Pittsburgh, Pittsburgh, PA

Background: N-(4-hydroxyphenyl)retinamide (4-HPR; fenretinide) is a synthetic amide derivative of all-trans retinoic acid. Clinical data from trials of earlier fenretinide formulations indicate that higher plasma levels of fenretinide correlate with improved patient responses. Although fenretinide intravenous emulsion (4-HPR-ILE) increased plasma concentration and yielded complete and partial responses in peripheral T-cell lymphomas, its dose-limiting hypertriglyceridemia mainly related to triglyceride from the soy oil vehicle posed a significant impediment to clinical development (Maurer BJ et al. *Clin Cancer Res.* 2017). **Methods:** A new formulation of intravenous fenretinide, designated ST-001 nanoFenretinide, is an innovative dosage form composed of phospholipid nanoparticles in a free-flowing solution (Patent number US 8709379 B2). ST-001 effectively eliminates the risk of vehicle-related hypertriglyceridemia, because it is free of triglycerides. It is also free of adjuvants, non-ionic surfactants, polyoxylated compounds, alkoxylated oils, and animal-derived substances known to cause allergy or hypersensitivity. ST-001 potentially provides a safer form of intravenous fenretinide for achieving therapeutic plasma concentrations. In this Phase 1a/1b clinical trial (NCT04234048), ST-001 is administered via intravenous infusion (IV) to patients with relapsed/refractory T-cell non-Hodgkin's lymphoma (NHL) following at least one prior treatment, including cutaneous (CTCL) and non-cutaneous T-cell lymphoma subtypes (angioimmunoblastic T-cell lymphoma, peripheral T-cell lymphoma not otherwise specified, and follicular T-cell lymphoma). The U.S.-based trial will enroll up to 54 patients across three stages: up to 9 patients (single patient cohorts) for Phase 1a accelerated dose escalation, up to 15 patients (3 patient cohorts) for Phase 1a standard dose escalation and determination of maximum tolerated dose (MTD), and 30 patients for Phase 1b to determine the optimal dose. The primary objectives are to determine the MTD, toxicity profile, adverse events and dose-limiting toxicities (DLTs) based on NCI Common Toxicity Criteria, and anti-tumor activity, when administered over 4 hours daily for 5 consecutive days every 3 weeks, for a maximum of 8 cycles. Secondary objectives include pharmacokinetic profiling and investigating potential mechanisms of action using pharmacodynamic biomarkers. The accelerated stage has completed enrollment, and the standard stage is open for enrollment as of January 2025. This study investigates a novel fenretinide formulation aiming to address treatment challenges in T-cell NHL, with a focus on safety, tolerability, clinical activity, and pharmacology. Clinical trial information: NCT04234048. Research Sponsor: None.

TPS7097 **Poster Session**

A phase 1 trial of BTM-3566 in relapsed/refractory mature B cell lymphomas. First Author: Michael Wang, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Relapsed/refractory (R/R) aggressive B-cell lymphomas, including diffuse large B-cell lymphoma (DLBCL) and mantle cell lymphoma (MCL), remain challenging to treat, particularly in patients who have exhausted approved therapies. BTM-3566, a novel compound demonstrated efficacy against diverse B-cell malignancies, with the most pronounced impact observed in DLBCL and MCL. BTM-3566 initiates the mitochondrial ATF-4-mediated integrated stress response (ISR) pathway via a unique mechanism governed by the mitochondrial protein FAM210B. In vitro, BTM-3566 induces apoptosis across multiple hematological and solid tumor cell lines with several in vivo models demonstrating tumor regression or significant tumor growth inhibition. This includes complete tumor regressions in DLBCL and MCL patient-derived xenograft (PDX) mouse models carrying genetic alterations linked to unfavorable prognosis such as double hit (DH) and triple hit lymphoma (TH) and MCL PDX models from patients previously treated with CAR T, rituximab, venetoclax and/or BTK inhibitors. **Methods:** This ongoing Phase 1, single-arm, open-label, multi-center trial is evaluating the safety, tolerability, and preliminary efficacy of BTM-3566 in adult patients with mature B-cell lymphomas. Eligible participants must have histologically confirmed mature B cell lymphoma that has progressed after at least two prior lines of systemic therapy. BTM-3566 is administered orally in two weeks cycles (7 days on, 7 days off). Primary endpoints include incidence of dose-limiting toxicities (DLTs) and treatment-emergent adverse events (TEAEs). Secondary and exploratory endpoints include objective response rate (ORR), duration of response (DoR), progression-free survival (PFS) pharmacokinetics and pharmacodynamic assessments. Enrollment is scheduled to start in Q1 2025 in US and Canada. Clinical trial information: NCT06792734. Research Sponsor: None.

7500 Oral Abstract Session

MRD-driven strategy following IsaKRD induction in transplant-eligible NDMM: Primary endpoints of the phase 3 MIDAS trial. First Author: Aurore Perrot, Toulouse University, CHU Oncopole, Toulouse, France

Background: The phase III IFM2020-02-MIDAS study (NCT04934475) evaluated a minimal residual disease (MRD)-driven consolidation and maintenance strategy following induction with isatuximab, carfilzomib, lenalidomide, and dexamethasone (IsaKRD) in transplant-eligible patients with newly diagnosed multiple myeloma (NDMM). Results from the IsaKRD induction phase have been previously published (Perrot et al., Blood, 2025). Here, we present the results from the MRD-driven consolidation phase of the trial. **Methods:** MIDAS is a multicenter, open-label, randomized phase 3 trial involving transplant-eligible patients aged 18-65 with NDMM. Patients achieving post-induction MRD negativity at a threshold of 10^{-5} by next-generation sequencing (NGS) were randomized to either 6 additional cycles of IsaKRD (Arm A) or autologous stem cell transplantation (ASCT) followed by 2 cycles of IsaKRD (Arm B), followed by lenalidomide maintenance. MRD-positive patients after induction (MRD $\geq 10^{-5}$) were randomized to either single ASCT plus 2 cycles of IsaKRD (Arm C) or tandem ASCT (Arm D) followed by isatuximab plus iberdomide maintenance. Randomization was stratified by cytogenetic risk and center for both comparisons, and by MRD negativity at 10^{-6} post-induction for the Arm A vs. Arm B comparison. The primary endpoint was MRD negativity at 10^{-6} (by NGS) prior to maintenance for both comparisons. **Results:** A total of 485 patients with post-induction MRD negativity were randomized to Arm A (n=243) or Arm B (n=242). The pre-maintenance MRD negativity rates at 10^{-6} were 84% in Arm A and 86% in Arm B (Odds Ratio [OR] 1.17, 95% confidence interval [CI] 0.64–2.76, p=0.64). Additionally, 233 MRD-positive patients (10^{-5}) were randomized to Arm C (n=109) or Arm D (n=124), with 19 patients (15%) not receiving the planned tandem ASCT. Pre-maintenance MRD negativity rates at 10^{-6} were 40% in Arm C and 32% in Arm D (OR 0.73, 95% CI 0.42–1.25, p=0.31). During the consolidation phase, 5 patients experienced disease progression (2 in Arm A, 0 in Arm B, 0 in Arm C, 3 in Arm D), and 2 patients died without progression in Arm A. No new safety signals were identified compared to the induction phase. The study is ongoing. With a median follow-up of 16.8 months in Arms A/B and 16.3 months in Arms C/D, sustained MRD negativity and progression-free survival (PFS) data are not yet available. **Conclusions:** After 6 induction cycles with IsaKRD, in patients who achieved MRD negativity at 10^{-5}, MRD negativity rates at 10^{-6} before maintenance were not significantly different between the transplant-based approach and IsaKRD consolidation alone, whereas in patients who do not achieve MRD negativity at 10^{-5}, tandem ASCT did not significantly improve MRD negativity rates at 10^{-6} before maintenance. Further follow-up, including sustained MRD negativity and PFS data, is needed to evaluate the long-term outcomes of this MRD-adapted strategy. Clinical trial information: NCT04934475. Research Sponsor: None.

7501 Oral Abstract Session

Subcutaneous daratumumab (Dara) + bortezomib/lenalidomide/dexamethasone (VRd) with Dara + lenalidomide (DR) maintenance in transplant-eligible (TE) patients with newly diagnosed multiple myeloma (NDMM): Analysis of sustained minimal residual disease negativity in the phase 3 PERSEUS trial. First Author: Philippe Moreau, University Hospital Hôtel-Dieu, Nantes, France

Background: Minimal residual disease (MRD) negativity (neg) and sustained MRD neg are associated with longer survival and are strong prognostic clinical endpoints. PERSEUS (NCT03710603) evaluated subcutaneous Dara + VRd induction/consolidation (ind/consol) + DR maintenance (maint) vs VRd ind/consol + R maint in TE NDMM. DVRd significantly improved PFS, complete response or better rate (≥CR), and MRD neg rate. Nearly two-thirds of patients (pts) on DR maint could stop treatment (tx) after achieving sustained remission, leading to DVRd being recommended by NCCN as a preferred TE NDMM regimen. Here, we report the impact of sustained MRD neg status on PFS inPERSEUS. **Methods:** TE pts with NDMM age 18–70 years (y) were randomized 1:1 to DVRd (DVRd ind/consol + DR maint) or VRd (VRd ind/consol + R maint). The primary endpoint was PFS; MRD neg rate (MRD neg 10^{-5} and ≥CR) was a key secondary endpoint. Sustained MRD neg, assessed in the intent-to-treat population, was defined as confirmed MRD neg ≥12 months (mo) apart and without MRD positivity in between. Functionally high risk (FHR) was defined as disease progression ≤18 mo from tx initiation, excluding pre-progression deaths. **Results:** A total of 709 pts were assigned to DVRd (n=355) or VRd (n=354). At 47.5-mo median follow-up, ≥12-mo sustained MRD neg rates were higher overall with DVRd (64.8%; n=230) vs VRd (29.7%; n=105), and across clinically relevant subgroups, including age ≥65 y and high-risk cytogenetics. Similarly, ≥24-mo sustained MRD neg rates were higher with DVRd (55.8%; n=198) vs VRd (22.6%; n=80). Pts with ≥12-mo sustained MRD neg vs those without had improved 48-mo PFS rates regardless of tx arm (Table). DVRd vs VRd reduced FHR rates (3.1% vs 6.8%), and rates of FHR or pre-progression deaths were lower with DVRd vs VRd (5.4% vs 11.0%) in the first 18 mo. **Conclusions:** In TE NDMM, nearly two-thirds of pts treated with DVRd induction and DR maint achieved ≥12-mo sustained MRD neg, associated with >95% 48-mo PFS rate. Moreover, ≥24-mo sustained MRD neg rates with DVRd were 2.5 times as high as VRd, and FHR incidence was halved with DVRd vs VRd. Collectively, these data further support the PERSEUS regimen as standard of care for TE NDMM. Clinical trial information: NCT03710603. Research Sponsor: Johnson & Johnson.

7502 Oral Abstract Session

Sustained MRD negativity in patients with newly diagnosed multiple myeloma treated with carfilzomib-lenalidomide-dexamethasone with or without isatuximab (phase III IsKia trial). First Author: Francesca Gay, Division of Hematology, AOU Città della Salute e della Scienza di Torino, University of Torino and Department of Molecular Biotechnology and Health Sciences, University of Torino, Torino, Italy

Background: The phase III IsKia trial assessed the efficacy and safety of isatuximab-carfilzomib-lenalidomide-dexamethasone (IsaKRd) as pre-ASCT induction and post-ASCT consolidation vs KRd. The rate of measurable residual disease (MRD) negativity was significantly higher in IsaKRd vs KRd patients (pts) after both induction and consolidation (Gay et al. ASH 2023). Here we report the rates of 1-year sustained (sust)MRD negativity and findings about the light consolidation phase. **Methods:** Transplant-eligible NDMM pts aged <70 years were enrolled. IsaKRd pts received 4 full-dose IsaKRd induction cycles, MEL200-ASCT, 4 full-dose IsaKRd consolidation cycles and, thereafter, 12 28-day light consolidation cycles [Isa 10 mg/kg IV on days (dd) 1, 15; K 56 mg/m^2 IV dd 1; R 10 mg PO daily dd 1–21; d 20 mg PO dd 1, 15]. Pts in the KRd arm received the same KRd schedule used in the other arm. MRD was tested by NGS in all pts who achieved ≥VGPR. 1-year sustMRD was defined as 2 sequential MRD-negative evaluations at least 1 year apart. Analyses were based on the ITT principle (pts with missing MRD data or who did not achieve VGPR were considered as MRD positive). The data cut-off was Jul 22, 2024. **Results:** 151 vs 151 pts were randomly assigned to the IsaKRd vs KRd arms. Pt characteristics were well balanced: 43% vs 41% had R2-ISS stage III/IV disease; 9% vs 11% had ≥2 high-risk cytogenetic abnormalities [CA; including del(17p), t(4;14), t(14;16), 1q+]. The median follow-up was 35 months (IQR 32–38). In the ITT analysis, the MRD negativity rates at the 10^{-5} cut-off after full-dose consolidation were 77% vs 67% (OR 1.67; p=0.049) with IsaKRd vs KRd; the rates of 10^{-5} 1-year sustMRD after light consolidation were 66% vs 59% (OR 1.36; p=0.21). The MRD negativity rates at the 10^{-6} cut-off after full-dose consolidation were 67% vs 48% (OR 2.29; p<0.001) with IsaKRd vs KRd; the rates of 10^{-6} 1-year sustMRD after light consolidation were 52% vs 38% (OR 1.82; p=0.012). The 10^{-6} 1-year sustMRD negativity advantage with IsaKRd was retained in all subgroups. In particular, the 10^{-6} 1-year sust MRD negativity rates were: 62% vs 20% in pts with ≥2 high-risk CA (OR 6.3, 95% CI 1.11–35.66) and 47% vs 35% in pts with R2-ISS III/IV (OR 1.62, 95% CI 0.77–3.41). During light consolidation, in the IsaKRd vs KRd arms, the main grade 3–4 hematologic AEs were neutropenia (17% vs 18%) and thrombocytopenia (2% vs 3%); the main grade 3–4 non-hematologic AEs included infections (8% vs 5%), gastrointestinal (4% vs 4%) and vascular AEs (3% vs 1%); discontinuation for toxicity occurred in 3% vs 2%; treatment-related deaths were 2 (1 cerebral ischemia, 1 pulmonary embolism) vs 0. **Conclusions:** The addition of isatuximab to KRd induction-consolidation and the prolonged light consolidation significantly increased the rates of 10^{-6} sustMRD negativity in NDMM pts, including those with high-risk disease. Clinical trial information: NCT04483739. Research Sponsor: Sanofi; Amgen.

7503 Oral Abstract Session

Randomized, multi-center study of carfilzomib, lenalidomide, and dexamethasone (KRd) with or without daratumumab (D) in patients with newly diagnosed multiple myeloma (NDMM): The ADVANCE clinical trial. First Author: Carl Ola Landgren, Myeloma Program and Experimental Therapeutics Program, University of Miami, Miami, FL

Background: The use of modern combination therapy in NDMM patients delivers deep and durable treatment responses independent of transplant status. In the current ADVANCE study (NCT04268498), patients were randomly assigned to receive 8 cycles of carfilzomib-lenalidomide-dexamethasone with or without daratumumab (DKRd vs KRd). Transplants were offered to patients who were minimal residual disease (MRD) positive after 8 cycles. All patients transitioned to lenalidomide maintenance. Primary endpoint was MRD negativity 10^-5 by NGS after up to 8 cycles of combination therapy. **Methods:** 306 NDMM patients were randomly assigned 1:1 to receive 8 cycles (28-day cycles) of either DKRd or KRd (D: 1800 mg SC, days 1, 8, 15, and 22 (C1-2), days 1 and 15 (C3-6), day 1 (C7-8); K: 20/56 mg/m2 IV, days 1, 8, and 15; R: 25 mg days 1-21; d: 40/20 mg). Stem cell collection was encouraged after 4 cycles for eligible patients. After completion of cycle 8, patients were evaluated for MRD (ClonoSEQ). Transplant was reserved for MRD-positive patients (post C8). MRD-negative patients transitioned to lenalidomide 10 mg maintenance (D1-21/28). Sustained MRD status was monitored annually. Key eligibility included NDMM with ECOG PS 0-2 and adequate organ function, independent of transplant status. The study was monitored and approved by an independent data safety monitoring committee. **Results:** At 2nd prespecified analysis (data cutoff 01/15/25) demographics and disease characteristics were well balanced and included: median age 62 y/o (range: 35-76), Hispanic: 23%, Black: 11%, ISS 2-3: 39%, ECOG PS 2: 6%, and high-risk cytogenetics: 35%. The primary endpoint of MRD negativity at 10^-5 by NGS was significantly higher in the DKRd arm compared to the KRd arm (59% vs 36%, adjusted OR=2.5, 95% CI: 1.5-4.2; P<0.0007). EFS, PFS and OS data are currently immature, however, at 32.7 months median follow-up, PFS events included one death in each arm, PD 4 vs 5%, and 86 vs 79% were progression-free and censored in the DKRd vs KRd arms, respectively. Overall, 98% had an adverse event (AE) with hematologic AEs occurring in 15 vs 24%; cardiac AEs: 13 vs 16%; gastrointestinal AEs: 68 vs 72%; infections: 61 vs 53%; acute kidney injury: 1 vs 4%; vascular disorders: 6 vs 2% with DKRd vs KRd, respectively. Serious AEs occurring in >1% included: febrile neutropenia: 2 vs 2%; pyrexia: 5 vs 2%; chest pain: 0 vs 3%; non-cardiac chest pain: 2 vs 0%; pneumonia: 3 vs 10%; sepsis: 2 vs 0%; COVID-19: 2 vs 0%; wound infection: 2 vs 0%; hip fracture: 2 vs 0%; infusion reaction: 2 vs 0%; back pain: 2 vs 0%; syncope: 2 vs 0%; acute kidney injury: 0 vs 3%; and dyspnea: 2 vs 0%, with DKRd vs KRd, respectively. **Conclusions:** In this large randomized, multicenter investigator-initiated trial for NDMM, treatment with DKRd (59%) compared to KRd (36%) showed a significant, 2.5-fold higher MRD negativity rate with no new safety concerns. Updated EFS, PFS and OS results will be presented at the meeting. Based on these results, DKRd should be a new standard for most NDMM patients receiving initial KRd-backbone therapy. Clinical trial information: NCT04268498. Research Sponsor: U.S. National Institutes of Health; P30CA240139; Janssen; Amgen.

7504 Oral Abstract Session

Elranatamab in combination with daratumumab and lenalidomide (EDR) in patients with newly diagnosed multiple myeloma (NDMM) not eligible for transplant: Initial results from MagnetisMM-6 part 1. First Author: Hang Quach, St Vincent's Hospital Melbourne, University of Melbourne, Melbourne, Vic, Australia

Background: Elranatamab (ELRA), a BCMA-CD3 bispecific antibody, induced deep and durable responses with a manageable safety profile in patients (pts) with relapsed/refractory multiple myeloma (RRMM). MagnetisMM-6 (NCT05623020) is a phase 3, open-label, randomized study evaluating the efficacy and safety of ELRA in combination with lenalidomide (R) ± daratumumab (DARA) (EDR or ER) vs DARA + R + dexamethasone (DRd) in pts with transplant-ineligible (TI) NDMM. Part 1 of the study evaluates the optimal dose of EDR or ER in pts with RRMM or NDMM to determine the recommended phase 3 dose for part 2. Initial results from part 1 dose level G (DLG) are presented. **Methods:** In DLG, eligible pts had TI (age ≥65 or age <65 years with comorbidities impacting the possibility of transplant) NDMM, measurable disease, ECOG ≤2, and adequate liver, renal and bone marrow function. Pts received subcutaneous (SC) ELRA with a priming regimen followed by ELRA 76 mg SC every 4 weeks (Q4W) on cycle (C) 1 day (D) 1; DARA 1800 mg SC weekly (D1, D8, D15, D22 in C1-C2), every 2 weeks (D1, D15 in C3-C6), and Q4W (D1 in C7+); and oral R 25 mg daily on D1-D21 in 28-day cycles. Endpoints assessed in DLG include safety and preliminary efficacy. **Results:** A total of 37 pts were enrolled in DLG; 34 received EDR. The median age was 75.0 years (range, 67-83); 37.8% were male; 86.5% were White, 13.5% Asian. Four patients (10.8%) had R-ISS stage III disease, 9 (24.3%) had ≥50% baseline bone marrow plasma cells, 1 (2.7%) had ECOG=2, none had EMD, and 9 (24.3%) were frail according to the simplified IMWG frailty score. At data cutoff (Dec 23, 2024), the median follow-up was 4.6 months (range, 1.2-6.2); treatment was ongoing in 33 pts. TEAEs were reported in 97.3% (G3/4 94.6%) of pts, hematological TEAEs in 78.4% (G3/4 70.3%), and infections in 64.9% (G3/4 18.9%). The most frequent TEAEs (any grade ≥25% or G3/4 ≥10%) are shown in the Table. CRS occurred in 62.2%, all ≤G2; 1 case of G2 ICANS was reported. There was one G5 candida pneumonia. Overall, 36 out of 37 pts are responders with 2 pending confirmation as of DCO. The confirmed ORR (95% CI) by investigator was 91.9% (78.1-98.3), 81.1% with VGPR or better. In pts enrolled ≥4 months before the DCO (n=23), confirmed ORR was 95.7% (78.1-99.9), all with VGPR or better. **Conclusions:** In pts with TI NDMM, EDR demonstrated a manageable safety profile consistent with the known toxicities of components. High response rate and early responses were observed. Enrollment in dose level H evaluating the ER combination is ongoing. Updated safety and efficacy data with a longer follow-up will be presented. Clinical trial information: NCT05623020. Research Sponsor: Pfizer.

TEAEs, %	Any grade	G3/4
Neutropenia, incl. neutrophil count decreased	70.3	67.6
CRS	62.2	0
Pyrexia	35.1	0
Anemia, incl. hemoglobin decreased	32.4	16.2
Injection site reaction	29.7	0
Nausea	27.0	0
Thrombocytopenia, incl. platelet count decreased	13.5	10.8
Asthenia	16.2	10.8

7505 Oral Abstract Session

First-in-human study of JNJ-79635322 (JNJ-5322), a novel, next-generation trispecific antibody (TsAb), in patients (pts) with relapsed/refractory multiple myeloma (RRMM): Initial phase 1 results. First Author: Niels W.C.J. van de Donk, Amsterdam University Medical Center, Vrije Universiteit Amsterdam, Department of Hematology, Amsterdam, Netherlands

Background: Bispecific antibodies (BsAbs) have begun to transform outcomes in MM. Emerging data suggest that targeting two MM antigens with T-cell redirection may overcome tumor heterogeneity and acquired resistance to further improve clinical outcomes. JNJ-5322 is a next-generation TsAb dually targeting BCMA and GPRC5D via T-cell redirection, comprising novel binding domains, including low affinity CD3, selected in vitro to enhance on-tumor effects and reduce off-tumor impact. We report first results from an ongoing phase 1 study of JNJ-5322 (NCT05652335). **Methods:** Dose escalation/expansion cohorts enrolled measurable RRMM pts previously exposed to a proteasome inhibitor, immunomodulatory drug, and anti-CD38 monoclonal antibody. Escalating fixed Q2W or Q4W SC doses (0.4–300 mg) were explored, including 100 mg Q4W, the putative recommended phase 2 dose (RP2D). Pts received 1 step-up dose (SUD) (5 mg) prior to receiving the 100 mg Q4W dose, allowing faster full dose initiation and attenuation of cytokine release syndrome (CRS) risk. Adverse events (AEs) were graded by CTCAE v5.0; CRS and immune effector cell-associated neurotoxicity syndrome (ICANS) were graded per ASTCT guidelines. Overall response rate (ORR) was assessed by IMWG criteria. **Results:** As of Jan 15, 2025, 126 pts received JNJ-5322 (36 at 100 mg Q4W); median follow-up (mFU) 8.2 mo. Median age 64 yrs; median 4 prior lines of therapy; 100% triple-class exposed (56% refractory); 31% high-risk cytogenetics; 23% had prior anti-BCMA/-GPRC5D therapy (77% naïve). The putative RP2D was identified as 100 mg Q4W. Overall, 99% of pts had ≥1 AE, most commonly CRS (59%; all grade [gr] 1 [45%]/2 [14%]; no gr ≥3), nail AEs (gr 1/2 56%), taste AEs (gr 1/2 56%), neutropenia (48%; gr 3/4 41%), and non-rash skin AEs (47%; gr 3/4 1%). Overall, 16% had weight decreases (no gr ≥3), 16% had rashes (no gr ≥3), 2% had ICANS (all gr 1), and 75% had infections (gr 3/4 28%). 5 pts had dose-limiting toxicities. 4 pts died due to AEs. In response-evaluable pts, ORR was 86% (75% ≥VGPR) at the RP2D (n=36), and 73% (66% ≥VGPR) overall (n=124). ORR was 100% (89% ≥VGPR) at the RP2D among pts naïve to anti-BCMA/-GPRC5D therapies (n=27), and all patients remain in response (mFU 8.5 mo). Median time to first response was 1.2 mo. **Conclusions:** In the largest data set for a next-generation dual antigen T-cell redirecting TsAb, the first clinical data for JNJ-5322 showed a 100% ORR at the putative RP2D in anti-BCMA/-GPRC5D naïve patients, with convenient Q4W dosing. Tolerability appeared improved, including lower incidence and severity of GPRC5D-associated AEs vs anti-GPRC5D BsAbs and manageable gr 3/4 infection rates. CRS was mostly gr 1 (no gr ≥3 CRS) using 1 SUD. First data with JNJ-5322 suggest a paradigm shift, offering ORRs similar to CAR-Ts but as an off-the-shelf therapy intended for outpatient dosing. Clinical trial information: NCT05652335. Research Sponsor: None.

7506 Oral Abstract Session

Isatuximab (Isa) subcutaneous (SC) via an on-body delivery system (OBDS) vs Isa intravenous (IV), plus pomalidomide and dexamethasone (Pd) in relapsed/refractory multiple myeloma (RRMM): Results of the randomized, non-inferiority, phase 3 IRAKLIA study. First Author: Sikander Ailawadhi, Mayo Clinic, Jacksonville, FL

Background: IV Isa-Pd is approved to treat RRMM patients (pts) based on the ICARIA-MM study. A Phase 1b study showed safety and efficacy of Isa SC via an OBDS, an investigational wearable bolus injector, plus Pd, in RRMM pts. Isa SC offers shorter duration, fixed dose and smaller administration volume. Here, we report results of the IRAKLIA trial (NCT05405166); Isa SC vs IV + Pd in RRMM pts, the first Phase 3 myeloma trial reporting the use of an OBDS. **Methods:** This multicenter, open-label study enrolled pts aged ≥18 years with ≥1 prior line of therapy (LOT). Pts were randomized 1:1 to Isa SC (1400 mg) or Isa IV (10 mg/kg) weekly in Cycle (C)1, then every 2 weeks + P (4 mg/day, Day [D]1–21) + d (40 mg [20 mg if age ≥75 years] weekly). Pts had 4-week cycles until progression, unacceptable toxicity or patient request. Co-primary endpoints were overall response rate (ORR; non-inferiority [NI] margin of 0.839) and Isa trough level (C_{trough}) at steady state (predose at C6D1; NI if lower limit of 90% CI of geometric mean ratio ≥0.8). **Results:** 531 pts (SC n=263; IV n=268 [4 not treated]) were randomized. Baseline characteristics were balanced (median age 66 years; median 2 prior LOT). After median 12 months follow-up, ORR was 71% (SC arm) and 71% (IV arm; relative risk [95% CI] = 1.008 [0.903–1.126]; lower CI > NI margin). Mean (SD) C_{trough} at C6D1 was 499 (259) μg/mL for SC and 340 (169) μg/mL for IV. C_{trough} geometric mean ratio (90% CI) was 1.532 (1.316–1.784); lower CI > NI margin. Co-primary and all 4 key secondary endpoints including pt experience are in the Table. Grade ≥3 treatment-emergent adverse events occurred in 82% (SC) and 76% (IV) of pts; with treatment discontinuation rates of 8% and 9%. Injection site reactions (ISRs) occurred in 4% (11/263) of the SC arm and in 19 (0.4%) of 5145 SC injections (all Grade 1–2). 99.9% of OBDS injections were completed without interruption. **Conclusions:** IRAKLIA met its co-primary endpoints, showing efficacy and pharmacokinetic NI between Isa SC vs IV + Pd. No new safety signal besides a low ISR incidence was observed, showing excellent Isa SC tolerability. Far fewer infusion reactions and higher pt satisfaction were also noted for SC vs IV. Efficacy and safety are comparable to Isa IV in ICARIA-MM. These results support potential use of Isa SC delivered via the OBDS, designed to improve pt experience and practice efficiency. Clinical trial information: NCT05405166. Research Sponsor: Sanofi.

CT4W, C_{trough} at 4 weeks; IR, infusion reaction; PK, pharmacokinetics; PP, per protocol; VGPR, very good partial response.

7507 Oral Abstract Session

Long-term (≥5 year) remission and survival after treatment with ciltacabtagene autoleucel (cilta-cel) in CARTITUDE-1 patients (pts) with relapsed/refractory multiple myeloma (RRMM). First Author: Peter M. Voorhees, Atrium Health / Levine Cancer Institute, Wake Forest University School of Medicine, Charlotte, NC

Background: CARTITUDE-1 evaluated cilta-cel in pts with heavily pretreated RRMM who historically have an expected median progression-free survival (PFS) of <6 months (mo) and median overall survival (OS) of ~1 year (y). At 33.4 mo median follow-up, median PFS was 34.9 mo, and median OS was not reached (36-mo OS rate, 62.9%; Lin et al, ASCO 2023). We report OS, ≥5 y progression-free outcomes, and safety with a median study follow-up of 60.3 mo. **Methods:** Pts in CARTITUDE-1 received a single cilta-cel infusion. Correlative analyses were performed utilizing drug product, baseline, and postinfusion samples. Pts are followed for progression, survival, and safety in a 15-y follow-up study, CARTinue (NCT05201781), with pt evaluations per local standard of care (reported annually at a minimum). **Results:** Of 97 pts treated, 32 (33.0%) remain alive and progression free for ≥5 y after cilta-cel, without further MM treatment. For these 32 pts, prior to enrollment in CARTITUDE-1, median time from start of last line of therapy (LOT) to progression was 4.0 mo (range, 0.7–48.6). Among the 32, median age was 60 y (range, 43–78), median number of prior LOT was 6.5 (range, 3–14), 23.3% had high risk cytogenetics, 12.5% had extramedullary disease (EMD), 90.6% were triple-class refractory, and 46.9% were penta-drug refractory. Baseline characteristics of pts who were progression free for ≥5 y, including those with high-risk cytogenetics and EMD, were comparable to pts with progressive disease (PD) within 5 y. Compared with pts who had PD within 5 y, biomarkers significantly associated with ≥5 y progression free status included a higher fraction of naïve T cells in the drug product, lower neutrophil to T cell ratio, higher hemoglobin and platelets at baseline, and higher effector-to-target ratio (Cmax to sBCMA at baseline). At Cmax, these pts also had significantly higher CD4 central memory CAR+ T cell subsets and CAR+ T cells that were positive for the activation markers CD38, CD25, and PD-1. Data were collected on a subset of pts from a single center where local serial MRD assessments were performed. All 12 pts at this center who were progression free for ≥5 y were MRD negative at 10^{-6} and imaging negative by PET/CT yearly for 5 y. Overall, at 60.3 mo median follow-up in CARTITUDE-1 (N=97), median OS was 60.6 mo (95% CI, 41.9–NE). With continued follow-up, 3 additional pts reported a second primary malignancy (1 of which was acute myeloid leukemia; onset, 2.8 y after infusion). No new cases of movement and neurocognitive disorders were reported. **Conclusions:** The median OS for pts enrolled in CARTITUDE-1 was 5 y, and 33% of pts remain progression free for ≥5 y following a single cilta-cel infusion. These data provide the first evidence that cilta-cel is potentially curative in pts with RRMM. Clinical trial information: NCT03548207, NCT05201781. Research Sponsor: None.

7508 Oral Abstract Session

Safety and efficacy data from Nexicart-2, the first US trial of CAR-T in R/R light chain (AL) amyloidosis, Nxc-201. First Author: Heather Jolie Landau, Memorial Sloan Kettering Cancer Center, New York, NY

Background: No FDA approved treatments exist for relapsed/refractory (RR) AL Amyloidosis. Chimeric antigen receptor T-cell (CAR-T) is a novel approach to treating RR AL Amyloidosis. In this study, we report safety and efficacy data from NEXICART-2, the first U.S. clinical trial of any CAR-T in RR AL Amyloidosis. **Methods:** NEXICART-2 (NCT06097832) is a single-arm, multi-site U.S. Phase 1b/2 dose escalation and expansion trial of autologous BCMA-targeted CAR-T NXC-201 in RR AL Amyloidosis. It will enroll 40 patients (pts) with a 6 patient safety run-in, that has now completed. Pts must have been exposed to bortezomib and anti-CD-38 antibody with persistent or relapsed disease. Lymphodepletion was with fludarabine and cyclophosphamide. The primary endpoint is complete hematologic response (CR) rate (Palladini. 2012). **Results:** 7 pt (4 F, 3 M), median age 66 years (range: 56-82) were included. Median follow-up 97 days (range 7-209). Median prior lines 4 (range: 2-9); including 4(57%) with prior autologous stem cell transplant; 6/7 had gain 1q. Median dFLC at enrollment were 5.4 mg/dL (range: 2.4-12.1). 57% (4/7) had cardiac involvement (Mayo stage I (N =2), II (N=4) and IIIa (N=1) with median NT-proBNP 909 pg/mL (range: 146 – 2,532)); 2/7 had New York Heart Association (NYHA) class II heart failure, 5/7 class I. 2 pts had kidney involvement, with 4.5 and 10.0gm of proteinuria in 24h. 3 pts received 150 million and four 450 million CAR+T cells. CRS was observed in 5 pts (grade 1 (N=4), grade 2 (N=1)); onset day 1 (N=3) or 3 (N=2), lasting $<$24 hours following 1 dose of tocilizumab in all pts. No pt had neurotoxicity. Adverse events included neutropenia (grade 3 (N=3), grade 4 (N=2). 1 pt with pre-existing stage 4 chronic kidney disease prior to enrollment had Grade 4 acute on chronic kidney injury. There was no febrile neutropenia, treatment-related infections, cardiac toxicity, and no deaths. All pts (7/7, 100%) normalized pathological disease markers after NXC-201. Pts 1, 2, 4, 5, 6, 7 normalized FLCs at median 7 days (range 7-14) following NXC-201, all with reduction of dFLC to $<$1 mg/dL. Pts 1, 2, 4, 5, 6 had MRD negativity in bone marrow by flow cytometry (10^{-6} sensitivity) at day 25 or 26 (Pt 7 was not MRD evaluable as of the cut-off date). Pt 3 had a renal organ response per AL criteria (reduction in albuminuria) and resolution of the m-spike 15 days following NXC-201 (0.79g/dl at enrollment). As of the data cutoff, all pts are in VGPR/CR, with no relapses recorded. Improvement in NYHA class from II to I occurred in 1 pt 14 days following NXC-201 treatment. 15 pts are expected to have been treated at presentation time. **Conclusions:** In this first reported U.S. CAR-T clinical trial experience in RR AL Amyloidosis, we demonstrate that NXC-201 can be given safely and resulted in rapid and deep hematologic responses in all pts treated. Our data suggests that the novel anti-BCMA CAR-T NXC-201 may become a valuable treatment option for RR AL pts. Clinical trial information: NCT06097832. Research Sponsor: Immix Biopharma; MSK Cancer Center Support Grant/Core Grant (P30 CA008748).

7509 Rapid Oral Abstract Session

Isatuximab, carfilzomib, lenalidomide, and dexamethasone (Isa-KRd) for high-risk (HR) newly diagnosed multiple myeloma (NDMM): First-time report of the full cohort of transplant-eligible (TE) patients in the GMMG-CONCEPT trial. First Author: Lisa B. Leypoldt, University Medical Center Hamburg-Eppendorf, Hamburg, Germany

Background: Patients (pts) with HR NDMM have shown impaired survival outcomes even in the era of modern combination therapies. Establishing Isa-KRd in an intensified first-line regimen, the Phase II CONCEPT trial (NCT03104842) aimed at improving outcomes for HR NDMM pts for whom clinical trials had long been missing. **Methods:** The prospective, multicenter, academic Phase II CONCEPT trial has 2 parallel treatment arms according to transplant-eligibility. Adult NDMM pts with HR disease, defined as $\geq$1 HR cytogenetic aberration (CA) (del(17p), t(4;14), t(14;16), $\geq$3 copies 1q21) in combination with ISS stage II/III were included. All pts received Isa-KRd induction (6 cycles), intensification (HD-MEL+ASCT [TE pts; arm A] or 2 cycles Isa-KRd [non-TE pts; arm B]), 4 cycles Isa-KRd consolidation and 2 years Isa-KR maintenance. Primary endpoint is minimal residual disease (MRD) negativity (NGF, 10^{-5}) at the end of consolidation, tested against the null hypothesis MRD-neg rate $\leq$50% (TE pts); key secondary endpoints include survival times (PFS, OS). The trial recruited in 2 phases: 2017-2020 (TE+TNE; 1st cohort) and 2021-2022 (TE only; 2nd cohort), with a switch in carfilzomib application implemented in 2021 (1x weekly instead of 2x weekly). Interim results of the 1st cohort have been shown before. Here, we report for the first time the final analysis on the primary endpoint from the full cohort of TE pts. **Results:** 219 TE pts (and 26 TNE pts) were included and dosed. At data cut-off (9 Jan 2025), 66 pts were still on treatment. Median age of TE pts was 60 years (range, 31-73) with 119 and 100 showing ISS II and III. Del(17p) and gain1q were the most common HRCA (40.6% and 46.6%) and 35.6% had $\geq$2 HRCA. The trial met its primary endpoint with an MRD-neg rate after consolidation of 73.2% in the MRD-analysis population (153/209; 10 not assessable). Further analyses confirmed the benefit across different CA subgroups. Overall, 58.4% reached MRD-neg $\geq$CR, 86.8% reached MRD-neg at any time. 64.8% and 40.6% retained $\geq$1-year- and $\geq$2-year-sustained MRD-neg. With a median follow-up (mFU) of 42 mo (0-85.5 mo), mPFS for TE pts was 69.7 mo, while mOS has not been reached. For TNE pts (mFU 60 mo), mPFS and mOS have not been reached. Reaching and remaining in MRD-neg state led to a significant PFS benefit (*hr* 0.16 [0.08;0.32], time-dependent Cox regression). Carfilzomib 1x weekly resulted in fewer K discontinuations than 2x weekly dosing (0.6% and 4.8%, TE pts), with more dose reductions in the 1x weekly dosing (9.5% and 5.5%, TE pts). **Conclusions:** The full CONCEPT cohort represents the largest prospective trial cohort of purely HR NDMM pts reported so far. Isa-KRd resulted in unprecedented rates of MRD-neg., sustained MRD-neg. and survival supporting the use of Isa-KRd as a standard-of-care regime in this hard-to-treat population. Clinical trial information: NCT03104842. Research Sponsor: University Medical Center Hamburg-Eppendorf; Sanofi; Amgen; BMS/Celgene.

7510 Rapid Oral Abstract Session

Linvoseltamab (LINVO) + bortezomib (BTZ) in patients (pts) with relapsed/refractory multiple myeloma (RRMM): First results from the LINKER-MM2 trial. First Author: Paula Rodríguez-Otero, Department of Hematology, Clínica Universidad de Navarra, Pamplona, Spain

Background: LINVO, a BCMA$\times$CD3 bispecific antibody, has shown high efficacy and generally manageable safety in triple-class exposed (TCE: anti-CD38 Ab + immunomodulatory drug [IMiD] + proteasome inhibitor [PI]) pts with RRMM. PIs such as BTZ have direct anti-MM activity and may enhance LINVO activity by improving immune function. We report safety and preliminary efficacy data from dose escalation and expansion in the LINVO + BTZ cohort of the phase 1b, open-label LINKER-MM2 trial (NCT05137054). **Methods:** Eligible pts were $\geq$18 yrs with RRMM that progressed after $\geq$3 lines of therapy (LoT), or $\geq$2 LoT if either TCE or double-class refractory (IMiD + PI). Prior BTZ was allowed if previously tolerated and $\geq$6 months (mos) had elapsed since last exposure. BTZ-refractory pts were allowed during dose escalation. Treatment (tx) began with LINVO alone (Cycle [C] 0: 2 step-up doses [5 and 25 mg] and $\geq$1 full dose [dose level [DL] 1 = 100 mg or DL2 = 200 mg]) before initiating standard dose BTZ (1.3 mg/m^2 twice weekly over 21-day cycles) at C1. LINVO was given once weekly (QW) in C1–4, then Q3W thereafter. BTZ dosing could be switched to QW after C3 and ended after a total of 8 cycles. Dexamethasone premedication was limited to C0–1. Primary endpoints were dose-limiting toxicities (DLTs; dose-finding portion) and incidence/severity of tx-emergent AEs (TEAEs). Secondary endpoints included objective response rate (ORR), duration of response (DOR), and progression-free survival (PFS). **Results:** As of Sept 30, 2024, 22 pts had received tx (DL1: n=6; DL2: n=16). Median follow-up duration was 6.3 mos (range 1–21), with 55% of pts still receiving tx. Median age was 68.5 yrs (range 45–77), 68% were male, 23% had ISS stage III, and 55% had extramedullary or paraskeletal disease. Median prior LoT was 3 (range 2–9), including 86% of pts with TCE and 41% with triple-class refractory disease; 59% were refractory to $\geq$1 PI (9% BTZ-refractory). Among evaluable pts, ORR was 79% (11/14; DL1 80% [4/5]; DL2 78% [7/9]). The 6-month DOR rate was 90% (95% CI 47–99) and 6-month PFS rate was 79% (95% CI 47–93). PK analysis found LINVO concentrations were not affected by addition of BTZ. The most common TEAEs were neutropenia (any Grade [Gr] 59%; Gr 3–4 45%), thrombocytopenia (50%; 36%), and cytokine release syndrome (55%; 0%). ICANS was reported in 4 pts (all Gr 1–2 with onset during step-up dosing). Infections were reported in 82% of pts (Gr 3–4 36%); 1 pt died of pneumonia $\leq$30 days after last dose before start of combination tx. One DLT occurred at DL2 (Gr 3 CMV colitis on day 48; resolved with tx delay and ganciclovir). **Conclusions:** LINVO + BTZ induced high response rates, with encouraging early DOR and PFS, in a population that was mostly PI-refractory. Safety was consistent with the known profile of each drug, and risk of Gr 3–5 infection was similar to LINVO monotherapy. These data will inform LINVO combination strategies for earlier LoT. Clinical trial information: NCT05137054. Research Sponsor: Regeneron Pharmaceuticals, Inc.

7511 Rapid Oral Abstract Session

Heterogeneity in the expression of GPRC5D between patients with multiple myeloma. First Author: Harsh Parmar, John Theurer Cancer Center, Hackensack University Medical Center, Hackensack, NJ

Background: G-protein-coupled receptor class C group 5 member D (GPRC5D) is a protein inducible by all-trans retinoic acid with expression levels that vary depending on cellular differentiation. This protein receptor is targeted by several therapeutic modalities including chimeric-antigen receptor T-cell therapy (CAR-T), T-cell engagers (TCEs) and antibody-drug conjugates (ADCs). However, our understanding of GPRC5D expression levels in multiple myeloma cells and patient-to-patient heterogeneity remains limited. We investigated the expression levels of GPRC5D in the plasma cells of patients with multiple myeloma and compared its level of expression with those of CD38, CD138 and BCMA (TNFRSF17). **Methods:** Plasma cells from the bone marrow aspirates of 290 patients with multiple myeloma were enriched using CD138 column. RNA was extracted from the CD138 enriched population and sequenced by next generation sequencing (NGS) using a targeted RNA panel of 1600 genes. The RNA expression levels of various genes were quantified and expressed as transcript per million (TPM). **Results:** There was significant variation in the expression of GPRC5D between myeloma samples. The median and standard deviations for CD38, CD138, BCMA, and GPRC5D were 89 and 113, 69 and 134, 58 and 132, and 10 and 166, respectively. There was significant correlation ($P <$ 0.00001) between CD38, CD138 and BCMA. However, there was no correlation between the levels of GPRC5D and CD38 (R=-0.05, P= 0.4), CD138 (R=0.3, P= 0.6) or BCMA (R=0.1, P=0.02). Ten samples (3%) had zero TPM expression of GPRC5D despite relatively high CD138 (between 33 TPM and 487 TPM). The ratio of GPRC5D: BCMA varied from 0 to 39 with one sample with an exceptionally high ratio of 459 due to very low BCMA with high CD138 due to anti-BCMA therapy. **Conclusions:** Analysis of these data suggests that unlike BCMA, there is a significant patient-to-patient heterogeneity in GPRC5D expression. GPRC5D expression levels show a wide variation with approximately 3% of patients showing an absence of GPRC5D expression. Clinical trials exploring anti-GPRC5D therapy should consider measuring GPRC5D expression levels and potentially explore other therapies that may induce its increased expression given our findings. Research Sponsor: None.

Belantamab mafodotin plus lenalidomide/dexamethasone in newly diagnosed intermediate-fit & frail multiple myeloma patients: Long-term efficacy and safety from the phase 1/2 BELARD clinical trial. First Author: Evangelos Terpos, Department of Clinical Therapeutics, National and Kapodistrian University of Athens, School of Medicine, Athens, Greece

Background: We report the long-term safety & efficacy results of a novel, extended dosing schedule of belantamab mafodotin (belamaf) combined with Lenalidomide & Dexamethasone (Rd), in transplant-ineligible newly diagnosed Multiple Myeloma patients (pts). **Methods:** Phase 1/2 BelaRd trial (NCT04808037) Part 1 evaluated the safety/tolerability of belamaf 2.5/1.9/1.4 mg/kg plus Rd & established a recommended phase 2 dose (RP2D) of 1.9 mg/kg Q8W, extended to Q12W for Ocular Adverse Events (OAEs, Best Corrected Visual Acuity [BCVA] change from baseline & keratopathy). Dosing was led by ophthalmologist-assessed OAEs. In Part 2 RP2D is assessed in 2 groups: Dosing in Group A is guided as in Part 1 & in Group B by Vision-Related Anamnestic (a 9-question tool on pt-reported ocular symptoms & their impact on daily functioning) & ≥Gr3 OAEs. Safety/efficacy results from both Parts of the trial are presented. **Results:** Of Part 1 pts (n=36; median age: 72.5; male: 53%), 25 (69%) are ongoing & 11 (31%) discontinued (8 [22%] due to fatal events; 1 [3%] progressive disease; 2 [6%] withdrew consent). 17%/75% of pts had stage I/II disease per R-ISS & 8% high-risk cytogenetics (HRC). At a median follow-up (FU) of 36.2 months, Overall Response Rate (ORR) was 100%. Meaningful BCVA decline (Snellen <20/50) was recorded in 12% & Gr2/≥Gr3 keratopathy in 12%/3% of ocular exams. Median time to resolution was 1.9/1.1 months for ≥Gr2 BCVA/keratopathy OAEs, respectively. The most common (≥10%) Gr≥3 non-ocular AEs were fatigue, diarrhea, rash, COVID-19, pneumonia & insomnia. Of Part 2 pts (n=30; median age: 75; male: 67%), 22 (73%) are ongoing & 8 (27%) discontinued (6 [20%] due to fatal events; 1 [3%] progressive disease; 1 [3%] withdrew consent). 27%/63% of pts had stage I/II disease per R-ISS & 17% had HRC. At a median FU of 19.7 months, ORR was 96.7%. Meaningful BCVA decline was recorded in 27% & Gr2/≥Gr3 keratopathy in 9%/<1% of ocular exams. Median time to resolution of ≥Gr2 OAEs was 1.75 months. The most common Gr≥3 non-ocular AEs were fatigue & rash. The 12/24/36-months Time to Progression rates for all 66 pts were 98.2%/98.2%/94.4% (table 1). **Conclusions:** As has also been shown in the DREAMM-7/-8 studies,belamaf exhibits substantial clinical activity, with rapid, deep & durable responses in an unfit pt population, with only 2 PDs observed after a median of ~2 years FU. Only a few high-grade OAEs were recorded, that resolved quickly & no new safety signals were observed. Moving forward, the BelaRd combination, with the extended belamaf dosing schedule, warrants further investigation in larger pt numbers. Clinical trial information: NCT04808037. Research Sponsor: None.

Time to progression (TTP) rates in the overall population (66 pts).

	TTP rate in % (95% CI)
12 months	98.21 (87.99-99.75)
24 months	98.21 (87.99-99.75)
36 months	94.44 (77.81-98.70)

7513 Rapid Oral Abstract Session

Linvoseltamab (LINVO) + carfilzomib (CFZ) in patients (pts) with relapsed/refractory multiple myeloma (RRMM): Initial results from the LINKER-MM2 trial. First Author: Salomon Manier, Hematology Department, Lille University Hospital, Lille, France

Background: LINVO, a T-cell redirecting BCMA×CD3 bispecific antibody, has demonstrated high efficacy and generally manageable safety in triple-class exposed (TCE: anti-CD38 Ab + immunomodulatory drug [IMiD] + proteasome inhibitor [PI]) pts with RRMM. Combination treatment (tx) with CFZ, a potent second-generation PI, may enhance clinical activity via rapid cytoreduction and complementary immunostimulatory mechanisms like immunogenic cell death and antigen spreading. We report safety and preliminary efficacy from dose escalation in the LINVO + CFZ cohort of the phase 1b, open-label LINKER-MM2 trial (NCT05137054). **Methods:** Eligible pts were ≥18 years with RRMM that progressed after ≥3 lines of therapy (LoT), or ≥2 LoT if either TCE or double-class refractory (IMiD + PI). Prior CFZ was allowed if previously tolerated and ≥6 months had elapsed since last exposure. CFZ-refractory pts were allowed during dose escalation. Tx began with LINVO alone (Cycle [C] 0) consisting of 2 step-up doses (5 mg and 25 mg) and 2 full doses (dose level [DL] 1 = 100 mg or DL1b = 150 mg) before initiation of CFZ (20/56 mg/m^2 on days 1, 2, 8, 9, 15, 16) at C1. LINVO was given once weekly (QW) in C1–4, and Q2W thereafter. CFZ dosing could be switched to QW after C2. Dexamethasone premedication was limited to C0–1. Primary endpoints were dose limiting toxicities (DLTs) and tx-emergent adverse events (TEAEs). Secondary endpoints included objective response rate (ORR), duration of response (DOR), and progression-free survival (PFS). **Results:** As of Sep 30, 2024, 18 pts were treated at DL1 (n = 12) or DL1b (n = 6). Median duration of follow-up was 16.9 (DL1) and 7.7 months (DL1b), with 67% and 83% of pts still receiving tx, respectively. Median age was 68 years (range 53–79), 50% were male, 6% had ISS stage III, 50% had extramedullary or paraskeletal disease, and 17% had high-risk cytogenetics. Median prior LoT was 3 (2–6), including 83% of pts with TCE and 33% with triple-class refractory disease. Among evaluable pts, ORR was 91% at DL1 (10/11; ≥VGPR 91%) and 100% at DL1b (6/6; ≥VGPR 80%). Median DOR was not reached at either DL. For DL1, the PFS rate was 91% (95% CI 51–99) at 6 months and 73% (95% CI 37–90) at 12 months. No PFS events had occurred at DL1b. PK analysis found LINVO concentrations were not affected by addition of CFZ. The most common TEAEs were neutropenia (any Grade [Gr] 78%; Gr 3–4 61%), thrombocytopenia (61%; 39%), and cytokine release syndrome (61%; Gr ≥3 0%). One pt experienced ICANS (Gr 1). Infections were reported in 89% of pts (Gr ≥3 44%). One DLT was observed at DL1, Gr 4 thrombocytopenia in the setting of tumor lysis syndrome, from which the pt recovered and afterward resumed tx. **Conclusions:** LINVO + CFZ induced a high rate of deep and durable responses with a safety profile consistent with the individual drugs, supporting further development. Enrollment at 200 mg LINVO in combination with CFZ is ongoing. Clinical trial information: NCT05137054. Research Sponsor: Regeneron Pharmaceuticals, Inc.

7514 Rapid Oral Abstract Session

Phase 1, first-in-human study of ISB 2001: A BCMAxCD38xCD3-targeting trispecific antibody for patients with relapsed/refractory multiple myeloma (RRMM)—Dose escalation (DE) results. First Author: Eben I. Lichtman, UNC Lineberger Comprehensive Cancer Center, Chapel Hill, NC

Background: MM remains an incurable disease and resistance mechanisms are emerging. ISB 2001, a first-in-class trispecific T cell engager, redirects cytotoxic T cells to BCMA and/or CD38-expressing myeloma cells. By simultaneously targeting two TAA, ISB 2001 enhances avidity binding to tumor cells in vitro, hence potency, while the distal positioning of the CD38 vs CD3 binders minimizes CD38-related off-tumor adverse events. **Methods:** We report data from the DE portion of a Phase 1 study of ISB 2001, assessing safety, tolerability, efficacy, pharmacokinetics (PK), and pharmacodynamics (PD) in RRMM patients (pts) exposed to immunomodulatory drugs, proteasome inhibitors, and anti-CD38 therapies and refractory or intolerant to established therapies. Prior BCMA-targeted and/or T-cell directed therapies were allowed. ISB 2001 was administered weekly subcutaneously (SC) in 28-day cycles, with initial step-up doses on Days 1 (15μg/kg) and 4 (variable). DE utilized an accelerated titration design (initial 3 cohorts with single-patient dosing) followed by a standard 3+3 design. DLTs were evaluated in the first 28 days. After DE, the study will proceed with Part 2 (dose expansion) to confirm safety and select the recommended Ph2 dose under FDA Project Optimus. **Results:** As of January 13, 2025, 24 pts were treated with ISB 2001 across 8 dose levels (5–1800 μg/kg) with a median follow-up of 6 months (range: 2–12). DL9 (2700 μg/kg) is last dose level and currently enrolling. Among 24 pts, median age was 66 years; 58% male, 83% white with a median of 6 prior lines of therapy (range: 3-11). All pts were triple-exposed, 17/24 (71%) penta-exposed, and 3/17 penta-refractory (18 %). No DLT, adverse events (AE) leading to treatment discontinuation or deaths occurred. Serious AEs were reported in 8 (33%) patients. Drug related Grade (Gr) 3-4 AEs were seen in 13 (54%) pts. CRS was reported in 17 (70.8%) patients, primarily Grade 1–2, with a median onset of 3 days and a median duration of 2 days. No neurologic AEs or ICANs. The Overall Response Rate (ORR) was 75% across all 8 doses, including stringent CR (sCR) 13%, CR 13%, VGPR 38%, PR 13%. Responses were observed from dose level as low as 50 μg/kg (MRD-neg, sCR) with an ORR of 82% at doses ≥50 μg/kg. Median time to response was 36 days. ISB 2001 showed near dose-proportional PK, a half-life >10 days, and consistent T-cell activation, supporting its mechanism of action. **Conclusions:** ISB 2001 was well tolerated with manageable CRS, no ICANS and demonstrated robust anti-myeloma activity in heavily pretreated RRMM pts (NCT05862012). Full clinical data, including PK and PD results from the dose-escalation portion of the study, will be presented at the conference. Clinical trial information: NCT05862012. Research Sponsor: IGI.

7515 Rapid Oral Abstract Session

Minimal residual disease (MRD) negativity (neg) in patients (pts) with relapsed or refractory multiple myeloma (RRMM) treated with belantamab mafodotin plus pomalidomide and dexamethasone (BPd) vs pomalidomide, bortezomib, and dexamethasone (PVd): Analysis from the DREAMM-8 trial. First Author: Suzanne Trudel, Department of Medical Oncology and Hematology, Princess Margaret Cancer Centre, Toronto, ON, Canada

Background: In DREAMM-8 (NCT04484623), BPd demonstrated a statistically significant, clinically meaningful benefit to progression-free survival (PFS) vs PVd in pts with RRMM who received ≥1 prior line of treatment including lenalidomide. MRD neg has been shown to be a predictor of PFS and overall survival (OS) in MM. We assessed efficacy outcomes by MRD status. **Methods:** Ptswere randomized (1:1) to BPd or PVd. The primary endpoint was independent review committee (IRC)–assessed PFS; OS, duration of response, and MRD status determined by next-generation sequencing with 10^{-5} sensitivity threshold was assessed in pts with complete response or better (≥CR) every 6 mo until progressive disease. Post hoc subgroup analyses of PFS and OS were conducted based on IRC-assessed response (≥CR or ≥VGPR) and MRD-neg status using Kaplan-Meier method; CIs were estimated using Brookmeyer-Crowley method. **Results:** 302 pts were randomized to BPd (n=155) or PVd (n=147). As previously reported (median follow-up, 21.8 mo), more pts with BPd had CR-based MRD neg vs PVd (37/155 [24%] vs 7/147 [5%]). A similar trend was seen in pts with ≥VGPR; 50/155 pts (32%) had VGPR-based MRD neg with BPd vs 8/147 (5%) with PVd. In the DREAMM-8 trial, MRD neg was associated with improved efficacy outcomes (Table). Pts with CR-based MRD neg had a lower risk of disease progression or death compared with pts without MRD neg (PFS HR, 0.14; 95% CI, 0.06-0.32; Table); median was NR overall and in each treatment arm (HR [BPd vs PVd], 0.90; 95% CI, 0.10-7.76). MRD neg pts had a lower risk of death (OS HR, 0.18; 95% CI, 0.07-0.49). In all pts who did not have CR-based MRD neg, pooled median PFS was 14.0 mo (95% CI, 11.1-18.6 mo; BPd, 19.6 mo; PVd, 10.2 mo; HR [BPd vs PVd], 0.67; 95% CI, 0.47-0.94), and the pooled 18-mo PFS rate was 46% (95% CI, 39%-52%; BPd, 52%; PVd, 39%). Median OS was NR overall, 33.0 mo (95% CI, 23.7-NR) with BPd and NR with PVd; 18-mo OS rate was 69% (95% CI, 63%-75%; BPd, 72%; PVd, 67%). **Conclusions:** Consistent with previous reports, MRD neg was associated with a robust benefit in PFS and OS, highlighting the significance of a greater response depth. Pts with BPd achieved a 5-fold improvement in CR-based MRD neg vs PVd (24% vs 5%). Pts who did not achieve CR-based MRD neg had a clinically meaningful benefit in PFS with BPd vs PVd. Clinical trial information: NCT04484623. Research Sponsor: Funding statement: This study sponsored by GSK. Editorial support provided by Nucleus Global and funded by GSK. Daratumumab plus bortezomib, lenalidomide, and dexamethasone (DVRd) in patients with newly diagnosed multiple myeloma (NDMM): Subgroup analysis of transplant-ineligible (TIE) patients in the phase 3 CEPHEUS study. First Author: Thierry Facon, University of Lille, CHU Lille, Lille, France

Background: After readout of the PERSEUS and CEPHEUS trials, daratumumab-based therapy + VRd is emerging as the standard of care in NDMM treatment. In CEPHEUS (NCT03652064), DVRd improved minimal residual disease negativity (MRD neg) and progression-free survival (PFS) vs VRd in patients (pts) with TIE or transplant-deferred (TD) NDMM. As transplant deferral is not a common clinical pathway in many regions, here we report a post hoc analysis of DVRd efficacy in TIE pts. **Methods:** CEPHEUS enrolled pts with TIE or TD NDMM, ECOG performance status (PS) 0–2, and an International Myeloma Working Group (IMWG) frailty score of 0 or 1. Pts were randomized (1:1) to DVRd or VRd. In this analysis, the primary endpoint of overall MRD neg rate (MRD neg at 10^{-5} and complete response or better [≥CR]), and key secondary endpoints, including PFS and sustained MRD neg (confirmed MRD neg ≥12 months [mo] apart without MRD positivity in between) were assessed in the CEPHEUS TIE population. **Results:** Of 395 pts, 289 were TIE (DVRd, n=144; VRd, n=145). TIE population baseline (BL) characteristics were generally well balanced between DVRd vs VRd. In the TIE vs intent-to-treat (ITT) population, median age was older (72 vs 70 years [y]), and a higher percentage of pts were intermediate fit per IMWG criteria (41.2% vs 35.2%). In TIE pts, overall MRD neg rate at 10^{-5} was 60.4% for DVRd and 39.3% for VRd (odds ratio [OR] 2.37; 95% CI 1.47–3.80; $P<0.0001$); at 10^{-6}, it was 45.8% vs 26.9% (OR 2.28; 95% CI 1.40–3.73; $P=0.001$). Sustained MRD neg rate (10^{-5}) was 46.5% vs 27.6% (OR 2.27; 95% CI 1.39–3.70; $P=0.0010$). Overall ≥CR rate was 80.6% vs 61.4% (OR 2.73; 95% CI 1.71–4.34; $P<0.0001$). At 58.7-mo median follow-up, median PFS was NR for DVRd and 49.6 mo for VRd, and the 54-mo PFS rate was 69.0% vs 48.0% (HR 0.51; 95% CI 0.35–0.74; $P=0.0003$); OS favored DVRd vs VRd (HR 0.66; 95% CI 0.42–1.03; after censored for deaths due to COVID-19, HR 0.55; 95% CI 0.34–0.90). Treatment effect was generally consistent across subgroups (Table). Safety profile was consistent with ITT and the known profile for daratumumab subcutaneous and VRd. **Conclusions:** In CEPHEUS TIE pts, the ≥CR rate was 80.6% and overall MRD neg rate (10^{-5}) was 60.4%, with ~50% of pts sustaining MRD neg for ≥1 y. Nearly 70% of pts were alive and progression free at 4.5 y. These subgroup data reinforce the strong efficacy of DVRd in the TIE population. Clinical trial information: NCT03652064. Research Sponsor: Johnson & Johnson.

Isatuximab, bortezomib, lenalidomide, and dexamethasone (Isa-VRd) in newly diagnosed multiple myeloma (NDMM): Outcomes in patients with 1q21+ status in the phase 3 IMROZ study. First Author: Meletios Athanasios Dimopoulos, Department of Clinical Therapeutics, School of Medicine, National and Kapodistrian University of Athens, Athens, Greece

Background: Gain or amplification of 1q21 (1q21+, ≥3 copies) is a chromosomal abnormality often detected in MM that can negatively affect prognosis by its involvement in resistance to therapy and MM progression. Results from the global, randomized Phase 3 IMROZ study (NCT03319667) demonstrated significant progression-free survival (PFS) benefit with Isa-VRd followed by Isa-Rd compared with VRd followed by Rd, along with deep and sustained responses, in transplant-ineligible patients (pts) with NDMM. To evaluate efficacy of combination treatment with Isa-VRd/Isa-Rd vs VRd/Rd in NDMM pts with 1q21+ status, we analyzed clinical outcomes (PFS, overall response, minimal residual disease negativity [MRD−]) for 1q21+ pts in the IMROZ study. **Methods:** In IMROZ, 446 pts were randomized 3:2 to receive Isa-VRd (n=265) in the initiation phase followed by maintenance with Isa-Rd vs VRd (n=181) followed by Rd. 1q21+ status was assessed by FISH (30% cutoff) and prespecified as ≥3 copies (gain=3, amplification >3). Isolated 1q21+ was defined as presence of 1q21+ and absence of high-risk chromosomal abnormalities [HRCAs; del(17p), t(4;14), t(14;16)]. MRD data by NGS were reported at 10^{-5} sensitivity threshold. **Results:** Overall, 35.9% and 38.7% of pts had 1q21+ status in the Isa-VRd and VRd arms, respectively (23.8% and 26.0% with gain(1q21), 12.1% and 12.7% with amp(1q21); 7.2% and 8.3% also had ≥1 HRCA). Treatment with Isa-VRd significantly prolonged PFS vs VRd in 1q21+ pts (with or without HRCA) and in pts with isolated 1q21+ (see Table) and led to higher rates of complete response (CR) and MRD−. A substantially greater proportion of pts with 1q21+ or isolated 1q21+ achieved MRD− CR and sustained MRD− for ≥12 months with Isa-VRd than with VRd. Data for gain(1q21) and amp(1q21) will be presented. **Conclusions:** Results from our analysis of outcomes in 1q21+ pts in the IMROZ trial demonstrate consistent PFS benefit with Isa-VRd vs VRd, as reported in the overall study population. Benefit was observed regardless of 1q21+ or isolated 1q21+ status.These findings are in line with similar analyses done with Isa-pomalidomide-dexamethasone and Isa-carfilzomib-dexamethasone in Phase 3 studies. Clinical trial information: NCT03319667. Research Sponsor: Sanofi.

Disease response at apheresis and association with long-term outcomes following CAR-T cells for relapsed/refractory multiple myeloma (RRMM). First Author: Thomas Luo, Abramson Cancer Center, Hospital of the University of Pennsylvania, Philadelphia, PA

Background: The two approved BCMA-targeted CAR-T products, cilta-cel and ide-cel, have significant efficacy in RRMM, but are not considered curative. Initial studies in ≥4th line RRMM required progressive disease (PD) at time of enrollment and T cell apheresis. We hypothesized that using CAR-T cells as a planned consolidation strategy (i.e. in patients (pts) with stable or responsive disease on their current therapy) may lead to lower toxicity and better long-term disease control. **Methods:** We conducted a retrospective review of all RRMM pts receiving commercial CAR-T cells at the University of Pennsylvania from 6/1/21 to 4/30/24, with at least 6 months of follow-up. Intent for consolidation was retroactively assigned by chart review. Kaplan-Meier methodology was used to determine PFS and OS. **Results:** We identified 149 pts for analysis, with a median follow-up of 14.4 months (mos). Median prior lines was 6 and 81% of pts were triple class-refractory; 46% had high-risk cytogenetics, 26% had extramedullary disease, and 17% had prior BCMA-directed therapy. Pts received either cilta-cel (54%) or ide-cel (46%), and 95% received bridging therapy. CAR-T cells were intended as planned consolidation in 51 pts (34%); of these, 36 (71%) had ≥PR at time of apheresis. For consolidation vs non-consolidation groups, this translated into greater depth of response post-CAR-T cells (≥VGPR, 86% vs. 66%, p=0.01), lower rates of ≥grade 3 CRS (1.9% vs. 9.1%, p=0.16), and longer PFS (median not reached vs. 10 mos, p=0.001), respectively. The PFS improvement was seen for both cilta-cel (p=0.01) and ide-cel (p=0.04). No differences in neurotoxicity were noted. We also performed analyses based on response at apheresis, regardless of intent (8% ≥VGPR, 23% PR, 27% stable disease (SD), and 42% PD). PFS at 20 mos was 88%, 47%, 55%, and 31% for ≥VGPR, PR, SD, and PD at apheresis, respectively (p=0.015). Median PFS of pts with at least SD (≥SD) at apheresis was not reached vs. 9.4 mos in those with PD (p= 0.003), with 20-month OS of 87% in the ≥SD group and 68% in the PD group (p=0.015). Subgroup analysis confirmed this PFS difference for both cilta-cel and ide-cel, while the OS impact was only seen for cilta-cel. On multivariate analysis, having ≥SD at apheresis was an independent predictor for PFS. No statistically significant differences in CRS and ICANS were observed based on response at apheresis. Pts with ≥SD at apheresis had higher absolute lymphocyte counts at days 7 and 14 post-CAR-T infusion than those with PD, indicating disease status at apheresis may be associated with CAR-T product quality. **Conclusions:** Our data suggest that disease control (≥SD) at time of T-cell collection is associated with more durable responses, supporting use of CAR-T cells as a consolidation strategy in RRMM. We cannot conclude these associations are causal. Further analyses of apheresed T cell characteristics are planned. Research Sponsor: None.

Second primary malignancy (SPM) in patients (pts) with multiple myeloma (MM) receiving chimeric antigen receptor T-cell (CAR T) therapy or other systemic anticancer therapy (SACT): A comparative study using a real-world database. First Author: Attaya Suvannasankha, Department of Medicine, Indianna University, Indianapolis, IN

Background: Cases of SPM have been reported following CAR T therapy, but comparative studies are scarce. We compared the risk of SPM following CAR T therapy vs other SACT in pts with MM. **Methods:** Pts aged ≥18 years with MM who initiated CAR T therapy or other SACT, except stem cell transplant, in second-line or beyond were identified from Komodo Health claims data (3/26/2021–1/31/2024). Incident SPM was identified by ≥1 diagnostic code through death, disenrollment, or data cutoff (4/30/2024), whichever was earliest. Cumulative incidence of SPM following CAR T therapy or other SACT was estimated through 24 months, weighted by baseline factors including prior MM treatments; p-values were calculated for differences in the area under the curves through 24 months. **Results:** Pts who received CAR T therapy (n=436) or other SACT (n=18,603) were followed for a median of 11.8 months (IQR 5.7–22.8). Compared to pts who received other SACT, pts who received CAR T therapy had nominally higher risk (cumulative incidence [95% CI]) of any SPM (p = 0.05; 24.1% [18.4%, 29.8%] vs. 18.1% [13.5%, 22.8%] at 24 months), driven by significantly higher heme SPM risk (p=0.01; 8.7% [6.1%, 11.4%] vs. 5.6% [3.0%, 8.8%] at 6 months, 12.1% [8.7%, 15.3%] vs. 7.2% [4.3%, 10.4%] at 12 months, and 17.9% [12.8%, 23.5%] vs. 8.7% [5.4%, 11.7%] at 24 months; respectively), including higher risks of myelodysplastic syndrome and leukemias. The risk of solid SPM was nominally lower following CAR T vs other SACT (p=0.28; 9.1% [6.2–12.3] vs 13.9% [9.6–18.4] at 24 months). In the sensitivity analysis requiring ≥2 diagnostic codes to identify an SPM, the absolute risk was reduced and the difference in heme SPM risk was attenuated (p=0.39; Table). Notably, pts were more likely to receive bone marrow examination following CAR T therapy vs other SACT (47% vs 10% at 0–3 months, respectively). **Conclusions:** Pts with MM appeared to have a higher risk of heme SPM through 24 months following CAR T therapy compared with other SACT. However, the difference was attenuated in a sensitivity analysis that required ≥2 diagnostic codes, assumed to represent a confirmed diagnosis. Potential detection bias may exist, suggested by a higher rate of bone marrow examination following CAR T therapy. Longer term studies are needed to further evaluate this association. Research Sponsor: Regeneron Pharmaceuticals, Inc.

Cumulative incidence (%) and 95% CI of SPM at 24 months.

SPM	Analysis	CAR T therapy	Other SACT	p-value
Any	Main	24.1 (18.4–29.8)	18.1 (13.5–22.8)	0.05
	Sensitivity	11.5 (8.1–15.1)	9.5 (6.3–13.2)	0.10
Heme	Main	17.9 (12.8–23.5)	8.7 (5.4–11.7)	0.01
	Sensitivity	5.5 (3.4–7.6)	4.7 (2.3–7.6)	0.39

Utilization and cost implications for collection and storage of excess autologous hematopoietic stem cells in patients with multiple myeloma. First Author: Liz Thaliath, Marshfield Clinic, Marshfield, WI

Background: Treatment for transplant-eligible patients with multiple myeloma (MM) is typically induction therapy followed by autologous hematopoietic cell transplantation (autoHCT). Guidelines recommend leukapheresis to collect sufficient hematopoietic progenitor cells (HPCs) for initial and potential second autoHCT. But with novel immune effector therapies, the need for salvage autoHCT has decreased. HPC mobilization and collection are resource-intensive, both in time and costs. We aimed to assess the utilization and costs of cryopreserved HPCs stored for potential second autoHCTs at our center to evaluate the impact for adopting a single-transplant collection strategy for all MM patients. **Methods:** We conducted a retrospective study using clinical and laboratory databases at a small transplant center in upper Midwest. A total of 97 patients (age ≥18 years) with confirmed diagnosis of MM who underwent HPC mobilization and collection between 2013 and 2023 were included. We extracted demographical patient information as well as clinical data including disease characteristics, previous lines of therapies, number of mobilization and apheresis sessions, and number of CD34 cells/kg collected, used, and stored. As part of our quality improvement, we proposed a target collection goal of ≥3.5x10^6 CD34 cells/kg versus current 5-10 x10^6/kg and used this to assess excess HPC apheresis collections. Based on our current institution-specific charges, estimate cost of 1 session of HPC collection was 7625, processing and cryopreservation per product 7792, and storage of excess cells after 1st transplant 3943 per year. **Results:** Of the 97 patients who underwent HPC collection for two autoHCTs (mean age at collection 64.5 ±8.7), only 4 (4.1%) underwent a salvage autoHCT. Based on the proposed reduced collection target, 29 (29.9%) patients had ≥1 excess collection sessions. Among the patients who underwent excess collections, median cost of these collections was 7625 per patient and median cost for processing and cryopreservation of those products was 23,308 per patient. Total cost for the excess collection sessions plus cryopreservation of the cells collected was 871,768. Median number of years of excess HPC cells stored beyond the 1st transplant but not used was 4 (0.2-11.8), with an estimated median cost of 23,576 per patient. Total storage cost for unnecessary excess HPCs for all patients was 2,471,775. **Conclusions:** This study demonstrates even for our small center excess HPCs collected during the first autoHCT are rarely used for 2nd or salvage transplant, incurring substantial costs for the institution and patient. Similar to prior HPC utilization studies, our results support changing collection practices for MM patients to improve resource allocation and reduce unnecessary expenditures. Impact of venous thromboembolism on survival in multiple myeloma patients receiving bispecific antibody therapy: Insights from real-world data. First Author: Vladimir Otasevic, Parexel International, Durham, NC

Background: Patients with multiple myeloma (MM) have a significantly higher risk of venous thromboembolism (VTE), up to 20 times greater than the general population. This risk is influenced by the disease, anti-myeloma treatments, and patient-related factors. However, there is limited information regarding the rates of VTE and survival outcomes with FDA-approved bispecific antibodies (BsAbs) such as teclistamab, elranatamab, and talquetamab. This study aims to assess these endpoints using real-world data (RWD). **Methods:** A retrospective, multicenter RWD analysis was conducted using the TriNetX database on Jan 17, 2025. Two cohorts were analyzed: 1) MM patients who have been treated with one of the FDA-approved BsAbs (teclistamab, elranatamab, or talquetamab) and who developed VTE (deep vein thrombosis or pulmonary embolism) within 18 months from initiation of BsAb treatment, 2) MM patients treated with the same BsAbs who did not develop VTE in the same time frame. Kaplan-Meier analysis, log-rank test, hazard ratios (HR), risk ratios (RR), and 95% confidence intervals (CI) were used to assess the primary outcomes, which were overall survival and risk of VTE development. Propensity score matching was used to control the impact of specific known confounders. **Results:** We identified 1530 MM patients treated with the aforementioned BsAbs and had data available regarding VTE development within 18 months of treatment initiation. The patients' mean age at the index event (treatment initiation and VTE) was 69±9.9 years, and 52.2% were males. The rate of VTE was 8.5% (n=130). The MM patients treated with BsAbs and developed VTE had a statistically significant higher risk of death compared to the patients without VTE (RR 1.475, 95% CI 1.117-1.946). The MM patients with VTE had statistically significantly shorter overall survival and higher risk of death (526 days vs. not reached median survival, 49.83% vs. 65.61% survival probability at 18 months, log-rank test p=0.003; HR 1.667, 95% CI 1.193-2.329). After propensity score matching for covariates [accounting for age, sex, ECOG, BMI, COVID-19, pneumonia types, certain infectious diseases, hypertensive diseases, surgery, and medications (dexamethasone, epoetin alfa, darbepoetin alfa)] although RR lost statistical significance (RR 1.333, 95% CI 0.888-2.001), the MM patients with VTE still had statistically significantly shorter overall survival and higher risk of death (50.07% vs. 72.27% survival probability at 18 months, log-rank test p=0.007; HR 1.989, 95% CI 1.190-3.325). **Conclusions:** RWD demonstrated that MM patients treated with BsAbs who developed VTE had a higher risk of death and shorter overall survival. Further analysis, possibly evaluating patient-level data on a larger cohort of patients with more sophisticated confounding controls, is needed to further clarify this finding. Investigating the association between peak post-infusion absolute lymphocyte count (ALC) and delayed toxicity in myeloma (MM) patients (pts) receiving cilta-cel. First Author: Kenneth J.C. Lim, Mayo Clinic, Rochester, MN

Background: Movement and neurocognitive treatment emergent adverse events (MNTs), cranial nerve palsies (CNPs) and immune-effector cell enterocolitis (IEC-EC) are late onset toxicities associated with cilta-cel and are associated with significant morbidity and mortality. We aimed to identify predisposing risk factors to allow for formulating risk-reduction strategies. **Methods:** Retrospective study of MM pts who received FDA approved cilta-cel at Mayo Clinic between Feb 2022-Dec 2024. Interrogated factors included demographics, disease and treatment characteristics, and selected lab values at different time points. In odds ratio (OR) analyses, pts were divided by toxicity type (1) No delayed toxicity (2) MNT (3) IEC-EC without MNT (4) isolated CNP. Differences between pts in the MNT, IEC-EC and CNP groups were compared separately in a pairwise manner vs. those with no delayed toxicity. **Results:** Of 235 pts, 26 (11%) had delayed toxicity [MNT = 8 (3%), IEC-EC = 9 (4%), CNP = 14 (6%)]; 3 pts had both MNT/IEC-EC and 2 had both CNP/IEC-EC. Median onset from CAR-T infusion for MNT, IEC-EC and CNP was 19 (range 8-96), 106 (35-169) and 21 (7-43) days respectively. Of 164 evaluable pts, those who had ICANS had increased odds for any delayed toxicity (OR 4.7; 95% CI 1.6-13.8). Pts who had ICANS (OR 7.7; 1.6-36.9), HLH/MAS (OR 6.2; 1.1-6.7) and Ferritin >400mcg/L at time of lymphodepletion (OR 6.3; 1.5-32) had increased odds for MNTs. Pts who received alkylator-based bridging therapy had increased odds (OR 6.1; 1.1-35) for IEC-EC. Analysis of serial post-CAR infusion lab values showed that peak ALC was the most significant variable with differences between groups shown in table. Median time to peak ALC was 12 days (IQR 11-13). ROC analysis determined peak ALC >3 x 10^9/L as a meaningful cut point. Pts with peak ALC >3.0 x 10^9/L had increased odds of developing any delayed toxicity (OR 9.3; 3.5-29.3), MNT and CNP (table). Absolute risk of any delayed toxicity was 33% in pts with peak ALC >3 x 10^9/L vs 5% without. At this threshold, number needed to treat was 3.6. **Conclusions:** Real-world data shows that cilta-cel associated delayed toxicity is seen in ~10% of patients, with specific toxicity rates between 4-8%. Factors associated with these toxicities predominantly occur in the post CAR-T infusion period. Given that ALC expansion in the first 2 weeks correlate with CAR-T expansion, peak ALC is potentially predictive of toxicity and 3 x 10^9/L may be an interventional threshold for primary prophylaxis. Research Sponsor: None.

Risk of second primary hematological malignancy post CAR-T cell therapy in relapsed/refractory multiple myeloma: Propensity-matched analysis using TriNetX database. First Author: Rushi Shah, Trinity Health Oakland/ Wayne State University School of Medicine, Pontiac, MI

Background: The Food and Drug Administration (FDA) issued a black box warning regarding the risk of T-cell lymphoma post CAR-T cell therapy has drawn global attention yet comprehensive profiling of Second Primary Malignancies is lacking in this group of patients. To address this knowledge gap, we aimed to comprehensively elucidate the current landscape of SPMs post CAR-T therapy in patients with multiple myeloma using real-world, large-scale data from TrinetX. Such efforts will be instrumental in guiding the lifelong safety monitoring of CAR-T products in the future. **Methods:** We conducted a retrospective study that included adult patients with RRMM who received CART cell therapy versus those who did not receive CART cell therapy using the TrinetX database network, a federated EMR network of more than 117 million de-identified patients. The outcomes of interest were assessing Second Primary Hematological Malignancies. Propensity matching analysis was done to assess the risk of SPM post-CART cell therapy. **Results:** A total of 803 RRMM patients received CAR-T cell therapy and 62038 RRMM patients without CART cell therapy were identified. Before matching the median follow-up was 12 months in the CART group versus 33.2 months in the non-CART group. After propensity matching analysis at a median follow-up of 12 months in the CART group and 34.4 months in the non-CART group, it was found that there was no significant increase in the risk of SPM in the CART group. (Table 1) The most common SPM remains to be AML (5%) followed by MDS (3.5%). No cases of Adult T-cell leukemia/lymphoma were detected. **Conclusions:** This real-world study shows no increased risk of second primary malignancies (SPM) following CAR T-cell therapy. Although we may have underestimated the cases if they were not admitted, and also due to limited follow-up which might not capture the late-onset SPMs. The group's next step is to re-evaluate the risk of SPM in this subgroup at five years of follow-up. Research Sponsor: None.

Hematological SPM post CART cell therapy after propensity matching analysis.

Type of SPM	RRMM post CART (n=800)	RRMM without CART (n=796)

Investigating metabolic connectivity in patients with multiple myeloma receiving BCMA CAR T cell therapy. First Author: Mehrnaz Jenabi, Memorial Sloan Kettering Cancer Center, New York, NY

Background: BCMA-targeted CAR T cell therapy is a highly effective treatment for patients with relapsed/refractory multiple myeloma (MM) with side effects such as CRS, ICANS, and movement and neurocognitive toxicities (MNTs). Regional changes on [^{18}F] fluoro-deoxy-2-D-glucose PET (PET) can be used to derive metabolic connectivity, an emerging technique that models brain function from the uptake on a PET, allowing us to investigate alterations of regional metabolism (SUV) and changes in metabolic brain networks (connectivity) peri-CAR T. **Methods:** Patients were included in this retrospective study if they were treated with commercially available BCMA-directed CAR T cells and had pre-and post-CAR therapy PET imaging. We analyzed the connectivity of the whole brain and parcellated the brain to generate global and regional connectivity matrices and investigated the association of regional metabolic differences and differences in metabolic connectivity with clinical parameters. **Results:** Of the 108 consecutive patients (65 Cilta-cel, 43 Ide-cel), there were 61 men and 47 women (median age 65), with PET a median of 12 days prior to infusion 28 days post infusion. Toxicities included CRS alone (n=66), CRS + ICANS (n=8), CRS+facial palsy (n=3), and CRS + Parkinsonism + facial palsy (n=2). Within the entire cohort, a significantly higher SUV-mean was noted in putamen ($p<0.0004$) post-CAR T compared to pre-CAR T, with other brain regions not showing a difference. These regional differences were significantly and inversely associated with the grade of ICANS (Post-Pre: Left: t=-1.76, p=0.08; Right t=-2.1 p=0.04). When comparing patients with (n = 79) and without (n=29) any post-CAR T cell CRS/ICANS/MNT, the post SUV-mean was significantly higher in the bilateral basal ganglia (BG) of patients who experienced toxicity ($p<0.05$). The SUV-mean was significantly lower in the bilateral inferior frontal opercularis, triangularis, and bilateral Rolandic operculum of those who developed ICANS (Grade 1-2, all with CRS, n=8) vs with CRS alone (all grade 1, n=46) ($p<0.05$). Globally, the metabolic connectivity network had less efficiency (post<pre: 0.69<0.75), and density (post<pre: 63<74). In local measurements, post-CAR T cell PET showed significantly lower local efficiency ($p=10^{-30}$), degree ($p=10^{-15}$), strengths (p=0.001), clustering coefficient ($p=10^{-12}$), and higher edge betweenness centrality (p=0.02) compared to the pre-CAR T timepoint. The decreases in network measurement were more severe in the frontal lobe and basal ganglia ($p=10^{-6}$ and p=0.004, respectively). **Conclusions:** Patients with neurotoxicity after BCMA CAR T had an increased SUV in the putamen, but decreased in the frontal regions and basal ganglia at Day 28. Metabolic networks were globally less efficient and less dense and have changes that signify injury or attempts at compensation. Research Sponsor: U.S. National Institutes of Health; R01CA293922.

Machine learning–based sequential analysis for optimal selection between IRD and KRD regimen in multiple myeloma patients. First Author: Taemin Park, Kyung Hee Corp., Seoul, South Korea

Background: Multiple myeloma (MM) is hematologic malignancy where personalized treatment strategies are essential to improve outcomes. Proteasome inhibitor-based therapy, including ixazomib (IRD) or carfilzomib with lenalidomide and dexamethasone (KRD), is one of the most commonly used regimens for treatment of MM. Early treatment response (ETR) and progression-free survival (PFS) are critically important, as these factors are among the most significant considerations in clinical decision-making for selecting optimal drug regimens in MM treatment. This study aimed to develop a machine learning (ML) model using real-world data (RWD) to predict ETR and PFS in MM patients treated with these two regimens. **Methods:** This was a retrospective analysis using real-world data (RWD) from 535 MM patients treated with either IRD or KRD regimens. We developed separate ML models for IRD and KRD treatment group to stratify the risk for inadequate treatment response for predicting ETR or PFS outcomes. ETR was assessed based on myeloma protein and the extent of plasma cell proliferation. Patients with complete response (CR), very good partial response (VGPR) were classified as the low-risk (LR) group, indicating optimal treatment response. The other patients were categorized as the high-risk (HR) group, reflecting a suboptimal treatment response. PFS was defined by the standard definition for MM treatment: LR group as at least 2 years of survival without disease progression and otherwise, HR group. ML models were trained using demographic, clinical and genetic data obtained at the initial diagnosis or prescription for IRD or KRD. Additionally, each patient's predicted ETR risk was incorporated as a feature in training the PFS model to enhance its predictive accuracy. **Results:** The area under the receiver-operating characteristic curve (AUROC) of of the PFS models improved significantly from 0.72 and 0.62 without predicted ETR as feature to 0.81 and 0.85 with ETR incorporated. ML models classified patients as 6 subgroups to suggest optimal drug selection for each group to improve ETR and PFS outcomes. Notably, IRD or KRD given to all patients without considering patient subgroups resulted in a PFS hazard ratio of 5.94 (95% CI: 1.59 – 10.31). Implementation of our ML models might inform drug drug selection in 369 patients (69.0%) among a total of 535 patients. **Conclusion:** In this study, ML models were developed to predict ETR and PFS in MM patients, facilitating personalized therapy in clinical practice. PFS models demonstrated improved performance by incorporating predicted ETR risk as an additional feature. The ETR-incorporated models with clinical and genetic data stratified patients into low-and high-risk groups proposing optimal treatment strategies to potentially improve PFS in 185 patients (35%). Our findings implicate the potential of RWD and ML to advance precision medicine and improve outcomes through ML-informed treatment decisions. Research Sponsor: None.

Efficacy and safety of isatuximab subcutaneous (SC) plus carfilzomib and dexamethasone (Isa-Kd) in patients with relapsed/refractory multiple myeloma (RRMM): Results of the phase 2 study IZALCO. First Author: Gurdeep Parmar, Illawarra Cancer Care Centre, Wollongong, NSW, Australia

Background: IV isatuximab (Isa) can provide benefit to patients (pts) in multiple combinations across the therapeutic spectrum for MM. SC administration would offer a more convenient treatment option for pts and caregivers.Results of a Phase 1b study demonstrated safety and efficacy of Isa SC administration via an on-body delivery system (OBDS; an investigational wearable injector), plus pomalidomide and dexamethasone in RRMM pts. In the Phase 2 IZALCO study, we evaluated efficacy (primary objective), safety, pharmacokinetics (PK), and pt preference for Isa SC administration by manual injection or OBDS, in combination with carfilzomib and dexamethasone (Kd), in RRMM pts. **Methods:** Isa SC 1400 mg was given weekly in cycle [C]1 then biweekly. In Part 1 of the study, pts received Isa injected SC manually. In Part 2, pts were randomized to Isa administered SC via OBDS (C1-C3) followed by manual injection (C4-C6), or to manual injection (C1-C3) followed by OBDS administration (C4-C6); from C7, pts could choose either treatment modality.All pts received treatment with carfilzomib (20 mg/m^2 on D1-2 then 56 mg/m^2 biweekly) and dexamethasone (20 mg). Primary study endpoint (EP) was overall response rate (ORR); pt preference for Isa SC administration modality was the key secondary EP. **Results:** Overall, 74 RRMM pts were enrolled: 8 in Part 1 and 66 in the randomized cohort (Part 2). At study entry, pts had a median age of 65 (44-85) yrs and a median of 1 prior therapy line (1-5); 56.8%, 32.4% and 10.8% had ISS stage I, II or III, respectively. The ORR rate was 79.7% (median follow-up 10.1 mo). After treatment with both modalities for Isa SC delivery, 74.5% of pts expressed a preference for the OBDS rather than manual injection (p=0.0004); 8.5% had no preference. Other key efficacy and safety results are shown in table. Treatment with Isa SC plus Kd was well tolerated. A single infusion reaction event (1 of Grade [G]1, 1 of G2) occurred in 2 pts (2.7%, both with manual injection at 1st dose). Six (8.1%) pts had 18 injection site reactions (17 of G1, 1 of G2) in 1297 (1.1%) manual or OBDS injections. Comparable PK exposure was observed between OBDS and manual administration. **Conclusions:** The study met its primary endpoint, demonstrating efficacy and safety of Isa SC administration in combination with Kd, either by manual injection or OBDS. Our study findings are comparable to those reported in the Phase 3 study IKEMA with Isa IV. Pts expressed a clear preference for receiving Isa SC by an OBDS. Clinical trial information: NCT05704049. Research Sponsor: Sanofi.

Long-term efficacy and safety of etentamig, a B-cell maturation antigen (BCMA) bispecific antibody in patients with relapsed/refractory multiple myeloma (RRMM). First Author: Muhamed Baljevic, Vanderbilt University Medical Center, Nashville, TN

Background: Etentamig (etenta) is a differentiated BCMA x CD3 bispecific T-cell engager composed of high avidity bivalent BCMA-binding domains, low-affinity CD3-binding domain designed to reduce cytokine release syndrome (CRS), and silenced Fc tail for extended half-life enabling convenient dosing. We present long term results from 2 ongoing Ph 1 studies evaluating efficacy and safety of etenta in patients (pts) with RRMM. **Methods:** Data were from a Ph 1 multicenter, open-label, dose escalation/expansion (NCT03933735) trial and Arm A of a Ph 1b, open label (NCT05650632) trial of etenta; both enrolled pts ≥18 years with RRMM, ≥3 prior lines of therapy (LoT), and triple-class exposed. Pts received 60 mg Q4W or 40 mg Q3W, both regimens with similar dose intensity, in the Ph 1 trial; pts from Arm A of the Ph 1b trial received a step-up dose (SUD) on day 1 and full dose of 60 mg Q4W on day 4. This pooled analysis assessed long-term efficacy, safety, and tolerability. Tumor response was assessed per IMWG 2016 criteria. **Results:** Of 146 pts with RRMM who received etenta, 87 (60%) were male, median age (range) was 68 (40–87) years, median prior LoT were 4 (3–23), and median duration of follow-up was 13 (1–48) months (mo). ORR was achieved in 96 (66%) pts and ≥VGPR in 79 (54%) pts. Response rates across subgroups are reported in the Table. Median duration of response was not reached (NR) (NR–NR) among responders; Kaplan-Meier (KM) estimate at 12 mo was 71% (58.5%–80.5%). Median PFS (mPFS) was NR (8.7–NR) mo; KM estimate at 12 mo was 55% (44.9%–63.1%). Any grade and G3/4 treatment emergent adverse events (TEAEs) occurred in 145 (99%) pts and 116 (79%) pts. Most common G3/4 TEAEs (≥15%) were neutropenia (38%), anemia (23%), lymphopenia (25%), and thrombocytopenia (16%). Infections G3/G4 were reported in 32 (22%) pts; most common infections G3/G4 (≥5%) were pneumonia (12%) and sepsis (5%). TEAEs leading to etenta discontinuation were reported in 13 (9%) pts. Deaths from TEAEs were reported in 13 (9%) pts; 10 were not attributed to etenta treatment. In Arm A of Ph 1 study where 60mg Q4W was administered with SUD and modified dex as premedication, CRS incidence was 30% (4% G2; No ≥G3 events) with median time to CRS onset of 22.3 (5.5–29.6) hours; and median time to CRS resolution of 20.7 (1.8–131.7) hours. **Conclusions:** Etenta with SUD demonstrated a low CRS incidence, durable response, and tolerability in pts with heavily pretreated RRMM. Efficacy across all subgroups was comparable and maintained, suggesting therapeutic benefits among a broad population and supporting further exploration in the ongoing Ph 3 Cervino study. Research Sponsor: AbbVie.

Subgroup	ORR, n (%)	≥VGPR, n (%)	mPFS, months (range)
Age ≥75years	26 (72)	23 (63.9)	NR (7.5–NR)

Efficacy and safety from the phase 1/2 MonumenTAL-1 study of talquetamab, a GPRC5D×CD3 bispecific antibody, in patients with relapsed/refractory multiple myeloma: Analyses at an extended median follow-up. First Author: Leo Rasche, University Hospital of Würzburg, Würzburg, Germany

Background: Talquetamab (Tal) is the first and only approved anti-GPRC5D bispecific antibody (BsAb) for relapsed/refractory multiple myeloma (RRMM). In previous results from the phase 1/2 MonumenTAL-1 study (CCO Jan 2024; median follow-up [mFU] 20–30 mo), Tal elicited deep, durable responses with low discontinuation rates. We report efficacy and ongoing safety from MonumenTAL-1 at an extended mFU of 30–38 mo, the longest mFU for any anti-GPRC5D agent. **Methods:** Patients (pts) were intolerant to or progressed on established therapies (phase 1, NCT03399799) or had ≥3 prior lines of therapy (LOT), including ≥1 PI, ≥1 IMiD, and ≥1 anti-CD38 mAb (phase 2, NCT04634552). Pts received recommended phase 2 doses (RP2D) of SC Tal 0.4 mg/kg weekly (QW) or 0.8 mg/kg every other week (Q2W), with step-up doses. **Results:** As of Sept 2024, mFU was 38.2, 31.2, and 30.3 mo in the QW (n=143), Q2W (n=154), and prior T-cell redirection (TCR; n=78, received either RP2D) cohorts, respectively. Across cohorts, overall response rate (ORR; 67–74%) was unchanged vs previous results. Median duration of response (mDOR) and median progression-free survival (mPFS) continued to demonstrate superior outcomes in the Q2W vs QW cohort (mDOR 17.5 vs 9.5 mo; mPFS 11.2 vs 7.5 mo). In the prior TCR cohort, mDOR was reached with longer mFU (19.2 mo), and mPFS was 7.7 mo. In the QW, Q2W, and prior TCR cohorts, median overall survival (OS) was 34.0 mo, not reached, and 28.3 mo (36-mo OS rates: 49%, 61%, and 45%), respectively (Q2W data not mature). In pts with <4 vs ≥4 prior LOT, ORR was higher (85% vs 72%), but responses were less durable (mDOR 6.8 vs 10.8 mo) in the QW cohort, whereas ORR was similar (71% vs 69%), but responses were more durable (mDOR 20.7 vs 16.8 mo) in the Q2W cohort. As previously reported, most common adverse events (AE) were CRS and GPRC5D-associated (oral and dermatologic) AEs, and most common grade 3/4 AEs were cytopenias. No new discontinuations occurred due to oral or dermatologic GPRC5D-associated AEs and no new discontinuations occurred due to weight loss. In QW, Q2W, and prior TCR cohorts, respectively, any-grade infections occurred in 61%, 71%, and 78% of pts; grade 3/4 infections (23%, 21%, 26%) were mostly limited to early treatment cycles. A new safety signal, ataxia/balance disorders, was recently identified in association with Tal and had low prevalence in MonumenTAL-1. Dose reduction and discontinuation rates due to AEs remained low. No pts died due to Tal-related AEs. **Conclusions:** At an extended mFU, high ORRs elicited by Tal were durable and led to promising 36-mo OS rates (45–61%). The safety profile was consistent with previous results and continued to show lower risk of high-grade infections relative to approved anti-BCMA BsAbs, potentially contributing to the OS benefit seen in pts receiving Tal. Clinical trial information: NCT03399799/NCT04634552. Research Sponsor: None.

Daratumumab + bortezomib, lenalidomide, and dexamethasone (DVRd) vs VRd in transplant-ineligible (TIE)/transplant-deferred (TD) newly diagnosed multiple myeloma (NDMM): Phase 3 CEPHEUS trial cytogenetic subgroup analysis. First Author: Nizar J. Bahlis, Arnie Charbonneau Cancer Research Institute, University of Calgary, Calgary, AB, Canada

Background: In CEPHEUS, DVRd significantly improved overall MRD negativity (MRD neg + ≥CR) and sustained MRD neg rates and PFS in patients (pts) with TIE/TD NDMM. In this post hoc analysis, we report outcomes in cytogenetic risk subgroups. **Methods:** Pts with TIE/TD NDMM were randomized 1:1 to DVRd or VRd. High-risk (HiR) cytogenetic abnormalities (HRCAs) were assessed by FISH. HiR was ≥1 of: del(17p); t(4;14); t(14;16). Revised HiR (R-HiR) was ≥1 of above or gain (3 copies) or amp(1q) (≥4 copies). Standard risk (SR) was 0 HRCAs; revised SR (R-SR) was 0 revised HRCAs. Additional risk groups included: gain or amp(1q) + other HRCAs; 1 and ≥2 revised HRCAs. We assessed overall MRD neg rate, sustained MRD neg, ≥CR rate, and PFS. We reported all MRD neg rates at 10^{-5} unless noted. **Results:** Of 395 randomized pts (DVRd, n=197; VRd, n=198), 298 had SR (DVRd, n=149; VRd, n=149) and 52 HiR (DVRd, n=25; VRd, n=27). 184 pts had R-SR (DVRd, n=94; VRd, n=90) and 167 R-HiR (DVRd, n=83; VRd, n=84). At median 58.7-month (mo) follow-up, overall MRD neg rate was higher with DVRd vs VRd in SR (64% vs 38%; $P<0.0001$) and R-SR pts (68% vs 38%; $P<0.0001$). Rates by treatment (tx) arm in HiR (48% vs 56%; $P=0.7816$) and R-HiR pts (55% vs 45%; $P=0.2169$) were comparable. DVRd improved ≥1-year (y) sustained MRD neg rate vs VRd in SR (51% vs 26%; $P<0.0001$) and R-SR pts (54% vs 24%; $P<0.0001$). Sustained MRD neg rates by tx arm were comparable in HiR (40% vs 37%; $P=1.0000$) and R-HiR pts (43% vs 30%; $P=0.0782$). PFS was improved with DVRd vs VRd in SR and R-SR pts and was comparable by tx arm in HiR and R-HiR pts (Table), including in MRD neg pts (R-SR: hazard ratio [HR]=0.63 [95% CI, 0.26–1.52]; $P=0.3003$; R-HiR: HR=0.71 [95% CI, 0.32–1.58]; $P=0.3995$). Remaining outcomes, including rates of ≥CR, ≥2-y sustained MRD neg, and overall and ≥1-y sustained MRD neg at 10^{-6}, were improved with DVRd in SR and R-SR pts and comparable by tx arm in HiR and R-HiR pts. **Conclusions:** In CEPHEUS, DVRd consistently improved the key response outcomes of MRD neg and PFS in (R-)SR pts. In HiR pts, MRD and PFS outcomes trended lower in both tx arms vs those in SR pts. Here, DVRd mostly improved PFS outcomes vs VRd; however, pt numbers were small, with the study underpowered for HiR pts. These data support use of DVRd for TIE/TD NDMM regardless of cytogenetic risk status. Clinical trial information: NCT03652064. Research Sponsor: Johnson & Johnson.

Assessment of normal plasma cell biomarkers after arlocabtagene autoleucel (arlo-cel) treatment in patients with ≥3L relapsed refractory multiple myeloma (MM). First Author: Kristina Jordahl, Bristol Myers Squibb, Princeton, NJ

Background: B-cell maturation antigen (BCMA) and G protein-coupled receptor class C group 5 member D (GPRC5D) are validated targets in MM. GPRC5D is expressed most strongly on MM cells with minimal expression on normal plasma cells (nPC), while BCMA is highly expressed on MM cells and nPCs. Anti-BCMA chimeric antigen receptor T cell therapy (CAR T) and T cell engagers (TCE), but not anti-GPRC5D TCE, are associated with B cell aplasia and worsened hypogammaglobulinemia. Uninvolved free light chain (uiFLC) and immunoglobulin G (IgG) were used as biomarkers of nPCs following treatment with arlo-cel, a GPRC5D-targeting CAR T therapy with promising efficacy and 19% grade 3/4 infection rate (Bal, et al. ASH 2024 Abstract 922), and treatment with a BCMA CAR T therapy. **Methods:** Clinical endpoints included treatment-emergent adverse events for patients treated with arlo-cel (NCT04674813; n = 84) and idecabtagene vicleucel (ide-cel, NCT03361748; n = 137). Biomarker analysis included complete responders (CR) treated with arlo-cel (n = 42) and ide-cel (n = 38). For uiFLC, Kaplan-Meier curves of time to clearance below the limit of detection (LOD; 1.3 mg/L for κ and 1.7 mg/L for λ) and time to first return above the LOD were used to calculate median time to event and compared using log-rank test. Logistic regression models adjusted for pre-treatment levels were used to test for differences in biomarker levels at specific time points. Hypogammaglobulinemia was defined as IgG levels < 500 mg/dL. Fisher's exact test was used to compare infection rates. All analyses were restricted to the first 6 months after infusion. P-values less than 0.1 were considered statistically significant. **Results:** Arlo-cel cleared uiFLC below the LOD in 67% of CR compared to 100% of ide-cel CR ($p < 0.0001$). When cleared, time to uiFLC clearance was the same (median = 29 days; p = 0.82), but time to return above the LOD was significantly faster for arlo-cel (median = 101 days) than for ide-cel (median = 264 days; p = 0.001), indicating faster nPC recovery for arlo-cel. Post-infusion uiFLC concentrations were lower in ide-cel CR at 2 (p = 0.09), 4 (p = 0.05), 5 (p = 0.02), and 6 months (p = 0.09) compared to arlo-cel. Despite more post-infusion intravenous immunoglobulin usage for ide-cel vs arlo-cel CR (89% vs 26%), IgG levels were lower for ide-cel CR at 2 (p = 0.09) and 3 months (p = 0.01). Among treated patients, the proportion with hypogammaglobulinemia at 3 months (p = 0.05) and the 6-month infection rate (p = 0.03) were lower for arlo-cel. **Conclusions:** Arlo-cel patients had higher levels of uiFLC from months 2–6, demonstrating greater anti-tumor specificity and preservation of humoral immunity. As a result, arlo-cel has the potential to achieve lower rates of hypogammaglobulinemia and infections compared to BCMA-targeting therapies, with fewer interventions. Clinical trial information: NCT04674813. Research Sponsor: Juno Therapeutics, Inc., a Bristol-Myers Squibb Company.

Indirect comparison of linvoseltamab versus elranatamab for triple-class exposed (TCE) relapsed/refractory multiple myeloma (RRMM). First Author: Sundar Jagannath, Icahn School of Medicine at Mount Sinai, New York, NY

Background: In the absence of head-to-head trials comparing anti-BCMA×CD3 bispecific antibodies in TCE RRMM, this study used an unanchored matching-adjusted indirect comparison (MAIC) to compare the efficacy of linvoseltamab and elranatamab. **Methods:** Patient (pt)-level data from LINKER-MM1 (117 pts receiving linvoseltamab 200 mg, data cut-off [DCO] 7/2024, median follow-up [mFU] 21.3 months [mos]) and published data from MagnetisMM-3 Cohort A (123 elranatamab pts, DCO 9/2024, mFU 33.9 mos) were analyzed. Ten LINKER-MM1 pts with prior BCMA antibody–drug conjugate exposure were excluded to align with MagnetisMM-3. LINKER-MM1 pts were weighted to match MagnetisMM-3 pts on prespecified prognostic factors deemed most important by an international expert panel: cytogenetic risk, age, refractory status, R-ISS stage, ECOG PS, extramedullary and/or paramedullary disease. Objective response rate (ORR), very good partial response or better (≥VGPR) and complete response or better (≥CR) rates, duration of response (DOR), progression-free survival (PFS), and overall survival (OS) were compared. DOR and PFS in LINKER-MM1 were recalculated to match MagnetisMM-3 censoring rules. Additional MAICs matched all available prespecified prognostic factors, included all 117 LINKER-MM1 pts, or matched to a MagnetisMM-3 subgroup with ECOG PS 0/1. **Results:** After matching, linvoseltamab effective sample size (ESS) was 71.3 (range of patient weights: 0.04–2.90). Linvoseltamab demonstrated statistically significant higher ORR and ≥CR rate, a numerically higher ≥VGPR rate, and longer DOR, PFS, and OS vs elranatamab (Table). The additional MAICs yielded directionally consistent findings. **Conclusions:** Linvoseltamab demonstrated significantly higher ORR and ≥CR rate, numerically better ≥ VGPR rate, DOR, PFS, and OS compared with elranatamab, though the follow-up was shorter. These results highlight the potential of linvoseltamab as a highly effective treatment option for TCE RRMM. Research Sponsor: Regeneron Pharmaceuticals, Inc.

Iberdomide, bortezomib, and dexamethasone (IberVd) in transplant-ineligible (TNE) newly diagnosed multiple myeloma (NDMM): Updated results from the CC-220-MM-001 trial. First Author: Darrell White, Dalhousie University and Queen Elizabeth II Health Sciences Centre, Halifax, NS, Canada

Background: Lenalidomide (LEN), bortezomib (BORT), and dexamethasone (DEX) are recommended for NDMM. Iberdomide (IBER), an oral CELMoD agent, has stronger tumoricidal and immune-stimulatory effects than LEN and shows synergy with DEX and BORT in preclinical models. IberVd has shown meaningful efficacy and safety in patients (pts) with TNE NDMM in the ongoing phase 1/2 CC-220-MM-001 trial (NCT02773030). Here we report updated results with longer follow-up from the IberVd dose-expansion cohort. **Methods:** Eligible pts had untreated NDMM and were TNE or deferred. Oral IBER was given on days (D) 1–14 of each 21-d cycle (C) in C1–8 and on D1–21 of each 28-d cycle in C $\geq$ 9, with subcutaneous BORT (starting at 1.3 mg/m^2) on D1, 4, 8, and 11 in C1–8, plus oral DEX on D1, 2, 4, 5, 8, 9, 11, and 12 in C1–8 and weekly in C $\geq$ 9 (20 or 10 mg if $>$ 75 y of age in C1–8; 40 or 20 mg if $>$ 75 y in C $\geq$ 9). Endpoints included efficacy, safety, pharmacokinetics, and minimal residual disease (MRD) assessment by next-generation flow cytometry. **Results:** As of May 29, 2024, 18 pts had received IberVd (1 pt 1.0 mg; 17 pts 1.6 mg). Median age was 77.5 (57–84) y, 12 (66.7%) pts were male, 17 (94.4%) White, 1 (5.6%) Hispanic/Latino, and 11 (61.1%) had high-risk cytogenetics. Median follow-up was 25 (0.7–29.5) mo. Median treatment duration was 24.9 (0.7–29.5) mo, median number of cycles received was 25 (1–34), and 11 (61.1%) pts remain on treatment; 3 pts discontinued due to withdrawal, 2 to adverse events (AEs), 1 to progressive disease, and 1 to physician decision. One death was reported during follow-up. In the safety population (n = 17), 14 (82.4%) pts had grade (Gr) 3/4 treatment-emergent AEs (TEAEs); primarily infections (47.1%), including pneumonia (17.6%) and COVID-19 (11.8%). The most common hematologic Gr 3/4 TEAE was neutropenia (29.4%); 2 (11.8%) pts had Gr 3–4 peripheral neuropathy. Other Gr 3/4 non-hematologic TEAEs like fatigue and diarrhea were rare. IBER dose interruptions and reductions due to TEAEs occurred in 14 (82.2%) and 10 (58.8%) pts, respectively. Dose reductions were mainly due to peripheral neuropathy (23.5%), neutropenia (11.8%), and thrombocytopenia (11.8%). TEAEs were manageable with dose modifications/interruptions and G-CSF use. In the evaluable pts (n = 16), the overall response rate was 100% with 8 stringent complete responses, 4 complete responses (CRs), 3 very good partial responses, and 1 partial response. Median time to response was 0.7 (0.7–3.9) mo, median duration of response was not reached, and 4 pts deepened response post 1 y treatment. MRD negativity at 10^{-5} was reported in 8 (50.0%) pts, and all had $\geq$ CR. **Conclusions:** With longer follow-up (13–25 mo), IberVd confirmed durable deep responses, with $\geq$ CR % rising from 56.3% to 75.0%, and an encouraging safety profile with no new signals in pts with TNE NDMM. These data support IberVd evaluation in the frontline setting. Clinical trial information: NCT02773030. Research Sponsor: Bristol Myers Squibb.

DREAMM-8 study of belantamab mafodotin plus pomalidomide and dexamethasone (BPd) vs pomalidomide plus bortezomib and dexamethasone (PVd) in relapsed/refractory multiple myeloma (RRMM): A subgroup analysis in patients with high-risk cytogenetic features. First Author: Suzanne Trudel, Department of Medical Oncology and Hematology, Princess Margaret Cancer Centre, Toronto, ON, Canada

Background: In DREAMM-8 (NCT04484623), BPd demonstrated a significant improvement in the risk of progression or death vs PVd in patients (pts) with RRMM who received $\geq$1 prior line of therapy, including lenalidomide. Pts with high-risk cytogenetic abnormalities (HRCAs) have a poor prognosis and need more efficacious treatments. Here we present a subgroup analysis in pts with HRCAs. **Methods:** Pts were randomized 1:1 to BPd (28-day cycles) or PVd (21-day cycles). Pts were treated until progressive disease, unacceptable toxicity, or death. Efficacy assessments occurred every 4 weeks. Pts with HRCAs were defined as having $\geq$1 of the following: t(4;14), t(14;16), amp1q, and del(17p13). Descriptive statistics were used to summarize the results, along with 95% exact CIs. Hazard ratios (HRs) for progression-free survival (PFS) were estimated using the Cox model, with 95% CIs based on the Brookmeyer-Crowley method. **Results:** The intention-to-treat population included 302 pts: 155 in the BPd arm and 147 in the PVd arm. In the BPd arm, 68 of 155 (44%) pts had HRCAs; of them, 23 (15%) had t(4;14), 7 (5%) had t(14;16), 32 (21%) had del(17p13), and 40 (26%) had amp1q. In the PVd arm, 60 of 147 (41%) had HRCAs; of them, 20 (14%) had t(4;14), 11 (7%) had t(14;16), 26 (18%) had del(17p13), and 33 (22%) had amp1q. Median PFS in pts with $\geq$1 HRCA was 21.1 mo (95% CI, 13.5 mo-NR) with BPd vs 9.2 mo (95% CI, 6.5-14.8 mo) with PVd (HR, 0.58; 95% CI, 0.36-0.95); 18-mo PFS rates were 53% and 33%, respectively. PFS benefit favored BPd across HRCA subgroups (HR [95% CI]: t(14;14), 0.74 [0.31-1.76]; del(17p13), 0.45 [0.22-0.92]; and amp1q, 0.49 [0.24-1.03]). In pts with $\geq$1 HRCA, overall response rate (ORR) was higher with BPd (n=52; 76%; 95% CI, 64.6%-85.9%) than PVd (n=39; 65%; 95% CI, 51.6%-76.9%), and more pts achieved $\geq$ complete response with BPd (Table). Benefit was maintained across HRCA subgroups. **Conclusions:** In pts with RRMM with HRC features, BPd demonstrated clinically meaningful PFS benefit, higher ORR, and a higher rate of deep responses vs PVd. These data support the potential use of BPd as a standard-of-care regimen in this key pt population with a high unmet need. Clinical trial information: NCT04484623. Research Sponsor: This study was sponsored by GSK. Editorial support was provided by Nucleus Global, an Inizio Company, and funded by GSK. Drug-linker technology licensed from Seagen Inc; monoclonal antibody produced using POTELLIGENT Technology licensed from BioWa.

Immune profiling to identify a functionally high-risk smoldering multiple myeloma patient population. First Author: Ross Firestone, Memorial Sloan Kettering Cancer Center, New York, NY

Background: Smoldering multiple myeloma (SMM), a precursor to active multiple myeloma (MM), is characterized by a high plasma cell burden but no evidence of the end-organ damage that defines MM. The Mayo 2/20/20 model, and others, relies on tumor-burden estimates to assign risk scores. We hypothesized that algorithm-assisted and explainable artificial intelligence (xAI) tools could ingest peripheral blood (PB) T cell profiles to identify immune signatures predictive of progression to active MM. **Methods:** We analyzed a cohort of Mayo risk-matched SMM patients with and without early progression to active MM. This included 9 patients with early progression from SMM to MM (median PFS 2.1 years) and a 9 patient "mayo risk matched" cohort without clinical progression (median follow-up 8.6 years). Using high-dimensional spectral cytometry with a 37-color T cell focused panel, we captured 1.4 million PB T cells from 18 SMM patients banked at the time of SMM diagnosis. Algorithm-assisted analysis was performed using dimensionality reduction analysis with UMAP and cell clustering using PhenoGraph. xAI analysis was performed by training a random forest (RF) classifier to predict clinical outcomes using single-cell data followed by feature importance analysis using Shapley Additive Explanations (SHAP) scores. **Results:** Analysis identified 21 unique T cell characteristic clusters across all patients. Among these, SMM patients with early progression had enrichment for CD8$^+$CD45RA$^+$CD62L$^-$CCR7$^-$ T effector cells re-expressing CD45RA when compared to non-progressing SMM patients (4.3-fold increase, p = 0.018). This cluster had the highest mean expression level of CD57 and TOX among all algorithm-defined clusters, demonstrating similar phenotypic characteristics to terminally exhausted effector T cells. The RF model to predict progression had an overall accuracy of 75% (stratified five-fold cross validated, repeated ten times). A UMAP analysis of c misclassified cells did not reveal any obvious patterns. SHAP analysis identified high expression of Granzyme B, CD272, Granzyme K, and CD45RA as the four most influential features for predicting progression. **Conclusions:** Our results show that patient-specific immune phenotypes could offer a method of prognosticating SMM outcomes separate from traditional tumor burden quantification. Both the clustering-based and feature importance analyses demonstrated that a more differentiated T cell phenotype is associated with early progression in SMM. Recent reports have found more differentiated T cell biology in MM patients compared to SMM patients. Our results support the hypothesis that SMM patients displaying an "MM-like" T cell phenotype are at increased risk of early progression to active MM. These results support work to identify a clinically usable patient-specific immune signature to identify SMM patients at increased risk of progression to overt MM. Research Sponsor: ASCO / CCF Young Investigator Award.

7535 Poster Session

Carfilzomib, lenalidomide, and dexamethasone (KRd) as maintenance therapy after autologous stem-cell transplantation (ASCT) in patients with newly diagnosed multiple myeloma (NDMM). First Author: Andrzej J. Jakubowiak, University of Chicago, Chicago, IL

Background: In patients with NDMM, therapy after ASCT aims to deepen remission and prolong survival. Although lenalidomide (R) monotherapy after ASCT is well established, the impact of combination therapy on survival remains to be established. Interim results of the ATLAS study suggested that extended KRd after ASCT treatment prolongs progression-free survival (PFS) compared with R alone in patients with NDMM (Dytfeld et al, Lancet Oncol. 2023; 24:139–150). Here we provide the results from the primary analysis of the ATLAS study. **Methods:** This international, open-label phase 3 study randomly assigned adults with NDMM who completed induction and had stable disease or better after ASCT 1:1 to KRd or R alone as maintenance therapy. Randomization was stratified by post-transplant response, presence or absence of $\geq$1 high-risk cytogenetic abnormality, and by country. For the KRd group, patients with standard-risk cytogenetics and measurable residual disease (MRD) negativity at 10^{-5} after cycle 6 were switched to R maintenance after cycle 8; remaining patients continued KRd up to 36 cycles and then switched to R. The preplanned primary endpoint was PFS. Secondary endpoints included overall survival (OS), MRD negativity, response rate, and safety. **Results:** At data cutoff (21 Oct 2024), median follow up was 5.7 years. The median number of treatment cycles initiated was 35 and 31 for KRd and R, respectively. After cycle 8, 40 of 81 patients on KRd switched to R. The 4-year PFS rate with KRd was superior to R (67.5% vs 36.8%; HR 0.46 [95% CI: 0.30, 0.70]; p=0.0002). The PFS benefit was consistent across subgroups, including high-risk cytogenetics (HR 0.52 [95% CI: 0.24, 1.1]) and MRD-positive status at randomization (HR 0.52 [95% CI: 0.29, 0.93]). Median PFS was 72.8 months and 37.3 months in the KRd and R groups, respectively. The 4-year OS rate also was increased with KRd vs R (84.3% vs 79.2%; HR 0.49 [95% CI: 0.26, 0.90]; p=0.02). The depth of response improved across all response categories; the rate of MRD $<10^{-5}$ and at least a complete response as best response was 74% and 51% (OR 2.7 [95% CI: 1.5, 5.1]; (p=0.002), and 12-month sustained MRD-negativity was 48% and 24% (OR 2.9 [95% CI 1.5, 5.5]; p=0.001) for KRd and R, respectively. No new safety signals were observed (Table). **Conclusions:** The ATLAS phase 3 study demonstrated superior PFS as well as longer OS with MRD-directed, risk-stratified KRd treatment compared with R alone in patients with NDMM after ASCT. Extended KRd maintenance treatment may represent a new standard of care. Clinical trial information: NCT02659293. Research Sponsor: Amgen Inc.; Celgene [Bristol Myers Squibb].

Belantamab mafodotin + pomalidomide + dexamethasone (BPd) vs daratumumab + bortezomib + dexamethasone (DVd) in relapsed/refractory multiple myeloma: An indirect comparison using patient-level data. First Author: Meral Beksac, Department of Hematology, Ankara Liv Hospital, Istinye University, Ankara, Turkey

Background: Belantamab mafodotin (belamaf) is being studied in combination with bortezomib + dexamethasone (BVd) or pomalidomide + dexamethasone (BPd) in the phase 3 DREAMM-7 (D7; NCT04246047) and DREAMM-8 (D8; NCT04484623) trials, respectively; both enrolled patients (pts) with relapsed/refractory multiple myeloma (RRMM) who had received ≥1 prior line of therapy. D7 compared BVd vs daratumumab + bortezomib + dexamethasone (DVd); D8 compared BPd vs bortezomib + pomalidomide + dexamethasone (PVd). In both trials, belamaf combinations showed significant progression-free survival (PFS) benefits vs comparators. In D7, median PFS (95% CI) was 36.6 mo (28.4-not reached [NR]) with BVd vs 13.4 mo (11.1-17.5) with DVd (HR, 0.41; 95% CI, 0.31-0.53; $P<.001$). In D8, median PFS (95% CI) was NR with BPd vs 12.7 mo (9.1-18.5) with PVd (HR, 0.52; 95% CI, 0.37-0.73; $P<.001$). This study compared the efficacy of BPd (D8 active arm) vs DVd (D7 comparator). **Methods:** The overlapping D7 and D8 RRMM population was analyzed. To align cohorts, D8 BPd pts refractory to any anti-CD38 were excluded, as were D7 DVd pts without prior lenalidomide exposure or pomalidomide-refractory disease. The primary endpoint was PFS. Secondary endpoints included overall survival (OS), minimal residual disease (MRD)−negativity rate, duration of response (DOR), overall response rate (ORR), and time to treatment discontinuation (TTD) with all treatments. This indirect comparison used inverse probability of treatment weighting to match baseline characteristics between DVd and BPd arms, estimating the average treatment effect in the treated population (IPTW-ATT). In the matched population, time-to-event analyses used the Kaplan-Meier method and Cox proportional hazards models. **Results:** Of 155 pts in the D8 BPd arm and 251 in the D7 DVd arm, 120 and 111, respectively, met inclusion criteria for this analysis. Baseline characteristics were generally balanced after IPTW-ATT. After adjustment, BPd significantly improved PFS vs DVd (median [95% CI], NR [21.1-NR] vs 11.1 mo [6.4-19.1]; HR, 0.41; 95% CI, 0.25-0.65; $P=.0002$). Median (95% CI) DOR was NR (24.9-NR) with BPd vs 10.5 mo (5.0-17.7) with DVd; adjusted MRD-negativity (CR+) rates (95% CI) were 30.2% (21-39.4) vs 5.3% (0.9-9.8), respectively (OR, 7.67; 95% CI, 3.10-22.72; $P<.0001$). ORR and TTD favored BPd vs DVd (ORR not significant). **Conclusions:** This post hoc indirect comparison analysis showed that BPd significantly improved PFS vs DVd (similar HR to BVd vs DVd in D7). Median PFS for the adjusted DVd population was similar to that reported with PVd in D8. These findings suggest that BPd may be a more effective treatment option vs DVd, warranting further studies of belamaf combinations in this population. Research Sponsor: GSK.

GPRC5D and BCMA bi-specific CAR-T: Ex vivo study to simulate early to late-line multiple myeloma (MM) with elevated soluble BCMA. First Author: Jincai Zhou, Oricell Therapeutics Co., Ltd., Shanghai, China

Background: GPRC5D and BCMA are near-universally expressed on MM cells, with independent target expression and double-negative cells relatively rare. This profile supports the rationale for developing a bi-specific CAR-T therapy to enhance patient coverage, improve efficacy, and reduce the risk of relapse due to antigen loss. Dual-targeting GPRC5D and BCMA represents a novel advancement in the developed antibody therapies. The clinical outcomes of combination of GPRC5DxCD3 and BCMAxCD3 were highly promising. Tri-specific antibodies (GPRC5DxBCMAxCD3) have exhibited superior preliminary efficacy compared to bsAbs or their combinations, However, these approaches require weekly administrations and may pose potential risk. A recent publication (Freeman et al., Blood, 2024) reported that elevated pre-lymphodepletion soluble BCMA (sBCMA) levels were significantly associated with high-risk characteristics as well as high incidence and severity of CRS & ICANS, and metabolic tumor volume (MTV) were correlated with poor clinical outcomes. To address these challenges, we have developed bi-specific CAR-Ts incorporating novel armors to effectively eliminate heavy MM burdens and enhance efficacy, even in the presence of sBCMA. **Methods:** Aiming to broadly eradicate MM subsets and reduce heavy tumor burden or extramedullary disease (EMD), we have developed a bi-specific CAR-T with two novel humanized VHH binders specifically targeting either BCMA or GPRC5D. Our design incorporates novel secreted and/or membrane-bound armors. Pre-clinical studies were conducted to evaluate the features and drugability of these armored and non-armored bispecific-CAR-Ts. **Results:** Targeting dual-Ag, the bi-specific CAR-T showed increased T cell activation, superior functionality, and enhanced expansion under re-stress. Notably, the bi-CAR-T retained its functionality against single-Ag expressing cells and displayed robust potency against MM cells with very low BCMA expression, even in the presence of high concentrations of sBCMA. Compared to industry benchmarks, Oricell's bi-CAR-T showed superior efficacy in a xenograft mouse model with heterogeneous MM cells. Armored bi-CAR-Ts were potent in eliminating heavy tumor burdens and enhancing T cell infiltration and expansion. **Conclusions:** The pre-clinical data demonstrated that the bi-specific CAR-T not only outperformed in targeting MM cells mimicking early or middle lines but also reduced the incidence of antigen-negative escape. By enhancing sensitivity and leveraging unique epitopes, the bi-CAR-T maintained robust efficacy in late-line MM models. Future clinical studies will be conducted to validate the safety and efficacy in treating high-risk MM patients. Research Sponsor: None.

Ciltacabtagene autoleucel (cilta-cel) vs standard of care (SOC) in patients (pts) with relapsed/refractory multiple myeloma (MM): CARTITUDE-4 survival subgroup analyses. First Author: Surbhi Sidana, Stanford University School of Medicine, Stanford, CA

Background: In CARTITUDE-4, a single cilta-cel infusion significantly improved progression-free survival (PFS; hazard ratio [HR] weighted, 0.29 [95% CI, 0.22–0.39]) and overall survival (OS; HR, 0.55 [0.39–0.79]; $P=0.0009$) vs SOC in pts with relapsed and lenalidomide-refractory MM after 1–3 prior lines of treatment (pLOT) at 33.6 mo median follow-up (Mateos et al, IMS 2024). PFS and OS from subgroups in the intent-to-treat (ITT) population are reported. **Methods:** Pts randomized to cilta-cel underwent apheresis, received pomalidomide, bortezomib, and dexamethasone (PVd), or daratumumab, pomalidomide, and dexamethasone (DPd) bridging treatment, lymphodepletion, and then cilta-cel infusion. Pts randomized to SOC received physician's choice of PVd or DPd until progression. HR for PFS was analyzed using unweighted Cox proportional hazards model for the ITT set. **Results:** As of May 1, 2024, median follow-up was 33.6 mo. PFS and OS benefit of cilta-cel over SOC in the ITT analysis was consistent across pts with standard-risk cytogenetics and high-risk cytogenetics, defined as del(17p), t(4;14), t(14;16), or gain/amp(1q) (Table). Comparing cilta-cel (n=21) vs SOC (n=18) in pts with extramedullary disease (EMD), median PFS was 13 mo vs 4 mo (HR, 0.71 [95% CI, 0.34–1.49]), respectively, and median OS was not reached (NR) vs 16 mo (HR, 0.61 [95% CI, 0.26–1.47]). In pts with 1, 2, or 3 pLOT (cilta-cel, n=68, 83, 57; SOC, n=68, 87, 56), median PFS was NR with cilta-cel across all pLOT vs 17 mo (HR, 0.41 [95% CI, 0.25–0.67]), 12 mo (HR, 0.30 [95% CI, 0.19–0.49]), and 8 mo (HR, 0.20 [95% CI, 0.11–0.34]) with SOC, respectively; median OS was NR with cilta-cel across all pLOT vs NR (HR, 0.56 [95% CI, 0.28–1.11]), NR (HR, 0.63 [95% CI, 0.36–1.09]), and 34 mo (HR, 0.49 [95% CI, 0.26–0.91]) with SOC. **Conclusions:** ITT analysis showed that cilta-cel improved PFS and OS vs SOC in all subgroups, including pts with EMD and 1 pLOT and beyond. Compared with SOC, cilta-cel improved PFS and OS in pts with high-risk cytogenetics, suggesting it may overcome the poor prognosis associated with these high-risk features. These data continue to support a positive benefit-risk ratio for cilta-cel in pts with lenalidomide-refractory MM as early as after first relapse. Clinical trial information: NCT04181827. Research Sponsor: Johnson & Johnson; Legend Biotech USA Inc.

Carfilzomib or bortezomib with lenalidomide, and dexamethasone (VRd) for initial therapy of newly diagnosed multiple myeloma (NDMM): Long-term follow-up of the ECOG-ACRIN ENDURANCE phase 3 trial. First Author: Shaji Kumar, Mayo Clinic Rochester, Rochester, MN

Background: The combination of a proteasome inhibitor (PI) with lenalidomide (R) and dex (d) has been a common initial therapy for newly diagnosed myeloma (NDMM). We designed a randomized phase 3 trial to examine if carfilzomib (K), a next generation PI, improved progression free survival (PFS) compared with bortezomib (V) when either is combined with Rd for initial treatment of NDMM. Initial analysis at a median follow up of 15.3 months (mos) showed comparable PFS for both triplets. We present the long-term results of the trial with ~70 months median follow up. **Methods:** Patients (Pts) with NDMM, were randomized 1:1 to receive VRd or KRd for 36 weeks followed by a 2nd randomization (1:1) to indefinite versus 2 yrs of R maintenance. Pts without del17p, t(14;16), t(14;20), plasma cell leukemia or high-risk GEP70 profile, were enrolled. VRd arm included V 1.3 mg/m^2 on days(d) 1, 4, 8, and 11 (d1, 8 for cycles 9-12), R 25 mg d1-14, and d 20 mg d1, 2, 4, 5, 8, 9, 11, 12 of a 3-week (wk) cycle for 12 cycles, while pts in the KRd arm received K 36 mg/m^2 d1, 2, 8, 9, 15, 16 with R 25 mg daily on d1-21 and d 40 mg wkly, in 4 wk cycles for 9 cycles. Maintenance used 15 mg R d1-21 q4 wks. **Results:** The study accrued 1087 pts (VRd=542, KRd=545). Median age was 65y; baseline characteristics including intent to transplant were similar across the arms. Median induction duration (mos; IQR) was 7.2 (3.4-8.9) and 8.4 (5.1-9.1) for VRd and KRd, respectively; 59.8% in VRd and 45.3% in KRd did not proceed to Step 2. Median PFS (mos) was VRd=41.9 and KRd=44.6; HR = 0.89 (0.76-1.04). Toxicity data, PFS sensitivity analyses and OS probabilities are as in the table. **Conclusions:** In this randomized trial, with median follow up of nearly 6 years, KRd and VRd had comparable PFS and OS in an intent to treat analysis. While similar numbers proceeded to SCT in the 2 arms, more did so during induction in the VRd arm while more patients in the KRd arm went to SCT later. VRd remains a standard triplet induction regimen in standard and intermediate risk NDMM, and a suitable backbone for 4 drug combinations. Clinical trial information: NCT01863550. Research Sponsor: None.

Clinical characteristics, cytogenetic associations, and outcomes in multiple myeloma with chromosome 1q abnormalities. First Author: Abdullah Ramzan, Mayo Clinic, Rochester, MN

Background: Multiple myeloma (MM) is characterized by recurrent cytogenetic abnormalities, including translocations involving the immunoglobulin heavy chain locus on chromosome 14 and trisomies, which are considered primary and clonal. Throughout disease progression, MM cells may acquire additional abnormalities, which include chromosome 1 abnormalities (gain or amplification of 1q or deletion of 1p) and chromosome 17 abnormalities (del 17p or monosomy 17p). All these factors are considered high-risk markers that predict below-average outcomes. While outcomes related to 1q have been documented, their relationship with other abnormalities and clinical characteristics is less clearly defined. **Methods:** We created a cohort of newly diagnosed MM (NDMM) patients from April 1996 to December 2023 for whom FISH testing was performed using a panel that included 1q findings. Data on clinical and laboratory characteristics, other FISH abnormalities, and survival outcomes were collected from existing databases and the electronic medical record (EMR). **Results:** The cohort included 875 patients, with a median age of 65. Of these patients, 60% were male and 91% identified as white. A 1q abnormality was observed in 443 patients (51%); 87% exhibited a gain of 1q, while 13% showed amplification of 1q. Among those tested, other abnormalities included del13 (58%), t(11;14) (25%), t(4;14) (17%), t(14;16) (6%), del 17p (13%), and trisomies (51%). The distribution of abnormalities concerning the presence of 1q is presented in the table. Patients with 1q abnormalities were more likely to present with additional high-risk cytogenetic abnormalities. The median overall survival (OS) for those with a 1q abnormality was 73 months, compared to 105 months for those without it. Among these, patients with 1q amplification tended to have worse outcomes than those with a 1q gain, though this observation did not reach statistical significance. **Conclusions:** Abnormalities of chromosome 1, including 1q gain and amplification, can be seen in nearly 50% of patients with NDMM who are tested. 1q abnormalities are associated with other high-risk cytogenetic abnormalities. Measures of disease burden are higher among those with a 1q abnormality. Interestingly, we observed a higher proportion of patients with lambda light chain and those with IgA among those with a 1q abnormality. The presence of a 1q abnormality was associated with inferior survival, with a trend towards worse outcomes among those with 1q amplification compared to 1q gain. Research Sponsor: None.

Real-world comparison of anti-BCMA vs anti-GPRC5D BiTE therapy in relapsed/refractory multiple myeloma without prior CAR-T cell exposure. First Author: Ali Younas Khan, West Virginia University, Morgantown, WV

Background: In recent years, three bispecific T-cell engager (BiTE) agents have been approved for Refractory/Relapsed Multiple Myeloma (rrMM). These have shown remarkable efficacy, particularly in patients who have failed multiple lines of prior therapy. However, there is a paucity of data to guide choice between available agents. **Methods:** We performed a multicenter, retrospective, propensity score matched (PSM), safety and efficacy comparison between anti-BCMA (Cohort 1: Teclistamab and Elranatamab) and anti-GPRC5D (Cohort 2: Talquetamab) therapy in rrMM, using TriNetX database. Patients with prior CAR-T therapy were excluded. Outcomes assessed included survival, remission rates, subsequent CAR-T therapy, subsequent alternate BiTE therapy, risk of infections, cytokine release syndrome (CRS), immune effector cell-associated neurotoxicity syndrome (ICANS), hypogammaglobulinemia and IVIG use with a follow up of 2 years following treatment. **Results:** A total of 888 and 296 patients were identified in cohort 1 (C1) and cohort 2 (C2), respectively. The two cohorts were matched for 25 characteristics yielding 266 patients in the PSM analysis. No differences in survival probability (HR 0.95; 95% CI 0.65-1.39, p=0.83) or remission rates (C1 vs C2: 37.2 vs 35.0 %, p=0.588) were observed. Subsequent CAR-T therapy was used in 3.8% in C1 and 15% of patients in C2. Any grade CRS (C1 vs C2: 34.6 vs 48.1%, p=0.002) was more common in the Talquetamab cohort, with majority being grade<3 CRS (C1 vs C2: 16.2 vs 27.8%, p=0.001). There was no difference observed for any grade ICANS (C1 vs C2: 14.7 vs 9.8%, p=0.08). No significant differences were found between rates of overall infection (C1 vs C2: 45.5 vs 43.6 %, p=0.63), bacterial (C1 vs C2: 23.3 vs 21.1%, p=0.53), viral (C1 vs C2: 28.6 vs 28.2 %, p=0.92), or fungal (C1 vs C2: 5.8 vs 8.9 %, p=0.29) infections rates. The incidence of hypogammaglobulinemia (C1 vs C2: 74.4 vs 77.8%, p=0.36) and treatment with IVIG (C1 vs C2: 52.3 vs 44.4 %, p=0.06) were similar across both groups. **Conclusions:** Our analysis of real-world patients with relapsed/refractory multiple myeloma (rrMM) showed similar efficacy and tolerability between anti-BCMA and GPRC5D BiTE therapies. However, the Talquetamab group had a higher rate of CRS, consistent with the high incidence observed in the phase 2 MonumenTAL-1 trial. The extent of comorbidities, safety profile of individual agents and plan for subsequent CAR-T cell therapy can guide the choice between available BiTE therapies. Research Sponsor: None.

BiTE therapy: Demographics and outcomes.

Correlation of a senescence-associated gene signature with prognosis in multiple myeloma. First Author: Andras Lanczky, Semmelweis University Department of Bionformatics, Budapest, Hungary

Background: Multiple myeloma (MM), an incurable malignancy of plasma cells, is predominantly a disease of aging. Cellular senescence, a fundamental biological process associated with aging, has been implicated in developing age-related malignancies, including MM. This study investigated the prognostic significance of senescence-associated genes within a large cohort of MM patients. **Methods:** Gene expression and clinical data from 1,416 MM patients were obtained from four GEO datasets (GSE24080, GSE4204, GSE57317, and GSE9782) and integrated into a unified database. Rigorous preprocessing of raw data ensured cross-platform comparability. We employed the SenMayo gene signature, a curated set of senescence-associated genes, computed as a weighted mean expression of the genes. Cox proportional hazards regression, Kaplan-Meier survival analysis, and multivariate models were used to evaluate the prognostic value of the SenMayo signature. Univaraite visualizations were plotted using the Kaplan-Meier plotter (www.kmplot.com). Clinical parameters, including gender, isotype, and molecular subtypes, were incorporated into multivariate analyses, and False Discovery Rate (FDR) correction was applied to correct for multiple hypothesis testing. **Results:** The SenMayo gene signature strongly correlated with overall survival (OS) in MM patients (HR = 0.6, 95% CI = 0.47–0.76, p = 1.7e-05). Patients in the low-expression group had an upper quartile survival duration of 36.1 months, compared to 57 months for those in the high-expression group. Independent validation across three datasets confirmed its prognostic value (GSE4204: HR = 0.58, 95% CI = 0.39–0.88, p = 0.0089; GSE24080: HR = 0.61, 95% CI = 0.45–0.83, p = 0.0012; GSE57317: HR = 0.25, 95% CI = 0.08–0.77, p = 0.0095). Multivariate analyses underscored the SenMayo signature as a prognostic factor, even after adjusting for established clinical parameters such as gender and isotype. **Conclusions:** These findings underscore the pivotal role of cellular senescence in the progression of MM. The senescence gene signature warrants further investigation to support its integration into clinical practice for improved risk stratification and informed therapeutic decision-making. Research Sponsor: None.

7544 Poster Session

Baseline ocular conditions and risk of ocular events in patients (pts) with relapsed/refractory multiple myeloma (RRMM) from the DREAMM-7 and DREAMM-8 trials of belantamab mafodotin (belamaf). First Author: Meral Beksac, Department of Hematology, Ankara Liv Hospital, Istinye University, Ankara, Turkey

Background: Belamaf combinations were evaluated for RRMM in the phase 3 DREAMM-7 (belamaf + bortezomib + dexamethasone [BVd]; NCT04246047) and DREAMM-8 (belamaf + pomalidomide + dexamethasone [BPd]; NCT04484623) trials, and significant progression-free survival benefits were reported over standard of care, with significant overall survival benefit reported for BVd. Ocular events (e.g., ocular adverse events [oAEs], blurred vision, dry eye) occurred with belamaf and most resolved with dose holds and modifications. We examined the baseline eye health of pts with RRMM receiving BVd or BPd, and whether baseline ocular conditions affected rates of treatment-emergent (TE) oAEs. **Methods:** Pts with ≥1 prior therapy were eligible for DREAMM-7/8; pts with ocular conditions were eligible except for corneal epithelial disease (mild punctate keratopathy was allowed). Mandatory ophthalmic examinations (best corrected visual acuity [BCVA], slit lamp, and funduscopic exams) were performed in both arms of the trials at baseline and routinely during treatment. oAEs were graded by Common Terminology Criteria for Adverse Events. Regardless of presence/absence of baseline ocular conditions, the same protocol-defined strategies were used for ocular event management during the studies. **Results:** In 392 pts treated with belamaf (n=242 DREAMM-7 and n=150 DREAMM-8), baseline ocular conditions were reported in 62% of pts (n=135 and 106); baseline conditions included cataract 50% (n=101 and 96), keratopathy 14% (n=33 and 23), dry eye 14% (n=31 and 24), visual acuity of 20/50 or worse 6% (n=18 and 7), glaucoma 6% (n=11 and 13), blepharitis 2% (n=4 and 3), age-related macular degeneration 1% (n=3 and 2), and diabetic retinopathy <1% (n=0 and 2). Any TE oAE was reported in 74% (n=100/135) and 87% (n=92/106) of pts with baseline ocular conditions in DREAMM-7 and DREAMM-8, respectively, compared with 79% (n=85/107) and 91% (n=40/44) of pts without baseline ocular conditions (Table). **Conclusions:** The safety profiles of belamaf combinations for oAEs were similar between patients with vs without baseline ocular conditions, suggesting that these baseline ocular conditions did not increase the risk of TE oAEs. The effect of each baseline ocular condition on TE oAEs, as well as TE corneal exam findings and visual acuity changes, will be presented. Clinical trial information: NCT04246047, NCT04484623. Research Sponsor: GSK (207499/207503); drug linker technology licensed from Seagen; monoclonal antibody produced using POTELLIGENT Technology licensed from BioWa.

DREAMM-7 study of belantamab mafodotin plus bortezomib and dexamethasone (BVd) vs daratumumab plus bortezomib and dexamethasone (DVd) in relapsed/refractory multiple myeloma (RRMM): A subgroup analysis in patients (pts) with high-risk cytogenetic (HRC) features. First Author: Maria-Victoria Mateos, Hospital Universitario de Salamanca/IBSAL/CIC/Ciberonc, Salamanca, Spain

Background: In DREAMM-7 (NCT04246047), BVd exhibited a significant improvement in the risk of progression or death vs DVd in pts with RRMM who had ≥1 prior line of treatment. In a post hoc analysis (Mateos et al; ASCO 2024) of pts with ≥1 HRC abnormality (HRCA), including t(4;14), t(14;16), and 17p13del, more pts had deep responses (defined as complete response [CR] or better) with BVd (45%; 95% CI, 32.6%-57.4%) than with DVd (13%; 95% CI, 6.1%-23.3%). Up to 70% of pts at early relapse have amp1q, which confers an increased risk of disease progression. Here we present an updated post hoc efficacy analysis in pts with HRCA, including amp1q. **Methods:** Pts were randomized 1:1 to BVd or DVd as previously reported. For this analysis, pts with HRC were defined as those having ≥1 HRCA, including t(4;14), t(14;16), t(14;20), 17p13del, and amp1q (defined as ≥4 copies of chromosome 1q21). Descriptive statistics were used to summarize results, with 95% exact CI. Hazard ratios (HRs) for progression-free survival (PFS) were estimated using the Cox model, with 95% CI based on the Brookmeyer-Crowley method. **Results:** The ITT population included 494 pts: BVd, n=243; DVd, n=251. In the BVd arm, 122/243 pts (50%) had HRC, of which 41 (17%) had t(4;14), 8 (3%) had t(14;16), 1 (0.4%) had t(14;20), 30 (12%) had 17p13del, and 94 (39%) had amp1q. In the DVd arm, 115/251 (46%) had HRC, of which 42 (17%) had t(4;14), 6 (2%) had t(14;16), 1 (0.4%) had t(14;20), 35 (14%) had 17p13del, and 79 (31%) had amp1q. Median PFS in pts with ≥1 HRCA was 33.2 mo (95% CI, 20.1 mo-not reached) with BVd vs 11.1 mo (95% CI, 9.0-15.1 mo) with DVd (HR, 0.40; 95% CI, 0.27-0.59), and 18-mo PFS rates were 61% and 38%, respectively. PFS benefit favored BVd across subgroups (HR [95% CI]): t(4;14), 0.36 [0.19-0.67]; 17p13del, 0.25 [0.11-0.61]; amp1q, 0.48 [0.31-0.73]; t (14;16) and t(14;20) were not analyzed due to low numbers. In pts with ≥1 HRCA, overall response rate was 81% (n=99; 95% CI, 73.1%-87.7%) with BVd and 69% (n=79; 95% CI, 59.4%-77.0%) with DVd; more pts achieved ≥CR with BVd than with DVd (Table). The benefit was maintained across subgroups. **Conclusions:** In pts with RRMM and ≥1 HRCA, PFS benefit favored BVd vs DVd, and BVd demonstrated a higher rate of deep response. Current outcomes in pts with HRC features are suboptimal, and these data support BVd as a potential standard-of-care regimen in these pts with high unmet need. Clinical trial information: NCT04246047. Research Sponsor: This study was sponsored by GSK. Editorial support was provided by Nucleus Global, an Inizio Company, and funded by GSK. Leveraging AI for validating the association between minimal residual disease (MRD) and survival outcomes in multiple myeloma. First Author: Zexin Ren, The George Washington University, Washington, DC

Background: Minimal residual disease (MRD) has been recently accepted by the Food and Drug Administration (FDA) as an endpoint for accelerated approval in Multiple Myeloma. However, emerging data from recent trials were not included in previous analyses. While literature-based meta-analyses on the correlation between MRD and approved clinical outcomes typically require extensive manual review, leveraging AI with expert-in-the-loop validation can efficiently generate reliable evidence from comprehensive clinical studies with up-to-date outcomes. **Methods:** An AI-assisted framework was developed to identify relevant studies and extract critical information via two independent objectives. The first objective examined trial-level associations, modeling treatment effects on MRD and clinical endpoints across patient populations using weighted least squares, with association strength measured by coefficients of determination (R^2) and 95% confidence intervals (CIs). The second objective analyzed individual-level associations using synthetic individual patient data (SynthIPD) generated from the published Kaplan-Meier plots and summary statistics of patient subgroups. **Results:** AI-assisted screening identified eligible studies (>50 patients per treatment arm) reporting progression-free survival (PFS), overall survival (OS), and MRD-negative complete response rates (MRD-CR rate) using multi-parameter next-generation flow cytometry or sequencing methods (sensitivity threshold $\geq 10^{-5}$), expanding previous analyses from 15 to 20 two-arm studies. Trial-level analysis demonstrated an R^2 of 0.69 (95% CI 0.50–0.89) for PFS log hazard ratio versus MRD-CR rate log odds ratio. Analysis of synthetic individual data from Kaplan-Meier curves using a novel digitization method yielded a global odds ratio of 7.28 (95% CI 5.60–8.95) for individual-level correlation between MRD-CR rates and PFS outcomes. **Conclusions:** This study validates MRD-CR rate as an endpoint for accelerated approval in MM through rapid AI-assisted literature review and synthetic individual patient data. The findings demonstrate moderate correlation between MRD-CR rate and median PFS at both trial and individual levels, consistent with previous literature but incorporating additional eligible studies. The novel SynthIPD approach presents an efficient alternative to traditional data-sharing methods while maintaining analytical robustness. These results align with current Oncologic Drugs Advisory Committee (ODAC) surrogacy analysis methods and support the utility of MRD assessment in MM clinical trials. Research Sponsor: None.

Efficacy and safety outcomes in patients (pts) with renal impairment in the phase 3 DREAMM-7 and DREAMM-8 trials. First Author: Marcelo Pitombeira de Lacerda, Universidade da Região de Joinville and Centro de Hematologia e Oncologia, Joinville, Santa Catarina, Brazil

Background: Renal impairment is a frequent complication in relapsed/refractory multiple myeloma (RRMM). Results from DREAMM-7 (NCT04246047) showed significant PFS and OS benefit favoring belantamab mafodotin (belamaf), bortezomib, and dexamethasone (BVd) vs daratumumab-Vd (DVd). DREAMM-8 (NCT04484623) showed significant PFS benefit with belamaf, pomalidomide, and dexamethasone (BPd) vs pomalidomide, bortezomib, and dexamethasone (PVd). In an ongoing phase 1 study (NCT04398745), renal impairment did not impact belamaf pharmacokinetics. We report outcomes in pts with mild/moderate renal impairment from DREAMM-7 and DREAMM-8. **Methods:** Renal function of eligible pts with RRMM was defined based on estimated glomerular filtration rate (eGFR) derived by local labs at screening: normal (≥90 mL/min/1.73 m^2), mild (≥60 to <90 mL/min/1.73 m^2), or moderate (≥30 to <60 mL/min/1.73 m^2) impairment. Pts with eGFR <30 mL/min/1.73 m^2 were ineligible for these trials. **Results:** Results included pts with mild/moderate renal impairment in DREAMM-7 (BVd, n=175; DVd, n=183) as of October 2, 2023, and DREAMM-8 (BPd, n=117; PVd, n=109) as of January 29, 2024. Median PFS was NR with BVd vs 12.6 mo with DVd (HR, 0.39; 95% CI, 0.29-0.53) in DREAMM-7 and 24.0 mo with BPd vs 9.7 mo with PVd (HR, 0.52; 95% CI, 0.35-0.76) in DREAMM-8. Belamaf-containing regimens in both trials had numerically higher 18-mo PFS rates, overall response rates (ORRs), and complete response or better (≥CR) rates (Table). OS benefit favored BVd vs DVd (HR, 0.58; 95% CI, 0.39-0.86) and BPd vs PVd (HR, 0.71; 95% CI, 0.46-1.09). Median OS was NR in either arm of both trials. In pts with mild/moderate renal impairment in DREAMM-7, 95% with BVd and 79% with DVd had a grade 3/4 AE. AEs leading to discontinuation of any study drug occurred in 33% and 18%, respectively. Fatal serious AEs occurred in 10% with BVd and 8% with DVd. In DREAMM-8, 90% with BPd and 73% with PVd had a grade 3/4 AE. AEs leading to discontinuation of any study drug occurred in 13% with BPd and 15% with PVd. Fatal serious AEs were observed in 13% and 12%, respectively. **Conclusions:** In pts with mild/moderate renal impairment, belamaf-containing regimens (BVd and BPd) showed improved efficacy vs standard triplets, indicating they are an efficacious alternative SOC in a broad range of pts with RRMM. Safety results in this pt population were consistent with the ITT populations. Research Sponsor: This study was sponsored by GSK. Editorial support was provided by Nucleus Global, an Inizio company, and funded by GSK. Drug linker technology licensed from Seagen Inc.; monoclonal antibody produced using POTELLIGENT Technology licensed from BioWa.

Efficacy and safety of less frequent dosing with elranatamab (ELRA) in patients with relapsed or refractory multiple myeloma (RRMM): A US subgroup analysis from MagnetisMM-3. First Author: Ajay K. Nooka, Winship Cancer Institute, Emory University, Atlanta, GA

Background: The ongoing phase 2 MagnetisMM-3 (NCT04649359) study demonstrated the efficacy and safety of ELRA in patients (pts) with RRMM and no prior BCMA-directed therapy (Cohort A). With a median follow-up of 33.9 mo, ORR was 61.0%, mPFS was 17.2 mo, and mOS was 24.6 mo. Here we report results for the subgroup of pts enrolled in MagnetisMM-3 in the US. **Methods:** Eligible pts had RRMM with disease refractory to ≥1 immunomodulatory drug, ≥1 proteasome inhibitor, and ≥1 anti-CD38 antibody. Pts were given subcutaneous ELRA as step-up priming doses followed by 76 mg QW for 6 cycles. Pts given QW dosing for ≥6 cycles who achieved partial response or better lasting ≥2 mo were transitioned to Q2W dosing and to Q4W after ≥6 cycles of Q2W dosing. The subgroup of pts within Cohort A enrolled in the US (n=47) was analyzed. As of the data cutoff date (September 10, 2024), the median follow-up was 33.8 mo (95% CI, 32.9-35.7; estimated by reverse Kaplan–Meier), approximately 32 mo after the last pt first dose. **Results:** Pts in the US subgroup received a median of 5 prior lines of therapy (range, 2-22); 93.6% were triple-class refractory, and 46.8% were penta-drug refractory. Eight (17.0%) pts were Black or African American. ORR (95% CI) by Blinded Independent Central Review was 66.0% (50.7-79.1); 42.6% of pts achieved complete response (CR + stringent CR). Median (range) time to response was 1.08 mo (0.95-7.36), and median time to CR or better was 4.76 mo (1.22-12.75). Median duration of response (95% CI) was not reached (NR) (24.0 mo-not estimable [NE]); the probability of maintaining response at 30 mo (95% CI) was 65.7% (43.3-81.0). Median (95% CI) PFS was 27.3 mo (4.3–NE). Median (95% CI) OS was NR (14.9–NE); the probability of survival at 30 mo (95% CI) was 55.8% (40.1-68.9). Any grade [G] and G3/4 treatment-emergent adverse events were reported in 100% and 78.7% pts, respectively. Infections (any G, G3/4, G5) were reported in 70.2%, 40.4%, and 0.0%, respectively; 51.1% received Ig replacement. Anti-viral, anti-pneumocystis jirovecii pneumonia, anti-bacterial, and anti-fungal prophylaxis were received by 80.9%, 21.3%, 14.9%, and 8.5% of pts, respectively. The rate of cytokine release syndrome (CRS) was 61.7% (G1, 34.0%; G2, 27.7%; G≥3, 0.0%). Immune effector cell-associated neurotoxicity syndrome was reported in 8.5% of pts (G1, 4.3%; G2, 4.3%; G≥3, 0.0%). 22 pts switched from QW to Q2W, and 8 pts further switched from Q2W to Q4W dosing. **Conclusions:** The pts with RRMM enrolled in MagnetisMM-3 Cohort A, including the US subgroup, were heavily pretreated. Consistent with overall Cohort A data, ELRA was associated with deep, durable responses in the US subgroup, with a mPFS of 27.3 mo. CRS was G1 and G2 only. Infections were consistent with what was observed in the overall study population; infection prophylaxis including Ig replacement are recommended. Clinical trial information: NCT04649359. Research Sponsor: Pfizer.

Belantamab treatment of multiple myeloma: Results from part 1 of the first-in-human phase 1/2 DREAMM-20 trial. First Author: Hang Quach, University of Melbourne, St Vincent's Hospital, Melbourne, VIC, Australia

Background: Belantamab mafodotin (belamaf) is a B-cell maturation antigen (BCMA)–targeted monoclonal antibody (mAb) conjugated with a monomethyl auristatin-F (MMAF) payload. In DREAMM-7 and DREAMM-8 phase 3 trials in relapsed/refractory multiple myeloma (RRMM), belamaf combinations significantly improved progression-free survival vs standard care, and DREAMM-7 showed significant overall survival benefit. Belantamab (GSK2857914) is the naked BCMA mAb without MMAF; therefore MMAF-related toxicities are not expected. DREAMM-20 is a phase 1/2 trial to evaluate safety, tolerability, and clinical activity of belantamab in patients (pts) with MM. We present the planned analysis of part 1 of belantamab dose escalation. **Methods:** Part 1 of DREAMM-20 (NCT05714839) is a phase 1, open-label, multicenter, dose-escalation study in pts with RRMM with ≥3 prior lines of therapy. Dose escalation was conducted using a modified toxicity probability interval method. The primary endpoint was incidence of adverse events (AEs), including dose-limiting toxicities (DLTs). Secondary endpoints included overall response rate (ORR). **Results:** Across 3 cohorts, 18 pts enrolled and received belantamab 300, 900 or 2000 mg IV Q2W (n=6 each). Data cutoff (DCO) was Aug 23, 2024. Median age was 76 y (range, 42-86 y), 17 of 18 pts were triple-class exposed, and 2 of 18 pts had prior BCMA-targeted therapy. The overall median duration of exposure was 63.5 days. No DLTs or treatment-related AEs (TRAEs) leading to permanent discontinuation were reported. The most common TRAEs were infusion-related reactions and hematologic AEs (Table). Two pts had grade ≥2 corneal events per the Keratopathy and Visual Acuity (KVA) scale that were considered unrelated to belantamab. The ORR was 28% (5/18 pts; very good partial response, n=2 [900 mg]; partial response, n=3 [1 in 300 mg and 2 in 2000 mg]) with responses across all cohorts. Median duration of exposure in the 5 responders was 253 days; none of the responders had progressed as of DCO. No pts had minimal response and 28% (5/18 pts) had stable disease. Follow-up is ongoing. **Conclusions:** Belantamab showed an encouraging safety profile with no DLTs, AEs leading to discontinuation, or belantamab-related grade ≥2 corneal events. Durable responses were observed across dose levels in this triple-class–exposed population. Results support the hypothesis that belantamab provides clinical antimyeloma activity with an acceptable safety profile. Clinical trial information: NCT05714839. Research Sponsor: This study was sponsored by GSK (study 218670). Editorial support was provided by Nucleus Global, an Inizio Company, and funded by GSK. Monoclonal antibody produced using POTELLIGENT Technology licensed from BioWa.

Positron emission tomography with computed tomography (PET/CT) and minimal residual disease (MRD) for efficacy assessment in transplant-ineligible newly diagnosed myeloma (Ti NDMM) patients (pts): IMROZ analysis. First Author: Elena Zamagni, Seragnoli Institute of Hematology, Bologna University School of Medicine, Bologna, Italy

Background: MRD is a measure of response in the bone marrow (BM) but is limited by patchy infiltration of BM plasma cells and lack of plasmacytoma assessment. Imaging-based MRD assessment, which is non-invasive, such as PET/CT, may overcome these limitations, and distinguish metabolically active MM from non-active. Isatuximab (Isa) is an anti-CD38 monoclonal antibody approved in combination with bortezomib, lenalidomide and dexamethasone (VRd) in Ti NDMM pts based on the Phase 3 IMROZ study. Here, we present an analysis of IMROZ (NCT03319667), investigating PET/CT negativity (−) with MRD− in front line efficacy assessment. **Methods:** In IMROZ, pts were randomized 3:2 to receive Isa-VRd or VRd as initiation, then Isa-Rd or Rd as maintenance. BM MRD was assessed by next generation sequencing at 10^{-5} sensitivity at baseline (BL), then in case of complete response (CR) or very good partial response at end of initiation, and every 6 months for 2 years, then once a year until disease progression (PD). PET/CT scans were assessed by central review and performed at BL, then yearly until PD; if positive for soft tissue plasmacytoma, repeated at time of CR and/or end of induction, then following time points for MRD assessment. PET/CT positivity (+) was defined as FDG 5PS Score ≥4, and PET/CT− as FDG 5PS ≤3. **Results:** Across the global and China populations, 244 Isa-VRd and 162 VRd pts had PET/CT at BL, of which 153 (62.7%) and 101 (62.3%) were PET/CT+, respectively. Of these, 121 (41.6%) and 83 (43.0%) had a post-BL PET/CT assessment. 155 pts presented with plasmacytoma at BL (95 Isa-VRd, 60 VRd), with comparable BL characteristics to the global population. Among PET+ pts at BL, the double negativity rate (PET/CT FDG 5PS score ≤3 + MRD−) was significantly higher in Isa-VRd pts than VRd (odds ratio [OR] 1.54; 95% CI 1.04-2.29; p=0.0155), and similarly for double negativity + ≥CR (OR 1.60; 95% CI 1.07-2.38; p=0.0108). As shown in Table, more Isa-VRd than VRd pts with plasmacytoma reached PET/CT 5PS ≤3 and MRD−, and PET/CT 5PS ≤3 with MRD− + ≥CR. Progression-free survival (PFS) in pts PET/CT+ at BL was in favor of the Isa-VRd arm (median PFS [mPFS] not reached [NR; 95% CI 59.4-NR]) vs VRd (mPFS 49.1 [95% CI 39.1 -NR]) (hazard ratio [HR] 0.58; 95% CI 0.39-0.88; p=0.6303), and HR was comparable to the intent to treat population. PFS in pts with plasmacytoma at BL was similar to the global population (HR 0.685; 95% CI 0.40-1.18; p=0.5332). **Conclusions:** This analysis of IMROZ shows the prognostic value of BL PET/CT findings. More Isa-VRd pts reached double negativity than VRd, including pts with plasmacytomas. This translated to a better PFS in pts treated with Isa-VRd. Clinical trial information: NCT03319667. Research Sponsor: Sanofi.

Impact of autoimmune disease on toxicity and outcomes after idecabtagene vicleucel in patients with multiple myeloma. First Author: Rebecca Albuquerque, USF Health Morsani College of Medicine, Tampa, FL

Background: Idecabtagene vicleucel (ide-cel), an autologous BCMA-directed chimeric antigen receptor (CAR) T-cell therapy, has the potential to cure patients with relapsed/refractory multiple myeloma (RRMM). However, cytokine release syndrome (CRS) and immune effector cell-associated neurotoxicity syndrome (ICANS) are common treatment-related adverse events. Historically, patients with autoimmune disease (AD) have been excluded from CAR-T trials due to uncertain outcomes. This study evaluates differences in ICANS, relapse, and survival in RRMM patients with and without AD treated with ide-cel. **Methods:** A retrospective study of RRMM patients with AD treated with ide-cel at Moffitt Cancer Center in Tampa, FL between 2021-2024 was conducted. Clinically significant AD requiring medical management prior to apheresis included AIHA, autoimmune thyroiditis, ITP, RA, AIDP, CIDP, UC, SLE and PMR. T-tests and Kaplan-Meier estimates analyzed associations between AD, toxicities, and survival. **Results:** Of 179 patients with RRMM who received ide-cel, 13 (7%) had clinical AD with a median age of 72 years (range: 58 - 81 years, 54% female [n=7]). The incidence of ICANS was 23.1%, versus 23.6% for patients without AD (n = 166). The incidence (p = 1) and duration (p = 0.822) of ICANS was not significantly different in those with or without AD. Two patients (with AIHA and ITP) were tapered off of prednisone prior to ide-cel. Per medical records, the remaining patients were not on immunosuppressive medications for AD at treatment. All AD patients experienced CRS versus 85% of patients without AD (p = 0.225). For AD patients who experienced ICANS, median LDH (202 U/L vs 189 U/L, p = 0.061) and ferritin (528 ng/mL vs 284 ng/mL, p = 0.866) 5 days prior to infusion (day -5) was not significantly higher versus AD patients with no ICANS. However, median CRP at day -5 was significantly higher (1.2 mg/L vs 0.365 mg/L, p = 0.05). In AD patients who experienced ICANS, median LDH (872 U/L vs 268U/L, p = 0.01) and ferritin (10200 ng/ml vs 3000 ng/ml, p = 0.05) were significantly higher at the day of maximum grade ICANS versus patients without AD. However, there was no difference in median CRP (7.46 mg/L vs 7.72 mg/L, p = 0.9). Among patients who experienced ICANS, AD patients did not have significantly lower progression free survival (PFS) versus patients without AD at 30 days, 12 months, and 18 months (p = 0.07). There was no difference in overall survival between patients with or without AD. **Conclusions:** This retrospective study shows that pre-existing AD does not increase the risk of ICANS in patients with RRMM who were treated with ide-cel. Although LDH and ferritin levels were similar, levels of CRP were significantly higher in AD patients who experienced ICANS versus those that did not. Given notable differences in levels of inflammation and relapse rates among patients with AD, these patients may benefit from close monitoring. Research Sponsor: None.

7553 Poster Session

Carfilzomib, iberdomide, and dexamethasone (KID) in patients with transplant-eligible newly diagnosed multiple myeloma (NDMM): Updated results from phase 1/2 study. First Author: Noa Biran, John Theurer Cancer Center, Hackensack University Medical Center, Hackensack, NJ

Background: SOC regimens for patients (pts) with transplant-eligible NDMM include VRd, D-VRd, and KRd. Iberdomide, a cereblon modulator, enhances immune stimulatory activity *in vitro* compared to thalidomide analogs. A phase 1 study reported the MTD of iberdomide 1.6 mg plus carfilzomib (CFZ) and dexamethasone (DEX), KID regimen, in NDMM pts (Biran 2023). Herein we report longer term safety and efficacy data from a phase 2 dose expansion study of KID in NDMM pts (NCT05199311). **Methods:** Adults with NDMM eligible for ASCT were enrolled in this multicenter, investigator-initiated phase 1/2 study. In the phase 2 portion, pts received CFZ (IV; 20 mg/m^2 on C1D1; then 56 mg/m^2 C1 D8, 15; then 56 mg/m^2 C2-4 D1, 8, 15), iberdomide (1.6 mg; D1-21), and DEX (40 mg if ≤75 years; 20 mg if >75 years; D1, 8, 15) in 28-day cycles for 2-3 cycles followed by ASCT. The primary objective is to evaluate the rate of CR + sCR. **Results:** As of 1/10/25, 38 pts signed consent, including 20 in follow-up, 7 off study (5 screen failures/1 consented/1 withdrew due to rash), and 4 on treatment (tx). Of 31 pts who received tx, median age was 66 years (range 41-78), 52% male, 77% White, 16% Black, 3% Asian, 58%/16%/6% ISS stage 1/2/3, respectively. Thirteen pts (42%) had high-risk cytogenetics: t(4;14) (n=3), t(4;16) (n=1), del(17p)/monosomy 17/*TP53* (n=2), 1q21 (n=9), and *MYC* (n=1). Two pts had double- and 1 was triple-hit MM. Thirty-one pts completed a median of 3 cycles (range 1-4) of KID. At end of induction, ORR was 96% (23/24, CR 4%, VGPR 42%, PR 50%). Twenty-three pts proceeded to ASCT; 8 did not (4 on tx/1 collecting cells/1 withdrawal/1 death). Median number of stem cells mobilized was 11.3 x 10^6 cells/kg (range 4.74-29.8). At 3 months post-ASCT, ORR was 100% (19/19, sCR 5%, CR 21%, VGPR 53%, PR 21%), CR + sCR is 26%, and of those, 100% are MRD-negative. Median tx duration was 84 days (IQR, 63-91). At median follow-up of 12.4 months, median PFS and OS were NR (95% CI, NA-NA). Most common hematologic TEAEs were anemia (19%), neutropenia (39%), and thrombocytopenia (23%). Most common non-hematologic TEAEs were pruritus (23%) and rash (23%). Grade 3 TEAEs occurred in 26% of pts; most common were neutropenia (26%), thrombocytopenia (6%), and rash (6%). Six pts developed grade 1-2 SAEs unrelated to tx. One patient experienced grade 3 SAE of fever and colonic hemorrhage that required hospitalization and supportive care. No tx-related deaths occurred; 1 patient died on study due to a possible thrombotic event in the setting of medication non-compliance. **Conclusions:** Induction therapy with KID appears safe and effective leading to deep responses and adequate stem cell collection despite short tx duration and 42% harboring high-risk cytogenetics. Long-term follow-up is needed to determine durability of response. Correlative studies are underway to evaluate immune phenotype and microbiome changes pre/post-tx. Clinical trial information: NCT05199311. Research Sponsor: Amgen; Bristol Myers Squibb.

Updated results from phase 2b study of selinexor in combination with carfilzomib, daratumumab, or pomalidomide in patients with multiple myeloma (MM) relapsing on current therapy. First Author: Noa Biran, John Theurer Cancer Center, Hackensack University Medical Center, Hackensack, NJ

Background: Selinexor is a potent selective inhibitor of nuclear export and exhibits synergistic effects when combined with other myeloma therapies. Preliminary results on the combination of selinexor with carfilzomib (CFZ), daratumumab (DARA), or pomalidomide (POM)-based regimens in patients relapsing on therapy were reported (Biran 2023); overall response rate (ORR) Arm 1 (33%), Arm 2 (29%), and Arm 3 (44%). Herein we present the updated results with longer follow-up of selinexor plus CFZ, POM or DARA in MM patients relapsing on current treatment (NCT04661137). **Methods:** Patients were enrolled to each arm if their disease was refractory to the specific drug. Patients on Arm 1 were treated with selinexor 80 mg on D1, 8, 15; CFZ 20 mg/m^2 IV on D1, 8, 15; and dexamethasone (DEX) on D1, 8, 15, 22. Arm 2 patients received selinexor 60 mg on D1, 8, 15; POM 4 mg on D1-21; and DEX on D1, 8, 15, 22. Arm 3 patients were treated with selinexor 100 mg on D1, 8, 15, 22; DARA 16 mg/kg IV or 1,800 mg SQ on D1, 8, 15, 22 for C1-2; then D1 and 15 for C3-6; then D1 for ≥C7; and DEX on D1, 8, 15, 22. The primary objective was to investigate the ORR of selinexor plus CFZ, POM, or DARA-based regimens. **Results:** As of Jan 10, 2025, 28 patients were enrolled. Twenty-four were evaluable for response; 7 withdrew consent in which 5 were due to disease progression. Median age was 68 years (range 52-82), 50% male, 54% White, 96% had prior autologous transplant and 21% had extramedullary disease. Nineteen (79%) patients had high-risk cytogenetics, including 1q21 duplication (n=11), t(4;14) (n=8) and *TP53* mutation (n=6). The ORR was 38% (95% CI, 19-59%) (PR, 8 [33%]) and clinical benefit rate (CBR) was 83% (95% CI, 63-95%) (PR, 8 [33%]; MR, 1 [4%]; SD, 11 [46%]). With a median follow-up of 11.0 months, the median PFS was 5.7 months (95% CI, 4.7-NR), and median OS was NR months (95% CI, 15-NR). Median DOR was 3.6 months (IQR, 2.5-5.1) with a median treatment duration of 4.0 months (range 0.3-10.8 mos). Most commonly reported Grade 1-2 TEAEs were electrolyte abnormalities (50%) and fatigue (38%). Most commonly reported grade ≥3 TEAEs were neutropenia (25%) and pneumonia (8%).Three patients experienced treatment-related grade 3 SAEs and recovered. One developed chest pain that required hospitalization. One had parainfluenza A-1 pneumonia requiring a treatment delay. One experienced sepsis and pneumonia which led to hospitalization and interruption of treatment. **Conclusions:** Selinexor as an add-on to CFZ, POM, or DARA-based regimens, in patients actively progressing on these regimens, is well tolerated and safe. This trial demonstrates that selinexor can restore sensitivity to regimens to which MM patients are actively refractory. Future studies can evaluate these combinations in the setting of chimeric antigen receptor T-cell bridging or in the post-bi-specific T-cell engager setting. Clinical trial information: NCT04661137. Research Sponsor: Karyopharm Therapeutics.

Clinical activity of novel targeting of S100A9 with tasquinimod for relapsed and refractory multiple myeloma (RRMM). First Author: Dan T. Vogl, Abramson Cancer Center, Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA

Background: S100A9, a protein produced by myeloid-derived suppressor cells in the bone marrow microenvironment, promotes multiple myeloma (MM) progression and confers therapeutic resistance. Tasquinimod (tasq), an oral S100A9 inhibitor, has pre-clinical anti-myeloma effects alone and combined with proteasome inhibitor (PI) and immunomodulator (Imid) therapy (Cancer Res Commun 2023;3(3):420) and improved progression-free survival in prostate cancer patients (pts) (JCO 2016;34(22):2636-43). We previously reported preliminary results of a phase 1 trial of tasq alone and in combination with ixazomib (ixa), lenalidomide (len), and dexamethasone (dex) (IRd) in pts with RRMM (JCO 2023;41(16) suppl:8042; NCT04405167). For single-agent tasq, the recommended phase 2 dose (RP2D) was 1 mg daily (qd) after a 1 week (wk) run-in at 0.5 mg qd. We now report updated results of tasq in combination with IRd. **Methods:** In dose escalation, pts were refractory, intolerant, or contraindicated to len, pomalidomide, bortezomib, carfilzomib, and an anti-CD38 monoclonal antibody. In dose expansion, pts were refractory to the most recent Imid/PI combination or triple-class refractory. Tasq was given in 28-day cycles at 1 mg daily with either a 2 wk run-in (dose level 1: 0.25 mg qd x1 wk then 0.5 mg qd x1 wk) or a 1 wk run-in (dose level 2: 0.5 mg qd x1 wk). In dose escalation, pts received full doses of ixa (4 mg days 1/8/15), len (25 mg days 1-21, adjusted for renal dysfunction), and dex (40 mg qwk), but in dose expansion, doses of ixa, len, and dex were reduced per investigator discretion. **Results:** 16 pts received tasq with IRd at dose levels 1 (3 pts) and 2 (13 pts: 3 in escalation, 10 in expansion). Median age was 67 y (range 52-81); 75% were male; 19% were African American and 81% Caucasian. Pts had received median 7 prior lines of therapy (range 3-19), and all were triple-class refractory, with 81% (13 pts) refractory to their most recent Imid/PI combination. In dose escalation, no dose limiting toxicities were observed, and dose level 2 was the RP2D of tasq with IRd. The most common treatment-emergent adverse events were fatigue (10 pts: grade [gr] 3 in 1 pt), pain (9 pts: 0 gr ≥3), respiratory infection (9 pts: 4 gr 3, 2 gr 5), nausea/vomiting (8 pts: 0 gr ≥3), dyspepsia/gastritis (5 pts: 1 gr 3), and thrombocytopenia (5 pts: 1 gr 3, 3 gr 4). Among all 16 pts, there was 1 partial response (PR) and 7 minimal responses (MR). Among the 13 pts who were previously refractory to their most recent Imid/PI combination and would therefore not be expected to respond to the IRd backbone, there was 1 PR (lasting 20 months) and 5 MRs (lasting 1, 1, 2, 2, and 7 months). **Conclusions:** Tasquinimod, an S100A9 inhibitor, is well tolerated in combination with IRd and has anti-myeloma activity, as evidenced by responses in patients previously refractory to Imid/PI combination therapy. Further study is warranted of tasquinimod in combination with standard myeloma therapies. Clinical trial information: NCT04405167. ASCOmind: Is instant ASCO abstract analysis possible with AI agents? First Author: Kyeryoung Lee, IMO Health, Rosemont, IL

Background: The ASCO Annual Meeting receives thousands of abstracts annually on ongoing therapies. Extracting actionable insights from this large volume of data through manual review is time-consuming. To reduce manual workload and accelerate evidence synthesis, we implemented an AI-Agent system to assess the feasibility of deploying AI agents for efficient, large-scale data analysis and insight generation. **Methods:** GPT4o-based ASCOmind was designed with a robust framework of six autonomous and collaborative AI agents: Pre-processor, Categorizer, MetadataExtractor, Analyzer, Visualizer, and ProtocolMaker to systematically generate and visualize insights from ASCO abstracts. We demonstrate and evaluate ASCOmind by applying it to 2024 multiple myeloma (MM) studies. Using human reviewers as the gold standard, we assessed the quality and efficiency of the system focusing on outcome data accuracy, visualized charts, and workflow recipes documentations. **Results:** ASCOmind processed abstracts in the plasma cell dyscrasia section, categorizing 60 MM abstracts into 26 clinical trials and 34 as real-world studies. Manual abstraction of 51 predefined data elements required >60 mins/abstract, whereas ASCOmind completed the same task in <5min/article. The ASCOmind not only significantly reduced the processing time but also instantly analyzed and visualized the extracted data within 10 min. For instance, 27 included high-risk populations with cytogenetic abnormalities (n=20), extramedullary disease (n=7), or elderly patients (n=4). Across 51 interventional studies, 33 targeted relapsed/refractory MM (RRMM) and 18 focused on newly diagnosed MM (NDMM). ASCOmind generated a treatment distribution table for RRMM and NDMM (Table 1), with one misclassification corrected by humans-Mezigdomide reclassified from ADC to the correct category. Additionally, granular efficacy/safety outcome values and summarized study findings were also successfully extracted and visualized. **Conclusions:** Our preliminary analysis of ASCOmind demonstrated high accuracy and efficiency in automating abstract analysis, enabling rapid analysis of trends and outcomes. This feasibility study highlights the scalability of AI systems across all cancer types, supporting decision-making. Research Sponsor: None.

Treatment distribution in RRMM and NDMM studies.

Total (N=51)	Therapy Category	Examples	No. of Studies	%
RRMM (N=33)	BCMA-CAR-T Therapies	Cilta-cel, Ide-cel, ARI0002h	8	24.3%
	BCMA-Bispecific Ab Therapies	Teclistamab, Talquetamab, Elranatamab, Linvoseltamab, ABBV-383	16	48.5%
	ADC	Belantamab mafodotin, Elotuzumab,	5	15.2%
	Cereblon E3 Ligase Modulator	Mezigdomide, Iberdomide,	2	6.0%
	Others	OriCAR017, Venetoclax	2	6.0%
	Triplet/Quadruplet SOC	VRd, Isa-VRd	8	44.5%
NDMM (N=18)	Transplantation	ASCT, Tandem Transplantation	6	33.3%
	ADC	Belantamab mafodotin,	2	11.1%
	BCMA-Directed Therapies	Cilta-cel + Lenalidomide, Teclistamab	2	11.1%

Gene-expression-profiling plus integrated multidisciplinary approach to detect new-generation risk-adapted prognostic index in smoldering myeloma and multiple myeloma (GIMPI). First Author: Claudio Cerchione, Hematology Unit, Istituto Romagnolo per lo Studio dei Tumori "Dino Amadori" - IRST IRCCS, Meldola, Italy

Background: In our Institution, a prospective study to test the combination of gene-expression-profiling (SKY92 gene signature) and new generation imaging (PET/CT + Whole body MRI) was applied to all consecutive patients affected by smoldering (SMM), newly diagnosed (NDMM) and relapsed/refractory (RRMM) MM and evaluated its potential to predict or correlate with established HR markers of this disease and potentially defining new basis for a personalized treatment. **Methods:** Patients' bone marrow aspirate, plasma, imaging and clinical data were collected in our Institute under approved protocol and according to the Declaration of Helsinki guidelines. **Results:** In this study a cohort of 139 patients referring to our Institute was enrolled (SMM n=47, NDMM n=54 and RRMM n=38): here we present only the molecular part of the study, combination with imaging analysis is currently ongoing. Proportion of patients with SKY92 HR increased from SMM (8.4%) to NDMM (36.7%) and RRMM (53.3%, p=0.0162). Virtual FISH in NDMM patients showed 100% accuracy (95% CI) (100.0-100.0) for both t(4;14) and gain(1q) and of 90.0 (71.4-100.0) for del(17p), and this could be really useful for the daily clinical practice. The concentration of sBCMA was measured in our patients' cohort and in healthy subjects (n=12, control) with a statistically significant increase of sBCMA in the blood of NDMM and RRMM with respect to SMM (p=0.0009, p=0.0222) and control (p<0.0001, p=0.0010). Consistently with the literature, no statistically significant differences were observed among NDMM and RRMM. Thus, we hypothesize that SKY92 HR could capture patients with high levels of sBCMA. We compared the concentration of this disease biomarker among SR and HR including SMM, NDMM and RRMM patients and we observed increased levels of sBCMA in HR patients with respect to SR (p=0.0049). A risk-based intragroup comparison showed a similar trend in SMM and RRMM and, importantly, this result was confirmed in NDMM patients (p=0.0445). However, in this category of MM patients ISS could partially recapitulate differences in sBCMA among risk classes with the only statistically significant difference between Class I and III (p=0.0381). Therefore, we combined ISS with SKY92 and we observed that n=11 patients considered as LR by ISS (Class I), were relocated to the IR from this analysis with an overall improvement in the distribution of sBCMA levels according to risk categories (SR vs HR p=0.0011, IR vs HR p=0.0036). **Conclusion:** The results of this first pilot Italian study, that in the next future will be framed in a national network contest, strengthen the prognostic relevance of SKY92 based on its potential to (i) predict HR cytogenetic markers of disease; (ii) capture MM patients with high levels of sBCMA supporting the introduction of this GEP-based tool in the clinical diagnostic practice. The impact of glucagon-like peptide-1 agonists on MGUS progression in patients with type 2 diabetes. First Author: Tajana Juranovic, Charleston Area Medical Center, Charleston, WV

Background: Monoclonal gammopathy of undetermined significance (MGUS) is a pre-malignant condition with limited interventions to reduce progression to multiple myeloma (MM). Glucagon-like peptide-1 (GLP-1) agonists, widely used for glycemic control and weight loss in type 2 diabetes mellitus (T2DM), have demonstrated cardiovascular, renal, and anti-cancer benefits, including reduced risks of obesity-associated cancers. This study assesses the association between GLP-1 agonists and MGUS progression in T2DM patients. **Methods:** We queried TriNetX – a Research Network - of 141 healthcare organizations from 30 countries between 2011 and 2024.MGUS patients with T2DM were divided into two cohorts: those on GLP-1 agonists and those not on GLP-1. Two sub-analyses were conducted: one in MGUS T2DM patients with a normal body mass index (BMI), and another in patients with BMI $\geq$25. Patients aged 18–80 years with monoclonal protein $<$3 g/dL, and GLP-1 use or other diabetic medications $\geq$2 years prior to MGUS diagnosis were included. Patients with prior diagnosis of MM, progression to MM within 1 year, kappa/lambda light chain $>$100 mg/dL, osteolytic lesions, creatinine $>$2 mg/dL, hemoglobin $<$10 g/dL, calcium $>$10.2 mg/dL, or prior treatment with bortezomib, lenalidomide, or daratumumab, were excluded. A 1:1 propensity score matching was performed to match the covariates (age, sex, race [white or African American], M protein, kappa/lambda ratio, and BMI). MM rates were compared at 2, 3, 5, 7, and 10 years. **Results:** The study included 5,901 MGUS patients with T2DM in the main analysis (22.45% on GLP-1 [n=1,325]; 77.55% not on GLP-1 [n=4,576]). The sub-analysis involved 818 normal-BMI patients (22.37% on GLP-1 [n=183]; 77.63% not on GLP-1 [n=635]). Matched cohorts (main analysis: n=1,319 each, sub-analysis n=181each) revealed significantly lower MM rates in GLP-1 users at 2- (1.21% vs 2.50, p=0.014), 3- (1.36% vs 2.50%, p=0.33), 5- (1.36% vs 2.57%, p=0.025), 7- (1.36% vs 2.57%, p=0.025) and 10-years (1.51% vs 2.65%, p=0.041). Similar findings were observed in the sub-analysis among patients with MGUS and T2DM with BMI $\geq$ 25 at 2- (1.08% vs 3.05%, p=0.001), 3- (1.18% vs 3.15%, p=0.002), 5- (1.08% vs 3.05%, p=0.001), 7- (1.18% vs 2.85%, p= 0.07, and 10-years (1.37% vs 3.05%, p=0.01). However, in the sub-analysis, normal-BMI GLP-1 users showed no difference in MM rates compared to non-users at 10-years (5.52% vs 5.52%, p=1.00). **Conclusions:** The use of GLP-1 agonists was significantly associated with reduced rates of MM among patients with T2DM and MGUS over a 10-year period, particularly in those with a body mass index $\geq$ 25. The lack of significant effects in normal-BMI patients suggests weight loss or related metabolic changes may mediate these protective effects. These results underscore GLP-1 agonists as a promising therapeutic strategy for managing MGUS in T2DM patients, especially those with elevated BMI. Research Sponsor: None.

Role of the combination of 3 T whole-body MRI and 18F-FDG PET/CT in the management of multiple myeloma and smoldering myeloma: The new era of imaging. First Author: Claudio Cerchione, Hematology Unit, Istituto Romagnolo per lo Studio dei Tumori "Dino Amadori" - IRST IRCCS, Meldola, Italy

Background: FDG-PET/TC and MRI are both imaging diagnostic tools adopted in diagnosis and/or response assessment in multiple myeloma (MM) which can be useful in smoldering, newly diagnosed as well in relapsed myeloma. **Methods:** From January 2021 to January 2025, we enrolled into a prospective trial 139 consecutive patients (54 Male; mean age, 67 years $\pm$ 10 [SD]) divided into 3 groups; 34 had a newly diagnosed MM according to the IMWG (group 1); 20 were in follow-up after autologous stem cell transplantation with clinical or laboratory data suspicious for relapse or progression (group 2) and 38 were affected by relapsed/refractory MM during treatment (group 3). In addition we enrolled 47 patients newly diagnosed high risk SMM, according to IMWG (19 Male, mean age 59 years+-10 [SD]). **Results:** On a per-patient basis, 126/139 (90%) had concordant PET/CT and WB-MRI scans, while 13/139 (10%) had discordant scans in terms of positivity/negativity. Among concordant studies, 47/139 (34%) were negative with both imaging methods while 93/139 (67%) were positive at both (including FLs and/or BMI). Among discordant studies, 8/9 had a positive WB-MRI scan and a negative PET-CT scan (6 cases with BMI or micronodular involvement alone), whereas 1/9 had a positive PET-CT and a negative WB-MRI. PET/CT detected FLs pattern in 83/139 patients, WB-MRI alone identified FLs pattern in 6 patients. PET-CT led to a change of treatment approach in 72/139 patients (52%), WB-MRI in 84/139 patients (60%), the combination of the two methods led to a change of management in 86/139 (62%), highlighted in the case of suspected post-transplant relapse. Furthermore, WB-MRI led to a change of management for incidental findings in additional 9 patients (8 suspected malignancies and 1 spinal cord compression). Interim analysis in HR- SMM showed discordance between the results of the two imaging modalities in 32/139 (23%). WB-MRI detected BMI pattern without any overt focal lesion in 11 patients (only 1 correlated with PET/CT) and FLs pattern in 7 patients (4 confirmed also in PET/CT), while PET/CT detected an additional FLs pattern in 1 patient, without bone lytic lesion evidence at the CT images. Both methods led to 6 changes of management, whereas MRI alone led to a change of treatment approach in 14 patients (10%), 13 diagnoses and 1 accessory finding of suspected cholangiocarcinoma. **Conclusions:** Our preliminary data underlines the fundamental role of functional imaging in the evaluation of FLs and BMI in MM with a superior detection rate of WB-MRI related to the ability to identify diffuse and micronodular pattern. A potential complementary role of the two methods in clinical management could be suggested in suspicion of relapsed or progressing MM. Furthermore our prospective trial supports the utmost role of WB-MRI (performed according to MY-RADS) in the assessment of high risk Smoldering Myeloma. Research Sponsor: None.

7561 Poster Session

Real-world analysis of thromboembolism in SAVED/IMPEDE risk-stratified newly diagnosed multiple myeloma (NDMM). First Author: Kian University Medical Rahbari, Vanderbilt University Medical Center, Nashville, TN

Background: The rate of thromboembolic (TE) events in NDMM patients (pts) treated with IMiD-containing regimens ranges from 11-19%, with venous events (VTE) being more common than arterial events (ATE). The SAVED and IMPEDE scores have been developed to risk-stratify thrombotic risk in NDMM. However, data on risk of VTE based on SAVED and IMPEDE VTE scores is largely unavailable for adequate contextual understanding of the problem. **Methods:** We queried the electronic medical record at Vanderbilt University Medical Center for pts with NDMM treated between January 2017 and May 2022, with a follow up for $\geq$ 2 years or until death. Information on incidence of TE, SAVED and IMPEDE scores at diagnosis, and the type of thromboprophylaxis (ppx) [any dose anticoagulation (AC) vs any dose aspirin (ASA) vs no ppx] present at induction therapy was analyzed. Pts were categorized as having elevated VTE risk if they had either SAVED $\geq$ 2 or IMPEDE $\geq$ 4 (patients with ATE were excluded). VTE rates were compared by χ^2 tests, and time to event was compared by Wilcoxon rank-sum test. **Results:** Among 178 pts with NDMM, the median (range) age was 65 (39-88) years. Upfront transplant was done in 76 (42.7%) of pts and IMiD containing therapy was used in 113 (63.5%) pts. The median (range) SAVED score was 1 (-2 to 7), and the median IMPEDE score was 2 (-3 to 12). Overall, 39 pts (21.9%) were diagnosed with TE [35 (19.7%) VTE, 4 (2.2%) with ATE]. Median (range) time to VTE was 7.7 months (mo) (0-42.3). Overall, 132 (74.1%) pts were on ASA, 26 (14.6%) were on AC, and 20 (11.2%) on no ppx. Among VTE pts, 25 (71.4%) were on ASA, 5 (14.3%) were on AC, and 5 (14.3%) on no ppx. Among VTE pts vs those without an event, a total of 20 (57.1%) vs 67 (48.2%) (p = 0.3) pts were categorized as having elevated risk, respectively. Among all pts with elevated VTE risk (n=84) vs not (n=90): VTE incidence was 23.8% (n=20) vs 16.7% (n=15) (p=0.24), and median (range) time to VTE was 5.5 (0-24.1) mos vs 9.1 (0-42.3) mos (p=0.12). Among those with elevated VTE risk, 18 (21.4%) received AC, 53 (63.1%) received ASA, and 13 (15.5%) were on no ppx. Among pts with elevated risk on AC versus ASA, VTE incidence was 11% (n=2) vs 26.9% (n=14) (p=0.3). Lastly, VTE rate was 19.1% (deep vein thrombosis (DVT) 12.2%, pulmonary embolism (PE) 6.9%), 19.2% (15.4% DVT, 3.8% PE), and 30% (10% DVT, 20% PE) among all pts on ASA, AC, and no ppx, respectively. **Conclusions:** Despite most patients harboring low predicted VTE risk at diagnosis by SAVED/IMPEDE, VTE rate was unacceptably high, and primarily occurred beyond 6 mos in our real-world NDMM cohort. Furthermore, VTE risk was not adequately mitigated in this ASA-ppx-enriched cohort. Though limited by small sample size, VTE events were numerically higher and had faster onset among patients with elevated SAVED/IMPEDE risk compared to those with low risk, while AC ppx in elevated-risk pts showed a trend towards reduced VTE incidence compared to ASA. Teclistamab in relapsed/refractory systemic AL amyloidosis. First Author: Vasil Mico, Tufts Medical Center, Boston, MA

Background: Systemic light chain amyloidosis (AL) is clonal plasma cell disorder characterized by the deposition of fibrils derived from immunoglobulin light chains. Treatment paradigms have been based on therapies for multiple myeloma. Teclistamab is a bispecific antibody approved for use in relapsed refractory multiple myeloma. We report on its impact in patients with AL. **Methods:** We analyzed data on hematologic and organ responses and treatment-related side effects in patients receiving Teclistamab for relapsed refractory AL. Mayo systems were used to characterize the disease stages. Adverse events were graded with the NCI CTCAE v5.0; CRS was graded according to ASTCT criteria. **Results:** Eight patients were identified (Table 1). All had relapsed refractory disease. Six had AL-λ and 2 AL-κ type. Five had cardiac involvement, 3 with stage III and 2 with stage II. Median prior lines of therapy was 4 (3-10). All were previously treated with Daratumumab and 5/8 had previously undergone autologous stem cell transplant. Median bone marrow plasmacytosis was 8.5% and median involved free light chain (iFLC) was 64.3mg/L (23.1 - 331). CD138-selected marrow findings included t(11;14), gain 1q and del 17p, each in 2 patients. Patients received escalating doses of Teclistamab. Two patients had grade 3 toxicities; one, a woman in her 80's, experienced a hepatic aminotransferase spike greater than 1000 the day after receiving the first 0.6mg/kg dose and subsequently after only that dose achieved an unmaintained CR that has continued for over 7 months; the other, a woman in her 70's, had grade 3 thrombocytopenia that has slowly resolved after Teclistamab was stopped. Two patients experienced grade 1 CRS. The hematologic response rate was 100% with 7 CR and 1 VGPR. The cardiac response rate was 29% (2/7; 1 CR, 1 PR) and the renal response rate was 20% (1/5). No patients have relapsed or died. **Conclusions:** In patients with relapsed refractory AL Teclistamab showed impressive hematologic activity and manageable side effects. A strong case exists for investigating Teclistamab prospectively in this population. Research Sponsor: None.

TPS7563 **Poster Session**

QUINTESSENTIAL: A multicenter phase 2 study evaluating the efficacy and safety of arlocabtagene autoleucel (arlo-cel) in triple- and quad-class exposed patients with relapsed or refractory multiple myeloma (RRMM). First Author: Krina K. Patel, Department of Lymphoma and Myeloma, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: There are limited treatment options for patients (pts) with RRMM who are triple-class exposed (TCEx: immunomodulatory drugs [IMiD], anti-CD38 antibodies [aCD38], and proteasome inhibitors [PI]) and quad-class exposed (QCEx: IMiD, aCD38, PI, and B-cell maturation antigen [BCMA]-targeted therapy). To address this unmet need, new treatment options are needed for late-line populations, which will continue to grow with more QCEx pts due to the approval of BCMA-targeted therapies in earlier lines. G protein-coupled receptor class C group 5 member D (GPRC5D) is an orphan receptor expressed on plasma cells, with limited expression elsewhere, making it a promising therapeutic target for MM. Data from a phase 1 first-in-human study (NCT04674813) suggested that arlo-cel, a GPRC5D-directed autologous chimeric antigen receptor (CAR) T-cell therapy, is safe and efficacious in pts with TCEx RRMM, including pts who received prior BCMA-targeted therapy. At the recommended phase 2 dose (RP2D) of 150×10^6 CAR T cells, overall response rate (ORR) was 91% (21/23), median progression-free survival (PFS) was 18.3 months, and median overall survival (OS) was not reached in those with ≥3 prior lines of therapy (LOT) (Bal S et al. ASH 2024. Abstract 922). Here, we present the study design of QUINTESSENTIAL, an open-label, multicenter, phase 2 study (NCT06297226) evaluating arlo-cel in pts with TCEx and QCEx RRMM. **Methods:** For analyses, enrollment is planned at ~138 pts with ~125 pts receiving therapy. Key inclusion criteria include age ≥18 years, confirmed diagnosis of MM as per IMWG criteria, ≥3 classes of MM treatment (including IMiD, PI, and anti-CD38), and ≥3 prior LOT. Pts must also have documented disease progression (PD) during or after the most recent regimen as per IMWG, measurable disease, and an ECOG performance status of 0 or 1. Pts who previously received a GPRC5D-targeted therapy are excluded. After screening, pts will undergo leukapheresis followed by bridging therapy. Pts will then receive lymphodepleting chemotherapy followed by a single infusion of arlo-cel at the RP2D of 150×10^6 CAR T cells (range: $120–180 \times 10^6$). The primary endpoint is ORR by IMWG response criteria per an independent review committee in pts who are QCEx and received ≥4 prior LOT. Key secondary endpoints are ORR and complete response rate in all pts. Other secondary and exploratory endpoints include time to response, duration of response, PFS, OS, minimal residual disease-negative status, and safety. Pts will be followed for ≤5 years after the last pt receives arlo-cel, with a subsequent long-term follow-up study continuing for ≤15 years. This study will recruit at 47 centers across the USA, Canada, and Japan. The first pt first visit was achieved on March 21, 2024. Clinical trial information: NCT06297226. Research Sponsor: Juno Therapeutics, Inc., a Bristol-Myers Squibb Company.

TPS7564 **Poster Session**

QUINTESSENTIAL-2: A phase 3 study comparing efficacy and safety of arlocabtagene autoleucel (arlo-cel) versus standard regimens in adult patients with relapsed or refractory multiple myeloma (RRMM) refractory to lenalidomide. First Author: Rakesh Popat, University College London Hospitals NHS Foundation Trust, London, United Kingdom

Background: Despite advances in MM treatment, nearly all patients (pts) will relapse, highlighting the need for new drug classes to improve outcomes in RRMM. Further, MM refractory to lenalidomide, an immunomodulatory drug (IMiD) used in frontline and maintenance therapies, poses an additional challenge as the disease is less likely to respond to subsequent treatment. G protein-coupled receptor class C group 5 member D (GPRC5D) is a promising therapeutic target for MM as the receptor is highly expressed on malignant plasma cells; it has little to no expression on non-plasma immune cells and limited expression elsewhere. Arlo-cel is a GPRC5D-directed autologous CAR T-cell therapy that has demonstrated safety and efficacy in patients with RRMM in a first-in-human ph1 study. Following a single infusion of arlo-cel at the recommended ph2 dose (RP2D) of 150×10^6 CAR T cells, overall response rate (ORR) was 96% (23/24) and 91% (21/23) in those with 1-3 and ≥3 prior lines of therapy (pLOT), respectively (Bal S, et al. ASH 2024. Abstracts 2069 and 922). Here we present the design of the QUINTESSENTIAL-2 study. **Methods:** QUINTESSENTIAL-2 (NCT06615479) is a randomized, open-label, multicenter, ph3 confirmatory study comparing the efficacy and safety of arlo-cel versus standard of care (SOC) in adults with RRMM. Pts aged ≥18 y must have received 1-3 pLOT (may include a proteasome inhibitor, IMiD, and anti-CD38 monoclonal antibody) and be refractory to lenalidomide (progression on or within 60 days of completing therapy). Additional inclusion criteria include confirmed MM diagnosis per International Myeloma Working Group criteria, measurable disease during screening, and Eastern Cooperative Oncology Group performance status 0 or 1. Eligible pts will be randomized 1:1 to one of 2 treatment arms. Arm A: single infusion of arlo-cel (RP2D of 150×10^6 CAR T cells), including leukapheresis within 3 days of randomization, bridging therapy of DPd (daratumumab, pomalidomide, dexamethasone) or Kd (carfilzomib, dexamethasone) per Investigator within 3 days of leukapheresis, and lymphodepleting chemotherapy prior to arlo-cel infusion. Arm B: SOC of DPd or Kd per Investigator, dosed per labeling. Primary endpoints are progression-free survival and minimal residual disease (MRD) negativity in complete response. Secondary endpoints include overall survival, ORR, MRD negative status, complete response rate, time to response, duration of response, pharmacokinetics, patient-reported quality of life outcomes, and safety. Pts will be followed for ≤5 years after the last patient is randomized, with a subsequent long-term follow-up study (≤15 years post infusion) for pts receiving arlo-cel. The trial is expected to enroll 440 pts across 111 sites globally, with first patient enrollment planned for Feb 2025. Clinical trial information: NCT06615479. Research Sponsor: Juno Therapeutics, Inc., a Bristol-Myers Squibb Company.

TPS7565 **Poster Session**

Prophylactic interventions for oral toxicities with the GPRC5D×CD3 bispecific antibody talquetamab in relapsed/refractory multiple myeloma: An update on the open-label, phase 2, randomized TALISMAN study. First Author: Rakesh Popat, University College London Hospitals NHS Foundation Trust, London, United Kingdom

Background: Talquetamab (Tal) is the first GPRC5D×CD3 bispecific antibody approved for the treatment of relapsed/refractory multiple myeloma (RRMM). Early onset oral toxicities, including dysgeusia, have been reported with Tal and can impact patient (pt) quality of life. Current CTCAE grading limits detailed assessment of dysgeusia. We provide an update on the TALISMAN study (NCT06500884), which investigates prophylactic interventions for GPRC5D-related oral toxicities using objective and subjective assessment tools that may establish a standard to measure taste changes and mitigation strategies in future studies with MM pts. **Methods:** This phase 2, multicenter, open-label, randomized study is enrolling pts aged ≥18 years with RRMM and prior exposure to a proteasome inhibitor, immunomodulatory drug, and anti-CD38 antibody; prior anti-GPRC5D therapy is not permitted. Pts must have an ECOG PS of 0/1 (ECOG PS of 2/3 permitted once physical limitations are stable) and cannot have a "severe" score for dysgeusia per the Waterless Empirical Taste Test (WETT) scale. Pts are randomized to 1 of 4 cohorts: 1 control cohort (Tal only) and 3 experimental cohorts (Tal plus an experimental prophylaxis). The experimental prophylaxes are dexamethasone mouthwash (0.5 mg/5 mL twice daily [BID]), oral pregabalin (50 mg BID), or clonazepam orally dissolving tablets (0.25 mg BID). Pts take their prophylaxis 7 days before the first step-up dose (cycle 1 day 1) of Tal (3 step-up doses followed by 0.8 mg/kg every other week). A dose reduction to every 4 weeks is permitted if a ≥VGPR or ≥PR is achieved at cycle 5 or 7, respectively. Study assessments and procedures include taste assessment using WETT strips; smell assessment using the University of Pennsylvania Smell Identification Test and threshold testing; pt-reported outcomes (PROs, including PRO-CTCAE); optional tongue and/or salivary gland biopsies (at selected sites); microbiome analysis via tongue swab (control cohort only); and salivary flow and salivary-specific protein content assessments. The 4 co-primary endpoints are the rate of occurrence of dysgeusia, rate of occurrence of severe dysgeusia, time to first onset of severe dysgeusia, and rate of resolution/improvement of dysgeusia at 3 and 6 months, as defined by the WETT score. Key secondary endpoints include changes from baseline in WETT score, body weight, and smell identification and smell detection threshold test scores over time; characterization of the safety and efficacy of Tal; change from baseline in PRO (including impacts of oral toxicities) assessments; and frequency of dose modifications. Enrollment opened in August 2024 for these 4 cohorts and target enrollment is 70–130 pts across 6 countries, with the potential to open additional cohorts. Clinical trial information: NCT06500884. Research Sponsor: None.

TPS7566 **Poster Session**

MagnetisMM-30: A phase 1b, open-label study of elranatamab in combination with iberdomide in patients with relapsed or refractory multiple myeloma (RRMM). First Author: Alexander M. Lesokhin, Memorial Sloan Kettering Cancer Center, New York, NY

Background: Elranatamab (ELRA), a BCMA–CD3 bispecific antibody, induced deep and durable responses with a manageable safety profile as a single agent in patients (pts) with RRMM enrolled in the phase 2 registrational MagnetisMM-3 study (Lesokhin et al, *Nat Med* 2023). Iberdomide (IBER) is a novel CELMoD agent that enhances antimyeloma tumoricidal and immunomodulatory activity in pts with RRMM (Lonial et al, *Lancet Haematol* 2022). While IBER in combination with ELRA has not been evaluated clinically, it may provide additional benefit to pts with RRMM based on the mechanisms of action of this novel combination. **Methods:** MagnetisMM-30 (NCT06215118) is a phase 1b, open-label, prospective study evaluating the safety, efficacy, and pharmacokinetics of ELRA in combination with IBER in pts with RRMM. The study has 2 parts: Part 1 guided by BOIN for dose-escalation and Part 2, randomized for dose optimization. In Part 1, after 2 step-up priming doses of subcutaneous (SC) ELRA followed by 1 full dose, pts will receive SC ELRA at dose level (DL) 1 or DL2 in 28-day cycles. IBER will be given daily for 21 days of each cycle. In DL1, pts will receive ELRA weekly followed by every 2 weeks (Q2W) and finally Q4W. In DL2, pts will receive ELRA Q2W followed by Q4W, with a higher IBER dose. If DL1 or DL2 is not tolerated, IBER dosing will be lowered (DL-1 and DL-2). Once 2 combination dose levels are selected from Part 1 as the recommended doses for expansion for ELRA and IBER, pts in Part 2 will be randomized 1:1 (stratified by the number of prior lines of therapy [LOTs; 1 vs >1]) to dose levels A or B. Key inclusion criteria are pts aged ≥18 years with a MM diagnosis per IMWG criteria, Eastern Cooperative Oncology Group performance status of 0-1, adequate organ and bone marrow function, and disease relapsed or refractory to the last antimyeloma regimen per IMWG response criteria. Pts who received 2-4 or 1-3 prior LOTs, including ≥1 immunomodulatory drug (IMiD) and ≥1 proteasome inhibitor (PI), are eligible for Parts 1 and 2, respectively. All pts must have received ≥2 consecutive cycles of an IMiD-containing regimen and ≥2 consecutive cycles of a PI or PI-containing regimen. Key exclusion criteria are pts with stem cell transplant ≤12 weeks prior to enrollment; active, uncontrolled infection; prior treatment with BCMA-directed or CD3 redirecting therapy or prior CELMoD agents (ie, IBER or mezigdomide). Primary endpoints are dose-limiting toxicities during the first cycle of treatment (Part 1) and AEs and lab abnormalities (Part 2). Secondary endpoints include AEs and lab abnormalities (Part 1 only), ORR, CRR, time-to-event outcomes, pharmacokinetics, minimal residual disease negativity rate, and immunogenicity. This study is ongoing; Part 1 and Part 2 will enroll up to approximately 36 and 60 pts, respectively. Clinical trial information: NCT06215118. Research Sponsor: Pfizer.

TPS7567 **Poster Session**

Design of the phase 3 DREAMM-10 study: Belantamab mafodotin plus lenalidomide and dexamethasone (BRd) vs daratumumab plus lenalidomide and dexamethasone (DRd) in transplant-ineligible, newly diagnosed multiple myeloma (TI-NDMM). First Author: Sagar Lonial, Winship Cancer Institute, Emory University Hospital, Atlanta, GA

Background: Treatment options have advanced for patients (pts) with TI-NDMM, but outcomes remain worse compared to pts with transplant-eligible NDMM, indicating a need for novel therapies to improve the prognosis of TI-NDMM. Belantamab mafodotin is an antibody-drug conjugate targeting B-cell maturation antigen. Phase 3 studies have shown significant survival benefits with belantamab mafodotin in combination regimens vs standard of care combinations for relapsed/refractory MM [1–3], and preliminary data have shown promising clinical activity with belantamab mafodotin combination regimens, including BRd, for TI-NDMM [4,5]. The design of the DREAMM-10 study, investigating BRd vs DRd in pts with TI-NDMM, is presented here. **Methods:** DREAMM-10 (NCT06679101) is a randomized, phase 3, open-label, multicenter study. Pts aged ≥18 years with TI-NDMM, measurable disease, and Eastern Cooperative Oncology Group performance status 0–2 are eligible. Specific reasons for transplant ineligibility will be collected. Pts who were previously treated for MM or smoldering MM are excluded. Approximately 520 eligible pts will be randomized 1:1 to BRd or DRd, stratified by age (<75, ≥75 years), International Staging System (I, II, III), and region (North America, rest of world). Belantamab mafodotin will be administered intravenously at 1.9 mg/kg every 8 weeks for 24 weeks, then 1.9 mg/kg every 12 weeks thereafter. Daratumumab will be administered subcutaneously using the approved dose and schedule. In both treatment arms, lenalidomide will be administered orally at 25 mg on Days 1–21, and dexamethasone will be administered orally at 40 mg on Days 1, 8, 15, and 22 of every 28-day cycle. Pts will be treated until disease progression, death, unacceptable toxicity, consent withdrawal, or end of study. The dual primary endpoints are progression-free survival (PFS) and minimal residual disease negativity rate. Key secondary endpoints are overall survival and PFS2 (time from randomization to progression on first subsequent anti-myeloma therapy or death). The statistical plan includes multiplicity adjustment for primary endpoints and hierarchical testing for key secondary endpoints. Other efficacy endpoints, safety (adverse events [AEs]/serious AEs), and health-related quality of life will also be assessed. The study opened for enrollment on December 30, 2024. 1. Hungria V, et al. *N Engl J Med* 2024. 2. Dimopoulos MA, et al. *N Engl J Med* 2024. 3. https://us.gsk.com/media/11819/belamaf-dreamm-7-os-full-data-press-release_final_us-version-08dec24.pdf. 4. TPS7568 **Poster Session**

MagnetisMM-32: A phase 3 randomized study of elranatamab vs EPd, PVd, or Kd in patients with relapsed or refractory multiple myeloma (RRMM) and prior anti-CD38–directed therapy. First Author: Steven Robert Schuster, UCHealth Cancer Care and Hematology, Fort Collins, CO

Background: Elranatamab (ELRA), a BCMA-CD3 bispecific antibody, has shown efficacy and manageable safety as a monotherapy in patients with RRMM. This study will evaluate ELRA monotherapy vs elotuzumab-pomalidomide-dexamethasone (EPd), pomalidomide-bortezomib-dexamethasone (PVd), or carfilzomib-dexamethasone (Kd) in patients with RRMM to determine whether ELRA can provide superior clinical benefit in early relapse (2L+). **Methods:** MagnetisMM-32 (NCT06152575), a phase 3, open-label, multicenter, randomized study, will enroll ≈492 patients. Patients will receive ELRA (Arm A) or investigator's choice of EPd, PVd or Kd (Arm B), until disease progression, unacceptable toxicity, withdrawal of consent, loss to follow-up, or study termination. Patients treated with ELRA will receive 2 step-up priming doses followed by weekly doses and subsequently less frequent doses in 28-day cycles. Patients will be randomized 1:1 (stratified by prior line of therapy [1 vs 2 vs 3/4] and International Staging System disease stage [1/2 vs 3]). Key inclusion criteria include age of ≥18 years, prior multiple myeloma diagnosis with measurable disease (per IMWG criteria), evidence of progressive disease or failure to achieve a response to last line of multiple myeloma therapy, 1 to 4 prior lines of therapy including an anti–CD38 antibody–containing regimen (for ≥2 consecutive cycles) and a lenalidomide-containing regimen (for ≥2 consecutive cycles), adequate bone marrow function, and an ECOG performance status of ≤2. Key exclusion criteria include stem cell transplant ≤12 weeks prior to enrollment or active graft vs host disease; active, uncontrolled infection; any other active malignancy <3 yrs prior to enrollment; ongoing grade ≥3 peripheral sensory or motor neuropathy; history of any grade ≥3 peripheral motor polyneuropathy, prior BCMA-directed or CD3-redirecting therapy; never achieved ≥PR with any treatment during disease course; and unable to receive any of the Arm B regimens (EPd, PVd, or Kd). The primary and key secondary endpoints are progression-free survival (PFS) by blinded independent central review (BICR) per IMWG criteria and overall survival (OS), respectively. Other secondary endpoints include PFS and PFS2 (PFS on next line of therapy) by investigator per IMWG, objective response rate, duration of response, very good partial response rate, complete response rate, duration of complete response, and time to response (all by BICR per IMWG), MRD negativity rate (including sustained for ≥12 months) and duration, safety and pharmacokinetics of ELRA, immunogenicity, and health-related quality of life outcomes. The primary endpoint and OS will be compared statistically between treatment arms by stratified log-rank tests. Study funding: Pfizer. Clinical trial information: NCT06152575. Research Sponsor: Pfizer.

LBA8000 Oral Abstract Session

Overall survival with neoadjuvant nivolumab (NIVO) + chemotherapy (chemo) in patients with resectable NSCLC in CheckMate 816. First Author: Patrick M. Forde, Trinity St. James's Cancer Institute, Trinity College Dublin, Dublin, Ireland

The full, final text of this abstract will be available at meetings.asco.org on the day of presentation and in the online supplement to the June 10, 2025, issue of the *Journal of Clinical Oncology*.

8001 Oral Abstract Session

Neoadjuvant (neoadj) osimertinib (osi) ± chemotherapy (CT) vs CT alone in resectable (R) epidermal growth factor receptor-mutated (EGFRm) NSCLC: NeoADAURA. First Author: Jamie E. Chaft, Thoracic Oncology Service, Memorial Sloan Kettering Cancer Center, New York, NY; Department of Medicine, Weill Cornell Medical College, New York, NY

Background: Based on the Ph 3 ADAURA study, adjuvant (adj) treatment (Tx) with osi, a 3rd-generation, EGFR-TKI, is SoC for resected EGFRm stage (stg) IB–IIIA NSCLC (AJCC 7th ed). Neoadj Tx may improve surgical and long-term outcomes. NeoADAURA (NCT04351555) is a global, Ph 3, randomized, controlled, 3-arm study assessing outcomes with neoadj osi ± CT vs CT alone, in EGFRm R-NSCLC. **Methods:** Eligible pts: aged ≥18 yrs; WHO PS ≤1; EGFRm (Ex19del/L858R) stg II–IIIB (AJCC 8th ed) R-NSCLC. Pts were stratified (stg II vs III; non-Asian vs Chinese vs other Asian; Ex19del vs L858R) and randomized 1:1:1 to neoadj osi 80 mg QD (≥9 wks) + CT (cis/carboplatin + pemetrexed; 3 cycles, Q3W), osi monotherapy (mono) 80 mg QD (≥9 wks) or placebo (PBO) QD + CT (3 cycles, Q3W). Osi/PBO + CT: double blind; osi mono: open label, sponsor blind. Adj osi was offered to all pts who completed surgery (Sx). Primary endpoint: major pathological response (MPR) by blinded central pathology review. Secondary endpoints included pathological complete response (pCR), event-free survival (EFS), and safety. Data cut-off: Oct 15, 2024. **Results:** Overall, 358 pts were randomized: osi + CT n=121/osi mono n=117/PBO + CT n=120; baseline characteristics were generally balanced across the respective arms (stg II: 49%/50%/51%; non-Asian: 27%/26%/25%; Ex19del: 50%/51%/51%). After neoadj Tx, 92%/97%/89% of pts underwent Sx in the osi + CT/osi mono/PBO + CT arms. Osi + CT (MPR rate 26%) and osi mono (25%) showed statistically significant improvement in MPR vs PBO + CT (2%): odds ratios were 19.8 ($p<0.0001$) and 19.3 ($p<0.0001$), respectively. Interim EFS (15% maturity) trended in favor of osi + CT and osi mono vs PBO + CT (Table); ≥80% of pts in each arm received adj osi. In the neoadj period, grade ≥3 all-cause AEs and AEs leading to discontinuation of any Tx occurred in 36%/13%/33% and 9%/3%/5% of pts, respectively, for osi + CT/osi mono/PBO + CT. No pts died within 30 days of Sx. **Conclusions:** Neoadj osi with or without CT showed statistically significant improvement in the MPR rate over CT alone. EFS data were immature and trended in favor of the osi containing arms. There were no new safety concerns. Neoadj osi ± CT should be considered when planning Tx for pts with EGFRm stg II–IIIB R-NSCLC. Clinical trial information: NCT04351555. Research Sponsor: AstraZeneca.

8002 Oral Abstract Session

Lung cancer diagnosis rates (LCDR) in lung cancer screening (LCS) and incidental pulmonary nodule (IPN) cohorts in the Mississippi Delta. First Author: Wei Liao, Baptist Cancer Center, Multidisciplinary Thoracic Oncology Program, Memphis, TN

Background: The LCDR in the CT screened cohort in the National Lung Screening Trial (NLST) was 1.1% over a median of 6.5 years follow up. We evaluated the LCDR in a regional US community. **Methods:** Prospective cohort study of patients in LCS and IPN programs in 22 facilities across a 125 county service area population. We compared LCDR over 3 years in LCS stratified by Lung-RADS (L-R) score (1 to 4X), IPN by nodule size (≤6, >6-15, >15-20, >20-30 mm) on initial CT scans. Comparisons used Chi-square tests, Wilcoxon tests, and Cox regression models with Hazard Ratios (HR) for lung cancer diagnosis adjusted for age, sex, race, and insurance. **Results:** From 2015 to 2023, 7121 persons were enrolled in LCS – 5447 (76%) L-R 1/2, 823 (12%) L-R 3, 452 (6%) L-R 4A, 205(3%) L-R 4B, and 114(2%) L-R 4X; and 22,455 in IPN - 8141 (36%) ≤6mm, 11177 (50%) >6-15 mm, 1596 (7%) >15-20 mm, 1535 (7%) >20-30 mm. Over this period, 334 (4.7%) and 1016 (4.5%) were diagnosed with lung cancer in LCS and IPN cohorts, respectively, including 91 (2%), 40 (5%), 60 (13%), 68 (33%), and 66 (58%) L-R 1-4X and 69 (1%), 421 (4%), 224 (14%) and 302 (20%) of IPN cohort in ascending order of nodule size. The cumulative LCDR at 36 months were: 5% (95% CI 4.4 – 5.6) in LCS- 1.9% (1.5-2.4), 5.0% (3.4-7.0), 14%(10-18), 33%(27-40), and 60% (49-68) for L-R 1 to 4X, respectively; and 4.4% (4.1 – 4.7)- 0.66% (0.49-0.88), 3.5% (3.2-3.9), 14% (12-16) and 20% (18-22) for the respective IPN cohorts. With L-R 1/2 as reference, aHR for lung cancer diagnosis was 2.9 (2.0 - 4.1, $p<0.0001$), 7.6 (5.4 - 10.6, $p<0.0001$), 24.1 (17.4 - 33.4, $p<0.0001$), and 66.3 (47.7 - 92.3, $p<0.0001$) for L-R 3, 4A, 4B & 4X in LCS cohort. With nodule >6-15 as reference, aHR was 0.2 (0.2 - 0.3, $p<0.0001$), 4.2(3.6 - 4.9, $p<0.0001$) and 5.7 (4.9 - 6.7, $p<0.0001$) in IPN cohort. **Conclusions:** LCDR of this Mississippi Delta LCS and IPN cohort was greater than 4-fold the NLST. The NLST significantly underestimates the potential impact of LCS in this population. Research Sponsor: Baptist Memorial Health Care Foundation; 15BD03.

8003 Oral Abstract Session

SWOG/NRG S1914: Randomized phase III trial of induction/consolidation atezolizumab + SBRT versus SBRT alone in high risk, early-stage NSCLC. First Author: Charles B. Simone II, New York Proton Center and Memorial Sloan Kettering Cancer Center, New York City, NY

Background: Stereotactic body radiation therapy (SBRT) is the standard of care (SoC) for early stage, medically inoperable non-small cell lung cancer (NSCLC). While rates of in-field control exceed 90%, regional and distant control after SBRT remain suboptimal. A prior phase II randomized trial suggested a benefit to adding immunotherapy (PMID 37478883). SWOG/NRG S1914 (NCT#04214262) is a randomized phase III trial evaluating neoadjuvant, concurrent and adjuvant atezolizumab plus SBRT for early-stage NSCLC vs SoC. **Methods:** Eligible patients (pts) had T1-3N0M0 NSCLC ≤7cm, were medically inoperable or declined surgery, and had ≥1 risk factor for increased recurrence: tumor diameter ≥2 cm, ≥6.2, moderately/poorly/undifferentiated histology. Randomization was to SoC SBRT (S [3-8 fractions, biologically effective dose ≥100 Gy]) or neoadjuvant, concurrent and adjuvant atezolizumab (AS [1200 mg IV Q3 week, 8 cycles]) with SBRT initiated with cycle 3, stratifying by tumor location (central vs peripheral), size (<4 cm vs ≥4cm) and ECOG performance status (PS, 0-1 vs 2). The primary objective was to compare overall survival (OS) between the arms. Secondary objectives included comparisons of progression free survival (PFS), failure patterns, toxicity and quality of life (QoL). OS and PFS were compared using a 1-sided stratified log-rank test at the 2.5% level, confidence intervals (CI) are 95%. The accrual goal was 432 eligible pts. **Results:** From 8/13/20 - 9/6/24, 417 pts were randomized, 403 met eligibility [201 to S, 202 to AS]. Accrual closed at the first interim analysis for futility based on OS and PFS per design. Median follow-up for pts still alive was 12 (range: 0.03-49) months. Median age was 73 (41-91) years and 89% had PS 0-1. Median tumor diameter was 2.3 cm. No protocol treatment was received for 6 pts on S and 8 on AS. With 49 deaths, OS was not different between the arms (HR (CI): 1.15(0.65-2.01), p=0.63; 2-year OS: 82% S vs 80% AS). With 88 events, PFS was not better with AS (HR (CI): 1.35(0.89-2.06), p=0.16); 2-year PFS was 71% on S vs 60% on AS. Regional (2% vs 3%) and distant (4% vs 5%) failures were not different; there were more local failures with AS (13% vs 7%). Among former (53%)/never (3%) smokers, AS had worse OS and PFS than S (HR(CI): 2.50 (1.11-5.59), p=0.03); HR(CI): 2.16(1.15-4.04), p=0.01), respectively. Grade (G) ≥3 adverse event (AE) rates were 12% on AS (N=21 G3, 1 G4, 1 G5 respiratory failure) vs 2% on S (N=3 G3, 1 G4). **Conclusions:** In the first reported phase III trial to assess immunotherapy (IO) added to SBRT in early-stage NSCLC, IO failed to improve survival. More G ≥3 adverse events were reported with AS. Central review of local recurrence events is ongoing. Additional investigation into subgroups, PD-L1 status, QoL and blood/tissue are pending to determine whether there are subsets who can benefit from this combination and shed further insights into these findings. Clinical trial information: NCT04214262. Research Sponsor: NIH/NCI grants U10CA180888, U10CA180819, U10CA180820, U10CA180821, U10CA180868; Genentech Pharmaceutical/Biotech Company.

Lurbinectedin (lurbi) + atezolizumab (atezo) as first-line (1L) maintenance treatment (tx) in patients (pts) with extensive-stage small cell lung cancer (ES-SCLC): Primary results of the phase 3 IMforte trial. First Author: Luis G. Paz-Ares, Hospital Universitario 12 de Octubre, H12O-CNIO Lung Cancer Unit, Universidad Complutense and Ciberonc, Madrid, Spain

Background: Despite improved efficacy when adding 1L PD-(L)1 inhibitors to platinum-based chemotherapy for ES-SCLC, long-term survival remains limited. We report primary results from the global open-label, randomized, Phase 3 IMforte study (NCT05091567) of 1L maintenance tx with lurbi + atezo vs atezo in pts with ES-SCLC. **Methods:** Tx-naive pts with ES-SCLC received standard induction tx with atezo, carboplatin, and etoposide for four 21-day cycles (q3w). After induction, eligible pts without disease progression (PD) were randomized 1:1 to receive maintenance tx q3w with lurbi (3.2 mg/m^2 IV; with G-CSF prophylaxis) + atezo (1200 mg IV) or atezo alone until PD, unacceptable toxicity, or withdrawal. Pts were stratified by liver metastases at induction baseline (BL; yes/no), receipt of prophylactic cranial irradiation before randomization (yes/no), ECOG PS (0/1) and LDH ($\leq$ULN/ $>$ ULN) at maintenance BL. Crossover was not allowed. Primary endpoints were independent review facility (IRF)–assessed PFS per RECIST v1.1 and OS assessed from randomization into the maintenance phase. **Results:** Of 660 enrolled pts, 483 were randomized to receive lurbi + atezo (n = 242) or atezo (n = 241). BL characteristics were generally balanced between arms. With a median 15.0-mo follow-up (data cutoff: Jul 29, 2024), IRF-PFS was significantly improved with lurbi + atezo vs atezo (stratified HR, 0.54 [95% CI: 0.43, 0.67]; $P<$ 0.0001; Table). A significant OS benefit was seen with lurbi + atezo vs atezo (stratified HR, 0.73 [95% CI: 0.57, 0.95]; $P=$ 0.0174). Median maintenance tx duration was 4.1 mo with lurbi and 4.2 mo with atezo in the lurbi + atezo arm (n = 242) and 2.1 mo in the atezo arm (n = 240). In the lurbi + atezo and atezo arms, respectively, treatment-related AEs (TRAEs) occurred in 83.5% vs 40.0% of pts, G3/4 TRAEs in 25.6% vs 5.8% and G5 TRAEs in 0.8% (2 pts; sepsis, febrile neutropenia) vs 0.4% (1 pt; sepsis); AEs led to tx discontinuation in 6.2% vs 3.3%. **Conclusions:** IMforte met both primary endpoints of IRF-PFS and OS, demonstrating a clinically meaningful benefit with 1L maintenance tx with lurbi + atezo vs atezo in pts with ES-SCLC. Lurbi + atezo was generally well tolerated, with no new or unexpected safety signals. IMforte is the first global Phase 3 study to show PFS and OS improvement with 1L maintenance tx for ES-SCLC and supports maintenance lurbi + atezo as a new option for pts with this aggressive disease. Clinical trial information: NCT05091567. Research Sponsor: Genentech, Inc.

A phase 2 dose expansion study of ZG006, a trispecific T cell engager targeting CD3/DLL3/DLL3, as monotherapy in patients with advanced small cell lung cancer. First Author: Xinghao Ai, Shanghai Chest Hospital, Shanghai, China

Background: ZG006 is a trispecific T cell engager (Tri-TE) targeting Delta-like ligand 3 (DLL3) and CD3, designed to bridge tumor cells and T cells by binding to two distinct DLL3 epitopes on tumor cells and CD3 on T cells, thereby mediating T cell-specific killing of DLL3-expressing tumor cells such as small cell lung cancer (SCLC). Here, we report the results from the phase 2 dose expansion study of ZG006 for the treatment of patients (pts) with advanced SCLC. **Methods:** This is a randomization, multi-center, open-label phase 2 study of ZG006 as monotherapy in SCLC pts failed to at least 2 prior lines of standard systemic treatments. Based on ZG006 phase 1 study results, both 10 mg and 30 mg Q2W dose levels with a priming dose of 1 mg are being evaluated in this phase 2 dose optimization study, 60 pts are to be randomized at a ratio of 1:1 to receive ZG006. The primary endpoint was objective response rate (ORR) according to RECIST1.1. DLL3 expression was not required but retrospectively evaluated by IHC. **Results:** As of Dec. 31, 2024, a total of 40 SCLC pts were randomized (19 on 10 mg, 21 on 30 mg) and received$\geq$1 dose of ZG006. Median age was 57.5 (range: 48-73) years. Of the 40 pts, 31 (77.5%) were males and 27 (67.5%) had smoking history; all had received $\geq$2 prior line treatments and 45.0% $\geq$3 lines; majority (72.5%) had prior anti-PD-(L)1 treatments. Baseline metastatic sites of liver and brain accounted 52.5% (21/40) and 20.0% (8/40), respectively. Among 27 (13 at 10 mg, 14 at 30 mg) efficacy-evaluable SCLC pts who had at least one post-baseline tumor scan, 18 (5 confirmed, others pending confirmed) achieved partial response (7 at 10 mg, 11 at 30 mg). Overall, the ORR was 66.7% and the DCR was 92.6%. For the 10 mg group, ORR was 53.8% and DCR was 84.6%; for the 30 mg group, ORR was 78.6% and DCR was 100.0%. DoR and PFS, not yet matured and will be updated with additional follow-up time. Among the all combined 27 pts, 21 (77.8%) pts had low (N = 17) or medium (N = 4) DLL3 expression at baseline, and they demonstrated reasonably great anti-tumor efficacy with 15 PRs and 71.4% ORR. Treatment-related adverse events (TRAEs) occurred in 35 pts (87.5%); most commonly ($\geq$20%): pyrexia (57.5%), cytokine release syndrome (CRS, 47.5%), vomiting (27.5%), rash (25.0%), decreased appetite (25.0%), aspartate aminotransferase increased (22.5%), white blood cell count decreased (22.5%) and platelet count decreased (22.5%). Only five pts (12.5%) experienced grade 3/4 TRAEs including one grade 3 CRS, and no pts experienced TRAEs leading to treatment discontinuation or death. Five pts (12.5%) experienced serious TRAEs. No significant difference was observed in the safety profile between these two dose groups. **Conclusions:** ZG006 exhibited promising efficacy and acceptable safety in SCLC pts receiving $\geq$2 lines of prior treatment, even in pts with low DLL3 expression. The enrollment of ZG006-002 study is ongoing. Clinical trial information: NCT06283719. Research Sponsor: None.

Tarlatamab versus chemotherapy (CTx) as second-line (2L) treatment for small cell lung cancer (SCLC): Primary analysis of Ph3 DeLLphi-304. First Author: Charles M. Rudin, Fiona and Stanley Druckenmiller Center for Lung Cancer Research, Memorial Sloan Kettering Cancer Center, New York, NY

The full, final text of this abstract will be available at meetings.asco.org on the day of presentation and in the online supplement to the June 10, 2025, issue of the *Journal of Clinical Oncology*.

8009 **Rapid Oral Abstract Session**

Association of post-surgical MRD status with neoadjuvant ctDNA dynamics, genomic mutations, and clinical outcomes in patients with resectable NSCLC (R-NSCLC) from the phase 3 AEGEAN trial. First Author: Martin Reck, Lung Clinic Grosshansdorf, Airway Research Center North, German Center for Lung Research, Grosshansdorf, Germany

Background: In AEGEAN, perioperative durvalumab (D) + neoadj CT significantly improved the primary endpoints of event-free survival (EFS) and pathological complete response (pCR) vs neoadj CT alone in pts with R-NSCLC. Prior analyses of AEGEAN suggest that pts without ctDNA clearance during neoadj Tx or with molecular residual disease (MRD; i.e. ctDNA detected) at a landmark timepoint after Sx (adj C1D1) had worse outcomes. Using data from all biomarker-evaluable pts, we report exploratory analyses for associations of post-Sx MRD status with pt characteristics, neoadj ctDNA dynamics, pathological response, genomic mutations and outcomes. **Methods:** AEGEAN is a double-blind PBO-controlled study (NCT03800134). Adults with Tx-naïve R-NSCLC (stage II–IIIB[N2]) and ECOG PS 0/1 were randomized 1:1 to receive neoadj platinum-based CT + D or PBO IV (Q3W, 4 cycles) before Sx followed by D or PBO IV (Q4W, 12 cycles) after Sx. Efficacy was assessed in the mITT population, which excluded pts with known *EGFR*/*ALK* aberrations. ctDNA analysis was performed on plasma collected before each neoadj Tx cycle, Sx, and adj C1, C3/4 and C10/11 using pt-specific tumor-informed assays. Whole exome sequencing analysis of diagnostic tumor biopsies was performed to identify mutations associated with MRD status at the post-Sx landmark. **Results:** Among MRD-evaluable pts, 10% (17/168) were MRD-positive (D, n=10; PBO, n=7) and 90% (151/168) were MRD-negative (D, n=78; PBO, n=73) at the landmark timepoint (median 6.9 wk post-Sx). 88% [15/17] of MRD-positive pts were initially diagnosed with stage III disease. In the D arm, the majority of MRD-positive pts (9/10) also had ctDNA detected at the pre-Sx visit. No MRD-positive pts in the D arm had pCR or major pathological response. As expected, overall disease-free survival (DFS) rates at 12 mo were worse in MRD-positive (14.3%; 95% CI, 2.4–36.3) vs MRD-negative pts (89.3%; 95% CI, 82.6–93.5). In both arms, MRD-positive pts had worse DFS outcomes vs MRD-negative pts (D: HR, 21.28; 95% CI, 7.70–58.83; PBO: HR, 14.29; 95% CI, 4.94–41.36) with DFS trends favoring the D vs PBO arm, particularly in pts with no ctDNA detected (MRD-negative: HR, 0.56; 95% CI, 0.26–1.20; MRD-positive: HR, 0.78; 95% CI, 0.26–2.36). Mutated genes associated with MRD-positive status in the D arm included *KEAP1* and *KMT2C*; despite small pt numbers, EFS benefit in the D vs PBO arm was not evident in pts with the mutations (m) *(KEAP1*m: HR, 1.39; 95% CI, 0.29–6.77; *KMT2Cm:* HR, 2.03; 95% CI, 0.70–5.91). In contrast, EFS benefit was evident in pts with wild type (wt) (*KEAP1*wt: HR, 0.54; 95% CI, 0.36–0.79; *KMT2C*wt: HR, 0.52; 95% CI, 0.35–0.78). **Conclusions:** Exploratory analyses based on post-Sx MRD status and genomic analysis identified a small high-risk subgroup of pts with markedly worse prognosis with potentially reduced benefit from the AEGEAN regimen. Clinical trial information: NCT03800134. Research Sponsor: AstraZeneca.

ctDNA-based MRD detection in unresectable NSCLC undergoing curatively intended chemoradiotherapy and durvalumab. First Author: Henrik Horndalsveen, Oslo University Hospital, Department of Oncology and Department of Cancer Genetics, Oslo, Norway

Background: Durvalumab consolidation after chemoradiotherapy (CRT) has improved clinical outcomes in patients with unresectable stage III non-small cell lung cancer (NSCLC). Despite durvalumab treatment, a substantial proportion of patients relapse, while up to 20% achieve long-term survival without durvalumab. Circulating tumor DNA (ctDNA)-based minimal residual disease (MRD) detection has shown promise as a tool for risk-adaptive and personalized treatment strategies in resectable NSCLC but is still underexplored as a biomarker in patients with stage III NSCLC treated with CRT and consolidative durvalumab. **Methods:** The DART study is a multicenter phase II clinical trial enrolling 86 patients with unresectable stage III NSCLC. All patients received two cycles of platinum-doublet chemotherapy concomitant with radiotherapy to a total dose of 60–66 Gy, followed by durvalumab. We prospectively collected serial plasma samples from all patients at baseline(before CRT), at the initiation of durvalumab (one month post-CRT), and at predefined timepoints during durvalumab treatment. Plasma samples were analyzed using a novel tumor-agnostic ctDNA MRD assay (MEDICOVER Genetics), tailored to each patient's cancer biomarker profile. This hybrid capture-based assay leverages genomic information in cell-free DNA from selected coding regions in 293 genes to classify plasma samples as positive ("ctDNA detected") or negative ("ctDNA not detected"). Here, we present results of the first MRD analysis conducted in the trial, involving a total of 138 plasma samples from 20 patients who completed all scheduled blood draws. **Results:** The baseline ctDNA detection rate was 91.8% in the entire study population and 73.7% in the 20 patients with completed longitudinal MRD analyses. Detectable ctDNA at baseline varied according to stage and histology and was not associated with PFS. Nine patients had detectable ctDNA in at least one plasma sample during the first four months after CRT, which was significantly associated with shorter progression-free survival (PFS) (HR: 4.7; 95% CI: 1.6–13.1; p = 0.004). When assessing specific timepoints, patients with detectable ctDNA four months post-CRT had shorter PFS compared to patients without detectable ctDNA at this timepoint (HR: 3.77; 95% CI: 1.32–10.74; p = 0.013). In contrast, detectable ctDNAone month post-CRT was not associated with shorter PFS (HR: 2.23; 95% CI: 0.78–6.36; p = 0.13). Preliminary overall survival data indicate that detectable ctDNA during the first four months post-CRT significantly increased the odds of death within 24 months (OR: 16.48; 95% CI: 1.29–1000.51; p = 0.017). **Conclusions:** Detection of ctDNA during consolidative durvalumab after CRT using a novel tumor-agnostic MRD assay was associated with inferior outcomes, demonstrating the potential of ctDNA as a biomarker to identify high-risk patients for tailored interventions. Clinical trial information: NCT04392505. Research Sponsor: Helse Sør-Øst RHF; AstraZeneca; Medicover Genetics.

8012 Rapid Oral Abstract Session

The preliminary results of a randomized phase II trial evaluating induction toripalimab plus chemotherapy followed by concurrent chemoradiotherapy and consolidation toripalimab in bulky unresectable stage III non-small-cell lung cancer (InTRist). First Author: Yu Wang, Department of Radiation Oncology, National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China

Background: Unresectable stage III NSCLC patients with large tumor volumes remain challenging. Our previous retrospective study has showed promising results of induction chemoimmunotherapy before definitive chemoradiotherapy (CRT) for these patients. Here we report preliminary results of the randomized phase II study on this regimen. **Methods:** This InTRist study is a randomized, single-center, phase 2 trial, enrolling patients with unresectable stage III NSCLC with bulky diseases, and without *EGFR/ALK* alterations. Bulky diseases were defined as primary tumor ≥5 cm in greatest dimension or metastatic lymph nodes ≥2 cm in shortest diameter. Eligible patients were 1:1 randomly assigned to receive induction toripalimab (240 mg every 3 weeks) plus platinum-based doublet chemotherapy for 2 cycles (toripalimab group) versus induction chemotherapy alone for 2 cycles (chemo group) followed by concurrent CRT (60 Gy radiotherapy plus concurrent platinum-based chemotherapy). All patients without disease progression or grade ≥2 pneumonitis after CRT received consolidation toripalimab (240 mg every 3 weeks) for up to 12 months. Randomization was stratified according to histologic type. The primary endpoint was progression-free survival (PFS) from randomization. This trial is registered with ClinicalTrials.gov, NCT05888402. **Results:** BetweenJanuary 20th, 2023 and October 8th, 2024, 52 patients were randomized to induction toripalimab (n = 27) or chemo (n = 25) groups. By the data cutoff date (January 15th, 2025), the median follow-up was 13.1 months. Induction toripalimab plus chemotherapy exhibited significantly longer PFS compared to chemotherapy alone (median not reached [NR] vs NR; hazard ratio 0.25 [95% CI, 0.07-0.90], *P*=0.034). The 12-month PFS rate was 89.4% (95% CI, 76.0%-100%) in the toripalimab group and 57.8% (95% CI, 40.7%-81.9%) in the chemo group. Objective response rate after induction therapy was 77.8% (21/27) for the toripalimab group and 40.0% (10/25) for the chemo group (median tumor reduction 32% vs 21%). Grade 2 pneumonitis occurred in 26.9% (14/52) of all patients, with 18.5% (5/27) in the toripalimab group and 36.0% (9/25) in the chemo group. Grade 3 pneumonitis occurred in 7.7% (4/52) of all patients, with 11.1% (3/27) in the toripalimab group compared to 4.0% (1/25) in the chemo group. No grade 4-5 pneumonitis. **Conclusions:** Induction toripalimab plus chemotherapy, followed by concurrent CRT and consolidation toripalimab, demonstrated potentially improved short-term efficacy and manageable toxicity for patients with bulky unresectable stage III NSCLC. Further follow-up is necessary to confirm these results. Clinical trial information: NCT05888402. Research Sponsor: Chinese Academy of Medical Sciences (CAMS) Innovation Fund for Medical Sciences; 2024-I2M-C&T-B-065.

8013 Rapid Oral Abstract Session

Safety and efficacy of lurbinectedin plus atezolizumab as second-line treatment for advanced small-cell lung cancer: Results of the 2SMALL phase 1/2 study (NCT04253145). First Author: Santiago Ponce Aix, Hospital Universitario 12 de Octubre and Oncosur Foundation, Madrid, Spain

Background: Small-cell lung cancer (SCLC) is an aggressive malignancy, accounting for 13% of all lung cancers, with a 5-year survival rate below 12%. Relapsed SCLC remains a major therapeutic challenge, underscoring the need for innovative second-line treatments. The combination of lurbinectedin (LUR) plus atezolizumab (ATZ) has shown synergy in immunocompetent models, and clinical feasibility in a phase I trial. Here we evaluate the efficacy and safety of the regimen as second line treatment for SCLC patients. **Methods:** This prospective, open-label, multicenter study enrolled patients with ECOG PS 0-1, measurable disease by RECIST 1.1, and progression after one prior platinum-based chemotherapy alone (cohort 1 - C1) or combined with PD-1/ PD-L1 blockade (cohort 2 - C2). Key inclusion criteria included a chemotherapy-free interval (CTFI) of ≥30 days, adequate organ function. Treated brain metastases previously managed with radiotherapy were permitted. Patients received LUR (3.2 mg/m² i.v. 1 hour infusion) following ATZ (1200 mg i.v. 30–60 minutes infusion) on day 1, every 3 weeks. Primary G-CSF prophylaxis was administered for 5 days. The primary endpoint was overall response rate (ORR) per RECIST v1.1. Secondary endpoints included progression-free survival (PFS), overall survival (OS), and safety. **Results:** Between June 2022 and March 2024, 218 patients were screened, and 151 were enrolled: 68 in C1 and 83 in C2. The median age was 64 years (range: 45–79), with 58% being male. Most patients (73%) had an ECOG 1, and 60.92% had a CTFI of ≥90 days. Efficacy results are summarized in Table 1. The combination was well-tolerated, with no unexpected safety signals. Treatment-emergent adverse events (TEAEs) were reported in 91% of patients. Grade ≥3 hematological toxicities included neutropenia (C1: 16.18%; C2: 7.23%), febrile neutropenia (C1: 2.94%; C2: 2.41%) and thrombocytopenia (C1: 8.82%; C2: 1.20%). Treatment- emergent deaths occurred in 7 patients (C1: 4; C2: 3). **Conclusions:** The combination of LUR and ATZ showed promising efficacy in patients with relapsed SCLC regardless of prior exposure to immunotherapy, including those with resistance to platinum. The associated safety profile is manageable. The regimen is being evaluated in a phase III trial in the maintenance setting (IMforte trial NCT05091567). Clinical trial information: NCT04253145. Research Sponsor: None.

8014 Rapid Oral Abstract Session

Clinical and molecular characteristics of early progressors (EPs) and long-term progression-free survivors (LTPs) from the phase 3 ADRIATIC trial of consolidation durvalumab (D) vs placebo (P) after concurrent chemoradiotherapy (cCRT) in limited-stage small-cell lung cancer (LS-SCLC). First Author: David Allen Barbie, Lowe Center for Thoracic Oncology, Dana-Farber Cancer Institute, Boston, MA

Background: At the first planned interim analysis of ADRIATIC, consolidation D significantly improved the dual primary endpoints of overall and progression-free survival (PFS) vs P in patients (pts) with LS-SCLC and no progression after cCRT. We assess clinical characteristics, patterns of progression, and associated molecular biomarkers in EPs (pts with PFS <6 mos) and LTPs (PFS or censored after >12 mos) in the D and P arms. **Methods:** Pts with stage I–III LS-SCLC, WHO performance status (PS) 0/1, and no progression after cCRT were randomized to D (n=264), D + tremelimumab (n=200; arm still blinded), or P (n=266) for up to 24 months. Pre-cCRT tumor samples were collected at screening and immune-related biomarkers (CD8, MHC I, PD-L1, T-cell inflamed signature [TIS], *CD8A*, and STING pathway) were assessed by immunohistochemistry or RNA sequencing for their role in response to immunotherapy (IO). **Results:** At data cutoff (15 Jan 2024), 83 (31.4%) and 113 (42.8%) pts in the D arm and 97 (36.5%) and 100 (37.6%) in the P arm were EPs and LTPs, respectively. For EPs and LTPs, respectively: 67.5% and 61.1% in the D arm and 74.2% and 72.0% in the P arm were male; 44.6% and 54.9% in the D arm and 51.5% and 48.0% in the P arm had WHO PS 0; and 90.4% and 89.4% in the D arm and 91.8% and 89.0% in the P arm were current/former smokers. Among EPs, 47.0% vs 45.4% had extrathoracic (ET) only progression, 43.4% vs 43.3% had intrathoracic (IT) only progression, and 6.0% vs 1.0% died without progression in the D vs P arms, respectively. Among LTPs, 16.8% and 25.0% of pts in the D and P arms had progression events, which were mostly IT (D: 14.2%; P: 16.0%). Similar rates of PD-L1+ tumors were observed in EPs and LTPs in both arms (Table). Trends for higher TIS and STING pathway expression were seen in LTPs vs EPs in the D arm but not the P arm. CD8 density, and *CD8A* and MHC I expressions were lower in EPs vs LTPs in both arms, regardless of D vs P (Table). **Conclusions:** Exploratory analyses suggest similar rates of IT and ET progression with D and P in EPs, but mostly IT progression in LTPs. Compared with EPs, LTPs were generally characterized by a pre-cCRT tumor microenvironment more conducive to fostering an IO response, with higher antigen presentation and cytotoxic marker expression potentially enhancing D's mechanism of action. Clinical trial information: NCT03703297. Research Sponsor: AstraZeneca.

Alectinib as neoadjuvant treatment in potentially resectable stage III ALK-positive NSCLC: Final analysis of ALNEO phase II trial (GOIRC-01-2020-ML42316). First Author: Alessandro Leonetti, University Hospital of Parma, Parma, Italy

Background: Stage III Non-Small Cell Lung Cancer (NSCLC) is a heterogeneous group of tumors with a wide spectrum of clinical presentations and no single definitive therapeutic approach. The role of neoadjuvant alectinib in stage III ALK-positive NSCLC is still unclear. Here, we present the final analysis of the phase II, open-label, single-arm, multicenter study aimed at investigating the activity and safety of alectinib in potentially resectable locally advanced stage III ALK-positive NSCLC patients (ALNEO trial, EUDRACT number 2020-003432-25). **Methods:** Treatment-naïve patients with potentially resectable stage III ALK-positive NSCLC, ECOG PS≤1 were registered to receive neoadjuvant alectinib for 2 cycles (8 weeks) followed by surgery and adjuvant alectinib for 24 cycles (96 weeks). The primary endpoint was major pathological response (MPR) by Blinded Independent Central Review (BICR). Secondary endpoints included pathological complete response (pCR) by BICR, objective response (OR), event-free survival (EFS), disease-free survival (DFS), overall survival (OS) and adverse events (AEs). According to the Simon's design (P0=20%, P1=40%), 18 and 33 patients were required for the first and second stage, respectively. **Results:** A total of 33 patients were registered in 20 Italian Oncology Centers from May 2021 to July 2024. Median age was 62 years (Interquartile Range [IQR], 49–74 years), 23 (70%) patients were female and 17 (52%) were never smokers. Clinical stage according to the 8th AJCC TNM was IIIA in 21 (64%) and IIIB in 12 (36%) patients. The most represented stage was T3N2 (n=8, 24%), followed by T1aN2 (n=4, 12%), T2aN2 (n=4, 12%), T4N0 (n=4, 12%) and T4N2 (n=4, 12%). All the patients completed the neoadjuvant phase and 28 (85%) underwent surgery, which consisted of lobectomy in 21 (64%), pneumonectomy in 3 (9%) and other surgery in 4 (12%) patients. Among patients who completed surgery, R0 was achieved in 24 (86%) patients. According to the BICR, MPR was documented in 15 (46%, 90% Confidence Interval [CI]: 31%–61%) patients and pCR in 4 (12%, 95% CI: 3%–28%) patients. Overall, an OR was observed in 22 (67%) patients. Adjuvant treatment was started in 26 (79%) patients with a median interval from surgery of 5.1 weeks (IQR, 3.6–6.0 weeks). After a median follow-up of 15.2 months (IQR, 6.8–27.8 months), 31 (94%) patients were alive and 5 (19%) patients completed the adjuvant treatment. Median EFS and OS were not reached. A total of 6 (18%) patients experienced disease progression/recurrence. Grade≥3 AEs occurred in 3 (9%) and 2 (8%) patients during neoadjuvant and adjuvant phase, respectively. **Conclusions:** ALNEO study met its primary endpoint, suggesting alectinib as a feasible peri-operative option in resectable locally advanced stage III ALK-positive NSCLC patients. The study was partially supported by Roche S.p.A. Clinical trial information: NCT05015010. Research Sponsor: Roche S.p.A.

Efficacy and safety of nivolumab plus ipilimumab for patients with pre-treated type B3 thymoma and thymic carcinoma: Results from the EORTC-ETOP NIVOTHYM phase II trial. First Author: Nicolas Girard, Institut du Thorax Curie Montsouris, Institut Curie, Paris, and UVSQ, Paris Saclay University, Versailles, France

Background: Thymic malignancies represent a therapeutic challenge in the advanced, metastatic setting, with limited options after the failure of platinum-based chemotherapy. **Methods:** NIVOTHYM is a multicenter phase II, 2-cohort, single-arm trial evaluating the use of nivolumab (N)+/-ipilimumab (I) in patients ≥18yo, with advanced/relapsed type B3 thymoma or thymic carcinoma (TC), after previous exposure to platinum-based chemotherapy.Primary endpoint wasProgression-Free Survival (PFS) rate at 6 months based on RECIST1.1 per independent radiological review. We report the results of cohort 2 with patients who received N 240 mg Q2W and I 1mg/kg Q6W. **Results:** From Feb 2021 to Jan 2023, 56 patients – 8 (14%) with type B3 thymoma, 48 (86%) with TC - were enrolled in 15 centers/5 countries, of which 37 (66%) men/19 (34%) women. Median age was 64 years. 23 (41%) patients had had surgery. After a median follow-up of 16.0 months, 50 patients had discontinued N+I for: progression in 36 (72%) pts, treatment-related adverse events (TRAEs) in 11 (22%) pts, completion in 2 (4%) pts, and pt decision for 1 pt (2%). Maximal grade of adverse events was 1/2 in 29 (52%) patients, and 3/4 in 27 (48%) patients. Grade ≥3 TRAEs occurred in 16 (29%) pts: myocarditis (2 pts), colitis (4 pts), infusion-related reaction/allergy (2 pts), skin rash (2 pts), heart failure, immune-related hepatitis, arthritis, myositis, hypophysitis, Gougerot Sjogren syndrome, pharyngitis, fatigue, fever, infusion-related reaction (1 pt each); there was no grade 5 TRAE. PFS rate at 6 months was 21.6%. Objective Response and Disease Control Rates were 17.7% and 60.8%, respectively. Median PFS and Overall Survival were 3.2 (95%CI 2.1-3.6) and 22.0 (95%CI 16.6-NR) months, respectively; median duration of response was 7.1 (95%CI 1.4-17.0) months, and 8 (14%) pts received treatment for ≥12 months. **Conclusions:** N+I demonstrated limited efficacy in advanced thymic tumors, as prespecified PFS rate at 6 months of 40% was not reached, compared to the previously reported cohort 1 of this trial with N as single-agent. Numerically more patients experienced grade ≥3 TRAEs, while efficacy endpoints were not numerically higher. Clinical trial information: NCT03134118. Research Sponsor: None.

Integrin $\alpha_V\beta_3$-targeted imaging for identification of lung cancer and mapping of lymph-node metastases: A prospective, multicenter, self-controlled phase 3 trial (TRIIL study). First Author: Zhaohui Zhu, Peking Union Medical College Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China

Background: Integrin $\alpha_V\beta_3$ mediates tumor formation, invasion, metastasis and angiogenesis. ^{99m}Tc-3PRGD2, a first-in-class radiopharmaceutical targeting integrin $\alpha_V\beta_3$, was advanced into a phase 3 clinical trial for evaluation of lung cancer via single photon emission computed tomography (SPECT)/computed tomography (CT), with mapping the lymph-node metastases as the primary objective. **Methods:** A prospective, multicenter, phase 3 trial of ^{99m}Tc-3PRGD2 SPECT/CT enrolled 409 patients with solid lung lesions ≥ 1.5×1.0 cm in high suspicion of lung cancer (TRIIL; ClinicalTrials.gov identifier: NCT04233476; chinadrug-trials.org.cn identifier: CTR20191465). A self-controlled design was used for a head-to-head comparison with the conventional metabolic imaging via F-18 fluorodeoxyglucose (^{18}F-FDG) positron emission tomography (PET)/CT. The primary outcome was to define the superiority of diagnostic specificity of ^{99m}Tc-3PRGD2 SPECT/CT over that of ^{18}F-FDG PET/CT in assessment of lymph-node metastases of lung cancer. The secondary outcomes included the other diagnostic values and safety. **Results:** No severe adverse event was observed in 407 patients with complete safety data. In 268 patients with pathological diagnosis of the lung tumors, no significant difference was found between ^{99m}Tc-3PRGD2 SPECT/CT and ^{18}F-FDG PET/CT for detection of lung malignancies (sensitivity, 96% vs 98%, P = 0.083). In 259 patients with pathological diagnosis of 1601 lymph-node stations, ^{99m}Tc-3PRGD2 SPECT/CT demonstrated superiority over ^{18}F-FDG PET/CT in the diagnostic specificity (74% vs 50%, $P <$ 0.001) and accuracy (70% vs 55%, $P <$ 0.001) for mapping the lymph-node metastases station-by-station, with a relatively lower sensitivity (55% vs 75%, $P <$ 0.001) mainly due to spatial resolution limitation of the current SPECT systems. In a semi-quantitative analysis of the tumor-to-background ratios in each method, the areas under the receiver operating characteristic curves were 0.69 for ^{99m}Tc-3PRGD2 SPECT/CT and 0.63 for ^{18}F-FDG PET/CT (P = 0.13), respectively, for discriminating lymph-node stations with and without metastasis. In a case-by-case analysis, the integrin $\alpha_V\beta_3$-targeting ^{99m}Tc-3PRGD2 SPECT/CT corrected the false-positive diagnosis of ^{18}F-FDG PET/CT in 344 lymph-node stations from 152 (59%) of the 259 patients, providing more accurate evaluation of lymph-node metastasis in 116 (45%) patients, whereas ^{18}F-FDG PET/CT held better diagnosis of the lymph-node involvement only in 40 (15%) patients. **Conclusions:** This trial substantiates the advantages of the integrin imaging for mapping the lymph-node metastases of lung cancer, and paves the way for ^{99m}Tc-3PRGD2 SPECT/CT to be evolved into a universally accessible and cost-efficient technique for tumor diagnosis and staging, and further towards precise therapy. Clinical trial information: NCT04233476. Research Sponsor: None.

8018 Poster Session

Assessment of survival benefit with immunotherapy in combination with adjuvant chemoradiation in pathologic stage II-IIIB non-small cell lung cancer. First Author: Natasha Venugopal, Penn State Health Milton S. Hershey Medical Center, Hershey, PA

Background: Since the Food and Drug Administration (FDA) approvals in 2021 and 2023, atezolizumab and pembrolizumab, respectively, became standard management for curatively resected stage II-III non-small cell lung cancer (NSCLC) based on improved disease-free survival. Because these studies excluded the planned use of adjuvant radiation therapy, survival benefit of adding immune checkpoint inhibitor (ICI) in those who are treated with adjuvant chemoradiation (CT+RT) have never been assessed. **Methods:** Using National Cancer Database (NCDB), we identified 8,235 cases that were completely resected, pathologic stage II-IIIB NSCLC per AJCC 8th edition and survived for at least 1 month without neoadjuvant CT or RT. Due to the timing of FDA approval and availability, only cases diagnosed in 2021 were investigated. They have been assigned into groups based on types of adjuvant treatments. Kaplan-Meier methods and multivariable Cox regression models were used for survival analysis. Propensity Score Matching (PSM) was performed to compare groups (adjuvant CT+RT+ICI vs CT+RT). A p-value of <0.05 was considered statistically significant. **Results:** Consistent with previous clinical trials, addition of ICI to adjuvant CT improved overall survival (OS) (2-year OS 90.1% vs 86.0%, Univariate and Multivariate HRs 0.72 and 0.66, p=0.0024 and 0.0003, respectively). However, no OS benefit was seen in those who received adjuvant CT+RT (2-year OS 77.8% vs 76.1%, Univariate and Multivariate HRs 0.83 and 0.85, p=0.3677 and 0.4369, respectively). PSM analysis showed similar results (2-year OS 77.8% vs 79.6%, Univariate and Multivariate HRs 0.91 and 0.87, p=0.7143 and 0.5868, respectively). **Conclusions:** Our retrospective real-world analysis suggests that adjuvant ICI do not improve survival outcome when combined with adjuvant CT+RT. This result appears to mirror recent negative trials using concurrent use of ICI with CT+RT in unresectable stage III NSCLC (PACIFIC2) and limited-stage SCLC (NRG-LU005). Further investigations are warranted. Research Sponsor: None.

Overall survival of p-stage II-IIIB NSCLC treated with designated therapy regimens.

Real world characteristics of stages II-III NSCLC patients (pts) who initiate neoadjuvant chemo-immunotherapy (NACT-I) and do not undergo surgical resection. First Author: Jair Bar, Jusidman Cancer Center, Sheba Medical Center, Ramat Gan, Israel

Background: Neoadjuvant and perioperative chemo-immunotherapy studies report 15%-20% of pts initiating NACT-I do not undergo surgical resection. **Methods:** Real-world data of pts who initiated NACT-I was collected retrospectively for January 1st 2022 till September 30th 2024. Pts and treatment details, reason for not undergoing resection (as assessed by the clinicians) and later treatments and outcomes were recorded. Total number of pts who initiated NACT-I in this period was identified from each center's records. Missing data was not imputed. **Results:** Data was collected from 10 centers in 4 countries (USA, Israel, Switzerland, France). Out of 330 pts that started NACT-I 43 pts (13%; range 4-33% in different centers) did not undergo surgical resection. Of these 43 pts, 34.9% became unresectable due to disease progression (PD). 20.9% in retrospect were non-resectable and did not regress as expected. 11.6% in retrospect were non-operable. 11.6% suffered toxicity and became unfit for surgery. 7% of pts refused surgery, 14% were not resected for other reasons (Table). Of the non-resected pts, 9.3% died prior to any second-line treatment. As a second line, 44.2% of the non-resected pts were treated with chemo-radiation, 14% with radiation alone, 7% chemotherapy and immunotherapy, 4.7% immunotherapy alone and 2.3% chemotherapy alone. 7% received palliative radiation followed by chemo or immunotherapy, 7% had follow-up alone. **Conclusions:** The rate of no surgical resection in this real-world multi-national cohort was 13%, in line with the rate in reported studies. Most un-resected pts underwent appropriate staging. Most were male, with high rate of T3/T4. Survival rate at 12 months was 73.7%. The most common causes for no surgery were PD or being upfront unresectable. The patients with the worst outcome were those who experienced PD during NACT-I. Research Sponsor: None.

	N (% out of 43 non-resected)	Male (%)	Age (median)	PET Done prior to any therapy (%)	Brain MRI staging (%)	Documented MDT decision of NACT-I (%)	Documented surgeon evaluation prior to NACT-I decision (%)	T3-4 (%)	N2a/b (9th V TNM; %)	Survival rate at 12 month (95% CI)

Adjuvant icotinib of 12 months versus observation as adjuvant therapy for completely resected EGFR-mutated stage IB non-small-cell lung cancer: 5-year update from CORIN (GASTO1003). First Author: Si Yu Wang, Shenshan Medical Center, Sun Yat-sen Memorial Hospital, Shanwei, China

Background: In the phase II CORIN trial,adjuvant therapy of icotinib for 1-year shows prolonged disease-free survival (DFS) and acceptable toxicity in patients with completely resected epidermal growth factor receptor (EGFR)-mutated stage IB non-small-cell lung cancer (NSCLC). Here, we report the 5-year survival update from this study. **Methods:** In the phase II, open-label, randomized CORIN trial, patients with completely resected, EGFR-mutated, stage IB (7th TNM staging) NSCLC without adjuvant chemotherapy according to physician and patient choice were randomly assigned in a 1:1 ratio to receive icotinib (125mg, three times daily, 12 months) or undergo observation. Therapy continued until disease recurrence or intolerable toxicity. The primary endpoint was DFS. Secondary endpoints included overall survival (OS) and toxicity. **Results:** Of 128 enrolled patients, 63 received icotinib and 65 underwent observation. At the December 20 2024 database lock, the median follow-up was 65.0 (95% confidence interval [CI], 58.4-71.5) months. A total of 30 recurrence events had occurred, including 9 in the icotinib arm and 21 in the observation arm. Icotinib for 1 year continued to improve DFS versus observation, with the 5-year DFS of 88.5% and 67.7%, respectively (log-rank P=0.012, hazard ratio [HR], 0.38; 95%CI: 0.18-0.83). Icotinib showed a marginal OS improvement versus observation (log-rank P=0.045, HR, 0.15; 95%CI: 0.02-1.27). The 5-year OS was 98.3% in the icotinib group and 90.5% in the observation group. No new safety signals were observed at this update. Additional efficacy outcomes will be presented. **Conclusions:** In this 5-year update analysis from CORIN, adjuvant icotinib continues to demonstrate durable DFS benefit versus observation in resected EGFR-mutated stage IB NSCLC, with a manageable safety profile. Icotinib sustained OS separation versus observation over time and demonstrated a marginal OS benefit, which is limited by the small sample size and wide CIs. Adjuvant icotinib for 1 year provides a treatment option for these patients. Clinical trial information: NCT02264210. Research Sponsor: None.

IMpower010: Genomic profiling and clinical outcomes with adjuvant atezolizumab in early-stage non-small cell lung cancer (eNSCLC). First Author: Heather A. Wakelee, Stanford University School of Medicine/Stanford Cancer Institute, Stanford, CA

Background: In metastatic NSCLC (mNSCLC), genomic alterations (MUT) are well studied and have led to the development of efficacious new drugs. However, the association of MUT in the adjuvant setting in eNSCLC is not as well understood. Here, we describe an exploratory, retrospective analysis of genomic profiling by whole exome sequencing and clinical association in IMpower010. **Methods:** Whole exome sequencing was done on baseline tumor samples and germline DNA from whole blood from the biomarker-evaluable population (n=623). Multiple MUT were identified in the full population, including by histology. Disease-free survival (DFS) and overall survival (OS) were assessed in the most common gene subgroups. **Results:** The distribution of MUT and co-occurrence patterns were similar to expected non-squamous and squamous patterns in mNSCLC, except for lower prevalence of *STK11* (17%) and *KEAP1* (12%) MUT. In non-squamous disease, *STK11*, *EGFR*, and *KEAP1* MUT were associated with increased prevalence in PD-L1−negative tumors, and *TP53* MUT with PD-L1−positive tumors (adjusted $P<0.1$). *KRAS* MUT were associated with Stage II; *STK11* MUT were associated with Stage I more than with Stages II and III (adjusted $P<0.1$). Increased enrichment of *KRAS*, *STK11*, *KEAP1*, and *TP53* MUT was seen in those with previous or current smoking status, and *EGFR* MUT were enriched in those who never smoked (adjusted $P<0.1$). In non-squamous disease, *STK11* MUT were a poor prognostic for OS but not DFS, whereas *KEAP1* MUT were not significantly associated with poor prognosis for DFS or OS (Table). Neither *STK11* or *KEAP1* MUT were significantly associated with differential atezolizumab vs best supportive care DFS or OS benefit (interaction $P>0.05$). **Conclusions:** This analysis represents the largest dataset evaluating the genomic profile of patients with eNSCLC who were treated with cancer immunotherapy. The prevalences of *STK11* and *KEAP1* MUT were lower than in mNSCLC and were enriched for PD-L1−negative non-squamous NSCLC. Unlike in mNSCLC, patients with tumors that harbored *KEAP1* MUT did not have poor prognosis in IMpower010. Data are hypothesis generating and require validation in independent eNSCLC datasets with larger numbers. Clinical trial information: NCT02486718. Research Sponsor: Genentech, Inc.; Medical writing assistance for this abstract was provided by Nimisha H. Bhoola, PhD, of Nucleus Global, an Inizio Company, and funded by F. Hoffmann-La Roche Ltd.

Evaluating the role of consolidative chest radiotherapy after chemoimmunotherapy in extensive-stage small cell lung cancer: A retrospective study. First Author: Jorge Raul Vazquez Urrutia, Penn State Health Milton S. Hershey Medical Center, Hershey, PA

Background: Consolidative chest radiotherapy (XRT) after chemoimmunotherapy may provide benefits in extensive-stage small cell lung cancer (ES-SCLC) due to the condition's high sensitivity to radiation. Current guidelines suggest chest XRT for ES-SCLC patients who respond to chemotherapy, given its association with improved 2-year overall survival (OS), and reduced progression and recurrence rates. However, its role in the era of chemo-immunotherapy in ES-SCLC remains unclear. **Methods:** Data from the National Cancer Database (NCDB) for ES-SCLC patients diagnosed between 2017 and 2020 were analyzed (n=24,676). Cases included those treated with multi-agent chemotherapy, with data for T, N, and M status, and chest XRT. Exclusion criteria included survival <30 days, limited-stage SCLC cases, and missing key data elements. The primary outcome was OS from diagnosis, analyzed using Kaplan-Meier and multivariate Cox regression models. Propensity Score Matching (PSM) was performed to compare outcomes in ES-SCLC patients receiving chest XRT after immunotherapy versus immunotherapy alone, adjusting for T, N, and M status, institution, sex, and CD score. A p-value of <0.05 was considered statistically significant. **Results:** The study stratified patients in two groups: 10,437 immunotherapy receivers and 14,239 not receiving immunotherapy. The proportion of chest XRT receivers was similar across both groups (13% vs. 14%, p=0.17). Receipt of XRT was significantly associated with younger age (<70), female sex, T3-4 stage, N2-N3, and M1a status; ($p<0.05$). Chest XRT was associated with a significant increase median OS in both groups: immunotherapy (13.1 months vs. 9.8 months; $p<0.001$) and non-immunotherapy (11.6 months vs. 8.4 months; $p<0.001$). XRT was an independent predictor of better OS in both groups after controlling for other covariates (HR 0.72 and 0.66; $p<0.001$). PSM analysis of 1,399 patients receiving XRT and 1,399 receiving immunotherapy alone confirmed the OS benefit of XRT after immunotherapy (13.1 months vs. 9.4 months; HR 0.63, $p<0.001$) with a 3-year survival of 16% (95%CI: 13.7-18.3%) vs 7% (95%CI: 5.3-8.7%), respectively. **Conclusions:** Our analysis shows that consolidative chest XRT is associated with improved overall survival in patients with ES-SCLC, especially when combined with chemoimmunotherapy. These findings are hypothesis-generating and support ongoing randomized studies evaluating consolidative radiotherapy in the chemoimmunotherapy era. Research Sponsor: None.

Ensartinib as postoperative adjuvant therapy in patients with ALK-positive non-small cell lung cancer (NSCLC): A registered, retrospective, real-world study. First Author: Lin Wang, National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College, Beijing Key Laboratory of Clinical Study on Anticancer Molecular Targeted Drugs, Beijing, China

Background: Ensartinib has been approved as ALK-positive locally advanced/metastatic NSCLC, but its role in adjuvant therapy remains unknown. This real-world study aimed to evaluate the efficacy and safety of ensartinib as adjuvant therapy in ALK-positive NSCLC. **Methods:** Data were retrospectively collected from "Ensacove Patient Assistance Program" held by Betta pharmaceutical company. The patients who were ≥18 years-old and had completely resected, histologically confirmed stage I-III NSCLC as classified according to the eighth edition of AJCC/UICC, were documented ALK-positive, and had at least one post-baseline CT scan. The primary endpoint is 2-year disease-free survival (DFS) rate. Secondary endpoints include DFS, safety and OS. **Results:** From November 19, 2020, to May 31, 2024, a total of 296 patients were screened. 222 patients were enrolled. The median age was 55 years-old. 128 females. 98 (44.1%) were stage I, 42 (18.9%) were stage II, 82 (36.9%) were stage III. 98.2% were lung adenocarcinoma. Thirty-two patients (14.4%) received postoperative chemotherapy. The median duration of ensartinib treatment was 25.3 (95% confidence intervals [CI], 3.1-47.2) months. At the data-cutoff date of December 29, 2024, median follow-up time was 23.5 months (95% CI, 21.7-26.2). The median DFS was immature. The 2-year DFS rate was 92.1% (95% CI, 86.6%-95.5%) for all patients, and 89.3% (95% CI, 77.9%-95.0%), 100.0% (95% CI, NR-NR) and 91.0% (95% CI, 80.6%-95.9%) for patients with stage I, stage II, and stage III, respectively. 16 patients had disease recurrence or death, including 7 patients with local recurrence and 9 patients with distant metastasis. The OS data was immature with only 2 deaths occurred. The treatment-related adverse events (TRAEs) of any grade occurred in 169 patients (76.1%), and 11 patients (5.0%) experienced ≥grade 3 TRAEs. The most common TRAEs were rash (60.8%). Serious TRAEs were 8 (3.6%) patients. TRAEs led to dose reductions, dose interruptions and permanent discontinuation were 21.2%, 9.0% and 3.2% of the patients, respectively. No deaths due to TRAEs were reported. **Conclusions:** To our knowledge, this real-world study has the largest sample size on postoperative adjuvant therapy with ALK inhibitors. In this real-world setting, ensartinib demonstrated encouraging efficacy and well-tolerated safety profile among stage IA1-IIIB ALK-positive NSCLC, providing a potential adjuvant therapy option in this patient population. Molecular profiling of neoadjuvant immunochemotherapy and identification of residual cancer cells in pCR NSCLC: A single-cell analysis of CTONG 1804 clinical trial. First Author: SiYang Maggie Liu, Guangdong Lung Cancer Institute, Guangdong Provincial People's Hospital (Guangdong Academy of Medical Sciences), Southern Medical University, Guangzhou, China

Background: Previously, we reported the clinical findings of stage-one enrollment from a phase II trial of neoadjuvant immunochemotherapy (IO) in untreated patients with resectable non-small cell lung cancer (NSCLC) (CTONG1804, NCT04015778). Recently, two-stage enrollment has been completed. This trial provided an opportunity to investigate the correlation of pathological response and early immune microenvironment during neoadjuvant IO. **Methods:** We conducted single-cell RNA sequencing (scRNA-seq) on fresh tumor tissue of 21 patients at pre- and post-IO treatment. Multi-omics sequencing was also used in this exploratory study, that included bulk RNA sequencing and tumor-informed MRD sequencing. **Results:** The pathological complete response (pCR) rate was 42.9% (9/21). Unexpectedly, a total of 143 cancer cells with genome alterations were identified in six (6/9=66.7%) patients with pCR. Only one pCR patient presented MRD positive within one month after surgery, who had the highest number of cancer cells. These residual cancer cells exhibited reduced proliferative capacity and diminished stem cell-like features but retained epithelial-mesenchymal transition (EMT) markers, suggesting metastatic potential and drug resistance. Elevated antigen presentation pathways, particularly involving CD74-MHC class II, were observed in pCR cancer cells, alongside a significant reduction in tumor neoantigen burden. When comparing the immune cells of different pathological response, we found that conventional dendritic cell type 2 (cDC2) emerged as a critical antigen-presenting cell subtype in pCR patients, enhancing T-cell activation and promoting immune response. Reduced CD4-Treg3 populations correlated with improved treatment outcomes, while CD8-MAIT cells exhibited functional plasticity, transitioning from tumor-promoting to tumor-rejecting phenotypes post-therapy. **Conclusions:** Our study highlights the persistence of residual cancer cells even in pCR patients and identifies key immune cell subsets, such as cDC2 and CD8-MAIT cells, that play pivotal roles in modulating anti-tumor response. These findings provide valuable insights into the mechanisms of immune activation and suppression in NSCLC and suggest potential biomarkers and therapeutic targets for optimizing neoadjuvant immunochemotherapy. Clinical trial information: NCT04015778. Research Sponsor: None.

Molecular profiling and survival in oncogene-addicted resected stage IIIAN2 non-small cell lung cancer (NSCLC): A study from the Lung ART IFCT 0503 trial. First Author: Victor Albarran-Artahona, Department of Cancer Medicine, Gustave Roussy, Villejuif, France

Background: Molecular profiling is standard-of-care in metastatic NSCLC and increasingly important in earlier stages as personalized approaches arise. The role of adjuvant radiotherapy (ART) in oncogene-addicted, fully-resected stage IIIAN2 NSCLC remains undefined. **Methods:** The LungART trial (NCT00410683) randomized 501 patients (pts) with resected stage IIIAN2 NSCLC (AJCC 7th ed.) to ART or observation. No disease-free survival (DFS) benefit was found for ART. For consenting pts, a tumor block was collected. A histological central review was performed in all cases. Molecular profiling was conducted by Whole transcriptome sequencing (WTS; mRNA capture with Agilent exome lit and Illumina NovaSeq 6000 S4 Reagent Kit v1.5-300 cycles paired sequencing) to identify relevant alterations, with findings treated as per standard procedures. **Results:** 282 pts had available samples, from which 50% received ART. 90% were current or former smokers. Baseline characteristics were well balanced (table 1). After review, 79% of pts were classified as non-squamous cell carcinoma. *TP53* was the most common mutation (mut) identified (46%). Targetable mutations included *KRAS* p.G12C (8.8%), *EGFR*-sensitizing -exon 19 in-frame deletion and L858R mut- (3.5%), and *BRAF* p.V600 (1.4%). Non p.G12C *KRAS* mut were found in 28 pts, while atypical *EGFR* mut including exon 20 insertion, and non V600 *BRAF* were identified in 3.1% and 2.8% of pts, respectively. A *ERBB2* exon 20 insertion mut was identified in one case. *STK11* and *KEAP1* mutation were identified in 5.3% and 3.5% of pts, respectively. No translocations were detected. In the *STK11* mut subgroup, a significant difference in DFS (p=0.032) and OS (p=0.0043) was observed. No differences in outcomes were observed for other major molecular alterations nor between treatment arms, including *TP53* (p=1.0 and 0.86 for DFS and OS, respectively). **Conclusions:** Our study did not found a significant outcomes difference among major oncogenic-driven alterations, probably due to population characteristics and small representation of oncogene addicted subgroups. Our findings confirm *STK11* as a poor prognostic factor in resected stage IIIAN2 NSCLC. Of note, *TP53* did not show any impact on survival. Further studies are needed to confirm these observations and explore its implications. Research Sponsor: None.

A panel of four protein tumor markers for effective and affordable lung cancer early detection by artificial intelligence. First Author: Mao Mao, Research & Development, SeekIn Inc, San Diego, CA

Background: Lung cancer is the most common and deadly malignancy worldwide. While low-dose computed tomography (LDCT) reduces mortality in high-risk populations, its high false-positive rate and the required specialized infrastructure and radiologists limit its application. This study assesses LungCanSeek, a novel blood-based protein test for lung cancer early detection. **Methods:** This study enrolled 1,814 participants (1,095 lung cancer, 719 non-cancer) from three independent cohorts. Blood samples were analyzed for four protein tumor markers (PTMs) using Roche cobas. Artificial intelligence (AI) algorithms were developed for lung cancer detection and subtype classification (lung adenocarcinoma (LUAD), lung squamous cell carcinoma (LUSC), and small cell lung cancer (SCLC)). A two-step lung cancer screening approach was modeled, using LungCanSeek for initial screening, followed by LDCT for LungCanSeek's positive cases. **Results:** LungCanSeek showed 83.5% sensitivity, 90.3% specificity, and 86.2% accuracy overall. Sensitivities of LUAD, LUSC, and SCLC were 83.3%, 81.4%, and 91.9%. Sensitivity increased with clinical stage in non-small cell lung cancer (NSCLC): 59.5% (I), 69.8% (II), 86.5% (III), and 91.3% (IV). Sensitivities of limited- and extensive-stage SCLC were 91.3% and 93.0%. The subtype classification accuracy was 77.4%. Compared with the other blood-based lung cancer early detection tests like OncImmune's EarlyCDT-Lung (41.0% sensitivity, 91.0% specificity) and DELFI's FirstLook-Lung (84.1% sensitivity, 50.9% specificity), LungCanSeek's performance was superior. LDCT had 93.1% sensitivity and 76.5% specificity in NLST study. A screening was modeled for 9 million high-risk adults, based on the number of 15 million eligible individuals in the USA in 2024 at a 60% rate, with a 1.2% lung cancer incidence. While LungCanSeek reduced false positives by 2.4-fold to 862,524 compared to 2,089,620 with LDCT, the two-step approach further lowered false positives by 10.3-fold to just 202,693. Additionally, LDCT's total cost was $2,493 million, exceeding LungCanSeek's $720 million by 3.5-fold and two-step's $978.5 million by 2.5-fold. **Conclusions:** LungCanSeek is a non-invasive, easy to perform, cost-effective (reagent cost $15) and robust test for lung cancer early detection. It also provides accurate subtype prediction that may guide patients' clinical management and monitor subtype switching during treatment. The two-step approach not only effectively reduces LDCT's high false positives but also yields substantial economic benefits, making it a cost-effective strategy for population-wide lung cancer screening. Genomic characterization of STAS in stage 1 EGFR-mutated NSCLC and prognostic implications. First Author: Stephanie Pei Li Saw, Division of Medical Oncology, National Cancer Centre Singapore, Singapore, Singapore

Background: Spread through air spaces (STAS) is a poor prognostic factor and was recently introduced as a histologic descriptor in the TNM edition 9 for stage 1 lung cancer. While STAS-positivity (STAS+) is known to be associated with adenocarcinoma, the molecular epidemiology and determinants of STAS+ specific to epidermal growth factor receptor-mutated lung cancer (EGFRm) and prognostic implications remain unknown. **Methods:** Consecutive patients from National Cancer Centre Singapore diagnosed with AJCC8 stage 1 lung adenocarcinoma with minimum 3 years follow up post-surgery and known EGFR and STAS status (+ or -) were included. Fresh frozen tumour and normal samples were subject to whole exome sequencing (WES) at 400X and 100X coverage respectively, with 50 million paired-end reads for RNA-seq per sample. PD-L1 expression by immunohistochemistry was scored using SP263. Wilcoxon and Fisher's exact tests were used for association analysis and Kaplan Meier method for survival. **Results:** Between 1/1/16-31/12/21, 300 patients were included (203 EGFRm; 97 EGFR-wildtype (EGFRwt)). While the incidence of STAS+ was similar between EGFRm and EGFRwt (49.8% versus (vs) 56.7%, p=0.316), 5-year disease-free survival (DFS) was significantly worse for STAS+ vs STAS- EGFRm (67.8% vs 93.2%, p=0.005) but not EGFRwt (78.9% vs 82.0%, p=0.6). Comparing STAS+ and STAS- EGFRm, there was no significant difference in the proportion of never-smokers (77.2% vs 76.4%, p=0.248) and females (52.5% vs 60.8%, p=0.292). Distribution of EGFR mutation subtype was also similar (ex19del 43.6% vs 41.2%; L858R 37.6% vs 44.1%; others 18.8% vs 14.7%, p=0.576). Lymphovascular invasion (LVI) (20.8% vs 3.9%, $p<0.001$) and high histological grade (32.7% vs 4.0%, $p<0.001$) were significantly more common in STAS+ vs STAS- EGFRm. Among EGFRm, 193 patients had available WES and RNA-seq. Incidence of TP53 co-mutations (60.7% vs 43.2%, p=0.020) and whole genome doubling (WGD) (34% vs 17%, p=0.013) was significantly more common among STAS+ than STAS- tumours. No other significant differences in co-mutations or copy number alterations were observed. The proportion of PD-L1 expression $\geq$1% (42.3% vs 21.2%, p=0.011) and non-TRU transcriptomic subtype (55.9% vs 22.2%, $p<0.001$) were also significantly higher in STAS+ compared to STAS- tumours. Controlling for stage (1A vs 1B), age, smoking status, gender, histological grade and LVI, STAS+ remained an independent predictor of inferior DFS in stage 1 EGFRm (hazard ratio: 4.0, 95% confidence interval: 1.1-15.2, p=0.04). **Conclusions:** Despite a similar incidence, STAS+ independently predicts for inferior DFS in patients with stage 1 EGFRm but not EGFRwt. STAS+ stage 1 EGFRm demonstrate a higher frequency of *TP53* co-mutations, WGD, non-TRU subtype and PD-L1$\geq$1% as compared to STAS- stage 1 EGFRm. Our findings highlight the molecular determinants of STAS+ and support STAS as a risk stratification factor for stage 1 EGFRm. Research Sponsor: National Medical Research Council of Singapore.

Genomic and immunophenotypic landscape of early-stage pulmonary carcinoid tumors. First Author: Song Xu, Tianjin Medical University General Hospital, Tianjin, China

Background: Pulmonary carcinoids (PCs), which encompass atypical carcinoids (ACs) and typical carcinoids (TCs), represent a rare category of lung cancer characterized by low to moderate malignancy. However, there is a limited understanding of the genomic and immune characteristics associated with PCs on a global scale. **Methods:** This study included a cohort of 126 surgically resectable Chinese PC patients, comprising 44 ACs and 82 TCs. Next-generation sequencing utilizing a 578-gene panel was conducted on 90 of PC patients, followed by the calculation of tumor mutation burden (TMB). Additionally, immunohistochemical staining for PD-L1 (n=108) and CD8 (n=94) was carried out to investigate the characteristics of the tumor microenvironment in PCs. **Results:** The most frequently altered genes in early-stage PCs were identified as *EGFR* (n=16, 18%), *KMT2C* (n=11, 12%), *LRP1B* (n=10, 11%), *MEN1* (n=10, 11%), and *NOTCH2* (n=9, 10%). Dysregulation of the RTK/RAS, NOTCH, and PI3K pathways was commonly observed in these PCs. Notably, genetic alterations in TP53, ARID1A, and CUL3 were more prevalent in ACs compared to TCs. However, TMB, PD-L1 expression, and CD8+ T cell infiltration were found to be low in early-stage PCs, with no significant differences observed between ACs and TCs. We identified age, gender, TNM stage, tumor type, smoking status, TMB, and *LRP1B* mutation, as indicators of poor prognosis, and further established a molecular classification that categorizes early-stage PCs into three distinct subtypes, each associated with varying clinical outcomes. **Conclusions:** We depicted the genetic and immune landscape of early-stage PCs and subsequently proposed a molecular classification based on the status of *LRP1B* mutation and smoking history. Our research offers novel insights into the biological mechanisms of PCs which contributes to the individualized treatment for Chinese PC patients. Research Sponsor: None.

Association of 8-gene signature with early recurrence in resected non-small cell lung cancer. First Author: Arsalan A Khan, Rush University Medical Center, Chicago, IL

Background: Limited evidence exists defining a genetic signature associated with early-recurrence in patients with non-small cell lung cancers (NSCLC). This study aims to identify a genomic panel associated with early recurrence, defined as recurrence within 12 months from surgery. **Methods:** Patients with resected pT1-2aN0 NSCLC that underwent tumor RNA sequencing at a single institution from 2010-2021 were included. Exclusion criteria included neoadjuvant therapy, unknown pN status, and no recurrence. Differential gene expression (DGE) analysis was performed using DESeq2 after count normalization, identifying 50 genes with a log2 fold change $>$ 1 or $<$ -1 and an adjusted p-value$<$0.05. Recursive feature elimination (RFE) with random forests was applied to evaluate subsets of genes, utilizing repeated 10-fold cross-validation to ensure robust performance estimation. Accuracy and model stability were compared across subsets to identify the gene panel most strongly associated with early recurrence. Cross-validation was performed using a secondary RFE random forest analysis optimized for AUC, to refine the gene selection process. A multivariable logistic regression analysis was conducted to examine the association between the gene panel and early recurrence, while controlling for potential confounders. **Results:** 118 patients met study criteria, of whom 54% (64/118) were female, 82% (97/118) had adenocarcinomas, and 59% (70/118) underwent lobectomy. The median tumor size was 1.8 cm (IQR 1.5–2.6). Early recurrence was observed in 25.4% (30/118). DGE analysis involved 61.4% (27,009/43,959) of genes. After filtering for low total counts, using an FDR $<$0.1, 2% (530/27,009) were upregulated and 1.3% (351/27,009) downregulated in patients with early recurrence. After RFE with random forests, an 8-gene panel was selected, including *ART3*, *SLC51A*, *SNAP25*, *CCNA1*, *GRK1*, *GPR63*, *CNTNAP2*, and *TNFRSF11B* achieving an accuracy of 71.7%. The panel had an area under the curve (AUC) of 79.1, sensitivity of 93.9%, and specificity of 33.3%. On multivariable logistic regression, after adjusting for tumor size, histology, surgical procedure, pack years, and number of nodes sampled, and performance status, patients with differential expression of four or more genes within the panel were associated with early recurrence (OR: 4.11, 95% CI:1.27–13.31, p=0.02). **Conclusions:** A unique tumoral 8-gene signature is associated with early recurrence in resected early-stage NSCLC patients. Research Sponsor: None.

Study on optimizing serum-based lung cancer diagnosis using a multi-biomarker approach. First Author: Hyejin Sung, Beyonddx, Gwangmyeong, South Korea

Background: Lung cancer remains the leading cause of cancer-related mortality, largely due to the challenges in early diagnosis. Elevated levels of serum carcinoembryonic antigen (CEA), serum amyloid A (SAA), and osteopontin (OPN) have been reported in various cancers. However, the diagnostic efficiency of these biomarkers as a combined panel for lung cancer detection is not well understood. This study evaluates the diagnostic value of combining these three biomarkers for lung cancer screening. **Methods:** Serum samples from 1,429 lung cancer patients and 1,000 healthy donors were analyzed for CEA, SAA, and OPN levels to assess their diagnostic accuracy. The data were divided into three independent cohorts: a development set, a training set, and a validation set. The diagnostic performance of each individual biomarker and the combined multi-biomarker panel was evaluated. **Results:** In the discovery set, the most influential variables in the support vector machine model were OPN, SAA, CEA, in that order, while the least influential were NSE, SCC, CYFRA. The optimized multi-biomarker panel comprising SAA, CEA, and OPN, with a cut-off value of 0.61, demonstrated sensitivity, specificity, positive predictive value (PPV), and negative predictive value (NPV) of 83.59%, 90.10%, 93.16%, and 77.29%, respectively, in the training set. Validation confirmed robust performance with sensitivity of 81.21%, specificity of 86.86%, PPV of 90.87%, and NPV of 74.15%. The multi-biomarker panel outperformed individual biomarkers across all stages of lung cancer, achieving AUC values of 0.9320 in the training set and 0.9230 in the validation set. **Conclusions:** The combined multi-biomarker panel of CEA, SAA, and OPN significantly improves diagnostic performance compared to single biomarkers. This panel represents a promising non-invasive tool for early and accurate lung cancer diagnosis. Research Sponsor: Ministry of SMEs and Startups(MSS, Korea); RS-2024-00437469.

A novel aptamer-based non-invasive test for lung cancer: A proof-of-concept. First Author: Line Nederby, Department of Biochemistry and Immunology, Vejle Hospital, University Hospital of Southern Denmark, Vejle, Denmark

Background: Lung cancer (LC) is the leading cause of cancer-related mortality, primarily due to late-stage diagnoses. Low-dose computed tomography (LDCT) screening lowers mortality rates by detecting LC at earlier stages, but the program is limited by high costs, capacity constraints, and low compliance. We describe the early-phase development of a test based on the APTASHAPE technology, designed as a cost-effective, scalable tool to pre-qualify individuals for LDCT screening. This technique uses RNA aptamers to analyze protein composition in lung cancer patients, identifying cancer-specific protein fingerprints across all stages. Variations in aptamer ratios reflect plasma protein composition, profiled through next-generation sequencing and machine learning. **Methods:** A discovery cohort of 24 LC patients (stage I+II, n=12; stage III+IV, n=12) and 24 individuals initially referred on suspicion of LC but ultimately diagnosed as non-cancer cases were analyzed. Additionally, a test cohort of 48 LC patients (stage I+II, n=24; stage III+IV, n=24) and 48 non-LC cases were analyzed. In four rounds of Systematic Evolution of Ligands by EXponential Enrichment (SELEX), a library of 10^{15} 2'-fluoro-protected RNA aptamers was incubated with a pool of plasma prepared from the LC patients in the discovery cohort to facilitate binding to the plasma proteins. Non-binders were removed, and bound aptamers were amplified by PCR. Following SELEX, linear regression identified the aptamers capturing LC-specific protein signatures. The selected aptamers were then applied to the test cohort and their ability to differentiate between LC and non-LC cases was evaluated using principal component analysis and receiver operating characteristic (ROC) curve. **Results:** In the discovery cohort, statistical analysis identified 13 aptamers whose binding to plasma proteins formed a cancer-specific fingerprint, able to discriminate participants with lung cancer from those without. We used this profile to predict LC in the test cohort and obtained an area under the curve (AUC) of 0.74 (95% confidence interval (CI) 0.62-0.87). Importantly, the discriminatory ability was equally effective for stage I+II and stage III+IV (AUC=0.71 (95% CI 0.58-0.84) and AUC=0.74 (95% CI 0.61-0.86), respectively). **Conclusions:** We present a proof-of-concept for a promising, cost-effective, and scalable technique for pre-qualifying individuals for LDCT screening. While still in the earliest stage of development, we anticipate that expanding the study population will improve the machine learning algorithm and markedly increase the AUC value. Importantly, this approach holds significant promise in detecting early-stage lung cancer -an area where blood-based technologies usually face substantial limitations. Ongoing optimizations aim to enhance its performance. Research Sponsor: None.

Diagnostic properties of a novel ctDNA assay for lung cancer detection. First Author: Peter Hjorth-Hansen, Department of Oncology, Vejle Hospital, Vejle, Denmark

Background: Lung cancer is a devastating disease, characterized by high mortality rates and limited treatment options once it progresses to advanced stages. Early detection is critical for improving survival outcomes, as curative treatments are only possible in the early stages of the disease. Developing a blood test for lung cancer detection would provide a minimally invasive, highly valuable tool for early diagnosis and could significantly enhance screening efforts. A novel digital droplet polymerase chain reaction multiplex assay was evaluated for its diagnostic accuracy in detecting hypermethylated circulating tumor DNA (ctDNA) in lung cancer in a high-risk population. **Methods:** The study enrolled 249 patients undergoing diagnostic evaluation for suspected lung cancer. Blood samples for ctDNA analysis were collected during the first hospital visit. Lung cancer diagnoses were subsequently determined through clinical workup and assessment by a multidisciplinary team (MDT). If the initial MDT assessment refuted the suspicion of lung cancer, participants were followed for at least 12 months to ensure they did not develop lung cancer in the follow up period. The assay targeted hypermethylated CpG-islands in five genes: *HOXA9, OTX1, MCIDAS, TFAP1B*, and *SP9*. ROC-analyses were performed for the five ctDNA markers alone and in combination. **Results:** The assay, using the combined model of the five markers, showed a sensitivity of 67% (95% Confidence Interval [CI]: 57–76) and a specificity of 77% (95% CI: 69–8) to discriminate cases from cancer-free controls. Positive and negative predictive values were 70% (95% CI: 60–78) and 75% (95% CI: 67–82), respectively. Sensitivity increased to 73% (95% CI: 62–83) in subgroup analysis of stages III and IV lung cancer and cancer-free controls. Notably, the assay successfully detected all 9 cases of small cell lung carcinoma (SCLC) within the cohort. Additional analysis revealed an association in stage IV participants between ctDNA and higher tumor burden, potentially explaining the improved assay performance in these advanced stages. Conversely, amongst the seven false negative stage IV cases, they all had lower tumor burden and were diagnosed with adenocarcinomas. **Conclusions:** The presence of aberrantly methylated ctDNA is a potential diagnostic biomarker for lung cancer. Further optimization of the multiplex assay might improve its overall performance making it a relevant tool for early detection of lung cancer. Importantly, this study was performed in a high-risk cohort, with a lung cancer prevalence of 43%, and hence, the assay would potentially perform better in a screening population. Actionable gene alterations in resected non-small cell lung cancer (AGA-R study). First Author: Ilaria Attili, Division of Thoracic Oncology, European Institute of Oncology IRCCS, Milano, Italy

Background: To date, molecular testing indication in resected non-small cell lung cancer (NSCLC) is limited to epidermal growth factor receptor (*EGFR*) mutations (mut) and anaplastic lymphoma kinase (*ALK*) rearrangements, because of demonstrated benefit and approval of adjuvant targeted therapies. The use of next generation sequencing (NGS), routinely adopted in the metastatic setting to guide treatment, is very limited in resected NSCLC. The prevalence of driver gene alterations other than *EGFR* and *ALK*, and their impact on adjuvant treatment outcomes, disease recurrence (DR) and survival remain unclear. **Methods:** We retrospectively analyzed molecular, clinical and survival data from consecutive Caucasian patients (pts) who underwent surgery for stage IA-IIIB NSCLC (AJCC 8th Edition) and had NGS performed on tumor tissue between January 2020 and December 2023 at our Institute. Primary endpoint was the prevalence of driver gene alterations in the overall cohort. Exploratory analyses were planned to evaluate DR, disease free survival (DFS) and overall survival (OS) and their relationship with the mutational status. **Results:** Overall, 216 resected NSCLC pts had NGS available. The prevalence of oncogenic driver alterations was 71%, the most common being *KRAS* (30%; 13% G12C and 17% non-G12C), followed by *EGFR* (26%; stage I: 29%), with exon 19 deletions (13%), exon 21 L858R substitution (6%), exon 20 insertion (2%), and uncommon mut (5%). Other detected alterations included *MET* exon 14 skip (6%; stage I: 8%), *BRAF* (4%; 2% V600), and *HER2* exon 20 mut (3%). Only 1% of cases had *ALK* or *RET* rearrangements. The overall prevalence of gene alterations was similar in men (69%) and women (70%), however *KRAS* and *MET* exon 14 skip were reported more frequently in men, *EGFR* in women. Among 181 pts with available follow up (median f up 14mo), n=52 DR events were observed. Median time to DR was 13.5 months (95% CI 11-16mo). Of note, among resected stage I pts with *EGFR* common mut who did not receive adjuvant TKI (n=10), 30% DR occurred. The overall highest DR rates (75%) were observed in the presence of gene fusions, exon 20 ins, and *BRAF* non-V600, followed by (50%) *KRAS* non-G12C and *HER2* mut. The lowest DR rate was observed in *MET* ex14 skip (8%) and BRAF V600 (0%). DR rate in other mut subtypes was similar to that observed in wild-type population. Median DFS was 32 months (24-NA), OS data are still not mature at data cut-off. **Conclusions:** Our study detected driver mutations in 70% of resected NSCLC, including stage I. The prevalence of *EGFR* and *MET* exon 14 skip mut in the early stage setting almost doubled the reported prevalence in the metastatic setting. Differential DR rates according to specific mut subtypes, are hypothesis-generating, and suggest the need of NGS testing to inform prognosis and personalize follow up in current clinical practice. Further investigation on tailored adjuvant treatments, also in stage I resected tumors, is supported by our results. Research Sponsor: None.

Tumor type prediction via tissue- and liquid-based comprehensive genomic profiling: High-specificity tobacco signature detection to support lung cancer diagnosis. First Author: Soo-Ryum Yang, Memorial Sloan Kettering Cancer Center, New York, NY

Background: Cigarette smoking exposes the lungs to tobacco mutagens, producing a distinct mutational pattern with elevated tumor mutational burden and strand bias for C>A mutations, aiding identification of lung origin in cancer of unknown primary (CUP). We evaluated a tobacco signature (TSig) caller for diagnosing lung cancer on tissue (TBx) and liquid biopsies (LBx) tested via the FoundationOne CDx (F1CDx) and FoundationOne Liquid CDx (F1LCDx) comprehensive genomic profiling (CGP) assays. **Methods:** We analyzed 351,611 TBx and 68,888 LBx samples, assessing TSigs (COSMIC v2 signatures 4 and 29) in a research use only capacity in cases with $\geq$10 somatic non-driver variants. For LBx, ctDNA tumor fraction (TF) was estimated via aneuploidy, fragment length, and variant features. TSig caller performance and co-occurring genomic alterations were evaluated against submitted diagnoses. Concordance was assessed in paired TBx and LBx samples (TF $\geq$1%) collected within 90 days of one another. **Results:** In all, 20.3% (71,211/351,611) of TBx and 13.6% (9,385/68,888) of LBx specimens had sufficient somatic variants for TSig analysis, with TSigs detected in 13.1% (9,302/71,211) of TBx and 10.2% (954/9,385) of LBx cases. Of TSig+ TBx cases, 87.5% (8,140/9,302) were submitted with a primary lung cancer diagnosis, 6.2% (579/9,302) as CUP, and 6.3% (583/9,302) as non-lung cancer. For TSig+ LBx cases, 81.9% (781/954) were submitted as primary lung cancers, 6.4% (61/954) as CUP, and 11.7% (112/954) as non-lung cancer. TSig+ cases were enriched for *TP53*, *KRAS*, *STK11*, *KEAP1*, *SMARCA4*, and *MET* alterations ($P < 0.001$), consistent with their association with smoking-related lung cancer, regardless of submitted diagnosis, indicating that many cases submitted as CUP or non-lung cancer represented misdiagnosed lung cancers. Conversely, TSig− lung cancers were enriched for *EGFR*, *ALK*, *ROS1*, and *RET* alterations ($P < 0.001$), common in non-smokers. For cases with sufficient variants for TSig analysis, the TBx TSig caller had a high specificity of 97.1% but a lower sensitivity of 26.3%, with an accuracy of 66.3%, positive predictive value (PPV) of 87.5%, and negative predictive value (NPV) of 63.1%. LBx performance was comparable, with 96.7% specificity, 18.6% sensitivity, 61.8% accuracy, 81.9% PPV, and 59.5% NPV. In 272 paired TBx and LBx lung cancer samples, the positive percent agreement for TSig detection was 61.0%. **Conclusions:** TSig analysis identified misdiagnoses in 6.3% of TBx and 11.7% of LBx cases and supported lung origin in 6.3% of CUP cases. High specificity and PPV established TSig+ results as strong indicators of lung cancer, while lower sensitivity reflected the intrinsic limitation of the biomarker in detecting non-smoking-related cancers. These data highlight the utility of F1CDx and F1LCDx TSig analysis in refining lung cancer diagnosis and treatment. Research Sponsor: None.

Racial and ethnic disparities in risk of second primary lung cancer among initial lung cancer survivors in the United States. First Author: Pragati Gole Advani, Roswell Park Cancer Institute, Buffalo, NY

Background: Previous studies have reported significant racial/ethnic disparities in incidence and mortality of lung cancer. However, with several studies reporting significantly increased risk of second primary lung cancer (SPLC) among these first primary lung cancer (FPLC) survivors, we sought to examine SPLC risk among FPLC survivors by race/ethnicity and age utilizing a large population-based database. **Methods:** From 17 United States population-based Surveillance, Epidemiology and End Results (SEER) program cancer registry areas, we identified 305,432≥12-month FPLC survivors diagnosed between 2000-2021. Standardized incidence ratios (SIRs) and accompanying 95% confidence intervals (CIs) quantified SPLC risk by race/ethnicity (non-Hispanic White, Black, Asian/Pacific Islander [API] and Hispanic), compared with the general population. Excess SPLC risks were calculated based on SIRs and excess absolute risks (EARs) per 10,000 person-years at risk (PYR). **Results:** Overall, we observed 13,005 SPLCs representing a 5.6-fold significantly increased risk (95% Confidence Interval [CI]=5.51-5.71) among FPLC survivors compared to the general population and an excess of 118 cases per 10,000 PYR. SPLC risk varied significantly by race/ethnicity with Hispanic FPLC survivors presenting highest risk ($SIR_{Hispanic}$=8.42; CI=7.73-9.16) followed by the API and Black patients (SIR_{API}=6.58; CI=6.11-7.07; SIR_{Black}=5.63; CI=5.32-5.96) ($P_{heterogeneity}<0.001$). Although 81% SPLC cases were reported among White FPLC survivors, the SIR compared to the other patients was relatively lower among the White (SIR_{White}=5.45; CI=5.35-5.56). Analysis by age at FPLC diagnosis reported a significantly increasing trend in SPLC risk with decreasing age ($P_{trend}<0.001$). Heterogeneity by race/ethnicity in SIRs was most pronounced in younger, particularly the adolescent and young adult (AYA) patients aged between 20 to 39 years at FPLC diagnosis. Strikingly elevated risk was observed among the Hispanic and API AYA FPLC survivors (SIRs of 49.62 and 87.17, respectively), followed by the corresponding Black and White patients (SIRs of 39.64 and 22.15, respectively) ($P_{heterogeneity}<0.001$). Similar pattern in racial/ethnic and age-related disparity was observed by latency, with higher SPLC risk among the young and minority patients within first 5 years since FPLC diagnosis. **Conclusions:** We observed substantial disparities in SPLC risk by race/ethnicity, with patients belonging to minority groups, particularly the Hispanic, and the AYA age group experiencing higher risks. Further research to understand drivers of these observed racial/ethnic and age-related heterogeneity is warranted. Similarly, tailored surveillance strategies are required to reduce disparities among FPLC survivors by accounting for these patient characteristics. Research Sponsor: None.

Longitudinal *EGFR* assessment in plasma and tissue samples in early non–small cell lung cancer (NSCLC). First Author: Sara Torresan, Department of Medicine (DME), University of Udine, Italy and Medical Oncology Department, Vall d'Hebron University Hospital and Vall d'Hebron Institute of Oncology, Barcelona, Spain

Background: Osimertinib has become the standard adjuvant treatment for patients (pts) with surgically resected, early-stage, *EGFR*-mutated non-small cell lung cancer (NSCLC), after the results of the ADAURA trial. However, the temporal distribution of *EGFR* mutations (mut) and its relation with recurrence patterns in this population have not been established yet. Aim of the study is to describe the prevalence of circulating tumor DNA and *EGFR* mut at different timepoints in early-stage NSCLC and the correlation between their presence and prognosis. **Methods:** This is a single center study conducted at the Vall d'Hebron Institute of Oncology, including consecutive pts with surgically resected, stage I-III NSCLC harbouring *EGFR* mut from 2008 to 2024. Next Generation Sequencing (NGS) with ONCOMINE panel was performed on tissue samples, archival when surgery pre-dated the start of the study. NGS on plasma samples was performed using Guardant360 panel at timepoints: 1, 3 and 6 months after surgery and at recurrence. For pts receiving adjuvant osimertinib, additional plasma samples were collected before drug initiation and during treatment. Pts were referred for genetic consultation if NGS on tissue samples detected a *TP53* mut with a variant allele frequency (VAF) >30%, or if NGS on plasma identified *TP53* or *BRCA* mut with a VAF >20%, or a basal T790M mutation. **Results:** Currently, 70 pts were enrolled, of which 24.3% were male. Median age was 68 years, and 35.7% were former/current smokers. Pts with stage IA were 37.1%, IB 24.3%, IIA 2.9%, IIB 11.4%, IIIA 14.3%, IIIB 5.7%. All pts had an EGFR mut, 54.2% detected by NGS on surgical or pre-surgical specimens. *EGFR* mut of the other samples were detected using PCR Cobas, and NGS are ongoing. *EGFR* mut was not detected on plasma after surgery (except for 1). Most pts harboured common mut (47.1% ex19del and 45.7% exon21 L858R on COBAS, 65.6% ex19del and 34.4% exon21 L858R on ONCOMINE). Interestingly, of the 43 pts with post-surgery NGS on plasma, 41.9% had a pathogenic mutation (*TP53* 50%, *ARID1* and *BRCA1/2* 11.1% each, 5.6% each *SMAD4, MPL, TSC1, NOTCH1, JAK2, APC, FGFR1* and *KRAS*) with a median VAF of 0.25% (tissue confirmation is needed to exclude hematopoietic origin). Liquid biopsies were obtained from all pts, with at least one sample collected post-surgery at varying time points. Adjuvant/neoadjuvant chemotherapy was administered to 31.4% of pts, while 17.1% received adjuvant osimertinib (100% after adjuvant osimertinib approbation by local label if indicated) and 11.4% also received radiotherapy. Disease recurrence occurred in 22 patients (31.4%), with 8 being local recurrence. At data lock 83% of pts were alive. **Conclusions:** Evaluation of *EGFR* in early-stage NSCLC should be standard procedure. We aim to identify a pattern associated with higher risk of recurrence and worse prognosis. Dynamic monitoring of *EGFR* could aid in personalising adjuvant treatments and follow-up scheduling. Research Sponsor: None.

Clinical utility of pathologist-directed comprehensive comparative molecular profiling for the classification of separate primary lung cancers vs. intrapulmonary metastasis. First Author: Douglas I Lin, Foundation Medicine, Inc., Cambridge, MA

Background: Lung cancers can present as multiple pulmonary tumors, representing either separate primary lung carcinomas (SPLCs) or intrapulmonary metastases (IPMs) arising from a single advanced cancer. Distinguishing SPLCs from IPMs is important for effective staging, prognosis, and treatment. Comparative molecular profiling (CMP) of paired tumors can elucidate their clonal relationship. We report real-world data on the use of CMP to distinguish SPLCs versus IPMs. **Methods:** Paired lung tumors from the same patients, submitted for FoundationOne CDx (F1CDx) comprehensive genomic profiling within a 12-month period from one another between 2014 and 2024, were centrally reviewed by a board-certified pathologist. After excluding clonal hematopoiesis and germline alterations, 1) tumors with different driver alterations were classified as SPLCs, 2) tumors with shared drivers and other alterations as IPMs, and 3) tumors with 1 common driver but different other alterations as SPLCs. The molecular landscapes of SPLCs and IMPs as defined by CMP were subsequently compared. **Results:** In all, 359 paired lung cancers were identified and analyzed using pathologist-directed CMP. Of these, 32.6% (117/359) were classified as SPLCs, 63.8% (229/359) as IPMs, and 1.1% (4/359) as misdiagnoses (i.e., not lung cancer). Among SPLC pairs, 89.7% (105/117) harbored actionable genomic alterations in one tumor but not the other. Classification of 2.5% (9/359) of pairs was inconclusive due to suboptimal sequencing quality control metrics. Misdiagnoses, based on the molecular results, included 2 metastatic HPV-associated carcinomas (supported by high-risk HPV reads), and 2 metastatic cutaneous squamous or basal cell carcinomas (supported by ultraviolet mutational signatures). Of 31 paired lung tumors with different histologies, 67.7% (21/31) were SPLCs, while 32.3% (10/31) were IPMs. Molecular landscape analysis showed that IPMs had significantly higher frequencies of *CDKN2B* (20.1% vs. 10.3%, P=0.03, OR=2.2) and *ERBB2* (6.3% vs. 0.9%, P=0.03, OR=7.8) alterations, while SPLCs were more likely to have elevated tumor mutational burden (i.e., TMB ≥10 Muts/Mb) (39.8% vs. 21.3%, P<0.0001). **Conclusions:** Pathologist-directed CMP using F1CDx facilitates the classification of multiple lung cancers as SPLCs or IMPs and may identify diagnostic errors associated with conventional histopathological examination. The higher prevalence of *ERBB2* alterations in IPMs suggests a role in their development and opportunities for targeted therapy, while the increased rate of elevated TMB in SPLCs indicates a field cancerization effect, driven by smoking or other exposures, and possible responsiveness to immunotherapy. Accurately classifying SPLCs and IPMs is important for proper staging and therapeutic planning in patients with lung cancer. Research Sponsor: None.

A window of opportunity study for preoperative brigatinib in resectable anaplastic lymphoma kinase (ALK)-positive non-small-cell lung cancer (NSCLC): WILDERNESS trial. First Author: Chang Gon Kim, Division of Medical Oncology, Department of Internal Medicine, Yonsei Cancer Center, Yonsei University College of Medicine, Seoul, South Korea

Background: Although ALK inhibitors are approved for patients with *ALK*-positive recurrent and/or metastatic NSCLC or resected NSCLC, their role as neoadjuvant therapy in resectable NSCLC remains unclear. Here, we report the results of a window-of-opportunity study evaluating neoadjuvant brigatinib in resectable *ALK*-positive NSCLC, aiming to identify the molecular mechanisms underlying drug-tolerant persister cells in cancer (NCT05361564). **Methods:** We conducted a single-arm, open-label, phase 2 trial of neoadjuvant brigatinib in patients with resectable *ALK*-positive NSCLC. Patients received brigatinib at a dose of 180 mg once daily following a 7-day lead-in period at 90 mg. Radiologic objective response rate (ORR), major pathologic response (MPR) rate, disease-free survival (DFS), event-free survival (EFS), and overall survival (OS) were evaluated. Single-cell transcriptomic analyses were performed to characterize the tumor microenvironment according to the achievement of MPR. **Results:** All 12 enrolled patients underwent surgical resection following neoadjuvant treatment without delays or increased surgical complications. The median time interval between neoadjuvant treatment initiation and surgical resection was 45 days (range: 38-64 days). The ORR was 83.3% (10/12), and MPR (defined as ≤10% residual cancer cells in the surgical specimen) was achieved in 7 patients (58.3%). The most common adverse event was elevated creatine phosphokinase (50.0%), and one patient experienced a grade 3 adverse event (asymptomatic creatine phosphokinase elevation). Over a median follow-up period of 602 days (range: 300–826 days), three patients experienced recurrence, resulting in a 2-year EFS rate of 70.1%. Single-cell transcriptomic analysis revealed that ZNF683-positive CD8+ T cells expressing effector-related genes including Blimp-1, were significantly enriched in patients with MPR. In contrast, FOXP3-positive regulatory CD4+ T cells were enriched in patients without MPR. **Conclusions:** Neoadjuvant brigatinib was effective and safe in patients with resectable *ALK*-positive NSCLC. Single-cell transcriptomic analysis highlights the balance between effector and regulatory T cell programs as a critical determinant of pathologic response and the clearance of drug-tolerant and persister cancer cells. Clinical trial information: NCT05361564. Research Sponsor: None.

Genomic landscape of NSCLC with no targetable driver mutation among different races: An exploratory analysis of the AACR Project GENIE Database. First Author: Yazan Hamadneh, University of Jordan, Amman, Jordan

Background: Non-small cell lung cancer (NSCLC) is the most prevalent subtype of lung cancer, and it has been historically associated with poor prognosis. Fortunately, recent advancements in targeted therapies have significantly improved the prognosis of this disease. However, around 40% of those diagnosed with NSCLC do not harbor a targetable oncogenic driver mutation. This percentage is not consistent among all races, as those who are eastern Asian or from eastern Asian descent have higher rates of targetable drivers and a unique genomic signature that makes them distinct to others. Even though Asians have higher rates of targetable NSCLC, about 20% of Asians diagnosed with NSCLC do not harbor targetable mutations. This raises the need to study the genomics of non-targetable NSCLC in different races to understand the nature of the disease and have a more precise understanding of its behavior in different populations. **Methods:** The Association for Cancer Research Project Genomics Evidence Neoplasia Information Exchange (AACR-GENIE) cohort v17.0-public registry was queried to study patients diagnosed with non-targetable NSCLC (n = 16,866). Non-targetable NSCLC was defined as NSCLC that does not harbor targetable driver mutation for the following genes (EGFR, NTRK1/2/3, KRAS, BRAF, MET, RET, NRG1, ERBB2) The patients were divided into three racial groups: White (85.2%), Black (9.5%), and Asian (5.3%). cBioportal was used to study the genetic mutations and clinical differences between the groups. Black & White groups were merged due to the patients' disease having similar genomic features and the group was named non-Asian (94.7%). Chi-squared test was used to measure the relationship between mutation frequencies between different groups. **Results:** A higher proportion of Asian patients with non-targetable mutations were males compared to the non-Asian group (61.96% vs 47.54%,$P < 0.001$). The most significant differences were found in 4 genes: *KRAS* (Asian 21.16%, non-Asian 30.22%, $P < 0.001$), *STK11* (Asian 9.88%, non-Asian 17.58%, $P < 0.001$), *KEAP1* (Asian 13.61%, non-Asian 20.50% ,$P < 0.001$), and *TERT* (Asian 12.22%, non-Asian 7.56%, $P < 0.001$). There was a significant difference in the prevalence of *TP53* mutations (Asian 52.13%, non-Asian 56.31%, P = 0.0232). **Conclusions:** Among non-targetable driver mutations, KRAS, KEAP1, STK11 and TP53 were less frequent in the Asian group vs non-Asian, while TERT was higher in the Asian group. These differences can be explained by variation in carcinogens exposure (smoking rates) and the unique genetic profile between ethnicities. It supports the significance of ethnicity and racial background even in the era of precision medicine. Research Sponsor: None.

Trends in lung cancer epidemiology and mortality over 12 years: Socioeconomic and demographic disparities. First Author: Ali Shahbaz Baloch, John H. Stroger, Jr. Hospital of Cook County, Chicago, IL

Background: Lung cancer (LC), the most common cancer worldwide, remains a significant health burden with high rate of incidence and mortality in the United States and worldwide. Studies show that Black patients are 15% less likely to obtain an early diagnosis and have lower 5-year survival compared to White patients. **Methods:** The National Inpatient Sample database (2010–2021) was analyzed to identify adult hospitalizations with LC as a primary or secondary diagnosis. Multivariate logistic regression assessed epidemiologic and mortality trends and their association with demographic factors. **Results:** A total of 1,462,998 hospitalizations were identified with LC between 2020 and 2021. Of these, 196,225 patients (13.4%, 95% CI: 13.2–13.6) received palliative care. For metastatic LC admissions (n = 574,935), 21.5% (123,577) received palliative treatment. In 2010, the mean patient age was 67.6 years, which went up to 69.1 years in 2021. The percentage of LC patients with age over 65 years increased from 62.7% to 68.3%, whereas for patients under 45 and those between 45 and 65 years old, the percentage decreased from 2.0% to 1.4%, and 35.3% to 30.3%, respectively. The percentage of women diagnosed with lung cancer increased from 47.1% to 52.3% in 12 years. From 2010-2021, overall mortality from LC decreased (OR 0.96, 95% CI: 0.95–0.96). However, mortality was found to be lower in females (OR 0.80, 95% CI: 0.78–0.82, $p < 0.001$), and higher in Blacks than Whites (OR 1.07, 95% CI: 1.02–1.17, p = 0.003), and higher in those over 65 than in those between the ages of 18 and 45 (OR 1.11, 95% CI: 0.99–1.24, p = 0.063). Mortality rates were greater among Black people across all genders. While age-related differences were not significant among females, older age was linked to higher mortality among males (OR 1.15, 95% CI: 0.99–1.34, p = 0.066). Across all ethnicities, the death rate was consistently lower for females. Only White people showed substantial variations in age-related mortality, with older patients having higher mortality. Mortality rates within the lowest income bracket were the same for any age and ethnic group. Conversely, Black people had a higher mortality rate than White people in the highest income category (OR 1.24, 95% CI: 1.08–1.41, p = 0.002). **Conclusions:** Over the years, while LC mortality has decreased overall, disparities persisted with Black patients showing higher mortality compared to Whites, even in the higher income brackets. Increased mortality was associated with older age and male gender. These findings highlight the need for targeted interventions to address racial, gender, and socioeconomic disparities and to improve the survival of the identified high-risk population, especially minorities. Safety and efficacy of radiotherapy combined with anlotinib in locally advanced non-small cell lung cancer patients intolerant to concurrent chemoradiotherapy: Preliminary result of a phase II clinical trial. First Author: Yupei Yuan, Cancer Hospital Chinese Academy of Medical Sciences, Beijing, China

Background: Concurrent chemoradiotherapy (cCRT) is the standard treatment for patients with unresectable locally advanced non-small cell lung cancer (LA-NSCLC). However, parts of patients only receive sequential chemoradiotherapy (sCRT) due to various reasons. This phase II study aimed to improve the outcomes of patients receiving sCRT by combining anti-angiogenesis therapy (anlotinib) during radiotherapy course. **Methods:** Patients with unresectable LA-NSCLC intolerable to cCRT were prospectively enrolled. Induction chemotherapy with or without immunotherapy were given for 4-6 cycles. Then patients were prescribed oral 12 mg anlotinib up for 3 cycles during radiotherapy. The primary endpoint is 2-year overall survival (OS). Acute adverse events (AEs) were defined as any treatment related events from the start of radiotherapy until 3 months post-radiotherapy. The trial has been registered in ChiCTR.org as ChiCTR2200060712. **Results:** From October 2020 to January 2024, 41 patients with stage II-III NSCLC were enrolled. 11 (26.8%) patients received induction chemotherapy and 30 (73.2%) patients received induction chemotherapy combined with immunotherapy. The rate of grade 3–4 acute hematological AEs was 29.3% (12 cases). The rates of grade 3 hemoptysis were 2.4% (1 case), with no grade 4 hemoptysis reported. The incidence of grade 3–4 radiation pneumonitis was 9.8% (4/41). No grade 5 AEs occurred in all patients. The median follow-up was 16.8 (range: 7.0–50.7) months. 22 (53.7%) patients experienced recurrence, including 5 patients (12.2%) with primary-site recurrence and 7 patients (17.1%) with regional-node recurrence, 12 patients (29.3%) had distant metastases. The median progression-free survival (PFS) was 18.9 months (95% CI 14.6-23.2 months) and 1-year PFS was 77.2%. 9 patients (22.0%) died, including 3 patients who died of covid-19 pneumonia during the follow-up period, 1 patient who died of hydatid pneumonia due to long-term bed rest after cerebral infarction, and 4 patients who died of tumor-related diseases. The 1-year overall survival was 89.9%. **Conclusions:** Our data first showed the combination of thoracic radiotherapy and anti-angiogenesis therapy (anlotinib) is of safety, well controlled toxicity, and efficacy for inoperable LA-NSCNC patients who cannot tolerate cCRT. Clinical trial information: ChiCTR2200060712. Research Sponsor: Beijing Hope Run Special Fund of Cancer Foundation of China (LC2020A14); Chinese Academy of Medical Sciences (CAMS) Innovation Fund for Medical Sciences (2024-I2M-C&T-B-065).

Clinical characteristics and prognosis of pulmonary lymphoepithelioma-like carcinoma: A multicentre retrospective study. First Author: Zan Hou, Department of Radiation Oncology, Sichuan Clinical Research Center for Cancer, Sichuan Cancer Hospital & Institute, Sichuan Cancer Center, Affiliated Cancer Hospital of University of Electronic Science and Technology of China, Chengdu, Sichuan, China

Background: Pulmonary lymphoepithelioma-like carcinoma (PLELC) is a rare form of squamous lung cancer, and large-scale clinical studies on its clinical features, prognosis at different stages, and outcomes following treatments are limited. **Methods:** Patients with PLELC diagnosed by pathology from January 2009 to December 2023 at Sichuan Cancer Hospital and Sun Yat-sen University Cancer Centre were retrospectively analysed. Survival curves were estimated using the Kaplan-Meier method, Log-rank tests were used to compare differences between groups, and the Bonferroni method was used to correct the p-value when two-by-two comparisons between multiple groups were involved. **Results:** A total of 1,106 PLELC patients were included in the study. Most patients were non-smokers (73.4%), and brain metastasis was rare (0.3%). Tumor-specific characteristics showed a low incidence of EGFR mutation (0.6%) but a high prevalence of PD-L1 positivity (71.6%). The median follow-up duration was 31.6 months. The two-year overall survival (OS) rates for stage I, II, III, and IV patients were 99.4%, 97.7%, 92.7%, and 70.4%, respectively, while the five-year OS rates were 94.8%, 88.7%, 70.6%, and 37.8%, respectively. No statistically significant differences in progression-free survival (PFS) or OS were observed between surgery alone and surgery combined with adjuvant therapy in stage I and II patients, or between radiochemotherapy and combined surgery-radiochemotherapy in stage IIIA and IIIB patients. However, in stage IV patients, chemotherapy combined with immunotherapy resulted in significantly better PFS and OS compared to chemotherapy alone. **Conclusions:** PLELC patients, mostly non-smokers with rare brain metastasis and high PD-L1 positivity, show favorable prognosis, but further research is needed to refine its optimal treatment strategies. Research Sponsor: None.

PFS and OS in patients with different stages.

Stage	Number of cases	Median PFS (months)	2-year PFS	95% CI	5-year PFS	95% CI	Median OS (months)	2-year OS	95% CI	5-year OS	95% CI

Neoadjuvant immunotherapy and surgery in patients with stage IIIB-IIIC (N3) non-small cell lung cancer. First Author: Wen-Yu Zhai, Sun Yat-sen University Cancer Center, Guangzhou, Guangdong, China

Background: Stage IIIB-IIIC (N3) non-small cell lung cancer (NSCLC) is generally seen as unresectable, and Durvalumab following concurrent chemoradiotherapy (CCRT) is the standard of care for these patients. The use of immune checkpoint inhibitor (ICI) in neoadjuvant therapy has resulted in unprecedented rates of pathological response and lymph node downstaging, which has made resecting previous unresectable disease possible. However, it remains uncertain whether certain N3 patients may derive survival benefit from surgery after neoadjuvant immunotherapy. **Methods:** This multicenter retrospective study included patients with cN3 NSCLC who received inducing immunochemotherapy and completed surgery. As a comparison, patients with cN3 NSCLC who received ICI following CCRT, ICI plus CCRT, and CCRT following inducing immunochemotherapy were also included. 1:1 Propensity score matching (PSM) was implemented to balance important baseline characteristics included gender, age, smoking history, histologic type, differentiated degree, cT stage between patients with surgery and radiotherapy. Log-rank test was used to compared progression-free survival (PFS). **Results:** The median follow-up time of 82 patients with surgery and 114 patients with radiotherapy was 28.1 months and 21.8 months, respectively. In patients with surgery, 29 patients reach complete pathological response (pCR) and 53 patients reached node clearance. After PSM, 74 patients with surgery and 74 patients with radiotherapy showed balanced baseline characteristics. Before PSM, patients with surgery displayed a significant advantage in median PFS (24.6 months vs 21.3 months, p=0.040) but this advantage disappeared after PSM (31.3 months vs 30.8 months, p=0.132). In post-treatment subgroup analyses, patients reached pCR had better PFS than patients with radiotherapy (median PFS not reach vs 30.8 months, p=0.001). In addition, patients reached node clearance also had better PFS than patients with radiotherapy (median PFS not reach vs 30.8 months, p=0.010). In pre-treatment subgroup analyses, surgery did not outperform radiotherapy in male or female patients, smokers or nonsmokers, squamous or non-squamous carcinoma and poorly differentiated carcinoma. In patients with high or moderately differentiated tumors, patients with surgery had better PFS than patients with radiotherapy (median PFS not reach vs 13.2 months, p=0.001). **Conclusions:** In patients with cN3 NSCLC, surgery after neoadjuvant immunochemotherapy do not transcend ICI with CCRT in PFS. Only patients with high or moderately differentiated tumors, or reached pCR, node clearance after surgery have better PFS than patients with radiotherapy. Prospective clinical is needed to evaluate the benefit of surgery after neoadjuvant immunotherapy for cN3 NSCLC. Research Sponsor: None.

Neoadjuvant durvalumab (D) + chemotherapy (CT) + novel anticancer agents and adjuvant D ± novel agents in resectable non-small-cell lung cancer (NSCLC): Updated outcomes from NeoCOAST-2. First Author: Tina Cascone, Department of Thoracic/Head and Neck Medical Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Perioperative CT + immune checkpoint inhibitor therapy has improved outcomes in resectable NSCLC but most patients (pts) still do not experience pathological complete response (pCR) and long-term benefit. We report final pCR rates, ongoing circulating tumor DNA (ctDNA) findings, and updated safety data from Arms 1/2/4 of NeoCOAST-2 (NCT05061550), a phase 2 platform study evaluating neoadjuvant and adjuvant D ± novel agent-based combinations in pts with untreated Stage IIA–IIIB resectable NSCLC. **Methods:** Pts were stratified by PD-L1 expression (<1% vs ≥1%) and randomized to neoadjuvant D + platinum-doublet CT + oleclumab (anti-CD73 monoclonal antibody [mAb]) then adjuvant D + oleclumab (Arm 1), neoadjuvant D + platinum-doublet CT + monalizumab (anti-NKG2A mAb) then adjuvant D + monalizumab (Arm 2), or neoadjuvant D + single-agent platinum CT + Dato-DXd (TROP2-directed antibody-drug conjugate [ADC]) then adjuvant D (Arm 4). Neoadjuvant therapy was given Q3W for 4 cycles. Adjuvant therapy was given for up to 1 year or until disease progression. Primary endpoints were pCR rate by blinded independent pathology review and safety and tolerability. Key secondary endpoints included major pathological response (mPR) rate, ctDNA clearance, and feasibility of surgery. **Results:** As of Dec 19 2024, 202 pts were randomized (Arms 1/2/4, N=76/72/54). Among dosed pts with confirmed NSCLC, pCR and mPR rates were numerically higher in Arm 4 vs Arms 1/2 overall and in pts with a PD-L1 TPS <1% or ≥1% (Table). Rates of ctDNA clearance in the neoadjuvant period were higher in Arm 4 vs Arms 1/2, and higher in pts with pCR vs non-pCR and with mPR vs non-mPR across arms. Among dosed pts, 69/74 (93.2%) pts in Arm 1, 66/71 (93.0%) pts in Arm 2, and 51/54 (94.4%) pts in Arm 4 underwent surgery; overall, grade ≥3 treatment-related adverse events occurred in 36.5%, 40.8%, and 20.4% of pts, respectively. **Conclusions:** All arms show that novel perioperative combinations may improve pCR rates and maintain tolerability and feasibility of surgery in resectable NSCLC. The final analysis of pCR and mPR rates in Arm 4 is the first for an ADC in this setting and confirms the encouraging efficacy and manageable safety profile of D + CT + Dato-DXd. Presurgical ctDNA clearance is associated with pathological responses. Clinical trial information: NCT05061550. Research Sponsor: AstraZeneca.

Initial treatment and survival outcomes for early-stage NSCLC in Veterans: Insights from cancer cube data. First Author: Madison Panell, Albany Medical Center Hospital, Albany, NY

Background: Non-small cell lung cancer (NSCLC) accounts for 85% of lung cancer cases and remains the leading cause of cancer-related deaths in the United States. Early-stage NSCLC (Stage I) is potentially curable, with surgical resection as the standard of care. However, for patients who are medically inoperable or decline surgery, stereotactic ablative radiotherapy (SABR) is an alternative. Prior studies suggest that demographic factors, including age, race, and sex, may influence treatment decisions and outcomes, particularly among veterans with a high burden of comorbidities. This study examines treatment patterns and survival outcomes for veterans with Stage I NSCLC using data from the Veterans Affairs Cancer Care Cube. **Methods:** This retrospective study included veterans diagnosed with Stage I NSCLC between 2000 and 2023. Patients were categorized by initial treatment (surgery or radiation therapy) and stratified by demographics (age, race/ethnicity, gender, and ECOG status). Survival outcomes were analyzed using Kaplan-Meier curves, log-rank tests, and Cox proportional hazards models to control for confounding variables. Logistic regression identified predictors of treatment choice. Patients with incomplete data or advanced-stage disease were excluded. Statistical analyses were conducted using R and Python. **Results:** Surgery demonstrated superior survival outcomes across all demographics. ▪ Age: Surgery offered significantly higher 5-year survival rates in younger (40–59 years, 41.77–54.32%) and older (>70 years, 42.32%) patients compared to radiation (0–24.68%). ▪ Race: Surgery utilization was consistent across racial groups, with the highest 5-year survival in Asian patients (60.87%). Native Hawaiian/Pacific Islander (NHPI) patients had the lowest survival for both treatments, highlighting disparities in care. ▪ Sex: Women were more likely to undergo surgery (71.79%) and had better survival outcomes than men, similar to trends seen in non-veteran populations. ▪ ECOG Status: Surgery remained the preferred treatment across all ECOG scores, though long-term survival declined with higher ECOG scores. ▪ Exposure Type: Agent Orange and asbestos exposure were associated with the best survival outcomes following surgery, while radiation offered limited long-term benefits regardless of exposure. **Conclusions:** Surgery consistently yields better survival outcomes than radiation therapy for veterans with early-stage NSCLC, even among subgroups with higher comorbidity burdens. Demographic and exposure-related disparities highlight the need for tailored interventions to optimize care. These findings inform clinical decision-making and emphasize the importance of equitable access to curative treatments in this vulnerable population. Research Sponsor: None.

Survival of induction aumolertinib followed by aumolertinib and concurrent radiotherapy (RT) in unresectable *EGFR*-mutated stage III NSCLC: Final analysis of the phase III ADVANCE trial and real-world data. First Author: Nan Bi, National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital & Shenzhen Hospital, Beijing, China

Background: The LAURA trial established concurrent chemoradiotherapy (cCRT) followed by consolidation targeted therapy as the standard for unresectable stage III EGFR-mutated non-small cell lung cancer (NSCLC). The phase III ADVANCE trial (ChiCTR2000040590) evaluated induction aumolertinib followed by aumolertinib and concurrent RT versus cCRT. **Methods:** Eligible patients (pts) aged 18-75 with unresectable stage III non-squamous NSCLC and centrally confirmed *EGFR* exon 19 deletion or L858R mutation were randomized 1:1 to receive aumolertinib+RT (experimental) or cCRT (control). The primary endpoint was progression-free survival (PFS), assessed by investigator. The accrual target was 98 pts, aiming for a hazard ratio (HR) of 0.5 (80% power, one-sided α =0.025). A real-world database (RWD; NCT04304638) from 6 trial sites was developed to validate long-term survival outcomes for pts treated with RT and third-generation EGFR TKIs. **Results:** Between March 2021 and March 2024, 43 eligible pts were randomized (24 to experimental, 19 to control) following early termination due to feasibility issues. At a median follow-up of 25.5 months (mo), the experimental group showed significantly longer PFS (34.0 vs. 7.8 mo; HR 0.15, 95% CI 0.06–0.24). Median overall survival (OS) was not reached in the experimental group but was 30.5 mo in the control (p = 0.17). The control group reported more neutropenia (52.6% vs. 16.7%, p = 0.01) and nausea (26.3% vs. 0.0%, p = 0.03), while quality of life was better in the experimental group. Among 18 experimental and 16 control pts completing RT without progression, the experimental group had significantly longer PFS (not reached vs. 12.8 mo; HR 0.05, 95% CI 0.01–0.16) and OS (HR 0.09, 95% CI 0.01–0.68). From 2012 to 2024, 125 consecutive pts were included in the RWD cohort: 31 in RT + TKI, 33 in CRT + TKI, and 61 in CRT. At a median follow-up of 32.7 mo, PFS and OS were significantly longer in RT + TKI and CRT + TKI compared to CRT (PFS: not reached vs. 36.7 vs. 9.8 mo; OS: not reached vs. not reached vs. 48.9 mo; p < 0.001). No significant differences in PFS and OS were observed between RT + TKI and CRT + TKI (p=0.59 and 0.80, respectively). **Conclusions:** The ADVANCE trial and RWD demonstrate that induction EGRF TKI followed by TKIs and RT delays progression and improves survival in unresectable stage III EGFR-mutated NSCLC. Clinical trial information: ChiCTR2000040590. Research Sponsor: None.

A prospective, single-arm, phase II study to evaluate the efficacy and safety of perioperative tislelizumab in resectable non-small-cell lung cancer (NSCLC). First Author: Daqiang Sun, Department of Thoracic Surgery, Tianjin Chest Hospital, Tianjin, China

Background: Perioperative immunotherapy has emerged as a promising strategy for the treatment of resectable non-small cell lung cancer (NSCLC). This study was designed to evaluate the efficacy and safety of a comprehensive perioperative regimen, comprising neoadjuvant tislelizumab in combination with chemotherapy, followed by surgical resection and adjuvant tislelizumab, in patients with resectable stage II-IIIB NSCLC. **Methods:** This open-label, single-arm, phase 2 trial was designed to enroll patients (pts) with resectable stage II-IIIB (N2) NSCLC (AJCC 8th edition). Participants received neoadjuvant therapy consisting of intravenous tislelizumab in combination with chemotherapy administered every 3 weeks for 2 to 4 cycles prior to surgery, and 0 to 2 cycles following surgery (totaling up to 4 cycles of perioperative therapy). This was followed by adjuvant tislelizumab monotherapy administered Q3W for 1 year. The primary endpoint of the study was the major pathological response (MPR) rate. Secondary endpoints included the pathological complete response (pCR) rate, objective response rate (ORR), event-free survival (EFS), overall survival (OS), and safety. **Results:** Between February 2023 and June 2024, a total of 30 patients were enrolled. The median age was 64 years (range: 43-77 years), with 25 males (83.3%). Twenty-eight patients (93.3%) had squamous cell carcinoma, while 2 patients (6.7%) had adenocarcinoma. In terms of disease stage, 12 patients (40%) were at stage II, and 18 patients (60%) were at stage III. For treatment, 23 patients (76.7%) received three cycles of neoadjuvant immunotherapy, and 7 patients (23.3%) received four cycles. The objective response rate (ORR) was 53.3% and surgical resection was performed in 27 patients (90%), with a complete (R0) resection rate of 96.3% (26/27). A major pathological response (MPR) was observed in 53.3% (16/30) of patients, and the pathological complete response (pCR) rate was 33.3%(10/30). With a median follow-up of 12.1 months, the median event-free survival (EFS) and overall survival (OS) data were not yet mature. In the intention-to-treat (ITT) population, the 1-year EFS rate and OS rate were 92.3% and 96.7%, respectively. During the neoadjuvant phase, the incidence of treatment-related adverse events (TRAEs) of any grade was 70%, with grade 3-4 adverse reactions occurring in 13% of patients. **Conclusions:** Perioperative tislelizumab achieved notable major pathological response (MPR) and pathological complete response (pCR) rates, while also demonstrating feasible surgical resection and manageable toxicity in patients with stage II-IIIB non-small cell lung cancer (NSCLC). The current data align with the initial findings and underscore the need for continued follow-up to further validate these outcomes. Clinical trial information: ChiCTR2300068140. Research Sponsor: None.

Characteristics, treatment patterns, and outcomes of HIV-associated lung cancer. First Author: Tina Roy, Georgetown Lombardi Comprehensive Cancer Center, Washington, DC

Background: Lung cancer is a leading cause of cancer-related mortality in people with HIV (PWH). Prior studies have shown worse survival in PWH with lung cancer compared to people without HIV (PWoH) with lung cancer. However, it is unclear whether this difference in survival is due to differences in tumor biology, socioeconomic factors, and/or treatment disparities. **Methods:** This is a retrospective study of PWH and lung cancer identified from 2005 - 2024 within MedStar Health serving a major urban area with a high burden of HIV. Age and race matched PWoH and lung cancer were used as a control group. Clinical, pathological, and molecular characteristics, along with social determinants of health, treatment patterns, and outcomes were collected. Factors associated with survival and receipt of stage-appropriate treatment were determined using multivariable analysis. **Results:** We analyzed 148 PWH with lung cancer and 127 PWoH with lung cancer. The median age at lung cancer diagnosis among PWH was 61.8 years, with a statistically significant trend of increasing age over the study period. PWH were disproportionately male (65%), unmarried (62%), had government provided health insurance (79%), and had more comorbidities compared to the control group. The stage at diagnosis was similar between both groups, with 68% of PWH and 66% of PWoH diagnosed at stage III and IV, and no evidence of stage migration to earlier stage observed over the study period. Similar rates of KRAS/EGFR/ALK/BRAF alterations were observed. Stage-appropriate treatment was received by 70% of PWH and 82% of PWoH (p=0.057). Median OS (mOS) in stages I and II was 5.8 years in PWH and 8.8 years in PWoH (p=0.22). Across all stages, mOS was 1.5 years in PWH and 1.9 years in PWoH (p=0.23); the difference in mOS was attenuated when comparing patients who received stage-appropriate treatment (p=0.52). Among PWH with lung cancer, factors associated with improved survival included receipt of chemotherapy (HR 0.35, p$<$0.001) and immunotherapy (HR 0.53, p=0.042), and higher CD4 count ($>$400 cells/mm3) at diagnosis (p=0.013). Factors that contributed to whether PWH received stage appropriate treatment were based on performance status, with an ECOG $\geq$3 significantly associated with lower likelihood of receiving treatment (OR 0.01, p=0.003). Among PWH, 96 were eligible for lung cancer screening per the USPSTF criteria, but only 7 patients (7.3%) were diagnosed through a screening CT scan. **Conclusions:** Decreased CD4 count, poor performance status at presentation, and advanced disease stage at diagnosis may contribute to worse outcomes in PWH with lung cancer. The lower rate of diagnosis through lung cancer screening and the potential number of eligible patients at the time of lung cancer diagnosis highlight missed opportunities for early detection in PWH. Targeted interventions to address barriers to timely diagnosis and stage-appropriate treatment could improve survival outcomes in PWH. Research Sponsor: U.S. National Institutes of Health.

Impact of lymph node characteristics on clinical outcomes in clinical N2 non-small cell lung cancer patients treated with chemoradiotherapy: Single- vs. multiple-stations, bulky vs. non-bulky and discrete vs. infiltrative. First Author: Yuki Kato, National Cancer Center Hospital East, Kashiwa, Japan

Background: Stage III, N2 non-small cell lung cancer (NSCLC) is a heterogeneous disease with various patterns of lymph node metastasis. Recently, chemoradiotherapy followed by immune-checkpoint inhibitors (ICIs) and neoadjuvant chemotherapy with ICIs followed by surgery have been developed as treatment strategies for clinical N2 (cN2) NSCLC. However, the difference of clinical outcomes according to cN2 subclassification, such as single- vs. multiple-stations, non-bulky vs. bulky and discrete vs. infiltrative, in NSCLC patients treated with chemoradiotherapy are still unclear. **Methods:** The clinical outcomes in cN2 NSCLC patients who received chemoradiotherapy at our institution were retrospectively investigated and compared according to cN2 subclassification; single- vs. multiple-stations, non-bulky vs. bulky (short-axis diameter$\geqq$2cm) and discrete vs. infiltrative. **Results:** A total of 146 cN2M0 NSCLC patients received chemoradiotherapy from May 2018 to December 2023, and 98 (67%) patients received durvalumab after chemoradiotherapy. As of January 2025, the median follow-up was 20.9 months. The characteristics of the patients were showed that the median age was 71 (range 40-88) year-old, 77% were male, 89% had smoking history, 99% were ECOG PS 0-1, 44% had histology of adenocarcinoma and 23% were PD-L1 (22C3) $\geq$50%. Among them, 69 patients (47%) had single-station N2, 90 patients (62%) had non-bulky N2, and 81 patients (55%) had discrete N2. There was no significant difference of the progression-free survival (PFS) in the patients who received chemoradiotherapy between single- vs. multiple-stations (median: 17.5 vs. 12.5 months, HR [95%CI]: 0.90 [0.60–1.37], *P* = 0.63), non-bulky vs. bulky (median: 15.6 vs. 12.3 months, HR [95%CI]: 0.98 [0.64–1.50], *P* = 0.92), and discrete vs. infiltrative (median: 18.2 vs. 12.0 months, HR [95%CI]: 0.72 [0.47–1.08], *P* = 0.11). Similarly, there was no significant difference in the overall survival (OS) in the patients who received chemoradiotherapy between single- vs. multiple-stations (median: NR vs. NR months, HR [95%CI]: 1.01 [0.59–1.72], *P* = 0.97), non-bulky vs. bulky (median: 51.4 vs. NR months, HR [95%CI]: 1.06 [0.61–1.84], *P* = 0.84), and discrete vs. infiltrative (median: 51.4 vs. NR months, HR [95%CI]: 0.89 [0.52–1.52], *P* = 0.67). In the patients who received durvalumab after chemoradiotherapy, there was no significant difference in the PFS and OS according to cN2 subclassification. The time to recurrence in the radiated field showed no significant difference between single- vs. multiple-stations, non-bulky vs. bulky and discrete vs. infiltrative. **Conclusions:** Lymph node characteristics have no impact on clinical outcomes in cN2M0 NSCLC patients treated with chemoradiotherapy. Research Sponsor: None.

Outcomes with neoadjuvant chemotherapy and/or osimertinib in patients with *EGFR*-mutant resectable non-small cell lung cancers. First Author: Prashasti Agrawal, Memorial Sloan Kettering Cancer Center, New York, NY

Background: There are currently no *EGFR*-tyrosine kinase inhibitors approved for neoadjuvant treatment of resectable *EGFR*-mutant non-small cell lung cancers (NSCLC). The phase III multi-center trial NeoADAURA aims to evaluate neoadjuvant osimertinib with or without chemotherapy versus chemotherapy alone in patients with resectable *EGFR*-mutant NSCLC. The primary endpoint of NeoADAURA is major pathologic response (MPR) rate. The statistical assumptions for the chemotherapy control arm were derived from the literature in NSCLC but not specific to an *EGFR*-mutant population. The true rates of pathologic response to neoadjuvant chemotherapy in patients with *EGFR*-mutant NSCLC are unknown. We report a multi-institutional analysis of surgical and pathologic outcomes in patients with resectable *EGFR*-mutant NSCLC treated with neoadjuvant therapies. **Methods:** This retrospective study evaluated patients at Memorial Sloan Kettering Cancer Center and Dana Farber Cancer Institute with stage II-IIIB N2 (AJCC v8) NSCLC with *EGFR* exon 19 deletions, exon 21 L858R mutations, or exon 18 G719X mutations who received neoadjuvant platinum-based doublet chemotherapy and/or neoadjuvant off-label osimertinib and underwent surgical resection with curative intent. Clinical characteristics, tumor next-generation sequencing results, R0 resection rate, pathologic complete response (pCR) rate, MPR rate, and downstaging rate were evaluated. **Results:** 51 patients with *EGFR*-mutant NSCLC met eligibility criteria and were treated with neoadjuvant osimertinib alone (N=23, 45.1%), platinum-based doublet chemotherapy alone (N=18, 35.3%), or osimertinib and platinum-based doublet chemotherapy (N=10, 19.6%). R0 resection rates were 91.3% with osimertinib, 72.2% with chemotherapy, and 90% with osimertinib and chemotherapy. Rates of pCR were 17.4% with osimertinib, 0% with chemotherapy, and 0% with osimertinib and chemotherapy. Rates of MPR were 43.5% with osimertinib, 0% with chemotherapy, and 10% with osimertinib and chemotherapy. Pathologic tumor downstaging occurred in 47.8% with osimertinib, 44.4% with chemotherapy, and 40% with osimertinib and chemotherapy; pathologic lymph node downstaging occurred in 34.8% with osimertinib, 27.8% with chemotherapy, and 40% with osimertinib and chemotherapy. Among the 4 patients with pCR, 3 had stage IIIA and 1 had stage IIIB adenocarcinomas at diagnosis; three had ex.19 deletions and 1 had an ex.21 L858R mutation. The most common co-occurring tumor genomic alterations were in *TP53* (49%), *CDKN2A/B* (14%), and *RB1* (10%). **Conclusions:** In this real-world multi-institution series, we did not observe pCR or MPR in patients with *EGFR*-mutant NSCLC treated with neoadjuvant chemotherapy. EGFR inhibitors may play an important role in the preoperative management of *EGFR*-mutant lung cancer. Research Sponsor: National Cancer Institute; P30 CA008748.

Leveraging electronic medical records for early lung cancer diagnosis: An evaluation of the C the Signs AI cancer prediction platform using the Mayo data platform. First Author: Seema Dadhania, Imperial College, London, London, United Kingdom

Background: In the US, only 27.4% of lung cancer cases are diagnosed early, with 5-year survival rates of 63% for localized and 27% for late-stage cancers. Despite recommendations since 2012 for screening high-risk individuals with low-dose CT, uptake has been limited, and most lung cancer diagnoses occur after symptoms appear. Similarly, chest x-rays, while commonly used as an initial test to investigate patients with symptomatic suspected lung cancer, have demonstrated limited sensitivities between 50-70% and specificities over 80%. Symptoms often overlap with common conditions, making detection challenging, and studies have identified median delays of 187 days from symptom onset to diagnosis. This prolonged interval presents an opportunity for improvement. This study examines the use of the AI cancer prediction platform, C the Signs, to passively screen for lung cancer by leveraging electronic medical records (EMRs) for early lung cancer detection. **Methods:** Utilizing the Mayo data platform, we conducted a retrospective analysis of EMR data from 894,409 patients, including 7,395 individuals diagnosed with lung cancer. We assessed the sensitivity and specificity of the AI cancer prediction platform, in identifying patients at risk of lung cancer. Additionally, we compared the timing of lung cancer risk identification by the AI cancer prediction platform with the timing of diagnoses made by physicians to determine whether the platform enabled earlier detection. **Results:** The AI cancer prediction platform detected 6,749 cases of lung cancer among the 7,395 individuals diagnosed, resulting in an early detection sensitivity of 91.5%. The platform identified 423,249 false positives among the 887,014 patients who did not have lung cancer, leading to a specificity of 52.3%. Additionally, it identified the risk of a lung cancer diagnosis in 26.6% of patients up to five years earlier than the diagnoses made by physicians. **Conclusions:** This study highlights the potential of leveraging EMR data and AI platforms like C the Signs to enhance early lung cancer detection. Chest X-rays, with their reduced sensitivity for early-stage lesions and reliance on symptom-driven use, remain limited as a screening tool. In contrast, the AI platform achieved a sensitivity of 91.5% and identified 26.6% of cases up to five years earlier than traditional diagnoses. These findings underscore the promise of AI-based platforms as supplementary tools for improving early detection and facilitating timely intervention to enhance patient outcomes. Survival impact of lymphocytopenia during chemoradiation in locally advanced NSCLC patients treated with adjuvant durvalumab. First Author: Monika Satoskar, The Ohio State University, Columbus, OH

Background: Adjuvant durvalumab has transformed the treatment landscape for patients with locally advanced non-small cell lung cancer (NSCLC) following concurrent chemoradiotherapy (CRT). However, in the landmark PACIFIC trial, only one-third of patients achieved long-term disease-free survival, underscoring the need for additional biomarkers to guide patient selection. Lymphocytopenia, a common side effect of CRT, has been associated with poor responses to immunotherapy. In this study, we investigate the incidence, degree, and timing of CRT-induced lymphocytopenia and association with survival among patients receiving durvalumab adjuvant therapy. **Methods:** This retrospective study included patients with unresectable Stage III NSCLC who underwent CRT followed by at least one dose of durvalumab at The Ohio State University. Clinical data was extracted through review of electronic medical records. Absolute lymphocyte count (ALC) was collected at baseline prior to CRT initiation, the lowest ALC during CRT, and 30 days post-CRT. Lymphocytopenia was classified using the Common Terminology Criteria for Adverse Events V5. Overall survival (OS) was calculated from CRT initiation to date of death or loss to follow-up. Cox proportional hazards model was used to evaluate the associations of baseline, lowest, post-CRT ALC, as well as the percentage change in ALC from baseline to lowest (relative ALC change) with OS. **Results:** This study included 118 patients with a mean age of 63.9 years (SD: 9.7), who received durvalumab within 12 weeks of completing CRT. Baseline characteristics were obtained (Table 1). Median baseline ALC was 1645 cells/μL (IQR: 1340–2190), dropping to 300 cells/μL (IQR: 200–450) during CRT and 755 cells/μL (IQR: 510–1040) post-CRT. Grade $\geq$3 lymphocytopenia occurred in 97 patients (82.2%) during CRT. Baseline, lowest, and post-CRT ALC were not associated with OS, but the relative decline in ALC from baseline was strongly associated. A 10% decrease in ALC from baseline was associated with a 48% increased risk of death (HR = 1.48; 95% CI: 1.14–1.91; $p < 0.01$) after adjusting for age, ECOG performance status (PS), histology, PD-L1 expression, chemotherapy regimen, and RT duration. **Conclusions:** Dynamic change in ALC from pre-treatment baseline to nadir during CRT is a strong prognostic indicator for OS in patients with advanced NSCLC receiving adjuvant durvalumab. Studies are warranted to elucidate the underlying mechanisms. Additionally, this highlights lymphocytopenia as a potentially modifiable side effect, which could be addressed with myeloprotective treatment. Research Sponsor: None.

Lung cancer screening in high-risk never-smokers with artificial intelligence (LC-SHIELD study). First Author: Molly SC Li, The Chinese University of Hong Kong, Hong Kong, China

Background: Approximately 50% of Asian lung cancer patients are never smokers. Screening with low-dose computed tomography (LDCT) of thorax in high-risk never-smokers with family history may reduce mortality. However, implementation of LDCT screening in Asia faces barriers including high cost and shortage of radiologists. Artificial intelligence (AI) programmes designed for automated detection of lung nodules may serve as first-readers, facilitating cost reduction and improving efficiency. LC-SHIELD is a prospective study designed to evaluate the feasibility and clinical utilization of AI-based lung cancer screening in a high-risk never smoker population. **Methods:** This study enrolled never smokers, defined as individuals with a lifetime exposure to fewer than 100 cigarettes, aged between 50 and 75 years, with at least one first-degree relative diagnosed with lung cancer. Participants underwent LDCT of thorax, and the scans were analyzed using LungSIGHT, an AI-assisted software fine-tuned with local data for lung nodule detection. Nodules with a maximum diameter of $\geq$5mm are classified as AI-positive and referred to radiologists for formal reporting and workup. As a gold standard all scans are retrospectively reviewed by radiologists who are blinded to the LungSIGHT results. Primary endpoint is baseline detection rate of early stage lung cancer and secondary endpoints include sensitivity and specificity of LungSIGHT in nodule detection compared to radiologist assessment. The target sample size is 1000 and here we report the interim analysis. **Results:** Between July and December 2024, total of 405 subjects were enrolled. Median age was 61 (range 50-75) and 266 (66%) were female. Three patients were diagnosed with invasive adenocarcinoma (lung cancer detection rate 0.7%, all EGFR mutation positive) and 12 individuals (3.0%) had suspicious lung nodules requiring further diagnostic workup. Testing of AI algorithm was based on the first 181 subjects. At the testing phase, 78 (43%) were AI-positive with sensitivity and specificity at 81% and 85%, respectively. In the validation cohort (n=224), 86 (39%) were AI-positive with sensitivity and specificity at 73% and 77%, respectively. **Conclusions:** AI assisted first-reader of screening LDCT in high-risk never smokers is feasible. LungSIGHT showed high sensitivity and specificity in lung nodule detection using standard radiologist assessment as gold standard comparator. Recruitment for the study is ongoing. Clinical trial information: NCT06295497. Research Sponsor: AstraZeneca.

Enhancing early detection of lung cancer: Methylation anchor probe for low-signal enrichment (MAPLE). First Author: Wenzhao Zhong, Guangdong Lung Cancer Institute, Guangdong Provincial People's Hospital (Guangdong Academy of Medical Sciences), Southern Medical University, Guangzhou, China

Background: Non-Small Cell Lung Cancer (NSCLC) is among the most lethal cancers worldwide. Lung adenocarcinoma (LUAD) and lung squamous cell carcinoma (LUSC) represent approximately 80% of NSCLC cases in China. While low-dose computed tomography (LDCT) is widely used for annual screening, its high false-positive rate highlights the need for more accurate early detection methods. Circulating tumor DNA (ctDNA) analysis provides a promising non-invasive alternative for early cancer detection. However, conventional hybrid capture methods lack the sensitivity to detect low-abundance ctDNA in early-stage cancers. Previously, we developed ultra-sensitive Methylation Anchor Probes for Low signal Enrichment (MAPLE) that significantly improved the detection of colorectal cancer (Xie et al., 2024). Here, we have advanced this technology to develop a novel assay to enhance early detection of NSCLC and distinguish LUAD from LUSC, paving the way for more personalized treatment strategies. **Methods:** NSCLC-related methylation haplotypes were identified using in-house whole-genome bisulfite sequencing data from lung cancer tumor tissues and paired normal adjacent tissues (NATs). Haplotype selection was performed by filtering for those with a frequency difference greater than 0.1 between tumor and NATs and a frequency below 0.001 in healthy cfDNA, resulting in a panel targeting 12,904 methylation haplotypes. The panel was evaluated on 234 clinical samples, including 44 LUSC patients, 43 LUAD patients, 19 individuals with chronic obstructive pulmonary disease (COPD), and 128 healthy controls. All cfDNA samples underwent bisulfite conversion, library preparation, hybrid capture using the custom panel, and next-generation sequencing (NGS). The dataset was split into a 75% training set and a 25% validation set. A primary classifier was developed to identify cancer samples, and true positives were further analyzed with a subtype classifier to differentiate between LUAD and LUSC. Model performance was assessed for robustness using 40 resampling processes. **Results:** The methylation panel combined with a machine-learning classifier achieved an AUC of 0.93 (0.93–0.93) in the training set and 0.91 (0.91–0.92) in the validation set in the detection of NSCLC. Furthermore, the assay effectively distinguished COPD patients from cancer cases, with a specificity of 92.5% (90.0%–95.9%). Additionally, the subtype classifier accurately differentiated LUAD from LUSC with 100% accuracy. **Conclusions:** We developed a technique to specifically enrich NSCLC-related methylation haplotypes, improving sensitivity for early-stage NSCLC detection. The assay demonstrated strong performance in accurately distinguishing LUAD from LUSC, highlighting its potential to guide treatment decisions. The MAPLE platform is versatile and shows promise for broader applications in cancer early detection. Research Sponsor: Shanghai Xiaohe Medical Laboratory Co., Ltd.

Hypofraction radiotherapy followed by immune checkpoint inhibitors for locally advanced non-small cell lung cancer: A phase I/II trial. First Author: Xiao-yang Li, Anhui Provincial Hospital, Hefei, China

Background: To explore the safety and primary efficacy of hypofraction radiotherapy followed by immune checkpoint inhibitors (ICI) for stage III locally advanced non-small cell lung cancer patients. **Methods:** Patients with stage III non-small cell lung cancer were enrolled to receive hypofraction radiotherapy (48-64Gy/12-16f) followed by ICI maintenance treatment. After the completion of radiotherapy, one-year maintenance ICI treatment was encouraged. The primary objective was to explore the toxicity of hypofractionated radiotherapy with immunotherapy. The secondary objective was survival outcome. We also performed multicolor immunohistochemistry (mIHC) of tumor tissues, peripheral blood single-cell RNA sequencing (scRNA-seq) and flow cytometry to characterize the immune microenvironment of enrolled patients. **Results:** According to the inclusion criteria, totally 51 patients were enrolled from June 2021 to January 2024. The median follow-up time was 28 months (8-22 months). After the completion of hypofractionated radiotherapy, 13 patients received no or less than 5 cycles of immunotherapy. All kinds of radiation-induced toxicity (≥ grade 3) occurred in 17 patients (33.3%). The rate of over grade 3 PBT injury and over grade 3 radiation-induced pneumonitis was 3.9% and 17.6% respectively, resulting in 11.8% of over grade 3 cough and 9.8% of over grade 3 dyspnea. No over grade 3 radiation-induced esophagitis occurred. The median progression-free survival (PFS) was 28 months with 1-year PFS rate of 72.1% and 2-year PFS rate of 54.7%. The median overall survival (OS) was not reached with 1-year OS rate of 84.0% and 2-year OS rate of 61.6%. In subgroup analysis, high-dose (60-64Gy/15-16f) group did not demonstrate survival benefit to low-dose group (48-52Gy/12-13f), but more grade III and higher toxicity (41.2% vs. 17.6%, p=0.002). In addition, mIHC, scRNA-seq and flow cytometry showed an increase in the number of anti-tumor immune cells in the treated tumor tissues, as well as an expansion of T-cell clones with cytotoxic T-cell phenotype and enhanced anti-tumor activity of neutrophils in the peripheral blood. **Conclusions:** Hypofraction radiotherapy (48-64 Gy/12-16f) with ICI treatment was safe and efficient. But the use of high dose (over 60Gy/15f) should be alerted due to its toxicity. Further, hypofraction radiotherapy can provide patients with an immune-activated tumor microenvironment that makes them respond better to immunotherapy. Clinical trial information: NCT05269485. Research Sponsor: NSFC 82102821.

Clinical outcomes with definitive surgery or radiotherapy after neoadjuvant immunochemotherapy in stage II-III NSCLC: Full cohort pragmatic analysis. First Author: Jie He, National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China

Background: Recently, several landmark randomized controlled trials on neoadjuvant immunochemotherapy (NIC) have significantly changed the treatment paradigm for locally advanced NSCLC. However, 8.8-19.0% of patients (pts) receiving NIC did not undergo surgery due to various reasons. The treatment strategies and clinical outcomes following NIC for stage II-III NSCLC, encompassing both surgical and non-surgical approaches, remain unclear. **Methods:** We conducted a multicenter, retrospective cohort study involving stage II-III (T1-4N0-2) pts who underwent radical surgery or radiotherapy after NIC in routine clinical practice across 12 medical centers in China between January 2018 and December 2023. For pts receiving radical radiotherapy, we documented the reasons for non-surgical management, and planned surgical procedures. Propensity score matching (PSM) was performed based on age, gender, smoking history, clinical stage, and histology to balance the clinicopathologic characteristics. The primary outcomes were progression free survival (PFS) and overall survival (OS). **Results:** 967 pts were included: 683 (70.6%) underwent surgery and 284 (29.4%) received radiotherapy. Reasons for radiotherapy after NIC included potentially resectable but declined surgery after shared decision-making (65.5%, 186/284), functionally unresectable (14.4%, 41/284), and technically unresectable (20.1%, 57/284), respectively. At the database lock (November 24, 2024; median follow-up: 23.3 months), PFS (HR: 0.32, 95% CI: 0.23-0.44, p<0.001) and OS (HR: 0.41, 95% CI: 0.26-0.66, p<0.001) were significantly improved in pts undergoing surgery after PSM. PFS across most key subgroups favored surgery: stage IIIA (HR: 0.34, 95% CI: 0.21-0.55, p <0.001), stage IIIB (HR: 0.39, 95% CI: 0.24-0.63, p <0.001), (planned) pneumonectomy (HR: 0.47, 95% CI: 0.26-0.85, p=0.013) and (planned) lobectomy (HR: 0.24, 95% CI: 0.13-0.45, p<0.001). However, the pts planned for pneumonectomy in radiotherapy group exhibited similar OS compared to those undergoing pneumonectomy. **Conclusions:** Among pts with locally advanced NSCLC treated with NIC, radical surgery demonstrated long-term clinical benefit. Research Sponsor: None.

ImmunoDriver-1: Driver alterations (dAlts) and their immunological implications in early and metastatic non-small cell lung cancer (NSCLC). First Author: Jay M. Lee, Division of Thoracic Surgery, University of California, Los Angeles (UCLA), Los Angeles, CA

Background: NSCLC treatments and clinical trials include targeted agents and immunotherapy (IO) across stages, yet dAlts and how they relate to the tumor immune microenvironment (TIME) are incompletely characterized in early NSCLC (eNSCLC; stage I-III) and metastatic NSCLC (mNSCLC; stage IV). Here, we evaluated the NSCLC TIME by dAlt status to inform IO biomarker strategies. **Methods:** From the Tempus Database, we selected de-identified lung adenocarcinoma samples sequenced by xT DNA assay (eNSCLC n=5,535; mNSCLC n=10,299), a subset with whole transcriptome analysis. Targetable dAlts were defined as classic (c) (L858R and exon 19 del) or non-classic (nc) *EGFR*, *KRAS* G12C, other non-G12C variants, other guideline defined dAlts (ALK, ROS1, RET, NTRK1-3 fusions, ERBB2 alt, METex14), or no dAlt. Immune cell proportions were estimated by quanTIseq. Additional markers, PD-L1 TPS (IHC) and TMB (mt/mB; DNAseq) were analyzed. Significance ($p<0.05$) was assessed using χ^2 or Wilcoxon/Kruskal-Wallis rank sum tests. **Results:** The dAlt prevalence was similar ($|\Delta| < 2\%$) across early and late stage (Overall %: cEGFR=13, ncEGFR=2.9, KRAS G12C=15 and KRASother=22). The prevalence of other dAlt were less than 4% across stages. The CD8 proportion was higher in eNSCLC than mNSCLC ($p<0.001$). Across stages, CD4 Treg and CD8 proportions in the *KRAS* G12C cohort were nearly identical to the non-dAlt cohort, while c/nc*EGFR* tumors exhibited the lowest percentage of CD8 cells and higher Tregs cells compared to non-dAlt tumors (Table). PD-L1 and TMB were similar between *KRAS* G12C and non-dAlt tumors and lowest among c/nc*EGFR* (Table). **Conclusions:** This real-world analysis demonstrated similar dAlt prevalence across eNSCLC and mNSCLC, while the TIME was distinct across stage and dAlts. The TIME of *KRAS* G12C tumors was similar to non-dAlt tumors, and was least immunogenic in the c/nc*EGFR* cohort. These findings highlight immunological differences across stages and dAlts that should be considered when developing IO strategies. Research Sponsor: Tempus AI, Inc.

Unique mutational landscape and therapeutic implications in non-small cell lung cancer with comorbid fibrotic interstitial lung disease. First Author: Jacob Michalski, Stanford Health Care, Stanford, CA

Background: Patients with established interstitial lung disease (ILD) have both increased risk of developing non-small cell lung cancer (NSCLC) and higher mortality than patients without a history of ILD. We hypothesized the mutational landscape of NSCLC arising in the setting of ILD would be different than sporadic or smoking-associated cancers, potentially leading to different treatment options given the question of safety of immune checkpoint inhibitors (ICIs) in this population. **Methods:** We retrospectively identified 330 patients with NSCLC, of which 77 patients had pre-existing diagnoses of ILD with probable or definite usual-interstitial pattern made by radiographic or biopsy findings for comparison to randomly selected patients with NSCLC without clinically apparent ILD. Clinical characteristics, histologic information, mutational data, and treatment regimens were collected using the Stanford Research Repository and compared between patients with NSCLC and established ILD (LC-ILD) and NSCLC without ILD (LC). Statistical comparisons between groups were done with Mann-Whitney testing with significance set at $p<0.05$. **Results:** Baseline characteristics including age, sex, race, ethnicity, smoking status, NSCLC type, and NSCLC stage at diagnosis did not differ between the LC-IPF and LC groups. There was significantly lower prevalence of *EGFR* mutations in the LC-IPF group (33.0% vs 3.0%, $p<0.0001$) and significantly higher prevalence of *KRAS G12D* mutations (19.0% vs 41.7%, p=0.05). Baseline tumor proportion score (TPS) between LC and LC-ILD groups was not significantly different (28.2% vs 16.3%, p=0.063) however there were significantly fewer patients with high PD-L1 expression (TPS ≥ 50%) in the LC-ILD group (32.0% vs 16.7%, p=0.036). Occurrence of clinically significant treatment-related pneumonitis occurred in 15 patients in the LC-ILD group with etiologies identified as radiation (n=8, N=20, 40.0%), surgery (n=1, N=40, 2.5%), osimertinib (n=1, N=1, 100%), pembrolizumab (n=2, N=5, 40.0%), docetaxel (n=2, N=4, 50.0%, and pemetrexed (n=1, N=19, 5.7%). **Conclusions:** These retrospective data highlight the differences in driver mutations in NSCLC in patients with preceding fibrotic lung disease, suggesting potentially divergent biologic underpinnings for tumorigenesis. These results, particularly the under-representation of *EGFR*-mutations, over-representation of KRAS G12D mutations, and scarcity of therapeutically actionable mutations in the LC-ILD population, lead to limited therapeutic options. Surgically-associated pneumonitis was rare, but radiation, docetaxel, and pembrolizumab appeared high risk for pneumonitis in treated patients, suggesting need careful consideration of risks when treating this unique population. Differential prognostic significance of distant and locoregional recurrence on survival in surgically resected non-small cell lung cancer post-chemotherapy: Multicenter dynamic prediction with landmark model. First Author: Zeliang Ma, National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China

Background: Recurrence remains a significant challenge in patients with surgically resected non-small cell lung cancer (NSCLC) following adjuvant chemotherapy. Recurrence status evolves over the course of follow-up, dynamically influencing survival outcomes. This study aimed to investigate the differential impact of distant metastasis (DM) and locoregional recurrence (LR) on survival, and to develop prognostic models to guide treatment strategies and individualize follow-up protocols. **Methods:** From four institutions, patients with pN2 NSCLC who underwent complete resection followed by four cycles of platinum-based doublet chemotherapy were included. A dynamic prediction landmark model was constructed to assess the impact of LR and DM on survival. The primary endpoint was overall survival (OS). Baseline factors included age, sex, smoking history, histology, tumor laterality, pT stage, and the number of positive lymph nodes, while DM and LR status were treated as time-dependent covariates. **Results:** A total of 2,120 patients were included in the study, with a median follow-up time of 55.80 months (IQR: 39.47–85.12). The landmark model identified older age, smoking history, advanced T stage, DM, and LR as significant factors associated with worse OS. DM had the most substantial impact on OS (odds ratio [OR], 3.85; 95% CI, 3.32–4.48; $P < 0.01$), while LR also significantly decreased OS (OR, 2.07; 95% CI, 1.73–2.47; $P < 0.01$). Multivariate Cox analysis revealed that the pT stage, number of positive lymph nodes, and histology were independently associated with DM. A nomogram was developed to predict the risk of DM for individual patients, categorizing them into three distinct risk subgroups. Postoperative radiotherapy did not significantly improve OS in the low- or high-risk subgroups but demonstrated a survival benefit in the medium-risk subgroup (hazard ratio [HR], 0.73; 95% CI, 0.63–0.87; $P < 0.01$). Intensified systemic therapy and closer monitoring would be required for patients in the high-risk subgroup. **Conclusions:** The dynamic prediction model estimated future survival probabilities based on individual recurrence status throughout follow-up in patients with surgically resected NSCLC post-chemotherapy. Both DM and LR significantly affected OS, with DM being more detrimental. The DM risk nomogram aids in assessing the benefits of additional treatments and guiding personalized follow-up strategies. Neoadjuvant hypofractionated radiotherapy plus tislelizumab with anlotinib followed by adjuvant tislelizumab with anlotinib in patients with resectable non-small cell lung cancer (NSCLC): Preliminary analysis of a phase II trial (NEO-PIONEER). First Author: Min Fang, Zhejiang Cancer Hospital (Zhejiang Cancer Center), Hangzhou, China

Background: Although neoadjuvant immune checkpoint inhibitors (ICIs) combined with chemotherapy is the current standard of care for resectable NSCLC, the optimal combination strategy to improve efficacy with low toxicity remains to be explored. Preclinical and clinical studies have shown that anti-angiogenic therapy can enhance the efficacy of immunotherapy and sensitize radiotherapy through a variety of mechanisms. We designed a trial to test the activity of triple therapy of radiotherapy, angiogenesis inhibitors and ICIs for resectable NSCLC. **Methods:** This is a prospective, single-arm, phase II (NCT06379087) to explore the efficacy and safety of hypofractionated radiotherapy followed by sequential tislelizumab and anlotinib in the perioperative treatment of resectable NSCLC. A total of 20 eligible patients aged 18 years or older, with histologically confirmed stage II/IIIA resectable NSCLC, and without prior systemic anticancer treatment or known EGFR mutations, ALK rearrangements or ROS1 fusions are enrolled. The treatment regimen involved hypofractionated radiotherapy on d1-3 (24 Gy/3 fractions), followed by tislelizumab plus anlotinib within 1 week for 2 cycles after radiotherapy. Patients without disease progression after two cycles were followed by surgical resection within 4-6 weeks after the last dose of neoadjuvant treatment, and receive adjuvant treatment with tislelizumab plus anlotinib after surgery up to 1 year. The primary endpoint was pCR rate. And the secondary endpoint was MPR rate, 1-year EFS rate and the incidence of treatment-related AE. **Results:** Between May 1, 2024, and December 31, 2024, a total of 10 patients were enrolled. 6 (60%) of them had pathological stage IIIA. All patients enrolled have completed radiotherapy and 2 cycles of neoadjuvant treatment with tislelizumab plus anlotinib. 1 patient experienced disease progression following neoadjuvant and did not receive surgery. 7 patients have underwent surgery. While 2 patients were waiting surgery. Among the 7 patients who underwent surgery, 5 (71.4%) of 7 patients achieved pCR, all 7 patients demonstrated a MPR. In terms of safety, 1 patient experienced grade 3-4 treatment related adverse events, which was alanine aminotransferase and aspartate aminotransferase. There were no treatment-related deaths reported during the study period. **Conclusions:** Preoperative hypofractionated radiotherapy followed by immunotherapy and anti-angiogenesis therapy is tolerable, leads to a clinically significant pCR. Clinical trial information: NCT06379087. Research Sponsor: None.

Five-year survival outcomes from CRES^{3}T: S-1 plus cisplatin with concurrent radical-dose radiotherapy followed by surgery for superior sulcus tumor. First Author: Kazuya Takamochi, Department of General Thoracic Surgery, Juntendo University School of Medicine, Tokyo, Japan

Background: CRES^{3}T is a multicenter, single-arm, confirmatory trial of S-1 plus cisplatin and concurrent radical-dose thoracic radiotherapy (TRT) followed by surgery in patients with superior sulcus tumor (SST). The 3-year overall survival (OS) and progression-free survival (PFS) rates were 73% (95% confidence interval [CI]; 60–83%) and 53% (95% CI; 40–65%), respectively. The primary endpoint, 3-year OS rate, was met. We report the exploratory analyses of survival outcomes approximately 5 years after the last patient was enrolled. **Methods:** Patients with SST (pathologically proven non-small cell lung cancer that directly invades the chest wall, including the first rib or further cephalad, subclavian artery, or subclavian vein according to computed tomography or magnetic resonance imaging) received induction therapy comprising three cycles of S-1 plus cisplatin with concurrent TRT (66 Gy in 33 fractions) followed by surgery. S-1 was administered orally at 40 mg/m^2 twice daily for 14 days along with an intravenous infusion of cisplatin (60 mg/m^2) on day 1. The treatment cycles were repeated every four weeks. The 5-year OS, 5-year PFS, and patterns of postoperative recurrence were analyzed. Prognostic factors of OS were analyzed in patients who underwent surgical resection using Cox proportional hazard model. **Results:** The median follow-up duration for 60 eligible patients was 67.1 months. The 5-year OS and PFS rates were 66.3% (95% CI; 52.8–76.8) and 48.1% (95% CI: 35.0–60.0), respectively. The median follow-up duration for 49 patients with surgical resection was 71.0 months. The 5-year OS and PFS rates were 71.0% (95% CI; 56.0–81.7) and 52.8% (95% CI: 37.9–65.6), respectively. Age was the only significant prognostic factor for OS (P = 0.01, HR 1.1, 95% CI; 1.02–1.20). Sex, smoking status, clinical T stage, clinical N stage (cN0 versus cN1/ipsilateral supraclavicular cN3), symptoms associated with brachial plexus involvement, histology, preoperative serum CEA and CYFRA levels, pathological complete response, and major pathological response had no significant prognostic impacts on OS. Twenty (41%) patients developed postoperative relapse. The patterns of postoperative relapse were locoregional only in one (2%), distant metastasis only in 16 (33%), and both in three (6%) patients. **Conclusions:** Better 5-year survival outcomes of CRES^{3}T compared to those in the pivotal studies (5-year OS: 56% in JCOG9806 and 44% in SWOG9416/INT0160) indicated that induction therapy using S-1 plus cisplatin and concurrent radical-dose TRT followed by surgery could be a new standard treatment for patients with SST. Clinical trial information: s031180401. Research Sponsor: None.

Initial results of a screening trial for evaluating oncogenic drivers in Japanese patients with surgically resected early-stage non-small cell lung cancer: LC-SCRUM-Advantage. First Author: Yuki Matsumura, National Cancer Center Hospital East, Kashiwa, Japan

Background: The LC-SCRUM-Advantage is a screening trial to evaluate oncogenic drivers in patients with surgically resected early-stage non-small cell lung cancer (NSCLC). Recent clinical trials, such as the ADAURA and ALINA trials, have demonstrated the efficacy of molecular targeted therapy as adjuvant therapy following surgery for patients with early-stage NSCLC harboring oncogenic drivers. Our study aims to determine the proportion of early-stage NSCLC with any actionable oncogenic drivers that are candidates for adjuvant targeted therapy. This abstract presents the initial data collected until Dec 2024. **Methods:** Patients with operable clinical stage I to III NSCLC were eligible for this study. Surgical tumor samples were collected post-surgery, and genomic analysis of oncogenic drivers was centrally evaluated using a next-generation sequencing system, the Oncomine Precision Assay, which targets 50 gene alterations. PD-L1 immunohistochemistry using the 22C3 antibody was also performed on the submitted tumor samples. If possible, preoperative biopsy tumor samples were also collected and evaluated using the AmoyDx Pan Lung Cancer PCR Panel. An actionable oncogene was defined as EGFR, ALK, ROS1, KRAS, BRAF, HER2, RET, MET, NRG1, or NTRK genes. **Results:** Between August 2022 and December 2024, 646 patients were enrolled in the LC-SCRUM-Advantage. Among them, 57% had stage I, 27% had stage II, 16% had stage III, and 71% had adenocarcinoma histology. Of the 591 evaluable patients in this analysis, an actionable oncogenic driver was found in 46% of cases (274/591). Identified oncogenic drivers included 190 (24%) EGFR mutations (89 L858R, 77 ex19del, 10 ex20ins, 14 uncommon), 26 (4%) MET ex14 skipping, 20 (3%) KRAS G12C, 18 (3%) HER2 mutations (including ex20ins), 7 (1%) ALK fusion, 5 (1%) NRG1 fusion, 4 (1%) BRAFV600E, 2 (<1%) RET fusions, 1 (<1%) ROS1 fusion, and 1 (<1%) NTRK fusion. PD-L1 expression was observed in 19% for >50%, 40% for 1-49%, and 41% for <1%. Among patients with paired tumor samples from surgery and preoperative biopsy, the concordance rate of detected actionable oncogenic drivers was 95%. **Conclusions:** Our study found actionable oncogenic drivers in 46% of Japanese patients with surgically resected early-stage NSCLC. Based on historical control, the proportion of any oncogenic drivers in early-stage NSCLC is similar to that in advanced NSCLC. Comprehensive genomic screening of patients with early-stage NSCLC will accelerate the development of clinical trials for adjuvant-targeted therapy. Are we casting the net wide enough? Applying the proposed lung cancer screening criteria in single centre lung cancer resections. First Author: Clement Lim, St John of God Subiaco Hospital, Perth, Australia

Background: The Australian National Lung Cancer Screening Program (NLCSP) commences in July 2025. Thoracic surgery is a key treatment option in screen-detected early-stage lung cancers. St. John of God Subiaco Hospital is a private hospital in Western Australia (WA) and is part of the Australian and New Zealand Thoracic Clinical Quality Registry (ANZTHOR) collaborative database as one of the inaugural sites. We examined the resected primary lung cancers at our centre to assess if our cohort aligned with the characteristics of the targeted at-risk patient population as defined by the NLCSP proposed screening criteria. **Methods:** Demographic patient data was retrieved from ANZTHOR at our centre who underwent surgical resection for primary lung cancer between March 2023 to November 2024. Retrospective data analysis was then conducted on the mode and symptoms at time of diagnosis, age and smoking history. The NLCSP criteria for screening (aged 50-70 years, history of $\geq$30 pack-years smoking in current smokers or ex-smokers who quit within the last 10 years) was then applied to this cohort of privately insured primary lung cancer patients to evaluate the proportion of patients that would have been eligible/ineligible for screening. **Results:** Of the 107 patients, median age was 71 (range 42-87) and 67 (63%) were females. 96 (90%) patients were asymptomatic and 98 (92%) were early-stage cancers (Stage 2 and below). 58 (54%) patients were $>$70 years old and 34 (32%) were never-smokers. **Conclusions:** A substantial proportion (86%) of this cohort of asymptomatic resected lung cancer patients would not have been identified via lung cancer screening by NLCSP screening criteria. This is likely in part related to the different demographics of patients attending private hospitals but nonetheless raises the possibility that the current screening criteria is overly stringent and will miss many primary lung cancer presentations. Supplementary methods (i.e. blood biomarker testing) may improve screen detection rates of lung cancer and enable better identification of at-risk groups. Research Sponsor: Bendat Family Research and Development Fund.

	Total patients (n=107)	Asymptomatic patients (n=96)
Ineligibility based on age	61 (57%)	56 (58%)
Ineligibility based on smoking history	73 (68%)	67 (70%)
Ineligibility based on full NLCSP criteria	91 (85%)	83 (86%)

Commission on Cancer lung cancer surgery quality metric and overall survival in a population-based cohort. First Author: Sora Ely, George Washington University, Washington, DC

Background: The American College of Surgeons Commission on Cancer (CoC) quality metric for curative-intent lung cancer surgery, Operative Standard 5.8 (OS 5.8), requires lymph node sampling from $\geq$3 mediastinal and $\geq$1 hilar ("3+1") stations. We assessed association between adherence to this standard and overall survival in a population-based lung cancer resection cohort. **Methods:** We evaluated the Mid-South Quality of Surgical Resection cohort, which includes data from all 14 hospitals performing $\geq$5 annual lung cancer resections across five Hospital Referral Regions in MS, AR, and TN. We compared clinical stage I-III curative-intent resections from 2009 to 2020, examining demographics, tumor characteristics, and outcomes between CoC OS 5.8-concordant and non-concordant groups using chi-squared tests. We calculated adjusted odds ratios (aORs) to quantify concordance association with binary outcomes using logistic regression and adjusted hazard ratios (aHRs) for overall survival with proportional hazards models, adjusting all models for age, race, sex, Charlson comorbidity index, insurance, rurality, institutional volume, smoking status, clinical stage, histology, surgical technique, extent of resection, margin status, and neoadjuvant therapy. **Results:** Of 5,536 patients, 1,859 (41%) were concordant and 2,677 (59%) were non-concordant. Concordant cases included more White patients (80% v 76%, p$<$0.0001), metropolitan residents (61% v 47%, p$<$0.0001), clinical stage II/III cases (25% v 22%, p=0.0055), and anatomic resections (99% v 87%, p$<$0.0001). Surgical complications were more common in concordant cases (48% v 42%, p=0.0001). After adjustment for key variables, concordance with OS 5.8 was associated with more frequent nodal upstaging (aOR 1.34, 95% CI: 1.11–1.60), adjuvant chemotherapy use (aOR 1.58, 95% CI: 1.33–1.88), and more complications (aOR 1.21, 95% CI: 1.06–1.38). Patients with OS 5.8 concordant resections had significantly lower hazard of death (aHR 0.85, 95% CI: 0.77–0.93, Table). **Conclusions:** Adherence to CoC OS 5.8 lymph node sampling standards for lung cancer resections was associated with greater nodal upstaging, adjuvant therapy use, and likelihood of postoperative morbidity. Overall survival was significantly better among OS 5.8-concordant cases, supporting the use of this quality metric for curative-intent lung cancer surgery. Research Sponsor: U.S. National Institutes of Health; R01CA172253.

Oncologic characteristics and outcomes in CoC OS 5.8-concordant v non-concordant resections.

	Concordant n=1859	Non-concordant n=2677	P-value
Clinical stage I	74%	78%	0.0055
Clinical stage II	17%	14%

Racial and ethnic disparities in receipt of guideline concordant treatment for early-stage non-small cell lung cancer in Los Angeles County. First Author: Miriam L Gorbatov, Department of Population and Public Health Sciences, Keck School of Medicine of USC, Los Angeles, CA

Background: Non-small cell lung cancer (NSCLC) is the leading cause of cancer mortality in California. Black patients experience the highest mortality rates (39 per 100,000) compared to Non-Hispanic White (NHW) (34 per 100,000), Asian/Pacific Islanders (A/PI) (23 per 100,000), and Hispanic patients (17 per 100,000). The most modifiable factor contributing to these differences is the receipt of guideline-concordant treatment (GCT), with surgical resection or radiation therapy recommended for all medically operable patients with stage I-II NSCLC. Despite rigorous clinical evidence supporting these guidelines, a higher proportion of Non-Hispanic Black (NHB) and Hispanic patients do not receive GCT compared to NHW patients. This study analyzed differences in receipt of GCT across racial and ethnic groups, leveraging data from a robust, population-based cohort of all early-stage NSCLC cases diagnosed in Los Angeles County. **Methods:** Patients diagnosed with early-stage NSCLC (tumors $<$4cm, no lymph node involvement, and no metastases) between 2012-2022 were identified from the Los Angeles County Cancer Surveillance Program. Using a logistic regression model, we evaluated the association between race and ethnicity and receipt of guideline concordant treatment, adjusting for confounders including age, sex, socioeconomic status, insurance type, marital status, and tumor size. Outcomes were defined as receipt of GCT (surgery or radiation only), while non-GCT included no treatment or any combination of multiple treatments. **Results:** A total of 2,033 patients with early-stage NSCLC were identified of which 57.2% were NHW, 8.9% were NHB, 14.8% were Hispanic, and 18.2% were A/PI. Patients with early-stage NSCLC were on average 70.3 years of age, majority female (63.7%), and had an average tumor size of 1.9 cm. While most patients (85.6%) received GCT, NHB patients had the highest proportion of non-GCT treatment (21.1%) followed by Hispanic patients (16.9%). NHB patients had significantly higher oddsof not receiving GCT compared to NHW patients (OR: 1.62, 95% CI: 1.05-2.46; p$<$0.05). No statistically significant differences in GCT receipt were observed for A/PI or Hispanic patients compared to NHW patients. **Conclusions:** Addressing disparities in GCT for patients diagnosed with early-stage NSCLC is critical to improving survival outcomes. Future studies identifying factors influencing a patient's decision to receive GCT and a physician's decision to recommend and adhere to GCT guidelines is needed to understand the complexity of treatment decision-making. Impact of time to neoadjuvant treatment initiation (TTI) for resectable non-small cell lung cancer (NSCLC) on clinical outcomes. First Author: Srinidhi Radhakrishnan, University of Maryland, Baltimore, MD

Background: There has been significant progress in the management of resectable NSCLC, now utilizing biomarker selected criteria. However, in the era of these new perioperative treatments, the impact of treatment initiation and surgical timing on clinical outcomes have yet to be explored. **Methods:** Using the NCDB, we compiled an analytic data set of patients with stage IB-IIIB (per AJCC 8th staging edition) who underwent definitive resection after receiving neoadjuvant systemic therapy between 2010-2021. These patients received neoadjuvant chemotherapy (CT), chemoradiotherapy (CRT) or chemoimmunotherapy (CIO). The following clinically relevant time intervals were estimated: time from diagnosis to systemic therapy initiation, from diagnosis to definitive surgery and from systemic therapy initiation to surgery. The association between these time intervals and overall survival (OS) were assessed using multivariable Cox proportional hazards model, stratified by clinical T-stage. Cox model was adjusted for year of diagnosis and age, treatment modalities, sex, race, Charlson score, income, and hospital affiliation. Data were analyzed using R studio and statistical significance was set at α = 0.05. **Results:** The analytic data set included 13,372 eligible patients. 40.5% of patients had stage I/II disease and 59.5% were diagnosed with stage III disease. Treatment included 45.2% CT, 48.3% CRT, 6.4% CIO, with median TTI being 108, 97 and 107 days, respectively. Compared to neoadjuvant CT, CIO combination conferred a positive impact on OS (HR=0.62, 95%CI: 0.52-0.74). Both time from diagnosis to treatment initiation and time from systemic therapy start to surgery increased by 7 days between 2010-2018 and 2019-2021. Time to neoadjuvant treatment initiation did not impact OS. However, surgical resection done later than 150 days from diagnosis was associated with lower OS (HR=1.12, 95%CI:1.04-1.19). Based on the multivariable Cox regression model, patients' survival was longer if they were diagnosed between 2019-2021, treated at an academic hospital, age $<$ 63 years at diagnosis, female, non-white, had lower Charlson score, income $>$ 40K, private-payer insurance, and if surgical resection was performed $\leq$ 150 days from diagnosis. **Conclusions:** Exploring the NCDB, neoadjuvant CIO showed significantly favorable impact on OS compared to CT. Despite increased TTI between the years of 2019-2021, there was no appreciable impact on timing of systemic therapy initiation on OS across our cohort. Time to surgical resection within 150 days, adjusted for other clinical and demographic parameters, was associated with improved OS. Pertinent demographic variables, including race, insurance status, and income level, significantly impacted OS and warrant further investigation in this clinical setting. Research Sponsor: None.

Driving precision oncology in lung cancer: Patient stratification through comprehensive genomic profiling. First Author: Vidya H Veldore, 4baseCare Precision Health Pvt Ltd., Bangalore, India

Background: Next Generation Sequencing (NGS)-guided targeted therapy is a standard practice in lung cancer, as recommended by professional guidelines. Various gene panels, exome, and genome sequencing strategies are employed to detect therapeutic targets. Selecting the right test is critical for achieving favorable patient outcomes. This study compares the efficacy and clinical utility of gene panels and exome sequencing in stratifying patients for different therapeutic options. **Methods:** We retrospectively analyzed genomic profiles of 1,224 advanced lung cancer patients (Stage III and Stage IV) sequenced using small gene panel (SP; 72 genes, NCCN biomarker driven TarGT First) and broad gene panel (BP; 1,212 genes, NCCN and pathways driven TarGT IndieGene. Tumor FFPE samples were screened for SNVs/InDels, CNVs, gene fusions, and immunotherapy biomarkers, including TMB, MSI, and PD-L1 expression. **Results:** Among the 1,224 patients, 791 were screened with small panels, 552 with broad panels, and 42 with exome sequencing. Sequencing with BP identified at least one driver/pathogenic mutation in 89.7% patients, which was higher than that detected in SP (73.6%). BP detected a higher proportion of patients with therapeutically targetable variants than SP (80.6% vs. 73.3%). Both SP and BP detected equivalent proportion of patients as eligible for level 1 (FDA-approved) therapy (SP 38.7% vs. BP 37.5%) and level 2 therapy (3.2% vs. 4%) and while a significantly higher number of patients eligible for level 3 (clinical trials) therapies were detected in BP (SP 31.5% vs. BP 39.1%). In a subset of 172 patients screened with both SP and BP. BP identified driver/pathogenic mutations in all patients (100% diagnostic yield) while SP identified mutations in 62.8% of the patients. BP also detected targetable variants in 84.9% of cases, compared to 62.8% detected in SP. Patients eligible for FDA-approved therapy (48.3% vs. 41.9%), off-label therapy (5.2% vs. 3.5%), and clinical trial therapies (38.4% vs. 17.4%) were more frequently detected with BP than in SP. **Conclusions:** BP outperform SP in detecting clinically significant drivers and therapeutic biomarkers, demonstrating their utility in precision oncology. This study highlights the advantages of comprehensive genomic profiling (CGP) over small panels for guiding prognosis and therapy decisions in advanced lung cancer during disease progression. Research Sponsor: 4baseCare internal funding.

	Patients with targetable variants (No. of patients; %)	Level 1 therapy (No. of patients; %)	Level 2 therapy (No. of patients; %)	Level 3 therapy (No. of patients; %)	No therapy (No. of patients; %)
Small panel sequencing (SP) (n=791 patients)	580; 73.3%	306; 38.7%	25; 3.2%	249; 31.5%	211; 26.7%
Broad panel sequencing (BP) (n=552 patients)	445; 80.6%	207; 37.5%	22; 4%	216; 39.1%	107; 19.4%

Real-world (rw) study to identify disparities in outcomes for patients (pts) with early-stage resected NSCLC who received biomarker-targeted adjuvant treatment (BTRx). First Author: Raymond U. Osarogiagbon, Baptist Cancer Center, Multidisciplinary Thoracic Oncology Program, Memphis, TN

Background: BTRx improves survival of pts with resected early-stage NSCLC, making thorough biomarker testing critical in this setting. Disparities in testing and receipt of guideline-supported BTRx may adversely impact outcomes. We evaluated rw biomarker testing patterns, outcomes, and receipt of BTRx in pts with resected NSCLC. **Methods:** This was a retrospective US cohort study of Flatiron Health data from pts with stage IB–IIIB (T3N2) NSCLC diagnosed during 2021–2023, who had surgical resection. Biomarker testing, BTRx rates, and clinical outcomes (rw recurrence-free survival [rwRFS]; overall survival [OS]) were evaluated and compared across clinical and sociodemographic groups. BTRx was defined as 1) osimertinib for EGFR+ (Ex19del/L858R) NSCLC; 2) atezolizumab or pembrolizumab (per PD-L1 status) for EGFR- and ALK-negative (-) NSCLC. **Results:** In this cohort (N=885), biomarker testing rates were lower among stage I (75%) vs III (93%), older (83%) vs younger (87%), non-Hispanic Black (74%) vs White (84%), and pts with smoking (83%) vs no smoking history (89%) (Table). 539 (61%) pts received adjuvant therapy; 231 (43%) had actionable biomarkers, of whom 137 (59%) received BTRx, with rates highest for pts with EGFR+ disease (85%) and lowest for pts with EGFR-/ALK- disease (49%). BTRx was received more often by pts who never smoked (76% vs 55% of pts who smoked) and pts of Asian ethnicity (100% vs 56% White) (all $p<0.05$). At 24 months, 90% of pts who had BTRx were alive vs 77% who did not ($p<0.05$). Median rwRFS was 35 months for BTRx vs 28 months for non-BTRx cohort ($p<0.05$). In multivariable analysis among pts who had BTRx, younger age was significantly associated with OS. **Conclusions:** In this large rw analysis, BTRx was significantly associated with OS in early-stage NSCLC, irrespective of age, stage and sex. Ensuring biomarker testing and BTRx for all pts may reduce outcomes disparities in NSCLC. Research Sponsor: AstraZeneca.

Definitive radiation as a nonsurgical option after chemoimmunotherapy for stage III lung cancer. First Author: Giorgio Caturegli, Yale School of Medicine, New Haven, CT

Background: The immunotherapy era has led to a resurgence of interest in surgical management of clinical Stage III non-small cell lung cancer (NSCLC). However, patient eligibility or interest in surgery may decline after neoadjuvant treatment, leaving many in need of a non-operative form of local therapy. Here we evaluate outcomes of definitive radiation after chemoimmunotherapy as a potential nonsurgical option for stage III NSCLC patients. **Methods:** Clinical Stage III lung adenocarcinoma and squamous cell carcinoma patients diagnosed in the National Cancer Database between 2017 and 2021 who received chemoimmunotherapy followed by thoracic radiation within 20 weeks were included. Patients receiving any palliative therapies were excluded. Three-year overall survival was assessed by Cox proportional hazards models and by the Kaplan-Meier method, after landmarking at 10 weeks (median time from immunotherapy to radiation). Propensity-matching was performed 2:1 on year, age, sex, race/ethnicity, Charlson-Deyo score, insurance, region, facility type, histology, and clinical T and N stage. **Results:** 873 patients were treated with radiation after chemoimmunotherapy. Over 90% received a total radiation dose of at least 50 Gy, and 90-day mortality after initiation of radiation was 4.9%. To evaluate radiation as a local therapy after chemoimmunotherapy, these patients were compared to those who received chemoimmunotherapy only (Table). Patients receiving radiation were less likely to have T4 tumors (37.7% vs. 44.2%, $p<0.0001$) but had a similar proportion of N3 tumors (28.2% vs. 29.9%, p=0.73) compared to chemoimmunotherapy alone. Three-year overall survival of propensity-matched patients was superior in the radiation group (50.8%) versus chemoimmunotherapy alone (35.9%, $p<0.001$). In a Cox model, the addition of radiation was associated with lower mortality risk (HR 0.66, 95% 0.58-0.84, $p<0.0001$) compared to chemoimmunotherapy alone. **Conclusions:** Radiation after chemoimmunotherapy appears to be a safe and effective regimen for Stage III NSCLC. Further study is indicated to evaluate radiation as a nonsurgical option for clinical stage III patients who begin with chemoimmunotherapy but do not progress to surgery. Research Sponsor: None.

Characteristics and survival of patients receiving chemoimmunotherapy with or without subsequent radiation.

	Chemoimmunotherapy followed by radiation (n=873)	Chemoimmunotherapy only (n=1408)	P (Chi-squared or Wilcoxon rank sum)
Age (median, IQR)	67 (60-73)	69 (62-75)	**<0.0001**
Female	369 (42.3%)	667 (47.4%)	**0.02**
Charlson-Deyo ≥ 2	131 (15.0%)	242 (17.2%)	0.34
Adenocarcinoma	463 (54.0%)	886 (62.9%)	**<0.0001**
Stage 3A	350 (40.1%)	579 (41.1%)	0.78
Stage T4	329 (37.7%)	622 (44.2%)	**0.0022**
Stage N3	255 (29.2%)	421 (29.9%)	0.73
3-Year Survival*	489 (56.0%)	630 (44.7%)	**<0.0001**

For reference: 3-year survival of immunotherapy after chemoradiation for Stage III NSCLC in the PACIFIC trial was 57%.

Sequential versus concurrent strategy of immunotherapy and radiotherapy in advanced non-small-cell lung cancer: A territory-wide multicenter study (OCEANUS study). First Author: Han Zhou, The University of Hong Kong-Shenzhen Hospital, Shenzhen, China

Background: Combination of immunotherapy with radiotherapy (iRT) has been a hot topic of research during last 10+ years with controversial results. In advanced non-small cell lung cancer (NSCLC), the optimal combination of iRT is not clear in the PACIFIC series of study. Using a prospective territory-wide multicenter study, this OCEANUS study aimed to compare the survival between sequential and concurrent iRT in locally advanced NSCLC. **Methods:** This real-world evidence study evaluated NSCLC patients treated in Hong Kong between January 1, 2010, and December 31, 2021. Patients diagnosed with unresectable locally advanced, de novo metastatic, or progressive NSCLC who received at least one cycle of immunotherapy combined with radiotherapy were included. The primary endpoint was real-world overall survival (rwOS). Survival outcomes were compared across various iRT combinations, with a focus on the impact of iRT strategies (concurrent versus sequential), the iRT time interval, and immune checkpoint inhibitor (ICI) maintenance duration. **Results:** A total of 3,522 patients received immunotherapy, of whom 338 underwent iRT (151 with initial iRT and 187 with salvage iRT). Patients who received iRT had significantly better overall survival (OS) compared to those who did not. Sequential iRT demonstrated significantly superior survival compared to concurrent iRT, with a 5-year rwOS of 45.3% (95% CI, 35.6–57.7%) versus 15.7% (95% CI, 7.2–33.8%; HR, 0.587; 95% CI, 0.382–0.901; P = 0.014). For salvage iRT, radiotherapy combined with maintenance ICIs achieved a median rwOS of 11.7 months (95% CI, 7.4–15.5), outperforming RT administered after ICI discontinuation (HR, 0.679; 95% CI, 0.470–0.979; P = 0.014). Shorter iRT intervals (<1 week) and 1 year of ICI maintenance were associated with additional survival benefits. **Conclusions:** The OCEANUS study provides significant real-world evidence supporting sequential iRT as the preferred strategy for unresectable locally advanced and de novo metastatic NSCLC. Salvage RT combined with maintenance ICIs was associated with improved rwOS in patients with progressive NSCLC. These findings offer actionable insights for optimizing iRT strategies in advanced NSCLC. Evaluating lung cancer clinical characteristics and tumor subtypes using cell-free DNA fragmentomes. First Author: Milou Schuurbiers, Radboud University Medical Center, Nijmegen, Netherlands

Background: Liquid biopsies provide an opportunity for non-invasive lung cancer detection and tumor subtyping when tumor tissue is not available. Here we evaluate a blood-based liquid biopsy approach and its relationship to clinical and tumor subtype characteristics of lung cancer cases using a cohort of 578 individuals from a prospective clinical trial (LEMA, NCT02894853). **Methods:** Pre-treatment plasma samples were processed using the DELFI assay, a cell-free DNA (cfDNA) approach using a genome-wide fragmentomics based machine learning classifier. Clinical data, including overall cancer stage (I=164, II=59, III=133, IV=184), tumor stage, histologic subtypes, lymph node invasion, comorbidities, medications, smoking history, treatment type, and overall-survival (OS) data were collected for all patients. Tissue molecular profiling was performed to identify actionable alterations in driver oncogenes (ALK, BRAF, EGFR, ERBB, KRAS, ROS1, RET, MET) and cancer-specific protein levels (CEA, CA153, CA125, CYFRA, HE4) were measured in the plasma collected from 445 cancer cases. **Results:** DELFI scores were significantly higher with increasing tumor stage. T2 cases had a 1.3-fold increase in mean scores compared to T1 ($p<0.001$, Wilcoxon rank-sum), while T4 cases had a 16.2-fold increase ($p<0.0001$). A similar trend was observed with node staging, with N2 cases having an 11.3-fold higher mean scores compared to N0 ($p<0.0001$, Wilcoxon rank-sum), while N3 stage cases had a 27-fold increase ($p<0.0001$). Lung adenocarcinoma (ADC) displayed lower DELFI scores compared to squamous cell carcinomas (SCC) ($p<0.01$, Wilcoxon rank-sum), while small-cell lung cancer cases had the highest scores among all subtypes ($p<0.0001$, Wilcoxon rank-sum). cfDNA fragmentome changes in patients with ADC and SCC reflected chromosomal alterations observed in TCGA cohorts (ADC n=518; SCC n=501). The combination of DELFI cfDNA fragmentome characteristics with plasma protein measurements were used to train and cross-validate a classifier that could differentiate ADC from SCC (AUC for stage I=0.71, II=0.85, III=0.85, IV=0.82). Patients with low DELFI scores (below the median) had longer overall-survival (OS) compared to patients with high DELFI score (low DELFI score=18.51 months; high DELFI score=6.58 months; $p<0.01$, log-rank). DELFI scores were unaffected by underlying patient comorbidities, tumor-specific mutations, or medication status. **Conclusions:** Overall, this study revealed that DELFI scores are related to tumor burden, predict survival outcomes, and that cfDNA fragmentome analyses can be used to identify lung cancer subtypes. These results suggest future opportunities for subtype-specific treatments in lung cancer based on non-invasive plasma-only analyses. Clinical trial information: NCT02894853. Research Sponsor: None.

EMBER-Lung: Electronic medical record boosting molecular testing in early stage NSCLC. First Author: Willdragon Wang, University of Pennsylvania, Philadelphia, PA

Background: Actionable alterations are identified in 30-40% of patients with advanced non-squamous (NSq) non-small cell lung cancer (NSCLC). Although previous efforts focused on testing for actionable alterations in the metastatic setting, the emergence of adjuvant targeted therapies and perioperative chemoimmunotherapy has made it imperative to perform molecular testing in the early stage setting as well. We present a prospective clinical trial evaluating an electronic medical record (EMR)-based nudge intervention to promote timely completion of molecular testing in patients (pts) with early stage NSq NSCLC. **Methods:** The EMBER-Lung trial prospectively enrolled pts undergoing surgical resection in the University of Pennsylvania Health System. The intervention included an EMR-based nudge at the time of the 1st post-operative visit prompting the clinician to accept an order for comprehensive molecular testing based on NCCN guidelines. A reflex alert detailing therapeutic options was sent to the pt's care team provided that the pt had at least one actionable alteration detected and tissue was consistent with NSq NSCLC. The primary endpoint was the proportion of pts who underwent comprehensive molecular testing in the pre and post intervention cohorts. Secondary outcomes included the delivery of appropriate adjuvant targeted therapy if a targetable alteration was detected. Clinical characteristics of the pre- and post-intervention cohorts were compared using the Chi-square test or Z score. **Results:** Between July 2021 and November 2023, 460 pts were included: 243 pts in the post-, and 217 pts in the pre-intervention cohorts. Median age was 68.4 years, 64.3% female; 74.1% were former or current smokers, and mostly stage I (I/II/III; 75.9%, 14.1%, 10.0%, respectively). Pt demographics, smoking, tumor stage, and histology were similar in the pre- and post-intervention cohorts. The proportion of pts with any molecular testing improved after the intervention (101/217, 46.5% vs 208/243, 85.6%, $p<0.00001$). Moreover, the proportion of pts whose molecular testing was comprehensive also increased post-intervention (80/217, 36.9% vs 197/243, 81.1%, $p<0.00001$); and this increase was observed across all stages (I-III). A greater proportion of pts with classical *EGFR* mutations were detected in the post-intervention setting (14/217, 6.5% vs 41/243, 16.9%, $p<0.001$). No *ALK* fusions were detected in the pre-intervention cohort, while 5/243 (2.1%) were detected in the post-intervention cohort. Of note, a higher proportion of *KRAS* G12C mutations were also found post intervention (12/217, 5.5%, vs 33/243, 13.6%, $p<0.01$). **Conclusions:** An EMR-based nudge intervention during the post-operative visit after resection of early stage NSCLC improved the proportion of patients with molecular testing. The intervention was feasible, and future research will incorporate this strategy earlier to inform neoadjuvant therapy. Research Sponsor: None.

A retrospective study of induction immunochemotherapy followed by definitive chemoradiotherapy and consolidation immunotherapy in unresectable locally advanced non-small cell lung cancer. First Author: Yuliang Meng, Shandong Cancer hospital and institute, Jinan, China

Background: The standard treatment for patients with unresectable stage III non-small cell lung cancer (NSCLC) involves concurrent chemoradiotherapy (cCRT) followed by one year of durvalumab consolidation therapy. Numerous clinical studies have sought to optimize this treatment paradigm to enhance clinical outcomes. In this retrospective real-world study, we evaluated the efficacy and safety of the addition of induction chemoimmunotherapy prior to the PACIFIC regimen compared with the standard PACIFIC regimen. The aim was to determine whether introducing immunotherapy earlier into the treatment strategy for unresectable stage III NSCLC could improve disease control rates. **Methods:** This study included patients with unresectable stage III NSCLC. Patients received either induction chemoimmunotherapy followed by cCRT or sequential chemoradiotherapy (sCRT) with consolidation immunotherapy, or cCRT/sCRT directly followed by consolidation immunotherapy. The primary endpoint was progression-free survival (PFS), defined as the time from the initiation of consolidation immunotherapy to disease progression or death. The incidence of radiation-induced immune pneumonitis was also assessed between the two groups. **Results:** A total of 210 patients with unresectable stage III NSCLC were included in this study, enrolled between July 2019 and April 2023. Among them, 76 patients received induction chemoimmunotherapy, and 134 patients were treated without induction chemoimmunotherapy. Baseline characteristics between the two groups showed no significant differences. The proportion of patients receiving cCRT in the induction chemoimmunotherapy group and the non-induction chemoimmunotherapy group was 29/76 (38.1%) and 110/134 (82.1%), respectively. Within each group, there was no statistically significant difference in progression-free survival (PFS) between patients treated with cCRT or sCRT. The induction chemoimmunotherapy group demonstrated superior median PFS (mPFS) compared to the non-induction chemoimmunotherapy group (not reached vs. 17.2 months, P=0.01). Overall survival (OS) data remain immature for analysis. The incidence of pneumonitis was observed in 52/76 (68.4%) patients in the induction chemoimmunotherapy group, with ≥Grade 2 pneumonitis occurring in 18/76 (23.7%) patients. In the non-induction chemoimmunotherapy group, pneumonitis occurred in 86/134 (64.2%) patients, with ≥Grade 2 pneumonitis in 30/134 (22.4%) patients. No significant differences in pneumonitis incidence or severity were observed between the two groups. **Conclusions:** The addition of induction chemoimmunotherapy prior to the PACIFIC regimen demonstrated improved disease control rates compared to the standard approach, with no increased risk of pneumonitis. Research Sponsor: None.

Association of radiomic features with disease-free survival following neoadjuvant chemoimmunotherapy in resectable NSCLC. First Author: Bryan Berube, Cleveland Clinic, Cleveland, OH

Background: Neoadjuvant chemoimmunotherapy (chemo-IO) has emerged as a promising approach to improve disease-free survival (DFS) in patients with surgically resectable non-small cell lung cancer (NSCLC). While recent clinical trials have demonstrated the efficacy of combining chemotherapy with immune checkpoint inhibitors in this setting, DFS remains variable among patients. Currently, there is no reliable biomarker to predict the risk of recurrence in this population. Predictors such as PD-L1 expression have shown limited utility, underscoring an unmet clinical need to identify robust biomarkers for DFS. This study investigates whether radiomic texture features derived from pre-treatment CT scans are associated with DFS in patients with NSCLC undergoing neoadjuvant chemo-IO prior to surgery. **Methods:** The study included 101 patients with NSCLC (median age: 66 years, range: 34–85) treated at the Cleveland Clinic. All patients received neoadjuvant platinum-doublet chemotherapy combined with an anti-PD-1 inhibitor prior to surgery. Radiomic features characterizing tumor heterogeneity were extracted from pre-treatment CT images. Patients were divided into a training set (St=50) and a validation set (Sv=51). A least absolute shrinkage and selection operator (LASSO) Cox regression model was used to identify prognostic features for DFS in St. A radiomic risk score (RRS) was computed as a linear combination of the selected features and their corresponding coefficients. High- and low-risk groups were determined based on the median RRS in St. A Cox regression analysis was performed to assess the impact of each factor on DFS. Kaplan–Meier survival analysis, accompanied by log-rank tests, was conducted to evaluate the prognostic performance of the biomarkers. **Results:** In a univariable analysis, the RRS was significantly associated with DFS in both St (HR = 2.77, 95% CI: 1.84 – 4.1, $P < 0.0001$) and Sv (HR= 2.28, 95% CI: 1.48 – 3.5, P = 0.0002). Kaplan-Meier analyses revealed significantly shorter DFS in the high-risk group compared to the low-risk group in both St ($P < 0.0001$) and Sv ($P < 0.011$). In a multivariable analysis that included clinicopathologic factors (age, race, tumor stage, and PD-L1 expression) along with RRS, both RRS and PD-L1 expression were significantly associated with DFS in St (RRS: HR = 2.99, 95% CI: 1.89 – 4.7, $P < 0.0001$; PD-L1: HR = 1.57, 95% CI: 1.14 – 2.15, P = 0.005). However, in Sv, RRS was the only factor significantly associated with DFS (RRS: HR= 2.31, 95% CI: 1.49 – 3.6, P = 0.0001), while PD-L1 expression was not (HR = 1.27, 95% CI: 0.35 – 4.6, P = 0.71). **Conclusions:** Identifying patients with locoregional NSCLC at risk of recurrence after neoadjuvant chemo-IO is crucial for effective treatment planning. Preliminary findings suggest that radiomic features hold promise as a reliable, non-invasive biomarker for risk stratification and guiding treatment decisions. Research Sponsor: None.

Real-world surgical and treatment patterns after neoadjuvant checkpoint inhibition in US patients with stage II/III non-small cell lung cancer. First Author: Jay M. Lee, Division of Thoracic Surgery, University of California, Los Angeles (UCLA), Los Angeles, CA

Background: Since 2021, several immuno-oncology (IO) agents were approved for use in patients with resectable non-small cell lung cancer. In the phase III neoadjuvant and perioperative IO trials, 16-26% of patients did not undergo surgery. The objectives of this study were to evaluate the real-world rate of surgery following neoadjuvant IO, reasons for preoperative attrition to resection, and subsequent treatment patterns for those who did not undergo surgery. **Methods:** This retrospective observational study used the nationwide Flatiron Health electronic health record-derived deidentified database. Included were patients diagnosed with stage II or III NSCLC between Jan 2022 and Oct 2023 who received nivolumab (nivo) and doublet chemotherapy (CT) as the first therapy within 90 days of diagnosis. We excluded patients with no documented neoadjuvant intent from the no surgery group. Per approved protocol, descriptive statistics were utilized for patient characteristics and treatment patterns. **Results:** A total of 484 patients received nivo. Among these, the average age was 67 years, 253/484 (52.3%) were male, 339/484 (70.0%) were white, and 403/484 (83.3%) were treated in a community setting. The rate of surgery was 317/484 (65.5%). Rates by stage and ECOG are found in Table 1. Among those most similar to the population in clinical trials (ECOG 0-1 and Stage IIA-IIIA) the rate was 238/334 (71.3%). The most common reasons for attrition were medical fitness (45/484; 9.2%), tumor resectability (30/484; 6.2%), and progression (28/484; 5.8%). Of those not receiving surgery, 131/167 (78.4%) received subsequent treatment, including 57 who received radiation (+/- chemo) during the follow-up period (median 10.5 months from diagnosis). **Conclusions:** In this real-world analysis, most patients were treated in community centers. The resection rate following neoadjuvant CT-IO in stage II and III NSCLC was high and comparable to the clinical trials. Medical operability, tumor resectability, and progression of disease as reasons for preoperative attrition to surgery occurred in a minority of patients that received neoadjuvant therapy. Many of the patients who did not undergo resection received subsequent therapy including consolidation radiation. Future research is needed to determine ways to improve surgical rates following neoadjuvant CT-IO. Research Sponsor: AstraZeneca.

Surgical rates by ECOG and stage at diagnosis.

	Stage IIA	Stage IIB	Stage II (unspecified)	Stage IIIA	Stage IIIB	Stage IIIC	Stage III (unspecified)
ECOG 0-1	28/35 (80.0%)	80/97 (82.5%)	7/10 (70.0%)	123/192 (64.1%)	11/24 (45.8%)	0/7 (0%)	5/5 (100.0%)
ECOG ≥2	1/4 (25.0%)	4/10 (40.0%)	0/0 (0%)	4/13 (30.8%)	1/5 (20.0%)	0/1 (0%)	0/0 (0%)
Unknown	5/6 (83.3%)	16/26 (61.5%)	1/1 (100.0%)	27/41 (65.9%)	2/4 (50.0%)	0/0 (0%)	2/3 (66.7%)
Overall	34/45 (75.6%)	100/133 (75.2%)	8/11 (72.7%)	154/246 (62.6%)	14/33 (42.4%)	0/8 (0%)	7/8 (87.5%)

Pronounced gender-based and regional disparities in lung cancer mortality in the US: Insights from five decades of nationwide mortality data. First Author: Muhammad Ahmad, Khyber Medical University, Peshawar, Pakistan

Background: Lung cancer remains the leading cause of cancer-related mortality in the United States, necessitating an understanding of long-term mortality trends to evaluate public health interventions and identify disparities. This study examines lung cancer mortality trends from 1968 to 2016 using data from the CDC WONDER database, stratified by demographic and regional characteristics. **Methods:** The analysis included deaths attributed to lung cancer, identified using International Classification of Disease (ICD) codes across three periods: ICD-8 (1968–1978), ICD-9 (1979–1998), and ICD-10 (1999–2016). Crude and age-adjusted mortality rates (AAMRs) per 100,000 population were calculated. Temporal trends were assessed with Joinpoint regression analysis to estimate annual percentage changes (APC) and average annual percentage changes (AAPC) with 95% confidence intervals (CIs). Data were stratified by gender, race, and U.S. Census regions. **Results:** Between 1968 and 2016, there were 6,289,300 deaths attributed to lung cancer in the U.S. The overall AAMR rose from 53.53 to 59.28, with an AAPC of 0.22 (95% CI: 0.19 to 0.25). Notable trends included a sharp rise from 1968 to 1980 (APC: 3.02; 95% CI: 2.88 to 3.18), a slowdown from 1980 to 1991 (APC: 1.72; 95% CI: 1.60 to 1.83), a decline from 1991 to 2004 (APC: -0.84; 95% CI: -0.92 to -0.75), a steeper drop from 2004 to 2012 (APC: -2.17; 95% CI: -2.36 to -1.96), and an acceleration from 2012 to 2016 (APC: -3.83; 95% CI: -4.40 to -3.40). Of the total, 37.1% of deaths were females (2,333,863) and 62.9% were males (3,955,437). The male AAMR decreased from 97.85 to 72.2 (AAPC: -0.65; 95% CI: -0.69 to -0.62), while the female AAMR rose from 17.96 to 49.24 (AAPC: 2.14; 95% CI: 2.10 to 2.19). Racially, 656,875 deaths (10.4%) involved Black or African Americans, who had higher AAMRs than the 5,534,744 deaths (88%) among Whites. Whites saw a more marked increase in AAMR (AAPC: 0.29; 95% CI: 0.27 to 0.32) compared to Blacks (AAPC: 0.095; 95% CI: 0.055 to 0.14). Regionally, the South had the highest AAMR at 83.2, while the West, with the lowest at 68.58, was the only region to experience an overall decrease from 52.74 in 1968 to 45.64 in 2016. **Conclusions:** The decline in overall mortality rates since 2004 underscores the effectiveness of smoking cessation programs and treatment advancements; yet, rising female mortality and high rates in the South call for a reassessment of outreach efforts to ensure public health strategies. Research Sponsor: None.

Radiomic signatures as predictors of pathological response to neoadjuvant chemoimmunotherapy in surgically resected NSCLC. First Author: Ryan Brown, Cleveland Clinic, Cleveland, OH

Background: Historically, pathological complete response (pCR), a potential early predictor of survival, was achieved by a small fraction of patients with non-small cell lung cancer (NSCLC) receiving neoadjuvant chemotherapy. Now with chemoimmunotherapy (chemo-IO) becoming the cornerstone of perioperative treatment, the rate of pCR has significantly increased to over 15%. Existing factors like PD-L1 expression and circulating tumor DNA clearance have shown limited efficacy in reliably predicting response to neoadjuvant chemo-IO, thus underscoring the need for novel biomarkers. In this study, we aim to investigate the potential of radiomic texture features derived from pre-treatment CT scans to predict pCR in patients with NSCLC undergoing neoadjuvant chemo-IO prior to surgery. **Methods:** The study included 101 patients with surgically resected NSCLC treated at Cleveland Clinic. All patients received neoadjuvant platinum-doublet chemotherapy combined with an anti-PD-1 inhibitor prior to surgery. Tumor stage, histology, PD-L1 expression levels, and treatment details (e.g., chemotherapy regimen, immunotherapy agent, number of treatment cycles) were collected for analysis. Pathological responses were assessed based on the percentage of residual viable tumor in the surgical specimen, with pathological complete response (pCR) defined as 0% viable tumor. Radiomic features were extracted from both intratumoral and peritumoral regions on pre-treatment CT images. Patients were randomly divided into training and validation cohorts, ensuring an equal distribution of pCR and non-pCR cases in the training set. The training cohort (St) comprised 50 patients, while the validation cohort (Sv) included 51 patients. A linear discriminant classifier (LDA) was trained using St and subsequently evaluated on Sv. The predictive performance was assessed using the area under the curve (AUC). **Results:** 37 of 101 patients (37%) achieved a pCR. Utilizing a combination of 5 peritumoral and intratumoral radiomic features extracted from pretreatment CT scans, the AUC for predicting pCR was 0.82 (95% CI: 0.79 − 0.86) in St and 0.78 (95% CI: 0.76 − 0.81) in Sv. In contrast, the predictive capability of PD-L1 expression alone yielded an AUC of 0.57 for pCR prediction. Moreover, no significant difference was observed in pCR rates between patients with low and high PD-L1 expression levels (P = 0.1). The integration of radiomic features with clinicopathologic factors, including age, race, tumor stage, and PD-L1 expression, resulted in a modest improvement in predictive performance (AUC = 0.8) but was not statistically significant (P > 0.5). **Conclusions:** This analysis suggests that radiomic features extracted from both intra- and peri-tumoral regions on pre-treatment CT images may be indicative of the probability of achieving a pCR in patients with NSCLC receiving neoadjuvant chemo-IO. Research Sponsor: None.

Impact of *MTAP* deletion on immunotherapy outcomes in patients with mesothelioma. First Author: Jessica Ross, Memorial Sloan Kettering Cancer Center, New York, NY

Background: *MTAP* (*methylthioadenosine phosphorylase*) is located on chromosome 9p21 and often co-deleted with *CDKN2A* across a variety of cancers. *MTAP* deletions (del) are found in about 30% of diffuse pleural mesotheliomas (DPM). *MTAP*del has been associated with resistance to immunotherapy (IO) treatment (tx) in multiple tumor types. In patients (pts) with DPM, objective response rate (ORR) on ipilimumab/nivolumab is 40%, disease control rate (DCR) 77%, and median progression-free survival (PFS) 6.8 months (mos): the implications of *MTAP* status on IO outcomes is unclear but represents a potential predictive biomarker. With multiple targeted therapies underway for *MTAP*del tumors, such as PRMT5 inhibitors, this alteration is also of therapeutic importance. **Methods:** We prospectively identified pts with pathologically confirmed DPM whose tumors were sequenced with MSK-IMPACT version 7, a 505-gene next generation sequencing panel that includes *MTAP* and *CDKN2A*. IO regimens included anti-PD(L)1 monotherapy, dual checkpoint blockade with additional anti-CTLA4 tx, and anti-PD(L)1 + chemotherapy. *MTAP*del was defined as low read count and confirmed by FACETS copy number when able. Radiologists reviewed imaging to determine best response and PFS on IO using mRECIST or, when not applicable, RECIST. Overall survival (OS) was compared between *MTAP*del and *MTAP*wildtype (WT) cohorts using Kaplan-Meier curves and log-rank tests. Baseline demographics were compared using Fisher's exact test. **Results:** We examined 156 pts with DPM: 39 had *CDKN2A*del (25%) and 32 had *MTAP*del (21%). 18/32 were treated with IO and available for analysis. 79 pts with *MTAP*WT DPM treated with IO were analyzed as a control. There were more pts treated with dual checkpoint blockade in the *MTAP*del vs *MTAP*WT group (83% vs 56%, single-agent IO 6% vs 39%, single-agent IO + chemo 11% vs 5%, p=0.03) and more men (94% vs 70%, p=0.04); there was no statistically significant difference in age (median 72 vs 69, p=0.5), histology (72% epithelioid vs 79%, p=0.5), or smoking status (current/former 61% vs 57%, p=0.9). All tumors with *MTAP*del also harbored a *CDKN2A*del: 5/79 tumors in the *MTAP*WT cohort had a *CDKN2A*del (p<0.001). Among the *MTAP*del cohort, 13 patients had (m)RECIST-evaluable disease. ORR on IO was 15% (2/13), DCR 38% (5/13), and median PFS 2.5 mos. OS was similar between the *MTAP*del and *MTAP*WT cohorts: median 25.4 vs 27.6 mos (HR 0.84, 95% CI 0.36 − 1.94, p=0.98). **Conclusions:** *MTAP*del (co-occurring with *CDKN2A*del) was identified in both epithelioid and non-epithelioid DPM and was associated with a low ORR and short PFS on IO, but OS was similar compared to *MTAP*WT. Larger, multi-institution cohorts are needed to validate this finding. If confirmed, this could have implications for tx selection, particularly among pts with epithelioid DPM, in which the optimal choice between 3 FDA-approved first-line regimens is uncertain. Test performance of a DNA methylation–based liquid biopsy biomarker for detection and classification of pleural mesothelioma (PM). First Author: Sabine Schmid, Inselspital, Universitätsspital Bern, Bern, Switzerland

Background: Circulating tumor DNA (ctDNA) profiling in pleural mesothelioma (PM) is challenging due to its molecular heterogeneity and lack of mesothelioma-specific mutations. Diagnosis can be challenging and may require repeat biopsies. Cell-free methylated DNA immunoprecipitation sequencing (cfMeDIP-seq) of plasma cell-free DNA (cfDNA) offers a non-invasive approach to analyzing differentially methylated regions (DMRs), providing insights into epigenetic changes that could serve as potential biomarkers for diagnosis, histological differentiation, and prognosis in PM. **Methods:** cfMeDIP-seq was performed on plasma samples from 55 PM patients and 24 asbestos-exposed non-cancer controls (NCC). Libraries were sequenced to an average depth of 70 million reads, and chromosomes 1-22 were binned into 300 bp windows for read tallying. For NCCs, bins with a mean beta-value <0.3 and CG density >2 (n = 3,537,691 windows) were analyzed. DMR analysis and pathway enrichment were conducted using R packages (limma, clusterProfiler), and machine learning models were developed with Python modules (pandas, numpy, sklearn). **Results:** Among the 55 PM patients (72% epithelioid, 13% biphasic, 15% sarcomatoid), the median age was 70 years, 85% were male, and 78% had prior asbestos exposure. Using a stringent filter (mean beta-value <0.1; CG density >5), a random forest classifier was developed with 141 windows, distinguishing PM from NCC with 91% accuracy, 88% precision (or positive predictive value, PPV), and an area under the ROC curve (AUC) of 0.94 across 5-fold cross-validation cohorts. DMR analysis of epithelioid vs. sarcomatoid PM revealed 1,585 significantly different windows (adjusted $p < 0.05$), achieving 83% accuracy, 74% precision, and an AUC of 0.98. Gene ontology analysis indicated significant enrichment in RNA processing pathways. Among epithelioid PM patients, distinct DMRs were identified between those with overall survival (OS) $\leq$ 6 months and $>$6 months (n = 1,824 windows, adjusted $p < 0.05$). Patients with OS $\geq$ 36 months and $<$36 months showed 37 significantly differential windows (adjusted $p < 0.05$), though test performance assessment was limited by the small sample size. **Conclusions:** If validated, global methylome profiling of ctDNA via cfMeDIP-seq offers a novel, non-invasive method that may enhance accurate diagnosis and histological differentiation. Additionally, identifying epigenetic biomarkers could provide deeper insights into PM biology, paving the way for personalized medicine and improved patient outcomes. Prognostic significance of VISTA expression in patients with malignant pleural mesothelioma treated with nivolumab: Results of a retrospective multi-institutional analysis (HOT1901). First Author: Hiroshi Yokouchi, Department of Respiratory Medicine, NHO Hokkaido Cancer Center, Sapporo, Japan

Background: Nivolumab as a second-line treatment for pleural mesothelioma (PM) has demonstrated efficacy in the MERIT phase 2 trial in Japan and the CONFIRM phase 3 trial in the UK. However, the response rate and survival outcomes were modest. Therefore, the exploration of biomarkers that can determine its efficacy and prognosis is crucial. Recently, V-domain immunoglobulin suppressor of T cell activation (VISTA), and other coinhibitory or costimulatory molecules which are expressed on T cells and tumor cells, have attracted attention as novel therapeutic targets and predictors of clinical outcomes beyond PD-L1 for immunotherapy against various solid tumors. However, few studies have explored the efficacy of nivolumab by examining these molecules, as well as specific gene mutation profiles, in patients with PM. Thus, we aimed to identify biomarkers associated with survival in our cohort. **Methods:** This retrospective, multi-institutional cohort study included patients with PM who received nivolumab monotherapy as a second-line or later treatment at 18 hospitals in Japan between August 2018 and October 2019. We investigated the association of progression-free survival (PFS) and overall survival (OS) with clinical variables, expression of CD4, CD8, OX40, PD-L1, Tim-3, LAG-3, and VISTA in tumor tissues via immunohistochemistry (IHC), and gene expression profiles using next-generation sequencing (NGS). **Results:** Fifty-five patients were enrolled in this study. IHC and NGS were performed in 42 and 33 patients, respectively. The median survival follow-up time for all patients was 12.3 months (range, 0.2–47.0 months). The median PFS was 4.8 months (95% confidence interval [CI], 3.6–6.0), and the median OS was 12.3 months (95% CI, 10.3–14.4). No differences in OS or PFS were observed based on histological type. The IHC analysis revealed that high VISTA expression in tumor cells was significantly associated with improved PFS and OS compared with low VISTA expression (PFS, median: 5.1 months [95% CI, 3.5–6.7] vs. 2.4 months [95% CI, 0.0–5.1], p = 0.001; OS, median: 12.8 months [95% CI, 11.0–14.6] vs. 4.3 months [95% CI, 1.2–7.3], p = 0.007). Multivariate analysis confirmed that high VISTA expression in tumor cells was an independent predictor of prolonged PFS and OS (PFS: hazard ratio [HR], 0.14; $p < 0.001$; OS: HR, 0.38; p = 0.044). NGS data showed that gene alterations commonly reported in PM, such as mutations in *CDKN2A*, *BAP1*, and *NF2*, were not associated with PFS or OS. **Conclusions:** For PM patients with low VISTA expression in tumor cells, nivolumab may not be the optimal treatment choice, and alternative therapies should be considered. These findings provide a basis for further biomarker exploration in combination therapies, such as nivolumab-ipilimumab or chemoimmunotherapy, for patients with PM. Research Sponsor: Research funding from the Department of Respiratory Medicine, Hokkaido Cancer Center.

Digital spatial profiling for identification of prognostic genes and molecular subgroups in pleural mesothelioma. First Author: Mercedes Herrera, Hospital Universitario 12 de Octubre, Madrid, Spain

Background: Pleural mesothelioma (PM) is an aggressive malignancy that harbors significant inter- and intra-tumoral heterogeneity. Spatial transcriptomics enables the dissection of the tumor's molecular architecture by facilitating compartment-specific gene expression profiling. We performed high-resolution RNA-seq analysis of tumor (Tm) and stroma (St) compartments in PM samples to identify gene expression patterns and their association with clinical outcomes. **Methods:** Formalin-fixed paraffin-embedded (FFPE) tumor samples from untreated PM patients (pts) across three institutions were analyzed using the NanoString GeoMx Digital Spatial Profiling (DSP) platform. Regions of interest (ROIs) were selected based on histopathological features and fluorescently labeled antibodies for tumor and stromal areas. RNA expression of $>$1800 genes from selected ROIs was analyzed using GeoMx Cancer Transcriptome Atlas (CTA). Differential gene expression was assessed utilizing R "limma" package. A cutoff of absolute fold change $\geq$1 and p-value <0.05, with the Benjamini-Hochberg false discovery rate method, was applied to identify significant differentially expressed genes (DEGs). Elastic Net regression optimized through cross-validation methods was employed to identify genes associated with overall survival (OS) outcomes. Data from the TCGA PanCancer Atlas was utilized for external validation. **Results:** A total of 72 pts, 80.3% male, median age of 71y (range: 44-94) were identified for the analysis. Among them, 87.5% (63/72) were epithelioid (Ep) and 12.5% (9/72) non-epithelioid (NEp). After quality control, RNA data was available from 71 and 67 pts in Tm and St compartments, respectively. Across 132 ROIs in the Tm compartment, we identified 4 significantly DEGs between NEp (upregulated *COL5A2, THBS1*; downregulated *CLU, KRT19*) and Ep subgroups. No DEG between Ep and NEp subgroups were identified in 115 ROIs from the St compartment. Unsupervised clustering identified four molecular subgroups with distinct gene expression in the Tm compartment, of which Cluster 1 showed significantly decreased OS (6.3m vs. 16.4m; HR 3.3, p =0.001). Elastic Net regression identified 31 genes predictive of OS (R^2 = 0.43, Harrell's c-index = 0.87), including nine genes (*IFNGR2, FCER1G, MFGE8, CKLF, CBL, HLA-DRB3, HK1, PLAT, CD163*) associated with worse prognosis. Tumors in Cluster 1 demonstrated higher expression of these genes. External validation using the TCGA cohort confirmed four genes *IFNGR2* (p = 0.02), *CBL* (p = 0.01), *HK1* ($p <0.001$), *PLAT* ($p <0.001$), as significantly associated with decreased OS in PM. **Conclusions:** Spatially resolved transcriptomic profiling suggests Tm-enriched regions as the primary drivers of PM subtype and aggressiveness, identifying nine genes and a molecular subgroup associated with poorer survival outcomes. Further validation and functional studies are warranted. Research Sponsor: TRANSCAN-3 Consortium; TRNSC18004PAZ.

Multiomics profiling for prediction of immunotherapy response in advanced pleural mesothelioma: Sub-study of the NIPU trial. First Author: Mehrdad Rakaee, University Hospital of North Norway, Oslo, Norway

Background: The combination of ipilimumab and nivolumab (IPI/NIVO) is a standard treatment for unresectable pleural mesothelioma. However, the objective response rate (ORR) is relatively low, and serious toxicity necessitating treatment cessation with or without steroid treatment is seen in 20%. Predictive biomarkers for IPI/NIVO in mesothelioma are needed to personalize treatment decisions. **Methods:** In the NIPU trial, 118 patients progressing after first-line chemotherapy were included in the study and were randomly assigned to IPI/NIVO alone or in combination with the telomerase UV1 vaccine. Whole-slide tumor tissues were available from 99 patients and analyzed using multiplex immunofluorescence (mIF) with a panel including CD8, CD20, CD66b, FoxP3, Granzyme-B, and pan-cytokeratin. Machine learning algorithms (XGBoost) were utilized and trained for immune cell subset classification and tissue subregion segmentation (tumor vs. stroma). Bulk RNA-sequencing (RNA-seq) was performed on 25 matched baseline fresh frozen tissues, followed by differential expression analysis (DESeq2), gene set enrichment analysis (GSEA) and immune cell deconvolution. Radiological evaluation was done by local assessment of immune version of the mesothelioma modified RECIST criteria. Disease control rate (DCR) was defined as the fraction of patients with partial response (PR) or stable disease (SD) compared to those with progressive disease (PD). **Results:** The DCR and ORR were 69% and 20%, respectively. From mIF analysis, stromal CD66b, CD20, and tumoral CD66b showed the highest area under the curve (AUC = 0.60 $\pm$ 0.1) for differentiating DCR groups. For ORR, tumoral CD8+FoxP3+ T-cells demonstrated the highest AUC (0.58) for identifying PR. Patients with tumoral CD66b% scores above the median ($>$0) had significantly longer progression-free survival (6.2 vs. 4.2 months; HR: 0.63, 95% CI: 0.42–0.97, P = 0.04) and showed a trend toward improved overall survival (HR: 0.65, 95% CI: 0.41–1.0, P = 0.07). These findings were consistent with RNA-seq-derived immune fraction scores. Lasso Cox regression identified natural killer cells, neutrophils, and CD4+ T cells as top predictive features for DCR groups. Additionally, GSEA hallmark analysis revealed significant enrichment of interferon-γ and -α pathways in the DCR PR/SD group ($Q <$ 0.001) compared to PD. **Conclusions:** High/positive levels of tumoral CD66b+ neutrophils show promise as predictive biomarkers for immunotherapy efficacy in advanced pleural mesothelioma. Larger, independent studies are needed to confirm these findings and validate their clinical utility. Clinical trial information: NCT04300244. Research Sponsor: Bristol Myers Squibb; South-Eastern Norway Regional Health Authority; Ultimovacs.

Phase III study on atezolizumab versus placebo in adjuvant therapy of pleural mesothelioma patients after pleurectomy/decortication: Preliminary results of the AtezoMeso study. First Author: Maria Pagano, Medical Oncology, Comprehensive Cancer Centre, AUSL-IRCCS, Reggio Emilia, Italy

Background: AtezoMeso Study is a multicentric double-blind, placebo-controlled, Phase III trial, that aims to evaluation the efficacy of adjuvant atezolizumab therapy versus placebo in patients with pleural mesothelioma (PM), who have undergone pleurectomy/decortication (P/D) and peri-operative chemotherapy. Here, we report preliminary data on disease recurrence and Next Generation Sequencing (NGS) testing. **Methods:** Patients with PM who have undergone P/D and perioperative platinum-pemetrexed chemotherapy are randomized 2:1 to receive atezolizumab or placebo for up to 12 months, or until unacceptable toxicity or patients'/physicians' decision. The primary objective of the study is disease free survival (DFS), with a sample size of 90 patients. Surgical specimens are analyzed centrally to determine the genomic profile using FoundationOne CDx Platform. **Results:** Between December 2021 and January 2025, 64 patients were randomized in 14 Italian centers. The characteristics of patients included 46 (71.88%) males and 18 (28.12%) females. %), with a median age of 67 years (range 48-79). Sixty (93.75%) patients had epithelioid histotype, and 4 (6.25%) non-epithelioid. Sixteen (25%) patients are ongoing the adjuvant treatment. At the median follow up of 8.3 months (1-30 months), 25 (53.19%) of 47 evaluable patients experienced a disease recurrence. Sixteen (64%) of 25 patients had a local recurrence of disease, 5 (20%) patients an extra-thoracic recurrence, and 4 (16%) patients both. The median DFS of all evaluable patients was 12 months (7.4 - 16.6 months). The histotype of all relapsed patients was epithelioid. NGS testing was performed in 43 (67.19%) of 64 patients. Median Tumor Mutational Burden (TMB) was 2 mutations/megabase (0-13). The most frequent genomic alteration detected were BAP1 found in 21 (48.83%) patients, CDKNA2A-B in 18 (41.86%), NF2 in 8 (18.60%), SETD2 and TP53 in 5 (11.63 %). One (2.32%) patient had a mutation of BRCA2. The co-occurrence of BAP1 and CDKNA2A-B mutations was detected in 7 (16.27%) patients, all of whom had a disease recurrence. **Conclusions:** These preliminary dataof AtezoMeso Study, regarding all randomized patients, show a median DFS longer than expected in control arm according with the study design hypothesis (9 months). The TMB of MPM patients is low. BAP1 mutations were identified as the most frequent molecular alterations. Furthermore the co-occurrence of BAP1 and CDKNA2A-B mutations was found in patients with disease relapse. Clinical trial information: NCT04996017. Research Sponsor: None.

Real-world efficacy and safety of tarlatamab in patients with relapsed extensive-stage small cell lung cancer. First Author: Mitchell Parma, Department of Hematopoietic Biology and Malignancy, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Tarlatamab, a bispecific T cell engager targeting Delta-Like ligand 3, received FDA approval in May 2024 for patients with relapsed extensive-stage small cell lung cancer (SCLC). While the clinical trials leading to its approval demonstrated impressive objective response, it has unique toxicities including cytokine release syndrome (CRS) and immune effector cell-associated neurotoxicity syndrome (ICANS). Here, we report a real-world case series of safety and efficacy data for patients treated with standard of care tarlatamab at MD Anderson Cancer Center. **Methods:** We queried the MD Anderson Lung Cancer GEMINI database for patients treated with tarlatamab and retrospectively collected demographic, clinical, and outcome data. From 7/1/2024-1/15/2025, a total of 39 patients received tarlatamab. 8 patients were excluded from analysis either due to diagnosis of extrapulmonary small cell cancer or rapid clinical deterioration due to disease progression around the time of the first tarlatamab infusion. The final cohort consisted of 31 patients. **Results:** The average age of our cohort was 66 years, 36% of patients were of non-white race, and their median lines of prior treatment was 2. 4 patients had transformed SCLC from classical EGFR-mutant lung adenocarcinoma (EGFR transformed), and 12 patients had untreated brain metastases (BM) prior to tarlatamab initiation. Safety data is summarized in the Table. At the cutoff, 17 patients had their first repeat systemic imaging: 59% had tumor shrinkage, 12% had stable or mixed tumor response, and 29% experienced tumor growth. Of the 3 EGFR transformed cases that had a repeat imaging on treatment, 2 had tumor growth. 18 patients underwent a repeat brain magnetic resonance imaging (MRI) after tarlatamab treatment. Out of 11 patients with untreated BM, 82% (9) had intracranial tumor shrinkage or stability, and 2 patients had mixed response, one of which was an EGFR transformed case. Of the 7 patients who either had no prior BM or had BM treated with radiation, only 1 had developed new BM (EGFR transformed). **Conclusions:** Preliminary data from this cohort show efficacy comparable to that observed in clinical trials. Notably, we report impressive intracranial response in patients with untreated BM. The toxicity profile reveals similar CRS but higher ICANS rates compared to those reported in the clinical trials. Additional data collection and analyses are ongoing at this time. Research Sponsor: None.

Safety data from C1D1 and C1D8 of Tarlatamab.

Adverse Event	Hospitalization for C1D1 of Tarlatamab 1 mg IV (N=31)	Hospitalization for C1D8 of Tarlatamab 10 mg IV (N=28)
Cytokine-release syndrome — no. (%)		
Overall	12 (39)	11 (39)
Grade 3 or more	1 (3)	1 (4)
Tocilizumab Administration	8 (26)	4 (14)
ICANS — no. (%)		
Overall	8 (26)	4 (14)
Grade 3 or more	3 (10)	0 (0)
Adverse event leading to ICU stay — no. (%)	4 (13)	1 (4)

A phase 1 dose escalation and expansion study of ZG006, a trispecific T cell engager targeting CD3/DLL3/DLL3, as monotherapy in patients with refractory small cell lung cancer or neuroendocrine carcinoma. First Author: Qiming Wang, The Affiliated Cancer Hospital of Zhengzhou University & Henan Cancer Hospital, Zhengzhou, Henan, China

Background: ZG006 is a unique designed T cell engager, targeting CD3 and Delta-like ligand 3 (DLL3) with two distinct DLL3 epitopes, and bridges tumor cells and T cells by strongly binding to DLL3 on tumor cells and CD3 on T cells, thereby mediating T cell-specific killing of DLL3-expressing tumor cells such as small cell lung cancer (SCLC) or neuroendocrine carcinoma (NEC). Here, we report the complete results for the phase 1 study of ZG006 for the treatment of patients (pts) with refractory SCLC or NEC. **Methods:** This is a multi-center, open-label, phase 1 clinical study of ZG006 as monotherapy in pts with SCLC or NEC who failed or were intolerant to the standard therapies. A standard "3+3" design, with an accelerated approach for the first two lower dose levels was used during the dose escalation stage. Patients were treated with doses from 0.1 to 100 mg, intravenous infusion, once every 2 weeks. Tumor response was assessed by RECIST1.1. DLL3 expression was retrospectively evaluated by IHC. **Results:** As of data cut-off in Dec 2024, a total of 45 pts (41 SCLC pts and 4 NEC pts) were enrolled and received≥1 dose of ZG006, 4 at the dose group of 0.1 mg, 3 at 0.3 mg, 3 at 1 mg, 3 at 3 mg, 5 at 10 mg, 12 at 30 mg, 11 at 60 mg and 3 at 100 mg. Patients included 35 males and 10 females, with median age 59 years (range: 43-72). The majority (86.6%) had received ≥2 lines of prior treatments and 44.4% received ≥3 lines. Twenty-six pts (57.8%) had prior anti-PD-(L)1 treatment. Only one patient in 100 mg group experienced DLT events (grade 3 cytokine release syndrome and grade 4 pneumonia). Treatment-related adverse events (TRAEs) occurred in all 45 pts; most commonly: cytokine release syndrome (CRS), pyrexia, anemia, white blood cell count decreased, pruritus, decreased appetite, hyponatraemia, asthenia, neutrophil count decreased, nausea, hypoalbuminaemia, alanine aminotransferase increased and constipation. CRS occurred mostly after the first two doses and usually recovered within 2 days. Eleven pts (24.4%) experienced serious TRAEs. There was no TRAE leading to treatment discontinuation or death and no ICANS was reported. Twenty-three SCLC patients receiving ZG006 10-60 mg were efficacy-evaluable with at least one post-baseline tumor assessment, and the ORR was 60.9% (14/23, 10 confirmed) and the DCR was 78.3% (18/23). Among the 18 pts who had low/medium DLL3 expressions, 12 pts achieved PRs with an ORR of 66.7%, which demonstrated that ZG006 had a great anti-tumor activity in SCLC pts. ZG006 demonstrated a nearly dose-proportional increase in concentration with a half life of approximately 4 days after multiple doses. **Conclusions:** ZG006 exhibited a promising antitumor activity with acceptable safety profiles. Phase 2 dose expansion studies have been initiated to further investigate the efficacy and safety of ZG006 in pts with SCLC or NEC. Clinical trial information: NCT05978284. Research Sponsor: None.

Efficacy and safety of envafolimab plus carboplatin and etoposide as first-line treatment for extensive-stage small-cell lung cancer: A prospective, single-arm, phase II trial. First Author: Shengjie Sun, Senior Department of Oncology, the Fifth Medical Center of PLA General Hospital, Beijing, China

Background: Extensive-stage small cell lung cancer (ES-SCLC) is related to high malignancy and the poor prognosis. At present, immunotherapy combined with chemotherapy resulted in favorable therapeutic efficacy, and had been established as the standard treatment regimen for first-line treatment of ES-SCLC. However, some patients may still experience intolerable AEs over the course of treatment, such as immune-related pneumonitis and enteritis. Additionally, currently marketed ICIs were administered by continuous intravenous infusion, which is inconvenient for patients. This trial aimed to evaluate the efficacy and safety of envafolimab, which is a subcutaneously administered fusion protein of humanized anti-PD-L1 monodomain antibody, plus chemotherapy as a first-line treatment for ES-SCLC. **Methods:** This prospective, single-arm, phase II trial was conducted at the Fifth Medical Center of Chinese PLA General Hospital. Eligible patients with histologically or cytologically confirmed ES-SCLC were consecutively enrolled. Patients were given four cycles of carboplatin (5-6 mg/mL/min, day 1 of each cycle) and etoposide (80-100 mg/m², days 1-3 of each cycle) with envafolimab (300 mg, Q3W, day 3 post-chemotherapy of each cycle), followed by envafolimab maintenance until disease progression or intolerable toxicity. The primary endpoint was progression-free survival (PFS), and the secondary endpoint included objective response rate (ORR), disease control rate (DCR), and safety. **Results:** Between October 2021 and November 2022, a total of 32 patients were enrolled in this study. 32 patients were included for safety analysis, and 31 patients were included for efficacy analysis. As of the data cutoff (September 15, 2024), the median follow-up was 27.7 months. The ORR was 87.1% (95% CI, 70.2-96.4%), and the DCR was 100% (95% CI, 88.8-100%). The median DoR was 5.47 months (95% CI, 3.43-10 months). The median PFS was 6.43 months (95% CI, 4.83-7.67 months), and median OS was 20 months (95% CI, 14.7-NA). Treatment-related adverse events (TRAEs) of any grade were reported in 59.4% of patients, with grade ≥ 3 TRAEs in 15.6% patients. No treatment-related deaths occurred. **Conclusions:** First-line envafolimab in combination with carboplatin and etoposide yielded favorable clinical efficacy with a manageable safety profile for patients with ES-SCLC, representing a promising treatment modality. Clinical trial information: ChiCTR2100044981. Research Sponsor: None.

Unveiling drivers of MHC repression and therapeutic strategies to counter immune evasion in small cell lung cancer. First Author: Triparna Sen, Icahn School of Medicine at Mount Sinai, New York, NY

Background: Small cell lung cancer (SCLC) is a highly aggressive neuroendocrine malignancy with a median survival of 9–11 months. Despite the addition of immune checkpoint blockade (ICB) to frontline chemotherapy, improvements remain limited. SCLC evades anti-tumor immunity by suppressing major histocompatibility complex class I (MHC-I) and antigen presentation (AP). The variability of MHC repression across molecular subtypes of SCLC and high-grade neuroendocrine tumors is not fully understood. This study analyzed clinical SCLC and neuroendocrine tumor samples to identify molecular subtypes and regulators of MHC repression, enhancing the understanding of immune evasion. **Methods:** Molecular profiling was conducted on 944 SCLC and 5056 non-small cell lung cancer (NSCLC) tumors using next-generation DNA (592-gene panel/whole exome), RNA (whole transcriptome) sequencing, and immunohistochemistry. Transcriptomic profiling of 40 SCLC cell lines and genetically engineered mouse models (GEMMs) was also performed. **Results:** Key regulators and gene networks driving MHC-I suppression in SCLC and other high-grade neuroendocrine tumors were identified. Canonical (MHC-I and II) and non-canonical AP expression scores characterized the spectrum of MHC-I repression across subtypes. Low MHC-I scores correlated with reduced immune signatures (e.g., T cell-inflamed, NK cell, and STING pathway signatures; Spearman = 0.87, 0.58, 0.62, respectively) and predicted poor OS and PFS to immunotherapy. Enhancer network and gene expression analyses identified actionable regulators of MHC-I repression, including interferon signaling. Knockout studies of top MHC-I regulators and single cell analyses revealed non-homologous end-joining (NHEJ) genes (like DNAPKCs) inversely correlated with HLA-A/B/C expression. DNAPKCs inhibition upregulated MHC-I, TAP1, and TAP2, enhanced antigen-specific T-cell-mediated cytolysis in SCLC. This inhibition activated the STING pathway, increased CD8+ T-cell infiltration, and enhanced MHC Class-I. Combining DNAPKCs inhibitor NU1774 with anti-PD-L1 reactivated MHC-I and led to significant tumor regression in aggressive murine SCLC models, supporting new combination therapies. **Conclusions:** We identified molecular subtypes and actionable pathways to restore MHC-I expression in SCLC, advancing understanding of immune evasion mechanisms. DNAPKCs is established as a key therapeutic target, enhancing PD-L1 blockade by reactivating antigen presentation. The developed MHC-I expression scores and associated biomarkers offer predictive tools for identifying patients likely to benefit from immunotherapy. These findings support biomarker-driven, personalized approaches to improve treatment for SCLC, addressing a critical unmet need in this devastating cancer. Research Sponsor: None.

Serplulimab versus placebo plus chemotherapy as first-line treatment for extensive-stage small-cell lung cancer: Efficacy and safety from the end-of-study analysis of the international phase 3 ASTRUM-005 study. First Author: Ying Cheng, Department of Oncology, Jilin Cancer Hospital, Changchun, China

Background: ASTRUM-005 is a randomized, double-blind, phase 3 trial comparing the efficacy and safety of anti-PD-1 antibody serplulimab plus chemotherapy (chemo) versus (vs) placebo plus chemo as first-line therapy for extensive-stage small-cell lung cancer (ES-SCLC). Significantly prolonged overall survival (OS) in the serplulimab arm was observed at interim analysis and sustained OS improvement at extended follow-up (2024 ASCO Annual Meeting No. 8100). Here we present end-of-study analysis of ASTRUM-005 at a median follow-up of 42.4 months. **Methods:** Patients with ES-SCLC who had not received prior systemic therapy were randomized 2:1 to receive serplulimab plus chemo (carboplatin and etoposide) or placebo plus chemo. Serpluliamb or placebo were administered intravenously at 4.5 mg/kg every 3 weeks. Up to 4 cycles of intravenous carboplatin and etoposide were given every 3 weeks. Stratification factors included PD-L1 expression level, brain metastases, and age. The primary endpoint was OS. Secondary endpoints included progression-free survival (PFS), objective response rate, duration of response, and safety. **Results:** Between Sep 12, 2019 and Apr 27, 2021, 585 patients were randomized (serplulimab group, n = 389; placebo group, n = 196) and received at least one dose of study treatment. All 585 patients were included in efficacy and safety analyses. As of data cutoff on May 7, 2024, consistent with previous reports, marked improvement in OS, PFS, ORR, and DOR were achieved by patients receiving serplulimab plus chemo than those receiving placebo plus chemo. Median OS was 15.8 vs.11.1 months (stratified HR 0.60, 95% CI 0.49–0.73) for respective arms; estimated 4-year OS rate (95% CI) was 21.9% (17.6–26.6) and 7.2% (3.8–12.1). Subgroup analysis of OS by age, sex, race, ethnicity, ECOG PS, smoking history, brain metastasis, or PD-L1 expression level revealed similar trends of improvement in the serplulimab arm. Median PFS according to independent radiology review committee (IRRC) assessment per RECIST v1.1 was 5.8 vs 4.3 months (stratified HR 0.47, 95% CI 0.38–0.57), respectively. The safety profile was consistent with previous findings. Serplulimab/placebo-related treatment-emergent adverse events of grade 3 or higher occurred in 136 (35.0%) and 57 (29.1%) patients in respective arms. No new safety signals were identified in this study. **Conclusions:** This end-of-study analysis showed that addition of serplulimab to chemo continued to confer survival benefit to previously untreated patients with ES-SCLC along with manageable safety. These results support serplulimab plus chemo for first-line treatment of ES-SCLC. Clinical trial information: NCT04063163. Research Sponsor: Shanghai Henlius Biotech, Inc.

DAREONTM-9, a phase Ib study of obrixtamig plus topotecan in patients (pts) with advanced small cell lung cancer (SCLC): Interim analysis results. First Author: Martin Wermke, TU Dresden University of Technology, NCT/UCC Early Clinical Trial Unit, Dresden, Germany

Background: Delta-like ligand 3 (DLL3) is highly expressed on SCLC cells and is a promising target for new therapeutic drugs. Obrixtamig (BI 764532) is a DLL3/CD3 IgG-like bispecific T-cell engager that binds simultaneously to DLL3 on tumor cells and CD3 on T-cells leading to tumor cell lysis. We report the first safety and preliminary efficacy data for the dose escalation part of the Dareon-9 trial, investigating the combination of obrixtamig and topotecan in pts with advanced SCLC (NCT05990738). **Methods:** Pts who progressed on or relapsed after ≥1 line of platinum-based treatment (Tx) ± anti-programmed cell death protein 1 (PD-1)/programmed death-ligand 1 (PD-L1) were eligible for the trial. Obrixtamig was given as step-up dosing followed by target dose (3 dose levels). Topotecan was given per label. Dose escalation of obrixtamig was guided by a Bayesian Logistic Regression Model with overdose control. Antitumor activity was assessed using RECIST 1.1. The ongoing dose confirmation part will assess obrixtamig at the dose selected at the end of dose escalation. **Results:** As of January 2, 2025, 25 pts had received ≥1 cycle of Tx. Median number of cycles for both obrixtamig and topotecan was 4 (range 1–13); median Tx exposure was 2.6 months (range ≤1–8.5). Median age was 65 years (range 38–78); ECOG PS was 0 in 13 pts (52%), 1 in 12 pts (48%); median number of prior lines of Tx was 1 (range 1–3), 92% had received prior anti-PD-1/PD-L1. Obrixtamig-related adverse events (AEs; any grade/grade ≥3) occurred in 23 (92%) and 7 (28%) pts, with no grade 5 AEs. Topotecan-related AEs (any grade/grade ≥3) occurred in 25 (100%) and 21 (84%) of pts, with no grade 5 AEs. No pts discontinued obrixtamig due to Tx-related AEs. No obrixtamig- or topotecan-related grade ≥2 neurologic events occurred. All cytokine release syndrome cases were low grade: grade 1 (44%) and grade 2 (4%). The most frequent (≥10%) Tx-emergent grade 3/4 AEs were: neutropenia and/or decreased neutrophil count in 15 pts (60%); thrombocytopenia and/or decreased platelet count in 13 pts (52%); decreased lymphocyte count in 8 pts (32%); anemia in 6 pts (24%); and fatigue in 4 pts (16%). Grade 3 febrile neutropenia was reported in 1 pt (4%). Preliminary efficacy data from evaluable pts (n=23) showed an unconfirmed ORR of 70% (95% CI 47–87); 1 pt (4%) had a CR and 15 (65%) pts had a PR. Disease control rate was 87% (95% CI 66–97). In the 13 pts with ≥2 post-baseline tumor assessments (follow-up >13 weeks), the confirmed ORR was 69%. Median duration of response was not reached. **Conclusions:** The obrixtamig plus topotecan combination was tolerable with no unexpected toxicities. AE frequency and severity reported for the combination were consistent with the expected safety findings for obrixtamig and topotecan as monotherapy. Preliminary efficacy data for the combination are encouraging and indicate an improvement on top of topotecan monotherapy. Clinical trial information: NCT05990738. Research Sponsor: Boehringer Ingelheim.

Lung cancer enrollment of demographic subgroups in US clinical trial sites. First Author: Evon Okidi, Dassault Systemes, New York, NY

Background: Most clinical trials globally are not representative of a diverse patient population and 78% of trial participants remain White. This may limit the generalizability of trial results to the broader population, create an insufficient understanding of drugs' safety and efficacy between different patient populations, and hinder equitable access to investigational drugs. We compare the racial and ethnic composition of US clinical trials sites for lung cancer to epidemiology data. **Methods:** The de-identified data was sourced from Medidata's clinical trial database. The cohort included clinical trial participants enrolled in US sites in phase 1-3 interventional lung cancer studies conducted between 2016 and 2022. Lung cancer incidence estimates were taken from the National Cancer Institute's incidence data. Sites were classified as at/above or below expected demographic composition based on a relative ratio calculation, RR = proportion of trial patients/proportion of population with lung cancer. RR ≥1 means site recruited at/above expected ratio for the demographic group and vice versa. A 10% tolerance was used to capture minor deviations. A Mann-Whitney U test was used to determine if the two site types have statistically different enrollment rates, with a p-value of 0.05 for significance. **Results:** The analysis cohort consisted of 6,988 lung cancer patients from 85 studies and 876 US sites. Most sites enrolled White non-Hispanic patients at/above the epidemiological threshold. Conversely, the majority of sites enrolled non-White patients below the threshold (Table 1). The overall enrollment performance of sites enrolling a representative cohort of Black, American Indian and White patients did not differ from their counterparts. However, sites enrolling at or above the epidemiological threshold of Asian non-Hispanic and Hispanic patients had a higher enrollment rate than sites underrepresenting these patient populations. **Conclusions:** The majority of US clinical trial sites underrepresent demographic subgroups except White non-Hispanic patients. Sites enrolling a representative pool of racial and ethnic demographic subgroups did not have a lower overall enrollment performance. Research Sponsor: None.

Enrollment rate of sites recruiting at/above vs. below epidemiological threshold.

	Enrollment Rate (pts/site/month) Median (IQR)				
	Sites Enrolling At or Above Epidemiological Threshold		Sites Enrolling Below Epidemiological Threshold		
Race/Ethnicity Sub-group	N (%) sites	Enrollment Rate	N (%) sites	Enrollment Rate	P-value
Asian (non-Hispanic)	67 (13%)	0.11 (0.03 - 0.23)	439 (87%)	0.04 (0.02 - 0.08)	<0.0001
Black (non-Hispanic)	96 (15%)	0.04 (0.02 - 0.08)	553 (85%)	0.04 (0.02 - 0.09)	0.99
American Indian (non-Hispanic)	6 (4%)	0.08 (0.06 - 0.12)	137 (96%)	0.04 (0.01 - 0.07)	0.19
White (non-Hispanic)	461 (59%)	0.04 (0.01 - 0.09)	326 (41%)	0.04 (0.02 - 0.07)	0.64
Hispanic	76 (14%)	0.07 (0.03 - 0.14)	447 (86%)	0.04 (0.02 - 0.08)	0.002

Comprehensive longitudinal immune cell monitoring in patients with extensive-stage small-cell lung cancer patients treated with chemo-immunotherapy to predict early relapse. First Author: Seren Durer, University Hospitals Seidman Cancer Center, Case Western Reserve University, Cleveland, OH

Background: Small cell lung cancer (SCLC) is characterized by rapid growth, and although initial chemo-immunotherapy achieves high response rates, relapse typically occurs within 6–12 months. Emerging data suggest that myeloid-derived suppressor cells (MDSCs) and lymphocyte subsets influence immunotherapy response and relapse kinetics. We conducted a detailed immune profiling study to characterize circulating myeloid and lymphoid populations in SCLC patients, comparing those with early vs. late (>200 days) relapse. **Methods:** Purified PBMCs collected at baseline and relapse were analyzed by high-parameter flow cytometry using panels containing myeloid and lymphocytic markers. **Results:** Patients with ES-SCLC treated with chemo-immunotherapy were prospectively enrolled in this biomarker trial. A total of 32 were accrued. Among patients with early (<200 days) vs. late (≥200 days) relapse, baseline frequencies of CD33+ myeloid cells were similar. At relapse, however, a marked decrease in activated CD15+/CD16+ neutrophils was observed in both groups. PMN-MDSCs showed distinct kinetics: early-relapse patients had elevated MDSCs at baseline, whereas late-relapse patients exhibited significant MDSC expansion only at relapse. Additionally, a P-selectin–high monocytic subpopulation (M-MDSC) emerged more prominently in the late-relapse cohort, potentially reflecting a protective or anti-tumor phenotype. On lymphocyte analysis, a significant decline in CD8+ cytotoxic T-cell frequencies was observed at relapse across all patients, indicating a potential mechanism of immune evasion. The analysis of CD107 expression further supported the decrease in cytotoxic T-cell activity at relapse. Notably, higher baseline frequencies of CD57+ T-cell correlated with relapse-free intervals greater than 200 days. Lastly, lower baseline frequencies of activated B cells were associated with longer relapse-free survival. **Conclusions:** Our results reveal novel findings, suggesting that unique kinetics of myeloid and lymphoid immunophenotype levels are associated with relapse timing in SCLC treated with chemo-immunotherapy. These findings suggest potential predictive biomarkers and inform the development of targeted immunomodulatory strategies. Research Sponsor: None.

Efficacy and safety of HTMC0435 combination with temozolomide in relapsed extensive-stage small-cell lung cancer (ES-SCLC): A phase Ib/II study. First Author: Yun Fan, Zhejiang Cancer Hospital, Hangzhou, China

Background: Treatment options for ES-SCLC in second-line setting are limited. HTMC0435, an oral PARP inhibitor, significantly reduced the ability of PARP to repair DNA damage and inhibited tumor cell proliferation when combined with temozolomide (TMZ) in preclinical studies. We investigated the safety and activity of this regimen in relapsed SCLC. **Methods:** This was a phase Ib/II dose-escalation (3+3 design) and dose-expansion study. ES-SCLC patients who had progressed after first- or second-line therapy were eligible. Pts were administered with HTMC0435 6 mg or 8 mg bid on days 1-21 in combination with TMZ 75 mg/m^2 on days 1-7 of each 21-day cycle. The study objectives were to evaluate safety, pharmacokinetics and preliminary efficacy of the combination regimen. **Results:** From Feb-2023 to Nov-2023, 59 eligible pts were enrolled, with 7 pts in dose escalation and 52 pts in dose expansion. No dose-limiting toxicity (DLT) occurred, and HTMC0435 8mg bid combination with TMZ was selected as recommended phase 2 dose (RP2D). As of 31 October 2024, the median follow-up time was 10.3 months. 55 pts received HTMC0435 8mg bid and TMZ. Among these patients, brain and liver metastases were in 41.8% (23/55) and 23.6% (13/55) pts, respectively. 61.8% (34/55) pts had received prior platinum-based and anti–PD-(L)1 therapy as first line therapy. Among 49 efficacy evaluable patients, the objective response rate (ORR) and disease control rate (DCR) were 24.5% (12/49, 95%CI: 12.0%-37.0%) and 63.3% (31/49, 95%CI: 49.3%-77.3%). The median duration of response (DoR) was 6.9 mos (95%CI: 1.22-12.58). The median progression-free survival (PFS) and overall survival (OS) were 2.8 mos (95%CI: 1.16-4.44) and 12.0 mos (95% CI: 7.85-14.75). 23 pts were platinum-resistant (chemotherapy-free interval < 90 days), with ORR of 25.0% (5/20, 95%CI: 8.7%-49.1%), DCR of 55.0% (11/20, 95%CI: 31.5%-76.9%), mDoR not reached, mPFS of 2.5 mos (95%CI: 1.38-5.03) and mOS of 12.6 mos(95%CI: 5.78-NC). Among the 29 platinum-sensitive pts (chemotherapy-free interval ≥ 90 days), ORR and DCR were 26.9% (7/26, 95%CI: 11.6%-47.8%) and 73.1% (19/26, 95%CI: 52.2%-88.4%), and the mDoR was 4.2 mos (95%CI: 4.14-NC). The mPFS and mOS were 4.2 mos (95%CI: 2.69-5.52) and 11.2 mos (95%CI: 8.38-NC). 96.6% (57/59) pts experienced treatment-related adverse events (TRAEs) and 55.9% (33/59) pts experienced grade 3-4 TRAEs. Most common TRAEs (grade 3-4) were neutropenia (35.6%), leukopenia (28.8%), thrombocytopenia (13.6%), anemia (8.5%). Six (10.2%) pts experienced TRAEs led to dose reduction of HTMC0435 and no TRAEs led to discontinuation of HTMC0435 were reported. **Conclusions:** This combination of HTMC0435 and TMZ showed promising anti-tumor activity and manageable safety both in platinum-sensitive and platinum-resistant SCLC patients. Clinical trial information: NCT05728619. Research Sponsor: Shanghai Yidian Pharma.

Debio 0123, a highly selective WEE1 inhibitor, in combination with carboplatin (C) and etoposide (E), in patients (pts) with recurrent small cell lung cancer (SCLC): Determination of recommended dose (RD) from a phase 1 escalation. First Author: Valentina Gambardella, Department of Medical Oncology, Hospital Clínico Universitario, INCLIVA Biomedical Research Institute, University of Valencia, Valencia, Spain

Background: Debio 0123 is an oral, brain-penetrant, highly selective WEE1 inhibitor. WEE1 inhibition leads to S phase and G2/M cell cycle checkpoint abrogation, allowing mitosis without DNA repair, leading to mitotic catastrophe and subsequent cell death. Debio 0123 is in clinical development in solid tumors, as monotherapy and in combination with different therapeutic agents. Debio 0123 has shown manageable safety profile and initial signals of antitumor activity. SCLC is an aggressive disease that carries a high mutational burden and genomic instability. Debio 0123 has shown to significantly improve the antitumor activity of DNA damaging agents, C + E, in preclinical SCLC models. **Methods:** This Phase 1 study (NCT05815160) is evaluating Debio 0123 in combination with C + E in pts with recurrent SCLC after first line of platinum-based chemotherapy. Of note, pts with stable brain metastasis were eligible. In the dose escalation, pts who had a chemotherapy-free interval (CFI)>45 days since the last dose of platinum chemotherapy, received escalating doses of Debio 0123 (D1–3 and D8–10) in combination with standard C (AUC5) on D1 and E (100 mg/m2) on D1-3 in 21-day cycles. **Results:** Dose escalation data (cut-off date Oct 24th, 2024) are presented. Overall, 16 pts were treated (44% female, mean age 63.3 years). Using a Bayesian Logistic model-guided dose escalation, tested doses of Debio 0123 ranged from 200-400 mg. The RD was selected at 200 mg. At this dose level, 3/10 pts experienced a dose-limiting toxicity. The treatment was considered well tolerated with a manageable overall safety profile, in line with that expected for the chemotherapy combination. Most frequent Debio 0123 -related toxicities are shown in Table 1. PK data showed Debio 0123 plasma levels increasing proportionally with the dose. Debio 0123 CSF/plasma ratio was ~40%, suggesting that Debio 0123 crosses the blood brain barrier. At 200 mg, confirmed partial responses (PR) occurred in 4/9 evaluable pts overall, and in 4/7 pts in the subgroup with CFI>90 days, including pt with intracranial response; 4 pts had SD of which 2 had tumor shrinkage of > 20 %. mPFS at the RD (n=10) was 7.2 months. **Conclusions:** Debio 0123 combined with C + E is well tolerated, with a manageable safety profile, up to 200 mg; this combination led to promising antitumor activity in pts with recurrent SCLC after prior platinum-based therapy with CFI > 45 days. Further investigation of Debio 0123 at 200 mg in pts with a CFI > 90 days is ongoing. Clinical trial information: NCT05815160. Research Sponsor: Debiopharm International.

Summary of treatment-emergent adverse events (TEAEs) related to Debio 0123 in ≥ 2 pts at the RD (200 mg).

TEAE	Any grade (N=10) n (%)	Grade ≥3 (N=10) n (%)
Neutropenia/neutrophil count decreased	4 (40)	3 (30)
Nausea	3 (30)	0
Diarrhea	2 (20)	1 (10)
Thrombocytopenia/platelet count decreased	2 (20)	1 (10)

Does early versus late initiation of immunotherapy in extensive-stage small cell lung cancer affect survival outcomes? First Author: Paresh Kumar, Indiana University School of Medicine, Indianapolis, IN

Background: Small cell lung cancer (SCLC) is an aggressive malignancy characterized by a rapid doubling time, high metastatic potential, and risk for relapse, prompting urgent treatment. Chemoimmunotherapy is the standard of care for first line treatment of extensive-stage SCLC (ES-SCLC). A study evaluating the National Cancer Database reported improvement in overall survival (OS) with initiation of chemotherapy after 28 days from a SCLC diagnosis. However, the optimal timing for initiation of immunotherapy for SCLC remains unclear. Here, we seek to understand if the timing of immunotherapy impacts outcomes for ES-SCLC. **Methods:** We retrospectively reviewed 149 charts of patients diagnosed with ES-SCLC treated at Indiana University (IU) Health and IU Simon Comprehensive Cancer Center from January 2018 to August 2024. Patients who received platinum-based chemotherapy combined with immune checkpoint inhibitor (ICI) as first line therapy were included. Patients were categorized into two groups based on ICI timing: (1) with the first cycle and (2) after the first cycle of chemotherapy. Additionally, patients were stratified by time-to-ICI-initiation from diagnosis (TII), ≤21 days vs >21 days. **Results:** A total of 75 patients diagnosed with ES-SCLC who received chemotherapy with either durvalumab (18.7%) or atezolizumab (81.3%) were identified. Across the entire cohort, median OS and progression-free survival (PFS) were 12.2 and 5 months, respectively. Patients with TII of ≤21 days had a median OS of 16.8 months, compared to 11.8 months for those with TII >21 days (P = .26). Median OS was 16 months for patients who received ICI with the first cycle of chemotherapy and 10 months for those who received it later (P = .43). Median PFS was similar between these groups. For univariate analysis, we used median OS for the entire cohort (i.e., 12.2 months) to define responders (OS ≥12.2 months, n=30) and non-responders (OS <12.2 months, n=42). In responders group, 60% received ICI with the first cycle of chemotherapy, compared to 53.3% in non-responders (P = .57). **Conclusions:** The timing of initiation of immunotherapy, either with first cycle of chemotherapy or within 21 days of diagnosis, does not significantly improve outcomes in patients diagnosed with ES-SCLC. At our institution, atezolizumab is more commonly utilized for ES-SCLC. Recent real-world data suggests a survival benefit with use of durvalumab. Further prospective investigation is warranted to understand if ICI selection and timing can impact outcomes in ES-SCLC. Research Sponsor: None.

Patients' clinical and demographic characteristics.

Variable	Overall N=75	Receipt of ICI with Cycle 1: No N=33	Receipt of ICI with Cycle 1: Yes N=42	P Value
Age	62.7 ± 9	61.5 ± 9.1	63.6 ± 8.9	0.299
ECOG PS ≥ 2	17 (25%)	9 (30%)	8 (21.1%)	0.679
Female	48 (64%)	22 (66.7%)	26 (61.9%)	0.670
Active tobacco use	43 (57.3%)	**25 (75.8%)**	**18 (42.9%)**	**0.007**
Presence of brain metastases	19 (25.3%)	6 (18.2%)	13 (31%)	0.207

Predictive and prognostic impacts of SCLC comprehensive index (SCI) in extensive-stage small-cell lung cancer (ES-SCLC) treated with chemo-immunotherapy. First Author: Songji Oh, Cancer Research Institute, Seoul National University, Seoul, Korea, Republic of

Background: First-line (1L) chemo-immunotherapy is standard of care for ES-SCLC with improved survival outcomes (IMpower133 and CASPIAN). However, there were no reliable biomarkers associated with survival outcomes in these patients (pts). This study aimed to develop a SCI signature using RNA profiling with the nCounter system to predict chemo-immunotherapy outcomes. **Methods:** The SCI genes were selected based on IMpower133 transcriptomic data (Cancer Cell 2024;42:429) by K-means clustering to determine optimal cut-offs and risk grouping. A gene scoring system was developed with weights being assigned to genes linked to better survival rates. The validation cohort consisted of 93 ES-SCLC pts who received 1L chemo-immunotherapy (etoposide, carboplatin, and atezolizumab) at Seoul National University Hospital (SNUH). NanoString nCounter analysis was performed on all FFPE samples and RNA-seq was validated on 40 samples. Cox proportional hazards models were used for univariable and multivariable analyses. **Results:** The SCI was developed using genes related to neural (N=7), epithelial-to-mesenchymal transition (N=5), tumor-associated macrophages (N=5), and the T-cell inflamed signature (TIS) (N=18). The SCI signature also included molecular subtypes (N=3), targetable genes (N=4) and 5 housekeeping genes. Our validation cohort included 93 pts with mean age of 69 years and male-to-female ratio of 7.5:1. The median progression-free survival (PFS) and overall survival (OS) were 5.7 months and 12.9 months, respectively. SCLC molecular subtypes were as follows: SCLC-ASCL1 (39%) -NEUROD1 (24%) -POU2F3 (3%) -YAP1 (32%) and -Inflamed (TIS) (9%). The SCI model using 47 genes stratified pts into high- (N=29), intermediate- (N=48), and low- (N=16) risk groups with median PFSs of 4.8, 5.9, and 9.9 months and median OSs of 8.1, 14.3, and 24.4 months, respectively. In this cohort, the high-risk group showed significantly worse PFS (HR=4.68, $P < 0.001$) and OS (HR=5.03, $P < 0.001$) compared to the low-risk group. Similarly, in the IMpower133 cohort, the high-risk group demonstrated poorer outcomes with PFS (HR=2.33, $P = 0.001$) and OS (HR=3.47, $P < 0.001$) compared to the low-risk group. **Conclusions:** The SCI 47-gene panel based on IMpower133 transcriptome was validated through nCounter analysis system and effectively stratified ES-SCLC pts into distinct risk groups with strong predictive and prognostic capacities. It provides a practical biomarker for guiding immunotherapy in pts with ES-SCLC. Correlative analyses of nCounter with RNA-seq and AI-powered TIL will be presented. Research Sponsor: None.

Multi-omic analysis and overall survival update of phase II TRIDENT study: Durvalumab plus olaparib in extensive-stage small-cell lung cancer (ES-SCLC). First Author: Yuanyuan Zhao, Department of Medical Oncology, State Key Laboratory of Oncology in South China, Guangdong Provincial Clinical Research Center for Cancer, Sun Yat-Sen University Cancer Center, Guangzhou, China

Background: Chemotherapy plus anti-PD1/PD-L1 therapy has revolutionized the standard first-line treatment for patients with ES-SCLC. Durvalumab plus Olaparib as maintenance therapy showed encouraging anti-tumor activity in TRIDENT study as previous report. Here, we aim to identify molecular biomarkers of ES-SCLC through multi-omic analysis. **Methods:** 60 treatment-naïve ES-SCLC patients were enrolled in the TRIDENT study (NCT05245994), receiving Durvalumab plus Olaparib as maintenance therapy after Durvalumab plus chemotherapy as first line treatment. Frozen tumor tissues were collected before treatment to employ transcriptome sequencing and high-resolution quantitative DNA methylation. Next-Generation Sequencing (NGS) and Proximity Extension Assay (PEA) of cytokine were conducted using baseline plasma. **Results:** At the data cutoff on December 31, 2024, the median duration of follow-up was 13.0 months. The median PFS was 6.77 months (95% CI, 5.75-8.97), median overall survival was 14.59 months (95% CI 12.98–22.34). The 1-2-3 survival rate was 61.7%, 21.7% and 1.7%. For DNA methylation analysis, unsupervised clustering was performed based on Non-negative Matrix Factorization (NMF) and samples were classified into two clusters, with a clear difference in methylation levels. Patients in DNA hypomethylation group demonstrated better survival outcomes. Differentially methylated genes in pathway enrichment analysis revealed that immune-related and antigen processing and presentation signaling pathways were activated, while glycolysis and oxidative phosphorylation, DNA damage and repair signaling pathways were suppressed in the hypomethylation group. Moreover, transcriptome data further indicated a significant suppression in pathways related to epithelial-mesenchymal transition (EMT), extracellular matrix (ECM) remodeling, and cell adhesion in the hypomethylation group. As for cytokine analysis, high serum levels of IL6, IL8, Gal-9, CCL23, CSF-1 and HO-1 were significantly associated with poorer OS, while pro-inflammatory cytokines MCP-2 was correlated with better survival outcomes. **Conclusions:** Our findings indicated that DNA hypomethylation levels may be associated with better efficacy and survival outcomes in ES-SCLC treated with the combination of Olaparib and Durvalumab. Clinical trial information: NCT05245994. Research Sponsor: AstraZeneca.

Impact of immunotherapy on small cell lung cancer survival: A focus on treatment setting, race, and socioeconomics. First Author: Pranali Santhoshini Pachika, University of Louisville, Louisville, KY

Background: Immunotherapy has transformed the treatment landscape for many cancers, but its benefit in small cell lung cancer (SCLC) has remained modest. Trials like IMpower133 and CASPIAN demonstrated survival gains of only 2 to 2.7 months in patients with extensive-stage SCLC. However, the ADRIATIC trial highlighted significant survival benefits with durvalumab in limited-stage SCLC. Our study examines survival trends in SCLC across the pre-immunotherapy (PIE) and immunotherapy eras (IE) using National Cancer Database data, though it does not account for the recent advances in limited-stage SCLC due to the dataset being capped at 2021. **Methods:** Kaplan-Meier plots estimate survival probabilities, and log-rank tests compare survival between the IE (2016-2021) and PIE (2010-2015). Median overall survival (OS) and 5-year OS are reported with 95% CI, using a p-value threshold of <0.05. Cox regression analyzes the impact of demographic, clinical, and socioeconomic factors on survival, with hazard ratios (HR) indicating mortality risk. **Results:** This study analyzed 244,973 SCLC patients, divided into IE (n = 124,774) and PIE (n = 120,199). The majority were White (85%), with a median age of 68 years and a near-equal sex distribution (48% male, 52% female). Most patients were diagnosed at Stage IV (63%), and only 5% at Stage I. Survival rates were better in the IE ($p < 0.001$) except for stage IV disease. Patients treated at academic centers and Asian/Pacific Islander patients had better outcomes. Cox regression identified disease stage, immunotherapy use, facility type, insurance, and socioeconomic factors as key survival determinants. Immunotherapy improved survival, while lower income, lack of insurance, and non-academic centers worsened outcomes, highlighting the need for accessible care and financial support. **Conclusions:** Immunotherapy has modest improvement in survival outcomes for SCLC, but disparities in treatment access and outcomes persist across different populations. Ensuring equitable access to specialized care and financial support is essential to further improving survival rates. Research Sponsor: None.

Safety, tolerability, and preliminary efficacy results of a phase 1 study of LB2102, a dnTGFβRII armored DLL3-targeted autologous CAR-T cell therapy, in patients with relapsed or refractory small cell lung cancer (SCLC) and large cell neuroendocrine carcinoma (LCNEC). First Author: Jacob Sands, Dana-Farber Cancer Institute, Boston, MA

Background*:* Delta-like- ligand 3 (DLL3) is a promising therapeutic target for SCLC and other neuroendocrine tumors. Here, we present preliminary results from the ongoing dose-escalation study of LB2102, an autologous CAR-T cell therapy engineered to target DLL3 and armored with a TGF-β receptor blockade to overcome the immunosuppressive tumor microenvironment. **Methods***:* This ongoing, open-label, multicenter, phase 1 study evaluates LB2102 in patients with SCLC/LCNEC who are relapsed/refractory to ≥1 prior line of therapy. Dose escalation follows a modified 3+3 design, with planned dose levels of 0.3, 1.0, 2.0, 4.0, 8.0, 12.0, 16.0 x 10^6 CAR+ T cells/kg. All subjects undergo 3-day lymphodepletion (LD) with fludarabine (30 mg/m^2), and cyclophosphamide (300 mg/m^2). The primary objective is to assess safety, tolerability and determine the recommended phase 2 dose (RP2D). **Results***:* As of December 13, 2024, 9 patients were treated with LB2102 across dose-level (DL) 1 at 0.3x10^6 (n=3), DL2 at 1x10^6 (n=3), and DL3 at 2x10^6 CAR+ T cells/kg (n=3). Eight subjects had SCLC and one subject on DL2 had LCNEC. The median age was 54 (range 20-61), and the median prior lines of therapy was 2 (range 1-7). Bridging therapy was administered in all patients. No Dose-limiting toxicities (DLT) and no neurotoxicity was observed. One subject in DL3 experienced grade 1 CRS. Grade >3 treatment-emergent adverse events (TEAEs) attributed to LB2102 included anemia (n=2), leukopenia (n=2) and neutropenia (n=2); none were classified as serious, and all were deemed related to lymphodepletion. At DL3, best observed response per RECIST1.1 was 1 partial response (with deepening of response over time) and 2 stable disease (SD). The best overall response for subjects at DL1 was progressive disease (n=3) and at DL2 was SD (n=3) (with increased tumor shrinkage in 1 subject). Significant CAR-T expansion in peripheral blood was observed as measured by qPCR at DL3 (n=3) with a median C_{max} of 694.4 copies/μg genomic DNA (range, 45.6-2256.7) and a median T_{max} of 15 days (range, 10-29). **Conclusions***:* LB2102 has been well tolerated with no DLT observed up to DL3 (2 x 10^6 CAR+ T cells/kg). There appears to be a dose-dependent efficacy signal observed at higher doses with responses correlating to CAR-T expansion, although the data is limited. Given no DLTs and preliminary efficacy signal up to DL3, further exploration of higher dose levels is warranted. Clinical trial information: NCT05680922. Research Sponsor: Legend Biotech USA Inc.

Dose levels (CAR+ T cells/kg)	Subject No.	Best Overall Change in Sum of Tumor Size (%)
DL1: 0.3 x 10^6	1	+22.8%
	2	Non-evaluable*
	3	+57.1%
DL2: 1 x 10^6	4	-31.6%
	5	-22.6%
	6	-4.8%
DL3: 2 x 10^6	7	-14.3%
	8	-69.8%
	9	-20.6%

*Subject had non-measurable disease at baseline and progressed during study period.

Association of IFITM3 with the efficacy of anti-PD1/PD-L1 therapy and regulation of immunosensitivity via MHC-I regulation in SCLC. First Author: Shengxiang Ren, Department of Oncology, Shanghai Pulmonary Hospital & Thoracic Cancer Institute, Tongji University School of Medicine, Shanghai, China

Background: Majority of small cell lung cancer (SCLC) patients exhibit resistance to immune checkpoint inhibitors (ICIs), which is associated with the downregulation of major histocompatibility complex class I (MHC-I) molecules. This study investigates the regulatory mechanisms underlying MHC-I expression and explores potential therapeutic strategies to enhance ICI efficacy. **Methods:** Single-cell and bulk RNA sequencing data from SCLC patient tumors were analyzed to identify key regulators of MHC-I expression. The IMpower133 cohort (116 patients treated with chemotherapy plus anti-PD-L1 therapy and 131 patients treated with chemotherapy alone) and an in-house cohort (39 patients treated with chemotherapy and anti-PD-1 therapy) were utilized to assess the association between IFITM3 expression and immunotherapy outcomes. Additionally, tumor samples from 42 extensive-stage SCLC patients receiving first-line chemotherapy plus anti-PD1/PD-L1 were evaluated via immunohistochemistry (IHC) to determine IFITM3 expression as a predictive biomarker. *In vitro* and *in vivo* functional studies were conducted to elucidate the role and mechanisms of IFITM3 in modulating tumor sensitivity to PD-1 inhibitors. **Results:** Integrative analysis of multiple real-world cohorts of SCLC confirmed a significant positive association between *IFITM3* and MHC-I expression. IFITM3 overexpression elevated MHC-I-related genes, activated antigen presentation pathways, and enhanced $CD8^+$ T cell activity. In the IMpower133 cohort, high IFITM3 expression was significantly associated with prolonged progression-free survival (PFS) in patients receiving chemoimmunotherapy (HR 0.65,95% CI 0.44-0.96, p=0.014) but not in those treated with chemotherapy alone (HR 1.97,95%CI 1.19-3.25, p=0.0069). Similarly, in the in-house cohort, high IFITM3 expression conferred a PFS advantage in patients receiving chemoimmunotherapy (HR 0.42,95% CI 0.19-0.90, p=0.023). Furthermore, patients with elevated IFITM3 protein levels, as determined by IHC H-scores, exhibited improved clinical outcomes following chemoimmunotherapy. Importantly, inducing IFITM3 expression directly or through treatment with Ethyl gallate (EG), an IFITM3 activator, effectively sensitized tumors to PD-1 blockade in SCLC mouse models. **Conclusions:** IFITM3 positively regulates MHC-I expression and predicts response to ICIs in SCLC. Combining EG with PD-1 inhibitors represents a promising strategy to improve immunotherapy efficacy in SCLC patients. Research Sponsor: None.

Implementation of tarlatamab treatment for small cell lung cancer using an outpatient care program. First Author: Jennifer W. Carlisle, Winship Cancer Institute, Emory University, Atlanta, GA

Background: Tarlatamab, a bispecific T-cell engager targeting DLL3, was FDA approved for relapsed small cell lung cancer (SCLC) in May 2024. It requires observation for 24 hours for the first two doses due to the risk of Cytokine Release Syndrome (CRS). We developed an outpatient program to administer tarlatamab at the Winship Cancer Institute and describe the initial experience in this report. **Methods:** Patients received tarlatamab in the outpatient infusion center then were observed in an outpatient oncology Immediate Care Center (ICC) onsite, staffed by advanced practice providers, to complete the 24-hour monitoring for CRS and immune effector cell-associated neurotoxicity (ICANS). Vital signs and ICE scores were monitored, and patients were hospitalized with $>$ grade 2 CRS or grade 1 ICANS based on American Society for Transplantation and Cellular Therapy Consensus Grading. Patients were prescribed dexamethasone 8mg to be taken at physician direction for later-onset symptoms prior to return to a health care facility. Demographics, disease characteristics, treatment history, toxicities, and outcomes were abstracted from the electronic medical record. **Results:** From June 2024 to January 2025, 29 patients with SCLC were treated, 27 of whom completed cycle 2 at data cut-off and were evaluated for safety and efficacy. Baseline demographics and clinical characteristics are shown in Table 1. Four patients were admitted prophylactically based on limited home support, distance from home, or location of administration; 6 patients required admission from the ICC during the first two cycles due to CRS/ICANS (CRS: 1, ICANS:1, both: 4) and one patient was admitted 48 hours after C1D8 for grade 1 CRS and nausea. CRS was observed 14 patients (grade 1: 7, grade 2: 4, grade 3: 3) and ICANS was observed in 10 patients (grade 1: 3, grade 2: 4, grade 3: 3). Eight patients required dose holds, with two who reinitiated step up dosing. Investigator-assessed radiographic responses included 9 partial response, 7 stable disease, 6 progressive disease, and 5 not evaluable. With a median duration of follow-up of 133 days (95% CI 91,168), the estimated median progression free survival was 101 days (95% CI 78, NA). **Conclusions:** Outpatient administration of tarlatamab is safe and feasible with appropriate monitoring, including for patients with an ECOG performance status of 2. Research Sponsor: None.

Cataloging genomic and transcriptomic features of relapsed SCLC. First Author: Sid Devarakonda, Swedish Cancer Institute, Seattle, WA

Background: Relapsed small cell lung cancer (R-SCLC) is characterized by poor outcomes and treatment resistance. The mechanisms driving treatment resistance in R-SCLC remain poorly understood. We comprehensively profiled R-SCLC samples along with patient-matched treatment-naive samples (TN-SCLC) using whole-exome (WES), whole-genome (WGS), and RNA-sequencing (RNA-seq) to catalog mechanisms of treatment resistance and identify actionable alterations. **Methods:** We analyzed 54 R-SCLC and 27 TN-SCLC samples (with 26 patient-matched TN-R pairs) using WES. At presentation, 31 patients were diagnosed with extensive and 23 with limited stage SCLC. R-SCLC samples were also analyzed by WGS (n = 28, including 18 TN-R pairs) and RNA-seq (n = 31, including 12 TN-R pairs). Differences in mutational signatures, structural variations, gene expression, alternative splicing, and neoantigen profiles were investigated between TN and R-SCLC samples. **Results:** R-SCLC samples contained mutation signatures characteristic of platinum exposure and APOBEC mutagenesis, which were absent in TN-SCLC. MYC family genes (MYC, MYCL, MYCN) were frequently amplified at relapse. Transcriptomic analyses revealed dysregulation of WNT signaling and IDO1. Extensive differences in alternative splicing, especially intron retention (IR), were observed (96% of all IR events were in TN-SCLC). IR in TN-SCLC affected genes involved in DNA repair, RNA metabolism, WNT and MYC pathways. TN-SCLC showed a median of 86 neoantigens, and R-SCLC 90 neoantigens per sample. *TP53* was the most frequently altered gene to result in a neo-antigen (48% of analyzed samples). Immune evasion mechanisms, including upregulation of CD24 and downregulation of MHC-I, were observed in R-SCLC samples. **Conclusions:** This study highlights the heterogeneity of treatment resistance in SCLC, driven by genomic instability, WNT and MYC dysregulation, and splicing aberrations. Potential therapeutic strategies for R-SCLC include targeting splicing machinery, WNT signaling, and immune evasion pathways. These findings advance our understanding of SCLC biology and provide a foundation for biomarker-driven drug development. Research Sponsor: None.

A prospective, single-arm, phase II trial of adebrelimab plus nab-paclitaxel and carboplatin in patients with unresectable advanced metastatic or recurrent thymic carcinomas. First Author: Ning Xu, School of Medicine, Shanghai Jiao Tong University, Shanghai Chest Hospital, Shanghai, China

Background: With the limited efficacy of chemotherapy (carboplatin/paclitaxel) for advanced thymic carcinomas (TCs), better treatments are in need. In this study (ChiCTR2300072705), we evaluated the efficacy and safety of adebrelimab in combination with nab-paclitaxel and carboplatin as first-line treatment for unresectable advanced metastatic or recurrent TCs. **Methods:** In this study, patients with unresectable UICC stage III or IV, recurrent, or metastatic TCs without any previous antitumor therapy were enrolled. Patients were treated with adebrelimab (20 mg/kg) plus nab-paclitaxel (260 mg/m^2) and carboplatin (AUC 5) every 3 weeks for up to 4-6 cycles, followed by adebrelimab (20 mg/kg) every 3 weeks for up to 2 years until progression or unacceptable toxicity. The primary endpoint was the objective response rate (ORR). Secondary endpoints included progression free survival (PFS), disease control rate (DCR), overall survival (OS), and safety. A Simon two-stage design was applied. If more than 4 out of the first 18 pts achieved a response, the cohort would expand to include 33 pts, and the outcome would be considered positive if more than 10 pts achieved a response. **Results:** Between August 2023 and September 2024, 18 pts were enrolled in the first stage. All pts were included in the efficacy and safety analysis. The median age was 58.0 years old (range 29-71). At data cutoff (Dec 1, 2024), 9 pts (50.0%) were undergoing treatment. Discontinuations occurred in 5 pts (27.8%) primarily due to disease progression, 2 (11.1%) due to adverse events (AEs), 2 (11.1%) due to patient's decision. Three (16.7%) of 18 pts had complete response, 9 (50.0%) had partial response, and 6 (33.3%) had stable disease. The ORR was 66.7% (12/18) and DCR was 100%. The median PFS was 10.2 months (95% CI, 8.8 - 11.6 months). AEs of any grade and of grade $\geq$3 severity occurred in 100% (18/18) and 61.1% (11/18) of pts, respectively. The most common treatment related AEs were white blood cell count decreased, neutrophil count decreased, and lymphocyte count decreased. The immune-related AEs of grade $\geq$3 severity occurred in 16.7% (3/18) of pts, including immune-mediated myositis, rash and lipase increased. None of the pts died from the treatment. **Conclusions:** In previously untreated advanced TCs, preliminary results showed that adebrelimab plus nab-paclitaxel and carboplatin is effective and safe. It provides a new treatment option in pts with advanced TCs. Clinical trial information: ChiCTR2300072705. Research Sponsor: None.

Combining SBRT with GM-CSF and peg-IFNα to induce abscopal effects in previously treated patients with stage IV thymic tumors: A single arm, single center, phase II trial. First Author: Min Fan, Fudan University Shanghai Cancer Center, Shanghai, China

Background: After the failure of first-line treatment, patients with stage IV thymic tumors have a poor prognosis and few therapeutic options. Combining stereotactic body radiotherapy (SBRT) with granulocyte-macrophage colony-stimulating factor (GM-CSF) and Pegylated interferon-α (Peg-IFNα) may induce abscopal effects and improve prognosis. **Methods:** We conducted this open-label, single-arm single center, phase II trial to evaluate SBRT plus GM-CSF and Peg-IFNα in previously treated patients with stage IV thymic tumors. A 21-day treatment cycle consisted of SBRT delivered to one metastatic lesion with 30 Gy in 5 fractions from day 1, synchronous subcutaneous injection of GM-CSF 125 μg/ m^2 once daily for 14 days, and subcutaneous injection of Peg-IFNα 90 μg on day 8. If the patient has more than two metastatic lesions, another treatment cycle was repeated. After the completion of 1 or 2 treatment cycles, Peg-IFNα therapy was maintained for at least half a year with a subcutaneous injection of 90 μg once a month. The two primary endpoints were the proportion of patients with abscopal effects and the objective response rate (ORR). The secondary endpoints included overall survival (OS), progression-free survival (PFS), and therapeutic safety. **Results:** A total of 27 patients were enrolled in the trial from March 2021 to September 2024. One patient died of cardiac arrest before ORR evaluation during COVID-19 pandemic and was excluded, leaving 26 patients in the analysis, with 1 (3.8%) type A thymoma, 1 (3.8%) type AB thymoma,4 (15.4%) type B1 thymoma, 3 (11.5%) type B2 thymoma, 1 (3.8%) type B3 thymoma, 1 (3.8%) type B2+B3 thymoma, 13 (50.0%) thymic squamous cell carcinoma and 2 (7.7%) thymic neuroendocrine tumor. At a median follow-up of 26.4 months, 8 (30.8%) out of 26 patients had abscopal effects, and the ORR was 38.5%. The median OS for patients with abscopal effect has not been attained yet. The median PFS was 13.0 months. We observed that patients with abscopal effects tended to have longer OS and PFS than those without abscopal effects. 5 patients (19.2%) experienced Grade 3 treatment-related adverse events (CTCAE version 5.0). **Conclusions:** Combining SBRT with GM-CSF and Peg-IFNα was well tolerated with acceptable toxicity and may represent a promising salvage therapy for previously treated patients with stage IV thymic tumors. The occurrence of abscopal effects is likely to improve patient outcomes. Clinical trial information: NCT04517539. Research Sponsor: None.

Association of immune-related adverse events with survival and treatment outcomes in thymic tumors treated with immune checkpoint inhibitors. First Author: Harold Nathan C. Tan, Department of Investigational Cancer Therapeutics, Division of Cancer Medicine, MD Anderson Cancer Center, Houston, TX

Background: Thymic tumors are rare cancers with limited therapeutic options, particularly in refractory cases. Immune checkpoint inhibitors (ICIs) such as anti-PD1 and anti-PD-L1 antibodies have transformed cancer treatment, but data in thymic tumors remain scarce. We investigated the safety, efficacy, and biomarkers of ICIs in thymic tumors, focusing on immune-related adverse events (irAEs) and clinical outcomes. **Methods:** This study included patients (pts) with thymic tumors treated with ICIs at the University of Texas MD Anderson Cancer Center. The primary objective was to assess the occurrence, type, and severity of irAEs. Secondary objectives included evaluating clinical response using RECIST 1.1 and analyzing overall survival (OS) and progression-free survival (PFS) through Kaplan-Meier analysis. Cox regression was used to identify predictors of OS. **Results:** Forty-two pts (median age 58.5 years, 55% male) were analyzed: 29 (69%) had thymic carcinoma, 8 (19%) thymoma, and 5 (12%) thymic malignancy with neuroendocrine features. Pts had a median of one prior line of therapy (range 1-6) and received ICIs as monotherapy (n=23, 55%) or in combination with chemotherapy (n=9, 21%), other immunotherapies (n=6, 14%), targeted therapies (n=2, 5%), or other agents (n=2, 5%). irAEs occurred in 60% of pts (100% of pts with thymoma), with 9 pts (21%) experiencing severe irAEs (≥G3). Median time to develop ≥G3 irAEs was 42 days. Common all-grade irAEs included fatigue (19%), musculoskeletal toxicities (17%), and rash (17%), while the most frequent ≥G3 irAEs were musculoskeletal, myasthenia gravis (MG)-like, myocarditis, and hepatobiliary toxicities. Among the three pts with thymoma who developed MG-like symptoms, only one pt had a pre-existing diagnosis of MG. Two thymoma patients developed concurrent myocarditis and MG. One treatment-related death occurred due to pneumonitis in a patient with thymoma. Clinical benefit was observed in 69% of pts, including 9 partial responses (PR) (21%) and 10 with stable disease. Most pts (84%) with any-grade irAEs had SD or PR as best response with ICI. Median PFS was 195 days, with a 1-year PFS rate of 45%, while median OS was 274 days, with a 1-year OS rate of 44%. Pts with any-grade irAEs had improved OS (HR 0.3, 95% CI 0.11 -0.98, p = 0.04). Other OS predictors included *TP53* mutations (HR 7.8, 95% CI 2.2 – 27.8, p = 0.002), *CDKN2A* alterations (HR 0.2, 95% CI 0.04-0.54, p = 0.004), African-American race (HR 10.9, 95% CI 3.7-32.3, $p < 0.001$), and lung metastases (HR 6.9, 95% CI 2.4 -19.8, $p < 0.001$). **Conclusions:** ICIs demonstrate promising efficacy in thymic malignancies, with higher toxicity rates in thymoma pts. The incidence of irAEs may serve as a prognostic marker for survival and treatment outcomes. Factors such as *TP53, CDKN2A* alterations, and lung metastases could guide patient selection for future ICI trials in thymic tumors. Research Sponsor: None.

Pathomics-based prediction of thymic epithelial tumor subtypes within the French RYTHMIC network. First Author: Lodovica Zullo, Department of Cancer Medicine, Gustave Roussy, Villejuif, France

Background: Thymic epithelial tumors (TETs) are classified into primary subtypes (A, AB, B1, B2, B3, C) and mixed classes, determined by varying proportions of tumoral and non-tumoral components, and different subtypes have different prognosis. This heterogeneity, combined with their rarity, poses significant diagnostic challenges that impact tumor treatment. We aim to develop and test a multiple-instance learning (MIL) model capable of classifying TETs major histological subtypes from hematoxylin-eosin/hematoxylin-eosin-saffron (HE/HES)-stained slides. **Methods:** Cases who underwent central revision by a panel of expert pathologist between 2012 and 2016 in the context of the French national RYTHMIC network were retrospectively collected, and their HE/HES slides were digitized in whole slide images (WSIs), forming the training cohort. A MIL model was trained exclusively on digitized WSIs, without clinical features, and internally validated using 3-repeated 2-fold cross-validation for the classification of major TET subtypes: A, AB, B1, B2, B3, C. Prospectively digitized WSIs from the RYTHMIC network (2022–2024) served as the testing cohort. Class predictions were assessed using AUC scores and ROC curves. Interpretability was explored through Shapley values and heatmaps. **Results:** A total of 456 WSIs from unique histological samples formed the training cohort, with 243 (53%) samples obtained via thymectomy. The most represented subtype was AB (n=129, 28%), followed by B2 (n=110, 24%). Internal validation achieved a mean AUC of 0.94 [sd 0.005] for histological subtypes classification. High-attention regions identified on the slides featured varying proportions of epithelial cells and lymphocytes, consistent with the biological characteristics of each subtype. The test set comprised 75 WSIs from unique histological samples, with 63 (84%) obtained via thymectomy. The most represented subtype was AB (n=35, 47%), followed by B2 (n=19, 25%). In the test set, the model achieved a mean AUC of 0.89 [95%CI 0.83–0.93] for histological subtypes classification. **Conclusions:** Our model shows promise for diagnosing TET major subtypes, emphasizing the value of digital pathology in identifying and classifying rare entities. We are currently reviewing discrepancies between MIL and pathologists' diagnoses in subtype classification within the test set to evaluate the potential of artificial intelligence in aiding the diagnosis of complex cases. The final results will be presented at the congress. Research Sponsor: None.

Comparing impact of treatment before or after surgery in patients with stage II-IIIb resectable non-small cell lung cancer (NSCLC; Alliance A082304-SWOG S2402). First Author: Raid Aljumaily, Stephenson Cancer Center at The University of Oklahoma Health Sciences Center, Oklahoma City, OK

Background: There are currently three approved approaches for patients with resectable NSCLC including neoadjuvant chemoimmunotherapy, adjuvant chemoimmunotherapy and perioperative treatment with neoadjuvant chemoimmunotherapy followed by adjuvant immunotherapy. All regimens were approved after showing event-free survival (EFS) or disease-free survival (DFS) benefit with the addition of immunotherapy to chemotherapy compared to chemotherapy alone. Each approach has its benefits and risks. Starting immunotherapy prior to surgery may improve treatment compliance and efficacy of immunotherapy. Nevertheless, neoadjuvant chemoimmunotherapy may result in missing an opportunity for curative surgery and increase the complexity of tumor resection. PROSPECT-LUNG (NCT06632327) is a randomized study evaluating whether starting chemoimmunotherapy before or after surgery leads to better outcomes. **Methods:** This is a randomized phase 3 trial in which patients will be randomized 1:1 to surgery followed by chemoimmunotherapy (adjuvant arm) or neoadjuvant chemoimmunotherapy followed by surgery and adjuvant therapy (perioperative arm). Patients with histologic or cytologic confirmation of surgically resectable stage IIA-IIIB NSCLC (per AJCC 9th edition) or stage IIA to IIIB per AJCC 8^{th} edition up to single ipsilateral mediastinal station (N2a), ECOG PS ≤ 2 (or Karnofsky ≥ 60%), no prior treatment for NSCLC and no previous malignancy within 3 years are eligible. The dual primary endpoints are real-world event free survival (rwEFS) defined as date from randomization to date of the first of the following events: failure to undergo resection for any reason, progression prior to surgery that precludes resection, recurrence or progression at any time after surgery or death from any cause, and overall survival (OS) defined as time from randomization to death from any cause. The target accrual is 1,100 patients assuming one-sided type I error of 0.03 for OS endpoint and 0.02 for rwEFS endpoint. This sample size will enable the detection of a 3-year rwEFS improvement from 55% in the adjuvant therapy arm to 64% in the perioperative arm with an 84% power. This sample size would detect an HR of 0.73 (improvement in median OS from 8.1 to 11 years in favor of the perioperative arm, 5-year OS from 65% in the adjuvant arm to 73% in the perioperative arm, assuming exponential survival) with 83.6% power. The study has a pragmatic design with minimal data collection, reporting of adverse events that lead to discontinuation of therapy, hospitalization or death only. It allows providers to choose therapy per standard of care (FDA approved or on NCCN), includes patients with ECOG performance status 2, permits use of local laboratory testing and imaging studies and determination of recurrence/progression will be done by local treating physicians with no use of RECIST. Clinical trial information: NCT06632327. Research Sponsor: National Cancer Institute; U10CA180821.

TPS8114 **Poster Session**

GEMINI-NSCLC study: Integrated longitudinal multi-omic biomarker profiling study of non-small cell lung cancer (NSCLC) patients. First Author: Douglas C. Palmer, AstraZeneca, Gaithersburg, MD

Background: Lung cancer is the global leading cause of cancer deaths. Despite treatment advances, NSCLC outcomes remain poor. The molecular landscape of NSCLC has identified various subtypes allowing targeted therapies, but some tumors lack a biomarker-directed therapy. Identifying improved surrogates of immunotherapy (IO) response is key to stopping ineffective treatments and empowering patients to switch therapies more rapidly. Combining next-generation sequencing (NGS) and circulating tumor DNA (ctDNA) technologies with high-resolution multi-omic data may revolutionize NSCLC management by enabling non-invasive monitoring, personalized treatment strategies, and the development of next-generation therapies to improve patient outcomes. **Methods:** The Gemini-NSCLC study is a multicenter, real-world observational study profiling patients with NSCLC undergoing IO standard-of-care (SOC) therapy. Cohort 1 (C1) includes patients with early-stage disease treated with curative intent therapies. Cohort 2 (C2) includes patients with late-stage disease receiving first-line IO, excluding those with targetable genomic drivers. Patients will have blood and tissue collected at study entry and longitudinally. They will undergo testing with DNA and RNA sequencing and novel assays, including baseline spatial transcriptomic profiling, serial tumor-informed ctDNA profiling, and scRNA sequencing with T-Cell receptor seq of peripheral immune cells. All patients will be assessed with cohort-relevant real-world endpoints, allowing correlation with longitudinal multi-omic data for biomarker discovery. Information from novel multi-omic assays will be descriptive and hypothesis-generating. For C1, the primary endpoint is real-world disease-free survival (rwDFS). Secondary endpoints include pathologic complete response (pCR) rate and real-world overall survival (rwOS) stratified by ctDNA status. Molecular endpoints include sensitivity, specificity, positive predictive value (PPV), and negative predictive value (NPV) of minimal residual disease (MRD) assay vs. conventional imaging. Patients are followed until recurrence or five years post-therapy. Patients in whom disease recurs may roll over to C2 for continued data collection. For C2, the primary endpoint is rwOS, with rwPFS as a secondary endpoint. Molecular endpoints include ctDNA dynamics with IO and correlation with rwOS. Exploratory endpoints include evolving genomic variants as resistance mechanisms. As of 01/2025, the study is enrolling and active at 49 of 60 planned sites, with accruals of 48/500 in C1, 20/700 in C2. Clinical trial information: NCT05236114. Research Sponsor: Tempus, AI, Inc.; AstraZeneca.

TPS8115 **Poster Session**

KEYMAKER-U01E: A phase 2 umbrella study with rolling arms of investigational agents with or without chemotherapy plus pembrolizumab for resectable stage II–IIIB (N2) non–small-cell lung cancer (NSCLC). First Author: Konstantin H. Dragnev, Dartmouth Cancer Center, Lebanon, NH

Background: Neoadjuvantpembrolizumab (pembro) + chemotherapy (CT) followed by adjuvant pembro significantly improved event-free survival (EFS), pathological complete response (pCR), major pathological response, and overall survival (OS) in early-stage NSCLC. Despite the expanding number of therapeutic options for early-stage NSCLC, there remains an unmet need to improve outcomes. Sacituzumab tirumotecan (sac-TMT/MK-2870/SKB264) is an antibody-drug conjugate composed of an anti-trophoblast cell surface antigen 2 antibody, a hydrolytically cleavable linker, and a belotecan-derivative topoisomerase I inhibitor payload (average drug-to-antibody ratio, 7.4). Sac-TMT monotherapy demonstrated encouraging antitumor activity in a phase 1/2 study in heavily pretreated, advanced NSCLC. The phase 2 KEYMAKER-U01E study (NCT06788912) is evaluating the addition of multiple investigational agents ± CT to pembro followed by surgery and adjuvant pembro in resectable stage II–IIIB (N2) NSCLC; the treatment arm presented here includes sac-TMT + pembro. **Methods:** This open-label, adaptive design study is enrolling participants (pts) aged ≥18 years with previously untreated, pathologically confirmed, resectable stage II, IIIA, or IIIB (N2) NSCLC (AJCC v8) with no *EGFR* mutations, and measurable disease per RECIST v1.1. Pts must be able to undergo surgery, have ECOG PS 0 or 1, and provide a tumor sample for biomarker analysis. Approximately 60 pts will be randomized 1:1 to Arm 1 or 2. In Arm 1 (reference arm), pts will receive neoadjuvant therapy of 4 cycles of pembro 200 mg intravenously (IV) + CT IV Q3W (cisplatin 75 mg/m^2 or carboplatin area under the curve 5 or 6 mg/mL/min on day 1 with gemcitabine 1000 mg/m^2 on days 1 and 8 for squamous histology, with pemetrexed 500 mg/m^2 on day 1 for nonsquamous, or with paclitaxel 175 or 200 mg/m^2 on day 1 for any histology). Pts in Arm 2 will receive 4 cycles of pembro 200 mg IV Q3W + 6 cycles of sac-TMT 4 mg/kg IV Q2W (treatment arm). Following surgery, all pts will receive up to 13 cycles of adjuvant pembro 200 mg IV Q3W. Additional agents may be included when available. Randomization will be stratified by histology (squamous vs nonsquamous) and tumor stage (II vs III). Dual primary endpoints are pCR (ypT0/ypN0) and percentage of residual viable tumor, assessed by blinded independent pathology review. Secondary endpoints are EFS and distant metastasis-free survival per investigator review, OS, objective response rate during neoadjuvant therapy, and safety. Postoperative tumor imaging occurs ≤4 weeks before the start of adjuvant therapy, with pts followed per study protocol until disease recurrence, development of new primary NSCLC, pregnancy, death, pt withdrawal, or end of study. AEs will be graded per NCI CTCAE v5.0. Enrollment is scheduled to begin in March 2025 at 34 sites globally. Clinical trial information: NCT06788912. Research Sponsor: Merck Sharp & Dohme LLC, a subsidiary of Merck & Co., Inc., Rahway, NJ, USA.

TPS8116 **Poster Session**

A randomized study of neoadjuvant REGN7075 + cemiplimab + chemotherapy (chemo) vs cemiplimab + chemo in patients (pts) with resectable non-small cell lung cancer (NSCLC). First Author: Ardy Davarifar, University of Tennessee Medical Center, Knoxville, TN

Background: Neoadjuvant chemo + anti–PD-1 checkpoint blockade, with/without adjuvant anti–PD-1, represents a new standard of care for pts with resectable NSCLC. However, most pts do not achieve major pathologic response (MPR) or pathologic complete response (pCR), and event-free survival (EFS) remains suboptimal; therefore, novel perioperative approaches are needed. REGN7075, a first-in-class costimulatory bispecific antibody, aims to bridge CD28+ T cells with EGFR-expressing tumor cells, facilitating T-cell activation through endogenous tumor antigens. Early efficacy and pharmacodynamic evidence suggest that REGN7075 can enhance immune responses and antitumor immunity even in "cold" tumors. In a first-in-human, open-label, Phase 1/2 study (NCT04626635), REGN7075 + cemiplimab (anti–PD-1) demonstrated clinical activity in PD-1–refractory, microsatellite stable colorectal cancer (Segal NH, et al. 2024). The addition of REGN7075 to cemiplimab + chemo may deepen antitumor responses in resectable NSCLC where EGFR is highly expressed, potentially representing a novel immunotherapy-based treatment (Tx) approach in this setting. In this perioperative platform study, multiple novel Tx approaches for resectable NSCLC will be evaluated in comparison to a control arm (cemiplimab + chemo). **Methods:** In this Phase 2, open-label, perioperative platform trial (NCT06465329), pts with resectable NSCLC will be randomized to an investigational arm (a novel antitumor agent + cemiplimab + chemo) or control arm (cemiplimab + chemo), stratified by tumor stage and PD-L1 expression. Here, we focus on the first investigational arm with REGN7075. The study will consist of neoadjuvant, surgical, and adjuvant periods. During the neoadjuvant period, pts assigned to the control arm will receive cemiplimab + chemo for up to 3 cycles before surgery. Pts in the investigational arm will receive REGN7075 with cemiplimab + chemo. Pts from both arms who proceed to surgery and undergo R0/R1 resection will then receive adjuvant cemiplimab. Eligibility criteria: histologically confirmed stage II–IIIB (N2) NSCLC considered resectable with curative intent (appropriate candidate for surgery), Tx naïve, no known *EGFR/ALK* alterations, ECOG PS ≤1. Primary endpoint: MPR. Secondary endpoints: safety, feasibility of surgery, pCR, and EFS. Pre-Tx and surgical tissue will be used for translational analysis and biomarker development. Up to 40 pts will be enrolled in each investigational arm, and the control arm will be open to enrollment throughout the study. A Bayesian statistical design will be used to evaluate the posterior probability of at least 15% improvement in MPR for investigational arms vs the control arm. This study is currently enrolling. Clinical trial information: NCT06465329. Research Sponsor: Regeneron Pharmaceuticals, Inc.

TPS8117 **Poster Session**

Phase 2 peri-operative study of fianlimab + cemiplimab + chemotherapy versus cemiplimab + chemotherapy in resectable early-stage non-small cell lung cancer (NSCLC). First Author: Ekaterine Arkania, LTD Israeli-Georgian Medical Research Clinic "Helsicore", Tbilisi, Georgia

Background: Co-blockade of lymphocyte activation gene 3 (LAG-3) and programmed cell death-1 (PD-1) may enhance the efficacy of anti–PD-1 therapies. Fianlimab (anti–LAG-3) and cemiplimab (anti–PD-1) are high-affinity, fully human, immunoglobulin G4 monoclonal antibodies. In a Phase 1 study (NCT03005782), fianlimab + cemiplimab showed promising clinical activity with durable responses and an acceptable risk–benefit profile in patients with programmed death-ligand 1 (PD-L1)-naïve, advanced NSCLC. Immuno-oncology + chemotherapy is a new standard of care in the perioperative setting, but potential improvements to outcomes in early-stage disease remain under investigation. **Methods:** This is a randomized, multicenter, double-blind, Phase 2 peri-operative study (NCT06161441) in patients with fully resectable stage II–IIIB (N2), operable, and treatment-naïve NSCLC with squamous or non-squamous histology. The aim of this study is to investigate the efficacy and safety of fianlimab + cemiplimab + chemotherapy versus cemiplimab + chemotherapy as peri-operative treatment. The study will be conducted globally at ~130 sites. Key inclusion criteria: age ≥18 years; newly diagnosed, histologically confirmed, fully resectable stage II–IIIB (N2) NSCLC; no distant metastases; evaluable PD-L1 immunohistochemistry results; no cancer treatment in the past 3 years, except adjuvant hormone therapy for hormone-sensitive cancers in long-term remission; Eastern Cooperative Oncology Group performance status ≤1; no known *EGFR* mutations or *ALK* aberrations; and adequate organ and bone marrow function. Mediastinal lymph node sampling is required for patients with mediastinal adenopathy. Enrolled patients (n=~180) will be stratified by clinical TNM stage (II vs III), histology (nonsquamous vs squamous), and PD-L1 expression (<1%, 1–49%, ≥50%), and randomized (1:1:1) to the following study arms for the neoadjuvant period (≤4 cycles; each cycle is every 3 weeks): arm A, placebo + cemiplimab 350 mg + platinum doublet chemotherapy; arm B, fianlimab dose 1 + cemiplimab 350 mg + platinum doublet chemotherapy; arm C, fianlimab dose 2 + cemiplimab 350 mg + platinum doublet chemotherapy. After surgery, in the adjuvant period (≤14 cycles), patients in all arms will continue the same IO regimen with approved maintenance chemotherapy. Treatment will last ~12 months (12 weeks' neoadjuvant therapy + 42 weeks' adjuvant therapy), or until disease recurrence, unacceptable toxicity, or a decision from the patient or investigator. Primary endpoint: pathological complete response as determined by blinded independent pathological review (BIPR). Key secondary endpoints: event-free survival and tumor response by investigator assessment, major pathological response by BIPR, safety, pharmacokinetics, immunogenicity, and patient-reported outcomes. Clinical trial information: NCT06161441. Research Sponsor: Regeneron Pharmaceuticals, Inc.

TPS8118 **Poster Session**

Safety, efficacy, and tumor immune microenvironment changes with neoadjuvant chemotherapy and cemiplimab with or without alirocumab in stage 1B-3A non-small cell lung cancer. First Author: Eziafa Oduah, Duke University, Durham, NC

Background: The addition of immune checkpoint blockade to neoadjuvant and adjuvant therapy is now standard of care in early-stage surgically resectable non-small cell lung cancer (NSCLC). However, resistance to immunotherapy limit their benefit for most patients. The pathological complete response (pCR) rate, a surrogate for long term survival, remains close to 20%, leaving many patients at a high risk of recurrence and death. Thus, there is a need to apply strategies to overcome immunotherapy resistance in earlier stages of NSCLC to improve cure. Proprotein convertase subtilisin/kexin type 9 (PCSK9), a major cholesterol regulator, has emerged as an inhibitory modulator of anti-tumor immunity. Preclinical evidence showed that PCSK9 downregulated MHC class I antigen expression on tumor cells. This effect was reversed by genetic or pharmacologic inhibition of PCSK9. PCSK9 inhibitor synergized with immune checkpoint blockade to increase cytotoxic T-cell mediated tumor death. Retrospective clinical analyses of NSCLC patients treated with immune checkpoint inhibitors also showed a correlation between higher PCSK9 levels and poorer survival. **Methods:** TOP 2301 is a multi-center, open label, two-arm, randomized, phase 2 trial of chemotherapy and cemiplimab (350mg IV every 3 weeks) with or without the PCSK-9 inhibitor, alirocumab (150 mg SC every 4 weeks), prior to surgery. Eligible patients will have stage IB-3A NSCLC, deemed surgical candidates, and have no EGFR or ALK mutations. One hundred and twenty-six patients will be randomized 1:1 to receive neoadjuvant SOC chemotherapy and cemiplimab versus SOC chemotherapy, cemiplimab and alirocumab. Approximately 64 participants are required in each arm to have 90% power to reject the null hypothesis. The primary objective is to compare the pCR rates for neoadjuvant chemotherapy plus cemiplimab versus chemotherapy, cemiplimab, and alirocumab. Secondary efficacy objectives for the experimental arm include: the objective response rate (ORR), disease free survival (DFS), and overall survival (OS). A secondary safety objective is to determine the safety and tolerability of neoadjuvant chemotherapy and cemiplimab with alirocumab in early-stage NSCLC. The correlative science objective will evaluate the difference in tumor infiltrating lymphocytes and dendritic cells through IHC, FACs analysis, and bulk RNA-seq with CIBERSORT from postsurgical specimens of patients treated with neoadjuvant chemotherapy and cemiplimab with or without alirocumab. The trial was open to enrollment on 12/15/2024. Clinical trial information: NCT06385262. Research Sponsor: None.

TPS8119 **Poster Session**

Neoadjuvant lazertinib with or without chemotherapy for patients with epidermal growth factor receptor (*EGFR*)-mutated resectable non-small cell lung cancer (NSCLC): NeoLazer trial. First Author: Hye Ryun Kim, Division of Medical Oncology, Department of Internal Medicine, Yonsei Cancer Center, Yonsei University College of Medicine, Seoul, South Korea

Background: While perioperative systemic treatment with checkpoint inhibitors plus chemotherapy has become a standard approach for resectable NSCLC, the benefit of systemic treatment in *EGFR*-mutated NSCLC remains unclear. In resectable *EGFR*-mutated NSCLC, adjuvant osimertinib has been shown to significantly improve disease-free survival and overall survival. However, neoadjuvant osimertinib alone has demonstrated limited efficacy, with a major pathologic response rate of less than 15% (NCT03433469). These data altogether highlight an unmet clinical need for optimizing perioperative systemic approach in resectable *EGFR*-mutated NSCLC. Lazertinib, a third-generation, central nervous system-penetrating EGFR tyrosine kinase inhibitor, has demonstrated superior efficacy compared to comparator EGFR tyrosine kinase inhibitor in treatment-naïve *EGFR*-mutated advanced NSCLC (NCT04248829). The NeoLazer trial (NCT06268210) is a phase II, randomized, controlled study designed to evaluate the efficacy and safety of neoadjuvant lazertinib with or without chemotherapy in patients with *EGFR*-mutated resectable NSCLC. **Methods:** Eligible patients must be ≥19 years of age, have an ECOG performance status of 0 or 1, non-squamous histology, stage IB–IIIB NSCLC based on the AJCC 8th edition, have confirmed sensitizing *EGFR* mutations (exon 19 deletion or L858R mutation), be deemed completely resectable by a multidisciplinary team, and demonstrate adequate organ and bone marrow function. The trial will enroll approximately 160 patients, who will be randomized 1:1 to receive either lazertinib (240 mg once daily) with chemotherapy (pemetrexed 500 mg/m² and carboplatin AUC5 every 3 weeks) or lazertinib alone (240 mg once daily) for three cycles before surgical resection. Randomization will be stratified by disease stage (IB–II vs. III) and *EGFR* mutation type (exon 19 deletion vs. L858R mutation). Following surgery, all patients will receive adjuvant lazertinib for three years. Neoadjuvant and adjuvant treatments will continue until unacceptable toxicity, disease progression or relapse, or patient withdrawal. The primary endpoint is major pathologic response, defined as ≤10% residual viable cancer cells in the surgical specimen. Secondary endpoints include safety based on CTCAE 5.0, type of surgical resection (segmentectomy vs. lobectomy), pathologic complete response, objective response rate based on RECIST 1.1, event-free survival, disease-free survival, and overall survival. In addition, the trial incorporates exploratory analyses, including whole-genome sequencing of tumor tissue and monitoring the dynamics of minimal residual disease through serial blood sampling. Clinical trial information: NCT06268210. Research Sponsor: None.

TPS8120 **Poster Session**

Neotrace: A multicenter phase II study of neoadjuvant sacituzumab govitecan plus zimberelimab followed by adjuvant zimberelimab with or without sacituzumab govitecan in patients with resectable non-small cell lung cancer. First Author: Friederike C Althoff, Goethe University Frankfurt, Frankfurt Am Main, Hessen, Germany

Background: Phase III trials, including KEYNOTE-671, have established combined neoadjuvant chemoimmunotherapy followed by adjuvant immunotherapy (IO) as the standard of care for resectable NSCLC. However, a notable challenge in KEYNOTE-671 and similar studies was that ~17-22% of patients did not proceed to surgery following neoadjuvant chemoimmunotherapy, highlighting the need for more tolerable regimens. Recent data from studies such as NEOpredict (which demonstrated a 100% surgical completion rate with neoadjuvant nivolumab with/without relatlimab), NeoCOAST-2 (which reported a 34% pathological complete response [pCR] rate using a neoadjuvant combination of an anti-TROP2 antibody drug conjugate [ADC], IO, and single-agent platinum, thereby surpassing the ~20% pCR rates achieved with neoadjuvant chemoimmunotherapy), and EVOKE-02 (which showed promising objective response rates of 69% and 44% with the anti-TROP2 ADC sacituzumab govitecan plus pembrolizumab in first-line metastatic NSCLC patients with PD-L1 ≥50% and PD-L1 0-49%, respectively) demonstrate that chemotherapy-sparing approaches may reduce toxicity while maintaining or enhancing efficacy. These findings highlight the potential synergistic effect of ADC plus IO, suggesting this strategy may also be an effective treatment option in the perioperative setting with potentially lower toxicity compared to chemoimmunotherapy. Additionally, long-term adverse events associated with platinum-based chemotherapy, such as neuropathy, may be lower or avoided altogether. This study aims to improve the pCR rate, reduce toxicity, enhance surgical eligibility, and personalize adjuvant treatment. **Methods:** NeoTRACE is a phase II, multicenter, open-label, single-arm study evaluating the neoadjuvant combination of sacituzumab govitecan (SG) and the PD-1 inhibitor zimberelimab (ZIM) in patients with resectable stage II to IIIB (N2) NSCLC with no known EGFR or ALK alterations. Patients will receive neoadjuvant SG 10 mg/kg IV on days 1 and 8, and ZIM 360 mg IV on day 1, every 3 weeks for 4 cycles, followed by definitive surgery as per local standards. In the adjuvant phase, patients will either continue adjuvant SG plus ZIM for up to 4 cycles, followed by ZIM only for a total of up to 13 cycles, or receive adjuvant ZIM monotherapy (as per physicians' choice). The primary endpoint is the rate of pCR in tumor and lymph nodes. Secondary endpoints include major pathological response, surgical resection rate, time to surgery, DFS, OS, safety, and quality of life. The study also explores circulating tumor DNA dynamics, TROP2 expression, and spatial transcriptomics and proteomics to identify potential biomarkers. As of June 2025, the NeoTRACE study is recruiting 50 patients across 15 sites in Germany. EudraCT: 2024-517561-16. Clinical trial information: 2024-517561-16 (EudraCT). Research Sponsor: None.

TPS8121 **Poster Session**

Efficacy of low-dose nivolumab combined with chemotherapy as neoadjuvant treatment for lung cancer. First Author: Aline Fusco Fares, University of Florida, Gainesville, FL

Background: Immune checkpoint inhibitors have revolutionized cancer treatment, providing durable responses in a substantial subset of patients. However, their high costs remain a significant barrier to access, especially in low- and middle-income countries (LMICs). Evidence from pharmacodynamic studies suggests that lower doses (LD) of anti-PD-(L)1 agents can achieve comparable receptor saturation and therapeutic efficacy without compromising outcomes. Mounting data supports the concept of treating patients with LD anti-PD(L)1 agents. For instance, the use of LD nivolumab (0.3 mg/kg) has demonstrated equivalent PD-L1 receptor occupancy and similar survival outcomes to standard doses, offering a more cost-effective alternative. Notably, at 0.3 mg/kg, up to 10 patients can be treated for the cost of treating a single patient with standard doses. While most supporting evidence pertains to advanced disease settings, data on the use of LD in curative-intent applications, such as neoadjuvant therapy for resectable non-small cell lung cancer (NSCLC), remain limited. This study investigates the efficacy and safety of LD nivolumab combined with platinum-based chemotherapy as a neoadjuvant treatment for resectable NSCLC, addressing the urgent need for affordable treatment options in LMICs. **Methods:** This is an ongoing investigator-initiated, single-arm, phase II trial conducted at Hospital de Base, São José do Rio Preto, Brazil. Eligible participants are adults with histologically confirmed stage IB-IIIA NSCLC, with known PD-L1 expression, and no actionable genomic alterations in EGFR, ALK, or ROS1. All patients will receive three cycles of nivolumab (0.3 mg/kg IV every three weeks) combined with carboplatin (AUC 5-6) and either pemetrexed or paclitaxel, selected based on tumor histology and physician preference. Surgery will be scheduled 9-12 weeks after initiating therapy. The co-primary endpoints are major pathologic response rate (MPR), defined as ≤10% viable tumor cells in the resected surgical specimen, and complete pathologic response. Secondary endpoints include disease-free survival, overall survival, and treatment-related adverse events (AEs) graded per CTCAE v5.0. Exploratory analyses will evaluate outcomes based on disease stage, PD-L1 levels, and smoking history. The trial employs a Simon two-stage design with an initial cohort of 17 patients to assess futility. If at least one MPR is observed, enrollment will expand to a total of 33 patients. This design aims to detect an improvement in MPR from 12% (null hypothesis) to 24% (alternative hypothesis), with a significance level of 0.1 and 80% power. All specimens will undergo pathological review, and blood samples will be collected for exploratory biomarker analyses, including circulating tumor DNA. Study enrollment began in January 2024, and as of December 2024, 5 patients have been screened, with 3 enrolled. Clinical trial information: NCT06667154. Research Sponsor: Hospital de Base de Sao Jose do Rio Preto.

TPS8122 **Poster Session**

Phase II study of pembrolizumab in combination with cisplatin or carboplatin and pemetrexed as induction chemoimmunotherapy in resectable epithelioid and biphasic pleural mesothelioma (CHIMERA study). First Author: Giulia Pasello, Oncology Unit 2, Istituto Oncologico Veneto (IOV-IRCCS), Padova, Italy

Background: Pleural mesothelioma (PM) is a rare cancer related to asbestos exposure, marked by complex histopathological diagnosis and dismal prognosis. Patients' survival is strongly influenced by the histological subtype and by the eligibility to a multimodal approach, which is reserved to very selected patients. Platinum-pemetrexed chemoregimen or the immunotherapy combination ipilimumab+nivolumab are the available first-line treatment options for unresectable PM patients. In this setting, pembrolizumab in combination with platinum-pemetrexed showed an improved overall and progression free survival (IND227/Keynote483 trial). In patients with resectable PM, the multimodality approach with platinum-pemetrexed chemotherapy and surgery is usually preferred, achieving pathological complete response (pCR) in 5% of cases. To date, the role of perioperative immunotherapy for PM has not yet been extensively investigated. **Methods:** This is a phase II single arm trial enrolling patients with resectable PM from 8 high volume Italian centers, with 18 months of enrollment and 12 months of follow-up. Inclusion criteria will be the histologically confirmed diagnosis of surgical resectable stage I-IIIA treatment-naïve epithelioid/biphasic PM. Patients will receive 3 cycles of pembrolizumab 200 mg plus cisplatin (75 mg/sm) or carboplatin (AUC 5) and pemetrexed (500 mg/sm) every 3 weeks. The surgical procedure of pleurectomy/decortication will be centralized in 2 centers and will be performed within 6 weeks after the last neoadjuvant cycle. The adjuvant treatment will start within 10 weeks from surgery and will be based on 14 cycles of pembrolizumab 200 mg every 3 weeks. The primary endpoint will be the pCR; secondary endpoints will include: major pathological response, objective response rate, event free survival, OS, surgery feasibility, safety. Translational analysis on tissue and blood samples will also be performed. In order to investigate an improvement of pCR from 5% to 18%, 36 patients and a minimum number of 4 pCR are needed to verify this hypothesis with a least 80% power and a probability of type I error of 0.05. Considering a 10% patients dropped-out because of disease progression precluding surgery, a total number of 40 patients will be included in the study. The trial is currently ongoing since November 2024; 5 patients have been enrolled so far. This is the first clinical trial assessing the activity and safety of pembrolizumab in combination with platinum-pemetrexed for resectable PM patients. Clinical trial information: NCT06155279. Research Sponsor: MSD.

TPS8123 **Poster Session**

Trial in progress: Sacituzumab govitecan for the treatment of patients with diffuse pleural mesothelioma. First Author: Michael Offin, Memorial Sloan Kettering Cancer Center, New York, NY

Background: Diffuse pleural mesothelioma (DPM) is an aggressive malignancy with poor outcomes and only three FDA-approved treatments (all first-line). Even when first-line treatment is effective, most patients experience progression within a year, and there are no approved, nor accepted, second-line approaches. Analysis of our novel library of DPM patient derived xenografts (PDXs) nominated TROP-2 as a candidate target for therapy. The role of TROP-2 expression in proliferation, colony formation, migration, and invasion was determined along with the antitumor efficacy of a TROP-2 targeting antibody-drug conjugate (ADC). Exogenous TROP-2 expression increased tumorigenicity *in vitro* and *in vivo* across multiple DPM models and induced upregulation of pro-oncogenic pathways. Treatment of PDXs with the TROP-2 ADC sacituzumab govitecanhziy (SG) inhibited tumor growth with higher efficacy than gemcitabine (a standard of care later-line treatment) or the cytotoxic payload alone (irinotecan; results previously presented at WCLC 2024). These data identified TROP-2 as a promising therapeutic target in DPM leading to the development of an investigator-initiated trial with Department of Defense support (HT9425-24-1-0754). **Methods:** A single arm phase 2 unblinded Simon two-stage single-institution study recently commenced at Memorial Sloan Kettering Cancer Center (MSK) assessing the primary endpoint of overall response rate to SG by modified (m)RECIST v1.1 in patients with recurrent and/or unresectable/metastatic pathologically confirmed DPM (NCT06477419). Secondary endpoints include overall survival, progression-free survival, and safety. Key eligibility criteria include receipt of at least one prior line of standard systemic therapy and agreement to undergo study biopsies at screening, prior to cycle 3, and end of treatment (optional) if safe and feasible. SG will be administered intravenously at the FDA-approved dose/schedule established in breast cancer (10 mg/kg on days 1 and 8 of a 21-day cycle). Patients will undergo imaging after the first 2 cycles and subsequently every 3 cycles until progression. In the first stage, 19 patients will be treated. If at least 4 responses are observed, then an additional 14 patients will be accrued. To date, 4 patients have been enrolled. Tumor material will undergo 1) routine histologic subtyping, TROP-2 immunohistochemistry, and next-generation sequencing (MSK-IMPACT), 2) flow cytometry, 3) proteomic analyses/mass-spectrometry, and 4) RNA sequencing/methylation analysis. These studies will characterize how SG alters tumoral expression of TROP-2 and signaling pathways supporting cancer growth and survival. Clinical trial information: NCT06477419. Research Sponsor: U.S. Department of Defense; HT9425-24-1-0754; Gilead Science.

TPS8124 **Poster Session**

TIGOS-LS, an open-label, randomized study of BMS-986489 vs durvalumab as consolidation therapy following chemoradiotherapy in limited-stage small-cell lung cancer. First Author: Melissa Lynne Johnson, Sarah Cannon Research Institute, Nashville, TN

Background: Standard treatment for limited-stage small-cell lung cancer (LS-SCLC) has recently changed to add durvalumab consolidation after concurrent chemoradiotherapy. Although durvalumab consolidation increases overall survival (OS; Cheng et al. 2024), other therapeutic agents may be able to provide further improvement. BMS-986489 is a potential first-in-class fixed-dose combination of atigotatug (BMS-986012) and nivolumab. Atigotatug binds to fucosyl-monosialoganglioside-1 (fuc-GM1), which is highly expressed on SCLC cells and is largely absent in normal tissues. This binding results in tumor cell death by antibody-dependent cellular cytotoxicity, antibody-dependent cellular phagocytosis, or complement-dependent cytotoxicity. The immune effects initiated by atigotatug may further enhance T cell activation by nivolumab, thereby improving outcomes after chemoradiotherapy. In a randomized phase II study in extensive-stage SCLC, atigotatug improved median OS when added to carboplatin, etoposide, and nivolumab (CE/NIVO): 15.6 months (95% confidence interval [CI]: 11.3-NE) vs 11.4 months (95% CI: 9.3-16.5) with CE/NIVO alone (Kalinka et al. 2024). **Methods:** TIGOS-LS is an open-label, randomized study to evaluate the safety and efficacy of BMS-986489 as consolidation therapy vs the new standard durvalumab following chemoradiotherapy in LS-SCLC. Approximately 250 participants will be enrolled at 80 sites within the US. Eligible participants will be adults (≥18 years) with an Eastern Cooperative Oncology Group (ECOG) performance status of 0 or 1 and histologically or cytologically confirmed LS-SCLC. All participants must have completed concurrent chemoradiotherapy for LS-SCLC without progression; prophylactic cranial irradiation (PCI) will be permitted before initiation of study treatment. Confirmation of fuc-GM1 expression will not be required. Participants will be stratified based on disease stage (I/II vs III) and receipt of PCI and will be randomly allocated in a 1:1 ratio to either the BMS-986489 or durvalumab arms. BMS-986489 or durvalumab will be administered intravenously at a fixed dose once every 4 weeks for up to 2 years or until other discontinuation criteria are met. Response will be evaluated by Response Evaluation Criteria in Solid Tumors (RECIST) v1.1. Survival follow-up will occur every 12 weeks for up to 3 years. The primary endpoint is OS. Key secondary endpoints include progression-free survival, objective response rate, clinical benefit rate, disease control rate, duration of response, and safety parameters. Enrollment is projected to start in April 2025. Clinical trial information: NCT06773910. Research Sponsor: Bristol Myers Squibb.

TPS8125 **Poster Session**

Radiotherapy integration strategy for small-cell lung cancer in extensive stage (RISE) with up to 10 metastases: A study protocol of a randomized phase II trial. First Author: Łukasz Kuncman, Department of External Beam Radiotherapy, Copernicus Memorial Hospital in Lodz Comprehensive Cancer Center and Traumatology, Lodz, Poland

Background: The standard of care (SoC) for patients with extensive-disease small-cell lung cancer (ED-SCLC) currently involves chemo-immunotherapy. Radiotherapy (RT) has proven effective as a chest consolidation therapy in ED-SCLC patients who respond to chemotherapy. However, there is limited evidence regarding the role of RT in both chest consolidation and metastasis-directed therapy for ED-SCLC patients undergoing chemo-immunotherapy. The RISE (Radiotherapy for Extensive-Stage Small-Cell Lung Cancer) study aims to evaluate the efficacy of various RT strategies targeting residual lesions in this patient population. **Methods:** A total of 165 patients with ED-SCLC will be recruited, with 55 patients assigned to each of the three study arms. Patients with stabilization or partial regression, according to the Response Evaluation Criteria in Solid Tumors (RECIST) version 1.1, during chemo-immunotherapy will be included. Arm I will serve as the control group, comprising patients who continue SoC of programmed death-ligand 1 (PD-L1)/programmed death-1 (PD-1) immunotherapy (durvalumab or atezolizumab) following platinum-based chemo-immunotherapy. Arm II will receive the SoC with consolidative RT to the chest area and potentially, according to palliative indications to metastatic lesions, delivered in 30 Gy in 3-Gy fractions. Arm III will receive SoC with RT of 45 Gy in 3-Gy fractions to the chest area and stereotactic body radiotherapy (SBRT) with 24 Gy in 8-Gy fractions to the metastatic lesions. Blood samples for circulating tumor DNA (ctDNA) will be collected before RT, during each week of treatment, and at the time of disease progression. The primary endpoint is progression-free survival (PFS) based on RECIST 1.1 or patient death. 1. Secondary endpoints are OS, treatment toxicity (frequency of G3 toxicity according to CTCAE v.5.0), area of progression (primary tumor localization/new lesions), Overall response rate (ORR), and the response rate in non-irradiated lesions. The study population of patients with ED-SCLC has a poor prognosis. Dose-escalated chest RT and SBRT (for up to 10 metastases) administered with modern techniques offer the possibility to improve OS and PFS. Trial registration: Clinicaltrials.gov NCT06529081 (Registered 26th Jul 2024). Clinical trial information: NCT06529081. Research Sponsor: Medical Research Agency; 2023/ABM/01/00040.

TPS8126 **Poster Session**

A phase 1/2 clinical trial of quaratusugene ozeplasmid gene therapy and atezolizumab maintenance therapy in patients with extensive stage small cell lung cancer (ES-SCLC). First Author: Bo Wang, Willamette Valley Cancer Institute and Research Center, Eugene, OR

Background: The addition of atezolizumab (atezo) to both induction therapy and maintenance therapy for patients with ES-SCLC has improved median progression free survival (PFS) and overall survival (New Eng J Med. 2018;379:2220-9). However, the median PFS from starting atezo maintenance was only 2.6 months (J Thoracic Onc. 2022;17:1122-9). Expression of TUSC2, a tumor suppressor gene, is absent in 41% of SCLC patients and is decreased in 100% of SCLC patients (Clin Cancer Res 2008;14(1):41–47). Quaratusugene ozeplasmid (QuarOze) gene therapy consists of a DNA plasmid expressing the *TUSC2* gene encapsulated in a positively charged lipoplex which delivers the *TUSC2* gene to cancer cells, restoring TUSC2 expression. Xenograft studies using a SCLC cell line in a humanized mouse model treated with a combination of QuarOze and atezo demonstrated significantly increased tumor cell killing compared to that of atezo alone. In addition, infiltration of immune cells was increased in the tumor tissue, whereas myeloid derived suppressor cells were decreased (Meraz IM et al, AACR/NCI/EORTC 2023). Thus, in this study QuarOze is added to atezo maintenance therapy with the aim of improving PFS after the start of maintenance therapy. **Methods:** Eligible patients have ES-SCLC and have completed 3-4 cycles of induction therapy with etoposide, a platinum agent, and atezo without disease progression, and are thus eligible for maintenance therapy. QuarOze is administered IV every 21 days in escalating dose cohorts in Phase 1 and atezo 1200 mg is also administered IV every 21 days. Dexamethasone, acetaminophen, and diphenhydramine are given prior to each treatment to prevent delayed infusion-related reactions. Efficacy is evaluated after every even cycle of treatment using RECIST 1.1 criteria. Safety is evaluated using CTCAE v5, with dose limiting toxicities generally defined as ≥Gr 3 adverse events (AEs). TUSC2 protein expression is measured by a validated immunohistochemistry assay in paraffin sections to determine if PFS is related to pretreatment TUSC2 levels. A validated assay measures pharmacokinetics in all patients. In Phase 1, two planned dose levels (0.09, and 0.12 mg/kg) of QuarOze were administered, and a standard dose escalation with 3-6 patients/dose level was used. The Phase 2 portion of the trial will enroll 50 patients which provides 80% power at a one-sided alpha level of 0.05 to detect an 18-week PFS rate of 52% compared to a historical 18-week PFS rate of 34% with atezo alone. This corresponds to a median PFS of approximately 4.3 months compared to a historical median PFS of 2.6 months with atezo alone. A Safety Review Committee (SRC) reviewed safety data at the end of each dose level of Phase 1 to make recommendations about dose escalation. The Phase 2 portion of the trial opened for enrollment in December, 2024. Clinical trial information: NCT05703971. Research Sponsor: Genprex, Inc.

TPS8127 **Poster Session**

The TIGOS trial: A randomized, double-blind phase 3 trial of atigotatug + nivolumab fixed-dose combination with chemotherapy vs atezolizumab with chemotherapy in patients with 1L extensive-stage small cell lung cancer (ES-SCLC). First Author: Luis G. Paz-Ares, Hospital Universitario 12 de Octubre, Universidad Complutense de Madrid, Madrid, Spain

Background: Atigotatug is an innate immune inducer monoclonal antibody that binds fucosyl-monosialoganglioside-1 (fuc-GM1) with high affinity and specificity, thereby inducing immune-mediated tumor cell death. Fuc-GM1, a cell surface target, is expressed in 50%–90% of SCLC tumors. In a randomized, open-label phase 2 study, atigotatug combined with nivolumab and chemotherapy vs nivolumab and chemotherapy alone has shown a promising trend in overall survival (OS) with median OS of 15.6 mo vs 11.4 mo, respectively (HR 0.71; 95% CI 0.44–1.16), as a first-line treatment in ES-SCLC. Based on these results, a confirmatory trial comparing this regimen to the standard of care is warranted. TIGOS (NCT06646276) is a randomized, double-blind, multicenter phase 3 trial to compare the efficacy and safety of atigotatug + nivolumab fixed-dose combination with chemotherapy vs atezolizumab with chemotherapy. **Methods:** Approximately 530 eligible patients will be randomized 1:1 to receive either atigotatug + nivolumab fixed-dose combination with carboplatin and etoposide Q3W (induction) followed by atigotatug + nivolumab fixed dose combination (maintenance) Q4W or atezolizumab with carboplatin and etoposide Q3W (induction) followed by atezolizumab (maintenance) Q4W. Patients will be stratified by ECOG performance status (PS) 0–1, presence of liver metastases, and presence of brain metastases at baseline. Treatment will continue until disease progression, unacceptable toxicity, death, or withdrawal of consent. Eligible patients must be ≥18 years old, have histologically or cytologically documented SCLC, ≥1 measurable lesion outside the central nervous system (CNS), any previous limited-stage SCLC treatment completed ≥6 months prior to study treatment initiation, and an ECOG PS of 0–1. Key exclusion criteria include prior treatment for ES-SCLC, untreated symptomatic CNS metastases, and prior treatment targeting T-cell co-stimulation, checkpoint pathways, and/or fuc-GM1. The primary endpoint is OS, and the secondary endpoints are time to definitive deterioration, safety, objective response, duration of response, and progression-free survival, as assessed by the investigator. Assessment of pre- and on-treatment changes in biomarkers will be part of an exploratory analysis. This study will be conducted in 180 locations, with a primary completion date expected in April 2028. Clinical trial information: NCT06646276. Research Sponsor: Bristol Myers Squibb.

TPS8128 **Poster Session**

An open-label, multicenter, phase 1/2 study of peluntamig (PT217), an anti-DLL3/anti-CD47 bispecific antibody, in patients with DLL3-expressing cancers such as SCLC, LCNEC and EP-NEC (SKYBRIDGE study). First Author: Jacob Sands, Dana-Farber Cancer Institute and Harvard Medical School, Boston, MA

Background: Neuroendocrine carcinomas (NECs) are aggressive cancers with limited median survival. Over 90% of the NEC cases originate from the lung, including small cell lung cancer (SCLC) and large cell neuroendocrine carcinoma (LCNEC) of the lung. The rest of the cases are extra-pulmonary NECs (EP-NECs), including gastroenteropancreatic neuroendocrine carcinoma (GEP-NEC) and neuroendocrine prostate cancer (NEPC). Despite the initial impressive responses to platinum-based chemotherapy with or without an immune checkpoint inhibitor (ICI), at progression, resistance and clinical deterioration are common. High mortality rates and limited treatment options with durability highlight a significant unmet medical need. NECs are known to be heterogeneous. One unifying feature is the consistent surface expression of DLL3, making targeting DLL3 an attractive treatment approach. Peluntamig (PT217) is an IgG1 based anti-DLL3/anti-CD47 bispecific antibody that activates both innate and adaptive immunity to target cells that express DLL3 and/or overexpress CD47. **Methods:** The study consists of 4 parts: Monotherapy Dose Escalation (Part A), Dose Expansion (Part B), Chemotherapy Combination Therapy (Part C), and ICI Combination Therapy (Part D). Each part includes multiple cohorts. The study is designed to evaluate the safety, tolerability, pharmacokinetic (PK), pharmacodynamic (PD), and preliminary efficacy of peluntamig. Parts A, C and D are on-going. Cohort C1 will enroll patients with first-line (1L) LCNEC of the lung and EP-NEC and patients with second-line (2L) SCLC who have (defined as progression ≥ 90 days after last dose of platinum therapy). Patients will receive peluntamig and SOC CE. Cohort C2 will enroll SCLC, LCNEC of the lung and EP-NEC patients eligible for 2L paclitaxel therapy. Patients will receive peluntamig and SOC paclitaxel. Cohort D1 will enroll 2L LCNEC of the lung, EP-NEC and ES-SCLC patients who have progressed/relapsed from their 1L treatment that may have included an ICI. Patients will receive peluntamig + atezolizumab. Cohort D2 will enroll 1L patients with ES-SCLC who have completed their induction therapy with CE plus atezolizumab and are eligible to continue with atezolizumab treatment. Patients will receive peluntamig + atezolizumab as maintenance therapy. Cohort D3 will enroll 1L patients with ES-SCLC who are treatment-naïve. Patients will receive peluntamig + CE + atezolizumab. Dose escalation, guided by a 3+3 design, will be conducted independently for each cohort. Patients will be backfilled to DLT-cleared dose levels to further evaluate safety, tolerability, PK and efficacy. Potentially active cohorts will be further investigated in dose randomization studies in Part B. Clinical trial information: NCT05652686. Research Sponsor: None.

TPS8129 **Poster Session**

A global phase III, double-blind, randomized trial of BNT327/PM8002 plus chemotherapy (chemo) compared to atezolizumab plus chemo in patients (pts) with first-line (1L) extensive-stage small cell lung cancer (ES-SCLC). First Author: Martin Reck, Thoracic Oncology Department, LungenClinic Grosshansdorf, Grosshansdorf, Germany

Background: SCLC is an aggressive form of lung cancer. Incorporating immunotherapy for ES-SCLC pts in the frontline has improved outcomes, but long-term benefit is still lacking. There is an urgent need for efficacious treatments that can extend the duration of response and improve survival in SCLC. BNT327 is an investigational bispecific antibody, targeting both PD-L1 and VEGF-A in the tumor and tumor microenvironment (TME). By binding to PD-L1 on tumor cells it is designed to restore effector T-cell function and by binding to VEGF-A within the TME it also reverses the negative impact of VEGF signaling on immune cell infiltration and activation. In addition, via VEGF-A neutralization, it normalizes tumor vasculature. This dual targeting of PD-L1 and VEGF-A aims to deliver better efficacy and safety. Preliminary results from a Phase II trial showed encouraging efficacy results and a manageable safety profile for BNT327 with paclitaxel as second-line (2L) treatment of pts with SCLC (1992P, ESMO 2023). Combining BNT327 with chemo is being investigated in several Phase II and III trials in both 1L and 2L, including a global dose optimization trial. This Phase III trial will further assess the efficacy and safety of BNT327 in combination with chemo for previously untreated pts with ES-SCLC in a global population. **Methods:** Thisglobal, randomized, double-blind, Phase 3 trial (NCT06712355) will enroll ~439 pts with histologically or cytologically confirmed SCLC, who have not received prior systemic therapy for ES-SCLC. Pts will be initially randomized 1:1:1 to receive combination therapy of atezolizumab (1,200 mg IV) plus chemo (etoposide + carboplatin) (Arm 1), BNT327 (2,000 mg IV) plus chemo (Arm 2), or BNT327 (1,400 mg IV) plus chemo (Arm 3) administered Q3W for four cycles, followed by maintenance therapy with atezolizumab (Arm 1) or BNT327 (Arm 2 and Arm 3) Q3W until confirmed disease progression, intolerable toxicity, participant withdrawal, trial termination or up to two years, whichever occurs first. Chemo will be dosed per local treatment guidelines. One of the BNT327 arms (Arm 2 or 3) is expected to be closed upon evolving insights on the optimal dose. Further pts will then be randomized (1:1) into Arm 1 or the remaining BNT327 arm. Stratification includes brain metastasis, liver metastasis, and geography. The primary endpoint is overall survival (OS). Secondary endpoints include progression-free survival (PFS), objective response rate, PFS rates and OS rates at defined timepoints, patient-reported outcomes, occurrence of treatment emergent adverse event (TEAEs) and occurrence of dose delay, infusion interruption, and discontinuation due to TEAEs; with efficacy endpoints per RECIST 1.1; safety per CTCAE v5.0. The Phase III trial is currently recruiting pts. Clinical trial information: NCT06712355. Research Sponsor: BioNTech SE.

TPS8130 **Poster Session**

IMMUNORARE[5]: A national platform of 5 academic phase II trials coordinated by Lyon University Hospital to assess the safety and the efficacy of the immunotherapy with domvanalimab + zimberelimab combination in patients with advanced rare cancers—The B3 Thymomas and Thymic Carcinomas Cohort. First Author: Michaël Duruisseaux, Louis Pradel Hospital, Hospices Civils de Lyon Cancer Institute, Cancer Research Center of Lyon (INSERM 1052, CNRS 5286), Université Claude Bernard Lyon 1, Université de Lyon, Lyon, France

Background: In patients with rare cancers, there is an unmet medical need for investigating innovative therapeutics. Indeed, these diseases are rarely assessed in clinical trials. Thymic epithelial tumors (TET) are rare heterogeneous thoracic malignancies. B3 TET and thymic carcinomas are more aggressive and prone to metastatic spreading. The standard 1st line treatment relies on platinum-based chemotherapy. Consensual 2nd line treatment has not been identified yet. Several studies showed limited efficacy of PD-1 blockade in B3 TET and thymic carcinomas. Concurrent blockage of TIGIT and PD-1 immune checkpoint B3 TET may improve outcomes according to translational studies. **Methods:** IMMUNORARE[5] (NCT06790706) is a platform of 5 single arm phase II trials testing the safety and efficacy of Domvanalimab (anti-TIGIT) and Zimberelimab (anti PD-1) in 5 independent cohorts of rare cancers. The trial, sponsored by Lyon University Hospital, is conducted in 15 French centers, in partnership with the corresponding French national reference centers. The B3 TET and thymic carcinomas cohort, led in collaboration with the RYTHMIC Network (www.rythmic.org), will enroll 26 patients after failure of at least one line of platinum-based chemotherapy, with evaluable lesions at baseline according to RECIST criteria. Patients previously treated with immunotherapy are not eligible. Patients will receive Domvanalimab and Zimberelimab intra-venous, every three weeks, until disease progression or unacceptable toxicity. The primary endpoint is the progression-free survival rate at 6 months. The secondary endpoints are overall response rate and duration of the response, progression-free survival, overall survival and tolerability. The trial is designed with a two-stage Simon design, with early termination for futility (5% one-sided alpha level, 80% power). The treatment would be considered interesting if the percentage of patients free from disease progression at 6-months is statistically higher than 40%; 65% is expected. Translational research projects will be developed aiming at deciphering cellular and molecular mechanisms involved in response to treatment. Moreover, data from the prospective database of the RYTHMIC network will be investigated to build a synthetic historical arm representative of the efficacy of the standard treatments in a similar population of patients. Clinical trial information: NCT06790706. Research Sponsor: GILEAD.

8500 **Oral Abstract Session**

First-line adagrasib (ADA) with pembrolizumab (PEMBRO) in patients (pts) with advanced/metastatic KRAS^{G12C}-mutated non-small cell lung cancer (NSCLC) from the phase 2 portion of the KRYSTAL-7 study. First Author: Pasi A. Jänne, Department of Medical Oncology, Lowe Center for Thoracic Oncology, Dana-Farber Cancer Institute, Boston, MA

Background: In the phase 2 KRYSTAL-7 study (NCT04613596), first-line ADA, a KRAS^{G12C} inhibitor, plus PEMBRO demonstrated clinical activity and a manageable safety profile in pts with advanced/metastatic *KRAS*^{G12C}-mutated NSCLC and PD-L1 ≥50% (Garassino et al. *Ann Oncol* 2023). Here we report efficacy and safety data, including the first disclosure of survival data, for pts across all PD-L1 tumor expression levels. **Methods:** Pts with advanced/metastatic *KRAS*^{G12C}-mutated NSCLC and known PD-L1 tumor proportion score received first-line ADA (400 mg orally BID) plus PEMBRO (200 mg IV Q3W). The primary endpoint was investigator-assessed objective response rate (ORR) per RECIST v1.1. Secondary endpoints included duration of response (DOR) and progression-free survival (PFS) assessed by investigator, overall survival (OS), and safety. **Results:** As of August 23, 2024, 149 pts had received ADA plus PEMBRO (median OS follow-up 22.8 mo): median age was 67 years, 48% were female, and 62% had ECOG PS 1. ORR was 44.3% (95% CI 36.2–52.7); median DOR was 26.3 mo (95% CI 14.9–not estimable [NE]); median PFS was 11.0 mo (95% CI 5.8–14.0) with an 18-mo PFS rate of 37.6% (95% CI 29.0–46.1); and median OS was 18.3 mo (95% CI 14.3–NE) with an 18-mo OS rate of 51.8% (95% CI 43.0–59.8). Efficacy outcomes per PD-L1 status are shown in the Table. Treatment-related adverse events (TRAEs) of any grade (G) were reported in 94.6% of pts (G3/4 in 68.4%); three G5 TRAEs were reported (pneumonia [n=2]; pneumonitis [n=1]). The most common hepatic TRAEs (any G) were increases in alanine aminotransferase (39.6%; G3/4 in 11.4%), aspartate aminotransferase (35.6%; G3/4 in 14.1%), and alkaline phosphatase (19.5%; G3/4 in 6.7%). The discontinuation rate due to hepatic TRAEs was 2.0% for ADA, 6.7% for PEMBRO, and 0.7% for both ADA and PEMBRO. **Conclusions:** In pts with advanced/metastatic *KRAS*^{G12C}-mutated NSCLC, first-line ADA plus PEMBRO demonstrated promising clinical efficacy and a manageable safety profile, regardless of PD-L1 status. These data represent the largest dataset evaluating a first-line KRAS^{G12C} inhibitor plus PD-(L)1 inhibitor in this population presented to date. The phase 3 portion of KRYSTAL-7, comparing first-line ADA plus PEMBRO vs PEMBRO monotherapy in pts with *KRAS*^{G12C}-mutated NSCLC and PD-L1 ≥50%, is ongoing and recruiting. Clinical trial information: NCT04613596. Research Sponsor: Mirati Therapeutics, a Bristol Myers Squibb company.

8501 **Oral Abstract Session**

TROPION-Lung02: Datopotamab deruxtecan (Dato-DXd) plus pembrolizumab (pembro) with or without platinum chemotherapy (Pt-CT) as first-line (1L) therapy for advanced non-small cell lung cancer (aNSCLC). First Author: Benjamin Philip Levy, Sidney Kimmel Comprehensive Cancer Center, Johns Hopkins Medicine, Baltimore, MD

Background: TROPION-Lung02 (NCT04526691) evaluated the TROP2-directed antibody-drug conjugate (ADC) Dato-DXd plus pembro combination with or without Pt-CT in aNSCLC. Here we report primary analyses of pts receiving combination therapy in the 1L setting. **Methods:** Pts across 6 cohorts were dosed with Dato-DXd (4 or 6 mg/kg) plus pembro 200 mg alone (doublet) or with pembro plus Pt-CT (triplet; cisplatin 75 mg/m^2 or carboplatin AUC 5) Q3W. PD-L1 expression (tumor proportion score) was assessed locally by immunohistochemistry (22C3 assay). Primary objectives were safety and tolerability; efficacy was a secondary objective. **Results:** As of Apr 29, 2024, 96 pts received either the doublet (n=42) or triplet (n=54) combination as 1L therapy; 29% and 15% of pts were ongoing, respectively. Median ages were 65 (doublet) and 64 years (triplet). Median treatment durations were 9.7 and 5.8 months, respectively. Stomatitis (doublet, 57%; triplet, 33%) and nausea (doublet, 42%; triplet, 48%), primarily Gr 1–2, were the most common adverse events (AEs) across both regimens. Treatment related serious AEs occurred in 5 (12%) and 12 (22%) pts in each cohort and no deaths related to study drug were seen. Efficacy outcomes, including by histology, are summarized in the Table. Biomarker analyses, including efficacy by PD-L1 status, will be presented. **Conclusions:** In this largest data set to date evaluating an ADC combined with an anti-PD-1/L1 agent in the 1L setting, the combination of Dato-DXd plus pembro treatment both with and without Pt-CT elicited durable antitumor activity in pts with aNSCLC. Tolerability of the combinations was as expected, based on known profiles of the individual agents. Clinical trial information: NCT04526691. Research Sponsor: Daiichi Sankyo, Inc.

CAMPASS: Benmelstobart in combination with anlotinib vs pembrolizumab in the first-line treatment of advanced non-small cell lung cancer (aNSCLC)—A randomized, single-blind, multicenter phase 3 study. First Author: Baohui Han, Shanghai Chest Hospital, Shanghai, China

The full, final text of this abstract will be available at meetings.asco.org on the day of presentation and in the online supplement to the June 10, 2025, issue of the *Journal of Clinical Oncology*.

8503 **Oral Abstract Session**

Efficacy of zipalertinib in NSCLC patients with EGFR exon 20 insertion mutations who received prior platinum-based chemotherapy with or without amivantamab. First Author: Helena Alexandra Yu, Memorial Sloan Kettering Cancer Center, New York, NY

Background: Despite the approval of amivantamab (ami) for EGFR exon 20 insertion (ex20ins) mutant NSCLC, an unmet need remains for well-tolerated oral targeted therapies with durable clinical benefit. Zipalertinib (zipa, CLN-081, TAS6417) is a novel EGFR TKI which showed promising clinical activity and manageable safety in a phase 1/2a study in pts with ex20ins NSCLC that progressed on platinum-based chemotherapy (plt-chemo). Here we report the primary data from the pivotal phase 2b REZILIENT1 study of zipa in patients (pts) with advanced or metastatic EGFR ex20ins mutant NSCLC that progressed after prior plt-chemo with or without prior ami. **Methods:** Pts were enrolled in two parallel cohorts (prior plt-chemo, prior plt-chemo and ami) and treated with zipa 100 mg BID. Tumor response was assessed by blinded independent central review (BICR) per RECIST v1.1. Pts with stable, asymptomatic, or treated brain metastases (mets) were allowed. **Results:** As of 10 December 2024 data cut off, 176 pts (51 with prior ami and 125 with plt-chemo) were enrolled with median follow-up of 9.3 months: median age: 65 (33-85), median lines of prior therapy: 2 (1-7), prior PD1/L1: 100 (56.8%), history of brain mets: 68 (38.6%). Among all pts treated, zipa demonstrated a confirmed ORR (cORR) of 35.2%, mDoR of 8.8 months, and mPFS of 9.5 months (table 1). In pts with plt-chemo without ami, the cORR was 40.0%. Of the 51 pts with prior ami, 30 had no other ex20ins-directed therapy, while 21 had also received other ex20ins drugs (such as mobocertinib, sunvozertinib, BLU-451, or poziotinib), the cORR was 30.0% and 14.3%, respectively. Among all pts with brain mets, systemic cORR was 30.9%. The most common treatment-emergent AEs (TEAEs, all-grade) were paronychia, rash, anemia, diarrhea, dry skin, nausea, and stomatitis and the majority of the TEAEs were CTCAE grade 1 or 2. **Conclusions:** Zipalertinib demonstrated clinically meaningful efficacy with a manageable safety profile in pts with exon20ins NSCLC who have received prior platinum-based chemotherapy and for those who received prior amivantamab, a significant and growing unmet need. Clinical trial information: NCT04036682. Research Sponsor: None.

8504 Oral Abstract Session

SOHO-01: Safety and efficacy of BAY 2927088 in patients with advanced *HER2*-mutant non-small cell lung cancer (NSCLC) who were pretreated but naïve to HER2-targeted therapy or had not received any treatment for advanced disease. First Author: Herbert H. Loong, The Chinese University of Hong Kong, Hong Kong SAR, China

Background: The potent, reversible HER2 tyrosine kinase inhibitor BAY 2927088 has demonstrated manageable safety and anti-tumor activity in patients with advanced NSCLC with *HER2*-activating mutations. Here we report safety and efficacy data from 2 cohorts of the ongoing, open-label, multicenter Phase I/II SOHO-01 trial. **Methods:** Patients with advanced NSCLC with *HER2*-activating mutations were enrolled and received oral BAY 2927088 20 mg twice daily. Patients in expansion/extension Cohort D had disease progression following ≥1 systemic therapies and were naïve to HER2-targeted therapy; patients in expansion Cohort F had not received any systemic therapy for locally advanced or metastatic disease. Safety (MedDRA v27.1 and CTCAE v5.0) was the primary endpoint; anti-tumor activity (RECIST v1.1) was a key secondary endpoint. **Results:** As of October 14, 2024, 81 (D) and 39 (F) patients were treated. Median age was 60 years (D) and 65 years (F), 61.7% (D) and 64.1% (F) were female, 61.7% (D) and 79.5% (F) had never smoked, and 43.2% (D) had received ≥2 systemic therapies. All patients were analyzed for safety and efficacy; response was based on the full analysis set. Treatment-related adverse events (TRAEs) were observed in 96.7% of patients; diarrhea was the most common TRAE leading to dose reduction in 8.3% of patients (Table). No patients discontinued BAY 2927088 treatment because of diarrhea, and no cases of interstitial lung disease were reported. Investigator-assessed objective response rates were 59.3% (95% CI 47.8, 70.1; D) and 59.0% (95% CI 42.1, 74.4; F). Disease control rates (confirmed response or stable disease for ≥12 weeks) were 84.0% (95% CI 74.1, 91.2; D) and 84.6% (95% CI 69.5, 94.1; F). One patient in Cohort D achieved a complete response. **Conclusions:** BAY 2927088 demonstrated manageable safety in both cohorts, consistent with previous reports. Diarrhea was the most common TRAE, but it was manageable and did not lead to treatment discontinuation. Similar response rates were observed in patients with advanced *HER2*-mutant NSCLC who were pretreated but naïve to HER2-targeted therapy and in those treated in the first-line setting. Clinical trial information: NCT05099172. Research Sponsor: Bayer AG.

	Cohort D (n=81)		Cohort F (n=39)	
n (%)	All grades	Grade ≥3	All grades	Grade ≥3
Any TRAE	78 (96.3)	31 (38.3)	38 (97.4)	8 (20.5)
Most common TRAEs occurring in ≥20% of all patients

LBA8505 Oral Abstract Session

Savolitinib (Savo) combined with osimertinib (osi) versus chemotherapy (chemo) in EGFR-mutant (EGFRm) and *MET*-amplification (*MET*amp) advanced NSCLC after disease progression (PD) on EGFR tyrosine kinase inhibitor (TKI): Results from a randomized phase 3 SACHI study. First Author: Shun Lu, Shanghai Chest Hospital, School of Medicine, Shan, Shanghai, China

The full, final text of this abstract will be available at meetings.asco.org on the day of presentation and in the online supplement to the June 10, 2025, issue of the *Journal of Clinical Oncology*.

8506 Oral Abstract Session

Patritumab deruxtecan (HER3-DXd) in resistant *EGFR*-mutated (*EGFR*m) advanced non-small cell lung cancer (NSCLC) after a third-generation EGFR TKI: The phase 3 HERTHENA-Lung02 study. First Author: Tony S. K. Mok, State Key Laboratory of Translational Oncology, Chinese University of Hong Kong, Hong Kong, China

Background: After disease progression on a 3rd-gen (3G) EGFR TKI for advanced *EGFR*m NSCLC, available therapies provide limited efficacy. HER3-DXd, an antibody-drug conjugate consisting of a fully human mAb to HER3 attached to a topoisomerase I inhibitor payload via a stable tetrapeptide-based cleavable linker, showed promising efficacy in HERTHENA-Lung01. **Methods:** HERTHENA-Lung02 (NCT05338970) is a phase 3, randomized, open-label study of HER3-DXd vs platinum-based chemotherapy (PBC) in patients (pts) with advanced *EGFR*m (Ex19del or L858R) NSCLC following disease progression on a 3G EGFR TKI. The primary endpoint is PFS by BICR, tested using a stratified log-rank test. The key secondary endpoint is OS. **Results:** 586 pts were randomized to HER3-DXd or PBC (median age, 64 y; 61% female; 60% Asian). At the 31 May 2024 data cutoff for primary analysis of PFS, median (range) study duration was 10.7 (5.2-21.9) mo, and treatment duration was 5.5 (0.7-16.8) mo and 4.6 (0.7-16.5) mo with HER3-DXd and PBC, respectively. HER3-DXd provided a significant improvement in PFS vs PBC (HR, 0.77; 95% CI, 0.63-0.94; *P*=.011). Median PFS (95% CI) with HER3-DXd vs PBC was 5.8 (5.5-6.8) mo vs 5.4 (5.0-5.6) mo. The PFS rate (95% CI) with HER3-DXd vs PBC was 0.50 (0.44-0.56) vs 0.38 (0.32-0.44) at 6 mo; 0.29 (0.23-0.35) vs 0.19 (0.14-0.25) at 9 mo; and 0.18 (0.12-0.25) vs 0.05 (0.01-0.13) at 12 mo. ORR (95% CI) was 35.2% (29.7%-40.9%) with HER3-DXd vs 25.3% (20.4%-30.6%) with PBC. Median DOR (95% CI) was 5.7 (5.1-7.3) mo with HER3-DXd vs 5.4 (4.1-5.6) mo with PBC. OS data were immature at this protocol-specified interim data cut. In pts with brain metastases at baseline (per CNS BICR), median (95% CI) intracranial PFS was 5.4 (4.0-5.9) mo with HER3-DXd (n=105) vs 4.2 (2.8-5.0) mo with PBC (n=95) (HR, 0.75; 95% CI, 0.53-1.06). TEAEs occurred in 100% of pts in the HER3-DXd arm and 99% in the PBC arm. TEAEs were associated with treatment discontinuation in 33 pts (11%) in the HER3-DXd arm and 27 (10%) in the PBC arm. The most common TEAEs (n [%]) in the HER3-DXd/PBC arms were nausea (168 [57.9]/118 [42.1], thrombocytopenia (151 [52.1]/76 [27.1]), and fatigue (146 [50.3]/118 [42.1]). Grade [G] ≥3 TEAEs occurred in 73% (HER3-DXd) and 57% (PBC) of pts; the difference was driven by a higher rate of G≥3 thrombocytopenia with HER3-DXd (30% vs 7.9%). Each arm had 1 G≥3 bleeding event associated with G≥3 platelet count decreased. Adjudicated drug-related ILD occurred in 14 pts (5%; 11 G1/2, 1 G3, 2 G5) in the HER3-DXd arm. **Conclusions:** HER3-DXd demonstrated statistically significant improvement in PFS vs PBC in pts with *EGFR*m NSCLC post EGFR TKI therapy. The safety profile was manageable, consistent with prior reports. Most common TEAEs were hematologic and gastrointestinal. Follow-up is ongoing, along with further exploration of secondary/exploratory/biomarker endpoints from this data cut. Clinical trial information: NCT05338970. Research Sponsor: Daiichi Sankyo Company, Limited; Merck Sharp & Dohme LLC, a subsidiary of Merck & Co., Inc., Rahway, NJ, USA.

8507 Oral Abstract Session

Sacituzumab tirumotecan (sac-TMT) in patients (pts) with previously treated advanced EGFR-mutated non-small cell lung cancer (NSCLC): Results from the randomized OptiTROP-Lung03 study. First Author: Li Zhang, Sun Yat-sen University Cancer Center, Guangzhou, China

Background: Sac-TMT (MK-2870/SKB264), a novel TROP2 ADC developed to conjugate a belotecan-derivative topoisomerase I inhibitor, has shown encouraging antitumor activity in EGFRm NSCLC pts in phase I trial (Fang *et al*. AACR 2024). Here, we report the results from a multicenter, randomized, controlled study comparing sac-TMT with docetaxel in previously treated EGFRm NSCLC pts (OptiTROP-Lung03, NCT05631262). **Methods:** Pts with advanced EGFRm NSCLC who had progressed after EGFR TKI and platinum-based chemotherapy were randomized (2:1) to receive sac-TMT 5 mg/kg Q2W or docetaxel 75 mg/m^2. Pts with verified progression on docetaxel could be crossed over to receive sac-TMT if eligible. Hierarchical fixed-sequence testing was employed for efficacy endpoints, including ORR (primary) and PFS, assessed by blinded independent review committee (BIRC), followed by OS. Pre-specified OS interim analysis was conducted alongside final PFS analysis, with the level at one-sided alpha of 1.23% determined by alpha spending function. The crossover-adjusted OS was derived using the rank-preserving structural failure time (RPSFT) model. **Results:** A total of 137 pts (median age 56 yrs; 43.8% male; 82.5% ECOG PS 1; 93.4% prior 3rd EGFR TKI) were randomized to receive sac-TMT (n=91) or docetaxel (n=46). At a median follow-up of 12.2 mo (data cutoff: Dec 31, 2024), 25.3% of pts (sac-TMT) vs 4.3% (docetaxel) remained on treatment. The study met its primary and key secondary endpoints. Sac-TMT achieved statistically significant clinical outcomes compared to docetaxel: confirmed ORR (BIRC: 45.1% vs 15.6%, 1-sided p=0.0004; investigator [INV]: 34.1% vs 8.7%), PFS (BIRC: median 6.9 vs 2.8 mo, HR 0.30 [95% CI: 0.20, 0.46], 1-sided p<0.0001; INV: median 7.9 vs 2.8 mo, HR 0.23 [95% CI: 0.15, 0.36]), and OS (median not reached [NR] for both groups, HR 0.49 [95% CI: 0.27, 0.88], 1-sided p=0.007), with 36.4% of pts in docetaxel group crossed over to receive sac-TMT. The RPSFT model adjusted median OS was 9.3 mo for docetaxel and NR for sac-TMT (HR for OS 0.36 [95% CI: 0.20, 0.66]). Grade ≥ 3 treatment-related adverse events (TRAEs) occurred in 56.0% of pts in sac-TMT group vs 71.7% in docetaxel group, and treatment-related SAEs were 16.5% vs 41.3%. Most common (≥ 10%) grade ≥ 3 TRAEs (sac-TMT vs docetaxel) were neutrophil count decreased (42.9% vs 58.7%), WBC count decreased (25.3% vs 52.2%), stomatitis (16.5% vs 2.2%), anemia (12.1% vs 4.3%) and febrile neutropenia (0% vs 19.6%). No cases of ILD were reported in sac-TMT group. **Conclusions:** Sac-TMT demonstrated improved ORR, PFS and OS compared to docetaxel, with manageable safety profile in pts with previously treated advanced EGFRm NSCLC. These results highlight significant survival benefits and suggest that sac-TMT could emerge as a new standard of care for this population. Clinical trial information: NCT05631262. Research Sponsor: Sichuan Kelun-Biotech Biopharmaceutical Co., Ltd.

8509 Clinical Science Symposium

First-in-class PD-1/IL-2 bispecific antibody IBI363 in patients (Pts) with advanced immunotherapy-treated non-small cell lung cancer (NSCLC). First Author: Jianya Zhou, The First Affiliated Hospital, Zhejiang University School of Medicine, Hangzhou, China

Background: IBI363 is a first-in-class PD-1/IL-2$^{\alpha\text{-bias}}$ bispecific antibody fusion protein to block PD-1 checkpoint and rejuvenate exhausted tumor-specific T cells by cis-activating α-bias IL-2. It has potential to address the unmet clinical need of patients (pts) with immunotherapy-resistant and cold tumors. Here, we report safety and efficacy results from a phase I, multicenter, first-in-human study (NCT05460767) of IBI363 in pts with advanced NSCLC. **Methods:** Eligible pts with advanced NSCLC who failed or were intolerant of standard therapy were enrolled and received IBI363 intravenously at dose levels of 2/10/300/600 ug/kg every week (QW), 0.3/0.6/1 mg/kg every two weeks (Q2W) or 1.5/2/3/4 mg/kg every three weeks (Q3W). Endpoints included safety, objective response rate (ORR), disease control rate (DCR), duration of response (DoR) and progression-free survival (PFS) by investigator per RECIST v1.1. **Results:** As of December 6, 2024, 136 NSCLC pts were enrolled (median age: 61 years; prior treatment lines ≥2: 72%). Most patients were treated with IBI363 at 0.6/1 mg/kg Q2W (n=56), 1.5 mg/kg Q3W (n=11) or 3 mg/kg Q3W (n=57). Treatment-emergent adverse events (TEAEs) occurred in 135/136 pts (≥G3: 42.6%). TEAEs led to treatment discontinuation in 9 (6.6%) pts and TEAEs led to death in 4 (2.9%) pts with only 1 (0.7%) event considered treatment-related (unexplained death). Most common TEAEs were arthralgia (51.5%; 3.7% ≥G3), anemia (43.4%; 3.7% ≥G3), and rash (38.2%; 4.4% ≥G3). In pts with squamous cell carcinoma who had at least 1 post-baseline tumor assessment, 30 (including 1 pt who had not received PD-(L)1 before enrolled) and 27 pts had been treated with IBI363 3 mg/kg and 1/1.5 mg/kg, respectively; more encouraging efficacy signals were observed in the 3 mg/kg group: ORR 43.3% vs 25.9%, confirmed ORR 36.7% vs 25.9%, DCR 90.0% vs 66.7%, median PFS 7.3 (95% CI: 6.0-11.7) vs 5.5 (95% CI: 1.5-8.3) months, with a median follow up time of 7.3 vs 11.1 months. In the PD-(L)1 treated adenocarcinoma pts with no actionable genomic alterations who had at least 1 post-baseline tumor assessment, 25 and 30 pts had been treated with IBI363 3 mg/kg and 0.6/1/1.5 mg/kg, respectively, similarly, 3 mg/kg group showed higher ORR (28.0% vs 16.7%), confirmed ORR (24.0% vs 13.3%), DCR (76.0% vs 63.3%) and median PFS (4.2 [95% CI: 3.0-not estimable] vs 2.8 [95% CI: 1.4-5.1] months, with a median follow up of 5.9 vs 16.5 months). A higher ORR of 29% versus 4% and a longer PFS of 5.3 months compared to 2.7 months were observed in smokers (N=31, 56.4%). Notably, in patients at all dose levels with a tumor cell proportion score (TPS) under 1%, the ORR was 45.5% for squamous cell carcinoma (N=22) and 29.4% for adenocarcinoma (N=17). **Conclusions:** IBI363 was well tolerated with encouraging and durable efficacy observed in pts with advanced NSCLC who progressed to PD-(L)1, especially in the squamous subtype. Clinical trial information: NCT05460767. Research Sponsor: Innovent Biologics (Suzhou) Co., Ltd.

8510 Clinical Science Symposium

Efficacy and safety of MHB088C, a novel B7-H3-targeted ADC, in patients with relapsed extensive-stage small cell lung cancer (ES-SCLC): Subgroup analysis from a phase 1/2 multicenter study. First Author: Lin Shen, Beijing Cancer Hospital, Beijing, China

Background: MHB088C is a novel B7-H3-targeted antibody-drug conjugate (ADC) containing the potent SuperTopoi payload that is 5 to 10 times more potent than Dxd. Initial findings from an ongoing phase 1/2 study indicated that MHB088C was generally well tolerated, with early signs of clinical activity (ASCO 2024, abstract #3012). This analysis presents efficacy and safety results for the subset of pts with ES-SCLC. **Methods:** This study consisted of 2 parts: dose-escalation (part 1) and expansion (part 2). Part 1 evaluated the safety and tolerability of MHB088C at doses ranging from 0.8 to 4.0 mg/kg, administered intravenously every 2 (Q2W) or 3 weeks (Q3W). Doses of 1.6 mg/kg Q2W, 2.0 mg/kg Q2W, and 2.4 mg/kg Q3W were selected for part 2. Part 2 focused on assessing safety and prospective efficacy of MHB088C in selected tumor types, including SCLC. **Results:** At data cutoff (January 3, 2025), a total of 91 pts with relapsed ES-SCLC had received ≥ 1 dose of MHB088C (1.6 mg/kg Q2W, n=28; 2.0 mg/kg Q2W, n=33; 2.4 mg/kg Q3W, n=30). MHB088C showed encouraging efficacy in relapsed ES-SCLC (Table). The objective response rates were 42.9%, 57.6%, and 46.7% in the 1.6, 2.0, and 2.4 mg/kg cohorts, respectively, with median progression-free survival (PFS) of 5.5, 5.9, 5.5 months. Safety data were consistent with previous reports. The most common grade≥3 treatment-related adverse events were neutropenia, platelet count decreased and anemia. The 1.6 and 2.0 mg/kg cohorts exhibited favorable safety profiles, with only single-digit rates of the aforementioned hematologic adverse events. One case (1.0%) of mild interstitial lung disease (ILD) was reported. **Conclusions:** MHB088C demonstrated promising anti-tumor activity and favorable safety in previously treated pts with ES-SCLC. A Phase 3 study is planned to compare the efficacy and safety of MHB088C with standard-of-care chemotherapy in relapsed ES-SCLC. Clinical trial information: CTR20231298. Research Sponsor: None.

8511 Clinical Science Symposium

First report of efficacy and safety results from a phase 2 trial evaluating BNT327/PM8002 plus chemotherapy (chemo) as first-line treatment (1L) in unresectable malignant mesothelioma. First Author: Ying Cheng, Jilin Cancer Hospital, Changchun, China

Background: Malignant mesothelioma is a rare neoplasm with a high unmet medical need. BNT327 is an investigational bispecific antibody, targeting both PD-L1 and VEGF-A in the tumor and tumor microenvironment (TME). By binding to PD-L1 on tumor cells it is designed to restore effector T-cell function and by binding to VEGF-A within the TME it also reverses the negative impact of VEGF signaling on immune cell infiltration and activation. In addition, via VEGF-A neutralization, it normalizes tumor vasculature. This dual targeting of PD-L1 and VEGF-A aims to deliver better efficacy and safety. BNT327 has shown encouraging preliminary activity in thoracic malignancies incl. SCLC (ESMO 2023) and NSCLC (ASCO & ESMO 2024). **Methods:** After a safety run-in (n=6), this ongoing, multicenter, single-arm phase 2 clinical trial recruited chemo naive pts (pts) aged ≥18 yrs with unresectable malignant mesothelioma (pleural (MPM) or peritoneal (MPeM)) to evaluate BNT327 30 mg/kg Q3W IV combined with 4-6 cycles pemetrexed and platinum, followed by BNT327 maintenance. Primary endpoints were efficacy (ORR per RECIST 1.1 for MPeM, mRECIST 1.1 for MPM) and safety (CTCAE V5.0). **Results:** As of 25 Oct 2023, 31 pts, median age 58 yrs (range 43-71), 80.6% ECOG PS 1 and 83.9% with metastatic disease had been enrolled, of which 23 had MPM and 8 MPeM. At the cutoff date of 20 Dec 2024, the median exposure duration was 16.0 mo (95% CI 8.1, 19.5) and median follow-up time 19.3 mo (95% CI 17.3, 20.9). In 23 pts with MPM, 1 pt had a CR and 9 had PRs as BOR, resulting in a confirmed ORR (cORR) of 43.5%. 10 pts had SD and 1 non-CR/non-PD, giving a DCR of 87.0%. Median PFS (mPFS) was 11.8 mo, and median DOR was 11.8 mo. The 12 mo OS rate was 82.6% (95% CI 60.1, 93.1), with median OS not yet reached. Among 13 pts with MPM of epithelioid histology, cORR was 30.8%, DCR was 84.6% and mPFS was 16.6 mo. Among 8 pts with MPeM, 6 had PR as BOR, leading to a cORR of 75.0%. 2 pts had SD, resulting in a DCR of 100%; median DOR was 16.3 mo. Median PFS and OS were not yet reached, with an OS rate of 62.5% (95% CI 22.9, 86.1) at 12 mo. 6 pts with MPeM of epithelioid histology displayed a cORR of 83.3%, DCR of 100% and mPFS of 19.5 mo. All pts experienced TRAEs, 93.5% of pts (29/31) of Grade (G) 3-4. 5 pts (16.1%) had G 3-4 treatment-related SAEs. 5 pts (16.1%) experienced an irAE, 1 (3.2%) of G 3-4. The most common TRAEs were decreased neutrophil count (27 pts, 87.1%), decreased white blood cell count (26 pts, 83.9%), proteinuria (24 pts, 77.4%), anemia (23 pts, 74.2%), decreased platelet count (19 pts, 61.3%), and nausea (16 pts, 51.6%). 6 pts discontinued treatment due to TRAEs; no treatment-related deaths occurred. 9 pts remain on treatment. **Conclusions:** BNT327 plus chemo as a 1L regimen for mesothelioma showed encouraging efficacy, including in tumors of epithelioid histology. AEs were consistent with those expected for the treatment regimen. Clinical trial information: NCT05918107. Research Sponsor: Biotheus Inc.

8512 Rapid Oral Abstract Session

Telisotuzumab adizutecan (ABBV-400; Temab-A), a c-Met protein–targeting antibody-drug conjugate (ADC), in patients (pts) with advanced *EGFR*-mutated (MT) non-squamous (NSQ) non-small cell lung cancer (NSCLC): Results from a phase 1 study. First Author: David Ross Camidge, University of Colorado Cancer Center, Aurora, CO

Background: c-Met protein (also known as MET protein) expression is increased in NSCLC and is a negative prognostic indicator. Temab-A is an ADC comprising the c-Met protein–targeting mAb telisotuzumab conjugated to a novel topoisomerase 1 inhibitor payload. A phase 1 study (NCT05029882) of Temab-A in advanced solid tumors is ongoing. In dose expansion, Temab-A had manageable safety and promising efficacy in pts with NSQ *EGFR* wildtype NSCLC (*Ann Oncol*. 2024;35:1257MO). Herein, we present the results for pts with advanced *EGFR* MT NSQ NSCLC. **Methods:** Pts (≥18 yr) whose disease had progressed after platinum-based chemotherapy doublet and tyrosine kinase inhibitor(s) (TKIs) were enrolled. Pts received Temab-A at 2.4 (n=36) or 3.0 (n=5) mg/kg Q3W. Primary objectives were evaluating safety, tolerability, PK, and preliminary efficacy of Temab-A. Tumor tissue c-Met protein expression was assessed centrally by IHC. **Results:** Forty-one pts were enrolled in the *EGFR* MT cohort. Median age was 64 yr (43–88), 63% were female, and 32% had baseline brain metastases. Median prior therapies was 3 (1–8); 93% had prior anti-EGFR treatment. Median treatment duration was 9.2 months; median follow-up was 9.7 months. TEAEs of any grade/grade ≥3 occurred in 100%/73% of pts. The most common any-grade TEAEs were hematologic (83%) and gastrointestinal (81%); any-grade TEAEs in ≥30% of pts were anemia (63%), nausea (61%), vomiting (37%), decreased appetite (34%), and neutropenia (34%). Grade ≥3 TEAEs were mostly hematologic (42%), and most common were anemia (27%) and neutropenia (22%). The any-grade adjudicated interstitial lung disease/pneumonitis rate was 7% (grade ≥3: 2%). TEAEs leading to discontinuation occurred in 20% of pts. Four deaths occurred; 1 (pneumonitis) was considered related to study drug. All pts with post-baseline data had some decrease in tumor burden. ORR was 63% (Table); similarly high ORR was observed regardless of c-Met protein expression. Responses occurred irrespective of *EGFR* L858R alterations, exon 19 deletions, or TKI resistance mutations including T790M and C797S. As of the data cut (Sep 2024), 19 (46%) pts remain on treatment. Time-to-event endpoints are immature; to date, 54% of responders have a DOR of ≥6 months. Exploratory biomarker analysis is ongoing. **Conclusions:** Temab-A has a manageable safety profile with promising clinical activity in pts with 3L+ NSQ *EGFR* MT NSCLC, meriting further investigation. Clinical trial information: NCT05029882. Research Sponsor: AbbVie Inc.; n/a

8513 Rapid Oral Abstract Session

Efficacy and CNS results from a randomized subset of the phase 2 SAVANNAH study comparing savolitinib (savo) + osimertinib (osi) combination with savo + placebo (PBO). First Author: Benjamin Philip Levy, Sidney Kimmel Comprehensive Cancer Center, Johns Hopkins University School of Medicine, Baltimore, MD

Background: The MET pathway is a known mediator of EGFR-TKI resistance and represents a therapeutic vulnerability to select MET-TKIs. Savo is an oral, highly selective MET-TKI that, when combined with osi, has the potential to overcome MET-driven resistance after progressive disease (PD) on osi. The Phase 2 SAVANNAH study has demonstrated clinically meaningful activity with the combination of savo + osi in patients (pts) with EGFR-mutated (EGFRm) advanced NSCLC and MET overexpression/amplification (NCT03778229). Isolating the efficacy of savo in the use of savo + osi is a key question for this combination. **Methods:** A subset of SAVANNAH included eligible pts who had EGFRm advanced NSCLC with MET overexpression (IHC 3+ intensity in ≥90% of tumor cells [IHC3+/≥90%]) and/or amplification (≥10 MET gene copies by FISH [FISH10+]) after PD on first-line (1L) osi; asymptomatic stable brain metastases (treated/untreated) were allowed. Pts were randomized 2:1 (double-blind) to savo 300 mg BID + osi 80 mg QD, or savo 300 mg BID + PBO (stratified by investigator [INV] assessed baseline [BL] brain metastases [yes/no]), until INV-assessed PD per RECIST 1.1. Brain imaging occurred at BL and PD; pts with brain metastases were re-imaged at each tumor assessment to PD. Endpoints included objective response rate (ORR), duration of response (DoR), and progression-free survival (PFS) by BICR and INV; CNS PFS, and presence/absence of CNS lesions at PD by BICR. **Results:** Overall, 73 pts were randomized (savo + osi n=48; savo + PBO n=25). At BL, median age: 67 vs 65 years, female: 73% vs 64%, White: 73% vs 52% in the savo + osi and savo + PBO arms, respectively. Efficacy outcomes (ORR, DoR, and PFS) were higher with savo + osi than savo + PBO (Table). CNS PFS events by CNS BICR occurred in 5/14 (36% savo + osi) and 2/4 pts (50% savo + PBO). In pts without BL brain metastases, none of the 13 pts (savo + osi) with RECIST PD by BICR had a new CNS lesion; 6/11 pts in the savo + PBO arm developed a new CNS lesion. **Conclusions:** In EGFRm advanced NSCLC with MET IHC3+/≥90% and/or FISH10+ status after PD on 1L osi, efficacy of savo 300 mg BID + osi was numerically greater than savo + PBO and showed promising CNS activity. To date, this is one of the largest randomized data sets presented evaluating an oral MET-TKI in EGFRm NSCLC. Efficacy findings from SAVANNAH suggest that targeting both EGFR and MET is key and support further investigation of savo + osi and CNS activity in the Phase 3 SAFFRON study. Clinical trial information: NCT03778229. Research Sponsor: AstraZeneca.

	Assessment	Savo + osi (n=48)	Savo + placebo (n=25)
ORR, % (95% CI)	BICR	58 (43, 72)	16 (5, 36)

8514 Rapid Oral Abstract Session

Phase 3 study of benmelstobart in combination with chemotherapy followed by sequential combination with anlotinib for the first-line treatment of locally advanced or metastatic squamous non-small cell lung cancer (sq-NSCLC). First Author: Yuankai Shi, National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College, Beijing Key Laboratory of Clinical Study on Anticancer Molecular Targeted Drugs, Beijing, China

Background: PD-1/ PD-L1 inhibitors plus platinum-based chemotherapy is the standard first-line therapy for locally advanced or metastatic sq-NSCLC. Improvements in clinical benefits of sq-NSCLC receiving antiangiogenic agents and immune-checkpoint inhibitors have remained elusive, highlighting an urgent need to develop new therapeutic strategies. TQB2450-III-12 is a multicenter, randomized, double-blind, parallel-controlled phase III study of benmelstobart (PD-L1 inhibitor) in combination with chemotherapy followed by sequential combination with anlotinib (multi-targeted angiogenesis inhibitor) versus tislelizumab plus chemotherapy as first-line therapy for locally advanced or metastatic sq-NSCLC. **Methods:** Patients with unresectable locally advanced or metastatic sq-NSCLC without prior systematic therapy were randomized 1:1 to receive benmelstobart (1200 mg, Q3W) plus chemotherapy for 4 cycles followed with benmelstobart plus anlotinib (10mg, P.O., D1-D14, Q3W) (group A) or tislelizumab (200mg, Q3W) plus chemotherapy for 4 cycles followed with tislelizumab (group B). Paclitaxel (175 mg/m^2, day 1) and carboplatin (area under the concentration [AUC] of 5, day 1) were given every 3 weeks. The primary endpoint was PFS per RECIST 1.1 by independent review committee and the key secondary endpoint was OS. Here we present the primary interim analysis for PFS per prespecified analysis plan. **Results:** As of March 1, 2024, 565 patients were randomized 1:1 to group A and group B. Baseline characteristics were well balanced. Median PFS was significantly improved in group A (10.12 months, 95% CI, 8.54–NE) versus group B (7.79 months, 95% CI, 6.87–9.69), HR=0.64 (98.35% CI, 0.45–0.93; P =0.0038). The subgroup analysis showed that PFS benefit favored group A in almost all subgroups, particularly in patients with ECOG PS 0 (HR 0.44, 0.23-0.84), PD-L1 expression (tumor proportion scoring) of 1-49% (HR 0.47, 0.30-0.73), and age <65 years (HR 0.59, 0.39-0.90). The ORR of group A and group B were 71.9% and 65.1%, respectively. The median DoR was longer in group A (9.69 months, 95% CI, 8.44, NE) than Group B (8.34 months; 95% CI, 5.78-NE) HR=0.58 (95% CI, 0.38, 0.88; P=0.0091). OS was immature. ≥Grade 3 benmelstobart/tislelizumab or anlotinib/ placebo-related adverse events was 61.57% in group A and 51.06% in group B. There was no difference of the grade 5 treatment-emergent adverse events (TEAE) between the treatment groups (group A: 5.69%, group B: 5.63%). The discontinuation of any treatment components by TEAE was 4.27% in group A and 5.28% in group B. **Conclusions:** Benmelstobart in combination with chemotherapy followed by sequential combination with anlotinib significantly improved PFS, with a manageable safety profile. It might be a new first-line treatment for sq-NSCLC. Clinical trial information: NCT05718167. Research Sponsor: Chia Tai Tianqing Pharmaceutical Group Co., Ltd.

8515 Rapid Oral Abstract Session

Plasma-guided adaptive first-line chemoimmunotherapy for non-small cell lung cancer (NSCLC). First Author: Julia K. Rotow, Lowe Center for Thoracic Oncology, Dana-Farber Cancer Institute, Boston, MA

Background: There is clinical uncertainty as to which patients with advanced/metastatic NSCLC require first-line treatment with chemoimmunotherapy (ChemoIO) versus treatment with immune checkpoint inhibitor (ICI) monotherapy. While PD-L1 expression can predict for ICI response, it is an imperfect biomarker. Cell-free DNA (cfDNA) clearance is a dynamic biomarker that predicts for benefit to immunotherapy in metastatic NSCLC. Here we evaluate the use of cfDNA clearance after initial cycles of first-line ICI monotherapy to guide early treatment intensification via addition of platinum-based chemotherapy. **Methods:** In this prospective clinical trial patients with advanced/metastatic PD-L1 positive (TPS ≥ 1%) NSCLC were treated with two cycles of pembrolizumab monotherapy and then assessed for plasma and radiographic response. Plasma response was defined as ≥50% reduction in the maximum variant allele fraction and/or persistent low-shedding status at cycle two day one compared to pretreatment using an amplicon-based plasma NGS assay. Patients with radiographic response or with radiographic stable disease with plasma response continued pembrolizumab monotherapy. Patients with RECIST stable disease without plasma response were intensified to carboplatin doublet (paclitaxel squamous/pemetrexed nonsquamous) plus pembrolizumab. Those with radiographic progression ended study treatment. **Results:** Forty patients were enrolled across six sites. 56.8% (n=21) had nonsquamous histology and 37.5% (n=15) were PD-L1 low (TPS 1-49%). 36 patients (90%) completed a C2D1 plasma response assessment, with plasma response to ICI monotherapy in 58.3% (n=21) patients (57.1% in PD-L1 low, 59.1% in PD-L1 high [TPS ≥ 50%]). At cycle 3, 52.8% (n = 19) continued pembrolizumab monotherapy (7 with PR, 12 with SD and plasma response). 19.4% (n=7) had radiographic SD and plasma non-response and received intensification to ChemoIO (pemetrexed in 6, paclitaxel in 1). 27.8% (n=10) went off study treatment for PD (n=4), death (n=1), adverse event (n=3), or patient/physician decision (n=2). 20% (n=3) of PD-L1 low patients and 16% (n=4) of PD-L1 high patients received treatment intensification to ChemoIO. The ORR to this adaptive treatment strategy was 50%, the median PFS was 11 months (95% CI 3.4-15.9 months), and the median OS was 14.9 months (95% CI 8.2-27.2 months). Median PFS was higher in patients with plasma response (16.4 vs 4.8 months; HR 0.34; 95% CI 0.12-0.92). Fewer patients were treated with platinum doublet chemotherapy than would have been predicted by PD-L1 status alone (17.5% vs 37.5%). **Conclusions:** The use of a cfDNA-guided adaptive treatment design resulted in a median progression-free survival which compared favorably to historical controls with less upfront exposure to platinum doublet chemotherapy. Further study within a randomized prospective trial design is needed to validate this treatment strategy. Clinical trial information: NCT04166487. Research Sponsor: Dunkin Donuts Breakthrough Grant; Dana-Farber Cancer Institute; ASCO CDA.

8516 Rapid Oral Abstract Session

Randomized trial of relevance of time-of-day of immunochemotherapy for progression-free and overall survival in patients with non-small cell lung cancer. First Author: Yongchang Zhang, Hunan Cancer Hospital/The Affiliated Cancer Hospital of Xiangya School of Medicine, Central South University, Changsha, China

Background: Recent retrospective studies across 10 cancer types suggest increased efficacy of Early rather than Late Time-of-Day (ToD) infusions of immune checkpoint inhibitors (ICIs). This first randomized controlled phase III trial aimed to determine the relevance of ToD of immunochemotherapy for efficacy in patients (pts) with non-small cell lung cancer (NSCLC). **Methods:** Eligible pts received ICI pembrolizumab or sintilimab combined with chemotherapy, as 1st line treatment for stage IIIC-IV NSCLC without driver mutation. Pts were randomly assigned in a 1:1 ratio to receive the initial four immunochemotherapy cycles either before 15:00 in the Early ToD group, or after 15:01 in the Late ToD group. We hypothesized an increase in median progression-free survival (PFS) from 6 months in the Late ToD group up to 10 months in the Early ToD group. A total of 210 pts was required to validate PFS differences, using a two-sided significance level (α, 0.05; β, 0.80). Secondary endpoints were overall survival (OS) and objective response rate (ORR). **Results:** From 09/2022 to 05/2024, 210 pts (median age, 61 y.o.; male sex, 90.5%; Stage IV, 80.5%) were randomized. The pts in each group had similar characteristics. After a median follow-up of 18.9 months (mo.), median PFS was 13.2 mo. [95% CI, 10.1-16.3] in the early ToD group and 6.5 mo. [5.9-7.1] in the late ToD group, with a hazard ratio (HR) of an earlier progression of 0.43 [0.31-0.60] ($P < 0.0001$). Median OS was not reached in the early ToD group, whereas it was 17.8 mo. [14.2-21.5] in the late ToD group (HR of an earlier death, 0.43 [0.27-0.69]; $P = 0.0003$). ORR was 75.2% [66.8%-83.6%] for early ToD and 56.2% [46.5%-56.8%] for Late ToD ($P = 0.007$). PFS, OS, and ORR were consistently improved in the early ToD group regardless of age, sex, performance status, tumor stage, histology, PD-L1 status, and ICI agent. **Conclusions:** In this randomized trial, all three efficacy endpoints of immunochemotherapy were significantly improved through Early vs Late ToD dosing in pts with previously untreated stage IIIC-IV NSCLC. The near doubling in PFS and OS in our trial support the need for further randomized trials to determine the relevance of ToD for ICI efficacy and their underlying circadian mechanisms in pts with various cancer types. Clinical trial information: NCT05549037. Research Sponsor: National Natural Science Foundation of China.

8517 Rapid Oral Abstract Session

Hypoxia-responsive CEA CAR-T cells therapy for relapsed or refractory non-small cell lung cancer: A single-arm, open-label, phase I trial. First Author: Shuang Wei, Department of Respiratory and Critical Care Medicine, Tongji Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, China

Background: Non-small cell lung cancer (NSCLC) is a leading cause of cancer-related mortality worldwide. Chimeric antigen receptor (CAR)-T cell therapy has achieved significant success in targeted tumor cells eradication. However, data on CAR-T therapies in NSCLC remain limited. This study evaluates the safety and efficacy of CEA CAR-T cell therapy in r/r NSCLC. **Methods:** Adult metastatic NSCLC patients with relapse after ≥2 lines of treatment were enrolled and administered intravenous CEA CAR-T cells at three dose levels (0.75×10^6, 1.5×10^6, and 3×10^6 CEA CAR-T cells/kg).Peripheral blood samples were collected on day 28 post-infusion and analyzed using 10x Genomics single-cell RNA sequencing (scRNA-seq).The primary endpoint was safety , and secondary endpoints including efficacy and pharmacological evaluation. **Results:** From August 1, 2023, to July 15, 2024, a total of 18 patients were screened, and 15 received CAR-T infusion. The median age was 60 years , with a median of 4 prior therapy lines (range 2-10 lines). Among 6 patients receiving the maximum dose (3×10^6 cells/kg), no dose-limiting toxicities, grade 4 cytokine release syndrome or ICANS were observed. No adverse events were observed during a three-month long-term safety evaluation. With a median follow-up of 5.7 months, 7 patients achieved PR, 6 had SD, and 2 experienced PD. The best DCR was 87%, and ORR was 47%. Notably, patients with ≥30% intense and complete CEA staining in tumor cells and no brain metastases showed better PFS (72.7% vs. 25.0%, p=0.03) and OS (90.9% vs. 0%, p=0.003). CEA CAR-T cells reached maximum concentration at a median of 10 days (range 7–60 days) post-infusion. At the third month, all 12/12 patients with available CAR-T cell copy number data maintained high levels of CAR-T cells, with a median of 8,236 gDNA copies/μg , and in the patient with a follow-up of 13 months, CEA CAR-T cells were still detectable at 50,760 gDNA copies/μg. The scRNA-seq was performed in 12 patients. Responders exhibited a higher percentage of NK cells in a less exhausted state, characterized by reduced activity of immunosuppressive pathways and lower expression of stress-associated genes. Further cell-cell communication analysis suggested HLA-DRB1 expression in NK cells might be influenced by interactions with the CD244 in $CD8^+$ T cells. **Conclusions:** A single infusion of hypoxia-responsive CEA CAR-T demonstrated promising efficacy and manageable safety in r/r NSCLC. The findings highlight the potential role of specific NK cell states and immune interactions in the therapeutic effects of CEA CAR-T therapy. 8518 Rapid Oral Abstract Session

S1900E: A phase II study examining impact of co-mutations on sotorasib for previously treated stage IV/recurrent *KRAS* G12C mutated (MUT) non-squamous (Non-sq) non-small cell lung cancer (NSCLC) (ECOG-ACRIN led Lung-MAP Sub-study). First Author: Sukhmani Kaur Padda, Fox Chase Cancer Center/Temple Health, Philadelphia, PA

Background: In previously treated *KRAS* G12C MUT NSCLC, the allosteric KRAS G12C inhibitor sotorasib had superior outcomes compared to docetaxel (ORR 28% vs 13%). S1900E was the first to prospectively test sotorasib in *KRAS* G12C MUT NSCLC according to co-mutations (CO-MUT) in tumor suppressor genes such as *TP53*, *STK11*, and *KEAP1*. We report on the results of *TP53* and *STK11* CO-MUT cohorts of S1900E and hypothesized that CO-MUT would not impact the efficacy of sotorasib. **Methods:** Pts with *KRAS* G12C MUT identified by FoundationOne CDx tissue assay in the LUNGMAP screening master protocol were assigned to S1900E. Pts with stage IV/recurrent non-sq NSCLC who had progressed after ≥1 line of systemic therapy, and were ECOG PS 0-1 were eligible. There were 3 biomarker cohorts: 1 (*TP53* CO-MUT & wild type [WT] *STK11*, *KEAP1/NFE2L2/CUL3)*; 2 (*STK11* CO-MUT & WT *TP53*, *KEAP1/NFE2L2/CUL3)*; 3 (all others). The primary objective was to evaluate the confirmed objective response rate (ORR) per RECIST 1.1 in each cohort. Accrual goals for Cohorts 1 and 2 were 40 and 25 evaluable pts, respectively, based on a 1-stage binomial design with 90% power to rule out a 14% ORR (historical second-line docetaxel ORR) at the 1-sided 5% level. **Results:** S1900E completed accrual with 118 total pts and 103 evaluable from Apr 2021-Dec 2024; 59 (57%) were female and 86 (84%) were non-Hispanic white. In the *TP53* CO-MUT (N=48; 40 evaluable) and *STK11* CO-MUT (N=28; 25 evaluable) cohorts, respectively, 48% and 68% received only one prior line of therapy, 70% and 76% received both platinum chemotherapy and PD-(L)1 immunotherapy, 68% and 24% were female, known PD-L1 expression (≥1% / ≥50%) was 95%/45% and 43%/0%, and almost all had smoked. In the *TP53* CO-MUT cohort, confirmed ORR was 35% (CI 23-47). In the *STK11* CO-MUT cohort, confirmed ORR was 16% (CI 4-28). Disease control rate (DCR), duration of response (DOR), investigator progression-free survival (PFS), and overall survival (OS) (Table 1) had numerically higher values in the *TP53* CO-MUT cohort. Adverse event rates ≥ Grade 3 were similar to prior reports of single agent sotorasib. **Conclusions:** *TP53* CO-MUT cohort met its primary endpoint, while the *STK11* CO-MUT cohort did not, suggesting that *STK11* CO-MUT have detrimental effect on sotorasib in *KRAS* G12C NSCLC. S1900E Cohort 3, which may include *KEAP1/NFE2L2* and other CO-MUT, will be reported later, as will resistance patterns identified through ctDNA analysis. Clinical trial information: NCT04625647. Research Sponsor: NIH/NCI/NCTN grants U10CA180888, U10CA180819.

8519 Rapid Oral Abstract Session

Safety and efficacy of olomorasib + immunotherapy in first-line treatment of patients with *KRAS* G12C-mutant advanced NSCLC: Update from the LOXO-RAS-20001 trial. First Author: Konstantin H. Dragnev, Dartmouth Cancer Center, Lebanon, NH

Background: Olomorasib, a potent, highly selective second-generation KRAS G12C inhibitor has demonstrated promising activity and a favorable safety profile in *KRAS* G12C-mutant NSCLC when combined with pembrolizumab. Here, we report updated results from LOXO-RAS-20001, a phase 1/2 trial (NCT04956640) of olomorasib, in patients (pts) with *KRAS* G12C-mutant NSCLC receiving olomorasib + pembrolizumab, and focus on pts receiving the combination as first-line (1L) therapy. **Methods:** Pts with advanced *KRAS* G12C-mutant NSCLC (tissue or plasma) in the 1L metastatic setting were eligible. Any PD-L1 level (0-100%) was permitted. Two dose levels of olomorasib (50 and 100 mg, orally twice daily) + pembrolizumab were evaluated. Adverse events (AE) were assessed across all treated pts; objective response rate (ORR) per RECIST v1.1 was assessed in pts with at least one post-baseline response assessment or who discontinued treatment before the first response assessment. **Results:** As of 13 November 2024, a total of 43 pts received olomorasib + pembrolizumab (50 mg, n=21; 100 mg, n=22) in the 1L setting with a median age of 70 years (range, 58-83); 10 (23%) were PD-L1 negative, 13 (30%) were PD-L1 1-49%, 19 (44%) were PD-L1 ≥50% and 1 (2%) was unknown. Median duration of follow-up was 5.5 months (range, 0.1-24.4). All grade TRAEs in ≥10% of pts (olomorasib- and/or pembrolizumab-related) were ALT/AST increased (33%/30%), diarrhea (28%), fatigue (16%), nausea (14%), pruritus (12%) and decreased appetite (12%); grade 3 TRAEs in ≥10% of pts were ALT/AST increased (26%/16%). Hepatic events were overall manageable with dose adjustments and/or corticosteroids. No pts had co-occurring total bilirubin increased or discontinued both study treatments due to hepatic events. Pneumonitis was reported in 2 pts (grades 2 and 4). The AE profile was generally comparable across doses. TRAEs led to olomorasib dose reduction in 16% of pts and discontinuation of combination treatment in 5% (2) pts. At time of data-cut, 33 pts remain on treatment and 10 discontinued. Among the 40 efficacy-evaluable 1L pts, at a median follow-up of 9 months (95% CI, 6-12), ORR was 70% (28/40; 95% CI, 54-83; 1 CR, 23 PR, 4 unconfirmed PR pending/ongoing) across all PD-L1 expression levels and disease control rate (DCR) was 90% (36/40; 95% CI, 76-97). In pts with PD-L1 ≥50%, ORR was 82% (14/17; 95% CI, 57-96) and DCR was 94% (16/17; 95% CI, 71-99). Median duration of response was not reached and progression free survival rate at 6 months was 80%. **Conclusions:** Olomorasib + pembrolizumab in the 1L metastatic setting demonstrated favorable safety and encouraging antitumor activity in pts with *KRAS* G12C-mutant advanced NSCLC across all PD-L1 expression levels. A global, registrational study investigating this combination in 1L NSCLC is currently enrolling (SUNRAY-01, NCT06119581). Clinical trial information: NCT04956640. Research Sponsor: Eli Lilly and Company.

8520 Rapid Oral Abstract Session

Sosimerasib monotherapy in patients with previously treated KRAS G12C–mutated non-small cell lung cancer: Primary results of a phase 2 study. First Author: Jia Zhong, Cancer Hospital, Chinese Academy of Medical Sciences, Beijing, China

Background: KRAS G12C mutation is a poor prognostic factor for Non-Small Cell Lung Cancer (NSCLC). Sosimerasib is a novel potent and highly selective KRAS G12C inhibitor. Here we report the primary results from a Phase 2 study of sosimerasib in patients with advanced NSCLC harboring the KRAS G12C mutation. **Methods:** In this open-label, multicenter, single-arm, pivotal phase 2 study, patients with locally advanced/metastatic KRAS G12C mutated NSCLC after failure with platinum-based chemotherapy and/or anti-PD-1/PD-L1 inhibitors were enrolled and treated with sosimerasib 500mg orally once daily. The primary endpoint was objective response rate (ORR) assessed by independent review committee (IRC) per RECIST v1.1. The secondary endpoints included duration of response (DOR), disease control rate (DCR), time to response (TTR), progression-free survival (PFS), overall survival (OS) and safety. **Results:** A total of 145 patients were enrolled. The median age was 63 years, 85.5% were male, and previous treatment lines ranged from 1 to 3, with 84.1% patients having received both platinum-based chemotherapy and anti-PD-1/PD-L1 inhibitors. By 3 November 2024, the median follow-up duration was 6.8 months (range: 0.4-10.9). IRC-confirmed ORR was 52.4% (95% CI: 44.0-60.8) with median TTR of 1.4 months (range: 1.2-8.4), DCR was 87.6% (95% CI: 81.1-92.5). Median PFS was 7.2 months (95% CI: 5.6-NA). Median DOR and median OS were not reached. At the data cutoff date, Treatment-related adverse events (TRAEs) were reported in 138 (95.2%) patients, grade 3-4 TRAEs occurred in 58 (40.0%) patients. No TRAE was fatal. Most common TRAEs were alanine aminotransferase increased (66.2%), aspartate aminotransferase increased (62.8%), anaemia (31.7%), gamma-glutamyl transferase increased (26.2%) and blood alkaline phosphatase increased (22.1%). TRAEs leading to drug interruption, dose reduction, and permanent discontinuation occurred in 35 (24.1%), 15 (10.3%), and 3 (2.1%) patients, respectively. **Conclusions:** Sosimerasib monotherapy has shown promising anti-tumor activity with manageable safety profile in locally advanced/metastatic NSCLC patients harboring KRAS G12C mutation. This study is still ongoing and longer follow-up will provide more solid evidence. Clinical trial information: ChiCTR2200059986. Research Sponsor: None.

8521 Poster Session

First-line (1L) datopotamab deruxtecan (Dato-DXd) + rilvegostomig in advanced or metastatic non-small cell lung cancer (a/mNSCLC): Results from TROPION-Lung04 (cohort 5). First Author: Saiama Naheed Waqar, Washington University School of Medicine in St. Louis, St. Louis, MO

Background: 1L anti–PD-(L)1 antibodies ± chemotherapy are standard of care for patients (pts) with a/mNSCLC without actionable genomic alterations (AGAs). However, not all pts experience response to treatment. Dato-DXd, a TROP2-directed antibody-drug conjugate, has shown efficacy in pts with a/mNSCLC alone or combined with PD-(L)1 inhibitors. Rilvegostomig, a bispecific antibody targeting PD-1 and TIGIT, has also shown preliminary efficacy in pts with a/mNSCLC. Consequently, the combination of Dato-DXd and rilvegostomig may have the potential to enhance responses. **Methods:** TROPION-Lung04 (NCT04612751) is a phase 1b, open-label, dose-escalation and expansion study enrolling pts with a/mNSCLC without AGAs. In cohort 5 (C5; C5a, PD-L1 tumor proportion score [TPS] ≥50% and C5b, PD-L1 TPS <50%) treatment-naïve pts received Dato-DXd (6 mg/kg) + rilvegostomig IV Q3W. Pts were treated until disease progression or unacceptable toxicity. The primary endpoint was safety. Secondary endpoints included objective response rate (ORR), duration of response (DoR) and progression-free survival (PFS) per investigator (RECIST v1.1). **Results:** At data cut-off (DCO; 24 Oct, 2024), 40 pts had received Dato-DXd + rilvegostomig (C5a, n=20; C5b, n=20); 29 (72.5%) had non-squamous histology. Median treatment duration was 5.1 months (range 0.7–18.6); 21 pts discontinued Dato-DXd (adverse events [AEs], n=9; progressive disease [PD], n=9), 20 discontinued rilvegostomig (AEs, n=8; PD, n=9) and 20 (50.0%) pts were still on any study treatment at DCO. All pts (N=40, 100%) had treatment-emergent adverse events (TEAEs); 60.0% (n=24) had grade ≥3 TEAEs and 50.0% (n=20) had serious TEAEs. The most common TEAEs were stomatitis (52.5%; grade 3, 2.5% [n=1]), fatigue (grouped term, 50.0%, all grade 1/2), alopecia (45.0%, all grade 1/2) and nausea (42.5%, all grade 1/2). Ocular surface events occurred in 12 pts (30.0%); grade 4, n=1. Adjudicated drug-related interstitial lung disease/pneumonitis was reported in 5 pts (grade 3, n=2). There were six fatal TEAEs (respiratory failure, general physical health deterioration, death, intestinal perforation, sepsis, cardiac arrest); however, none were related to either study treatment. Confirmed ORR for all pts was 57.5% (95% CI 40.9, 73.0); disease control rate was 95.0% (95% CI 83.1, 99.4). Responses were observed across both squamous (45.5%; 95% CI 16.7, 76.6) and non-squamous histologies (62.1%; 95% CI 42.3, 79.3) and all PD-L1 levels. DoR and PFS were immature at DCO. **Conclusions:** The safety profile for the combination of Dato-DXd + rilvegostomig was consistent with the expected toxicities of each agent and without new safety findings. Dato-DXd + rilvegostomig had encouraging activity as 1L treatment for pts with a/mNSCLC without AGAs, with responses seen in both histologies and across all PD-L1 levels. Clinical trial information: NCT04612751. Research Sponsor: This trial is sponsored by AstraZeneca. In July 2020, Daiichi-Sankyo entered into a global development and commercialization collaboration with AstraZeneca for datopotamab deruxtecan (Dato-DXd).

Exploratory ctDNA analyses for the EVOKE-1 study in metastatic non-small cell lung cancer (mNSCLC). First Author: Enriqueta Felip, Vall d'Hebron University Hospital and Vall d'Hebron Institute of Oncology, Barcelona, Spain

Background: In NSCLC, ctDNA analysis complements assessment of clinical efficacy and identifies molecular alterations that may be prognostic or predictive of treatment. EVOKE-1 compared sacituzumab govitecan (SG) vs docetaxel in mNSCLC that had progressed on platinum-based and anti–PD-(L)1 therapy. Although statistical significance was not met, SG showed numerical improvement in overall survival (OS) vs docetaxel. Here, we assessed the value of ctDNA as a biomarker in available samples from EVOKE-01. **Methods:** The biomarker evaluable population (BEP) comprised 497 patients (pts), representing 82% of the ITT population. Cell-free DNA was extracted from blood collected at baseline and cycle 2 day 1 (C2D1). Samples were analyzed using the Guardant Infinity assay, a tumor-agnostic platform that measures ctDNA levels and gene variants from a comprehensive gene panel. **Results:** ctDNA was detected at baseline in 449 pts (90.3% of BEP), and higher ctDNA was a negative prognostic for OS, regardless of treatment. mOS was 12.7 vs 10.0 mos (HR 1.58, 95% CI: 1.11–2.26) for < vs ≥ median ctDNA level with SG and 10.8 vs 7.2 mos (HR 1.78, 95% CI: 1.28–2.46) with docetaxel. ctDNA was undetectable in 48 pts who had a longer survival (mOS NR in either arm) than those with detected ctDNA. At C2D1, median ctDNA reduction was 59% and 75% with SG and docetaxel (*P*=.33); ≥50% reduction was achieved in 103 (44%) vs 121 pts (51%), respectively. Changes in ctDNA levels at C2D1 were prognostic, with pts achieving ≥50% reduction having a longer OS than those with <50% reduction of ctDNA. Actionable genomic alterations identified included *KRAS*, *EGFR*, *ALK*, *ROS*, *ERBB2*, *MET*, and *NTRK* alterations. As expected from the required local/central testing for mutations at study entry, only a small number of pts with *EGFR/ALK* alterations were identified. *KRAS* mutations had a negative prognostic effect, whereas the group of pts with *EGFR/ALK/ROS* alterations was too small for conclusive results. Analysis of mutations (*TP53*, *KEAP1*, *STK11*) potentially contributing to anti–PD-(L)1 resistance showed that between SG and docetaxel, 167 (68%) and 171 pts (68%) had *TP53* mutations and 184 (75%) and 194 pts (77%) had ≥1 of these 3 mutations. The frequency of these mutations was similar across pts with PD/SD and those with CR/PR as best response to last prior PD-(L)1 therapy. Harboring *TP53* mutations was a negative prognostic factor in both arms: mOS was 11.3 mos vs NA (HR 1.67, 95% CI: 1.11–2.54) with *TP53* mutation vs wildtype with SG and 9.2 vs 13.9 mos (HR 1.71, 95% CI: 1.18–2.47), respectively, with docetaxel. *KEAP1/STK11* mutations were also negative prognostic markers. **Conclusions:** This analysis did not identify differences in ctDNA clearance with SG vs docetaxel. Regardless of treatment and in line with previous reports, high ctDNA was a negative prognostic marker for OS in mNSCLC. Furthermore, alterations of *KRAS*, *TP53*, and *KEAP1/STK11* represent negative prognostic factors. Clinical trial information: NCT05089734. Research Sponsor: Gilead Sciences, Inc.

Whole-genome and transcriptome landscape of actionable driver-negative lung adenocarcinoma. First Author: Masahiro Torasawa, Department of Respiratory Medicine, Juntendo University Faculty of Medicine and Graduate School of Medicine, Tokyo, Japan

Background: Driver-negative lung adenocarcinoma (DN-LUAD) without actionable genomic alterations (AGAs) has a poor prognosis. A deeper understanding of its molecular background, particularly across the entire genome, is crucial for improving risk assessment and therapeutic development. **Methods:** We performed deep whole-genome sequencing (WGS; tumor depth: 100–120x, normal depth: 30x, paired-end reads: 150 bp) and RNA sequencing using fresh-frozen tissues from four institutions. DN-LUAD was defined as LUAD without known actionable mutations or gene fusions. We analyzed somatic mutations, copy number alterations (CNAs), and structural variations (SVs). Tumors were classified as whole-genome doubling (WGD) if more than half of the autosomal tumor genome showed at least two copies in the major copy numbers of somatic cells. HRDetect score ≥0.7 was used to determine the presence of homologous recombination DNA repair deficiency (HRD) (Davies H, et al. Nat Med. 2017). Gene Set Enrichment Analysis (GSEA) was used for pathway analysis. **Results:** Among the 745 patients (pts), 517 were classified as having DN-LUAD. WGS identified AGAs undetected by whole-exome sequencing (WES) in 33 (4.4%) pts (*EGFR* 13, *KRAS* 7, *BRAF* 5, *ERBB2* 4, *MET* 4, and *HRAS* 1). The frequently observed genomic alterations in DN-LUAD are shown in the Table. WGD was observed in 62.1% (n = 321) of DN-LUADs and was significantly associated with higher TMB, CNA, and SV burden. Tumor suppressor gene (TSG) mutations in *TP53*, *STK11*, and *KEAP1*, as well as *CDKN2A* copy number loss and SVs, were significantly more frequent in WGD pts. HRD was identified in 19 DN-LUAD pts (3.7%), with a significantly higher frequency in the WGD group (WGD vs. without WGD; 4.98% vs. 1.5%, p = 0.016). GSEA showed significant (q < 0.0001) upregulation of cell cycle pathways (E2F targets, G2M checkpoint, and MYC targets) and downregulation of immune pathways (allograft rejection and interferon-gamma response) in DN-LUADs with WGD. **Conclusions:** This largest-ever WGS study identified AGAs undetectable by WES and uncovered a subgroup of DN-LUAD characterized by increased genomic instability driven by multiple TSG alterations associated with WGD, which was also more likely to exhibit HRD. WGD was associated with the upregulation of cell cycle pathways and the downregulation of immune pathways. These findings highlight the critical role of WGS in elucidating the pathogenesis of DN-LUAD. Research Sponsor: None.

Potential biomarker of PD-L1 expression phenotypes in tumor and immune cells for combined PD-1 and CTLA-4 blockade therapies in advanced NSCLC. First Author: Jun Miyakoshi, Department of Thoracic Oncology, National Cancer Center Hospital, Tokyo, Japan

Background: Pembrolizumab-based chemo-immunotherapies (Pembro) and nivolumab plus ipilimumab-based immunotherapies with or without 2 cycles of chemotherapies (Nivo+Ipi) have improved survival in patients with advanced NSCLC compared to the conventional chemotherapy. However, biomarkers to support appropriate choice in these immunotherapies remain unclear. **Methods:** From 2019 to 2023, this multicenter, observational study retrospectively reviewed advanced NSCLC patients who received first-line Pembro or Nivo+Ipi and had evaluable PD-L1 expression status on tumor cells (tumor proportion score [TPS], 22C3) and immune cells (immune cell [IC] score, SP142). Survival curve comparisons between treatments were conducted using restricted mean survival time (RMST) estimation in place of Log-rank test, when the proportional hazard assumption was not met. Additionally, the genomic and expression profiles associated with TPS and IC score were assessed using whole-exome sequencing and RNA sequencing in available NSCLC samples. **Results:** A total of 198 patients were included (Pembro/Nivo+Ipi: 137/61). In the Pembro cohort, patients with high TPS (≥ 50%) had significantly longer progression-free survival (PFS) than those with low TPS (< 50%) (median PFS [mPFS, months]: 8.1 vs. 7.1, *P* = 0.02; hazard ratio [HR] = 0.59 [0.38–0.92]), while no significant difference in PFS was observed based on IC score (high vs. low: mPFS 7.4 vs. 6.8, *P* = 0.11, HR = 0.72 [0.49–1.07]). In the Nivo+Ipi cohort, PFS did not significantly differ by TPS (high vs. low: mPFS 4.0 vs. 4.0, *P* = 0.26; HR = 0.51 [0.16–1.68]), whereas patients with high IC score (≥ 1) had significantly longer PFS than those with low IC score (= 0) (mPFS: 7.7 vs. 2.8, *P* = 0.04; HR = 0.53 [0.28–0.98]). A durable PFS benefit of Nivo+Ipi over Pembro was observed only in patients with low TPS/high IC score (mPFS: 12.4 vs. 6.6; Schoenfeld individual test: $P < 0.05$; $RMST_{Nivo+Ipi}/RMST_{Pembro}$ [2 years] = 1.5, *P* = 0.049, Table). Sequence analyses revealed that tumors with low TPS/high IC score had significantly higher tumor mutational burden (TMB) than other tumors (median TMB: 18.2 vs. 1.9 [/mb]; $P < 0.001$) and showed distinct enrichment in antigen presentation and T-cell receptor signaling pathways. **Conclusions:** Nivolumab plus ipilimumab-based immunotherapies demonstrated superior durable response compared to pembrolizumab-based chemo-immunotherapies in patients with low TPS/high IC score. PD-L1 phenotypes based on TPS and IC score could guide the optimal selection of immunotherapies for advanced NSCLC patients. Research Sponsor: None.

Efficacy comparison in patients with low TPS (< 50%)/high IC score (≥ 1).

Treatments	mPFS (months)	PFS rate at 2 years	RMST at 2 years	$RMST_{Nivo+Ipi}/RMST_{Pembro}$ at 2 years	P value
Pembrolizumab-based chemo-immunotherapies	6.6	6%	8.5	1.5 [1.0–2.3]	0.049
Nivolumab plus ipilimumab-based immunotherapies	12.4	41%	12.9

Effects of immediate elevation of inflammatory cytokines after platinum, pemetrexed, and pembrolizumab on antitumor efficacy in advanced non-squamous, non-small cell lung cancer. First Author: Yuichi Ozawa, Department of Respiratory Meidcine/ Medical Oncology, Hamamatsu Medical Center, Hamamatsu-Shi, Japan

Background: Inflammatory cytokines play a crucial role in the tumor microenvironment and may serve as potential biomarkers for the sustained efficacy of PD-1/L1 inhibitors combined with chemotherapy. Numerous studies have been conducted on cytokines to date; however, studies on cytokine fluctuations immediately after administration remain notably limited. **Methods:** A prospective observational study at Wakayama Medical University enrolled 110 patients with thoracic malignancies receiving PD-1/L1 inhibitors as first line therapy from Oct 2019 to Nov 2023. We analyzed 41 patients with advanced or recurrent non-squamous, non-small cell lung cancer treated with platinum, pemetrexed, and pembrolizumab (CPP). Peripheral blood samples were collected at baseline, day 3($\pm$1), day 7($\pm$1), and day 42. 40 serum proteins were quantified using a Luminex 200 analyzer and a Milliplex MAP system. The association between cytokine increase and progression-free survival (PFS) was statistically analyzed. **Results:** Patient characteristics were as follows: median age (range), 71 (46-84) years; male/female, 33/8; adenocarcinoma/other, 36/5; performance status (PS) 0/1, 8/33; stage IV/recurrence, 31/10; cisplatin/carboplatin, 16/25; PD-L1 tumor proportional score (TPS) $<$1/1-49/$\geq$50, 14/12/15. The dose of dexamethasone at the first treatment was 6.6 mg (3.3-9.9 mg). Among the 40 measured cytokines, 10 showed an average increase of $\geq$50% from baseline to Day 3, of which 7 were inflammatory or immune-stimulatory (IL-1α, G-CSF, CXCL10, CXCL13, IL-6, IL-15, MCP-1). Five of them decreased by Day 7. Eight cytokines showed an increase of $\geq$50% from baseline to Day 7, of which 4 were inflammatory, and all of them were among those $\geq$50% elevated at Day 3 (IL-1α, G-CSF, IL-6, MCP-1). A univariate Cox proportional hazard analysis revealed that an increase in IL-6 or MCP-1 at day 3 (Day 3/0 ratio $>$1) was significantly associated with longer PFS [IL-6: HR 0.41 (95%CI 0.17-0.97), p=0.049; MCP-1: HR 0.43 (95% CI 0.19-0.97), p=0.042]. After adjustment for age, PS, and PD-L1 TPS in the multivariate analysis, MCP-1 remained a significant predictive factor (HR 0.36, 95% CI 0.13-0.97, p=0.043). PFS curves were significantly different between MCP-1 increased and decreased cases (median PFS 463 vs. 201 days, p=0.036), with 12-month PFS rates of 60% and 31%, and 25-month PFS rates of 50% and 8%, respectively. **Conclusions:** This study demonstrated that inflammatory cytokines increased immediately after CPP, despite the concomitant use of dexamethasone for antiemesis. Furthermore, the immediate increase in MCP-1 after treatment was associated with prolonged PFS, suggesting its potential as a predictor of treatment efficacy and providing insights into the mechanisms of chemo-immunotherapy. Characterization of histology-dependent immunobiological differences in metastatic NSCLC: Implications for treatment with PD-1 and LAG-3 inhibitors. First Author: Hossein Borghaei, Fox Chase Cancer Center/Temple Health, Philadelphia, PA

Background: The treatment paradigm for metastatic non-small cell lung cancer (mNSCLC) without actionable genomic alterations does not differentiate between histologic subtypes for the use of checkpoint inhibitors. However, there is growing recognition of differences between squamous (SQ) and non-squamous (NSQ) lung cancer that may impact response to treatment. For example, in the RELATIVITY-104 study, addition of the LAG-3 inhibitor relatlimab to anti-PD-1 + platinum-doublet chemotherapy (PDCT) showed improved clinical benefit among patients with PD-L1 $\geq$1%, which was further enriched with NSQ histology. There is an unmet need to understand differences in tumor biology between NSQ and SQ histologies in patients with mNSCLC to inform on mechanisms underlying differences in clinical activity of anti-PD-1 + PDCT, alone or in combination with a LAG-3 inhibitor. **Methods:** Data were obtained from molecular profiling of baseline tumor samples of treatment-naive patients enrolled in the phase 3 CheckMate 227 (NCT02477826) study. PD-L1 (N=1739) and LAG-3 expression (N=540) were evaluated using immunohistochemistry. Somatic mutations and copy number alterations were assessed using the FoundationOne panel (N=1368). Gene expression, analyzed through RNA sequencing (N=465), was used to characterize differences in tumor immunobiology, including differential gene expression, pathway enrichment, and calculation of cell type-specific scores representing different immune and stromal cell types. **Results:** Transcriptional and mutational analyses revealed clear differences between NSQ and SQ tumors. NSQ tumors showed enrichment of immune pathways (e.g., antigen presentation and T cells), while SQ tumors exhibited enrichment of pathways consistent with rapid cell growth and numerous oncogenic alterations (e.g., p53 and PIK3CA). Differences in the relationship between tumor PD-L1 expression and the tumor microenvironment by histology were observed; PD-L1 expression was positively correlated with immune infiltration scores in NSQ but not SQ tumors, suggesting that drivers of PD-L1 expression may differ by histology. Consistent with previously published reports for mNSCLC, PD-L1 expression enriched for 1L anti-PD-1 + PDCT benefit in NSQ but not SQ tumors (CheckMate 227 Part 2). Differences in LAG-3 ligand expression by histology and PD-L1 expression were noted. Both canonical LAG-3 ligands, MHC-II and FGL-1, were expressed at higher levels in NSQ tumors. Within NSQ tumors, relative expression of each ligand varied by PD-L1 expression, with high MHC-II expression specifically in NSQ, PD-L1 $\geq$1% tumors. **Conclusions:** These data provide a supporting mechanistic rationale for the use of tumor histology in addition to PD-L1 expression to identify patients who would benefit from the addition of a LAG-3 inhibitor to PD-1 inhibitor + PDCT. Clinical trial information: NCT02477826. Research Sponsor: Bristol Myers Squibb.

8527 Poster Session

Unraveling relatlimab (RELA)-specific biology: Biomarker analyses in patients (pts) with metastatic non-small cell lung cancer (mNSCLC) treated with 1L nivolumab (NIVO) + RELA high-dose (HD) and platinum-doublet chemotherapy (PDCT). First Author: Martin Reck, Thoracic Oncology Department, LungenClinic Grosshansdorf, Grosshansdorf, Germany

Background: The addition of RELA HD, a lymphocyte activation gene-3 (LAG-3) inhibitor, to NIVO + PDCT has improved clinical benefits vs NIVO + PDCT for pts with PD-L1 expression $\geq$1% and NSQ histology in RELATIVITY-104 study. We report exploratory biomarker analyses from this study to elucidate mechanisms underlying NIVO + RELA HD + PDCT activity. **Methods:** Baseline and on-treatment blood samples were analyzed by flow cytometry for pharmacodynamic (PD) changes in immune cell populations including proliferating LAG-3-expressing CD4+ and CD8+ effector memory (EM) and central memory (CM) T cells. Baseline tumor samples were analyzed by monoplex immunohistochemistry (IHC) for tumor cell PD-L1, LAG-3, and CD8 expression. Associations between biomarkers and overall response rate (ORR) and progression free survival (PFS) were assessed. **Results:** NIVO + RELA HD + PDCT significantly modulated levels of proliferating LAG-3 expressing EM and CM T cells in the periphery on-treatment; no such PD change was observed with NIVO + PDCT. Among pts with NSQ histology, baseline tumor LAG-3 expression $\geq$1% showed improved ORR and median PFS in both treatment arms compared with LAG-3 $<$1%. Further, the benefit of RELA HD addition to NIVO + PDCT was also seen in patients with LAG-3 $<$1%, suggesting that baseline LAG-3 expression at 1%, unlike PD-L1 expression, would not help identify patients who can benefit from LAG-3 inhibition (Table). In contrast to NSQ, the same association trend of PD-L1 and LAG-3 expression with efficacy was not observed in pts with SQ histology, which could be partly attributable to the limited sample size in some SQ subgroups. Interestingly, PD-L1 $\geq$1% is more strongly correlated with CD8 T cells in NSQ as compared to SQ. **Conclusions:** These data represent the first in-depth biomarker analyses from a randomized phase 2 study to reveal that RELA can expand proliferating LAG-3 expressing T cells in NSCLC. NIVO + RELA HD + PDCT activity might be particularly robust in pts with NSQ histology and PD-L1 expression $\geq$1%, where CD8 T cells are enriched. The ongoing phase 3 RELATIVITY-1093 study is evaluating 1L NIVO + RELA HD + PDCT vs standard-of-care pembrolizumab + PDCT in mNSCLC. Clinical trial information: NCT04623775. Research Sponsor: Bristol Myers Squibb.

Efficacy of NIVO + RELA HD + PDCT vs NIVO + PDCT in pts with NSCLC by baseline histology, PD-L1 and LAG-3 expression.

Genomic and circulating tumor DNA landscape in young-onset non-small cell lung cancer. First Author: Fatemeh Ardeshir Larijani, Winship Cancer Institute, Emory School of Medicine, Atlanta, GA

Background: To explore the underlying biology in young patients (pts) with non-small cell lung cancer (NSCLC), we analyzed the genomic diversity of serial circulating tumor DNA (ctDNA). **Methods:** We analyzed ctDNA data from a national database Guardant Health NGS panel of 83 loci from a population of 5210 NSCLC pts between the ages of 18-50 collected between 1/20-6/2020, with longitudinal samples from 931 pts (2 samples), 286 pts (3 samples), and 166 pts ($>$ 3 samples) with at least 90 days between the first and last sample. We evaluated statistical significance using Spearman correlation, the Mann-Whitney U test, the signed-rank test, or Fisher's exact test. We used Gene Ontology enrichment analysis and Ingenuity for genomics and MetaboAnalyst for metabolomic pathway analysis. **Results:** Out of 5,210 young adult (YA) NSCLC pts, 6,624 liquid NGS tests were conducted, of which 9% of pts were between 18 and 35 years old, defined as very young adults (VYA), and 91% were between 35 and 50 years old, defined as young adults (YA). Overall, mutation frequency increased significantly with age (Spearman r = 0.08, p = 1.9 · 10-10). Most pts were female (2,826, 54%).Mutation frequency was higher in males (Mann-Whitney p = 1.8 · 10^{-5}). The rate of targetable alterations was 48% in YA and 46% in VYA-NSCLC patients, with EGFR being the most common alteration (24% in YA, 18.4% in VYA). Of the 13 genes with mutation frequencies of at least 5%, there are 11 genes with more alterations in males and 2 in females. Immune-related pathways were infrequently altered (4.8%), while TP53/DNA damage (50%), EGFR/RAS (30%), PI3K (35%), and β-catenin/APC (28%) pathways were frequently altered. Endocrine resistance pathways altered second most (p=0.03), likely due to distinct biology or treatment effects. Metabolomic analysis identified methylation-related pathways (28.6%), including MAT1A, as the most prominent metabolomic pathways (p = 0.02). Longitudinal analysis revealed increased ctDNA burden with tumor progression. Comparing the first-to-last ctDNA in the same pts, we identified genes with distinct patterns of alteration in YA and VYA pts (Tab-1). TP53 and EGFR remain highly mutated but with stable mutation rates (TP53: 51% to 52%, EGFR: 41% to 41%). **Conclusions:** Targetable alterations are highly prevalent in YA and VYA NSCLC, exhibiting distinct ctDNA mutation frequencies upon serial testing. DNA methylation can potentially regulate gene expression in metabolic pathways, suggesting therapeutic avenues. Research Sponsor: None.

Highest positive and negative changes in mutation frequencies from first to last sample in YA and VYA NSCLC using Guardant serial ctDNA.

Sacituzumab tirumotecan (sac-TMT) in combination with tagitanlimab (anti-PD-L1) in first-line (1L) advanced non-small-cell lung cancer (NSCLC): Non-squamous cohort from the phase II OptiTROP-Lung01 study. First Author: Wenfeng Fang, Sun Yat-sen University Cancer Center, Guangzhou, China

Background: Sac-TMT (MK-2870/SKB264) is a TROP2 ADC developed with a novel linker to conjugate a belotecan-derivative topoisomerase I inhibitor. The complementary mechanisms of action of sac-TMT and PD-1/L1 inhibitor may provide more potent antitumor activity. Sac-TMT was safety combined with tagitanlimab (anti-PD-L1, KL-A167) and demonstrated promising activity for the combination in 1L NSCLC (*Fang et al. 2024*). Here, we report updated results by PD-L1 expression with additional enrolled patients (pts) and extended follow-up from non-squamous cohort in the phase II OptiTROP-Lung01 study (NCT05351788). **Methods:** Advanced NSCLC pts with no prior systemic therapy and no actionable genomic alterations were enrolled to receive sac-TMT (5 mg/kg Q3W or Q2W) plus tagitanlimab (1200 mg Q3W or 900 mg Q2W) until disease progression or unacceptable toxicity. Tumor assessments per RECIST 1.1 were performed once every 6 weeks for the first 12 months (mo), and every 12 weeks thereafter. The PD-L1 tumor proportion score (TPS) was detected by IHC 22C3 pharmDx assay. **Results:** As of 30 Dec 2024, 81 pts (median age: 60.0 years; male: 79.0%; ECOG PS 1: 91.4%) with non-squamous histology were enrolled. The majority (66.7%) had PD-L1 TPS$<$ 50% (42.0% for $<$ 1%, 24.7% for 1% - 49% and 33.3% for $\geq$ 50%). After median follow-up of 17.1 mo, the confirmed objective response rate (ORR) was 59.3%; The disease control rate (DCR) was 91.4%; Median duration of response (mDOR) was 16.5 mo (95%CI: 11.7, 22.1); Median progression free survival (mPFS) was 15.0 mo (95%CI: 10.8, 24.8). Among pts with PD-L1 TPS$<$ 1%, the confirmed ORR was 47.1%; mPFS was 12.4 mo (95%CI: 7.6, 15.4); while for pts with PD-L1 TPS$\geq$ 1%, the confirmed ORR was 68.1%; mPFS was 17.8 mo (95%CI: 14.5, NE). Among pts with PD-L1 TPS$\geq$ 50%, the confirmed ORR was 77.8%; mPFS was 17.8 mo (95%CI: 10.8, NE). Most common ($\geq$ 10%) Grade $\geq$ 3 treatment-related adverse events (TRAEs) were neutrophil count decreased (45.7%), anemia (16.0%), white blood cell count decreased (14.8%) and stomatitis (11.1%). No TRAE led to treatment discontinuation or death. **Conclusions:** Sac-TMT in combination with tagitanlimab demonstrated promising antitumor activity in treatment-naive advanced non-squamous NSCLC. The durable clinical activities were observed regardless of PD-L1 expression. This combination therapy showed a tolerable safety profile based on known profiles of the individual agents, with no new safety signals observed. A phase 3 study comparing sac-TMT plus pembrolizumab *vs.* chemotherapy plus pembrolizumab as 1L treatment for PD-L1 negative pts with advanced non-squamous NSCLC is ongoing (NCT06711900). Clinical trial information: NCT05351788. Research Sponsor: Sichuan Kelun-Biotech Biopharmaceutical Co., Ltd.

Clinical, genomic, and pathological features and therapeutic outcomes of non-small cell lung cancer with MTAP-loss. First Author: Hibiki Udagawa, National Cancer Center Hospital East, Kashiwa, Japan

Background: MTAP-cooperative PRMT5 inhibitors are under development for MTAP-loss solid tumors. However, clinical, genomic, and pathological features of non-small cell lung cancer (NSCLC) with MTAP-loss are still unclear. **Methods:** Using the large-scale clinical-genomic database of LC-SCRUM-Asia, the clinical, genomic, and pathological features and therapeutic outcomes of patients with NSCLC with MTAP-loss were investigated. MTAP-loss, CDKN2A-loss, targetable genomic alterations, and tumor mutation burden (TMB) were analyzed using FoundationOne CDx. PD-L1 TPS was evaluated using PD-L1 IHC 22C3. **Results:** MTAP status was successfully analyzed in 253 samples from NSCLC patients between February 2017 and May 2018. MTAP loss was detected in 54 of 253 (21%) NSCLCs distributed in 33 of 170 (19%) adenocarcinoma, 15 of 60 (25%) squamous cell carcinoma and 6 of 23 (26%) others. The patients with MTAP-loss NSCLC showed no significant difference in age, sex, smoking history, and ECOG PS compared to the patients with MTAP-intact NSCLC. In the patients with MTAP-loss NSCLC, the median age was 68 years old, 63% were male, 78% were ever smokers, and all had ECOG performance status (PS) 0-1. CDKN2A-loss was detected in 100% of MTAP-loss and 12% of MTAP-intact. The frequency of targetable genomic alterations did not differ significantly between MTAP-loss and MTAP-intact NSCLC (44% vs 38%). The frequencies of EGFR and KRAS mutations in MTAP-loss NSCLC were 20% and 15%, respectively, and those in MTAP-intact NSCLC were 21% and 10%, respectively. TMB was significantly lower in MTAP-loss NSCLC than in MTAP-intact NSCLC (Median 6.3 vs. 7.6 Mut/Mb, P = 0.03). MTAP-loss NSCLC tended to have lower PD-L1 TPS than MTAP-intact NSCLC (TPS $\geq$1%; 50 % vs 63%, P = 0.08). In the adenocarcinoma without targetable genomic alterations cohort, eight patients with MTAP-loss and 47 patients with MTAP-intact received platinum-based chemotherapies without immune-checkpoint inhibitors (ICIs) as the first-line treatment and six patients with MTAP-loss and 45 patients with MTAP-intact were treated with ICIs alone as any line treatment. There was no significant difference in the progression-free survival (PFS) of platinum-based chemotherapies as the first line between the patients with MTAP-loss and MTAP-intact (median 4.7 vs 4.6 months, HR [95%CI] 0.74 [0.35-1.55], P = 0.42). On the other hand, the patients with MTAP-loss treated with ICIs alone showed significantly shorter PFS compared to the patients with MTAP-intact treated with ICIs alone (median 1.9 vs 6.2 months, HR [95%CI] 3.62 [1.05-12.5], P = 0.04). **Conclusions:** The relatively low TMB and PD-L1 TPS might be involved in shortening the PFS in patients with MTAP-loss treated with ICIs alone. Other than that, NSCLC with MTAP-loss showed no distinct feature in patient characteristics, histopathology, and co-occurring targetable genomic alterations. Tumor-derived ILT5 and suppression of T cell immunity in non-small cell lung cancer. First Author: Xuebing Fu, Department of Thoracic Radiation Oncology, Shandong Cancer Hospital and Institute, Shandong First Medical University and Shandong Academy of Medical Sciences, Jinan, China

Background: Immune checkpoint inhibitors targeting PD-(L)1 pathways have revolutionized the treatment of non-small cell lung cancer (NSCLC) since last decade. However, the efficacy is still limited because the immunosuppressive tumor microenvironment (TME) restricts ICI-primed T cell immunity. Therefore, it is quite crucial to block the potential mechanisms in inducing immunosuppression to improve ICI efficacy. Immunoglobulin-like transcript (ILT) 5 is an important immunosuppressive molecule expressed in a wide range of myeloid cells and predicts tumor progression. Our group was the first to report ILT5 expression in solid tumor cells (colorectal cancer). However, the expression and function of ILT5 in NSCLC are still unknown. **Methods:** ILT5 expression in NSCLC tissues and tumor cell lines was determined by PCR, western blotting and immunofluorescence. The impact of tumor-derived ILT5 on T-cell phenotypes and functions was evaluated using flow cytometry and immunofluorescence. ILT5-regulated downstream signals and molecules were determined by RNA sequencing, PCR, western blotting, and flow cytometry. Tumor transplantation and immunotherapeutic models were established in C57/BL6 and NSG mice to explore the effect of ILT5 on tumor progression and the synergies of ILT5 blockade with ICIs. **Results:** ILT5 is highly expressed in NSCLC cells, predicting poor patient survival. ILT5 induced $CD8^+$ T cell exhaustion rather than senescence and apoptosis in the TME. Mechanistically, ILT5 upregulated PD-L1 through the activation of PI3K-AKT-mTOR signaling pathway, which in turn increased PD-1 expression in $CD8^+$ T cells and induced their exhaustion. PIR-B (ILT5 orthlog in mice) overexpression in mice induced $CD8^+$T cell exhaustion and tumor growth in vivo, while PIR-B knockdown had the opposite effect. More importantly, inhibition of ILT5 synergistically enhanced the tumoricidal effect of PD-1 inhibitor in NSCLC immunotherapeutic models. **Conclusions:** Enriched ILT5 expression in NSCLC cells induces $CD8^+$T cell exhaustion via activation of PI3K-AKT-mTOR-PD-L1 pathway. ILT5 inhibition synergistically enhanced the efficacy of PD-1 inhibitor. Our findings identifies a novel mechanism for tumor immunosuppression and develops a promising strategy for improving ICI efficacy. Research Sponsor: None.

Prognostic value of baseline and dynamic circulating tumor cell monitoring in advanced lung cancer patients receiving immunotherapy. First Author: Zhihui Wang, Department of Thoracic Oncology, the Fifth Affiliated Hospital of Sun Yat-Sen University, Zhuhai, China

Background: Circulating tumor cells (CTCs) and PD-L1 expression on CTCs (bPD-L1) are emerging biomarkers for predicting immunotherapy response. This study assessed the prognostic value of baseline and dynamic CTC monitoring in advanced lung cancer patients receiving immune checkpoint inhibitors. **Methods:** We prospectively enrolled 53 advanced lung cancer patients (stages III-IV) undergoing immune checkpoint therapy from June 2023 to January 2025 at The Fifth Affiliated Hospital of Sun Yat-sen University. Baseline characteristics (age, gender, histology, treatment modality) were recorded. CTCs and bPD-L1 status were assessed at baseline, and treatment responses were evaluated using RECIST 1.1 criteria. Serial blood samples were collected at Day 42 (T1) and subsequent visits (T2, T3, or Tn) for CTC dynamics monitoring. **Results:** Baseline Characteristics and CTC Detection: Of the 53 patients, 47 (84.6%) were male and 8 (15.4%) were female, with a median age of 63 years (range: 32–89). Histological subtypes included adenocarcinoma (62.6%), squamous cell carcinoma (16.1%), and small cell lung cancer (17.2%). Treatments included PD-1/PD-L1 inhibitors and chemotherapy. At baseline, CTCs were detected in 60.9% of patients, with detection rates varying by histology: adenocarcinoma (59.6%), squamous cell carcinoma (60.7%), and small cell lung cancer (50.0%). PD-L1-positive CTCs (bPD-L1+) were found in 44.8% of patients, with subtype-specific positivity rates of 41.3%, 39.3%, and 40.0%, respectively. Among 53 patients who completed at least two cycles of immunotherapy, the bPD-L1-positive group (n=17) had an ORR of 64.7% and a DCR of 100%, while the bPD-L1-negative group (n=36) had an ORR of 13.9% and a DCR of 83.3% ($p<0.001$). Multivariate analysis identified bPD-L1 positivity as an independent predictor of ORR (p=0.04). Serial blood samples from 37 patients at Day 42 (T1) showed that all patients with DCR had stable or decreased CTC counts, while all PD patients showed an increase in CTC count. Extended monitoring in 13 patients revealed consistent patterns: CTC counts increased in PD cases and decreased or remained stable in DCR cases, supporting its role in monitoring treatment efficacy. A linear mixed-effects model showed a significant positive association between PD status and elevated CTC counts (β = 0.821, $p<0.05$), while non-PD showed a trend towards lower CTC counts (β = -0.370, p=0.1). This suggests that CTC counts may serve as a biomarker for disease progression, particularly in identifying PD patients. **Conclusions:** Baseline and dynamic CTC monitoring, particularly bPD-L1 status, provides strong predictive and prognostic value in advanced lung cancer patients undergoing immunotherapy. These findings suggest CTCs as a non-invasive liquid biopsy for treatment stratification and real-time monitoring of treatment response. Clinical trial information: ChiCTR2400080132. Research Sponsor: None.

Host immune classifier to predict survival with chemoimmunotherapy in PD-L1 ≥50% metastatic NSCLC. First Author: Vamsidhar Velcheti, Laura and Isaac Perlmutter Cancer Center, New York, NY

Background: In the 1st line treatment of advanced NSCLC with PD-L ≥50%, immune checkpoint inhibitor (ICI) monotherapy and chemoimmunotherapy have demonstrated survival benefits over chemotherapy alone. However, no additional biomarkers are currently available to guide the choice between these options. Here we report an analysis from the INSIGHT study evaluating the Host Immune Classifier (HIC), a clinically validated blood-based test, to determine its potential to stratify patient survival and optimize treatment selection. **Methods:** Pre-treatment plasma samples were collected from 271 IIIB/IV NSCLC, 1st line ICI-treated (PD-L1 ≥50%) patients enrolled in the prospective, multicenter observational INSIGHT study (NCT03289780). Samples were analyzed by the HIC test, which categorizes patients as Hot or Cold based on the expression profile of eight proteins measured by MALDI mass spectrometry. Survival outcomes were compared between patients treated with ICI monotherapy (ICI-M) and chemoimmunotherapy (ICI-C), grouped by HIC result. To ensure comparable cohorts, baseline clinical characteristics were balanced using inverse probability weighting (IPW). Overall survival (OS) was evaluated using Kaplan-Meier estimates (95% CI) and the log-rank test. Hazard ratios were calculated with Cox proportional hazards models. **Results:** Among the analysis cohort, 171 subjects received ICI-M, and 100 received ICI-C. After IPW, baseline characteristics, including age, sex, smoking history, ECOG PS, and histology, were balanced. The distribution of HIC classifications was similar, with 70% Hot and 30% Cold. In HIC-Hot subjects, overall survival (OS) did not differ significantly between treatment groups (log-rank p=0.15, Table 1). In contrast, HIC-Cold subjects had significantly better OS with ICI-C than ICI-M (log-rank p=0.012, Table 1). Multivariate analysis confirmed the HIC test as an independent predictor of OS, adjusting for other prognostic factors. **Conclusions:** The HIC test is a robust, independent predictor of OS, unaffected by common prognostic factors. HIC-Hot patients had similar OS when treated with ICI-M or ICI-C, suggesting the potential for treatment de-escalation. Conversely, HIC-Cold patients experienced significantly poorer OS with ICI-M but showed improved OS with ICI-C, indicating the need for more aggressive treatment. These findings underscore the potential clinical utility of the HIC test in guiding 1st line ICI treatment strategies for NSCLC with PD-L1 ≥50%. Clinical trial information: NCT03289780. Research Sponsor: Biodesix Inc.

HIC Test Classification	Treatment	N	12 Month % OS	p value	24 Month % OS	p value	Median OS (Months)	Hazard Ratio (95% CI)	p value
Hot	ICI-M	114	58% (48%, 67%)	0.273	46% (35%, 56%)	0.448	18 (11, 31)	0.7 (0.5, 1.1)	0.14
	ICI-C	66	66% (52%, 77%)		52% (37%, 65%)		Median Not Reached

Lipid metabolic gene expression and association with decreased overall survival and immunogenicity in *KRAS-STK11* NSCLC. First Author: Joshua Pothen, University of Illinois Chicago, Chicago, IL

Background: Approximately 30% of patients (pts) with non-small cell lung cancer (NSCLC) have alterations (alt) in *KRAS*. How co-alt such as STK11 affect the tumor microenvironment and survival requires further characterization. Recently, our group found that lower expression of lipid metabolic genes in *KRAS* G12C co-alt tumors was associated with worse overall survival (OS). Here, we seek to confirm these findings utilizing a large real-world (rw) patient de-identified database. **Methods:** Approximately 2,187 pts (61%, stage IV) with *KRAS* G12C alt NSCLC who underwent sequencing via the Tempus xT/xR assay with co-alt in *TP53 (44%), STK11 (17%), or LRP1B (4%)* were selected. The groups are mutually exclusive. Single-sample GSEA (ssGSEA) based on 775 lipid metabolic genes (LMG) was used to calculate enrichment scores (LMG ES) for each pt. Pts were dichotomized into low vs. high groups based on their median LMG ES. Immune cell infiltration predicted from gene expression patterns, TMB, and PD-L1 from IHC was evaluated. Risk-set adjusted rwOS was calculated from sample collection date to death from any cause. Hazard ratios (HR) were calculated using Cox proportional hazards model, and p-values were calculated using the Wald test. **Results:** Among pts with *KRAS* G12C alt, the median age was 68, 58% were female, and 84% were White. Pts with *KRAS* G12C/*STK11* alt had the lowest TMB, neoantigen burden, and PDL-1 positivity compared to other cohorts ($p<0.001$ for all). Importantly, the proportion of total immune cells, M1, M2, NK cells, CD8 T cells and regulatory T cells was lowest in tumors with *KRAS* G12C/*STK11* alt ($p<0.001$ for all). To determine if lipid genes were associated with immunogenic changes, LMG ES was compared to immune infiltration. The ES was associated with immune cell infiltration percentages for M1 macrophages (OR 1.11 (1.03-1.21) p=0.012), M2 macrophages (OR 1.27 (1.15-1.40) $p<0.001$) and neutrophils (OR 1.12 (1.04-1.22) p=0.005), with a trend towards significant association with CD4 T cells (OR 1.08 (1.00-1.17) p=0.062). Pts with *KRAS G12C/STK11* alt and low LMG ES had decreased median rwOS (5.4 vs 18.2 months, p=0.0002) compared to pts with a high ES. Multivariate analysis demonstrated that lower LMG ES correlated with reduced rwOS (HR = 1.75 (1.22-2.51, p = 0.002) compared to pts with high ES. Individual gene analysis showed that low *LPL* (HR = 1.85 (1.147-2.97) p=0.012), *LDLRAD4* (HR = 1.72 (1.082-2.72) p = 0.022) and *LDLR* (HR = 1.58 (1.009-2.46) p=0.045) expression was associated with poorer rwOS. **Conclusions:** Low lipid gene expression in *KRAS-STK11* NSCLC was associated with decreased OS. Lipid gene expression and tumor immune cell infiltration were associated, suggesting that lipid metabolism may regulate tumor immunogenicity. These data suggest that lipid metabolic genes should be further explored as potential therapeutic targets for pts with NSCLC and *KRAS-STK11* alt. Research Sponsor: This work was funded by Tempus AI, Inc.

A large validation study of AI-powered PD-L1 analyzer compared to pathologists' assessment of PD-L1 expression in lung cancer. First Author: Yoshitaka Zenke, Department of Thoracic Oncology, National Cancer Center Hospital East, Kashiwa, Japan

Background: Programmed death ligand 1 (PD-L1) expression is a useful biomarker for immune checkpoint inhibitors in advanced lung cancer. However, pathologists' manual evaluation of PD-L1 expression has practical limitations, including observer bias. The development of artificial intelligence (AI)-powered PD-L1 evaluation models has recently progressed. We evaluated the concordance rate of PD-L1 expression as assessed by pathologists and an AI-powered PD-L1 analyzer in lung cancer patients. **Methods:** This multicenter prospective observational study included patients with stage II to IV or recurrent lung cancer (LC-SCRUM-IBIS). PD-L1 Tumor Proportion Score (TPS) was assessed in lung biopsy specimens, by using a 22C-3 Immunohistochemistry (IHC) assay and scanned at ×40 magnification using a whole-slide images scanner (Hamamatsu Photonics). The results of PD-L1 TPS were evaluated independently by three lung pathologists trained in IHC assessment of PD-L1 expression. We examined an AI-powered PD-L1 TPS analyzer, namely Lunit SCOPE PD-L1. **Results:** Between February 2017 and May 2018, 1,017 lung cancer patients were enrolled. Of these, adequate tumor samples allow for PD-L1 IHC assays; 847 non-small cell lung cancer (NSCLC) patients and 102 small cell lung cancer (SCLC) patients. Lunit SCOPE PD-L1 training included annotations of a total of 64,245,935 tumor cells. Regarding patients characteristics, the median age was 66, 31% were female, 75% were ever smokers, and the distribution of stages was as follows: stage II, III, IV, or recurrence in 37, 97, 632, and 183 patients, respectively. The histological subtypes included in NSCLC, non-squamous (666 patients), squamous (181 patients). Additionally, 85% were diagnosed by biopsy specimens. In comparing PD-L1 TPS assessed by AI and pathologists, the overall concordance rate was 70% with a kappa value of 0.56 (95% confidence interval [CI], 0.49–0.61). The concordance rate according to PD-L1 TPS ≥50%, 1-49%, and <1% was 84%, 94%, and 44%, respectively. Of the 416 patients whom pathologists determined to be TPS <1%, 231 (55%) were TPS 1-49%, and only one patient was determined to be TPS ≥50% by AI analyzer. In SCLC patients' analysis, 84% of patients were determined to be PD-L1 <1% by pathologists, with a low concordance rate of 61% (k = 0.29) between pathologists and AI analyzer. **Conclusions:** PD-L1 TPS demonstrated a high concordance between pathologists and AI analyzers in lung cancer patients with TPS ≥50% and 1-49%. However, the concordance rate of TPS <1% was low regardless of histology. We will confirm if the AI analyzer accurately predicts treatment outcome, especially in TPS <1%. Clinical trial information: UMIN000026425. Research Sponsor: Lunit Company.

Artificial intelligence-powered spatial analysis of tumor microenvironment in non-small cell lung cancer patients who acquired resistance after EGFR tyrosine kinase inhibitors. First Author: Yeong Hak Bang, Division of Hematology-Oncology, Department of Medicine, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, South Korea

Background: We evaluated dynamic changes in the tumor microenvironment (TME) after EGFR tyrosine kinase inhibitor (TKI) treatment using an artificial intelligence (AI)-powered spatial TME analyzer and assessed the predictive efficacy of immune checkpoint inhibitors (ICIs) as monotherapy or in combination therapy. **Methods:** An AI-powered whole-slide image (WSI) analyzer (Lunit SCOPE IO, Lunit, Seoul, Korea) segmented cancer area (CA), stromal area (CS), and identified tumor-infiltrating lymphocytes (TILs), tertiary lymphoid structures (TLS), fibroblasts (Fibs), and endothelial cells (ECs) in tumor tissue. We analyzed 143 non-small cell lung cancer (NSCLC) samples post-resistance to EGFR TKIs from two cohorts: 1) patients (pts) treated with ICIs at Samsung Medical Center, Korea (October 2015–July 2022), and 2) pts from the ATTLAS phase 3 trial comparing atezolizumab plus bevacizumab, paclitaxel, and carboplatin (ABCP) versus pemetrexed plus carboplatin (PC). Among these, 89 pts received ICI monotherapy, and 54 were from the ATTLAS trial (ABCP: 36, PC: 18). Paired pre-treatment samples were available for 89 pts (62.8%), and whole transcriptome sequencing was performed on 42 samples. **Results:** In the combined pre- and post-TKI samples, TLS area per CA correlated with the TLS signature (ρ=0.439, P=0.003), Fibs with the cancer-associated fibroblast signature (ρ=0.581, $P<0.001$), TILs with the interferon-gamma signature (ρ=0.498, $P<0.001$), and ECs with the angiogenesis signature (ρ=0.315, P=0.042), but not VEGF signatures (ρ=0.183, P=0.71). Post-TKI samples showed reduced TILs in CA (P=0.045) and increased ECs in CA (P=0.005), with no significant changes in Fibs (P=0.819) or TLS area (P=0.884). Changes differed by EGFR mutation subtype: L858R mutations were linked to increased ECs (P=0.009), while T790M mutations and exon 19 deletions (19del) were linked to reduced TILs (P=0.033, P=0.045). Higher TILs in CA were associated with better overall response rate (ORR, 41.7% vs. 9.7%, P=0.003) and progression-free survival (PFS, 4.9 vs. 1.8 months, HR=0.41 [95% CI: 0.21–0.79]). Similarly, higher EC levels in CA correlated with improved ORR (19.3% vs. 3.7%, $P<0.01$) and PFS (2.0 vs. 1.4 months, HR=0.44 [95% CI: 0.28–0.71]). In the ATTLAS cohort, these factors were associated with clinical benefits from ABCP, with a significant association for TILs (HR=0.42 [95% CI: 0.19–0.91, P=0.027]) and a marginal association for ECs (HR=0.29 [95% CI: 0.07–1.15, P=0.067]). **Conclusions:** EGFR-TKI alters the immune landscape of NSCLC. Higher TILs or ECs in CA were significantly associated with favorable outcomes to ICI or combination treatment. Research Sponsor: None.

Molecular analysis of lung adenocarcinomas from the SAFIR02-Lung trial explores metastasis-associated alterations and potential prognostic markers. First Author: Abderaouf Hamza, Institut Curie Paris, Paris, France

Background: Lung adenocarcinoma (LUAD) molecular heterogeneity influences diagnosis, prognosis, and treatment. Molecular profiling of advanced lesions remains limited compared to early tumors. We analyzed tumors from the SAFIR02-Lung trial to identify molecular alterations associated with advanced LUAD. **Methods:** We analyzed 366 advanced LUAD tumor samples (250 locoregional [lrmLUAD], 116 distant metastases [dmLUAD]) from metastatic patients in the SAFIR02-Lung trial using targeted sequencing of 45 cancer-related genes and comparative genomic hybridization arrays. Data from The Cancer Genome Atlas (TCGA) and three public datasets—MSK-MET, Jee et al., and the AACR Project GENIE—validated our findings. **Results:** Advanced tumors exhibited greater chromosomal instability than early-stage lesions, (fraction of genome altered: 28.0% in lrmLUAD, 29.1% in dmLUAD and 7.2% in early-stage LUAD, $p < 0.01$). Copy-number alterations implicated *LAMB3, TNN/KIAA0040/TNR*, *KRAS, DAB2, MYC, EPHA3, VIPR2* in tumor progression and *AREG, ZNF503, PAX8, MMP13, JAM3, MTURN* and *CDKN2A* in metastasis. *CDKN2A* homozygous deletions correlated with poor outcomes in early-stage LUAD (hazard ratio = 2.17, 95% CI: 1.43–3.28, p = 0.01). *KRAS* mutant allele-specific imbalance (MASI), marked by mutant allele amplification, was enriched in advanced samples (8.4% lrmLUAD, 13% dmLUAD, 2.8% early-stage LUAD). Public cohort validation confirmed higher *KRAS* MASI prevalence in metastatic samples vs. primary tumors (3.17% vs. 1.4%; pooled odds ratio = 2.23, 95% CI: 1.43–3.51, $p < 0.01$). *KRAS* MASI tumors were enriched in *CDKN2A, MYC, TP53, and NKX2-1* alterations, and displayed less *STK11* and *KEAP1* variants. **Conclusions:** Chromosomal instability drives disease progression in LUAD. *CDKN2A* homozygous deletions are a negative prognostic biomarker in early-stage tumors. Metastasis-associated alterations, including *KRAS* MASI and *CDKN2A* deletions, highlight mechanisms of progression and potential prognostic biomarkers, warranting further investigation and therapeutic exploration. Clinical outcomes and characterization of HER2 alterations in non-small cell lung cancer (NSCLC). First Author: Nikita Dahake, Temple University Hospital, Philadelphia, PA

Background: Subsets of NSCLC carry alterations in the human epidermal growth factor receptor 2 (HER2) gene such as mutations (mt), amplification (amp), and protein overexpression. These alterations reflect distinct patient (pt) populations and disease biology, translating to variable outcomes with immunotherapy +/- chemotherapy. HER2-directed therapies have shown significant efficacy for HER2 mt and to a lesser extent HER2 3+ NSCLC. We describe the genomic landscape of HER2-altered NSCLC in a large cohort of tumors from the Caris database and explore pt outcomes. **Methods:** Next-generation sequencing of DNA (592-gene or WES) and RNA (WTS) was performed on NSCLC samples (n=52,690, Caris Life Sciences, Phoenix, AZ). IHC was performed on FFPE sections (HER2 staining intensity of 2+, >5%). HER2 amp was defined as copy number > 6. Tumor microenvironment studies were calculated by QuantiSeq. Significance was calculated using chi-square, Fisher's exact, or Mann-Whitney U test, with p-values adjusted for multiple comparisons ($q<0.05$). Overall survival (OS) was estimated from insurance claims data using Cox proportional hazards model to calculate hazard ratio (HR) and log-rank tests to calculate P values. **Results:** 670 tumors were HER2 mt (N=492 within the kinase domain, 133 extracellular domain, 47 transmembrane domain, 16 other, 400 HER2 amp, and 272 HER2 IHC 2+. Treatment (tx) received prior to tumor sample collection is not reported in 64.2% HER2 mt, 68.8% HER2 2+, 56.5% HER2 amp (may reflect tx naive pts). Among female pts, HER2 mt was more common than amp or overexpressed 3+ (59.7% vs. 39.8% vs 36.2% $p<0.01$). HER2 mt correlated with improved OS compared to HER2 amp and a cohort of NSCLC driverless tumors (wild type EGFR, ALK, ROS1, RET, KRAS, and HER2). When compared to ROS1+, ALK+ and EGFR mt, HER2 mt had shorter OS (Table). Higher frequency of co-mts are noted in HER2 amp vs mt, including TP53 (90% vs 57%), EGFR (10% vs 6%), SMARCA4 (12% vs 5%), CDKN2A (16% vs 5%), NKX2-1 (2% vs 0.5%) and TMB-H (47% vs 21%), all $p<0.001$. No differences in PD-L1 expression were observed. Higher frequency of co-mts for HER2 IHC 2+ vs HER2 mt, including KRAS (33% vs 3%), KEAP1 (21% vs 7%), BRAF (5% vs 0.8%), EGFR (13% vs 6%) and SMARCA4 (11% vs 5%), all $p<0.001$. HER2 mt tumors had greater infiltration of NK cells, B cells, M2 macrophages, neutrophils and Tregs (FC 1.2-1.3) vs. HER2 IHC 2+. **Conclusions:** This study highlights the significant differences in OS and co-alterations for HER2 mt vs other HER2 altered and NSCLC driverless tumors. This data confirms the unmet need to further explore these differences to optimize tx and improve OS. Research Sponsor: None.

NSCLC cohorts compared to HER2 mt cohort (22.0 months).

NSCLC Cohort	Survival (months)	HR, 95% CI	p-value
HER2 amp	12.3	0.67 (0.57-0.79)	<0.001
HER2 2+	14.1	0.92 (0.77-1.09)	0.33
Driverless	16.2	0.85 (0.77-0.94)	<0.01
ROS1 fusion	35.3	1.3 (1.0-1.7)	0.02
ALK fusion	47.4	1.9 (1.6-2.3)	<0.001
EGFR mt	30.7	1.3 (1.2-1.5)	<0.001

Spatial transcriptomic profiling of the tumor microenvironment in EGFR and KRAS mutant non-small cell lung cancer. First Author: Fabian Johannes Bolte, University of Virginia Cancer Center, Charlottesville, VA

Background: Immune checkpoint inhibitors have greatly improved outcomes in advanced non-small cell lung cancer (NSCLC). However, patients with EGFR mutant NSCLC have a poor response to immune checkpoint inhibitor therapy. Emerging evidence suggests that an immunosuppressive tumor microenvironment plays an important role in this setting, however, we still lack fundamental knowledge about tumor endothelial cell biology. We hypothesized that oncogene specific changes in the expression of immune-related genes in tumor endothelial cells account for differences in the tumor microenvironment and efficacy of immune checkpoint inhibitor therapy. **Methods:** We utilized spatial transcriptomics (GeoMx Digital Spatial Profiling) on resected tumor tissue of EGFR mutant (n = 5) and KRAS mutant (n = 5) NSCLC patients to investigate the transcriptional signature of tumor, endothelial and stromal cells. Additionally, we used NicheNet to explore intercellular communication between tumor, endothelial, and stromal cells. Immune gene set enrichment analysis scores were calculated using ESTIMATE. Immune cell type proportions were estimated using CIBERSORT. **Results:** Using spatial transcriptomics, we dissected the tumor microenvironment into tumor, stromal and endothelial compartments. By analyzing predicted cellular communication, we found that tumor and stromal cells primarily affect an interferon-related gene signature in tumor endothelial cells. Notable differentially expressed interferon-related genes, that were significantly up-regulated in KRAS mutant and down-regulated in EGFR mutant NSCLC patients, included CXCL9, STAT1, WARS1, IRF1 and ICAM1. In the stromal compartment, immune gene set enrichment analysis scores were significantly lower in EGFR mutant than KRAS mutant NSCLC (median, 355 vs. 713, P = 0.026) indicating an immunosuppressive tumor microenvironment. We observed substantial heterogeneity while exploring the cellular landscape of the stromal compartment in EGFR mutant and KRAS mutant NSCLC. Notably, we found a significantly decreased proportion of pro-inflammatory macrophages in the stromal compartment of EGFR compared to KRAS mutant NSCLC (P = 0.006). **Conclusions:** We identified distinct interferon-related gene signatures in tumor endothelial cells of patients with EGFR and KRAS mutantNSCLC associated with variations in the cellular composition of the tumor microenvironment. This may provide a better understanding for the development of spatial biomarkers to identify which oncogene-driven NSCLC patients are most likely to benefit from immune checkpoint inhibitor therapy. Immune landscape of liver metastases in advanced lung cancer. First Author: Kamya Sankar, Cedars-Sinai Medical Center, Los Angeles, CA

Background: The liver is a frequent site of metastasis and carries a poor prognosis in patients with non-small cell (NSCLC) and small cell lung cancer (SCLC). Patients with liver metastases (LM) derive limited benefit from immune checkpoint inhibitors (ICI), due to hepatic myeloid derived suppressor cell (MDSC) mediated T cell elimination. Here, we used imaging mass cytometry (IMC) to perform single cell, highly multiplexed, analysis of LM and primary lung tumors to investigate how vascular endothelial growth factor (VEGF) influences T cell depletion within the tumor immune microenvironment (TIME) of LM. **Methods:** We comprehensively characterizedthe TIME in LM and primary lung tumors in 21 patients with NSCLC or SCLC using IMC. A panel of 40 antibodies was assembled to interrogate immune subsets and VEGF pathway markers. Each antibody was conjugated to a unique metal isotope. After validation, the antibody cocktail was used to stain the biopsies. Tissue images were segmented using Mesmer, and hierarchical clustering was applied to single-cell expression data to identify phenotypes. Similar clustering of cell neighbor profiles was applied to obtain spatial motifs. Phenotypic and motif frequencies, together with functional expression across phenotypes, were compiled from all samples and compared across conditions. **Results:** Initial visualization of the raw, unsegmented data revealed higher infiltration of $CD8^+$ and $CD4^+$ T cells in LM compared to the lung TIME. After segmentation, marker expression heatmaps uncovered complex cell-cell interaction ecosystems. The liver samples were enriched with M2 macrophages ($CD163^+$), MDSC ($CD11b^+$), and proliferative endothelial cells ($CD105^+$) whereas the lung samples were enriched in tumor cells ($TTF1^+$ for NSCLC and $INSM1^+$/synaptophysin$^+$ for SCLC) and T cells ($CD4^+$, $CD8^+$). Spatial neighborhood profiling of NSCLC liver tissues identified 12 neighborhood types, showing a general trend of mutual exclusivity between MDSCs and $CD4^+$/$CD8^+$ T cells across neighborhoods. Notably, $CD8^+$ T cells in MDSC-enriched neighborhoods exhibited consistently higher FAS expression, a key apoptotic marker. Heterogenous FAS and VEGF signaling across neighborhoods suggested a mixed immune-suppressive and vascularized response in the liver TIME, supporting VEGF's role in mediating MDSC-driven hepatic $CD8^+$ T cell depletion in patients with LM. **Conclusions:** Our findings highlight significant differences in the TIME between LM and primary lung tumors, with LM demonstrating a more immunosuppressive and VEGF-enriched milieu. The spatial association of MDSCs with $CD8^+$ T cells, along with elevated FAS expression and VEGF signaling suggests a mechanistic role for VEGF in driving immune evasion within liver tumors. These results underscore the potential of VEGF blockade as a therapeutic strategy to overcome T cell suppression and improve ICI efficacy in patients with lung cancer metastatic to liver (NCT05588388, PI Sankar). Biomarker testing of lung cancer in North America versus globally. First Author: Matthew Paul Smeltzer, University of Memphis School of Public Health, Memphis, TN

Background: Biomarker testing is essential to optimize lung cancer (LC) care, yet uptake of testing is suboptimal due to lack of access, cost, and long turnaround times (TAT). Recent advances now require biomarker testing in early-stage LC. In 2024, the International Association for the Study of Lung Cancer (IASLC) launched a 2nd global survey to measure improvements and barriers to implementation of testing. We compared results from North America (NA) with global results by high income (HIC) and low or middle income countries (LMIC). **Methods:** A multi-disciplinary committee of oncologists, pathologists, pulmonologists, epidemiologists, and advocacy partners created the survey. We used mixed methods, with focus groups and in-depth interviews informing the quantitative survey with IRB oversite. Chi-square tests were utilized to compare frequencies between NA v Other HIC (OHIC) and HIC v LMIC. **Results:** Of the 1677 responses globally, 1501 were from HIC and 176 from LMIC. HIC included 337 responses from NA (287 United States and 50 Canada). Nearly all NA respondents (99%) believe biomarker testing significantly impacts patient outcomes and 94% report a clear understanding of who should be tested (v 91% OHIC, p=0.09). In NA, 66% and 40% ranked biomarker testing as highly important in late- and early- stage LC, respectively (64% and 28% OHIC, p=0.68 and p<0.01). Only 45% of NA respondents were satisfied with biomarker testing conditions (v 52% OHIC, p=0.03), and 69% estimate at least half of LC patients receive biomarker testing (71% OHIC), an increase from 45% in the 2018 survey (p<0.01). We found 40% of respondents from NA sometimes or often began treatment prior to obtaining biomarker results (41% OHIC). Key barriers identified were cost (23%), time (22%), and sample quality (20%), consistent with global and OHIC trends. Mean TAT in NA was 17.1 days (SD 7.8) v 16.1 days (SD 9.0) in HIC. Insufficient tumor was the primary cause for re-biopsy in late and early-stage patients for NA (58%) and HIC (48%). Lastly, 14% of NA reported no additional training in next-generation sequencing beyond medical education (16% OHIC). Globally, conditions were worse in LMIC v HIC including those who sometimes or often begin treatment prior to obtaining biomarker results (73% v 41%, p<0.01) and those who are confident or extremely confident in the adequacy of testing at their institution (48% v 68%, p<0.01). **Conclusions:** Respondents from NA believe they understand the value of biomarker testing for LC and who should be tested. Testing practices have reportedly improved since 2018, yet less than half of NA respondents are satisfied with biomarker testing practices and many patients are still treated without biomarker information. Responses from NA were similar to OHIC, with some exceptions, but significant disparities were evident in LMIC. We identified key barriers that should be addressed to optimize testing practices and patient outcomes. Prediction of site-specific immune-related adverse events of PD-L1 blockade in advanced non-small cell lung cancer through baseline organ-metastatic landscape: Pooled post-hoc analyses of two randomized controlled trials. First Author: Si-Heng Wang, The First Affiliated Hospital, Sun Yat-sen University, Guangzhou, China

Background: The patterns of immune-related adverse events (irAEs) during immunotherapy vary among tumors of different origins. However, it remains unknown whether metastases in different organs confer varying susceptibility to irAEs in a specific tumor type. Herein, we explored the impact of the baseline organ-metastatic landscape on the irAE patterns following PD-L1 blockade in advanced non-small cell lung cancer (NSCLC). **Methods:** We conducted a pooled post-hoc analysis of 708 patients with advanced NSCLC who received atezolizumab from two randomized controlled trials (OAK and POPLAR). The association between the baseline metastatic status and both overall and site-specific irAEs was analyzed using multivariate logistic regression and multivariate Cox regression. The Kaplan-Meier method with the log-rank test was leveraged to compare the cumulative risk of irAEs based on organ-specific metastatic status. **Results:** Patients harboring different organ metastases yielded varying vulnerability of irAEs (p = 0.047). Overall, irAEs were less likely to occur in patients with bone metastases (OR = 0.52, p = 0.039) and pleural effusion metastases (OR = 0.65, p = 0.039), while more frequent in patients with brain metastases (OR = 1.96, p = 0.023). Besides, patients with bone metastases experienced a significant delayed onset of irAEs compared to those with metastases to other organs (HR = 0.65, p = 0.007). In terms of the incidence of site-specific irAEs, hepatitis (OR = 0.55, p = 0.03), hypothyroidism (OR = 0.27, p = 0.008), and rash (OR = 0.63, p = 0.039) were less frequent in patients with bone metastases, whereas pneumonia (OR = 3.25, p = 0.046), adrenal insufficiency (OR = 12.71, p = 0.019) and ocular inflammatory toxic (OR = 21.17, p = 0.017) were more concentrated in patients with brain metastases; adrenal insufficiency was particularly prevalent in patients with adrenal metastases (OR = 15.22, p = 0.023). As for the onset of site-specific irAEs, patients with bone metastases experienced significantly earlier onset of hypothyroidism (HR = 0.27, p = 0.008), while those with metastases to brain (HR = 7.81, p = 0.029) and adrenal glands (HR = 12.54, p = 0.029) developed later onset of adrenal insufficiency; liver metastases were associated with earlier onset of hepatitis (HR = 1.8, p = 0.018) and colitis (HR = 5.49, p = 0.033). **Conclusions:** The baseline organ-metastatic landscape might be a predictive factor for overall and site-specific irAEs in advanced NSCLC patients received PD-L1 blockade. Our findings enhance the understanding of organ-specific immunity in immunotherapy under the metastatic setting of NSCLC and may inform personalized immunotherapy strategies. A phase II trial to evaluate the safety and efficacy of SSGJ-707, a bispecific antibody targeting PD-1 and VEGF, as a monotherapy in patients with advanced NSCLC. First Author: Lin Wu, Hunan Cancer Hospital, Changsha, China

Background: SSGJ-707 is a recombinant humanized bispecific molecule built on IgG4 that targets the human programmed death 1 (PD-1) and vascular endothelial growth factor (VEGF). The increase of SSGJ-707 affinity for PD-1 was 10-fold more than that of Ivonescimab in the presence of VEGF. Here, we report the initial results from a phase II study of SSGJ-707 monotherapy in patients (pts) with advanced NSCLC(SSGJ-707-NSCLC-II-01, NCT06361927). **Methods:** Pts with treatment naive advanced NSCLC (without actionable genomic alterations and PD-L1 expression≥1%) were enrolled to receive SSGJ-707 monotherapy until disease progression or unacceptable toxicity. Tumor assessments based on RECIST 1.1 were performed every 6 weeks by investigators. **Results:** As of Jan 10, 2025, 83 NSCLC pts have received SSGJ-707 at dose of 5mg/kg Q3W (n=31), 10mg/kg Q3W (n=34), 20mg/kg Q3W (n=12), 30mg/kg Q3W(n=6). Overall, the median age was 64 years, 83.1% had ECOG PS of 1, 44.6% of pts with squamous cell carcinoma, 66.3% and 33.7% of pts had PD-L1 expression 1%-49% and ≥50%. Among the 76 pts completed at least one efficacy evaluation, ORR and DCR were 29.6% (8/27)/85.2% (23/27), 61.8%(21/34)97.1% (33/34), 54.5% (6/11)/90.9% (10/11) and 25% (1/4)/75% (3/4) at doses of 5mg/kg Q3W, 10mg/kg Q3W, 20mg/kg Q3W and 30 mg/kg Q3W, respectively. SSGJ-707 10mg/kg Q3W demonstrated promising efficacy results in treatment naive advanced NSCLC. Select subgroups are summarized in SSGJ-707 10mg/kg Q3W. The ORR were 54.5% (12/22) and 75%(9/12) in non-squamous and squamous pts respectively. And the ORR were 57% (12/21) and 69%(9/13) in PD-L1 TPS 1%-49% and ≥ 50% pts respectively. 25 pts completed at least two efficacy evaluation in SSGJ-707 10mg/kg Q3W, the ORR was 72% (18/25), DCR was 100% (25/25). For the 83 pts, 65 pts (78.3%) experienced treatment related adverse events (TRAEs), 20 pts (24.1%) experienced grade≥3 TRAEs. The most common TRAEs included hypercholesterolaemia (18.1%,15/83), hypertriglyceridaemia (18.1%,15/83), alanine aminotransferase increased (15.7%,13/83) and aspartate aminotransferase increased (15.7%,13/83). TRAE leading to discontinuation occurred in 6% of pts. **Conclusions:** SSGJ-707 monotherapy demonstrated promising efficacy results in treatment naive advanced NSCLC with manageable safety profile. Monotherapy and combination trials with chemotherapy for NSCLC are still ongoing. Research Sponsor: 3S BIO.COM. Clinical trial information: NCT06361927. Clinical features associated with an exceptional response to immunotherapy in patients with metastatic non-small cell lung cancer (NSCLC). First Author: Yunan Nie, Yale Cancer Center, New Haven, CT

Background: Immunotherapy with PD1 axis inhibitors is approved for metastatic non-small cell lung cancer (NSCLC). Outside of tumor PD-L1 expression, which predicts immunotherapy sensitivity in metastatic NSCLC, no clinicopathologic characteristics have been identified that reliably predict long-term survival after immunotherapy. To identify clinicopathologic predictors of exceptional response, we compared patients with dissimilar outcomes after immunotherapy. **Methods:** Patients with advanced NSCLC treated at Yale Cancer Center with immunotherapy between 2010–2020 were enrolled on an IRB-approved protocol allowing chart review of clinicopathologic data and further archival tumor tissue analysis. Data collection cutoff was January 14, 2025. We defined three subsets of patients who received immunotherapy without concurrent chemotherapy: Exceptional responders (ER) (continued response without progression ≥3 years after first dose), non-exceptional responders (NER) (initial response followed by progression within 3 years), and primary progressors (PP) (best response of progressive disease). **Results:** 50 ER, 45 NER, and 62 PP were identified. At a median follow-up of 7.2 years, 25, 9, and 6 ER had continued response at 5, 7, and 10 years. ER had a lower frequency of baseline lung, bone, and liver metastases, prior chemotherapy (p=0.005), or lymph node/thoracic radiation (p=0.016) than NER and PP. ER had higher pre-treatment absolute lymphocyte count (ALC) and lymphocyte-to-albumin ratio (LAR), with lower platelet-to-lymphocyte ratio (PLR) and monocyte-to-lymphocyte ratio (MLR). Of 24 evaluable ER patients, 19 had tumor PD-L1 TPS score ≥50%, compared to 13/21 evaluate NER and 14/34 valuable PP. 47/50 ER were nonsquamous, compared to 36/45 NER and 53/62 PP. Compared to NER only, ER were less likely to have bone metastases (p=0.049) or prior lymph node/thoracic radiation (8% vs 24%, p=0.028). Variables associated with primary progression were female sex (OR = 3.73, 95% CI 1.55–8.9), lung metastases (OR 6.46, 95% CI 2.73–15.27), and low albumin (OR 0.29, 95% CI 0.12–0.72). The presence of brain metastases was not different between cohorts. **Conclusions:** Patients with metastatic NSCLC exhibiting exceptionally durable responses to immunotherapy demonstrate distinct baseline features, with higher pre-treatment ALC and LAR, lower PLR and MLR, and lower prevalence of lung, bone, or liver metastases. They were less likely to have had thoracic/lymph node radiation, suggesting lymph node radiation may influence immunotherapy response. Ongoing molecular studies of biospecimens from these patients include genomic/transcriptomic analysis, HLA typing, and tumor microenvironment analysis of archived tissue to further characterize drivers of differential immunotherapy response. Research Sponsor: None.

Breaking barriers for patients with stage IV non-small cell lung cancer with brain metastases: Insight into the impact of immunotherapy on survival and survival disparities. First Author: Reema Tawfiq, Mayo Clinic Florida, Jacksonville, FL

Background: Brain metastases (BM) correlate with poor prognosis, occurring in 10% of non-small cell lung cancer (NSCLC) patients (pts) at diagnosis and up to 40% over the disease course. Immunotherapy (IO) with or without chemotherapy has become the new standard of care for stage IV NSCLC. However, the survival benefit of IO in pts with BM remains unclear as most studies are limited to small sample sizes or highly selected pts with asymptomatic or treated BMs. This study represents the largest real-world data analysis evaluating the survival benefits of IO in stage IV NSCLC pts with BM. **Methods:** Demographics, clinical features, and survival were analyzed in stage IV NSCLC pts with BM from the National Cancer Database (NCDB) from 2014-2020. A multivariate Cox proportional hazards modeling assessed factors impacting mortality. **Results:** Of 204,249 pts with stage IV NSCLC, 30% had BM. The mean age was 68 years, with 54% male. Most pts were White (82%), followed by Black (12%) and Asian (3.1%). Government insurance covered 70% of pts, and 26% had private insurance. Adenocarcinoma was the predominant histology (62%), followed by squamous cell carcinoma (SCC) (20%). Liver and bone metastases were observed in 19% and 42% of pts, respectively. Among pts with BM, 18% received immunotherapy, 53% received chemotherapy, 66% received whole-brain radiation, and 18% received limited-brain radiation. Multivariate Cox analysis showed that pts receiving IO had a 46% lower mortality risk compared to not receiving IO (HR: 0.54, 95% CI: 0.51–0.56, $p < 0.001$), demonstrating the independent benefit of IO in pts with BM, regardless of brain radiation or chemotherapy. Females had a lower mortality risk than males (HR: 0.88, 95% CI: 0.85–0.91, $p < 0.001$). Asian (HR: 0.71, 95% CI: 0.64–0.79), Hispanic (HR: 0.76, 95% CI: 0.65–0.89), and Black pts (HR: 0.88, 95% CI: 0.84–0.93) had improved survival as compared to White. Pts with private insurance have lower mortality risk (HR: 0.94, 95% CI: 0.90–0.98), compared to lack of insurance (HR: 1.19, 95% CI: 1.08–1.31). SCC was linked to worse survival (HR: 1.28, 95% CI: 1.22–1.35). **Conclusions:** IO significantly improves survival in pts with NSCLC with BM, regardless of brain radiation therapy or chemotherapy. However, survival disparities based on histology, insurance status, and demographic factors persist, highlighting the need for more equitable treatment strategies. Research Sponsor: None.

Association between pretreatment emotional distress and survival outcomes in patients with advanced non–small-cell lung cancer: An individual patient data meta-analysis of 4632 patients in 7 trials. First Author: Jian-Guo Zhou, The Second Affiliated Hospital of Zunyi Medical University, Zunyi, China

Background: Emotional distress (ED) associated with worse survival outcomes in patients with melanoma and non-small-cell lung cancer treated with immune checkpoint inhibitors (ICIs). However, several preclinical studies suggest the association between stress and cancer treatment extends beyond ICIs alone. Here we used an individual patient data (IPD) meta-analysis of 4632 patients in 7 trials and a Kaplan-Meier analysis to verify broader connection between ED and survival outcomes in NSCLC patients. **Methods:** We searched Vivli data-sharing platform for studies which reported clinical trials of advanced NSCLC patients treated with atezolizumab and used the EORTC QLQ-C30 scale to define ED status of patients. Integrating IPD and grouped them into four groups according to ED status and treatment, Kaplan-Meier analysis was conducted to estimate median overall survival (mOS) and progression-free survival (mPFS) for each group. Next we utilized the Cox proportional hazards model to estimate hazard ratios (HRs) and 95% CIs for OS and PFS of each trials. The IPD meta-analysis was conducted to generate summary estimates of results of aggregated data. **Results:** Among a total of 4632 participants, 2753 (59.43%) received first-line treatment; 3162 (68.26%) received ICIs; 1802 (38.90%) classified as ED and 2830 (61.10%) classified as non-ED. Kaplan-Meier analysis indicate that ED patients associate with worse survival outcomes, regardless of ICIs or chemotherapy (CT) (HROS=1.21, p=0.01; HRPFS=1.19, p=0.01). Compared with non-ED, ED patients had worse OS in both ICIs (ED vs non-ED, mOS, 13.34 m vs 16.07 m; p=0.01; HR, 1.21 [1.09-1.34]) and CT (ED vs non-ED, mOS, 12.02 m vs 13.93 m; p=0.01; HR, 1.19 [1.04-1.37]). IPD meta-analysis indicate that the ED group exhibited worse OS outcome (HR=1.18 [1.07-1.30], p=0.01). Subgroup analysis confirmed this association in both ICIs (HR=1.18 [1.04-1.34], p=0.01) and CT groups (HR=1.18 [1.00-1.39], p=0.05). Excluded clinical trials which PFS not primary outcome, and investigated the association with ED and PFS in first-line clinical trials. Similarly, Kaplan-Meier analysis show ED patients had worse PFS regardless of ICIs (mPFS, 5.52 m vs 5.58 m; p=0.01; HR, 1.19 [1.06-1.33]) or CT (mPFS, 5.55 m vs 5.59 m; p=0.06; HR, 1.17 [0.99-1.37]). IPD meta-analysis of PFS also supported results above (HR=1.15 [1.03-1.28], p=0.02). **Conclusions:** The NSCLC patients with ED are significantly associated with adverse survival outcomes regardless of CT or ICIs. The findings recommend the implementation of ED status assessment in clinical practice for NSCLC patients to improve their survival outcomes. Research Sponsor: None.

First-in-human study of CJRB-101, a live biotherapeutic product in combination with pembrolizumab in selected types of advanced or metastatic cancer. First Author: Jii Bum Lee, Division of Medical Oncology, Department of Internal Medicine, Yonsei Cancer Center, Severance Hospital, Yonsei University College of Medicine, Seoul City, South Korea

Background: CJRB-101 is a live biotherapeutic product containing a novel strain belonging in the species *Leuconostoc mesenteroides*. Preclinical data support the role of CJRB-101 in eliciting anti-tumor response via induction of macrophage and recruitment of $GZMB^+$ CD8 T cell, thereby eliciting synergy with pembrolizumab. **Methods:** This is a multi-national, open label, phase 1/2 study to evaluate the safety and preliminary efficacy of CJRB-101 with pembrolizumab in patients with non-small cell lung cancer (NSCLC), head and neck squamous cell carcinoma (HNSCC), and melanoma who are immune checkpoint inhibitor (ICI)-naïve or have progressed with ICIs. Patients were treated with pembrolizumab 200 mg every 3 weeks with dose level 1 (1 capsule QD) or 2 (2 capsules BID) of CJRB-101 until unacceptable toxicity or progression of disease. Exploratory endpoints included bulk RNA sequencing of baseline and post-treatment (prior to C2D1) FFPE samples. **Results:** As of Jan 17, 2025, a total of 32 patients were enrolled, including 13 ICI-naïve and 19 ICI-refractory patients. No dose limiting toxicity was observed in the lead in part (dose level 1, n=12) or in subsequent patients in level 2 (n=20). At a median follow-up of 59 days, the median number of treatment cycles was 3. Treatment-related adverse events accounted for 21.9% (n=7/32), mostly grade 1 or 2. Only 1 patient (3.2%) experienced grade > 3 TRAE which was anemia related to CJRB-101. Preliminary efficacy outcomes are shown in Table. Of the 20 patients deemed efficacy evaluable with at least 1 on-treatment scan (ICI naïve, n=10; ICI refractory, n=10), the ORR was 44% for ICI naïve, metastatic NSCLC (n=4/9), and DCR was 30% (n=3/10) for ICI-refractory NSCLC. Bulk-RNA sequencing of baseline samples (n=14) showed that patients who derived clinical benefit (CB, PR+SD, n=7) showed enrichment in T cell activation, and upregulation of innate and adaptive immune response compared to those with no-clinical benefit (NCB; PD, n=7). On treatment biopsied sample showed significant decrease in $PD\text{-}1^+Tim\text{-}3^+$ CD4 (P=0.002) and CD8 (P=0.006) T cells in CB group compared to the NCB group. **Conclusions:** CJRB-101 plus pembrolizumab was well tolerated with manageable safety profile. Preliminary efficacy data show anti-tumor activity in metastatic NSCLC, and early biomarker data support the role of immune activation of CJRB-101. Exploratory analysis of PBMCs, multiplex IHC, PD biomarker, and fecal microbiota metagenomics analysis are ongoing. Clinical trial information: NCT05877430. Research Sponsor: None.

Camrelizumab combined with 2 cycles of chemotherapy as first-line treatment for advanced non-small cell lung cancer (NSCLC): A two-arm, single-center, phase 2 study. First Author: Hongbing Liu, Department of Respiratory and Critical Care Medicine, The Second Affiliated Hospital of Nanjing Medical University, Nanjing, China

Background: In the treatment of advanced non-small cell lung cancer (NSCLC), the combination of anti-PD1 and chemotherapy has demonstrated an advantage over chemotherapy alone. First-line treatment of advanced NSCLC with camrelizumab in combination with platinum-based chemotherapy shows promising clinical activity. Nonetheless, the impact of varying chemotherapy cycles on efficacy and safety requires investigation through data from prospective studies. **Methods:** This was a two-arm, single-center, phase 2 clinical trial (ChiCTR2200065078) in which we assigned patients with stage IIIb-IV advanced non-small cell lung cancer (NSCLC) to receive 2 or 4 cycles of platinum-based chemotherapy combined with camrelizumab 200 mg, followed by camrelizumab maintenance therapy until 2 years. The primary endpoint was progression-free survival, and secondary endpoints were objective response rate (ORR), overall survival (OS) and safety. **Results:** As of December 1, 2024, 40 patients were enrolled in this study, including 16 patients in the 2-cycle platinum-based chemotherapy combined with camrelizumab groups (Group A), and 24 patients in the 4-cycle platinum-based chemotherapy combined with camrelizumab groups (Group B) with a median follow-up of 17.6 months. The patients in Group A are older than those in Group B (75.50 [72.75, 77.25] vs. 69.00 [63.75, 72.25]). The median progression-free survival (PFS) were 5.4 months (95% CI, 4.9 to 5.9) for the group A and 13.0 months (95% CI, 5.6 to 20.4) for the group B, respectively (P=0.195). The confirmed overall response (ORR) was 6.2%, (95% CI, 0.6% to 26.4%) for the Group A and 41.7%, (95% CI, 20.7% to 65.9%) for the Group B, respectively (P=0.036). The median OS were 11.4 months (95% CI, 8.6 to 14.2) for the group A and 24.1 months (95% CI, 17.4 to 30.8) for the Group B, respectively (P=0.079). Across the overall population, 97.5% of patients reported any grade of treatment-related adverse event (TRAE), with 6.2% experiencing grade ≥ 3 TRAEs for Group A, and 12.5% for Group B. **Conclusions:** The 2-cycle group did not show superior progression-free survival (PFS) relative to the 4-cycle platinum-based chemotherapy when combined with camrelizumab. However, the 4-cycle platinum-based chemotherapy group may have resulted in a higher probability of developing grade ≥ 3 treatment-related adverse events. A combination of a 2-cycle chemotherapy and immunotherapy may be more suitable for elderly patients with advanced lung cancer. Clinical trial information: ChiCTR2200065078. Research Sponsor: None.

Evaluation of the combination of regorafenib + avelumab in patients with non-small cell lung cancer without oncogenic addiction: The phase II REGOMUNE study. First Author: Sophie Cousin, Early Phase Clinical Trials Unit and Thoracic Unit, Institut Bergonié, Bordeaux, France

Background: Combining anti-angiogenic agents with immune checkpoint inhibitors (ICI) in NSCLC has a strong biological rational. This strategy may enhance antitumor immunity by downregulating PD-1/PD-L1 expression, increasing TIL infiltration, and reducing immunosuppressive Tregs and MDSCs, potentially resensitizing patients to ICI therapy. **Methods:** This phase II, single-arm, multicentric trial evaluated the combination of regorafenib (160 mg daily, 3 weeks on/1 week off) and avelumab (10 mg/kg Q2W) in advanced/metastatic NSCLC patients without EGFR/ALK/ROS1 alterations. Eligible patients were previously treated with anti-PD(L)1 inhibitors for $\geq$4 months and had received $\leq$2 prior systemic lines. The primary endpoint was the 6-month progression-free rate (PFR6) per RECIST 1.1. Secondary endpoints included overall response rate (ORR), progression-free survival (PFS), overall survival (OS), and safety. Correlative studies analyzed baseline tumor samples to identify biomarkers of response. A Simon's two-stage design was used, requiring $\geq$13 non-progressions among 43 patients to demonstrate efficacy. **Results:** Between February 2021 and April 2024, 46 patients were enrolled across four centers (median age: 63, range: 41-88). Median follow-up was 13.4 months. Most patients (94%) had prior platinum-based chemotherapy. Dose adjustments for regorafenib were required in 78.3% of patients due to adverse events. Common grade 3/4 toxicities included erythroderma (15.2%) and oral mucositis/palmar-plantar erythrodysesthesia (13% each). No treatment-related deaths occurred. Among 34 evaluable patients, PFR6 was 35.3% (90% CI: 21.8-50.8), with 6 (17.6%) achieving partial responses and 16 (47.1%) having stable disease. The median duration of the response was 20.3 months (95% CI: 5.1-22.0). Median PFS was 3.7 months (95% CI: 1.9-8.7), and median OS was 25.5 months (95% CI: 8.7-NR). **Conclusions:** The combination of avelumab and regorafenib demonstrated the ability to resensitize a subset of anti-PD(L)1-exposed NSCLC patients to immune checkpoint inhibition, leading to durable responses and a promising 6-month PFR. Biomarker analyses will also be presented, providing insights into predictors of response. Clinical trial information: NCT03475953. Research Sponsor: None.

Identification of immunotherapy early treatment failure in non-small cell lung cancer (NSCLC) using a novel cell-free DNA (cfDNA) tissue-agnostic genome-wide methylome enrichment assay. First Author: Tuan Hoang, Princess Margaret Cancer Centre, University Health Network, Toronto, ON, Canada

Background: Immune checkpoint inhibitor treatment failure constitutes a significant clinical challenge in non-small cell lung cancer (NSCLC). Molecular residual disease (MRD) detection in NSCLC may allow earlier detection of disease recurrence/progression and enable early treatment intensification or clinical trial enrolment. We have developed a novel tissue-agnostic genome-wide methylation enrichment platform based on cell free methylated DNA immunoprecipitation and high throughput sequencing (cfMeDIP-seq). Here, we present data on its application as an MRD assay to predict early recurrence or progression in patients (pts) with NSCLC receiving immunotherapy. **Methods:** The study population consists of pts with stage III/IV NSCLC at the Princess Margaret Cancer Centre, treated with definitive chemoradiation followed by consolidative durvalumab (stage III) or with PD-1 inhibitors +/- chemotherapy (stage IV). Pts underwent serial blood collection prior to initiation of treatment, 2-4 weeks after treatment initiation and approximately 6-8 weeks thereafter until progression. 5-10 ng of cfDNA was isolated from plasma. A classifier was trained on an independent set of lung and non-cancer samples to quantify relative circulating tumor DNA (ctDNA) content. The analysis considered multiple timepoints. Results were considered "positive" if there was a detected result at any follow-up timepoint. Results were considered "negative" if all follow-up timepoints were reported as not detected. Progression-free survival (PFS) was compared between groups using a log-rank test. Hazard ratio (HR) was estimated using Cox proportional hazards model. **Results:** A total of 187 samples from 63 unique pts (44% stage III and 56% stage IV) were analyzed and correlated with PFS. Pts with a positive MRD test showed significantly worse PFS than those who tested negative (HR 4.8; 95% CI, 2.1-10.8, P$<$0.0001), sensitivity 80%, specificity 91%. The lead time between MRD positivity and progression was up to 12.6 months, with a mean of 5.1 months. Secondary analysis of pts with stage III NSCLC revealed significantly worse PFS in MRD-positive pts compared to MRD-negative pts (HR 8; 95% CI, 1.4-46.7, P=0.007). **Conclusions:** MRD detection using genome-wide methylome enrichment correlates strongly with PFS in pts with advanced NSCLC receiving immunotherapy. This tissue agnostic assay shows promise for early identification of treatment failure, enabling timely selection of patients for treatment intensification or clinical trials. Research Sponsor: None.

8551 Poster Session

A phase I trial of intratumoral adenovirus-interleukin-12 (IT-ADV/IL-12) and atezolizumab in metastatic non-small cell lung cancer (NSCLC) progressed on first-line immunotherapy. First Author: Zainub Ajmal, Houston Methodist Neal Cancer Center, Houston, TX

Background: Interleukin-12 (IL-12) is a cytokine that enhances anti-tumor immunity via interferon-gamma release and has demonstrated synergistic effects with immune checkpoint inhibitors (ICIs) in immunoquiescent tumors. We report results of phase I trial of intratumoral adenovirus-interleukin-12(IT-ADV/IL-12)plus atezolizumab in metastatic NSCLC patients who progressed on prior ICI. **Methods:** This institutional single-arm, open-label phase I trial enrolled 13 patients with metastatic NSCLC who progressed on ICI from October 2021 to February 2024. First 2 patients received IT-ADV/IL-12 at 5×10^{11} viral particles (vp), while the remaining 11 patients received a reduced dose of 3×10^{11} vp as per protocol. Atezolizumab (1200 mg) was given every 3 weeks for up to 1 year or till disease progression. Endpoints were safety (as per Common Terminology Criteria for Adverse Events v5.0) and disease control rate (DCR), including complete response (CR), partial response (PR), or stable disease (SD) as defined by RECIST v1.1. **Results:** 12/13 patients were included in analysis (1 patient excluded due to rapid progression before starting atezolizumab). All patients had initial response to prior ICI (4/12 with CR and 8/12 with PR) but later developed resistance. DCR was 50% (6/12), median progression-free survival (PFS) was 2 months, and median overall survival (OS) was 10.5 months. 2/12 (25%) patients were alive at the time of analysis with median follow up time of 22 months. PD-L1 expression did not affect treatment response. Grade $\geq$3 treatment-related adverse events (TRAEs) occurred in 4 patients, who demonstrated a higher likelihood of treatment response (p = 0.06), with all 4 achieving stable disease (SD). Most common TRAE of any grade was fatigue (4/12, 33%). There were no grade 4 or 5 events, and no treatment discontinuation related to TRAE. Next-generation sequencing results were available in 10/12 patients. The most common mutation was TP53, detected in 9/10 patients. There was no statistically significant association between the presence of TP53 mutation and treatment response. **Conclusions:** IT-ADV/IL-12 plus atezolizumab was safe, tolerable, and showed promising clinical benefit in metastatic NSCLC with acquired resistance to ICI, without new safety concerns. Presence of TP53 mutation did not impact the treatment response. Research Sponsor: Genentech.

Circulating CD28-KLRG1+CD8+ T cells as prognostic indicators in advanced NSCLC chemoimmunotherapy. First Author: Cihui Yan, Department of Immunology, Tianjin Medical University Cancer Institute and Hospital, Tianjin, China

Background: Chemoimmunotherapy has become the standard first-line treatment for advanced non-small cell lung cancer (NSCLC), but patient responses vary. Consequently, identifying predictive biomarkers is crucial to optimize therapeutic strategies. Circulating T cells are a promising focus due to the convenience of blood sampling and the feasibility of repeated monitoring. Deciphering the specific T-cell subsets that respond to chemo-immunotherapy is critical for personalizing treatment and improving outcomes in advanced NSCLC patients. **Methods:** We conducted unsupervised analysis using multi-color flow cytometry on peripheral blood samples from 30 NSCLC patients enrolled in a phase 2 clinical study (ClinicalTrials.gov NCT04836728) to explore correlations between immune cell subsets with therapeutic outcomes. We integrated single-cell RNA and T cell receptor sequencing data from peripheral blood, tumor, and non-tumor tissues of 8 NSCLC patients to study the transcriptional state of key cell types involved in these correlations. **Results:** Flow cytometry analysis revealed that a higher proportion of CD28-KLRG1+ CD8+ T cells was found in the peripheral blood of patients with durable clinical benefit (DCB) and improved overall survival (OS). Within these T cells, the CD57+ subset was positively correlated with OS at baseline, while the CD57- subset was negatively correlated. However, during treatment, both subsets showed a positive association with OS, highlighting the predictive value of CD28-KLRG1+ CD8+ T for chemoimmunotherapy response. Further phenotypic and functional analyses demonstrated that CD28-KLRG1+ CD8+ T cells are highly proliferative (Ki67) and produce anti-tumor cytokines (IFN-γ, IL-2, and TNF-α) upon TCR stimulation, indicating their immune-responsive role. Although these cells expressed relatively low levels of exhaustion markers such as PD-1 and TIGIT, they exhibited high expression of TCF1 and TOX, pointing to a progenitor exhausted T cell state characterized by reduced exhaustion and enhanced functional potential. Single-cell transcriptomic and TCR profiling revealed that CD28-KLRG1+ CD8+ T cells underwent significant clonal expansion in the peripheral blood during chemoimmunotherapy, evidenced by the higher clonality index and lower Inverse Simpson index, indicating their superior clonal expansion capacity upon activation. Longitudinal analysis showed that these cells had the highest proportion of expanded clones during treatment, primarily distributed in the effector T cell clusters, suggesting their anti-tumor activity during chemoimmunotherapy. **Conclusions:** Circulating CD28-KLRG1+ CD8+ T cells are a valuable biomarker for predicting outcomes in first-line chemoimmunotherapy for patients with advanced NSCLC. These findings highlight their functional activity, clonal expansion, and role in antitumor immunity during treatment. T-cell effector cytokine signature as predictor of survival and toxicity in metastatic NSCLC patients treated with immunotherapy. First Author: Varshini Odayar, University of Michigan Medical School, Ann Arbor, MI

Background: Immune checkpoint inhibitors (ICIs) have led to significant prolongation of survival in patients with advanced non-small cell lung cancer (NSCLC). However, less than 20% have durable long-term survival. Presence of a pre-existing tumor immune response that can subsequently be unleashed by ICIs predicts success to ICI. Specifically, a T- cell effector replete tumor immune microenvironment predicts for improved survival, following ICI. Given intra-tumor heterogeneity, we asked whether baseline and on treatment T cell effector mediated serum cytokines predict benefit from ICI in metastatic NSCLC. We also asked whether cytokines predicted immune related adverse events (iRAEs) from ICI in these patients. **Methods:** To assess whether serologic markers were associated with response and toxicity to immunotherapy, we conducted a multiplex ELISA for a panel of 70 innate and adaptive immune cytokines and chemokines in 100 NSCLC patients treated with PD-1 inhibitors, either as monotherapy or in combination with chemotherapy. Cytokine expression was correlated with outcomes (progression- free and overall survival, PFS/OS) and occurrence of any grade 3 or greater iRAE. Kaplan Meier analyses were performed for survival analyses, with the median value used to stratify cytokines. We then compared the predictive value of this cytokine signature with other predictive signatures for outcomes from ICIs. **Results:** Increased concentrations of baseline TRAIL correlated with improved PFS and OS; conversely, decreased baseline IL-3, IL-6, IL-8, APRIL, IL20, IL33, MCP4, IL-7, and TARC correlated with improved PFS. Increased baseline SDF1 and TRAIL correlated with OS; conversely, decreased baseline IL-6, IL-8, TPO, I-TAC, IL-3, APRIL, IL-20, IL-33, MCP4, MCP2, IL-15, MCSF, PDGFa, VEGFA, and MIP1d correlated with improved OS. Increased concentrations of TRAIL correlated with increased concentrations of SDF1, Perforin, and GzmB (T effector cell, Teff signature). A high Teff signature was associated with a statistically significant improvement in OS, in univariate and multivariate analysis. IL1b and IL-17a were statistically higher in on treatment samples taken from in patients who developed IRAE, whereas Eotaxin3 and MIP1d were lower in on treatment samples taken from in patients who developed IRAE. **Conclusions:** We report that an increase in a Teff cell cytokine signature at baseline predicts long term survival from ICI and may reflect the presence of a pre-existing immune response characterized by increased T-effector cells that are then subsequently unleashed by ICI therapy. Conversely, higher baseline levels of IL-1β and IL-17 indicate the presence of a heightened inflammatory state that predisposes to the occurrence of iRAEs, following ICI therapy. Comparative efficacy of osimertinib with and without radiation therapy in EGFR-mutated non-small cell lung cancer with brain metastases. First Author: Rafi Aibani, Charleston Area Medical Center, Charleston, WV

Background: Osimertinib has demonstrated efficacy in managing brain metastases in EGFR-mutated non-small cell lung cancer (NSCLC). However, the optimal approach—using CNS-penetrant tyrosine kinase inhibitor (TKI) therapy alone versus combining it with radiation therapy—remains uncertain. This study examines whether Osimertinib combined with radiation provides superior intracranial control and outcomes compared to Osimertinib alone. **Methods:** Patients aged $\geq$18 years with NSCLC and brain metastases diagnosed between January 2010 and December 2024 were identified via the TriNetX Research Network. Two cohorts were analyzed: those receiving Osimertinib with stereotactic radiation or radiosurgery within six months (cohort 1) and those without radiation (cohort 2). Propensity score matching balanced baseline characteristics. Outcomes included survival, hospitalization rates, CNS complications, and second-line treatment initiation. A Kaplan-Meier analysis evaluated survival and mortality while a Cox proportional hazards model assessed the effects of covariates. **Results:** A total of 76,474 NSCLC patients were identified, 13,377 had brain metastases, and 743 received Osimertinib. Kaplan-Meier analysis indicated lower mortality in cohort 1 at 3 years (HR = 0.674, p = 0.0029), 5 years (HR = 0.719, p = 0.0091), and overall (HR = 0.709, p = 0.0063). CNS complications (risk difference = 20.28%, $p < 0.0001$) were higher in cohort 1, with 11 patients diagnosed with radiation necrosis after treatment, representing a 5.28% risk. Additionally more people in cohort 1 developed interstitial lung disease (risk difference = 9.1%, p=0.0016). Second-line treatment initiation (HR = 1.741, p = 0.0166) was also higher in cohort 1. Key predictors of increased mortality included hypertension (HR = 1.366, p = 0.0047), bone metastases (HR = 1.608, $p < 0.0001$), and liver metastases (HR = 1.319, p = 0.0408). Stereotactic radiosurgery in particular was associated with a lower hazard ratio (HR = 0.487, p = 0.0031). **Conclusions:** Combining Osimertinib with stereotactic radiation or radiosurgery improves survival in NSCLC with brain metastases but may increase CNS complications and second-line treatment rates. These findings highlight the need to balance survival benefits with treatment risks to optimize patient care. Research Sponsor: None.

Updated analysis from NEJ045A study: Safety and efficacy of durvalumab plus carboplatin and etoposide for previously untreated extensive-stage small-cell lung cancer patients with a poor performance status. First Author: Tetsuhiko Asao, Department of Respiratory Medicine, Juntendo University Hospital, Tokyo, Japan

Background: Although the combination of an anti-PD-L1 antibody and platinum-based chemotherapy has become the standard care for extensive-stage small-cell lung cancer (ES-SCLC) patients (pts), its safety and efficacy for those with a poor PS are unclear. In the NEJ045A study, by adjusting the doses of carboplatin (CBDCA) and etoposide (ETP), durvalumab (DUR) plus CBDCA and ETP demonstrated tolerability and efficacy for ES-SCLC pts with a poor PS, meeting the primary endpoint of tolerability. Here, we report the updated data from NEJ045A, including the long-term effects of ICIs. **Methods:** Previously untreated ES-SCLC pts with PS 2–3 were enrolled. Eligible pts received 1500 mg DUR plus CBDCA and ETP every 3 to 4 weeks for up to 4 cycles, followed by DUR maintenance therapy. Initial dosages of CBDCA and ETP were AUC 4 and 80 mg/m^2 in PS 2 and AUC 3 and 60 mg/m^2 in PS 3. The dosages for the subsequent cycles were adaptively determined based on the adverse events (AEs) of the previous cycles. **Results:** From April 2021 to October 2023, 57 pts (43 pts with PS 2 and 14 pts with PS 3) were enrolled. At the data cutoff (Oct 3rd, 2024), the median follow-up period for overall survival among patients with censored data was 23.4 months (12.9-32.7) in the FAS population. The median age was 74 years old (range 55-86). 79% was male. The median number of cycles of induction therapy was 4 (range 1-4), and the median number of cycles of durvalumab maintenance was 3 (range 1-16) in PS 2 and 7 in PS 3 (1-22). A total of 34 patients (64%) completed induction therapy, comprising 28 pts (67%) in PS 2 and 6 pts (50%) in PS 3. Doses of CBDCA and/or ETP were increased during induction therapy in 24% of PS 2, and 18% of PS 3. Updated median PFS in PS 2 and PS 3 were 4.5 months (95% CI, 3.1-5.8) and 4.5 months (95% CI, 1.4-8.2). The 1-year survival rates in PS 2 and PS 3 were 50% (95% CI, 37.0-67.7) and 18% (95% CI, 5.2-63.7). Updated median OS in PS 2 and PS 3 were 11.3 months (95% CI, 6.7- 16.1) and 5.1 months (95% CI, 2.1-8.5). Patients who completed induction therapy demonstrated longer OS compared to those who did not (median OS, 15.0 vs. 3.8 months). Treatment was discontinued in 100% of PS 2 and 93% of PS 3, and the reasons for discontinuation (PD/AE/other) were 79%/12%/9% in PS 2 and 38%/54%/8% in PS 3. **Conclusions:** DUR + CBDCA + ETP therapy was well tolerated for ES-SCLC with poor PS, and completion of induction therapy was associated with an improvement in OS. Clinical trial information: CRB3180025. Research Sponsor: Astra Zeneca.

Avidity engineered multifunctional antibodies for stimulation and orchestration of innate and adaptive immune cells in tumor tissues. First Author: Robert Friesen, Avidicure B.V., Naarden, Netherlands

Background: Antibodies and ADCs are mainstays in the treatment of cancer. However, given difficulties in achieving a deep and sustained response, significant improvements are desirable. We report on first in class "Booster" molecules, based on clinically validated ADCC-competent antibodies, equipped with two immunomodulatory domains that are affinity engineered to be functional only when in contact with a tumor cell. We see strong expansion and increased cytotoxicity of immune cells in the presence of cancer cells *in vitro*, activation of relevant immune cell types *ex vivo*, and reduction of tumor burden *in vivo*, with significantly better activity than adoptive cell therapy or control antibody without these immunomodulatory domains. **Methods:** NRG mice were engrafted with luciferase-expressing SKOV3 cells via intraperitoneal injection 7 days prior to treatment. Mice received 1 million human NK cells isolated from healthy donors. Compounds were administered biweekly, and low dose IL2 thrice weekly. Blood was collected weekly, and tumor burden monitored weekly *via* bioluminescence. *ex vivo*: *in situ* activation of tumor infiltrating immune populations was evaluated by nanostring in freshly isolated tumor tissue. *in vitro*: cytotoxicity was measured by quantifying the number of alive tumor cells using automated microscopy. Expansion was performed by stimulating NK cells weekly with tumor cells that were opsonized with Booster or antibody, NK cells were counted weekly to determine expansion. **Results:** Mice treated with a TROP2 targeting Booster demonstrated superior tumor control than sacituzumab treated mice, with strong tumor remission by day 35. High NK counts were observed in the blood of Booster treated mice, and no NK cells were detected in that of sacituzumab treated mice. In the peritoneal cavity, NK counts were up to 100x higher in Booster treated mice than in sacituzumab treated mice. Our Booster reprograms the immune microenvironment *ex vivo* in freshly isolated tumor tissue, transforming a cold tumor into a hot tumor. It activates multiple cytotoxic and IFN-γ pathways, stimulates CD8+ T cell activation, downregulates pro-tumor pathways in Tregs and induces a phenotypic shift in macrophages from the immunosuppressive M2 to the pro-inflammatory M1 phenotype. In separate *in vitro* assays we saw sustained expansion and enhanced cytotoxicity of NK cells for at least 6 weeks. Cells stimulated with TROP2 Booster showed prolonged tumor control, whereas sacituzumab antibiody stimulated cells failed to sustain tumor control beyond 21 days. **Conclusions:** In correlation with extensive *in vitro* and *ex vivo* data, we observe a prolonged and significant improvement in tumor control in mice treated with Boosters compared to mice treated with control antibody. Work is ongoing to develop these molecules, with the first clinical trial expected to start next year. Research Sponsor: None.

Predictive value of circulating tumor DNA detection for long-term survival in patients with advanced lung cancer undergoing chemoimmunotherapy. First Author: Hui Li, Zhejiang Cancer Hospital, Hangzhou, China

Background: Chemoimmunotherapy (ChemoIO) has emerged as the first-line standard treatment option for advanced non-small cell lung cancer (NSCLC) without drive gene mutation. However, only a portion of patients experienced long-term survival, even among those who achieved partial or complete response (PR or CR) in early assessments. This study assessed circulating tumor DNA (ctDNA) detection in predicting long-term survival in advanced NSCLC patients using a novel 2365-gene fixed panel integrating mutation, copy number variation (CNV), and fragmentomics (Frag). **Methods:** Based on the SheildingUltra panel developed by Geneseeq, using a discovery cohort composed of over 200 lung cancer and healthy plasma samples, AI-driven models were developed to improve the ctDNA detection sensitivity by incorporating mutations, CNV, and Frag. The enhanced panel was retrospectively validated in a cohort of 107 advanced NSCLC patients using plasma samples collected during PR/CR stages of ChemoIO. Moreover, the fixed panel was prospectively evaluated in an independent cohort of 38 patients who achieved PR/CR in early assessments, with blood samples collected both before treatment and on Day 1 of Cycle 5 (C5D1) of therapy. The value of ctDNA detection results for predicting long-term survival was subsequently evaluated in both cohorts. **Results:** The enhanced fixed panel demonstrated robust performance in the discovery cohort, effectively discriminating lung cancer patients from healthy individuals through the integration of mutations, CNV, and Frag. In the retrospective validation cohort including 107 patients in PR/CR status, ctDNA-negative patients had significantly longer progression-free survival (PFS) (median PFS: not reached [NR] vs. 14.1 months, hazard ratio (HR): 0.36 (95% confidence interval [CI]: 0.18-0.74), P=0.004) and overall survival (OS) (median OS: NR vs. NR, HR: 0.10 (95% CI:0.02-0.43), P≤0.001) compared to ctDNA-positive patients. In the prospective validation cohort, the ctDNA status determined from plasma collected at C5D1 successfully stratified patients into groups with long- and short- PFS and OS. The median PFS was NR for both groups, with a HR (95% CI) of 0.19 (0.04-0.92) and a p-value of 0.021. The median OS was also NR for both groups, with a HR (95% CI) of 4.56e-10 (0-infinity) and a p-value of 0.011. However, the pre-treatment ctDNA status was not significantly associated with survival. **Conclusions:** Using a novel ctDNA detection panel incorporating mutation, CNV, and Frag, we found the ctDNA status during the treatment may serve as a potential biomarker for predicting long-term PFS in advanced NSCLC patients undergoing ChemoIO. Additional prospective studies are needed to confirm these results and guide clinical decisions for optimal immunotherapy in NSCLC patients. Research Sponsor: None.

Phase 2 study of pembrolizumab (pembro) plus plinabulin (plin) and docetaxel (doc) for patients (pts) with metastatic NSCLC after progression on first-line immune checkpoint inhibitor alone or combination therapy: Initial efficacy and safety results on immune re-sensitization. First Author: Yan Xu, Department of Respiratory and Critical Care Medicine, Peking Union Medical College Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College, Beijing, China

Background: Immune checkpoint inhibitor (ICI)-based treatment regimens have become the standard of care for first-line treatment of EGFR/ALK wild-type NSCLC. However, >60% pts inevitably develop progressive disease (PD) from acquired resistance (AR), which could be due to T cell exhaustion and antigen presenting cell (APC) pathway mutation. For patients with PD, the standard of care (SOC) is still doc, while the efficacy is limited with ~10% ORR, median PFS 3.7 months in TROPION-Lung01. Thus, there is a huge unmet need for this setting of patients. Plin is a selective immunomodulating microtubule-binding agent which promotes dendritic cell maturation and enhances anti-tumor T cell response. The mechanism of action has been validated via *in vitro*, *in vivo* models, and human trials, suggesting that plin may have the potential to overcome immunotherapy AR. This phase 2 study was aimed to evaluate the efficacy and safety of pembro combined with plin and doc in pts with metastatic NSCLC who had progressed after ICI. **Methods:** In this single-arm phase 2 trial, metastatic NSCLC pts who developed acquired resistance on immunotherapy alone or in combination with platinum-doublet chemotherapy were enrolled. Participants received pembro 200 mg, plin 30 mg/m^2, and doc 75 mg/m^2 intravenously day 1 every 21days. The primary endpoint is investigator-based ORR per RECIST 1.1. The secondary endpoints included PFS, OS, DoR and safety. The sample size is 47 patients. The ORR and DOR was assessed in the evaluable set. **Results:** At of the 21th Jan, 2025, data cutoff, 47 pts were enrolled, the median follow-up time was 8.7 months, median age of 67.5 (rang 44-83), 80.9%(n=38) were male, 68.1% had smoking history. Histology included 66% with non-squamous, 34% with squamous cell carcinoma. Efficacy and safety were analyzed in the 45 patients, 40 patients were evaluable. The ORR was 20% (confirmed ORR was 17.5%) and the median DoR was 9.4 m; the DCR was 81.6% (defined as PR and SD> 4 months), median PFS was 8.2 m (current 6 m PFS rate was 60.2%, 12 m PFS rate was 29.9%), OS had not been reached (6 death since the first patient enrollment of 02/2023) . G3 or higher treatment-related AEs (TRAEs) were reported by 37.8% of pts, ≥5% TRAEs include diarrhea (6.7%), myelosuppression (8.9%) and hypertension (8.9%). **Conclusions:** Pembro plus plin and doc in pts with metastatic NSCLC who developed PD on ICI shows promising efficacy, with doubling PFS and DCR compared with historical data of doc. The AEs of the triple combination treatment is manageable. Further investigations into which pts would benefit from continued ICI treatment after progression is warranted. Clinical trial information: NCT05599789. Research Sponsor: BeyondSpring and MSD China. Plinabulin was provided by BeyondSpring and pembrolizumab by MSD China.

A phase 2 study of HLX07 plus serplulimab with or without chemotherapy versus serplulimab plus chemotherapy as first-line therapy in advanced squamous non-small cell lung cancer. First Author: Yi-Long Lung Cancer Wu, Guangdong Provincial People's Hospital, Guangzhou, China

Background: Approved first-line therapies of PD-L1/PD-1 inhibitors plus chemotherapy conferred significant survival benefits for advanced squamous non-small cell lung cancer (sqNSCLC). However, the prognosis remains to be improved. The epidermal growth factor receptor (EGFR) is highly expressed in sqNSCLC and associated with a poor prognosis. This study aimed to compare the efficacy of HLX07, a novel humanized anti-EGFR antibody, plus serplulimab (anti-PD-1 antibody) ± chemo versus serplulimab plus chemo as first-line option for advanced sqNSCLC. **Methods:** This randomized, multicenter phase 2 study consisted of 4 parts that assessed varied combinations of HLX07 (at different doses), serplulimab, and chemotherapy. Part 3 evaluated the preliminary efficacy of the three-drug combination and is presented below. Patients with stage IIIB/IIIC or IV sqNSCLC that was not amenable to surgery or radiation therapy and high tumor expression of epidermal growth factor receptor (H score≥150) and no prior systemic therapy were randomized 1:1 to receive intravenous HLX07 at 800 mg (group A) or 1000 mg (group B), in combination with serplulimab (300 mg) and chemotherapy (carboplatin and nab-paclitaxel), once every three weeks. The primary endpoints were independent radiological review committee (IRRC)-assessed objective response rate (ORR) and progression-free survival (PFS) per RECIST 1.1. **Results:** As of 31 December 2024, 27 patients were enrolled and randomly assigned to group A (n=13) and group B (n=14) in part 3. 15 (55.6%) patients had metastatic disease. With a median follow-up of 16.0 months, IRRC-assessed confirmed ORR per RECIST 1.1 was 69.2% (95% CI 38.6–90.9) in group A and 71.4% (95% CI 41.9–91.6) in group B. Disease control rate was 92.3% (95% CI 64.0–99.8), and 100% (95% CI 76.8–100.0), respectively. Median PFS was 15.1 (95% CI 4.1–not available) months in group A and not reached in group B. The median overall survival and duration of response were not reached in either group as of the data cutoff date. All the patients in both groups reported treatment-emergent adverse events (TEAEs); most common TEAEs of any grade included neutrophil count decreased (92.3% vs. 71.4%), white blood cell count decreased (84.6% vs. 85.7%), anemia (84.6% vs. 78.6%), platelet count decreased (76.9% vs. 71.4%), hypokalemia (53.8% vs. 64.3%), rash (46.2% vs. 57.1%), alopecia and hypocalcemia (46.2% vs. 50.0% for each). 6 (46.2%) patients, and 8 (57.1%) in group A, and B reported immune-related adverse events, respectively. **Conclusions:** First-line HLX07 plus serplulimab and chemotherapy showed encouraging preliminary efficacy with a manageable safety profile in patients with advanced sqNSCLC which warrants further investigation. Clinical trial information: NCT04976647. Research Sponsor: Shanghai Henlius Biotech, Inc.

Differential predictive impact of PD-L1 expression on immunotherapy outcomes and immunophenotype in squamous versus non-squamous NSCLC. First Author: Valentina Santo, Lowe Center for Thoracic Oncology, Dana-Farber Cancer Institute, Harvard Medical School, Boston, MA

Background: PD-L1 tumor proportion score (TPS) is a key biomarker for immune checkpoint inhibitors (ICIs) efficacy in non-small cell lung cancer (NSCLC), but its predictive value in patients (pts) with squamous (SQ) histology remains uncertain, highlighting the need for histology-specific studies. **Methods:** Clinicopathologic, genomic, and outcomes data were collected and analyzed from advanced NSCLC pts treated with ICIs ± chemotherapy (CT) at Dana-Farber Cancer Institute, Memorial Sloan Kettering Cancer Center and MD Anderson Cancer Center. Cox regression tested the association between PD-L1 levels and survival to ICIs by histology, adjusting for potential confounders such as treatment regimen and line. Multiplexed immunofluorescence (mIF) on baseline tissue samples quantified CD8+, PD1+, CD8+/PD1+, and FOXP3+ densities, stratifying by PD-L1 TPS and histology. **Results:** Among 4967 NSCLC pts treated with ICIs ± CT, 727 (14.6%) had SQ histology. Among pts with available PD-L1 TPS, 1359 (37.9%) had TPS <1%, 1061 (29.6%) 1–49%, and 1167 (32.5%) ≥50%. Increasing PD-L1 TPS of <1%, 1–49% and ≥50% correlated with significant stepwise improvements in progression-free (PFS) and overall survival (OS) in pts with NonSQ NSCLC but not in those with SQ (Table 1). In SQ NSCLCs, there was no difference in PFS and OS between pts with PD-L1 TPS of 1–49% vs ≥50%, while only a dichotomized PD-L1 TPS (<1% vs ≥1%) was predictive of longer survival in this histology (PFS adjusted hazard ratio [aHR]: 0.72, p<0.01; OS aHR: 0.76, p=0.02). Comparing histologies, PFS and OS to ICIs ± CT were similar between SQ and NonSQ NSCLCs in PD-L1 TPS subgroups of <1% and 1–49%. However, among pts with a PD-L1 TPS ≥50%, those with NonSQ NSCLC had longer survival compared to SQ (PFS aHR: 1.30, p=0.01; OS aHR: 1.43, p<0.01), indicating stronger predictive value of increasing PD-L1 TPS levels only in NonSQ. mIF analysis (229 samples: 22 SQ, 207 NonSQ) showed lower intratumoral CD8+, PD1+, CD8+/PD1+, and FOXP3+ densities in SQ vs NonSQ. Increasing PD-L1 TPS significantly correlated with higher CD8+ cells in NonSQ NSCLCs (R = 0.25, p<0.01) but not in SQ (R = -0.034, p = 0.89). A similar association was observed for PD1+, CD8+/PD1+, and FOXP3+ cells. **Conclusions:** Increasing PD-L1 levels show stepwise PFS and OS improvements in NonSQ but not in SQ NSCLCs, where TPS acts as a dichotomous (<1% vs ≥1%) rather than continuous predictor. These findings have implications for treatment decision making as well as ICIs trial design and interpretation. Research Sponsor: None.

Clinical outcomes and predictors of response to PD-(L)1 blockade in patients with oncogene-driver negative NSCLC who have never smoked. First Author: Eleonora Gariazzo, Lowe Center for Thoracic Oncology, Dana-Farber Cancer Institute, Harvard Medical School, Boston, MA

Background: Non-small cell lung cancer (NSCLC) in patients (pts) who have never smoked is associated with poor response to immune checkpoint inhibitors (ICI). However, most studies have focused on pts with actionable oncogenes (e.g., EGFR, ALK, ROS1, RET, MET), and it remains unclear whether specific clinicopathologic and genomic features can predict ICI response in those without these actionable drivers. **Methods:** Clinicopathologic characteristics and outcomes data were collected from pts with metastatic, oncogene driver-negative, NSCLC who received ICI across 5 academic cancer centers in US and EU. Single sample gene set enrichment analysis was performed on NSCLC samples from the Stand Up To Cancer (SU2C) cohort to characterize transcriptomic correlates of response to ICI monotherapy in responders and non-responders. **Results:** Of 5639 pts with metastatic NSCLC analyzed, 708 (12.6%) tested negative for actionable oncogene drivers and had never smoked. Among these, median age was 64 years, 59.5% were women, 65.2% had ECOG PS 0/1, and 83.8% had adenocarcinoma. At a median follow-up of 36.9 months (mo), objective response rate (ORR) was 21.8%, median progression-free survival (mPFS) was 4.5 mo, and median overall survival (mOS) was 16.9 mo in this patient population. Pts with PD-L1 TPS $\geq$1% had significantly higher ORR (31.1% vs. 16.1%, $p<0.01$), and longer mPFS (HR 0.74, $p<0.01$) compared to those with PD-L1 <1%. Similarly, pts with very high TMB ($\geq 90^{th}$ percentile) had higher ORR (52.2% vs 22.8%, $p<0.01$), longer mPFS (HR 0.50, $p<0.01$), and mOS (HR 0.40, $p<0.01$) compared to those with a TMB $<90^{th}$ percentile. Pts with positive PD-L1 expression $\geq$1% and very high TMB had the highest ORR and the longest mPFS and mOS compared to pts with either one of these biomarkers alone. Treatment outcomes also varied by regimen: pts receiving dual PD-(L)1+CTLA-4 blockade or PD-(L)1 blockade + chemotherapy had higher ORR compared to those receiving PD-(L)1 monotherapy (30.0% vs 36.5% vs 10.3%, respectively, $p<0.01$). Dual PD-(L)1+CTLA4 inhibition was also associated with significantly longer mPFS (9.4 vs 6.9 vs 2.9 mo, $p<0.01$) and mOS (47.5 vs 19.7 vs 14.7 mo, $p<0.01$) compared to PD-(L)1 + chemotherapy and PD-(L)1 monotherapy, respectively. These differences were validated in pts receiving these regimens as first-line therapy. In NSCLC samples from pts who had never smoked without oncogenic driver mutations in the SU2C cohort, responders to ICI showed upregulation of innate and adaptive immune responses pathways, including enhanced MHC I/II antigen presentation, as well as increased T-cell activation, proliferation, and chemotaxis. **Conclusions:** These results emphasize how PD-L1$\geq$1%, very high TMB, and use of dual checkpoint blockade are associated with improved outcomes in pts who have never smoked with oncogene-driver negative NSCLC, aiding personalized ICI use in this neglected population. Efficacy and safety of metronomic oral vinorelbine combined with PD-1 inhibitors as first-line therapy in advanced non-small-cell lung cancer in elderly patients. First Author: Lin Li, Department of Medical Oncology, Beijing Hospital, National Center of Gerontology, Institute of Geriatric Medicine, Chinese Academy of Medical Sciences, Beijing, China

Background: Elderly individuals aged over 70 constitute the majority of Non-small cell lung cancer(NSCLC) patients. However, their poor general status, multiple co-morbidities, and limited social support present significant challenges in antitumor treatments, especially standard platinum-based chemotherapy. Metronomic chemotherapy (MCT) involves the regular administration of chemotherapy drugs at low doses, offering improved safety, anti-angiogenic tumor effects, and immune modulation compared to conventional chemotherapy. In light of these considerations, we have designed a phase II trial to evaluate the efficacy and safety of PD-1 inhibitors plus metronomic oral vinorelbine (mOV) as first-line therapy for elderly patients with metastatic NSCLC. **Methods:** Elderly patients($\geq$70 years) with previously untreated locally advanced or metastatic NSCLC without a sensitising EGFR mutation, ALK fusion or ROS1 fusion and with an Eastern Cooperative Oncology Group (ECOG) performance status score of 0 or 1 were recruited for this study. Patients received PD-1 inhibitors combined with mOV (30mg, TIW1, day 1-3-5 per week) for 6 cycles, followed by PD-1 inhibitors maintenance until disease progression or intolerable toxicities. The primary endpoint was progression-free survival (PFS). Secondary endpoints included overall survival (OS), objective response rate (ORR), disease control rate (DCR), and safety profiles. **Results:** From March 2021 to November 2024, 37 patients were enrolled in the study. The median age was 77 with 31 (83.8%) males. Median follow-up time was 13.5 months (range 1.8 months-44.7 months). The median PFS was 10.9 months (95%CI: 1.0 months-20.9 months) and the median OS was 26.2 months (95%CI: (6.7 months-45.7 months). The ORR and DCR were 33.3% (95%C1: 17.3%-47.5%) and 86.1% (95%CI: 71.9%-95.7%), respectively. Compared to those with low PD-L1 expression (PD-L1 TPS <50%), patients with high PD-L1 expression (PD-L1 TPS $\geq$50) had significant prolonged PFS [mPFS=6.1 months vs 23.0 months, p=0.01, HR = 0.19 (95%CI 0.05-0.69)] and OS [mOS=6.1 months vs not reached, p=0.02, HR = 0.09 (95%CI 0.01-0.70)]. Adverse events (AEs) of any grade were observed in 29 (78.4%) patients of which immune-related adverse events (irAEs) occurred in 14 (37.8%) patients. Grade 3-4 adverse reactions were reported in 5 (13.5%) patients, 4 of which were irAEs, including immune-associated pneumonia, myocarditis, myositis, enteritis and hepatitis. No grade 5 adverse events were reported. **Conclusions:** The regimen of PD-1 inhibitors plus mOV as first-line therapy showed significant survival benefits and a favorable safety profile in elderly patients with driver-gene-negative metastatic NSCLC, particularly those with high PD-L1 expression. Clinical trial information: ChiCTR2300074586. Research Sponsor: National High Level Hospital Clinical Research Funding of China; BJ-2023-073.

Analysis of genomic and immune microenvironment differences in Chinese populations: Revealing potential mechanisms of poor immunotherapy outcomes in patients with EGFR mutation and ALK fusion non-small cell lung cancer. First Author: Junhong Lü, Thoracic Surgery, Guangzhou Overseas Chinese Hospital, Guangzhou, China

Background: Non-small cell lung cancer (NSCLC) patients with EGFR mutations or ALK fusions often exhibit suboptimal responses to immunotherapy, yet the genomic and immunological basis for this remains poorly understood. This study aims to elucidate the genomic and immune microenvironment differences in NSCLC patients harboring EGFR mutations or ALK fusions that may contribute to their distinct immunotherapy responses. **Methods:** We analyzed tumor specimens from 12,528 NSCLC patients using a comprehensive next-generation sequencing (NGS) panel targeting 733 genes. Of these, 191 patients also underwent multiplex fluorescence immunohistochemistry (mIHC) analysis to assess the immune microenvironment. Subgroups included patients with EGFR mutations, ALK fusions, both EGFR mutations and ALK fusions, and those wild-type for both EGFR and ALK. We compared these groups for DNA damage response (DDR) gene mutation frequencies, tumor mutational burden (TMB), intratumoral heterogeneity (ITH), and immune microenvironment. **Results:** Among the cohort, 6389 (51%) harbored EGFR mutations and 300 (2.4%) had ALK fusions. Patients with EGFR mutations or ALK fusions exhibited significantly lower DDR mutation frequencies compared to their wild-type counterparts ($P<0.001$). TMB levels showed a gradient: wild-type > EGFR mutation > EGFR mutation with ALK fusion > ALK fusion ($P< 2.2e-16$), with wild-type patients having markedly higher TMB than any other group ($P< 2.22e-16$, P=0.0047, $P< 2.22e-16$). Conversely, ITH was lowest in wild-type patients and progressively higher with ALK fusions (P=0.017), EGFR mutations ($P< 2.22e-16$), and combined mutations ($P< 2.22e-16$). Lower ITH was associated with higher immunogenic neoantigen production, correlating with improved immunotherapy responses. Immunohistochemical analysis revealed that EGFR-mutant tumors had significantly fewer M1 tumor-associated macrophages (CD68+ HLA-DR+) ($P<0.001$) within the tumor parenchyma and reduced CD4+ T cell (P=0.013) infiltration in the tumor stroma compared to wild-type. **Conclusions:** Our findings suggest that low TMB, high ITH, and a suppressed immune microenvironment characterize EGFR-mutant and ALK-fusion NSCLC, potentially undermining their immunotherapy efficacy. These genomic and immunological signatures, particularly ITH and immune cell distribution, might be critical factors affecting the immunotherapy responsiveness of these patient subsets, warranting further investigation into tailored therapeutic strategies. Research Sponsor: None.

A phase II study of durvalumab, doxorubicin, and ifosfamide in recurrent and/or metastatic pulmonary sarcomatoid carcinoma (KCSG LU-19-24). First Author: Bhumsuk Keam, Department of Internal Medicine, Seoul National University Hospital, Seoul, South Korea

Background: Pulmonary sarcomatoid carcinomas (PSCs) are very rare and aggressive tumors with poor prognosis. While conventional cytotoxic agents have limited efficacy in PSC, immune checkpoint inhibitors or doxorubicin showed potential efficacy. We evaluated the efficacy and safety of durvalumab, doxorubicin, and ifosfamide for recurrent and/or metastatic PSC. **Methods:** Patients with recurrent or metastatic PSC received durvalumab (1500 mg, day1), doxorubicin (20 mg/m² IV, days 1–3) and ifosfamide (1.5 g/m² IV with mesna, days 2–4) every 3 weeks for up to 4 cycles, followed by durvalumab monotherapy until disease progression or unacceptable toxicity, upto 12 months. The primary endpoint was objective response rate (ORR). The secondary endpoints included progression-free survival (PFS), overall survival (OS), duration of response (DOR) and toxicity. **Results:** A total of 20 patients (15 male, 5 female) were enrolled, and the median age was 63.5 (range, 44-75). Sixteen (88.9%) of the 18 evaluable cases were PD-L1 positive. Six (30.0%) out of 20 patients had previously received palliative chemotherapy. Among them, 18 patients were evaluable for the primary endpoint. ORR was 35.0% (95% CI, 17.7-55.8%) based on modified RECIST version 1.1. and the median DOR was 5.3 months (95% CI, 1.7-not estimated). After a median follow-up duration of 7.0 months (range, 1.2-37.6), the median PFS and OS were 4.8 months (95% CI, 2.0-6.5 months) and 9.4 months (95% CI, 5.5-26.8 months), respectively. Adverse events (AEs) of any grade were reported in 19 patients with serious AEs in 10 patients. The most common AEs were nausea (9.7%), anemia (7.5%), vomiting (5.4%). No treatment-related deaths were reported. **Conclusions:** Given its rarity and aggressiveness of PSC, the combination of durvalumab, doxorubicin, and ifosfamide demonstrated promising efficacy in recurrent and/or metastatic cases. Further studies are required to validate these findings and optimize treatment strategies for PSC. Clinical trial information: NCT04224337. Research Sponsor: None.

Race-associated clinicogenomic correlates of outcomes to immune checkpoint inhibitors alone or with chemotherapy in non-small cell lung cancer (NSCLC). First Author: Nirosha D. Perera, Department of Cancer Medicine, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: PD-L1 low and STK11 mutations are associated with immune checkpoint inhibitor (ICI) resistance in non-small cell lung cancer (NSCLC). It is unclear whether there are differences in clinicogenomic predictors by race and ethnicity. **Methods:** We retrospectively studied NSCLC patients 18 or older, without targetable EGFR or ALK alterations, treated with frontline combination chemotherapy with ICI (ICI-chemo) or ICI monotherapy (ICI-mono) between January 2014 and February 2020 at MD Anderson Cancer Center. We analyzed clinicogenomic and survival characteristics by race/ethnicity. Differences in clinicogenomic predictors were assessed through log-rank and chi-squared comparison of proportions tests. Survival differences were estimated via Kaplan-Meier method. **Results:** 1648 patients met inclusion criteria. Poor performance status (PS) frequency was statistically significantly different among groups, highest in African American (AA) (30.7%) and Native Alaskan/Hawaiian or American Indian (NAHAI) (30%) patients (Table). Steroid prescription within one month of ICI start was also more frequent in AA (46.4%) and NAHAI (40%) patients. However, heavy smoking was more frequent in White (62%) patients. Mutation rates were statistically significantly different for KRAS and STK11 but not TP53 (Table). KRAS mutations were most frequent in White (24.7%) and AA patients (24.2%). STK11 mutations were most frequent in AA (14.4%) patients. TP53 mutations were most frequent in HL and Black (43.6%, 41.8%) patients. Median overall survival (OS) was lower (21.3 and 24.5 months) for HL and NAHAI patients and higher (25.4, 26.4, and 30.7 months) for White, Black, and Asian patients, though not statistically significantly different (Table). **Conclusions:** AA and HL patients had lower rates of heavy smoking but higher rates of poor genomic prognostic factors. Asian patients had the lowest rates of heavy smoking, KRAS, TP53, and STK11 mutations, but the highest rates of PD-L1 <1%. Despite several traditional clinicogenomic prognostic factors being poor for minority racial/ethnic groups, OS difference was not statistically significant. Research Sponsor: Philanthropic Contributions to The University of Texas MD Anderson Lung Moon Shot Program; P30 CA016672.

Predictive implications of immune-related adverse events after exposure to VEGF inhibitors on outcomes in patients with advanced NSCLC treated with prior immune check point inhibitor. First Author: Jinah Kim, University of Vermont Medical Center, Department of Hematology and Oncology, Burlington, VT

Background: Immune-related adverse events (irAEs) have been associated with enhanced antitumor immune activity, potentially correlating with improved clinical outcomes. Implications of delayed irAE after exposure to VEGF inhibitors on clinical outcomes remain poorly defined. We hypothesize that patients who develop irAEs during or following immune checkpoint inhibitors (ICIs) therapy will demonstrate improved overall survival (OS) and progression-free survival (PFS) compared to those who do not develop irAEs. **Methods:** We conducted a single center retrospective chart review of patients with non-small cell lung cancer (NSCLC) who had received at least one line of immunotherapy and subsequently underwent treatment with ramucirumab upon progression. Patients were categorized based on the presence or absence of irAEs during or after ICIs. 41 patients were identified. Kaplan-Meier estimates and log-rank tests were used for survival analyses, while Cox proportional hazards regression model was used to estimate hazard ratios (HRs) and 95% confidence intervals (CIs). **Results:** Of 41 identified subjects, median age was 63, 83% had adenocarcinoma, 56% had metastatic disease at presentation and 93% had received previous chemotherapy. Initial immunotherapy received was pembrolizumab 66%, nivolumab 20% and durvalumab 10%. For second line treatment, 85% received ramucirumab with docetaxel. 37% (n=15) of patients experienced irAE after ICIs. From the start of ramucirumab, the median OS was 8.0 months for patients with irAEs versus 6.0 months for those without, and the median PFS was 7.0 months versus 3.0 months, respectively. HRs suggested a trend favoring longer survival for patients with irAEs (HR for PFS = 0.52; 95% CI: 0.25–1.08; p=0.0072 and HR for OS = 0.62; 95% CI: 0.29–1.27; p=0.0192), though not statistically significant. Patients who developed delayed irAEs (after the start of ramucirumab) (n=4, 9.7%) had significantly prolonged OS, 34.5 months (HR 0.22; 95% CI: 0.05–0.94; p=0.0406) and PFS 33.5 month (HR 0.18; 95% CI: 0.043–0.80; p=0.0234) compared to those without. The most common irAEs were colitis (47%), rash (20%), and pneumonitis (13%). **Conclusions:** Our findings suggest that the occurrence of irAEs during or after immunotherapy may be associated with improved outcomes in patients with advanced NSCLC who receive ramucirumab-based treatment. Although the observed survival benefit for patients with any irAE was not statistically significant, those who developed delayed irAEs after initiating ramucirumab exhibited significant prolongation of OS and PFS. This raises the possibility that delayed irAEs after exposure to VEGF likely suggests a reinvigorated immune response and may serve as a prognostic marker. Further prospective validation in larger patient cohorts is warranted to investigate these findings. Research Sponsor: None.

Digital pathology–based AI spatial biomarker to predict outcomes for immune checkpoint inhibitors in advanced non-small cell lung cancer. First Author: Feyisope Eweje, Department of Radiation Oncology, Stanford University School of Medicine, Stanford, CA

Background: Accurate prediction of outcomes with anti-PD-1/PD-L1 immune checkpoint inhibition (ICI) remains a significant challenge in non-small cell lung cancer (NSCLC). In this study, we develop an artificial intelligence (AI) approach for single-cell analysis of H&E-stained whole-slide images (WSIs) to predict objective response and clinical benefit of ICI in two independent cohorts of NSCLC patients. **Methods:** For biomarker discovery, we analyzed WSIs and clinical data from 118 advanced lung cancer patients at Stanford University. Of these, 46 patients (39%) were treated with ICI monotherapy and 72 (61%) patients were treated with ICI and concurrent chemotherapy. For external validation, 233 advanced lung cancer patients treated with ICI monotherapy at MSKCC were used. Deep learning models were deployed for automated tumor area detection and segmentation of cell nuclei in WSIs. We developed a fully automated cell annotation approach that leverages multiplex immunofluorescence and trained a deep learning model to classify nuclei into 10 cell types on H&E images, including tumor cells and major immune and stromal cells such as T cells, B cells, neutrophils, macrophages, fibroblasts, and endothelial cells. A total of 331 features were computed to quantify cell composition and cell-cell spatial interactions in the tumor microenvironment. Treatment outcomes were assessed using progression-free survival (PFS) and best objective response per the Response Evaluation Criteria in Solid Tumors (v1.1), with statistical significance reported at the 95% confidence level. **Results:** Five spatial features were included in the prediction model that characterize the cell-cell interactions between tumor cells, fibroblasts, T cells, and neutrophils. In the validation cohort, the spatial biomarker had a strong association with PFS (hazard ratio=5.46, $P<0.0001$), while the association of PD-L1 expression with PFS was modest (hazard ratio=1.67, P=0.002). For patients with high PD-L1 expression (TPS>50%), the spatial biomarker significantly stratified patients for PFS (hazard ratio=5.21, 95% CI 3.21-8.48, $P<0.0001$). For predicting objective response, a multivariate model consisting of the spatial features achieved AUROC=0.76 compared to AUROC=0.66 for PD-L1 TPS, while combining the spatial features with PD-L1 expression led to AUROC=0.78. **Conclusions:** A single-cell computational pathology approachidentifies interpretable spatial biomarkers that predict ICI response and outcomes in advanced lung cancer. The spatial biomarker could help to select patients with high tumor PD-L1 expression who are most suited for ICI monotherapy. Further validation of these findings is warranted. Research Sponsor: None.

SMET12 and toripalimab combined chemotherapy in patients with advanced non-small cell lung cancer who are treatment-naive or have developed resistance to standard therapy. First Author: Jinghui Lin, Clinical Oncology School of Fujian Medical University, Fujian Cancer Hospital (China), Fuzhou, China

Background: SMET12 is a recombinant anti-EGFR and CD3 bispecific antibody independently developed by Zhejiang Shimai Pharmaceutical. This study aims to evaluate the efficacy and safety of SMET12 in combination with toripalimab and chemotherapy in treatment-naïve, post-first-line immune checkpoint inhibitor-resistant, and EGFR mutation-positive advanced non-small cell lung cancer (NSCLC) patients who are resistant to TKI treatment. **Methods:** This is a single-arm, cohort clinical study involving three cohorts. The primary inclusion criteria are histologically confirmed EGFR protein-expressing metastatic NSCLC patients, specifically divided into: (1) Cohort A: treatment-naïve subjects; (2) Cohort B: subjects resistant to first-line immune checkpoint inhibitor therapy; (3) Cohort C: EGFR mutation-positive subjects resistant to TKI treatment. All subjects will receive a combination regimen of SMET12, toripalimab, and chemotherapy after entering the treatment phase, with the chemotherapy cycle being 2-4 cycles. After chemotherapy, subjects with stable or effective results will enter the maintenance therapy phase with SMET12 and toripalimab until disease progression or unacceptable toxicity occurs. The treatment regimen is as follows:SMET12 30μg Q2W + toripalimab 3mg/kg Q2W+ chemotherapy Q3W. Specific chemotherapy regimens are: Cohort A: pemetrexed + carboplatin Q3W for lung adenocarcinoma; nab-paclitaxel + cisplatin Q3W for lung squamous cell carcinoma; Cohort B: docetaxel Q3W; Cohort C: pemetrexed + carboplatin Q3W. The primary endpoints are safety and efficacy indicators, including objective response rate (ORR), duration of response (DOR), disease control rate (DCR), and progression-free survival (PFS). **Results:** From March 7, 2024, to January 21, 2025, a total of 31 patients participated in this study, of which 27 patients were evaluable for efficacy. The results showed: the ORR for Cohort A was 83.3%, DCR was 100%, and the median PFS was 8.3 months (95%CI: 3.79, 12.8); the ORR for Cohort B was 22.2%, DCR was 66.7%, and the median PFS was 4.2 months (95%CI: 3.62, 4.78); the ORR for Cohort C was 41.7%, DCR was 100%, and the median PFS was 7.2 months (95%CI: 5.0, 9.4).Grade ≥3 treatment-related adverse events included leukopenia (19.4%), pneumonia (16.1%), immune-related pneumonitis (13.0%), immune-related hepatitis (3.2%), immune-related myositis (3.2%), and anemia (3.2%). **Conclusions:** SMET12 in combination with toripalimab and chemotherapy shows good tolerability and efficacy in treatment-naïve, post-immune therapy-resistant EGFR protein-expressing, and post-TKI treatment-resistant EGFR mutation-positive advanced NSCLC patients. Clinical trial information: NCT06208033. Research Sponsor: None.

Exploratory study on the impact of intestinal low-dose radiation on the efficacy and prognosis of immunotherapy in metastatic non-small cell lung cancer. First Author: Baiyang Huang, Department of Radiation Oncology, Shandong Cancer Hospital and Institute, Shandong First Medical University and Shandong Academy of Medical Sciences, Jinan, Shandong, China

Background: Radiotherapy (RT) can be a palliative measure for metastases of metastatic non-small cell lung cancer (mNSCLC). However, RT to abdominopelvic metastases can cause additional intestinal radiation, that may lead to microbial imbalance. Recent research have revealed the influence of intestinal microbiota on immunotherapy (IO). Thus, this study aims to explore the impact of intestinal radiation doses on the efficacy and prognosis of IO for mNSCLC. **Methods:** Collect clinical data from patients with mNSCLC who underwent IO combined with abdominopelvic RT for metastases at Shandong Cancer Hospital over the past five years. Use the Varian Eclipse system to outline the contours of the large and small intestines and record the dosimetric parameter. Calculate overall survival (OS) and progression-free survival (PFS) using the Kaplan-Meier method, compare inter-group differences using the log-rank test, and analyze risk factors associated with OS and PFS through Cox regression analysis. **Results:** Exploratively, we set 1 Gy and 3 Gy as the thresholds for the mean intestinal radiation dose. A total of 232 patients were included, with 76 patients (32.8%) having small intestine mean radiation dose (SIMRD) $<$ 1 Gy, and 67 patients (28.9%) having SIMRD between 1-3 Gy. 153 patients (65.9%) received first-line IO, while 79 patients (34.1%) received second-line IO. Compared with the $<$ 1 Gy and $\geq$ 3 Gy groups, patients with SIMRD between 1-3 Gy not only had the highest objective response rate (ORR) after 3 months (21.1% vs. 43.3% vs. 7.9%), but also significantly prolonged OS (14.8 months vs. 22.6 months vs. 7.7 months, P $<$ 0.001) and PFS (7.2 months vs. 10.0 months vs. 4.3 months, P $<$ 0.001). Subgroup analysis of first-line and second-line therapy patients yielded similar conclusions. Compared with the $<$ 1 Gy and 1-3 Gy groups, patients with colon mean radiation dose $\geq$ 3 Gy also exhibit relatively poor OS (14.8 months vs. 12.6 months vs. 10.1 months, P = 0.036) and PFS (7.4 months vs. 7.3 months vs. 4.2 months, P = 0.006). Multivariate Cox regression analysis showed that SIMRD between 1-3 Gy was an independent predictive factor for OS (HR = 0.41, P $<$ 0.001) and PFS (HR = 0.56, P $<$ 0.001). We prospectively enrolled 14 patients with mNSCLC who received first-line IO combined with metastasis RT, with 9 patients undergoing efficacy evaluation. The results revealed that the ORR was highest (66.7%) in the group with SIMRD between 1-3 Gy, and both 2 patients with progression were in the group with SIMRD $\geq$ 3 Gy. **Conclusions:** In patients with mNSCLC receiving IO combined with metastasis RT, low SIMRD may significantly enhance the long-term prognosis of IO, potentially relying on the interaction between host immunity and gut microbiota. To validate this hypothesis, we are prospectively collecting blood and feces from patients before and after RT, with the prospective cohort being enrolled. Artificial intelligence-powered spatial analysis of tumor infiltrating lymphocytes and tertiary lymphoid structures in non-small cell lung cancer patients treated with immune-checkpoint inhibitors±chemotherapy. First Author: Yeong Hak Bang, Division of Hematology-Oncology, Department of Medicine, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, South Korea

Background: This study evaluates the predictive utility of an artificial intelligence (AI)-powered whole-slide image (WSI) analyzer for assessing Tumor-infiltrating lymphocytes (TILs) and tertiary lymphoid structures (TLSs) in patients (pts) treated with ICIs, either as monotherapy or in combination with chemotherapy. **Methods:** An AI-powered WSI analyzer (Lunit SCOPE IO, Lunit, Seoul, Korea) was utilized to segment cancer area (CA) and cancer stroma (CS), and identification of tumor infiltrating cells (TILs) and tertiary lymphoid structure (TLS) on tumor tissues. Pre-treatment H&E-stained WSIs were obtained from Samsung Medical Center (n = 533), and other multi-center cohorts (Shen et al, 2024, n=634). After quality control, 1,144 samples (98.0%) were used included in the final analysis. Pts were stratified into risk groups; good risk (high TILs in CA and high TLS area per CA), poor risk group (low TILs in CA and low TLS area per CA), and intermediate risk group (others). Among them, 988 pts had available PD-L1 expression data, 435 underwent whole transcriptome sequencing, and 292 underwent whole exome sequencing. **Results:** TILs in CA correlated significantly with the interferon gamma pathway (ρ=0.49, P$<$0.001), and the T-cell inflamed score (ρ=0.56, P$<$0.001). Similarly, TLS area per CA was significantly correlated with TLS imprinting (ρ=0.48, P$<$0.001), and B cell receptor signature (ρ=0.42, P$<$0.001). Among 1,144 pts, 1,044 received ICI monotherapy, and 100 underwent combination therapy with ICI and chemotherapy. ICIs were administered as first-line therapy in 245 pts (24.1%), and second line in 524 (45.8%). The risk groups were distributed as follows: good risk (n=279, 24.4%), intermediate risk (n=437, 38.2%), and poor risk (n=428, 37.4%). Pts with PD-L1 tumor proportion score $\geq$50% were more frequent in the good-risk group (47.3%) than in intermediate (37.5%) or poor-risk groups (30.6%, P=0.001). Smoking history showed no significant association with risk groups (P=0.958). Pts receiving ICI monotherapy showed significant differences in overall response rate (ORR: 28.9% vs. 19.7% vs. 16.3%, P$<$0.001), median progression-free survival (mPFS: 6.1 vs. 3.5 vs. 2.4 months, P$<$0.001), and median overall survival (mOS: 26.4 vs. 14.6 vs. 11.3 months, P$<$0.001) among the good, intermediate, and poor-risk groups, respectively. Similar trends were observed in pts receiving ICI plus chemotherapy: mPFS (10.3 vs. 8.4 vs. 4.7 months, P=0.005), and mOS (27.9 vs. 22.4 vs. 17.6 months, P=0.047). Notably, *KEAP1* mutations were significantly more frequent in the poor-risk group (17.4% vs. 7.9%, P=0.020). **Conclusions:** AI-powered analysis of TILs and TLSs effectively stratifies NSCLC pts into risk groups, predicting efficacy outcomes of ICIs with or without chemotherapy. Research Sponsor: None.

First-line envafolimab in combination with recombinant human endostatin and chemotherapy for advanced squamous non-small cell lung cancer: Updated results from a prospective, single-arm, multicenter phase II study. First Author: Lian Liu, Department of Medical Oncology, Qilu Hospital, Cheeloo College of Medicine, Shandong University, Jinan, China

Background: Immunotherapy combined with chemotherapy has been established as the standard first-line treatment for patients with advanced squamous NSCLC (sq-NSCLC) without oncogenic driver mutations. Antiangiogenic drugs enhance immunotherapy efficacy by normalizing blood vessels and remodeling the tumor microenvironment. However, they pose a high bleeding risk in sq-NSCLC treatment. Recombinant human endostatin (Rh-endostatin), the only approved agent for sq-NSCLC, can prolong survival without increasing bleeding risk. This trial aimed to investigate the efficacy and safety of Envafolimab, the first approved subcutaneous single-domain anti-PD-L1 antibody, plus Rh-endostatin and chemotherapy as first-line treatment for advanced sq-NSCLC. **Methods:** This prospective, single-arm, multicenter, phase II trial was conducted at 3 research centers in China (NCT05243355). Patients with pathologically confirmed primary advanced or locally advanced unresectable sq-NSCLC. were enrolled. Patients received Envafolimab (300 mg, subcutaneously, day 1) and Rh-endostatin (210 mg, continuous intravenous infusion over 72 hours, day 1-3) combined with paclitaxel (175mg/m^2, day 1) or albumin paclitaxel (260 mg/m^2, day 1), and cisplatin (75 mg/m^2 , day 1-3), or carboplatin (AUC 5, IV, day 1); every 3 weeks for 4-6 cycles, followed by maintenance Envafolimab until disease progression (PD), unacceptable toxicity, or patient refusal. The primary endpoint was the 1-year PFS rate, and the secondary endpoints included objective response rate (ORR), disease control rate (DCR), progression-free survival (PFS), overall survival (OS), safety, and tolerability. **Results:** From December 2021 to December 2024, 33 eligible patients were enrolled, 26 of whom were included in the safety and efficacy analysis. As of December 16, 2024, the median follow-up was 16.5 months (95%CI: 8.1, NA). According to RECIST v1.1, the ORR was 65.4%, and the DCR was 96.2%. The median PFS (mPFS) was 12.4 months (95%CI: 11.4, NA) with a 1-year PFS rate of 59.9% (95%CI: 43.0%, 83.3%). The median OS (mOS) was 24.6 months (95%CI: 12.2, NA) with 1-year OS rate of 70.7% (95%CI: 54.2%, 92.1%) and a 2-year OS rate of 54.7% (95%CI: 36.9%, 81.1%). Overall, adverse events (AEs) of any grade were reported in 84.8% (28/33) of patients. The most common AEs were myelosuppression, alopecia, and nausea, which were more likely to be chemotherapy-related. 33.3% (11/33) of patients experienced immune-related AEs (irAEs). No unexpected AEs were observed. **Conclusions:** Our results demonstrated that Envafolimab in combination with Rh-endostatin and chemotherapy resulted in favorable clinical outcomes with a manageable safety profile, representing a promising treatment modality as first-line therapy for advanced sq-NSCLC. Clinical trial information: NCT05243355. Research Sponsor: None.

First-line immunotherapy with or without chemotherapy versus BRAF plus MEK inhibitors for patients with BRAF^{V600E}-mutated metastatic non-small cell lung cancer: The FRONT-BRAF study. First Author: Alessandro Di Federico, Lowe Center for Thoracic Oncology, Dana-Farber Cancer Institute, Harvard Medical School, Boston, MA

Background: Patients (pts) with BRAF^{V600E} mutated non-small cell lung cancer (NSCLC) can be effectively treated with BRAF and MEK inhibitors (BRAFi+MEKi) or with immune checkpoint inhibitors ± chemotherapy (ICI±CT). Which one should be prioritized as initial systemic treatment in this population remains unclear. **Methods:** Clinicopathologic data were collected from pts with metastatic BRAF^{V600E} mutated NSCLC treated with 1st line ICI±CT or BRAFi+MEKi between 2015 and 2024 at 17 centers across the United States, Europe, and Brazil. **Results:** Of 284 patients, 88 received ICI±CT and 196 received BRAFi+MEKi. Compared to pts treated with BRAFi+MEKi, pts receiving ICI±CT were more likely to have a history of smoking (83% vs. 61%, P$<$0.001) and a higher median PD-L1 tumor proportion score (TPS) (68% vs 30%, P$<$0.001). ICI±CT, compared to BRAFi+MEKi, was associated with a lower objective response rate (ORR, 49% vs 63%, P=0.03), similar median progression-free survival [mPFS, 9.6 vs.12.2 months (mo.), HR 1.13, P=0.43], but significantly improved median overall survival (mOS, 40.9 vs 25.1 mo., HR 0.69, P=0.039), even after adjusting in a multivariable model (HR 0.66, P=0.02). Consistent results were observed in a propensity score-matched cohort (1:1 ratio, N=75 pts per treatment group), where ICI±CT, compared to BRAFi+MEKi, was associated with improved mOS (40.9 vs 22.7 mo., HR 0.63, P=0.04), but similar ORR and mPFS. In key subgroup analyses, ICI±CT, compared to BRAFi+MEKi, was associated with longer mOS in pts with a history of tobacco smoking (HR 0.60, P=0.01), PD-L1 TPS $\geq$1% (HR 0.66, P=0.039), and without brain metastases (HR 0.66, P=0.045). A shorter mPFS was noted in pts without tobacco smoking history (HR 1.94, P=0.03). In evaluating genomic correlates of treatment efficacy, pts with *TP53* co-mutations (N=107) had worse outcomes compared to pts with wild-type *TP53* (N=121) when treated with BRAFi+MEKi, including shorter mPFS (HR 1.67, *P*=0.01) and mOS (HR 1.77, *P*=0.01), but not with ICI±CT. Notably, pts with *TP53* co-mutations had longer mOS with ICI±CT compared to BRAFi+MEKi (48.4 vs 18.8 mo., HR 0.46, *P*=0.005). In contrast, pts with *IDH1* co-mutations (N=9) had worse outcomes compared to pts with wild-type *IDH1*(N=188) when treated with ICI±CT, including shorter mPFS (HR 4.04, *P*=0.03) and mOS (HR 6.12, *P*=0.007), as well as shorter mPFS with BRAFi+MEKi (HR 2.73, *P*=0.03). Safety of BRAFi+MEKi was comparable whether administered as 1st line or as 2nd line therapy following ICI±CT, with similar rates of adverse events of any grade (71% vs 76%, P=0.58) and grade $\geq$3 (22% vs 23%, P=0.92). **Conclusions:** Initial therapy with ICI±CT, compared to BRAFi+MEKi, showed a lower ORR, similar PFS, but superior OS, particularly among specific subgroups of pts. A prospective evaluation of the optimal 1st-line therapy for this population is warranted. Research Sponsor: None.

8575 Poster Session

A meta-analysis of safety and efficacy of datopotamab deruxtecan and sacituzumab govitecan for second line treatment of metastatic non-small cell lung cancer (NSCLC). First Author: Omar Shukri Yaghi, George Washington University, Department of Medicine, Washington, DC

Background: Subsequent line treatment options for metastatic NSCLC remain limited. We sought to analyze the efficacy and safety of two Anti-TROP-2/topoisomerase inhibitor antibody-drug conjugates (ADCs), sacituzumab govitecan (SG) and datopotamab deruxtecan (Dato-DXd), for NSCLC treatment via a meta-analysis. **Methods:** A systematic search in PubMed, Scopus, and Cochrane identified 2348 studies. After excluding duplicates (1263) and screening abstracts (1085), 25 studies underwent full-text review, and 5 RCTs (3 Dato-DXd, 2 SG) were included. All included studies involved patients with advanced NSCLC that progressed on first-line treatment. Binary random effects and pooled proportions were calculated separately for Dato-DXd and SG using OpenMeta. The Mantel-Haenszel method with random effects estimated risk ratios and odds ratios with 95% confidence intervals for ADCs vs. docetaxel. Heterogeneity was assessed using I^2 statistics. **Results:** 616 Dato-DXd and 353 SG patients were included. Pooled proportions (PP) for grade 3 adverse events were 34.0% (Dato-DXd) and 75.4% (SG) while drug discontinuation rates were 7.1% (Dato-DXd) and 7.0% (SG), respectively. Efficacy outcomes included event rate, disease control rate, and overall response rate. For Dato-DXd, these pooled proportions were 52.0%, 76.5%, and 29.4%; for SG, they were 44.8%, 67.6%, and 14.3%. PPs and relevant statistics are included in table 1. When compared to docetaxel, combined ADCs showed no significant risk reduction in progression [RR: 0.96 (0.89 – 1.05), p=0.40, I^2=7%] or mortality [RR: 0.90 (0.58 – 1.38), p=0.63, I^2=43%]. Odds ratios for disease control rate [1.39 (0.76 – 2.54), p=0.29, I^2=83%] and overall response rate [1.33 (0.40 – 4.42), p=0.64, I^2=94%] were also insignificant. **Conclusions:** Direct comparisons between ADC (Dato-Dxd and SG) and docetaxel did not show a significant difference in disease progression or death rate. This study was limited by the small number of participants and heterogeneity of published literature as many clinical trials are still ongoing. Despite this, SG and Dato-DXd had a promising overall response rate of 67.6% and 76.5%, respectively. Research Sponsor: None.

Pooled proportions of Dato-Dxd and SG to docetaxel.

Efficacy of immune checkpoint inhibitors (ICIs) in advanced large cell neuroendocrine carcinoma (LCNEC) of the lung: A systematic review and meta-analysis. First Author: Parth Sharma, University of Missouri - Kansas City, Kansas City, MO

Background: LCNEC of the lung is a high-grade neuroendocrine carcinoma with characteristics of both small cell lung cancer (SCLC) and non-small cell lung cancer (NSCLC). Guidelines for optimal treatment for LCNEC are lacking due to the paucity of randomized control trials. Treatment regimens are often extrapolated from SCLC and NSCLC. Immunotherapy has revolutionized the outcomes of solid malignancies, including lung cancers, in the past decade. In this study, we assess the efficacy of ICIs in advanced LCNEC. **Methods:** A systematic literature search was conducted on PubMed, Embase, and Google Scholar for studies assessing the role of ICIs in advanced LCNEC of the lung. The study followed the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) Guidelines. A random effects model was used to pool the outcomes along with 95% confidence intervals (CI). Statistical analyses were performed using program R version 4.4.1. **Results:** We included 12 studies- 11 retrospective and 1 prospective analysis. The total number of advanced LCNEC patients across all the studies was 470. 241 patients received ICIs in total, either as monotherapy or in combination with chemotherapy or anti-angiogenic agents. The pooled Objective Response Rate (ORR) for patients receiving ICIs was 34.71% (95% CI: 27.75-41.97, I^2: 26.2%), whereas the pooled Disease Control Rate (DCR) was 71.87% (95% CI: 59.57-82.92, I^2: 67.7%). The most common ICIs across the cohort were atezolizumab, camrelizumab, nivolumab, and pembrolizumab. A subgroup analysis of three double-arm studies comparing chemotherapy alone (n=42) versus a combination of chemotherapy and ICIs (n=42) as a first-line treatment was performed. We found a favoring trend of the combination over chemotherapy alone for ORR (RR=1.58, 95% CI: 0.92-2.70; p=0.095), although non-significant, but significant advantage for DCR (RR=1.32, 95% CI: 1.04-1.68; p=0.021). **Conclusions:** ICIs have become the standard of care for treating SCLC and NSCLC in various combinations. ICIs, based on our meta-analysis, have also demonstrated encouraging results in advanced LCNEC. However, tumor factors such as molecular subtypes, genomic profiles, and other predictors influencing the response to ICIs need to be elucidated. Further larger prospective studies are awaited to determine their potential in this rare but aggressive subtype of lung cancer. Research Sponsor: None.

Artificial intelligence for immunotherapy response assessment in lung cancer using PET-CT reports. First Author: Ozden Altundag, Baskent University, Bahçelievler, Turkey

Background: Accurate and timely assessment of immunotherapy response is vital for optimizing lung cancer management. This study evaluates the efficacy of a large language model (LLM), Gemini 1.5 Pro, in automating response assessment using positron emission tomography/computed tomography (PET/CT) reports based on the European Organization for Research and Treatment of Cancer (EORTC) criteria. **Methods:** Google Gemini 1.5 Pro was selected due to its large context window capacity and its free availability via the web interface.The model was utilized with explicit instructions on applying EORTC criteria and fine-tuned using few-shot prompting. Pre- and post-immunotherapy PET-CT reports in text format from 33 lung cancer patients, anonymized in compliance with HIPAA regulations, were independently classified by the LLM and an experienced nuclear medicine specialist. Performance metrics, including precision, recall, F1-score, and support, were calculated for each response category. Inter-rater agreement was assessed using Cohen's Kappa. **Results:** The nuclear medicine specialist classified 5, 21, 6, and 1 cases as complete metabolic response (CMR), progressive metabolic disease (PMD), partial metabolic response (PMR), and stable metabolic disease (SMD), respectively, while Gemini 1.5 Pro classified 5, 20, 7, and 1 cases accordingly. The LLM achieved an overall accuracy of 97% and demonstrated excellent agreement with the expert (overall Cohen's Kappa: 0.945). F1-scores were 1.00 for CMR and SMD, 0.98 for PMD, and 0.92 for PMR, with per-label Kappa scores ranging from 0.904 (PMR) to 1.00 (CMR and SMD) (Table 1). **Conclusions:** Gemini 1.5 Pro exhibits strong potential for automating accurate immunotherapy response assessment in lung cancer using PET-CT reports. Its high concordance with expert evaluations underscores its utility in streamlining clinical workflows and improving efficiency. Validation with larger, more diverse datasets is warranted to support its clinical implementation. Research Sponsor: None.

Performance metrics of Gemini 1.5 Pro for immunotherapy response assessment.

Response	Precision	Recall	F1-score	Support	Cohen's Kappa
CMR	1.00	1.00	1.00	5	1.000
PMD	1.00	0.95	0.98	21	0.936

Multimodal AI using host, tumor, and ghost biomarker for predicting immunotherapy efficacy in NSCLC. First Author: Vanja Miscovic, Fondazione IRCCS Istituto Nazionale dei Tumori di Milano, Milan, Italy

Background: Almost all NSCLC patients (pts) without driver alterations received a first-line based immunotherapy (IO). It is unclear if pts with very poor (VP) overall survival (OS <6 months) will benefit from IO, advancing the hypothesis that this population might benefit more from next-generation drugs or supportive care. Non-response to IO is often linked to host immune fitness, such as circulating immune profiling (CIP). These "ghost biomarkers" can guide clinicians in making critical decisions, such as sparing IO in VP pts. APOLLO 11 study, aimed to develop an AI multimodal tool combining real-world data (RWD), CT-radiomics (CTRAD), and CIP to identify IO survival prediction VP pts. **Methods:** Data collected at Istituto Nazionale Tumori di Milano included: CTRAD features extracted using both a CT-scan Foundation Model (FM CTRAD) and PyRadiomics (pyRAD) features. The two methods were compared. Fluorescence-Activated Cell Sorting (FACS) analysis focused on identifying circulating low-density neutrophils and myeloid cells. Machine Learning (ML) multimodal pipelines for both classification (using LASSO as feature selector) and survival (using COX-ML) were developed using respectively OS < 6 months as threshold and overall survival as continuous outcome. SHAP explainability was applied to identify the most influential features contributing to model predictions. **Results:** Among 932 screened NSCLC pts treated with IO a (720 retrospective-R, 212 prospective-P), 495 had available baseline CT scans, with 638 lesions in the lung (397), lymph nodes (208), and pleura (29). Baseline FACS analysis was performed on 236 patients (162 R, 74 P). 117 pts had all three modalities. 4000 FM RAD features were extracted and reduced to 52 using PCA, while 107 features with pyRAD. Bimodal models with RWD and FACS achieved better performance (AUC 0.71±0.11) than bimodal models with RWD and CTRAD achieving an AUC 0.66±0.07 with pyRAD and 0.62±0.08 with FMRAD). The multimodal ML model, including all data modalities, achieved AUC 0.76 (±0.12). SHAP showed that high frequency of total myeloid cells (CD11b) and of immature neutrophils (CD10-CD16-), high LDH, high ECOG, low BMI, and two rad features as the most important for predicting VP. The survival multimodal model achieved a c-index of 0.76 ±0.10. **Conclusions:** The multimodal tool including all data modalities demonstrated superior performance in predicting OS. SHAP identified all data modalities as relevant, highlighting key "ghost biomarkers" for predicting OS and identifying VP pts. Given that this biomarker is fast (results within one day) and cheap (approximately €/$300), it can be easily integrated with RWD and RAD, which are readily available in clinical practice. This tool can reduce financial toxicity by guiding pts to the appropriate treatment. Finally, pyRAD features compared to FM features seem to perform better in bimodal models. Clinical trial information: NCT05550961. Research Sponsor: FONDAZIONE IRCCS ISTITUTO NAZIONALE DEI TUMORI DI MILANO.

Longitudinal plasma proteomic analysis: A monitoring strategy for NSCLC patients treated with immunotherapy. First Author: Yehonatan Elon, Oncohost Ltd, Binyamina, Israel

Background: Real-time monitoring is critical for tailoring treatments to individual patient responses in clinical oncology. Plasma proteomics offers a comprehensive systemic view of disease progression, tumor activity, immune responses, and various biological processes, making it a powerful tool for clinical decision-making. This study explores the feasibility of three specific plasma proteomic signatures for longitudinal monitoring of treatment responses in patients with non-small cell lung cancer (NSCLC) undergoing therapy with immune checkpoint inhibitors (ICIs). **Methods:** Plasma samples were collected from patients with advanced NSCLC receiving PD-1/PD-L1 inhibitor-based regimens. Cohort-1 (n=225) includes samples collected before treatment (T0) and 4-6 weeks after treatment initiation (T1). Cohort-2 (n=56) included samples collected pre-treatment and every three months, up to 36 months. Aptamer-based proteomic profiling quantified ~7,000 plasma protein analytes per sample. Three proteomic signatures were derived from T0–T1 changes in Cohort-1 and tracked in Cohort-2, then compared with radiologic imaging-based response evaluation. **Results:** Three distinct plasma proteomic signatures were identified. The first, featuring soluble PD-1 and PD-L1, indicates drug presence in circulation. The second reflects T-cell activation (e.g., CD8A, LAG3, IL2R), linked to drug uptake, without confirming a favourable tumor response. The third includes intracellular proteins indicative of lung tissue damage, allowing dynamic disease monitoring. Lung tissue damage signature correlated with radiologic imaging-based response evaluation (PR: *n* = 79, −4.19 [−12.47, 3.58]; SD: *n* = 125, 1.03 [−1.87, 5.01]; PD: *n* = 30, 3.37 [0, 7.27]; KW *P-value* = 0.01). Longitudinal analysis of these signatures facilitated early detection of non-responders in an average of 6.6 months [4 - 9.2 months, n=13] prior to radiologic evaluation. Among progressors, nine cases identified responders who later developed acquired resistance, distinguishing them from patients who did not respond to therapy at all. These findings highlight the potential of proteomic profiling to provide comprehensive systemic insights. A comparative analysis with ctDNA will also be presented to further validate these results. **Conclusions:** Our study demonstrates the feasibility of using plasma proteomic signatures to monitor responses to ICIs in NSCLC. We highlight the potential and emphasize the need to further develop these plasma-based monitoring tools through more extensive prospective studies. Such advancements are essential for establishing proteomic signatures as dependable decision-support tools in NSCLC treatment protocols. Research Sponsor: None.

Phase 2 study of atezolizumab with carboplatin plus pemetrexed followed by maintenance atezolizumab with pemetrexed for elderly patients with advanced non-squamous non-small cell lung cancer: CJLSG1902. First Author: Hidetoshi Itani, Department of Respiratory Medicine, Japanese Red Cross Ise Hospital, Ise, Japan

Background: Chemotherapy, including immune checkpoint inhibitors and platinum-containing agents, is a standard of care for patients with advanced non-small cell lung cancer (NSCLC). Pembrolizumab in combination with pemetrexed and cisplatin/carboplatin is approved as first-line treatment for patients with metastatic non-squamous NSCLC based on the results of KEYNOTE-189. However, data on the efficacy and safety of this regimen are limited in patients ≥75 years old. On the other hand, the results of the post hoc integrated analysis of IMpower130 and IMpower132 suggest that the efficacy and safety of atezolizumab in combination with platinum-based chemotherapy is maintained in patients ≥75 years old. **Methods:** This multicenter, open-label, phase 2 trial was conducted at 28 institutions in Japan to evaluate the efficacy and safety of atezolizumab with carboplatin plus pemetrexed followed by maintenance atezolizumab with pemetrexed. Eligible patients had metastatic/recurrent non-squamous NSCLC without sensitizing EGFR or ALK mutations, were aged ≥75 years, had received no prior systemic chemotherapy, and had an ECOG performance status of 0 or 1. For induction therapy, patients received atezolizumab (1,200 mg/body), pemetrexed (500 mg/m^2) and carboplatin (area under concentration-time curve 5 mg/mL/min) on day 1 of each 21-day cycle. For maintenance therapy, patients received atezolizumab (1,200 mg/body) and pemetrexed (500 mg/m^2) on day 1 of each 21-day cycle. Treatment continued until radiographic progression or unacceptable toxicity was observed. The primary endpoint was progression-free survival (PFS). Secondary endpoints were objective response rate (ORR), overall survival (OS), and safety. This trial is registered with the Japan Registry of Clinical Trials (jRCTs041200032). **Results:** From July 2020 to January 2023, 60 patients were enrolled in this study. Median age was 77.0 years (range 75-86), 84.1% of the patients were male, and 25.5% had a PD-L1 TPS ≥50%. The median PFS was 7.49 months (80% CI 5.52-7.75, exceeding the threshold of 5.5 months), and the median OS was 16.82 months (80% CI 14.49-20.93). The ORR was 55.9% (95% CI 42.4-68.8). The most common grade 3 or 4 adverse events were neutropenia (40.7%), leukopenia (35.6%), anemia (35.6%), and thrombocytopenia (30.5%). Serious adverse events were observed in 19 patients (6 with pneumonitis, 6 with febrile neutropenia). No treatment-related deaths were observed. **Conclusions:** This study met the primary endpoint of PFS. Atezolizumab with carboplatin plus pemetrexed followed by maintenance atezolizumab with pemetrexed showed favorable efficacy and the safety profile was manageable. This combination therapy is an encouraging option as a first-line treatment strategy for elderly patients with metastatic non-squamous NSCLC. Clinical trial information: 041200032. Research Sponsor: Chugai Pharmaceutical Co., Ltd.

Radiomic phenotypes of tumor angiogenesis compared with PD-L1 in pre-treatment prediction of outcomes across immunotherapy regimens in NSCLC: An external validation study. First Author: Vamsidhar Velcheti, Laura and Isaac Perlmutter Cancer Center, New York, NY

Background: Tumor angiogenesis is critical to cancer progression and treatment resistance, as evidenced by the success of therapies targeting both immune activation and neoangiogenesis. Conventional biomarkers like PD-L1 unreliably predict long-term patient outcomes such as overall survival (OS). Quantitative Vessel Tortuosity (QVT) isolates tumor-associated vessels and quantifies abnormal vascular architecture from pre-treatment radiography. We developed novel QVT Phenotypes of chaotic tumor angiogenesis and externally validated their use in the pre-treatment prediction of long term survival across multiple immunotherapy treatment strategies. **Methods:** QVT Phenotype is a radiomic AI biomarker developed and validated using a real-world dataset of 639 NSCLC patients from 6 institutions. Pre-treatment CT scans of 375 patients from institutions 1-3 were used for phenotype discovery (Dataset A). Deep learning models automatically extracted lung lesions and adjacent vessels. 910 QVT metrics of vascular abnormalities (e.g. curvature, twistedness, and branching) were computed and used to identify intrinsic vascular phenotypes via an unsupervised clustering agnostic. Two validation cohorts from external institutions 4-6 were used to evaluate association with 3-year OS: ICI monotherapy (Mono-ICI) recipients of mixed PD-L1 status (Dataset B, n=172) and Chemo-ICI recipients with PD-L1 TPS<50% (Dataset C, n=90). **Results:** 38% of patients were QVT High, with twisted and erratic growth patterns on pre-treatment CT scans indicating chaotic angiogenesis. Across validation cohorts (Datasets B+C), QVT-High emerged as a strong marker of poor survival (HR=2.26; p=<1E-5). In Dataset B, QVT-High better predicted poor Mono-ICI outcomes (HR=2.23, p=0.00080) than PD-L1 status (HR=1.99, p=0.032), with a 23.0 month reduction in median OS compared to QVT Low. QVT Phenotype maintained significance within the subset (n=61) of PD-L1 High patients (HR=3.02, p=0.017). In Dataset C, QVT-High stratified Chemo-ICI recipients by OS (HR=2.71, p=0.00060), while PD-L1 status failed to reach significance (HR=1.70, p=0.083). QVT-High Chemo-ICI patients had a 16.3 median OS reduction compared to QVT-Low patients. **Conclusions:** This validation study establishes QVT Phenotype as a non-invasive biomarker using standard-of-care pretreatment radiographic scans. QVT Phenotype of chaotic tumor angiogenesis is both interpretable and treatment-agnostic. QVT Phenotype predicted survival across multiple immunotherapy regimens in NSCLC, outperforming PD-L1. QVT phenotyping can be used to identify patients unlikely to benefit from existing SOC treatments. Future work will explore using QVT Phenotypes to identify patients who may benefit from escalated therapeutic strategies, including those incorporating anti-angiogenic mechanisms. Validation of HistoTME-predicted immune subtypes and immunotherapy outcomes using human interpretable features (HIFs) from H&E images in non-small cell lung cancer. First Author: Meghdad Sabouri Rad, SUNY Upstate Medical University, Syracuse, NY

Background: Tumor microenvironment (TME) plays a critical role in tumor progression and response to treatment, especially in improving the response to immune checkpoint inhibitors (ICIs) in non-small cell lung cancer (NSCLC). However, current methods are costly and not feasible for routine clinical use for characterizing the TME. Addressing this, we recently developed Histo-TME, an AI-powered tool that accurately characterizes TME subtypes and ICI responses from routine hematoxylin-eosin (H&E) scanned images. This study aims to validate and interpret HistoTME-predicted subtypes using a series of machine learning (ML) models (PathExplore, PathAI, Boston, MA) that output human interpretable features (HIFs) to quantitatively characterize the TME. **Methods:** We analyzed 1375 H&E images from 689 NSCLC patients using PathExplore algorithm, which yielded 171 HIFs spatially characterizing tumor-immune cell interactions. Unsupervised k-means clustering (UMAP) identified distinct patient subgroups based on these HIFs. We compared these subgroups to Histo-TME classifications from the same cohort and evaluated their association with immunotherapy response using Kaplan-Meier (KM) and Cox proportional hazards analyses. **Results:** Five distinct clusters with varying immune infiltration were identified using the 171 HIFs in UMAP clustering. Three out of five clusters characterized by the abundance of macrophages, plasma cells, lymphocytes and fibroblasts within proximity of tumor cells (i.e. 40μm radius), resembled the "Immune Inflamed" subgroup as predicted by HistoTME. There was no survival difference between HIF- and HistoTME-predicted immune inflamed and immune-desert clusters in KM analysis (p>0.05). Both HIF-defined clusters and the HistoTME subtypes had similar median overall survival times (4.33 vs. 4.18 years for "Immune Inflamed", p>0.05; 1.84 vs. 2.62 years for "Immune Desert", p>0.05) in KM analysis. Multivariate analysis adjusted for AJCC stage, age, smoking, ECOG, and CCI demonstrated that both methods have comparable predictive values for overall survival (HIF clusters; HR: 0.69, CI: 0.58-0.81; p<0.001 vs. HistoTME subtypes; HR: 0.80, CI: 0.68-0.94; p=0.008). **Conclusions:** This study independently validates our published HistoTME method, confirming its ability to accurately identify patients who are likely to respond to ICI therapy using H&E scanned images. Our findings underscore the importance of incorporating TME characteristics using AI-based approaches in routine histopathology and clinical decision-making workflows. Research Sponsor: None.

Survival and safety of two year-fixed duration vs continuous immune checkpoint inhibitor therapy in advanced or metastatic NSCLC: A systematic review. First Author: Toshali Pandey, University of Arkansas for Medical Sciences, Little Rock, AR

Background: The optimal duration of immune checkpoint inhibitor (ICI) therapy in advanced or metastatic non-small cell lung cancer (NSCLC) is unknown. While multiple randomized clinical trials (RCTs) have shown the benefit of ICI-based regimens over chemotherapy, they were not designed to test optimal duration of ICI. Most trials opted to continue ICI indefinitely or stopping at two years if no progressive disease or treatment limiting immune-related adverse events (irAEs) emerged. There is concern for increased cumulative risk of irAEs with indefinite treatment. **Methods:** A systematic review of randomized controlled trials (RCTs) and real-world evidence (RWE) studies was performed for adult patients with advanced/metastatic NSCLC treated with ICI therapy (alone or in combination) up to August 24, 2024. Studies were included if they specifically reported on patients who completed a minimum of 2 years of therapy. Databases, conference abstracts and clinical trials were queried. Patients were divided into two cohorts: a two year-fixed cohort where ICI therapy was discontinued after 2 years, and a continuous cohort where ICI therapy was continued beyond 2 years. **Results:** The database search identified 8741 records of which 174 articles were screened. The final qualitative analysis included 20 studies (11 RCTs and 9 RWE studies) and 5027 patients. There were 23 cohorts that belonged to the 2 year-fixed group (N=2051) and 7 that belonged to the continuous group (N=2976). Outcomes of patients in the 2 year-fixed arms from RCTs were excellent with 5-year overall survival (OS) rates in the range of 69-83%. This was supported by RWEs which showed similar OS rates. Continuous treatment with ICIs had similar OS rates in both RCTs and RWE and was comparable to the 2 year-fixed arms. Four RWE studies compared hazard ratios (HR) for survival outcomes among 2 year-fixed vs continuous arms and did not find any statistically significant difference. Patients that completed 2 years of therapy in RCTs tended to have greater rates of irAEs compared to the baseline population but lower rates of grade 3 or 4 events. Three out of four RWEs reported higher rates of irAEs in the continuous vs 2 year-fixed arms. These findings were likely associated with longer exposure to immunotherapy. A large proportion of patients that developed progressive disease after the 2 year-mark in both 2 year-fixed and continuous arms was alive at data cut-off. Many of these were re-challenged with ICI therapy. Data from RWEs showed that larger/academic centers tended to favor 2 year-fixed therapy whereas the reverse was true for community centers. **Conclusions:** Survival outcomes after ICI discontinuation at 2 years are comparable to continuous therapy in advanced/metastatic NSCLC. Immune-related adverse events tend to accumulate over time. Progressive disease is often localized and amenable to ICI re-challenge. Research Sponsor: None.

Phase 2 study of telomere-targeting agent THIO sequenced with cemiplimab in third-line immune checkpoint inhibitor–resistant advanced NSCLC: Evaluation of overall survival (OS). First Author: Tomasz Jankowski, Medical University in Lublin, Lublin, Poland

Background: Despite advancements in third line treatments, long-term survival for advanced non-small cell lung cancer (NSCLC) remains suboptimal, with median survival follow-up of only 5.8 months.[1] Among patients treated with prior platinum chemotherapy and immune checkpoint inhibitors (ICIs), the median survival was reported to be 6.47 months[2]. Treatment options for ICI-resistant patients are limited. THIO, a telomere-targeting agent that modifies telomeres in cancer cells, demonstrates improved overall survival (OS) independent of PD-L1 expression. **Methods:** NCT05208944 is a phase 2, multicenter, open-label study that enrolled 79 patients with advanced NSCLC who relapsed after 1–4 prior treatments, including ICIs. In the third line therapy 22 patients treated with THIO (60, 180, or 360 mg) were evaluated for OS and their prior PD-L1 expression at the time of study enrollment (C1D1). **Results:** In the third line therapy 22 patients have a current median survival follow-up of 13 months which significantly surpassed the benchmark value, and in the 180 mg dose group (n=10) it reached 16.9 months compared to 5.8 months for the benchmark.[1] THIO followed by cemiplimab was generally well tolerated in this difficult-to-treat population. The response to THIO and cemiplimab, demonstrated by partial response (PR) and stable disease (SD) was independent of baseline PD-L1 status. This indicates that THIO can be effective across patients regardless of their PD-L1 status. **Conclusion:** THIO demonstrates clinically meaningful OS improvement in third line patients with advanced NSCLC, independent of PD-L1 status. The improved OS observed in patients treated with THIO in sequential combination with an ICI, compared to standard chemotherapy, supports its potential to expand treatment options for ICI-resistant advanced NSCLC. Clinical trial information: NCT05208944. Research Sponsor: MAIA Biotechnology Inc.

Efficacy profile of pembrolizumab for primary pulmonary NUT carcinoma: A systematic review and meta-analysis. First Author: Amruth Akhil Alluri, American University of the Caribbean School of Medicine, Cupecoy, Sint Maarten (Dutch part)

Background: Primary pulmonary NUT carcinoma is an exceedingly rare and aggressive malignancy characterized by chromosomal rearrangements involving the NUT gene. With limited therapeutic options and an extremely poor prognosis, treatment strategies have focused on identifying effective targeted and immunotherapeutic approaches. Pembrolizumab, an anti-PD-1 immune checkpoint inhibitor, has shown promise in various malignancies, particularly those with high tumor mutational burden or PD-L1 expression. However, despite its use, its efficacy in NUT carcinoma remains poorly understood due to the rarity of this disease and a paucity of robust clinical data. This systematic review and meta-analysis aim to explore the available evidence on the clinical data of pembrolizumab in treating primary pulmonary NUT carcinoma, focusing on progression-free survival (PFS), and overall survival (OS) by consolidating outcomes from case reports and case series. **Methods:** A systematic review and meta-analysis were conducted to evaluate the effectiveness of pembrolizumab in the treatment of primary pulmonary NUT carcinoma. A comprehensive search of PubMed, Embase, and Cochrane was performed for articles published between January 2014 and December 2024, using the keywords "pembrolizumab," "Pulmonary NUT carcinoma," and "NUT midline carcinoma." Inclusion criteria included reports of patients treated with either pembrolizumab monotherapy or pembrolizumab in conjunction with other therapies for Primary Pulmonary NUT Carcinoma for any duration. Reports that did not mention PFS or OS were excluded. **Results:** A total of 39 reports involving 56 patients with primary pulmonary NUT carcinoma treated with pembrolizumab, either in conjunction with other therapies or monotherapy, were analyzed. The median overall survival (OS) was 7.3 months (95% CI: 5.2–8.8), and the median progression-free survival (PFS) was 4.6 months (95% CI: 3.1–5.7). Among three patients receiving pembrolizumab monotherapy as a second-line or later treatment, the median PFS was 2.9 months. **Conclusions:** Pembrolizumab has been explored as second-line or later therapy for primary pulmonary NUT carcinoma based on its success in treating NSCLC. Our analysis revealed a median progression-free survival of 4.6 months and a median overall survival of 7.3 months for patients with primary pulmonary NUT carcinoma receiving pembrolizumab, illustrating the continuing challenge of treating this rare malignancy. Importantly, there are no randomized controlled trials investigating pembrolizumab in this rare malignancy, highlighting a critical gap in evidence. Prospective clinical trials and further research into biomarkers predictive of treatment response are urgently needed to optimize therapeutic strategies and improve outcomes for patients with this aggressive disease. Research Sponsor: None.

8587 Poster Session

Survival after osimertinib dose-reduction, discontinuation in 1L *EGFR*-mutated metastatic non-small cell lung cancer (mNSCLC). First Author: Adam Barsouk, Abramson Cancer Center, Penn Medicine, Philadelphia, PA

Background: Osimertinib (osi) has become standard of care in 1L EGFR mt (+) mNSCLC following the FLAURA trial in patients (pts) with classical sensitizing mutations. However, limited data are available on the effect of osimertinib dose reductions on survival outcomes compared to pts on full dose. **Methods:** We performed a single-institution retrospective analysis of pts with *EGFR*-mutated mNSCLC treated with 1L osi from 2018-2023 Clinical trial pts were excluded. Pts who underwent dose reduction were compared to those maintained on full dose (at least 80mg daily). Baseline demographics, disease characteristics, treatment history, toxicity, and clinical outcomes were abstracted from the electronic medical record (EMR) and compared using independent sample t-tests and chi-square analyses as appropriate. Median progression free survival (mPFS) and overall survival (mOS) were compared via Kaplan-Meier log-rank analysis and Cox regression analysis, with sex, race, age, PS, smoking hx, CNS involvement, and mutation status included *a priori*. **Results:** 171 pts with mNSCLC treated with 1L osi were identified. 26 (15%) required dose reduction. Patient sex (p=0.458), racial distribution (p=0.421), ECOG PS>1 at diagnosis (p=0.730) and smoking history (p=0.485) were comparable between reduced dose and full dose pts (Table 1). 44% vs 34% had CNS metastases at diagnosis (p=0.192). Rates of *TP53* (p=0.712) and atypical *EGFR* mutations (p=0.393) were also comparable. All dose-reduced pts experienced AEs, compared to 48% of full-dose pts ($p<0.001$). Dose-reduced pts had inferior mPFS (17.0 months [11.5-22.5]) compared to full-dose pts (24.6[19.2-28.8]; p=0.043. PFS with dose-reduction was inferior compared to full dose with (p=0.041) or without CNS metastases (p=0.048). On multivariable analysis, dose-reduction was associated with inferior PFS (p=0.047) regardless of baseline characteristics. OS, however, was comparable in pts with and without dose-reduction (36.7 [28.1-45.4] vs 39.2 [34.8-43.7]; p=0.749)). 14 pts (8%) discontinued osi due to AEs, of whom 9 (64%) were previously dose reduced. mPFS was comparable (p=0.334) between pts who discontinued and those who did not, as was mOS (p=0.910). **Conclusions:** Dose reduction of osimertinib was relatively uncommon and associated with inferior PFS but similar OS in 1L pts with *EGFR*-mutated mNSCLC. Research Sponsor: None.

Baseline characteristics and survival.

Baseline Characteristics	Dose reduced (n=26)	Full dose (n=145)	Sig (p)

Clinical relevance of starting alectinib at a reduced dose in patients with ALK-positive non-small cell lung cancer. First Author: Junkyu Kim, Division of Hematology-Oncology, Department of Medicine, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, South Korea

Background: Alectinib has been approved for Anaplastic lymphoma kinase (ALK)-positive non-small cell lung cancer (NSCLC) at a lower dose (300 mg twice daily: b.i.d.) in Japan than the rest of the world (600 mg b.i.d.). To evaluate the clinical relevance of reducing the starting dose of alectinib, we compared the clinical outcomes of patients treated with one of the two doses. **Methods:** This study included patients with advanced ALK-positive NSCLC who received alectinib at Samsung Medical Center, Korea. The progression-free survival (PFS), overall survival, cumulative incidence of central nervous system (CNS) progression, and safety profiles were retrospectively reviewed and compared. **Results:** Among 306 patients, 32 and 274 received alectinib at either 300 or 600 mg b.i.d., respectively. The 300 mg group showed a slight but not significant advantage in PFS (HR 0.82, 95% CI 0.44-1.51, p=0.51) and overall survival (HR 0.51, 95% CI 0.20-1.21; p=0.13) compared with the 600 mg group. Interestingly, the superior survival outcome in the 300 mg group was remarkable in patients with lower body weight (≤60 kg). However, this advantage diminished at higher body weights (>60~75 kg or >75 kg). In addition, there was a slight tendency toward a higher incidence of CNS failure in the 300 mg group of patients with baseline brain metastasis (HR 1.76, 95% CI 0.53-5.8; p=0.36). Although the safety profiles were mostly mild and manageable in both groups, the 600 mg group showed more frequent adverse events than the 300 mg group and required dose reduction in 137 patients (50%). **Conclusions:** Alectinib at 300 mg b.i.d. seems an acceptable dose in patients with ALK-positive NSCLC even in areas outside Japan. Notably, our data favor 300 mg b.i.d. in patients with lower body weight and no baseline brain metastasis, considering the more tolerable safety profiles and the potential to reduce medical costs. Research Sponsor: None.

Depth of response and progression-free survival in patients with advanced *ALK*-positive non–small-cell lung cancer treated with lorlatinib. First Author: Rosario Garcia Campelo, University Hospital A Coruna HRS4R Universia gal, A Coruña, Spain

Background: After 5 years of follow-up in patients with *ALK*-positive non-small cell lung cancer (NSCLC) treated with lorlatinib, median progression-free survival (PFS) was still not reached in the phase 3 CROWN study (NCT03052608). This represents the longest PFS for any single-agent molecular targeted treatment in advanced NSCLC and all metastatic solid tumors. Depth of response (DepOR) is defined as the best percent shrinkage in tumor size compared with baseline. In this post hoc analysis of data from the CROWN study, we assessed the association between DepOR and PFS. **Methods:** The CROWN study is an ongoing, international, open-label, randomized, phase 3 trial comparing lorlatinib vs crizotinib in patients with previously untreated *ALK*-positive advanced NSCLC. Patients were randomized 1:1 to receive oral lorlatinib 100 mg once daily or crizotinib 250 mg twice daily. This analysis examined how DepOR is associated with baseline demographics, tumor characteristics, PFS, and tumor biomarkers. Patients were evaluable for DepOR if they had target lesions at baseline and ≥1 adequate postbaseline assessment up to the time of progressive disease or new anticancer therapy. A genAI tool (12/20/24; Pfizer; GPT-4o) developed the 1st draft; authors assume content responsibility. **Results:** In the lorlatinib group, 142 of 149 (95%) randomized patients were evaluable for DepOR; 29 (20%) had 0%-50% DepOR, 65 (46%) had >50%-75%, and 48 (34%) had >75%-100%. Baseline demographics and tumor characteristics were similar between the DepOR groups, although the percentage of patients with baseline brain metastases was higher in the greater DepOR group. PFS improved with increasing DepOR (Table). Key biomarker analyses evaluating *EML4-ALK* long- and short-variant subgroups and circulating tumor DNA dynamics, based on DepOR groups, will be reported. **Conclusions:** Greater DepOR was associated with PFS benefit in patients with advanced *ALK*-positive NSCLC treated with lorlatinib. Clinical trial information: NCT03052608. Research Sponsor: Pfizer.

Impact of lorlatinib dose modifications on adverse event outcomes in the phase 3 CROWN study. First Author: Geoffrey Liu, Princess Margaret Cancer Centre, Toronto, ON, Canada

Background: In an updated analysis of the CROWN study (NCT03052608), after 5 years of follow-up, lorlatinib continued to show superior efficacy over crizotinib in patients with previously untreated advanced *ALK*+ non-small cell lung cancer (NSCLC), with median progression-free survival (PFS) still not reached. A post hoc analysis of CROWN found no impact on PFS or time to intracranial progression with lorlatinib dose reductions within the first 16 weeks. These findings underscore the importance of dose modifications to mitigate toxicity and maintain long-term treatment efficacy. The objective of this analysis was to further characterize lorlatinib dose reductions and their impact on safety and adverse event (AE) outcomes. **Methods:** The CROWN study is an ongoing, international, open-label, randomized phase 3 trial comparing lorlatinib vs crizotinib in patients with previously untreated advanced *ALK*+ NSCLC. Patients were randomized 1:1 to receive lorlatinib 100 mg once daily (QD; n=149) or crizotinib 250 mg twice daily (n=147). This post hoc analysis used data from the 5-year follow-up to assess time to dose reduction, duration of treatment with reduced dose, and its impact on AEs and outcomes associated with lorlatinib. A genAI tool (12/13/24; Pfizer; GPT-4o) developed the 1st draft; authors assume content responsibility. **Results:** At 5 years of follow-up, 49 of 149 patients in the lorlatinib arm had ≥1 lorlatinib dose reduction. Treatment is ongoing in 33% of patients who had 1 dose reduction (n=24) and in 20% who had 2 dose reductions (n=25). In patients who had 1 dose reduction to 75 mg QD, median time to dose reduction was 7.1 months (range, 1.7-64.8), and median duration of treatment with the 75-mg dose was 42.2 months (range, 0.2-68.3). In patients who had 2 dose reductions (dose reduced to 75 mg QD and then again to 50 mg QD), median time to second dose reduction was 11.3 months (range, 2.5-56.9), and median duration of treatment with the 50-mg dose was 20.7 months (range, 0.5-61.8). In patients who had 1 or 2 dose reductions, all-cause AEs associated with dose reductions are shown in the table. Of the 30 AEs leading to 1 dose reduction, 27% of events resolved and 13% partially resolved. Of the 59 AEs leading to 2 dose reductions, 46% of events resolved and 5% partially resolved. **Conclusions:** This post hoc analysis of the CROWN study showed that dose reductions were effective in managing AEs associated with lorlatinib. These findings show the importance of dose modifications to mitigate toxicity and continue lorlatinib treatment for prolonged periods of time in patients with advanced *ALK*+ NSCLC. Clinical trial information: NCT03052608. Research Sponsor: Pfizer.

Dynamic changes in target protein expression following treatment in NSCLC: Simultaneous evaluation of MET, TROP2, HER2, B7-H4, and MDM2 expression in paired biopsies. First Author: Saori Murata, Department of Thoracic Oncology, National Cancer Center Hospital, Tokyo, Japan

Background: Antibody-drug conjugates and bispecific antibodies targeting non-small cell lung cancer (NSCLC) tumor surface antigens are under development, but the impact of prior treatments on target protein expression remains unclear. This study evaluates changes in the expression of multiple therapeutic target proteins in the same patient before and after treatments. **Methods:** Patients diagnosed with NSCLC underwent rebiopsy after treatments at the National Cancer Center Hospital between 2014 and 2023 were eligible. Tissues were obtained by surgery, bronchoscopy, or needle biopsy with an interval of at least 100 days of systemic anti-cancer therapy. We investigated clinicopathological features in paired specimens focusing on tumor-associated surface proteins potentially related to novel drug development such as MET, TROP2, HER2, B7-H4, and MDM2. TROP2, B7-H4, and MDM2 were evaluated using the H-score. HER2 was evaluated on a scale from 0 to 3+, as previously reported. For MET, a scoring system was adopted in which overexpression (OE) was defined as IHC 3+ positive cells representing 25% or more of the cells. **Results:** A total of 51 cases were included in this study. The median age was 64 years. Of the patients, 27 (57%) were male, 33 (65%) were smokers, and 45 (88%) had lung adenocarcinoma. EGFR 24 cases (47%)/ALK 8 cases (16%)/BRAF 1 case (2%)/ROS1 1 case (2%) were identified among 34 cases with actionable genetic alterations (AGAs). The proportion of MET OE before and after treatment was 33.3%/45.1% overall. In subgroup analyses, the proportions were 38.2%/47.1% (AGA positive), 23.5%/41.2% (AGA negative), 36.0%/52.0% (PD-L1 positive), and 30.8%/38.5% (PD-L1 negative). For HER2 positive (2+, 3+) cases, the overall proportions were 20.9%/11.6%, while subgroup proportions were 15.2%/12.1%, 40.0%/10.0%, 20.0%/15.0%, and 21.7%/8.7%, respectively. The proportion of patients who experienced change in protein expression after previous treatment was as follows: MET, 31.4%; TROP2, 29.4%; HER2, 27.9%; B7-H4, 0.0%; MDM2, 51.0%. **Conclusions:** MET, TROP2, HER2, and MDM2 showed expression changes before and after treatment in approximately 30% of patients. There were differences in the rate of change depending on whether AGA was present, with a higher rate of change in AGA negative patients. Based on these findings, rebiopsy after treatment is recommended when considering therapies targeting tumor surface protein antigens. Research Sponsor: None.

Percentage change in MET, TROP2, HER2, B7-H4, and MDM2 following previous treatment.

	MET (%)	TROP2 (%)	HER2 (%)	B7-H4 (%)	MDM2 (%)
Proportion changing (n=51)	31.4	29.4	27.9	0.0	51.0

RC108 in combination with furmonertinib in patients with locally advanced or metastatic EGFR-mutated non-small-cell lung cancer (NSCLC) with MET overexpression: Results from a phase Ib/II trial. First Author: Yutao Liu, National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College, Beijing Key Laboratory of Clinical Study on Anticancer Molecular Targeted Drugs, Beijing, China

Background: Patients (pts) who have progressed on EGFR-TKI treatment have limited treatment choices when accompanied by MET overexpression. RC108 is a MET-directed ADC with the microtubule inhibitor monomethyl auristatin E (MMAE) as the cytotoxin and it may overcome primary/secondary MET-driven resistance to EGFR-TKI. We report the preliminary safety and efficacy results of RC108+furmonertinib (F, a third-generation EGFR-TKI) in pts with MET-overexpressing and EGFR-mutated locally advanced or metastatic (la/m) NSCLC who failed prior EGFR-TKI from a phase 1b/2 trial (NCT05821933). **Methods:** The key eligibility criteria were histologically or cytologically confirmed la/m NSCLC with at least one documented EGFR sensitizing mutation, MET-overexpression (defined as IHC 1+/2+/3+ in ≥10% of tumor cells), and disease progression on prior 1st/2nd/3rd-generation EGFR-TKI treatment. Pts received RC108 (at doses of 1.5 or 2.0 mg/kg, Q3W) + F (80 mg, QD) until disease progression or intolerable toxicity. Radiological tumor assessment was performed every 6 weeks by investigators per RECIST v 1.1. The primary endpoints were safety and objective response rate (ORR). Data cutoff date for this analysis was Sep 12, 2024. **Results:** A total of 31 pts were enrolled and received at least one dose of treatment, including 2 and 29 pts in the 1.5 and 2.0 mg/kg cohorts, respectively. The most frequent treatment-related adverse events (TRAEs) were nausea (51.6%), asthenia (48.4%), decreased appetite (45.2%), vomiting (45.2%), white blood cell count decreased (35.5%), alopecia (35.5%), and hypoesthesia (32.3%). Grade ≥3 TRAEs occurred in 7 (22.6%) pts. TRAEs led to treatment discontinuation in 1 (3.2%) pt. One pt died due to abnormal hepatic function, possibly related to the study treatment per the investigator's assessment. Among the 24 pts with at least one post-baseline tumor assessment in the 2.0 mg/kg cohort (79.2% with ECOG PS 1, 58.3% with exon 19 deletion, 33.3% with exon 21 L858R, and 62.5% with ≥2 prior lines of treatment), the ORR was 37.5% (95% CI: 18.8-59.4) and disease control rate (DCR) was 75.0% (95% CI: 53.3-90.2). In the 18 pts with ≥10% of tumor cells with 1+/2+/3+ membrane staining and ≤20% tumor cells with strong (3+) cytoplasmic staining, ORR was 50.0% (95% CI: 26.0-74.0) and DCR was 83.3% (95% CI: 58.6-96.4). The progression-free survival data were immature and under follow-up. **Conclusions:** RC108+F showed encouraging antitumor activity with manageable safety profile in pts with MET-overexpression. At the same time, this study demonstrated better efficacy in the population with lower MET expression in the cytoplasm. We will continue to explore more beneficial populations in future studies. Clinical trial information: NCT05821933. Research Sponsor: RemeGen Co., Ltd.

Impact of standard vs reduced dosing of sotorasib on efficacy and toxicity in KRAS G12C–mutated advanced non-small cell lung cancer: A systematic review and meta-analysis. First Author: Wint Yan Aung, Zuckerberg Cancer Center, Northwell Health, Lake Success, NY

Background: KRAS is the most common oncogenic driver in lung adenocarcinoma. Advances in targeted therapies such as Sotorasib have improved outcomes, but optimizing dosing strategies is crucial to balance efficacy and tolerability. Sotorasib serves as an illustrative example, as it was the first drug for which the FDA requested a dose optimization strategy. The FDA's decision to maintain 960 mg dose was influenced by CodeBreaK100 and CodeBreaK200 trials. CodeBreaK100, which demonstrated an ORR of 36%, formed the basis for accelerated approval, while CodeBreaK200 confirmed clinical benefit. A post-approval dose randomization study comparing 240 mg and 960 mg doses found no clear exposure-safety relationships, though ORR was numerically higher for 960 mg. However, tolerability remains challenging with 960 mg dose, often requiring dose reductions in clinical practice. This systematic review and meta-analysis evaluates the impact of starting at 960 mg of Sotorasib versus reduced dose on efficacy and toxicity, with implications for optimizing dosing strategies in targeted therapies. **Methods:** We conducted a systematic search of PubMed, EMBASE, SCOPUS, CINAHL, and Web of Science up to Oct 1,2024. Eligible studies included randomized clinical trials, prospective and retrospective studies, reporting efficacy outcomes (ORR, PFS), and treatment-related adverse events. Pooled estimates for efficacy and toxicity outcomes were calculated using random effects model. **Results:** Out of 4510 studies screened, 145 full-text articles were assessed for eligibility, resulting in 14 studies, of which 9 focused on Sotorasib. The pooled ORR was 32% (95%CI 28%-36%) for patients starting at 960 mg (n=889), compared to 26% (95%CI 19%-34%) for those starting at a reduced dose (n=130) with no statistically significant difference (RR 1.26, 95%CI 0.87-1.83). The pooled hazard ratio for PFS did not show a significant benefit for starting at 960 mg compared to at reduced dose (HR 0.77, 95%CI 0.56-1.05). Adverse events leading to dose reduction and discontinuation at 960 mg were 16% (95%CI 10%-23%) and 9% (95%CI 6%-13%), respectively. Limited toxicity data were available for those who started treatment at reduced dose, precluding direct comparison. **Conclusions:** While the standard 960 mg dose of Sotorasib showed a trend toward higher ORR compared to starting at reduced doses, it is associated with significant toxicity, resulting in frequent dose reductions and treatment discontinuation. No significant PFS benefit was observed with starting at 960 mg dose, highlighting the need to optimize dosing strategies that balance efficacy with tolerability.Future studies should include subgroup analyses of efficacy and tolerability for dose reductions to guide optimal dosing regimens, aligning with initiatives like the FDA's Project Optimus to improve patient outcomes. Research Sponsor: None.

Area deprivation index and EGFR-mutated non-small-cell lung cancer. First Author: Michael Seth Weinfeld, University of Illinois Chicago, Chicago, IL

Background: Survival outcomes in patients with non-small-cell lung cancer (NSCLC) have improved in recent decades with availability of immunotherapy and targeted therapies such as inhibitors of mutated epidermal growth factor receptor (EGFR). However, significant disparities in lung cancer outcomes exist, with many patients not offered biomarker testing and subsequent underuse of targeted therapies. Because it is not well known how social determinants of health (SDOH) impact the use of targeted therapies, we conducted a study to determine the association between area deprivation index (ADI) and presence of mutated EGFR in a large electronic health record (EHR) database. ADI is a validated measure of neighborhood socioeconomic deprivation, a SDOH metric. **Methods:** This retrospective, observational study used Epic Cosmos, a United States database of deidentified data derived from EHR, to measure the association between ADI and EGFR mutations in patients with stage IV NSCLC treated between January 1, 2015 and December 31, 2022. Receipt of EGFR inhibitors (EGFRIs) was used as a surrogate marker for mutated EGFR, as pathology and molecular data for individual patients were not available from aggregate data. Chi square analysis was used to compare ADI between those who did and did not receive EGFRIs. **Results:** From a total of 6866 patients meeting criteria for inclusion in our analysis, 653 (9.5%) received EGFRIs while 6213 (90.5%) did not. In the EGFR population, 210 (32.2%) were in the top two quintiles of ADI (most deprivation) while 275 (42.1%) were in the bottom two quintiles of ADI (least deprivation). For the non-EGFR population, 3137 (50.5%) were in the top two quintiles while 1373 (22.1%) were in the bottom two quintiles. Patients who received EGFRIs were more likely to be in the bottom two quintiles of ADI compared to those who did not (OR 2.99, 99% CI 2.32-3.84, $p<0.0001$). To control for confounding variables, this analysis was repeated after stratifying by geography, sex, smoking status, insurance, and race. This difference in ADI between the EGFR and non-EGFR groups persisted within strata of similar patients including White females with a smoking history in the Northeast with Medicare (OR 7.28, 99% CI 1.56-34.01, p=0.0009) and White females with a smoking history in the Midwest with Medicare (OR 4.76, 99% CI 1.19-19.10, p=0.0038). **Conclusions:** These data suggest that patients with EGFR mutations, as determined by receipt of EGFRIs, were more likely to reside in neighborhoods with less socioeconomic deprivation. Because of limitations posed by our analytic approach, we were unable to determine if there was a direct association between ADI and the molecular profile of NSCLC, or if these findings are primarily related to differential access to care. Nonetheless, the association persisted within strata of similar demographics, suggesting that it is not entirely explained by confounding related to geography, race, sex, or smoking status. Research Sponsor: None.

Final results of afatinib plus chemotherapy with genomic profiling in osimertinib-refractory EGFR-mutant NSCLC: NEJ025B. First Author: Akihiko Miyanaga, Department of Pulmonary Medicine and Oncology, Graduate School of Medicine, Nippon Medical School, Tokyo, Japan

Background: Osimertinib is commonly used as a first-line treatment for EGFR-mutated advanced NSCLC. However, the optimal treatment following osimertinib failure remains unclear. This study evaluated afatinib plus chemotherapy for EGFR-mutated NSCLC resistant to osimertinib. Initial findings were presented at ASCO2023, and this report provides final data, including blood NGS analysis. **Methods:** Patients (pts) with EGFR mutations (Del19 or L858R) after osimertinib failure were treated with afatinib (20 mg daily) combined with carboplatin (AUC5 mg/mL/min) and pemetrexed (500 mg/m² every 3 weeks), followed by maintenance therapy with afatinib plus pemetrexed until progression or unacceptable toxicity. The primary endpoint was the 6-month progression-free survival rate (6M-PFSR). Secondary endpoints included PFS, OS, ORR, DOR, and safety. Blood samples were collected before and during treatment, and at progression, to evaluate biomarkers using CAPP-SEQ. **Results:** Between June 7, 2020, and January 19, 2022, 36 pts were enrolled. One pt met exclusion criteria, leaving 35 pts for efficacy analysis. The mean age was 70 years; 60% were women, and 54.3% were nonsmokers. The median observation period was 29.1 months (cutoff date: January 18, 2024). The primary endpoint, 6M-PFSR, was 57.1% (95% CI, 39.3–71.5), exceeding the threshold of 35%. Notably, 28.6% of pts achieved long-term PFS of ≥1 year. ORR was 51.4%, DCR was 88.6%, median PFS was 8.2 months, median DOR was 5.6 months, and median OS was 22.5 months. By mutation type, ORRs were similar for Del19 and L858R (46.7% and 55.0%, respectively), but median PFS was longer for Del19 than for L858R (9.6 vs. 5.2 months). Pts who had responded to prior osimertinib (CR/PR, n=29) had longer median PFS than non-responders (SD/PD/NE, n=6) (8.5 vs. 5.8 months). Adverse events (AEs) from TKI and chemotherapy were common but manageable. The most frequent AEs were diarrhea (52.8%), anorexia (47.2%), fatigue (36.1%), and paronychia (36.1%). Interstitial pneumonia occurred in 3 pts (8.3%), with one treatment-related death. In plasma NGS analysis, clearance of EGFR mutations during treatment was a key predictive factor. Pts without EGFR mutation clearance had shorter PFS and OS compared to those with clearance (PFS: 5.7 vs. 12.0 months; OS: 15.7 vs. 34.4 months). Efficacy was observed even in pts with p53 mutations, a known resistance factor. MET gene amplification was detected in 4 pts upon resistance. **Conclusions:** Afatinib combined with platinum-based chemotherapy demonstrated satisfactory efficacy and manageable toxicity in pts with tumors refractory to osimertinib. EGFR mutation clearance during treatment was predictive of therapeutic outcomes. This regimen may be a promising second-line option after osimertinib failure. Clinical trial information: 021200005. Research Sponsor: Boehringer Ingelheim.

Final results of a phase 1 study of EP0031, a next generation selective RET inhibitor (SRI) in patients with SRI naïve or pretreated advanced RET-altered tumors. First Author: Guzman Alonso, Vall d'Hebron Institute of Oncology (VHIO), Barcelona, Spain

Background: EP0031 (A400/KL590586), a first in class next gen selective RET inhibitor (SRI) with FDA Fast Track Designation, has broad potency against common RET alterations, including resistance mutations. It has greater potency, antitumor activity, and CNS penetration/activity compared with 1st gen SRIs (Garralda et al. JCO 2024; 42:16; abstr 8556; Zhou et al. JCO 2023; 41:16, abstr 3007). We report final data from the dose finding and optimization Phase 1 trial in the US and Europe. **Methods:** The study recruited pts with RET-altered NSCLC, medullary thyroid cancer (MTC) and other solid tumors and included pts ≥ 18 years, PS 0 or 1, with/without asymptomatic, stable brain mets, who received EP0031 QD in 28 days' cycles. **Results:** A total of 40 pts (23 F, 17 M, median age 59 y), 22 NSCLC (20 SRI pre-treated, 1-6 prior lines), 12 MTC (7 SRI pre-treated, 1-4 prior lines) and 6 pts with other tumors (4 SRI pre-treated) were enrolled across 4 cohorts: 20 (n=3), 60 (n=10), 90 (n=16) and 120 (n=11) mg QD. The 60, 90 and 120mg cohorts were expanded for dose optimization. 9 pts had stable brain mets at baseline. No DLTs were observed. Most frequent G1/2 TEAEs (≥20%) were headache, anemia, ALT/AST increase, constipation, dizziness, hyperphosphatemia, blurred vision, keratitis, blood creatinine increased, dry mouth, dyspnea and fatigue. G3 TEAEs were rare and included (≥5%): hyponatremia, hypertension, anemia, AST/ALT increase, headache, diarrhea and ulcerative keratitis. Interruptions, reductions and discontinuations related to study drug were seen in 16 (40%), 8 (20%) and 1 (2.5%) pt. 25 pts with prior SRI were response evaluable. 5 PRs and 6 SDs reported in 15 NSCLC pts, with complete resolution of brain mets in 3/5 pts. Median DoR was 7.3mo (range 5.4-16.3). In 7 MTC pts, 2 PRs (DoR 6.6 – 9.2mo) and 2 SDs seen. Of 3 pts with other tumors, a pancreatic cancer pt had SD for 3.5 mo, and a pt with papillary thyroid cancer was clinically stable for 9 mo. In pts who were SRI naïve, 1 CR and 1 PR were reported in 2 NSCLC pts; and 5 PRs (1 uPR) were reported in all MTC pts. Baseline on-target RET resistance mutations were detected in 6/31 prior SRI pts (19.4%) with evidence of activity in 3, and sustained reduction and clearance of ctDNA (including RET resistant mutations: G810R solvent front and L730V, L730I roof mutations). Plasma exposures increased proportionately with dose. 90mg QD was selected as RP2D, with plasma levels $>IC_{90}$ for all relevant RET fusions/mutations. **Conclusions:** There is a need for new treatments for pts that progress on 1st gen SRIs. EP0031 was associated with durable responses in advanced RET altered solid tumors previously treated with SRI, including pts with brain mets, with a manageable safety profile. These data confirm that the first in class next gen SRI EP0031 has the potential to address a high unmet need. Phase 2 trials are evaluating EP0031/KL590586 in US, Europe, UAE and China. Clinical trial information: NCT05443126. Research Sponsor: Ellipses Pharma.

8599 Poster Session

Longer follow-up for survival and safety from the EVOKE-01 trial of sacituzumab govitecan (SG) vs docetaxel in patients (pts) with metastatic non-small cell lung cancer (mNSCLC). First Author: Niels Reinmuth, Asklepios Lung Clinic, German Center for Lung Research (DZL), Munich-Gauting, Germany

Background: EVOKE-01 (NCT05089734) assessed the efficacy and safety of SG vs docetaxel in pts with mNSCLC that progressed after platinum-based chemotherapy and anti–PD-(L)1 (IO) treatment. The study did not meet statistical significance for overall survival (OS) at final analysis. Here, we report updated survival and safety outcomes after longer follow-up, providing insight into the tolerability of SG over a prolonged period of administration. **Methods:** Pts were randomized 1:1 to receive SG (n = 299; 10 mg/kg IV, days 1 and 8) or docetaxel (n = 304; 75 mg/m^2 IV, day 1) in 21-day cycles until progression or unacceptable toxicity. OS was the primary endpoint, while safety was a key secondary endpoint. **Results:** As of Oct 21, 2024, median follow-up was 23.5 months. Median exposure with SG vs docetaxel was 3.5 vs 2.3 months; 33.4% vs 17.7% of pts, respectively, were exposed to study drug for ≥6 months. The longer follow-up preserved the numerical improvement in OS favoring SG in the intent-to-treat population (HR 0.89, 95% CI: 0.74–1.07; *P* = .1028) and in subgroups of interest, including nonresponders to prior IO, and across squamous and nonsquamous histologies (**Table**). Most common any-grade treatment-emergent adverse events (TEAEs) with SG vs docetaxel were fatigue (57.8% vs 56.6%), diarrhea (52.7% vs 33.7%), and alopecia (43.6% vs 30.2%). In line with the primary analysis, 68.6% vs 76.0% of pts receiving SG vs docetaxel experienced grade ≥3 TEAEs, mainly neutropenia (25.3% vs 36.8%), fatigue (12.5% vs 9.7%), and diarrhea (10.5% vs 3.8%). Discontinuations due to TRAEs were seen in 7.4% vs 14.2% of pts receiving SG vs docetaxel. There were no additional AEs leading to death reported with longer follow-up (Table). **Conclusions:** Consistent with the final analysis, SG showed a numerical improvement in OS vs docetaxel. Long-term safety showed SG is well tolerated, consistent with minimal increase in AE rates since prior report and an improved safety profile over docetaxel, despite longer treatment exposure. Clinical trial information: NCT05089734. Research Sponsor: Gilead Sciences, Inc.

A retrospective study of anlotinib plus third-generation EGFR-TKIs in advanced non-small cell lung cancer with gradual or oligo progression after EGFR-TKIs treatment (ALTER-L058). First Author: Caicun Zhou, Shanghai East Hospital, Tongji University, Shanghai, China

Background: Despite the significant improvement in progression-free survival (PFS) for non-small cell lung cancer (NSCLC) patients with EGFR mutations, attributed to the advent of third-generation EGFR tyrosine kinase inhibitors (TKIs), the inevitable development of acquired resistance continues to pose a critical challenge that severely affects the long-term efficacy of these treatments. This study aims to evaluate the efficacy and safety of anlotinib in combination with third-generation EGFR-TKIs in advanced NSCLC patients experiencing gradual or oligo progression following EGFR-TKIs. **Methods:** ALTER-L058 was a retrospective study conducted at 16 hospitals in China. Eligible patients aged 18 to 75 years with histologically or cytologically confirmed NSCLC who tested positive for EGFR mutations and exhibited gradual or oligo progression following treatment with third-generation EGFR-TKIs. Patients continued their regimen of EGFR-TKIs with or without anlotinib after gradual or oligo progression. Anlotinib was administered orally at a dose of 8-12 mg per day for two weeks, followed by a one-week break, within a three-week cycle. The primary endpoint was PFS. Secondary endpoints included objective response rate (ORR), disease control rate (DCR), overall survival (OS), and safety profiles. **Results:** From 1/2020 to 12/2023, a total of 150 patients were enrolled in the study. Among these, 100 patients received third-generation EGFR-TKIs plus anlotinib treatment, while 50 patients only received third-generation EGFR-TKIs. From treatment initiation of EGFR-TKIs, compared with third-generation EGFR-TKIs alone, median PFS was prolonged with third-generation EGFR-TKIs plus anlotinib (23.2 versus 19.5 months; hazard ratio (95%CI): 0.56 (0.36-0.86); P = 0.0008). From gradual or oligo progression after EGFR-TKIs treatment, mPFS was significantly extended with the combination of third-generation EGFR TKIs and anlotinib compared to third-generation EGFR TKIs alone (9.2 versus 5.4 months; hazard ratio (95% CI): 0.40 (0.25-0.65); P < 0.0001). The incidence of grade 3 or higher treatment-related adverse events was 37.0% (third-generation EGFR-TKIs plus anlotinib) and 34.0% (third-generation EGFR-TKIs), respectively. **Conclusions:** Continuous treatment with anlotinib after the emergence of gradual or oligo progression during the third-generation EGFR-TKIs therapy prolonged the clinical benefit of EGFR-TKIs, demonstrating favorable survival outcomes and manageable toxicity. Clinical trial information: ChiCTR2500095741. Research Sponsor: None.

First-in-human phase I/II study of BYS10 in patients (pts) with locally advanced or metastatic RET-altered solid tumors: Preliminary dose escalation results. First Author: Jianchun Duan, Shanxi Cancer Hospital, Beijing, China

Background: RET alterations occur in non-small cell lung cancer (NSCLC, 2%), thyroid cancer (TC, 10%–20%) and a range of tumor types (<1%). RET inhibitors substantially improved the clinical outcomes of pts with RET-altered solid tumors. BYS10 is a highly potent and RET-specific inhibitor that overcomes RET V804 and G810 mutations, and exhibits high selectivity for RET over KDR. This study is to evaluate safety, tolerability, pharmacokinetics (PK) and efficacy of BYS10 in Chinese pts with RET-altered solid tumors. **Methods:** In phase I, following an accelerated titration and BOIN design, eligible pts were treated with BYS10 at 25 to 600 mg daily dose. Primary endpoints included safety, tolerability, MTD and DLTs. Secondary endpoints included PK and preliminary antitumor activity. **Results:** As of 10 July, 2024, a total of 51 pts were enrolled in dose escalation cohorts at 25/50 mg QD (n = 1/1) and 50/100/200/250/300 mg BID (n = 3/12/12/9/13). The MTD was not reached. Treatment related adverse events (TRAEs) occurred in all subjects, the most common TRAE were elevated AST (64.7%), elevated ALT (58.8%), elevated TBIL (45.1%), decreased WBCs (43.1%), decreased NEUT (33.3%), hyperuricaemia (31.4%), hypertension (29.4%), hypoalbuminemia (25.5%), Elevated SCr (23.5%) and headaches (23.5%). Grade 3 to 4 TRAEs >5% included elevated AST (25.5%), elevated ALT (13.7%) and hypertension (9.8%) reported at 100 to 300 mg BID doses. Serious adverse events were recorded in 7 pts. Exposure of BYS10 increased in a dose-dependent manner from 25 to 600 mg. In 40 evaluable pts, the confirmed overall response rate (ORR) and disease control rate (DCR) by independent review committee per RECIST v1.1 were 62.5% and 85%, In pts with RET-fusion NSCLC (n=30), RET-fusion thyroid cancer (TC, n=6) and RET-mutant medullary thyroid cancer (MTC, n=4), the ORR/DCR were 60%/80%, 83.3%/100% and 50%/100%, respectively. Intracranial antitumor activity was observed by investigators in 4 pts with at least 1 measurable intracranial lesion (one intracranial complete response). The ORR/DCR by IRC in 200 mg and 300 mg BID cohorts were 66.7%/100% and 75%/91.7%, respectively. **Conclusions:** BYS10 was well tolerated and showed dose-dependent exposure. Preliminary antitumor activity was observed in pts with RET-altered NSCLC, TC and MTC. The study is still ongoing. Clinical trial information: ChiCTR2400085264. Research Sponsor: Baiyunshan Pharmceutical Holdings Co., Ltd. Baiyunshan Pharmceutical General Factory.

Dysregulation of DNA damage repair in lung cancer driven by *MTAP* loss: Mechanistic insights and target discovery. First Author: Bo Jiang, The Eighth Affiliated Hospital, Sun Yat-Sen University, Shenzhen, China

Background: *MTAP* loss leads to methylthioadenosine (MTA) accumulation, disrupting downstream metabolic pathways. Targeting synthetic lethal interactions with *MTAP* loss offers a promising therapeutic strategy. The DNA damage response (DDR) pathway, essential for genomic stability, is commonly dysregulated in lung cancer, impacting treatment response and prognosis. Emerging evidence has highlighted potential association between *MTAP* loss and mutations in DDR genes, suggesting that investigating their relationship is critical for uncovering disease mechanisms and identifying novel biomarkers and therapeutic targets. **Methods:** Hybridization capture sequencing with StarPanel NGS Assay (1,326 genes) was conducted on 2,258 Chinese lung cancer patients' tumor and matched peripheral blood samples. Then somatic and germline mutations, and TMB values of each sample were obtained. Based on a depth-based algorithm, differences between tissue and control samples in CNVs from the gene level were analyzed. Besides, we utilized shifts in germline heterozygous SNPs within the gene region to assist in determining if the loss was homozygous or heterozygous. **Results:** Homozygous and heterozygous deletions of *MTAP* were detected in 11.07% and 6.95% of all samples. Notably, 61.67% of these samples exhibited co-loss of *MTAP*, *CDKN2A* and *CDKN2B*. The median TMB was significantly higher in samples with *MTAP* loss (3.85 mut/Mb) compared to those with intact *MTAP* (2.56 mut/Mb). In samples with homozygous *MTAP* loss, the top somatically co-altered genes were *EGFR* (76.00%), *TP53* (57.60%) and *CDKN2A* (52.80%). Gain-of-function (GoF) mutations were most prevalent in *EGFR* (56.80%), *KRAS* (12.00%) and *MDM2* (10.00%), while Loss-of-function (LoF) mutations were most common in *TP53* (50.40%), *RBM10* (11.60%) and *PTEN* (7.60%). Notably, LoF mutations in *MTAP*-loss samples showed a higher prevalence of DDR genes compared to *MTAP*-intact samples, including *RAD50* (2.40% vs. 0.00%, $p < .0001$) and *POLQ* (2.40% vs. 0.00%, $p < .0001$). Enrichment analysis further revealed LoF mutations unique to *MTAP*-loss samples were significantly enriched in the DDR pathway ($p < .0001$). For top germline pathogenic mutations, two DDR genes, *RECQL4* (0.80% vs. 0.38%, $p = 0.29$) and *BRCA2* (0.40% vs. 0.43%, $p = 1$), showed no significant differences between *MTAP*-loss and *MTAP*-intact samples. **Conclusions:** Potential association exists between *MTAP* loss and DDR pathway dysregulation, which may impact tumorigenic processes and therapeutic vulnerabilities. The enrichment of DDR-related LoF mutations indicates *MTAP* loss could exacerbate genomic instability by impairing DNA damage repair mechanisms, thereby increasing TMB and driving cancer progression with a distinct molecular profile. These vulnerabilities are primarily driven by somatic mutations, providing a rationale for exploring personalized treatment strategies. Research Sponsor: None.

8603 Poster Session

Real-world treatment patterns and time-to-treatment discontinuation among advanced ALK-positive non-small cell lung cancer patients. First Author: Rahul Mudumba, University of Southern California, Los Angeles, CA

Background: Advanced anaplastic lymphoma kinase (ALK)-positive non-small cell lung cancer (NSCLC) is typically treated with ALK tyrosine kinase inhibitors (TKIs) in the first-line (1L) setting. While clinical trials provide efficacy data, real-world evidence on treatment patterns and time-to-treatment discontinuation or death (TTD) remains scarce. Such evidence may better inform modern clinical practice and decision-making regarding long-term treatment planning and sequencing decisions. **Methods:** This retrospective observational cohort study analyzed patients with advanced ALK+ NSCLC in the Optum Clinformatics Data Mart (2016–2021). Eligible patients were ≥18 years of age, with ≥6 months of continuous enrollment prior to the index date, a lung cancer diagnosis identified via ICD-10 codes, and ≥1 prescription fill for an ALK TKI. Outcomes included TTD for 1L and second-line (2L) therapies, assessed using the Kaplan-Meier (KM) method. Treatment patterns, including discontinuation rates and transitions to 2L therapy, were also evaluated. **Results:** Among 680 patients, 1L therapy distribution was as follows: crizotinib (n=366, 53.8%), alectinib (n=267, 39.3%), brigatinib (n=22, 3.2%), and ceritinib (n=25, 3.7%). Lorlatinib (n=16) was excluded from the analysis due to its atypical use in 1L during the study period, potentially reflecting unique clinical scenarios. The median TTD for 1L therapy was 8.3 months overall (95% CI: 6.7–9.7). TTD by therapy was as follows: alectinib, 15.3 months (95% CI: 11.0–21.4); brigatinib, 7.8 months (95% CI: 3.6–18.1); ceritinib, 7.6 months (95% CI: 4.3–23.5); crizotinib, 5.7 months (95% CI: 4.7–6.8). Only 168 (24.7%) patients transitioned to another ALK TKI in 2L, with alectinib being the most common among 1L crizotinib recipients, and lorlatinib being the most common among 1L alectinib and brigatinib recipients. Median TTD for 2L therapies was 8.0 (95% CI: 5.7-11.7) months overall. **Conclusions:** This study provides real-world evidence on TTD and treatment patterns among advanced ALK+ NSCLC patients. Transition rates to 2L ALK TKIs were lower than expected based on clinical trials, with high rates of discontinuation without transition. With alectinib, brigatinib, and lorlatinib equally recommended as 1L options in US clinical guidelines, these findings provide real-world evidence to help clinicians differentiate among therapies and guide treatment sequencing decisions. Research Sponsor: None.

1L ALK TKI (n)	Transition to 2L ALK TKI (%)	Median 1L TTD (Months, 95% CI)
Alectinib (267)	51 (19.1%)	15.3 (11.0–21.4)
Brigatinib (22)	2 (9.1%)	7.8 (3.6–18.1)
Ceritinib (25)	14 (56.0%)	7.6 (4.3–23.5)
Crizotinib (366)	101 (27.6%)	5.7 (4.7–6.8)
Overall (680)	168 (24.7%)	8.3 (6.7–9.7)

1L first-line, *2L* second-line, *ALK* anaplastic lymphoma kinase, *TKI* tyrosine kinase inhibitor, *TTD* time-to-treatment discontinuation or death, *CI* confidence interval.

Osimertinib plus repotrectinib phase I trial in TKI-resistant non-small cell lung cancer (NSCLC) with EGFR mutations. First Author: Andrés Aguilar Hernandez, Instituto Oncológico Dr Rosell (IOR), Dexeus University Hospital, Barcelona, Spain

Background: NSCLC patients with EGFR mutations develop resistance when treated with EGFR TKI. We previously reported that osimertinib combined with TPX-0005 (repotrectinib) ablated STAT3, paxillin, and YAP1 phosphorylation in a preclinical model. Osimertinib-induced Src and FAK phosphorylation was abrogated with TPX-0005 alone or in combination with osimertinib in H1975 (EGFR L858 and T790M) cell line. TPX-0005 potentiated the effect of osimertinib in PC9 and H1975 tumor xenografts without substantial toxicity (Karachaliou et al. eBioMedicine 2017). The findings prompted us to carry out the current study with osimertinib plus TPX-0005, which inhibit Src/FAK/JAK2, in addition to ALK, ROS1 and NTRKs. **Methods:** TOTEM (NCT04772235) is a phase I, two-part study to assess safety, tolerability, pharmacokinetics, and antitumor activity of repotrectinib plus osimertinib in EGFR-mutant patients resistant to previous lines of treatment. Phase Ia was a dose escalation (3+3). Treatment naïve patients were treated with osimertinib 80mg QD plus: repotrectinib 80mg QD, 160mg QD and 160mg BID. In part Ib, patients should have received osimertinib or osimertinib plus chemotherapy as first line treatment. Results from part Ia are presented in this abstract. **Results:** Phase Ia included 15 patients with a median age of 61 yrs (34-71). Of these patients: 10 were female (66.7%), 9 had PS1 (60%), and 7 had brain metastasis (48.7%). At the time of starting treatment, two patients had exon 18 (G719X) mutations (p.E709_T710delinsD and p.G719A), 5 had exon 21 (4 p.L858R, 1 p.L861Q) and 8 had exon 19 deletion. Eight patients had p53 co-mutations, other co-alterations included PIK3CA, RET, FAT1, FGFR3 and MYC mutations, CDK4 and EGFR amplification, and MET, ROS1, EGFR and FGFR3 over-expression. Six patients were treatment-naive, four were osimertinib progressors, and five had received two or more previous lines of treatment. With repotrectinib plus osimertinib, intracranial complete response was attained in 3 of the seven patients with brain metastasis (42.85%). The overall objective response rate (ORR) was noted in 5 patients (33.3%), and stable disease in 8 patients (53.3%). Median PFS was 4.4 mo. (95% CI 2.9-NR). Among the adverse events, transient, manageable dizziness was observed in 76% of the patients, and dysgeusia occurred in 48% of cases. Most side effects were grade 1-2, including anemia, diarrhea, fatigue, and liver enzyme elevation. Pharmacokinetic analysis indicated a favorable profile of the combination. Dose level 3 (160mg BID) was safe, therefore, part Ib continued with repotrectinib 160mg BID plus osimertinib 80mg QD in 15 patients enrolled. **Conclusions:** In Part Ia osimertinib + repotrectinib showed impressive intracranial ORR with a manageable safety profile. Part Ib with repotrectinib 160 mg BID plus osimertinib 80 mg is ongoing. Updated results will be presented. Clinical trial information: NCT04772235. Research Sponsor: None.

MK-1084 for KRAS G12C-mutated (mut) metastatic non–small-cell lung cancer (mNSCLC): Results from KANDLELIT-001. First Author: Adrian G. Sacher, Princess Margaret Cancer Centre, University Health Network & University of Toronto, Toronto, ON, Canada

Background: MK-1084 is an oral, next-generation, selective KRAS G12C-GDP covalent inhibitor. The phase 1 KANDLELIT-001 study (NCT05067283) showed manageable safety and antitumor activity for MK-1084 monotherapy in *KRAS* G12C-mut solid tumors and MK-1084 + pembrolizumab (pembro) in *KRAS* G12C-mut mNSCLC. We report additional NSCLC and preliminary ctDNA data from this study. **Methods:** Pts had confirmed *KRAS* G12C-mut, RECIST-measurable disease and ECOG PS 0-1. Pts with any advanced solid tumor and ≥1 prior systemic therapy received MK-1084 monotherapy 25-800 mg/d in arms 1 and 3. Pts with previously untreated mNSCLC and PD-L1 TPS ≥1% received MK-1084 25-400 mg/d + pembro 200 mg Q3W in arm 2 dose escalation and expansion cohorts. Pts with previously untreated nonsquamous mNSCLC received MK-1084 50-200 mg/d + pembro 200 mg, carboplatin, and pemetrexed Q3W in arm 4. Dose-limiting toxicities (DLTs), AEs, and AEs leading to discontinuation were the primary endpoints; ORR, DCR, and PFS per RECIST v1.1 by investigator review were secondary. *KRAS* G12C variant allele fraction (VAF) and maximum somatic allele frequency (MSAF) in ctDNA were assessed in serial blood samples collected from 23 pts in arm 1 using the Guardant Health OMNI panel. **Results:** There were 99 pts in arms 1+3 (21 with NSCLC), 34 in arm 2 escalation cohorts, 26 in arm 2 expansion cohorts, and 24 in arm 4 as of the 12 Aug 2024 data cutoff. Median study follow-up was 14.8 mo, 16.2 mo, 2.5 mo, and 4.1 mo, respectively. DLTs occurred in 1 pt in arm 2 (gr 3 ALT and AST increase) and 1 pt in arm 4 (gr 3 diarrhea). Drug-related AEs occurred in 62% of pts in arms 1+3, 88% of pts in arm 2, and 96% of pts in arm 4, were gr ≥3 in 9%, 33%, and 58%, and led to discontinuation of any drug in 1%, 20%, and 17%. There was 1 drug-related death (myelosuppression and platelet count decrease in arm 2). Rates of drug-related ALT increase (any/gr ≥3) were 16%/3% in arm 1, 33%/10% in arm 2, and 33%/4% in arm 4. Rates of drug-related AST increase (any/gr ≥3) were 17%/3%, 30%/8%, and 25%/4%. Efficacy is shown in the Table. Median *KRAS* G12C VAF was 14.0% at baseline and 0.9% at week 6; median MSAF was 26.0% and 2.2%, respectively. **Conclusions:** In pts with *KRAS* G12C-mut mNSCLC, MK-1084 shows manageable safety and antitumor activity as monotherapy for previously treated disease and in combination with pembro ± chemo as first-line (1L) therapy. The >90% decrease from baseline in *KRAS* G12C VAF in ctDNA confirms MK-1084 target engagement. The phase 3 KANDLELIT-004 study is evaluating MK-1084 + pembro as 1L therapy for *KRAS* G12C-mut mNSCLC with PD-L1 TPS ≥50%. Clinical trial information: NCT05067283. Research Sponsor: Merck Sharp & Dohme LLC, a subsidiary of Merck & Co., Inc., Rahway, NJ, USA; N/A.

	ORR		DCR		PFS	
Arm	n[a]	% (95% CI)	n[a]	% (95% CI)	n	Med (95% CI), mo
1+3 NSCLC (MK-1084 alone)	21	38 (18-62)	21	76 (53-92)	21	8 (4-NR)
2 escalation (MK-1084 + pembro)	34	74 (56-87)	34	91 (76-98)	34	25 (9-NR)
2 expansion (MK-1084 + pembro)	20	40 (19-64)	20	80 (56-94)	26	NR (NR-NR)
4 (MK-1084 + pembro + chemo)	22	41 (21-64)	22	82 (60-95)	24	NR (5-NR)

Clinicogenomic analysis of *EGFR*-mutant lung cancers for identification of Rb inactivation as a hallmark of squamous transformation. First Author: Mark Yungjie Jeng, Memorial Sloan Kettering Cancer Center, New York, NY

Background: Histologic transformation to squamous carcinoma (LUSC) is a recognized mechanism of resistance in *EGFR*-mutant lung adenocarcinoma (EGFR+ LUAD) and can occur in 5-8% of patients treated with osimertinib. While our prior work identified the AKT pathway as a possible mediator of LUSC transformation, comprehensive clinicogenomic assessment of this process remains lacking. **Methods:** We performed genomic characterization of *EGFR*-mutant patient samples undergoing LUSC transformation, including: (1) pre- and post-transformation specimens transformed after TKI treatment, and (2) microdissected distinct LUAD and LUSC components obtained from adenosquamous (LUAS) tumors. Retrospective analysis of clinical outcomes such as time-to-treatment discontinuation (TTD) were evaluated in patients with EGFR+ LUAD on frontline osimertinib who have undergone MSK-IMPACT (n=181). Xenograft models (using PC9 and HCC827) mimicking squamous transformation were treated with osimertinib (5-10 mice/group). Phenotypic markers of LUSC (P40 and CK5/6) were assessed by IHC. **Results:** Among patients with EGFR+ LUAD undergoing LUSC transformation (n=20), 50% and 60% had alterations in the AKT or Rb pathway, respectively. When compared to a cohort of never-transforming EGFR+ LUAD (n=1515), patients with transforming LUAD had a higher frequency of AKT (44% vs 18%) and Rb (56% vs 32%) pathway mutations. Clinically, patients with EGFR+ LUAD on first line osimertinib harboring baseline Rb/AKT pathway mutations (n=70) experienced shorter TTD (median 18 vs 24 months, p=0.0261) compared to a Rb/AKT wild-type cohort (n=111). In xenograft models of squamous transformation, Rb inactivation through CRISPR deletion of *RB1* or upstream regulators *CDKN2A/B* led to greater *in vivo* tumor growth in immunodeficient mice treated with osimertinib compared to controls. Histologic assessment revealed induction of squamous markers P40 and CK5/6 in xenografts with Rb inactivation. **Conclusions:** Genomic alterations in Rb and AKT pathways are detected at higher frequency in patients with EGFR+ LUAD undergoing squamous transformation and are associated with worse clinical outcomes to frontline osimertinib. Rb inactivation in xenograft mouse models led to increased squamous-like phenotype and resistance to osimertinib. Detection of these mutations may help identify patients at high risk of treatment resistance and transformation. Research Sponsor: None.

Shifting landscape of resistance to next-generation ALK inhibitors with evolving treatment paradigm in ALK+ lung cancer. First Author: Sarah Waliany, Massachusetts General Hospital, Boston, MA

Background: Next-generation (gen) ALK tyrosine kinase inhibitors (TKIs) are standard first-line (1L) therapy for patients (pts) with *ALK*-rearranged (ALK+) metastatic non-small cell lung cancer (mNSCLC), having supplanted crizotinib (criz). While past studies uncovered mechanisms of resistance to next-gen ALK TKIs, vast majority of analyzed biopsies (bx) were obtained from pts treated with next-gen TKIs after 1L criz, reflecting the outdated treatment paradigm. Limited knowledge exists on the mechanisms of resistance to second- (2G) and third-gen (3G) ALK TKIs received without 1L criz exposure. **Methods:** This retrospective study included pts with ALK+ mNSCLC who received 2G ALK TKIs (alectinib, brigatinib, ceritinib, ensartinib) or 3G TKI lorlatinib (lorl) and had post-progression tissue (TBx) or liquid bx (LBx) assessed by next-generation sequencing (NGS). Frequency (freq) of *ALK* mutations (mut) (on-target) or *MET* amplification (amp) and histologic transformation (off-target) was compared in pts who had vs had not received prior 1L criz. **Results:** We identified 270 pts (median age, 52; 61.1% women) who received 2G TKI (1L criz, n=116; no 1L criz, n=106) and/or 3G TKI (1L criz, n=69; no 1L criz, n=59) and underwent TKI-resistant bx (116 pts with $\geq$2 bx). In total, 436 post-next-gen TKI bx (280 post-2G TKI, 156 post-lorl) underwent NGS. Post-2G TKI bx detected lower freq of *ALK* mut in pts without vs with prior criz exposure (TBx: 36.8% vs 64.3%, p$<$0.001; LBx: 44.4% vs 71.7%, p=0.006). Of pts with post-lorl TBx, 43.8% had $\geq$1 *ALK* resistance mut detected, of which 23.6% had $\geq$2 co-occurring *ALK* mut. Post-lorl Tbx detected lower freq of *ALK* mut (29.7% vs 53.8%, p=0.024) and lower freq of $\geq$2 co-occurring *ALK* mut in pts without vs with prior criz (10.8% vs 32.7%, p=0.036), with consistent findings by LBx. In terms of off-target resistance. *MET* amp was detected by post-2G TKI TBx at higher freq in pts without vs with prior criz (17.2% vs 2.5%, p=0.002), but with no significant difference post-lorl without vs with prior criz (13.9% vs 5.8%, p=0.26). Of note, the two post-1L lorl TBx both had *MET* amp or polysomy, without *ALK* mut. Histologic transformation occurred at similar freq in pts without vs with 1L criz after 2G TKIs (4.3% vs 1.2%, p=0.33) and after lorl (2.7% vs 3.8%, p=0.99). Among pts with post-1L 2G TKI bx, on-target resistance (*ALK* mut) was more common with *EML4::ALK* variant 3a/b vs variant 1 (TBx: 56.3% vs 20.0%, p=0.038; LBx: 75.0% vs 13.3%, p=0.003). **Conclusions:** In this largest analysis of post-2G/3G ALK TKI TBx/LBx to date, on-target resistance was less freq after 2G/3G TKIs in pts treated with the current paradigm (upfront 2G/3G ALK TKIs) than the past approach (2G/3G TKI after 1L criz). These findings crystallize a shifting resistance landscape and indicate an increasing role for off-target resistance with upfront 2G/3G TKIs, highlighting a need to uncover and therapeutically address off-target resistance. Real-world comparative outcomes of alectinib and brigatinib in ALK-positive non–small cell lung cancer: A retrospective cohort analysis using HIRA data. First Author: Hyun Woo Lee, Department of Hematology-Oncology, Ajou University School of Medicine, Suwon, South Korea

Background: Alectinib and brigatinib are both recommended as first-line treatments for patients with ALK-positive non–small cell lung cancer (NSCLC). However, direct real-world comparisons of these agents remain limited. **Methods:** We retrospectively reviewed patients diagnosed with ALK-positive NSCLC between 2007 and 2023 who did not undergo surgical resection. Among these, 1,009 patients received either alectinib (n=868) or brigatinib (n=141) as first-line therapy on HIRA data. Baseline characteristics, comorbidities (e.g., diabetes, hypertension), and outcomes—including overall survival (OS) and progression-free survival (PFS)—were collected. Cox proportional hazards models adjusted for age $\geq$70 years, sex, and comorbidities were used to estimate hazard ratios (HRs) for death and disease progression. **Results:** The mean age was 61.56 years (SD 13.72), and 49.45% of patients were male. Patients receiving alectinib were older on average (p$<$0.001), but no significant differences in major comorbidities were observed between the two groups. In unadjusted analyses, brigatinib was associated with a lower risk of death compared with alectinib (HR 0.60, 95% CI 0.40–0.90; p=0.013), but this association was not significant after multivariable adjustment (HR 0.69, 95% CI 0.46–1.03; p=0.07). Conversely, alectinib was associated with significantly longer first and second PFS compared with brigatinib (1st PFS HR 1.53, p=0.012; 2nd PFS HR 4.02, p$<$0.001). Both alectinib- and brigatinib-treated patients who transitioned to lorlatinib demonstrated notably prolonged survival. **Conclusions:** In this real-world study, both alectinib and brigatinib provided favorable survival outcomes in patients with ALK-positive NSCLC. While brigatinib showed a trend toward reduced mortality in univariable analysis, this was not maintained in adjusted models. Alectinib conferred a longer duration of disease control (PFS) in both first- and second-line settings. Further prospective studies are warranted to clarify the optimal sequencing of ALK inhibitors and to validate these findings. Research Sponsor: None.

High-dose furmonertinib combined with bevacizumab and pemetrexed in non-small cell lung cancer patients with EGFR mutations and leptomeningeal metastasis: A prospective real-world study. First Author: Qi Zhao, Department of Internal Medicine, The Affiliated Cancer Hospital of Zhengzhou University & Henan Cancer Hospital, Zhengzhou, China

Background: Leptomeningeal metastasis (LM) in lung cancer is always associated with poor prognosis. Our previous study has demonstrated that high-dose furmonertinib offers promising efficacy in non-small cell lung cancer (NSCLC) patients with epidermal growth factor receptor(EGFR) mutations and LM. In this study, we aim to further evaluate the efficacy and safety of high-dose furmonertinib combined with bevacizumab and pemetrexed in NSCLC patients with EGFR mutations and LM in the real world. **Methods:** Eligible patients had histologically or cytologically confirmed NSCLC harboring an EGFR mutation. Patients were diagnosed as LM according to the EANO-ESMO criteria. They were treated with high-dose furmonertinib (240 mg, daily), bevacizumab (15 mg/kg, every 3 weeks), and pemetrexed (50 mg, intrathecal chemotherapy or 500 mg/m², intravenous chemotherapy, every 3 weeks). The primary endpoint was overall survival (OS). Secondary endpoints included time to treatment failure (TTF), ORR-LM (objective response rate in leptomeningeal metastasis) according to the RANO-LM radiologic criteria, clinical response rate (assessed with improvement of neurologic symptoms or signs and changes in the performance status), and adverse events (AEs) (graded according to CTCAE v5.0). **Results:** Between March 10, 2023 and December 31, 2024, 33 patients were enrolled at Henan Cancer Hospital. 10 patients (30.3%) had EGFR exon 19 deletions, 18 patients (54.5%)had exon 21 L858R mutations, and the other 5 patients (15.2%) had non-classical mutations. 20 (60.6%) had an ECOG score of 1-2, while 13 (39.4%) had an ECOG score of 3. Additionally, 22 patients (66.7%) had received at least two prior lines of treatment, and 23 patients(69.7%) had previously been treated with third-generation EGFR-TKIs. 6 patients (18.2%) received pemetrexed via intravenous administration, while 27 patients (81.8%) received intrathecal chemotherapy of pemetrexed. The clinical response rate was 72.7%, the ORR-LM and disease control rate (DCR) assessed by investigator according to RANO-LM radiologic criteria were 64.7% and 94.1%.At the data cut off point of December 31, 2024, 7 (21.2%) patients had died. The median follow-up was 7.8 months. The median OS was not reached. 25 (75.8%) patients experienced treatment-related adverse events (TRAEs) of any grade. Grade 3 adverse events included: diarrhea (6.1%), leukopenia/neutropenia (9.1%), anemia (6.1%), and thrombocytopenia (3%). One patient experienced grade 4 leukopenia and thrombocytopenia. The dose of furmonertinib was reduced to 160mg in 4 patients and intrathecal chemotherapy was discontinued in one patient. **Conclusions:** High-dose furmonertinib combined with bevacizumab and pemetrexed demonstrates remarkable clinical efficacy and tolerable safety in NSCLC patients with EGFR mutations and LM. Clinical trial information: NCT06643000. Research Sponsor: None.

Efficacy and safety of larotrectinib in patients with TRK fusion lung cancer: An updated analysis. First Author: Daniel Shao-Weng Tan, Division of Medical Oncology, National Cancer Center Singapore and Duke-NUS Medical School, Singapore, Singapore

Background: *NTRK* gene fusions are oncogenic drivers in various tumor types, including lung cancer. Larotrectinib is the first-in-class, highly selective, central nervous system (CNS)-active TRK inhibitor approved for tumor-agnostic use in patients with TRK fusion cancer based on a robust and durable objective response rate in patients with various cancers. Here, we report updated long-term efficacy and safety data in the subset of patients with TRK fusion lung cancer treated with larotrectinib. **Methods:** Patients with TRK fusion lung cancer enrolled in 2 larotrectinib clinical trials (NCT02122913, NCT02576431) were included. Larotrectinib was administered at 100 mg twice daily. Responses were independent review committee-assessed per Response Evaluation Criteria in Solid Tumours version 1.1. The data cutoff was July 20, 2024. **Results:** At data cutoff, 32 patients were enrolled; 12 patients had known CNS metastases at baseline. The median age was 56 years (range 25–81). One patient (3%) was systemic treatment-naïve in the metastatic/unresectable setting, and 19 (59%) patients received 2 or more prior therapies. All *NTRK* gene fusions were identified by next-generation sequencing (NGS). The overall response rate was 69% (95% confidence interval [CI] 50–84): 4 (13%) complete responses, 18 (56%) partial responses, 6 (19%) stable disease, 2 (6%) progressive disease, and 2 (6%) not evaluable. Median time to response was 1.8 months (range 1.5–7.3). Median duration of response (DoR), progression-free survival (PFS), and overall survival (OS) were 34 months (95% CI 13—not estimable [NE]), 22 months (95% CI 10–39), and 41 months (95% CI 17—NE), respectively, at median follow-ups of 37, 38, and 46 months. The 4-year rates for DoR, PFS, and OS were 33% (95% CI 7–60), 26% (95% CI 6–45), and 48% (95% CI 29–68), respectively. The median duration of treatment was 20 months (range 2–75). At data cutoff, 8 (25%) patients remained on treatment: 7 had responded and 1 was not evaluable for response. Treatment-related adverse events (TRAEs) were predominantly Grade 1/2. Grade 3/4 TRAEs were reported in 10 (31%) patients. One (3%) patient discontinued treatment due to TRAEs (increased alanine aminotransferase, aspartate aminotransferase, and gamma-glutamyl transferase). **Conclusions:** Larotrectinib demonstrates rapid and durable responses, extended survival, clinical benefit, and a favorable safety profile in patients with advanced TRK fusion lung cancer. These results support the wider adoption of NGS panels that include *NTRK* gene fusions in patients with lung cancer to identify those who may benefit from targeted treatment. Clinical trial information: NCT02122913, NCT02576431. Research Sponsor: These studies were funded by Bayer HealthCare Pharmaceuticals, Inc.

Interim results of PDL1V (PF-08046054), a vedotin-based ADC targeting PD-L1, in patients with NSCLC in a phase 1 trial. First Author: Elisa Fontana, Sarah Cannon Research Institute UK, London, United Kingdom

Background: PDL1V is an investigational antibody-drug conjugate that delivers the cytotoxic agent monomethyl auristatin E to cells expressing programmed cell death ligand 1 (PD-L1). In addition to cytotoxicity, PDL1V elicits antitumor activity via the bystander effect and immunogenic cell death. Here we present the safety profile and preliminary efficacy in patients with metastatic, relapsed/refractory non-small cell lung cancer (NSCLC) enrolled in the phase 1 trial. **Methods:** C5851001 (NCT05208762) is a phase 1 study enrolling patients with relapsed or refractory solid tumors, including NSCLC, whose disease has progressed on standard-of-care therapies. Patients received the PDL1V recommended expansion dose of 1.5 mg/kg on days 1 and 8 of a 21-day cycle using adjusted ideal body weight, and were required to have measurable disease per RECIST v1.1 and ECOG PS $\leq$1. Patients with genomic alterations were not excluded. The primary objectives of this study are safety, tolerability, and pharmacokinetics, with antitumor activity as a secondary objective. **Results:** As of December 20, 2024, 30 patients with NSCLC have been treated at the recommended expansion dose. The median age was 60 years (range 44-73); 43.3% were male, 66.7% had ECOG PS 1, 23.3% had squamous histology, and 83.3% were PD-L1 positive. The median number of prior lines of therapy was 2.0 (1, 8); 96.7% and 66.7% of patients were previously exposed to anti-PD-1/PD-L1 antibodies and taxanes, respectively. There have been no dose-limiting toxicities at the recommended expansion dose. Peripheral sensory neuropathy (27.2%), nausea (25.0%), diarrhea (23.9%), and fatigue (21.7%) were the most common treatment-related adverse events (TRAEs) for all patients treated in the Phase 1 trial at the recommended expansion dose (N=92); the majority of TRAEs were grade 1-2 in severity, and 5.4% of patients discontinued therapy due to TRAEs. The most common grade $\geq$3 TRAE was anemia (5.4%). The incidence of treatment-related immune-mediated AEs by investigator assessment was 14.1%; 5.4% for grade 3, with no grades 4 or 5. The investigator-assessed confirmed objective response rate (cORR) for patients with NSCLC was 26.7%, while the cORR was 32.0% for those with PD-L1 expressing tumors. The median duration of confirmed response was 7.8 months (95% CI 4.8, –), and the median follow-up was 10.0 months (95% CI 4.9, 13.1). Objective responses were observed in patients with PD-L1 expressing squamous (n=6) and non-squamous (n=19) tumors (33.3% and 31.6% cORR, respectively). **Conclusions:** PDL1V monotherapy at the recommended expansion dose was generally well tolerated with a manageable safety profile. Encouraging preliminary efficacy in NSCLC was observed, independent of histology. Based on these results, further development of PDL1V in NSCLC is ongoing. Clinical trial information: NCT05208762. Research Sponsor: Pfizer Inc.

Exploring decisional needs of patients considering first line treatment of advanced EGFR+ lung cancer: An interpretive descriptive study. First Author: Rena Seeger, Faculty of Medicine, University of Ottawa, Ottawa, ON, Canada

Background: With expanding treatment options for EGFR+ metastatic non-small cell lung cancer (mNSCLC), shared decision-making is important in aligning treatment plans with patient values. Targeted therapies like osimertinib offer convenience and independence. New studies like FLAURA2 and MARIPOSA explore therapeutic combinations with intravenous drugs, demonstrating potentially superior efficacy but more side effects, highlighting the need for unbiased and patient-centered approaches. This study explores the decisional needs of patients considering first-line treatments. **Methods:** We conducted an interpretive descriptive qualitative study guided by the Ottawa Decision Support Framework to explore the experiences and perspectives of EGFR+ mNSCLC patients. Interviews were conducted via Microsoft Teams. Inclusion criteria: 18+ years; mEGFR+ NSCLC; current/prior osimertinib therapy; proficient in English. Interviews were conducted using a standardized interview guide with inductive thematic analysis. A sample size of 10-12 was considered sufficient to saturate ideas from participant responses, with additional 3 recruited to ensure saturation. Themes were mapped onto the Ottawa Decision Support Framework. **Results:** Sixteen participants were interviewed from Sep-Nov 2024: age 48-83 (median 62 years); 11 female; 13 currently taking osimertinib; 10 diagnosed $>$1 year. Many patients reported relying on oncologist recommendation without participation in decision making. Patients with young children had an increased desire to be actively involved in treatment decisions. Key themes from preliminary analysis identified: patients overwhelmingly *trusted their oncologist*, felt *pressure to start treatment quickly*, were *overwhelmed with the diagnosis*, had *inadequate knowledge of the treatment* and potential side effects, and felt *highly responsible to ensure proper drug administration*. Patients valued e*ase and convenience of* [osimertinib] *treatment, few severe side effects, being alive, continuing day to day living*, and *remaining independent for family and travel.* When asked about combination therapy, patients valued *quality of life, avoiding increased hospital trips and side effects*, but indicated a *willingness to try*. **Conclusions:** Key themes from preliminary analysis identify crucial components at initial diagnosis, with patients feeling overwhelmed and having inadequate knowledge, thus relying on their trusted oncologists' recommendation. While patients highly valued independence, fewer visits and quality of life, they were willing to try combination therapy, highlighting the importance of oncologists understanding their patient's individual needs and goals of treatment. Treatment choices should reflect the patient's values. These results will be used to create a decision aid that we can pilot in our oncology clinics. Research Sponsor: None.

MYTX-011, a cMET-targeting antibody-drug conjugate (ADC), in patients with previously treated, advanced NSCLC: Updated dose escalation results in the phase 1 KisMET-01 study. First Author: Rebecca Heist, Massachusetts General Hospital, Boston, MA

Background: MYTX-011 is a novel cMET-targeting vcMMAE ADC engineered for pH-dependent binding. This results in more efficient payload delivery, which drives efficacy in tumors over a wide range of cMET expression, including potentially $>$50% of NSCLC patients (pts). Here we report safety and preliminary efficacy from dose escalation pts who received $\geq$4.0 mg/kg (mpk), the clinically active dose range, in the Phase 1 KisMET-01 study. **Methods:** KisMET-01 (NCT05652868) is a multicenter, first-in-human study of MYTX-011 in pts with previously treated, locally advanced or metastatic NSCLC. The study comprises dose escalation in pts with NSCLC of any histology or cMET expression, followed by dose expansion in cMET-positive (cMET+) pts selected by immunohistochemistry (Ventana SP44). In dose escalation, cMET expression is analyzed whenever tumor tissue is available. **Results:** As of 7 Jan 2025, 85 pts received $\geq$1 dose of MYTX-011 (1.0–8.3 mpk Q3W), and 59 pts received doses $\geq$4.0 mpk. PK showed near dose proportional exposure and low unconjugated MMAE across dose levels. In pts who received $\geq$4.0 mpk, median age was 67 yr (43–83) and median prior lines of therapy was 3 (1–10); median follow-up was 4.2 mo (0.1–10.4). TRAEs of any grade (Gr)/Gr $\geq$3 occurred in 90%/48% of pts; the most common (any Gr TRAE $\geq$20% of pts) were blurred vision (49%), keratopathy (44%), nausea (29%), fatigue (20%), AST increased (20%), and keratitis (20%). Gr 3 or higher TRAEs that occurred in $\geq$5% of pts were keratopathy (15%), blurred vision (12%), and neutropenia (10%). Ocular events led to treatment discontinuation in 5 (8%) pts, with 3 of 5 treated at doses higher than 5.0 mpk. Unadjudicated pneumonitis/ILD was reported in 2 (3%) pts, both Gr 1 or 2 with 1 leading to treatment discontinuation. Peripheral neuropathy was reported in 15%; all were Gr 1 or 2 and did not lead to dose reduction or discontinuation. No treatment-related death was reported. 35 of 59 pts who received $\geq$4.0 mpk were cMET+ (2+ at $\geq$25% tumor cells) with a median follow-up of 3.7 mo (0.7–10.3). ORR was 38% in cMET+ pts with $\geq$1 post-baseline disease assessment (n=29). DCR at 6 wk/12 wk/24 wk was 97%/83%/53%. ORR was 44% in cMET+ Non-squamous (NSQ) EGFR wild-type (n=16), 38% in NSQ EGFR-mutant (n=8), and 25% in squamous cell carcinoma (n=4). Antitumor activity was similar in cMET+ pts across expression levels and known cutoffs, and no clear dose-response relationship was observed in doses $\geq$4.0mpk. Doses of 5.0 mpk Q3W with dose-break (2-on 1-off) and 4.0 mpk Q3W were selected for further evaluation in dose expansion. **Conclusions:** MYTX-011 is well tolerated with low rates and severity of AEs commonly associated with cytotoxic and cMET-targeting agents. Preliminary anti-tumor activity suggests MYTX-011 can potentially benefit a wide range of cMET-expressing NSCLC pts. Dose expansion is currently ongoing as of January 2025. Clinical trial information: NCT05652868. Research Sponsor: Mythic Therapeutics.

8614 **Poster Session**

GBC-11004: An AI-driven novel kinase target with potential to overcome osimertinib resistance in NSCLC. First Author: Hyunjeong Lee, Gradiant Bioconvergence Inc., Seoul, South Korea

Background: Osimertinib resistance poses a significant clinical challenge in the treatment of non-small cell lung cancer (NSCLC), with diverse mechanisms complicating patient outcomes. Conventional next-generation sequencing (NGS) analysis methods often fall short in identifying effective therapeutic targets due to the complexity and heterogeneity of resistance mechanisms. **Methods:** To address this issue, we have developed an artificial intelligence (AI)-driven target discovery platform designed to identify novel and effective drug target genes capable of overcoming Osimertinib resistance in NSCLC, thereby surpassing the capabilities of traditional NGS analysis. Our platform integrates three key components: deep learning (G-TAC), statistical significance testing (G-SET), and a large language model (G-LAT). G-TAC and G-SET evaluate and rank genes according to their responsiveness to Osimertinib and tumor-specific expression. G-LAT assesses these genes based on publications and clinical trials to ensure novelty and efficacy of the identified targets. **Results:** We identified a novel kinase target named GBC-11004, as one of the top-ranked target genes that were found to be overexpressed in patient-derived organoids (PDOs) resistant to Osimertinib. To ascertain the functional impact of GBC-11004, target validation was conducted using PDOs and CRISPR/Cas9-based gene editing. Gene editing in Osimertinib resistant PDOs resulted in a significant decrease in cell viability corresponding to increased indel frequency. Furthermore, we have initiated lead compound optimization by preliminary IC50 analyses using compounds targeting GBC-11004 and observed significantly enhanced sensitivity in the combination therapy group (Osimertinib + GBC-11004 inhibitor) compared to the Osimertinib monotherapy group in resistant PDO models. **Conclusions:** Our results demonstrate the potential of GBC-11004 as a novel therapeutic target for overcoming Osimertinib resistance in NSCLC treatment and emphasize the capability of our PDO-based AI-driven target discovery platform in identifying high-priority novel targets. Research Sponsor: None.

Sacituzumab tirumotecan (sac-TMT) in patients (pts) with previously treated locally advanced or metastatic (LA/M) non-small cell lung cancer (NSCLC) harboring uncommon EGFR mutations: Preliminary results from a phase 2 study. First Author: Li Zhang, Sun Yat-sen University Cancer Center, Guangzhou, China

Background: Pts with NSCLC harboring uncommon *EGFR* mutations generally have limited treatment options compared to those with the more common *EGFR* mutations. Sac-TMT (MK-2870/SKB264) is a TROP2 ADC developed with a hydrolytically cleavable linker to conjugate a belotecan-derivative topoisomerase I inhibitor. Sac-TMT has shown encouraging antitumor activity in NSCLC pts with the more common *EGFR* mutations (Fang *et al*. AACR 2024). Here we present the preliminary efficacy and safety of sac-TMT in treating uncommon *EGFR*-mutated advanced NSCLC from the Phase 2, open-label, multiple-cohort study (NCT05631262). **Methods:** Advanced NSCLC pts harboring uncommon *EGFR* mutations, including G719X in exon 18, S768I in exon 20, L861Q in exon 21 and exon 20 insertions (ex20ins), who had progressed on or after standard systemic therapy were enrolled. Pts received sac-TMT 5 mg/kg Q2W until disease progression or unacceptable toxicity. Tumor response was assessed per RECIST v1.1 by investigator. **Results:** As of 01 Dec 2024, 42 pts (median age 61 years; 33.3% male; 85.7% ECOG PS 1) were enrolled, including 23 pts with *EGFR* G719X in exon 18, S768I in exon 20, or L861Q in exon 21 and 19 pts with *EGFR* ex20ins. Median number of prior treatment regimens for advanced disease was 2 with 35.7% of pts having ≥3. After a median follow-up of 9.2 months, the objective response rate (ORR) was 35.7% (15/42, 3 pending confirmation). The disease control rate (DCR) was 85.7%. Responses were durable with the median duration of response (mDoR) not yet reached, and the 6-month DoR rate was 90.9%. The median progression-free survival (mPFS) was 9.5 months (95% CI: 5.6, 10.9). In the subset of pts with uncommon non-ex20ins, the ORR was 34.8% (8/23, 1 pending confirmation); the mPFS was 10.9 months (95% CI: 5.6, NE). In the subset of pts with ex20ins, the ORR was 36.8% (7/19, 2 pending confirmation); the mPFS was 9.0 months (95% CI: 2.4, NE). Grade ≥3 treatment-related adverse events (TRAEs) occurred in 52.4% of pts. The most frequent grade ≥3 TRAEs (≥5%) were neutrophil count decreased (45.2%), WBC count decreased (21.4%), anemia (14.3%), and stomatitis (9.5%). No TRAE led to treatment discontinuation or death. No cases of interstitial lung disease/pneumonitis were reported. **Conclusions:** Sac-TMT monotherapy demonstrated promising clinical activity with a manageable safety profile in previously treated advanced NSCLC pts with uncommon *EGFR* mutations. These findings warrant further investigation of sac-TMT as a potential therapy for this population. Clinical trial information: NCT05631262. Research Sponsor: Sichuan Kelun-Biotech Biopharmaceutical Co., Ltd.

8616 **Poster Session**

Phase I/II study of DZD6008, a 4th-generation EGFR TKI with full BBB penetration, in EGFR-mutant NSCLC. First Author: Mengzhao Wang, Department of Respiratory and Critical Care Medicine, Peking Union Medical College Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College, Beijing, China

Background: NSCLC patients whose disease progressed after 3rd generation EGFR TKI treatment often have CNS metastasis and acquired EGFR resistance mutations, such as C797S mutation. DZD6008 is a 4th generation EGFR TKI, designed to target EGFR sensitizing mutations (L858R/del19), resistant double (T790M and L858R/del19) and triple mutations (C797X, T790M and L858R/del19). Preclinical data shows that DZD6008 has high selectivity against wildtype EGFR and other kinases and is fully blood-brain-barrier (BBB) penetrant. Here we report results from the ongoing phase 1/2 studies in advanced EGFR mutation positive (EGFRm) NSCLC. **Methods:** TIAN-SHAN2 (CTR20241790) is a multi-center, first-in-human phase 1/2 study with expansion designed to evaluate the safety, tolerability, and anti-tumor activity of DZD6008 in EGFRm NSCLC patients who failed prior EGFR TKI treatment. DZD6008's BBB penetration capability was evaluated by measuring the ratio of free drug concentrations in CSF and blood, as well as tumor response of brain lesions. **Results:** Preclinically, DZD6008 showed equal potencies against multiple variants of single, double or triple EGFR mutations, with >50-fold selectivity over wild-type EGFR. In osimertinib-resistant CDX and PDX models carrying EGFR triple mutations, DZD6008 induced profound tumor shrinkage in a dose-dependent manner. As of December 24, 2024, 12 patients with EGFRm NSCLC had been enrolled into dose escalation cohorts of TIAN-SHAN2 study, and treated with DZD6008 at 20 mg to 90 mg once daily (QD). The median age was 61 years, 67% were female, and 50% had an ECOG PS of 1. All patients had adenocarcinoma and carried various types of single, double or triple EGFR mutations. The median lines of prior therapies was 5 (range 2 - 8). All patients had been treated with EGFR TKIs and chemotherapy, and 11 had received prior third-generation EGFR TKI treatment. DZD6008 was well tolerated across the doses investigated, and no dose limiting toxicities were reported. The maximum tolerated dose was not reached. DZD6008 exhibited dose-proportional and linear pharmacokinetic characteristics, with excellent blood-brain-barrier penetration (CSF to free plasma ratio >1) in patients with baseline brain metastasis. Ten out of 12 patients (83.3%) showed target lesion tumor shrinkage following DZD6008 treatment. Partial response was observed at ≥ 20 mg in patients with various EGFR mutations. Anti-tumor activity was observed in patients with brain metastasis. The longest duration on treatment was >6 months (treatment ongoing). **Conclusions:** DZD6008 is a novel, highly selective, full-BBB penetrant EGFR TKI with broad-spectrum of activity against different EGFR mutations. In heavily pre-treated EGFRm NSCLC patients, DZD6008 monotherapy was well-tolerated and showed encouraging anti-tumor activity. TIAN-SHAN2 study is ongoing and updated data will be presented at the meeting. Clinical trial information: CTR20241790. Research Sponsor: None.

Patient and caregiver treatment preferences for ALK+ non-small cell lung cancer in the United States. First Author: Christopher Danes, Takeda Pharmaceuticals U.S.A., Inc., Cambridge, MA

Background: Treatment options for non-small cell lung cancer (NSCLC) with ALK rearrangement (ALK+) have distinct benefits and risks. As patients often use ALK inhibitors for years, balancing these considerations is crucial. This study quantified how benefits and risks drive treatment preference and trade-offs between them from patients' and caregivers' perspectives. **Methods:** A discrete choice experiment (DCE) was completed online by Stage 4 ALK+ NSCLC patients and caregivers, recruited via physicians and the ALK Positive advocacy group. The DCE (developed based on literature review, phase 3 trial data and qualitative interviews) repeatedly asked participants to choose between 2 hypothetical treatments described by 7 benefit/risk attributes, each with a plausible clinical level. A mixed logit model estimated the relative impact of each attribute on preferences as relative attribute importance (RAI) and maximum acceptable loss (MAL) of 3-year progression-free survival (PFS) for reduced treatment risks. **Results:** 205 patients (mean age 61.9 years old; mean time since diagnosis: 2.7 years; 34.1% with brain metastasis) and 125 caregivers participated. 29.8% patients and 33.6% caregivers chose treatments based solely on PFS. Treatment preferences were mainly driven by 3-year PFS with less importance placed on adverse events (RAI: patients 4.0-11.0%; caregivers 3.7-13.3%) (Table). Patients were willing to forgo 3.9-8.7% of 3-year PFS to reduce risks of any grade cognitive/mood effects, grade ≥3 abnormal lab results, grade ≥3 lung complications, grade ≥3 weight gain, and any grade myalgia; caregivers were willing to trade 3.7-7.2% of 3-year PFS to reduce any grade cognitive/mood effects, grade ≥3 abnormal lab results, and grade ≥3 lung complications, but not any grade myalgia or grade ≥3 weight gain. **Conclusions:** Patients and caregivers highly prioritized achieving a higher chance of 3-year PFS when choosing treatments. Most were willing to trade PFS benefit for reduced risks, although there was a subset of caregivers who were unwilling to trade any benefit for reduced risks. The extent varied between patients and caregivers. Shared treatment decision making between physicians and patients/caregivers should consider the balance between benefits and risks. Research Sponsor: Takeda Development Center Americas, Inc.

RAI and MAL.

	RAI		MAL of 3-year PFS	
Attributes (Levels)	**Patients (n=205)**	**Caregivers (n=125)**	**Patients (n=205)**	**Caregivers (n=125)**
3-year PFS (30-65%)	50.8%	51.6%	NA	NA
Any grade cognitive/mood effects (0-25%)	11.0%	13.2%	8.7%	7.2%
Grade ≥3 lung complications (0-6%)	9.3%	6.7%	5.4%	3.7%
Grade ≥3 abnormal lab results (0-30%)	8.7%	13.3%	6.8%	5.5%
Grade ≥3 weight gain (0-20%)	8.5%	4.5%	4.7%	NS
Any grade myalgia (0-20%)	7.6%	7.2%	3.9%	NS
Tumor progression in the brain within 3 years (10-55%)	4.0%	3.7%	6.1%	NS

NS: not statistically different to zero (p≥0.05), indicating unwillingness to forgo 3-year PFS to reduce these risks.

LUMINOSITY, a phase 2 study of telisotuzumab vedotin in patients with c-Met protein–overexpressing non-squamous *EGFR*-wildtype advanced NSCLC: Efficacy outcomes by prior therapy. First Author: Jonathan W. Goldman, David Geffen School of Medicine at University of California, Los Angeles, Los Angeles, CA

Background: Telisotuzumab vedotin (Teliso-V) is a c-Met–directed antibody-drug conjugate comprising the mAb telisotuzumab and the microtubule polymerization inhibitor monomethyl auristatin E. In the phase 2 LUMINOSITY trial (NCT03539536), Teliso-V monotherapy 1.9 mg/kg showed durable responses and a generally manageable safety profile in patients (pts) with c-Met protein–overexpressing (OE) non-squamous (NSQ) *EGFR*-wildtype (WT) non-small cell lung cancer (NSCLC). Herein we present an analysis of efficacy outcomes according to prior platinum or prior platinum and immune checkpoint inhibitor (ICI)-based therapies. **Methods:** Pts (≥18 years) with locally advanced/metastatic c-Met protein–OE NSQ *EGFR*-WT NSCLC who had ≤2 prior lines of therapy, including ≤1 line of chemotherapy, were treated with 1.9 mg/kg Teliso-V Q2W. c-Met protein overexpression (by immunohistochemistry clinical trial assay for MET [SP44] [Roche]) was defined as ≥25% tumor cells with 3+ staining intensity (high: ≥50% 3+; intermediate [int]: 25 to <50% 3+). The primary endpoint was overall response rate (ORR) by independent central review per RECIST v1.1. **Results:** As of 21 Feb 2024, 172 pts received ≥1 dose of Teliso-V and 168 pts were included in efficacy analyses (c-Met high, n=84; c-Met int, n=84). In the c-Met OE total population, 97.6% of pts received prior platinum and 78.6% received prior platinum + ICI. Efficacy data for pts with prior platinum and platinum + ICI therapies are shown in the Table. Among the 172 dosed pts, the most common any-grade treatment-related adverse events (TRAEs) were peripheral sensory neuropathy (31%), peripheral edema (16%), and fatigue (14%). The most common grade ≥3 TRAE was peripheral sensory neuropathy (7%). **Conclusions:** This analysis demonstrated that Teliso-V elicited durable responses in pts with c-Met protein–OE NSQ *EGFR*-WT NSCLC regardless of whether they had received prior platinum or platinum + ICI therapies; the efficacy outcomes in these subgroups were consistent with those in the overall pt population. Clinical trial information: NCT03539536. Research Sponsor: AbbVie, Inc.; n/a

EATON: A phase I trial of nazartinib (EGF816) and trametinib in EGFR-mutant (EGFRmut) non-small cell lung cancer (NSCLC). First Author: Sebastian Yves Friedrich Michels, University of Cologne, Faculty of Medicine and University Hospital Cologne, Center for Integrated Oncology Aachen Bonn Cologne Düsseldorf, Department I for Internal Medicine, Lung Cancer Group Cologne, Cologne, Germany

Background: EGFR inhibitors (EGFRi) are highly effective in EGFRmut NSCLC, but resistance inevitably emerges. Among the mechanisms of acquired resistance, RAS/MEK pathway activation has been identified in both cell models and patients. Preclinical and clinical data support efficacy of dual MEK and EGFR inhibition in this setting. In the EATON trial we investigated the combination of the MEK inhibitor (MEKi) trametinib (TMT) and the third-generation (3gen) EGFRi nazartinib (NAZ) in patients with EGFRmut NSCLC. **Methods:** EATON (NCT03516214, AIO-TRK-0216) is an academic multicenter, phase I, dose-escalation trial conducted in Spain and Germany. Primary endpoint: maximal tolerated dose (MTD)/recommended phase 2 dose (RP2D); secondary endpoints: pharmacokinetics (PK), safety, preliminary efficacy. Key eligibility criteria: Advanced/metastatic EGFRmut NSCLC, EGFR p.T790M-positive/-negative, no MET amplification, any treatment line. Dose escalation was based on a modified 3+3 up-and-down design in up to 18 patients [Storer, 1989]. TMT and NAZ were dosed once daily (qd) at pre-defined dose levels (DL) of 0.5 mg/100 mg (DL -1), 1.0 mg/100 mg (DL 1), 1.5 mg/100 mg (DL 2), 1.5 mg/150 mg (DL 3), 2 mg/150 mg (DL 4). The dose-limiting toxicities (DLT) period comprised the first 28 treatment days. **Results:** In total, 19 patients were dosed (mean age, 62 years (range, 44-81); 14 female (73.7%)). Prior EGFRi and 3gen EGFRi use were noted in 17 (89.5%) and 14 (73.7%), respectively. Patients were treated at DL -1 (N=4), DL 1 (N=13), and DL 2 (N=3), with 18 (94.7%) eligible for dose-escalation decisions. DLTs were observed in 4 (22.2%) patients (Grade 3 creatinine phosphokinase elevation, N=3; Grade 3 hypertension, N=1). The MTD was determined to be TMT 1.0 mg qd and NAZ 100 mg qd. After repeated dosing (C1D15) at the MTD, geo-mean C_{max} of NAZ was 336 ng/ml (N=14, CV % 44.8) and of TMT 19.5 ng/ml (N=7, CV% 22.6). Geo-mean AUC_{tau} of NAZ was 3950 ng/ml*h (N=14, CV% 48.7) and of TMT 301 ng/ml*h (N=7, CV% 27.3). Treatment-related adverse events (TRAEs) of any grade were observed in all patients (N=19; 100%) and of Grade ≥3 in nine (47.4%). Discontinuation rates were 26.3% (N=5) and 21.1% (N=4), for TMT and NAZ. Sixteen (84.2%) patients were evaluable for RECIST 1.1 response assessment and 19 (100%) for time-to-event outcomes. One patient had a partial response (ORR, 6.3%; 95% CI, 1.6-30.2) and six had stable disease (37.5%). Median progression-free survival was 2 months (95% CI, 1.7-2.2). Molecular determinants of response and resistance were investigated by 3' RNA and DNA sequencing. **Conclusions:** At the MTD, treatment was safe and moderately tolerable. Preliminary efficacy in this unselected and heavily pre-treated population was limited. A comprehensive biomarker-driven approach may help identify patients more likely to derive clinical benefit. Clinical trial information: NCT03516214. Research Sponsor: German Federal Ministry of Education and Research (BMBF); Novartis.

Patient-reported outcomes (PRO) evaluating physical functioning and symptoms in patients with pretreated HER2-mutant advanced non-small cell lung cancer (NSCLC): Results from the Beamion LUNG-1 trial. First Author: Joshua K. Sabari, Division of Medical Oncology, Perlmutter Cancer Center, New York University Langone Health, New York, NY

Background: Zongertinib is an irreversible tyrosine kinase inhibitor that selectively inhibits HER2 while sparing EGFR, thereby limiting associated toxicities. Beamion LUNG-1 (NCT04886804) is a Phase Ia/Ib first-in-human study evaluating safety and efficacy of zongertinib in patients with HER2-mutant advanced NSCLC (Phase Ib). Here, we report PRO data on NSCLC-related symptoms, physical functioning, symptomatic adverse events (AEs) and their burden from Phase Ib Cohort 1. The PRO analysis included patients with previously treated HER2-mutant NSCLC who received 120mg QD zongertinib. **Methods:** EORTC QLQ-C30 physical functioning scale, NSCLC-SAQ (cough, dyspnea, pain, fatigue and poor appetite), EORTC IL46/Q168 (side effect burden) and nine PRO-CTCAE items (mouth and/or throat sores, taste changes, nausea, vomiting, diarrhea, rash, skin dryness, itching, and numbness/tingling) were collected at cycle 1: days 1, 8 and 15, and day 1 of cycles 2, 3, 5, 7 and 9. Change from baseline (CFB) to cycle 5 in EORTC QLQ-C30 physical functioning (0-100, higher=better) and NSCLC-SAQ total score (0-20, lower=fewer symptoms) were analyzed using mixed model repeated measures. EORTC IL46 (1 = 'Not at all', 4 = 'Very much') and PRO-CTCAE (0 Never/None to 4 Almost Constant/Very Severe) were analyzed descriptively; maximum baseline-adjusted proportions of patients were calculated. Post-hoc analysis includes contextualizing results based on clinically meaningful thresholds and exploring associations between PRO and clinical endpoints such as objective response. **Results:** The PRO analysis set comprised of 30 patients. High completion rates were observed, over 86%, across PROs and visits. Longitudinal MMRM analysis showed improvements for EORTC QLQ-C30 physical functioning and NSCLC-SAQ total score, with rapid improvement which was maintained to cycle 9; CFB to cycle 5: LS means 9.6 (95% CI: 6.3, 12.9), and -3.9 (95% CI: -4.8, -2.9) respectively. Patients reported low overall side effect burden (EORTC IL46); patients reporting side effect burden on treatment as 'Quite a bit'/ 'Very much' was equal to baseline reporting (6.7%), with the exception only at cycle 1 day 15 (10%). Patient reported adverse event frequency/severity (PRO-CTCAE items) reflected expected toxicity profiles; diarrhea was reported at the highest frequency (maximum baseline adjusted: 'Frequent'/ 'Almost constant'=30%), low percentages of patients reported high levels of severity or interference for any adverse event. **Conclusions:** Zongertinib-treated patients reported a rapid improvement followed by stability in physical functioning and NSCLC-SAQ total score. The frequency and severity of patient-reported symptomatic AEs and the overall side effect burden demonstrated favorable tolerability of zongertinib. Clinical trial information: NCT04886804. Research Sponsor: Boehringer Ingelheim.

Advancing evidence-based NSCLC testing and treatment across academic and community-based settings. First Author: Gilberto Lopes, Sylvester Comprehensive Cancer Center, University of Miami, Miami, FL

Background: Comprehensive testing for guideline-recommended driver mutations in advanced non-small cell lung cancer (aNSCLC) remains underutilized. **Methods:** From Feb to Mar 2024, 20 healthcare professionals (HCPs) were surveyed from one academic and one community-based oncology system in the same region and retrospective chart audits (N=100) were performed to assess current practices, challenges/barriers, and areas for improvement in biomarker testing and use of targeted therapies in aNSCLC. Based on these baseline findings, an expert steering committee, including an oncologist, pathologist, surgeon, and site representatives, developed a NSCLC biomarker toolkit to support evidence-based testing. Clinical teams reviewed the data in audit feedback sessions and developed and implemented action plans to address identified gaps. **Results:** Both academic and community HCPs (aHCPs, cHCPs; 60%) cited *determining the appropriate molecular tests to order for treatment decisions* as their top challenge in integrating targeted therapies into practice. Significant variation was reported in which team member checks insurance authorization for molecular testing and submits the order, and how the medical oncologist is notified when test results are available. Most HCPs (93%) said molecular test results are not consistently scanned into the same chart locations. Compared to aHCPs, cHCPs were more likely to start NSCLC treatment before receiving molecular test results and reported significantly lower confidence in shared decision-making with pts. Top challenges in adverse event (AE) management were *patient communication about recognizing AEs* for aHCPS (80%), and *staying updated on AEs from targeted therapies* (50%) for cHCPs. Chart audits revealed greater variability in frontline therapies prescribed to pts treated in a community setting. Molecular testing was ordered for 86% of pts overall, including 100% in academic settings and 72% in community settings; 81% of pts had a documented mutation. As a result of this initiative, systems developed action plans to integrate the biomarker testing tool into practice, improve workflows for reflex testing, standardize molecular test documentation in EMRs, and utilize AI dashboards and dedicated phone lines to streamline communication with NSCLC patients about treatments and side effects. Additional follow-up data will be presented. **Conclusions:** This project uncovered real-world gaps in biomarker testing and evidence-based integration of targeted therapy for aNSCLC and revealed unique differences between academic and community settings, driving action plans to improve clinical workflows and communication. The biomarker testing toolkit and sustainable process changes implemented in this QI initiative represent key opportunities for improvement that can be implemented in clinics across the country to improve NSCLC care. Novel potent and selective fourth-generation inhibitors targeting EGFR for NSCLC therapy. First Author: Gauthier Errasti, PMC Isochem, Paris, France

Background: Epidermal growth factor receptor (EGFR)-activating mutations (Del19 or L858R) are oncogenic drivers of non-small cell lung cancer (NSCLC). Most patients treated with tyrosine kinase inhibitors (TKIs) will eventually develop resistance mutations including the T790M gatekeeper mutation. Osimertinib, a third-generation covalent TKI, is efficacious against the T790M resistance mutation and prevents its onset. However, treatment with Osimertinib inevitably induces additional mutations, especially the C797S mutation, as well as various off-target resistance mechanisms. To date, there are no approved therapies capable of overcoming mutational or non-mutational resistance to third-generation EGFR TKIs. **Methods:** We have characterized the efficacy of two novel fourth-generation EGFR inhibitors, CCM-205 and CCM-308, which are potent against both mutational and non-mutational tumor resistance to Osimertinib. Enzymatic binding affinities were determined by KdELECT assay. Cell-Titer-Glo (CTG) assay was used to assess cytotoxicity (cellular IC_{50}) of CCM-205 and CCM-308 *in vitro* on EGFR triple mutant and other Osimertinib-resistant cell lines, with comparison to both Osimertinib and fourth-generation EGFR inhibitor BLU-945. *In vivo* tumor growth inhibition (TGI) was determined in Osimertinib-resistant xenografts including the triple mutant PC9-DTC (Del19/T790M/C797S) model. **Results:** In Ba/F3 EGFR DTC and LTC cells, CCM-205 / CCM-308 inhibit proliferation with IC_{50}s of 137 nM / 40 nM and 198 nM / 61 nM respectively, while Osimertinib antiproliferation is limited to 1.225 μM and 1.562 μM respectively. Moreover, CCM-205 / CCM-308 spare Ba/F3 EGFR WT better than Osimertinib with IC_{50}s of 577 nM / 294 nM (182 nM for Osimertinib). CCM-205 / CCM-308 also bind tightly to double mutants targeted by Osimertinib with K_ds for EGFR LT (L858R/T790M) of 4.9 nM / 1.2 nM. CCM-205 and CCM-308 are more potent against PC9 DTC cells (IC_{50}s: 1.02 μM and 220 nM, respectively) than Osimertinib (4.10 μM) and are comparable to BLU-945 (559 nM). In addition, CCM-205 / CCM-308 are highly potent against Osimertinib-resistant PC9 (IC_{50}s: 728 nM / 321 nM) and H1975 (IC_{50}s: 1.716 μM / 684 nM) cell lines generated through 8-week treatment with 1 μM Osimertinib (Osimertinib IC_{50} = 3.81 μM and 4.70 μM, respectively), while EGFR-specific fourth-generation inhibitors targeting C797S such as BLU-945 lose potency (IC_{50}s: 7.96 μM and $>$ 10 μM, respectively). In the PC9-DTC xenograft, CCM-205 completely inhibited tumor growth and induced tumor regression ($>$ 100% TGI) exceeding that of BLU-945, while the tumor was resistant to Osimertinib ($<$ 20% TGI), when agents were delivered orally at similar fractions of their maximum tolerated doses (MTDs). **Conclusions:** Novel fourth-generation EGFR inhibitors have been developed that can potentially overcome both on-target and off-target resistance in NSCLC and have potential clinical applications. Research Sponsor: CCM Biosciences.

Final overall survival analysis for a phase 3 randomized trial comparing afatinib to chemotherapy in treatment-naïve non-small cell lung cancer with a sensitizing uncommon epidermal growth factor receptor mutation (ACHILLES/TORG1834). First Author: Kyoji Tsurumi, Department of Respiratory Medicine, Miyagi Cancer Center, Natori, Japan

Background: The phase 3 randomized trial comparing afatinib to chemotherapy in treatment-naïve non-small cell lung cancer (NSCLC) with a sensitizing uncommon epidermal growth factor receptor mutation (*EGFR*) (ACHILLES) met its primary endpoint at the interim analysis. This trial demonstrated statistically significant improvement in progression-free survival (PFS)with hazard ratio 0.421; 95% confidence interval (CI), 0.251–0.706; p = 0.0010). Here, we report the final updated survival data. **Methods:** In this open-label phase 3 study, treatment-naïve patients (n=109) with sensitizing uncommon *EGFR* mutant NSCLC were randomized 2:1 to receive oral afatinib (30 mg or 40 mg daily) or a combination of platinum (cisplatin 75 mg/m^2 or carboplatin AUC 5 or 6) and pemetrexed (500 mg/m^2), followed by pemetrexed maintenance therapy every 3 weeks. The primary endpoint was PFS according to RECIST 1.1 criteria. Overall survival (OS) was a secondary endpoint. Post-protocol treatment was administered at the physician's discretion. **Results:** As of the 2 December 2024 database lock, the median follow-up time was 33.6 months. Afatinib continued to improve PFS compared with chemotherapy (median, 10.8 months vs 7.0 months; HR [95% CI], 0.528 [0.338–0.827], p = 0.0052). The updated OS HR for afatinib compared to chemotherapy was 0.645 (95% CI, 0.359–1.160; p = 0.1433; 49/109 events, 44.9% maturity). The median OS was 45.0 months (range, 27.0–not estimated) in the afatinib group and 27.0 months (range, 15.9–50.4) in the chemotherapy group. The crossover rate to EGFR-TKI was 90.6% in the chemotherapy arm. Notably, the subgroup receiving a starting dose of 40mg afatinib and the subgroup of younger patients ($<$ 75 years) showed a favorable OS HR (HR 0.371, 95%CI, 0.140–0.986; HR 0.422, 95%CI, 0.201–0.886). No new safety signals were observed in this update analysis. **Conclusions:** This final survival analysis confirmed the superiority of afatinib compared to chemotherapy for uncommon or compound *EGFR* mutation-positive advanced NSCLC. Clinical trial information: jRCTs 031180175. Research Sponsor: None.

Epigenetic and transcriptional consequences of MTAP-loss in lung adenocarcinoma. First Author: Swati Pothukuchi, Department of Internal Medicine, University of California, Davis, Davis, CA

Background: Lung adenocarcinoma (LUAD), the most common lung cancer subtype, has poor survival rates and limited treatment options. Among its molecular drivers, loss of methylthioadenosine phosphorylase (MTAP) is linked to aggressive development and poor outcomes, yet its downstream effects remain unclear. MTAP is essential for purine biosynthesis and S-adenosyl methionine (SAM) production, a key methyl donor for epigenetic regulation. MTAP-loss leads to methylthioadenosine (MTA) accumulation, which inhibits methyltransferase activity and disrupts epigenetic control. However, the impact of MTAP deficiency on transcriptional and metabolic programming in LUAD is still largely unknown, highlighting a critical gap for targeted therapy. This study examines these molecular consequences to identify potential therapeutic vulnerabilities in MTAP-deficient LUAD. **Methods:** RNA-sequencing data for 510 LUAD samples were obtained from The Cancer Genome Atlas (TCGA) via cBioPortal. Samples were classified as MTAP-loss (n=64) or MTAP-normal (n=446) based on mutational data. Differential gene expression was performed using the DESeq2 package for R and the Benjamini-Hochberg procedure was used to control for false discovery rate. DNA methylation (Illumina Human Methylation 450k) was compared between MTAP-loss (n=46) and MTAP-normal (n=404) cohorts. Significantly altered probes were mapped to differentially expressed genes (DEGs). Pathway and gene ontology (GO) analyses were conducted using KEGG, GO, and EnrichR to identify dysregulated pathways. **Results:** DNA methylation analysis revealed 581 hypomethylated and only 51 hypermethylated probes in MTAP-loss samples, underscoring a global hypomethylation phenotype likely driven by MTA accumulation. We identified 343 differentially expressed, hypomethylated genes in MTAP-loss LUAD samples. Of these, upregulated genes were highly enriched in mitochondrial function and stress response pathways, whereas downregulated genes were linked to cell differentiation and developmental processes, suggesting an epigenetically driven metabolic reprogramming. Notably, these alterations may confer heightened cellular survival and adaptability under stress, while curtailing normal differentiation programs. **Conclusions:** Our findings indicate that MTAP loss in LUAD leads to a coordinated shift in DNA methylation and gene expression, promoting survival-focused metabolic and stress responses at the expense of normal regulatory pathways. These results highlight novel vulnerabilities in MTAP-deficient tumors and suggest potential targets for precision therapies. Research Sponsor: None.

Rare ALK: Clinical characteristics and efficacy of targeted therapy in NSCLC with ALK fusions other than EML4::ALK. First Author: Felix Carl Saalfeld, Department of Medicine I, University Hospital Carl Gustav Carus Dresden, TU Dresden, Dresden, Germany

Background: More than 90% of ALK rearrangements in NSCLC lead to recurrent fusions with EML4. The remainder is a heterogeneous group involving more than twenty different fusion partners. Data on prognosis and management of these patients is limited to case reports. **Methods:** This is an international, multicenter, retrospective analysis of advanced NSCLC patients with a non-EML4::ALK-fusion (*rare ALK*) compared to a control cohort of patients harboring typical EML4::ALK-translocations. **Results:** Out of 26,152 NSCLC patients tested by NGS 0.2% showed *rare ALK* with 21 distinct fusion partners identified. The prevalence of typical EML4::ALK fusions in the cohort was within the expected range (1.9%). Sufficient clinical data was available for a total of 51 *rare ALK* and 277 EML4::ALK patients. Median age within the *rare ALK* cohort was 66 years. 59% were male. The majority (88%) presented with adenocarcinoma, 10% had squamous-cell carcinoma. The choice of first-line TKI in *rare ALK* patients was similar to the EML4::ALK control cohort and with alectinib used predominantly (around 50%). Compared to EML4::ALK, patients with *rare ALK* were significantly older, more likely to have ever smoked (59% vs 35%) and, among smokers, had more pack years (15 vs 7 pack years). Objective response rate (ORR) to firstline ALK inhibitor treatment across all treatment lines in patients with *rare ALK* was 68% (95% confidence interval [CI] 53%-80%), while EML4::ALK patients had an ORR of 85% (CI 80%-89%; p=0.01). ALK inhibitors in first-line palliative treatment led to similar PFS in the *rare ALK* (23 months [mo]; CI 7.1-38.9) and the EML4::ALK cohort (25 mo; CI 19.9-30.1; HR 0.92; CI 0.6-1.5; p=0.7). Median overall survival (OS) was 40 mo (CI censored) for *rare ALK* compared to 57 mo (CI 50.7-63.3) for EML4::ALK (HR 0.9; CI 0.5-1.6; p=0.6). Within the *rare ALK* cohort, first-line treatment with platinum-doublet chemotherapy was associated with shorter PFS as compared to ALK inhibitors (5 mo vs 23 mo; HR 3.1; CI 1.2-8.0; p = 0.021) and trended towards shorter OS (24 mo vs 40 mo; HR 2; CI 0.7-5.9; p=0.2). **Conclusions:** Acknowledging the limitations of a retrospective analysis, our data suggest that, compared to EML4::ALK, patients with *rare ALK* fusions derive similar benefit from treatment with ALK inhibitors, which should be preferred over platinum-based therapies as first-line palliative treatment. Research Sponsor: None.

8626 Poster Session

Clinico-genomic characteristics of clinical trial participation and its impact on clinical outcome in metastatic NSCLC: A nationwide database analysis in Japan. First Author: Kentaro Gosho, Division of Genome Biology, National Cancer Center Research Institute, Tokyo, Japan

Background: The clinico-genomic factors influencing clinical trial participation and their impact on clinical outcomes remain unclear. We investigated which clinico-genomic characteristics predict clinical trial participation in patients with metastatic NSCLC and whether trial participation improves clinical outcomes compared to non-participation, using a nationwide database. **Methods:** We retrospectively analyzed 2,966 patients with metastatic NSCLC who underwent comprehensive genomic profiling (CGP) testing from March 2019 to December 2023 in the Center for Cancer Genomics and Advanced Therapeutics, a nationwide database. Multivariable logistic regression identified clinico-genomic factors associated with trial participation. Multivariable Cox model compared OS between trial participants and non-trial participants, adjusting for age, sex, smoking status, performance status, liver/brain metastases, FDA-approved/potentially druggable genes, PD-L1 tumor proportion score (TPS). Overall response rate (ORR) by the line of therapy was evaluated. **Results:** Of 2,966 patients, 167 (6%) participated in clinical trials. In the multivariable analysis, *EGFR* mutation (mut), non-squamous (sq) histology, and male sex were associated with a higher likelihood of trial participation, whereas *STK11* mut was associated with a lower likelihood of trial participation. After stepwise selection, biomarker factors (*EGFR* mut, *KRAS* G12C mut, *RET* fusion, *MET* exon 14 skipping mut, PD-L1 TPS $\geq$ 50%) explained 72% of the increased trial participation odds, while clinical factors (age $<$ 65, male sex, non-sq histology) accounted for 28%. Among patients with lung adenocarcinoma (LUAD), *KRAS* G12C and male sex predicted higher trial participation; among those with lung sq cell carcinoma (LUSC), *KRAS* G12C predicted higher trial participation. Participation did not confer an OS benefit in the overall NSCLC cohort (HR, 0.94; 95% CI, 0.74–1.19), in LUAD (HR, 1.03; 95% CI, 0.78–1.37), or in *EGFR*-mut patients (HR, 0.99; 95% CI, 0.52–1.88), but was significantly associated with improved OS in LUSC (HR, 0.29; 95% CI, 0.10–0.78). ORR was not significantly different between trial participants and non-trial participants in 1L (49% vs. 57%, P=0.25), 2L (30% vs. 34%, P=0.75), and 4L (25% vs. 19%, P=0.56) therapy lines, but was significantly higher among trial participants in 3L (46% vs. 23%, P=0.002) and $\geq$5L (48% vs. 18%, P=0.0001). **Conclusions:** Biomarker factors contributed to 72% of the likelihood of trial participation in patients with metastatic NSCLC, underscoring the importance of CGP. Clinical trial participants exhibited survival outcomes comparable to those of nonparticipants. Their higher ORR in later lines of therapy suggests that clinical trial participation may be a potent therapeutic option, particularly after standard treatment. Research Sponsor: None.

Osimertinib plus anlotinib in patients with untreated, EGFR-mutated, advanced non-small-cell lung cancer with concurrent gene alterations: A single-arm, prospective, multicenter phase II study. First Author: Guanming Jiang, Dongguan People's Hospital, Dongguan, China

Background: The standard first-line treatment for advanced EGFR-mutated non-small cell lung cancer (NSCLC) is EGFR tyrosine kinase inhibitors (EGFR-TKIs). However, co-existing mutations can reduce the efficacy of EGFR-TKIs, and combination treatments may offer superior outcomes. Some studies suggest that the combination of Osimertinib and Anlotinib may enhance anti-tumor activity. This study explores the efficacy and safety of this combination as a first-line treatment for advanced NSCLC with EGFR co-existing mutations. **Methods:** This prospective, multicenter phase II trial enrolled patients (pts) with untreated, advanced NSCLC carrying EGFR exon 19 deletions or L858R mutations plus at least one additional mutation in TP53, PI3KCA, or RB1. pts received oral Osimertinib (80 mg daily) and Anlotinib (10 mg daily for 2 weeks, followed by 1 week off), repeated every 3 weeks until disease progression, unacceptable toxicity, or withdrawal. The primary endpoint was the 1-year progression-free survival (PFS) rate. Secondary endpoints included median overall survival (mOS), median PFS (mPFS), objective response rate (ORR), disease control rate (DCR), and safety. Exploratory analyses evaluated changes in circulating tumor DNA (ctDNA) and their correlation with clinical outcomes. **Results:** As of June 24, 2024, 38 pts (median age 65 years; 39.5% male; 78.9% ECOG PS 1) were enrolled. EGFR mutations included exon 19 deletions (47.4%) and L858R (52.6%), with co-existing mutations in TP53 (78.9%), PI3KCA (28.9%), and RB1 (2.6%). At baseline, 47.4% of pts had brain metastases. With a median follow-up of 14.5 months, the 1-year PFS rate was 85% (95% CI: 70%-95%), and median PFS was 29.0 months (95% CI: 22.5-NA). The ORR was 76.7%, and DCR was 97.4%. Among the 18 pts with brain metastases, the ORR was 83.3%, and median PFS was 22.3 months (95% CI: 14.6-30.4). All pts experienced treatment-related adverse events (TRAEs), with 18.3% having Grade 3 or higher TRAEs. Common TRAEs included rash (81.6%), hand-foot syndrome (71.1%), oral mucositis (50.0%), hypertension (60.5%), liver function impairment (47.4%), decreased appetite (44.7%), and diarrhea (36.8%). In the 11 pts monitored via next-generation sequencing (NGS), ctDNA clearance post-treatment correlated significantly with improved PFS (median PFS: NR vs. 17.8 months, P=0.015). **Conclusions:** The combination of Osimertinib and Anlotinib shows promising efficacy and manageable toxicity as a first-line treatment for advanced NSCLC with EGFR co-existing mutations, particularly in pts with brain metastases. Post-treatment ctDNA clearance appears to be a potential biomarker for predicting therapeutic response and prognosis. Further investigation is warranted to confirm these findings and explore personalized treatment strategies in NSCLC. Clinical trial information: ChiCTR2300070023. Research Sponsor: None.

Association of circulating tumor DNA (ctDNA) variant allelic frequency (VAF) with outcomes on matched targeted therapies (TT) in advanced non-small cell lung cancer (aNSCLC). First Author: Amin Nassar, Yale Cancer Center, New Haven, CT

Background: There is a critical gap in our understanding of the correlation between ctDNA driver VAF and outcomes in patients (pts) with aNSCLC treated with TT. We explore the landscape of driver alterations (alts) in aNSCLC by ctDNA VAF and assess the association with outcomes in pts treated with matched TT. **Methods:** We analyzed 3,146 pts with aNSCLC with a driver positive liquid biopsy (LBx) (FoundationOneLiquid CDx) Targetable driver altswere defined as alts listed in NCCN guidelines and were stratified by VAF. Clinical outcomes were assessed for pts included in the nationwide (US-based) de-identified Flatiron Health-Foundation Medicine aNSCLC clinico-genomic database (FH-FMI CGDB) originating from approximately 280 US cancer clinics (~800 sites of care). For 224 pts receiving matched TT within 60 days of LBx collection, multivariate Cox proportional hazard models were employed to evaluate the association of VAF on real-world progression-free (rwPFS) and overall (rwOS) survival adjusting for clinical and demographic factors. **Results:** Among 3,146 pts with targetable alts detected in LBx, the frequency of drivers with VAF $<$1% in ctDNA was 36% (1,185/3,262 alts). Distribution of drivers by VAF is shown in the table. For pts in the FH-FMI CGDB treated with matched TT following driver positive LBx, clinical and demographic characteristics were balanced between pts with driver VAF $<$1% (n = 75) and those with VAF $\geq$1% (n = 147), except for the presence of liver metastases, which were more common in pts with VAF $<$1% (12% v 26%; p = 0.0002). There was no significant difference in the median rwPFS for pts with driver VAF $<$1% vs those with VAF $\geq$1% (10.8 vs 8.7 months; HR = 1.40 [0.92-2.00]; p=0.12). Similarly, there was no significant difference in median rwOS (32.4 vs 23.2 months; HR 1.20 [0.74-2.00]; p=0.45). To account for potential bias due to varying effectiveness of TT by driver, we limited the analysis to pts treated with EGFR inhibitors: VAF of the *EGFR* mutation did not affect rwPFS (10.8 vs 9.8 months; HR 1.14 [0.69-1.90]; p=0.61) or rwOS (18.3 vs 23.2 months; HR 1.1 [0.61-2.00]; p=0.74). **Conclusions:** Outcomes in pts with aNSCLC receiving matched TT after LBx were comparable between pts with driver VAF $<$1% and those with VAF $\geq$1%. Our findings highlight that the presence of a detectable targetable driver alt in aNSCLC is actionable, regardless of ctDNA VAF. Research Sponsor: Foundation Medicine, Inc.

Safety and efficacy of ifebemtinib (IN10018) combined with garsorasib (D-1553) in KRAS G12C mutant solid tumors from a phase Ib/II study: Results from single-arm of non-small-cell lung cancer (NSCLC) and randomized part of colorectal cancer (CRC). First Author: Zhengbo Song, Zhejiang Cancer Hospital, Hangzhou, China

Background: RAS inhibitors (RASi) need to be combined with optimal partner(s) to maximize their efficacy. Ifebemtinib (ifebe) is a highly potent and selective oral inhibitor of focal adhesion kinase (FAK) demonstrating synergies with RASi both preclinically and clinically. D-1553 is a novel KRAS G12Ci approved in China for KRAS G12C mutant NSCLC. We previously reported a promising ORR of 90.3% in KRAS G12C mutant NSCLC receiving ifebe + D-1553 with pending durability of efficacy. Here we are updating the follow-up (FU) results in NSCLC and also reporting preliminary results of ifebe + D-1553 vs D-1553 in KRAS G12C mutant CRC from a randomized part to decipher the relative contribution of ifebe. **Methods:** Locally advanced or metastatic KRAS G12C mutant NSCLC patients (pts) without any prior systemic anticancer therapy were enrolled in a single arm and received ifebe (100mg QD) + D-1553 (600mg BID). Metastatic KRAS G12C mutant CRC pts with at least 1 prior line of systemic anticancer therapy were enrolled in a randomized part and randomized 1:1 to ifebe (100mg QD) + D-1553 (600mg BID) or D-1553 (600mg BID) alone. **Results:** As of 22-Jan-25, 33 front-line NSCLC pts (81.8% stage IV) were enrolled and received ifebe + D-1553, and 36 previously-treated metastatic CRC pts were enrolled and randomized 1:1 to receive ifebe + D-1553 or D-1553 alone. In NSCLC with a median FU of 13.8 months (range: 1.1, 20.9), 12-month PFS rate is 67.9%, and Kaplan-Meier curve of PFS flattens as treatment continues, predicting durable efficacy. The mDOR, mPFS and mOS are not reached by the cut-off date. In the randomized part of CRC, all 36 pts are radiologically evaluable. The ORR is 33.3% (95%CI: 13.3, 59.0) vs 16.7% (95%CI: 3.6, 41.4) and DCR is 100.0% (95%CI: 81.5, 100.0) vs 77.8% (95%CI: 52.4, 93.6) in ifebe + D-1553 vs D-1553 alone, respectively. The mDOR, mPFS and mOS has not matured yet. The safety profiles of ifebe + D-1553 in both NSCLC and CRC pts are comparable to each single agent. No ifebe- or D-1553-related death or AEs leading to drug withdrawal were reported. The incidence of SAEs and $\geq$Grd.3 AEs are listed in Table 1. **Conclusions:** Combination of ifebe and D-1553, as a dual-oral regimen, is safe and highly efficacious against KRAS G12C mutant NSCLC with ORR over 90% and durable efficacy. Preliminary results from the randomized part of CRC demonstrated ORR doubling with the combo, validating the add-on benefits of ifebe. Our data suggest that ifebe could be an ideal partner of RASi. Clinical trial information: NCT06166836; NCT05379946. Research Sponsor: None.

Clinical outcomes of tepotinib and immune checkpoint inhibitor therapy for MET exon 14 skipping NSCLC: A multicentric retrospective analysis. First Author: Kazuhito Misawa, Department of Thoracic Oncology, Saitama Cancer Center, Saitama, Japan

Background: The VISION study demonstrated that tepotinib, a MET inhibitor, is effective against MET exon 14 (METex14) skipping NSCLC, but the clinical data on the efficacy and safety of this drug are scarce, and the utility of immune checkpoint inhibitors (ICIs) in patients with METex14 requires further investigation. The present, multicentric, retrospective study evaluated the clinical efficacy and safety of tepotinib and ICIs in patients with METex14 skipping NSCLC. **Methods:** Data on the patient characteristics, treatment details, efficacy, and safety of tepotinib and ICIs in patients with METex14 skipping NSCLC diagnosed at any of six Japanese hospitals between August 2020 and December 2024 were extracted from electronic medical records and retrospectively analyzed. **Results:** Of the 98 patients enrolled, 57 (58.2%) and 41 (41.8%) were male and female, respectively. 60 patients (61.2%) had a smoking history. Histological data indicated adenocarcinoma in most of the patients (68.4%). There were 50 patients (51.0%) with PD-L1 $>$ 50%. Tepotinib was administered to 79 patients with a median age of 75 years (range: 55–90 years). Most of these patients had advanced-stage cancer. Tepotinib was administered as the first-line therapy in 62 patients (78.5%), with 19.0, 55.7, 17.7, 6.3, and 1.3% of this subgroup having ECOG PS 0, 1, 2, 3, and 4, respectively. The median observation period was 29.1 months (range: 1.5–51.5 months). First-line tepotinib therapy achieved a 61.4% overall response rate (ORR; 95% confidence interval [CI]: 48.8–74.0), median progression-free survival (PFS) of 8.2 months (95% CI: 6.3–10.1), and median overall survival (OS) of 24.4 months (95% CI: 9.5–39.2). The most common adverse event (AE) was edema (71.0%), with Grade 3 or higher edema occurring in 12.9% of the patients. Notably, these patients had significantly longer PFS than those without edema (10.8 months [95% CI: 8.0–13.6] vs. 4.2 months [95% CI: 2.8–5.5]; hazard ratio: 0.31; 95% CI: 0.16 to 0.60; P $<$ 0.001). Treatment-related AEs led to tepotinib discontinuation in 15.0% of the cohort, and dose interruption and dose reduction were required in 59.5% and 62.0% of the cohort, respectively. ICI therapy, which was administered to 34 patients at various times, achieved a median PFS of 28.8 months (95% CI: 9.3–52.5) and a median OS of 45.2 months (95% CI: 20.9–77.0). **Conclusions:** The present, real-world analysis corroborated the findings of the VISION study demonstrating the efficacy and safety of tepotinib therapy against METex14 skipping NSCLC. The association between tepotinib-related edema and longer PFS warrants further investigation. Importantly, ICIs appear to be a promising treatment option for this population and deserve further study. Research Sponsor: None.

Vebreltinib plus PLB1004 in EGFR-mutated NSCLC with acquired MET amplification or overexpression after failure on EGFR-TKI treatment: A phase Ib/II study. First Author: Fei Zhou, Shanghai East Hospital, Shanghai, China

Background: MET amplification (METamp) or overexpression (METov) is the most common "off-target" mechanism that drives resistance to EGFR-TKIs. Vebreltinib is a potent and selective c-Met inhibitor, while PLB1004 is an oral, potent, irreversible, and selective EGFR-TKI with potent blood-brain barrier penetration and broad tyrosine kinase activity. **Methods:** This open-label, multicenter phase Ib/II study evaluated vebreltinib and PLB1004 in Chinese patients (pts) with EGFR-mutated NSCLC with METamp or METov after EGFR-TKI failure. Patients were eligible if they were METamp positive by NGS or FISH, or METov by IHC (3+). Phase Ib part established vebreltinib 150 mg BID and PLB1004 80 mg QD as the RP2D. Phase II further investigated the efficacy and safety of RP2D in four cohorts, stratified by MET gene status and previous EGFR-TKIs: 1: Progression after 1st-/2nd-generation EGFR-TKIs, T790M (-), with METamp (GCN $\geq$ 5 and/or MET/CEP7 $\geq$ 2 by FISH). 2: Progression after 3rd-generation EGFR-TKIs with METamp (GCN $\geq$ 5 and/or MET/CEP7 $\geq$ 2 by FISH). 3: Progression after EGFR-TKIs, T790M (-) for 1st-/2nd-generation TKIs, with METamp (GCN $<$ 5 and MET/CEP7 $<$ 2 by FISH, but positive by NGS). 4: Progression after EGFR-TKIs (1st-/2nd-/3rd-generation), T790M (-) for 1st-/2nd-generation TKIs, with METov (IHC 3+), and without METamp (GCN $<$ 5 and MET/CEP7 $<$ 2 by FISH, and negative by NGS). **Results:** There were 56 pts enrolled, with 13 in phase Ib and 43 in phase II (2/35/1/5 in four cohorts). The mean age was 58.8 $\pm$ 8.9 years, and 53.6% were male with the majority of patients having stage IV disease (98.2%). Prior EGFR-TKIs included 1st- (7.1%), 2nd- (5.4%), and 3rd-generation (87.5%) TKIs. Confirmed overall response rate (ORR) was 50.0%, and all cases (n=28) were partial response (PR). Disease control rate (DCR) was 89.3% (50/56). The median progression-free survival (mPFS) was 9.9 months. In 19 pts with brain metastases, ORR was 42.1% and mPFS was 9.5 months. There were 47 METamp-positive pts as detected by NGS (regardless of FISH), and these pts had an ORR of 53.2% and mPFS of 9.6 months. All pts (100%) reported treatment-related adverse events (TRAEs), with grade $\geq$ 3 TRAEs in 11 pts (19.6%). Serious adverse events were observed in 5 pts (8.9%), all of which were treatment-related. None discontinued treatment or died due to TRAE. The most common TRAEs were rash (64.3%), oedema peripheral (60.7%) and paronychia (48.2%). **Conclusions:** Vebreltinib and PLB1004 at RP2D demonstrates notable efficacy and manageable safety in EGFR-mutated NSCLC with METamp or METov after EGFR-TKIs failure. Findings from our phase Ib+II data suggest that NGS reported METamp+ could be utilized to identify target patients to receive combination of PLB1004 + Vebreltinib. Further studies are warranted to confirm these findings. Clinical trial information: NCT06343064. Research Sponsor: None.

Hypothesis generative head-to-head study comparing efficacy of afatinib and osimertinib based on immunological biomarkers in Japanese NSCLC patients with *EGFR* mutations: Heat on Beat randomized phase II study. First Author: Nobuhiko Seki, Division of Medical Oncology, Department of Internal Medicine, Teikyo University School of Medicine, Tokyo, Japan

Background: Osimertinib (Osi) has been established as a standard of care for patients (pts) with *EGFR*-mutant advanced non-small-cell lung cancer (NSCLC). However, in the FLAURA study, survival superiority of Osi over first-generation EGFR-TKIs was not demonstrated especially in Japanese pts (hazard ratio [HR], 1.39; 95% confidence interval [CI], 0.83 to 2.34; P = 0.22). This is presumably due to the different impact of adverse events or tumor antigen-specific cytotoxicity of T cells on subsequent therapy between both EGFR-TKIs in Japanese pts. On the other hand, there has been no clinical trial comparing second- with third-generation EGFR-TKIs. Therefore, optimal first-line EGFR-TKI may not have been identified in Japanese pts. **Methods:** This was a randomized, open-label, multicenter, phase II study to compare overall survival (OS) between initial treatment with afatinib (Afa) (n = 50) and Osi (n = 50) in pts with advanced or recurrent *EGFR*-mutant NSCLC. Exploration of immunomonitoring through peripheral blood mononuclear cells (PBMC) was also performed, before, during, and after treatment. The co-primary endpoints were the superiority of Afa over Osi at 3-year survival rate and the exploration of immunological biomarkers for treatment outcomes. Enrollment started in May 2020 at 28 sites in Japan with a minimum follow-up of 3 years. **Results:** Overall, 95 eligible pts were analyzed (47 to Afa and 48 to Osi). Objective response rates were 63.8% for Afa vs. 62.5% for Osi. Median progression-free survival (PFS) was 16.7 months (mos) for Afa vs. 14.5 mos for Osi (HR, 1.17; 95% CI, 0.72 to 1.90; P = 0.52). Median OS was 38.8 mos for Afa and not reached for Osi (HR, 1.15; 95% CI, 0.64 to 2.05; P = 0.64), resulting in 54.7% (95% CI, 39.4 to 67.7) for Afa vs. 57.5% (95% CI, 42.2 to 70.1) for Osi at 3-year survival rate. Predominant adverse events with Afa or Osi were diarrhea (92% vs. 31%) and pneumonitis (11% vs. 21%; Grade 5, 0% vs. 6%). Treatment discontinuation rates due to adverse events were 21% with Afa vs. 29% with Osi. The efficacy of Osi varied significantly dependent on the immunological biomarkers, Th7R (stem cell-like CD4 T cells) and Th2. Pts with high Th7R (7.83% or more) had promising PFS (31.0 mos [n = 28] vs. 6.6 mos [n = 20]; HR, 0.38; P = 0.006) and OS (not reached vs. 35.5 mos; HR, 0.56; P = 0.18). In contrast, pts with high Th2 (7.20% or more) had poor PFS (6.6 mos [n = 27] vs. 31.0 mos [n = 21]; HR, 1.78; P = 0.11) and OS (35.5 mos vs. not reached; HR, 2.77; P = 0.03). On the other hand, no immunological biomarkers affected PFS and OS of Afa. **Conclusions:** Afa and Osi both demonstrated favorable clinical activity as first-line treatment in Japanese NSCLC patients with *EGFR* mutations. Although their outcomes are comparable, immunological biomarkers (Th7R/Th2) may refine treatment decisions and warrant further prospective validation. Clinical trial information: jRCTs031190221. Research Sponsor: Boehringer Ingelheim Foundation.

Therapeutic responses in 555 advanced NSCLC patients enrolled in phase I studies at MD Anderson Cancer Center. First Author: Jeong Uk Lim, Department of Investigational Cancer Therapeutics, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Lung cancer remains the deadliest solid tumor, with non-small cell lung cancer (NSCLC) accounting for 80–85% of cases. Patients enrolling in Phase I studies are often heavily pretreated and face limited treatment options. Understanding their demographics and therapeutic responses is crucial to improving patient outcomes. This study aimed to analyze therapeutic responses in NSCLC patients enrolled in Phase I studies. **Methods:** Data on NSCLC patients treated at the Investigational Cancer Therapeutics (ICT) department, a dedicated Phase I unit at The University of Texas MD Anderson Cancer Center (MDACC), were reviewed from January 2016 to December 2024, using MDACC CHIMERA platform. Collected data included age, gender, histologic type, Eastern Cooperative Oncology Group (ECOG) performance status, prior lines of treatment, treatment regimen, trial details and best response to treatment. **Results:** A total of 555 NSCLC patients were identified, of whom 267 (48.1%) were female. The median age was 64 years. The number of prior chemotherapy lines included: one line (50.3%), two lines (16%), and three lines or more (11.0%). The most frequent histologic type was adenocarcinoma (80.0%), followed by squamous cell carcinoma (15.7%) and NSCLC not otherwise specified (3.1%). The median number of treatment cycles was three, and the median duration of treatment was 2.0 months. The best response was evaluable in 449 cases (80.9%). The overall objective response rate (ORR) was 21.2%, and the disease control rate (DCR) was 71.3%. Clinical trial enrollment were categorized into seven groups: Targeted Monotherapy (TM), 227 cases (40.9%); Targeted Combination (TC), 49 cases (8.8%); Immunotherapy Monotherapy (IM), 81 cases (14.6%); Immunotherapy Combination, 57 cases (IC) (10.3%); Targeted + Immunotherapy (TI), 70 cases (12.6%); Antibody-Drug Conjugates (ADC) Monotherapy, 64 cases (11.5%); and Others (O), 7 cases (1.3%). When the ORR was compared among these groups, the TM group demonstrated the highest ORR at 32.6%, followed by the O group at 28.6% and the TC group at 28.2%. **Conclusions:** Phase I studies, especially those involving regimens containing targeted therapy, may serve as a promising treatment option for pretreated patients with advanced NSCLC. Research Sponsor: None.

Artificial intelligence-powered real-time model for predicting survival in advanced *EGFR*-mutant NSCLC. First Author: Hyun Ae Jung, Division of Hematology-Oncology, Department of Medicine, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, South Korea

Background: Novel targeted therapies have led to improved survival in *EGFR*-mutant NSCLC. However, survival outcomes and cancer progression vary. Accurate and practical prediction of progression, survival, and T790M status in advanced *EGFR*-mutant NSCLC is crucial for optimizing patient outcomes and personalizing treatment strategies. This study developed and validated an AI model for predicting survival, and the T790M mutation, integrating clinical, pathological, laboratory, and radiologic data. **Methods:** The model was developed and internally validated using data from Samsung Medical Center (SMC) collected baseline data (at the time of starting EGFR-TKI) and longitudinal laboratory data (during the EGFR-TKI treatment and follow-up) of patients with *EGFR* (deletion 19 or L858R) mutant NSCLC who received EGFR-TKI between 2008 and 2023. The primary outcome was the prediction of progression-free survival (PFS) event within 3, 6, and 12 months from each monitoring point during EGFR-TKI treatment. Secondary outcomes included predicting overall survival (OS) within 3, 6, and 12 months from each monitoring points and the detection of the T790M mutation. **Results:** A total of 3,095 patients participated in the study, with a median follow-up period of 41.5 months. At the time of data lock, 2,713 (87.7%) patients had experienced disease progression, 311 (10.0%) patients continued on first-line EGFR TKI treatment, and 71 (2.3%) patients were lost to follow-up. Among the patients who progressed on first-line EGFR-TKI, 1,083 (39.9%) patients acquired the T790M mutation, and 815 patients received third-generation EGFR-TKI as second-line treatment. Of the 1,630 patients without T790M or with an unknown T790M status, 174 received third-generation EGFR-TKI (117 for leptomeningeal seeding and 57 in a clinical trial), 865 were treated with cytotoxic chemotherapy or other therapies, and 591 were lost to follow-up. A total of 2,985 patients were included in the AI model. Median PFS in total population was 24.0 months (95% CI, 22.5-25.0). and medial overall OS was 50.7 months (95% CI, 48.7-52.9). The training set consisted of 1,910 patients, the validation set had 478 patients, and the test set included 597 patients. The AUC for predicting PFS events at 3, 6, and 12 months from the monitoring point was 0.780, 0.755, and 0.698, respectively. The AUC for predicting OS events at 3, 6, and 12 months from the monitoring point was 0.924, 0.886, and 0.812, respectively. The AUC for predicting T790M detection from the monitoring point at 3, 6, and 12 months was 0.768, 0.737, and 0.666, respectively. **Conclusions:** This study demonstrates a real-time AI-powered model to predict survival outcomes and T790M mutation status in advanced EGFR-mutant NSCLC during EGFR-TKI treatment. The model's ability to accurately forecast PFS, OS, and T790M acquisition offers valuable insights for personalized treatment strategies. Research Sponsor: None.

Efficacy and omics-based insights of TROP2 ADC in non–small cell lung cancer with or without actionable genomic alterations (AGAs). First Author: Anlin Li, Department of Medical Oncology, Sun Yat-Sen University Cancer Center, Guangzhou, China

Background: TROP2 antibody–drug conjugate (ADC) has emerged as a promising strategy for advanced non-small cell lung cancer (NSCLC). A trend of enhanced efficacy has been observed in patients with actionable genomic alterations (AGAs), but the validity of AGA status for patient selection remains controversial. Current evidence suggests that endocytosis is a key factor in TROP2 ADC activity. However, systematic analyses of clinicopathological and genetic associations with endocytosis are lacking. This study combined a meta-analysis and omics analyses to identify potential NSCLC populations that respond or are resistant to TROP2 ADC. **Methods:** For the meta-analysis, we searched for trials of TROP2 ADC in advanced or metastatic NSCLC. Overall survival (OS), progression-free survival (PFS), and objective response rate (ORR) were pooled in the overall population and AGA subgroups. For the omics analysis, given that STK11/KEAP1 mutations are generally mutually exclusive with AGAs and define special subsets, we assessed TROP2 expression and endocytosis activity in three NSCLC categories: AGA-positive (AGA+), AGA−negative/STK11 or KEAP1-mutated (AGA−/SK+), and AGA-negative/STK11 and KEAP1-wild-type (AGA−/SK−). Each NSCLC AGA and key tumor suppressor driver mutation was also evaluated independently. **Results:** A total of 1,387 NSCLC patients from two randomized clinical trials (TROPION-Lung01 and EVOKE-01) and two single-arm trials (TROPION-Lung05 and KL264-01) were meta-analyzed. TROP2 ADC did not significantly improve OS (HR = 0.89, P = 0.12), PFS (HR = 0.90, P = 0.25), or ORR (OR = 1.68, P = 0.39) compared to docetaxel. The pooled ORR for the TROP2 ADC arm was 30% [18%-42%], with higher rates in AGA+ (43% [35−50%]) and EGFR-mutant subsets (45% [37−54%]). However, there was no significant difference in the advantage of TROP2 ADC over docetaxel between patients with and without AGAs ($P_{interaction}$=0.11, 0.51, and 0.79 for OS, PFS, and ORR, respectively). AGA+ tumors exhibited significantly higher TROP2 expression (FDR=0.01) and endocytosis activity (FDR=0.001) than AGA−/SK+ tumors, but no differences were observed between AGA+ and AGA−/SK− tumors. Within AGA− populations, SK− tumors had evidently higher TROP2 expression (FDR=0.0001) and endocytosis activity (FDR=0.01) than SK+ tumors. Among common NSCLC mutations, STK11 mutations showed the lowest levels of both TROP2 expression and endocytosis activity. **Conclusions:** AGA+ NSCLC tends to be more responsive to TROP2 ADC, but AGA status is not a reliable predictive biomarker for patient selection, likely due to heterogeneity within AGA− population. AGA−/SK+ defines a subgroup with the low TROP2 expression and endocytosis activity that may confer primary resistance to TROP2 ADC. We'll present in vitro experiments and clinical data regarding the primary resistance to TROP2 ADC in SK+ NSCLC at ASCO. Research Sponsor: None.

8638 Poster Session

Real-world data on the efficacy and safety of iruplinalkib (WX-0593) in ALK-positive advanced lung adenocarcinoma patients previously treated with lorlatinib. First Author: Fen Wang, Department of Oncology, Peking University Shenzhen Hospital, Shenzhen, China

Background: Iruplinalkib (WX-0593) is a novel anaplastic lymphoma kinase (ALK) tyrosine kinase inhibitor (TKI). Here we report the results from a retrospective observational study on efficacy and safety of iruplinalkib in ALK-positive lung adenocarcinoma (LUAD) patients who had previous treatment with lorlatinib. **Methods:** Patients with ALK-positive advanced LUAD who either experienced disease progression on or were intolerant to lorlatinib were evaluated for clinical outcomes including objective response rate (ORR), disease control rate (DCR), progression-free survival (PFS), overall survival (OS), and safety profiles. **Results:** A total of 11 patients were enrolled in this study, of which five (45%) were male, eight (73%) experienced treatment failure with lorlatinib, and seven (64%) received prior two or more second-generation TKIs. The median age was 49-years old. All patients received 180 mg of iruplinalkib orally daily. The median treatment line with iruplinalkib was six. Brain metastasis and prior treatment were summarized in the table. As of the data cut-off date on December 31, 2024, the median follow-up was 8.1 months. The ORR was 27%, and the DCR was 91%. The 12-month PFS rate was 53.0%, while the median PFS and OS were not reached. Eight (73%) and one (9%) patient experienced any grade and grade $\geq$ 3 treatment-related adverse event (TRAE), respectively. **Conclusions:** Iruplinalkib exhibited promising efficacy and acceptable toxicity in patients with ALK-positive advanced LUAD patients who were previously treated with lorlatinib. Research Sponsor: None.

Parameters	Results (n=11)
Baseline brain metastasis	9 (82%)
Prior ALK TKIs	
Crizotinib + second-generation + lorlatinib	10 (91%)
Second-generation + lorlatinib	1 (9%)
Detailed second-generation ALK TKI	
Aletinib	8 (73%)
Ceritinib	6 (55%)
Brigatinib	3 (27%)
Ensartinib	3 (27%)
Prior chemotherapy	5 (45%)
Prior anti-angiogenesis	8 (73%)
Prior immune checkpoint inhibitor	2 (18%)
Best objective response	
Partial response	3 (27%)
Stable disease	7 (64%)
Progressive disease	1 (9%)
Objective response	3 (27%)
Disease control	10 (91%)
PFS event	3 (27%)
12m PFS rate	53.0%
Median PFS, months	NR
Any grade TRAE	8 (73%)
Grade ≥ 3 TRAE	1 (9%)
TRAE leading to dose interruption/reduction/discontinuation	1 (9%) /0/0

Amivantamab plus chemotherapy vs chemotherapy in *EGFR*-mutant advanced NSCLC after disease progression on osimertinib: Outcomes by osimertinib resistance mechanisms in MARIPOSA-2. First Author: Raffaele Califano, Department of Medical Oncology, The Christie NHS Foundation Trust and Division of Cancer Sciences; The University of Manchester, Manchester, United Kingdom

Background: Amivantamab (ami), an EGFR-MET bispecific antibody with immune cell–directing activity, combined with chemotherapy (chemo) is approved for patients with *EGFR*-mutant advanced NSCLC after disease progression on an EGFR TKI. In the phase 3 MARIPOSA-2 study (NCT04988295), ami-chemo significantly improved progression-free survival (PFS) vs chemo after disease progression on osimertinib (osi; HR, 0.48; $P<0.001$). Nearly all patients develop resistance after osi, most commonly *MET* amplifications (*MET*amp) and *EGFR* resistance mutations (Chmielecki *Nat Commun* 2023; Besse *Ann Oncol* 2024; Yang *JTO* 2024). We evaluated outcomes by baseline osi resistance mechanisms in MARIPOSA-2. **Methods:** MARIPOSA-2 enrolled participants (pts) with *EGFR*-mutant (Ex19del or L858R) advanced NSCLC whose disease progressed on osi; ~1/3 received osi as 2L therapy. This analysis included pts randomized to ami-chemo (n=131) or chemo (n=263). Pathogenic alterations were identified by next-generation sequencing (NGS) of blood circulating tumor DNA (ctDNA) with Guardant360 CDx or PredicineCARE assay. **Results:** Baseline ctDNA for NGS analysis of pathogenic alterations was available for 341 pts (87%; ami-chemo, n=120; chemo, n=221). Characteristic of post-osi resistance, the most commonly detected baseline alterations for ami-chemo vs chemo were *MET*amp (10% vs 14%) and secondary *EGFR* (C797X, L718X, G724X, L792X, G796X) resistance mutations (13% vs 18%). Ami-chemo improved median PFS (mPFS) vs chemo among pts with *MET*amp (HR, 0.51; P=0.078) and secondary *EGFR* mutations (HR, 0.55; P=0.125; Table). Furthermore, ami-chemo significantly prolonged mPFS vs chemo for pts with *EGFR*/*MET* independent (HR, 0.54; P=0.025) and unknown (HR, 0.31; $P<0.001$) resistance mechanisms. **Conclusions:** Ami-chemo improved mPFS vs chemo across baseline resistance subgroups, including *EGFR*/*MET* dependent, independent, and unknown resistance. Ami-chemo is an important treatment option, regardless of baseline osi resistance mechanism, for pts with *EGFR*-mutant advanced NSCLC after progression on an EGFR TKI. Clinical trial information: NCT04988295. Research Sponsor: Janssen Research & Development, LLC, a Johnson & Johnson company.

Vabametkib in MET exon 14 skipping non-small-cell lung cancer: Efficacy and safety from the open-label, phase 2, cohort-1 trial. First Author: Xiuning Le, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Vabametkib (ABN401) is a tyrosine kinase inhibitor (TKI) targeting MET. It has previously demonstrated preliminary efficacy in patients(pts) with MET genomic aberrations including MET exon 14 skipping mutation (METex14) in lung cancer. Here, we present the efficacy and safety data from cohort 1 (TKI-naïve, METex14 non-small cell lung cancer [NSCLC]) **Methods:** Phase 2 Cohort 1 trial (NCT05541822) is an open-label, global, multicenter study designed to evaluate the safety and efficacy of vabametkib in pts with NSCLC harboring METex14. METex14 status is confirmed via NGS testing and the status is further validated centrally using digital droplet PCR (ddPCR). Pts receive oral vabametkib at a dose of 800 mg once daily (QD) until disease progression or the occurrence of unacceptable toxicity. The primary endpoint is the objective response rate (ORR). Additional outcomes being evaluated include pharmacokinetics (PK), duration of response (DoR), disease control rate (DCR), progression-free survival (PFS), and overall survival (OS). **Results:** This study was conducted across 24 centers in three countries (US, South Korea, and Taiwan). A total of 40 pts with METex14 NSCLC were enrolled and treated, including 24 males (60%) and 16 females (40%), between January 17, 2023, and June 14, 2024. Pts were aged 43-86 years, with 35 Asians and 5 Caucasians. Twenty-one pts were treatment-naive, while 19 had received prior treatment. As of December 24, 2024, the objective response rate (ORR) in the evaluable population (n=37) was 43.2% (95% CI: 27.10–60.51), with 16 out of 37 patients achieving a response. The median PFS was 15.9 months (95% CI:10.9, NA) for treatment-naive pts and 6.2 months (95% CI:5.9, NA) for previously treated pts. The median follow-up for the efficacy population was 7.7 months. Vabametkib's safety was assessed in all 40 treated pts, the most common treatment-related adverse events were nausea (n=28; 70%), diarrhea (n=14; 35%), and vomiting (n=8; 20%) and peripheral oedema (n=5; 12.5%). Grade 3 or higher adverse events occurred in 5 (12.5%) pts, no grade 3 edema were reported in the study population (0%). No grade 5 events in this cohort. **Conclusions:** Vabametkib demonstrates good antitumor activity in pts with METex14 NSCLC, and better toxicity profile with excellent tolerability, compared to FDA-approved MET inhibitors, supporting vabametkib continued clinical development for METex14 NSCLC pts. Clinical trial information: NCT05541822. Research Sponsor: None.

Dermatologic prophylaxis and impact on patient-reported outcomes in first-line *EGFR*-mutant advanced NSCLC treated with amivantamab plus lazertinib: Results from the phase 2 COCOON trial. First Author: Jill Libles Feldman, EGFR Resisters – Patient Advocacy Group, Deerfield, IL

Background: The phase 2 COCOONtrial (NCT06120140) is evaluating the impact of enhanced dermatologic management (DM) in combination with amivantamab (ami) + lazertinib (laz) on reduction of skin and nail adverse events (AEs). At the interim analysis, enhanced DM (COCOON DM) significantly reduced the incidence of grade ≥2 dermatologic AEs by Wk 12 vs standard of care dermatologic management (SoC DM). We assessed patient-reported outcomes (PROs) from COCOON to determine if reducing dermatologic AEs impacts the quality of life (QoL) of patients with *EGFR*-mutant advanced NSCLC. **Methods:** Participants (pts) with previously untreated *EGFR*-mutant (Ex19del/L858R) advanced NSCLC were randomized 1:1 to receive COCOON DM or SoC DM per site practice. Pts received the approved doses of IV ami + oral laz. COCOON DM included oral doxycycline/minocycline (100 mg BID Wks 1–12), clindamycin 1% lotion on scalp (QD Wks 13–52), chlorhexidine 4% to wash hands and feet QD, and non-comedogenic ceramide-based moisturizer to body and face QD. The COCOON DM arm received a digital health tool with training on dermatologic AEs and reminders to increase adherence to the DM regimen. Dermatologic symptoms and impact on pts' health-related QoL were measured with PRO instruments every 2 weeks. The Skindex-16 questionnaire assesses the impact of skin conditions on QoL using 3 subscales (functioning, emotional, symptoms) and an average score (0 – no effect to 100 – effect experienced all the time). Patient's Global Impression of Severity (PGI-S) is a self-reported 4-point rating scale (no symptoms, mild, moderate, severe) assessing severity of nail infection, skin condition, and rash over time. All *P* values reported are nominal. **Results:** As of 13 Nov 2024, 138 pts received COCOON DM (n=70) or SoC DM (n=68) and had ≥12 wks of follow-up (median, 4.2 mo). This analysis focuses on PROs through 12 wks of follow-up (three 28-day ami+laz treatment cycles). Substantial and consistent separation favoring COCOON DM was observed in all post-baseline Skindex subscales indicating lower severity of dermatologic AEs and reduced impact of those AEs on QoL. More specifically, at Cycle 3 Day 15 (~10 wks), a lower average Skindex total score was observed with COCOON DM vs SoC DM (*P*=0.02). More pts in the COCOON DM arm vs SoC DM reported mild or no PGI-S rash, skin condition, or nail infection across the first 3 cycles. At Cycle 3 Day 15, there was a meaningful 3-fold difference for COCOON DM vs SoC DM in pts reporting no symptoms for PGI-S rash (21% vs 7%; *P*=0.04) and skin condition (23% vs 7%; *P*=0.02). There was also a numeric improvement in pts reporting no symptoms for nail infections (27% vs 16%; *P*=0.13). **Conclusions:** Among pts with *EGFR*-mutant advanced NSCLC, COCOON DM reduced the severity of dermatologic AEs and reduced the impact of those AEs on QoL compared to SoC DM. Clinical trial information: NCT06120140. Research Sponsor: Janssen Research & Development, LLC, a Johnson & Johnson company.

Use of targeted therapy, healthcare costs, and survival with large panel testing, narrow testing, or no molecular testing in patients with metastatic non-small cell lung cancer (mNSCLC). First Author: Julie Anna Wiedower, Guardant Health Inc., Redwood City, CA

Background: Treatment guidelines recommend broad molecular profiling for patients with mNSCLC. With the availability of molecular tests with different genes, panel sizes, and specimen types, the testing landscape has become complex. This study aimed to evaluate use of biomarker-targeted therapy, healthcare costs, and overall survival with large panel, narrow, or no molecular testing for mNSCLC. **Methods:** This retrospective analysis used de-identified administrative claims from the Optum Labs Data Warehouse from 01/01/2016 to 03/31/2023. Commercial and Medicare Advantage enrollees with claims evidence of newly diagnosed mNSCLC between 08/01/2020 and 12/31/2022 were identified (index date = first diagnosis code for metastatic disease). Using procedure codes and laboratories on claims around the index date, patients were grouped by use of molecular testing as: 1) large panel (≥51 genes) testing; 2) narrow (individual gene or ≤50 gene panel) testing, or 3) no observed molecular testing. Outcomes evaluated in the variable follow-up period were targeted therapy use, healthcare costs (2022 adjusted) per patient per month (PPPM) in the first 180 days of follow-up, and overall survival. **Results:** Of 8,783 patients, 3,634 (41%) had large panel testing, 2,660 (30%) had narrow testing, and 2,057 (23%) had no observed testing; the remaining 5% of patients had molecular testing of unknown size. Use of targeted therapy was higher with large panel testing than narrow testing (12% vs. 8%, $p<0.001$) or no observed testing (3%, $p<0.001$). For commercial patients, mean ± SD total healthcare costs PPPM were higher for patients with large panel vs. narrow testing ($43,629 ± 33,097 vs. $38,642 ± 33,948, p=0.02) and were driven by higher pharmacy costs, but total healthcare costs PPPM were similar for patients with large panel vs. patients with no observed testing ($37,545 ± 50,329, p=0.11). For Medicare Advantage patients, mean total healthcare costs PPPM were similar ($p>0.10$) for patients with large panel ($18,321 ± 18,073), narrow ($18,462 ± 25,555), or no observed testing ($17,130 ± 31,955). Patients with large panel testing had higher median overall survival than patients with narrow testing (10.6 vs. 8.5 months, $p<0.001$) or no observed testing (10.6 vs. 5.9 months, $p<0.001$). **Conclusions:** Patients with large panel testing received targeted treatment at higher rates and had better overall survival than patients with narrow testing or patients with no observed testing. Total healthcare costs were similar with large panel testing vs. no testing and similar or higher (but driven by higher pharmacy costs) with large panel vs. narrow testing. Research is ongoing to assess outcomes among patient subgroups with treatment after adjusting for baseline differences between cohorts. Research Sponsor: None.

Comparable efficacy and safety of taletrectinib for advanced ROS1+ non–small cell lung cancer across pivotal studies and between races and world regions. First Author: Maurice Perol, Department of Medical Oncology, Léon Bérard Cancer Center, Lyon, France

Background: Taletrectinib is a highly potent, next-generation, central nervous system–active, selective ROS1 tyrosine kinase inhibitor (TKI) that was evaluated in 2 pivotal ROS1+ non–small cell lung cancer (NSCLC) phase 2 trials: the regional TRUST-I (NCT04395677) and global TRUST-II (NCT04919811) studies. While earlier trials suggest its safety and efficacy data are consistent across racial and geographic factors, further analysis is required to confirm the consistency of outcomes and applicability of results across regions. Here, we compare the efficacy and safety of taletrectinib within and between the pivotal regional TRUST-I and global TRUST-II studies through predefined subgroup analyses. **Methods:** The pivotal cohorts of TRUST-I (N=173) and TRUST-II (N=159) had similar study designs, which included the same primary endpoint (confirmed objective response rate [cORR] by independent review committee per RECIST v1.1) and secondary endpoints, as well as similar inclusion/exclusion criteria and safety evaluation methods. Key efficacy and safety profiles were compared in 3 ways: (a) between TRUST-I and TRUST-II, (b) across Western (North America and Europe) and Asian regions, and racial subgroups, in the pooled study population of TRUST-I and TRUST-II, and (c) between Western and Asian regions and other subgroups in the global TRUST-II study. Relative risk (RR) and associated 95% confidence intervals (CIs) via the Wald method were used to compare data (data cutoff June 2024). **Results:** When comparing TRUST-I and TRUST-II, cORRs were consistent for TKI-naive (91% vs 85%; RR: 0.94 [95% CI: 0.83, 1.07]) and TKI-pretreated pts (52% vs 62%; RR: 1.20 [95% CI: 0.87, 1.66]). Rates of grade ≥3 treatment-emergent adverse events (TEAEs) were consistent across both studies (51% vs 51%, RR: 1.0 [95% CI: 0.81, 1.24]). TEAEs leading to dose interruptions (41% vs 40%) and discontinuations (6% vs 8%) were similar. In subgroup analyses of the pooled patient population by race, Asian and non-Asian patients had similar cORRs in both TKI-naive (89% vs 84%; RR: 0.94 [95% CI: 0.77, 1.15]) and TKI-pretreated (52% vs 68%; RR: 1.30 [95% CI: 0.93, 1.82]) groups. Comparison of different efficacy and safety profiles among subgroups in the pooled data set also showed consistency among races and regions. Within the multiregional TRUST-II study, cORRs were high in TKI-naive patients regardless of region (Western: 81%; Asia: 88%), prior chemotherapy (yes: 90%; no: 84%), and race (White: 83%; Asian: 86%; other: 86%). Similarly, major safety profiles were comparable between Asian and Western patients and between races within TRUST-II. **Conclusions:** Taletrectinib showed comparable efficacy and safety that were not impacted by geographic and racial factors. Therefore, the clinical benefit of taletrectinib is broadly applicable to ROS1+ NSCLC patients globally. Clinical trial information: NCT04395677, NCT04919811. Research Sponsor: Nuvation Bio Inc.

Efficacy and safety of pralsetinib in patients with advanced *RET*-fusion-positive NSCLC: Final data from the phase 1/2 ARROW study. First Author: Gilberto Lopes, Sylvester Comprehensive Cancer Center, University of Miami Miller School of Medicine, Miami, FL

Background: *RET* fusions are targetable oncogenic drivers in 1-2% of non-small cell lung cancers (NSCLC). ARROW (NCT03037385) study results (final data lock May 20, 2024) supported the US FDA approval of pralsetinib, a highly potent, oral, selective RET inhibitor for metastatic *RET*-altered NSCLC. Here, we present final study results. **Methods:** ARROW was a phase 1/2 open-label study conducted at 84 sites in 13 countries. Phase 2 included patients with *RET*-fusion-positive NSCLC who received 400 mg pralsetinib once daily (QD). Initially, treatment-naïve patients were not candidates for platinum-based therapy and presented with several unfavorable prognostic factors; this requirement was removed by protocol amendment in July 2019. Primary objectives were overall response rate (ORR, per RECIST v1.1) and safety. Progression-free survival (PFS) and overall survival (OS) are reported in the full efficacy population; the measurable disease population (MDP) was the primary analysis population for ORR and duration of response (DOR). **Results:** 281 patients with *RET*-fusion-positive NSCLC received pralsetinib 400 mg QD, with a median duration of treatment of 14.95 months (mos). Median age was 60 years; 46% were male. In the MDP (n=259), ORR was 70.3% (95% confidence intervals [CI]: 64.3, 75.8) and median DOR was 19.1 mos (95% CI: 14.5, 27.9; Table). In the efficacy population (N=281), median OS was 44.3 mos (95% CI: 30.9, 53.1) with median follow up of 47.6 mos (95% CI: 44.8, 49.2), and median PFS was 13.1 mos (95% CI: 11.4, 16.8). ORR (Table) and median PFS were markedly higher in the US (25.9 mos, n=64) vs. Asia (12.6 mos, n=122) or Europe (12.9 mos, n=95). In the safety population, 95% of patients experienced treatment-related adverse events (TRAEs); 66% experienced ≥grade 3. Common TRAEs included increased AST (n=128 [46%]), anemia (n=121 [43%]), increased ALT (n=98 [35%]), and hypertension (n=77 [27%]). 3 patients died due to TRAEs (pneumonia, n=2; interstitial lung disease and rhabdomyolysis, n=1 each). No new safety signals were identified with this update. **Conclusions:** Pralsetinib produced clinically meaningful and durable responses in patients with *RET*-fusion-positive NSCLC (regardless of prior therapies) with a manageable safety profile, confirming with this longer follow up previously published results. Clinical trial information: NCT03037385. Research Sponsor: Rigel Pharmaceuticals, Inc.; Blueprint Medicines; Genentech/Roche.

Final results of a phase II study of cabozantinib in patients with *MET*-altered lung cancers. First Author: Guilherme Harada, Memorial Sloan Kettering Cancer Center, New York, NY

Background: *MET* alterations define a subgroup of non-small cell lung cancers (NSCLC) sensitive to MET tyrosine kinase inhibitors (TKIs). Currently, only type I MET TKIs are approved for treating these patients. We evaluated the activity of cabozantinib, a type II multikinase inhibitor, in MET-altered lung cancers. **Methods:** This is a single-arm, phase 2 trial in which patients with metastatic MET-altered lung cancers received cabozantinib (60 mg daily) until disease progression or intolerable toxicity. A Simon two-stage minimax design was used, with a null hypothesis (H0) of a 10% response rate and an alternative hypothesis (H1) of 30%. With a type I error of 10% and a power of 90%, 16 patients were enrolled in the first stage, with at least two responses required to advance to the second stage, enrolling an additional nine patients. The primary endpoint was objective response rate (ORR) and would be considered met if five or more patients provided an objective response among the 25 evaluable patients treated. Secondary endpoints included progression-free survival (PFS), overall survival (OS), and safety. **Results:** Twenty-eight patients were treated. The median age was 68 (range 38–85) years. Most patients (82%; 23/28) had MET exon 14 alterations; 7% (2/28) had MET amplification only, and 12% (3/28) had concurrent MET exon 14 alteration and amplification. The median number of prior systemic therapies was two (range 1–6), and 86% had previously received a MET TKI. Among the 25 evaluable patients, the ORR was 20% (95% CI, 8.9–39.1). Four out of five patients who achieved a partial response had received prior MET TKI: two with crizotinib, one with tepotinib, and one with capmatinib. The median PFS and OS were 4.5 (95% CI, 3.3-5.7) months and 7.2 (95% CI, 2.9-11.5) months, respectively. Treatment-related adverse events were primarily grade 1 or 2, with the most common being fatigue (39%), diarrhea (39%), palmar-plantar erythrodysesthesia (36%), and anorexia (36%). Grade 3 or higher events included hypophosphatemia (14%), hypertension (11%), and elevated lipase (11%). No treatment-related deaths occurred. **Conclusions:** This trial met its primary endpoint. Cabozantinib demonstrated activity in MET-altered NSCLC, and prospective clinical proof-of-concept that type II MET TKI switching can rescue type I MET TKI progression was established. Clinical trial information: NCT01639508. Research Sponsor: Exelixis.

8646 Poster Session

Rechallenge with first-generation RET inhibitors in *RET*-rearranged NSCLC pre-treated with selpercatinib or pralsetinib: Results from the RET MAP registry. First Author: Arianna Marinello, Cancer Medicine Department, Gustave Roussy, Villejuif, France

Background: *RET* fusions occur in 1-2% of patients with advanced non-small cell lung cancer (aNSCLC). First-generation RET inhibitors (RETi, selpercatinib and pralsetinib), have improved outcomes across treatment lines. Options at progression remain limited, especially in the absence of novel generation RETi. In real-world settings, rechallenge with the same class RETi is sometimes attempted, though efficacy and safety data are lacking. **Methods:** This multicenter retrospective analysis of the RET MAP registry included patients with *RET*-rearranged aNSCLC initially treated with selpercatinib or pralsetinib, followed by rechallenge with the same or a different first-generation RETi, as a single agent or in combination therapy. Clinical features, reasons for initial RETi discontinuation, treatment outcomes, and toxicity were assessed for both treatment courses. **Results:** Among 354 patients treated with first-generation RETi, same class RETi were re-administered in later lines in 33 (9.3 %) patients. At first RETi administration vs rechallenge, median prior lines were 2 (IQR 2–3) vs 4 (IQR 3–5), ECOG PS 0–1 was observed in 26 (78%) vs 25 (76%) patients, and brain metastases in 9 (27%) vs 13 (39%). Reasons for discontinuation of the first RETi were disease progression in 25 (76%) patients and toxicity in 8 (24%). RETi re-administration involved a change of first-generation RETi in 14 (42%) patients, monotherapy in 22 (67%), combination therapy in 11 (33%) (8 with other targeted agents for by-pass resistance, 3 with chemotherapy). It was given immediately after a prior RETi in 13 (39%) patients. At subsequent RETi treatment after progression on a prior RETi, ORR and median PFS were 18% and 2.17 months (95% CI 1.63–NR), respectively, with single-agent RETi (N=17), and 20% and 4 months (95% CI 3.55–NR), respectively, with RETi combined with other targeted agents (N=8). Patients who previously discontinued RETi due to toxicity (N=8) received a different RETi, with ORR and median PFS of 57% and 9.89 months (95% CI 5.33–NR), respectively. In this subgroup, 3 (37.5%) experienced serious side effects at re-administration of a different first-generation RETi. **Conclusions:** Rechallenge a different RETi of the same class is effective after initial discontinuation due to toxicity, though recurrent toxicity may occur in one-third of patients. In contrast, RETi rechallenge after progression demonstrates limited efficacy, primarily in selected cases treated with combination therapies. Research Sponsor: None.

TPS8647 Poster Session

TROPION-Lung14: A phase 3 study of osimertinib ± datopotamab deruxtecan (Dato-DXd) as first-line (1L) treatment for patients with *EGFR*-mutated locally advanced or metastatic (LA/M) non-small cell lung cancer (NSCLC). First Author: Shun Lu, Shanghai Chest Hospital, School of Medicine, Shan, Shanghai, China

Background: Despite the benefit observed with osimertinib, most patients with LA/M *EGFR*-mutated NSCLC develop resistance and treatment options on or after disease progression are limited. Phase 3 clinical trial data, using agents with broad antitumor activity, have demonstrated the potential to extend the clinical benefit of 1L osimertinib and delay the onset of resistance. Dato-DXd, an antibody-drug conjugate composed of a humanized anti-TROP2 monoclonal antibody conjugated to a potent topoisomerase I inhibitor, has demonstrated efficacy as monotherapy in NSCLC in TROPION-Lung01, including in patients with *EGFR*-mutated advanced NSCLC. TROPION-Lung14 is evaluating the efficacy and safety of osimertinib ± Dato-DXd as 1L therapy in patients with *EGFR*-mutated LA/M NSCLC. **Methods:** TROPION-Lung14 (NCT06350097) is an ongoing phase 3, open-label, multicentre, randomized study. The study is enrolling patients (aged ≥18 years) with histologically or cytologically confirmed stage IIIB/IIIC or IV non-squamous, *EGFR*-mutated (exon 19 deletion or L858R) NSCLC, no prior EGFR tyrosine kinase inhibitor or other systemic therapy for stage IIIB/IIIC or IV disease, at least one measurable lesion per RECIST 1.1, and WHO performance status (PS) of 0 or 1. Prior to the randomized study period, ~20 patients will receive osimertinib + Dato-DXd in a non-randomized single-arm safety run-in . Following safety run-in, ~562 patients will be randomized 1:1 to osimertinib (80 mg orally [PO] QD) or osimertinib (80 mg PO QD) + Dato-DXd (6 mg/kg IV Q3W). Patients will be stratified by *EGFR* mutation type (Ex19Del vs L858R), WHO PS (0 vs 1) and central nervous system (CNS) metastasis status (yes vs no). Treatment will continue until RECIST v1.1-defined progression or unacceptable toxicity. The primary study endpoint is progression-free survival (PFS) assessed by blinded independent central review. Overall survival is a key secondary endpoint; other secondary endpoints include PFS by investigator, objective response rate, duration of response, PFS2, safety, pharmacokinetics and immunogenicity. Enrollment is ongoing. Clinical trial information: NCT06350097. Research Sponsor: AstraZeneca. This trial is sponsored by AstraZeneca. In July 2020, Daiichi-Sankyo entered into a global development and commercialisation collaboration with AstraZeneca for datopotamab deruxtecan (Dato-DXd).

TPS8648 **Poster Session**

SOHO-02: Phase III trial of BAY 2927088 in patients with locally advanced or metastatic NSCLC with *HER2*-activating mutations. First Author: Xiuning Le, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Approximately 2-4% of non-small cell lung cancer (NSCLC) harbor activating human epidermal growth factor receptor 2 (*HER2*) mutations. This represents a major area of unmet medical need as no first-line HER2-targeted therapies are currently approved for patients with locally advanced or metastatic NSCLC with *HER2*-activating mutations. BAY 2927088 is an oral, reversible tyrosine kinase inhibitor that potently targets HER2 and mutant epidermal growth factor receptor. Preliminary evidence from the Phase I/II SOHO-01 trial has demonstrated anti-tumor activity and a manageable safety profile in previously treated patients with NSCLC with *HER2*-activating mutations (PL04.03 presented at IASLC 2024 World Conference on Lung Cancer). Here we introduce the SOHO-02 trial evaluating the efficacy and safety of BAY 2927088 as first-line therapy in patients with locally advanced or metastatic NSCLC with *HER2*-activating mutations. **Methods:** SOHO-02 is an ongoing Phase III, open-label, randomized, multicenter trial of BAY 2927088 in patients with locally advanced or metastatic NSCLC with *HER2*-activating mutations (NCT06452277). Eligibility criteria include patients aged ≥18 years with: documented histologically or cytologically confirmed, locally advanced or metastatic non-squamous NSCLC; documented activating mutation in the tyrosine kinase domain of HER2; measurable disease per RECIST v1.1; no previous systemic therapy for locally advanced or metastatic disease; and eligibility to receive treatment with the selected platinum-based doublet-chemotherapy and pembrolizumab. Overall, 278 eligible patients will be randomized to BAY 2927088 p.o. 20 mg twice daily or standard of care (SoC; pembrolizumab in combination with cisplatin/pemetrexed or carboplatin/pemetrexed) in 21-day cycles. The primary endpoint is BAY 2927088 efficacy vs. SoC on progression-free survival per RECIST v1.1 as assessed by blinded independent central review (BICR). Key secondary endpoints include BAY 2927088 efficacy vs. SoC on overall survival, overall response rate, disease control rate, and duration of response per RECIST v1.1 by BICR, and BAY 2927088 safety and tolerability vs. SoC. Impact of BAY 2927088 on patient health-related quality of life and symptom severity will be evaluated using EORTC QLQ-C30 and NSCLC-SAQ. Enrollment is ongoing. Clinical trial information: NCT06452277. Research Sponsor: Bayer AG.

TPS8649 **Poster Session**

Onkoras-101: A phase 1a/1b open-label study evaluating the safety, tolerability, pharmacokinetics, and efficacy of BBO-8520 in subjects with advanced KRAS^{G12C} mutant non-small-cell lung cancer. First Author: Benjamin J. Solomon, Peter MacCallum Cancer Centre, Melbourne, VIC, Australia

Background: BBO-8520 is a first-in-class, potent, selective, directly binding, orally bioavailable, covalent inhibitor of KRAS^{G12C}. It is effective against both the active GTP-bound (ON) state and the inactive GDP-bound (OFF) state of KRAS^{G12C}. BBO-8520 is being developed to treat patients with advanced cancer harboring the KRAS^{G12C} mutation. The oncogenic KRAS^{G12C} mutation results in an increased abundance of KRAS^{G12C} in the active GTP-bound (ON) state. While recent approvals of KRAS^{G12C}-targeted therapies provide a new treatment option for patients with KRAS^{G12C}-driven cancers, these agents exclusively target the GDP-bound (OFF) state of the protein, enabling the emergence of heterogeneous adaptive resistance. Thus, there is an urgent need for agents that can provide durable treatment benefit. **Methods:** This first-in-human, multicenter, open-label, Phase 1a/1b study evaluates the safety, tolerability, pharmacokinetics and preliminary antitumor activity of BBO-8520 as monotherapy and in combination with pembrolizumab in subjects with advanced non-small-cell lung cancer (NSCLC) with a KRAS^{G12C} mutation. BBO-8520 is administered orally once daily, in a 21-day treatment cycle. Patients enrolled in the trial must have histologically documented locally advanced or metastatic NSCLC with a KRAS^{G12C} mutation. Patients with treated or stable brain metastases are allowed to participate in the study. During Phase 1a dose escalation, BBO-8520 will be evaluated at escalating doses as monotherapy and in combination with pembrolizumab. The primary objective of Phase 1a is to evaluate the safety and tolerability of BBO-8520 monotherapy or in combination with pembrolizumab and determine the optimal dose(s) for Phase 1b dose expansion. Patients with KRAS^{G12C} -mutant NSCLC who have received prior treatment with KRAS^{G12C} (OFF) inhibitors are allowed to participate in Phase 1a. During Phase 1b dose expansion, BBO-8520 will be evaluated as monotherapy in expansion cohorts of: (1) patients with advanced NSCLC and prior treatment with KRAS^{G12C} (OFF) inhibitors; and (2) patients with advanced NSCLC and no prior treatment with KRAS^{G12C} inhibitors. BBO-8520 will also be evaluated in combination with pembrolizumab in an expansion cohort of patients with advanced NSCLC and no prior treatment with immune checkpoint or KRAS^{G12C} inhibitors. The primary objective of Phase 1b is to verify safety and tolerability of BBO-8520 monotherapy and in combination with pembrolizumab and evaluate antitumor activity (objective response rate evaluation). Clinical trial information: NCT06343402. Research Sponsor: BridgeBio Oncology Therapeutics.

TPS8650 **Poster Session**

Phase 1/2 clinical trial of JIN-A02, a 4th generation EGFR-TKI in EGFR-mutated advanced/metastatic non-small cell lung cancer. First Author: Sun Min Lim, Yonsei Cancer Center, Yonsei University College of Medicine, Seoul, South Korea

Background: Epidermal growth factor receptor (*EGFR*) mutations are the predominant drivers of NSCLC. While EGFR tyrosine kinase inhibitors (TKIs) are the primary treatment for *EGFR*-mutant NSCLC patients, resistance inevitably develops, leading to disease progression. JIN-A02, a novel 4th generation EGFR-TKI, intended for oral administration, selectively and reversibly binds to *EGFR* mutations, including the C797S and/or T790M mutation that causes resistance to 3rd generation of EGFR-TKIs. Preclinical studies with *EGFR* C797S and/or T790M mutated cell lines and C797S+ xenograft mice model showed that JIN-A02 inhibits cell and tumor growth in a dose dependent manner and exhibits high selectivity over wild-type *EGFR*. Moreover, JIN-A02 has been shown to penetrate the blood-brain barrier and exhibit anti-tumor activity in an intracranial tumor model. This phase 1/2 study is designed to evaluate the safety and anti-tumor activity of JIN-A02 in *EGFR*-mutant NSCLC patients. **Methods:** JIN-A02 is under evaluation in Phase 1/2, multicenter, an open-label trial (NCT05394831) for subjects with advanced NSCLC harboring C797S and/or T790M mutation as a monotherapy. The primary objective is to assess safety, tolerability, pharmacokinetics, and anti-tumor effect for determining the recommended phase 2 dose (RP2D) of JIN-A02. Inclusion criteria are that the subject (≥ 18 years) must have advanced or metastatic NSCLC showing progressive disease post-treatment with approved standard EGFR-TKIs and/or platinum-based anticancer chemotherapy, with ECOG status 0 or 1. The study consists of 3 parts: dose escalation (Part A), dose exploration (Part B), and dose expansion (Part C). In Part A, JIN-A02 is administered orally once daily from 12.5 mg, and at least 3 subjects are recruited per cohort conducted over 28 days cycles to evaluate the maximum tolerated dose. Dose escalation between cohorts is made at up to twice the prior dose level. Dose-limiting toxicities (DLTs) are assessed over 21 days. Part B aims to further evaluate JIN-A02 safety to determine the RP2D using two preliminary effective dose levels from Part A. In Part C, subjects are divided into 5 cohorts based on the EGFR mutation status (both or single positive for C797S and T790M), and the anti-tumor activity of JIN-A02 is evaluated according to RECIST v1.1 at the RP2D. Clinical trial information: NCT05394831. Research Sponsor: None.

TPS8651 **Poster Session**

Phase 3 trial of the therapeutic cancer vaccine OSE2101 versus docetaxel in patients with metastatic non-small cell lung cancer and secondary resistance to immunotherapy. First Author: Stephen V. Liu, Georgetown University, Washington, DC

Background: OSE2101 (TEDOPI) is a therapeutic cancer vaccine composed of multiple peptides restricted to HLA-A2 phenotype targeting tumor-associated antigens (CEA, HER-2, MAGE-2, MAGE-3, P53) frequently expressed in non-small cell lung cancer (NSCLC). In prior studies, OSE2101 strongly induced T cell immune responses, with higher immune responses associated with longer survival (OS). In the randomized ATALANTE-1 study, OSE2101 significantly improved OS with a better safety profile and quality of life (QoL) compared to third-line chemotherapy (CT) in patients with NSCLC with progressive disease (PD) after at least 12-weeks of second line anti-PD(L)1 monotherapy. The aim of the phase III ARTEMIA study is to confirm the benefit of OSE2101 versus CT in second-line treatment of patients with NSCLC and secondary resistance to immune checkpoint inhibitor (ICI) given in the first line setting. **Methods:** HLA-A2 positive patients with metastatic NSCLC without known EGFR, ALK, ROS1 actionable gene alterations, no brain metastases, ECOG PS 0 or 1, who had PD ≥ 24 weeks after first line CT-ICI including at least 12 weeks of maintenance ICI without cytotoxic therapy, will be randomized 2:1 to receive either OSE2101 or docetaxel. Randomization will be stratified by histology (squamous vs non-squamous), and ECOG PS (0 or 1). Patients will receive subcutaneous OSE2101 every 3 weeks for 6 injections, then every 8 to 12 weeks up to end of year 2. In the control group, patients will receive docetaxel at 75 mg/m2 per standard of care. Primary endpoint is OS defined as time from randomization to death of any cause. Secondary endpoints include QoL Physical, Role, and Global Health Score by EORTC QLQ-C30 questionnaire, and time to ECOG PS deterioration. Other endpoints are safety, tumor assessments by RECIST 1.1 and Net Treatment Benefit. For patients who agree, biomarkers in tumor biopsies and blood are planned. The primary estimand is OS in all randomized and treated patients using treatment policy approach for intercurrent events and the hazard ratio (HR) as population-level summary.Assuming a HR of 0.70 with a power of 80% using a 2-sided log-rank test, 363 patients will be enrolled to reach 269 events. An interim analysis is planned. The ARTEMIA phase 3 study aims to confirm the benefit on survival and quality of life of the therapeutic cancer vaccine OSE2101 compared to docetaxel in second-line treatment of HLA-A2 positive patients with NSCLC and secondary resistance to immune checkpoint inhibitor. Recruitment is ongoing in North America and Europe. Clinical trial information: NCT06472245. Research Sponsor: OSE Immunotherapeutics.

TPS8652 **Poster Session**

KEYMAKER-U01 substudy 01A: Phase 1/2 study of pembrolizumab plus ifinatamab deruxtecan (I-DXd) or patritumab deruxtecan (HER3-DXd) with or without chemotherapy in untreated stage IV non–small-cell lung cancer. First Author: Charu Aggarwal, Division of Hematology-Oncology, Department of Medicine, Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA

Background: A standard-of-care option for metastatic non–small-cell lung cancer (NSCLC) with no targetable genetic alterations includes pembrolizumab plus chemotherapy. However, there remains an unmet need for patients who do not respond to standard treatment. Ifinatamab deruxtecan (I-DXd) and patritumab deruxtecan (HER3-DXd) are investigational antibody-drug conjugates (ADCs) against B7 homologue 3 and human epidermal growth factor receptor 3, respectively, two proteins that are highly expressed in NSCLC tumors. Both I-DXd and HER3-DXd are conjugated with a topoisomerase 1 inhibitor payload, resulting in apoptosis of target cells. Preclinical and preliminary clinical data suggest that combining an immune checkpoint inhibitor with an ADC may provide robust antitumor activity. KEYMAKER-U01 substudy 01A (NCT04165070) is a phase 1/2, two-part, rolling arm, open-label study assessing the efficacy and safety of pembrolizumab plus an investigational agent (part A: vibostolimab, boserolimab, MK-4830, and MK-0482; part B: I-DXd and HER3-DXd), with or without chemotherapy in untreated stage IV NSCLC. We present the study design for KEYMAKER-U01 substudy 01A part B. **Methods:** Eligible participants for KEYMAKER-U01 substudy 01A part B are aged ≥18 years with previously untreated histologically or cytologically confirmed stage IV (per American Joint Committee on Cancer v8) squamous or nonsquamous NSCLC and measurable disease per RECIST v1.1 as assessed by investigator and verified by blinded independent central review (BICR). Additional eligibility criteria include ECOG PS of 0 or 1, provision of an archival tumor sample or newly obtained biopsy of a nonirradiated tumor for biomarker analysis, and no *EGFR, ALK, or ROS1* mutations for which first-line targeted therapy is indicated. In part B, 10–30 participants will be allocated to treatment arms 5–7. In Arms 5 and 6, participants will receive I-DXd plus pembrolizumab 200 mg Q3W (Arm 5) or I-DXd plus pembrolizumab with 4 cycles of carboplatin area under the curve 5 or 6 mg/ml/min (Arm 6); I-DXd dose will be at 8mg/kg. In Arm 7, participants will receive HER3-DXd 3.2, 4.8, or 5.6 mg/kg plus pembrolizumab and carboplatin. Participants can receive I-DXd and HER3-DXd until disease progression or unacceptable toxicity and pembrolizumab up to 35 cycles. The primary endpoint is incidence of dose-limiting toxicities until the start of cycle 2, and AEs and treatment discontinuations due to AEs until 40 days after last treatment (90 days for serious AEs); secondary endpoints include ORR and DOR, both per RECIST v1.1 by BICR, and pharmacokinetic parameters, including maximum concentration (C_{max}) and maximum trough concentration (C_{trough}) of I-DXd and HER3-DXd. Enrollment will be ongoing globally. Clinical trial information: NCT04165070. Research Sponsor: Daiichi Sankyo Company, Limited and Merck Sharp & Dohme LLC, a subsidiary of Merck & Co., Inc., Rahway, NJ, USA.

TPS8653 **Poster Session**

ARTEMIDE-Lung03: A phase 3, randomized, double-blind, multicenter, global study of rilvegostomig or pembrolizumab in combination with platinum-based chemotherapy as first-line treatment for patients with metastatic non-squamous non-small-cell lung cancer whose tumors express PD-L1. First Author: Clarissa Mathias, Oncoclínicas&Co. and Hospital Santa Izabel, Salvador, Bahia, Brazil

Background: In the United States, non-squamous histology accounts for approximately 70% of all non-small-cell lung cancers (NSCLCs), and stage IV disease with no targetable alterations is associated with poor prognosis, with a median overall survival of around 2 years. Immunotherapy targeting programmed cell death (ligand)-1 (PD-1/PD-L1) with or without platinum-based chemotherapy (PBC) is a standard of care first-line (1L) chemotherapy for patients with advanced non-squamous NSCLC. Despite the efficacy of this approach, not all patients respond to PD-1/PD-L1 immunotherapy and more effective therapeutic strategies are needed. Inhibition of the co-inhibitory T cell immunoglobulin and immunoreceptor tyrosine-based inhibitory motif domain (TIGIT) pathway in combination with PD-1/PD-L1 blockade to increase immunotherapy efficacy is being investigated in NSCLC, as well as other cancer types. Preliminary results (Hiltermann TJN, et al. *J Thorac Oncol [WCLC]* 2024; abstract OA11.03) show that rilvegostomig, a monovalent, bispecific, humanized IgG1 monoclonal antibody targeting both PD-1 and TIGIT receptors, achieved encouraging antitumor response rates and durable responses with a manageable safety profile in NSCLC. The phase 3, randomized, double-blind, multicenter ARTEMIDE-Lung03 study (NCT06627647) will assess the efficacy and safety of rilvegostomig versus pembrolizumab, in combination with platinum-based doublet chemotherapy, as 1L treatment for participants (pts) with non-squamous metastatic NSCLC (mNSCLC). **Methods:** Approximately 878 pts will be randomized 1:1 to either Arm A: rilvegostomig + PBC (pemetrexed + cisplatin or carboplatin) intravenous (IV) every three weeks (Q3W) for 4 cycles followed by rilvegostomig + pemetrexed maintenance treatment IV Q3W, or Arm B: pembrolizumab + chemotherapy IV Q3W for 4 cycles followed by pembrolizumab + pemetrexed maintenance IV Q3W. Eligibility criteria include histologically or cytologically confirmed non-squamous mNSCLC not amenable to curative treatment, tumors expressing PD-L1 (TC ≥1%), an Eastern Cooperative Oncology Group performance status of 0 or 1, no sensitizing *EGFR* mutations, *ALK* or *ROS1* rearrangements, or mutations in other oncogenes with approved 1L therapies available. Dual primary endpoints are progression-free survival (Response Evaluation Criteria in Solid Tumors v1.1 by blinded independent central review) and overall survival. Safety/tolerability and biomarkers will also be assessed. The study will be conducted across approximately 350 sites in 25−30 countries. Clinical trial information: NCT06627647. Research Sponsor: AstraZeneca.

TPS8655 **Poster Session**

Phase 1b/2 study evaluating telisotuzumab adizutecan (ABBV-400; Temab-A) in combination with budigalimab in patients (pts) with advanced non-squamous (NSQ) non-small cell lung cancer (NSCLC) with no prior treatment for advanced disease and no actionable genomic alterations. First Author: David Ross Camidge, University of Colorado Cancer Center, Aurora, CO

Background: c-Met (MET) protein expression is frequently increased in NSCLC and is associated with poor prognosis. 24% of pts with NSQ *EGFR* wildtype (WT) NSCLC exhibit increased c-Met protein expression, ie, ≥25% 3+ via IHC. Addition of programmed cell death (ligand) 1 (PD-[L]1) inhibitors to chemotherapy (CT) has improved treatment of NSCLC regardless of PD-(L)1 expression. However, more-effective therapies are needed, particularly for pts with no known actionable genomic alterations. Temab-A is an antibody-drug conjugate comprising the c-Met protein–targeting antibody telisotuzumab and the potent topoisomerase 1 inhibitor adizutecan payload attached via a stable cleavable linker. In an ongoing phase 1 study (NCT05029882), Temab-A monotherapy demonstrated manageable safety and promising efficacy in pts with advanced/metastatic (a/m) NSQ *EGFR* WT NSCLC in second line and later, with an objective response rate (ORR) of 48% (23/48) across all c-Met expression levels and clinical benefit rate of 85% (41/48) (De Miguel et al. *Ann Oncol*. 2024;35:S805-S806). Herein, we describe a study evaluating Temab-A in combination with the PD-1 inhibitor budigalimab. **Methods:** This multicenter, global,open-label, phase 1b/2, randomized (in part 2) study (NCT06772623) will enroll ~172 pts (≥18 yr) with a/m NSQ NSCLC. Eligible pts have ECOG 0 or 1, measurable disease per RECIST v1.1, and documented *EGFR* WT and PD-L1 status. Primary objectives are to evaluate safety and tolerability, assess efficacy as measured by ORR by blinded independent central review, and select the recommended phase 3 dose of Temab-A combined with budigalimab. Secondary objectives include assessment of efficacy outcomes (PFS, DOR, OS, and disease control rate), characterization of PK and immunogenicity, and evaluation of PD and potential predictive biomarkers. The study has 2 parts: a safety dose-escalation part 1 and a dose-optimization part 2. Part 1 enrolls ~12 pts who have received ≤1 prior systemic therapy for a/m NSCLC, including platinum-based CT, an immune checkpoint inhibitor, or targeted therapy. Pts receive escalating doses of Temab-A IV Q3W guided by BOIN design in combination with a fixed dose of budigalimab IV Q3W. Dose-limiting toxicities are evaluated during cycle 1. Part 2 enrolls ~160 pts who have not received prior systemic therapy for a/m NSCLC. Pts are randomized 1:1:1:1 to Temab-A at 1 of 2 doses determined in part 1 + budigalimab, to budigalimab + CT, or to SOC (pembrolizumab + CT) arms. Randomization is stratified by PD-L1 expression and history of brain metastases. Treatment continues until disease progression, intolerable toxicity, or other discontinuation criteria are met. The first dosing of the first patient enrolled is planned in March 2025. Clinical trial information: NCT06772623. Research Sponsor: AbbVie Inc.; n/a

TPS8656 **Poster Session**

Krascendo 2: A phase III study of divarasib and pembrolizumab vs pembrolizumab and chemotherapy in patients with previously untreated, advanced or metastatic, *KRAS* G12C-mutated non-small cell lung cancer (NSCLC). First Author: Ferdinandos Skoulidis, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: *KRAS G12C* mutations are found in ~12% of NSCLC cases. The recommended first-line treatment for patients (pts) with advanced or metastatic non-squamous *KRAS G12C*-mutated (*G12C*+) NSCLC is immunotherapy (most commonly pembrolizumab [pembro]) ± chemotherapy (chemo); however, there is an unmet need in this pt population for more efficacious therapies with tolerable and manageable safety profiles. Divarasib is a potent KRAS G12C inhibitor that has shown efficacy and safety as a monotherapy in pts with previously treated, advanced or metastatic *KRAS G12C*+ NSCLC. Previous reports suggest that combinations of KRAS G12C inhibitors and pembro have promising anti-tumor activities with manageable safety profiles. We hypothesize that divarasib plus pembro may be an effective and well tolerated first-line chemo-free treatment option in pts with advanced or metastatic *KRAS G12C*+ NSCLC. **Methods:** Krascendo 2 (CO45042; NCT06793215) is a randomized, open-label, multicenter, global, phase III study, evaluating the efficacy and safety of first-line treatment with divarasib and pembro vs pembro and chemo (pemetrexed + carboplatin/cisplatin), in pts with advanced or metastatic *KRAS G12C*+ NSCLC. Eligible pts (≥18 years old) must have an Eastern Cooperative Oncology Group performance status (ECOG PS) of 0–1, measurable disease per RECIST version 1.1, and histologically/cytologically confirmed advanced or metastatic, non-squamous NSCLC that is not eligible for curative surgery and/or definitive chemoradiotherapy and is previously untreated. Pts must also have known programmed death-ligand 1 (PD-L1) expression status and *KRAS G12C*+ status. Asymptomatic individuals with stable and treated central nervous system (CNS) metastases are eligible. Pts will be randomized 1:1 to receive either oral divarasib daily and intravenous (IV) pembro (in 21-day cycles), or IV pembro, pemetrexed and four cycles of platinum-based chemo (in 21-day cycles), until disease progression, or unacceptable toxicity. Pts will be stratified by PD-L1 expression status (tumor proportion score or tumor cell <1% vs 1–49% vs ≥50%), ECOG PS (0 vs 1), and history of CNS metastases (yes vs no). Pts who show clinical benefit per investigator judgment may continue study treatment after disease progression at the investigator's discretion. Primary endpoints are progression-free survival by blinded independent central review (BICR) and overall survival. Secondary endpoints include confirmed objective response rate and duration of response by BICR, changes in patient-reported symptoms and functioning from baseline to Cycle 5 assessed via questionnaires, and safety. Tumor assessments will occur at screening, every 6 weeks (±7 days) for the first 72 weeks after randomization, and then every 9 weeks (±7 days). Clinical trial information: NCT06793215. Research Sponsor: This study is sponsored by F. Hoffmann-La Roche Ltd. Third-party medical writing assistance, under the direction of the authors, was provided by Tahmina S. Alam, MA, of Ashfield MedComms, an Inizio company, and was funded by F. Hoffmann-La Roche Ltd.

TPS8657 **Poster Session**

FIRST-NEC (GFPC 01-2022): A multicenter phase II study evaluating the efficacy and safety of the combination of durvalumab with etoposide and platinum as first line treatment in patients with advanced large-cell neuroendocrine lung carcinomas (LCNECs). First Author: Dominique Arpin, Hôpitaux Nord Ouest VIllefranche sur Saone, Gleizé, France

Background: LCNECs of the lung are rare lung tumors (2%) with difficult histopathological diagnosis (70-80% confirmation rate after centralized review). Platinum–based regimen is currently the recommended first-line treatment for advanced LCNECs. However it results in poor median progression-free survival (PFS) and overall survival (OS) of 5 months and 7.7 months, respectively. Retrospective studies have suggested efficacy of immune checkpoint inhibitors against LCNECs with significantly prolonged OS. In addition, the CASPIAN trial demonstrated the superiority of durvalumab plus platinum-etoposide over chemotherapy alone in patients with extensive-stage neuroendocrine small cell lung cancer, with an acceptable toxicity profile. **Methods:** This ongoing single-arm phase II trial is designed to evaluate the efficacy and safety of durvalumab in combination with platinum-etoposide as first line treatment in pts with locally diagnosed advanced LCNEC. Key selection criteria are age $\geq$ 18 years, ECOG PS 0-1, measurable disease (RECIST 1.1) and locally advanced (Stage III) ineligible for loco-regional therapy or metastatic (Stage IV). Central confirmation of the histopathological diagnosis will be performed for all pts at the start of treatment. All pts will receive 4 cycles of induction with durvalumab 1500mg, platinum (either carboplatin AUC5 or cisplatin 80mg/m² at D1) and etoposide 100mg/m² (D1-D3), repeated every 3 weeks. Durvalumab 1500mg will be continued alone every 4 weeks for a maximum of 24 additional cycles or until disease progression or unacceptable toxicity. The primary endpoint is to determine, in pts with confirmed diagnosis, 12-month progression-free rate (12M-PFR) as per central radiological review. Secondary endpoints include PFS, OS and safety. Radiological criteria will be described using the RECIST 1.1 both as per investigator's assessment and as per central radiological review. Biomarkers will be studied as predictive and prognostic factors of efficacy. Efficacy will be assessed sequentially every ten pts using a Bayesian approach. Analogous to a frequentist approach from an A'Hern-Fleming single-stage design, 51 evaluable pts will be enrolled. A futility stopping rule will stop the trial if there is a high probability ($>$80%) that the 12M-PFR is less than or equal to P0 (15%). Finally, a trial emulation will be performed as an exploratory analysis to assess PFS and OS compared to an external control arm by using real-world data from the ESME database. Since the start of recruitment (June 2024), 13 patients with a confirmed diagnosis have been included. Clinical trial information: NCT06393816. Research Sponsor: French ministry of health / French National Cancer Institute (INCa); PHRC-K23-033; Astrazeneca; Not applicable (drug supply).

TPS8658 **Poster Session**

TeliMET NSCLC-04: A phase 2, open-label, randomized, global study of 2 telisotuzumab vedotin regimens in patients with previously treated c-Met protein–overexpressing, locally advanced/metastatic non-squamous *EGFR* wildtype non-small cell lung cancer. First Author: Alona Zer, Rambam Health Care Campus, Haifa, Israel

Background: c-Met protein (also known as MET protein) overexpression is observed in ~25% of patients with non-squamous *EGFR* wildtype (WT) non-small cell lung cancer (NSCLC) and is associated with poor prognosis. Telisotuzumab vedotin (Teliso-V) is a c-Met–directed antibody-drug conjugate consisting of the monoclonal antibody telisotuzumab and the cytotoxic payload monomethyl auristatin E. The primary analysis of the phase 2 LUMINOSTY trial (NCT03539536) demonstrated that Teliso-V at 1.9 mg/kg once every 2 weeks (Q2W) was associated with durable responses in patients with previously treated c-Met protein–overexpressing (OE) advanced/metastatic (a/m) non-squamous *EGFR* WT NSCLC, and adverse events (AEs) were generally manageable. The overall response rate was 28.6% among all patients with c-Met protein overexpression and 34.6% among those with c-Met high protein overexpression (Camidge et al. *JCO* 2024; 42:3000-11). **Methods:** This global, multicenter, open-label, randomized phase 2 study (NCT06568939) evaluates the safety and efficacy of Teliso-V monotherapy at 1.6 mg/kg Q2W and 1.9 mg/kg Q2W in patients with previously treated c-Met protein OE, a/m non-squamous *EGFR* WT NSCLC. Eligible patients are $\geq$18 years old with c-Met protein OE ($\geq$25% tumor cells at 3+ intensity by immunohistochemistry assay [investigational use only assay for MET (SP44) (Roche)]), a/m non-squamous *EGFR* WT NSCLC. Patients must have measurable disease according to RECIST v1.1, ECOG PS 0–1, and documented disease progression on $\geq$1 prior lines of therapy ($\leq$1 line of prior chemotherapy) in the a/m setting. Approximately 100 patients will be randomized 1:1 to receive Teliso-V monotherapy at either 1.6 mg/kg or 1.9 mg/kg Q2W until disease progression or other protocol-specified discontinuation criteria are met. The primary safety endpoints are treatment-emergent AEs (TEAEs; any grade and grade $\geq$2), interstitial lung disease (any grade and grade $\geq$2), peripheral neuropathy (any grade and grade $\geq$2), ocular surface disorders (any grade and grade $\geq$2), TEAEs leading to discontinuation, and grade 5 TEAEs. The primary efficacy endpoint is objective response based on RECIST v1.1 by blinded independent central review (BICR). Secondary endpoints are pharmacokinetics, patient-reported outcomes, duration of response by BICR, progression-free survival by BICR, and overall survival. Clinical trial information: NCT06568939. Research Sponsor: AbbVie, Inc.; n/a.

TPS8659 **Poster Session**

Phase 2, multicenter study of frontline maintenance therapy with lifileucel plus pembrolizumab in advanced non-small cell lung cancer. First Author: Ben C. Creelan, Moffitt Cancer Center and Research Institute, Tampa, FL

Background: Tumor-infiltrating lymphocyte (TIL) therapy with lifileucel plus pembrolizumab (pembro) demonstrated durable and deepening responses with an objective response rate (ORR) of 64.3% in patients (pts) with anti–PD-1/PD-L1–naive, *EGFR* wild-type, locally advanced or metastatic non-small cell lung cancer (mNSCLC) in cohort 3A of the IOV-COM-202 phase 2 open-label study (NCT03645928), with 4 of 5 ongoing responses lasting $>$20 months from start of therapy and no new safety signals. We added two new cohorts within this basket study, 3D and 3E, which evaluate if adding lifileucel to pembro $\pm$ pemetrexed in the maintenance phase of standard-of-care (SOC) therapy (from tumors procured in treatment-naive pts [3D] versus those who had already started receiving SOC chemotherapy [3E]) is feasible and provides added benefit with an acceptable safety profile. Incorporating TIL with current SOC has the potential to address a major unmet need by improving outcomes that are not durable or adequate for many pts with NSCLC. **Methods:** Pts have tumor resection before cycle 1 (3D) or between cycles 1 and 4 (3E) of frontline platinum-doublet chemotherapy plus pembro. After completion of SOC chemotherapy, a dose of pembrolizumab will be given followed by nonmyeloablative lymphodepletion (NMA-LD) (day $-$5 to day $-$3: cyclophosphamide 20 mg/kg/day; day $-$5 to day $-$2: fludarabine 25 mg/m2/day). Lifileucel is administered on day 0, followed by IL-2 continuous infusion on days 1–4. Following lifileucel and IL-2, pembro (plus pemetrexed if nonsquamous histology) will be continued for up to 2 years or until disease progression or unacceptable toxicity. Eligible adults have histologically confirmed mNSCLC, no actionable mutations with effective targeted therapy, no prior systemic therapy for metastatic NSCLC, ECOG performance status 0–1, estimated life expectancy $\geq$6 mo, and $\geq$1 resectable lesion $>$1.5 cm in diameter to generate lifileucel. Prior organ allograft or cell transfer therapy, symptomatic brain metastases, current systemic steroid therapy $>$10 mg/day of prednisone or other steroid equivalent, and active illnesses or autoimmune disorders are not permitted. Endpoints include ORR, complete response rate, disease control rate, and PFS by investigator-assessed RECIST v.1.1, OS, percentage of manufactured lifileucel drug products that meets release specification, and incidence of grade $\geq$3 treatment-emergent adverse events. Selected exploratory endpoints include in vivo T-cell persistence, correlative biomarkers, and circulating tumor DNA. Enrollment of approximately 20 pts per cohort will take place in Europe and North America. Clinical trial information: NCT03645928. Research Sponsor: Iovance Biotherapeutics, Inc.

TPS8660 **Poster Session**

NAPISTAR 1-01: An international phase I/II trial of the novel ADC TUB-040 in platinum-resistant ovarian cancer (PROC) and relapsed/refractory adenocarcinoma non-small cell lung cancer (NSCLC). First Author: Toon Van Gorp, University Hospitals Leuven, Leuven Cancer Institute, Leuven, Belgium

Background: NaPi2b, encoded by SLC34A2, is a sodium-dependent phosphate transporter overexpressed in various cancers, particularly high levels in high-grade ovarian cancer (HGSOC) and non-small cell lung cancer (NSCLC) adenocarcinomas. This tumor-selective expression pattern makes NaPi2b a compelling target for therapeutic development. TUB-040 is an innovative antibody-drug conjugate (ADC) combining a NaPi2b-specific Fc-silenced monoclonal antibody with the cytotoxic payload exatecan, a potent topoisomerase-I inhibitor exhibiting a robust bystander effect. This ADC utilizes a cleavable dipeptide linker (P5) to achieve a uniform drug-to-antibody ratio of 8, optimizing its potency against heterogeneous tumors. **Methods:** NAPISTAR 1-01 (NCT06303505) is an open-label, multicenter, Phase I/IIa study investigating TUB-040 in platinum-resistant ovarian cancer (PROC) and advanced NSCLC adenocarcinoma . Phase I employs a stepwise dose escalation strategy using adaptive titration design (ATD), followed by a Bayesian Optimal Interval (BOIN) model. The dose escalation framework includes initial double-dosing steps, transitioning to modified Fibonacci increments with intra-patient escalation permissible at low exposure levels. An independent Dose Escalation Board manages safety oversight. Phase IIa involves randomized dose optimization at multiple dosing levels to identify the optimal therapeutic window. Enrollment of approximately 100 patients across the US, EU and UK is planned, with dose escalation currently underway. Clinical trial information: NCT06303505. Research Sponsor: None.

TPS8661 **Poster Session**

A multicenter, open-label, single-arm phase I/II study to assess the efficacy and safety of WSD0922-FU in patients with EGFR C797Sm+ advanced non-small cell lung cancer (NSCLC) in China (NCT06631989). First Author: Wei Zhong, Wayshine Biopharm Inc., Corona, CA

Background: Although 3rd-generation EGFR TKIs, such as Osimertinib, Almonertinib, Furmonertinib, Befotertinib etc. are highly effective in front-line metastatic *EGFR*-mutated (*EGFR*m) NSCLC, treatment resistance ultimately occurs, including the emergence of the on-target C797S mutation for which there are no approved TKIs. WSD0922-FU is an oral, central nervous system (CNS)-penetrant, wildtype-sparing, ATP non-competitive, reversible EGFR inhibitor targeting EGFR aberrations in NSCLC and High-Grade Astrocytoma. It has shown promising preclinical and clinical data, including antitumor CNS activity that may improve patient outcomes. Additionally, combining WSD0922-FU with standard therapies may provide enhanced disease control across multiple lines of treatment, including against heterogenous tumors, in patients with *EGFR*m+ NSCLC. WSD0922-102 (NCT06631989) is an ongoing phase 1/2, open-label, multicenter trial evaluating the efficacy and safety of WSD0922-FU in patients with EGFR C797Sm+ NSCLC in China. **Methods:** Adult patients with EGFR C797Sm+ NSCLC were initially treated with oral WSD0922-FU, with three doses selected from phase I dose escalation (MC1914, NCT04197934) as a bridging PK study in China. After DLT evaluation, expansion was initiated for each dose followed by extension for the dose selected as the recommended phase 2 dose (RP2D). Key inclusion criteria include patients $\geq$18 years of age with metastatic *EGFR* C797Sm+ NSCLC; Eastern Cooperative Oncology Group performance status 0–1; and failed in the previous 3rd generation EGFR-targeted TKI treatment for bridging PK study, with only one 3rd generation EGFR TKI for expansion and with only one first-line 3rd generation EGFR TKI for extension. All patients must harbor an EGFR C797S resistance mutation (locally assessed for tissue/liquid samples). Key exclusion criteria are tumors harboring EGFR T790M mutations, EGFR exon 20 insertions, or MET aberrations. Dose escalation primary endpoints are maximum tolerated dose, RP2D and safety. The expansion and extension primary endpoints are overall response rate (ORR) by RECIST 1.1. Secondary endpoints include ORR (dose escalation), duration of response, disease control rate, progression-free survival, overall survival, antitumor CNS activity (iORR) by RANO-BM, and safety (dose expansion and extension). The phase 1 dose escalation adopts a 3+3 design. Patients will be enrolled into 3 treatment cohorts: dose escalation (n≈12-15), dose expansion (n≈20), and dose extension (n≈70). Patients may receive treatment until disease progression, unacceptable toxicity, or other discontinuation criteria are met. Enrollment in this study for dose expansion cohorts is ongoing and 15 sites are open across China. Clinical trial information: NCT06631989. Research Sponsor: None.

TPS8662 **Poster Session**

Phase 2 cohort-2 trial in progress: Vabametkib plus lazertinib for patients with EGFR-mutant NSCLC who developed resistance to 1st-line, 3rd-gen-EGFR TKIs via C-Met dysregulation. First Author: Dae Ho Lee, Asan Medical Center, Seoul, South Korea

Background: Third-generation Epidermal Growth Factor Receptor Tyrosine Kinase Inhibitors (EGFR TKIs) have emerged as a promising first-line treatment for Non-Small-Cell Lung Cancer (NSCLC) patients with EGFR T790M mutations, as well as EGFR exon 19 deletions and exon 21 L858R mutations. Recently, lazertinib, combined with amivantamab, has been approved as a potential first-line therapy for NSCLC. Despite these advancements, there remains a significant unmet medical need for patients who develop resistance to first-line third-generation EGFR TKIs. ABN401 (vabametkib), a selective oral c-MET inhibitor, has shown anti-tumor activity in preclinical studies, both as monotherapy and in combination with other treatments. Currently in a phase 2 clinical trial, this study aims to evaluate the combination of vabametkib and lazertinib in patients who have developed resistance to 3rd generation EGFR TKIs. **Methods:** ABN401-003 phase 2 cohort-2 is a multicenter, open-label trial that evaluates the dose escalation, safety and efficacy of the combination therapy of vabametkib and lazertinib in patients resistant to first-line EGFR TKIs. Enrollment criteria include MET amplification (GCN $>$10 by NGS or FISH) or c-MET overexpression (IHC score $\geq$90). The study consists of three parts: Part 1 (safety run-in), a traditional 3+3 dose-escalation study assesses the safety of vabametkib combined with lazertinib. Up to 18 patients will be evaluated in safety run-in, with dose adjustments based on dose-limiting toxicities (DLTs). Part 2: Randomized Dose Optimization – Two combination dose levels, determined from Part 1, will be tested in 40 patients to identify the optimal dose. Part-2 may be skipped if the maximum tolerated dose (MTD) is established in Part 1. Part 3 [randomized clinical trial – The optimal dose combination will be compared to the standard of care (SOC) in 80 patients. Key secondary endpoints include objective response rate (ORR), disease control rate (DCR), progression free survival (PFS) and duration of response (DOR). Additionally, safety and patient-reported outcome will be evaluated. Clinical trial information: NCT05541822. Research Sponsor: None.

TPS8663 **Poster Session**

A phase 1/2 open-label, multicenter, first-in-human study of the safety, tolerability, pharmacokinetics, and antitumor activity of BH-30643 in adult subjects with locally advanced or metastatic NSCLC harboring EGFR and/or HER2 mutations (SOLARA). First Author: Xiuning Le, Department of Thoracic Head and Neck Medical Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Clinical outcomes for patients with metastatic *EGFR*-mutant NSCLC have steadily improved with successive generations of EGFR tyrosine kinase inhibitors (TKIs). However, there remains significant need for further advancement in progression-free survival (PFS) and overall survival (OS), as these outcomes still fall short when compared to the remarkable benefits observed with newer TKIs in *ALK* and *ROS1* driven NSCLC. BH-30643 is a first-in-class EGFR TKI with a novel macrocyclic structure offering potent, reversible, mutant selective inhibition of classical and atypical *EGFR* activating mutations without vulnerability to common on-target resistance mutations. Cellular activity of BH-30643 was recently described (AACR 2025) demonstrating sub-nanomolar potency for EGFR exon 19del and L858R classical mutations which are maintained in the presence of T790M +/- C797S. High potency was also observed against atypical *EGFR* mutations (e.g., G719X, L861Q, S768I) and exon 20 insertions, as well as mutant *HER2*. Such an OMNI-EGFR inhibitor may have the potential to overcome some of the limitations of earlier agents. **Methods:** SOLARA (NCT06706076, BH-30643-01) is a Phase 1/2, multicenter, open-label, dose escalation, first-in-human study to determine the safety, tolerability, pharmacokinetics, and antitumor activity of BH-30643, in adult subjects with locally advanced or metastatic NSCLC harboring *EGFR* and/or *HER2* mutations. Enrollment based on local molecular testing and/or liquid biopsy is permitted. Asymptomatic brain metastases (treated or untreated) are eligible. BH-30643 is administered orally twice daily until disease progression or intolerable toxicity. The study consists of an initial dose escalation part using a Bayesian optimal interval design to identify Recommended Dose(s) for Evaluation (RDE). Dose-limiting toxicities (DLTs) are evaluated for the first 21 days of treatment. A subsequent expansion part will further evaluate the RDE(s) to identify a Recommended Phase 2 Dose (RP2D), studying cohorts with or without prior systemic therapy across a range of *EGFR*/*HER2* driver mutations. Efficacy will be evaluated by RECIST 1.1 criteria and toxicity by CTCAE V5.0. Plasma is collected for circulating tumor DNA (ctDNA) analysis at baseline and on treatment. Enrollment is underway, with planned enrollment across ~35 sites in multiple continents. Clinical trial information: NCT06706076. Research Sponsor: BlossomHill Therapeutics, Inc.

TPS8664 **Poster Session**

A randomized phase 3 study of ivonescimab plus chemotherapy versus pembrolizumab plus chemotherapy for the first-line treatment of metastatic non–small cell lung cancer: HARMONi-3. First Author: Jianjun Zhang, Department of Thoracic/Head and Neck Medical Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: The additionof antiangiogenic agents to standard first-line treatment with a programmed cell death protein 1 (PD-1) inhibitor and platinum doublet chemotherapy has shown efficacy in patients with metastatic non–small cell lung cancer (NSCLC). Ivonescimab is a novel tetravalent bispecific antibody that targets PD-1 and vascular endothelial growth factor. In a phase 2 trial, ivonescimab plus chemotherapy showed objective response rates (ORRs) of 71.4% and 54.2% and median progression-free survival (PFS) of 11.1 and 13.3 months in patients with metastatic squamous (SQ) and nonsquamous (NSQ) NSCLC, respectively (1). **Methods:** The multiregional, randomized, double-blind, phase 3 HARMONi-3 trial (NCT05899608) will compare the efficacy and tolerability of ivonescimab plus chemotherapy with pembrolizumab plus chemotherapy as first-line treatment in patients with metastatic SQ or NSQ NSCLC who have not previously received systemic treatment for metastatic disease and whose tumors have no known actionable mutations for which approved first-line therapies are available. Patients will be randomly assigned (1:1) to receive ivonescimab 20 mg/kg every 3 weeks (Q3W) or pembrolizumab 200 mg Q3W combined with chemotherapy (paclitaxel or nab-paclitaxel plus carboplatin for SQ or pemetrexed plus carboplatin for NSQ) for up to 4 cycles, followed by maintenance with ivonescimab or pembrolizumab alone for SQ or in combination with pemetrexed for NSQ for up to 24 months. Randomization will be done in blocks by histology (SQ and NSQ) and stratified by sex (female vs male), age ($<$65 vs $\geq$65 y), geographic region (East Asia vs rest of world), presence or absence of liver or brain metastases at baseline, previous PD-1 or programmed death ligand 1 (PD-L1) inhibitor treatment $>$6 months before the development of metastatic disease (yes vs no), and PD-L1 tumor proportion score ($\geq$1% or $<$1%). The dual primary end points are overall survival and PFS (assessed by investigators per RECIST v1.1). The secondary end points are ORR, disease control rate, duration of response, safety, pharmacokinetics, and immunogenicity. Patients are being recruited in Asia, Europe, and North America, with a target enrollment of 1080 patients (45-50% SQ and 50-55% NSQ). 1. Zhang L et al, ELCC 2024, FPN: 68P. Clinical trial information: NCT05899608. Research Sponsor: Summit Therapeutics, Inc.

TPS8665 **Poster Session**

NVL-330, a selective HER2 tyrosine kinase inhibitor, in patients with advanced or metastatic HER2-altered non-small cell lung cancer: The phase 1 HEROEX-1 study. First Author: Xiuning Le, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Oncogenic mutations and gene amplifications in the HER2 receptor tyrosine kinase are detected in approximately 2-4% and 1-5% of non-small cell lung cancers (NSCLC) in the US, respectively. Exon 20 insertion mutations (exon20ins) are the predominant *HER2* mutations in NSCLC, and ~50% of patients with *HER2*-mutant metastatic NSCLC develop brain metastases. The antibody drug conjugate (ADC) trastuzumab deruxtecan (T-DXd) has received FDA accelerated approval for *HER2*-mutant NSCLC, but no tyrosine kinase inhibitors (TKIs) are currently approved for this indication. NVL-330 is a novel, brain-penetrant, HER2-selective investigational TKI, designed to address the medical need of targeting *HER2*-mutant tumors, and treating brain metastases, while minimizing treatment related adverse events due to off-target inhibition of wild-type EGFR. **Methods:** HEROEX-1 (NCT06521554) is a first-in-human, Phase 1a/1b trial. The Phase 1a dose escalation portion employs a Bayesian optimal interval design with a 3+3 run-in, followed by a Phase 1b dose expansion. The study population includes adult patients with advanced or metastatic NSCLC with a *HER2* oncogenic mutation (Phase 1a/1b) or amplification (Phase 1a only) determined by local testing. Eligible patients must have received at least one prior systemic therapy including platinum-based chemotherapy with or without immunotherapy, or are unsuitable candidates for available therapies. Prior HER2-directed antibodies and HER2-directed ADCs are allowed. Prior HER2 TKIs are allowed in Phase 1a only. Patients will receive NVL-330 by oral administration once or twice daily. The primary objectives are to evaluate safety and tolerability, determine the recommended Phase 2 dose, and, if applicable, the maximum tolerated dose of NVL-330. Additional objectives include assessment of preliminary activity and characterization of the pharmacokinetic and pharmacodynamic profiles of NVL-330. Analyses will be performed to evaluate tumor and blood-based biomarkers of response and other relevant biomarkers. The study is open to accrual. Clinical trial information: NCT06521554. Research Sponsor: Nuvalent.

TPS8666 **Poster Session**

Neladalkib (NVL-655), a highly selective anaplastic lymphoma kinase (ALK) inhibitor, compared to alectinib in first-line treatment of patients with ALK-positive advanced non-small cell lung cancer: The phase 3 ALKAZAR study. First Author: Sanjay Popat, The Royal Marsden NHS Foundation Trust, London, United Kingdom

Background: Oncogenic *ALK* gene fusions are detected in ~5% of advanced non-small cell lung cancer (NSCLC) cases. Among these patients, the incidence of brain metastases at diagnosis is ~40%. Prior generations of ALK tyrosine kinase inhibitors (TKIs) present limitations that may influence efficacy and tolerability, such as inadequate control of brain metastases, treatment-emergent drug-resistant *ALK* mutations, or off-target adverse events, particularly neurological events associated with inhibition of the structurally related TRK kinases. Neladalkib is a potent, brain-penetrant, ALK-selective TKI with preclinical activity against diverse *ALK* fusions and resistance mutations (Lin et al., Cancer Discovery 2024). In the Phase 1/2 ALKOVE-1 study, neladalkib showed encouraging preliminary efficacy in patients with heavily pretreated *ALK+* NSCLC, including in those with *ALK* single or compound resistance mutations and brain metastases (Drilon et al., ESMO 2024). It also exhibited a favorable safety profile consistent with its ALK-selective, TRK-sparing design. The Phase 3 ALKAZAR study aims to demonstrate the superiority of neladalkib over a current standard of care, alectinib, in TKI-naïve patients with advanced *ALK+* NSCLC. **Methods:** ALKAZAR (NCT06765109) is a global, Phase 3, randomized, controlled, open-label study in adult patients with locally advanced or metastatic NSCLC harboring an *ALK* rearrangement per local testing of tissue or blood. Prior systemic anticancer treatment for metastatic disease is not allowed. Patients who received prior alectinib in the adjuvant setting are not eligible. Patients are required to have measurable disease by RECIST. Patients with untreated central nervous system (CNS) disease without progressive neurological symptoms or increasing corticosteroid doses are eligible. Patients with non-ALK oncogenic driver alterations are excluded. Approximately 450 patients will be randomized in a 1:1 ratio to receive either oral neladalkib (150 mg once daily) or oral alectinib (600 mg twice daily), stratified by brain metastases, ethnic origin (Asian vs. non-Asian), and Eastern Cooperative Oncology Group (ECOG) performance status (PS) score (0 vs.1 vs. 2). The primary endpoint is progression-free survival by blinded independent central review. Secondary endpoints include intracranial activity, objective response rate, duration of response, overall survival, safety and tolerability, and patient-reported outcomes. Additional analyses will be conducted to investigate candidate biomarkers and molecular mechanisms of response and resistance to neladalkib and alectinib. The study is open to accrual. Clinical trial information: NCT06765109. Research Sponsor: Nuvalent.

TPS8667 **Poster Session**

A phase 2 safety and efficacy study of PRT3789 in combination with pembrolizumab in patients with advanced or metastatic solid tumors and a *SMARCA4* mutation. First Author: Timothy A. Yap, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Genes encoding subunits of the switch/sucrose non-fermentable (SWI/SNF) chromatin remodeling complex are often mutated in cancer (~20% of all human cancers). The SWI/SNF complex contains either SMARCA2 or SMARCA4 enzymatic subunits for ATP-dependent chromatin remodeling. Since SMARCA2 and SMARCA4 function as mutually exclusive catalytic subunits of the SWI/SNF complex, cells exhibiting SMARCA4 loss rely on its paralog, SMARCA2, making SMARCA2 an attractive therapeutic target. In NSCLC, *SMARCA4* mutations are associated with aggressive and invasive disease. PRT3789 has been shown to increase antigen processing and presentation of unique MHC class I peptides, and increase T-cell activity and IFN-γ production in *SMARCA4*-mutated cancer cells. SMARCA2 degradation by PRT3789 promoted the effects of anti-PD1 therapy in SMARCA4-deficient mouse models, and PRT3789 combined with pembrolizumab (pembro), a humanized immunoglobulin G4 monoclonal antibody, promoted cell death of SMARCA4-deficient NSCLC cells. While inhibitors targeting the PD-1/PD-L1 axis have shown remarkable clinical activity across a broad range of tumor types, some patients demonstrate an inadequate response and disease progression consistent with the natural disease course that may be tied to innate resistance mechanisms. Other patients progressed after a period of disease control, which may be associated with acquired resistance mechanisms. PRT3789 + pembro may re-sensitize resistant cancers to subsequent anti–PD(L)-1 therapy. **Methods:** This is an open-label, 2-part, multicenter study to evaluate the safety, tolerability, efficacy, pharmacokinetics (PK), and pharmacodynamics (PD) of PRT3789 + pembro in patients who are resistant to prior anti–PD(L)-1 therapy. Adults with any advanced, recurrent, or metastatic solid tumor and any *SMARCA4* mutation are eligible to enroll into part 1, a safety run-in to establish the initial safety of PRT3789 376 mg intravenous (IV) once weekly + pembro 200 mg IV every 3 weeks. Part 2 will target adults with advanced, recurrent, metastatic NSCLC or upper gastrointestinal cancer with a *SMARCA4* loss-of-function mutation. Other key eligibility criteria include documented prior or acquired resistance to anti–PD(L)-1 therapy, or received prior standard-of-care therapy, but naive to anti–PD(L)-1 therapy due to PD-L1 negative expression. A safety review committee will evaluate dose-limiting toxicities (DLTs) in part 1 and advise on opening part 2 and regularly review accumulated safety data during the study. The primary endpoints are safety, tolerability, and incidence of DLTs in part 1, and overall response rate and duration of response in part 2. Secondary endpoints include progression-free survival, clinical benefit rate, PK, and PD of PRT3789. This study is actively recruiting. Clinical trial information: NCT06682806. Research Sponsor: Prelude Therapeutics Incorporated.

TPS8668 **Poster Session**

TACTI-004: A double-blinded, randomized phase 3 trial in patients with advanced/metastatic non-small cell lung cancer receiving eftilagimod alfa (MHC class II agonist) in combination with pembrolizumab (P) and chemotherapy (C) versus placebo + P + C. First Author: Giuseppe Lo Russo, Thoracic Oncology Unit, Medical Oncology Department, Fondazione IRCCS Istituto Nazionale Tumori, Milan, Italy

Background: Eftilagimod alfa (E), an antigen presenting cell activator, binds to a subset of MHC class II molecules to mediate T cell (CD4/CD8) recruitment/activation.Prior studies in first line (1L) non-small cell lung cancer (NSCLC) (TACTI-002 [NCT03625323]: combining E + pembrolizumab (P); INSIGHT-003 [NCT03252938] combining E with chemotherapy + P [SoC]) showed encouraging efficacy results across all PD-L1 strata & excellent safety profiles. TACTI-004 is a double-blinded, randomized, placebo-controlled phase 3 study testing E + SoC vs. placebo + SoC in 1L NSCLC patients (pts). **Methods:** Approximately 756 pts with 1L NSCLC will be enrolled, irrespective of PD-L1 status, & randomized 1:1 to receive either E + SoC or placebo + SoC. The dual primary endpoint (EP) is overall survival & progression-free survival (RECIST 1.1). Secondary EPs include ORR, disease control rate, duration of response, quality of life, safety & biomarkers. Pts will receive 30 mg E SC q2w for 24 weeks, then q3w and P IV at 200 mg (30 min) q3w; both treatments for up to 2 yrs. Chemotherapy choice will be histology-dependent: non-squamous NSCLC pts will receive IV cisplatin (75 mg/m^2) or carboplatin (AUC 5 or 6) + pemetrexed (500 mg/m^2) q3w for 3 mo, then maintenance pemetrexed q3w. Squamous NSCLC pts will receive carboplatin (AUC 5 or 6) + paclitaxel (175 or 200 mg/m^2) q3w for 3 mo. Imaging will be performed q6w until week 18, q9w until week 54 & q12w thereafter. Testing for PD-L1 (22C3) & genetic alterations will be prospectively assessed. Key inclusion criteria: Adults diagnosed with measurable advanced/metastatic (A/M) NSCLC (squamous or non-squamous), not amenable to curative treatment nor locally available oncogenic driver mutation-based 1L therapy. Treatment-naïve for systemic therapy (previous palliative radiotherapy for A/M disease acceptable). Expected survival $>$3 months & ECOG 0 or 1. Tumour tissue must be available for PD-L1 central testing. Pts may not have tumours with EGFR mutations nor ALK or ROS1 translocations. Stable brain metastasis is acceptable. Clinical trial information: NCT06726265. Research Sponsor: None.

TPS8669 **Poster Session**

A biomarker-directed, multi-center phase II/III study of ctDNA molecular response adaptive immuno-chemotherapy in patients with non-small cell lung cancer (BR.36). First Author: Valsamo Anagnostou, Sidney Kimmel Comprehensive Cancer Center, Johns Hopkins School of Medicine, Baltimore, MD

Background: Minimally invasive analyses of circulating cell-free tumor DNA (ctDNA) have shown clinical value as an early endpoint of immunotherapy response, allowing patients with primary resistance to be rapidly and accurately identified. In the first of two independent stages, the BR.36 trial demonstrated a sensitivity of ctDNA response for radiographic RECIST response of 82% and a specificity of 75%, with a median time to ctDNA response of 2.1 months. **Methods:** BR.36 is a multi-center, open-label, biomarker-directed, phase II/III clinical trial of ctDNA molecular response adaptive immuno-chemotherapy in patients with treatment-naïve metastatic NSCLC. The main objective is to evaluate if adding chemotherapy to pembrolizumab for patients who have persistent ctDNA on liquid biopsy after 6 weeks of pembrolizumab, will result in better PFS and OS compared to patients who remain on pembrolizumab until radiographic clinical progression. Key eligibility criteria include: age ≥18 years, ECOG performance status 0-2, metastatic NSCLC, EGFR and ALK mutation negative and PD-L1 Tumor Proportion Score (TPS) ≥ 50%, at least and not more than 2 cycles of the 200 mg or 2 mg/kg IV Q3W dose/schedule of pembrolizumab as first line systemic immunotherapy at the time of screening and RECIST non-PD or clinically stable PD documented prior to enrolment that can continue on immunotherapy if randomized to that arm. The phase II primary endpoint is PFS and has secondary endpoints of feasibility, overall response rate and safety/tolerability. Sex, RECIST response and ECOG status represent stratification criteria. With 110 randomized patients evaluable for progression (55 patients per arm and 71 PFS events observed in this phase of the clinical trial), we would be able to detect a hazard ratio difference of 0.67 with a 1-sided alpha of 0.2 and power of 0.80 using a phase II screening design. The trial will not stop accrual for the phase II analysis of PFS if feasibility endpoints are achieved. In the phase III portion, a total of 210 randomized patients recruited over 3 years and followed for an additional 24 months are required to detect an OS hazard ratio difference of 0.67 with 1-sided alpha of 0.05 and power of 0.8. The total number of events for the final analysis is expected to be 156, and assuming 10% of patients are lost to follow-up, we are targeting 230 patients to be included overall. The primary endpoint of the phase III portion is overall survival, with secondary endpoints of best overall response, response duration, progression-free survival and safety/tolerability. Exploratory endpoints include longitudinal ctDNA analyses by targeted next-generation sequencing and whole genome sequencing approaches. The BR.36 clinical trial is open to enrollment and to date 2 patients have been registered (ClinicalTrials.gov ID: NCT04093167). Clinical trial information: NCT04093167. Research Sponsor: Cancer Research Institute; The Mark Foundation for Cancer Research; LabCorp.

TPS8670 **Poster Session**

A global phase 2/3, randomized, open-label trial of BNT327/PM8002 in combination with chemotherapy (chemo) in first-line (1L) non-small cell lung cancer (NSCLC). First Author: Solange Peters, Centre Hospitalier Universitaire Vaudois Lausanne (CHUV), Lausanne, Switzerland

Background: The introduction of immune checkpoint inhibition for the treatment of 1L NSCLC has improved survival, however long-term outcomes remain suboptimal, highlighting the need for more efficacious treatments. BNT327 is an investigational bispecific antibody, targeting both PD-L1 and VEGF-A in the tumor and tumor microenvironment (TME). By binding to PD-L1 on tumor cells it is designed to restore effector T-cell function and by binding to VEGF-A within the TME it also reverses the negative impact of VEGF signaling on immune cell infiltration and activation. In addition, via VEGF-A neutralization, it normalizes tumor vasculature. This dual targeting of PD-L1 and VEGF-A aims to deliver better efficacy and safety. Data published on BNT327 has indicated a tolerable safety profile and encouraging anti-tumor activity in patients (pts) with NSCLC (ASCO 2023, ASCO and ESMO 2024). This global Phase 2/3 trial will further assess safety and efficacy of BNT327 plus chemo (Phase 2) and BNT327 plus chemo versus pembrolizumab plus chemo (Phase 3) in pts with advanced NSCLC. **Methods:** This Phase 2/3, multisite, randomized, open-label trial will enroll ~982 pts with stage IIIB/C and stage IV non-squamous cell (NSQ) NSCLC (Substudy A) and squamous (SQ) NSCLC (Substudy B) without actionable EGFR mutations or ALK rearrangements. Each substudy consists of a Phase 2 and a Phase 3 part. During the Phase 2 part, pts will be randomized 1:1 to receive BNT327 at either 1400 mg (Arm 1) or 2000 mg (Arm 2) plus chemo (carboplatin + pemetrexed for Substudy A, carboplatin + paclitaxel for Substudy B) Q3W IV for four cycles, followed by Q3W IV maintenance BNT327 at previously administered doses (with maintenance pemetrexed for Substudy A). In the Phase 3 part, pts will be randomized 1:1 to receive BNT327 at the selected dose (based on the Phase 2 part) plus chemo (carboplatin + pemetrexed for Substudy A, carboplatin + paclitaxel for Substudy B) or pembrolizumab 200 mg plus chemo Q3W IV, followed by Q3W IV maintenance BNT327 or pembrolizumab (both with maintenance pemetrexed for Substudy A). Chemo will be administered at approved doses. Primary endpoints include occurrence of adverse events (AE) and serious AEs, rates of dose interruption, reduction and discontinuation due to treatment-emergent (TE) AEs, objective response rate (ORR) and best percentage change from baseline in tumor size (Phase 2), and both progression free survival (PFS) per blinded independent central review and overall survival (OS) (Phase 3). Secondary endpoints include duration of response, disease control rate (Phase 2), PFS per investigator, ORR, landmark PFS and OS, patient reported outcomes and occurrence of AEs, and rates of dose interruption, reduction and discontinuation due to TEAEs (Phase 3); with efficacy endpoints per RECIST 1.1; safety per CTCAE v5.0. The trial is enrolling. Clinical trial information: NCT06712316. Research Sponsor: BioNTech SE.

9000 Clinical Science Symposium

Implementation of a fellow-led tumor board to enhance learning and support in fellow continuity clinic. First Author: Neha Hippalgaonkar, University of Illinois Chicago, Chicago, IL

Background: Hematology/oncology fellows in our program manage diverse and complex cases in continuity clinic (CC), including uncommon malignancies and challenging clinical scenarios, providing a rich educational opportunity. To further enhance case-based learning and in response to fellows' feedback from an internal program survey, we implemented a Fellow Tumor Board (FTB) to provide clinic-specific additional guidance and structured learning. **Methods:** The FTB was integrated into an existing biweekly didactic virtual didactic to minimize added burden and encourage participation. Investment in learning was fostered by focusing on fellows' own cases. Chief fellows reviewed recent CC consults, selecting cases involving new malignancies, rare conditions, or complex management scenarios, and invited guest faculty experts for targeted feedback. Each 30-minute FTB, moderated by chief fellows, included multiple 5-minute case discussions: fellows presented cases, posed clinical questions, and received expert and peer input. Chief fellows summarized key recommendations and clinical pearls while senior fellows provided insights and mentorship. This collaborative format enabled fellows to learn from their own and peers' cases. An anonymous electronic survey was distributed six months after FTB implementation to assess its impact. Fellows rated their experiences on a Likert scale (1 = strongly disagree to 4 = strongly agree). **Results:** Survey responses (12) showed positive reception. Fellows reported feeling more supported in managing CC patients (3.6 $\pm$ 0.4), empowered to seek guidance (3.6 $\pm$ 0.4), found expert input valuable (3.7 $\pm$ 0.4), that FTB fostered a collaborative environment (3.5 $\pm$ 0.5) and that case-based learning was effective (3.4 $\pm$ 0.4). However, 4/12 fellows disagreed that they learned from their co-fellows' cases. All respondents agreed that the FTB should continue as part of the didactic curriculum. Additional informal feedback highlighted improved confidence, ability to present cases in tumor boards, and mentorship while faculty praised the active learning environment. In-training exam scores to assess knowledge retention and program survey responses to evaluate supervision quality at year-end will be tracked to further evaluate FTB's impact and will be available at time of presentation. **Conclusions:** FTB is a feasible and adaptable innovation that addresses gaps in CC education. By promoting case-based learning, collaboration, and mentorship, it enhances fellows' support, knowledge, confidence and preparedness for oncology practice. To optimize its effectiveness, strategies to encourage fellows to engage and learn from their peers' cases – not just their own – should be explored. Research Sponsor: None.

9001 Clinical Science Symposium

Integration of a podcast curriculum (PC) to improve hematology oncology fellow (HOF) knowledge: A multi-center cluster randomized control trial. First Author: Vivek Patel, Vanderbilt University Medical Center, Nashville, TN

Background: Medical podcasts are widely used as learning resources, yet their integration into fellowship curricula remains unstudied. We present the final analysis of a multicenter cluster randomized trial comparing a supplemental PC with the standard curriculum (SC) to SC alone for HOFs. **Methods:** Twenty-seven U.S. HOF programs were randomized to receive a novel PC with SC (podcast arm) or SC alone (control arm). The PC arm accessed a website with links to podcast episodes (PEs) and show notes covering breast cancer (BC), myeloma (MM), bleeding disorders (BD), and heparin induced thrombocytopenia (HIT). PEs were developed by *The Fellow on Call* and *Two Onc Docs* podcasts. Show notes were developed by *The Fellow on Call*. Pre- and post-intervention qualitative surveys (QS) and knowledge assessments (KA) were administered via REDCap. HOFs rated their comfort managing topics using a 7-point Likert scale. The KA was a 16-question multiple-choice test. ANCOVA analysis was used to compared post-intervention results. This study was powered for dual primary endpoints of mean QS improvement by 0.5 and KA improvement by 10% as previously published. **Results:** Pre-intervention QS and KA were completed by 220 (52%) and 187 (45%) HOFs, respectively. Post-intervention, 53/107 (49%) HOFs in the podcast arm and 46/113 (40%) in the control arm completed assessments. PGY distribution was similar between podcast and control arms: PGY 4 25% and 37%, PGY 5 32% and 30%, and PGY 6+ 43% and 33% (p=0.38). At baseline, 37 (69%) podcast-arm and 24 (52%) control-arm HOFs listened to medical podcasts. Detailed didactic characteristics for each institution and HOF learning preferences were previously presented. Baseline mean comfort levels ($\pm$SD) were comparable in podcast vs. control: BC (4.4$\pm$1.5 vs. 4.5$\pm$1.4), MM (4.5$\pm$1.2 vs. 4.4$\pm$1.4), BD (3.9$\pm$1.2 vs. 3.7$\pm$1.2), and HIT (5.5$\pm$1 vs. 5.5$\pm$1). Post-intervention paired mean comfort level difference ($\pm$SD) significantly improved in the podcast vs. control across topics ($p<0.01$): BC (1.4$\pm$0.4 vs. 0.9$\pm$0.2), MM (1.5$\pm$0.4 vs. 0.9$\pm$0.3), BD (1.6$\pm$0.3 vs. 1$\pm$0.2), and HIT (1.2$\pm$0.6 vs. 0.8$\pm$0.4). Composite mean KA improved from 39.7%$\pm$18.9 to 62%$\pm$19.2 in the podcast arm vs. 43.5%$\pm$19.2 to 50.3%$\pm$19.8 in the control arm. The podcast arm had significantly greater improvement with an adjusted mean difference of 15.5% ($p<0.01$). In the podcast arm, 44 (83%) utilized >50% of show notes and found them helpful, and 47 (89%) planned to continue using these podcasts. Results were not impacted after adjusting for baseline podcast use. **Conclusions:** To our knowledge, this is the largest cluster randomized trial of a pragmatic educational intervention in graduate medical education. The study met its dual primary endpoints, demonstrating that the podcasts significantly improved fellow comfort and knowledge in representative topics. Despite limitations of dropout and respondent bias, findings support integrating these podcasts as a recommended resource in hematology oncology education. Research Sponsor: None.

9002 Clinical Science Symposium

Perception and concerns of the hematology and oncology (HemOnc) workforce about artificial intelligence (AI) in clinical practice (CliPr) and medical education (MedED). First Author: Guilherme Sacchi de Camargo Correia, Mayo Clinic, Jacksonville, FL

Background: The field of AI is rapidly evolving. With recent development of more user-friendly AI software, its integration into healthcare across different medical specialties, including HemOnc has emerged. Data detailing the perception and concerns of the HemOnc workforce about AI's roles is lacking and is needed if AI is to be integrated in HemOnc CliPr and MedEd. **Methods:** Questionnaires about the perception and concerns regarding AI in CliPr and MedEd were created on REDCap and approved by IRB. We surveyed the entire HemOnc workforce at the 3 Mayo Clinic major sites between 11/07/24 and 01/20/25, including physicians, both faculty (FAC) and fellows (FEL), advanced practice providers (APP), and nurses (RN). Participation was voluntary. Simple statistical analyses were employed for the results. **Results:** 344 participants (PTP) responded to the survey, 118 physicians (41 FEL and 77 FAC), 49 APP, and 177 RN. 64% of PTP report having used AI but only 31% used it in HemOnc MedEd, and 28% in HemOnc CliPr, with 67% considering themselves to have little to no knowledge about AI. 94% of PTP believe AI will be integrated in HemOnc MedEd, with such integration being seen as beneficial by 90%. Among physicians, 85% of FEL and 92% of FAC report that fellowship programs should incorporate AI training into curricula. 95% of PTP believe AI will be incorporated into HemOnc CliPr. Meanwhile, 62% of PTP (50.8% of physicians, and 68% of APP and RN) are concerned about risks it may pose to CliPr. Nevertheless, 90% of PTP would embrace AI's use in HemOnc. Table 1 details the perceptions and concerns about AI in HemOnc MedEd and CliPr. The main perceived risks are decreased time spent with patients (pts), and inaccuracies or worse pt care. Meanwhile, 33% believe AI would increase efficiency and quality of care, while 30% believe it would increase time spent with pts. 14% of PTP worry their role could be replaced by AI. **Conclusions:** To the best of our knowledge, this is the largest assessment of HemOnc workforce's perception and concerns about AI. Based on our survey, the HemOnc workforce, in general, endorses AI use, but with some concerns raised. While incorporation in MedEd is perceived with excitement, many envision the use in CliPr involves risks and challenges. Proper systematic education of the workforce about AI, with well-designed CliPr integration methods are needed to mitigate the legitimate existing concerns. Research Sponsor: None.

Perceptions & concerns about AI in HemOnc MedEd & CliPr.

	FEL %	APP %	RN %	FAC %
AI will assist documentation in CliPr	98	82	79	92
AI will be used in pt communication	73	80	78	87
AI will screen pts for clinical trial enrollment	85	86	76	96
AI will increase the efficiency and quality of CliPr	43	37	24	46
AI will increase time spent with pts	39	27	25	38
AI will decrease time spent with pts	29	41	48	23
AI will lead to inaccuracies or worse CliPr	12	20	25	20
AI may replace the HemOnc workforce	11	16	19	5

9003 Rapid Oral Abstract Session

Research productivity of international medical graduate (IMG) hematology and oncology fellows in the United States (US). First Author: Arya Mariam Roy, The Ohio State University, Columbus, OH

Background: IMGs constitute one-third of practicing oncologists in the US. However, there is limited data on their academic contributions. We analyzed the research productivity of IMG hematology-oncology fellows in US fellowship programs. **Methods:** Hematology-oncology fellows enrolled in an ACGME accredited training program as of June 2024, were identified from publicly available institutional fellowship program websites. Baseline characteristics (presumed gender, institution, additional graduate degrees [AD]) and academic profiles were abstracted. Research productivity data, including number of PubMed-listed manuscripts, original articles, review articles, first-author and senior-author manuscripts, google scholar (GS)-listed abstracts/articles, high-impact (impact factor $\geq$ 10) articles, citations, H-index, I-10 index were obtained from PubMed and GS. Fellows were categorized as IMGs or AMGs, based on whether they completed medical school outside or within the US, respectively. Chi-squared and Wilcoxon rank-sum/T-tests were used for categorical and numeric variables, respectively. Linear regression identified factors associated with higher research productivity. **Results:** Out of the total 1,858 fellows included, 42.3% were female, and 11% held ADs (e.g. master's, PhD). Among all fellows, 30.5% were identified as IMGs. AMGs were more likely than IMGs to hold ADs (12% vs. 8.3%, p=0.019) and PhDs (8.9% vs. 3.4%, $p<0.001$). However, IMG fellows exhibited significantly higher research productivity, including more manuscripts (mean, 95% CI: 14.9 [12.6, 17.3] vs. 9.5 [8.6, 10.4]), abstracts (14.9 [9.2, 20.6] vs. 7.3 [3.5, 10.9]), review articles (4.9 [3.9, 6.0] vs. 2.4 [2.2, 2.7]), first-author manuscripts (4.3 [3.6, 5.0] vs. 2.7 [2.5, 2.8]), compared to AMGs (all $p<0.001$), Table 1. IMGs had an estimated 5.7 more manuscripts on average than AMGs after adjusting for gender and ADs ($p<0.001$); this difference varied by gender (8.7 higher in males, $p<0.001$, and 2.0 higher in females, p=0.2). **Conclusions:** IMG hematology-oncology fellows exhibit higher research productivity than their AMG counterparts, despite having fewer additional degrees. Our results highlight the substantial contributions of IMG fellows, underscore their critical role in academic medicine, and emphasize the importance of addressing potential structural barriers to practice at academic medical centers upon graduation. Research Sponsor: EMORY STAT CORE, NIH21.

Research profile of IMG/AMG hematology-oncology fellows.

Research productivity (median, IQR)	IMG (N= 566)	AMG (N= 1292)	p-value
PubMed manuscripts	7.5 (3, 16)	6 (2, 11)	<0.001
GS articles	14 (6, 33)	9 (3, 18)	<0.001
Abstracts	3 (1, 13)	2 (0, 6)	<0.001
Original articles	4 (1, 11)	3 (1, 8)	<0.001
Review articles	2 (0, 5)	1 (0, 3)	<0.001
First-author manuscripts	2 (0, 5)	2 (0, 4)	<0.001

9004 Rapid Oral Abstract Session

International medical graduates (IMGs) in leadership roles within academic oncology in the United States (US). First Author: Shipra Gandhi, Roswell Park Comprehensive Cancer Center, Buffalo, NY

Background: Although IMGs comprise one-third of US oncologists, their leadership presence at academic centers with affiliated oncology fellowship training programs has not been studied. **Methods:** Using Electronic Residency Application Services website for training programs, and publicly available information on corresponding institutional websites, data were collected on leadership (cancer center director, division chair, fellowship program director (PD), subspecialty chiefs) and clinical faculty (August to December 2024). Leadership level data included whether the institution is NCI-designated, its geographic region, presumed gender, additional graduate degree (AD: Master's, PhD), H-index and citations. Leaders and faculty were categorized into American Medical Graduate (AMG) and IMG, who completed medical school within and outside the US, respectively. Logistic regression was used to assess factors associated with leadership. **Results:** Leaders (n=1057) and faculty (n=4338) from 186 oncology fellowship programs (medical, radiation, surgical oncology) were included. Among 146 cancer center directors, 26% were IMGs. IMGs represented 30% of division chairs and 32% of fellowship PDs in medical oncology; however, their representation in surgical and radiation oncology leadership and faculty was more modest (Table). There was no difference in AD (30.8% vs 30.2%), H index (44.3 $\pm$ 39 vs 45.9 $\pm$ 34.5) or citations (13,133 $\pm$ 26,228 vs 14,151 $\pm$ 23,529) between IMG and AMG leaders, respectively. IMG leadership varied regionally (Midwest 30%, Northeast 26%, South 23%, Southwest 31%, West 16%, p=0.03) and was underrepresented in NCI-centers (21.3% vs 33.3%, $p<0.05$) vs other centers. There was no difference in male AMG leaders (48.9% vs 47.1%, p=0.77), however, the proportion of female AMG leaders was higher in NCI- vs other centers (28.8% vs 19.7%, $p<0.01$). Female IMGs had lowest leadership representation (7.3% at NCI-centers, 9.2% at other centers), similar to their limited faculty presence (9.2%). Female IMGs were less likely to be leaders compared to male IMGs (odds ratio [OR] 0.66 [95% CI 0.49-0.89], $p<0.01$) and male AMGs (OR 0.71 [0.55-0.93], $p<0.05$). **Conclusions:** Despite similar academic productivity, IMGs are under-represented in leadership in NCI-cancer centers, and in the West with female IMGs having lowest representation. Our results highlight the need to address these regional, gender and institutional disparities to foster a more inclusive workforce. Research Sponsor: EMORY Stat Core, NIH21.

9005 Rapid Oral Abstract Session

Burnout, professional fulfillment, and associated factors in academic oncology physicians. First Author: Jennifer A. Ligibel, Dana-Farber Cancer Institute, Boston, MA

Background: Occupational burnout has negative consequences on the health of individual physicians (MDs), patients, and health care systems. We assessed the prevalence of burnout and professional fulfillment (PF) in academic hematologists/medical oncologists (HO), general internists (GIM), and other internal medicine subspecialties (IMS) and evaluated factors associated with burnout and PF across specialty groups. **Methods:** Academic medical institutions participating in the Healthcare Professional Well-being Academic Consortium (PWAC) administered surveys including validated measures of burnout and PF, as well as variables influencing these domains. MDs with a subspecialty of HO, GIM, or IMS were included. Descriptive statistics were used to summarize characteristics of the cohort. Logistic regression was used to assess relationships between respondent characteristics (subspecialty, gender, age) and burnout/PF. **Results:** Fifteen academic medical centers administered surveys between 10/2019 and 7/2021.Of 19,532 (50.7% response rate) respondents, 579 were HO, 1912 GIM, and 1922 IMS. No significant difference in the proportion of respondents who met criteria for burnout was observed across groups (41.7% HO, 38.0% IMS, 40.4% GIM, p=0.11). HO MDs were more likely to have high professional fulfillment (44.5% HO, 38.8% IMS, 35.8% GIM, p-value <0.001). Determinants of burnout and PF varied across groups (Table) with HO MDs reporting less favorable scores for impact of work on personal relationships ($p<0.001$), self-valuation ($p<0.001$), and electronic health record (EHR) helpfulness (<0.001), but more favorable scores for meaning in work (p=0.02), control over schedule ($p<0.001$), and perceived gratitude for their work ($p<0.001$). Factors most closely associated with risk of burnout in HO MDs included negative impact of work on personal relationships (Cohen's D 1.10), self-valuation (Cohen's D 0.98), and control over schedule (Cohen's D 0.90). **Conclusions:** In a large, multi-center study, HO MDs had similar rates of burnout but higher PF than other IM specialties. These results highlight the challenges and rewards of working in oncology and identify priority domains to improve oncologists' work environments. Research Sponsor: None.

9006 Rapid Oral Abstract Session

Who's on the podium? Geographic and career diversity of ASCO Annual Meeting presenters. First Author: Aysche Stern, Temecula Valley Hospital, Temecula, CA

Background: The ASCO annual meeting is the world's preeminent meeting of oncology professionals. Giving an oral presentation at the ASCO annual meeting is a landmark in a career. We examined the training and geographic diversity of presenters. **Methods:** We identified all oral abstract or moderator presentations from the ASCO Annual Meeting 2021-2024 using asco.org. Further information on each speaker was gathered from publicly available information through internet searches of institutional websites and professional social media. We queried degree, pronoun use, medical school, institutions of post-graduate training and years of graduation. Institutions were classified by geographic region (country, state, and U.S. Census Geographic Area), type (academic versus community) and NCI-designation. Presentations per population (PPP) of 10^6 persons were standardized by state and region level 2020 US Census data. Study was IRB exempt at investigators respective institutions. **Results:** Between 2021-2024, there were 1563 oral presentations in abstract sessions from 1310 speakers representing 491 institutions. 253 (19%) presented more than once (range: 1-5). 57% use the 'he' pronoun. Most presenters were from US institutes (66.7%; n=1043), 6.3% (n=99) from China, 4.0% (n=63) from France, and 3.2% (n=50) from the UK. 69.7% (n=1090) were from North America, 17.6% (n=275) from Europe/UK, 10.2% (n=16) from Asia, and 2% (n=31) from Australia. Few presentations were given by speakers from institutions in the Middle East (0.1%, n=2) or South America (all Brazil; 0.3%, n=4), and no presentations were given by speakers from African institutions. 22% (n=347) of presentations were from the top 5 presenting institutions, all of which were in the US and 3 of 5 on East coast. 87.1% (n=768) of presentations from US institutions were from NCI-designated centers. 21 of 33 (64%) US based plenary presenters were from New England or Mid Atlantic states, while 25% (n=11/44) were from non-US institutions. PPP were highest in northeast 6.0/10^6 compared to Midwest (2.9/10^6), South (2.6/10^6), and West (2.2/10^6). Highest PPP states were MA (15.5/10^6), DC (11.6/10^6), and CT (8.6/10^6) while 13 states had no presenters. Presenters were a median of 13.0 (SD: 9.2) years post training (YPT). By ASCO definitions, 6.8% (n=63) were students/trainees, 6.1% (n=57) were early career (<3 YPT), 53.8% (4-15 YPT) were mid-career, and 35.1% (n=326) were later career (>15 YPT). Trainee and early career speakers gave 0 plenary presentations, 9.6% (n=91) of oral abstract presentations, and 22.1% (n=40) of rapid oral abstracts ($p=<0.001$). **Conclusions:** Oral presenters were most frequently mid to late career, medical oncologists and from Northeastern, US, academic, NCI-designated centers while few speakers were from community sites or early career/trainees suggesting there is room for continued diversification to represent all oncologists and those they treat. Research Sponsor: None.

Board certification and billing practices of international medical graduate hematologists and oncologists. First Author: Austin Wesevich, University of Chicago, Chicago, IL

Background: International medical graduates (IMGs) comprise a substantial portion of the oncology workforce in the United States (US). IMGs may help address oncology workforce shortages with an aging US population, but IMGs face considerable barriers to becoming practicing oncologists in the US. We analyzed the credentialing and billing practices of IMG hematologists and oncologists (HO) to better describe the IMG workforce. **Methods:** We linked publicly available data from the Centers for Medicare & Medicaid Services (CMS) and the American Board of Internal Medicine to describe credentialing and billing practices of all HO who billed Medicare Part B in 2022 and whose medical school was specified in CMS data. Physicians were dichotomized as IMGs versus graduates of a US, Canadian, or Puerto Rican medical school (USMGs). We defined academic as working in a teaching hospital and research as having non-federal research funds. **Results:** Of 12,019 HO identified, 48% were IMGs. Even though they had a similar median number of years since medical school graduation, IMGs more frequently obtained initial hematology and medical oncology board certification (72% vs 58%, $p<0.001$) and maintained certification (79% vs 75%, $p<0.001$) than USMGs (Table). On average, IMGs billed Medicare more and had more outpatient visits and inpatient days with Medicare beneficiaries than USMGs. Most (55%) Medicare inpatient days were billed by IMGs. While USMGs were more frequently academic researchers than IMGs (35% vs 31%, $p<0.001$), IMGs were more frequently community clinicians than USMGs (13% vs 11%, $p<0.001$); there was no difference in IMG versus USMG representation for academic clinicians or community researchers. **Conclusions:** IMGs make up almost half of the US oncology workforce. Compared to USMGs, IMGs are more frequently double-boarded and maintaining board certification. Plus, they have more clinical productivity and higher representation in community-based oncology care than USMGs. Additional efforts should be instituted at a national level to eliminate training barriers and mitigate the biases faced by IMGs so that we can meet the growing demand for oncology care in the US. Research Sponsor: None.

Hematologist & oncologist credentialing and billing by medical school location.

Characteristic	USMG, n=6,288	IMG, n=5,731	p-value
Female gender	2,267 (36%)	2,005 (35%)	0.22
Median years since medical school graduation (IQR)	24 (16-36)	25 (17-34)	0.19
Oncology Single-Boarded	2,415 (38%)	1,485 (26%)	<0.001
Hematology Single-Boarded	241 (4%)	148 (3%)	<0.001
Hem/Onc Double-Boarded	3,632 (58%)	4,098 (72%)	<0.001
Maintenance of Certification	4,704 (75%)	4,537 (79%)	<0.001
Median Medicare Payments in 2022 (IQR)	$78,938 ($35,507-$234,627)	$88,401 ($41,329-$240,705)	<0.001
Median Medicare Outpatient Visits in 2022 (IQR)	480 (216.5-902)	506 (237-925)	0.004
Median Medicare Inpatient Patient-Days in 2022 (IQR)	45 (0-138)	62 (0-171)	<0.001

Recognizing international medical graduates: Awards and committee membership in ASCO. First Author: Karun Neupane, H. Lee Moffitt Cancer Center and Research Institute, University of South Florida, Tampa, FL

Background: International Medical Graduates (IMGs) comprise one third of practicing oncologists and half of hematology-oncology fellows in the US. This study explores the previously unexamined distribution of ASCO awards, Fellow of ASCO (FASCO) designation and ASCO committee memberships between IMGs and American Medical Graduates (AMGs). **Methods:** Between 2019-2023, we gathered data from the ASCO website on ASCO awards including career development awards (CDA), young investigator awards (YIA), MERIT and Other awards, and FASCO distinctions. Between 2021-2023 we gathered information on ASCO committee memberships. We searched for medical school and degree of each individual to classify them as IMGs, AMGs, International physicians or non-physicians. We used the world bank geographical distribution comparing IMGs' country of origin. Chi-square, Fisher's Exact, and Cochran-Armitage Trend tests were performed as appropriate using SAS v. 9.4. **Results:** Out of a total of 2,514 entries, 2,342 physicians were included for analyses (1583 ASCO awards, and 759 FASCO designation/committee memberships) and 172 non-physician entries were excluded. Among 1583 physicians with ASCO awards, 22% were IMGs (133 Female (F), 209 Male (M)), 58% were AMGs (410F, 508M) and 20% were international physicians (150F, 173M). Among 759 physicians with FASCO designation/committee membership, 18% were IMGs (61F, 77M), 71% were AMGs (293F, 245M) and 11% were international physicians (41F, 42M). IMGs were significantly underrepresented compared to AMGs ($p<0.001$) in receiving YIA (18% vs 82%), CDA (21% vs 79%), MERIT (35% vs 65%) and Other awards (15% vs 85%). The ratio of CDA-YIA to Merit/Other awards were 0.36 and 0.83 for IMGs and AMGs, respectively ($p<0.001$). This underrepresented trend of IMGs for ASCO awards remained unchanged between 2019-2023 (p=0.6).Compared to the major career awards (YIA and CDA) through these years, FASCO designation for IMGs has an increasing trend (p=0.03). The proportion of FASCO granted to IMGs increased from 9% in 2019 to 25% in 2023. Female IMGs were the least represented group for the awards (25%, p=0.07) and FASCO/committee membership (17%, p=0.03) when compared to AMGs. Majority of these IMGs were from South Asia (30%) and Europe/Central Asia (24%) while Sub-Saharan Africa had the lowest representation (3%) based on world bank classification. **Conclusions:** IMGs' receipt of major career awards (CDA, YIA) remains significantly underrepresented while their contributions to ASCO volunteering activities is on the increasing trend as evidenced by increase in FASCO designee IMGs. Barriers for major career awards for IMGs remain to be explored. Research Sponsor: EMORY Stat Core, NIH21.

Year wise trend of IMGs with ASCO CDA/YIA awards and FASCO designation.

Year	CDA+YIA n (%)	FASCO n (%)	P-value
2019	11 (84.6)	2 (15.4)	0.03
2020	17 (81)	4 (19)	
2021	21 (77.8)	6 (22.2)	
2022	22 (68.8)	10 (31.2)	
2023	21 (60)	14 (40)	
Total	92	36	

9009 Rapid Oral Abstract Session

Career transitions and practice patterns among international medical graduates in oncology workforce: A US nationwide analysis. First Author: Jiazhang Xing, Sinai Hospital of Baltimore, Baltimore, MD

Background: International Medical Graduates (IMGs) are a vital component of the US oncology workforce, representing nearly half of practicing medical oncologists. However, systemic barriers may influence their career trajectories differently. Understanding these challenges is essential for addressing workforce disparities and optimizing cancer care delivery across diverse geographic regions. **Methods:** We conducted a cross-sectional study of 13,497 medical oncologists using the 2024 Dec CMS Provider Dataset linked with the 2023 Rural-Urban Continuum Codes (RUCC). Medical oncologists were identified by their self-reported primary specialties, including Hematology/Oncology, Medical Oncology, and Hematopoietic Cell Transplant. Physicians were categorized by graduation origin (based on their self-reported medical school), career stage (early: 0–10 years, mid: 11–30 years, late: >30 years post-medical school graduation). The primary outcomes included practice at Main Campus of NCI Designated Cancer Centers (as an indicator of academic practice) and the geographical location of their practice (Metro, Non-Metro, Mixed). We employed chi-squared tests for statistical comparisons and performed stratified analyses by career stage to evaluate transition patterns over time. **Results:** 6920 IMGs constituted 48.7% of the oncology workforce, with similar gender distributions between IMG and non-IMG oncologists (37.9% vs 36.5% female, p=0.068). Notably, early career oncologists were less likely to be IMGs (IMG vs non-IMGs: 8.2% vs 12.5%, $p<0.001$). Compared to Non-IMGs, IMG oncologists are less likely to practice at main campuses of NCI Center (19.9% vs. 27.7%, $p<0.001$), especially as their career advances (all $p<0.01$). (Table). IMGs had higher representation in non-metropolitan areas than non-IMGs (11.4% vs 9.1%, $p<0.001$), particularly in late-career stages (14.7% vs 12.3%, p=0.033), indicating their unique role in serving underserved regions. (Table). **Conclusions:** Our findings reveal that, IMGs are less likely to practice at main campuses of NCI-Cancer Center than their non-IMG colleagues. Meanwhile, IMG oncologists are disproportionately serving rural communities. Supporting IMG pathways in oncology is critical to ensure a balanced cancer care delivery across the United States. Research Sponsor: None.

Practice setting distribution and academic affiliation among international medical graduates (IMGs) and US graduates (USGs) by career stage.

9010 Rapid Oral Abstract Session

Productivity of National Cancer Institute K Awardees and their transition to independent funding. First Author: Mariah Malak Bilalaga, MedStar Health Georgetown University, Baltimore, MD

Background: The National Cancer Institute (NCI) mentored career development (K) awards program plays an essential role in supporting early-career scientists in the United States.Understanding factors that influence the transition from mentored to independent funding is crucial to optimize support for early-career cancer researchers. Here, we examine the productivity of K awardees and explore factors that predict a successful transition to independence. **Methods:** This retrospective cohort study utilized publicly available data from: 1) the National Institutes of Health Research Portfolio Online Reporting Tools Expenditures and Results database to obtain data on awards, total costs, and funding mechanisms, and 2) the NIH iCite database to obtain data on publications, citations, and mean relative citation ratio. We included principal investigators (PIs) who received NCI mentored K awards between 1981 and 2013 to allow for at least 10 years of follow-up. Multivariable logistic regression models were employed to explore predictors of attaining an R01-equivalent award. **Results:** Between 1981-2013, 1,778 K awards were awarded by the NCI, with a median total cost of $128,036 (interquartile range [IQR]: 89,420-138,085) per award/year. Of the 1,778 PIs, 759 (42.7%) received an R01-equivalent award over a total of 4,827 person-years, with a median time to award of 5.52 years (IQR: 3.88-7.79) and an incidence rate of 0.16 awards per person-year (95% CI: 0.15, 0.17). In multivariable logistic regression models, PIs who received a K08 (odds ratio [OR]=1.47 [95% CI=1.09, 1.99]), K22 (OR=1.72 [95% CI=1.06, 2.77]), or a K99 (OR=1.55 [95% CI=1.06, 2.29]) displayed greater odds of attaining an R01-equivalent award compared to K01 awardees. Similarly, PIs based in independent hospitals (OR=1.45 [95% CI=1.12, 1.88] vs. institutes of higher education), who focused on molecular/cellular research (OR=1.37 [95% CI=1.03, 1.81] vs. human research), had a greater number of publications per year (OR=1.40 [95% CI=1.25, 1.57]; per additional publication/year), had a higher mean relative citation ratio (OR=1.65 [95% CI=1.31, 2.15]; per 5 units increase), and published for a longer time interval (OR=1.09 [95% CI=1.06, 1.12]; per additional year), displayed greater odds of receiving an R01-equivalent award, while total cost did not (p=0.14). **Conclusions:** Between 1981 and 2013, 42.7% of K awardees received an R01-equivalent award, with a median transition time of 5.52 years. Productivity metrics, including greater publication and citation rates, were associated with a higher likelihood of successful transition. These findings underscore the crucial role of mentored awards in advancing scientific careers and emphasize the importance of providing mentorship and resources to early-career scientists to enhance their overall research impact. Research Sponsor: None.

9011 Rapid Oral Abstract Session

Trends in racial and gender diversity among adult hemato-oncology trainees over last decade and impact of Covid. First Author: Ohm Tripathi, University of Connecticut, Storrs, CT

Background: We aim to examine trends in racial and gender diversity of trainees within adult and pediatrics hemato-oncology (H-0) fellowships, and evaluate the impact of COVID on the racial and gender proportions of trainees within H-0 training programs. **Methods:** Accredited Council for Graduate Medical Education (ACGME) data were queried to identify hemato-oncology trainees between 2014 and 2024. Trainees were identified based on self-reported race and gender. We defined 2016-17 to 2019-20 and 2020-21 to 2023-24 era as pre and post COVID years. Student T-tests were used to assess differences between groups and trends. **Results:** Average number of the female H-0 fellows (44.1%) is significantly lower compared with men (55.4 %) [$p<0.005$] . There is a slow but steady increase in female representation in H-0 fellowship across the study period as the gender gap has declined from 15.4 % in 2016-2017 to 7.2 % in 2023-2024. There is a non-statistical increase in the proportion of females in H-0 fellowships (44.1%) post covid compared with pre covid era (42.3%) [p = 0.0054]. Blacks (3.4%) represented a lower proportion of H-0 fellows compared to Whites (37.2%, $p < 0.005$), Asians (34.0%, $p<0.005$), and Hispanics (5.0%, $p<0.005$). Asian H-0 fellows saw the highest increase in the percentage (12.7%) from 2014-2015 to 2022-2023 followed by white H-0 fellows (3.4%) while the Hispanics and blacks H-0 fellows (2.8 and 2.4% respectively) had miniscule increase in the same time frame . There is also a significant increase in Asian H-0 fellows (10.8%) post covid compared to Black fellows (1.5%). **Conclusions:** This study reveals persistent gender and racial/ethnic disparities within H-0 fellowships in the United States. While the proportion of female trainees has gradually increased in H-0, they remain underrepresented compared to men. Regarding diversity, the data shows underrepresentation of Black and Hispanic individuals in H-0 fellowships, with Asian trainees experiencing the greatest growth. Importantly, the COVID-19 pandemic did not significantly impact these existing disparities. These findings underscore the need for targeted efforts to address systemic barriers limiting diversity and inclusion in the hematology-oncology workforce. Potential strategies include holistic admissions, mentorship programs, and pipeline initiatives to support underrepresented minority students and trainees. Research Sponsor: None.

A cluster analysis of clinician distress trajectories when caring for seriously ill hospitalized patients. First Author: Anessa M Foxwell, University of Pennsylvania, Philadelphia, PA

Background: Millions of Americans are hospitalized every year; many of whom are seriously ill with one or more co-morbidities. Clinicians, including physicians and advanced practice providers (APPs) care for these complex patients while also juggling competing clinical demands from fielding multiple specialty recommendations to navigating interprofessional relationship. But clinicians are distressed, which has the potential to impact the quality of healthcare delivery at the moment of care and in the future. To date there is limited empirical inquiry examining the longitudinal trajectory of clinician distress and its potential impact on healthcare quality. Study objective was to describe unique clinician distress trajectories in general medicine hospital clinicians caring for seriously ill patients based on their level of distress over time through mobile ecological momentary assessments (mEMAs). **Methods:** Latent class cluster analysis of prospective serial mEMAs. Exploratory analysis of patient and clinician variables was then performed using generalized estimating equations univariate ordinal logistic regression. Total participants consisted of 184 hospital encounters for hospital clinicians (n=68) caring for seriously ill patients (n=151). **Results:** The main outcome of clinician distress typology was identified by latent class cluster analysis. Distress was measured by serial mEMA distress thermometer levels over two days. The sample included more physicians (60.3%) than APPs (39.7%) and clinicians had an average of 8.4 years' experience (range 0-31 years). Patients average age was 65.4 years, majority were male (53.6%) and White (61.6%) The majority of patients had a primary serious illness of a solid tumor malignancy (50%), followed by hematologic malignancy (27.9%) then non-cancer chronic illness (22.1%). Clinicians fell into four typology clusters: low distress (23.2%), moderate distress (33.1%), variable distress (19.7%) or high distress (23.9%). Credentials (APP vs. physician; x^2=9.11, p=0.0025) and clinician emotional experience (x^2=11.29, p=0.0008) were significantly associated with clustering by typology. Compared to physicians, APPs were six times more likely to be in a higher distress typology (OR=6.16, p=0.003). Clinicians who had reported more emotions were more likely to be in a higher distress typology (OR=1.90, p=0.001). Mid-career clinicians were more likely to be distressed than either early or late career clinicians (OR=1.80, p 0.370). Patient and clinician demographics were not otherwise significantly related to clusters. **Conclusions:** Clinicians experience distress throughout their workday. This study identifies unique distress trajectories measured in real-time and specific characteristics of those trajectories that can be leveraged by healthcare systems when designing interventions and support resources for hospital clinicians. Oncologists' attitudes and beliefs toward crying with patients and its correlation with burnout. First Author: Hannah Z. Catzen, University of Michigan Medical School, Ann Arbor, MI

Background: This pilot study examines oncologists' perspectives on expressing emotion, particularly crying, in the presence of patients, the frequency of such moments, and their potential correlation with burnout. We developed a survey to assess these factors and hypothesized that oncologists with more positive attitudes toward emotional expression would report lower burnout scores. **Methods:** We surveyed physicians who practice oncology and administer cytotoxic therapy to adults at Michigan Medicine, identified using the cancer center directory. The survey, developed by the authors based on a literature review and expert opinion, included 28 questions to assess attitudes and behaviors towards crying, 7 demographic questions, and the 22-question Maslach Burnout Inventory for Healthcare professionals (MBI-HSS). We used Spearman correlations to analyze the relationship between survey questions about frequency and appropriateness of crying and the MBI-HSS subscales: Emotional Exhaustion (EE), Depersonalization (DP), and Personal Accomplishment (PA). **Results:** We analyzed data from 50 respondents (78.6% response rate). In response to "How often do you cry with your patients," 45% of providers indicated that they never or rarely (less than once a year) cried, 47% cried 1-3 times a year, 8% cried often (once every 1-2 months) and none cried more frequently (once a week). In response to "Is it appropriate to cry with patients," 12% of providers indicated that they disagree or strongly disagree, 43% indicated that they neither agree nor disagree, and 45% indicated that they agree or strongly agree. More emotionally expressive physicians had higher Personal Accomplishment scores. Personal Accomplishment was positively correlated with likelihood of crying (r = .36, p = .01) and perceived appropriateness of crying (r = .30, p = .03). Although not statistically significant, physicians with positive attitudes toward the appropriateness of crying showed a trend towards lower Emotional Exhaustion scores (r = -0.24, p = .1). **Conclusions:** This pilot study highlights the diverse attitudes of oncologists toward crying in the presence of patients. While nearly half of the respondents viewed crying as appropriate, 12% disagreed, and 45% expressed neutrality, suggesting a lack of consensus on the role of emotional expression in patient care. Oncologists who viewed crying more favorably or engaged in emotional expression more frequently reported higher Personal Accomplishment and showed a trend toward lower Emotional Exhaustion. These findings suggest that fostering open discussions among physicians about healthy emotional expression and its role in humanizing patient care may help address burnout. Future studies should also incorporate patients' perspectives to better understand the impact of physicians' emotional expression on the therapeutic relationship and overall care experience. Research Sponsor: None.

9014 Poster Session

The impact of burnout on oncologists and hematologists: *Nunc agendum est* (now is the time to act). First Author: Rajesh Sharma, Manage Health Foundation, Ahmedabad, India

Background: Burnout among oncologists is a pressing global issue, with prevalence rates ranging from 25% to 70%. South Asia, in particular, has reported alarmingly high rates, primarily driven by heavy patient load, long working hours, administrative demands, and very limited resources. This study aims to explore the prevalence of burnout, its associated stress symptoms, coping mechanisms, and the role of institutional support, with a focus on practical strategies to mitigate burnout. **Methods:** A cross-sectional survey involving 342 oncologists and hematologists in India was conducted using the Maslach Burnout Inventory (MBI) framework. This framework assessed 3 key dimensions of burnout: emotional exhaustion (EE), depersonalization (DP), and reduced personal accomplishment (PA). Additional variables included stress symptoms, burnout severity, contributing risk factors, and coping strategies. Statistical analyses such as Pearson correlation, logistic regression, and factor analysis were performed. Odds Ratios (ORs) were calculated to assess impact of various risk factors, while factor loadings were used to identify underlying domains contributing to burnout. **Results:** Burnout Prevalence: Moderate-to-severe burnout was reported by 43% of respondents. Emotional exhaustion was experienced occasionally by 34.4% and frequently by 31.2%. Depersonalization affected 17.6%. Key Risk Factors: Long working hours increased burnout risk by 2.45 times (OR: 2.45, 95% CI: 1.72–3.48). Administrative workload strongly correlated with emotional exhaustion ($r = 0.68$, $p < 0.01$). Core Domains (Factor Analysis): Systemic Challenges: High patient loads and administrative tasks (factor load > 0.75). Individual Resilience: Practices like meditation and yoga reduced burnout (factor load > 0.70). Organizational Support: Psychological resources and peer discussions were critical (factor load > 0.80). Coping Strategies: Meditation reduced burnout likelihood (OR: 0.64, 95% CI: 0.42–0.96). Peer discussions and group therapy eased depersonalization symptoms ($p < 0.05$). Specialty-Specific Insights: Medical Oncologists: Highest emotional exhaustion (45%). Radiation Oncologists: Moderate depersonalization (41%). Surgical Oncologists: Strongly benefited from peer support (factor load = 0.78). **Conclusions:** Burnout among oncologists requires immediate action. Effective solutions include reducing systemic burdens, providing institutional psychological support, and encouraging individual resilience strategies like meditation and peer discussions. Addressing burnout is critical to improving oncologists' well-being and ensuring quality patient care. Research Sponsor: None.

Statistical associations of risk factors with burnout.

Risk Factor	OR (95% CI)	p-value
Long Working Hours	2.45 (1.72–3.48)	<0.01
Administrative Workload	2.10 (1.56–2.89)	<0.01
Lack of Work-Life Balance	1.85 (1.34–2.56)	<0.05
Poor Institutional Support	1.96 (1.40–2.75)	<0.05

9015 Poster Session

Rethinking future workforce planning by developing novel metrics of complexity in cancer care. First Author: Philip Q. Ding, Oncology Outcomes (O2) Program, University of Calgary, Calgary, AB, Canada

Background: The decision to recruit additional oncologists is often based on simple workload measures such as new patient volumes. This approach may be appropriate previously when cancer management was less complex and at a time when attrition from cancer mortality was significant. We hypothesized that cancer care complexity has increased over time and that new metrics are needed to optimize workforce planning. **Methods:** We conducted a population-based, retrospective cohort study of adult patients diagnosed with common solid and blood cancers in Alberta, Canada. We focused on cases from 2004 to 2018 to ensure adequate follow-up. We evaluated indicators of complexity including patient characteristics at the time of diagnosis, clinical course within 2 years of diagnosis, and longevity as measured by overall survival (OS). For these complexity indicators, we used logistic and Cox regression models to estimate relative changes over the 15-year study period. **Results:** A total of 141,040 patients were included in the study cohort, with a median age of 66 years (range 18-107) and 51.7% male. Breast cancer was most common (25.6%), followed by prostate (24.0%), lung (20.2%), colorectal (17.9%) and leukemia/lymphoma (12.4%). Across all sites, annual cancer incidence rate was 249.9 per 100,000 in 2004 and 284.4 per 100,000 in 2018. Age distribution remained largely stable throughout the study period. Meanwhile, specific indicators of complexity increased over time, including polypharmacy at diagnosis (odds ratio [OR] 1.30, 95% confidence interval [CI] 1.28-1.32), multimodality treatment (OR 1.06, 95% CI 1.05-1.08), and hospital admission via the emergency department (OR 1.08, 95% CI 1.07-1.10). These metrics also demonstrated increasing complexity in multivariable analyses after adjusting for age, sex, and cancer site. Similarly, there was a trend towards greater longevity as measured by OS (hazard ratio 0.98, 95% CI 0.98-0.98). **Conclusions:** Cancer care complexity has increased over time. Workforce planning using antiquated workload metrics, such as incident patient volumes alone, may not align with the actual demands of providing increasingly complex cancer care. Recruitment strategies should consider multi-faceted indicators that reflect complexity in addition to quantity. Research Sponsor: None.

Trends in metrics of patient complexity, by time era.

	Year of diagnosis		
Characteristic	2004-2008, n = 39,465	2009-2013, n = 46,408	2014-2018, n = 55,167

Parenting challenges of international medical graduate hematologists-oncologists in the United States. First Author: Vera Kazakova, UMass Chan Medical School, Worcester, MA

Background: Almost two-thirds of physicians report delaying childbearing due to medical training. Amongst hematologists-oncologists (HOs), up to 75% report burnout related to parenting. International Medical Graduates (IMGs) account for a third of all practicing HOs; yet little is known about the unique challenges they face in navigating parenthood. This cohort study aimed to explore parenting challenges of IMG HOs in the U.S. **Methods:** An anonymous survey was distributed electronically via social media and the ASCO community of practice between December 2024 and January 2025. Descriptive statistics were employed to compute frequencies and percentages of survey responses. Chi-square tests for independence were performed to evaluate associations between key survey variables. **Results:** Among 73 respondents, majority were aged 30–39 (50%) and were women (75%). At the start of their first U.S. post-graduate training, 51% of respondents were on J1/ H1B visa. The majority (77%) delayed parenthood due to medical careers with higher rates of delay in non-citizen/non-permanent resident (NCNPR) IMGs compared to those with permanent residence/citizenship (81% versus 71%). A Chi-square test indicated an association between immigration status and the likelihood of delayed parenthood (p=0.03). Parenthood delay correlated with work hours, financial strain, and lack of social support (Table 1). Key factors affecting career trajectory included decreased academic productivity (66%), reduced conference participation (64%), and declined advancement opportunities (53%). After having children, the most common challenges were achieving work-life balance (95%), lack of social support (93%), and increased burnout (92%). Visa status contributed to parenthood challenges for 38% of NCNPR IMGs. Respondents cited the need for childcare resources, enhanced leave policies, workplace accommodations, visa assistance, stronger support and mentorship. **Conclusions:** IMG HOs face significant challenges balancing parenthood and career, including higher burnout rates than previously reported amongst physicians. Within the cohort of IMG HOs, there is a significant association of immigration status with likelihood of delaying parenthood. Findings highlight the need for systemic support through improved childcare resources, workplace accommodations, mentorship, and visa assistance. Research Sponsor: None.

Correlation between parenthood delay and determinants of parenthood timing.

Factor	Chi-Square	p-value
Duty hours	44.41	<0.0001
Financial strain	22.91	0.0285
Unsupportive work environment	34.5	0.0006
Lack of accommodations during pregnancy	29.79	0.003
Lack of/unclear parental leave policy	30.1	0.0027
Lack of accommodations post parental leave	26.28	0.0098
Lack of social support	39.96	0.0001
Impact on career trajectory	31.99	0.0014
Delay in training completion	30.06	0.0027

Communication skills training program for medical staff in cancer genomic testing: A mixed-methods assessment of an educational initiative. First Author: Shuhei Suzuki, Department of Clinical Oncology, Yamagata University, Yamagata, Japan

Background: Cancer genomic testing presents unique communication challenges for medical staff, particularly regarding low treatment access rates, the complex psychological needs of patients, and concerns about germline findings. While communication skills training (CST) has shown promise in oncology settings, it has not yet been specifically applied to genomic testing conversations. This Pfizer Global Medical Grants Initiative 2023 was designed to address this critical educational gap in the implementation of cancer genomic medicine. **Methods:** A mixed-methods evaluation was conducted of a structured CST program implemented across 10 institutions under Pfizer's educational initiative framework. The program incorporated SHARE protocol-based training (Fujimori *et al. JCO*. 2014), role-playing sessions, and specialized modules addressing genomic testing-specific challenges. The quantitative assessment utilized pre- and post-intervention 4-point categorical assessments. The qualitative evaluation employed semi-structured interviews (median duration 12 minutes, range 7-21) analyzed using a modified grounded theory approach until theoretical saturation. **Results:** Among 251 participants (22% physicians, 37% nurses, 25% other healthcare professionals, 12% administrative staff, 4% others; median experience 9 years, range 0-39), 95% initially reported a psychological burden when explaining genomic testing results. Post-intervention, 94% reported a reduced psychological burden ($p< 0.001$, Chi-square), with 84% expressing satisfaction with the training program. An ordinal logistic regression analysis revealed a significantly greater improvement in nurses than in other professionals (OR 3.52, 95%CI 1.88-6.58, $p< 0.001$). A qualitative analysis of 19 interviews (58% medical staff, 42% patients/families) revealed four major conceptual categories through a constant comparative analysis: 1) multilayered information needs with psychological support requirements, 2) experiential uncertainty in communicating germline findings, 3) perceived competency gaps in genomic counseling, and 4) organizational support needs for sustained practice changes. A thematic analysis identified a strong demand for program continuation and expansion. **Conclusions:** This educational initiative revealed significant effectiveness in addressing critical communication challenges in cancer genomic medicine. The mixed-methods evaluation provides a robust framework for implementing specialized CST programs in genomic medicine practice. These results will contribute to the evolving landscape of cancer genomic medicine education and support the value of structured, evidence-based educational initiatives in advancing the delivery of precision oncology care. Research Sponsor: Pfizer Global Medical Grants; 75412385.

Competencies for practicing medical oncology with common sense: A global curricula review. First Author: Haydee Cristina Verduzco-Aguirre, Queen's University, Kingston, ON, Canada

Background: The Common Sense Oncology (CSO) movement advocates for high-quality, patient-centered cancer care by emphasizing evidence-based, patient-relevant outcomes and equitable access to care through improved evidence generation, interpretation, and communication. A key part of CSO's mission is training oncologists to incorporate these principles into their practice. Therefore, this study aimed to evaluate how competencies in global postgraduate medical oncology curricula align with CSO principles. **Methods:** We conducted a document analysis of publicly available postgraduate medical and clinical oncology curricula. Curricula were identified through: (1) searches in Education Source, EMBASE, and PubMed using the terms 'oncology', 'curriculum', and 'competency-based'; (2) a grey literature search; and (3) requests to medical education experts. Curricula in English, Spanish, Italian, Portuguese, or Hebrew were included to ensure regional representation, while accounting for the research team's language proficiency. Competencies were categorized into eight domains aligned with CSO principles, including critical appraisal, cost and value of cancer care, communication about outcomes and treatment risks, equity in accessing cancer care, ethical principles, and integration of psychosocial oncology, survivorship, and palliative care. Two team members reviewed each curriculum, resolving discrepancies collaboratively, with unresolved cases adjudicated by the first or senior author. **Results:** We analyzed 16 curricula (Australia/New Zealand, Brazil, Canada, the European Union, India, Ireland, Italy, Japan, Mexico, Nigeria, Pakistan, Spain, the United Kingdom, the United States, and the ESMO/ASCO joint curriculum). Ten (63%) were from high-income regions, and six (37%) were from low/ middle-income countries (LMIC). The most frequently identified domains were critical appraisal (94% of curricula), communication (94%), palliative care (94%), and cost/value of care (88%). Less frequent domains were equity in accessing cancer care (56%), ethical principles (56%), and survivorship care (63%). Four (25%) curricula, all from high-income regions, covered all CSO-relevant domains, while three (19%) addressed four or fewer. Competencies related to equity and ethics were found in 70% of high-income curricula but only in 33% of LMIC. **Conclusions:** Competencies reflecting CSO principles were identified in global oncology curricula, with emphasis on critical appraisal, communication, palliative care, and psychosocial oncology. Competencies related to equity, ethical principles and survivorship care were less frequently observed. Notable gaps were observed between high-income countries and LMIC, though language limitations may have influenced our findings. Our results will inform the development of a globally relevant competency framework for common sense in oncology. Research Sponsor: None.

9019 Poster Session

Enhancing radiotherapy planning skills through structured deliberate practice and artificial intelligence integration: A pilot study. First Author: Ivy Weishan Ng, National University Cancer Institute, Singapore, NA, Singapore

Background: In many cancer treatment protocols, radiotherapy plays a pivotal role in achieving disease control. A key component of radiotherapy planning is contour delineation, which involves accurately outlining tumors and nearby structures to target radiation effectively and minimize toxicity. However, formal training in this skill often falls short, with surveys indicating up to 80% of learners and practitioners calling for a need for more robust educational methods (Leung et al. J Med Imaging Radiat Oncol 2019). While advances in artificial intelligence (AI) can improve contouring speed and consistency, radiation oncologists must also develop the skills to evaluate AI-generated results to maintain high-quality care critically. This pilot study aimed to determine whether a structured training approach that incorporates deliberate practice, personalized feedback, and AI integration could improve the contour delineation proficiency of radiation oncology trainees and practitioners. **Methods:** A baseline survey was conducted to identify existing gaps in contour training. Participants practiced with four anonymized thoracic imaging standardized datasets offline. Each participant's initial contours were compared against expert consensus using the Dice similarity coefficient (DSC), a standard metric for spatial overlap. Slice-by-slice visual comparisons and self-reported confidence ratings provided additional qualitative feedback. Over six months, participants engaged in structured lessons, repeated practice sessions (including real clinical cases), expert mentoring, and AI contour assessments. **Results:** At baseline, 24 heart contours were consistently accurate (DSC $>$ 0.9), while tumour and oesophagus delineation showed wide variability (DSC 0.4–0.9 and 0.2–0.9, respectively). Over time, learners demonstrated measurable improvement. By the final assessment, variability in tumour and oesophagus contours decreased (DSC 0.6–0.9 and 0.7–0.9, respectively), while heart contours remained consistently accurate. Learners also demonstrated improved confidence in both manual and AI-augmented contour delineation. **Conclusions:** This study suggests that a structured training approach incorporating a deliberate practice curriculum augmented by personalized feedback and AI integration can improve contour delineation skills. Future studies with larger datasets and diverse learner populations could further validate this approach, ultimately aiming to improve patient safety and treatment outcomes across the broader oncology landscape. Research Sponsor: None.

9020 **Poster Session**

On-shift resident education about hematologic and oncologic emergencies: A needs-based assessment. First Author: Leah Ann Goldberg, University of Chicago, Chicago, IL

Background: Hematology/oncology (H/O) is a fundamental topic for the American Board of Internal Medicine (ABIM); however, there are few resources designed for resident-level education. While asynchronous approaches have gained popularity, there can be a synergistic effect to cementing understanding during clinical exposure. Rotations provide this opportunity, but limited tools exist to augment practice-based learning. Multimodal approaches, such as self-directed text and near-peer educational models, are rarely accessible on shift. The breadth and depth of such resources can make it difficult for users to distill salient information during patient care. This needs-based assessment (NBA) sought to characterize residents' attitudes towards on-shift learning as well as their comfort with diagnosing and treating 3 common H/O emergencies. **Methods:** An NBA survey was sent to 104 internal medicine (IM) and medicine-pediatrics (MP) residents at an academic medical center. Descriptive statistics are reported. **Results:** Fifty-five of 104 residents completed the survey, for a response rate of 53%. Forty-seven percent were post-graduate year (PGY) 1, 25.5% were PGY-2, 25.5% were PGY-3 and 2% were PGY-4. While 98% of respondents use educational resources on shift, only 6% had a H/O specific resource. The most used resources were Up-to-Date (98%), the Mass General Hospital WhiteBook (75%), PubMed (47%), and artificial intelligence (AI) (47%). The biggest barriers to resource utilization were lack of time due to clinical responsibilities (76%) and length of resource (69%). Ninety-one percent indicated interest in a resource designed for shift-based learning and would most value guideline inclusion (80%). While most residents (62%) were comfortable diagnosing tumor lysis syndrome (TLS) and febrile neutropenia (FN) (69%), they were neutral/uncomfortable with diagnosing hyperleukocytosis (71%). Most were comfortable treating FN (53%) but were neutral/uncomfortable with treating TLS (60%) or hyperleukocytosis (96%). There was a statistically significant difference between PGY-1 and PGY-2+ in comfort with diagnosis ($p=.0018$) and treatment ($p<.001$) of FN as well as the treatment ($p=.0132$) of TLS. There was no significant difference in comfort with TLS diagnosis, or hyperleukocytosis diagnosis or treatment among PGY. **Conclusions:** This assessment demonstrates an overwhelming interest in an easily accessible, guidelines-based, electronic resource for residents to utilize during clinical care. Though a medical emergency, hyperleukocytosis is a H/O diagnosis that our program's residents are not comfortable identifying or managing. These results highlight the opportunity for growth in H/O education of IM/MP residents and will guide the design of a digital education resource, as well as its implementation and evaluation at our institution. Research Sponsor: None.

The hidden toll: Defining impacts of home call on oncology fellows. First Author: Erica Andres, Mayo Clinic Rochester, Rochester, MN

Background: Home call is an expected trainee responsibility in many hematology-oncology (HO) training programs although the specific duties and frequency vary. Home call is associated with sleep deprivation and burnout . The Accreditation Council for Graduate Medical Education (ACGME) outlines that home call should not prevent adequate rest or personal time and that the clinical time spent must be counted toward duty hours. However, little is known about the educational value or impact of home call. We sought to analyze the volume, perceived value, and effects of oncology home call on HO fellows. **Methods:** We completed a review of the pager log of the outpatient/after hours oncology pager (OP) at a single 2059 bed tertiary medical center from 1/1/23-12/31/24. The HO fellow carries the OP afterhours and on weekends except for 7am-12pm on Saturday/Sunday. The pager receives all consult calls from the emergency department and inpatient teams requesting verbal communication (in addition to the electronic order), critical results, and outpatient patient calls on matters related to oncology (hematology not included). Patient calls are not triaged and are routed through the hospital operator directly to the OP. Overnight home call is maximum 3 times per week without a post call day. An optional survey was distributed to fellows in May 2024 to assess fellows' experiences with the OP using a 5-point Likert scale and free response. **Results:** There were 80,672 and 87,605 oncology patient visits in 2023 and 2024 respectively at the analyzed institution. The OP received a total of 7,239 pages over the analyzed period. Fellows received a mean of 5.8 pages per weeknight call shift and 8.8 pages per weekend call shift. The survey response rate was 19/33 (42%) HO fellows. Respondents were 58% male and included first (42%), second (26%), and third year (32%) fellows. 89% of respondents reported that most pages overnight were from outpatients and 0 respondents felt that answering patient calls required a physician. Most fellows (79%) did not report educational value from holding the OP and 63% of fellows felt that holding the OP negatively impacted their performance at work the next day. For nights that received more than 3 calls, 95% fellows reported feeling not well rested. In addition, a majority of negative impact on their wellness including anxiety and inability to exercise or socialize when holding the OP. **Conclusions:** The results from our single-institution study indicate that home call could represent a major opportunity to improve the wellness of trainees without negatively impacting their education. More research is needed to understand what the primary contributors are for the negative experiences and perceptions while developing sustainable systems and approaches for efficiently handling oncology pager traffic. Research Sponsor: None.

Successful intervention to bridge the knowledge gap in recognizing and managing chemotherapy hypersensitivity reactions among oncology fellows in southeast Michigan. First Author: Jailan Elayoubi, Oncology Department, Wayne State University, Detroit, MI

Background: Recognizing hypersensitivity reactions (HSRs) to paclitaxel and carboplatin in patients receiving multi-drug chemotherapy regimens combined with monoclonal antibodies (mAb) and distinguishing them from infusion-related reactions (IRRs) is challenging due to overlapping clinical presentations, rarity, and severity. To address this, we designed a continuing professional development (CPD) activity to enhance knowledge and awareness of these life-threatening reactions. **Methods:** The CPD activity was designed using Kern's six-step approach, targeting Hematology/Oncology (H/O) fellows, Gynecological Oncology (GO) fellows, and chemotherapy infusion center nurses (Chemo RNs). A questionnaire featuring real-life HSRs and IRRs scenarios was administered anonymously before and after a 60-minute, in-person, interactive educational lecture. Paired statistical comparisons were not performed, as both surveys were kept anonymous to encourage participation. **Results:** A total of 42 participants attended the CPD activity, including 30 H/O fellows from 3 fellowship programs, 3 GO fellows from 1 program, and 9 Chemo RNs from a comprehensive cancer center in Southeast Michigan. Participation in pre- and post-lecture questionnaires among fellows was 87.8% and 72.7%, respectively. Recognition rates among fellows improved from 82.7% to 100% for paclitaxel HSRs, 58.6% to 95.8% for carboplatin HSRs, and 93.1% to 91.6% for mAb IRRs, with the most notable improvement in recognizing HSRs to carboplatin. For Chemo RNs, paclitaxel HSRs and mAb IRRs recognition rates were 100% at baseline and post-lecture, while carboplatin HSRs recognition improved from 71.4% to 88.8%. **Conclusions:** A knowledge gap was identified among oncology fellows in recognizing HSRs to paclitaxel and carboplatin, while Chemo RNs demonstrated exceptional baseline knowledge of paclitaxel HSRs and mAb IRRs. CPD activities aimed at raising awareness of various HSRs and their management were effective and well-received by the healthcare staff, supporting their integration into H/O fellowship curricula. Research Sponsor: None.

Key points from the educational lecture.

	Carboplatin	Paclitaxel
Timing	Mostly occurs towards the end of infusion or up to days after. Cumulative effect, highest incidence by the 8th exposure.	Occurs within the first 10 minutes during the first or second infusion.
Most characteristic feature	Itching, rash on palms and soles,abdominal cramps, back pain.	Flushing and hemodynamic instability.
Pre-medications	Corticosteroids, H1/H2 antagonists do not prevent HSRs.	Dexamethasone, diphenhydramine, H2 receptor antagonists before paclitaxel infusion decrease HSRs.

Introducing a capacity building model to improve cancer research in MENA. First Author: Sara Ahmad Al-Banna, King Abdullah University Hospital, Amman, Jordan

Background: The Middle East and North Africa (MENA) region faces a rising cancer burden, straining healthcare systems. The scarcity of cancer research in the region highlights the need for research-focused capacity building. Our project aims to reduce this burden by empowering scientific research for better understanding and strategic implementation. **Methods:** The Science Health Education (SHE) Center was founded by the Dana-Farber Cancer Institute in 2019 to empower cancer research in MENA by offering mentorship, fostering international scientific collaborations, and supporting the next generation of researchers. Capacity-building efforts within the past six years were implemented through 21 in-person and virtual workshops that combined interactive and theoretical approaches, with data collected via pre- and post-assessment forms. The workshops covered topics including Research Basics and Manuscript Writing, Research Administration & Gap Analysis, Mentorship, CV Writing and Leadership. Data were analysed using independent t-tests to compare pre- and post-workshop scores, with Cohen's d calculated to quantify effect sizes, demonstrating the scale of skill improvement. **Results:** A total of 573 healthcare workers from four MENA countries (Jordan (n= 267, 47%), Iran (n=187, 33%), United Arab Emirates (n=65, 11%), and Morocco (n=54, 9%)) have attended our workshops. In Jordan, over 67% of the 267 participants were women. The attendees included 96 medical students and 171 healthcare professionals (HCPs) from various departments, including Scientific Affairs (n=54, 32%%), Pharmacy (n=16, 9%), and Nursing (n=16, 9%). HCPs attended four Manuscript Writing Workshops, which covered theoretical basics, manuscript drafting, peer review, and US-based review by our editors. Fifty manuscripts from 73 participants across two workshops were edited by the Center and submitted for publication, with a publication rate of 34% thus far. Medical students participated in four Professional Development Workshops. Pre- and post-assessments conducted for 20 participants from the latest pilot analysis in Jordan showed significant improvement in manuscript writing skills. Participants reported enhanced self-rated writing ability ($P=0.003$, $d=1.072$), increased familiarity with IMRaD structure ($P=0.057$, $d=0.661$), better understanding of journal selection ($P=0.004$, $d=1.033$), greater confidence in formatting references and citations ($P=0.004$, $d=1.053$), and improved knowledge of handling peer review feedback ($P<0.001$, $d=1.382$). **Conclusions:** The SHE Center is a successful model for training cancer researchers in developing their research and publishing skills. Further capacity building will help trainees develop advanced skills, preparing them to mentor the next generation. This model has potential to be adopted in other low- and middle-income countries to enhance research productivity and improve cancer care. Research Sponsor: None.

Enhancing educational experiences through standardization of inpatient hematology curriculums. First Author: Prasanth Lingamaneni, Mayo Clinic Rochester, Rochester, MN

Background: Comprehensive hematology education during fellowship is essential for delivering high-quality healthcare. Variability in individual learning experiences can lead to trainee dissatisfaction and suboptimal clinical acumen. Fellowship programs must strive for a well-rounded and equitable educational experience for all fellows to prepare them for real-world practice in the increasingly dynamic field of hematology. **Methods:** Hematology fellows (n=30) at Mayo Clinic (Rochester) were invited to complete a survey about the inpatient Fellow Hematology Curriculum (FHC) during 2021-2022. Responses were recorded in a five-point Likert scale and free-text. Using the initial results, we implemented a structured inpatient hematology curriculum starting in 2022 and conducted a post-implementation survey in Spring 2024 to assess its success and sustainability. **Results:** The initial survey was completed by twenty fellows, with a response rate of 66%. All respondents agreed that the FHC could be improved. Only 45% agreed that structured education is adequately paired with clinical duties. In the open-ended responses, a structured curriculum covering a set list of topics was the most common recommendation given to improve the FHC. This prompted a longitudinal QI initiative to implement standardized rotation-specific lectures created by fellows and distributed to faculty and fellows prior to the associated 4-week rotations. Twelve fellows (40%) completed the post-implementation survey. Summary of key responses are shown in table 1. Although there remained high variability among consultants regarding their engagement in education, significant improvements were noted. Agreement that the curriculum has well-defined objectives for each rotation increased from 25% to 58%. Additionally, 83% of fellows agreed that structured education was effectively paired with clinical duties, up from 45%. Open-ended responses highlighted variability in consultants' utilization of the curriculum but reflected overall satisfaction. **Conclusions:** The need for a well-structured FHC was identified as a gap in equitable hematology education. This was addressed through a fellow led longitudinal QI project generating easily accessible educational material relevant to weekly themes on inpatient hematology services. The introduction of a structured and clinically relevant curriculum was well-received. Research Sponsor: None.

Summary of survey responses.

	Pre-implementation	Post-implementation
Statement	Agreed or strongly agreed (%)	Agreed of strongly agreed (%)
I know what topics and to what extent I'm expected to learn	25	67
The FHC has well-defined objectives for each rotation	25	55
There is high variability among consultants with engagement in education	95	75
Structured education is paired with clinical duties	45	83
I can easily locate lectures given by hematology consultants	5	42

Leveraging the power of diagnostic metrics to competency based medical education (CBME) implementation in medical oncology (MO) across Canada. First Author: Anna T. Tomiak, Queen's University, Kingston, ON, Canada

Background: MO training programs across Canada implemented CBME in 2018. Early implementation focused primarily on immediate "structural" changes, and included the adoption of new stages of training, new assessment practices and the creation of Competence Committees. To explore elements that would reflect broader and transformational change related to a true shift to an individualized and competency-based approach to education, program leaders sought to identify, develop, and pilot indicators that could be used by programs to evaluate their implementation of the Competence by Design (CBD) model. It was anticipated that implementation and evaluation of these indicators would be challenging. **Methods:** In phases one and two of the study, program leaders established a consensus regarding qualities they considered to transformative, and qualitative information regarding how these qualities are reflected in programs was obtained. In phase three, electronic resident portfolios at 2 sample sites were investigated for data regarding specific indicators to determine the feasibility of use by program directors to track implementation progress and aid in program review. Opinions of program leaders in all 14 Canadian programs were obtained through a consensus process. Educators from all sites were invited to participate in semi-structured interviews and a 100% response rate obtained. Data from the 2 sample sites was collected from portfolios, de-identified and reported in aggregate to help maintain confidentiality. **Results:** 7 key priority indicators were identified. These centered around 6 themes: direct observation, personal learning plans, curricular change, coaching, data sources used by Competency Committees and general concerns about CBD. Variability was found in the extent of implementation of these across programs and in adaptations made locally. At the 2 sample sites, extraction of key metrical indicators from resident portfolios had to be completed manually and was challenging as electronic databases had not been designed to allow easy review and analysis of these specific indicators. **Conclusions:** Program leaders of Canadian MO training programs were able to reach consensus regarding key data indicators they believe to be transformative and reflective of core CBD principles. Despite this consensus, variability was found in the implementation of these across programs and practical challenges encountered in extracting data related to key indicators from resident portfolios at 2 sample sites. To provide program leaders with data they feel is important for optimal CBD implementation, electronic databases will need ongoing attention and adaptation to facilitate access to key indicators considered important for program review and evaluation. Research Sponsor: Royal College of Physicians and Surgeons of Canada (RCPSC).

Implementation of clinical trial communication skills training for oncology fellows. First Author: Carma Bylund, University of Florida, Gainesville, FL

Background: Effective physician-patient communication about cancer clinical trials (CCTs) is critical for improving participation, particularly in underrepresented populations. Most eligible patients are willing to participate when invited through clear, patient-centered discussions, yet treating oncologists often do not discuss trials or do so ineffectively. Communication skills training is well-suited for the fellowship stage; however, most Hematology/Oncology (Hem-Onc) education programs do not formally teach CCT communication skills. To address this gap, we implemented COMM-CCT, a previously developed CCT communication skills workshop for Hem-Onc fellows and assessed the acceptability and feasibility of its implementation in Hem-Onc fellowship programs. **Methods:** We implemented the COMM-CCT workshop at seven Hem-Onc programs in the U.S. The three-hour, synchronous Zoom-based workshop included a one-hour didactic session that covered barriers to patient trial participation (e.g., patient, physician, institutional) and introduced the COMM-CCT framework (Check-In, Outline Options, Make a Shared Decision, Map Out Next Steps) for discussing CCTs. This was followed by a two-hour role-play session where fellows practiced communication skills with cancer survivors who were trained to act as patients, while faculty facilitators and peers gave constructive feedback. At each site, "fellow champions" encouraged peers to participate in the workshop. We assessed implementation (i.e., feasibility and acceptability) by surveying and interviewing participating fellows. **Results:** Regarding acceptability, fellows (n=54) reported high satisfaction (on a 1-5 scale) with the workshop (M=4.30, SD=0.79), its content (M=4.28, SD=0.79), its organization and execution (M=4.5, SD=0.61), and the faculty and facilitators (M=4.56, SD=0.63). They were comfortable with communication skills taught (M=4.15, SD=0.71) and felt the skills were compatible with the realities and resources of their clinical practice (M=4.35, SD=0.70). Fellows further agreed what they learned would be useful to (M=4.33, SD=0.73) and able to be incorporated into (M=4.22, SD=0.72) their clinical practice. When interviewed, fellows (n=9) found the workshop acceptable, describing it as "well-organized," "very helpful," and relevant. The role-plays with "real survivors" were noted as a strength, as was learning by observation in a group setting. Feasibility was evidenced by fellows reporting incorporating COMM-CCT concepts into practice, such as by initiating discussions with patients about cancer clinical trials since participating in the workshop. **Conclusions:** The COMM-CCT workshop is acceptable and feasible to implement in Hem-Onc fellowship programs. Findings will inform its refinement, broader scaling, and continued integration into graduate medical education programs. Research Sponsor: The Leukemia & Lymphoma Society.

GUIDE-G: An artificial intelligence-powered platform for dynamic NCCN guideline visualization in breast cancer (BC). First Author: Nataly Valeria Torrejon, Baylor College of Medicine, Houston, TX

Background: Breast cancer (BC) management has evolved rapidly, with 17 FDA approvals in the past five years. Increasing complexity in NCCN guidelines has resulted in prolonged decision-making times and complex clinic preparation processes. GUIDE-G, an AI-powered, web-based platform, was developed to address these challenges by enabling hierarchical visualization of NCCN guidelines and providing efficient, point-of-care clinical decision support. **Methods:** The primary objective was to assess the feasibility of GUIDE-G. SUMMARIZATION of NCCN Guidelines in BC was performed using Large Language Model-based feature extraction, applying targeted prompts for accurate content retrieval and generating structured markup output. Manual curation by a panel of BC experts at Baylor College of Medicine ensured alignment with the guidelines, with accuracy measured by edits per generated content. VISUALIZATION involved transforming the markup into dynamic hierarchical diagrams using markmap-lib framework, supported by Node.js. GitHub-based version control ensured automated updates, with mobile-compatible HTML enabling cross-platform accessibility. **Results:** GUIDE-G (https://elkhanany.github.io/cancer_workflow/) achieved 90% accuracy in guideline summarization, as validated by expert review. The feasibility objective was met, with seamless integration into clinical workflows. Anecdotal feedback from 20 BC fellows highlighted the platform's ability to reduce per-patient preparation time by approximately 5 min. Although formal survey data is pending, preliminary observations suggest the platform enhances learner engagement and supports real-time clinical decision-making. Visualization performance demonstrated consistent sub-second rendering on major mobile platforms, ensuring accessibility at the point of care. Formal impact evaluation is underway, with IRB approval for studies assessing workflow efficiency and learner satisfaction. **Conclusions:** GUIDE-G offers a transformative approach to BC guideline implementation, combining scalable architecture and version-controlled deployment for sustained adaptation to evolving guidelines. Learner impact is being collected via 16-point survey instruments. Preliminary findings demonstrate potential for significant improvements in clinical workflow efficiency and educational outcomes, paving the way for implementation across oncology subspecialties and transforming evidence-based care delivery. Research Sponsor: None.

Implementation of a novel interdisciplinary pharmacology curriculum in a hematology/oncology fellowship program. First Author: Rebecca Forman, Yale New Haven Hospital, New Haven, CT

Background: Thoroughly understanding cancer therapeutics is a critical component of Hematology/Oncology (HO) training, with pharmacology comprising a large part of the ASCO/ESMO Recommendations for a Global Medical Oncology Curriculum. Prior studies demonstrated that interdisciplinary approaches to education lead to more teamwork and enable learners to gain from multiple perspectives. We created and implemented a novel pharmacology curriculum in our HO fellowship program using a case-based, interdisciplinary format grounded in learning science principles. **Methods:** We used a pre-post design to evaluate and transform HO fellowship pharmacology training. The pre-existing pharmacology curriculum was organized by drug mechanism of action (MOA) and delivered via a didactic lecture by a pharmacist. HO fellows completed a baseline survey assessing satisfaction and garnering feedback. Based on this feedback, a case-based curriculum was piloted, organized by disease type and given jointly by a pharmacist and clinician. Lectures involved active learning with call and response questions with guidance in treatment decision making, dosing considerations, patient counseling, and toxicity management. This was followed by a post-survey to assess changes in perceptions and effectiveness. **Results:** 34% of HO fellows filled out the initial survey (11/32) and 17 (53%) completed the post-lecture survey with results in Table 1. Among the 12 post-survey respondents who had attended pharmacology lectures the previous year, all rated the new format as an improvement. Thematic qualitative analysis emphasized increased absorption of material and increased relevance due to clinician inclusion and case-based format. Comments noted the new series as a "marked improvement" and "more clinically relevant." **Conclusions:** HO fellows found a case-based, interdisciplinary, disease-specific pharmacology curriculum conducive to learning and retaining information, and a significant improvement over a passive lecture series organized by MOA. The new format increased fellows' confidence and abilities in managing cancer-directed therapies, and improved perceived skills related to interdisciplinary patient care. This curriculum could serve as a model for implementation at HO fellowship programs in other institutions. Research Sponsor: None.

Pre- and post-intervention survey results.

Pre-survey statement	% Agree, n/total
I did not retain a significant amount from the lectures	63%, 7/11
I did not find the format conducive to learning	73%, 8/11
I would prefer a case-based approach	91%, 10/11
Post-survey statement	
The new format is conducive to my learning	94%, 16/17
The interdisciplinary format enhanced my learning	94%, 16/17
The lectures increased my confidence in prescribing/ managing therapies	88%, 15/17
The lectures improved my ability to discuss treatment options with patients/other providers	71%, 12/17

9029 **Poster Session**

Applying learning science principles (LSP) through a simulation session (SIM) for oncology trainees (OT) about fertility preservation (FP) in patients (pts) with cancer and treatment (tx) of pregnant pts (TPP) with cancer. First Author: Tanmayi Pai, Mayo Clinic, Jacksonville, FL

Background: Addressing guideline concordant FP and TPP with cancer is challenging, especially for OT. SIM, a well-known education tool, has not been traditionally used to teach these topics. As part of the hematology/oncology fellowship curriculum, we designed a SIM applying LSP to bridge this educational gap. **Methods:** Applying LSP of contrasting cases, elaboration, feedback, generation and just-in-time telling, chief OTs and faculty designed a SIM with 3 clinical scenarios (CS) and 3 standardized pts (SP): FP for a female pt hospitalized for acute lymphoblastic leukemia tx, FP for a male pt in clinic for germ cell tumor tx, and breast cancer tx for a pregnant pt in 2nd trimester. OT received written educational materials (WEM) and attended a lecture 1 week and 1 day pre SIM, respectively. OT were split into 2 groups; 1 started in the FP CS and 1 in the TPP CS, and then they switched. To reduce cognitive overload, each OT participated in 1 of 2 FP CS: half in the female FP CS and half in the male. Faculty and chiefs led debriefing sessions after all CS. The FP debrief ended with a special "learner as a teacher" part, where OT who attended the female CS taught those from the male CS about their topic and vice versa. The SIM concluded with "take-home" points. Pre (after having WEM) and post SIM anonymous surveys and verbal feedback assessed OT comfort, perceptions, and knowledge. **Results:** A 3 hour SIM with 14 OT and 5 faculty was completed successfully. SIM ended with all OT verbally sharing a learning point and positive feedback. All OT filled pre and post SIM surveys. Pre SIM, 17% reported having prior FP education, and 42% had prior TPP education. However, only 8% and 25% felt adequately prepared for FP and TPP discussions, respectively. Post SIM survey showed major improvement in comfort and knowledge about FP and TPP (see table 1). 75% of OT favored a combination of SIM and learning by teaching over other SIM formats. 83% supported having a TPP lecture before SIM. 100% reported satisfaction with FP and TPP SIM's quality and wanted similar activities in the future. 92% were satisfied with the learner as a teacher tool. 100% felt education about FP and TPP with cancer should be part of fellowship training. Moral/cultural concerns were discussed as possible challenges in FP education. **Conclusions:** The application of LSP through SIM significantly increased OTs' comfort discussing FP and TPP with cancer, and objectively enhanced their knowledge on these topics compared to after reading WEM. The SIM was largely perceived as a successful activity to educate about challenging topics and should become part of fellowship curriculum. Research Sponsor: None.

	Pre SIM %	Post SIM %
Comfortable addressing FP	17	92
Comfortable addressing TPP	8	100
Correct answers about female FP	63	83
Correct answers about male FP	67	94
Correct answers about TPP with cancer	68	98

9030 **Poster Session**

Linking comfort levels and knowledge gaps in hematology/oncology (HO) fellowship education: Insights from a multicenter survey. First Author: Ronak Mistry, Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA

Background: HO fellowship programs lack standardized educational approaches. This can impact learning & self-assessment of learning gaps. This study investigates the relationship between HO fellows' (HOF) comfort levels & objective knowledge assessments across diverse HO topics, addressing a critical need for data in this area. **Methods:** HOF from 27 U.S. programs were invited to complete an anonymous survey (Sept-Oct 2023) in which they rated their comfort managing representative HO diseases, namely breast cancer (BC), plasma cell dyscrasias (PCD), hemophilia, von Willebrand disease (vWD), & heparin-induced thrombocytopenia (HIT), on a 7-point Likert scale (1 = extremely uncomfortable, 7 = extremely comfortable). An optional multiple choice knowledge quiz on these topics followed, including an option for "not sure & need to look it up." Fellows were categorized into low (1–3), moderate (4–5), & high (6–7) comfort groups. One-way ANOVA assessed differences in knowledge scores by comfort levels. **Results:** In total,222 HOF completed the comfort survey (53% response rate): 82 PGY4 (37%), 72 PGY5 (32%), & 69 PGY6+ (31%). Also, 189 HOF completed the knowledge quiz (46% response rate): 71 PGY4 (38%), 57 PGY5 (30%), & 60 PGY6+ (31%). Mean comfort levels ($\pm$SD) were: BC diagnosis 4.8$\pm$1.4, localized BC management (mgmt.) 4.2$\pm$1.5, metastatic BC mgmt. 4.2$\pm$1.5, PCD diagnosis 4.8$\pm$1.4, MGUS/smoldering myeloma mgmt. 4.7$\pm$1.4, front-line myeloma treatment 4.5$\pm$1.6, maintenance myeloma treatment 4.1$\pm$1.5, inherited/acquired hemophilia mgmt. 3.7$\pm$1.5, vWD diagnosis 4$\pm$1.4, vWD mgmt. 3.8$\pm$1.4, HIT diagnosis 5.4$\pm$1.1, & HIT mgmt. 5.4$\pm$1.1. Mean knowledge scores were 41% for BC, 39% for PCD, 47% for hemophilia, 33% for vWD, & 51% for HIT. When evaluated by comfort level groups (low, medium, & high), knowledge scores increased significantly with higher comfort levels for BC (25%, 43%, 55%; $p<0.01$), PCD (25%, 38%, 51%; $p<0.01$), hemophilia (29%, 55%, 77%; $p<0.01$), & vWD (13%, 39%, 62%; $p<0.01$). HIT scores showed no significant difference by comfort levels (p=0.89). The number of "not sure" responses (%) significantly decreased ($p<0.01$) with greater comfort across topics: BC (53%, 20%, 10%), PCD (39%, 23%, 7%), hemophilia (52%, 28%, 2%), vWD (69%, 40%, 12%). HIT "not sure" responses showed no significant difference by comfort levels. **Conclusions:** This multicenter analysis demonstrates a correlation between HOF comfort levels & knowledge assessments. Despite overall low performance on knowledge tests, comfort levels effectively discriminated between knowledge groups, underscoring their potential utility as a surrogate for educational progress. These data highlight the need for interventions to bridge gaps between perceived & actual knowledge. Future studies to validate these results across broader topics & institutions to inform optimal education strategies in HO training programs are needed. Research Sponsor: None.

Enhancing bereavement education and emotional preparedness: A global survey of oncology residency programs. First Author: Giusti Raffaele, Medical Oncology Unit, Sant'Andrea Hospital of Rome, Rome, Italy

Background: Bereavement care is a vital yet underemphasized aspect of oncology, requiring both clinical expertise and emotional resilience. Despite its importance, bereavement training is rarely integrated into residency programs, leaving residents unprepared and at risk of emotional fatigue and burnout. Addressing this gap is critical to improving caregiver support and resident well-being. This study evaluates the global state of bereavement training, its impact on preparedness, and the need for tailored interventions. **Methods:** A cross-sectional survey was conducted among 115 oncology residents from 21 countries. The survey included questions on demographics, bereavement training, interactions with grieving caregivers, preparedness, barriers, and interest in education. Descriptive statistics summarized the data, chi-square tests evaluated associations between training and preparedness, and correlation analysis assessed the relationship between caregiver interaction frequency and preparedness. **Results:** Participants were 58% female and 42% male. Most worked in academic hospitals (53%), followed by the public (44%) and private centers (3%). Residents represented 21 countries, with Italy contributing 61% of responses. Other countries included the UK, Pakistan, Romania, Kenya, Portugal, Bosnia, Saudi Arabia, Germany, Malaysia, Ukraine, Ireland, Russia, France, Egypt, Turkey, Australia, Iraq, Yemen, Georgia, and Norway. Bereavement training was absent for 80% of participants. Preparedness levels were rated as "Somewhat prepared" by 44.3%, "Not very prepared" by 43.5%, "Not at all prepared" by 8.7%, and "Very prepared" by 3.5%. Barriers included emotional fatigue (62%), lack of training (48%), and time constraints (41%). Emotional distress was common, with 61% reporting occasional impact, 33% deep impact, and 38% considering leaving residency due to emotional demands. Residents with formal training declared significantly higher preparedness (χ^2 = 13.83, p = 0.003). A weak positive correlation (r = 0.19) was found between caregiver interaction frequency and preparedness. **Conclusions:** Oncology residents face significant challenges in bereavement care due to insufficient training, high emotional demands, and systemic barriers like time constraints. The finding that 38% considered leaving residency underscores the emotional toll of inadequate preparation. Integrating bereavement training into oncology curricula is essential to enhance confidence, resilience, and caregiver support. Training should address grief management, pathological bereavement, and communication skills. Experiential learning, such as mentorship and reflective practices, can further improve preparedness. These interventions aim to meet residents' emotional and professional needs while enhancing patient and caregiver outcomes. Research Sponsor: None.

Evaluation of NCI Designated Cancer Centers medical student education and training initiatives. First Author: Ana I. Velazquez Manana, University of California, San Francisco, San Francisco, CA

Background: The rising incidence of common cancers, an aging oncology workforce, and workforce shortages underscore the importance of medical education in oncology. However, U.S. medical students report that cancer education is underemphasized in their curriculum, and non-surgical oncology clerkships are infrequently required. Providing medical students with exposure to cancer care and research is crucial for encouraging them to pursue careers in oncology. This study evaluates the current landscape of medical student education and training initiatives at National Cancer Institute-designated cancer centers (NCIDCCs). **Methods:** In January 2025, we conducted a qualitative evaluation of the education and training webpages of NCIDCCs. Each webpage was reviewed to identify programs and training opportunities available to medical students. Programs specifically designed for medical students, as well as those for which medical students are eligible, were included. Data were summarized using descriptive statistics. **Results:** Of the 72 NCIDCCs, 71 had evaluable education and training webpages. The majority (n = 63, 89%) listed at least one education, training, or professional development initiative for medical students. Five institutions offered more than five programs for medical students. Most NCIDCC medical student initiatives focused on research training, with the most common opportunities being summer research fellowships, Medical Scientist Training Programs (MSTP), and travel awards. Only a few NCIDCCs listed clinical electives or internships among their offerings. Additionally, only 14 (20%) NCIDCCs advertised medical student programs focused on students from diverse backgrounds. **Conclusions:** Expanding cancer education and training in medical school is essential to addressing the growing need for an oncology workforce. While multiple research training opportunities exist at NCIDCCs, few cancer centers offer clinical electives or internships that provide medical students with direct exposure to clinical cancer care. Our analysis is limited to publicly available webpage listings; as a next step, we will conduct a survey of NCIDCC offices of education and training to further evaluate medical student initiatives. Given their multidisciplinary focus and integration of research with clinical care, NCIDCCs are uniquely positioned to develop and train the next generation of oncologists and clinical researchers through enhanced oncology education and training programs for medical students. Research Sponsor: None.

Advancing gender-responsive cancer control: A mixed methods evaluation of the leadership program for women in oncology. First Author: Meritxell Mallafré-Larrosa, City Cancer Challenge Foundation, Geneva, Switzerland

Background: Women constitute nearly 70% of the global health and social workforce but hold only 25% of senior leadership roles. Increasing women's representation in leadership is essential to addressing global health challenges and delivering equitable solutions. Leadership programs for women in healthcare enhance skills, confidence, and career progression. The Leadership Program for Women in Oncology (LPWO), developed by City Cancer Challenge (C/Can) in partnership with the American Society of Clinical Oncology (ASCO), aims to empower mid-career women oncologists in C/Can cities to lead transformative cancer care improvements. Combining in-person and virtual training, networking, and mentorship, the LPWO's first cohort was evaluated to assess its impact on participants, institutions, and communities. **Methods:** Data were collected through surveys and key informant interviews (KIIs) with the 10 program participants from diverse geographic and professional backgrounds. Surveys, conducted at five time points, assessed knowledge across 11 leadership domains. Descriptive and inferential statistical analyses were used to evaluate changes over time. **Results:** Significant improvements were observed across all leadership domains, with mean scores increasing ($p<0.05$). KIIs revealed broader impacts, including strengthened team dynamics, strategic institutional involvement, and community engagement. Participants emphasized mentorship and coaching as a cornerstone of the program, fostering professional growth, project development, and connections with global experts. **Conclusions:** The LPWO demonstrates the potential of targeted leadership programs to drive systemic change. By equipping women oncologists with essential leadership skills, it enables them to advance institutional practices and reduce health disparities. Furthermore, the LPWO plays a critical role in fostering gender-responsive health systems by empowering women leaders to advocate for equitable and inclusive cancer care. Continued investment in similar initiatives, paired with rigorous evaluation, is critical for achieving sustainable global health outcomes. Research Sponsor: None.

Board certification practices of US hematologists and oncologists. First Author: Austin Wesevich, University of Chicago, Chicago, IL

Background: United States (US) fellowship programs train physicians in both hematology and medical oncology (HO), yet fellows often focus on only one of these specialties. Historically, single-subspecialty boarding has been viewed as a feasible career pathway for medical oncologists pursuing academic careers; single-boarding in hematology was uncommon while dual-boarding was favored for clinical practice. Real-world HO board certification practices and how these partition with career pathways are presently unknown. **Methods:** We linked Centers for Medicare & Medicaid Services (CMS) and American Board of Internal Medicine (ABIM) publicly available data to describe the credentialing practices of all US HO who billed Medicare Part B in 2022. Physicians were single-boarded (only obtained hematology or oncology certification) or double-boarded. Current position was dichotomized per CMS as teaching versus non-teaching hospital and metropolitan versus non-metropolitan per rural-urban commuting area codes (1-3 vs 4-10). Researchers had non-federal research funding in 2022 per CMS Open Payments while clinicians did not. **Results:** Of 12,394 physicians, 32% single-boarded in oncology, 3% single-boarded in hematology, and 64% double-boarded. Single-boarded hematologists were more frequently employed at teaching hospitals in metropolitan areas (Table). Researchers or those who graduated from a top 20 ranked medical school were more frequently single-boarded. Maintenance of certification was most common for those who initially double-boarded and least common for those who single-boarded in hematology. Physicians who maintained both boards or only oncology boards were most frequently clinicians at teaching hospitals while those who only maintained hematology boards were most frequently researchers at teaching hospitals. **Conclusions:** Over one-third of US HO fellowship graduates single board, with single-boarding in oncology being 10x more common than single-boarding in hematology. Single-boarded hematologists were more likely to work at teaching hospitals than single-boarded oncologists or dual-boarded physicians. Consideration could be given to tailoring US HO fellowship training requirements to more appropriately fit the interests and career pathways of HO fellows. Research Sponsor: None.

Physician characteristics by initial ABIM hematology/oncology credentialing.

Characteristic	Oncology Single-Board, n=4,012	Hematology Single-Board, n=400	Hem/Onc Double-Board, n=7,982	p-value
Female gender	1,402 (35%)	13 (34%)	2,878 (36%)	0.38
Years Since Medical School Graduation (SD)	28.8 (11.9)	29.8 (14.7)	25.0 (11.0)	<0.001
Top 20 Medical School	641 (16%)	57 (14%)	645 (8%)	<0.001
Teaching Hospital	3,317 (83%)	361 (90%)	6,549 (82%)	<0.001
Metropolitan Area	3,777 (94%)	388 (97%)	7,508 (94%)	0.04
Non-Federal Research Funds	1,586 (40%)	156 (39%)	2,602 (33%)	<0.001
Maintenance of Certification	2,859 (71%)	252 (63%)	6,450 (81%)	<0.001

Exploring DORIS: A cancer-focused AI knowledge platform for diagnosis and treatment information. First Author: Joseph Monforte, Wild Type Advocates, Lincolnshire, IL

Background: Clinicians in oncology have high demands on their time due to lack of sufficient staffing, leading to the need to work additional hours outside of practice, "pajama time", and high levels of stress. Key approaches to improving the situation for clinicians include: (a) increasing staffing and resources, (b) improved teamwork, (c) utilization of ambient AI for notetaking, and (d) the use of AI assistants for medical knowledge access and interpretation. We're focused on (d). Regarding the use of AI assistants, our informal survey of oncology fellows and attendees has revealed that over 90% of them are using a general AI chat tool to help them find key medical information. The use of a general AI chat tool is problematic since there is no medical review or curation, leading to errors and gaps in the information provided. **Methods:** Our team has built an alternative to general AI chat, called DORIS (Dynamic Oncology Reference Information System). The DORIS for breast cancer prototype was built in alignment with ASCO's Guiding Principals for AI, and targets easy access to information around 5 pillars of medical knowledge needed for cancer care: molecular biomarkers, diagnostic testing, treatment pathways, drug-drug comparison, and clinical trial search. The system uses a Large Language Model (LLM) to facilitate access to a carefully curated set of medical documents covering the 5 pillars, including treatment pathways (with digitization of flow diagram logic), FDA, NIH and other publicly accessible datasets. To be accurate, the curation of DORIS' knowledgebase needs to be kept up-to-date, while removing out-of-date information (something general AI platforms don't do). To further increase the ease of use, DORIS includes different approaches to query for information while also using its embedded intelligence to suggest follow up questions. **Results:** Medical review of DORIS is ongoing. Early errors were identified related to omissions from curation. Other errors occurred due to bugs within the LLM, e.g. the responses suddenly shifted to Spanish. The reference materials have been expanded to reduce omissions and code implemented to double check responses from the LLM. We are on target for onboarding over 250 users for the early access program. **Conclusions:** Early user feedback has been positive with regards to relevance and utility. We will report on the first 6 months of use of this prototype platform, providing multiple metrics on how it is being used, and an analysis of user feedback on the value of the tool. Research Sponsor: Bridgewest Ventures New Zealand; Callaghan Innovation - Government of New Zealand.

The value of observerships abroad: Lessons from UA-MED supporting Ukrainian cancer care during the war. First Author: Nataliya Kovalchuk, Stanford University, Help Ukraine Group, Stanford, CA

Background: This study evaluates the influence of international observerships organized by the coalition of healthcare professionals from academic institutions - the Ukrainian Alliance for Medical Exchange and Development (UA-MED) - on the professional development, knowledge transfer, and clinical practice improvement of Ukrainian oncology professionals during the war. **Methods:** A total of 126 international observerships were facilitated for various Ukrainian medical professionals across 17 participating institutions the US, Canada, Europe, and Australia. A survey was administered to assess the impact of observerships on oncology care in Ukraine, focusing on procedural knowledge gained, lessons learned, and challenges faced when implementing new techniques upon return. **Results:** Eighty-six respondents participated in the survey. Seventy-three percent of respondents were oncology professionals, including 30.1% radiation oncologists, 31.7% surgeons, 15.9% medical oncologists, and 14% medical physicists. The median duration of the observerships was 4 weeks with 79.7% observers attending a professional conference. The average satisfaction score for the observerships was 9.6 $\pm$ 0.7 out of 10. Importantly, 93% of respondents reported a shift in their perception of how to practice medicine, 90% learned new procedures and techniques, and 71.2% implemented these new procedures upon returning to Ukraine. However, despite this progress, significant barriers to implementation were encountered, including lack of material resources (70.7%), human resources (43.1%), and support from department leadership (43.1%) and colleagues (32.8%). Encouraged to disseminate their knowledge, participants provided informal training to colleagues (78.0%), prepared presentations for their institutions (69.5%), national conferences (44.1%), and incorporated learned materials into educational lectures (49.2%). Notably, 83.0% of participants maintained ongoing mentorship contact with their training institutions. Key institutional advancements included transition from Co-60 to linear accelerators at few centers, the launch of an allogeneic bone marrow transplant program, and the development of educational programs across various specialties. Participants emphasized improved confidence in their clinical decision-making and highlighted the value of multidisciplinary team approaches they observed abroad. **Conclusions:** The international observerships played a crucial role in enhancing the skills and knowledge of Ukrainian cancer care professionals during the war. Despite the ongoing conflict, significant improvements were made in clinical practice, medical education, and the implementation of new procedures. The success of these observerships underscores the potential for similar programs to be replicated in other LMICs/UMICs. Research Sponsor: None.

Dissecting publication timelines: Insights from high-impact oncology journals. First Author: Abdulmalek Aljafari, Brody School of Medicine at East Carolina University, Greenville, NC

Background: Efficient dissemination of research findings is critical in oncology, where timely access to new knowledge impacts clinical care and outcomes. This study analyzes publication timelines of high-impact oncology journals to identify patterns and determinants, including research categories and study designs. **Methods:** This is a retrospective observational study. Journals with the highest impact factors and available publication timeline data were included: *Journal of Clinical Oncology, Molecular Cancer, Clinical Cancer Research,* and *Cancer Discovery*. All articles published in 2023 were analyzed for submission-to-acceptance, acceptance-to-publication, and total publication times. Data were processed using SPSS, and statistical comparisons were made with the Kruskal-Wallis test (significance: $p<0.05$). **Results:** A total of 875 articles were analyzed. The overall median total publication time (TT) was 7.1 months (IQR: 5.7–8.9), with submission-to-acceptance (AT) and acceptance-to-publication (PT) medians of 4.8 months (IQR: 3.5–6.3) and 2.2 months (IQR: 1.6–2.6), respectively. Among journals, *Molecular Cancer* exhibited the shortest TT (median: 4.7 months; IQR: 3.1–6.6), while *Cancer Discovery* had the longest TT (median: 8.8 months; IQR: 6.8–10.6). Similarly, *Molecular Cancer* achieved the fastest AT (median: 3.9 months; IQR: 2.2–5.4) and PT (median: 0.6 months; IQR: 0.4–1.1). Conversely, *Cancer Discovery* recorded the slowest AT (median: 6.0 months; IQR: 4.5–7.8) and PT (median: 2.8 months; IQR: 2.4–3.2). In terms of research categories, blood cancer articles accounted for the largest proportion of publications (14.4%), followed by gastrointestinal cancer (13.9%). Articles in genitourinary (median TT: 6.4 months; IQR: 5.5–8.8) and cardiac cancer (median TT: 6.5 months; IQR: 5.9–6.9) categories had the shortest TT, while endocrine (median TT: 7.9 months; IQR: 5.6–10.9) and immunotherapy (median TT: 9.1 months; IQR: 6.8–10.5) categories exhibited the longest TT ($p<0.05$). Clinical trials were the most common study design (37.6%), followed by cross-sectional studies (19.5%). Systematic reviews had the shortest TT (median: 2.4 months; IQR: 1.9–9.2), while proof-of-concept studies required the longest TT (median: 9.5 months; IQR: 8.7–10.7) ($p<0.05$). Systematic reviews and database studies also had the shortest PT (median: 1.5 months), whereas proof-of-concept studies had the longest PT (median: 2.8 months; $p<0.001$). **Conclusions:** Publication timelines in oncology journals vary significantly by journal, research category, and study design. *Molecular Cancer* demonstrates the fastest publication processes, while *Cancer Discovery* exhibits the slowest. Genitourinary and dermatologic oncology categories, as well as systematic reviews, achieve the most expedited timelines, emphasizing the need to consider category and study design in publication planning. Research Sponsor: None.

The evolving landscape of academic and industry partnerships in gynecologic oncology clinical trials. First Author: Kevin Ji Li, Geisel School of Medicine at Dartmouth, Hanover, NH

Background: To determine trends in the financial relationships of study investigators in gynecologic oncology trials. **Methods:** From 2011-2024, phase III trials were identified from clinicaltrials.gov. Data was collected from the conflict-of-interest (COI) statements of 54 clinical trials. Chi-square and Fisher's exact tests were used for statistical analysis. **Results:** Of1,390 total co-authors from 54 clinical trial publications, we found that 46.3% of authors were from European nations, 28.3% were based in the United States, and 16.9% were from East Asian nations, with the remaining 8.5% from other nations (including, but not limited to, Australia, Canada, and Mexico). Of the listed authors' titles, 82.8% held MDs and 17.2% held non-MD degrees (PHD, MPH, MSc). Most (74.0%) of the trials were on ovarian cancer, with the remainder being on cervical (13.0%) and endometrial (13.0%) cancer. The majority (79.5%) of trials were sponsored by pharmaceutical companies, while the remainder were academic/cooperative-led trials. Among the pharmaceutical and industry sponsors, Roche / Genentech sponsored the most trials (27.8%), followed by Merck Sharp & Dohme (16.7%) and AstraZeneca (14.8%). Overall, 61.8% of total authors had some form of COI; of the total authors, 40.9% were consultants, 29.1% received research funding, 9.6% attended speaker bureaus, 18.6% received travel funds, and 9.8% declared employment/stock ownership. In all trials, the majority of authors disclosed COI regardless of if the trial was pharmaceutical or cooperative-led, at 63.5% and 55.2%, respectively. To evaluate trends, we divided the data into three time periods, 2011-2015, 2016-2019, and 2020-2024. Over time, there was a statistically significant increase in the number of authors who were consultants: 27% to 40% to 44% ($p<0.001$); who received research funding: 16% to 25% to 33% ($p<0.0001$); and who received travel funds: 8% to 19% to 20% ($p<0.01$). There was no change in speaker bureau participation (p=0.63) or employment/stock ownership (p=0.20). **Conclusions:** Financial relationships between study investigators and pharmaceutical companies have increased, particularly in consulting and research funding. As industry involvement grows, academic cooperative groups should maintain close collaboration to ensure scientific integrity and guide trial design. Research Sponsor: None.

Addressing gender disparities in oncology and hematology education: Insights from social media engagement analysis. First Author: Viviana Cortiana, University of Bologna, Bologna, Italy

Background: Gender disparities in professional visibility pose significant challenges to equity in oncology and hematology education. Women represent only 34% of speakers at major oncology conferences and author just 37% of high-impact oncology publications. MedNews Week (MNW), a global platform dedicated to combating medical misinformation and fostering inclusivity, aims to address these gaps by amplifying diverse voices and promoting equitable professional representation. This study analyzed speaker engagement data to identify visibility disparities and propose actionable strategies to enhance representation in oncology and hematology education. **Methods:** MNW hosted 20 speakers during Years 2 and 3 of its programming. Social media engagement metrics were collected and analyzed for male and female speakers across five platforms: Twitter, LinkedIn, Instagram, YouTube, and TikTok. Metrics included average engagements per post (likes, shares, comments) and overall engagement trends. Gender-specific differences in engagement were evaluated using statistical analyses, including independent t-tests, to determine significance. Data were normalized to account for variations in platform algorithms and audience size. **Results:** Male speakers achieved nearly three times the total engagement of female speakers, averaging 123,745 engagements per event compared to 41,133 for females, a difference representing approximately 75% of total engagement by males. A t-test demonstrated a highly significant disparity in engagement levels ($t = -14.01$, $p = 3.48 \times 10^{-16}$). Twitter emerged as the dominant platform for both genders, with male speakers averaging 46,870 engagements, compared to 37,717 for females. However, female speakers excelled on TikTok (94 average engagements, with no male presence) and achieved near parity on LinkedIn (2,849 vs. 2,901). YouTube engagement favored females, with an average of 85 versus 61 for males. **Conclusions:** Male speakers demonstrated significantly higher overall engagement; however, female speakers achieved parity, or even outperformed, on emerging platforms like TikTok and YouTube. These findings underscore persistent challenges to achieving gender equity while also highlighting the potential of innovative platforms to amplify underrepresented voices. This analysis reinforces the need for targeted strategies, such as leveraging emerging platforms and expanding professional visibility initiatives, to enhance inclusivity and equity in oncology and hematology education. Research Sponsor: None.

Engagement metrics across social media platforms for speakers.

Platform	Female Engagement (Average)	Male Engagement (Average)	Difference
Twitter	37,717	46,870	24.3% higher (male)
LinkedIn	2,849	2,901	1.9% higher (male)
Instagram	203	279	37.0% higher (male)
TikTok	94	0	Female only
YouTube	85	61	39.4% higher (female)

Harnessing social media for cancer prevention and early detection: Challenges, opportunities, and pathways to equity. First Author: Viviana Cortiana, University of Bologna, Bologna, Italy

Background: Social media is a valuable tool for cancer prevention and early detection but faces challenges like gender disparities, misinformation, and minority underrepresentation. Women receive 28% fewer views and 41% less engagement than men, while most cancer screening content on YouTube and TikTok is low quality and contains misinformation. MedNews Week (MNW), a global education platform, addresses these issues by promoting accurate and inclusive digital health communication. This study assesses engagement and platform effectiveness to improve cancer communication strategies. **Methods:** A systematic review of 225 articles from PubMed, supplemented by MedNews Week (MNW) outreach data, was conducted to evaluate the role of social media in cancer prevention and early detection. Metrics analyzed included platform effectiveness, engagement trends, content themes, and challenges related to misinformation and representation. **Results:** Twitter, utilized in 57% of studies, was effective in facilitating cancer prevention discussions. Breast cancer dominated interventions at 52%, while colorectal and lung cancers were underrepresented. Content quality was a concern, with 98% of YouTube and 100% of TikTok videos on prostate cancer screening rated low to moderate. Additionally, 88% of YouTube and all TikTok videos contained moderate to high misinformation. Representation gaps showed African American and Hispanic populations featured in only 10% and 6% of YouTube videos, and 20% and 12% of TikTok videos. Discussions of high-risk groups appeared in 46% of YouTube but just 8% of TikTok videos. Promising misinformation detection methods included linguistic models analyzing Twitter posts, achieving a macro F1 score of 79.7 for predicting unreliable information. **Conclusions:** Social media has great potential to improve cancer awareness, prevention, and early detection but is hindered by misinformation, lack of inclusivity, and inconsistent content quality. Overcoming these challenges requires platform-specific strategies, collaboration with healthcare entities and influencers, and a focus on diverse representation. MNW's efforts demonstrate the importance of providing reliable, inclusive health information to reduce disparities and promote equitable digital health communication. Research Sponsor: None.

Metrics of social media engagement for cancer awareness and detection.

Platform	Primary Use	Representation Gaps	Content Quality	Misinformation Levels	Engagement
Twitter	Prevention	N/A	N/A	N/A	Effective
YouTube	Prostate cancer screening	Black: 10%, Hispanic: 6%	98% low to moderate	88% moderate to high	Limited
TikTok	Emerging platform	Black: 20%, Hispanic: 12%	100% low to moderate	100% moderate to high	Minimal
LinkedIn	Professional engagement	N/A	N/A	N/A	Gender parity
Instagram	Awareness	N/A	N/A	N/A	Effective

Empowering medical oncologists: Exploring the impact and engagement of telegram channels for professional development in Russia. First Author: Anastasia Danilova, Moscow City Oncology Hospital 62, Moscow, Russian Federation

Background: Social media use has gained popularity among medical professionals, with X being one of the most popular platforms globally by medical oncologists. Physicians worldwide use it for conference communication, sharing scientific articles, breaking geographical barriers, and engaging with peers globally. Recently, there has been increasing interest in leveraging former Twitter as an educational tool among medical oncologists, proving effective for accessing the latest news and sharing opinions. However, lot of social networks are unavailable in Russia, prompting a surge in interest in other social media platforms. Over the past three years, numerous Professional Medical Channels have emerged on Telegram, a popular platform among Russian speakers worldwide. Here, we describe the extensive use, engagement, and professional impact within the medical oncology community utilizing these educational channels. **Methods:** We analyzed Medical Oncology Telegram Channels with over 2 thousand followers. The authors (all practicing oncologists) share conference news, conduct tumor boards, clinical cases and other high yield educational materials. Ensuring the authors' credibility as established physicians in the oncology community, we analyzed engagement metrics, follower counts, and conducted an online survey among users to assess the channels' impact on daily medical practice. We present the results of this analysis. **Results:** We analyzed Telegram medical oncology channels with over 2 thousand followers, averaging 6,354 followers each. The average post reached 2,260 users, with 53% of followers engaging with posts. The online survey comprised 338 medical professionals, including practicing medical oncologists (41%), community-based oncologists (11.5%), surgical oncologists (19.6%), oncology residents (19.6%), medical students (9%), and other medical professions. Most respondents (95%) were based in Russia, with smaller percentages from Belarus, Kazakhstan, Uzbekistan, and Israel. When asked about the channels' impact on daily clinical practice, 33% reported significant changes, 50.6% reported slight changes, and 16.3% noticed no change. Additionally, 87.6% felt more confident in treatment choices due to shared information. Respondents also noted increased job satisfaction and support in combating physician burnout, with 83.3% expressing a sense of community and support through these channels. **Conclusions:** Telegram channels are gaining traction among Russian-speaking medical professionals, offering a new avenue for sharing medical updates, conference coverage, exchanging ideas, and fostering community. Especially during challenging times, such support is crucial. Further research is warranted to explore how social media engagement can enhance professional development among Russian-speaking medical oncologists. Research Sponsor: None.

The bubble effect: Impact of ASCO digital promotion on *Journal of Clinical Oncology* (*JCO*) download metrics (2023). First Author: Oyepeju Folashade Abioye, Allegheny Health Network, Pittsburgh, PA

Background: The impact of digital promotion on scientific article metrics remains debated. This study examined how ASCO's digital promotion via Twitter (X) and podcasts influenced download rates for articles published in the Journal of Clinical Oncology (JCO) between January and December 2023. **Methods:** We conducted a retrospective review of articles published in print between January and December 2023 in JCO. Monthly download numbers from each article's month of publication till November 2024 were collected from the official JCO webpage. Promotions by the JCO Twitter (X) account (@JCO_ASCO) and JCO Podcasts - *JCO Cancer Stories: Art of Oncology Podcast* and *ASCO Guidelines Podcast* were tracked. Articles with print dates post-December 2023, those without print dates, and manuscript categories including Correspondence, Errata, Retractions, and Acknowledgments, were excluded. To evaluate the association between monthly downloads and digital promotion, multivariable mixed-effects Poisson regression models were employed. Articles were treated as random effects, while digital promotion and months since publication were treated as time-varying covariates. Free access options were included as fixed effects. Monthly rate ratios per unit change in each covariate, with corresponding 95% confidence intervals (CI) were used to summarize associations. **Results:** In total, 563 articles, of which 297 were original reports were analyzed. Digital promotion and free access significantly increased download rates. Articles promoted via official tweets experienced a 27.6% increase in download rates, while those featured in podcasts saw a more modest but still significant increase of 9.2%. When focusing on original reports, podcast promotion had a greater relative impact, with a 19.1% increase in downloads (Table 1). **Conclusions:** Digital promotion of scientific articles via Twitter (X) and Podcasts significantly boosts downloads. However, interpreting the impact of free access is challenging due to incomplete data on when articles became freely accessible. Future studies should address these limitations and explore broader metrics such as citation counts, journal impact factors, and author H-indices to better understand the influence of digital promotion on scientific dissemination. Research Sponsor: None.

Multivariable analysis of digital promotion and monthly paper downloads - eligible papers vs Original Reports only.

Variable*	ELIGIBLE PAPERS (N=563) Rate ratio (95%CI; p-value)	ORIGINAL REPORTS ONLY (N=297) Rate ratio (95%CI; p-value)
Official tweet (Yes vs. No)	1.276 (1.270, 1.281; p<0.001)	1.128 (1.121, 1.135; p<0.001)
Official podcast (Yes vs. No)	1.092 (1.084, 1.100; p<0.001)	1.191 (1.180, 1.202; p<0.001)
Open/free/partial access (Yes vs. No)	3.706 (2.766, 4.965; p<0.001)	1.411 (0.331, 6.020; p=0.642)

*Months since online publication and papers were included in the model for adjustment.

Racial, ethnic, sex, and subspecialty demographic composition of initial fellow of the Fellow of the American Society of Clinical Oncology (FASCO) recipients through 2024. First Author: Victoria Shiqi Wu, Case Western Reserve University School of Medicine, Cleveland, OH

Background: Disparities in cancer care, including underrepresentation in the healthcare workforce, leadership, and recognition, remain a significant challenge. The Fellow of the American Society of Clinical Oncology (FASCO) designation honors individuals for their commitment to ASCO, the largest clinical oncology organization in the world. In 2022, the FASCO selection process transitioned to a more transparent, merit-based system requiring 100 points for FASCO designation. However, recipient demographics of FASCO recipients remain largely unexplored. **Methods:** All FASCO recipients through 2024 were identified and reviewed using publicly available data from the ASCO website, documenting name, degree, and award year. Providers with National Provider Identifiers were linked to Medicare Part B data. Race, ethnicity, sex, specialty, medical school graduation year, and fellowship graduation year were verified or determined through Medicare data and website reviews. Analyses included Pearson's chi-squared test, Fisher's exact test, and the Mann-Kendall trend test. **Results:** Among 644 FASCO recipients, 400 (62%) are male, 244 (38%) are female, 540 (84%) are White, 20 (3.1%) are Black, and 616 (96%) have non-Hispanic ethnicity. Medical oncologists constituted 512 (80%) of recipients, followed by 43 radiation oncologists (6.7%), 25 surgical oncologists (3.9%), and 64 (9.9%) from various specialties and professions, including pediatric and gynecological oncology, family practice, palliative care, radiology, urology, oral oncology, software engineering, non-profits, health policy, social work, research, and patient advocacy. The average time in practice before FASCO designation is 23 years. Between 2007 and 2024, FASCO awards increased significantly in both overall number and diversity, with non-White recipients rising from 16.1% to 22.7% ($p < 0.001$), Hispanic recipients from 4.3% to 13% ($p < 0.001$), and female recipients from 38% to 49% ($p = 0.003$). Following the 2022 selection change, recipient diversity improved, with 25.5% non-White recipients, 7.8% Hispanic recipients, and near gender parity achieved (122 men, 121 women, $p < 0.001$) from 2022 to 2024. **Conclusions:** In this first definitive review of FASCO recipients, nearly two-thirds of recipients are male, 84% are white, and 80% are medical oncologists. Over time, the diversity of recipients in terms of gender, race, and ethnicity has gradually improved, accelerated by the implementation of a more transparent, merit-based system in 2022. These changes in the FASCO selection process have significantly enhanced diversity among recipients, highlighting the critical role equitable and transparent practices play in promoting diversity and inclusion within professional organizations. Advancing gender equity in cancer research across north Africa: A comprehensive analysis of women's role and men's supportive efforts—Final findings from the GEORGiNA-1 study. First Author: Khalid El Bairi, Faculty of Medical Sciences, University Mohammed VI Polytechnic, Ben Guerir, Morocco

Background: Despite limited research on gender inequity in North Africa, this male-dominated region provides a unique context for exploring gender dynamics in academic oncology. The GEORGiNA-1 study (Gender Equity in Oncology Research Group in North Africa) examined the representation of female oncologists in publications, cancer societies, and editorial boards of peer-reviewed journals, while also evaluating the outcomes of a mentorship program aimed at supporting their professional development. **Methods:** An updated analysis of articles published from 2018 to 2022 was conducted. Data extraction was performed manually using a standardized template, capturing gender and publishing features. Gender representation was further evaluated in leadership roles within oncology societies, editorial boards of regional journals, and through a pilot men-led mentorship program aimed at supporting women in cancer research via training, project development, and academic publishing guidance. Factors associated with gender distribution were studied using Chi-squared and Fished Exact tests as well as logistic regression. **Results:** A total number of 7,774 publications including 6,142 original articles were analyzed. Females accounted for 50.7% of first authors position. There was a significantly higher percentage of females as first authors in Tunisia ($p<0.001$). In last author positions, male authors were more prevalent, accounting for 63.5% of publications. Male researchers were found to have significantly higher representation as principal investigators (PIs) ($p < 0.001$). Female first authors were significantly more likely to collaborate with female co-authors ($p < 0.001$). Similarly, when females held PI positions, there was a statistically significant increased number of female co-authors ($p < 0.001$) and female first authors as well ($p < 0.001$). Female first authors were found to publish significantly more original research ($p < 0.001$), but they published significantly less original research when holding PI positions ($p < 0.001$). Additionally, female PIs received significantly less funding ($p < 0.001$). The percentage of local female speakers at cancer meetings consistently outpaced that of male speakers. Male dominance was evident across most journals. Fifteen female mentees were selected for the mentorship program. Among those who achieved most of the program's goals (n=12), they produced significant outputs, including an edited book, original studies, reviews, conference abstracts, and multiple poster and oral presentations at oncology meetings. **Conclusions:** Although women in cancer research seem to hold a fair position in North Africa, barriers such as insufficient funding and limited international collaboration continue to hinder progress toward gender equity. Research Sponsor: None.

A multifactorial analysis of first-author retention in ASCO accepted works. First Author: Taha Huda, HCA Healthcare/USF Morsani College of Medicine GME: Bayonet Point Hospital, Hudson, FL

Background: Ensuring clinician oncologists remain engaged with research is an important step in maintaining optimal patient care in a rapidly changing field, and can be especially difficult for clinicians of marginalized groups. To identify trends in research engagement among oncologists, we performed a retrospective analysis on first-author retention in ASCO accepted works from 2019-2024, focusing on year presented, presentation type, and gender. **Methods:** Data from publicly available ASCO works from 2019 to 2024 were obtained from ASCO online materials, including first author (or speaker/chair) and presentation type (limited to education session, oral abstract, poster discussion session, poster session, and online-only ASCO meeting publication). Gender was identified by name using Namsor, a public web-tool. Names that could not be predicted by the web-tool were identified manually by physical presentation on institutional websites, if possible. An original script was created to identify first-author retention year-to-year, outputting the proportion of first authors found in both years and appropriate statistical tests. This analysis focused on comparing one-year retention (e.g. 2019-2020, 2020-2021, etc.). **Results:** We found that the period with the highest one-year first-author retention of all works was during 2022 to 2023, with 22% retention (985 of 4445 first-authors). First-author retention remained 20-22% for all other periods analyzed, except during 2023-2024 where retention decreased to 15% (806/5568; Two-proportion test comparing 2022-2023 and 2023-2024: $p < 0.001$). Focusing on specific presentation types, education sessions were found to have the lowest one-year retention, averaging 5.1%, as compared with poster sessions, which had the highest average one-year retention of 15.3% (Two-proportion test: $p < 0.001$). Looking at gender, we found that education sessions were the least male-prevalent, with an average of 49.6% retained speakers being male across all years. For oral abstracts, poster discussion sessions, and online-only publications, 53-54% of retained first-authors were male. Notably, first-author retention in poster sessions was much more male-prevalent, with an average of 62.7% of first-authors being male (Two-proportion test comparing male proportion in education and poster sessions: $p = 0.002$). Lastly, we found that five-year first-author retention of all works from 2019 to 2024 was significantly male-dominated, with 61% of those retained being male (267/437; one-proportion test $p < 0.001$). **Conclusions:** Trends of retention at a major oncology conference were identified, including recent decreases in retention, which could be due to a relative increase in first-time authors. The male prevalence in poster sessions and decrease in first-author retention of women over longer periods of time reveal specific areas to create more equitable opportunities for women in research. Research Sponsor: None.

TPS9046 **Poster Session**

A randomized controlled trial of high-fidelity simulation versus mentoring training for residents: ACACIAS 2. First Author: Elise Deluche, CHU Dupuytren, Limoges, France

Background: In medical oncology, the "know-how-to-be" aspect of training is crucial but often underemphasized in resident education. Typically, residents develop their interpersonal skills through direct patient interactions. The challenge lies in delivering cancer diagnoses with empathy and effectively managing the patient experience through advanced communication strategies. High-fidelity simulation training has proven effective in educating professionals, including those in surgical fields. Our previous feasibility studies established a simulation framework for cancer consultation processes. This study aims to demonstrate that high-fidelity simulation training provides greater benefits for residents compared to traditional mentoring by reducing perceived stress levels. **Methods:** ACACIA2 (*n° HDH :* F20221011092723) is a prospective, randomized, open-label, national, multicenter trial that aims to enroll 100 young doctors. After one high-fidelity simulation evaluation, they were randomly assigned (1:1) to have traditional mentoring (Arm A or control arm)+/- 2 sessions of high-fidelity simulation with theoretical training with a certified coach/actor (Arm B) during 6 months. This training adapted to the announcement has been validated in preliminary studies (ACACIA programme)(Figure 1). All the cases worked on in the sessions are taken from real life. Inclusion criteria include healthcare professionals aged 18 and older, actively participating in specialties where they frequently deliver cancer diagnoses, such as surgical and medical disciplines. The primary endpoint is to compare changes in stress levels between residents receiving simulation training and those undergoing conventional mentoring. Secondary objectives include assessing stress changes as measured by a coach/actor, evaluating self-assessed attitudes and skills during simulation sessions, comparing self-assessments before and after training, monitoring heart rate variability, exploring the relationship between skill development and heart rate changes, and assessing participant satisfaction. The first resident was enrolled in November 2022. Clinical trial information: F20221011092723. Research Sponsor: None.

TPS9047 **Poster Session**

Evaluating the use of educational videos in a medical oncology sarcoma clinic to improve patient knowledge and satisfaction. First Author: Fabio Murtas, Princess Margaret Hospital, Toronto, ON, Canada

Background: The first clinic visit is a pivotal step in the journey of a cancer patient (pt), often accompanied by anxiety due to future uncertainty. During this initial visit, pts receive extensive information regarding their diagnosis, treatment plan and prognosis. Early education and tailored guidance can potentially enhance understanding, aid decision-making, and alleviate distress. This study evaluates the impact of sarcoma-specific educational videos on improving pts' knowledge of their disease and treatment options *before their first clinic appointment*. Results will help to identify ways to enhance pt education and satisfaction. **Methods:** All newly diagnosed, English speaking, sarcoma pts referred to the sarcoma medical oncology clinic at Mount Sinai Hospital and Princess Margaret Cancer Centre will be eligible. The primary objective is to assess changes in pts' and caregivers' knowledge and perceptions of sarcoma and its treatment after educational intervention as measured by changes in global responses between baseline and post educational intervention surveys. Secondary endpoints include understandability and satisfaction with the educational videos, using validated tools including Pt Education Materials Assessment Tool (PEMAT) and Suitability Assessment of Materials (SAM) instrument. A pilot study (n = 20) will first be performed to assess feasibility, acceptability and determine sample size. For the interventional study, pts will be randomized in 1:1 ratio to either view the educational videos prior to their consult, or a control arm where they will receive standard of care information. Pts on the experimental arm will view four short educational videos (approximately 5-7 minutes each) which focus on 1) what to expect at their initial visit, 2) sarcoma team composition and respective roles, 3) systemic therapy overview and 4) introduction to clinical trials. The study will involve distribution of surveys at 3 different timepoints, each consisting of 15-20 multiple choice questions and taking 3-5 minutes to complete. The first baseline survey will be completed by pts in both arms before their initial consult and is designed to assess pts' initial knowledge and perceptions of their sarcoma and treatment options. The second survey, to be completed only by pts on the experimental arm after watching the educational videos, will measure changes in pts' perceptions and overall satisfaction. A third and final survey will be completed by pts in both arms after their initial consult with the medical oncologist to assess for any further changes. A knowledge quiz will also be given to the pts on the experimental arm both before and after they watch the educational videos to evaluate changes in their understanding of sarcoma and its management. If pts are accompanied by a caregiver, they will also be invited to participate in this study. Research Sponsor: None.

9502 **Oral Abstract Session**

Neoadjuvant-adjuvant pembrolizumab in clinical stage IIB/C melanoma. First Author: John Miura, University of Pennsylvania, Media, PA

Background: Neoadjuvant immune checkpoint therapy has shown improvement in event-free survival outcomes in patients with resectable clinical stage III and IV melanoma. Whether there is benefit to neoadjuvant immune therapy in patients with clinical stage IIB/C melanoma is unknown. **Methods:** In a single arm multicenter investigator-initiated phase 2 trial, patients with clinical stage IIB/C melanoma received a single dose of neoadjuvant pembrolizumab (200 mg intravenously) 3 weeks prior to wide excision and sentinel lymph node (SLN) biopsy followed by 1 year adjuvant pembrolizumab every 3 weeks or until unacceptable toxicity or disease progression. Primary endpoint was SLN positivity rate. A sample size of 63 patients had 80% power detect a 50% difference when compared to a predetermined historical SLN positivity rate in treatment naïve patients (25% Stage IIB and 40% Stage IIC) weighted by proportion of clinical tumor stage in eligible study patients. Secondary endpoint included recurrence-free survival. Safety outcomes, including overall toxicity and immune related adverse events, were also assessed. **Results:** Of 63 evaluable patients (33 IIB; 30 IIC at initial biopsy), the SLN metastasis rate in the neoadjuvant study group was 27%. 28 patients (44%) had residual primary tumor after single dose pembrolizumab; 4 patients had their primary tumors upstaged to IIC. Compared to a SLN metastasis rate in a historical treatment- naïve cohort based on tumor staging at wide excision (33.1%), there was a 18% reduction in SLN positivity rate in the neoadjuvant group, although this was not statistically significant (p = 0.302). In a subgroup analysis, stage IIC patients in the neoadjuvant study group had a SLN metastasis rate of 16.7% versus 40% (p = 0.009) based on initial biopsy and 23.5% versus 40% (p = 0.0499) based on primary tumor staging at wide excision. With median follow-up of 20.4 months, the 2-year recurrence free-survival in the study group was 84% with median time to recurrence (n = 10) of 9.9 months. Overall treatment-related grade 3/4 adverse events were 14 (22%) with 9 (14%) immune-related adverse events; there was no delay in definite surgery secondary to neoadjuvant treatment. **Conclusions:** Rate of SLN metastasis among patients with clinical stage IIB/C melanoma undergoing neoadjuvant pembrolizumab did not differ significantly compared to expected historical rates in treatment-naïve patients; however, in a secondary subgroup analysis among patients with clinical stage IIC disease, a decrease in SLN positivity rate was noted. Neoadjuvant therapy in clinical stage IIB/C was safe and feasible, with no significant delay in surgery or new or unexpected toxicities noted in these patients. Translational studies are under way, including flow cytometric and transcriptional studies, that may reveal immunologic determinants of efficacy versus resistance. Clinical trial information: NCT03757689. Research Sponsor: Merck; U.S. National Institutes of Health.

NeoACTIVATE arm C: Phase II trial of neoadjuvant atezolizumab and tiragolumab for high-risk operable stage III melanoma. First Author: Tina J. Hieken, Mayo Clinic, Rochester, MN

Background: Neoadjuvant ± adjuvant immunotherapy improves event-free survival relative to adjuvant immunotherapy alone for patients with high-risk resectable stage III melanoma. However, the optimal regimen balancing efficacy and tolerability is not known. T-cell immunoglobulin and ITIM domain (TIGIT) is a promising immune checkpoint but its therapeutic potential in stage III melanoma is underexplored. **Methods:** In this phase II trial, patients with resectable, macroscopic stage III melanoma received four 21-day neoadjuvant cycles of 1200mg IV atezolizumab (atezo, anti-PD-L1) + 600mg IV tiragolumab (tira, anti-TIGIT), followed by therapeutic lymph node dissection (TLND) and eight 21-day adjuvant cycles of 1200mg IV atezo. Primary endpoints were pathologic response (of all patients initiating neoadjuvant therapy) and recurrence-free survival (RFS) from the time of TLND in patients who were operated on per protocol and received adjuvant therapy. Secondary endpoint was adverse events (AEs); exploratory endpoints included event-free survival (EFS) and distant metastasis-free survival (DMFS). **Results:** Thirty-four patients, median age 59 years, were accrued and initiated neoadjuvant atezo/tira. 76.5% had >1 metastatic lymph node involved at baseline and 73.5% presented with Stage IIIC disease. All 34 patients were evaluable for AEs, pathologic response and EFS. Four patients were diagnosed with metastatic disease during neoadjuvant treatment, while 30 had TLND per protocol and 28 received adjuvant treatment and were evaluable for RFS and DMFS. Major pathologic responses (MPR, ≤10% viable tumor) were observed in 16/34 patients (47.1%, Table). With 19.9 months median follow-up from registration, 12-month EFS was 72.0% (95% CI 57.9 to 89.5%). With 16 months median follow-up from operation, 12-month RFS was 73.3% (n=28, 95% CI 56.9 to 94.5%), while 12-month DMFS was 86.0% (n=28, 95% CI 72.2 to 100%). In the 16 patients with an MPR, 2 did not receive adjuvant treatment and were followed for 33.3 and 10.8 months without recurrence/death. In the remaining 14 patients, 12-month RFS and 12-month DMFS were both 91.7% (95% CI 77.3 to 100%). 5 patients (14.7%) experienced any grade 3+ AE with 2 (5.9%) at least possibly related to the neoadjuvant regimen. **Conclusions:** Among patients with high-risk resectable stage III melanoma, neoadjuvant atezo/tira was a promising regimen with a favorable safety profile and warrants further study. Identification of predictive biomarkers will allow for optimization of neoadjuvant therapy for individual patients. Clinical trial information: NCT03554083. Research Sponsor: Stand Up to Cancer-Genentech; SU2C-AACR-CT1017; Mayo Clinic Center for Clinical and Translational Science; cCATS Award 92541640-2020/Mayo Clinic.

Pathologic response.

	N=34
Major Pathologic Response	16 (47.1%)
Pathologic complete response (no viable tumor)	13 (38.2%)

DREAMseq: A phase III trial of treatment sequences in BRAFV600-mutant (m) metastatic melanoma (MM)—Final clinical results. First Author: Michael B. Atkins, Georgetown Lombardi Comprehensive Cancer Center, Washington, DC

Background: The DREAMseq trial compared efficacy and toxicity of the sequence of nivolumab/ipilimumab (N/I) followed by dabrafenib/trametinib (D/T) to the reverse sequence in patients (pts) with BRAFV600m MM. In 9/2021, with 59% of pts 2+ years (yr) from enrollment, the DSMC and NCI CTEP recommended halting the trial and releasing data that showed a 20% difference in 2-yr OS (72% vs 52%) favoring the N/I first sequence. Here we update data to median ~5 yr from entry and report secondary analyses including time to CNS relapse and percent unconfirmed responses (ucOR). **Methods:** Eligible pts with untreated BRAFV600m MM were stratified by ECOG Performance Status 0 or 1 and LDH, and randomized 1:1 to Step 1 treatment with either N/I (Arm A) or D/T (Arm B) and at disease progression (PD) were eligible for Step 2 alternate therapy, D/T (Arm C) or N/I (Arm D). Imaging was done at baseline and q12 weeks (wks). The primary endpoint was 2-yr OS. Secondary endpoints included: 3-yr OS, efficacy (PFS, ORR and DOR) and toxicity. **Results:** 267 out of 300 proposed pts were enrolled (135 Arm A; 132 Arm B). As of 7/23/24, median follow-up of 58 months (mo) (range:0-101), 30 pts had switched to Arm C and 52 to Arm D. 2-yr OS for those assigned to Arm A was 68.3% (95% CI: 60.8-76.9) and for Arm B 54.1% (95% CI: 46.1-63.7%) (log-rank $p < 0.01$). 3 and 5-yr OS by sequence and 2, 3 and 5-yr PFS for initial arms, and median PFS, ORR and DOR for all arms are shown in Table. There were 125 deaths (Arm A-C:47; Arm B-D:78). 76% of responders in Arm A and 24% in Arm B remain in response. At 12 wks, 59 pts on Arm A and 85 on Arm B had RECIST PR of which 10 (16.9%) and 35 (41.2%), respectively were ucOR by wk 24. CNS was the first site of PD in 24 pts on Arm A and 44 pts on Arm B. Median time to CNS PD: Arm A 12.2 mo (0.7-46.5); Arm B 8.4 mo (1.3-78.1) ($p < 0.01$). **Conclusions:** At nearly 5 yr median f/up, the N/I first treatment sequence continues to show superior efficacy over the D/T first sequence for treatment-naïve BRAFV600m MM with a near doubling (30% absolute difference) in 5-yr OS and a tripling of 5-yr PFS. While confirmed ORR were similar between Arms A and B, shorter DOR and more ucOR and more and earlier CNS PD were seen with initial D/T contributing to its worse efficacy. Clinical trial information: NCT02224781. Research Sponsor: This study was conducted by the ECOG-ACRIN Cancer Research Group (Peter J. O'Dwyer, MD and Mitchell D. Schnall, MD, PhD, Group Co-Chairs) and supported by the National Cancer Institute of the National Institutes of Health:; U10CA180820, U10CA180794, U10CA180821, U10CA180868, U10CA180888, UG1CA189953, UG1CA233184, UG1CA233193, UG1CA233196, UG1CA233234, UG1CA233290, UG1CA233331, and UG1CA239758.

Secondary Endpoint (95% CI)	Arm A to C (n=135)	Arm B to D (n=132)	Log-rank p
3 yr OS rate	65.6% (57.3, 73.9)	44.8% (36.7, 54.6)	p<0.01
5 yr OS rate	63.3% (55.4, 72.3)	33.9% (25.9, 44.3)	
2 yr PFS rate	Arm A	Arm B	
	50.8% (42.8, 60.3)	22.9% (16.5, 31.7)	p<0.01
3 yr PFS rate	45.0% (37.0, 54.8)	15.9% (10.5, 24.0)	
5 yr PFS rate	39.4% (31.3, 49.5)	12.8% (7.9, 20.7)	
Median PFS (mo)	Arm A	Arm B	
	26.7 (11.2-47.3)	8.5 (8.1-12.6)	
	Arm C (n=30)	Arm D (n=52)	
	11.2 (9.5, 22.3)	5.9 (2.9, 22.4)	
ORR	Arm A (n= 132)	Arm B (n=131)	
	51.5% (42.7, 60.3)	51.1% (42.3, 60.0)	
	Arm C (n=30)	Arm D (n= 52)	
	70% (37.4, 74.5)	46.2% (32.2, 60.5)	
Median DOR (mo)	Arm A (n=68)	Arm B (n=67)	<0.01
	Not reached	15.5 (11.2, 23.5)	
	Arm C (n=17)	Arm D (n=20)	p=0.03
	14.7 (8.2, NR)	45.2 (19.5, NR)

A first-in-human study of DYP688, an antibody drug conjugate delivering a direct Gq/11 inhibitor, in patients with metastatic uveal melanoma (MUM) and other GNAQ/11 mutant melanomas. First Author: Matteo S. Carlino, Sydney Medical School, Faculty of Medicine and Health Sciences, The University of Sydney, Camperdown and Melanoma Institute Australia, Sydney, and Crown Princess Mary Cancer Centre, Westmead and Blacktown Hospitals, Westmead, NSW, Australia

Background: GNAQ/11 mutations occur in up to 95% of uveal melanomas (UM) and a subset of non-uveal melanomas. Cell surface PMEL17 (gp100) is highly and broadly expressed in melanoma (including UM). SDZ475 (FR900359) is a potent GNAQ/11 inhibitor, however in vivo toxicity has precluded clinical development. DYP688 is an antibody drug conjugate that binds to PMEL17 to deliver the payload SDZ475. **Methods:** This first-in-human, open-label, multicenter, single-arm study (NCT05415072) of DYP688 in patients (pts) with MUM and other GNAQ/11 mutant melanomas aimed to evaluate safety and tolerability, determine recommended dose(s) (RDs) of DYP688 (primary objective), and evaluate antitumor activity, pharmacokinetics (PK), and immunogenicity (secondary objectives). Here we present data from the ongoing Phase I dose-escalation. **Results:** As of 25 Oct 2024, 66 pts were treated with DYP688 at 4 (n=5), 8 (n=12), 12 (n=13), 16 (n=14), and 24 (n=11) mg/kg biweekly (Q2W) and at 12 (n=5) and 16 (n=6) mg/kg once weekly (QW) in 28-day cycles. Tumor types included MUM (n=60) and non-MUM (n=6). Of the 66 treated pts, 60 (90.9%) had prior antineoplastic therapy; 38 (57.6%) received $\geq$2 lines, and 22 (33.3%) received prior tebentafusp. The majority (n=57, 86.4%) of pts had liver metastases and elevated LDH (n=43, 65.25%) at baseline. Preliminary PK demonstrated a nearly dose-proportional exposure of total monoclonal antibody and active conjugated payload. Most treatment-related adverse events (TRAEs) were grade $\leq$2 with 4 grade 3 events: hypotension, hypercalcemia, anemia, and increased GGT. One dose limiting toxicity was reported (grade 3 hypotension at 24mg/kg Q2W). Most common TRAEs (all grades/doses, $>$15%) were hypercalcemia (22.7%), dry mouth (19.7%), fatigue (18.2%) and peripheral edema (16.7%). At data cutoff, 27 (40.9%) pts remained on study treatment and 39 (59.1%) pts had discontinued, mainly due to disease progression (PD) and none due to AEs. Of the 55 pts treated at doses $\geq$8 mg/kg Q2W who were eligible for RECIST v1.1 evaluation, confirmed objective responses were seen in 12 (21.8%) pts with 1/12 at 8 mg/kg (Q2W), 3/13 (1 complete response) at 12 mg/kg (Q2W), 5/8 at 16 mg/kg (Q2W), 2/5 at 12 mg/kg (QW) and 1/6 at 16 mg/kg (QW), with evidence of deepening response over time. Best response of PD was seen in 6/55 (10.9%) pts and stable disease in 35/55 (63.6%) pts. Median (range) duration of treatment by Kaplan Meier was 7.0 ($<$1 – 20.7) months. Analysis of mutational profiles from tissue and circulating tumor DNA is ongoing. **Conclusions:** DYP688 shows favorable safety and tolerability at all doses tested and promising preliminary clinical efficacy at doses $\geq$ 12mg/kg Q2W; the RDs for dose optimization are yet to be declared and dose exploration is ongoing. Clinical trial information: NCT05415072. Research Sponsor: Novartis Pharmaceutical Corporation.

9510 **Rapid Oral Abstract Session**

A phase II study of the interleukin-6 (IL-6) receptor blocking antibody sarilumab (Sari) in combination with ipilimumab (Ipi), nivolumab (Nivo) and relatlimab (Rela) in patients with unresectable stage III or stage IV melanoma. First Author: Janice M. Mehnert, Perlmutter Cancer Center of NYU Langone Health/NYU Grossman School of Medicine, New York, NY

Background: Combination immune checkpoint inhibitor regimens, especially those utilizing anti-CTLA-4 blockade, demonstrate higher response rates compared with single agent anti-PD-1 therapy but also increased rates of immune related adverse events (irAEs). IL-6, a key cytokine in driving inflammatory and autoimmune responses, is a compelling target to reduce irAEs through the use of IL-6 receptor (IL-6R) inhibitors. We conducted a clinical trial of 1L Nivo, Rela, and Ipi combined with the IL-6R inhibitor Sari in patients with advanced melanoma. **Methods:** 33 patients with advanced stage III/IV melanoma were treated in a single arm phase II trial. Patients received Nivo/Rela 480 mg/160 mg Q4W, Ipi 1 mg/kg Q8W and Sari 200mg q2 weeks for 12 doses over 24 weeks followed by maintenance Nivo/Rela 480 mg/160 mg Q4W and Ipi 1 mg/kg Q8W. Prior adjuvant immunotherapy was allowed if $>$ 6 months before enrollment. Patients with controlled brain metastases could enroll. The co-primary endpoints were rate of grade (gr) 3-5 irAEs and antitumor activity defined by RECIST best overall response rate at 24 weeks. With 33 patients, a difference of $\geq$ 22% from the known irAE rate of Nivo, Rela, and Ipi could be detected using a binomial test (2-sided alpha = 0.05, 80% power). BORR was estimated with an exact 95% Clopper Pearson confidence interval. Circulating IL-6 signaling mediators were measured over time in 14 patients using Luminex assays. **Results:** 33 patients (40% F, 60% M, PS 0-1, median age 63) were treated. Median follow-up was 9.8 months (95% CI: 8.5, 12.6 months; data lock, 12/12/24). 3% had acral and 9% mucosal melanoma. 24% had $>$ M1c disease and 39% elevated LDH. BRAF status, known for 81% of patients, was positive in 26%. BORR at 24 weeks was 63.6% (95% CI: 45.1%, 79.6%). Median PFS and OS were not reached (25th percentile for PFS = 8.3 (95% CI: 2.77, NA) months). Median treatment duration was 28 weeks and 9% discontinued therapy for toxicity. At 24 weeks 12.1% (n = 4) experienced $>$ gr 3/4 irAEs, significantly lower than the expected known irAE rate (2-sided p = 0.0007, 95% CI: 12.1%-28.2%). 27% (n = 9) had gr 3/4 toxicity over study duration; 93.9% (n = 31) had any grade irAE. Circulating IL-6Ra and IL-4 were significantly reduced at Cycle 2 ($P < 0.05$). **Conclusions:** Nivo, Rela, Ipi, + Sari demonstrated encouraging efficacy and tolerability. At 24 weeks, 63.6% BORR and 12.1% gr 3/4 irAE rate were observed. 2 patients had gr 4 toxicity; no gr 5 events were reported. These results compare favorably with published combination regimens including CTLA-4 blockade. Decreases in IL-6Ra and the inflammatory marker IL-4 observed post-treatment will be evaluted in a larger cohort of samples. An ongoing randomized cohort of Nivo + Rela + Ipi +/- Sari will further define the impact of IL-6R blockade on clinical outcomes in metastatic melanoma. Clinical trial information: NCT05428007. Research Sponsor: Bristol Meyers Squibb; Regeneron.

Clinical outcomes of the DIET study: A randomized controlled phase 2 trial of a high fiber diet intervention (HFDI) in patients with melanoma receiving immune checkpoint blockade (ICB). First Author: Yufan Qiu, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Dietary fiber intake is associated with response to ICB in melanoma. HFDIs favorably modulate the microbiome in non-cancer populations and in preclinical models. However, whether diet intervention can favorably modulate the microbiome and immune response in cancer patients is unknown. We conducted a proof-of-principal randomized trial of a fully controlled feeding study comparing HFDI with healthy control diet in melanoma patients receiving ICB. The primary objective was to establish the effects of HFDI on the structure and function of the gut microbiome. Here we report an exploratory objective of cancer-specific outcomes by arm. **Methods:** Patients initiating ICB treatment for melanomawere randomized (2:1) to either HFDI (30 g/d fiber ramped-up biweekly via whole foods to 50 g/d) or healthy control diet (20 g/d fiber). Diets in both arms met cancer prevention guidelines, were isocaloric and macronutrient-controlled, such that participants were provided all calorie-containing meals/snacks and met weekly with the dietitian for the study duration (up to 10 weeks). Objective response rate (ORR, per RECIST 1.1), pathological response rate (per INMC), progression-free survival (PFS), event-free survival (EFS, defined as the time from treatment initiation to disease progression, recurrence or death), recurrence rate (RR), recurrence-free survival (RFS) and immune-related adverse event (IRAE) rates were assessed and compared across arms. **Results:** 45 patients were randomized, of which 43 (F/M 22/21, median age 57 years, 79% cutaneous) initiated ICB and diet intervention: 28 in the HFDI arm and 15 in the control arm. ICB was administered in adjuvant, neoadjuvant and unresectable setting in 19, 12, and 12 patients, respectively. ICB regimens include pembrolizumab or nivolumab monotherapy (n = 19), ipilimumab + nivo (n = 16), and nivo + relatlimab (n = 7). At the time of data cut-off, October 2024, the median follow-up was 22.6 months (95% CI: 22.05-24.95 months). In the combined neoadjuvant/unresectable cohort (n = 24), ORR was 77% (HFDI) and 29% (control, p = 0.06). In the neoadjuvant cohort (n = 12), pathological complete response rate was 57%(HFDI) vs 50% (control, p = 1.0). Median EFS was not reached (HFDI) versus 20 months (control, p = 0.03). In the adjuvant cohort (n = 19), at a median follow-up of 27.6 months, RR was 14% (HFDI) versus 33% (control, p = 0.56). Median RFS was not reached (HFDI) versus 27.8 months (control, p = 0.49). Any grade IRAEs were observed in 71.4% of the patients in the HFDI arm versus 93.3% in the control arm (p = 0.13). Grade $\geq$3 IRAE rates were 28.6% and 40.0% in the HFDI and control arms (p = 0.51), respectively. **Conclusions:** Our study suggests potential benefits of HFDI on clinical outcomes and toxicity profile with ICB, warranting further study in Phase III trials powered for disease outcomes. Clinical trial information: NCT04645680. Research Sponsor: None.

9512 **Rapid Oral Abstract Session**

Neoadjuvant camrelizumab plus apatinib and temozolomide for resectable stage II/III acral melanoma: The CAP 03-NEO trial. First Author: Lili Mao, Department of Melanoma and Sarcoma, Peking University Cancer Hospital & Institute, Beijing, China

Background: The CAP 03 study demonstrated significant efficacy for camrelizumab combined with apatinib and temozolomide as first-line therapy for advanced acral melanoma (AM), achieving a 64.0% objective response rate and a median progression-free survival of 18.4 months. SWOG1801 and NADINA trials suggested that neoadjuvant therapy may provide greater benefits than adjuvant therapy in melanoma. CAP 03-NEO explores the efficacy and safety of this triple-drug regimen as neoadjuvant therapy in patients (pts) with resectable stage II/III AM. **Methods:** This two-stage clinical trial (ClinicalTrials.gov identifier: NCT05512481) aimed to enroll 60 pts with resectable stage II/III AM aged 18–75 years. In stage 1, 30 pts received two 4-week cycles of neoadjuvant camrelizumab (200 mg intravenously every 2 weeks), apatinib (250 mg orally once daily), and temozolomide (200 mg/m² intravenously daily on days 1–5 of each cycle), followed by surgery and 15 cycles of adjuvant camrelizumab (200 mg every 3 weeks). The primary endpoint was pathological complete response (pCR). Secondary endpoints included event-free survival (EFS), overall survival, and safety. Based on pathologic non-response (pNR) rate and risk-benefit assessment, stage 2 extended enrollment to an additional 30 pts receiving the same treatment. **Results:** As of December 2024, all 30 pts in stage 1 were enrolled, with a median follow-up of 18.5 months. The median age was 54 years (IQR: 41–61). Of 28 pts undergoing surgery, 16 (57.1%) achieved any pathological response, including 7 (25.0%) with pCR, 5 with near pCR, and 4 with partial pathologic response (pPR). Additionally, 12 pts (42.9%) achieved major pathological response (MPR), which includes both pCR and near-pCR. Surgery was canceled for two pts due to personal reasons and new metastatic disease. Among stage II pts, 3 achieved pCR, 1 achieved pPR, and the pNR was 64%. Among stage III pts, 4 achieved pCR, 5 near PCR, and 3 pPR, with pNR of 29.4%. The median EFS has not been reached, with a 12-month EFS rate of 74.1% (95% CI: 53.1-86.7%). The most common adverse events (AEs) were increased blood bilirubin (11, 37%), decreased white blood cell count (9, 30%), and constipation (8, 27%), with no grade 4-5 AEs observed. Neoadjuvant therapy did not increase surgical complications. **Conclusions:** Stage 1 results of CAP 03-NEO demonstrated the potential of neoadjuvant camrelizumab, apatinib and temozolomide in pts with resectable stage II/III AM. The pNR result support advancing to stage 2 to further assess the efficacy and safety of this regimen in pts with stage III disease. Clinical trial information: NCT05512481. Research Sponsor: None.

9513 **Rapid Oral Abstract Session**

Single dose of neoadjuvant ipilimumab and nivolumab in resectable melanoma with CD8+ cell imaging: Interim results of the C-IT Neo trial. First Author: Sarah E. Lochrin, Memorial Sloan Kettering Cancer Center, New York, NY

Background: Neoadjuvant (neoadj) immune checkpoint blockade (ICB) is standard of care for patients (pts) with resectable stage III/IV melanoma. A single ICB dose induces substantial peripheral immune activation and 1 dose of neoadj pembrolizumab has promising activity. The efficacy of 1 dose of combination ICB is unknown and clinically important to describe given the toxicity of sequential combination ICB. **Methods:** In this phase II single-arm trial, pts with resectable stage IIIB-IV melanoma received 1 dose of neoadj nivolumab (nivo) 1mg/kg and ipilimumab (ipi) 3mg/kg 4 weeks prior to resection. The primary endpoint is major pathologic response (MPR), defined as pathologic complete response (pCR) or near CR (≤10% viable tumor). Using a Simon minimax two-stage design, MPR $<$ 30% is deemed not promising and $>$ 50% promising; positive if $>$12 MPR in 28 pts. Secondary endpoints were response rate (RECIST 1.1), recurrence free survival (RFS), and safety. CD8-PET imaging was done pre-ICB and pre-surgery, using ^{89}Zr-radiolabeled crefmirlimab to evaluate association with MPR. Autoradiography and CD8 cell infiltrate by IHC were used to verify the on-target binding of crefmirlimab in surgical specimens. **Results:** Stage I successfully met the interim efficacy threshold with 5 of 12 pts demonstrating an MPR, thus advancing to stage II. Here we report interim results of the 19 pts enrolled by data cut-off 01/02/2025. Baseline stages were IIIB (53%, n = 10), IIIC (42%, n = 8) and IV (5%, n = 1); 80% cutaneous, 10% acral and 10% unknown primary melanoma. An MPR was observed in 53% (95% CI: 29,76) of pts (n = 10, 7 pCR, 3 near pCR), partial pathologic response (PR) in 21% (n = 4), and non-response in 26% (n = 5). Of the 18 evaluable, RECIST response was 28% (n = 5, all PR), 61% (n = 11) had stable disease, and 11% (n = 2) progressive disease (PD). The rate of grade $>$3 treatment-related adverse events (TRAE), in neoadj and adjuvant setting, was 11% (n = 2); 1 pt was hospitalized with adrenal insufficiency, no grade 5 events occurred on study. All pts proceeded to surgery with median time to surgery of 29 days (IQR 26,31). 14 pts (74%) received adjuvant therapy; 13 anti-PD-1 and 1 BRAF targeted therapy. Median follow-up was 16 months (IQR 8;23) and 12-month RFS from surgery was 91% (95% CI: 75, 100). Of the 3 pts with recurrent or progressive disease; 0 had an MPR and 2 died from progressive melanoma. CD8-PET was completed in 19 pts pre-ICB and 17 pts pre-surgery. SUVmax pre-ICB, pre-surgery and the percent change over-time was not significantly associated with MPR. CD8-PET tracer evaluation by autoradiography correlated with CD8+ cell infiltrate on IHC by pathologist assessment. **Conclusions:** C-IT-Neo is the first study evaluating a single dose of combination ICB in the neoadjuvant setting. Interim results show one dose has low grade 3+ TRAE and high efficacy with MPR of 53%. The trial is actively enrolling, with ongoing analysis of CD8-PET imaging and immune biomarkers. Clinical trial information: NCT05289193. Research Sponsor: Melanoma Research Alliance; ImaginAb.

9514 **Rapid Oral Abstract Session**

A phase II study of neoadjuvant lenvatinib plus pembrolizumab in Merkel cell carcinoma. First Author: Andrew Scott Brohl, H. Lee Moffitt Cancer Center and Research Institute, Tampa, FL

Background: Given the success of checkpoint inhibitor therapy in the advanced setting in Merkel cell carcinoma (MCC), there is interest in exploring immunotherapy as a neoadjuvant approach, which additionally allows a window of opportunity to assess the efficacy of new immunotherapy combinations. **Methods:** We conducted a single center, phase II open label trial (NCT04869137) in patients (pts) with resectable stage II-IV MCC. All pts were to receive six weeks of neoadjuvant therapy with pembrolizumab 200mg IV q3 weeks plus lenvatinib 20mg PO daily before planned surgery ± adjuvant radiation therapy. Following local therapy, pts were to receive continued adjuvant pembrolizumab monotherapy to complete 1 year total of systemic therapy. Target accrual was 26 pts. Pathological complete response (pCR) rate was the primary endpoint of the study, with ≥15 pCR needed for the combination therapy to be considered as promising compared to a historical benchmark of ~40% pCR for single-agent anti-PD1. **Results:** Twenty-six pts were enrolled between 06/2021 and 09/2024, including 5 (19.2%) with clinical stage II disease, 20 (76.9%) with stage III, and 1 (3.8%) with stage IV. Pts were predominantly male (77%) and with a median age of 69 (range 53-88). Following neoadjuvant treatment, 2 pts (7.7%) were unable to undergo planned surgery, one due to progressive disease (PD) and one due to toxicity. Two pts who achieved a clinical response to neoadjuvant therapy declined surgery and underwent post-neoadjuvant therapy biopsies for pathological assessment. On intention to treat, 15 of the 26 pts (57.7%) achieved a pCR. With a median follow-up of 20 months, 6 pts (23.1%) have experienced disease progression, 2 during neoadjuvant therapy, 2 during and 2 after adjuvant treatment. Among pts with pathological assessment of response, pCR was associated with a lower risk of relapse, though this result was not statistically significant (13.3% vs. 33.3%, p = 0.33). Thirteen of 15 pts who achieved pCR following surgery omitted adjuvant radiation therapy and there have been no local recurrences in pCR cases. Thirteen pts (50%) experienced at least one G3 treatment related adverse event (TRAE), most commonly G3 hypertension in 10 pts (40%) that improved with dose interruption and/or dose reduction of lenvatinib. No G4-5 TRAEs were observed. At the time of analysis, one pt (neoadjuvant PD) has died from progressive MCC. Two pts have died from other causes without evidence of recurrence at last follow-up. **Conclusions:** Lenvatinib plus pembrolizumab demonstrated encouraging efficacy with anticipated toxicity when used as neoadjuvant therapy for Merkel cell carcinoma. The primary endpoint of the study was met with 57.7% of patients achieving a pathological complete response. Pts with a pCR had a lower risk of recurrence vs those without, but recurrences were seen even after pCR. Ongoing correlative studies may help to identify biomarkers for response. Clinical trial information: NCT04869137. Research Sponsor: Merck Sharp & Dohme LLC.

9515 **Rapid Oral Abstract Session**

Lifileucel in patients with advanced melanoma: 5-year outcomes of the C-144-01 study. First Author: Theresa Medina, University of Colorado Comprehensive Cancer Center, Aurora, CO

Background: Lifileucel is a personalized, one-time tumor-derived autologous T-cell immunotherapy approved for the treatment of adult patients (pts) with advanced (unresectable or metastatic) melanoma previously treated with a programmed cell death-1 (PD-1)–blocking antibody, and, if *BRAF* V600 mutation–positive, a BRAF inhibitor with or without a MEK inhibitor. In the registrational C-144-01 study (NCT02360579), pts with advanced melanoma who received lifileucel had an objective response rate (ORR) of 31.4%. Follow-up in therapeutic trials targeting refractory patients with refractory melanoma typically span months rather than years due to lack of activity. Reflective of the durability of lifileucel, we nowreport 5-year survival outcomes from the C-144-01 study. **Methods:** C-144-01 (NCT02360579) is a phase 2, multicenter, multicohort, open-label study of lifileucel. Eligible pts had advanced melanoma that had progressed on or after immune checkpoint inhibitor and targeted therapy, where appropriate. Before lifileucel infusion, pts underwent nonmyeloablative lymphodepletion (NMA-LD; cyclophosphamide, 60 mg/kg × 2 d plus fludarabine 25 mg/m² × 5 d). Pts received cryopreserved lifileucel followed by up to 6 doses of interleukin-2 (IL-2; 600,000 IU/kg every 8–12 hours). The primary endpoint was ORR assessed by an independent review committee (IRC) using RECIST v1.1. Key secondary endpoints were duration of response (DOR), overall survival (OS), and safety. **Results:** Among pts who received lifileucel (n = 153; median age, 56 y; range, 20–79), 54% were male. All pts had an Eastern Cooperative Oncology Group Performance Status of 0 or 1 and previously received anti–PD-1/PD-L1 therapy. Pts had a median of 3 prior lines of therapy (range, 1–9) and 55% were primary refractory to anti–PD-1/PD-L1 therapy. At a median follow-up of 57.8 mo, all pts have completed or discontinued the study, with 28 (18.3%) pts having completed the 5-year study follow-up. The ORR was 31.4% (complete response, 5.9%; partial response, 25.5%). Median DOR was 36.5 mo (95% confidence interval [CI]: 8.3–not reached), with 31.3% of responders completing the 5-year assessment with a sustained response. Median time to best response was 1.5 mo (range, 1.3–30.4). Median OS was 13.9 mo (95% CI: 10.6–17.8); the 5-year OS rate was 19.7% (95% CI: 13.3–27.0). Treatment-emergent adverse events were consistent with known safety profiles of NMA-LD and IL-2. The extended follow-up revealed no new safety signals. **Conclusions:** This 5-year analysis of the C-144-01 trial is the longest follow-up of the largest group of pts with melanoma treated with tumor-infiltrating lymphocytes in a single study. This study illustrates lifileucel's continued durability of response and survival benefit up to 5 years after a single administration without any long-term safety concerns. Clinical trial information: NCT02360579. Research Sponsor: Iovance Biotherapeutics Inc.

Infusion product characteristics to predict response to tumor-infiltrating lymphocyte (TIL) therapy in metastatic melanoma (MM). First Author: Lilit Karapetyan, H. Lee Moffitt Cancer Center and Research Institute, Tampa, FL

Background: Identification of the TIL therapy product (TILp) characteristics associated with objective response to therapy is critical to improve future adoptive TIL-based therapy. In this study we performed comprehensive phenotypic analysis of TILp in association with TIL therapeutic outcomes in consecutive patients with MM. **Methods:** Data were extracted from early-phase clinical trials of MM patients treated with TIL only, TIL plus ipilimumab, TIL plus nivolumab, and TIL plus vemurafenib at Moffitt Cancer Center. The immunophenotypic features of TILp were evaluated by flow cytometry using antibodies against checkpoints, costimulatory molecules, T cell subsets and TCRβ sequencing. Tumor reactivity was measured using HLA-matched cell lines. The relationship between TILp characteristics and both objective response and progression-free survival (PFS) was assessed in treated patients. **Results:** A total of 50 patients, 21 female (42%) and 29 male (58%), median age 49 [IQR 40–55] received lymphodepleting chemotherapy followed by TIL and interleukin-2 (IL-2). Median numbers [IQR] of infused TIL and IL-2 dose were $59e^9$ [42-$84e^9$] and 5 [4–6], respectively. Patients with objective response had a significantly higher total number of infused TIL, total number of infused $CD8^+$ TIL, and proportion of $CD8^+$ cells in the infusion product ($p < 0.05$), with high $CD8^+$ TIL being associated with improved PFS ($p = 0.0001$). The total number and proportion of infused stem cell-like memory $CD8^+$T cells ($T_{SCM,}$ $CD8^+CD45RA^+CCR7^+CD62L^+CD95^+$) were significantly higher in responders and associated with improved PFS ($p < 0.01$). TILs from responders had distinct patterns of co-inhibitory and co-stimulatory receptors' expression and were characterized by significantly higher proportion of $LAG3^+$ and $LAG3^+TIGIT^+$ co-expressed TIL of total $CD3^+$ TIL ($p < 0.05$). Proportions of $LAG3^+CD8^+$ and $TIGIT^+CD8^+$ cells were also increased in responders ($p < 0.05$) with no significant differences observed in $PD1^+CD8^+$, $BTLA^+CD8^+$, and $TIM3^+CD8^+$ cells. There was an increased proportion of $OX40^+CD8^+$ and $OX40^+4\text{-}1BB^{neg}CD8^+$ cells among responders ($p < 0.01$). T cell clonal analysis using top 20 clones revealed high persistence in responders ($p < 0.01$) measured by TCRβ overlap between ACTP and post-treatment peripheral blood. There were no significant differences in clonality, diversity and evenness in responders *vs.* non-responders. Using HLA-matched cell lines there was a trend towards HLA-matched reactive TIL and improved PFS ($p = 0.058$). **Conclusions:** Response to TIL therapy is associated with TIL persistence and distinct TILp immunophenotypic features characterized by enhanced proportion of $CD8^+$ TIL, T_{SCM} $CD8^+$ cells, and high surface expression of $LAG3^+TIGIT^+$ and $OX40^+$. Novel strategies to modulate *ex vivo* TIL expansion toward this optimal TIL phenotype may result in increased response for future trial design. Research Sponsor: None.

OBX-115 engineered tumor-infiltrating lymphocyte (TIL) cell therapy with regulatable membrane-bound IL15 (mbIL15) in patients (pts) with immune checkpoint inhibitor (ICI)–resistant advanced melanoma: Phase 1 results of the Agni-01 multicenter study. First Author: Jason Alan Chesney, UofL Health – Brown Cancer Center, University of Louisville, Louisville, KY

Background: OBX-115 TIL are engineered to express mbIL15 regulated by the FDA-approved small-molecule drug acetazolamide (ACZ), abrogating the need for toxic high-dose IL2 after TIL infusion. Single-center phase 1 data (NCT05470283) demonstrated differentiated early safety (Amaria ASCO 2024). We report the first data evaluating OBX-115 in pts with advanced melanoma in the multicenter phase 1/2 Agni-01 study (NCT06060613). **Methods:** This single-arm, open-label study assesses safety, tolerability, and efficacy of the OBX-115 TIL cell therapy regimen in pts with advanced melanoma and NSCLC (Shoushtari AACR 2025). Phase 1 characterizes safety (treatment-emergent adverse events [TEAEs]: AEs ≤30 d after OBX-115 infusion) and tolerability in escalating dose levels of OBX-115 and ACZ to establish a recommended phase 2 dose (RP2D). Phase 2 evaluates efficacy of the regimen at RP2D (RECIST v1.1 per investigator). OBX-115 is manufactured from pt tumor tissue (core needle biopsy or surgical excision) and infused after standard- or low-dose (Cy 750 $mg/m^2/d \times 3$; Flu 30 $mg/m^2/d \times 4$) lymphodepletion (LD). No IL2 is administered. Oral ACZ starts day of OBX-115 infusion (QD up to 14 d), and is redosed (QD up to 7 d) every 6 wks after recovery from LD. **Results:** In phase 1,as of 01 Jan 2025, OBX-115 was successfully manufactured and infused for 11 pts with ICI-resistant advanced melanoma (median study follow-up, 22.3 wks [range, 13.3–52.1]) including 6 treated at RP2D (OBX-115 $1–100\times10^9$ cells, ACZ 500 mg/d). Majority (n = 10) received low-dose LD, including 1 in the outpatient setting. There was no dose-limiting toxicity (DLT), treatment-emergent ICU transfer, or treatment-related mortality (TRM). Eight pts had G≥3 nonhematologic TEAEs (events in > 1 pt: hyponatremia, hypokalemia [n = 2 each]). One pt reported 2 OBX-115–related serious AEs, including 1 CRS event (G2) without IL6 elevation (IL6 < 100 pg/mL). Across dose levels (n = 11), confirmed ORR was 36% (4 PR, 5 SD; DCR 82%). For 6 pts receiving RP2D, ORR was 67% (4 PR, 2 SD; DCR 100%). **Conclusions:** Early data support clinical benefit (RP2D ORR 67%, DCR 100%) of OBX-115regulatableengineeredTIL cell therapy in the absence of IL2, including with outpatient low-dose LD. The safety profile is highly differentiated, without TRM, ICU transfer, or high-grade CRS. ACZ redosing is well-tolerated and offers an opportunity to deepen responses by inducing re-expression of mbIL15 on engrafted OBX-115 TIL, a unique capability among adoptive cell therapies. These attributes may comprehensively address the unmet need in post-ICI advanced melanoma and other cancers, and data support continued investigation of OBX-115 in the ongoing phase 2 portion of the Agni-01 study. Clinical trial information: NCT06060613. Research Sponsor: Obsidian Therapeutics.

Neutralizing antibodies and lymphocyte count as biomarkers in patients receiving oncolytic adenovirus TILT-123 and adoptive cell transfer of tumor-infiltrating lymphocytes for metastatic melanoma refractory to immune checkpoint inhibitors. First Author: Lyna Haybout, TILT Biotherapeutics Ltd., Helsinki, Finland

Background: Metastatic melanoma refractory to immune checkpoint inhibitors (ICI) remains a significant challenge. Adoptive Cell Transfer of Tumor-Infiltrating Lymphocytes (ACT-TILs) shows promise but can cause adverse events. Oncolytic adenovirus TILT-123 (igrelimogene litadenorepvec) coding for TNF and IL2 combined with ACT-TILs, offers an approach without conditioning therapies. We report long-term survival data from a phase I trial (TUNINTIL NCT04217473), and correlative clinical, histologic, and immunologic biomarker analyses. **Methods:** The aim was to evaluate safety of TILT-123 and ACT-TILs in patients with metastatic melanoma refractory to ICIs. Treatment was deemed safe and feasible. TILT-123 was given intravenously (IV) and intratumorally, ACT-TILs were given IV, without preconditioning chemotherapy or post-conditioning IL2. Five cohorts were completed in a 3+3 dose-incremental design without dose-limiting toxicities. Tumor biopsies were analyzed for adenoviral (Ad) genomes, PD-L1 expression and presence of CD4+ regulatory (reg), CD4+ and CD8+ T cells by multiplex immunofluorescence (mIF). TILT-123 DNA was quantified in tumors by qPCR, anti-Ad neutralizing antibodies (nAbs) analyzed in serum using luminescence titering assay. Disease control rate (DCR) was defined as Stable Disease or better using RECIST1.1, iRECIST, and PET criteria. Association of factors with survival and DCR was determined using Spearman's rank correlation and multivariate analysis. **Results:** Patients varied in melanoma subtype (cutaneous n=8, mucosal n=5, uveal n=4), with a median age of 67 years (25-75 years). Following TILT-123 monotherapy, the DCR on D36 was 35% by RECIST 1.1 and iRECIST, and 63% by PET criteria. PET responses were seen in 31% of patients by D36. In the combination phase (D78) DCR per RECIST 1.1 or iRECIST was 38%, and 47% by PET criteria. Responses were seen in 27% of patients on D78 in PET, including a partial response lasting >8 months and a durable complete response in a mucosal melanoma patient. Median overall survival (mOS) was 447 days. Virus DNA was detected post-treatment in both injected and uninjected tumors. Patients with elevated titers of nAbs (by D22) showed a decrease in metabolism in non-injected lesions by day 36 (p=0.0101). Blood lymphocyte count decrease after TILT administration was associated with better DCR (p= 0.0188). mIF data showed patients achieving disease control had a higher percentage of intratumoral CD8+ T cells (p=0.037). **Conclusions:** ICI refractory melanoma patients receiving TILT-123 and ACT-TILs without preconditioning show signs of CD8+ T cell trafficking to the tumor microenvironment. nAbs and lymphocyte count decrease can be further investigated as biomarkers. Clinical trial information: NCT04217473. 9519 Poster Session

OBX-115 engineered tumor-infiltrating lymphocytes (TIL) with regulatable membrane-bound IL15 (mbIL15): Translational data from a single-center phase 1 trial in patients (pts) with immune checkpoint inhibitor (ICI)–resistant advanced melanoma. First Author: Rodabe Navroze Amaria, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Non-engineered TIL cell therapy is approved for ICI-resistant advanced melanoma, but requires co-administration of toxic high-dose IL2. OBX-115 engineered TIL express mbIL15 under pharmacologic regulation using the FDA-approved small-molecule drug acetazolamide (ACZ), abrogating the need for IL2. We present data supporting OBX-115 mechanism of action. **Methods:** Trial design and clinical results were previously reported (Amaria ASCO 2024; NCT05470283); briefly, pts received lymphodepletion (Day [D] -7 to -1) followed by OBX-115 infusion (D0) and ≤7 days of orally administered ACZ (D2–9). Peripheral blood (PB) and tumor tissue samples were collected for longitudinal ddPCR analysis and immune profiling. **Results:** Eight pts received OBX-115 (fresh) and are included in this analysis. PB samples demonstrated ACZ-driven OBX-115 TIL expansion, reaching a median of 1697 cells/μL at D14 (approximate day of OBX-115 expansion peak); in 3 pts with ≥6 mo follow-up, OBX-115 remained detectable through 6 mo and ongoing up to 15 mo. In the immediate post-infusion phase (up to D14), PB flow cytometry indicated expansion of product-derived CD3+CD8+ cells expressing Ki67 (during ACZ exposure) and endogenous NK cells (CD3-CD56+), while CD4+ cell levels decreased (Table). Post-infusion tumor tissue demonstrated presence of IL15-expressing T cells (of CD3+: D21, 68.6%; D42, 88.4%). Importantly, median post-infusion serum levels of IL15 and IL7 were not significantly elevated above Baseline through D42 (paired one-tailed t-test adjusted for multiple comparisons; Table); IL6 was below limit of detection at all timepoints, even in pts with fevers. T-cell receptor (TCR) clonotypes present in the OBX-115 infusion product were enriched in post-infusion PB and tumor (Table). **Conclusions:** These data support the proposed OBX-115 mechanism of action, demonstrating ACZ-driven OBX-115 TIL expansion, engraftment, and persistence; endogenous NK cell expansion, presumably driven by transactivation via mbIL15 on OBX-115, without systemic cytokine elevation; and TCR repertoire remodeling with tumor-derived, antigen-specific T cells. Investigation of OBX-115 TIL cell therapy in pts with advanced solid tumors (NCT06060613) is ongoing. Clinical trial information: NCT05470283. Research Sponsor: Obsidian Therapeutics, Inc.

Homologous recombination deficiency signature (HRDsig) in advanced cutaneous melanoma (ACM): A genomic landscape study. First Author: Nimisha Srivastava, SUNY Upstate Medical University, Syracuse, NY

Background: HRDsig can aid in identifying tumors with DNA repair deficiencies, guiding PARP inhibitor (PARPi) use. It expands treatment options beyond breast cancer gene (BRCA) mutations enabling personalized therapy. Combining PARPi with targeted therapy or immunotherapy shows promise in overcoming resistance and improving outcomes for treatment-resistant ACM. **Methods:** Formalin-fixed paraffin-embedded (FFPE) primary tumors and metastatic biopsies from 9,576 ACM cases were analyzed using hybrid capture-based comprehensive genomic profiling (CGP), evaluating all classes of genomic alterations (GA). Central pathology review was conducted for all cases. Microsatellite instability-high (MSIH) status, tumor mutational burden (TMB), genomic ancestry, and mutational signatures were derived from sequencing data. HRDsig was assessed using copy number changes and genomic scars. PD-L1 expression was determined via immunohistochemistry [Dako 22C3; tumor proportion score (TPS)]. Statistical comparisons were made using Fisher's exact test with Benjamini-Hochberg correction. **Results:** Among 9,576 ACM cases, 198 (2.1%) were HRDsig positive (HRDsig+). HRDsig+ cases when compared to HRDsig negative (HRDsig-) were older (median age: 69 vs. 67 years; p=0.034), more often female (49.5% vs. 36.2%; p=0.001), and had more GA per tumor (median: 7 vs. 6; p=0.026). HRDsig+ cases were more often of African (5.6% vs. 1.2%; $p<0.0001$) or American ancestry (8.1% vs. 4.1%; p=0.026) and less often European (84.3% vs. 94.0%; $p<0.0001$). GA more common in HRDsig+ included *IGF1R* (5.1% vs. 1.3%; p=0.003), *KIT* (11.6% vs. 5.6%; p=0.004), *KRAS* (7.1% vs. 2.7%; p=0.005), *NF1* (38.4% vs. 21.4%; $p<0.0001$), *RAD21* (6.7% vs. 3.0%; p=0.037), and *TP53* (40.4% vs. 24.3%; $p<0.0001$). HRDsig- cases exhibited higher TMB (median: 13.8 vs. 6.1; $p<0.0001$), more frequent TMB >10 mutations/Mb (60.9% vs. 39.9%; $p<0.0001$), and more UV light exposure trinucleotide signatures (57.3% vs. 36.4%; $p<0.0001$). GA more common in HRDsig- cases included *BRAF* (including V600E) (44.6% vs. 23.2%; $p<0.0001$), *CDKN2A* (49.2% vs. 36.9%; p=0.003), *NRAS* (28.0% vs. 11.6%; $p<0.0001$), and *TERT* (74.4% vs. 29.8%; $p<0.0001$). In both positive and negative groups, PD-L1 low-level expression (1-49% TPS) was comparable (43.3%-39.7%), while BRCA1/2 alterations (<2.0%) and MSIH status (0.0%-0.1%) remained rare. **Conclusions:** HRDsig+ status is rare in ACM but more frequent in non-white genomic ancestries. HRDsig+ ACM cases are less likely to have BRAF GA, more likely to have KIT GA and lower TMB levels. These findings may guide the future development of clinical trials employing combination therapies and PARPi in ACM. Research Sponsor: None.

Association of KIT mutations with risk of central nervous system (CNS) metastasis (met) in patients (pts) with mucosal melanoma (MM). First Author: Afsaneh Amouzegar, Department of Melanoma Medical Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: The CNS is a frequent site of distant met in pts with cutaneous melanoma (CM). Previous studies have identified clinical, pathological, and molecular risk factors for CNS met in CM pts. However, little is known about the incidence of and risk factors for CNS met in MM pts, who overall have a worse prognosis than CM pts. **Methods:** We performed an institutionally approved retrospective review of pts diagnosed with clinically localized or regionally metastatic MM at MD Anderson Cancer Center from 1/1/1988 to 12/31/2023. Pts who presented with distant met were excluded. Pt and tumor features (including clinical testing for BRAF, NRAS, and KIT mutations) and distant recurrence events (CNS met; non-CNS met) were assessed. Tumor samples from a subset of MM pts were stained and scored for expression of PTEN (Absent vs Present), PD-L1 (<1% vs ≥1%), and KIT (Above vs Below median H-score) protein by immunohistochemistry (IHC). Time-to-CNS met and Time-to-non-CNS met were computed from the date of initial MM diagnosis (dx) to date of CNS/non-CNS met. Cumulative incidence of distant met events was determined using competing risks (death); pts alive with no met at last follow-up (f/u) were censored. Group differences were evaluated by Gray's test, and associations between measures of interest were determined using proportional sub-distribution hazards regression models. **Results:** 579 MM pts with clinically localized (73%) or regionally metastatic (27%) disease were included in the analysis. At a median f/u of 34.4 months (range 0 – 525.8), 111 pts (19.2%) had developed CNS met. The cumulative incidence of CNS met at 1, 2, 3 and 5 years was 5%, 10%, 14% and 18%, respectively. For pts with CNS met, median time from MM dx to CNS met was 26.1 months (range, 2.3 – 211.0). Most pts with CNS met presented with brain met only (90%), followed by brain met and LMD (6%), and LMD only (4%). On univariate analysis, KIT mutation (Hazard Ratio [HR] 2.78; 95% Confidence interval [CI] 1.74 – 4.44), $p<0.001$), mitotic rate 5-9/mm^2 (vs. 0-4/mm^2; HR 2.22; 95% CI 1.14 – 4.34, p=0.020), and lymphovascular invasion (HR 1.63; 95% CI 1.03 – 2.56, p=0.036) were associated with increased risk of CNS met. On multivariable analysis, KIT mutation (HR 2.77; 95% CI 1.71 – 4.51, $p<0.001$) remained significantly associated with increased risk of CNS met. In contrast, KIT mutation predicted a lower risk of non-CNS met in multivariate analysis (HR 0.55; CI 0.34 – 0.87, p=0.011). Among the 87 MM pts for whom IHC was performed on tumor samples, PTEN, KIT, and PD-L1 protein expression were not associated with risk of CNS or non-CNS met. **Conclusions:** KIT mutation is significantly associated with increased risk of CNS met in patients with clinically localized or regionally met MM. These results highlight distinct CNS met risk factors, and potential surveillance strategies, for MM compared to CM pts. Serum thymidine kinase activity (TKa) as a potential biomarker in the sequential immunotherapy and targeted therapy for metastatic BRAF V600 mutated melanoma (SECOMBIT) trial. First Author: Hildur Helgadottir, Karolinska Institute and Karolinska University Hospital, Stockholm, Sweden

Background: In melanoma, there is a need for biomarkers for predicting treatment efficacy. Thymidine kinase 1 (TK) is a cytosolic enzyme that plays a pivotal role in DNA synthesis and repair as it is part of the reaction chain to introduce thymidine into the DNA strand. Dividing cells release TK during mitotic exit and TK can be measured in blood as a biomarker of cell proliferation. Elevated levels of TK enzyme activity (TKa) have been detected in blood samples from patients with several tumor types and correlated with disease stage, prognosis, and treatment efficacy. This study is the first to evaluate the role of TKa as a biomarker in a prospective clinical trial in patients with metastatic melanoma, the SECOMBIT study (NCT02631447). **Methods:** SECOMBIT was a randomized, three-arm, phase II trial where melanoma patients received, in ARM A: BRAF+MEK inhibitors (encorafenib (E) + binimetinib (B)) and at progressive disease (PD), immune checkpoint inhibitors (ICI) (ipimumab (I) + nivolumab (N), in ARM B: I+N and at PD E+B, and in ARM C: 8-week induction of E+B before a planned switch to I+N, and at PD E+B. Serum TKa was analyzed as DiviTum Unit of Activity (DuA) by the FDA cleared and CE-labelled assay (Biovica). **Results:** Baseline serum TKa was available from 81 (38.8%) of the patients in SECOMBIT, 25, 27 and 29 in ARM A, B and C, respectively. Patients were divided into TKa-HIGH (n=41) and TKa-LOW (n=40) by the median TKa value 110 DuA (range 39-2343, IQR 74-183). The median total progression-free survival (tPFS) was 17 months (95% CI 12 to 22), and the median overall survival (OS) was 19 months (95% CI: 12 to 26) in TKa-HIGH, while the median tPFS and OS were not reached at 76 months in the TKa-LOW group (tPFS: p=0.004 and OS: $p<0.001$). In ARM A and B, TKa-HIGH patients had significantly worse tPFS and OS while the survival difference between TKa-HIGH and TKa-LOW was not statistically significant in ARM C (Table 1). TKa predicts prognosis independently of LDH in multivariate analysis. **Conclusions:** Baseline serum TKa levels efficiently predicted the outcome of patients with BRAF V600 mutated metastatic melanoma treated with different sequences of ICI and BRAF+MEK inhibitors. Patients with elevated TKa is an evident poor prognosis group and appears to benefit from the regime received in ARM C, with an 8-week induction of BRAF-MEK inhibitors, before ICI (sandwich approach). TKa merits further study as a potential biomarker in metastatic melanoma. Clinical trial information: NCT02631447. Research Sponsor: None.

Survival according to study arm and TKa level.

	ARM A	ARM B	ARM C
tPFS at 5 years, (rate, 95% CI)			
TKa-HIGH	10.0 (0-28.6)	38.5 (12.0-65.0)	47.1 (23.4-70.8)
TKa-LOW	52.5 (26.8-78.2)	78.6 (57.0-100)	44.4 (4.6-84.2)
P value	0.010	0.019	0.51
OS, at 5 years, (rate, 95% CI)			
TKa-HIGH	20.0 (0-44.7)	38.5 (12.0-65.0)	46.3 (22.2-70.4)
TKa-LOW	60.0 (35.3-84.7)	78.6 (57.0-100)	75.0 (50.0-99.5)

Circulating tumor DNA (ctDNA) dynamics during anti-PD-1 based therapy to predict clinical outcomes in advanced stage melanoma: A multicenter retrospective study. First Author: Caroline Burkey, University of Wisconsin Hospitals and Clinics, Madison, WI

Background: ctDNA has shown promise as a prognostic biomarker for disease relapse in resected tumors. The significance of ctDNA changes in the advanced or metastatic disease setting for predicting treatment response and survival characteristics is still under investigation. In our study, we evaluated the association between early ctDNA changes after anti-PD-1 based therapy initiation and clinical outcomes in patients with advanced stage melanoma. **Methods:** We performed a multicenter, retrospective analysis using a personalized, tumor-informed ctDNA assay (Natera) on prospectively collected plasma samples from patients with unresectable stage III/IV melanoma treated with anti-PD-1 based therapy. Baseline ctDNA levels were assessed prior to the start of treatment and at 6-8 weeks. Patients were divided into 3 cohorts based on ctDNA changes: ctDNA clearance (6-8 week level undetectable or 0 MTM/mL), ctDNA decrease (6-8 week level decreased from baseline but detectable), or ctDNA increase (6-8 week level increased from baseline). Logistic regression models were used to evaluate the odds of disease control based on the change in ctDNA levels between both time points. Cox proportional hazard models were used to study the effects of ctDNA changes on progression-free survival (PFS) and overall survival (OS). **Results:** We identified 95 patients with unresectable stage III (18%; n=17) or stage IV (82%; n=78) melanoma with cutaneous (72%; n=68), uveal (12%; n=11), mucosal (8%; n=8), or unknown (8%; n=8) primaries who were treated with dual anti-PD-1/anti-CTLA-4 (60%; n=57), dual anti-PD-1/anti-LAG-3 (17%; n=16), or anti-PD-1 monotherapy (23%; n=22). At baseline, median age was 75, median baseline ctDNA was 363 mTM/ml, and median follow up was 13.1 months; 29% (n=28) had liver metastases, 26% (n=25) had brain metastases. Using ctDNA clearance (n=40) as reference, patients with ctDNA decrease (n=23) had lower odds of disease control (OR=0.09, 95% CI 0.01-0.85, p=0.035), and shorter PFS (HR=5.15, 2.25-11.79, $p<0.001$), and OS (HR=5.72, 1.52-21.56, p=0.010); patients with ctDNA increase (n=32) had even lower odds of disease control (OR=0.01, 0.00-0.09, $p<0.001$) and even shorter PFS (HR=5.67, CI 2.62-12.24, $p<0.001$) and OS (HR=8.76, CI 2.55-30.11, p=0.001). 12-month PFS for ctDNA clearance, ctDNA decrease, and ctDNA increase were 94.3%, 63.0%, and 48.2%, respectively. 12-month OS for ctDNA clearance, ctDNA decrease, and ctDNA increase were 95.4%, 64.6%, and 50.5% respectively. **Conclusions:** ctDNA dynamics after 6-8 weeks of anti-PD-1 therapy in patients with advanced stage melanoma may be predictive of disease control, progression-free survival, and overall survival. ctDNA clearance is associated with favorable clinical outcomes. Larger studies are needed to validate the role of ctDNA as an early response biomarker in advanced disease. Application of a novel multiplex imaging-based immunotherapy panel and AI-powered analysis solution for predictive spatial biomarker identification on immunotherapy-treated melanoma patients. First Author: Paolo Antonio Ascierto, Department of Melanoma, Cancer Immunotherapy and Development Therapeutics, Instituto Nazionale Tumori – IRCCS - Fondazione G. Pascale, Naples, Italy

Background: There is an urgent need for more robust methods to differentiate immunotherapy responders from non-responders. In this study, we present a novel multiplex imaging (MI)-based immunotherapy panel and a comprehensive analysis pipeline to characterize the spatial distribution and function of immune cells and its application for spatial biomarker detection in a cohort of immunotherapy-treated melanoma patients. **Methods:** We designed a 28-plex panel to perform sequential immunofluorescence (seqIF) on the COMET platform to target key biomarkers associated with tumor microenvironment (TME), immune cell infiltration, and immune checkpoint pathways. Pre-treatment biopsies were obtained from 12 patients with known long-term response or rapid progression to immunotherapy combination treatment from the SECOMBIT Trial (NCT02631447) and profiled utilizing Nucleai's deep-learning-based MI analysis pipeline, aiming to identify spatial biomarkers that can differentiate between long-term responders and non-responders. We identified 15 cell types, including 10 immune cell populations, in addition to 10 cell state markers. Cells were assigned to the tumor area or TME, and spatial features were calculated based on cell type, marker positivity, and gross area assignment. **Results:** Our novel MI panel and analysis pipeline demonstrated highly balanced accuracy (> 0.8) and F1 scores (> 0.8) in cell typing and protein quantification for most cell types and markers. This analysis pipeline enabled the quantification of known biomarkers such as T cell activation states, T cell infiltration patterns, and tertiary-lymphoid structure maturation. A comparison of calculated spatial features between long-term responders and rapid progressors revealed distinct immune cell interactions and differences in activation status across the tumor areas associated with response. Within the tumor area, the reciprocal interactions of tumor cells, cytotoxic CD8 T-cells and antigen-presenting cells (APC) were associated with a better outcome. In contrast, a high percentage of proliferating regulatory T cells within the tumor invasive margin was associated with a worse outcome. In the adjacent TME, endothelial cell interactions with T-cells and macrophage proliferation were associated with immunotherapy resistance. In contrast, the interaction between HLA-DR-expressing macrophages and APC cells was associated with an improved clinical outcome. **Conclusions:** Integrating MI with AI analysis has the potential to enhance our understanding of treatment efficacy and resistance mechanisms. Our preliminary data demonstrate that area-specific immune niches contribute to the success or failure of immunotherapy response and highlight the importance of spatial biology in predicting immunotherapy outcomes. Clinical trial information: NCT02631447. Research Sponsor: Lunaphore.

RELATIVITY-020: Intracranial (IC) activity of nivolumab + relatlimab (NIVO + RELA) in patients (pts) with PD-(L)1 refractory melanoma with melanoma brain metastases (MBM). First Author: Hussein A. Tawbi, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: NIVO + RELA is an anti-PD-1 + anti-LAG3 combination approved for the treatment of pts with advanced melanoma, but data on activity in pts with MBM are lacking. NIVO + RELA prolonged time to and decreased incidence of development of new brain lesions vs NIVO in RELATIVITY-047 (Tawbi, 2024 ASCO). Preliminary BLUEBONNET data (n = 9) showed a NIVO + RELA IC overall response rate (ORR) of 44% (Phillips, 2024 SNO/ASCO). This post hoc analysis investigated IC activity in pts with PD-(L)1–refractory melanoma treated with NIVO + RELA in the phase I/IIa RELATIVITY-020 trial (NCT01968109). **Methods:** Pts with anti-PD-(L)1–refractory melanoma treated with NIVO + RELA in RELATIVITY-020 parts C, D, or E with possible IC lesions were included. Brain imaging from these pts (eg, those with stable MBM at baseline) were interpreted by blinded independent central review (BICR) using modified RECIST v1.1 specific to the CNS. Efficacy endpoints for BICR-confirmed pts included confirmed IC response, target IC lesion reduction, and time to IC progression. **Results:** BICR analysis confirmed 27 pts had ≥ 1 MBM; of these, 59% had an ECOG PS 0, 30% had a *BRAF* mutation, and 48% had liver lesions. Pts had a median (range) of 2 (1–10) prior therapies, including anti-PD-(L)1 (100%), anti-CTLA-4 (63%, including 44% NIVO + ipilimumab), BRAF/MEKi (26%), and brain radiotherapy (81%, with 26% receiving the radiotherapy < 3 mo prior to first dose). With a minimum follow-up of 54.4 mo, confirmed IC ORR was 22% and clinical benefit rate (CBR) was 63% (table). Median duration of IC response was not reached. Target IC lesions were identified in 17 pts; 14 had both a baseline lesion and ≥ 1 on-treatment brain scan. Median best reduction from baseline for those 14 pts was 19.5%; 6 pts had a reduction $\geq 30\%$. Median time to IC progression (as first progression) was not reached, with 63% of pts event free for > 3 y (events/N = 7/27). Median overall survival was 21.5 mo (95% CI, 10.9–29.4) with rates of 70% at 1 y and 27% at 3 y (events/N = 22/27). **Conclusions:** A previous Part D report of this study showed a heavily pre-treated anti-PD-(L)1 refractory melanoma pt population with 12% ORR in response to NIVO + RELA irrespective of tumor location; here a subpopulation of similar pts with IC lesions compared favorably: 22% ORR and 63% CBR per CNS-specific modified RECIST v1.1. Prospective and larger studies are needed to confirm these findings. Clinical trial information: NCT01968109. Research Sponsor: Bristol Myers Squibb.

Randomized dose evaluation of nivolumab + relatlimab (NIVO + RELA) in patients (pts) with advanced melanoma: Results from RELATIVITY-020. First Author: Georgina V. Long, Melanoma Institute Australia, Faculty of Medicine and Health, The University of Sydney, and Mater and Royal North Shore Hospitals, Sydney, NSW, Australia

Background: NIVO + RELA is approved at 480 mg NIVO + 160 mg RELA Q4W (480/160) dosing for treatment of advanced melanoma based on RELATIVITY-047. A higher dose of 480 mg NIVO + 480 mg RELA (480/480) is under investigation in other tumor types. Here, we report results from RELATIVITY-020 Part E, which aimed to compare efficacy and safety of first-line (1L) 480/480 vs 480/160 dosing in pts with treatment-naive advanced melanoma and evaluate 480/480 dosing in pts with advanced melanoma who progressed on prior anti–PD-1 therapy (PD-1 refractory [RF]). **Methods:** RELATIVITY-020 (NCT01968109) is a phase 1/2a, dose-escalation and cohort-expansion, open-label trial. For Part E, pts with treatment-naive advanced melanoma were randomized 1:1 to 480/480 vs 480/160 A single-arm cohort was enrolled to evaluate 480/480 dosing in pts with PD-1 RF advanced melanoma. Primary endpoints were safety and objective response rate (ORR) per BICR using RECIST v1.1. Secondary endpoints included duration of response (DOR) and PFS. Exploratory analyses included OS and pharmacodynamics. **Results:** As of clinical cutoff (May 22, 2024, min follow-up 33 mo), ORR was higher with the 1L 480/480 vs the 480/160 dose, while median (m) DOR, mPFS, and mOS were similar across the two arms, with numerically lower mPFS and 24-mo PFS/OS rates with the 480/480 dose (Table). With the 1L 480/480 vs 480/160 doses, 34% vs 36% of pts had grade 3–4 treatment-related AEs (TRAEs), and any grade TRAEs led to treatment discontinuation (d/c) in 29% vs 19% of pts, respectively. There was 1 treatment-related death (immune-mediated lung disease) in the 1L 480/480 arm vs none in the 480/160 arm. Treatment duration was shorter with the 1L 480/480 (m 5.6 mo) vs 480/160 dose (m 8.3 mo). Higher LAG-3 occupancy was observed with 1L 480/480 vs 480/160 dosing; however, there was no difference in Th1-associated cytokine levels. For the RF 480/480 arm (Table), outcomes were similar to published Part D data for RF 480/160 dosing. **Conclusions:** Although the 480/480 dose yielded higher ORR and LAG-3 occupancy levels than the 480/160 dose, it did not translate into improved survival outcomes or differences in Th1 cytokine levels. The 1L 480/480 dose also led to a higher rate of d/c due to TRAEs than the 480/160 dose. RF 480/480 dosing yielded similar results to RF 480/160 dosing from RELATIVITY-020 Part D. Clinical trial information: NCT01968109. Research Sponsor: Bristol Myers Squibb.

Real-world comparison of survival with nivolumab (NIVO) + relatlimab (RELA) vs NIVO + ipilimumab (IPI) in advanced melanoma. First Author: Michael A. Postow, Memorial Sloan Kettering Cancer Center, New York, NY; Weill Cornell Medical College, New York, NY

Background: An indirect-treatment (Tx)-comparison (ITC) suggested first-line (1L) NIVO + RELA may have similar efficacy vs NIVO + IPI in clinical trial patients (pts) with untreated advanced melanoma. However, there is no real-world study comparing these Tx. This study compared survival outcomes among pts with advanced melanoma treated with 1L NIVO + RELA or NIVO + IPI in the Flatiron Health EHR-derived de-identified database, which includes ≥ 280 oncology clinics across the US. **Methods:** Data were extracted for pts aged ≥ 18 yrs who received 1L NIVO + RELA or NIVO + IPI between March 18, 2022 (date of NIVO + RELA FDA approval) and March 31, 2024. Pts who received adjuvant Tx, including anti–PD-1, were included, while pts with other primary cancers or treated in any clinical trial were excluded. Endpoints were OS and real-world PFS from start of 1L Tx. Outcomes were summarized using Kaplan–Meier methods, and Tx were compared using Cox models adjusted for age, sex, practice type, BRAF, brain metastases (mets), liver mets, prior adjuvant anti–PD-1 monotherapy, time from advanced melanoma diagnosis to start of 1L Tx, ECOG PS, stage, and LDH. Missing data for ECOG PS, BRAF, stage, and LDH were imputed. **Results:** Median (m) follow-up was 7.4 mo for NIVO + RELA (N = 408) and 7.7 mo for NIVO + IPI (N = 600). The NIVO + RELA group was older (m [IQR], 74.1 [65.9–81.5] yrs) than the NIVO + IPI group (66.2 [57.3–74.5] yrs), but generally had better prognostic factors (Table). Prior anti–PD-1 adjuvant Tx was 12% in both groups, while time from end of adjuvant Tx to 1L Tx and time from advanced melanoma diagnosis to 1L Tx trended longer with NIVO + RELA vs NIVO + IPI (Table). 74% of the NIVO + RELA group and 70% of the NIVO + IPI group were missing PD-L1 status, while 16% vs 20%, respectively, had PD-L1 $> 1\%$ (P = 0.61). mOS was not reached (NR) for both groups, with 95% CIs of 20.1–NR mo for NIVO + RELA vs 21.5–NR mo for NIVO + IPI (adjusted HR, 0.91 [95% CI, 0.70–1.18]). Median rwPFS was longer with NIVO + RELA (11.5 [8.9–18.7] mo) vs NIVO + IPI (4.8 [3.7–6.3] mo; adjusted HR, 0.75 [0.61–0.91]). **Conclusions:** This real-world study supports the ITC observation that NIVO + RELA and NIVO + IPI convey similar OS benefits for pts with advanced melanoma. The longer rwPFS for NIVO + RELA vs NIVO + IPI warrants additional research with longer follow-up and further evaluation of baseline characteristics, as the NIVO + IPI group had poorer prognostic factors. Important limitations included short follow-up, covariate missingness, and potential unmeasured confounding. Research Sponsor: Bristol Myers Squibb.

Characteristics and predictors of chronic immune-related adverse events (irAEs) following anti-PD-1 (PD1) treatment for melanoma. First Author: Roma A. Kankaria, Vanderbilt University School of Medicine, Nashville, TN

Background: Adjuvant PD1 treatment improves clinical outcomes in high-risk resected melanoma. We have shown that adjuvant PD1 can lead to irAEs that become chronic in up to 46% of treated patients (pts). We performed longer follow-up (f/u) to further characterize chronic irAEs from adjuvant PD1 treatment and assessed risk factors to determine predictors for their development. **Methods:** We retrospectively analyzed pts treated with adjuvant PD1 for resected stage III-IV melanoma from 2015-2024 from 6 institutions. All pts had at least 12 months of f/u after PD1 initiation. We collected demographics, treatment details, and outcomes. We characterized type, grade, management, duration, and resolution of acute (onset during PD1) and chronic (persisting at least 3 months after PD1 cessation) irAEs. We performed Olink 96-protein inflammation assay in plasma from pts with and without chronic non-endocrine irAEs at 12 months after PD1 initiation. **Results:** We included 304 pts; 184 (61%) were male, and median age at PD1 initiation was 64 years. Among all pts, 221 (73%) developed acute irAEs, and 147 (48%) developed chronic irAEs; 59 pts had chronic endocrine irAEs, 99 had chronic non-endocrine irAEs, and 11 had both. At last f/u (median 61.4 months), 104 (34%) pts had ongoing irAEs. The most common chronic irAEs were hypothyroidism/thyroiditis (n=45, 15%), arthritis (n=25, 8%), dermatitis (n=17, 6%), hypophysitis/adrenal insufficiency (n=16, 5%), and xerostomia (n=10, 3%). Twenty (7%) pts experienced chronic toxicities outside of classical irAEs, most often fatigue (n=14, 5%), orthostasis (n=2, 1%), and headache (n=2, 1%). We then assessed risk factors for chronic irAEs compared with acute, resolving irAEs (excluding endocrine irAEs since nearly all become chronic). We found that peak steroid dose was similar in patients with and without chronic irAEs (median 50 mg for both groups, p=0.33). Time to irAE onset was similar in patients with and without chronic irAEs (median 91 vs. 114 days, p=0.78). Time to steroids from symptom onset trended longer for those with chronic irAEs (median 7 vs. 4 days, p=0.18) but was not statistically significant. In proteomic analysis, 24/96 cytokines had higher expression (0 with lower expression) in pts with chronic irAE (n=17) compared with controls (n=10), including IL-8 (p=0.02), IL-17 (p=0.049), TNF (p=0.02), VEGFA (p=0.005), and soluble PD-L1 (p=0.03). **Conclusions:** Among this large cohort of pts with melanoma treated with adjuvant PD1, chronic irAEs were common, persistent, and associated with elevated circulating cytokines, which could suggest possible therapeutics. No obvious predictors of chronic irAEs were identified outside of organ affected; analyses are ongoing. Given the long-term survival of pts treated with adjuvant PD1, monitoring and managing chronic irAEs is crucial. Research Sponsor: None.

Safety and efficacy analysis of DNV3 plus toripalimab and chemotherapy in advanced melanoma: An open-label investigator-initiated trial. First Author: Jing Lin, Department of Medical Oncology, Clinical Oncology School of Fujian Medical University, Fujian Cancer Hospital, Fuzhou, China

Background: Previous studies have shown that combining LAG-3 and PD-1 inhibitors is effective in advanced melanoma. Here, we presented the safety and efficacy of DNV3, a LAG-3 inhibitor, in combination with a PD-1 inhibitor and chemotherapy for patients with advanced acral and mucosal melanoma. **Methods:** Eligible patients were adults with confirmed unresectable or metastatic melanoma and an ECOG performance status of 0 or 1. BRAF-mutant patients must had progressed after BRAF inhibitor treatment. The dosages for chemotherapy (albumin-bound paclitaxel at 260 mg/m² on Day 1 and cisplatin at 25 mg/m² on Days 1 to 3 for the first 6 cycles) and DNV3 (administered at 3 mg/kg) were based on body surface area and weight, while Toripalimab was given at a fixed dose of 240 mg. The combination therapy was administered every 3 weeks. DNV3 and Toripalimab were continued for up to 2 years or until withdrawal from the study. The primary endpoint is the objective response rate (ORR), with secondary endpoints including progression-free survival (PFS), duration of response (DOR), disease control rate (DCR), and overall survival (OS). **Results:** Overall, 27 patients participated (13 mucosal melanoma; 6 acral melanoma; 5 cutaneous melanoma; 3 unknown primary melanoma). 77.8% patients had prior anti-PD-(L)1 therapy. At a Nab-Paclitaxel dose of 260mg/m², 94.4% had treatment-related adverse events (TRAEs), with 50% facing severe TRAEs like infection and bone marrow suppression, leading to one death and a dose reduction for 9 patients. At 200mg/m², 77.8% had TRAEs, and 22.2% had severe TRAEs, mainly decreased PLT/WBC counts and bacteremia, with no further deaths. Among the 15 patients (55.6%) who experienced immune-related adverse events (irAEs), 6 (22.2%) had grade 3 or 4 irAEs, with no reported grade 5 cases. The most common grade 3 irAE was infection. An ORR of 37.0% (95% CI: 19.4% to 57.6%) was observed in 10 patients , 6 of whom had liver metastases according to RECIST 1.1 criteria. The median DOR had not yet been reached (95% CI: 3.65 months to not evaluable). Among the 27 patients, the overall ORR was 37%, with subtypes showing 38.5% for mucosal, 80% for cutaneous, and 16.7% for acral melanomas. Expression levels of BRAF or PD-L1 did not predict ORR within these subgroups. As of the cutoff date, neither median PFS nor OS had been achieved. **Conclusions:** The study provided preliminary evidence of the tolerability and potential efficacy of the combination of DNV3 plus Toripalimab with chemotherapy in patients with advanced melanoma, particularly in those with mucosal melanoma and liver metastases. Clinical trial information: ChiCTR2400079387, ChiCTR2400079543. Research Sponsor: None.

Prognostic implications of glycemia in non-diabetic patients with metastatic melanoma undergoing immunotherapy. First Author: Domenico Mallardo, Istituto Nazionale Tumori IRCCS "Fondazione G. Pascale", Naples, Italy

Background: Immune checkpoint inhibitors (ICIs) have revolutionized the cancer therapeutic landscape, significantly improving the survival of patients (pts) with advanced malignancies. Previous studies have shown that diabetic pts have a higher risk of cancer-related mortality compared to those without diabetes. This retrospective study aimed to investigate the prognostic impact of glycemia on ICI treatment outcomes in non-diabetic metastatic melanoma pts. **Methods:** Glycemic levels were assessed at three distinct time points within a two-week period prior to the initiation of ICI therapy in 1079 non-diabetic metastatic melanoma pts treated with anti-PD1 and anti-CTLA4 either as monotherapy or in combination. Blood glucose concentrations were determined enzymatically using the cobas c-501 system (Roche, normal range 70-110 mg/dL). Interleukin-6 (IL-6) levels were assessed in 378 pts using Electrochemiluminescence Immunoassays and gene profiling analysis was performed on 95 baseline RNA using NanoString IO360 panel. Pts characteristics are listed in Table 1. Spearman's correlation was used to assess the association between variables. Survival rates were analyzed using the Kaplan-Meier method. **Results:** ROC curve analysis identified a blood glucose cut-point of 93.33 mg/dL. Pts with low glycemia had a better overall survival (median: 27.7 vs 14.5 months, HR=0.68, $p < 0.0001$) and progression free survival (median: 7.4 vs 4.3 months, HR=0.74; $p < 0.001$) compared to pts with elevated glycemia. This trend was confirmed in subgroups analysis (anti-PD1; anti-CTLA4), except for pts treated with the combination of anti-PD1 plus anti-CTLA4 as well as in line of treatment stratification (first, second and ≥ 3). Glycemia was found to be positively associated with elevated IL-6 levels (rho 0.16, $p<0.01$). Transcriptomic analysis showed an association between glycemia and genes related to inflammatory activity (S100A12; CD40) and cell cycle regulation (CNTFR; PTEN). Glycemia predicts prognosis independently of LDH and line of treatment in multivariate analysis. **Conclusions:** Elevated glycemia is associated with poor prognosis in pts with metastatic melanoma treated with ICIs. Biomarker analysis revealed an association between glycemia levels with pro-inflammatory cytokine IL-6 and genes linked to inflammation and cell cycle progression. Further investigations are needed in order to endorse the data and validate the glycemia cut-point. Research Sponsor: None.

Trick-MCC: Final results from the proof-of-concept investigator-initiated study of combination therapy with anti–PD-1, anti–LAG-3, and anti–TIM-3 in participants with advanced or metastatic PD-(L)1 refractory Merkel cell carcinoma (NCT06056895). First Author: Natalie J. Miller, University of Washington, Seattle, WA

Background: Merkel cell carcinoma (MCC) is an aggressive and highly immunogenic skin cancer associated with the Merkel cell polyomavirus. Over 50% of patients with metastatic MCC do not derive durable benefit from PD-(L)1 therapy alone. High expression of additional immune checkpoints LAG-3 and TIM-3 on MCC-specific CD8 T cells suggested that concurrent triple checkpoint blockade may overcome immune evasion in patients with PD-(L)1 refractory MCC. **Methods:** TRICK-MCC (Triple Immune Checkpoint Inhibition in MCC) is an investigator initiated, single center, proof-of-concept clinical trial studying concurrent treatment with anti-PD-1 (retifanlimab, q4w), anti-LAG3 (tuparstobart, q2w) and anti-TIM-3 (verzistobart, q2w) in patients with advanced/metastatic MCC that progressed after PD-(L)1 therapy. After receiving standard frequency dosing for the first 24w, benefitting patients are transitioned to reduced frequency dosing at q6w for up to 2 years total or until disease progression, unacceptable toxicity, or study withdrawal. Primary endpoint is objective response rate (ORR). Secondary endpoints include duration of response, disease control rate, progression free and overall survival, and incidence and severity of adverse events (AE). Serial tumor biopsies and blood samples are obtained in all patients, unless not feasible/safe. **Results:** Twelve (out of planned 20) patients were enrolled between Nov 2023 and Jan 2025, before the study was closed to enrollment for administrative reasons by the funding sponsor. At the time of abstract submission, ORR and AE data are available for 10 patients. Two of 10 patients (20%) have partial response and one (10%) has stable disease (26% decrease in tumor size) per RECIST 1.1. Therapy has generally been well tolerated, with immune-related AEs observed in 4 (40%) patients, all Grade 1-2. One patient discontinued therapy due to an AE, grade 5 encephalopathy (anti-IgLON5 disease) diagnosed 7 mo into treatment with unclear relationship to study agents. Correlative studies of pre- and post-treatment tumor and blood specimens are ongoing to characterize the prevalence and significance of cancer-specific T cell exhaustion markers (including PD-1, LAG-3 and TIM-3), and additional mechanisms of PD-(L)1 resistance. Updated translational and clinical results will be presented at the meeting. **Conclusions:** Concurrent triple immune checkpoint blockade of PD-1, LAG-3 and TIM-3 appears to be generally well tolerated and associated with clinical activity in our cohort of patients with PD-(L)1 refractory MCC. Our data suggests TIM-3 and LAG-3 are contributing to immune evasion in a subset of patients with PD-(L)1 resistant MCC, providing support for further investigation of these pathways in larger trials. Clinical trial information: NCT06056895. Research Sponsor: Incyte Biosciences; Kuni Foundation; Jacob Green Foundation.

Resistance to anti-PD-1 immunotherapy for stage III and IV melanoma: Results from a global multi-site chart review. First Author: XiangLin Tan, Merck & Co, Inc., Rahway, NJ

Background: Anti-PD-1 immunotherapy has been approved for the treatment of stage III and IV melanoma. Real-world data on its resistance is needed to facilitate the development of combinatorial approaches to overcome anti-PD-1 resistance. Objectives: To estimate the percentage and understand patient/disease characteristics and survival of those receiving anti-PD1 therapy who experience primary resistance and late relapse in the adjuvant (resectable) setting, and primary, secondary resistance and late progression in the advanced (unresectable/metastatic) setting. **Methods:** A retrospective chart review was conducted in 22 sites in Australia, France, Germany, South Korea, UK and USA. Adult patients who began anti-PD-1 therapy for stage III or IV melanoma from 1 Jan 2018 until 12 months before the start of data collection were included. SITC Immunotherapy Resistance Taskforce definitions of resistance were used, and late relapse/progression defined if occurring more than 12 weeks after last dose of anti-PD-1. The percentage of patients with primary, secondary resistance or late relapse/progression were calculated. Time to death was analysed using Kaplan-Meier. Univariate tests were used to compare baseline characteristics and survival by type of resistance. **Results:** Of 981 eligible patients, 738 were included in the full analysis set. In the adjuvant setting (n=240), 53 (22.1%) patients developed primary resistance and 60 (25.0%) experienced late relapse. In the advanced setting (n=498), 222 (44.6%), 50 (10.0%) and 64 (12.9%) patients developed primary, secondary resistance, and late progression, respectively. In the adjuvant setting, a greater proportion of patients with primary resistance (66%) or late relapse (75%) were male than in those with no relapse (52%) (p=0.007). Asian patients experienced less late relapse (0.0%) than White patients (28.2%) but more primary resistance (61.5% vs. 18.4%) ($p<0.001$). In the advanced setting, 48.6% of Asian patients developed primary resistance, 37.8% secondary resistance, 5.4% late progression vs. 40.8%, 8.8% and 12.7% of White patients ($p<0.001$). No significant difference was observed in age, BMI, disease severity, Charlson index score and comorbid conditions by type of resistance. In both settings, time to death varied significantly by type of resistance ($p<0.001$). Patients with primary resistance had the poorest survival: a mean of 42 months in the adjuvant setting and 31 months in the advanced setting (39 months in those with secondary resistance). **Conclusions:** A large proportion of patients developed resistance or late relapse/progression and require alternative therapy after anti-PD-1, highlighting a substantial unmet medical need. A greater proportion of Asian patients developed resistance compared to White patients, possibly due to differences in melanoma subtype. Patients with primary resistance had the poorest survival. Research Sponsor: Merck & Co., Inc.

CemiplimAb-rwlc survivorship and epidemiology (CASE): Interim results from a prospective study of the safety and effectiveness of cemiplimab in patients with advanced cutaneous squamous cell carcinoma (CSCC) in a real-world setting. First Author: Soo J. Park, Department of Medicine, Division of Hematology and Oncology, University of California San Diego, San Diego, CA

Background: Cemiplimab is the first PD-L1 inhibitor approved for the treatment of patients with locally advanced (la) or metastatic (m) cutaneous squamous cell carcinoma (CSCC) not amenable to curative therapy. Here, we present an analysis of cemiplimab-treated patients with advanced CSCC enrolled in the CASE study (NCT03836105). **Methods:** CASE is a phase IV, multicenter, prospective, noninterventional study evaluating the effectiveness and safety of cemiplimab in patients with laCSCC/mCSCC and basal cell carcinoma. Data were collected from participating US academic and community oncology centers treating patients ≥18 years of age with intravenous cemiplimab per standard of care. The protocol was reviewed and approved by an institutional review board/ethics committee at each site and patients provided informed consent for study participation. Effectiveness outcomes included investigator-assessed (both physical and radiological) ORR (CR plus partial response) and progression-free survival (PFS). Safety outcomes included treatment-related immune-related adverse events (irAEs), infusion-related reactions (IRRs), and serious adverse events (SAEs). **Results:** As of December 4, 2024, 254 patients (including 44 [17%] immunocompromised/immunosuppressed) across 65 centers with advanced CSCC received ≥1 dose of cemiplimab. Median duration of exposure was 35 weeks (interquartile range: 15.0, 65.9). Most patients were aged ≥65 years (82.7%), male (78.3%), and white (89.0%). Demographics and disease characteristics were similar to those from the EMPOWER-CSCC-1 trial, with the exception of patients with Eastern Cooperative Oncology Group Performance Status of 2-3, which were excluded from the trial but represented 10.7% (27/254) of our real-world study analysis set. 64.2% of patients had laCSCC and 35.8% had mCSCC. ORR, including all patients regardless of missing response data, was 111/254 (43.7%; 95% CI: 37.5, 50.0) patients. CR was reached by 40/254 (15.7%) patients. ORR in patients with at least 1 response assessment reported was 111/201 (55.2%; 95% CI: 48.1,62.2) patients, and CR was reached by 40/201 (19.9%) patients. The overall response rate of the clinical trial (52.7%) fell within the range of our response data (43.7-55.2%). Median PFS was 14.7 (95% CI: 12.5, 21.1) months, with survival at 12 months estimated at 59.5% (95% CI: 51.4, 66.7). Treatment-related irAEs occurred in 76/254 (29.9%) patients and treatment-related SAEs occurred in 19/254 (7.5%) patients; one patient reported an IRR. **Conclusions:** The interim results of this Phase IV study demonstrate robust effectiveness and a generally manageable safety profile of cemiplimab in patients with laCSCC/mCSCC in real-world practice that are comparable to the results of the EMPOWER-CSCC-1 trial. Clinical trial information: NCT03836105. Research Sponsor: Regeneron Pharmaceuticals, Inc.

Biosafety analysis from the skin cancer cohorts in the IGNYTE clinical trial of RP1. First Author: Trisha Michel Wise-Draper, University of Cincinnati Cancer Center, University of Cincinnati, Cincinnati, OH

Background: RP1 (vusolimogene oderparepvec) is an HSV–based oncolytic immunotherapy administered intratumorally. RP1 + nivolumab (nivo) has demonstrated deep, durable responses with favorable safety in advanced melanoma. We report biodistribution and shedding data from the skin cancer cohorts of the IGNYTE trial (NCT03767348). **Methods:** Following RP1 injection into superficial and/or deep lesions, injection sites were covered with occlusive dressings. Injection sites, dressings and mucosa were swabbed, and blood and urine were collected pre-dose, during treatment, and at follow-up visits. Samples were assessed for RP1 DNA by qPCR. Swab samples positive for RP1 DNA were further assessed by TCID50 assay for live RP1. **Results:** The highest incidence of RP1 DNA was from injection-sites where RP1 was detected in ~35% of samples for up to 15 days post-injection. Blood samples showed the presence of low copy numbers of RP1 DNA (122/1573 [7.8%]) in ~20% (53/274) of pts during or after RP1 treatment. The highest levels were detected in blood within 6 hours of injection and decreased thereafter. RP1 was only very rarely detected and at low copy number in urine samples (3/1976 [0.2%]) from 0.7% (2/273) pts at 15 days post-injection, with all subsequent samples testing negative. RP1 DNA was detected on injection-site dressing exteriors less often (9.5% of 1114 samples) than from injection sites (18.4% of 1947 samples), demonstrating that the dressings act as a barrier to RP1. RP1 DNA was rarely present on oral mucosa (0.9% of 2052 samples). At follow-up (30-100 days post last dose), RP1 DNA was detected only at injection-sites. All available samples were negative for live RP1 by TCID50. Eight swab samples from 7 pts were collected from suspected herpetic infections but all tested negative for live RP1. There were no reports of systemic herpetic infections in pts, nor of transmission to contacts. **Conclusions:** RP1 DNA was primarily detected on the surface of injected lesions for up to 15 days, with no live RP1 being detected at 30, 60 and 100 days post the last RP1 dose. Collectively, these data demonstrate that RP1 is rapidly cleared from blood and urine, with negligible likelihood of environmental dissemination or transfer to contacts, and that the use of occlusive dressings contains RP1.Defining the biodistribution and shedding of RP1 is relevant to the education of healthcare providers and to the development of best practices for the proper administration, handling and clean down. Clinical trial information: NCT03767348. Research Sponsor: Replimune, Inc.

Clinical and biomarker analyses of first-line nivolumab and relatlimab (nivo-rela) in advanced or resectable melanoma (mel). First Author: Lilit Karapetyan, H. Lee Moffitt Cancer Center and Research Institute, Tampa, FL

Background: Simultaneous blockade of lymphocyte activation gene-3 (LAG-3) and programmed death-1 (PD-1) pathways enhances antitumor activity in patients (pts) with mel. While efficacy of nivo-rela has been demonstrated in a large cohort of therapy-naïve advanced mel, it remains important to assess clinical activity of this combination in real-world settings focusing on resectable mel and on tumor microenvironment (TME) factors impacting response to nivo-rela. In this study we report the clinical activity of nivo-rela and the relation of TME characteristics to response to therapy. **Methods:** This study included pts with mel treated with first-line nivo-rela in the neoadjuvant or advanced settings between 2022-2024 at Moffitt. Safety, progression-free (PFS), overall survival (OS) and pathologic response rates were evaluated in relation to mel characteristics. To assess the impact of TME on response to nivo-rela in advanced mel, we performed NanoString GeoMx proteomic analysis using immune cell profiling, immune cell typing, and IO drug target panels. Differential proteomic analysis (fold change ≥0.05, FDR <0.05) was performed using selected baseline samples (n=16) from responders (R) and non-responders (NR). **Results:** The study included 128 mel pts treated with nivo-rela in the advanced (n=101, [C1]) and neoadjuvant (n=27, [C2]) settings, 48 female (38%) and 80 male (62%), median age 71 [IQR 62–78]. In C1, with a median follow up of 13 months, mPFS and mOS with 95% CI were 19m (10-NR), and NR (25-NR), respectively. In C2, 6 (22%) of pts did not undergo definitive surgery due to disease progression (n=4) and clinical response to therapy (n=2). Among path-evaluable pts (n=21), major pathologic response rate was 10 (48%) including 6 complete (29%) and 4 near-complete responses 19%), with partial response in 3 (14%) and non-response in 8 patients (38%). Adverse events included adrenal insufficiency and myocarditis in 12 (9%) and 4 (3%) of all pts. TME assessment revealed no significant differences in expression of LAG3, PD-1, PDL-1, $CD8^+$ among R vs NR. Baseline tumors from NR were characterized by high expression of B7-H3 in both tumor and immune compartments. No significant correlations were found between B7-H3 and PDL-1, LAG-3, and CTLA-4. High B7-H3 ROIs were enriched by $CD163^+$, $CD68^+$, $CD14^+$, and fibroblast activation protein alpha. **Conclusions:** In a real-world setting, first-line nivo-rela in advanced mel resulted in potentially better PFS while in resectable pts the major pathologic response rate was lower than previously reported in clinical trials. Mel TME with high B7-H3 protein expression was enriched with M2-skewed macrophages and fibroblasts in association with non-response to nivo-rela. This finding warrants further investigation of B7-H3 targeting agents in mel pts. Research Sponsor: None.

Final results of POD1UM-201, a phase 2 study of retifanlimab, a humanized anti–PD-1 antibody, in patients with advanced or metastatic Merkel cell carcinoma (MCC). First Author: Giovanni Grignani, Candiolo Cancer Institute, FPO – IRCCS, Candiolo, Torino, Italy

Background: Retifanlimab is approved in the United States and Europe for treatment of adults with metastatic or recurrent locally advanced MCC, based on previously reported results from the open-label single-arm POD1UM-201 study (NCT03599713). As previously reported, objective response rate (ORR) was 54% (95% confidence interval [CI], 43, 64) and probability of remaining progression free at 12 months was 71% (Grignani G, et al. *Ann Oncol.* 2023;34(suppl 2):S686). Safety profile was as expected for the PD-(L)1 inhibitor class. Here, we present the final results from POD1UM-201 based on extended follow-up. **Methods:** Eligible patients were aged ≥18 years with metastatic or recurrent unresectable locoregional MCC, an Eastern Cooperative Oncology Group performance status (ECOG PS) of 0-1, and measurable disease per Response Evaluation Criteria in Solid Tumors (RECIST) v1.1. Prior systemic treatment for MCC was not allowed. Retifanlimab 500 mg was administered intravenously once every 4 weeks for up to 2 years. Premedication prophylaxis was not routinely administered. The primary endpoint was ORR assessed by independent central review per RECIST v1.1. Key secondary endpoints were duration of response (DOR), disease control rate, progression-free survival, overall survival, and safety. **Results:** The study enrolled 101 patients in North America and Europe between February 12, 2019, and June 16, 2021. Patients had a median age of 71 (range: 38, 90) years, 68 (67%) were male, 77% were White, 74 (73%) had an ECOG PS of 0, and 1 (1%) patient was HIV positive. 91 patients (90%) had stage IV disease, 69 (68%) had prior surgery, and 37 (37%) had prior radiotherapy. Merkel cell polyomavirus and PD-L1 expression were detectable in 73 (72%) and 83 (82%) patient tumor samples, respectively. Median follow-up duration was 36 (range: 1, 60) months. Summary efficacy results are shown in the Table. ORR was 55% (95% CI, 44, 64), with complete response observed in 18 patients (18%). Median DOR was not reached and probability of remaining progression free at 36 months was 57%. Most common immune-related adverse events (irAEs) were skin reactions (10%), including pruritus (4%) and rash (3%), and hypothyroidism (8%); 11% of patients had grade ≥3 irAEs and 9% discontinued treatment due to irAEs. **Conclusions:** Retifanlimab is a highly active treatment for advanced MCC with a safety profile that is representative of the PD-(L)1 inhibitor class. Clinical trial information: NCT03599713. Research Sponsor: Incyte Corporation.

Summary of efficacy.

Study Endpoint	N=101
Overall response rate (95% CI), %	55 (44, 64)
Complete response, n (%)	18 (18)
Partial response, n (%)	37 (37)
Disease control rate (95% CI), %	60 (50, 70)
Duration of response, median (range), months	NR (23, NE)
Progression-free survival, median (range), months	16 (9, 32)
Overall survival, median (range), months	NR (45, NE)

CI, confidence interval; NE, not estimable; NR, not reached.

Response analysis for injected and non-injected lesions and of the safety and efficacy of superficial and deep/visceral RP1 injection in the registrational cohort of anti–PD-1–failed melanoma patients of the IGNYTE trial. First Author: Gino Kim In, University of Southern California Norris Comprehensive Cancer Center, Los Angeles, CA

Background: The IGNYTE trial (NCT03767348) primary analysis of RP1 (vusolimogene oderparepvec) plusnivolumab (nivo) showed clinically meaningful durable efficacy (ORR, 32.9%; median DOR, 33.7 mos, by RECIST 1.1 and independent central review) in patients (pts) with advanced melanoma, including deep responses in non-injected visceral lesions, demonstrating systemic efficacy. Here we present an analysis of efficacy in injected and non-injected lesions and safety and efficacy in pts receiving superficial and/or deep/visceral RP1 injections. **Methods:** Pts with confirmed progression during anti–PD-1 ± anti–CTLA-4 for ≥8 weeks were enrolled. RP1 (1×10^6 PFU/mL x1, then Q2W 1×10^7 PFU/mL x7, up to 10 mL) was injected into superficial and/or deep/visceral tumors using imaging guidance. Nivo was given (240 mg Q2W) from the 2nd dose of RP1 through dose 8, then alone (240 mg Q2W or 480 mg Q4W) for 2 yrs, with additional RP1 injections allowed if indicated. **Results:** For the 46 responding patients by RECIST 1.1 (of the 140 enrolled) 197 lesions were measured, 78 injected, 119 non-injected of which 98.7% and 96.6% had any reduction and 93.5% and 79.0% >30% reduction, respectively. For visceral lesions, 85.7% of injected and 96.2% of non-injected lesions had any reduction and 85.7% and 65.4% had >30% reduction, respectively. 104 patients had superficial only injections, and 36 had deep/visceral +/- superficial injections. Treatment-related adverse event (TRAEs) rates were comparable in patients who were injected superficially compared to patients who received deep/visceral injections, except for chills, influenza-like illness, and injection-site pain, which were numerically higher in the deep/visceral +/- superficial group. Grade ≥3 TRAEs occurred in 14.4% of pts by superficial injection and 8.3% by deep/visceral +/- superficial injection. Grade 1/2 pneumothorax occurred in 3/52 (5.8%) lung injections. No liver function abnormalities or significant bleeds were reported after liver injections. The ORR for pts with superficial injection only was 29.8%, and 41.7% for deep/visceral +/- superficial. **Conclusions:** Meaningful systemic responses were observed independent of the injection status of individual lesions or their anatomical site. Overall response was therefore driven by the response of both injected and non-injected lesions. The safety profile of deep/visceral injection was comparable to that of superficial injections, with efficacy also being similar. Clinical trial information: NCT03767348. Research Sponsor: Replimune, Inc.

9538 **Poster Session**

Long-term outcomes after discontinuation of retifanlimab in patients with advanced or metastatic Merkel cell carcinoma (MCC) in the POD1UM-201 trial. First Author: Giovanni Grignani, Candiolo Cancer Institute, FPO – IRCCS, Candiolo, Torino, Italy

Background: Retifanlimab is a humanized programmed cell death protein-1 (PD-1)–blocking antibody that is approved for treatment of adults with metastatic or recurrent locally advanced MCC in the United States and Europe. Approval was based on primary results from the phase 2, open-label, single-arm POD1UM-201 study (NCT03599713). Here, we present long-term outcomes in patients with MCC who discontinued retifanlimab for reasons other than confirmed disease progression, as previous studies have suggested high rates of recurrence in patients discontinuing treatment after initial response. **Methods:** POD1UM-201 enrolled patients with metastatic or recurrent unresectable locoregional MCC who had not received prior systemic treatment. Retifanlimab was administered every 4 weeks (q4w) intravenously (IV) for a maximum of 2 years, or until progressive disease (PD) or unacceptable toxicity. Patients with complete response (CR) were permitted to discontinue treatment after a minimum of 6 months at investigator discretion. Patients who discontinued retifanlimab for reasons other than PD were closely followed for disease status by independent central review (ICR) until disease progression or death. **Results:** The study enrolled 101 patients with a median (range) follow-up duration of 36 (1, 60) months. Objective response rate was 55% and disease control rate was 60%, including 18 patients (18%) with CR, 37 (37%) with partial response (PR), and 6 (6%) with stable disease (SD) for ≥6 months. Sixty-four patients (63%) discontinued treatment prior to completion of therapy, most commonly due to tumor progression. Forty-one patients were continuing to demonstrate ICR confirmed benefit when treatment was discontinued (CR, n=15; PR, n=21; SD, n=5). Of these patients, 26 (63%) completed the protocol-defined maximum 2 years of therapy, 3 (7%) discontinued at the discretion of the investigator after CR was achieved, and 12 (29%) discontinued due to toxicity. Among the patients with CR or PR, 30 (83%) were alive without disease progression at time of last follow-up after a median (range) of 18 (2, 46) months. Patients who achieved a CR or PR had a lower rate of PD or death compared with those with SD; 7% of patients with a CR experienced PD during follow-up vs 24% of patients with a PR and 60% of patients with SD. **Conclusions:** Retifanlimab 500 mg administered q4w IV for up to 2 years led to durable clinical responses in the majority of patients with advanced MCC. Most patients with an ongoing objective response (CR or PR) remain progression free beyond discontinuation of therapy, suggesting sustained benefit is possible in patients with this highly aggressive disease. Clinical trial information: NCT03599713. Research Sponsor: Incyte Corporation.

9539 **Poster Session**

Updated analyses from a global meta-analysis in metastatic uveal melanoma (mUM) to determine progression free and overall survival benchmarks by line of therapy: An international rare cancers initiative (IRCI) ocular melanoma study. First Author: Leila Khoja, University of Birmingham, Birmingham, United Kingdom

Background: PUMMA is an individual trial patient level meta-analysis that established survival and prognostic benchmarks in metastatic uveal melanoma (Khoja et al, 2019) in 912 patients treated 2000-2016. **Methods:** Herein we describe the dataset further by line of treatment to assist in establishing benchmarks of activity needed to satisfy synthetic control arm surrogates for regulatory purposes for benchmarks of PFS (Progression Free Survival) and OS (Overall Survival) in months (m). **Results:** Within the PUMMA dataset, 567 (62.2%) received 1st line treatment, 161 (17.7%) received 2nd /3rd line treatment. OS was comparable by line of treatment (P=0.2513) with 12m OS rates being 41.3% and 40.5% respectively. Median OS by line of treatment was 9.95 m (95% CI 9.23-10.74) for 1st line and 10.15 m (7.69-11.60) for 2nd/3rd line. PFS was also comparable by line of treatment (p=0.51) with 12m PFS rates being 11.7% and 7.2% respectively. Median PFS by line of treatment was 2.76 m (95% CI 2.66-3.38) for 1st line and 2.86 m (95% CI 2.73-3.52) for 2nd/3rd line. Multivariable analysis of the 1st and 2nd/3rd line treatments separately suggested statistically significant ($p<0.05$) variables associated with inferior PFS in the first line setting included male sex, LDH>2X ULN, ALP>2X ULN whilst inferior PFS in the 2nd/3rd line was predicted by LDH>2X ULN only. Inferior OS in the 1st line setting was statistically significantly associated with ECOG>2, Age > 65, male sex, LDH>2X ULN, ALP>2X ULN whilst inferior OS in the 2nd/3rd line was associated with ECOG>2, LDH>2X ULN, and ALP>2XULN. **Conclusions:** PUMMA continues to show value in providing benchmarks of activity for future clinical trials or regulatory purposes in mUM. The prognostic ability of LDH>2XULN retains important value across multiple lines of treatment scenarios in the PUMMA dataset. Research Sponsor: None.

9540 Poster Session

A phase II, open-label study to improve compliance and time of treatment after obtaining complete response (CR) through a tailored schedule of sonidegib in locally advanced basal cell carcinomas (laBCC): The SONIBEC trial. First Author: Carlo Resteghini, Department of Biomedical Sciences, Humanitas University; IRCCS Humanitas Research Hospital, Pieve Emanuele, Italy

Background: Sonidegib is an efficacious treatment of LA laBCC but is associated with a high risk of treatment-related adverse events (TRAEs) causing treatment discontinuation. Following a CR, treatment discontinuation rate reaches up to 60% after a year, leading to 3 years relapse free survival rate of 35%. We aimed at evaluating sonidegib tailored schedule (TS) after CR to increase treatment duration by reducing TRAEs, thus allowing CR maintenance. **Methods:** We conducted a multicenter, open-label, single-arm phase II study enrolling adult patients (pts) with laBCC who obtained a CR to sonidegib regardless of the tumor's subtype and burden. Eligible pts received TS1 with sonidegib 14 days on and 14 days off. Pts on TS1 who experienced grade 2-3 toxicity (except alopecia) lasting >28 days moved to TS2 (7 days on and 21 days off). Treatment continued until progression or unacceptable toxicity. Primary endpoint was the rate of pts maintaining sonidegib 12 months after study enrolment (H0 31%, H1 60%). Evaluable pts were defined as all pts who were either on treatment or suspended treatment for reasons other than treatment-unrelated adverse events or death. Secondary endpoints were safety, treatment compliance, rate of disease relapse at 1 and 2 years, overall survival, quality of life, use of concomitant medications and of medical resources, and translational analysis. **Results:** Between Jan 2021 and Dec 2023, 22 pts from 10 Italian centers were enrolled; the data cut-off was Jan 2025. Pts characteristics are reported in table 1. The median follow-up was 22 months (range 2-33). Three disease and treatment-unrelated deaths occurred before completing 1 year of TS and therefore 19 pts were evaluable. At data cut-off, 12 pts had discontinued treatment: 26% (5) due to disease progression, 11% (2) to sonidegib's unacceptable toxicity, the remaining either to personal or physician's choice. Twelve out of 19 evaluable pts (63%) were still on treatment after 1 year from TS start (median duration 20 months, range 2-29), meeting the primary endpoint. The most common TRAEs episodes were muscle cramps (13), alopecia (6), dysgeusia (5) with overall TRAEs grade G1 (29), G2 (11), G3 (3). Twelve pts had dose reduction to TS2. **Conclusions:** Tailored maintenance schedule with pulsed sonidegib allows for longer treatment duration and fewer relapses in CR laBCC pts. Study follow up to evaluate secondary endpoints outcome and translational analysis are ongoing. Clinical trial information: 2020-002613-17. Research Sponsor: This is an investigator initiated trial partially supported by an unconditional grant by SunPharma.

AI-detected tumor-infiltrating lymphocytes and response to PD-1 based treatment in advanced melanoma. First Author: Mark Schuiveling, University Medical Center Utrecht, Utrecht, Netherlands

Background: Biomarkers to predict response to immune checkpoint inhibition (ICI)-treated melanoma are limited. This study evaluates AI-detected tumor-infiltrating lymphocytes (TILs) on pretreatment metastatic pathology specimens as a biomarker for response and survival in ICI-treated patients. **Methods:** Patients treated with first-line anti-PD1 ± anti-CTLA4 for advanced melanoma were retrospectively identified from 11 Dutch melanoma centers. Pretreatment TILs were quantified on H&E stained slides using the Hover-NeXt algorithm trained on an independent melanoma dataset with 166.718 pathologist checked manually annotated cells. The average percentage of TILs per 200 μm^2 tumor area was calculated. The primary outcome was response to ICI per RECIST 1.1 with overall survival (OS) and progression free survival (PFS) as secondary outcomes. Univariable and multivariable logistic and Cox regression analyses assessed associations between a 10% increase in TILs present in pretreatment metastatic slides and clinical outcomes. Multivariable analyses were adjusted for age, sex, disease stage, BRAF mutation, LDH and performance score. Objective response rate and Kaplan Meier survival analysis were stratified by TIL tertiles. **Results:** Metastatic melanoma specimens were available for 1246 patients, 441 received anti-PD1 + anti-CTLA4. Median TIL percentage was 10.2% (interquartile range 5.5% – 17.2%). A 10% higher baseline TIL percentage was associated with response (adjusted OR 1.39 [95% 1.21-1.58]), PFS (adjusted HR 0.87 [95% CI 0.81 – 0.94]) and OS (adjusted HR 0.84 [95% CI 0.77 – 0.93] in univariable and multivariable analysis (Table 1). Stratified analysis showed significant associations between TILs, response, and survival in both anti-PD1 monotherapy and combination therapy. **Conclusions:** AI-quantified TILs in pre-treatment melanoma metastases are correlated with improved response rates and survival in ICI treated patients. This correlation is independent of known clinical predictors. Research Sponsor: The Netherlands Organization for Health Research and Development (ZonMW); 848101007; Stichting Hanarth Fonds.

Real-world clinical outcomes of patients with BRAF-mutated melanoma with or without brain metastases receiving frontline immune-checkpoint inhibitors in the US community oncology setting. First Author: Wolfram Samlowski, Comprehensive Cancer Centers of Nevada, Las Vegas, NV

Background: Patients with BRAF-mutated melanoma are at increased risk of melanoma brain metastasis (MBM) which has historically led to worse outcomes. The prognosis of patients with MBM has improved with approval of immune checkpoint inhibitors (ICI) and targeted therapy. However, there is limited information on the impact of the MBM on outcomes in patients with BRAF mutations treated with frontline (1L) ICI. This study aims to describe clinical outcomes of patients with BRAF-mutated metastatic melanoma treated with 1L ICI in the community oncology setting, with a focus on patients with MBM. **Methods:** This was a retrospective observational cohort study of patients with BRAF-mutated metastatic melanoma who initiated 1L ICI (index) between 1/1/16-6/30/22 in The US Oncology Network and non-Network practices and were followed through 6/30/24. Patient characteristics and genomic alterations were sourced from structured electronic health records data and genomic testing results. Patients with mucosal or uveal melanoma, clinical trial participation, treatment for other primary cancers or evidence of co-mutations were excluded. Kaplan-Meier analyses of overall survival (OS), real-world time to treatment discontinuation (rwTTD) and time to next treatment (rwTTNT) were assessed from index, overall and in patients with MBM. **Results:** Of 798 metastatic melanoma patients with a BRAF mutation, 41 (5%) had documentation of a co-mutation and were excluded, resulting in 757 patients in the final analysis set. Median follow-up was 14.6 months, and median age at index was 64 years. Among patients with available data, most were male (63%), White (97%) and had an ECOG of 0-1 (87% among reported) within 60 days prior to index. Among patients with mutation-specific data (n=704), the most common mutation types were V600E (83%) and other V600 (13%) point mutations. The most common 1L ICI regimens were nivolumab+ipilimumab (45%), pembrolizumab (30%), and nivolumab (22%). MBM was documented in 46 (6%) patients at 1L ICI treatment initiation, and an additional 28 (4%) patients developed MBM during the follow-up period, resulting in a total of 74 (10%) patients with MBM. **Conclusions:** Although lower-than-expected rates of MBM were observed, in this large real-world dataset from the community setting, patients with a BRAF mutation had similar rwTTD, rwTTNT, and OS following ICI therapy, irrespective of the presence of MBM. It is reasonable to consider combination ICI therapy in BRAF mutant melanoma patients diagnosed with MBM who lack known contraindications. Further research on the impact of the somatic mutational background on MBM outcomes is ongoing. Research Sponsor: None.

Outcome, median (95% CI)	Overall (N=757)	MBM, any time (N=74)
OS, months	20.3 (16.6, 25.8)	20.3 (10.4, 33.8)
rwTTD, months	3.5 (2.9, 3.9)	3.7 (2.4, 5.6)
rwTTNT, months	5.7 (4.9, 6.5)	5.6 (3.7, 7.5)

9543 Poster Session

Real-world safety and effectiveness of avelumab in immune-compromised (IC) and non-IC patients with Merkel cell carcinoma (MCC): Results from a prospective German registry (MCC-TRIM). First Author: Jurgen Becker, University Hospital Essen, German Cancer Consortium (DKTK), Partner Site Essen/Düsseldorf, German Cancer Research Center (DKFZ), Heidelberg, Germany

Background: MCC is a rare and aggressive form of skin cancer. Avelumab was the first immunotherapy approved for patients with metastatic MCC in Europe. Immunosuppression is an established risk factor for developing MCC, but IC patients have typically been excluded from clinical trials of immunotherapies. We report an analysis of clinical characteristics, survival outcomes, and safety in IC and non-IC patients with MCC treated with avelumab in routine clinical practice in Germany. **Methods:** This prospective, noninterventional, multicenter, dynamic cohort study (MCC-TRIM; EUPAS25338) enrolled patients with MCC in Germany between April 2019 and September 2023. Primary data from a study-specific electronic case report form and secondary data from the German national skin cancer registry were combined. For this analysis, avelumab-treated patients were grouped as IC or non-IC based on prespecified comorbid conditions and concomitant medications. Survival outcomes with first-line avelumab treatment were assessed using the Kaplan-Meier method. **Results:** Among 875 patients with MCC (various disease stages) enrolled in the study, 243 were treated with avelumab, of whom 189 (77.8%) were considered non-IC and 54 (22.2%) were considered IC. Patient characteristics are summarized in the Table. At data cutoff (March 2024), median follow-up (IQR) was 14.3 months (6.4-29.4) in the non-IC subgroup and 8.9 (4.2-22.8) in the IC subgroup. In non-IC and IC subgroups, median (95% CI) overall survival from start of first-line avelumab was 38.2 (15.7-not estimable) and 9.9 (4.8-29.8) months, and median progression-free survival was 7.9 (4.0-11.6) and 4.3 (1.0-7.8) months, respectively. The incidence rate of ADRs related to avelumab was 1.01 (95% CI, 0.75-1.34) events per person-year in the non-IC subgroup and 0.71 (95% CI, 0.32-1.45) events per person-year in the IC subgroup. **Conclusions:** Results from this German nationwide registry showed the safe and effective use of avelumab in routine clinical practice for IC and non-IC patients with MCC. Research Sponsor: the healthcare business of Merck KGaA, Darmstadt, Germany (CrossRef Funder ID: 10.13039/100009945).

Progression-free survival (PFS) assessment by blinded independent central review (BICR) versus local investigator (LI) in metastatic melanoma (MM) randomized controlled trials (RCT): A systematic review and meta-analysis. First Author: Islam Eljilany, Department of Cutaneous Oncology, H. Lee Moffitt Cancer Center and Research Institute, Tampa, FL

Background: Although BICR may reduce assessment variability, it introduces additional financial and logistical burdens to trial operations. This study analyzed the discrepancy indexes (DIs) to evaluate differences between PFS assessments evaluated by LIs and BICR in RCTs of patients (pts) with MM. **Methods:** A comprehensive literature search was conducted on PubMed, Embase, and Cochrane databases until June 30, 2023. Studies were eligible for inclusion in the meta-analysis if they were 1) Phase II or III RCTs with accessible, published data; 2) inclusion of pts diagnosed with MM; 3) availability of PFS data assessed through both LI and BICR; and 4) publication in English. The study complied with the PRISMA guidelines to ensure methodological rigor. Two independent researchers performed data extraction to minimize bias and ensure accuracy. A fixed-effects meta-analysis approach was applied to summarize treatment outcomes, producing pooled estimates and corresponding 95% confidence intervals (CIs). The primary outcome was DI, which was calculated for each trial as a ratio of the hazard ratios $(HR)_{BICR}$ by HR_{LI}. The agreement between PFS HRs was also evaluated using the intraclass correlation coefficient (ICC) and Pearson's correlation coefficient (r). The risk of bias was evaluated using the Cochrane Risk of Bias tool v.2 (RoB 2). **Results:** A total of 12 studies comprising 4,915 pts were included in the meta-analysis that spanned from 2012 to 2023. Of these, 10 studies (83%) were Phase III , 11 (92%) were cutaneous melanoma and all identified PFS as the primary endpoint. Most studies (n = 8, 75%) had a DI $>$ 1 and the overall combined DI was 1.08 (95% CI: 1.01–1.15), indicating a statistically significant numerically small difference (8%) in PFS evaluations conducted by the two assessments, suggesting that BICR tended to be more conservative in PFS assessments. These results were primarily driven by the Phase II or double-blinded studies, which showed a higher median (interquartile range) (IQR) DI [1.14 (o.o8) and 1.16 (0.13), respectively] than phase III or open-label trials [DI 1.04 (0.12) or 1.0 (0), respectively] . However, there was an overall significant strong correlation [ICC: 0.87, $p < 0.001$); r= 0.89, 95% CI 0.67-0.96, $p < 0.0001$)] between BICR and LI assessments and most (86%) of the PFS comparisons led to the same statistical inference. Finally, 10 studies had a low risk of systematic bias, and none had publication bias. **Conclusions:** This study demonstrated a slim statistically significant difference in PFS assessments between LI and BICR, but with strong agreements overall. These findings challenge the necessity of universally implementing BICR in all RCTs, supporting appropriate use in selected scenarios, primarily Phase II RCT. Also, supports the value of double-blinded studies. Research Sponsor: None.

Efficacy and safety of transcatheter arterial infusion of immune checkpoint inhibitors in locoregional unresectable or in-transit acral melanoma: A multi-center real-world study. First Author: Ziluan Chen, Sun Yat-sen University Cancer Center, Guangzhou, China

Background: Acral melanoma (AM) is highly invasive. Standard treatment options, including surgical resection and systemic immunotherapy, frequently yield insufficient control over local lesions. Although various local treatment strategies are currently available, such as isolated limb perfusion (ILP), isolated limb infusion (ILI), intralesional therapies, and radiotherapy, there is still no universally recognized safe and effective method. Previous studies have suggested that transcatheter arterial infusion (TAI), as a locoregional therapeutic strategy, may enhance the management of local lesions through targeted drug delivery. However, the existing literature on the efficacy and safety of TAI utilizing immune checkpoint inhibitors (ICIs) is limited. The aim of this study was to assess the efficacy and safety of TAI of ICIs in patients diagnosed with AM, as well as to investigate clinical factors that may affect treatment outcomes. **Methods:** This study involved a retrospective analysis of patients with AM who underwent TAI of ICIs across multiple centers. Participants received TAI of PD-1 inhibitors or a combination of PD-1 and CTLA-4 inhibitors every three weeks, in conjunction with systemic therapy. The primary endpoint was the objective response rate (ORR), while secondary endpoints included the disease control rate (DCR), progression-free survival (PFS) of locoregional lesions, duration of response (DoR), and overall survival (OS). **Results:** A total of 44 patients with AM were enrolled and analyzed between May 2019 and January 2025. All participants had received at least two TAI treatments and had at least one evaluable locoregional lesion in the extremities, as determined by enhanced MRI or CT imaging. The cohort consisted of 23 females (52%) and 21 males (48%), with a median follow-up period of 10.6 months. The overall ORR was 36.4%, and the DCR was 86.4%. The ORR and DoR for lesions treated with TAI were 40.9% and 90.1%, respectively. Five patients (11%) achieved a complete response (CR), one of whom demonstrated a pathological complete response. The median DoR and OS were recorded at 11.8 months and 32.2 months, respectively. First-line treatment exhibited a significantly higher ORR (82.4% vs. 14.8%, P $<$ .001) and longer PFS (24.9 months vs. 3.5 months, P $<$ .001) compared to subsequent-line treatments. Adverse events were primarily classified as grade 1-2, with no instances of grade 4-5 events, and there were no treatment-related discontinuations or fatalities. **Conclusions:** This study provides evidence for the safety of TAI of ICIs and suggests that it may represent an effective first-line treatment option for Chinese patients with locoregional unresectable lesions of AM, demonstrating significant local control efficacy in real-world clinical settings. The phase 1 clinical trial of anti–PD-1 ab plus intrahepatic injection of oncolytic virus (OH2) combined radiotherapy of liver metastasis in stage IV melanoma. First Author: Xuan Wang, Department of Melanoma and Sarcoma, Key Laboratory of Carcinogenesis and Translational Research (Ministry of Education/Beijing), Peking University Cancer Hospital and Institute, Haidian District, China

Background: Patients with melanoma and liver metastases generally exhibit reduced responses to systemic immunotherapy. Oncolytic herpes simplex virus 2 (OH2), is an oncolytic virus with potential therapeutic benefits. Preliminary clinical trials have demonstrated the efficacy of combining PD-1 antibody therapy with intrahepatic intralesional injections of OH2. Additionally, liver metastasis radiotherapy may modulate the tumor microenvironment, potentially enhancing the efficacy of immunotherapy combinations. In this phase I study, we aim to evaluate the safety and efficacy of OH2 and Pucotenlimab, in combination with liver metastasis-directed radiotherapy in patients with melanoma. **Methods:** Eligible pts included those over 18 with injectable liver metastasis confirmed by biopsy with or without extrahepatic metastasis; the ocular melanoma and brain metastasis were excluded. Pts received intravenous Pucotenlimab Q3W combined with ultrasound guided intrahepatic injection of OH2 Q2W (10^7CCID50/mL, 8ml per injection) after SBRT (24-30Gy/3Fx) of liver metastasis. The primary endpoint was ORR. Clinical trial: NCT05068453. **Results:** From Dec 2021 to Jan 2025, 20 pts were enrolled. 77.8% had received at least one prior treatment; 52.9% presented with extrahepatic metastases. The median size of enrolled lesions was 34.56 mm (13.0–271.0 mm). The median number of liver metastases was 5.5. Among these patients, 17 were evaluable for efficacy. One iCR, four iPR, resulting in an ORR of 29.4% and a DCR of 52.9%. Nearly 60.0% of pts exhibited a reduction in target lesions, including 65.2% of intrahepatic lesions, and 41.7% of extrahepatic lesions with a maximum reduction of 100.0%. Among injection target lesions, 58.3% demonstrated shrinkage,. In non-injection target lesions, 54.5% exhibited shrinkage. The median follow-up was 17.0m. The 1-year survival rate observed was 60.0%, while the 2-year was 51.4%. The OS has not been reached. Interestingly, no clear correlation has been established between imaging evaluations and patient prognosis. Among the pts classified as having PD, 10 individuals continued treatment due to clinical benefits. Notably, their OS was comparable to that of the overall population, with 2-year survival rate 60.0%. No treatment-related deaths reported. Adverse events were minimal, with only two grade 3 TRAEs observed: pneumonia and colitis. Biopsies of 17 pts with injected lesions were analyzed 8 to 12 weeks after the first injection. Of these, five pts (1 iCR, 1 iPR, and 3 SD) showed no residual tumor cells, accompanied by TIL infiltration. All five pts exhibited long PFS. **Conclusions:** The combination of systemic anti-PD-1 therapy with intralesional injection of an oncolytic virus and radiotherapy has demonstrated a remarkable ORR and excellent OS in patients with melanoma and liver metastases, with manageable toxicity. Clinical trial information: NCT05068453. Research Sponsor: None.

Influence of tumor infiltrating lymphocytes (TIL) monotherapy on persistent clinical and immunological responses in Asian metastatic melanoma patients with specific CD8+ TIL proportions: A phase I trial. First Author: Chuanliang Cui, Key Laboratory of Carcinogenesis and Translational Research (Ministry of Education/Beijing), Department of Renal Cancer and Melanoma, Peking University Cancer Hospital & Institute, Beijing, China

Background: TIL therapy, as one of the most promising adaptive cellular immunotherapy, has shown success in metastatic melanoma, with a median overall response rate (ORR) of 28% and median PFS (progression free survival) of 7.2 months. This phase I clinical trial aimed to explore the safety, feasibility, and efficacy of TILs monotherapy in Asian metastatic melanoma pts. **Methods:** Pts with metastatic melanoma who had progressed on standard therapies, had both resectable and measurable tumors were eligible to be enrolled. Pts received a lymphodepletion regimen which consisted of cyclophosphamide (30mg/kg) for 2 days, followed by Fludarabine (25mg/m^2) for 5 days, approximately 24 hours before receiving the intravenous autologous LM103 (TILs) infusion and then high dose IL-2 for 6 doses (200000IU/Kg, 1 dose per day. Doses can be adjusted based on pts tolerance to support T cell survival and proliferation. **Results:** Twelve pts (aged 26-68 yrs) with metastatic melanoma were enrolled and treated, including 8 males. Among the primary melanoma types, 6 were acral, 3 mucosal, 2 unknown, and 1 cutaneous. 7 pts had distant organ metastases. As of Jan 2025, 8 out of 12 pts were assessable, one could not be evaluated due to rapid brain metastases and 3 remained under safety observation (median follow-up, 6 wks; range, 2-48 wks). Resected tumors used for TIL production were from 8 metastatic lymph nodes and 4 subcutaneous nodules. The infused autologous TIL contained 8.24-19.47X10^{10} viable cells. The median duration of IL-2 infusion were 5.08 days, with a median dose of 13.75 IU/Kg/day. The most frequent treatment-emergent adverse events (TEAEs) were myelosuppression (100%), fever (100%), anemia (100%), and hypotension (100%). Grade 3-4 TEAEs included neutropenia (100%), lymphopenia (100%), leukopenia (100%), fever (75%), thrombocytopenia (62.5%), and anemia. The ORR was 50% (4/8, 4PR, 2SD, 2PD) per RECIST v1.1. The median PFS was not reached and the longest PFS was 11.4 months. Responders demonstrated a larger number of T cell clones, higher T cell receptor (TCR) diversity (Inverse Simpson Index), and lower TCR clonality compared to non-responders (P=0.031,*P=0.049* and *P=0.033*), based on real time peripheral monocytes analysis. These findings suggest that the LM103 in responders recognized a broader antigen spectrum. Notably, about 50% of initial TCR clones can be detected 18 wks post-infusion, suggesting LM103 persistence. Post-hoc analysis revealed that responders had a CD8+ T-cells proportion of 60-80%, while non-responders exhibited extreme proportions ($<$10% or $>$80%). **Conclusions:** LM103 was well tolerated and demonstrated durable responses in Asian patients with advanced melanoma. Patients with 60-80% CD8+T-cell proportions are more likely to respond to TIL therapy. Clinical trial information: CTR20233999. Research Sponsor: None.

Intensive surveillance and aggressive multi-modal treatment for liver metastases from uveal melanoma. First Author: Hemant M. Kocher, Queen Mary University of London, London, United Kingdom

Background: We report utility of diagnostic laparoscopy and long-term survival outcome for patients undergoing multi-modal treatment for liver metastasis from uveal melanoma (LMUM). **Methods:** All consecutive patients with suspected oligo-metastatic LMUM diagnosed on screening ultrasound were discussed at Hepato-Pancreatico-Biliary (HPB) Tumour Boards (Jan2010-Nov2024) and were offered multiple lines of surgical / ablation, liver directed and systemic therapies as appropriate, with data censored on 30th November 2024. Liver specific overall survival was calculated from date of index liver resection to date of last follow-up (censored) or death. **Results:** Out of the 58 patients LMUM, 13 (22%) patients had multifocal disease or other concurrent cancer diagnosed on further imaging assessments (dedicated MRI liver and FDG-PET scan). Of the remaining 45 patients assessed with diagnostic laparoscopy a further 15 (33%) had multifocal hepatic metastasis. Thus 27 patients (46%) had multifocal disease precluding liver resection / ablation (Group A). 21 of 58 patients with LMUM had liver resection as a primary modality with majority (18/21) achieving a R0 resection margin and a further 10 had liver ablation (Group B). Both groups received additional lines of treatment. Patients with oligo-metastatic disease undergoing liver resection / ablation as primary modality of treatment (Group B) had longer overall survival (median liver-specific OS = 45.1 (95% CI: 31 – not reached) months; $p<0.0001$, log-rank (Mantel-Cox) test, Hazard ratio (HR): 7.86, 95%CI: 3.52-17.5) after treatment of metastatic disease compared to multi-focal disease treated with immunotherapy as primary modality (Group A, median 18.6 (95% CI: 13-26) months). Whilst the age of diagnosis of LMUM was similar for both Groups A (multifocal metastasis, median 68 years) and B (oligometastatic disease, median 63 years) (two-tailed Mann Whitney U test, p=0.12), patients group B were younger at time of diagnosis of primary UM (median 57 (B) versus median 66 years (A), two tailed Mann Whitney U test, p=0.03) with a longer interval to metastatic progression (median 1325 days (B) versus median 704 days (A), two tailed Mann Whitney U test, p=0.006). **Conclusions:** This largest series of patients with LMUM from the United Kingdom emphasises the vital role of diagnostic laparoscopy to rule out bi-lobar miliary disease. We report impactful overall survival with multimodal treatment for LMUM and highlight prognostic features for further validation. Research Sponsor: The London Clinic.

High-dose 1,3-bis-(2-chloroethyl)-1-nitrosourea (BCNU) chemoembolization for treatment-naïve patients with limited uveal melanoma hepatic metastases. First Author: Carin F. Gonsalves, Sidney Kimmel Comprehensive Cancer Center, Thomas Jefferson University, Philadelphia, PA

Background: Nearly 50% of patients with uveal melanoma (UM) develop metastases with the liver being the primary site of disease in $>$ 90% of cases. Control of hepatic tumors is crucial to prolonging overall survival (OS) for metastatic uveal melanoma (MUM) patients. We report results of aPhase II prospective trial [NCT04728633] using high-dose BCNU chemoembolization (TACE) as first-line treatment for limited UM hepatic metastases. **Methods:** MUM patients with $<$ 50% hepatic tumor burden and no significant extrahepatic disease were treated with hepatic artery infusion of 300mg of BCNU diluted in ethiodized oil followed by gelatin sponge embolization until maximum clinical benefit, hepatic and/or extrahepatic disease progression (PD), or development of significant adverse events (AE). Tumor response (RECIST 1.1) was assessed using CT and MRI. Treatment breaks were allowed for patients with disease control (partial response [PR] + stable disease [SD]) to reduce toxicities and optimize quality of life. Retreatment with TACE was permitted if PD occurred during treatment breaks. OS, progression-free survival from liver (PFS-L) and systemic metastases were analyzed. Toxicities were assessed using CTCAE v5.0. **Results:** Twenty-eight patients (17 men; median age, 62; range, 39 - 84) were enrolled from October 2021 to January 2025. Bilobar (n=25) or unilobar (n=3) BCNU TACE was performed every 4 or 7 weeks (+/- 7 days), respectively. Median follow-up was 11.6 months (range, 1.8 – 37.6). Median OS was 14.1 months (range, 1.8 – 37.6) with 13 surviving patients. Best treatment response included PR in 8, SD in 18, and PD in 2 patients for an overall response rate of 28.6% and a disease control rate of 92.9%. Twenty-two (78.6%) patients with disease control had treatment breaks. One patient withdrew from the trial to pursue percutaneous hepatic perfusion despite SD for 25 months. Median PFS-L was 9.9 months (range, 1.8 – 36.8). Sixteen (57.1%) patients developed new/nontarget hepatic tumor progression (n=13) or progression of target and nontarget lesions (n=3). Treatment-related grade 3 AEs included pain (n=5), hypertension (n=4), incidental pulmonary emboli (n=3), thrombocytopenia (n=1) and an infected biloma. Self-limiting grade 3 or 4 liver enzyme elevation occurred in 6 patients. Fifteen (53.6%) patients developed extrahepatic disease (median, 7.3 months); 11 patients (7 with stable liver tumors) started systemic therapy off-trial. Three patients developed life-limiting AEs due to checkpoint inhibitor therapy. **Conclusions:** High-dose BCNU TACE provided disease control in the majority of treatment-naïve patients with limited UM hepatic metastases. PD typically occurred during treatment breaks, as expected. Future trials exploring the combination of BCNU TACE with systemic therapies to address both hepatic and extrahepatic metastases are warranted. Clinical trial information: NCT04728633. Research Sponsor: Guerbet.

Gotistobart in combination with pembrolizumab in patients with advanced melanoma who have progressed on PD-1 inhibitors with or without CTLA-4 inhibitors. First Author: Siwen Hu-Lieskovan, University of Utah Health, Salt Lake City, UT

Background: Patients with advanced melanoma who progress on PD-1 and CTLA-4 inhibitors (IO-R/R) have poor prognosis. Gotistobart is a pH-sensitive anti-CTLA-4 mAb and we hypothesized that gotistobart in combination with pembrolizumab (pembro) could improve outcomes for ipilimumab plus nivolumab (ipi/nivo) treatment failure. PRESERVE-001 (NCT04140526) is a phase 1/2 study that evaluates safety and efficacy of gotistobart with pembro in patients with IO-R/R advanced melanoma. **Methods:** Patients with IO-R/R advanced melanoma were treated with 3 mg/kg or 6 mg/kg gotistobart plus 200 mg of pembro, Q3W. Treatment beyond progression was allowed at the physician's discretion. Primary endpoints were ORR (RECIST 1.1) and safety. Exploratory endpoints included OS and an ad-hoc analysis of next-treatment free survival (NTFS; next treatment was identified as initiation of a new antineoplastic agent). **Results:** As of December 19, 2024, 33 and 34 patients received 3 mg/kg and 6 mg/kg gotistobart plus pembro, with median follow up associated with OS of 14.7 and 10.7 months, respectively. Of these, 67% (22/33) and 68% (23/34) had progressed on ipi/nivo. 30% (20/67) had tumors $\geq$10cm at study entry. Unconfirmed ORR (uORR) was 25.0% (8/32) and 26.5% (9/34), respectively, with 2 patients achieving CR in the 6 mg/kg group. Of patients who had prior ipi/nivo, uORR was 23.8% (5/21) and 21.7% (5/23), respectively. Efficacy was noted regardless of BRAF mutation status. NTFS rates at 12 months were 45.3% (95% CI 26.0–62.7) and 38.5% (95% CI 20.3–56.4), respectively. OS rates at 18 months were 61.7% (95% CI 40.1–77.5) and 51.9% (29.3–70.4), respectively. Grade $\geq$ 3 TRAEs were observed in 51.5% and 61.8% of patients in the 3 mg/kg and 6 mg/kg groups, respectively, with colitis/diarrhea or AST/ALT increase being most common. 30.3% and 32.4% of patients, respectively, were able to continue treatment after dose reduction. **Conclusions:** Gotistobart 3 mg/kg or 6 mg/kg plus pembro 200 mg, Q3W, provided durable response and clinically meaningful OS benefit, regardless of prior ipi treatment, with nearly half of patients being next-treatment free at one year follow up. To our knowledge,this is one of the largest cohorts ever studied in patients with advanced melanoma R/R to ipi/nivo. Clinical trial information: NCT04140526. Research Sponsor: OncoC4 Inc; BioNTech SE; SBIR; R44CA250884; National Cancer Institute.

Additional parameters	Gotistobart 3 mg/kg (N = 33)	Gotistobart 6 mg/kg (N=34)
Median age (range)	62 (29–83)	66 (24–81)
Female n (%)/Male n (%)	12 (36%)/21 (64%)	12 (35%)/22 (65%)
ECOG score = 1 (of 0 or 1)	18 (55%)	16 (47%)
Prior treated with ipi/nivo	22 (67%)	23 (68%)
Gotistobart treatment duration in weeks, median (range)	19.0 (3–96)	8.9 (3–130)
uORR % (n)	25.0% (8/32)	26.5% (9/34)
uORR in patients prior treated with ipi/nivo % (n)	23.8% (5/21)	21.7 (5/23)
DCR % (95% CI)	50 (31.9, 68.1)	50 (32.4, 67, 6)
NTFS rates at 12 months % (95% CI)	45.3 (26.0, 62.7)	38.5 (20.3, 56.4)
OS rate at 18 months % (95% CI)	61.7 (40.1–77.5)	51.9 (29.3–70.4)

Nautilus, a phase 1b/2 trial of combining oral HDAC inhibitor (HDACi) with MEK inhibitor (MEKi) in patients with NRAS-mutated metastatic melanoma (MM). First Author: Rodabe Navroze Amaria, The University of Texas MD Anderson Cancer Center, Melanoma Medical Oncology, Houston, TX

Background: Activating NRAS mutations occur in 15-20% of MM cases. The MEK inhibitor binimetinib has modest single agent activity with 15% objective response rate (ORR) and 2.8 month progression-free survival (PFS). Bocodepsin (OKI-179) is a novel Class I-selective, oral histone deacetylase inhibitor that was found to have synergistic efficacy with MEKi in preclinical models of NRAS-mutated melanoma. Cells displayed unrepaired double strand DNA breaks and cellular apoptosis, while regressions were observed in xenograft models. Here we present the results of the phase 2 portion of a clinical trial of this combination in NRAS-mutant MM (NCT05340621). **Methods:** In this Phase 2 study, only patients with NRAS-mutant MM previously treated with immunotherapy were enrolled and treated with bocodepsin at the recommended phase 2 dose (300 mg daily, 4 days on, 3 days off, continuously) with binimetinib (45 mg twice daily, continuously). Primary endpoint was ORR, with secondary endpoints including safety and PK analyses. **Results:** As of 1/3/2025, 36 total patients were enrolled; 14 in phase 1b dose escalation and 22 in phase 2, including a total of 24 NRAS-mutant melanoma patients. Median age of NRAS-mutant MM patients was 69 years, and 47% of patients were males. Median numbers of prior therapies was 3 and LDH elevations were found in 41% of patients. There were no grade 3/4 toxicities seen in $>$10% of patients, including no episodes of high grade rash. Of the 20 evaluable patients with NRAS-mutant MM, ORR was 30%. The median PFS was 7.25 months (5-92 weeks). **Conclusions:** The combination of bocodepsin and binimetinib in patients with NRAS-mutant melanoma is tolerable with manageable AEs and no high grade rash. Initial response data in patients with NRAS-mutant melanoma are supportive of potential combinatorial activity of a MEK inhibitor and HDACi bocodepsin. Further investigation is crucial as MM patients with disease progression after immunotherapy remain in need of rational therapeutic options. Thus, MEKi + HDACi warrants further study in a larger patient cohort. Clinical trial information: NCT05340621. Research Sponsor: OnKure.

First-line lenvatinib plus pembrolizumab versus placebo plus pembrolizumab in Chinese patients with unresectable or metastatic melanoma: Results from LEAP-003. First Author: Jun Guo, Beijing Cancer Hospital, Beijing, China

Background: Results of the global, phase 3 LEAP-003 study, showed that lenvatinib (len) + pembrolizumab (pembro) significantly improved PFS compared with pembro alone in participants (pts) with predominantly cutaneous melanoma at the first interim analysis, but this benefit was not maintained with additional follow-up and there was no improvement in OS. Previous studies have shown that mucosal and acral melanomas, which are the predominant subtypes in Chinese patients, may benefit from combination therapy. Here, we present results for Chinese participants (pts) enrolled in the LEAP-003 global (NCT03820986) and China extension (NCT04889118) studies. **Methods:** Eligible pts were aged ≥18 y, had previously untreated unresectable stage III or IV melanoma, an ECOG PS of 0 or 1, and measurable disease per RECIST v1.1. Pts were randomly assigned 1:1 to len 20 mg or placebo (pbo) PO QD + pembro 200 mg IV Q3W for ≤2 y. Dual primary end points were PFS per RECIST v1.1 by BICR and OS. Secondary end points were ORR, DOR, and safety. **Results:** 131 pts from China enrolled and received treatment (len + pembro, n = 64; pbo + pembro, n = 67). Median time from first dose to data cutoff (Jan 18, 2023) was 18.1 mo (range, 12.7-29.5). In the overall China subgroup, median PFS was 6.1 mo (95% CI, 4.1-8.1) for len + pembro vs 2.0 mo (95% CI, 2.0-2.1) for pbo + pembro (HR, 0.55; 95% CI, 0.37-0.81); 18-mo PFS was 20.0% vs 12.8%. Median OS was 19.9 mo (95% CI, 11.9-26.8) for len + pembro vs 17.0 mo (95% CI, 12.7-25.7) for pbo + pembro (HR, 0.93; 95% CI, 0.58-1.48); 18-mo OS was 53.4% vs 49.6%. ORR was 26.6% (95% CI, 16.3-39.1; 4 CR, 13 PR) for len + pembro vs 16.4% (95% CI, 8.5-27.5; 4 CR, 7 PR) for pbo + pembro; median DOR was 13.7 mo (range, 3.8-21.4) vs NR (range, 4.2-21.4+). Among 30 pts with mucosal melanoma, median PFS was 8.1 mo (95% CI, 5.9-12.4) for len + pembro (n = 16) vs 2.0 mo (95% CI, 1.9-4.1) for pbo + pembro (n = 14; HR, 0.44; 95% CI, 0.20-0.97); 12-mo PFS was 33.5% vs 21.4%. Median OS was 26.8 mo (95% CI, 10.6-NR) for len + pembro vs 14.3 mo (95% CI, 9.0-NR) for pbo + pembro (HR, 0.51; 95% CI, 0.17-1.55); 18-mo OS was 68.8% vs 49.0%. ORR among pts with mucosal melanoma was 50.0% (95% CI, 24.7-75.3; 1 CR, 7 PR) for len + pembro vs 7.1% (95% CI, 0.2-33.9; 1 PR) for pbo + pembro. Treatment-related AEs occurred in 96.9% in the len + pembro arm vs 97.0% in the pbo + pembro arm (grade 3-5: 62.5% vs 16.4%). One pt (1.5%) in the pbo + pembro arm died due to treatment-related immune-mediated lung disease. **Conclusions:** In Chinese pts, the efficacy and safety profile observed with len plus pembro vs pembro alone was consistent with the global population. Numerical improvements in PFS and ORR in the mucosal melanoma subtype treated with len + pembro were notable, although the data should be interpreted with caution due to the limited sample size. These results support first-line pembro monotherapy as a standard-of-care for this population. Clinical trial information: NCT03820986, NCT04889118. Research Sponsor: Merck Sharp & Dohme LLC, a subsidiary of Merck & Co., Inc., Rahway, NJ, USA, and Eisai Inc., Nutley, NJ, USA.

Efficacy and safety of first-line (1L) nivolumab plus relatlimab (NIVO + RELA) versus NIVO plus ipilimumab (NIVO + IPI) in advanced melanoma: An updated indirect treatment comparison (ITC) with 4-year follow-up data. First Author: Dirk Schadendorf, University of Essen and the German Cancer Consortium, Essen, Germany

Background: An ITC comparing NIVO + RELA and NIVO + IPI, approved dual immunotherapy treatment options for patients (pts) with advanced melanoma, was previously conducted using pt-level data from the pivotal RELATIVITY-047 (RELA-047; NIVO + RELA vs NIVO) and CheckMate 067 (CM-067; NIVO + IPI or NIVO vs IPI) trials (Long JCO 2024). Here we present updated results using 4-year follow-up data from RELA-047. **Methods:** Inverse probability of treatment weighting was used to adjust for cross-trial imbalances in baseline characteristics. CM-067 follow-up was truncated (median 41.0 mo) to best align with the follow-up length in RELA-047 (median 34.9 mo). Progression-free survival (PFS) per investigator, confirmed objective response rates (ORRs) per investigator, overall survival (OS), and melanoma-specific survival (MSS) were analyzed. Outcomes were also evaluated across key subgroups. The weighted NIVO arms from each trial were compared for internal validation. **Results:** After weighting, key baseline characteristics were balanced for NIVO + RELA (n=339) and NIVO + IPI (n=297). Outcomes after weighting were similar between NIVO + RELA and NIVO + IPI (hazard ratio [HR] [95% CI]: PFS 1.08 [0.89–1.33]; OS 0.95 [0.76–1.19]; table). Outcomes were similar between the NIVO arms, validating the ITC methodology. Across subgroups, efficacy appeared similar between treatments, although trends favoring NIVO + IPI were observed for ORR among pts with BRAF-mutant disease or serum lactate dehydrogenase >2x the upper limit of normal. Results when NIVO + IPI follow-up was untruncated were consistent with the truncated analyses. **Conclusions:** Consistent with previous results, this updated ITC with longer follow-up from RELA-047 suggests that 1L treatment with NIVO + RELA may have comparable efficacy to NIVO + IPI in pts with advanced melanoma, including most—but not all—subgroups. Results should be interpreted with caution given differences in study design and changes in the treatment landscape over time. Research Sponsor: Bristol Myers Squibb.

Efficacy outcomes after weighting.

	NIVO + RELA (n = 339)	NIVO + IPI (n = 297)	HR/odds ratio [OR] (95% CI)	NIVO RELA-047 (n = 338)	NIVO CM-067 (n = 288)	HR/OR (95% CI)
Median PFS per INV, mo (95% CI)	12.0 (8.2–17.1)	11.2 (8.5–18.1)	1.08 (0.89–1.33)	6.6 (4.6–10.1)	5.7 (3.9–9.1)	0.96 (0.79–1.16)
Confirmed ORR per INV, %	48	50	0.91 (0.73–1.14)	40	40	1.00 (0.79–1.28)
Median OS, mo (95% CI)	64.5 (38.6–NR)	NR (37.1–NR)	0.95 (0.76–1.19)	35.1 (27.3–48.8)	35.7 (26.4–NR)	1.02 (0.83–1.26)
Median MSS, mo (95% CI)	NR (NR–NR)	NR (NR–NR)	0.87 (0.68–1.12)	51.2 (34.7–NR)	44.8 (32.3–NR)	0.96 (0.76–1.21)

NR: not reached; HR/OR are NIVO+RELA vs NIVO+IPI.

Phase 2 study of axitinib + nivolumab in mucosal melanoma with pilot addition of stereotactic body radiotherapy or ipilimumab in select progressors. First Author: Sarah E. Lochrin, Memorial Sloan Kettering Cancer Center, New York, NY

Background: Mucosal melanoma (MM) is an aggressive subtype of melanoma with distinct biology, and outcomes in advanced disease are inferior compared with cutaneous melanoma. Frontline Chinese studies in MM have shown efficacy of combined VEGF/R and PD-1 blockade, but studies in more diverse populations and options in PD-1 resistance are lacking. **Methods:** We conducted a phase 2/1b single-center trial in patients (pts) with untreated, unresectable or advanced MM. Pts received standard nivolumab (nivo) plus axitinib (axi) 5mg PO twice daily. Primary endpoint of the phase 2 doublet arm was objective response rate (ORR) by RECIST 1.1 (H0=23%, Ha=48%). Clinical benefit rate (CBR) was defined as ORR or stable disease (SD) >6 months (mos). Upon progression with good tolerance, the phase 1b triplet arm pts received the addition of either stereotactic body radiotherapy (SBRT, 30Gy/5 fractions) or ipilimumab (ipi, 1mg/kg < 4 doses) to ongoing nivo + axi. The primary endpoint of the triplet was safety by CTCAE v5.0 and adverse events (AEs) of special interest (AESIs). Kaplan-Meier methods estimated time to event outcomes; ORR and AEs were reported as proportions with exact 95% confidence intervals. **Results:** N=21 pts were enrolled; N=20 were evaluable for efficacy. See Table for baseline population characteristics. Median follow up was 15 mos (IQR 6, 21), 45% of pts (95% CI: 23, 68) had an objective response; 3 complete and 6 partial responses. Median duration of response was 13 mos (8.6, not reached (NR)). SD persisted ≥ 6 mos in 2 of 7 pts; CBR was 55% (95% CI: 32,77). Median progression free survival (PFS) was 6.3 mos (3.5, NR), and 12-mos estimated PFS and overall survival was 37% (20,67) and 71% (52, 96), respectively. Rate of grade ≥3 treatment related AEs (TRAE) in the doublet arm (n=21) was 67% (95% CI: 43,85), most commonly hypertension & hepatitis, with two pt deaths; 1 nivo-related myasthenia gravis / myositis, and 1 nivo-related pancreatitis with steroid-related PJP pneumonia. 14 pts (70%) progressed on doublet therapy, of which 7 enrolled on the triplet arm. N=5 received ipi and N=2 SBRT (both to anorectal primaries and adjacent lymph nodes). There were 2 grade ≥3 TRAEs in the ipi triplet arm (hepatitis), 0 in the SBRT arm, no grade 5 events, and no AESIs. Zero of 4 evaluable pts in ipi triplet and 1 of 2 in the SBRT triplet responded (4+ mos, ongoing). **Conclusions:** The frontline combination of nivolumab and axitinib was effective in patients with unresectable or advanced outside of China, and a prospective global study randomized against immune checkpoint blockade is warranted. Adding either ipi or SBRT to nivo-axi appears safe in select pts with progressive disease and further studies are needed for pts with PD-1 resistant MM. Clinical trial information: NCT05384496. Research Sponsor: National Comprehensive Cancer Network (NCCN); Pfizer.

Phase I dose escalation trial of STX-001, an LNP-encapsulated self-replicating mRNA expressing IL-12, in patients (pts) with advanced solid tumors. First Author: Sarina A. Piha-Paul, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: STX-001 is a lipid nanoparticle-encapsulated self-replicating mRNA that activates innate immunity, promotes immunogenic cancer cell death, and expresses IL-12 to induce immune responses against tumors. Preclinical models demonstrated significant immune modulation and antitumor activity. **Methods:** Eligible pts had treatment-refractory advanced solid tumors with ≥ 1 clinically injectable lesions. Bayesian Optimal Interval design was used with an initial 3 + 3 run-in for dose escalation. STX-001 was administered intratumorally every 3 weeks. Dose-limiting toxicities (DLTs) were assessed during the first treatment cycle and response was evaluated by RECIST 1.1. **Results:** From May 29, 2024 to data cutoff (Dec 16, 2024), 14 pts were enrolled across four dose levels (30 - 900 μg). Common Gr ≥ 3 treatment-related adverse events, which included transient neutropenia (4 pts; 29%), lymphopenia (3 pts; 21%), ALT increase (2 pts; 14%), and AST increase (2 pts; 14%), were largely acute and self-limiting, and allowed ongoing dosing. There was no febrile neutropenia or drug-induced liver injury. One pt in the 900 μg cohort experienced DLTs (Gr 3 cytokine release syndrome and Gr 4 lymphopenia) but remained on study. IL-12 expression and robust IFN-γ induction were observed in the plasma. Tumor biopsies showed robust increases in PD-L1 and CD4/CD8 T cell staining post-treatment in both injected and non-injected lesions compared to baseline. 7 pts had undergone on-treatment disease assessment. 5 out of 7 pts had melanoma and were all refractory to PD-1 + CTLA-4 or LAG-3 inhibitors. 3 out of 5 melanoma pts had shrinkage of non-injected lesions (abscopal effects) including one with a confirmed RECIST complete response (CR; 100 μg cohort; prior treatments: PD-1 + LAG3, CTLA-4, and PD-1 inhibitors; metastases in skin and lymph nodes; subcutaneous lesion injected), one with a RECIST partial response (PR; 30 μg cohort; prior treatments: PD-1 + CTLA-4, PD-1, PD-1 + LAG3, and CTLA-4 inhibitors; metastases in skin, lung, and muscle; subcutaneous lesions injected), and one with 100% target lesion reduction with pronounced inflammatory response across multiple cutaneous/visceral lesions (30 μg cohort; prior treatments: PD-1 and CTLA-4 + PD-1 inhibitors; metastases in skin, lymph nodes, and lung; [sub]cutaneous lesions injected) and on-going clinical benefit (despite initial RECIST progression). ctDNA analysis, peripheral blood and tumor microenvironment profiling, PK, and other translational analyses are ongoing. **Conclusions:** STX-001 demonstrates promising preliminary efficacy, robust immune activation, and a favorable safety profile. These results support the continued development of STX-001 both as monotherapy and in combination with immune checkpoint inhibitors. Dose optimization is ongoing. Clinical trial information: NCT06249048. Research Sponsor: None.

Outpatient treatment-related toxicity after hospital discharge among patients receiving lifileucel for advanced melanoma. First Author: James William Smithy, Memorial Sloan Kettering Cancer Center, New York, NY

Background: While inpatient toxicity associated with tumor infiltrating lymphocyte (TIL) therapy and IL-2 administration is well characterized, risks facing patients after hospital discharge are less understood. Better characterization of outpatient adverse effects (AEs) could guide the optimal frequency and duration of follow up for this growing patient population. **Methods:** We conducted a retrospective analysis of all patients with advanced melanoma discharged from Memorial Sloan Kettering Cancer Center after receiving investigational or commercial lifileucel from October 2020 to October 2024. We reviewed incidence and timing of new Grade 3+ treatment-related AEs (TRAEs), blood product administration, and readmission among all patients from the time of hospital discharge to the time of the start of a subsequent systemic therapy or death. **Results:** Fifty-three patients successfully discharged after lifileucel administration were identified; patient demographics are included in Table 1. The median follow up time from discharge in survivors was 5 months (interquartile range (IQR): 3, 18). Two patients (4%) developed new Grade 3+ TRAEs following hospital discharge, including new Grade 3 neutropenia 73 days after discharge and new Grade 3 hypoxia 104 days from discharge. Hypoxia was secondary to pleural effusions that developed in the setting of renal thrombotic microangiopathy. Four patients (7.5%) were readmitted for TRAEs including cytopenias, dyspnea, and syncope while 7 patients (13%) were readmitted for melanoma progression. Readmissions occurred a median of 85 (IQR: 39, 128) days after lifileucel infusion and 69 days (IQR: 19, 98) after initial discharge. Twelve patients (23%) received at least one outpatient blood product transfusion, including packed red blood cells (PRBCs; 10 patients) and platelets (6 patients). Within 30 days of initial discharge, six patients (11%) received at least one PRBC transfusion and 3 patients (5.7%) received at least one platelet transfusion. The median number of transfused PRBC units was 2 (IQR: 1,4) and the median number of platelet transfusions was 4 (IQR: 2, 4). **Conclusions:** Rates of new severe toxicity and treatment-related readmissions were low among patients discharged post-lifileucel. About one in four patients required blood products after discharge. Identification of risk factors for the development of outpatient TRAEs may inform personalized care following lifileucel administration. Research Sponsor: None.

Results of phase III clinical trial of novel biosimilar of pembrolizumab (RPH-075). First Author: Ilya Pokataev, Moscow City Oncological Hospital No. 1 Named After S.S. Yudin, Moscow, Russian Federation

Background: Pembrolizumab is a high-affinity humanized antibody to the PD-1 receptor. This study investigated the efficacy and safety profile of RPH-075, a biosimilar of original pembrolizumab, in patients with advanced skin melanoma. **Methods:** CL01860211 was an international, multicenter, double-blind, randomized, phase III comparative study. The study was based on the following hypothesis: RPH-075 is non-inferior to pembrolizumab (Keytruda) in objective response rate (ORR) at 24 weeks from the start of therapy in patients with unresectable or metastatic melanoma as 1st or 2nd line therapy, not previously treated with pembrolizumab or other anti-PD-1/PD-L1/PD-L2 agents. Pembrolizumab was administered intravenously at a dose of 200 mg Q3W until progression or intolerable toxicity (but no longer than 2 years). ORR was assessed in the per protocol (PP) population according to RECIST 1.1 and iRECIST criteria by an Independent Radiology Review Committee. Disease control rate (DCR), progression-free survival (PFS), were the secondary endpoints. Safety assessment was carried out throughout the study. Adverse events (AE) were assessed by CTCAE v5.0. Immunogenicity was also evaluated over 24 weeks of therapy. **Results:** A total of 266 patients were randomized in 2 groups (n=137 in RPH-075 group and n=129 in pembrolizumab group). The median age was 66 years (range 27–87). The majority of patients had ECOG 0-1 – 96.24%. Most of the patients (90.60%) received pembrolizumab as 1st line treatment. Metastases in the CNS were identified in 10.53% patients. ORR was 28.35% [95% CI: 21.23; 36.73] in RPH-075 group and 24.56% [95% confidential interval (CI): 17.57; 33.21] in pembrolizumab group (p = 0.604). The relative risk was 1.154 [95% CI: 0.755; 1.764]. The lower margin of the obtained 95% CI is higher than the lower margin (0.664) established in the hypothesis. DCR was 48.03% in RPH-075 group and 35.09% in pembrolizumab group (p = 0.057). Median PFS was 3.02 months in RPH-075 group and 2.76 in pembrolizumab group (p = 0.058). Treatment-related adverse events of any grade were registered for 39.13% of patients in RPH-075 group and for 43.75% of patients in pembrolizumab group (p = 0.457). During the main period, anti-drug antibodies (ADA) were detected in 6 patients: 3 (2.36%) in the RPH-075 group and 3 (2.46%) in the pembrolizumab group. None of the patients with detected ADA had neutralizing activity of antibodies to pembrolizumab and no imAEs were registered. **Conclusions:** The non-inferior efficacy of RPH-075 relative to pembrolizumab had been confirmed along with similar safety profile. Clinical trial information: NCT06320353. Research Sponsor: None.

ctDNA versus 18F-FDG PET-CT in predicting long-term disease control in patients with advanced melanoma undergoing immune checkpoint blockade therapy. First Author: Milton Jose De Barros E Silva, A.C. Camargo Cancer Center, São Paulo, Brazil

Background: Imaging remains the gold standard for assessing response to systemic immunotherapy in patients with advanced melanoma. Several studies have demonstrated a strong correlation between metabolic response evaluation using 18F-FDG PET-CT and long-term prognosis in patients with advanced melanoma treated with immunotherapy. Meanwhile, ctDNA kinetics has emerged as a promising alternative method to support the evaluation of patients receiving immunotherapy. **Methods:** We prospectively collected blood samples for liquid biopsy assessments using next-generation sequencing (NGS-Ion S5 platform; Thermo Fisher) to detect tumor somatic mutations with a 409-gene panel, and tumor mutations were tracked in plasma samples collected from advanced melanoma patients undergoing immune checkpoint blockade therapy at AC Camargo Cancer Center at baseline, Day 30 (D30), and Day 60 (D60). ctDNA was considered positive if the variant allelic fraction (VAF) exceeded 0.5% and was at least twice that in negative controls. ctDNA results were compared with Day-90 PET-CT and correlated with long-term disease control outcomes. Assessments at D30 and D60 were classified into three categories: molecular responders (MR), molecular non-responders (MNR), and negative pattern (NP), following the framework of the KEYNOTE-942 study. **Results:** This analysis included 15 stage IV melanoma patients treated with nivolumab (3 mg/kg) and ipilimumab (1 mg/kg). Seven patients (47%) showed an objective response on PET-CT. After a median follow-up of 26 months (range: 1–44 months), 31% of patients exhibited controlled disease. PET-CT demonstrated 78% accuracy in predicting long-term disease status (controlled vs. uncontrolled). Baseline ctDNA analysis showed that 10 patients (67%) were ctDNA-positive. The accuracy of baseline ctDNA (positive vs. negative) in predicting long-term disease control status was 71%. On D30, 13 cases were analyzed and classified as follows: 4 (MR), 6 (MNR), and 3 (NP). The accuracy of the D30 liquid biopsy analysis in predicting long-term disease status was only 31%. On D60, 11 cases were analyzed and classified as follows: 5 (MR), 4 (MNR), and 2 (NP). The accuracy of the D60 liquid biopsy analysis in predicting long-term disease status was 73%. **Conclusions:** ctDNA status at baseline and D60, as well as 18F-FDG PET-CT at D90, appear to have similar accuracy in predicting long-term disease control in patients with advanced melanoma treated with immune checkpoint blockade. Research Sponsor: Oncomine Clinical Research Grant.

Electronic health records (EHR)-based machine learning (ML) approach to predict risk of progression to metastatic melanoma after initial diagnosis. First Author: Ryan Pindale, ConcertAI, Cambridge, MA

Background: Strategies to predict progression to metastasis in early-stage melanoma patients have relied on a limited sample size and a limited set of clinical or genomic features. Prior studies were able to achieve good discrimination in small cohorts, but applying advanced machine learning techniques to large datasets with deep clinical and molecular data may yield tools with enhanced generalizability and clinical utility. **Methods:** We employed a machine learning approach to predict the likelihood of progression to metastatic melanoma for a cohort with an initial diagnosis of stage 0-3 (n=7477) using both structured and human-curated information in the ConcertAI Patient360 melanoma EHR dataset. Patients with uveal melanoma, a second primary malignancy, or clinical trial participation status were excluded. A total of 68 features including staging, demographic, testing, biomarker, and clinical tumor information recorded within 30 days of initial melanoma diagnosis were used to train several machine learning frameworks to predict the likelihood of progression to metastatic melanoma. A logistic regression, random forest classifier, gradient boosting decision tree, and XgBoost framework were compared using the AUC from a 20% hold-out set to determine the optimal framework after hyperparameter tuning. Additional evaluation metrics, which include accuracy, precision, recall, and F1 were computed for the final model. Feature importance measures were determined using Shapley Additive Explanation (SHAP) dependence plots. Permutation (N=1000) was utilized to evaluate the predictive power of the final model. **Results:** An XgBoost approach produced a test AUC of 0.708 with a pseudo-p value = 0.001 from permutation. Notably, the model produced a precision of 0.709 on the hold-out set. SHAP dependence measures showed that the most important features used for predictions include those involving initial staging and clinical measures of the tumor. Specifically, lower initial stage corresponded with lower predicted probability of metastatic progression. Similarly, higher values of mitotic rate and tumor thickness corresponded with higher predicted probability of progression. In addition, more complex interactions between features also contributed to the improved performance of the XGBoost framework. **Conclusions:** An XgBoost framework trained on a large set clinical features for 7477 melanoma patients predicted metastatic progression with significant predictive power (p = 0.001) yielding an AUC of 0.708. The model relied heavily on staging information at initial diagnosis and information on tumor size, mitotic rate, and ulceration status to make predictions, which were typically reported in unstructured EMR. These results indicate the clinical utility for machine learning models trained on real world data for both providers and patients. Research Sponsor: None.

Delineating the role of the microbiome and tumor microenvironment interactions driving mucosal melanoma (MM) response and resistance to immune checkpoint inhibitor (ICI) treatment. First Author: Florentia Dimitriou, Department of Surgical Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: MM is a rare melanoma subtype with distinct biology and low response rates to ICIs. We seek to prospectively profile a cohort of MM patients to determine the interplay of gut, mucosal and tumor microbiome and modifiable risk factors on ICI response and resistance. **Methods:** Patients (pts) with MM presenting at MD Anderson are being prospectively enrolled for longitudinal collection for molecular, microbiome, and lifestyle factor profiling. Planned analyses will evaluate (1) fecal specimens [whole metagenome shotgun (WMS) sequencing, microbiome profiling and 16S rRNA gene sequencing (16S)]; (2) mucosal surface swabs (WMS sequencing); (3) formalin-fixed paraffin embedded (FFPE) tumor specimens [Bruker Digital Spatial Profiling (DSP)]; and (4) fresh tumor samples [whole exome (WES) and whole genome (WGS) of normal and tumor tissue, RNA sequencing, and T cell receptor sequencing]. **Results:** 82 pts with sequenced fecal specimens and mucosal surface swabs were enrolled as of 12/2024. MM primary sites included 25 (30%) naso-oral (including sinonasal), 14 (17%) urogenital, 30 (37%) anorectal, 10 (12%) conjunctival and 3 (4%) other. Disease stages were IVM1a/M1b in 9 (9%) pts, and IVM1c/M1d in 27 (33%) pts. Initial analysis of gut and mucosal surface swabs' microbiome by MM primary site displayed a wide range of intrasample heterogeneity and microbial signatures that correlate with the MM primary site. WES and WGS data analysis indicate low tumor mutational burden (TMB) of 1.34mut/Mb (median, range 0.52 – 14.72). Common mutations included *SF3B1* (23%), *KIT* (15%) and *NRAS* (8%). Anorectal and urogenital tumors contributed to mutational signatures associated with DNA mismatch repair and microsatellite instability (COSMIC v3.211). Conjunctival and naso-oral tumors showed an association with UV exposure. Results in the gut microbiome analysis from 78 pts treated with ICIs showed compositional differences in the presence and proportion of bacterial taxa in responders (R), compared to non-responders (NR). Distinct bacteria such as *Streptococcus, Collinsella*, and *Blautia* were identified in R, and *Butyricicoccus* in NR. DSP analysis by treatment response showed higher expression of CD56 and CD20 in the immune and tumor compartments in R. **Conclusions:** This is an ongoing prospective study that is expected to drive insights into the tumor/microenvironment/host interactions and factors regulating immunogenicity to predict response and resistance to ICIs in a rare and understudied melanoma subtype. Interrogation of the role of the gut microbiome and its modifiable determinants will lead to the investigation of new therapeutic strategies to modulate the microbiome to improve treatment outcomes in MM. Multidimensional, spatially resolved immunologic hallmarks of response to neoadjuvant immune checkpoint blockade (ICB) therapies. First Author: Zichao Liu, The Jackson Laboratory for Genomic Medicine, Farmington, CT

Background: The groundbreaking neoadjuvant ICB clinical trials have established beyond doubt that ICB before surgery will become the new standard of care for metastatic melanoma. Importantly, the shift from radiographic to pathologic response scoring offers an unprecedented window of opportunity to interrogate a goldmine of 'on-treatment' biospecimens. To date, single-cell profiling and region-based spatial transcriptomics (ST) have highlighted the importance of tertiary lymphoid structures (TLS) and stem-like T-cells as positive predictors of ICB response. However, the molecular mechanisms by which tumor infiltrating lymphocytes communicate and organize multicellular immune hubs within the spatial context of the tumor ecosystem remains poorly understood. **Methods:** To identify robust biomarkers of response to neoadjuvant ICB, we assembled a cohort of 58 stage III melanoma patients treated with neoadjuvant ICB [24 ipilimumab-nivolumab (IPI-NIVO), 21 NIVO-relatlimab (RELA), 13 PD1 mono] and deployed transformative technologies and computational methods, including single-cell FFPE sequencing, multiplexed FISH single-cell ST (MERFISH 305 genes), digital pathology, 3D open-top light-sheet imaging and AI-based computational pathology, to decipher the complex neoadjuvant ICB tumor ecosystem in response to therapy. We also developed 2 critical computational tools, SCIRA (Spatial Cellular Interaction and Receptor Activation), to compute receptor-ligand (R-L) interactions in whole slide images, and GC-SCAN (graph-based spatial clustering against noise), a graph-based algorithm that quantifies locally clustered structures from spatial -omics data. **Results:** Our results showed that the quantity and size of hyper-expanded germinal center/TLS, with increased GC: non-GC B-cell ratio, plasma cells and spatially resolved stem-like T-cells are strongly associated with response. IPI-NIVO elicited significantly stronger GC proliferation compared to NIVO-RELA and PD1 monotherapy, suggesting anti-CTLA4 can robustly induce germinal center/TLS proliferation. SCIRA spatial R-L analyses revealed the critical chemokine R-L interactions that organize the GC- and T-cell zones in response to therapy. Lastly, 3D light-sheet imaging revealed remarkable morphologic heterogeneity in 3D, with interconnected GC-TLS networks that are indicative of long-range molecular gradients. **Conclusions:** Our investigations herein have provided a comprehensive characterization of the immune architectures, cellular communications and 3D large-scale morphologic organizations of the TME that drive response to neoadjuvant ICB therapy. We believe the results of this study will enable the development of robust predictive biomarkers to guide the design of next generation combination ICB therapies in the clinical trial setting for melanoma and other cancer types. Long-term outcomes following melanoma metastasectomy categorized by response to immune checkpoint inhibitor (ICI) therapy. First Author: Aravind Sreeram, Johns Hopkins University School of Medicine, Baltimore, MD

Background: Patients undergoing surgical resection of Stage III/IV melanoma after response to ICIs show favorable survival, particularly with pathologic complete response (pCR). However, long-term outcomes of such patients stratified by ICI response remain undescribed. As surgery is increasingly employed in both PD-1 sensitive and refractory settings (e.g. tumor-infiltrating lymphocytes (TIL) therapy), better-defined outcomes and a clearer understanding of surgery's role are much needed. **Methods:** Patients treated with ICI (2003-2023) followed by metastasectomy were identified from a prospectively maintained database. Pre-surgery ICI response was assessed radiographically, and patients were categorized as having either stable/responding disease (R), an isolated site of disease progression (IP), or multiple progressing sites of disease (MP) for which surgery was pursued due to acute symptoms or palliative intent. Clinicopathologic factors examined included response to ICI, resection to no evidence of disease (NED), and pCR. Kaplan-Meier analyses with log-rank tests were used to compare disease-specific survival (DSS) from surgery date. Cox proportional hazards models identified independent predictors of DSS. **Results:** Among 513 patients, 426 (83%) had stage IV and 87 (17%) had stage III disease at ICI initiation. Patients were categorized as either R (n=76), IP (n=227), or MP (n=210). Fifty-three percent of patients received subsequent systemic therapy including 20 TIL patients, 12 of whom were in the MP group. Median follow-up after surgery among survivors was 2.51 years (IQR 0.93, 6.72). Median DSS following surgery was 4.1 years (95% CI: 2.5, NR). Resection to NED at the first operation post-ICI (n = 202, 39%) was associated with improved 5-year DSS [81% (75%, 88%) vs. 26% (20%, 33%); $p < 0.001$], with similar findings in only Stage IV patients (n = 426) [75% (67%, 84%) vs. 24% (19%, 32%); $p<0.001$]. Patients who underwent resection for an R or IP tumor had a 5-yr DSS of 89% (80%, 98%) or 62% (55%, 70%), respectively, compared to 20% (14%, 28%) for MP lesions ($p < 0.001$). Independent predictors of DSS also included NED resection and pCR (Table 1). **Conclusions:** Disease control after metastasectomy following ICI is durable, especially in patients with responding, stable, or isolated progressing disease, in addition to those achieving resection to NED or pCR. Alternative therapeutic strategies should be considered for patients with MP tumors as DSS remains poor after surgery alone. Research Sponsor: None.

Immunological phenotype as a predictor for response after isolated limb perfusion for patients with melanoma in-transit metastasis. First Author: Anna Constantinescu, Sahlgrenska Centre for Cancer Research, Department of Surgery, Institute of Clinical Sciences, Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden

Background: Isolated limb perfusion (ILP) is a regional treatment for patients with melanoma in-transit metastases (ITM) confined to extremities, using a high dose of melphalan. ILP has a high response rate, with approximately 60% having a complete response (CR). This study aimed to validate if pre-operative immunological phenotype could be a predictive factor for CR after ILP. **Methods:** A total of 132 patients undergoing ILP as a first treatment for melanoma ITM between January 2012 and March 2023 were included in this study. The number and percentage of naïve and memory T and B cell subtypes, as well as natural killer (NK) cells were characterized by analyzing pre-operative blood samples using fluorescence activated cell sorting (FACS). Univariable and multivariable analysis were used to investigate if any of these subtypes were predictive for response after ILP. **Results:** Out of the 132 patients included in the study, 53% achieved a CR. Immunological and clinical factors significantly and independently associated with an CR after ILP were: number of metastases (OR 0.98, 95% CI 0.97-1.00, p=0.036), size of largest metastases (OR 0.96, 95% CI 0.93-0.99, p=0.009), percentage of CD3+8+ cells (OR 1.07, CI 95% 1.02-1.13, p=0.012) and percentage of CD3+8+45RA+ cells (OR 1.11, CI 95% 1.01-1.22, p=0.029). **Conclusions:** Immunological phenotype described as percentage of cytotoxic T-cells and naïve cytotoxic T-cells are together with tumor burden important predictive factors for response after ILP for patients with melanoma in-transit metastasis. This could potentially contribute to better patient selection and individualized treatment algorithms, but might also be a foundation for future novel treatment combinations, where an ongoing trial is currently combining ILP with a PD-1 inhibitor (ClinicalTrials.gov NCT03685890). Anxiety, depression, fear of cancer recurrence (FCR) and health-related quality of life (HRQL) in people with melanoma receiving adjuvant therapies. First Author: Julia Elizabeth Lai-Kwon, Peter MacCallum Cancer Centre, Melbourne, VIC, Australia

Background: One year ofadjuvant anti-programmed cell death protein-1 (anti-PD1) or dabrafenib-trametinib are standards of care for patients (pts) with resected stage III-IV melanoma. Emotional distress has been linked to inferior disease outcomes following neoadjuvant immunotherapy for stage III melanoma. We aimed to assess the anxiety, depression, FCR and HRQL in a real-world population up to 2 years post initiation of adjuvant therapy. **Methods:** A prospective, longitudinal study of pts with resected stage IIB-IV melanoma receiving adjuvant anti-PD1 or dabrafenib-trametinib at an Australian comprehensive cancer center. The Patient-Reported Outcomes Measurement Information System (PROMIS) Network Emotional Distress-Anxiety 7a and Depression 8b, Fear of Cancer Recurrence Inventory-Short Form (FCRI-SF), and Functional Assessment of Cancer Therapy-General (FACT-G) were collected pre-treatment, and at 1, 3, 6, 12, and 24 months post treatment initiation. PROMIS t-scores were categorized as mild (55-59), moderate (60-69) and severe ($\geq$70). Clinically significant FCR was categorized as a FCRI-SF score $\geq$22. **Results:** From September 2021-December 2024, 70 pts were eligible and 52 (74%) consented: 17 (33%) female, median age 64 years (IQR 60-71), 46 (89%) resected stage III, 32 (62%) on adjuvant anti-PD1. 41 pts had completed treatment and 11 were still receiving treatment at data cut off (17 December 2024). 51 pts completed at least 1 set of surveys. The prevalence of mild, moderate or severe anxiety, depression and clinically significant FCR up to 2 years post initiation of adjuvant therapy is shown in the table. People experiencing anxiety or depression at 24 months reported worse HRQL compared to those without (mean FACT-G score- anxiety: 67.8 vs 82.8; depression: 69.7 vs 84.2). Of the 18 pts with data at both 12 and 24 months, all those with clinically significant FCR at 12 months continued to report FCR at 24 months. All those with clinically significant FCR at 24 months reported worse HRQL compared to those without clinically significant FCR at 24 months (mean FACT-G score: 67.7 vs 80.5). **Conclusions:** A significant number of pts report anxiety, depression, and clinically significant FCR up to 2 years post initiation of adjuvant therapy, which is associated with worse HRQL. Screening for psychological issues can identify those who may benefit from psychological and/or pharmacological intervention to improve disease outcomes. Research Sponsor: None.

	Pre-treatment (n= 51)	1 month (n= 46)	3 months (n=44)	6 months (n= 38)	12 months (n=31)	24 months (n=18)
Anxiety (n, %)	20 (40%)	19 (41%)	16 (36%)	15 (39%)	13 (42%)	7 (39%)

Identification of patients at high risk for relapse by Merlin assay (CP-GEP) in an independent cohort of melanoma patients (pts) that did not undergo sentinel lymph node biopsy: An H&N subgroup analysis. First Author: Teresa Amaral, Skin Cancer Center, Eberhard Karls University of Tübingen, Tübingen, Germany

Background: Sentinel lymph node biopsy (SLNB) is still the gold standard for nodal assessment used in the clinical staging of cutaneous melanoma (CM) pts by AJCC v8. Recently, we showed in a small cohort that CP-GEP also has the potential to risk stratify pts who did not undergo SLNB in low and high-risk for recurrence (Amaral et al, EJC 2023). SLNB may be challenging in pts with head and neck (H&N) melanoma, due to the regional course of cranial nerves and lymphatic drainage. Here we focus on the ability of CP-GEP to stratify pts with H&N melanoma in particular those with lentigo maligna, who did not undergo SLNB, for their risk of recurrence. **Methods:** We analyzed formalin-fixed paraffin-embedded primary tumor samples of 930 pts of which 206 were localized in the H&N region, with stage I/II CM diagnosed between 2000-2017 who did not receive SLNB. The CP-GEP model used combines the expression of 8 genes (SERPINE2, GDF15, ITGB3, CXCL8, LOXL4, TGFBR1, PLAT and MLANA) by quantitative reverse transcription polymerase chain reaction with age and Breslow thickness to obtain a binary output: CP-GEP Low- or High-Risk. Relapse-free survival (RFS), distant metastasis free survival (DMFS) and Melanoma Specific Survival (MSS) were evaluated using Kaplan-Meier curves. **Results:** We included 930 pts (stage IA-IIC) of which 206 pts (22.3%) were diagnosed with H&N melanoma. Patient characteristics: 41% were females, median age was 73-year-old, median Breslow thickness was 0.5 mm and 75.6% were lentigo maligna melanomas. Median follow up was 51 months (RFS). All H&N pts showed the following survival: 5-year RFS 82.5%, DMFS 94.0 and MSS 95.5%. CP-GEP risk stratification identified 17 patients as CP-GEP High-Risk and 188 as CP-GEP Low-Risk. The 5-year RFS rate was 86.7% for CP-GEP Low-Risk and 39.7%% for CP-GEP High-Risk pts (HR 7.85; $p<0.001$), 5-year DMFS was 96.3% for CP-GEP Low-Risk and 68.9% High-Risk pts (HR 10.26; $p<0.001$) and the 5-year MSS was 98.5% for CP-GEP Low-Risk pts and 64.7% for CP-GEP High-Risk pts (HR 24.45; $p<0.01$). **Conclusions:** Pts with H&N CP-GEP Low-Risk tumors have a good long-term survival compared to High-Risk pts even though SLN status was not assessed. This prognostic information may allow the clinicians to skip SLNB in this difficult anatomic localization and in frail and/or older pts. Research Sponsor: SkylineDx.

Distinct effect of neoadjuvant PD1 alone, PD1+IPI, and PD1+lenvatinib in the peripheral immune profile of melanoma patients (pts) and correlation with pathological (path) response. First Author: Ines Esteves Domingues Pires da Silva, Melanoma Institute Australia, The University of Sydney, Sydney, Australia, Wollstonecraft, Australia

Background: Neoadjuvant immunotherapy (NeoIT) has significantly improved clinical outcomes for pts with macroscopic stage III resectable melanoma and is the current standard of care for these pts. Here, we analysed longitudinal peripheral immune profiles and their correlation with path response for 3 different PD1-based NeoIT regimens. **Methods:** Pts with macroscopic stage III resectable melanoma treated with neoadjuvant PD1-based regimens (PD1 alone, PD1+IPI and PD1+Lenvatinib) for 6 weeks, followed by surgery, were included. Cytometry by time-of-flight (CYTOF; 39-marker panel) was performed on peripheral blood mononuclear cells (PBMCs) at baseline and week 6 (wk 6; pre-surgery). **Results:** Of 64 pts included, 17 PD1 alone (7 [41%] had major pathological response [MPR; $\leq$ 10% of viable tumour cells at the surgical specimen]), 26 PD1+IPI (20 [77%] had MPR) and 21 PD1+Lenvatinib (12 [57%] had MPR). We analysed >200 peripheral immune cell types/phenotypes, and present the statistically significant treatment effects (from baseline to wk 6), overall and based on path response (MPR vs. non-MPR), in patients treated with PD1 alone, PD1+IPI and PD1+lenvatinib (see Table). **Conclusions:** IPI+PD1 and PD1+Lenvatinib induced stronger peripheral blood immune activation, compared with PD1 alone, irrespective of path response. There were differences in the MPR vs non-MPR pts, particularly for PD1 alone. A more in-depth analysis of the effects of these PD1-based regimens and their association with recurrence is underway to identify key immune cell types/phenotypes associated with response & resistance to NeoIT. Research Sponsor: None.

Effect of neoadjuvant PD1 alone, PD1+IPI and PD1+lenvatinib in the peripheral immune profile of melanoma patients.

	Overall treatment effect	MPR (vs. non-MPR)	Non-MPR (vs. MPR)
PD1	Increase in: - OX40+ / ICOS+ regulatory T cells (Tregs) - KI67+ ICOS+ CD4 T cells	Increase in: - GZM+ CD4+ & CD8+ T cells - Double negative [CD27- IgD-] B cells	Increase in: - Non-classic [CD14low+CD16++] HLA-DR+ monocytes Decrease in: - CD4 T effector memory cells - Th1 cells
PD1+IPI	Increase in: - Tregs - Activated [ICOS+ / LAG3+ / TIGIT+] CD4+ T cells - TIM3+ CD4+ & CD8+ T cells - Non-classic [CD14low+CD16++] monocytes - Cytotoxic [CD56dim CD16+] NK cells Decrease in: - Stem-like [TCF7+] CD4+ & CD8+ T cells		Increase in: - OX40+ / T-BET+ CD127- CD8+ T effector memory cells
PD1+lenvatinib	Similar changes seen with PD1+IPI, as well as an increase in: - Th1 - Th17 - CD8+ T effector memory cells Decrease in: - Double negative [CD27- IgD-] B cells	Increase in: - CD127- Tregs	Increase in: - HLA-DR+ non-classic [CD14low+CD16++] monocytes

Rational use of adjuvant anti-PD-1: Multi-omics model of recurrence in stage III melanoma. First Author: Tuba Nur Gide, Melanoma Institute Australia, Faculty of Medicine and Health, The University of Sydney, Sydney, NSW, Australia

Background: Stage III melanoma patients (pts) undergoing adjuvant anti-PD-1 immunotherapy have a high risk of recurrence (43% within one year) and treatment-related adverse events (25% severe). This study developed multi-omics models that accurately identify pts at high risk of recurrence who may benefit from alternative treatment strategies or closer surveillance. **Methods:** We analyzed a cohort of 131 pts with stage III melanoma (47% IIIA/B and 53% IIIC/D) who received adjuvant anti-PD-1 therapy. The nodal burden was micrometastatic (35%) and macrometastatic (54%), with in-transit metastases in 11% of pts. Comprehensive multi-omics profiling included DNA sequencing (tumor mutational burden [TMB]), whole-transcriptome sequencing (gene expression profiling [GEP]), and multiplex immunohistochemistry (tumor microenvironment [TME]) of the baseline tumor sample. We developed predictive models for 12-month recurrence using multivariable penalized logistic regression with consensus-nested cross-validation incorporating clinical, TMB, GEP, and TME features. Internal validation was performed using optimism bias through 500 bootstrap iterations. **Results:** Clinical factors (nodal burden, stage, and site of primary melanoma) alone achieved a modest AUC of 0.66 (95% CI: 0.56-0.75) for predicting recurrence. Addition of TME features, particularly CD16+ cells interacting with PD-L1+CD16+ macrophages, significantly improved predictive accuracy (AUC: 0.81, 95% CI: 0.72-0.91). Further enhancements were observed with TMB and BRAF mutation status (AUC: 0.83, 95% CI: 0.74-0.92) and GEP-derived natural killer (NK) cell and interferon-gamma (IFNg) signatures (AUC: 0.83, 95% CI: 0.73-0.93). A consensus model integrating these features achieved an optimal AUC of 0.86 (95% CI: 0.78-0.94). This model demonstrated robust performance across macroscopic (AUC: 0.88, 95% CI: 0.78-0.98) and microscopic (AUC: 0.86, 95% CI: 0.70-1.00) nodal diseases. **Conclusions:** This study demonstrates the potential of multi-omics profiling to significantly enhance recurrence risk prediction in stage III melanoma pts receiving adjuvant anti-PD-1 therapy. We developed a robust model with high predictive accuracy by integrating clinical data with TME, TMB, and GEP features (AUC, 0.86). This model can help identify pts at high risk of recurrence who may benefit from alternative treatment strategies or closer surveillance. Research Sponsor: None.

AUC scores of various models.

Model	AUC
Clinical	0.66
Clinical+TME	0.81
Clinical+TMB	0.83
Clinical+GEP	0.83

Combining machine learning with the immunohistochemical expression of AMBRA1 and loricrin to identify non-ulcerated AJCC stage I/II melanomas at high-risk of metastasis. First Author: Penny Lovat, Newcastle University, Newcastle upon Tyne, United Kingdom

Background: Precision-based personalised biomarkers able to identify both low-risk and high-risk patient subpopulations with localised cutaneous melanoma are urgently needed to guide clinical follow up and treatment stratification. The combined immunohistochemical expression of AMBRA1 and Loricrin (AMBLor) in the epidermis overlying non-ulcerated AJCC stage I/II melanomas as prognostic biomarker able to accurately identify genuinely low-risk patient subpopulations (NPV >96%, clinical sensitivity >95%, Ewen *et al* Brit J Dermatol. 2024). To further identify distinct subsets of patients at high risk of metastasis, the present study aimed to develop a machine learning (ML) risk-prediction model combining AMBLor 'at-risk' status with six specific patient clinical and tumour pathological features. **Methods:** Using common and widely used ML models a Naïve Bayes and a Generalized Linear Model with adaBoost, ML algorithms were trained and tested using three geographically distinct retrospective-prospective cohorts of AMBLor at-risk non-ulcerated AJCC stage I/II melanomas from Australia, USA and Spain (n=552), with validation studies performed in a 4th independent retrospective-prospective cohort of 120 AMBLor at-risk non-ulcerated localised melanomas derived from the UK. **Results:** Based on a training: test data split of 50:50, 20% of patients were defined as high-risk, with a 5-year recurrence-free survival (RFS) probability of 56% (Log-rank [Mantel-Cox) $P < 0.0001$, HR 6.88, 95% CI 3.03-15.63, clinical specificity 87.2%, PPV 44.4%). Further validation of the ML algorithms in the UK validation cohort identified 24% patients as high-risk, with a 5-year RFS of 56.3% (Log-rank [Mantel-Cox) $P < 0.0001$, HR 7.59, 95% CI 2.94-19.6, clinical specificity 82.1%, PPV 50%). **Conclusions:** Through the proven negative predictive power of AMBLor with the cumulative power of prognostic clinical and pathological features these data provide a novel and improved risk- prediction model to stratify patients with non-ulcerated localised melanomas at low or high risk of tumour recurrence thereby aiding optimal personalised patient management and treatment stratification. Longitudinal ctDNA monitoring for post-surgical molecular residual disease in patients with stage I-IIIb melanoma. First Author: George Ansstas, Division of Medical Oncology, Department of Medicine, Washington University School of Medicine, St. Louis, MO

Background: Circulating tumor DNA (ctDNA) has emerged as an important biomarker for early recurrence detection and monitoring disease status in patients with cancer, including melanoma. Here, we evaluate the prognostic value and utility of post-operative ctDNA detection in patients with stage I-IIIb melanoma using a clinically validated, personalized, tumor-informed ctDNA assay. **Methods:** We conducted a retrospective analysis of real-world data of patients with stage I-IIIb melanoma (N=197), including ctDNA results using a personalized, tumor-informed, 16-plex mPCR-NGS assay (Signatera, Natera, Inc.). Adjuvant treatment decision and post-surgical plasma (N=1,718) sample collection during treatment for ctDNA analysis was at the provider's discretion. ctDNA results were correlated with clinical outcomes. **Results:** Across 197 patients analyzed for ctDNA, a median of 7 tests (range: 2-44) per patient were performed over a median period of 24.7 months (range: 3.7-74.7).ctDNA-positivity at any postoperative timepoint was significantly associated with shorter relapse-free survival (RFS; hazard ratio [HR]: 15.0, 95% CI: 7.3–31.0, $P < 0.0001$). This finding was pronounced for patients with distant/regional recurrence (HR: 27.0, 95% CI: 10.0–71.0, $P < 0.0001$). Multivariate analysis confirmed ctDNA-positivity to be the most significant prognostic factor associated with RFS when compared with other clinicopathologic factors such as adjuvant treatment, stage, sex, and mitotic rate (N=163, HR: 10.50, 95% CI: 3.891–28.32 $P < 0.001$). Finally, we explored the utility of ctDNA-positivity and its impact on clinical decision-making and observed that ctDNA-positivity influenced changes in treatment management in 73.7% (N=28/38) of patients, ranging from imaging escalation to treatment initiation, switch, or escalation. **Conclusions:** Our findings highlight the prognostic value of post-surgical, personalized ctDNA detection and monitoring of molecular residual disease in stage I-IIIb melanoma and provide information on real-world clinical decision practices based on ctDNA changes. Efficacy of adjuvant anti-PD-1 antibodies and interferon in patients with nail apparatus melanoma: A retrospective, multicenter study (ADJ-NAIL study). First Author: Takaya Komori, Department of Skin Oncology/Dermatology, Saitama Medical University International Medical Center, Saitama, Japan

Background: The clinical efficacy of anti-PD-1 antibodies (PD-1) for nail apparatus melanoma (NAM) is less effective than that for advanced cutaneous melanoma. Despite the significant need for effective adjuvant (adj) therapies to improve survival in NAM, the efficacy of adj PD-1 and interferon (IFN) is unknown because of the rarity of NAM. Thus, this study aimed to investigate the efficacy of adj PD-1 and adj IFN therapies for NAM. **Methods:** Thisretrospective study reviewed data of patients with stage IIB, IIC, and III NAM without adj therapies (observation: OBS), who received adj PD-1 therapy (adj-PD-1) and adj IFN therapy (adj-IFN) after complete resection across 42 Japanese institutions. The Kaplan–Meier analysis and multivariable Cox proportional hazard models were used to estimate survival probabilities. Propensity-score matching (PSM) was employed to adjust for differences in the baseline characteristics between each group. **Results:** A total of 397 patients with NAM (OBS, n = 219; adj-PD-1, n = 99; adj-IFN, n = 79) were included. The baseline characteristics were significantly different among the three groups in terms of age ($P < 0.001$) and stage ($P < 0.001$). The other baseline characteristics were comparable. A significant difference was noted in the recurrence-free survival (RFS) among the OBS, adj-PD-1, and adj-IFN groups (5-year RFS 42% vs. 21% vs. 48%; $P = 0.02$). However, distant metastasis-free survival (DMFS) and overall survival (OS) were not significantly different among the three groups (5-year DMFS 50% vs. 44% vs. 54%; $P = 0.15$, 5-year OS 59% vs. 46% vs. 58%; $P = 0.28$). Multivariable Cox proportional hazard models revealed that adj-PD-1 and adj-IFN did not positively affect survival outcomes compared with OBS (adj-PD-1: RFS hazard ratio [HR] 1.14; $P = 0.47$, DMFS HR 1.04; $P = 0.84$, OS HR 1.19; $P = 0.50$, adj-IFN: RFS HR 0.73; $P = 0.11$, DMFS HR 0.77; $P = 0.21$, OS HR 0.96; $P = 0.84$). After PSM, the patient backgrounds were balanced at a 1:1 ratio between the OBS and adj-PD-1 groups (n = 71 each) and adj-IFN groups (n = 75 each). No significant differences were found in the survival outcomes between the OBS and adj-PD-1 groups (5-year RFS 30% vs. 20%; $P = 0.96$, 5-year DMFS 39% vs. 39%; $P = 0.95$, 5-year OS 49% vs. 39%; $P = 0.53$) and between the OBS and adj-IFN groups (5-year RFS 35% vs. 48%; $P = 0.06$, 5-year DMFS 41% vs. 54%; $P = 0.09$, 5-year OS 56% vs. 57%; $P = 0.73$). In patients who experienced a relapse and were treated with nivolumab/ipilimumab combination therapy, the progression-free survival from the initiation of combination was significantly shorter in the adj-PD-1 group than in the OBS group (median PFS 1.8 months vs. 4.0 months; $P = 0.03$). **Conclusions:** In NAM, adj-PD-1 and adj-IFN did not improve survival. Furthermore, the use of adj-PD-1 may attenuate the efficacy of nivolumab/ipilimumab combination therapy after relapse. The 31-gene expression profile as a guide to better risk-aligned care decisions for patients with stage I–III cutaneous melanoma: An NCI-SEER analysis. First Author: Merve Hasanov, The Ohio State University Comprehensive Cancer Center, The James, Columbus, OH

Background: Current management guidelines for cutaneous melanoma (CM) are based on AJCC staging to stratify patients into risk groups. However, this approach can result in under- and over-estimation of risk for individual patients. The 31-gene expression profile (31-GEP) test has been prospectively validated to provide a more personalized likelihood of sentinel lymph node positivity, as well as risk of recurrence, distant metastasis, and mortality, than AJCC staging alone (Class 1A=low risk, Class 1B/2A=intermediate risk, and Class 2B=high risk). Using expanded SEER registry cohorts, we assessed the ability of the 31-GEP to independently stratify patients with high and low mortality risk categories, and to evaluate whether 31-GEP testing itself was associated with improved patient outcome. **Methods:** SEER registry data for patients with stage I–III CM (2013–2019) were linked to patients with 31-GEP test results provided by Castle Biosciences (N=13,560) using a registry trusted independent third party. Five-year melanoma-specific survival (MSS) was estimated using Kaplan-Meier analysis; survival differences between groups were compared using log-rank test. Multivariable analysis was performed to determine significant predictors of melanoma-specific mortality (MSM). Survival differences between 31-GEP tested and untested patients were performed by matching tested and untested patients according to clinicopathological factors, diagnosis year, ethnicity, and socioeconomic status. **Results:** Patients with a Class 1A 31-GEP result had a significantly higher 5-year MSS than those with Class 1B/2A or Class 2B results (99.1%, 92.5%, vs. 85.9%, $p<0.001$). Multivariable analysis showed that a Class 2B result (HR=4.20, $p<0.001$), Class 1B/2A result (HR=3.21, $p<0.001$), a positive lymph node (HR=2.78, $p<0.001$), Breslow thickness (HR=1.10, p=0.001), ulceration (HR=1.41, p=0.033), age (HR=1.04, $p<0.001$), and mitotic rate (HR=1.05, p=0.022) were significant predictors of MSM. In staging subset analyses, patients with a Class 1A 31-GEP result had a significantly higher 5-year MSS than those with Class 2B results in stage I-IIA CM (1A=98.8%, 1B/2A=95.5% vs. 2B=93.0%, $p<0.001$), stage IIB–IIC CM (1A=94.2%, 1B/2A=91.2% vs. 2B=82.3%, p=0.002), and stage III CM (1A=94.8%, 1B/2A=75.0% vs. 2B=77.6%, $p<0.001$). Among all stages, 31-GEP-tested patients had a lower MSM (HR=0.68, $p<0.001$) than untested propensity score-matched patients. **Conclusions:** In a large, real-world cohort of clinically tested patients with stage I–III CM, the 31-GEP stratified mortality risk within all staging groups, which could better help clinicians and patients make risk-aligned treatment and clinical management decisions. Research Sponsor: Castle Biosciences, Inc.

Comparison of surveillance circulating tumor DNA and Merkel polyomavirus antibody titer for detection of Merkel cell carcinoma recurrence. First Author: Joshua Elbridge Chan, Stanford University School of Medicine, Stanford, CA

Background: Circulating tumor DNA (ctDNA) is emerging as a robust biomarker for detecting recurrences in Merkel cell carcinoma (MCC). This study aims to compare the performance of ctDNA against the Merkel polyomavirus antibody titer (AMERK) test in predicting MCC recurrence risk. **Methods:** We conducted a longitudinal, multi-center observational study involving 171 MCC patients undergoing disease surveillance, including serial ctDNA and AMERK testing (median testing interval: 92 days). All patients had detectable antibodies by AMERK at initial diagnosis and both tests were conducted within 45 days of each other. ctDNA tests were classified as positive if ctDNA was $>$ 0 MTM/mL. An AMERK test was positive if antibody titers rose $\geq$ 30% from the prior titer. Clinical recurrences were identified through routine imaging and clinical examinations. The diagnostic performance of ctDNA and AMERK tests was assessed using positive and negative predictive values (PPV and NPV), recurrence-free survival after any positive test vs. all negative tests, and corresponding hazard ratios (HRs) from Cox regression. **Results:** 718 pairs of ctDNA and AMERK tests were collected from 171 patients. Over a median follow-up of 445 days, there were 38 clinical recurrences, 91/718 (13%) positive ctDNA tests, and 73/718 (10%) positive AMERK tests. A significantly increased clinical recurrence rate was observed in patients with a positive ctDNA test compared to those with consistently negative results (HR: 27.4, 95%CI: 11.0-68.3) (Table 1). Although a positive AMERK test was similarly associated with higher clinical recurrence (HR: 5.8, 95%CI: 3.0-11.1), the rate was distinctly lower than that for a positive ctDNA test (HR: 5.8 vs. 27.4; $p < 0.001$). The PPV for clinical recurrence at 1 year after a positive test was significantly higher for ctDNA vs. AMERK (PPV: 73% [95% CI: 58-84%] vs. 51% [95% CI: 29-70%]; p=0.014). NPV for recurrence within 4 months of a negative test for the ctDNA test was similarly higher for ctDNA vs. AMERK (NPV: 98% [95% CI: 97-99%] vs. 95% [95% CI: 92-97%]; p=0.001). The median lead time between the first positive test and a clinically detected recurrence was 3.1 months for ctDNA (among 30 recurrences preceded by a positive test) and 1.9 months for AMERK (among 19 recurrences preceded by a positive test) (p=0.063). **Conclusions:** Our results indicate that, in a cohort of AMERK positive patients, ctDNA outperforms AMERK for detection of MCC recurrence. ctDNA may be a viable alternative to AMERK in clinical practice and may better identify high-risk patients who benefit from more aggressive monitoring or adjuvant therapy trials. Research Sponsor: None.

Hazard ratios for subsequent MCC clinical recurrence: Comparison of positive ctDNA and AMERK tests.

Test	HR	(95% CI)	P-value
Positive ctDNA	27.4	(11.0, 68.3)	$<$0.001
Positive AMERK	5.8	(3.0, 11.1)	$<$0.001
Difference (ctDNA / AMERK)	4.7	(2.1, 15.9)	$<$0.001

Overall survival outcomes in stage III melanoma patients treated with adjuvant immunotherapy vs targeted therapy: A National Cancer Database analysis. First Author: Siavash Bolourani, Providence Saint John's Cancer Institute, Santa Monica, CA

Background: Adjuvant therapy with immunotherapy (IO) and targeted therapy (TT) has significantly improved outcomes in Stage III melanoma following surgical resection. While both approaches demonstrate efficacy, head-to-head comparisons remain limited, and real-world evidence on overall survival (OS) across diverse subgroups is sparse. This study compares OS between adjuvant IO and TT using data from the National Cancer Database (NCDB) from 2018 to 2020, offering insights into subgroup-specific benefits. **Methods:** We conducted a retrospective cohort study of Stage III melanoma patients from the NCDB diagnosed between 2018 and 2019 who underwent definitive surgical resection followed by either IO or TT. Patients receiving neoadjuvant therapy were excluded. OS was analyzed using Kaplan-Meier survival curves and compared using log-rank tests. Hazard ratios (HR) with 95% confidence intervals (CI) were derived from Cox proportional hazards models, adjusted for demographic and clinical covariates. Subgroup analysis was performed to identify populations deriving differential benefit from IO. **Results:** A total of 1,493 patients met the inclusion criteria (IO: 1,352; TT: 141). Overall survival (OS) was significantly higher in the IO group (74.9%; 95% CI: 72.2–77.8% at 3 years) compared to the TT group (62.1%; 95% CI: 52.5–73.3% at 3 years) ($p = 0.0055$). Subgroup analysis revealed that the survival benefit with IO was more pronounced in patients aged $<$65 years (HR 0.49; 95% CI: 0.32–0.75), males (HR 0.54; 95% CI: 0.37–0.77), those with private insurance (HR 0.45; 95% CI: 0.27–0.76), and primary tumors located on the head and neck (HR 0.44; 95% CI: 0.22–0.89). No subgroup demonstrated superior outcomes with TT. **Conclusions:** In this NCDB-based analysis, adjuvant IO was associated with a significant OS advantage compared to TT in Stage III melanoma patients. However, NCDB limitations, including lack of information on specific agents (e.g., BRAF/MEK inhibitors or checkpoint inhibitors), must be acknowledged. Additionally, this analysis reflects OS rather than melanoma-specific survival (MSS). In the NCDB sample, there was a 10:1 preference for IO over TT, reflecting marked community preference for IO. These findings appear to indicate that IO is the preferred adjuvant strategy, though further prospective studies are required to validate subgroup-specific outcomes and confirm these results. Research Sponsor: None.

Survival impact of adjuvant treatment in resected stage III cutaneous melanoma patients: Results from a real-life cohort study (TAMARIS). First Author: Charlee Nardin, Université de Franche-Comté, Inserm 1098 RIGHT, Besançon, France

Background: Anti-PD-1 immunotherapies and BRAF+MEK inhibitors (BRAFi/MEKi) (specifically for BRAF V600E/K-mutant melanoma) have been shown to improve recurrence-free survival (RFS) in patients (pts) with resected stage III metastatic melanoma in phase III trials. However, none of these studies has demonstrated a significant improvement in overall survival (OS). Notably, adjuvant BRAFi/MEKi therapy has shown better OS only in the BRAF V600E subgroup of patients. In this context, we evaluated the real-world impact of adjuvant therapies on OS. **Methods:** TAMARIS is a national multicenter retrospective study designed to evaluate the efficacy of adjuvant treatment (anti-PD-1 or BRAFi/MEKi) in pts with resected AJCC 8th edition stage III melanoma using data from the French RIC-Mel prospective database. The primary endpoint was OS analyzed using the Kaplan-Meier method, comparing pts who received adjuvant treatment (adjuvant group) within 3 months of surgery to those who did not (control group). Demographic and clinical characteristics were compared using chi-square analyses. Secondary endpoints included OS in specific subgroups and RFS. **Results:** A total of 1,172 pts (median age: 65 years [IQR: 53–74]) with resected stage III melanoma were included between 2018 and 2023. Among them, 796 pts (68%) received adjuvant treatment with anti-PD-1 (n=676) or BRAFi/MEKi (n=120). The median treatment duration was 10.8 months (IQR: 5.6–11.9). Most pts had a history of SSM (54%) with a median Breslow thickness of 2.8 mm [range, 0-47] and stage IIIB (31%) or IIIC disease (49%). Surgical interventions for metastases prior to adjuvant treatment included lymph node dissection in 53% of cases, sentinel lymph node biopsy in 38%, and cutaneous metastasis resection in 8%. Pts in the control group were older (median age: 69.7 vs. 63.0 years, $p < 0.0001$). The median follow-up was 30.4 months (IQR: 16.7-43.3). OS was significantly longer in the adjuvant group compared to the control group (HR: 0.617; 95% CI: 0.474-0.802; $p = 0.0003$), with a 2-year OS of 90% (95% CI: 88-92) in the adjuvant group versus 79% (95% CI: 74-83) in the control group. There was a trend toward better OS with BRAFi/MEKi compared to anti-PD-1 (HR: 0.569; 95% CI: 0.312-1.037; $p = 0.065$). Subgroup analyses demonstrated a significant positive impact of adjuvant treatment on OS across most subgroups, except for pts aged $\leq$75 years, those with stage IIIA disease, primary melanomas with a Breslow thickness $<$2.8 mm, or without ulceration. RFS also favored the adjuvant group (HR: 0.545; 95% CI: 0.458-0.649; $p < 0.0001$), with a 2-year RFS of 67% (95% CI: 63-70) and 45% (95% CI: 40-50) in the control group. **Conclusions:** Adjuvant treatment appears to provide an OS benefit in patients with resected stage III melanoma in real-world settings. Further research is required as age-related differences may influence prognosis. Research Sponsor: None.

Financial toxicity and employment outcomes in people with melanoma receiving adjuvant therapies. First Author: Julia Elizabeth Lai-Kwon, Peter MacCallum Cancer Centre, Melbourne, VIC, Australia

Background: One year ofadjuvant anti-programmed cell death protein-1 (anti-PD1) or dabrafenib-trametinib are standards of care for patients (pts) with resected stage III-IV melanoma. The impact of adjuvant therapy on a pt's employment, income, and level of financial toxicity are unknown. We examined these outcomes up to 2 years post initiation of adjuvant therapy. **Methods:** A prospective, longitudinal study of pts with resected stage IIB-IV melanoma receiving adjuvant anti-PD1 or dabrafenib-trametinib at an Australian comprehensive cancer center. Two customized employment surveys assessed impact on employment and income. Survey 1 (7 items) was administered pre-treatment, Survey 2 (11 items) at 12 and 24 months post treatment initiation. The Comprehensive Score for Financial Toxicity (FACIT-COST) was collected pre-treatment and at 1, 3, 6, 12, and 24 months post treatment initiation. FACIT-COST scores were categorized into none ($\geq$26), mild (14-25), moderate (1-13) and severe (0) financial toxicity. **Results:** Between September 2021-December 2024, 70 pts were eligible and 52 (74%) consented: 17 (33%) female, median age 64 years (IQR 60-71), 46 (89%) had resected stage III, 32 (62%) on adjuvant anti-PD1. 41 pts had completed treatment and 11 were still receiving treatment at data cut off (17 December 2024). Employment surveys were completed by 51 pts pre-treatment, 31 at 12 months and 18 at 24 months. Most (18/31, 58%) were working at 12 months, with the majority (17/18, 94%) in the same job as pre-treatment. Only half (9, 50%) were working the same number of hours or earning the same income (10, 56%) as pre-treatment (the remainder, less). Barriers to returning to work at 12 months were ongoing symptoms (45%), financial concerns (26%), and work environment (21%). 18 pts completed both the 12 and 24 month surveys. 9 (50%) had returned to work by 12 months and the majority (n=8) were still working at 24 months. At 24 months, 6 (75%) were working the same number of hours but only 5 (63%) were earning the same income as pre-treatment (the remainder, less). The prevalence of financial toxicity is shown in the table and ranged from 16% at 6 months to 36% at 12 months. **Conclusions:** Half of pts reported reduced working hours and income 12 months post therapy initiation, mostly due to ongoing symptoms. A third reported financial toxicity at 12 months, even with universal healthcare. This data can inform shared decision-making about risks and benefits of adjuvant therapy and highlights the importance of screening for financial toxicity to identify pts who require support. Research Sponsor: None.

FACIT-COST category	Pre-treatment (n= 51)	1 month (n=46)	3 months (n=44)	6 months (n=38)	12 months (n=31)	24 months (n=18)
None	37 (72.5)	32 (69.6)	35 (79.5)	32 (84.2)	20 (64.5)	13 (72.2)
Mild	13 (25.5)	11 (23.9)	6 (13.6)	5 (13.2)	10 (32.3)	2 (11.1)
Moderate	1 (2.0)	2 (4.3)	3 (6.8)	1 (2.6)	1 (3.2)	3 (16.7)
Severe	0	1 (2.2)	0	0	0	0

A pooled analysis of clinical outcomes with anti-PD1-based neoadjuvant immunotherapy (NeoIT) in cutaneous squamous cell carcinoma (cSCC). First Author: Ines Esteves Domingues Pires da Silva, Melanoma Institute Australia, Faculty of Medicine and Health, Charles Perkins Centre, The University of Sydney, Sydney, NSW, Australia

Background: Anti-PD1 immunotherapy has shown improved clinical outcomes in patients (pts) with advanced cSCC, and recently, in the neoadjuvant setting for resectable disease. Pathological (path) response is predictive of recurrence in melanoma and recent NeoIT trials suggests the same in cSCC; however, an analysis of clinical outcomes in pts with resectable cSCC treated with intended anti-PD1-based NeoIT in larger datasets remains unknown. **Methods:** Pts with resectable cSCC treated with intended anti-PD1-based NeoIT from 17 cancer centres globally were included. Baseline patient and disease characteristics, treatment regimen, path response and recurrence-free survival (RFS) or progression-free survival (PFS) were collected and examined. **Results:** 134 pts with resectable cSCC were treated with intended anti-PD1-based NeoIT. Median age was 75 years old (range, 39-97), 72% (n=97) were male. One fifth (22%, n=29) were immunocompromised and 43% (n=58) had ECOG PS of $\geq$1. Of 125 (93%) pts with known primary cSCC, 82% (n=102) were from the head & neck. Most pts (79%, n=106) were stage III/IV. The majority had anti-PD1 monotherapy (91%, n=122) and 9% (n=12) had anti-PD1+/-investigational agent. Median follow-up from commencement of NeoIT was 10 months (95% CI, 9 - 12). Nearly half of the pts (49%, n=66) underwent surgery; 37 (56%) pts had major pathological response (MPR; $\leq$10% viable tumour cells at the surgical specimen; 31 [47%] had complete path response [0% of viable tumour cells] and 6 [9%] had near complete path response [1-10% of viable tumour cells]), 6 (9%) had partial path response (pPR; $>$10% and $\leq$50% of viable tumour cells), and 23 (35%) had path non-response (pNR; $>$50% of viable tumour cells). Of the 66 pts who underwent surgery, 11% (n=7) had recurrence (5 loco-regional and 2 distant recurrence), all non-MPR pts (1 pPR and 6 pNR). 12-months RFS was improved with MPR vs non-MPR (100% vs 79%, p=0.004). 52% (n=34) pts had adjuvant treatment (23 anti-PD1 alone, 7 anti-PD1+/-investigational agent, 2 platinum and 2 cetuximab). Within non-MPR pts, 12 had adjuvant treatment (3 recurred; 25%), while 17 did not have adjuvant treatment (4 recurred; 24%). Fifty-one percent (n=68) of pts did not have surgery; 9 (13%) due to progressive disease (PD) and 53 (78%) due to clinical response. Of the 53 pts with a clinical response, 5 (9%) subsequently progressed. Fourteen (10%) pts have died, 6 (4%) related to cSCC; 2 had surgery (non-MPR) and 4 did not have surgery (all due to PD). **Conclusions:** Anti-PD1-based NeoIT is an active regimen in resectable stage II-IV cSCC and is associated with high clinical response and MPR rates. No pts with MPR from NeoIT has recurred to date, however, 9% of pts who did not have surgery due to clinical response eventually progressed. These findings highlight the importance of further research to investigate the role of surgery in this subgroup of patients. Research Sponsor: None.

Use of artificial intelligence to identify high risk profiles in early stage melanoma patients from pathology slides. First Author: Christina Kanaan, Department of Pathology, Gustave Roussy, Villejuif, France

Background: To refine prognostication in primary cutaneous melanoma (CM) and optimize adjuvant treatment decisions, we evaluate SmartProg-MEL (SPM), an AI-based histology-driven algorithm developed by DiaDeep and applied to H&E-stained whole-slide images (WSI) at the time of diagnosis. SPM provides a risk stratification score, under 15 minutes, for overall survival (OS) and relapse-free (RFS) outcomes to support clinical decision-making. **Methods:** SPM was evaluated on a retrospective cohort of 383 primary CM with 5-year follow-up (46% IA, 15% IB, 9% IIA, 7% IIB, 6% IIC, 13% III, 4% IV). The model stratifies patients into high- or low-risk groups based solely on the WSI of the primary tumor. Kaplan-Meier curves are used to compare RFS and OS between risk groups, with statistical significance assessed using the log-rank test. A multivariable Cox regression analysis was performed to evaluate the independent prognostic value of SPM after adjusting for pathological factors. The negative and positive predictive values (NPV and PPV) of the SMP are explored. **Results:** Patients with a low risk score had a significantly higher 5-y OS and RFS than patients of the high risk group (93.1% vs 62.5%, $p<0.001$ and 92.8% vs 47.1%, $p<0.001$). In multivariable analysis, SPM risk score was the strongest predictor (OS: HR=3.95, $p<0.005$, RFS: HR=5.03, $p<0.005$). In the I-IIA group, 29% (n=78) were assigned to the high risk profile with a decrease of the OS and RFS compared with the low risk group (OS: 95.4% vs 86%, $p<0.05$; RFS: 94.3% vs 74%, $p<0.01$). SPM has a NPV of 96%, 100% and a PPV of 17% and 69% in stages I/IIA and IIB/C respectively. **Conclusions:** The AI-based risk stratification algorithm, SPM, demonstrates greater performance than stage in identifying high and low risk profiles, especially in early-stage CM patients. This new prognostic tool opens avenues for a routine clinical application to precise therapeutic decisions in an adjuvant setting. Research Sponsor: None.

Cohort statistics: Event occurrences and five-year OS and RFS endpoints survival rates, segmented by AJCC stage and SPM risk stratification.

		RFS		OS	
	# patients	# events (%)	5-y RFS [CI]	# events	5-y OS [CI]
I/IIA	266	21	88.1 [82.1 to 92.2]	14	92.5 [87.6 to 95.6]
SPM Low Risk	188 (70.7%)	8(38.1%)	94.3 [88.9 to 97.2]	5(35.7%)	95.4 [89.8 to 98.1]
SPM High Risk	78(29.3%)	13(61.9%)	74.1 [58.4 to 84.4]	9 (64.3%)	86.1[73.8 to 92.8]

Identification of novel RNA biomarkers for the differential diagnosis of cutaneous melanoma and nevi. First Author: Igor Samoylenko, FSBI "N.N. Blokhin National Medical Research Center of Oncology" of the Ministry of Health of the Russian Federation, Moscow, Russian Federation

Background: The differential diagnosis of nevi and melanomas remains a significant clinical challenge, as misclassification can result in overtreatment or delayed care. Despite advances in clinical, dermatoscopic, and histopathological methods, benign lesions are frequently misclassified as nevi, SAMPUS, or MELTUMP, while atypical melanomas are often mistaken for nevi. This study aimed to identify novel RNA markers for the differential diagnosis of nevi and melanomas. **Methods:** Ninety histological samples of melanocytic neoplasms were analyzed, including 45 morphologically confirmed nevi and 45 melanomas. Massive parallel sequencing was performed using the NextSeq 550 system (Illumina, USA) with the "NextSeq High Output 150 Cycles Kit" reagent set, following the manufacturer's protocol. Data normalization employed FPKM and TPM metrics, and differential gene expression analysis utilized 26 algorithms on the RNA-Seq 2G web server. Selected RNA markers were further validated on an independent cohort of 120 samples (60 verified nevi and 60 melanomas) using RT-PCR. **Results:** The study analyzed the expression of over 18,000 coding and 42,000 non-coding RNAs (primarily long non-coding) in histologically confirmed melanomas and nevi, balanced between "classical" and dysplastic nevi. Initial RNA-Seq quality control confirmed high data integrity and sufficient sequencing depth in 87 of 90 samples. Melanoma-specific markers identified included CSAG1, CXCL1, CXCL8, CXCL9, DUXAP8 + DUXAP9 + DUXAP10, FCRL3, IGHA1, IGHG1, LRP2, MAGEA3 + MAGEA6 + MAGEA12, MMP1, OR2I1P, SPP1, and VGF, while nevus-specific markers included CD44-AS1, CDR1-AS (LINC00632), DSCAS, and ENSG00000287270. For RNA marker testing at the next stage, all 120 samples were deemed suitable for analysis. Modeling of multimarker tests achieved an AUROC of 0.94, with a model incorporating only 5 preselected markers outperforming those with a larger number of markers. The most informative logistic regression model included the following marker combinations: MAGEA3 + MAGEA6, CXCL8 + LINC00632, DUXAP8 + DUXAP9 + DUXAP10, CSAG1, and CXCL1. **Conclusions:** The model, incorporating only 5 markers, achieved an AUROC of 0.94 in an independent validation cohort. It is now positioned for further validation in cohorts enriched with samples of uncertain malignant potential based on histological evaluation. Clinical trial information: NCT04353050. Research Sponsor: Ministry of Health of the Russian Federation.

Animated patient's guide to melanoma: Assessing patient understanding, shared decision-making, and health outcomes. First Author: Kyleigh LiPira, Melanoma Research Foundation, Washington, DC

Background: Patients with melanoma who participate in informed, personalized-care discussions with their healthcare providers are better prepared to carry out shared decision-making (SDM) and achieve best attainable health outcomes. In a 2018 Cancer Registry Experience study of 114 melanoma survivors, a majority of respondents did not feel knowledgeable or prepared to discuss treatment options with their healthcare team. The complexity of melanoma treatments and patients' limitations due to poor health literacy are obstacles to SDM. In November 2018, the *Melanoma Research Foundation* introduced *An Animated Patient's Guide to Melanoma (APGM),* an online resource aimed at improving patient knowledge, informed SDM, and achieving best outcomes. **Methods:** APGM was developed with highly visual formats of learning on a website, comprised of melanoma educational animations, expert videos, patient experience videos, slide shows, infographics, and self-assessment tools. Learners on the website have the option to voluntarily participate in evaluations, including pop quizzes and surveys. From the website, learner responses were collected from surveys over a period of 72 months, ending January 2025. Patient responses to these questions were aggregated to measure outcome-based questions, and patient intention to discuss key decisions with healthcare providers. **Results:** Our 6-year reported data is based on 443,015 total views and 272,191 unique visitors aggregated from the APGM online resource. Unique US visitors were 54% (N=146,983); and 46% (N=125,208) from other countries. In terms of US participants/learners: 72% (N=105,828) were patients; 12% (N=17,638) were family and caregivers; 6% (N=8,819) were healthcare providers; and 10% (N=14,698) were other/undisclosed. Of the respondents who volunteered to complete the surveys, 95% (N=1,059) were patients who reported they *'will use information learned to better self-manage their melanoma'*; 93% (N=969) of patients *'will discuss information learned with their doctor'*; and 95% (N=694) of patients *'will discuss melanoma treatment options with their doctor'*. **Conclusions:** Our data shows that animated formats of learning tailored to the needs and learning styles of patients with melanoma provide effective translational learning resources, improve self-management skills, and facilitate engagement in SDM. Visual formats of learning are effective resources in helping inform patients with melanoma and improving outcomes. Our APGM initiative validates the utility of visual formats of learning which may be utilized in other oncology settings to benefit patient outcomes. Research Sponsor: None.

9582 Poster Session

A phase II trial of perioperative oral itraconazole for the management of low risk basal cell carcinoma. First Author: Rodrigo Perez Pereira, Unidade de Pesquisa Clínica em Oncologia, Porto Alegre, Brazil

Background: Recently, new treatment options have emerged for advanced basal cell carcinoma (BCC), including oral Hedgehog pathway inhibitors like Vismodegib. Itraconazole has also shown promising clinical activity in these cases by targeting the SMO receptor. This study aimed to assess the clinical and molecular efficacy of oral Itraconazole in BCC patients with low-risk disease. **Methods:** Patients with localized BCC who were eligible for surgical excision were enrolled. They received 200 mg of Itraconazole twice daily for 60 days prior to resection. Clinical assessments were based on the RECIST 1.1 criteria, with target lesions measuring at least 10 mm following a confirmatory biopsy. Molecular markers associated with cellular activity and angiogenesis (Ki67, GLI, CD105) were evaluated using immunohistochemical staining. Adverse effects were graded according to NCI-CTC v4. **Results:** A total of 26 patients were treated, with 61% female and a mean age of 62 years. The most common BCC subtype was nodular (54%), and the most frequent tumor location was the trunk (65%). Patients presented with stable disease (92%), partial response (4%), and complete response (4%). Notably, no disease progression occurred during the treatment period, and all patients underwent the planned surgical excision. The median tumor diameter prior to treatment was 14 mm (range: 11–16 mm), and after treatment, it was 13 mm (range: 11–15 mm). This reduction was statistically significant, as determined by the Wilcoxon test ($p < 0.0001$). Additionally, biological activity of Itraconazole was demonstrated through the measurement of Ki67, GLI, and CD105. The percentage of the stained area for CD105 or Endoglin decreased significantly following Itraconazole treatment, from 0.11 [0.01–1.86] to 0.03 [0.00–0.22], with this reduction also being statistically significant ($p \leq 0.0001$). **Conclusions:** Preoperative oral Itraconazole demonstrated both clinical and molecular activity in localized, low-risk BCC lesions, with no patients showing disease progression and two patients exhibiting partial and complete responses, respectively. The median tumor diameter significantly decreased after the treatment period. In addition to the reduction in tumor size, there was a notable decrease in the expression of CD105, marking the first study to demonstrate this correlation in this context. Endoglin, a well-established marker for endothelial cell proliferation, particularly in angiogenesis in regenerating tissues or inflamed tumors, underscores the anti-angiogenic potential of Itraconazole. These findings align with previously published results and suggest that oral Itraconazole could be a promising candidate for managing low-risk BCC, while also opening the opportunity for further investigation in advanced disease settings. Clinical trial information: NCT03972748. Research Sponsor: None.

9583 Poster Session

Comparison of the tolerability and safety of hedgehog inhibitors in real-life: A cohort of 330 patients with locally advanced basal cell carcinoma. First Author: Florian Herms, APHP, Hôpital Saint Louis, Paris, France

Background: Two hedgehog pathway inhibitors (HHIs) have been approved for the treatment of locally advanced basal cell carcinoma (laBCC): vismodegib and sonidegib. Efficacy of both seem similar, even though no head-to-head comparison has been performed. However, adverse events (AEs) in pivotal trials seemed less frequent with a later onset with sonidegib. CARADERM is a French national database created in 2013 to improve the management of rare skin tumors, including laBCC. The objective of our study was to compare the safety profile of HHIs in this real-life cohort. **Methods:** LaBCC patients from the CARADERM database were reviewed. Patients who started either vismodegib or sonidegib at least one year before analysis were included. Type and grade of AEs were collected when available. Cumulative incidence of the first occurrence of adverse events was estimated, with treatment discontinuation as a competing event. **Results:** In the total cohort of 452 laBCC patients, 330 met the inclusion criteria: 280 (85%) treated with vismodegib and 50 (15%) with sonidegib. The median follow-up was 22.3 months. Clinical characteristics (including age, gender, performance status, localization and tumor size) were similar for both groups. The cumulative incidence of the first AE was significantly lower with sonidegib (43.5%, 95% confidence interval (95%CI) = 29.0-57.2 at 12 months) than with vismodegib (63.5%, 95%CI = 57.5-68.9 at 12 months, p=0.0014) (Table 1). For vismodegib treated patients, 191 (68%) experienced at least one AE. The most frequent were cramps (n=123, 44%), dysgeusia (n=123, 44%) and alopecia (n=88, 31%). For sonidegib treated patients, 22 (44%) experienced at least one AE. The most frequent were cramps (n=8, 16%), alopecia (n=7, 14%) and dysgeusia (n=6, 12%). Major AEs seemed to be less frequent and to appear later with sonidegib, with a significant difference for cramps (p=0.007) and dysgeusia (p=0.001), but not significant for alopecia (p=0.059). **Conclusions:** We present here the largest real-life comparison of HHIs in a real-life cohort of laBCC patients. The cumulative incidence of the first AE was significantly lower with sonidegib. Even though the range of AEs was similar with both HHIs, dysgeusia and cramps were less frequent with sonidegib. These data highlight the difference in terms of tolerance of both HHIs, with a later onset and lower frequencies of AEs with sonidegib. However, though both groups were clinically comparable, vismodegib was overrepresented compared to current prescriptions of HHIs, and further analyses are mandatory to confirm these data. Research Sponsor: None.

Cumulative incidence of first adverse event at 3, 6 and 12 months.

	3 months [95CI]	6 months [95CI]	12 months [95CI]
Sonidegib	16.3 % [7.5 ; 28.0]	26.8 % [15.2 ; 39.8]	43.5 % [29.0 ; 57.2]
Vismodegib	31.6 % [26.2 ; 37.2]	55.5 % [49.5 ; 61.2]	63.5 % [57.5 ; 68.9]

95CI = 95% confidence interval.

Sensitivity of circulating tumor DNA (ctDNA) for disease recurrence or relapse in melanoma patients. First Author: Vincent The-Luc Ma, Division of Hematology, Medical Oncology, and Palliative Care, Department of Medicine, University of Wisconsin, Madison, WI

Background: ctDNA has emerged as a biomarker for minimal residual disease (MRD) detection in colorectal cancer and other cancer types. Its role in MRD monitoring and disease detection for melanoma patients merits further investigation. We aimed to assess the sensitivity of a commercially available ctDNA test to detect recurrence or relapse in patients with melanoma. **Methods:** A retrospective cohort analysis was performed using a personalized, tumor-informed, ctDNA assay (Natera) on prospectively collected plasma from patients with a diagnosis of melanoma from December 2021 to January 2025 with longitudinal follow up. Inclusion criteria were patients with no evidence of disease (NED) following definitive surgery or clinical remission with systemic therapy; and an undetectable ctDNA level. We evaluated the sensitivity of ctDNA detection of patients who had biopsy and/or radiographic confirmation of recurrence or relapse; and further stratified this based on anatomic sites of recurrence or metastasis (mets). Sensitivity was computed and logistic regression models were conducted to assess predictors of ctDNA detection. **Results:** 116 patients met the inclusion criteria. 48% (n=56) had confirmed recurrence or relapse. Among these patients, 82% (n=46) had NED following surgery and 18% (n=10) had clinical remission with systemic therapy. 75% (n=42) were resected stage II/III, 7% (n=4) were resected stage IV, 4% (n=2) were unresectable stage III in remission, and 14% (n=8) were unresectable stage IV in remission. Melanoma primaries included: 82% (n=46) cutaneous, 7% (n=4) mucosal, 5% (n=3) uveal, 5% (n=3) unknown. ctDNA was detected in 30 out of 56 patients with confirmed recurrence/relapse, with an overall sensitivity of 53.6%. Sensitivity varied by site of recurrence/relapse. Sensitivity for ctDNA detection of brain mets was 33.3% (4/12); skin/mucosa/muscle recurrence or mets was 37.5% (6/16); lung mets was 61.5% (8/13); bone mets was 75% (3/4); liver mets was 87.5% (7/8), and lymph node mets was 87.5% (14/16). The odds of detecting ctDNA at relapse or recurrence were significant amongst patients with lymph node mets (OR=10.5, 95% CI 2.10-52.58, p=0.004) and patients with multiple anatomic sites (2+) of mets (OR=7.61, 95% CI 1.27-66.67, p=0.032). **Conclusions:** ctDNA monitoring shows potential in detecting recurrence or relapse in patients with melanoma. We found that location of metastatic disease impacts the shedding of ctDNA and its detection of macroscopic disease. Larger studies are needed to refine the role of ctDNA monitoring and its clinical application in melanoma surveillance. Research Sponsor: Clinical and Translational Science Award (CTSA); UL1TR002373.

Multiomic analysis of cutaneous squamous cell carcinoma (cSCC) and association with response to anti-PD1 therapy (PD1). First Author: Yu-Ju Kuo, Melanoma Institute Australia, The University of Sydney, National Taiwan University Hospital Hsin-Chu Branch, Sydney, Australia

Background: PD1 induces a durable response and improves the survival of patients (pts) with advanced cSCC; however, about 40% of pts are resistant to this treatment. Multiomic analysis (e.g., tumor mutational burden [TMB] and gene expression profiling [GEP]) has shown predictive value for PD1 response in various cancer types. This study aims to perform multiomic analysis of cSCC and study its association with the response to PD1. **Methods:** cSCC pts were prospectively enrolled in the PIP-PREDICT study (NCT06536257). Baseline tumor tissues were sent for: a) targeted TSO500 DNAseq (NGS), for TMB and mutational status, and b) NanoString Pancancer 360IO, for GEP. Baseline characteristics and clinical outcomes were collected. Pts treated with PD1 were categorized as responders (complete/partial response) or non-responders (progressive disease) based on RECIST 1.1. Pts with stable disease were further categorized into responders/ non-responders based on PET response (PERCIST). **Results:** 26 cSCC pts were enrolled; the median age was 79 (range 39-98) and 73% (n=19) were male. 7 pts (27%) were immunocompromised and 4 were on immunosuppressants. Head and neck (HN) primaries were present in 54% (n=14), and 58% (n=15) of the pts had stage IV disease. NGS was performed on 21 pts, revealing a median TMB of 39.2 mut/Mb (range 17.3-122.2). TP53 mutations were present in all cases (100%), with other frequent mutations observed in CDKN2A (43%), TERT promoter (43%), FAT1 (38%), NF1 (24%), PIK3CA (24%), TGFBR2 (19%), and CREBBP (19%). GEP of 22 pts showed that cSCC with HN primaries exhibited higher cancer-associated fibroblast (p=0.018) and stromal (p=0.035) signatures (sig), compared to non-HN pts. Pts on immunosuppressants demonstrated lower expression of cytokine (p=0.031), effector cell (p=0.019), and NK cytotoxicity (p=0.0498) sig compared to those not on immunosuppressants. 18 pts received PD1 for advanced cSCC with evaluable disease; ORR was 61.1% and DCR was 72.2%. After a median follow-up of 12.4 months (95% CI, 4.1-20.7), the 12-months PFS and OS rates were 57.9% and 94.7%, respectively (the median PFS and OS were not reached). Responders to PD1 exhibited higher expression of MHC-I (p=0.003), T cells (p=0.039), NK cells (p=0.009), interferon-gamma (p=0.03), cell adhesion molecules (p=0.039), and antigen presentation (p=0.03) sig. Conversely, non-responders showed higher levels of angiogenesis (p=0.005), endothelium (p=0.005), hypoxia (p=0.039), and CCR8 (p=0.017) sig. No differences were observed in the expression of immune checkpoints (e.g. PD-1, LAG3), TMB, or specific mutations in responders vs. non-responders. **Conclusions:** cSCC responsive to PD1 have higher expression of immune sig and lower expression of stromal and hypoxic sig. Well-known predictive features of response to immunotherapy (e.g. TMB, PD-1 sig) were not associated with response in this cohort. Research Sponsor: None.

Immunoembolization for patients with uveal melanoma hepatic metastasis: A single-institution real-world data analysis. First Author: Rino S. Seedor, Sidney Kimmel Comprehensive Cancer Center, Thomas Jefferson University, Philadelphia, PA

Background: Metastatic disease occurs in up to 50% of patients with uveal melanoma (UM) despite successful treatment of the primary eye tumor. The liver is the predominant organ of involvement in more than 90% of patients, and control of liver metastases is essential to prolonging overall survival (OS). Immunoembolization (IE) with granulocyte-macrophage colony-stimulating factor +/- interleukin-2 is considered a 1st line liver-directed therapy for those with <50% hepatic tumor burden at our institution. It is well tolerated, has limited side effects, no cumulative toxicities, and affords good quality of life between scheduled treatments. **Methods:** A retrospective single-institution chart review was performed on consecutive series of metastatic UM (MUM) patients with hepatic metastasis who were treated at Thomas Jefferson University with IE treatment. The following data were collected from medical records: age, gender, IE treatment history, treatment history before and after IE, last follow-up date, and date of death. **Results:** 604 MUM patients (median age 62, range 19-91) received IE treatment for UM hepatic metastasis from 11/2000 to 01/2025 for a total of 3,715 IE treatments. 22 patients continue to receive IE. Patients received a median of 4 IE treatments (range 1-45) over 4 months (range 1-118 months). With a median follow-up of 18.3 months (range 0.1-176.4), median OS after IE treatment initiation was 20.0 months (95%CI 18.2-22.3). OS was 73.2% at 1 year, 41.8% at 2 years, 25.3% at 3 years, and 11.2% at 5 years. 30% of patients had treatment of metastatic disease prior to IE and 83% had treatment after IE. 134 patients (22%) had concurrent therapy with IE, most commonly checkpoint inhibitor therapy (48%). Median OS was 21.5 months (95%CI 18.9-23.4) for patients who received IE as first-line metastatic therapy. Except for one patient who died of takotsubo cardiomyopathy after the first IE treatment, IE treatments were well tolerated without serious or long-term complications. Of the subset of patients that experienced a prolonged OS of ≥3 years with IE (n=117), they received a median of 10 treatments over 16 months. Of the patients with prolonged OS of ≥5 years with IE (n=33), they received a median of 12 treatments over 19 months. Patients that experienced prolonged OS with IE ≥3 years were more likely to be female (69%). The longest patient treated with IE was a female who received 45 IE treatments over 10 years. **Conclusions:** We conducted the largest retrospective study of MUM patients who have received IE treatment. Our real-world data indicates that IE is a safe and effective liver-directed therapy for UM hepatic metastases, and IE should be considered a mainstay of treatment for patients with limited hepatic tumor burden. Research Sponsor: None.

Real-world outcomes of immunosuppressed patients with Merkel cell carcinoma treated with immune checkpoint inhibitors. First Author: William J Mullally, Department of Medical Oncology, Princess Alexandra Hospital, Brisbane, QLD, Australia

Background: Merkel cell carcinoma (MCC) is a rare, aggressive neuroendocrine skin cancer that disproportionately affects older adults & the immunosuppressed. Immune checkpoint inhibitors (ICI) are highly effective in advanced MCC (aMCC), but pivotal ICI trials excluded immunosuppressed patients, highlighting an unmet need for this cohort. **Methods:** Clinical databases from 10 centers across 3 countries, were retrospectively analysed to identify immunosuppressed patients with aMCC who have received ICI. These patients were categorized into solid organ transplant (SOT), human immunodeficiency virus (HIV), hematological malignancies (HM) & autoimmune (AI) diseases. The overall aim was to assess treatment outcomes in patients excluded from trials. **Results:** This retrospective multicenter study identified 46 immunosuppressed patients (80% male) with aMCC and treated with ICI. The median age was 72 years (Table 1). The objective response rate (ORR) to anti-PD1/PDL1 ICI was 47.8%, with median progression-free survival (PFS) & overall survival (OS) of 23.4 & 40.9 months, respectively. 56.5% of patients have died at data cutoff. Cause of death included MCC (69.2%), comorbidities/others (15.4%), hematological malignancies (11.5%), and ICI-pneumonitis (3.9%). There were no deaths from graft failure, AI diseases or HIV. 8.7% developed ≥ grade 3 ICI-related adverse event (irAE). There was no difference in ORR (44% vs. 40%), OS (43.6 vs. 40.5 months, p = 0.68) or PFS (26.7 vs. 22.6 months, p = 0.18) in patients who experienced any grade irAE compared to those who did not. Clinicians were less likely to offer first line ICI to SOT patients (60%), particularly non-renal SOT patients 50%, compared with non-SOT immunosuppressed patients (89%). SOT patients had numerically lower response rates vs. non-SOT patients (ORR 30% vs 56%), significantly shorter PFS & OS at 6.5 months vs. 34.6 months (p= 0.001) & 13.1 months vs. 47.6 months (p = 0.002), respectively. **Conclusions:** Real world data shows that immunosuppressed MCC patients derive significant clinical benefit from ICI with acceptable rates of irAEs. Majority of immunosuppressed MCC patients (69%) died of disease progression, with 3.9% dying from an irAE & 11.5% from deterioration in HM. This suggests pre-existing immunosuppression should not significantly deter the use of ICI in patients with MCC. Patients with SOT have worse outcomes when treated with ICI compared with other immunosuppressed groups. Clinicians were more likely to reserve ICI use beyond first line. Research Sponsor: None.

Tobacco smoking as a risk for cutaneous squamous cell carcinoma in skin of color. First Author: Tahira Naqvi, WVU Medicine, Morgantown, WV

Background: Ultraviolet radiation (UVR) along with immunosuppression, tobacco smoking and age are the major risk factor cutaneous squamous cell carcinoma (cSCC) in White individuals. However, the risk factors for cSCC in skin of color (SOC), where UVR may be less important, remain inadequately explored. **Methods:** A retrospective cohort study of real-world aggregate patient data from the TriNetX global federated research network was used to identify patients with cSCC. Cohorts were created for Asian, Black/African American, White/Caucasian, and Hispanic patients with ICD-10 codes for cSCC. These cohorts were then 1:1 propensity matched with a control group of the same race/ethnicity with ICD-10 codes for benign skin lesions. Propensity matching was performed for age at cSCC diagnosis and patients' sex. The number of patients in the smokers in the cSCC group was then compared to the number of smokers in the control group. **Results:** We identified 2122 Asian subjects, 5237 Black subjects, 4256 Hispanic subjects and 227,683 White subjects with cSCC. We also identified a control cohort of each race/ethnicity with a diagnosis of benign neoplasm of the skin. After propensity matching for age at diagnosis and sex, White subjects diagnosed with cSCC were 2.3 fold more likely to have a previous history of cigarette smoking than White subjects with the control diagnosis ($P<0.001$). When looking at SOC, Black subjects were 3.3 fold ($p<0.001$), Asians 3.6 were fold ($p<0.001$), and Hispanics were 2.5 fold ($p<0.001$) more likely to have a cigarette smoking diagnosis than subjects of the same race with the control diagnosis. **Conclusions:** This study suggests that smoking is a major risk factor in for cSCC in SOC. These findings emphasize this importance of tailored preventative strategies to address disparities in tobacco smoking behaviors. Future research should seek to further elucidate the underlying socioeconomic, cultural, and healthcare access factors contributing to differences for optimization of equitable care. Independent validation of a 16-protein test to assess malignant potential of small uveal melanocytic tumors. First Author: David Alan Reichstein, Tennessee Retina, Nashville, TN

Background: Uveal melanocytic tumors of indeterminate malignant potential (UMTIMP) are usually managed by a "watch and wait" approach before the decision to treat. Although the aggressiveness of these lesions can be assessed by tumor-biopsy based molecular testing, serial tumor biopsies may be impractical and not always feasible for routine clinical management of UMTIMPs. In contrast, aqueous humor (AH) sampling can be safely performed as an outpatient procedure and is repeatable. AH protein biomarkers strongly associated with aggressive UM could be used as a sensitive and objective biological marker of malignant transformation, facilitating earlier tumor biopsy and treatment when clinically indicated. The purpose of this study was to validate a previously developed 16-protein algorithmic test for identification of high-risk tumor biology in AH sample. **Methods:** All study participants were clinically diagnosed with UM and had the 15-GEP, PRAME and 7-gene UM panel next-generation sequencing (NGS) test results available. AH samples (N=71) were prospectively collected at 3 independent sites under IRB approved protocols. The samples were analyzed with the Olink Target 96 Oncology II panel. The low-risk group included Class 1 and BAP1 wild type samples, and the high-risk group included Class 1 BAP1-mutant samples and all Class 2. Algorithmic analyses were performed in R and demographics analysis was performed in GraphPad Prism (version 10). **Results:** The sample distribution was representative of a typical UM patient cohort: average age was 62.4±15.1 years, tumor diameter 11.16±3.56 mm, and tumor thickness 4.85± 2.94 mm. The 15-GEP identified 48/71 of tumors as Class 1, and 23/71 tumors as Class 2. There was a significant difference in tumor diameter (P=0.003) and tumor thickness (P=0.001) between Class 1 and Class 2 patients. The proteins primarily belonged to Signal Transduction, Disease, and Cytokine Signaling pathways, based on Olink's Pathway Browser. The 16-protein test had a sensitivity of 92%, specificity 52%, NPV 92%, and PPV 51%. **Conclusions:** A novel 16-protein algorithmic test for predicting high-risk tumor biology of the uveal melanocytic lesions was independently validated in a multi-center study. This high sensitivity test would help to accurately identify high-risk melanocytic lesions based on AH sample and provide a clinically useful ancillary approach for guiding decisions for definitive tumor biopsy and treatment. Research Sponsor: None.

9591 **Poster Session**

PD-1–directed intratumoral immunotherapy for cutaneous carcinomas: Interim results from an ongoing study of INTASYL PH-762. First Author: Mary C Spellman, Panclarity LLC, San Francisco, CA

Background: Immune checkpoint-targeted antibodies directed at PD-1 or PD-L1 block co-inhibitory receptors expressed by anti-tumor T cells, breaking immune tolerance against tumor cells and generating cancer immunity. PH-762 is an INTASYL compound designed to precisely silence PD-1 mRNA. INTASYL is a patented, self-delivering RNAi technology designed to impart specific properties to small interfering RNAs. PH-762's unique structural and chemical modifications ensure an optimized cell and tissue uptake profile with intratumoral (IT) administration. Local delivery of immunotherapy minimizes systemic exposure and off-target toxicities and may decrease tumor size and improve surgical morbidity. The efficient uptake of PH-762 by human T cells, silencing of PD-1 mRNA and subsequent protein reduction has been demonstrated preclinically. Murine-targeted PH-762 (mPH-762) injections are able to silence PD-1 mRNA in T cells within the murine tumor and increase the secretion of IFN-γ. **Methods:** This open-label Phase 1 clinical study (NCT 06014086) is designed to evaluate the safety and tolerability of neoadjuvant use of IT PH-762 in cutaneous squamous cell carcinoma, melanoma, or Merkel cell carcinoma, to determine the pharmacokinetic profile of PH-762 after IT injection, to observe pathologic and immunologic tumor responses, and to determine the recommended dose for development. Escalating dose concentrations of PH-762 (from 1.14 mg/mL through 22.00 mg/mL) are tested serially in cohorts of 3 patients each. Patients receive IT PH-762 once weekly, 4 times over a 3-week period prior to surgical excision, which occurs 5 weeks after the initial injection. Tumor changes are evaluated per iRECIST criteria and pathological response. **Results:** Seven patients in two dose cohorts have received IT PH-762 (1.14 or 2.39 mg/mL). No dose-limiting toxicities or serious adverse events have been reported. Pathologic response was reported following surgical excision of the tumor (or tumor site). Of the 6 patients with SCC, 2 had complete response, 2 had partial response (1 near complete with $<$10% viable tumor), and 2 were non-responders. One patient with metastatic melanoma had no response. **Conclusions:** IT PH-762 has been well tolerated, with no evident safety signals or reported systemic or off-target toxicities, and dose escalation has resumed per protocol. Clinical and histologic evidence of tumor response is encouraging. PH-762 may decrease tumor bulk or provide a non-surgical alternative in specific circumstances, while minimizing systemic exposure and off-target toxicities. Clinical outcomes, coupled with pharmacokinetic and immunologic response data will inform continued clinical development of PH-762. Clinical trial information: 06014086. Research Sponsor: Phio Pharmaceuticals.

TPS9592 **Poster Session**

Phase I/Ib study of concurrent intravenous (IV) and intrathecal (IT) nivolumab (N) and relatlimab (R) for metastatic melanoma (MM) patients (pts) with leptomeningeal disease (LMD). First Author: Isabella Claudia Glitza, University of Texas MD Anderson Cancer Center, Houston, TX

Background: Pts with LMD face dismal prognosis, with median overall survival (OS) measured in months. We previously reported the safety and efficacy data from an open label, single arm and center phase I/IB trial for MM pts with LMD, using IT/IV N (*Nature Medicine*, Glitza et al.). 50 pts were treated. Median OS was 7.5 months and the toxicity was minimal. This approach was adopted into the NCCN guidelines, as these data suggest a subset of pts benefit from IT/IV N without high toxicity. N (anti-PD1) and R (anti-LAG3) represents a fixed- dose combination (FDC) approved by the FDA in 2022 for the treatment of unresectable MM. IV N/R has shown improved outcomes vs N in MM pts, and we identified LAG3 expression on CD8 T cells in the cerebrospinal fluid (CSF) of MM pts with LMD, in a pattern very similar to the expression of PD1. Subsequent work on C57BL/6 murine models with B16 and YUMM3 established LMD confirmed that combined treatment with IT/systemic anti-PD1/anti-LAG3 was the only treatment to significantly improve OS versus IT/systemic control treatment. We therefore added a non-randomized arm of concurrent IT/IV N/R to the previous study. Based on the prior tolerated dose of IT N 50mg, and the approved FDC ratio for IV N/R, we chose a FDC of IT N/R 50mg/16.7mg with concurrent with IV N/R at 480mg/160mg. We hypothesize that IT/IV N/R will be safe and an effective treatment for MM pts with LMD. **Methods:** This is a Phase Ib, non- randomized, single center trial of concurrent IT/IV N/R in adult ($\geq$18 years) MM pts with LMD (NCT03025256). Up to 20 pts will receive IT N/R every 28 days, and Cycle 1 (C1) will consist of IT N/R only. In subsequent cycles the IT dose will be followed by an IV dose of N/R. Most pertinent inclusion criteria are radiographic and/or CSF cytological evidence of LMD, ECOG PS of $\leq$ 2, $\leq$ 4 mg per 24 hours of dexamethasone (or the equivalent), with adequate organ function. Prior radiation and treatment with immunotherapy is allowed, as is the use of concurrent BRAF/MEK inhibitors. Primary endpoint is safety, and Bayesian toxicity monitoring rule will be used. Secondary endpoints are OS, survival rates at 3,6 and 12 months, and median duration of treatment. CSF, blood and microbiome samples will be collected at various time points. The first patient was enrolled in October 2024 and accrual of patients is ongoing (NCT03025256). Clinical trial information: NCT03025256. Research Sponsor: Bristol Myers Squibb.

TPS9593 **Poster Session**

Phase I/IIa dose finding study of triplet regimen of relatlimab (RELA), ipilimumab (IPI), and nivolumab (NIVO) in first-line therapy of metastatic melanoma (TRINITY). First Author: Elizabeth M. Burton, Department of Genomic Medicine, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: NIVO (anti-PD1) alone or in combination with IPI (anti-CTLA-4) or RELA (anti-LAG3) are approved immune checkpoint blockade (ICB) agents for the treatment (tx) of patients (pts) with advanced, unresectable metastatic melanoma. Doublet combinations induce higher rates of durable disease control vs single agent, translating into nominal improvements in survival. While there is no established dose-response relationship for NIVO alone or with RELA, IPI at higher doses induces higher objective response rate (ORR) but increased grade $\geq$3 immune-related adverse events. Deeper mechanistic understanding points towards potential synergy given IPI's role in expanding the TCR repertoire and modulating suppressive T cell populations while NIVO+RELA regulate the exhaustion signatures of activated T cells and allow for improved effector function. Recently, results from RELATIVITY-048 combining all three ICB agents (NIVO 480 mg Q4W + RELA 160 mg Q4W + IPI 1 mg/kg Q8W) demonstrated impressive efficacy with high response rates (59% ORR) and seemingly improved progression free and overall survival (PFS, OS) over previously reported doublet regimens. This study evaluated a markedly lower IPI dose than the approved regimen and did not include a dose escalation component to optimize the IPI dosing strategy. Our team seeks to optimize the dose and schedule of IPI to combine with NIVO+RELA in order to determine the recommended phase II dose (RP2D) for triplet ICB and maximize clinical benefit while maintaining a toxicity profile comparable to approved regimens. **Methods:** In this single center, investigator initiated, phase I/IIa study evaluating triplet ICB (NCT06683755), all pts will receive FDA approved regimen of NIVO 480mg + RELA 160mg IV Q4W along with escalating doses of IPI . Dose escalation (DE) with IPI will begin at 0.5mg/kg Q4W 4 induction doses and will incrementally escalate up to 2mg/kg Q4W. Maintenance tx will consist of NIVO+RELA Q4W. Bayesian optimal interval (BOIN) design will be used to identify the maximum tolerated dose (MTD) and RP2D (primary objective) in the DE portion, accruing an estimated 12-18 pts. The PhIIa portion will accrue an additional 12-18 pts at the RP2D to better characterize safety, and determine the ORR, (primary objective) by RECIST 1.1. Secondary objectives include PFS, OS, and tumor and immunological correlatives obtained on pre and post tx blood and tumor samples. Pts must be previously untreated, unresectable, or advanced melanoma. Non IPI containing prior adjuvant or neo-adjuvant tx will be permitted if the last dose has been $>$6 months. Pts with asymptomatic brain metastasis are allowed, provided no immunesuppressive doses of corticosteroids are required. Safely biopsiable lesions are required for pts enrolled in the PhII portion. This study is open for accrual at MD Anderson Cancer Center in Houston, Texas. Clinical trial information: NCT06683755. Research Sponsor: BMS.

TPS9594 **Poster Session**

A multicenter, randomized, controlled, open-label, phase 2 study of the PD-1/IL-2$^{\alpha\text{-bias}}$ bispecific antibody fusion protein IBI363 in mucosal and acral melanoma. First Author: Bin Lian, Peking University Cancer Hospital & Institute, Beijing, China

Background: Although several immune checkpoint inhibitors have been approved for advanced melanoma, there remain significant unmet clinical needs, particularly for immune-cold subtypes such as mucosal and acral melanoma, which are frequently observed in Chinese patients (pts). IBI363 targets and activates tumor-specific T cells that express both PD-1 and IL-2Rα, leading to enhanced antitumor activity and reduced toxicity. Previous phase 1 studies of IBI363 reported manageable safety profiles with encouraging efficacy in advanced melanoma (2024 ASCO Annual Meeting [9562], ESMO Virtual Plenary [VP4-2024], SITC [1502]). Here, we present the trial in progress of a phase 2 study evaluating efficacy and safety of IBI363 monotherapy versus pembrolizumab in mucosal and acral melanoma. **Methods:** This multicenter, randomized, controlled, open-label, phase 2 study planned to enroll 180 pts. Main inclusion criteria are: 1) locally advanced unresectable or metastatic mucosal or acral melanoma; 2) no previous systemic treatment for melanoma; 3) at least one measurable tumor lesion (target lesions) per RECIST v1.1. Pts with active or symptomatic central nervous system metastasis are excluded. Pts are randomized in a 1:1 ratio to receive IBI363 1 mg/kg Q2W (with a priming dose of 100 μg/kg administered 7 days before the full dose) in the experimental arm or to receive pembrolizumab 200 mg Q3W in the control arm. Stratification factors include subtype (mucosal vs acral) and M staging (M0 vs M1a(0)/M1b(0) vs M1a(1)/M1b(1) or M1c/M1d, (0) indicating baseline lactate dehydrogenase [LDH] $\leq$ upper limit normal [ULN] and (1) indicating baseline LDH $>$ ULN). The primary endpoint is progression-free survival (PFS) assessed by independent radiological review committee (IRRC) per RECIST v1.1. The secondary endpoints include investigator-assessed PFS, IRRC-assessed and investigator-assessed objective response rate (ORR), disease control rate (DCR), duration of response (DoR), time to response (TTR) per RECIST v1.1, overall survival (OS), safety, pharmacokinetics (PK) and immunogenicity. No interim analysis is planned. A total of 118 PFS events among 180 pts is estimated to demonstrate the superior efficacy of IBI363 compared to the control, with a power of 90% (α=0.025, one-sided). Clinical trial information: CTR20250280. Research Sponsor: Innovent Biologics (Suzhou) Co., Ltd.

TPS9595 **Poster Session**

NivoReach: Integrated study to demonstrate similarity of JPB898 to reference nivolumab in combination with ipilimumab in patients with advanced melanoma. First Author: Piotr Rutkowski, Department of Soft Tissue/Bone Sarcoma and Melanoma, Maria Sklodowska-Curie National Research Institute of Oncology, Warsaw, Poland

Background: JPB898 is being developed as a biosimilar to reference nivolumab. Analytical and functional in vitro similarity of JPB898 to reference nivolumab has been demonstrated. NivoReach will assess the pharmacokinetic (PK) and efficacy similarity of JPB898 to reference nivolumab in patients with untreated advanced melanoma. Induction therapy with nivolumab 1 mg/kg and ipilimumab 3 mg/kg is approved for advanced melanoma, before nivolumab maintenance therapy. However, the unfavorable toxicity profile of this regimen, attributed mainly to ipilimumab, has led to investigation of alternative regimens. The Phase IIIb/IV CheckMate 511 trial compared the approved regimen with an "inverse dosing" regimen comprising nivolumab 3 mg/kg and ipilimumab 1 mg/kg. Similar response and overall survival rates were observed between the treatment groups, as well as a lower incidence of immune-related toxicities and a lower rate of discontinuation due to treatment-related adverse events with the inverse regimen versus the approved regimen (Lebbé C, et al. J Clin Oncol 2019;37:867–75). Therefore, inverse dosing is an appealing combination regimen for use in NivoReach, providing a treatment option with a more favorable risk–benefit ratio to a broader advanced melanoma patient population versus the approved regimen. Currently, the study is approved in 19 countries, including the USA and some EU member states. **Methods:** This global, randomized, double-blind, parallel-group study is recruiting participants with untreated, unresectable Stage III or metastatic Stage IV melanoma, measurable per RECIST v1.1. Participants must have an ECOG performance status ≤1. Participants will not be eligible if they have active brain metastases, ocular melanoma, or other active malignancy that is untreated or requires concomitant systemic therapy. Eligible participants will be randomized 2:1:1 to JPB898, or US-licensed or EU-authorized nivolumab, in combination with ipilimumab. Randomization will be stratified by *BRAF* V600 mutation status, PD-L1 expression status, and metastasis stage. In the 12-week induction phase, participants will receive 4 cycles of the inverse regimen (nivolumab 3 mg/kg + ipilimumab 1 mg/kg, Q3W). In the maintenance phase, participants will receive fixed-dose monotherapy (480 mg, Q4W) with JPB898 or reference nivolumab from Week 16 to 48. The co-primary PK endpoints are area under the serum concentration–time curve (AUC) after the first dose and AUC after the fourth dose in the induction phase. The primary efficacy endpoint is best overall response (complete or partial response) up to 28 weeks. Other PK, efficacy, safety, and immunogenicity endpoints will also be assessed up to 52 weeks. The planned randomized sample size is 720 participants. Clinical trial information: NCT06587451. Research Sponsor: Sandoz.

TPS9596 **Poster Session**

A randomized phase 2 peri-operative (neoadjuvant plus adjuvant) study of fianlimab (anti–LAG-3) plus cemiplimab (anti–PD-1) versus anti–PD-1 alone in patients with resectable stage III and IV melanoma. First Author: Rodabe Navroze Amaria, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Prior studies demonstrated use of neoadjuvant plus adjuvant immune checkpoint inhibitors (ICIs) improves event-free survival (EFS) compared with upfront surgery and adjuvant ICI therapy alone, supporting that peri-operative (neoadjuvant plus adjuvant) ICI therapy improves survival outcomes in patients (pts) with clinical stage III and resectable IV melanoma (Mel). Initial efforts in Mel trials to explore combined blockade by anti-programmed cell death-1 (anti–PD-1) and anti-lymphocyte activation gene 3 (anti–LAG-3) antibodies produced incrementally better efficacy than blockade of the PD-1 pathway alone. However, these efforts may not have provided optimal blockade of the two pathways. We have utilized VelocImmune technology to create potentially best-in-class, high-affinity, fully human immunoglobulin G4-blocking antibodies, fianlimab (FIAN; anti–LAG-3) and cemiplimab (CEMI; anti–PD-1). In a multicohort study (NCT03005782), FIAN + CEMI demonstrated reproducibly high clinical activity (objective response rate [ORR]: 57%; median progression-free survival: 24 months; N=98) in three independent cohorts of pts who were naïve to anti–PD-1 treatment in the advanced Mel setting, with an acceptable safety profile. Thus, the combination of FIAN + CEMI warrants an investigation as a peri-operative regimen in resectable, clinically detectable, high-risk, stage III and IV cutaneous Mel. **Methods:** This is a randomized Phase 2 peri-operative study (NCT06190951) in pts with clinical stage III/IV Mel with resectable disease. Pts will receive 3 cycles of neoadjuvant therapy followed by complete surgical resection, and continue with an optional 15 cycles of adjuvant therapy, based on pathological response. The primary objective is to compare the effect of FIAN + CEMI versus CEMI alone as measured by the pathological complete response (pCR) rate. Approximately 150 pts will be randomized 1:1:1 to three arms (intravenously once every 3 weeks): Arm A, CEMI 350 mg + placebo; Arm B, High Dose FIAN + CEMI 350 mg; Arm C, Low Dose FIAN + CEMI 350 mg. Pts will be stratified based on tumor, node, metastasis (TNM) stage and geographical region. Key inclusion criteria: age ≥18 years; resectable clinical stage III/IV histologically confirmed Mel; pts with stage III Mel must have clinically detectable disease; Eastern Cooperative Oncology Group performance status 0 or 1; adequate bone marrow, hepatic, and kidney function. The primary endpoint is pCR rate by blinded independent pathological review performed centrally. The secondary endpoints are pCR rate (by local assessment), major pathological response (by local and central review), EFS, overall survival, distant metastasis-free survival, relapse-free survival, ORR, safety, pharmacokinetics, immunogenicity, and patient-reported outcomes. Clinical trial information: NCT06190951. Research Sponsor: Regeneron Pharmaceuticals, Inc.; NA.

TPS9597 **Poster Session**

A randomized, phase 2/3 clinical trial investigating RP2 plus nivolumab vs ipilimumab plus nivolumab in immune checkpoint inhibitor-naïve patients with metastatic uveal melanoma. First Author: Joseph J Sacco, The Clatterbridge Cancer Centre and University of Liverpool, Wirral and Liverpool, United Kingdom

Background: Uveal melanoma (UM) is the most common primary intraocular malignancy, accounting for nearly 90% of ocular melanomas and up to 5% of melanomas overall. Approximately 50% of patients (pts) with UM will develop metastatic disease, with the liver being the most common site of metastases (~90%). The prognosis for pts with metastatic UM (mUM) is poor, with a median overall survival (OS) of approximately 1 year. Effective treatment options for mUM are limited as it responds poorly to single-agent immune checkpoint inhibitors (ICIs; <10% response rate). Response rates are slightly higher with combination therapies (12%–18%), but often at the expense of increased toxicity. Tebentafusp is FDA approved for mUM based on survival benefit; however, its use is restricted to pts who are HLA-A*02:01 positive, and only ~10% of pts achieve an objective response. RP2 is a selectively replication-competent herpes simplex virus type 1–based oncolytic immunotherapy expressing GM-CSF, a fusogenic glycoprotein (GALV-GP-R–), and an anti–CTLA-4 antibody-like molecule. Prior phase 1 preliminary clinical data of RP2 as monotherapy or in combination with nivolumab (nivo) demonstrated a promising safety profile and anti-tumor activity with an ORR of 29.4% in 17 patients with mUM, most of whom had received prior ICIs. This study will assess the efficacy and safety of RP2 + nivo vs ipilimumab (ipi) + nivo in pts with ICI-naïve mUM (NCT06581406; RP2-202). **Methods:** This is a randomized, controlled, phase 2/3 study. Key eligibility criteria include age ≥18 years and confirmed unresectable mUM with lesions amenable to injection. Pts with metastatic disease who have had prior exposure to ICIs since the time of UM diagnosis, involvement of >33.3% of the liver, or a history of prior liver- or lesion-directed therapy are not eligible for enrollment. Enrolled pts (N = ~280) will be randomized 1:1 to receive either RP2 + nivo or ipi + nivo. In the RP2 + nivo arm, RP2 will be given intratumorally initially at 1 x 10^6 PFU/mL, then every 2 weeks (Q2W) at 1 x 10^7 PFU/mL for 7 doses in combination with intravenous (IV) nivo (240 mg). In the ipi + nivo arm, pts will receive IV ipi (3 mg/kg) and IV nivo (1 mg/kg) Q3W for 4 doses. Pts in both arms may then receive IV nivo at 240 mg Q2W or 480 mg Q4W for up to 2 years from the first dose. The co-primary endpoints are OS and progression-free survival by independent central review using RECIST 1.1. Secondary endpoints are overall response rate, duration of response, disease control rate, clinical benefit rate, duration of clinical benefit, and safety, including incidence of treatment-emergent adverse events (AEs), serious AEs, and immune-mediated AEs. Clinical trial information: NCT06581406. Research Sponsor: Replimune, Inc.

TPS9598 **Poster Session**

The MATRiX trial: A multicenter, randomized, phase II study of ATR inhibition (via tuvusertib) with or without avelumab in patients with advanced anti-PD-(L)1–refractory Merkel cell carcinoma. First Author: Rashmi Bhakuni, University of Washington Medicine Dermatology, Seattle, WA

Background: Merkel cell carcinoma (MCC) is a rare neuroendocrine skin cancer driven by UV mutations or the Merkel cell polyomavirus (MCPyV).It is aggressive, with a high Ki-67 proliferative index.Despite an initial high response rate (~55%) to PD-1 pathway inhibitors, >50% of patients exhibit primary or acquired resistance.ATR (ataxia telangiectasia and Rad3-related) kinase, a critical cell cycle checkpoint regulator, ensures genome fidelity in cancer cells experiencing high replication stress, including MCC.Our preclinical findings suggest anticancer activity of ATR inhibition via transcriptional induction of NF-κB-associated proinflammatory mechanisms.The potent, selective, orally administered ATR inhibitor tuvusertib (M1774) has shown antitumor activity in patients with unresectable solid cancers in Phase I trials, with a recommended Phase II dose of 180 mg daily on an intermittent schedule.We hypothesize that tuvusertib ± anti-PD-(L)1,may induce tumor regression in advanced anti-PD-(L)1-refractory MCC. **Methods:** The multicenter, randomized Phase II MATRiX trial tests the safety and efficacy of tuvusertib monotherapy (Arm 1) and tuvusertib plus avelumab (Arm 2) in patients with metastatic MCC refractory to PD-(L)1 blockade. Patients with progressive disease per Response Evaluation Criteria in Solid Tumors (RECIST) v1.1 within 120 days of their last anti-PD-(L)1 therapy are eligible. Subjects randomized to Arm 1 receive tuvusertib 180 mg QD on days 1-14 of each 21-day cycle. Subjects in Arm 2 also receive avelumab 1600 mg IV on day 1 of each 21-day cycle. Imaging studies performed 9 weeks after treatment initiation and every 12 weeks thereafter will be assessed per RECIST v1.1. Patients in Arm 1 with progressive disease may receive tuvusertib + avelumab. Treatment-emergent adverse events are graded per Common Terminology Criteria for Adverse Events version 5.0. The primary endpoint is progression-free survival (PFS). Between June 2024 and January 2025, 13 subjects were enrolled across 10 centers. With a targeted enrollment of 50 patients, this trial has 83% power to observe a statistically significant (one-sided level of 10%) difference in PFS if the true hazard ratio for failure is 2.0. A stratified (primary vs. acquired resistance) log-rank test will be used, and binary outcomes will be compared using a Mantel-Haenzel test. A Wieand-like futility rule will be used for an interim analysis after the 23rd event occurs. Tumor biopsies, blood, and stool specimens will be profiled to gain integrated insight into transcriptomic, proteomic, and metabolic signatures associated with immune-mediated therapeutic outcomes. This orthogonal approach to solid tumor immunotherapy, relevant to analogous cancers, will guide future combination strategies to better harness the anti-tumor immune response. Clinical trial information: NCT05947500. Research Sponsor: NCI Cancer Therapy Evaluation Program-Experimental Therapeutics Clinical Trials Network; P30CA015704.

TPS9599 **Poster Session**

A randomized, controlled, multicenter, phase 3 study of vusolimogene oderparepvec combined with nivolumab vs treatment of physician's choice in patients with advanced melanoma that has progressed on anti–PD-1 and anti–CTLA-4 therapy (IGNYTE-3). First Author: Jason J. Luke, UPMC Hillman Cancer Center and University of Pittsburgh, Pittsburgh, PA

Background: Melanoma is the fifth most common cancer, with ~100,000 new cases and ~8000 related deaths estimated in the US for 2024. First-line systemic treatment with immune checkpoint inhibitors improves the objective response rate (ORR) and extends progression-free survival (PFS) and overall survival (OS) for patients with advanced disease. Among available treatments, combination anti–PD-1 (nivolumab) + anti–CTLA-4 (ipilimumab) therapy is associated with the highest ORR and best PFS and OS. However, only ~50% of patients respond to treatment, and limited options exist for patients whose melanoma progresses following anti–PD-1–based therapy. Vusolimogene oderparepvec (VO; also known as RP1) is a selectively replication-competent herpes simplex virus type 1–based oncolytic immunotherapy that expresses human granulocyte-macrophage colony-stimulating factor and a fusogenic glycoprotein (GALV-GP-R–). Data from a registration-intended cohort of the IGNYTE study (NCT03767348) showed that intratumoral VO + intravenous nivolumab was well tolerated and demonstrated durable, clinically meaningful antitumor activity (ORR, 32.9% per independent central review using Response Evaluation Criteria in Solid Tumors 1.1) in patients with advanced melanoma and confirmed progression on prior anti–PD-1 therapy. IGNYTE-3 will evaluate the OS and clinical benefit of VO + nivolumab for patients with advanced cutaneous melanoma whose disease has progressed after anti–PD-1 and anti–CTLA-4 therapy (or who are ineligible for anti–CTLA-4 therapy) vs physician's choice. **Methods:** IGNYTE-3 (NCT06264180) is a global, randomized, controlled, multicenter, phase 3 trial (currently recruiting). Key eligibility criteria include age ≥12 years; stage IIIb–IV/M1a–M1d cutaneous melanoma; disease progression on ≥8 weeks of an anti–PD-1 and anti–CTLA-4 treatment (administered in combination or in sequence, with anti–PD-1 last); ≥1 measurable and injectable tumor (≥1 cm); and adequate hematologic, hepatic, and renal function. Patients who are not candidates for anti–CTLA-4 therapy may enroll following progression on anti–PD-1 therapy alone. Patients with BRAF V600-mutant melanoma must have received anti-BRAF ± anti-MEK targeted therapy prior to enrollment. Patients (N = ~400) will receive VO + nivolumab or physician's choice (nivolumab + relatlimab, anti–PD-1 monotherapy rechallenge [nivolumab or pembrolizumab], or single-agent chemotherapy [dacarbazine, temozolomide, or paclitaxel/albumin-bound paclitaxel]). The primary endpoint of the study is OS; the key secondary endpoints are PFS and ORR per RECIST 1.1. Clinical trial information: NCT06264180. Research Sponsor: Replimune, Inc.

TPS9600 **Poster Session**

A phase 1, open-label, dose expansion cohort of the tolerability of tolododekin alfa (ANK-101) in combination with cemiplimab in cutaneous squamous cell carcinoma. First Author: Jong Chul Park, Massachusetts General Hospital, Boston, MA

Background: IL-12 stimulates innate and adaptive tumor immunity. Tolododekin alfa (ANK-101) is an anchored drug conjugate that creates a strong link between full-length IL-12 and aluminum hydroxide through an alum-binding protein (ABP) which localizes IL-12 to the tumor microenvironment (TME), resulting in sustained drug release, prolonged antitumor immune activation, increased PD-L1 expression, and minimal systemic adverse events. Cemiplimab is an anti-PD-1 monoclonal antibody approved in several countries worldwide for the treatment of metastatic or locally advanced cutaneous squamous cell carcinoma (CSCC) who are not candidates for curative surgery or radiation. This phase 1 clinical trial is designed to combine tolododekin alfa and cemiplimab to determine tolerability and initial biologic and clinical activity. **Methods:** This is an open-label study to evaluate locally administered tolododekin alfa and cemiplimab in patients with advanced CSCC who progressed on, are refractory to, or intolerant of prior SOC treatment. The combination cohort will consist of 15 participants. Participants will be treated with tolododekin alfa in combination with cemiplimab. Treatment will consist of up to eight cycles of tolododekin alfa in combination with cemiplimab followed by cemiplimab alone for up to one year. Follow-up imaging assessments will be performed every 12 weeks. Eligible participants must have histologically confirmed high-risk locally advanced or metastatic CSCC not amenable to surgical management, accessible tumors for injection and biopsy, and measurable disease by RECIST v1.1. Key exclusion criteria include tumors close to vital structures, uncontrolled bleeding disorders, and prior ≥ Grade 3 immune-mediated adverse events (imAEs) following treatment with an agent that blocks the PD-1/ PD-L1 pathway. Primary objectives include safety and tolerability of tolododekin alfa and cemiplimab. Secondary objectives include immunogenicity (ADA), and preliminary clinical activity measured by ORR, DCR, DOR, and PFS by RECIST v1.1. Exploratory objectives include QOL using FACT-G and immune pharmacodynamic (PD) changes. This clinical trial is in progress. Clinical trial information: NCT06171750. Research Sponsor: Ankyra Therapeutics.

TPS9601 **Poster Session**

The TIME trial: Phase II randomized controlled trial of time-of-day–specified immunotherapy for advanced melanoma. First Author: Zachary Buchwald, Department of Radiation Oncology, Winship Cancer Institute of Emory University, Atlanta, GA

Background: Ipilimumab + nivolumab is standard of care for advanced melanoma patients based on data from the CheckMate 067 trial. The recent 10-year outcomes results were reported with a melanoma specific survival of 52%. While data are very encouraging, 50% of patients still succumb to their disease by 10-years. Preclinical data suggests that the circadian rhythm may influence the anatomic localization, function and activity of T cells, the target of immunotherapy. More T cells in the tumor or tumor-draining lymph node during initial immunotherapy administration may improve clinical responses and long-term outcomes. To investigate this idea, we performed a retrospective analysis, the MEMOIR study, finding that more evening infusions of immunotherapy were associated with significantly worse progression free and overall survival for metastatic melanoma patients. These findings have now been reproduced in other cancer types, in a large meta-analysis, and in pre-clinical mechanistic studies. In light of these data, we hypothesize that patients receiving morning or midday infusions of immunotherapy will have better outcomes than patients receiving infusions in the evening. **Methods:** The TIME trial is a three-arm phase II study of time-of-day specified administration of standard dose ipilimumab + nivolumab for metastatic melanoma. Newly diagnosed unresectable metastatic melanoma patients will be randomized to receive 4 cycles of ipilimumab + nivolumab every 3 weeks between either 8:00-11:00 (Arm A), 11:00-14:00 (Arm B), or 14:00-17:00 (Arm C). Following these 4 cycles, they will receive standard of care maintenance nivolumab in a time-of-day agnostic fashion. Eligible adult patients must have Stage III-IV unresectable cutaneous, acral or mucosal melanoma, no prior immunotherapy within 1 year, ECOG performance status of 0-1, and only asymptomatic brain metastases less than 2 cm. The primary objective is to determine whether progression free survival for Arm A or Arm B is superior to Arm C. Secondary objectives include assessments of adverse events, melanoma specific survival and overall survival. We also plan to evaluate the immune profiles of blood and tumor, when available, to assess the impact of time-of-day administered ipilimumab + nivolumab on the circulating immune responses and the tumor immune microenvironment. A sample size of 99 patients (33 in each arm) was selected for at least 80% power to detect a HR of 0.50 with a Type 1 error rate of 0.1 (2-sided) for a comparison of A vs. C and B vs. C. Research Sponsor: None.

TPS9602 **Poster Session**

Phase I dose escalation and expansion study of PRAME T-cell receptor (TCR) engineered IL15-transduced cord blood–derived natural killer (NK) cells in patients with recurrent and/or refractory melanoma (PRAMETIME-Mel). First Author: Derrick Law Tao, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: For patients with relapsed and/or refractory metastatic melanoma (RRFM), there is a critical need to test novel strategies with improved anti-tumor response and safety profile. Adoptive cell therapy (ACT) has been recognized as a promising avenue for addressing the unmet need for more potent anti-tumor approaches. Allogeneic cord blood (CB)-derived natural killer (NK) cell therapies have emerged as a therapeutic alternative to adoptive T-cell therapies given decreased toxicity and feasibility as an "off-the-shelf" therapy, bypassing the manufacturing time and treatment delays associated with autologous T-cell products. PRAME (PReferentially expressed Antigen in MElanoma), a cancer-testis antigen expressed on approximately 95% of cutaneous melanomas and not expressed outside of immune-privileged sites such as the testis, ovary, placenta, and endometrium, is a promising target for allogeneic NK cells engineered with a T cell receptor (TCR) to selectively target melanoma cells. In contrast to autologous T cell therapies that require exogenous systemic IL-2 as a supportive factor, NK cells engineered to express IL-15 have been observed to have minimal side effects while significantly enhancing the in vivo expansion and persistence of the transduced NK cells. PRAME TCR/IL-15 NK, an engineered TCR NK cell therapy, has demonstrated efficacy against melanoma cell lines in vitro and in vivo and safety against normal human cell lines. Building upon these preclinical findings, we propose this trial to explore the safety and efficacy of PRAME TCR/IL-15 NK cells in patients with RRFM. **Methods:** This phase I, single-center, open-label trial will assess the safety, tolerability, and efficacy of PRAME TCR/IL-15 cells in patients with HLA A*02:01 positive RRFM, with no prospective PRAME testing. The primary endpoints are to determine the safety, tolerability, maximum tolerated dose and recommended phase II dose. The secondary endpoints are to assess response and survival. The study will be comprised of dose escalation (4 dose levels, with a dose level -1 in case of excessive toxicities observed in dose level 1) and dose expansion. A maximum of 39 patients will be enrolled, including 24 patients in the dose escalation cohort and up to 15 patients in the dose expansion cohort. Enrolled patients will receive lymphodepletion chemotherapy (fludarabine 30 mg/m^2 and cyclophosphamide 500 mg/m^2) on days -6 to -3, followed by a single dose of PRAME TCR/IL-15 NK cells on day 0. Longitudinal blood and tissue samples will be collected for correlative immune analysis. Clinical trial information: NCT06660420. Research Sponsor: None.

TPS9603 **Poster Session**

Multicenter, randomized, double-blinded, placebo-controlled trial of IFx-Hu2.0 (IFx) as adjunctive therapy with pembrolizumab (pembro) in checkpoint inhibitor (CPI)-naïve patients with advanced or metastatic Merkel cell carcinoma (MCC). First Author: Andrew Scott Brohl, H. Lee Moffitt Cancer Center and Research Institute, Tampa, FL

Background: CPIs have revolutionized the treatment of a wide variety of cancers. Despite their success, the majority of cancers do not respond primarily due to tumor-intrinsic mechanisms allowing immune evasion, and obviating activation of tumor specific cytotoxic T cells (cTc), which are required for CPIs to work. Activation of tumor-specific cTc is thus the goal for most therapies aiming to overcome primary resistance to CPIs. IFx is an innate immune agonist designed to overcome primary resistance to CPIs. It consists of a plasmid DNA, pAc/emm55, encoding for an immunogenic gram+ bacterial protein streptococcal Emm55, combined with a cationic polymer that facilitates cellular uptake of DNA. Intralesional injection of IFx results in Emm55 expression on the surface of tumor cells. Pathogen-associated molecular patterns on gram+ bacteria are recognized by toll-like receptors (TLRs) on innate immune cells. TLRs with CD14 as a co-receptor binds to these bacterial proteins, activating an innate immune response against the tumor cell and the expressed bacterial protein. This causes non-self tumor neoantigen presentation to naïve B and T cells, resulting in activation of tumor specific cTc and antibodies. Unlike oncolytic viral approaches which rely on tumor lysis and distribution of tumor neoantigens into the tumor microenvironment, IFx causes phagocytosis of intact tumor cells and may provide more comprehensive and efficient antigen presentation, promoting inter-antigenic epitope spreading. In a Phase 1b trial among 23 patients with MCC or cutaneous squamous cell carcinoma (cSCC) that failed to respond to anti-PD(L)-1 therapy, intralesional IFx was well tolerated at weekly injections x3 dosing regimen. Post-protocol rechallenge with CPI resulted in 7 of 11 (63%) patients with MCC experiencing durable (median 19 mos.) complete or partial responses, despite prior failure of the same class of CPI. Based on these results, a randomized, double-blind, placebo-controlled trial to evaluate the potential for adjunctive IFx and pembro to improve response rates in the first-line treatment of CPI naïve patients with advanced or metastatic MCC is planned. **Methods:** 118 CPI naive adults with MCC will be assigned via 1:1 randomization to IFx (0.1mg) or placebo given weekly x3 concurrent with pembro 200 mg IV q3w for up to 2 years, or progression or toxicity. Responses assessed by blinded independent central review per RECIST v1.1 q12w during the first 24 months and q24w thereafter up to 5 years. Adverse events (AEs) will be assessed per CTCAE v5.0 up to 90 days after final treatment. Primary and key secondary endpoints include objective response rate and progression-free survival respectively. Other secondary endpoints are safety, duration of response, and overall survival. Clinical trial information: Pending as of submission deadline. Research Sponsor: TuHURA Biosciences, Inc.

TPS9604 **Poster Session**

TeLuRide-006: An adaptive phase 2/3 study of EIK1001, a Toll-like receptor 7/8 (TLR7/8) agonist, in combination with pembrolizumab in patients with advanced melanoma. First Author: Jason J. Luke, UPMC Hillman Cancer Center, Pittsburgh, PA

Background: Immune checkpoint inhibitors (ICIs) relieve immunosuppression of tumor-reactive T cells and enhance antitumor response. Significant advances for the treatment of advanced melanoma have been made using ICIs, with overall survival (OS) benefit conferred by ICI monotherapy. While encouraging results have been observed with combinations of ICIs, no α-controlled, statistically significant OS benefit of combinations over monotherapy has been demonstrated in Phase 3 studies. Despite these advances, 5-year survival for advanced disease is only 15 to 20%, motivating development of new therapies. EIK1001 is a TLR7/8 agonist that stimulates myeloid and plasmacytoid dendritic cells, activating immune and inflammatory responses. This dual activity, distinct from effects on checkpoint proteins, enhances antitumor T-cell activity alone or in combination with ICIs. **Methods:** TeLuRide-006 (NCT#06697301) is a global, multicenter, randomized, double-blind, adaptive Phase 2/3 study of EIK1001 or placebo in combination with pembrolizumab (pembro) as first-line therapy in participants (pts) with advanced melanoma. This study includes dose-optimization (DO), in which pts are randomized 1:1:1 to receive 1 of 2 doses of EIK1001 or placebo in combination with pembro, followed by adaptive Phase 2/3 expansion at the Selected Dose of EIK1001 + pembro or placebo + pembro. Interim analyses will determine whether the study advances from DO to Phase 2 to Phase 3. EIK1001 or placebo is administered intravenously QW until the end of Week 27 then Q3W. Pts are stratified by prior anti-PD-1 adjuvant therapy, LDH level, and BRAF mutational status. Key eligibility criteria: pts $\geq$ 18 years of age with a life expectancy of $\geq$ 3 months, Stage 3 (unresectable) or Stage 4 metastatic melanoma, known BRAF V600 mutational status (or consent to BRAF mutation testing), $\geq$ 1 measurable lesion by RECIST v1.1, and no history of or current pneumonitis/interstitial lung disease. Primary objectives are to evaluate the efficacy and safety of 2 doses of EIK1001 in combination with pembro (DO only) and to compare progression-free survival per RECIST 1.1 by blinded independent central review (BICR) and OS of pts receiving EIK1001 + pembro relative to pts receiving placebo + pembro (at Selected Dose). Secondary objectives include evaluation of the safety and tolerability of the Selected Dose of EIK1001 + pembro relative to placebo + pembro, as well as evaluation of objective response rate and duration of response per RECIST 1.1 by BICR. Exploratory objectives include evaluation of time to objective response, evaluation of potential EIK1001 exposure-response relationships, and evaluation of health-related quality of life, health utilities, and melanoma concerns in pts receiving EIK1001 + pembro relative to placebo + pembro. This study opened on 24 December 2024. Clinical trial information: 06697301. Research Sponsor: None.

TPS9605 **Poster Session**

A phase II study of binimetinib plus imatinib in patients with unresectable KIT-mutant melanoma. First Author: Katy K. Tsai, Helen Diller Family Comprehensive Cancer Center, University of California, San Francisco, San Francisco, CA

Background: Patients (pts) with melanoma refractory to immune checkpoint inhibition (ICI) remain in need of rational therapeutic options. Pts with rare melanoma subtypes (acral, mucosal) are in particular need given lower objective response rates (ORR) to ICI, and lower incidence of BRAF V600-mutant disease. Such BRAF mutations are found in only 5-10% of acral/mucosal melanomas, while KIT mutations/amplifications are found in 10-20%. Even when present, a KIT alteration does not guarantee response to KIT inhibition, with only one-third responding as shown in previous phase II studies. A significant number of KIT-mutant melanomas have been shown to demonstrate NF1 or SPRED1 loss, with recent preclinical work showing these alterations to be associated with loss of negative suppression of RAS, resulting in RAS activation and MEK dependence. We hypothesize that NF1 or SPRED1 loss cooperates with KIT mutations to drive melanomagenesis and resistance to KIT inhibition, and propose to target this vulnerability with a combination targeted therapy approach. This phase II study will be the first to evaluate the efficacy and safety of binimetinib plus imatinib in pts with KIT-mutant melanoma. **Methods:** This is a multicenter, investigator-initiated phase II study of binimetinib in combination with imatinib in pts with KIT-mutant unresectable melanoma who have progressed on or who are ineligible for ICI. Pts will be $\geq$18 yo with performance status ECOG 0-2, and have unresectable Stage IIIB/C/D or Stage IV melanoma that is KIT-mutant by CLIA-certified testing platform. Pts will have progressed on prior ICI or other standard-of-care (SOC) therapies, or be ineligible for/unable to tolerate SOC therapies. Pts with brain metastasis will be eligible if clinically stable with no need for CNS-specific treatment required prior to study start. Pts previously treated with a MEK inhibitor will be excluded. A Simon 2-stage Minimax design will be used; the null hypothesis that the true response rate is 0.1 will be tested against a one-sided alternative. 15 pts will be accrued in the Stage 1. If there are $<$1 responses, the study will be stopped. Otherwise, 10 additional pts will be accrued in Stage 2 for a total of 25. The null hypothesis that the true response rate is 0.1 will be rejected if $\geq$6 responses are observed. This yields a type I error rate of 0.05 and power of 0.8017 when the true response rate is 0.3. Primary endpoint: ORR (RECIST). Secondary endpoints: duration of response, progression-free survival, overall survival, clinical benefit rate (CR, PR, or SD $\geq$16 weeks), safety profile (CTCAE). Exploratory objectives include investigation of association between clinical response and baseline NF1 and SPRED1 status, and pathologic correlates of acquired resistance. 11 pts have been screened; 8 of planned 15 pts in Stage 1 have been enrolled. Enrollment is ongoing at UCSF and UCSD. Clinical trial information: NCT04598009. Research Sponsor: None.

TPS9606 **Poster Session**

Neoadjuvant cemiplimab in cutaneous basal cell carcinoma of the head and neck. First Author: Eric Mastrolonardo, Department of Otolaryngology Head & Neck Surgery, Thomas Jefferson University, Philadelphia, PA

Background: Surgical resection of locally advanced basal cell carcinoma of the head and neck (laBCCHN) is often not feasible due to tumor size and proximity to vital structures with risk of significant deformity. Prior data suggest that neoadjuvant therapy could have a major impact on preserving critical structures, especially in the head and neck. The PD-1 inhibitor cemiplimab (REGN2810) has shown significant response rates for metastatic BCC after progression or intolerance of Hedgehog inhibitor (HHI) therapy. However, cemiplimab has not been investigated in the neoadjuvant setting for laBCCHN. To address this gap, this multi-center phase II study seeks to assess the response to neoadjuvant cemiplimab in the treatment of HHI-naïve laBCCHN. **Methods:** Patients with HHI-naive laBCCHN will receive response-adaptive, neoadjuvant IV cemiplimab 350mg every 3 weeks for an initial 2 cycles. The primary endpoint is the fraction of patients demonstrating clinical response after 2 cycles. All patients will undergo RECIST v1.1 response assessment by CT or MRI, and if not radiographically measurable, caliper measurement will be utilized to evaluate the primary endpoint. Those with RECIST v1.1 progression or stable disease with $>$5% growth will be considered non-responders and will proceed with surgery or other standard of care (e.g. HHI). Patients with stable disease (+5% to -20%) and RECIST v1.1 response will be considered responders and will continue to additional cycles of therapy and clinical assessment (imaging every 2 cycles, total cycles = 6). Patients with complete clinical response prior to completing 6 cycles may proceed to surgery for resection or biopsy of tumor site. Secondary endpoints include rate of functional organ preservation, pathologic response, safety, and quality of life. Correlative analyses will be performed on pre- and post-cemiplimab tumor specimens and peripheral blood samples to assess treatment-related changes in the immune microenvironment related to functional changes in immune cell composition. This study is open with 22 patients enrolled at the time of submission, with a planned total enrollment of 35 patients. Clinical trial information: NCT05929664. Research Sponsor: Regeneron Inc.

TPS9607 **Poster Session**

A phase 1/2 study of vusolimogene oderparepvec (RP1) in primary melanoma (mel) to reduce the risk of sentinel lymph node (SLN) metastasis. First Author: Urvashi Mitbander Joshi, UPMC Hillman Cancer Center, Pittsburgh, PA

Background: The majority of 100,000 annual new U.S. cases of mel consist of localized early-stage disease that undergo wide local excision (WLE) +/- SLN biopsy (SLNB). The tumor draining lymph node is the initial site of immune response including formation of tumor mediated immune suppression and pre-metastatic niches. SLN positivity is a key prognostic factor in early stage mel. Thus, the SLN is a target for local immune intervention to boost the antitumor response. Vusolimogene oderparepvec (RP1) is an intratumorally administered oncolytic immunotherapy with unique potential for neoadjuvant therapeutic application. RP1 is constructed from a high potency HSV1 strain (RH018A) modified to replicate selectively in tumors (deletion of neurovirulence factors ICP34.5 and ICP47). RP1 encodes GM-CSF and a fusogenic GALV-GP R- protein to maximize oncolytic potency and induce immunogenic cell death. Preclinical and clinical data demonstrate robust antitumor efficacy (including non-injected lesions) of RP1 alone and in combination with checkpoint inhibitors in advanced mel. This trial addresses a crucial gap in understanding the impact of RP1 on SLN dynamics and preventing disease recurrence in high-risk patients (pts). We hypothesize that in pts with high risk, clinically node negative mel (pT3b-T4b), RP1 will reduce rates of SLN positivity as compared to a historic control by favorably reshaping the immune landscape of the primary tumor, SLN, and the peripheral blood. **Methods:** This is an investigator-initiated, single arm phase 1/2 trial (NCT06216938) designed to assess efficacy and safety of neoadjuvant RP1 in high-risk, clinically node-negative, non-uveal mel. Eligibility criteria: pT3b, T4a, or T4b non-uveal mel with visible residual tumor or positive biopsy margins, ECOG $\leq$1, and no prior oncolytic virus therapy. Pts receive 3 doses of neo-adjuvant RP1 (10e6 PFU day 1, 10e7 PFU on days 15 and 21), injected at the primary tumor site followed by standard WLE and SLNB within 35 days of dose 1. Biopsy of residual tumor or archival tumor tissue is obtained pre-RP1 and archival tissue from WLE and SLNB is obtained post-RP1. Blood samples are obtained with each RP1 dose and 3 months post-therapy. Pts are followed for 3 years. Primary endpoint: rate of SLN positivity in the overall cohort. Secondary endpoints: treatment related adverse events (per CTCAE), recurrence free survival, and overall survival. Exploratory endpoints: immunophenotype and microenvironment of the primary tumor, SLN and peripheral blood pre- and post-RP1 (via IHC, IF, and flow cytometry). The observed rate of SLN positivity will be compared to the predicted rate (Melanoma Institute of Australia Prediction Tool for SLN metastatic risk) with a one-sided, one-sample proportion test. Kaplan-Meier estimates will be provided for survival endpoints. The trial is active with 13 of 25 pts enrolled in January 2025. Clinical trial information: NCT06216938. Research Sponsor: Replimune.

TPS9608 **Poster Session**

Lymph node excision (LNEx) for patients with stage III melanoma with one clinically positive node: Excision of Lymph Node trial (EXCILYNT). First Author: Craig L. Slingluff Jr., University of Virginia, Charlottesville, VA

Background: When melanoma metastases are detected clinically in regional lymph nodes (cLNs) without distant metastasis, standard surgical management is therapeutic lymph node dissection (TLND), which can cause lifelong lymphedema, delay return of function, and reduce quality of life (QOL). Among patients with cLN, 40-50% have metastasis confined to just 1 LN. The goal of this trial is to test a limited lymph node excision (LNEx) for patients with 1 cLN. In a multicenter retrospective analysis of 21 patients treated with LNEx rather than TLND, only 1 (4.8%) developed a LN recurrence in the same node basin, prior to distant disease (same node basin-only recurrence: sNBoR) over ~3 years. Also, only 1 (4.8%) developed lymphedema. To provide more precise estimates of sNBoR and lymphedema rates in a prospective study, and to collect data on HRQOL and return to normal activity after surgery, the EXCILyNT trial was initiated in 2024. The primary hypothesis is that LNEx will provide regional control, with sNBoR of $\leq$5% at 3 years. The secondary hypothesis is that LNEx will induce lymphedema in $\leq$6% at 3 years. Exploratory objectives are to assess overall morbidity and HRQOL, to identify features of tumors that may most accurately identify patients with only 1 pathologic LN, and to estimate overall DFS, MSS, and overall survival rates. **Methods:** EXCILyNT is a multicenter, phase II clinical trial for patients with 1 cLN, enrolled on either of two cohorts. All are treated surgically with LNEx: those undergoing surgery first (cohort 1) and those treated with neoadjuvant systemic therapy prior to LNEx (cohort 2). Participants on cohort 2 may receive standard of care neoadjuvant therapy or may be concurrently enrolled in a clinical trial of neoadjuvant therapy, as long as that trial does not mandate TLND. Major eligibility criteria: informed consent, age $\geq$18 years, ECOG PS 0-2, confirmed metastatic melanoma to only 1 cLN in the axilla, groin, or iliac basin; able to undergo LNEx. The following are excluded: prior LND or radiation therapy of the cLN basin; in-transit or satellite metastases within 1 year; distant metastasis; pre-existing lymphedema that precludes assessment of lymphedema; systemic or intratumoral therapy within 3 months of enrollment. Correlative studies include: evaluation of tumor-involved nodes for immune infiltrates, tumor cell proliferation rates, and somatic mutations; serum collection for cell-free tumor DNA; Health-related quality of life (HRQOL) surveys, FACT-M and Work Productivity and Activity (WPAI) Questionnaire: General health (WPAI:GH) V2.0. The target sample size of 60 eligible participants is chosen to estimate the 3-year rate of sNBoR with an upper CI precision of 7.5% (upper CI limit of 12.5%) using a one-sided Clopper-Pearson exact test. Enrollment is planned to include 7 centers. Thus far, 12 of planned 60 patients have been enrolled at the first 2 centers. Clinical trial information: NCT05839912. Research Sponsor: Philanthropy.

TPS9609 **Poster Session**

NEOSENT: Neoadjuvant anti-PD-1 therapy for patients with high-risk clinical stage II melanoma with a scheduled sentinel lymph node biopsy. First Author: Milton Jose De Barros E Silva, A.C. Camargo Cancer Center, São Paulo, Brazil

Background: High-risk clinical stage II melanoma patients are already indicated for adjuvant anti-PD-1 therapy, regardless of the sentinel lymph node biopsy (SLNB) result, due to the high risk of relapse associated with pathological stages IIB/IIC or IIIC. Additionally, sentinel lymph node biopsy (SLNB) has no therapeutic effect, although studies have highlighted its prognostic value. Recent data also emphasize that delays in initiating adjuvant anti-PD-1 therapy are linked to poorer relapse-free survival rates. This study aims to investigate whether the early initiation of adjuvant anti-PD-1 therapy, or neoadjuvant anti-PD-1 therapy (for cases where sentinel node biopsy is subsequently classified as positive), is associated with improved outcomes. **Methods:** NEOSENT is a prospective cohort study with a historical control (quasi-experimental study). The inclusion criteria for the prospective cohort are as follows: high-risk clinical stage II melanoma (IIB/IIC) after excisional biopsy with negative margins, age over 18 years, absence of significant concomitant diseases, indication for sentinel lymph node biopsy (SLNB), and access to anti-PD1 treatment. Patients will undergo wide excision margins (WEM) and SLNB, scheduled for week 5 after initiating anti-PD1 therapy. A total of 1 year of anti-PD1 treatment is planned, consisting of either pembrolizumab (200 mg IV every 3 weeks for 18 cycles) or nivolumab (480 mg IV every 4 weeks). The protocol was reviewed and approved by the Institutional Review Board (IRB) prior to implementation. The historical cohort (control arm) includes patients with clinical stage IIB/IIC melanoma who were treated at the AC Camargo Cancer Center with WEM and SLNB, followed by at least one cycle of adjuvant anti-PD1 therapy. The primary objective of the study is to reduce the median time to initiation of anti-PD1 therapy by more than 30 days in the NEOSENT arm compared to the historical cohort. Secondary objectives include comparing relapse-free survival rates between the NEOSENT arm and the historical cohort using propensity score matching, as well as describing the pathological findings of SLNB after neoadjuvant anti-PD1 therapy and their correlation with survival outcomes. Research Sponsor: None.

TPS9610 **Poster Session**

A phase 2 study to determine the clinical and pathological (path) response to neoadjuvant nivolumab (nivo) and relatlimab (rela) in stage II to IV (M0) resectable cutaneous squamous cell carcinoma (Neo-SCC). First Author: Maria Gonzalez, Melanoma Institute Australia, Sydney, NSW, Australia

Background: Cutaneous squamous cell carcinoma (cuSCC) is the second most common skin cancer worldwide (Bray et al. 2018). While 90% of cases are cured surgically (Kauvar et al. 2015), approx. 5% spread regionally or distantly, with an OS rate $<$ 20% at 10 years if regional lymph nodes (LN) are involved (Ogata et al. 2019). Immunotherapy trials have shown efficacy in advanced disease. Neoadjuvant therapy (NAT) is a powerful treatment platform to rapidly assess drug activity in resectable cancers. In melanoma, a major path response to immunotherapy ($\leq$10% viable tumor) correlates with low risk of recurrence in resectable stage III disease (Menzies et al. 2021), and improved OS and EFS when anti-PD1 monotherapy or in combination with anti-CTLA-4 is given neoadjuvantly vs. monotherapy adjuvant (adj) treatment (Patel et al. 2023; Blank et al. 2024). In a study of NAT anti-PD1 monotherapy with cemiplimab, in pts with resectable stage III or IV (M0) cuSCC (N = 20), 55% of pts had a path complete response (pCR) (0% viable tumour) (Ferrarotto et al. 2021). In a larger NAT cemiplimab trial (N = 79) 51% pts achieved pCR (Gross et al. 2022). The De-Squamate cuSCC trial, evaluating NAT anti-PD1 monotherapy with pembrolizumab (N = 27), showed a 63% combined rate of pCR and clinical complete response (CCR) resulting in the de-escalation of surgery and post operative radiotherapy (RT) in 48% of pts, and avoidance of post-operative RT in 15% of pts (Ladwa et al. 2024). The Neo-SCC trial will evaluate if combined PD-1 plus lymphocyte-activation 3 (LAG3) checkpoint inhibition achieves high path response, while allowing for response-driven surgical and RT de-escalation in pts with resectable cuSCC. **Methods:** Pts with histologically confirmed, resectable cuSCC AJCC (8th ed, head/neck) or UICC (9th ed, non-head/neck) clinical stage II, III or IV (M0) are eligible (N = 20). All pts undergo resection (RES) at week 6 following NAT with 2 doses of nivo (480 mg, IV) plus rela (160 mg, IV) at week 0 and 4. LN disease pts undergo baseline index-LN marking and RES at week 6, with subsequent total LN RES if there is no pCR in the index-LN. Synchronous primary/in-transit metastases undergo wide excision during index-LN resection. Non-LN disease pts showing CCR at week 6 receive an incisional biopsy of the baseline tumor site. All non-LN pts undergo definitive excision except those with CCR or pCR on biopsy. RT follows standard care. Imaging includes CT and FDG PET/CT at BL, prior to RES, and during the 5-year follow-up period. Tumor, blood and faecal samples are collected at BL, RES, and recurrence. The primary endpoint is the pCR rate at RES. The sample size is powered to detect a difference $>$ 25% in pCR rate with the historical control. Secondary endpoints include surgical/RT de-scalation rates, RFS, OS, safety/tolerability, surgical outcomes, QOL, and biomarker analyses. Clinical trial information: NCT06288191. Research Sponsor: Bristol Myers Squibb (drug only).

TPS9611 **Poster Session**

A phase Ib study to assess the safety and efficacy of autologous tumor infiltrating lymphocytes (lifileucel) with adjuvant pembrolizumab (PEMBRO) for treatment of immunotherapy naïve patients with high-risk clinical stage IIIb-d resectable melanoma (MEL). First Author: James Isaacs, Cleveland Clinic, Cleveland, OH

Background: Despite significant advances in the treatment (Tx) of stage III MEL, there remains a high risk of recurrence after surgical resection. Adjuvant immune checkpoint inhibitors (ICI) are a standard of care, but recurrence rates remain greater than 40% at 5 years. Neoadjuvant ICI have shown improved event-free survival compared to adjuvant ICI. However, at time of surgery a significant proportion of patients' (PTS) MEL still do not show a response. Lifileucel is an autologous tumor infiltrating lymphocyte therapy (TIL) that was recently FDA-approved after showing sustained high tumor response rates for pts with ICI-refractory metastatic MEL. For patients with IO naïve stage IV MEL, ORR was 65% for lifileucel + PEMBRO. Offering TIL at earlier stages of MEL may offer several potential benefits to anti-PD-1 alone. In the Tx-naïve setting, T cells are not previously exposed to ICI that can impact the quality of the TIL product. After curative-intent resection, pts will be rendered clinically tumor-free. When TIL are then utilized to address residual microscopic MEL, they will be less impacted by an immunosuppressive tumor microenvironment often accompanying larger disease burden. Earlier stage also limits tumor heterogeneity that can emerge in more advanced Tx-refractory metastatic MEL. Here we share details of a first clinical trial to evaluate lifileucel with adjuvant PEMBRO for resectable clinically detected high-risk MEL. **Methods:** This phase 1B trial is enrolling pts with clinically detectable stage IIIB-D MEL who are planned to undergo surgical resection and eligible for standard adjuvant anti-PD1. Pts' MEL must be considered fully resectable and pts cannot have previously received ICI. Pts proceed to standard of care resection after enrollment at which time tumor is procured for lifileucel/TIL manufacturing. Once the TIL product has completed manufacturing, pts will receive lymphodepleting chemotherapy followed by TIL infusion and IL2, for up to 6 doses. At week 12 after receiving lifileucel, pts start adjuvant PEMBRO to complete 1 year of Tx. The primary endpoints of this trial are disease free survival at 1 year and safety. The trial is planned to enroll 12 pts. Sample size justification is aimed on detecting 20% improvement on 12-month RFS for lifileucel+ PEMBRO compared to standard Tx. Based on Simon's two-stage design with a one-sided type I error of 0.05 and power of 80%, if 7 or fewer of 11 pts remain relapse-free at 12 months, futility is determined. If 8 or more of 11 are still relapse-free at 12 months, then futility is rejected. Correlative studies include analysis of the phenotype, function and TCR repertoire of baseline TIL samples. Serial PBMC will be collected to monitor TIL persistence (based on TCR analysis) and functional activity. Clinical trial information: NCT06190249. Research Sponsor: Iovance.

TPS9612 **Poster Session**

Trial in progress: A phase 3 randomized study of low-dose intralesional cemiplimab versus primary surgery for patients with early-stage cutaneous squamous cell carcinoma (CLEAR CSCC). First Author: Michael Robert Migden, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Cemiplimab 350 mg administered intravenously every 3 weeks is approved for the treatment of advanced cutaneous squamous cell carcinoma (CSCC). Surgery is the standard of care for early-stage CSCC; however, for patients who prefer non-surgical management of early-stage CSCC, low-dose intralesional (IL) cemiplimab has demonstrated promising clinical activity in a pilot study (NCT03889912). The purpose of this study (NCT06585410) was to determine the non-inferiority of IL cemiplimab versus primary surgery, along with its safety, tolerability, and efficacy in patients with early-stage CSCC. **Methods:** In this phase 3, randomized, open-label, multicenter study, approximately 369 patients with early-stage CSCC will be randomized 2:1 to cemiplimab (5 mg IL every week for 6 weeks) versus primary surgery. Key inclusion criteria include: patients aged $\geq$18 years; a histologically confirmed invasive CSCC target lesion that is $\geq$1.0–$\leq$2.0 cm (longest diameter) located in the head and neck, hand, or pre-tibial surface; adequate performance status; and adequate hepatic, renal, and bone marrow function. Key exclusion criteria include target lesion of keratoacanthoma, autoimmune disease requiring treatment with systemic autoimmune suppressants, concurrent or prior solid tumor or hematologic malignancy (except for protocol-allowed exceptions), and a history of solid organ transplant. Patients will be followed for approximately 3 years. The primary objective is to assess the non-inferiority of IL cemiplimab versus primary surgery by event-free survival. Secondary objectives include safety, tolerability, longest diameter of surgical defect after resection in both arms, and composite complete response in the experimental arm. Study recruitment is planned to start in 2025. Enrollment is planned at study sites across North America, Australia, and Europe. Clinical trial information: NCT06585410. Research Sponsor: Regeneron Pharmaceuticals, Inc.

TPS9613 **Poster Session**

A phase II randomised study to evaluate the antitumour activity of roginolisib, a novel non-ATP competitive and allosteric modulator inhibiting PI3Kδ, in patients with metastatic uveal melanoma (OCULE-01). First Author: Paul D. Nathan, Mount Vernon Hospital, Northwood, United Kingdom

Background: Uveal melanoma (UM) is a rare malignancy that develops from melanocytes in the eye. At least half of the patients develop metastases, primarily in the liver, and survival outcome from the time of metastatic disease is poor. Patients with second or third line systemic therapy may have a median Overall Survival (OS) ranging from 7 to 12 months. The small molecule roginolisib (IOA-244) is a novel highly selective, non-ATP competitive, allosteric modulator targeting phosphoinositide 3-kinase delta (PI3Kδ). The clinical development of roginolisib investigates its role in PI3Kδ-dependent malignancies. PI3Kδ in solid tumours, including cutaneous and uveal melanoma. Based on previous non-clinical studies, PI3Kδ appears to be up-regulated in tumour cells through inflammation and cellular transformation. In addition to this tumour-cell intrinsic mechanism, roginolisib is designed to block tumour-cell extrinsic mechanisms, including T regulatory (Treg) cells, B cells, and, to a lesser extent, myeloid-derived immune cells. **Methods:** The study OCULE-01 is a Phase II open-label, randomised, parallel-arm, multicentre study, which will assess the clinical efficacy of oral roginolisib as monotherapy against a control consisting of Investigator´s treatment in patients with metastatic UM who have progressed on prior first line treatment. Eighty-five patients will be enrolled across 20 sites in the EU, UK, and US. Patients will have progressed following at least 1 prior immunotherapy treatment. Patients will be randomised to one of 3 treatment arms; Arm 1: (n=50) IOA-244 80mg daily, Arm 2: (n=25) Investigator's choice of therapy, Arm 3: (n-10) IOA-244 40 mg daily. The primary objective is to assess the overall survival of roginolisib versus Investigators' choice of therapy. Secondary endpoints include PFS, OR, Safety, and Quality of Life impact. Correlative aims include assessing blood and tissue biomarkers (i.e. Treg, ctDNA, gene expression, proteomics etc.) for association with clinical benefit and radiomic analysis of imaging. A final analysis will be performed to assess efficacy after 72 patients become evaluable. Study Centres are currently being opened for enrolment. Clinical trial information: NCT06717126. Research Sponsor: iOnctura.

10000 **Oral Abstract Session**

Association of immunotherapy of high-risk neuroblastoma patients with long term infusion of dinutuximab beta with survival over short term infusion: Results from the HR-NBL1/SIOPEN trial. First Author: Ruth Lydia Ladenstein, St. Anna Children's Hospital and St. Anna Kinderkrebsforschung, Department of Paediatrics, Medical University Vienna, Vienna, Austria

Background: Dinutuximab beta (DB) delivered as long-term infusion is associated with a lower frequency and magnitude of side effects compared to short-term infusion (STI). Here, we evaluated the efficacy (event free survival- and cumulative incidence of relapse-rates at 5 years) of LTI compared to STI within the HR-NBL1/SIOPEN trial (EudraCT:2006-001489-17). **Methods:** High-risk patients as defined by metastatic disease (stage M) or local stage with MYC-N amplification received high intensity induction, surgery, high dose therapy with busulfan/melphalan followed by autologous stem cell transplantation (HDT/SCT) and local radiotherapy. Patients who achieved at least a partial response prior to HDT/SCT within equal or less than 9 months between diagnosis and HDT/SCT without progression were randomized to receive 5 cycles of 100 mg/m^2 DB per cycle either as STI (20 mg/m^2 per day as 8 h infusion; days 1-5) with or without subcutaneous interleukin-2 (scIL2) (6 $\times$ 10^6 IU/m^2 per day; days 1-5 and days 8-12) (R2 randomization) or as LTI (10 mg/m^2 per day as 24h infusion; days 1-10) (d8-17) $\pm$ 3x10^6 IU/m^2 scIL2 (d1-5; d8, d10, d12, d14, d16) (R4 randomization). All patients received 160 mg/m^2 oral isotretinoin (d19-32). **Results:** From 2009-2018, 705 patients (pts) from 18 countries were randomized and eligible for this analysis. The median follow-up time is7.7 years. Key patient characteristics were age 1.5-5yrs: 65% (460 pts), disease status before HDCT: CR 56% (396 pts) versus non-CR 38% (268 pts), MYC-N amplification (MNA): 43% (304 pts); $>$ 1 metastatic compartment (MC): 78% (553 pts); time between diagnosis to DB treatment start: $>$ 9 months 48% (302 pts). There were no significantly different patient characteristics between STI and LTI cohorts, except for time to DB start $>$ 9 months: 59% in the LTI cohort vs. 37% in STI.The 5yr EFS was 0.65$\pm$0.03 for LTI vs. 0.56$\pm$0.03 for STI (p = 0.041). The cumulative incidence of relapse was 0.33$\pm$0.03 for LTI vs. 0.42$\pm$0.03 for STI (p = 0.034). Multivariable pseudovalue-regression analysis for 5-year EFS found a significantly worse outcome for stage 4 patients with $>$ 1MC (p = 0.025; cHR = 1,97), $<$ CR (p = 0.059; cHR = 1.32) and for STI (p = 0.044; cHR = 0.74). **Conclusions:** We previously reported that LTI of DB increased the safety profile (less pain and inflammation) (Lancet Oncol 2018;19(12):1617-1629; J Clin Oncol 37, 2019 (suppl; abstr 10013). Here we demonstrate that LTI is also associated with an improved outcome. Clinical trial information: 2006-001489-17. Research Sponsor: None.

10001 **Oral Abstract Session**

A phase 2 randomized study of chemoimmunotherapy with or without eflornithine (DFMO) in relapsed/refractory neuroblastoma: A Children's Oncology Group (COG) report. First Author: Margaret E. Macy, Department of Pediatrics, University of Colorado and Center for Cancer and Blood Disorders, Children's Hospital Colorado, Aurora, CO

Background: Dinutuximab, irinotecan, temozolomide and GM-CSF (DIT) is widely used in first relapsed/ refractory high-risk neuroblastoma (r/r HRNB), however $<$50% of patients (pts) respond. ODC1 is a key enzyme important for NB cell survival. Difluoromethylornithine (DFMO) irreversibly inhibits ODC1, suppressing polyamine biosynthesis and driving anti-NB activity. DFMO also inhibits arginase and may enhance immunotherapy in r/r NB. COG ANBL1821 was a randomized phase 2 study for pts with r/r NB that evaluated response to DIT with or without DFMO (NCT03794349). **Methods:** Patients with first episode of r/r NB were randomized 1:1 to DIT (Arm A) or DIT with DFMO (6750 mg/m^2 divided TID; Arm B). They were stratified by measurable/evaluable disease, *MYCN* status, prior anti-GD2 therapy, and prior DFMO therapy. Cycles were 21 days. On Arm B, DFMO was initially given continuously; discontinuous DFMO dosing (days 1-7 and 15-21) was instituted due to ototoxicity in the initial cohort. Objective Response Rate [(ORR); sum of complete (CR), partial (PR), and minor (MR) responses per the 2017 International Neuroblastoma Response Criteria (INRC)] was determined based on central review of imaging. Toxicities were graded per CTCAE v5.0. **Results:** 91 eligible and evaluable pts (44 Arm A, 47 Arm B) were randomized May 2019-Jan 2024. 28/44 (63.6%) of Arm A pts and 32/47 (68.1%) of Arm B pts had relapsed or progressive disease (RPD); the remaining pts had refractory disease. The ORR was 61.4% (27/44) for Arm A and 57.4% (27/47) for Arm B (p=0.566). On Arm A, 22/44 (50%) achieved CR or PR compared to 23/27 (48.9%) on Arm B. Response rates for pts with RPD were similar to those with refractory disease in both arms. The 1-year progression-free survival (PFS) for Arm A was 70.0$\pm$8.0% and 56.8$\pm$8.2% for Arm B. Overall survival was 87.0$\pm$5.7% and 81.4$\pm$6.3% for Arms A and B, respectively. The most common toxicities reported on both arms were hematologic and gastrointestinal. Fewer pts on Arm B (n=7) had Grade 3+ pain than on Arm A (n=15) (p=0.0326). Hearing loss was a toxicity of interest; with continuous dosing, 55.6% (5/9) of Arm B pts developed hearing loss requiring DFMO dose hold. With discontinuous dosing, hearing loss was 15.8% (6/38) on Arm B compared to 6.3% (2/32) on Arm A (p=0.275). 14/16 (87.5%) NB+ marrows were GD2+ at enrollment; loss of GD2 was not detected on persisting NB cells in on therapy marrows analyzed. **Conclusions:** The addition of DFMO to DIT did not improve response rates in pts with first r/r HRNB, though the response rates in both arms confirmed DIT activity in this population. The ORR to DIT is higher than previously reported, likely due to use of the 2017 INRC that includes MR in calculation of ORR. Rates of CR+PR in this trial were similar to those previously reported. DFMO was associated with an increased incidence of hearing loss which was partially mitigated by discontinuous dosing. Clinical trial information: NCT03794349. Research Sponsor: National Cancer Institute/U.S. National Institutes of Health; U10CA180886; National Cancer Institute/U.S. National Institutes of Health; U10CA180899.

10002 **Oral Abstract Session**

Vincristine and topotecan versus carboplatin-, etoposide-, and vincristine-based chemotherapy for ocular salvage in group D and group E intraocular retinoblastoma: A randomized, comparative trial. First Author: Prashant Prabhakar, Division of Pediatric Oncology, Department of Pediatrics, AIIMS, New Delhi, India

Background: India has the highest burden of retinoblastoma worldwide. The access to Intra-arterial chemotherapy is limited and systemic chemotherapy remains the standard of care in low-middle income countries(LMIC) like India. There is a need to find alternative systemic chemotherapy due to growing concerns of long-term toxicities with standard Carboplatin and Etoposide based therapy. Topotecan is an attractive option as it is devoid of late toxicities and found to be effective in retinoblastoma. However, the data is very limited. **Methods:** We did a randomised comparative trial in children with group D/E intraocular retinoblastoma (IORB) to compare 2 different chemotherapy regimens. Between October 2021 and March 2023, participants fulfilling the inclusion criteria were randomised to receive either vincristine, topotecan(VT-arm) or high dose carboplatin, etoposide, and vincristine(HDCEV-arm) chemotherapy every 3-weekly for 6 cycles with focal therapy after 2-cycles. The reassessment was done every two cycles.The primary objective was to compare the treatment failure rates at the end of 6-cycles, which was defined as need for non-protocol therapy, enucleation or external beam radiotherapy(EBRT). The secondary objectives were to compare final globe salvage rates (which includes all forms of therapy except EBRT) and toxicities. **Results:** Forty(42 eyes) newly diagnosed cases with group D/E IORB were enrolled. Out of which 19 children(20 eyes) received VT and 21(22 eyes) received HDCEV- based regimen. Baseline parameters were comparable in both arms. After a median follow up of 12.4 months (range, 5.7-22.6), the treatment failure rate was significantly less in HDCEV-arm compared to VT-arm (45.5% vs 75%,HR-2.64, 95% CI, 1.13-6.13, p = 0.02). The 24 months enucleation free-survival was 54.5% in HDCEV-arm and 35% in VT-arm ($p < 0.01$). There were no deaths in any arm and both treatments were tolerated well. However, the incidence of febrile neutropenia (73.6% vs 43%, p = 0.05) and episodes of grade 3/4 diarrhoea (13 vs 4,p = 0.02) was more in VT-arm compared to HDCEV-arm.The response after 4-cycles was comparable with 90% and 85% showing partial response in HDCEV and VT-arm respectively(p = 0.92) but this effect could not be sustained in VT-arm. **Conclusions:** Administration of Topotecan is feasible even in LMIC setting without therapeutic drug with manageable toxicity in children. VT is inferior to HDCEV in globe salvage and has slightly more toxicity. The initial response achieved with VT could not be translated into globe salvage. There is a need to find alternative therapy and the combination of VT with carboplatin can be an attractive option. Clinical trial information: 2021/09/047121. Research Sponsor: None.

10003 **Oral Abstract Session**

Safety and efficacy of the EZH1/2 inhibitor valemetostat tosylate (DS-3201b) in pediatric patients with malignant solid tumors (NCCH1904): A multicenter phase I trial. First Author: Ayumu Arakawa, Department of Pediatric Oncology, National Cancer Center Hospital, Tokyo, Japan

Background: Valemetostat tosylate (DS-3201b; valemetostat) is a first-in-class dual inhibitor targeting the epigenetic regulators EZH1 and EZH2. In Japan, valemetostat has been approved for the treatment of r/r adult T-cell leukemia/lymphoma and peripheral T-cell lymphoma. These enzymes are implicated in tumors characterized by SMARCB1/INI1 deficiencies, such as malignant rhabdoid tumors or epithelioid sarcoma, which frequently occur during childhood and adolescence. Valemetostat is expected to show antitumor activity against such malignancies. **Methods:** This open-label, multicenter phase I trial evaluated the safety, efficacy, and recommended phase 2 dose (RP2D) of valemetostat in pediatric patients with malignant solid tumors. Valemetostat was administered orally once daily in 28-day cycles. The dose-escalation phase used a 3 + 3 design, testing three dose levels (150, 200, and 250 mg/1.7 m^2). Following RP2D determination, 15 patients were enrolled in the expansion cohort. The primary endpoint was dose-limiting toxicity (DLT) incidence in the dose-escalation cohort. **Results:** Between March 2020 and January 2023, 30 pediatric patients were enrolled (median age: 8 yr; range: 3–19 yr). Among these, 13 (43.3%) patients were INI1-negative by immunohistochemistry. Diagnoses included atypical teratoid/rhabdoid tumor (AT/RT, *n* = 6), malignant rhabdoid tumor (*n* = 1), neuroblastoma (NB, *n* = 8), and chordoma (*n* = 3). No DLTs were observed among 12 evaluable patients, and 250 mg/1.7 m^2 was established as the RP2D. Common grade $>$3 adverse events included lymphocytopenia (26.7%), neutropenia (26.7%), and anemia (16.7%). Notable treatment-related adverse events included grade 3 pneumocystis pneumonia (*n* = 1, 3.3%) and pneumonitis (*n* = 2, 6.7%). One patient with NB developed acute lymphocytic leukemia as a secondary malignancy. Pharmacokinetic analysis revealed no significant differences in T_{max} and T1/2 compared with the phase II study in Japanese adults (J201 study); however, C_{max} and AUC_{tau} were lower within the range of variation in adults. Objective response was observed in two of 14 patients (14.2%) with measurable disease, both with AT/RT. Long-term disease control exceeding 1 yr were noted in NB (*n* = 2), chordoma (*n* = 1), rhabdoid tumors (AT/RT; *n* = 1), and glioma (*n* = 1). **Conclusions:** Valemetostat was safe in Japanese pediatric patients, demonstrating antitumor activity against INI1-negative tumors, such as AT/RT. These findings support further exploration of valemetosat in combination therapies targeting SMARCB1/INI1-deficient tumors. Additionally, the durable control of tumor observed in NB suggests potential efficacy of valemetostat against this malignancy. This study was supported by the Japan Agency for Medical Research and Development and Daiichi Sankyo Co., Ltd. Clinical trial information: jRCT2031190268. Research Sponsor: Japan Agency for Medical Research and Development.

Alectinib in children and adolescents with solid or CNS tumors harboring ALK-fusions: A data update from the iMATRIX alectinib phase I/II open-label, multi-center study. First Author: Francois Doz, SIREDO Center (Care, Innovation, Research in Pediatric, Adolescent and Young Adults Oncology), Institut Curie and University Paris Cité, Paris, France

Background: Alectinib is a next generation oral inhibitor of ALK-fusion proteins, being investigated in children and adolescents with ALK-fusion bearing tumors at diagnosis or relapse. Here we present updated safety and efficacy data from the iMATRIX Alectinib phase I-II study (NCT04774718). **Methods:** Patients, less than 18 years of age, with ALK fusion-positive solid or CNS tumors for whom prior treatment had proven to be ineffective or for whom there was no satisfactory treatment available were eligible. Patients were recruited to Part 1 to confirm the recommended phase 2 dose (RP2D) and to monitor drug pharmacokinetics. Investigators reported Best Overall Response according to RANO (CNS tumors) or RECIST v1.1 (solid tumors) criteria with a data cut off of July 2024. **Results:** In total 22 patients with a median age of 8 years were enrolled. Fourteen patients were diagnosed with solid tumors: inflammatory myofibroblastic tumor (n = 9), renal cell carcinoma (n = 2), mesothelioma (n = 1), nephroblastoma (n = 1), and atypical melanocytic tumor (n = 1). Six patients were diagnosed with CNS tumors: high grade glioma (n = 5) and pleomorphic xanthoastrocytoma (n = 1). Two patients had ineligible conditions: histiocytosis (n = 1) and anaplastic large cell lymphoma (n = 1). Among the 22 patients, 14 had not received prior systemic therapy. ALK fusion partners were EML4 and CLTC in 3 patients, TPM3 and KIF5C in 2 patients, and DCTN1, FN1, KIF5B, NPM, PPP1CB, STRN, CLIP1, RANBP2, ZEB2, PLEKHA7, CDC42BPB and HNRNPA3 in 1 patient each. In the 21 safety evaluable patients, only 1 DLT of Grade 3 increased alanine aminotransferase, in the context of multiple viral infections, was reported. The DLT resolved after treatment interruption and Alectinib was restarted at a reduced dose level, and then tolerated well. Eighteen patients (86%) experienced at least one Adverse Event (AE) reported as related to Alectinib, the majority being of Grade 1 and 2 severity. Grade $\geq$ 3 AEs related to alectinib were reported for 5 patients (23.8%) and there were 2 patients with serious AEs related to Alectinib. There were no new safety signals detected. Investigator reported Best Overall Response rate in 16 patients was 87.5%; (14 PRs) and 2 patients were reported to have stable disease. A partial response was observed in 5/5 evaluable patients with CNS tumors and in 9/11 evaluable patients with solid tumours. Six patients were excluded from the efficacy analysis due to ineligible tumor type (n = 2), not dosed (n = 1), no measurable disease according to RANO criteria (n = 1) or lack of response assessment by the analysis cut-off date (n = 2). **Conclusions:** Alectinib continues to have a favourable safety profile in pediatric patients. Despite this being a very challenging population to treat, clinical efficacy results are transformational with the majority of patients experiencing a tumor response. Clinical trial information: NCT04774718. Research Sponsor: Hoffmann-La Roche.

10005 **Oral Abstract Session**

Results of a phase II trial of olaparib in combination with ceralasertib in patients with recurrent and unresectable osteosarcoma. First Author: Suzanne J. Forrest, Dana-Farber/Boston Children's Cancer and Blood Disorders Center, Boston, MA

Background: Osteosarcoma is the most common bone tumor of children, adolescents, and young adults and patients with recurrent osteosarcoma have very poor outcomes. The observed response to cisplatin in osteosarcoma, in vitro susceptibility of osteosarcoma cell lines to ATR and PARP inhibitors, and the presence of mutations in genes involved in DDR served as the basis for the development of this trial. **Methods:** In this single arm, open label phase II trial of olaparib and ceralasertib patients aged 12-40 weighing $>$ 40 Kg with recurrent osteosarcoma and measurable unresectable disease were eligible for Cohort 1. The primary endpoint for Cohort 1 was event-free status at 4-months. Secondary endpoints included objective response rate (ORR) and event-free survival (EFS). After an early study amendment changing the dosing strategy based on clinical data generated from other trials, patients received Olaparib 150mg twice a day on days 1-28 and ceralasertib 80mg twice a day on days 1-14 of a 28-day cycle. Using a two-stage design and a planned sample size of 34 evaluable Cohort 1 patients receiving the amended dosing strategy there is 90% power to detect a 20% increase (39% vs 19%, selected based on a historical benchmark) in the proportion of patients who are event-free at 4-months. Interim analysis required $\geq$2 of 15 patients to be 4-months event-free to proceed to Stage 2; at Stage 2, $\geq$11 of 34 patients 4-months event-free for evidence of efficacy. **Results:** The study proceeded to full accrual based on the interim analysis. As of 1/21/2025 data-cut off, 38 patients from four centers were enrolled in Cohort 1 between November 2020 and November 2024; 37 were eligible and evaluable for safety, objective response, and survival analyses. Excluding four patients enrolled before the study amendment updating dosing, 33 patients were evaluable for the primary objective. Median age was 19.6 years (range 12.7-38.2). Patients received an average of 4.2 (range 1-9) prior therapy regimens, including 26 (70%) patients with prior multi-tyrosine kinase inhibitor treatment. Four of the 33 evaluable were event-free at 4-months (12%; 95% CI: 4%-29%). One of 37 patients had an objective response (ORR: 2.7%; 95% CI: 0.14%-16%). The 4-month EFS$\pm$SE was 13.5$\pm$5.6% (n = 37). The most common $\geq$ grade 3 adverse events were platelet count decreased and anemia (38% and 27%, respectively). **Conclusions:** The study did not meet the predetermined threshold for efficacy for Cohort 1; however, a subset of patients may be benefit from this combination treatment. Results of Cohort 2 (resectable osteosarcoma limited to the lung parenchyma) will be reported separately. Assessment of potential biomarkers of response is underway. Clinical trial information: NCT04417062. Research Sponsor: The Osteosarcoma Institute; AstraZeneca.

10006 **Oral Abstract Session**

Phase II assessment of carboplatin with etoposide and high-dose ifosfamide in rEECur, an international randomised controlled trial of chemotherapy for the treatment of recurrent and primary refractory Ewing sarcoma (RR-ES). First Author: Martin McCabe, University of Manchester, Manchester, United Kingdom

Background: rEECur, the first randomised controlled trial (RCT) in RR-ES, has previously defined high dose ifosfamide (IFOS) as the most effective regimen in this setting compared to gemcitabine-docetaxel, irinotecan-temozolomide and topotecan-cyclophosphamide. Platinum drugs show activity in RR-ES and are frequently given with etoposide in this setting. **Methods:** Patients aged at least 2 years with RR-ES were randomised to 3-week cycles of either IFOS 15 g/m^2 by continuous intravenous (IV) infusion over 5 days or IV carboplatin 400 mg/m^2 day 1 and etoposide 120 mg/m^2 days 1 to 3 (CE). Primary outcome was event-free survival time (EFS). Secondary outcomes included overall survival time (OS), toxicity and quality of life (QoL). A probability-based Bayesian approach was used. **Results:** 139 patients recruited between 22/03/21 and 28/05/24, were randomised 1:1 to IFOS (n = 69) or CE (70). Median age was 18 years (range 3-59). Patients had refractory disease (14%), 1st recurrence (81%), $>$ 1strecurrence (6%). Sites of progression were primary site only (21%), pleuropulmonary metastases only (24%), and other or combined metastatic disease (55%). More CE patients had baseline GFR $<$ 90 ml/min/1.73m^2(41% versus 23%). Median follow-up (reverse Kaplan-Meier) was 18 months (mos). Median EFS was 5.1 mos (95% CI 3.1, 6.3) for IFOS and 3.5 mos (95% CI 2.5, 6.1) for CE. Median OS was 14.4 mos (95% CI 11.5, 20.7) for IFOS and 19.0 mos (95% CI 11.2, 24.6) for CE. Given the observed data the posterior probabilities that EFS and OS were better after IFOS than after CE (ie Pr[true hazard ratio $>$ 1 | data]) were 87% and 55% respectively. Grade 3+ adverse events present in $>$ 5% of patients randomised to IFOS (left hand values) compared with CE were febrile neutropenia (30% v 10%), anaemia (9% v 9%) and thrombocytopenia (3% v 7%). Acute kidney injury was present in 2% v 0% and encephalopathy in 5% v 0%. There were no measurable differences in QoL. **Conclusions:** There was insufficient evidence of efficacy with CE compared to IFOS to continue recruitment to phase III in this first RCT of a platinum-etoposide combination in RR-ES. IFOS remains the most effective regimen in this disease setting. The trial remains open, comparing IFOS with and without the tyrosine kinase inhibitor lenvatinib. Funded by Cancer Research UK (C22436/A28028, CTUQQR-Dec22/100006, A28474). Clinical trial information: ISRCTN36453794. Research Sponsor: None.

10007 **Oral Abstract Session**

ONITT: A phase I study of nanoliposomal irinotecan with talazoparib or temozolomide in children and young adults with recurrent or refractory solid tumors. First Author: Sara Michele Federico, St. Jude Children's Research Hospital, Memphis, TN

Background: Talazoparib (TAL), a potent PARP inhibitor, demonstrated preclinical activity in Ewing sarcoma when combined with irinotecan (IRN) and temozolomide (TMZ). A phase I study (BMNIRN, NCT02392793) showed clinical benefit of TAL + IRN + TMZ; but dose escalation was limited due to hematologic and gastrointestinal toxicity. We therefore evaluated, for the first time in children, nanoliposomal irinotecan (nal-IRI) in combination with either TAL or TMZ. **Methods:** Patients (pts) aged 1-30 with recurrent or refractory solid tumors were eligible to receive nal-IRI + TAL (Arm A) or nal-IRI + TMZ (Arm B) using a Bayesian keyboard design. Nal-IRI dosage was escalated with fixed TAL and TMZ doses. Each cycle was 21 days. Maximum tolerated dosage(s) (MTD) and recommended phase 2 dosage(s) (RP2D) were determined. Nal-IRI and TAL plasma pharmacokinetics (PK) were evaluated. Toxicities were assessed using CTCAE v.5 and responses were evaluated by RECIST 1.1. UGT1A1 polymorphisms and serial circulating tumor DNA (ctDNA) samples were evaluated. **Results:** Forty-six pts enrolled at 5 sites. The first 9 (5 Arm A; 4 Arm B) received nal-IRI days 1, 8. Four pts had dose limiting toxicities (DLTs), so day 8 nal-IRI was removed (Amend 1). After Amend 1, 37 pts (23 male; median age 14 years, range 1-23) enrolled (19 Arm A; 18 Arm B). The most common diagnosis was Ewing sarcoma (n = 16, 35%). Table 1 summarizes DLTs in Cycle 1 and response. The most common serious adverse events included febrile neutropenia (12 Arm A; 2 Arm B), colitis (4 Arm A; 2 Arm B), vomiting (4 Arm A), and diarrhea (3 Arm A). Confirmed responses were seen in five Arm A (1 CR, 4 PR) and five Arm B (1 CR, 4 PR) pts with Ewing sarcoma, CIC-DUX4 sarcoma, synovial sarcoma, and rhabdomyosarcoma. Seven pts (5 Arm A; 2 Arm B) had stable disease. Results of PK, UGT1A1 and ctDNA will be presented. **Conclusions:** The MTDs were nal-IRI 160mg/m^2 plus TAL (Arm A) and nal-IRI 200mg/m^2 plus TMZ (Arm B). The RP2Ds are pending FDA review. These regimens are feasible with evidence of anti-tumor activity and warrant further investigation. Clinical trial information: NCT04901702. Research Sponsor: None.

10008 Oral Abstract Session

Phase Ib study of the combination of regorafenib with conventional chemotherapy in patients with newly diagnosed multi-metastatic Ewing sarcoma: The Rego-Inter-Ewing-1 study. First Author: Pablo Berlanga, Department of Pediatric and Adolescent Oncology, Gustave Roussy Cancer Campus, Villejuif, France

Background: Regorafenib monotherapy has shown interesting but limited activity against relapsed Ewing sarcoma. We present the first results of the phase Ib study to identify the maximum tolerated dose (MTD) of regorafenib in combination with standard multimodal treatment in patients with newly diagnosed multi-metastatic Ewing sarcoma (NCT05830084). **Methods:** International multi-center phase Ib study of the combination of regorafenib with interval-compressed chemotherapy (VDC/IE) in patients aged 2-50 years with newly diagnosed metastatic (excluding lung/pleura only) Ewing sarcoma. VDC/IE chemotherapy was administered at the standard doses. Regorafenib was given orally for 21 days of a 28-day cycle (from day 5) at a starting dose level of 66 mg/m^2/day (capped at 120 mg, DL0, 80% of the pediatric recommended phase 2 dose (RP2D)) and escalated to 82 mg/m^2/day (100% RPD2, capped at 160 mg, DL1) or de-escalated to 50 mg/m^2/day (60% RPD2, DL-1). The study implemented the Bayesian Optimal Interval (BOIN) design (Yuan et al, Clin Cancer Res 2016). Primary tumour local treatment was surgery and/or radiotherapy. Adjuvant therapy consisted of VC/IE cycles or high dose chemotherapy consolidation with Busulfan/Melphalan (BuMel) and autologous stem cell rescue (ASCR). Regorafenib was given concomitant to adjuvant VC/IE cycles and primary tumor radiotherapy to the extremities but permanently discontinued in those receiving BuMel/ASCR or primary tumour radiotherapy to sites other than extremities. **Results:** Thirteen patients (DL0: n=2, DL1: n= 11) with a median age of 15.2 years (range, 8.1-23.5), were enrolled between June 2023 and December 2024 in 7 centres and 3 countries. All were evaluable for toxicity. One dose-limiting toxicity (DLT) occurred in one patient at DL1 (pressure ulcer grade 2, requiring regorafenib dose interruption and reduction in a 17-year old patient). After the DLT period, one patient had regorafenib dose interruption/reduction. One patient presented with a grade 3 veno-occlusive disease after Bu-Mel/ASCR. Detailed toxicity data after the DLT period and pharmacokinetic data will be presented. At data cut-off of 21/01/2025, two patients had experienced disease progression before primary tumour local treatment, eight patients had finished all treatment cycles (three received Bu-Mel/ASCR consolidation) and three patients were on therapy. **Conclusions:** Regorafenib combined with VDC/IE chemotherapy is well tolerated with a MTD of 82 mg/m^2/day (capped 160 mg). The efficacy of the addition of regorafenib to standard multimodal treatment in newly diagnosed patients with metastatic Ewing sarcoma will be tested in the Inter-Ewing-1 trial developed by the Euro Ewing Consortium (planned initiation in Q3 2025). Recruitment to the Rego-Inter-Ewing-1 continues at DL1 (maximum 24 patients), until Inter-Ewing-1 initiates. Clinical trial information: NCT05830084. Research Sponsor: Fight Kids Cancer 2021 Call; Bayer (drug supply and partial funding for drug labelling/shipping).

10009 Oral Abstract Session

Promoting Resilience in Stress Management (PRISM): A randomized controlled trial of a psychosocial intervention for adolescents and young adults with advanced cancer. First Author: Abby R. Rosenberg, Dana-Farber Cancer Institute, Boston, MA

Background: Adolescents and Young Adults (AYAs) with advanced cancer report poor quality of life (QOL), high psychological distress, and minimal engagement in their healthcare decisions. We assessed the effect of a novel resilience coaching program with embedded elements of advance care planning (Promoting Resilience in Stress Management for Advanced Cancer, PRISM-AC) on AYA outcomes. **Methods:** We conducted a multisite randomized trial of PRISM-AC vs Usual Care (UC) among English-speaking AYAs aged 12-24 years and diagnosed with advanced cancer within 2 weeks before enrollment. PRISM-AC consists of 4 core sessions targeting AYA-endorsed "resilience resources" (skills in stress-management, goal setting, cognitive reframing and meaning-making) plus an optional session focused on elements of advance care planning (i.e., communication preferences and priorities). Participants completed surveys at baseline, 3-, 6-, 9-, and 12-months post-enrollment. The primary outcome was QOL (Pediatric Quality of Life scale) at 3-months; secondary outcomes included 3-month changes in resilience (Connor-Davidson Resilience scale) and hope (Snyder Hope scale) and trajectories of QOL, anxiety and depression (Hospital Anxiety and Depression Scale) over 12-months. We explored PRISM-AC's impact on AYA-engagement in critical healthcare conversations as documented in the electronic health record. We applied linear mixed effects regression models to examine the association between PRISM and changes in patient-reported outcomes. **Results:** We enrolled and randomized 195 AYAs (96 UC, 99 PRISM) between April/2019 and January/2024. They were mean aged 16.5 years (SD 3.9), mostly White (63%), non-Hispanic (59%), and publicly insured (53%). At 3-months, PRISM-AYAs reported significantly more improved resilience [mean change-score +1.3 (5.9) vs -1.4 (7.5), p=0.038] and hope [+2.4 (10.4) vs -2.8 (11.2), p=0.001] than UC-AYAs, although we detected no significant differences between study arms in QOL, anxiety, or depression. Over the 12-month study period, PRISM-AYAs reported progressively more improvements in QOL and anxiety, with significant differences at later time points [i.e., PRISM-associated improvements in QOL at 6 months: +3.4 (95% CI 0.1, 6.6, p=0.043) and 12 months: +6.8 (95% CI 3.3, 10.3, p$<$0.001)]. Over time, PRISM-AYAs also appeared to participate more in key healthcare discussions. **Conclusions:** A novel resilience coaching intervention led to immediately improved resilience and hope, and longer-term improvements in quality of life among AYAs with advanced cancer. Clinical trial information: NCT03668223. Research Sponsor: National Institutes of Health; National Cancer Institute; R01 CA222486.

10010 Oral Abstract Session

Longitudinal change in cardiac function after doxorubicin and dexrazoxane: A report from COG ALTE11C2. First Author: Erin Michele Mobley, Department of Surgery, University of Florida College of Medicine Jacksonville, Jacksonville, FL

Background: Dexrazoxane (DRZ) has been associated with reduced adverse left ventricular (LV) remodeling shortly after doxorubicin (DOX) treatment ($<$5y) and preserved LV function in long-term ($>$15y) survivors of childhood cancer. What remains less clear are longitudinal changes in echocardiographic (echo) measures in this population. **Methods:** ALTE11C2 analyzed participants who received DOX treatment and were enrolled on COG protocols P9404, P9425, P9426, P9754, and Dana Farber Cancer Institute 95-01. Except for P9754, all other protocols featured upfront 1:1 randomization with DRZ (10:1mg/m^2 DRZ:DOX dose). Central echo remeasurements were used when possible, otherwise we used data from abstracted echo reports. Echo values were converted to age- or BSA-specific z-scores. Differences in z-scores by $\pm$DRZ were estimated as a function of time using generalized estimating equations, adjusting for age, sex, DOX dose, chest radiotherapy, and data type (directly remeasured vs report). **Results:** 895 patients (67% male; 67% white non-Hispanic; mean age at diagnosis 11.4y; median DOX dose 360 mg/m^2; 32% chest radiotherapy) had evaluable echo data (n=2279 echos; 1581 centrally remeasured; 698 report only; mean of 1.0-1.7 echos per patient per time period, with an average of 1.4 echos per patient $\geq$15y). In multivariable analysis, DRZ was overall associated with more normal LV fractional shortening and less LV end-diastolic and end-systolic dilation, a pattern consistent with less subclinical dilated cardiomyopathy directionality. These cardioprotective changes associated with DRZ were seen most clearly in patients treated with DOX $\geq$250 mg/m^2 with this length of follow-up. **Conclusions:** DRZ exerts significant DOX cardioprotective effects on cardiac function and remodeling, detectable within 5y and persisting beyond 10y of follow-up. Research Sponsor: National Cancer Institute; P01 CA068484, R01 CA211996, U10 CA098543, U10 CA098413, U10 CA180886, U10 CA180899, U10 CA095861, UG1 CA189955; St Baldrick's Foundation, Leukemia and Lymphoma Society, Sofia's Hope, Rally Foundation.

Z-score difference by $\pm$DRZ as a function of time, adjusted for sex, age, echo type, DOX dose, chest radiotherapy.

Long-term off-label MAPK inhibitor therapy in children with severe/refractory Langerhans cell histiocytosis: An international observational study of 277 cases. First Author: Jean Donadieu, Hopital Trousseau, Paris, France

Background: Long-term off-label use of MAP kinase inhibitors (MAPKi) to treat, refractory childhood Langerhans cell histiocytosis (LCH) was evaluated within the European consortium for histiocytosis network (www.echo-histio.net). **Methods:** 277 patients from 26 countries treated with MAPKi were classified according to the clinical indication: refractory risk organ positive/negative (RO+/RO-), isolated lung destruction (Lung), sclerosing cholangitis (SC), neurodegeneration (ND), and diabetes insipidus (DI). 252 patients had received one or several lines of chemotherapies prior to MAPKi: VBL/steroids (n = 243) then 2CdA/AraC (n = 48), 2CdA alone (n = 52), clofarabine (n = 5), VCR/AraC (n = 70) before being considered refractory. The 25 treated front line by MAPKi were newborn with aggressive disease (n = 7), or had chronic manifestations like ND, SC or DI. *BRAFV600E* was detected in 95% of the cases. **Results:** Median age at diagnosis was 1.3 years. MAPKi indication was RO+ (n = 138); RO– (n = 72); Lung (n = 7); SC (n = 9), ND (n = 45), DI (n = 2). Median age at MAPKi onset was 2.3 years, with median follow-up of 3.5 years (IQR 1.6-5.9). Vemurafenib (n = 177), Dabrafenib (n = 105), Encorafenib (n = 3), Cobimetinib (n = 41), Tramatinib (n = 41), and Binimetinib (n = 1) were prescribed mainly in monotherapy, sometimes (n = 44) with various chemotherapies or HSCT (n = 5). The short-term response (before wk 8) varied from 98% in RO+ and RO-, to 30% in Lung to a null response in ND, DI and SC, although some long-term response (after 6 months) was observed in Lung and ND. Skin rash was the most frequent adverse event (AE), affecting 55% of patients. Other AEs were observed in 7 (cardiomyopathy n = 1, retinitis n = 6). Five tumors or malignancies were observed not related to MAPKi; only in patients heavily treated by 2CdA, AraC or Clofarabine. Six deaths were observed; 5-year survival was 98%. MAPKi discontinuation for 111 patients led to LCH 66 reactivations. None of the various empirical maintenance therapies used was able to prevent secondary reactivation. Among the 133 assessable patients free of ND at MAPKi initiation, ND was observed in 52 with a 5-year risk of 55%. In some cases, ND was reversible after MAPKi dose adaptation. **Conclusions:** MAPKi appeared quick, safe and effective in children with refractory LCH while the response to Lung, SC, DI and ND was limited or delayed. Further studies are needed to find effective maintenance therapy. ND should be monitored in the follow up of patients treated by MAPKi. Research Sponsor: Association Histiocytose france.

10012 Oral Abstract Session

Understanding the molecular landscape of rare tumors through the CCDI-COG Molecular Characterization Initiative. First Author: Lauren Marie Vasta, WRNMMC, Bethesda, MD

Background: Through collaboration with the National Cancer Institute as part of the Childhood Cancer Data Initiative, the Children's Oncology Group offers prompt paired tissue and germline sequencing for newly diagnosed rare tumor subtypes. **Methods:** Individuals are eligible for paired germline and somatic blood/tissue sequencing if they are age 25 or younger, have been diagnosed with a rare tumor in the past 6 months and have both germline and tissue samples available. The paired samples undergo DNA and RNA extraction, followed by whole exome sequencing (paired tumor and germline) of cancer associated genes and RNA targeted fusion analysis. Results are returned to the primary institution within 2-3 weeks of receipt of both samples. **Results:** Between 09/12/2022 and 11/01/2024, 490 individuals from 123 institutions were enrolled with a total of 98 distinct diagnoses reported. The most common diagnosis groups were thyroid carcinoma (n = 120), neuroendocrine tumors (n = 53), sex cord stromal tumors (n = 41), and other carcinomas (n = 83). Of the 490 patients enrolled, 438 had submitted samples with successful return of exome results in 351/438 (80.1%) and fusion results in 302/438 (69.1%) by the data cut. Tier I/II germline single nucleotide (SNV) or copy number (CNV) variants were identified in 88 (25.1%) of patients that completed sequencing. The most prevalent germline alterations included SNVs in DICER1 (n = 20, 5.7%), TP53 (n = 7, 2.0%), RB1 (n = 7, 2.0%), CHEK2 (n = 6, 17%), SDHB (n = 5, 1.4%) and VHL (n = 5, 1.4%). 98% of samples demonstrated a Tier I/II somatic variant across 26 genes, most commonly found in DICER1 (n = 39, 11.1%), BRAF (n = 30, 8.5%), TP53 (n = 22, 6.3%) and CTNNB1 (n = 14, 4.0%). RNA fusion analysis identified positive results in 22.8% of samples. Testing identified over 33 distinct fusions. Fusions were most commonly associated with thyroid cancer; RET in 16 and NTRK in 12, or desmoplastic small round cell tumor; EWSR1::WT1 in 8. In 16.5% (n = 58) of the samples, the final diagnosis was refined based on the results of the molecular testing and 6.8% (n = 24) of the centers reported using a commercially available treatment targeting an identified molecular alternation. **Conclusions:** The MCI has enabled access to genetic sequencing to patients across the Children's Oncology Group across a wide range of rare tumor diagnoses. Information about the available data can be accessed through the CCDI Hub Explore. Germline cancer predisposition was identified in a quarter of these samples, highlighting the importance of tumor-normal profiling to allow genetic counselling in these patients and appropriate surveillance. These results have the potential for lasting impact on understanding and treating individuals with rare cancers and the development of targeted future clinical trials. Research Sponsor: National Cancer Institute.

10013 Oral Abstract Session

CCDI-COG molecular characterization initiative: The expanding data on childhood cancer. First Author: Erin R. Rudzinski, Indiana University, Indianapolis, IN

Background: The Molecular Characterization Initiative (MCI), a collaboration between the Children's Oncology Group (COG) and the NCIs Childhood Cancer Data Initiative (CCDI) which is intended to define a standardized genomic characterization of pediatric cancer, provides rapid, clinical sequencing for newly diagnosed central nervous system (CNS) tumors, rare tumors, soft tissue sarcomas (STS), or advanced stage neuroblastoma (NB) to guide diagnosis and treatment for these children. **Methods:** Patients enrolled on APEC14B1-MCI who are $\leq$25 years of age with an eligible tumor type treated at national or international COG sites with available snap frozen or FFPE tissue and paired germline samples undergo RNA/DNA extraction. Whole exome sequencing (paired tumor and germline), targeted RNA fusion (excluding NB) and methylation array (CNS clinical / STS, NB and rare tumor research only) analyses are performed, with clinical results returned in 2-3 weeks. **Results:** Between 3/31/22 and 11/1/24, MCI provided results for 3,972 patients, including 2,666 with CNS tumors, 781 with STS, 372 with rare tumors and 153 with NB, across 188 institutions. 89% of the $>$ 10,000 individual tests resulted within 2 weeks of receiving nucleic acids for sequencing. Tier I/II germline single nucleotide (SNV) or copy number (CNV) variants were identified in 528 (14.1%) patients [10.4% (NB) to 25.1% (rare tumors)]. The most common germline alterations included SNVs in *TP53* (n = 52,1.4%), *CHEK2* (n = 50,1.3%), *DICER1* (n = 35,0.93%), *NF1* (n = 29,0.78%) and *ATM* (n = 24, 0.64%). Somatic SNVs or CNVs were identified in 85% of samples overall. Somatic SNVs most commonly involved TP53 (n = 309,8.3%), BRAF (n = 222,6.9%), or CTNNB1 (n = 166,4.4%). Targeted RNA sequencing identified gene fusions in 30% overall (23% rare, 27% CNS, 40% STS). Methylation array resulted in positive subclassification of CNS tumors in 90% of patients, including 522 patients with medulloblastoma. Additional characterization of residual nucleic acid samples is planned, with data available through the database of Genotypes and Phenotypes (dbGaP). Follow up data has been collected for 1236 patients (NCI-CCDI Hub), including frontline treatment (chemotherapy and/or radiation), response to therapy, and vital status. Additionally, 749 reported on the utility of MCI testing six months following enrollment. MCI results were used for: enrollment on a clinical trial (n = 86,11.5%), treatment with a targeted therapy (n = 8,10.7%), and/or refining the pathologic diagnosis (n = 223,29.5%). **Conclusions:** The MCI has resulted $>$ 10,000 sequencing assays from 3,972 children with cancer in 31 months. This has directly impacted the diagnosis and/or management of patients with newly diagnosed tumors, providing access to timely molecular testing (including methylation in CNS tumors and fusion testing in STS), and guiding therapy and clinical trial enrollment for many patients. Research Sponsor: None.

10014 Oral Abstract Session

Genomic newborn screening for cancer risk: A retrospective cohort study. First Author: Lisa Diller, Dana-Farber/Boston Children's Cancer and Blood Disorders Center, Boston, MA

Background: Population-based newborn screening (NBS) improves outcomes through early detection of rare pediatric conditions. Cancer is a leading cause of pediatric morbidity and mortality, but biomarkers for cancer risk are not included in NBS. NBS for detection of germline variants in genes associated with elevated risks of early onset childhood cancer could promote surveillance and early detection. **Methods:** Infants born in Michigan between 1987 and 2020 who developed a solid or CNS tumor before age 8 were identified through the Michigan Cancer Registry and linked to the state dried blood spot (DBS) biobank. DNA was extracted from 3.2 mm DBS punches and underwent t-NGS of 11 early-onset cancer predisposition genes (*RB1, TP53, WT1, RET, SMARCB1, PTCH1, SUFU, APC, DICER1, ALK* and *PHOX2b).* Deleterious single nucleotide, short insertion and deletion variants (SNV/indels) and copy number variants (CNVs) were identified using an automated variant classification platform (Fabric Genomics) including Clinvar classification. CNV's were manually reviewed for evidence of deletion of at least one exon in a targeted gene. **Results:** 1948 DBS from infants who developed a solid or brain cancer before age 8 were identified. DNA extraction and tNGS with $>$ 20X coverage was successful for 99.9% of DBS. A heterozygous deleterious variant was detected in 133 infants (116 SNV/indels and 17 CNVs), or 6.8% of the cohort. The distribution, by diagnostic group and gene is shown below. No activating ALK variants were detected. Germline deleterious predisposition variants (PV) in *RB1* were detected in 40/50 bilateral retinoblastoma cases. 14/132 (11%) of medulloblastoma cases demonstrated a PV involving *SUFU* (6), *PTCH1* (3), *SMARCB1* (4) or *TP53* (1). Heterozygous PV in *RET* were detected in 6/6 medullary thyroid carcinoma cases. Median age at cancer diagnosis was 14 months in cases with PV compared to 32 months in cases without PV ($p < .001$). Lower overall survival was noted in sarcoma cases with PV vs. those without PV and in brain tumor cases with PV vs. those without (Logrank test, p = .04 and $p < .004$, respectively). PV carriers developed proportionally more second cancers (9.5% vs 5%; p = 0.02) and 20% of PV carriers who received radiation therapy developed second cancers. **Conclusions:** Population-based genomic NBS could identify newborns at risk for early onset childhood cancers, enabling early surveillance, diagnosis and treatment. Inclusion of *RB1* in a NBS test would identify 80% of children at risk for bilateral retinoblastoma. Further research focused on implementation of NBS for cancer risk is needed. Research Sponsor: Bridge Foundation.

The gut microbiome in pediatric diffuse midline gliomas: Correlative study results from the PNOC022 trial. First Author: Raoull Hoogendijk, Princess Máxima Center for Pediatric Oncology, Utrecht, Utrecht, Netherlands

Background: The gut microbiome exerts a multifaceted influence on treatment outcomes across various cancers, yet its potential role in diffuse midline gliomas (DMGs) remains under-explored. In this report, we present the gut microbiome findings from cohort 2 in the DMG–Adaptive Combination Trial (DMG-ACT, PNOC022). **Methods:** PNOC022 is an open-label, multi-institutional, international clinical trial using a Bayesian drug combination platform trial design. This report focuses on the combination therapy arm involving dordaviprone and paxalisib, administered to patients (aged 2–39 years) who had completed standard-of-care radiation therapy (Cohort 2). Stool samples were collected at baseline (n = 22), cycle 1 day 1 (n = 15), cycle 7 day 1 (n = 9), and at progression (n = 4). Microbiome profiling was performed with shotgun metagenomic sequencing (NovaSeq X Plus Series, PE150). Progression-free survival (PFS) and overall survival (OS) were analyzed using the Kaplan-Meier method. Longitudinal shifts in microbial communities were evaluated using α-diversity (Shannon-index) and β-diversity (Bray-Curtis dissimilarity index). Baseline α-diversity associations with PFS and OS were examined with log-rank tests and further validated through age-adjusted Cox regression analysis. **Results:** Between November 2021 and October 2023, 69 biopsy-confirmed DMG patients enrolled (median age 9 years [range 3-37], n = 42 female [61%]) in cohort 2. Median OS from time of diagnosis was 15.6 months (95% CI 12.9-19.5), with a median follow-up time of 19.5 months (95% CI 17.9-23.9). Microbiome analyses were performed for 33 DMG patients (48%). Alpha-diversity and β-diversity remained stable across timepoints. Using baseline samples (n = 22) and a median α-diversity cutoff of the respective group's values, patients were stratified into two categories (low- vs. high-diversity). Low-diversity was associated with significantly worse PFS and trended worse for OS, resulting in a 6-month PFS: 73% (95%CI 51-100) vs. 100%; $p < 0.001$) and 12-month OS: 46% (95%CI 24-87) vs. 78% (95%CI 55-100; p = 0.19). Validation using age adjusted Cox regression analysis confirmed a decrease in the risk of progression or death with increasing α-diversity. PFS hazard ratio (HR) was 0.2 (95% CI: 0.1–0.5; $p < 0.01$) and OS HR was 0.3 (95% CI: 0.1–0.7; $p < 0.01$). **Conclusions:** Baseline high alpha-diversity in the gut microbiome is significantly associated with improved PFS and trended towards improved OS in pediatric patients with DMG in cohort 2 of PNOC022. Age-adjusted survival models reinforced its prognostic value for PFS and OS. These findings highlight the potential impact the gut microbiome has on outcomes and will be explored further and warrant our ongoing investigation in PNOC022. Cognitive outcomes following proton vs. photon radiotherapy for CNS non-germinomatous germ cell tumors: A Children's Oncology Group study. First Author: David Y. Mak, Princess Margaret Cancer Centre - University Health Network, Toronto, ON, Canada

Background: The Children's Oncology Group (COG) study ACNS1123 (stratum 1) treated children with localized non-germinomatous germ cell tumors (NGGCT) of the brain with chemotherapy followed by whole ventricular (WV) radiotherapy (RT, 30.6 Gy) followed by a focal tumor bed boost (54 Gy total dose). Previous work has shown that WVRT with proton therapy, compared to photon RT, resulted in lower RT doses to the brain. However, it was unclear whether this dosimetric difference led to superior cognitive outcomes. **Methods:** The ACNS1123 study was a prospective, phase II trial conducted by the COG that enrolled 107 patients. Evaluation of cognitive functioning of children was a co-primary objective of the study. Cognition was prospectively examined at 9, 30 and 60 months post-diagnosis, using the COG Standard Neuropsychological and Behavioral Battery. The primary endpoints were attention/concentration, estimated intelligence quotient (IQ), and processing speed. Linear mixed-effect models were created to model cognitive endpoints with treatment exposures, including RT modality (proton vs. photon RT) or RT dose to brain structures. Cognitive evaluations completed post-recurrence were excluded. **Results:** Seventy patients were evaluable and received WVRT followed by RT boost, of which 20 received proton therapy. Mean age of all patients was 11.8 $\pm$ 4.3 years old at the start WVRT, and were predominantly male (n = 52). Mean doses to the brain were significantly lower with proton vs. photon RT (mean 18.8 $\pm$ 1.8 [SD] vs. 24.7 $\pm$ 3.7 Gy, $p < 0.0001$), left hippocampus (41.1 $\pm$ 5.2 vs 46.2 $\pm$ 5.3 Gy, p = 0.0005), and right hippocampus (41.8 $\pm$ 5.1 vs 46.0 $\pm$ 5.3Gy, p = 0.0038). A total of 56, 60 and 61 patients were evaluable for attention/concentration, estimated IQ and processing speed, respectively, with 1 or more evaluation. Nine, 20 and 20 patients had data at all 3 time points for attention/concentration, estimated IQ and processing speed, respectively. Multivariable modelling demonstrated that photon therapy was associated with a decline in IQ over time (p = 0.0401), as compared with proton RT, adjusted for age at RT and gender. In a separate multivariable model, higher mean brain dose was also associated with poorer recovery of IQ over time (p = 0.0216), adjusted for gender. There were no identified associations between use of proton RT or hippocampal dose with processing speed or attention/concentration. **Conclusions:** Compared to proton therapy,WVRT delivered with photons was associated with a significant decline in IQ and adverse recovery of IQ over time. To our knowledge, this data is the first to demonstrate such an association for children with NGGCT. Research Sponsor: None.

Efficacy and safety of dordaviprone (ONC201) in prospective clinical trials of adult and pediatric recurrent H3 K27M-mutant diffuse glioma patients. First Author: Ashley Love Sumrall, Levine Cancer Institute, Charlotte, NC

Background: Dordaviprone (ONC201), a first in class imipridone, has demonstrated safety and efficacy in an integrated analysis of patients with recurrent H3 K27M-mutant diffuse midline glioma across clinical studies. Here, we report efficacy and safety findings from two prospectively defined clinical trial arms that evaluated single-agent dordaviprone response in recurrent H3 K27M-mutant glioma. **Methods:** Phase 2 trialONC013 (Arm B) and Phase 1 trial ONC014 (Arm F) were designed to evaluate the objective response rate (ORR) by RANO-HGG criteria of dordaviprone in adult and pediatric patients, respectively, with recurrent H3 K27M-mutant diffuse glioma. Open label dordaviprone was administered once weekly at 625 mg for adults and at a dose scaled by body weight for pediatrics. Responses were investigator-assessed by RANO criteria. Eligibility required measurable enhancing recurrence by RANO-HGG criteria, radiotherapy completed $\geq$90 days prior to dordaviprone unless unequivocal progression qualified per RANO, Karnofsky or Lansky performance status $>$60. DIPG, spinal tumors, leptomeningeal disease, and CSF dissemination were excluded. **Results:** ONC013 Arm B enrolled 30 patients (median age 32, range, 21-66 years) with the majority having a primary midline non-brainstem tumor (n = 19, 63.3%) and one prior recurrence (n = 22, 73.3%). The ORR was 16.7% (95% CI, 5.6-34.7) with 5 partial responses (PR). The median duration of response (DOR) and time to response (TTR) were 15.1 months (7.5-not reached) and 3.8 months (1.8-4.6), respectively. Three patients experienced a grade $\geq$3 treatment-related adverse events (TR-AE), none had treatment-related serious AEs (TR-SAEs), and 1 had TR-AE leading to dose reduction (ALT increase). ONC014 Arm F enrolled 11 patients (median age 14, range 11-19 years). Most had a primary midline non-brainstem tumor (n = 7, 63.6%) and 1 prior recurrence (n = 6, 65.6%). Two (18.2%) radiographic responses were reported, 1 response (9.1%) qualified by RANO criteria. One PR occurred with $>$ 95% tumor regression and an 8.5-month DOR (1.9-month TTR). Another patient experienced a $>$ 50% tumor regression (4.3-month TTR) that did not meet RANO PR criteria due to initiation of 2.5 mg dexamethasone post-baseline. 12-month PFS rate was not reached; 12-month OS rate was 27.3% (6.5, 53.9). One patient experienced a grade $\geq$3 TR-TEAE (9.1%); no TR-SAEs, treatment-related deaths, or TR-AE leading to treatment discontinuation occurred. **Conclusions:** In prospective clinical trials designed to evaluate ORR, single-agent dordaviprone response and safety in adult and pediatric recurrent H3 K27M-mutant diffuse glioma were similar to previously pooled analyses. Clinical trial information: NCT03295396 and NCT03416530. Research Sponsor: Chimerix, Inc.

Metabolic-only response assessment for omission of residual node radiation therapy (RNRT) for patients with classical Hodgkin lymphoma (cHL) and impact on event free (EFS) and overall survival (OS): A report from the Pediatric Hodgkin Consortium's phase 2 study cHOD17 (NCT03755804). First Author: Jamie Flerlage, University of Rochester, Rochester, NY

Background: The AEPA/CAPDac (brentuximab vedotin, etoposide, prednisone, doxorubicin [cumulative dose = 160mg/m^2], cyclophosphamide, vincristine, prednisone, and dacarbazine) regimen results in excellent EFS and OS rates for pediatric cHL but resulted in 65% of patients requiring RNRT using metabolic and anatomic response criteria. We aimed to determine if use of a metabolic-only response assessment would allow omission of consolidative prednisone and RNRT for the majority of high-risk patients while maintaining a high EFS. **Methods:** cHOD17 is an open-label, single-arm, multicenter, phase 2 trial with a stratum for patients $\leq$25 yrs of age at diagnosis of high-risk (stage IIB, IIIB, or IV), CD30+ cHL. ^{18}FDG-PET only (rather than + anatomic) was used to guide therapy following 2 cycles of AEPA [adapted from the HLHR13 trial (NCT01920932), without mandated growth factor] at the early response assessment (ERA). Complete (CMR) and inadequate metabolic responses (IR) were defined as Deauville $\leq$3 and $\geq$4, respectively. Patients in overall CMR received 4 CADac cycles without prednisone or RNRT. IR patients received 4 CAPDac (with prednisone) followed by consolidative IR site directed RNRT (25.5 Gy). The primary objective was to estimate EFS utilizing this approach. **Results:** 114 patients were enrolled at 7 institutions from January 2019 to February 2024. Median (range) age at diagnosis was 16.4 (6.7-24.1) yrs and follow-up 2.5 (0.4-5.7) yrs. Most (79.8%) were nodular sclerosing histology. Stages included 22.8% IIB, 16.7% IIIB, 20.2% IVA, and 40.4% IVB. One patient discontinued therapy due to treatment-related toxicity and was unavailable for response assessment. Of 113 remaining, 69 (61.1%) achieved a CMR at ERA and were spared RNRT and glucocorticoids during the CAPDac cycles. The 2-yr EFS was 94.7% (95% CI: 90.3%-99.4%) and OS 100% (95% CI: 100%-100%). Five of six relapses ($<$ 3 mo (N = 1), 3-12 mo (N = 2), and $>$ 12 mos (N = 3) following therapy) occurred in individuals with an IR. The most frequent grade $\geq$3 toxicities were lymphopenia (84.2%) and neutropenia (91.2%). Grade 3 and 4 febrile neutropenia occurred in 21.1% and 1%, respectively. Neuropathy grade $\geq$3 was not observed. Serious adverse events were rare (n = 4) and included: multi-organ failure during cycle 1 that recovered (n = 2), therapy-related myeloid leukemia in remission following allotransplant (n = 1), and infection-related death during allotransplant for relapse (n = 1). **Conclusions:** A metabolic-only response assessment in the AEPA-CAPDac regimen results in high rates of omission of consolidative RT and glucocorticoids while limiting cumulative anthracycline exposure and maintaining excellent 2-year EFS of 94.7% and OS of 100%. Clinical trial information: NCT03755804. Research Sponsor: Supported by Seagen Inc, which was acquired by Pfizer in December 2023.

Second malignant neoplasm risk after mediastinal radiotherapy for pediatric Hodgkin lymphoma on Children's Oncology Group AHOD1331. First Author: Sarah Milgrom, University of Colorado School of Medicine, Aurora, CO

Background: The reported incidence of second malignant neoplasms (SMN) in long-term survivors of Hodgkin lymphoma (HL) is derived from patients treated with outdated radiation therapy (RT) techniques. We modeled the risk of SMN in pediatric patients with high-risk classic HL treated with modern mediastinal RT. **Methods:** In patients who received mediastinal RT on the Children's Oncology Group study AHOD1331, we modeled the lifetime attributable risk (LAR) at 70 years of age of thyroid, lung, and breast carcinoma. This value indicates the absolute increased risk of SMN at 70 years of age due to RT, above the baseline population risk (mean baseline rates at 70 years of age are 0.7%, 3.3%, and 8.9% for thyroid, lung, and breast carcinoma, respectively, https://seer.cancer.gov/data/). **Results:** In 296 patients who received protocol-directed mediastinal RT, median age at diagnosis was 15.1 years, 55% were female, and 98% had large mediastinal adenopathy. Following 5 cycles of chemotherapy, patients received RT targeting the mediastinum based on criteria of this study; in addition, some patients received RT to other supradiaphragmatic sites that contained slowly responding lesions, including the axilla (n = 3, 1%), lung (n = 7, 2.4%), upper neck (n = 4, 1.3%), and lower neck (n = 8, 2.7%). The RT modality was proton therapy in 25.3%, photon intensity modulated RT (IMRT) in 45.6%, and photon 3-dimensional conformal RT (3D-CRT) in 27.7%. The RT prescription dose was 21 Gy in 83% and 30 Gy in 16% who had a partial metabolic response at the completion of chemotherapy. The mean (range) doses to the thyroid, lungs, and breasts were 12.8 Gy (0-30.3), 8.0 Gy (0.1-15.2), and 4.2 Gy (0.2-14.5), respectively. For the complete cohort, the mean LAR at 70 years of age of thyroid carcinoma was 0.063% and of lung carcinoma was 5.34%. For females, the mean LAR at 70 years of age of breast carcinoma was 2.92%. The Table summarizes the LAR for each SMN, stratified by RT modality. **Conclusions:** In patients treated with mediastinal RT on a recent multi-institutional study of pediatric HL, the predicted long-term risk of SMN is substantially lower than in historical cohorts. Clinicians should consider the toxicity associated with a current RT approach when selecting therapies and counseling patients. Clinical trial information: NCT02166463, this is a post hoc modeling study that includes patients enrolled on this study. Research Sponsor: None.

Mean [range] lifetime attributable risk (%) at an attained age of 70 years for thyroid, lung, and breast carcinoma.

Mortality in survivors of childhood cancer diagnosed with subsequent thyroid cancer: A report from the Childhood Cancer Survivor Study. First Author: Dana Barnea, Tel Aviv Sourasky Medical Center, Tel Aviv, Israel

Background: Childhood cancer survivors are at increased risk of developing a subsequent thyroid cancer, particularly following radiotherapy. In the general population, thyroid cancer has a very low mortality rate. Mortality after a diagnosis of subsequent thyroid cancer in survivors is unknown. **Methods:** We calculated the standardized mortality ratio (SMR) following the development of subsequent thyroid cancer in a cohort of 24,683 5-year survivors of childhood cancer diagnosed between 1970 and 1999 using the age-sex-calendar-year-specific general population all-cause mortality rates from the CDC as the reference rates. We estimated all-cause mortality post the diagnosis of thyroid cancer (time-dependent covariate), adjusting for development of other subsequent malignant neoplasms (SMN) and chronic health conditions (CHC), using a piecewise exponential model. Thyroid cancer-specific mortality among survivors was compared to SEER cases with thyroid cancer, adjusting for age, sex, race and calendar-year. SEER data was also used to compare thyroid cancer characteristics in childhood cancer survivors with thyroid cancer patients without a history of childhood cancer. **Results:** Among 397 survivors with subsequent thyroid cancer, 63% were female, 83% had received radiotherapy for treatment of their primary childhood cancer with fields that included the thyroid gland, and 92% had at least one severe or life-threatening chronic condition. Thyroid tumor size was significantly smaller in survivors, with 33% of cases in survivors and 24% in SEER being less than 1 cm ($p < 0.001$). There were 82 deaths with 7 deaths due to thyroid cancer. Within the cohort of survivors of childhood cancer, the rate of all-cause mortality did not increase with a diagnosis of thyroid cancer, adjusting for development of other SMNs and CHCs (RR = 1.0, p = 0.96), but it was 7 times higher than that of the general population (SMR = 6.9, 95% CI 5.5-8.5). Compared to adults diagnosed with thyroid cancer in the general population, survivors with subsequent thyroid cancer did not have an increased risk of thyroid cancer-specific death (RR = 0.9, 95% CI 0.4-1.9). Mortality risk was higher among those with older age at subsequent thyroid cancer diagnosis, male sex, Black and Hispanic race and ethnicity and tumor size $>$ 1 cm. **Conclusions:** The rate of all-cause mortality does not increase with a diagnosis of subsequent thyroid cancer in childhood cancer survivors. This finding suggests that thyroid cancer screening in this population should be based on reducing morbidity since it likely will not provide survival benefit. Enhanced attention to CHC management may be critical for long-term survival. Research Sponsor: U.S. National Institutes of Health.

Social determinants of health (SDOH) and late mortality among survivors of childhood cancer: A report from the Childhood Cancer Survivor Study (CCSS). First Author: Cindy Im, University of Minnesota, Minneapolis, MN

Background: Neighborhood-level SDOH may increase disparities in adverse cancer-related outcomes. The US CDC-constructed Social Vulnerability Index (SVI) reflects 4 SDOH domains (socioeconomic status [SES]; household composition; minority status/language; housing/transportation) and captures the vulnerability of underserved communities. The impact of neighborhood-level SDOH on late mortality among survivors of childhood cancer is not known. **Methods:** Analyses included 5-year survivors in the US diagnosed in 1970-1999 participating in the CCSS, a multi-institutional retrospective cohort study. We evaluated geocoded SVI quintiles (Q1 to Q5, from least to most vulnerable) based on residential addresses and personal SES factors including income, education level, and health insurance status collected at CCSS baseline. The impact of SVI and personal-level SES on all-cause and cause-specific mortality rates were evaluated using cumulative incidence and relative rates (RRs) from piecewise exponential regression models adjusted for age, sex, diagnosis age, and treatments. **Results:** Among 20,261 survivors with geocode data (mean age at cancer diagnosis and baseline evaluation, 7y and 24y respectively, with a mean follow up of 17y), 2,439 survivors died. All-cause late mortality was greater in survivors living in more vulnerable areas (Q5 vs. Q1, at 20y: 14.7% vs. 10.8%, $P<0.001$). We observed a dose-response relationship between worsening SVI and the all-cause mortality rate (Q5 vs. Q1 RR 1.52, 95% CI 1.32-1.76, $P_{trend}<0.001$) as well as for mortality rates due to specific health causes (Table). Among the SDOH domains, neighborhood SES (Q5 vs. Q1 RR 1.68, 95% CI 1.45-1.95) showed the strongest association with all-cause mortality followed by household composition (RR 1.43, 95% CI 1.24-1.66). Notably, these findings remained largely consistent after adjusting for personal-level SES as well as in analyses stratified by income and insurance coverage. **Conclusions:** Living in socially vulnerable neighborhoods during young adulthood is associated with a ~50% increased risk for late mortality among survivors of childhood cancer and is largely unaffected by favorable personal-level SES. Policies and interventions targeting neighborhood-level SDOH during the transition to survivorship care are needed to reduce mortality risk in this population. Research Sponsor: None.

Adjusted RRs and 95% confidence intervals for overall and cause-specific mortality.

SVI	All cause	Subsequent neoplasm cause	Cardiovascular cause	Other health causes
Q2	1.00 (0.88 - 1.14)	0.90 (0.74 - 1.11)	1.09 (0.76 - 1.55)	1.09 (0.85 - 1.39)
Q3	1.16 (1.02 - 1.32)	1.03 (0.84 - 1.27)	1.18 (0.82 - 1.70)	1.24 (0.97 - 1.59)
Q4	1.24 (1.08 - 1.42)	1.12 (0.90 - 1.39)	1.29 (0.88 - 1.90)	1.44 (1.11 - 1.86)
Q5	1.52 (1.32 - 1.76)	1.35 (1.07 - 1.69)	1.54 (1.02 - 2.33)	1.83 (1.38 - 2.42)

SVI Q1 (least vulnerable) is the referent.

10022 Rapid Oral Abstract Session

Five-year cardiomyopathy risk prediction in survivors of childhood cancer using electrocardiogram. First Author: Luke Patterson, Wake Forest School of Medicine, Winston-Salem, NC

Background: Childhood cancer survivors (CCS) face an increased risk of developing cardiomyopathy during adult life due to late onset of treatment (e.g. anthracyclines and chest directed radiation) associated cardiotoxicity. Early identification of survivors at elevated risk using low cost and easily accessible data modalities can identify survivors in need of echocardiographic screening. Our goal is to utilize 12-lead electrocardiogram (ECG) develop and externally validate an artificial intelligence model (ECG-AI) for prediction of five-year risk for cardiomyopathy among CCS. **Methods:** We developed three deep learning models including a modified ResNet (a convolutional neural network architecture), an encoder-attention network, and a dual attention network to predict cardiomyopathy risk from 10 second 12-lead ECGs. We used the St Jude Lifetime Cohort Study (SJLIFE) for model building using a 60/20/20 patient-level split for training, validation, and holdout testing. We evaluated model performance for all cardiomyopathy grades (Common Terminology Criteria for Adverse Events) and specifically grade 3 (severe) cases. The final model was externally validated in the Dutch Childhood Cancer Survivor Study (DCCSS-LATER) cohort. For the DCCSS-LATER cohort, we evaluated accuracy of ECG-AI for the five-year cardiomyopathy risk prediction. **Results:** SJLIFE analytical cohort included 7,632 ECGs from 4,795 unique participants with no cardiomyopathy. 228 participants developed cardiomyopathy at least one year after index ECG date. Participants were 79% white, 11% Black, and 49% male with mean age at ECG of 33 ± 10 years. In SJLIFE holdout, the encoder-attention model achieved the highest performance (area under the receiver operating characteristic curve (AUC) 0.75 for all grades and 0.84 for $\geq$grade 3 cases). The modified ResNet and dual attention models achieved AUCs of 0.69 and 0.72, respectively. DCCSS-LATER data included 749 ECGs with from 330 unique patients (48% male, age at ECG of 28 ± 10 years). 22 patients developed cardiomyopathy at least one year after index ECG date. The encoder-attention model achieved an AUC of 0.74 for 5-year cardiomyopathy risk prediction. We note that the cardiomyopathy grading was not available in DCCSS-LATER, this study instead used a broader cardiomyopathy diagnosis information. **Conclusions:** ECG-AI analysis of standard 10 second 12-lead ECGs can identify childhood cancer survivors at risk for future cardiomyopathy with moderate to high accuracy depending on the cardiomyopathy severity. Future studies will focus on improving accuracy by incorporating clinical data such as B-type natriuretic peptides, left ventricular ejection fraction. 10023 Rapid Oral Abstract Session

Does early phase study enrollment for pediatric oncology patients have an impact on symptom burden and quality of life (QOL)? A national Canadian study report. First Author: Kendra Rodden, The Children's Hospital of Eastern Ontario, Ottawa, ON, Canada

Background: There are few therapeutic options for pediatric patients with relapsed or refractory cancers. The impact of early phase trial enrolment on the quality of life (QOL) and symptom burden in this patient population is unknown. We hypothesized that this information could inform future clinical trial design and would be of value to clinicians, patients and their families. The primary aim was to determine if those enrolled on a phase I or II trial had improved QOL measured using the PedsQL 3.0 Acute cancer Module compared to those eligible, not not enrolled on a trial. **Methods:** In this Canadian multi-site study, we included patients 2-18 years of age who were enrolled on a phase I/II clinical trial and those who would have been eligible but did not enroll. The PedsQL 3.0 Acute Cancer Module was completed at baseline, week 4 and week 8 by guardians and by patients, for those age 5 and older. The PedsQL 3.0 Acute Cancer Module total scores were compared separately for patients and guardians using a mixed linear registration model with a random effect for a patient. **Results:** Of the 80 patients, 31 (39%) patients were enrolled on an early phase trial and 49 (61%) were not enrolled. The majority of patients had a brain tumor (63.3% of those enrolled; 32.7% of those not), followed by a bone tumor (16.7% of those enrolled; 24.5% of those not). In both groups, the majority of patient were included at the time of their first relapse (64.5% of those enrolled and 69.9% of those not). No significant difference was found between PedsQL3.0 patients or guardians; p = 0.09). The PedsQL3.0 total scores were significantly higher for patients enrolled on an early phase trial compared to those patients not enrolled (p = 0.01). However, after adjusting for baseline levels, the difference between enrolled patients vs not was not statistically significant (p = 0.8). **Conclusions:** Being enrolled on an early phase trial does not appear to have a negative effect on one's quality of life. The results have also demonstrated that it is feasible to evaluate patients enrolled and not enrolled on early phase trials and compare their symptom experience using the PedsQL 3.0 Acute cancer Module. Continued efforts will focus on more recruitment and using SSPedi to further investigate differences in QOL. Determining the recommended phase 2 dose (RP2D) of dose-intense irinotecan combined with IVA chemotherapy (I_RIVA) in newly diagnosed very high risk rhabdomyosarcoma: A phase Ib study within the EpSSG Frontline and Relapsed Rhabdomyosarcoma study (FaR-RMS). First Author: Hans Merks, Princess Máxima Center for Pediatric Oncology, Utrecht, Netherlands

Background: Event-free survival for patients in the highest risk groups of rhabdomyosarcoma (RMS) remains poor. The COG ARST0431 study showed that dose-intensified chemotherapy benefits a subset of metastatic RMS patients. This phase Ib trial defined the safety profile, highest tested dose (HTD), and recommended phase 2 dose for dose intense irinotecan on days 8-12 combined with the standard European 3-weekly Ifosfamide, Vincristine, Actinomycin D (IVA) regimen within the European *paediatric* Soft tissue sarcoma Study Group (E*p*SSG) Frontline and Relapsed Rhabdomyosarcoma (FaR-RMS) study (ClinicalTrials.gov: NCT04625907). **Methods:** Patients aged >1 to ≤25 years with Very High Risk (VHR) RMS (FOXO1 fusion-positive, node-positive, Subgroup G and metastatic, Subgroup H) were included in designated Phase I centres. Participants received IVA (Ifosfamide 3000 mg/m² on days 1–2; vincristine 1.5 mg/m2 on days 1 and 8 and on day 15 in cycle 1 and 2 only; actinomycin D 1.5 mg/m2 on day 1 with irinotecan on days 8–12. The irinotecan starting dose was 20 mg/m²/day, with dose escalation/de-escalation to a maximum of 50mg/m2/day utilising a rolling six design. The Dose Limiting Toxicity (DLT) period was defined as up to 28 days after the start of cycle 2. All Adverse events (AEs) were assessed against the DLT definition during this time. DLTs included Grade 3 diarrhoea, enterocolitis, ileus or oral mucositis persisting > 3 days; Grade 4 diarrhoea; neutropenia or thrombocytopenia delaying treatment > 7 days; Grade 3/4 toxicities resulting in treatment discontinuation, or any Grade 5 toxicity (death) related to trial treatment. First radiological response assessment was after cycle 3 I_RIVA. **Results:** A total of 22 patients (Subgroup G, 3; Subgroup H, 19) were enrolled across 4 dose levels (20 mg/m2/day (n = 5); 30 mg/m2/day (n = 5); 40 mg/m2/day (n = 6); 50 mg/m2/day (n = 6)). Median age was 13.4 years; interquartile range, 5.2-16.3 years. All patients were evaluable for DLTs. One DLT of Grade 3 enterocolitis was observed at dose level 50 mg/m². The HTD and RP2D of irinotecan in combination with IVA were established as 50 mg/m²/day. The most common Grade 3/4 AEs occurring in > 30% of patients, during the first 3 treatment cycles were: febrile neutropenia 13 (59.1%), neutropenia 13 (59.1%); leukopenia 12 (54.5%); anaemia 10 (45.5%), and lymphopenia 7 (31.8%). The overall Response Rate (Complete or Partial Response) at first assessment was 81.8% (18/22). **Conclusions:** The RP2D for irinotecan on days 8-12 within I_RIVA was identified as 50 mg/m²/day. The intensified I_RIVA regimen is under evaluation in randomised questions, in adults and children with paediatric-type RMS, within the FaR-RMS trial in High Risk patients (IVA vs I_RIVA) and VHR patients (IVA plus doxorubicin vs I_RIVA). Clinical trial information: NCT04625907. Research Sponsor: Cancer Research UK.

Integrated molecular characterization of pediatric soft tissue sarcomas: A report from the COG and CCDI molecular characterization initiative. First Author: Sapna Oberoi, CancerCare Manitoba, Winnipeg, MB, Canada

Background: The Molecular Characterization Initiative (MCI), a partnership between the Children's Oncology Group (COG) and the NCI's Childhood Cancer Data Initiative (CCDI), provides standardized genomic profiling of tumors and germline for subjects with newly diagnosed pediatric soft tissue sarcomas (STS). Here, we report on STS patients <25 years enrolled in MCI from July 2022 to July 2023. **Methods:** MCI enrollment was offered to COG institutions through APEC14B1 (Project: EveryChild), enabling patient consent, collection of clinical data, and submission of tissue/blood samples. Bio-pathology Center centrally managed sample processing, quality control, and nucleotide extraction, while molecular assays were performed at Nationwide Children's Hospital's Institute for Genomic Medicine. Whole-exome sequencing (WES) of tumor/normal, DNA methylation arrays and RNA fusion analysis were conducted in a CLIA-certified environment. Clinical reports, except methylation results, were returned to treating institutions within 21 days, and clinical, sequencing and methylation data were deposited in NCI's Cancer Data Service. **Results:** In total, 226 rhabdomyosarcoma (RMS),158 non-rhabdomyosarcoma soft tissue sarcoma (NRSTS), and 36 non-malignant soft tissue tumors (21 desmoid tumors) from 129 institutions were enrolled. Of 172 RMS patients, 56 were fusion-positive (FP) (46 with *FOXO1* fusion and 10 with fusions of other genes). WES of 179 RMS patients identified somatic mutations in 33 genes in 110 patients (61.4%). Most frequently mutated genes included *FGFR4* [25/179,14%; FN (fusion-negative) RMS:21%, FP RMS:2%), *TP53* (21/179,12%; FN RMS:15%, FP RMS: 7%), and *NRAS* (18/179, 10%; FN RMS:14%, FP RMS: 3%). Somatic copy number variants (CNVs) were detected in 164/179 (92%) of RMS patients. Germline variants were identified in 18 of 179 RMS (10%; FN RMS:15%, FP RMS: 2%); and most commonly germline altered genes included *TP53* (4/179, 2%), *APC* (2/18, 1%), and *ATM* (2/179,1%). Among 158 NRSTS > 20 histologies were enrolled, most common being synovial sarcoma (n = 16, 8%). Of 49 patients with an initial diagnosis of undifferentiated sarcoma, round cell sarcoma, spindle cell sarcoma and sarcoma NOS, 32 underwent fusion testing, and 28 had WES: in 13 (40%) sequencing resulted in specific diagnosis [CIC::DUX4 in 5, BCOR::CCNB3 in 4, *NTRK* rearrangement in 2, SS18::SSX2 in 1 and EWSR1::ETV1 in 1], and 5 (15%) had rare fusions involving *NUTM1*, *NSD3*, *EGFR* and *COL1A1* genes;16 exhibited somatic CNVs; 5(18%) had somatic mutations; and 2 (7%) carried germline variants in *TP53* and *RET* genes. Overall, MCI results, as reported by institutions, facilitated clinical trial enrollment in 15%, receipt of targeted therapy outside trials in 17%, and diagnostic refinement in 25% of tested patients, respectively. **Conclusions:** CCDI's MCI program provides comprehensive genomic profiling of pediatric and adolescent STS, uncovering distinct somatic genetic alterations, rare fusions, actionable genomic targets and germline variants. 10026 **Rapid Oral Abstract Session**

Gut microbiome changes in pediatric AML and association with event free survival. First Author: Oren Gordon, Children's Hospital of Colorado, Aurora, CO

Background: Pediatric acute myeloid leukemia (AML) is characterized by months of hospitalization with a high risk for infections and a higher rate of relapse than many pediatric leukemias. Recent studies have highlighted the relationship between gut microbiome changes, long term cancer outcomes, and development of comorbidities. However, no study to date has examined the longitudinal changes in the gut microbiome in pediatric AML patients. **Methods:** In this retrospective study, longitudinal stool samples were taken from 14 pediatric patients with AML treated at Children's Hospital Colorado. Sample collection started after initial diagnosis for 11 patients and after first relapse for 3 patients. These samples were analyzed using 16S ribosomal RNA (rRNA) gene sequencing along with clinical data extracted via manual chart review. **Results:** We found that the relative abundance of genus *Fusobacterium* was associated with relapses. Analysis indicated that Fusobacterium was significantly elevated in the stool of 3 of 6 newly diagnosed patients who relapsed within 5 years (using a linear model that also accounted for risk stratification based on genetics and treatment response (p = 0.03)). These patients had elevated *Fusobacterium* at multiple timepoints during treatment. Samples from the 5 newly diagnosed patients who did not relapse showed minimal *Fusobacterium*. *Fusobacterium* has previously been associated with other cancers, oncogenesis and immune evasion. Of the 14 patients, 5 experienced 1-4 cases of *Streptococcus mitis* bacteremia (SMB) during the sample collection period. Genus *Streptococcus* abundance in stool samples collected immediately prior to SMB did not correlate with positive blood cultures, although this genus was highly prevalent in the gut microbiome of patients with repeated episodes. Using mixed effects random forest model (MERFM) to broadly survey whether changes in any other gut bacteria predicted a positive SM blood culture, we found evidence for a negative relationship between SMB and change in relative abundance of genus *Blautia*, and a positive relationship with the genera *Marvinbryantia, Anaerococcus, Parabacteroides* and *Dielma*. This suggests that other aspects of microbiome composition may influence whether *Streptococcus* can translocate into the bloodstream. Of the 14 patients, 4 developed *Clostridioides difficile* infections (CDI) during the collection period. Increases in genus *Clostridioides* relative abundance occurred prior to clinical CDI. Using MERFM, Faith Phylogenetic Diversity was negatively related to development of CDI and presence of the genera *Anarofustis, Bilophila, Alistipes* and was positively related to CDI. **Conclusions:** These results show that the gut microbiome may be implicated or serve as a prognostic indicator for relapse in pediatric AML. Additionally, longitudinal gut microbiome changes in patients may be associated with various clinical complications. Research Sponsor: None.

New pediatric formulation of asciminib in children with chronic myeloid leukemia in chronic phase: Second interim analysis of pharmacokinetics and safety from the ASC4Kids study. First Author: Nobuko Hijiya, Pediatric Hematology, Columbia University Irving Medical Center, New York, NY

Background: More treatment (tx) options to improve efficacy and long-term safety to minimize adverse effects on growth are needed for pediatric patients (pts) with Philadelphia chromosome-positive (Ph+) chronic myeloid leukemia in chronic phase (CML-CP). Asciminib (ASC) is the first BCR::ABL1 inhibitor that Specifically Targets the ABL Myristoyl Pocket (STAMP), approved for adults with newly diagnosed or previously treated CML-CP. The phase Ib/II, multi-center, open-label ASC4Kids study (NCT04925479) aims to identify the pediatric formulation (PF) dose (with food) leading to ASC exposure comparable to the adult formulation (AF) dose (fasted) of 40 mg twice daily (BID) and assess its safety. **Methods:** Pts aged 1– < 18 years (yrs) with CML-CP, without the T315I mutation, treated with ≥1 prior tyrosine kinase inhibitors are included. The primary objective is to characterize the pharmacokinetic (PK) profile of ASC in pediatric pts. Secondary endpoints include safety and molecular responses. In an exploratory AF group, pts 14– < 18 yrs were treated with the AF. In Part 1 (dose determination), the PF dose of 1.3 mg/kg BID was confirmed based on exposure in adult studies (40 mg BID) and no observed dose-limiting toxicities (DLTs) over the first 28 days. In Part 2 (dose expansion), additional pts are treated with the confirmed PF dose for further evaluation of exposure and DLTs (across Parts 1+2; 10 pts per group: 1– < 12 yrs and 12– < 18 yrs). In Part 3, 10 more pts will be enrolled to receive PF 2.6 mg/kg once daily (QD). This interim analysis was conducted after 10 pts in the PF 12– < 18 yrs group had completed 28 days of tx in Parts 1+2. **Results:** 19 pts were enrolled in the PF group (7 in 1– < 12 yrs and 12 in 12– < 18 yrs groups, respectively). At data cutoff (19-Aug-2024), all pts continued to receive tx. For the PF group (12– < 18 yrs), 10 pts were evaluable for PK. Averaged ASC exposure with PF 1.3 mg/kg BID was comparable to that observed in adult studies (median last measured concentration [AUClast]: 7091 vs 5130 hr*ng/mL; median maximum plasma concentration [Cmax]: 1031 vs 939 ng/mL, respectively). For all pts in the PF group, no DLTs were observed. With a median duration of exposure of 36.7 weeks, 18 pts experienced adverse events (AEs; any grade); 2 had Grade ≥3 AEs. From baseline (BL) to data cutoff for height percentile shift in the PF group; 9 pts stayed in the same percentile, 4 dropped and 6 increased. Four of 19 pts had notably low bone age at BL; 3 of these also at Week 52. At BL,16/18 pts in the PF group had *BCR::ABL1*^{IS} ≤10% and 6 were in major molecular response (MMR). Of 11 and 9 pts evaluable for efficacy at Weeks 28 and 40, 10 and 9 had *BCR::ABL1*^{IS} ≤1%, and 7 and 6 were in MMR, respectively. **Conclusions:** The confirmed PF ASC dose of 1.3 mg/kg BID was well tolerated in pediatric pts, with evidence of efficacy and no new safety signals. In Part 3, a 2.6 mg/kg dose QD will be evaluated. Clinical trial information: NCT04925479. Research Sponsor: Novartis Pharmaceuticals.

Financial toxicity and association with treatment outcomes during pediatric CAR T therapy. First Author: Daniel J. Zheng, Children's Hospital of Philadelphia, Philadelphia, PA

Background: Chimeric antigen receptor T cell (CAR) therapy has revolutionized the treatment of relapsed/refractory pediatric B cell malignancies. However, the financial toxicity (FT) experienced by families is unknown despite the likely high burden imposed by clinic visits, hospital admissions, and potential travel/relocation to referral centers. We present the first report of pediatric FT among families of children receiving CAR therapy including prevalence, trajectory, and impact on outcomes. **Methods:** This is a prospective cohort analysis of patient (pt) and caregiver-reported FT outcomes for pediatric and young adult pts receiving CD19-directed CAR therapy at the Children's Hospital of Philadelphia. Caregivers (for pts $<$ 18 years old) or pts (if $\geq$ 18 years old) completed the Comprehensive Score for Financial Toxicity (COST) prior to CAR infusion (baseline), 1 month, and 3 months post-infusion. COST is a self-report FT measure that has been used in adults with specific validated grading criteria (0-3) anchored on independent differences in health-related quality of life. We described baseline FT and tested its association with treatment-related toxicity (occurrence of any cytokine release syndrome [CRS]) and outcomes (complete response [CR] at day 28) using multivariable models adjusted for time from diagnosis, prior CAR exposure, and disease burden at infusion. FT was hypothesized to impact outcomes through physiologic stress affecting immunologic response. In pts with COST data through 3 months, we described longitudinal FT trajectories. **Results:** From 9/2019-12/2024, 144 pts (33% racial/ethnic minority, 8% public insurance) or their caregivers (28% less than college degree, 22% annual household income $<$ $50,000) completed baseline COST measures. 94% of the cohort had caregiver-reported FT. 81% of pts were external referrals. The median baseline COST score was 20.0 (IQR: 11.0-29.0), which corresponds to Grade 1 FT. Two-thirds of pts reported FT, with 37%, 29%, and $<$ 1% of families experiencing grades 1-3 FT, respectively. 80% of pts had CRS; 89% had CR at day 28. Baseline FT was not associated with CRS or day 28 response (all $p > 0.2$). A subset of n = 80 had complete longitudinal data and follow up of at least 3 months. In this cohort, median COST score at baseline, month 1, and month 3 was 19.5 (IQR: 10.0-29.3), 18.5 (IQR: 11.0-27.3), 16.0 (IQR: 9.8-27.0), respectively. Strikingly, 23% and 25% of pts had clinically worse grades of FT at 1 month and 3 months post-infusion (compared to baseline), respectively. Race/ethnicity, language, insurance, caregiver education, and income were not associated with worsened FT over time. **Conclusions:** There is a high prevalence of FT at time of CAR infusion for families of pediatric and young adult pts. Reassuringly, FT at the time of infusion was not associated with two key treatment outcomes, but more investigation is needed. For a notable proportion of families, FT worsens over time and highlights the need for interventions to address cumulative financial burden. Research Sponsor: American Cancer Society.

Growth recovery in patients with *BRAF* altered pediatric low-grade gliomas (LGG) after discontinuation of tovorafenib. First Author: Cassie Kline, Children's Hospital of Philadelphia, University of Pennsylvania, Philadelphia, PA

Background: Tovorafenib is a selective, CNS-penetrant, type II RAF inhibitor that targets BRAF and CRAF. Based on preclinical data, CRAF plays an essential role in chondrocyte maturation, a required step in linear bone growth. Children treated with tovorafenib in early phase studies demonstrate a reversible decrease in growth velocity consistent with CRAF inhibition with no signs of premature closure of growth plates or adverse effects on bone such as fractures or treatment emergent osteopenia. Here we report a combined analysis of off-treatment growth recovery in patients treated with tovorafenib in 3 clinical studies. **Methods:** Patients aged $<$ 18 years with *BRAF* altered relapsed/refractory LGG treated with tovorafenib in the Phase 1 PNOC014 study (NCT03429803), Phase 2 FIREFLY-1 study (NCT04775485), or Expanded Access Program (EAP) for patients (NCT05760586) were included. Relevant medical history, neuroendocrine medications, growth parameters, and tovorafenib dosing were collected. Pre- and post-treatment annualized growth velocity (AGV) was calculated for all patients with growth data available $\geq$90 days post-discontinuation of tovorafenib. **Results:** As of 17-Jan-2025,38/167 (23%) patients were evaluable for growth recovery. Among these evaluable patients, median age at start of treatment was 9.5 yrs (range 3.5 -16.5). Eighteen (47%) patients had a tumor associated endocrinopathy or comorbidity that may affect growth including growth hormone deficiency (8), thyroid disease (8), precocious puberty (6) and panhypopituitarism (4) at baseline. Four (11%) were receiving a gonadotropin-releasing hormone analogue for precocious puberty and 2 (5%) were receiving growth hormone replacement concurrent with tovorafenib. Median baseline height Z-score was -0.13 (range -2.57, 2.64) with 4 patients having Z-score $>$ 2 or $<$ -2. Median on-treatment AGV was 1.7 cm/yr [n = 36, interquartile range (IQR) 0.4 - 2.2] at 12 mo and 2.3 cm/yr (n = 25, IQR 0 - 3.3) at 24 mo. Median age at end of treatment was 11 yrs (range 4.4 - 17.5), and median off-treatment follow up was 10.3 mo (range 3.2 - 37.2). Median off-treatment AGV was 4.3 cm/yr (n = 38; IQR 1.8 - 7.6) at 3 mo, 10.2 cm/yr (n = 26, IQR 2.3 - 13.8) at 6 mo and 7.7cm/yr (n = 5, IQR 4.1 - 13.9) at 12 mo. Thirty-four (89%) patients had recovery of AGV, and 28 (74%) had an increase in Z-score towards baseline indicating catch-up growth. Patients with slow AGV recovery tended to be $>$ 15 years, younger females with precocious puberty/Tanner stage 4, or have only 3 months of off-treatment follow up. **Conclusions:** Decreases in growth velocity were common during tovorafenib treatment. Majority of patients to date demonstrate AGV recovery as early as 3 months with signs of catchup within 6-12 months after stopping tovorafenib. Preliminary findings indicate tumor-associated precocious puberty/Tanner stage 4 in females may be a risk factor for slow AGV recovery. Cerebrospinal fluid proteome during chemotherapy for childhood leukemia: Identifying pathways associated with treatment and system toxicity. First Author: Justin Tanner, St. Jude Children's Research Hospital, Memphis, TN

Background: Acute Lymphoblastic Leukemia (ALL) is the most common childhood cancer with a 5-year survival rate $>$ 90%. Survivors treated on contemporary chemotherapy-only protocols are at heightened risk for musculoskeletal, endocrine, cardiac, and neurological/neurocognitive late-effects. Chemotherapy treatment doses and administration routes (i.e., intrathecal) are associated with the late-effects and alterations in targeted cerebrospinal fluid (CSF) proteins. We aimed to identify CSF proteome pathways linked to patient variables, treatment exposures, and early adverse events (AE). **Methods:** At diagnosis and the end of induction, CSF samples were collected from 178 ALL patients (71 females, mean age [range] 7.6 [0.5-18.8] years at diagnosis) treated on a chemotherapy-only protocol. Expression of 3188 proteins was measured via tandem-mass-tag mass spectrometry and clustered via Weighted Gene Co-expression Network Analysis (WGCNA). Severe/life threatening (CTCAE grade 3/4) AEs across multiple organ systems were compiled per patient. Trait-Cluster association was assessed by generalized linear models, linking cluster-specific eigenvalues to final treatment risk stratum (Standard/High vs Low) and AE occurrence, with false discovery rate corrected significance threshold of $p < 0.2$. Protein-Protein Interaction (PPI) network and enrichment analysis were performed by STRING within target clusters. **Results:** Patients experienced AEs in 24 organ systems (86% post-induction) and $>$ 5% of patients experienced toxicities in 6 systems during and 11 after induction. A total of 1770 proteins were measured at both time points and WGCNA revealed 8 clusters at diagnosis (T1; 1046 proteins) and 13 after induction (T2; 1184 proteins). Four T1 clusters were associated with post-induction Hepatobiliary/Pancreas AEs ($p < 0.022$). Five T2 clusters were associated with treatment risk ($p < 0.055$) and eight were associated with AEs: Hepatobiliary/Pancreas ($p < 0.184$), Musculoskeletal/Soft Tissue ($p < 0.151$), or Neurology ($p < 0.196$). In four T2 clusters associated with both risk and AEs, PPI analysis revealed 251 pathways involved in nervous system development, skeletal/cardiac development, and immune regulation. **Conclusions:** The associations of Musculoskeletal/Soft Tissue, Neurology, and Hepatobiliary/Pancreas AEs with risk-associated clusters suggest pathological protein dynamics exacerbated by treatment intensity. These changes are reflected in different T1 and T2 cluster composition and the emergence of new clusters after induction. Associations between protein clusters, treatment risk, and AEs biologically connect treatment exposures to toxicities, providing mechanistic targets to reduce late-effects. Future work includes isolating enriched pathways and hub proteins to gain insight into specific protein dynamics contributing to AEs. Research Sponsor: None.

Unraveling gut gram-negative antibiotic-resistant colonization dynamics in hematologic cancers: Insights from bioinformatics and immune signatures. First Author: Mahdi Malekpour, Shiraz University of Medical Sciences, Shiraz, Iran

Background: Infections account for ~60% of cancer-related deaths. Hematologic cancers have a 3x higher infection-related mortality than solid tumors, with resistant Gram-negative (GN) bacteria causing ~50% of bloodstream infections, highlighting the need to study the microbiome, antibiotic resistance, and infection risks. **Methods:** Stool samples from newly diagnosed hematologic cancer patients were collected at baseline, post-chemotherapy, and subsequent admission at Amir Hospital, a referral cancer center in southern Iran, to analyze microbial colonization dynamics. Patients enrolled in a 16-month observational program to investigate the correlation between clinical factors and infectious outcomes. Carbapenem-resistant and ESBL-producing were cultured on MacConkey agar with meropenem and ceftriaxone. ESBL and carbapenemase production assessed adhering to CLSI guidelines. To support our findings, we used the microbioTA database to identify highly elevated 16S rRNA expression in blood and lymph nodes of hematologic cancer patients, exploring microbiome-host interactions worldwide. We used gutMgene, GIMICA, and AMIDIS databases to explore key microbe-immune factor associations trough network centrality analysis of the immune factors. Central factors further examined in the Amir Cancer Registry datasets to assess their association with infectious events. STATA v27 used for statistical analyses. **Results:** Among 73 pediatric patients, GN drug-resistant bacteria was detected in 51 before hospitalization. *Escherichia coli* (86.6% of positive samples) and *Klebsiella pneumoniae* (9.5%) were the predominant pathogens. Drug-resistant E. coli persisted across samples, indicating gut colonization, consistent with microbioTA data showing E. coli detection at baseline and post-induction therapy. ESBL and carbapenemase-producing strains were 56.8% and 15.8%. Colonized patients had a 13.8% mortality rate, with bloodstream infections and typhlitis more common in K. pneumoniae and carbapenem-resistant strains. Previous antibiotic exposure, malignancy relapse, and colonization status were risk factors for mortality and infection. Investigation of the microbioTA database identified 10 datasets from Asia, Europe, and America revealed the detection of *Bacillus cereus* in 9 datasets, followed by E.coli (8) and Enterobacterales like *Salmonella enterica* (5) and K.pneumoniae (3), approving the high impact of E.coli worldwide. IL-4, IL-6, and TNF-α showed high centrality, with retrospective analysis linking their upregulated serum baseline levels to infection outcomes in Amir hospital datasets. **Conclusions:** Our study links GN microbial colonization, traced by elevated immune markers, to infectious complications, highlighting the need for microbiota-specific diagnostic and treatment protocols. Research Sponsor: None.

Association of baseline clinical factors with outcomes in patients with localized Ewing sarcoma treated on frontline trials with interval compressed chemotherapy (ICC): A report from the Children's Oncology Group. First Author: Ajay Gupta, Roswell Park Comprehensive Cancer Center, Buffalo, NY

Background: Identifying clinical and biological factors associated with outcomes in localized Ewing sarcoma (ES) will enable risk-stratified clinical trials with the goal of improved outcomes for high-risk patients and decreased treatment toxicity for low-risk patients. The specific aims of this analysis in localized ES patients were 1) to classify extraosseous (EO) primary tumors with subdivisions into deep (viscera, glands, body cavities, muscle, nerves) and superficial (cutaneous and subcutaneous) sites, and 2) to understand the relationship between baseline clinical factors (age, sex, primary tumor site, size (maximum dimension and volume)) and event-free survival (EFS). **Methods:** The analytic cohort included ES patients treated with ICC on AEWS0031 and AEWS1031. Primary tumor sites were defined as pelvic, non-pelvic, and EO (deep vs. superficial). Post-enrollment EFS was the primary endpoint. Univariate analyses used the Kaplan–Meier method (logrank test). Multivariable analyses used Cox proportional hazards models. To assess the impact of tumor volume as a continuous variable, a subgroup analysis was conducted using AEWS1031 only, as tumor volumes were collected prospectively on this study. Visual exploration of effects of continuous variables on EFS event hazard used restricted cubic splines with 3 knots. Tests were performed at the 5% level. **Results:** AEWS0031 (n = 628) and AEWS1031 Regimen B (n = 283) yielded 911 patients. In univariate analyses, difference in risk of EFS event was observed between tumor sites (P= 0.03). EO tumors had the highest estimated EFS compared to pelvic and non-pelvic (5 year EFS 84.7% vs. 72.4% and 75.9%). Superficial EO appeared to be a very low-risk group, albeit interpretations are limited by the small group size and singular event (one second malignant neoplasm among 15 patients). In multivariable analysis of the combined cohort, sex, race, and ethnicity were not prognostic. EO tumors may be associated with decreased hazard compared with non-pelvic bone primaries (HR 0.58, P= 0.07), and tumors $\geq$200 mL with increased hazard (HR 1.56, $P<$ 0.01). In the subgroup analysis, tumor volume and age were prognostic and in visualizations age was non-linearly related to the hazard of EFS event, increasing until approximately 15 years. Tumor volume was non-linearly related to the hazard of EFS event and increased until approximately 400 mL. **Conclusions:** Patients with ES and primary tumors $\geq$200 mL continue to be at higher risk of an EFS event when treated with ICC, and EO tumors may be lower risk compared with other sites. Risk of an event appears to remain constant in ES patients $\geq$15 years or with primary tumors $\geq$400 mL. These findings should be validated in prospective trials and tumor biology integrated with clinical factors to improve risk stratification for localized ES. Research Sponsor: None.

Demographic characteristics and survival outcomes of pediatric clear cell sarcoma of the kidney: A National Cancer Database retrospective study. First Author: Assal Sadighian, UC Riverside, Riverside, CA

Background: Clear Cell Sarcoma of the Kidney, CCSK, is a rare malignancy diagnosed during childhood. Compared to other pediatric renal neoplasms, CCSK is particularly aggressive due to its propensity for bone metastasis, resulting in a poorer overall survival rate. CCSK has a higher incidence in males than females. Given its rarity, investigating diagnostic patterns may reveal important epidemiological insights. This study analyzed the demographic factors in CCSK patients from the National Cancer Database (NCDB). **Methods:** A retrospective National Cancer Database (NCDB) from 2004 to 2020 analyzed patients who had a histologically confirmed diagnosis of CCSK (ICD-O-3 8964). Descriptive statistics were used to analyze Demographic factors (age, sex, race, Hispanic status, educational attainment, insurance status, facility type, distance from facility, and Charles/Deyo score). Regression analysis was utilized to interpret incidence trends. **Results:** Between 2004 and 2020, the NCBD identified 237 patients with confirmed CCSK, indicating a stable incidence rate (R^2 = 0.0043). The median age at diagnosis was 3 years old (SD = 24.83; range, 0–86). Males comprised 56% of the cohort, and 44% were females. Most patients were White (78%) and non-Hispanic (79%). Nearly all primary tumors (99%) occurred in the kidney and renal pelvis, with a median tumor size of 120 mm (SD = 42.33; range, 13–202). Over half of patients (54%) had private insurance, while 27% were on Medicaid. The majority (93%) had a Charlson/Deyo comorbidity score of 0. Most patients (99%) did not receive palliative therapy. 71% of the patients underwent a surgical procedure at the primary site, 70% received radiotherapy, and 76% received it as part of their primary treatment. Most patients (90%) lived in metropolitan areas, and they resided a median distance of 15 miles (SD = 57.1; range, 0.5-377.3) from the reporting hospital. The two-year, five-year, and ten-year survival rates were 86%, 81%, and 76%, respectively, with a mean survival of 163 months. **Conclusions:** To the best of our knowledge, this is the first NCDB analysis of CCSK, addressing a significant knowledge gap. Nearly all CCSK cases originated in the kidney or renal pelvis, consistent with literature indicating the kidney as the primary site with a stable incidence over time. These are the first socioeconomic factors of CCSK patients that have been described in the literature: CCSK patients are more likely to be white and non-Hispanic, male, have private insurance, and live in metropolitan areas. Further research is essential to better understand how demographic and socioeconomic factors influence the diagnosis, treatment choices, and overall survival of patients. Research Sponsor: None.

Late effects in high-risk neuroblastoma survivors who received MIBG therapy. First Author: Prerna Kumar, University of Illinois College of Medicine, Peoria, Peoria, IL

Background: Meta-iodobenzylguanidine radiolabeled with iodine-131 (^{131}I-MIBG) is used to treat high-risk neuroblastoma (HRNB) as monotherapy as well as in combination with other therapies, however associated late toxicities have not been well studied. The aim of this study was to describe the characteristics of HRNB survivors who received ^{131}I-MIBG and determine if ^{131}I-MIBG is associated with subsequent malignancy, growth impairment, thyroid toxicities, and other major organ (musculoskeletal, gonadal, gastrointestinal, cardiac, or pulmonary) toxicities. **Methods:** The Children's Oncology Group LEAHRN study, ALTE15N2, evaluated HRNB survivors diagnosed after 2000 and at least five years from diagnosis. Clinical history was abstracted via study questionnaires. Clinical characteristics, treatment history, and the prevalence of late effects were descriptively summarized for subjects treated with ^{131}I-MIBG (cases). Subjects who did not receive ^{131}I-MIBG therapy were randomly selected and matched by age at diagnosis and relapse history (controls) in a 1:2 case-control study design. Chi-squared analysis was used to evaluate the association between ^{131}I-MIBG and late toxicities. P-values were adjusted using the Holm-Bonferroni approach. **Results:** Of 375 subjects enrolled in LEARHN, 32 (8.5%) received ^{131}I-MIBG. Of these, 17 (53%) reported relapsed or refractory disease. Mean age at ^{131}I-MIBG treatment was 5.1 years. 56% were male. Disease extent included an adrenal primary in 62%, multiple bone metastases in 72%, and bone marrow involvement in 63%. Thyroid toxicity (hypothyroidism, hyperthyroidism, or thyroid nodules) was similar in both groups, reported in 10/32 cases compared with 11/63 controls. One case (1/32) and four controls (4/64) reported a subsequent malignancy. Growth failure was reported in 35% of cases (11/31) and 23% of controls (16/63). Other major organ toxicities were also similar with no significant differences between cases and controls. **Conclusions:** In survivors of HRNB, the burden of late toxicities appeared similar in those treated with ^{131}I-MIBG compared to those who were not. This provides critical information for long-term follow-up care and clinical trial design. Survival and prognostic factors of patients with Ewing sarcoma at first recurrence following modern era multimodal therapy: A report from the Children's Oncology Group (COG). First Author: Sarah Cohen-Gogo, The Hospital for Sick Children, Toronto, ON, Canada

Background: Ewing sarcoma (EwS) is a rare malignancy of children, adolescents and young adults for which outcomes have progressively improved through intensification of conventional chemotherapy, including interval compression of cycles. Prior cooperative group reports of relapsed EwS included patients treated less intensively and with fewer treatment options at relapse. Here, we report overall survival (OS) and prognostic factors post-first recurrence in patients with EwS treated with frontline interval-compressed chemotherapy. **Methods:** We included patients treated on the last three phase 3 COG EwS studies treated with interval compressed chemotherapy, which accrued from 2001-2019. Patients with initially localized disease (L-EwS) were treated on AEWS0031 arm B and AEWS1031. Patients with initially metastatic disease (M-EwS) were treated on AEWS1221. The primary outcome was OS from first relapse. Demographic and clinical data from original diagnosis and from relapse were analyzed as potential prognostic factors. Kaplan-Meier survival curves were constructed and groups compared with log-rank tests. **Results:** 366 patients experienced disease recurrence as first event and were included in this analysis (AEWS0031 arm B, n = 69, AEWS1031, n = 115, for a total of 184 with L-EwS; AEWS1221, n = 182, all with M-EwS). Median age at relapse was 16 years. Median time from initial enrollment to first relapse was 1.52 years and was shorter for patients with M-EwS (Kruskall-Wallis, $p < 0.001$). First relapses were isolated local, isolated distant, and combined in 24%, 70%, and 6.4% of patients, respectively. Metastatic stage at initial diagnosis was associated with increased risk of post-first recurrence OS event ($p < 0.0001$). Two-year OS post-first recurrence (OS_{2y}) was 25.6% for patients with M-EwS and 48.5% for patients with L-EwS. Time to first recurrence was also a predictor of post-recurrence survival ($p < 0.0001$): patients with initial L-EwS and relapse $<$ 2 years from diagnosis had OS_{2y} of 31.4% vs. 70.8% for later relapses. Patients with initial M-EwS and relapse $<$ 2 years from diagnosis had OS_{2y} of 18.9% vs. 71.2%. Patients with combined relapses had higher risk of post-relapse death compared to other patterns of failure ($p = 0.003$), an effect that was largely driven by the one seen in patients with initial L-EwS. **Conclusions:** Overall survival of patients with first recurrent EwS after having received modern era therapy with interval compressed chemotherapy on recent COG trials remains poor, particularly for M-EwS, early relapse and combined relapses. These data will inform the design of trials for this relapsed population and provide critical data to help counsel patients about goals of care at first relapse. Neurocognitive outcomes following 30.6-Gy whole-ventricular radiotherapy with 54-Gy total dose focal tumor bed boost for CNS non-germinomatous germ cell tumors: A Children's Oncology Group study (ACNS1123). First Author: Sunita K. Patel, City of Hope Comprehensive Cancer Center, Duarte, CA

Background: COG ACNS1123 stratum 1 was a prospective, phase II trial treating children with localized non-germinomatous germ cell tumors of the brain with chemotherapy followed by whole ventricular (WV) radiotherapy (RT, 30.6 Gy) and a focal tumor bed boost (54 Gy total dose) Given the potential adverse impact of RT on survivors' neurocognitive development, ACNS1123 had a co-primary objective to evaluate and longitudinally model cognitive and behavioral outcomes. **Methods:** Cognition was prospectively examined at 9, 30, and 60-months post-diagnosis via COG protocol ALTE07C1. Attention/concentration, processing speed (PS), and estimated intelligence quotient (est. IQ) were assessed by Wechsler Intelligence tests. Survey-reported attention and executive functioning (EF) were also obtained. Multivariable linear mixed-effects models examined trends over time, as well as associations and interactions with age, gender, tumor location (pineal gland versus other) and insurance type (private versus other and private versus public). **Results:** Seventy patients were evaluable and received WVRT followed by focal RT boost. Mean age at initiation of RT was 11.8 $\pm$ 4.3 years; 74% were male. A total of 56, 60, and 61 patients had at least one valid assessment score across 3 time points for attention/concentration, est. IQ and PS, respectively. Nine, 20 and 20 patients had data at all 3 time points for attention, est. IQ and PS, respectively. The average PS scores fell below the normative mean at all three time points. The average Est.IQ was below the normative mean at 9 months only. Males had higher attention scores on average ($p < .01$), while patients with other insurance had lower attention compared to the private group ($p < .01$). For the model-estimated longitudinal trajectories and their interactions with clinical factors, younger children had declining processing speed (p = 0.012), females had declining est.IQ scores ($p < .01$) and patients with tumors at pineal gland had improving est.IQ scores (p = 0.010) over time. For survey-reported outcomes, there was no change in attention while younger children had improved EF over time (p = 0.045). **Conclusions:** Treatment associated with the ACNS1123 stratum 1 protocol had variable impact on patient's longitudinal neurocognitive functioning. Younger age at irradiation and female gender were risk-factors for worse neurocognitive outcomes on examiner-administered measures. Only average PS was significantly below the normative mean at all 3 times in the collective sample. Patients should be proactively monitored for cognitive and educational supportive care services. These data could potentially serve for comparison of neurocognitive outcomes in future clinical studies that modify treatment approaches; however, the notable attrition must be considered as a limitation. Research Sponsor: U.S. National Institutes of Health; NCTN Operations Center Grant (U10CA180886); U.S. National Institutes of Health; NCTN Statistics & Data Center Grant (U10CA180899); St. Baldrick's Foundation.

10037 Poster Session

Post hoc analysis of rashes reported in patients (pts) with *BRAF*-altered relapsed/refractory (r/r) pediatric low-grade glioma (pLGG) treated with the type II RAF inhibitor tovorafenib in FIREFLY-1. First Author: Olaf Witt, Hopp Children's Cancer Center Heidelberg (KiTZ), German Cancer Research Center (DKFZ), Heidelberg University Hospital, German Cancer Consortium (DKTK), National Center for Tumor Diseases (NCT), Heidelberg, Germany

Background: Targeted therapies have become a mainstay in the treatment of pLGG. While effective, toxicities, including cutaneous adverse events (AEs), are common. Tovorafenib received accelerated FDA approval in April 2024 for the treatment of *BRAF*-altered r/r pLGG in pts $\geq$6 months of age based on FIREFLY-1 (NCT04775485) trial results. Maculopapular rash, dermatitis acneiform, and erythematous rash were the most commonly reported rashes (Kilburn LB, et al. *Nat. Med.* 2024). An update on the incidence, recurrence, and resolution of rash AEs in pts who received tovorafenib in FIREFLY-1 is provided. **Methods:** This post hoc analysis included 137 pts with pLGG (arm 1/registrational: 77; arm 2/extension: 60) treated with $\geq$1 dose of tovorafenib. Treatment-emergent rashes, graded by investigators, were grouped as maculopapular/erythematous/eczematous (M/E/E) or acneiform/pustular (A/P) (May 10, 2024 data cutoff). A rash episode included all rash events occurring over continuous days. A new rash was any subsequent episode occurring a day or more after the prior episode end date. **Results:** Median duration of tovorafenib treatment was 21.0 months (mos). 93% (128/137) of pts had a treatment-emergent rash. Of those, 59% (76) had only M/E/E rashes, 11% (14), only A/P rashes, and 30% (38), both types. As expected, A/P rashes occurred more often in pts $\geq$12 years of age (y/a). The rash was graded as G1 in 36% (46), G2 in 50% (64), and G3 in 14% (18) of pts. Most experienced 1 (53% [68]) or 2 (31% [40]) rash episodes. First rash episode median time to onset (TTO) was 0.43 mos, with 47% (60) G1, 41% (52) G2, and 13% (16) G3. First rash episodes resolved for 74% (95/128) of pts within a median of 2.67 mos. Resolution of first rash was more common among pts with M/E/E vs A/P rashes. Among any rash episodes (27% [58/219]) that remained unresolved, final severity was G1 (22% [48/219]) or G2 (5% [10/219]). All G3 rashes resolved. 47% (60) of pts experienced $\geq$2 rash episodes, of which 82% (49) were the same/lower grade episode. Of the 11 pts with a more severe second episode, 8 (73%) resolved completely. 80% (102) of pts received standard of care (SOC) treatments for rash, primarily topical steroids/antibiotics, oral antihistamines, and emollients. Only 1 (1%) pt had a rash-related tovorafenib discontinuation. 18% (23) of pts had dose interruptions due to rash. 11% (14) of pts had a dose reduction due to rash; of those, 57% (8) required no additional dose reductions due to rash. **Conclusions:** Rashes were common in pts treated with tovorafenib in FIREFLY-1. They typically occurred early in treatment, most were G1 or G2, resolved within a median of ~3 mos, and were manageable with SOC treatment and/or tovorafenib dose modifications. A/P rashes occurred more frequently in pts $\geq$12 y/a; there were no other significant trends in rashes experienced between the two age groups. Clinical trial information: NCT04775485. Safety and efficacy of pucotenlimab combined with standard chemotherapy regimens in the neoadjuvant treatment of pediatric patients with intermediate or high-risk rhabdomyosarcoma: A phase I/II study. First Author: Yi Que, Sun Yat-sen University Cancer Center, Guangzhou, Guangdong, China

Background: Previously, we defined the pathological complete response rate (pCR) for pediatric patients with intermediate or high-risk rhabdomyosarcoma who underwent preoperative chemotherapy alone (SIOP- 2024-ID 582). In this study, we aimed to determine the effect of preoperative pucotenlimab combined with the standard chemotherapy regimen as neoadjuvant treatment on the safety and pCR of rhabdomyosarcoma. **Methods:** In this single-arm phase I/II trial (NCT06456892), patients with rhabdomyosarcoma received neoadjuvant chemoimmunotherapy with pucotenlimab combined with standard chemotherapy intravenously on the first day of each three-week cycle for three cycles. During the dose-escalation phase, patients were infused with pucotenlimab at doses of 1, 3, and 6 mg/kg respectively. The primary endpoints in phase I were dose-limiting toxicities (DLTs) as well as the evaluation of safety and tolerability. Secondary endpoints included pathological complete response (pCR), major pathological response (MPR), and survival outcomes. **Results:** Herein, we report the adverse events and pCR in the phase I study. At the time of data analysis, the survival outcomes were not yet mature. Between June 2024 and September 2024, 15 patients were enrolled and received neoadjuvant chemoimmunotherapy. Among them, 7 patients have proceeded to surgical resection. The pCR rate was 3/7 (42.9%) , and 1/7 (14.3%) patients achieved an mPR. Treatment-related adverse events of grade 3 or 4 occurred in 11 patients , which mainly due to the chemotherapy. By the safety data cutoff, no DLTs were observed in the three dose groups. Most immune-related adverse events were grade 1 or 2, including hyperthyroidism (2/15), hypothyroidism (1/15), and fever (11/15). **Conclusions:** This study demonstrates the safety and potential efficacy of neoadjuvant pucotenlimab plus chemotherapy, with an acceptable safety profile, in patients with pediatric rhabdomyosarcoma. Clinical trial information: NCT06456892. Research Sponsor: None.

Summary of safety profile of 15 patients received pucotenlimab combined with the standard chemotherapy regimen.

Adverse effects	Grade 1	Grade 2	Grade 3	Grade 4

Irinotecan, temozolomide and naxitamab plus GM-CSF (HITS) and naxitamab plus GM-CSF and ifosfamide, carboplatin, etoposide (NICE) for patients with relapsed or refractory high-risk neuroblastoma: A single center, open-label phase 2 clinical trial. First Author: Jaume Mora, Hospital Sant Joan de Deu, Barcelona, Spain

Background: Patients with relapsed/refractory (R/R) high-risk neuroblastoma (HR-NB) have a poor prognosis, underscoring the need to explore new therapies. In this single institution, Phase 2 clinical trial (EudraCT 2020-000538-17), we evaluated the safety and efficacy of HITS and Naxitamab (NAX) in combination with ICE (NICE) in patients (pts) with R/R HR-NB with incomplete response (partial response (PR), minor response (MR), or stable disease (SD)) to HITS. **Methods:** Eligible pts received 2-4 cycles of HITS. Patients achieving a complete response (CR as per 2017 INRC) to HITS after 2 or 4 cycles had the CR consolidated with 5 cycles of NAX+GM-CSF. Patients with an incomplete response to HITS transitioned to NICE (up to 4 cycles) and those with progressive disease (PD) discontinued. CRs to NICE were consolidated with 5 cycles of NAX+GM-CSF. HITS consisted of Irinotecan 50 mg/m2/day IV from day 1-5 concurrently with temozolomide 150 mg/m2/day orally; NAX 2.25mg/kg IV on days 2, 4, 9 and 11; and GM-CSF 250 mcg/m2/day SC on days 7-11. NICE cycles consisted of NAX 2.25 mg/kg IV on days 2, 4, 9 and 11; GM-CSF 250 mcg/m2/day SC on days 7-11; ifosfamide 1.5 gr/m2/day IV from day 1-3 concurrent with etoposide 100 mg/m2/day IV and carboplatin 400 mg /m2/day IV on day 1. HITS/NICE cycles were administered out/inpatient, respectively. NAX was infused according to the Step-Up protocol. Treatment cycles were repeated every 4 weeks. Follow-up continued quarterly after end of treatment visit for up to 3 years. **Results:** From September 2020 until December 2022, 47 patients were screened and 34 enrolled. Of the 34 pts, 2 (5.9%) had primary refractory and 32 (94.1%) relapsed refractory disease. Prior treatments included chemotherapy (34; 100%); surgery (29; 85.3%); radiotherapy (17; 50%); autologous stem cell transplant (11; 32.4%); and anti-GD2 immunotherapy (15; 44.1%. 11 NAX and 4 dinutuximab beta). Of the 19 pts with an incomplete response after HITS, 13 (68.4%) received at least one cycle of NICE, and 5 completed all therapy. For HITS, the objective response rate (ORR) was 50% and best overall response (OR) was CR = 8 (23.5%); PR = 9 (26.5%); SD = 10 (29.4%); and PD = 7 (20.6%). For NICE ORR was 53.8% and OR: CR = 2 (15.4%); PR = 5 (38.5%); and SD = 6 (46.2%). No treatment related deaths occurred. All pts receiving NICE experienced grade 3-4 AEs (most frequent were pain (29.5%); urticaria (27.4 %); and thrombocytopenia (6.8%)), one leading to treatment discontinuation. **Conclusions:** Our clinical trial results suggest different chemotherapy combinations with naxitamab have the potential to rescue patients with R/R HR-NB. No unexpected toxicities were found when combining NAX with different chemotherapeutic agents. Clinical trial information: EudraCT 2020-000538-17. Research Sponsor: None.

Pembrolizumab in pediatric participants with relapsed or refractory microsatellite instability-high solid tumors: Results from the phase 1/2 KEYNOTE-051 trial. First Author: Alberto S. Pappo, St. Jude Children's Research Hospital, Memphis, TN

Background: KEYNOTE-051 (NCT02332668) is an open-label, multicohort, phase 1/2 study evaluating pembrolizumab in children with advanced cancers. Results from participants with melanoma, PD-L1–positive solid tumors, or PD-L1–positive lymphomas showed pembrolizumab had a manageable safety profile, encouraging antitumor activity in relapsed or refractory (R/R) Hodgkin lymphoma, and limited efficacy in most other tumor types. Here, we present results from the cohort of participants with R/R microsatellite instability–high (MSI-H) solid tumors. **Methods:** Eligible participants were aged 6 months to <18 years and had advanced R/R MSI-H solid tumors determined locally by immunohistochemistry or polymerase chain reaction, measurable disease per RECIST v1.1, and a performance status of ≥50. All participants received pembrolizumab 2 mg/kg (up to a maximum of 200 mg) every 3 weeks for up to 35 doses or until other discontinuation criteria were met. The primary end points were safety and objective response rate (ORR) per RECIST v1.1 by investigator. Secondary end points included duration of response, disease control rate (DCR), and progression-free survival (PFS) per RECIST v1.1, and overall survival (OS). **Results:** Seven participants with MSI-H solid tumors were enrolled and received treatment. At the data cutoff (Jan 18, 2022), 6 had discontinued treatment and 1 was ongoing. Median age was 11.0 years (range, 3-16), 5 were female, 6 had a central nervous system malignancy (glioblastoma, n = 4; anaplastic astrocytoma, n = 1; high-grade glioma, n = 1), and 1 had an adenocarcinoma. Median time from first dose to data cutoff was 27.6 months (range, 0.3-47.5). Treatment-related AEs occurred in 3 participants; grade 3 or 4 events occurred in 1 participant and included grade 4 lymphocyte count decreased and grade 3 pyrexia. No participants died due to AEs. The ORR per RECIST v1.1 was 0% (95% CI, 0-41); the DCR was 14% (95% CI, 0-58), with 1 participant with adenocarcinoma exhibiting stable disease. Among 6 participants with a postbaseline assessment, 2 had any reduction from baseline in target tumor size, of whom 1 had a reduction of ≥30%. Median PFS was 1.7 months (95% CI, 0.4-NR); 6-month PFS was 17%. Median OS was 7.7 months (95% CI, 1.9-NR); 6-month OS was 50%. One participant with glioblastoma had a complete response at cycle 6 after initial progression, and the complete response was maintained through cycle 20. **Conclusions:** The safety profile of pembrolizumab in children with MSI-H R/R solid tumors was manageable and consistent with other tumor types. One participant with glioblastoma had a prolonged complete response after initial progression. Further evaluation of pembrolizumab in pediatric MSI-H central nervous system malignancies is ongoing. Clinical trial information: NCT02332668. Research Sponsor: Merck Sharp & Dohme LLC, a subsidiary of Merck & Co., Inc., Rahway, NJ, USA.

Socioeconomic disparities in survival outcomes among children with non-metastatic Ewing sarcoma treated on upfront Children's Oncology Group clinical trials. First Author: Rahela Aziz-Bose, Dana-Farber/Boston Children's Cancer and Blood Disorders Center, Boston, MA

Background: Poverty is emerging as an adverse risk factor for relapse and death across many pediatric cancers. Socioeconomic disparities have not been comprehensively investigated in Ewing sarcoma. We leveraged Children's Oncology Group (COG) data to investigate socioeconomic disparities in survival outcomes in children with non-metastatic Ewing sarcoma treated on upfront phase III clinical trials from 2001-2005 and 2010-2017. **Methods:** This was a retrospective cohort study of US patients aged 0-21 years with non-metastatic Ewing sarcoma enrolled on COG AEWS0031 and AEWS1031. The analytic cohort was restricted to participants with complete data on exposures and covariates. Poverty was the primary exposure of interest, defined at the household (sole means-tested public insurance) and neighborhood (census-defined high-poverty ZIP code with ≥20% of population below 100% Federal Poverty Level) levels. Cox proportional hazards regression models evaluated associations between poverty exposures, event-free survival (EFS), and overall survival (OS) from time of trial enrollment. Multivariable models adjusted for age (as a continuous variable), sex, race/ethnicity (non-Hispanic White vs Other), initial tumor volume (≤200 ml vs > 200 ml), primary disease site (pelvic/non-pelvic/extraosseous), and assignment to interval compressed chemotherapy (yes/no). **Results:** Among 551 complete cases, 23% (n = 128) were household poverty-exposed and 19% (n = 106) were neighborhood poverty-exposed. Median age at trial enrollment was 12 years; median event-free follow-up time was 8.7 years. In multivariable models, household poverty-exposed children experienced a 52% increased hazard of EFS-event compared to unexposed children (adjusted hazard ratio [aHR] 1.52, 95% CI 1.03, 2.26, p = 0.04), and a 64% increased hazard of death compared to unexposed (aHR 1.64, 95% CI 1.03, 2.62, p = 0.04). Neighborhood poverty-exposure was not associated with increased hazard of EFS or OS event. **Conclusions:** Household poverty, as proxied by public insurance, is an adverse risk factor for EFS-event and death among children and young adults with non-metastatic Ewing sarcoma despite standardized treatment on national clinical trials. Investigation of mechanisms driving these disparities—including treatment delays and differential local control approaches—is ongoing. These data highlight an immediate need to evaluate poverty-targeted interventions alongside new therapeutic agents to improve outcomes. Research Sponsor: None.

HLA allele, TCR V- and J-gene segment usage combinations and their association with survival in neuroblastoma. First Author: Eddie Fung, USF Morsani College of Medicine, Tampa, FL

Background: Neuroblastoma has variable outcomes across different risk groups. In children with stage 4 neuroblastoma, five-year overall remains around 50% in high-risk children despite the emergence of anti-GD2 antibodies. T- and NK-cell infiltration is prognostic in therapy-resistant neuroblastoma, and higher HLA class I expression is linked to better overall survival (OS). In other cancers, specific HLA alleles and T-cell receptor (TCR) V, J- gene segments have been associated with survival. Thus, we conducted a retrospective study in stage 4S neuroblastoma patients to assess whether specific HLA allele, TCR V- and J-gene segment usage combinations correlated with OS in NBL. Among combinations that were associated with OS, we also identified changes in expression of immune marker genes. **Methods:** We obtained HLA allele data from exome files of the TARGET-NBL dataset using the xHLA software. The TCR recombination reads were obtained from the TARGET-NBL RNAseq files representing tumor specimens from 99 cases, utilizing a high-stringency search algorithm. The TCR recombination reads were translated, and the complementarity determining region-3 (CDR3) amino acid sequences were obtained. HLA and TCR datasets were integrated to assess OS probabilities, comparing cases with and without specific HLA allele, TCR V- or J-gene usage combinations. Significance was determined only if independent HLA allele or V- and J-gene usage assessments were not statistically significant, but significant in the corresponding HLA allele, TCR V- or J-gene segment usage combinations. HLA allele and TCR usage combinations were grouped by association with better or worse OS probabilities, and immune marker gene expression correlations were assessed via Student's t-test and Mann-Whitney U test with a Bonferroni-corrected threshold of p = 0.00114. **Results:** We identified 73 HLA allele, TCR V- and J-gene usage combinations with significant OS distinctions: 20 associated with improved OS and 53 with worse OS. For example, 20 TARGET-NBL cases with the HLA-DQB1*04:02 and TRAJ29 usage combination did not reach the median compared to the 1319-day OS median for all remaining cases (log-rank p = 0.009). Among the cases with at least one HLA allele, TCR V- or J-gene segment usage combination with improved OS, we found that the RNAseq values for the immune markers *CD4, CD22, CD38, RPH1*, *TNFRSF17*, and *TNFRSF13B* were upregulated, as assessed via a Mann-Whitney U analysis. **Conclusions:** Identifying specific HLA allele, TCR V- and J- gene segment usage combinations associated with survival may further indicate patients who could benefit from immunologic-boosting treatments. Studies employing functional assays, immunogenomic profiling, and targeted immune pathway analyses may advance immunotherapeutic strategies and predictive biomarkers for neuroblastoma, particularly in high-risk patients. Research Sponsor: None.

MYC amplification and protein expression as prognostic markers in pediatric and young adult osteosarcoma. First Author: Matthew Nagy, Boston Children's Hospital, Boston, MA

Background: Risk stratification in osteosarcoma relies on metastatic status and tumor necrosis after chemotherapy. Despite a complex genomic landscape, genomic biomarkers are not yet used for predicting therapy response. *MYC* amplification has previously been identified as a potential biomarker for chemotherapy resistance but studies of MYC expression are limited. This study evaluated the relationship between *MYC* amplification and protein expression and between these biologic features and survival in pediatric and young adult osteosarcoma. **Methods:** In a cohort of 93 patients with high-grade osteosarcoma, *MYC* copy number was evaluated using a targeted sequencing panel, and MYC protein expression was quantified via IHC with an H-Score. The relationship between copy number and protein expression were evaluated via spearman correlation. Amplification (AMP) was defined as > 7 copies, and high expression (EXP) as > 175 H-score. The primary outcome, overall survival (OS), was assessed using Kaplan Meier analysis (median [IQR]) for unadjusted models and cox proportional hazard analysis (HR±SE) with models adjusted for metastatic status at diagnosis. **Results:** Among the 93 patients, 64% were male, with a median age of 14 years [range: 4–29]. *MYC* AMP was present in 16 (17%) patients, high MYC EXP in 19 (20%), and both AMP + high EXP in 8 (9%) patients. Copy number status was positively correlated with expression (r = 0.57, p < 0.0001). Patients with AMP were more likely metastatic at diagnosis (75% vs 38%, p = 0.011) and more so for AMP + high EXP (100% vs 39%, p = 0.0009), but not high EXP alone (63% vs 39%, p = 0.11). OS was reduced for AMP compared to non-AMP (median OS: 1.3 [1.0, 2.6] vs 6.2 [2.8, 12.8] years, p < 0.0001; Adj HR 3.2±0.4, p = 0.001) and high EXP compared to low EXP (median OS: 1.5 [1.0, 3.1] vs. 6.2 [2.8, 12.8] years, p < 0.0001; Adj HR 5.6±0.4, p < 0.0001). A dose-response relationship was seen with higher copy number or expression linked to reduced OS. Compared to non-AMP + low EXP (median OS: 7.23 [3.1, 12.8] years) there was reduced OS for AMP-only/high EXP-only (median OS: 3.1 [2.0, 4.0] years, p = 0.01; Adj HR 2.8±0.4, p = 0.009) and further reduced OS for AMP + high EXP (median OS: 1.0 [0.5, 1.0] years, p < 0.0001; Adj HR 15.3±0.5, p < 0.0001). Metastasis at diagnosis predicted reduced OS compared to localized disease (median OS: 2.0 [1.0, 4.5] vs 6.2 [4.0, 12.8] years, p < 0.0001), but age, sex, and tumor necrosis were not associated with OS. **Conclusions:** *MYC* amplification and protein expression are positively correlated, and both independently and synergistically predict poor OS in osteosarcoma, even after adjusting for metastatic status at diagnosis. Incorporating *MYC* amplification and expression status into risk stratification may help identify patients with worse prognosis. These data also underscore the need for therapeutic approaches tailored to the genetic basis of osteosarcoma tumor biology. Research Sponsor: None.

Updated data of efficacy and safety of luvometinib (FCN-159) in pediatric participants with neurofibromatosis type 1 from a multi-center, open-label, single-arm phase 2 study. First Author: JinHu Wang, The Children's Hospital of Zhejiang University School of Medicine, Hangzhou, China

Background: Neurofibromatosis type 1 (NF1) is an autosomal dominant genetic disease characterized by multiple progressive tumor and non-tumor manifestations, with abnormal activating MAPK pathway. Plexiform neurofibromas (PN) presents in 20-50% of NF1 patients (pts) and may cause serious complications. One MEK1/2 inhibitor was approved for pediatric pts with NF1-related PN in US, EU and China, but therapeutic options remain limited. Luvometinib is a highly potent selective anti-tumorigenic inhibitor of MEK1/2, potentially effective in NF1-related PN. Previous studies have confirmed that luvometinib is expected to be a targeted therapy for neurofibromatosis type 1 in pediatric patients (pts). **Methods:** This multi-center, open-label phase 2 clinical trial is to assess safety and efficacy of luvometinib in pediatric pts with NF1- related PN. The primary endpoint was objective response rate (ORR) evaluated by investigators (INV). The key secondary endpoint was ORR evaluated by Blinded independent review committee (BIRC), and other secondary endpoints include 1-year PFS and others. Preliminary findings from the phase 2 trial were previously disclosed at ASCO 2024. Here, we present the updated efficacy and safety results in pediatric participants. **Results:** As of data cut-off (September 23, 2024), 46 pediatric pts were enrolled and treated with a dose of 5 mg/m^2 (the recommended phase 2 dose according to phase 1 study). The median follow-up time was 25.1 months. ORR evaluated by INV was 60.5% (95%CI: 44.4, 75.0), and 26 pts had partial response. ORR evaluated by BIRC was 44.2% (95%CI: 29.1, 60.1), and 19 pts had partial response. 11 of 14 pts (78.6%) with tumor pain at baseline (overall tumor pain NRS$\geq$2) decreased to 0 points. The median DOR and median PFS were still not reached. 1-year PFS rate evaluated by INV was 95.3%. 45 pts (97.8%) experienced treatment-related adverse events (TRAEs). Among these, grade $\geq$3 TRAEs occurred in 10 pts (21.7%), including folliculitis(4.3%), dermatitis acneiform (4.3%), blood creatine phosphokinase increased (4.3%), ejection fraction decreased (2.2%), upper respiratory tract infection (2.2%), pneumonia (2.2%), anemia (2.2%) and gastrointestinal disorders (2.2%). 2 pts (3.1%) reported treatment-related serious adverse events. 14 pts (30.4%) experienced TRAEs led dose interruption. No reported TEAE led to dose reduction, discontinuation or death. No new safety signal was observed. **Conclusions:** Overall, luvometinib was well-tolerated and demonstrated promising anti-tumor activity in pediatric participants with NF1-related PN. Long-term efficacy and safety follow-up are ongoing. Clinical trial information: NCT04954001. Research Sponsor: Shanghai Fosun Pharmaceutical Industrial Development Co., Ltd.

***MYC* amplification as a prognostic biomarker in osteosarcoma: A report from the Children's Oncology Group.** First Author: Sarah Whittle, Texas Children's Cancer Center/Baylor College of Medicine, Houston, TX

Background: Osteosarcoma is characterized by complex chromosomal alterations and genomic instability. *MYC* copy number (CN) gains are observed in 10%-60% of cases, and *MYC* amplification is associated with poor outcomes in single-center cohorts and genomic studies of relapsed or high-risk patients. This study aimed to validate the prognostic role of *MYC* amplification in a large, multi-center cohort of patients enrolled on Children's Oncology Group (COG) up-front treatment and biobanking protocols. We also assessed other genes linked to survival. **Methods:** This retrospective, IRB-approved case-control study used banked FFPE DNA from 137 osteosarcoma samples from the COG biorepository for SNP microarray (Affymetrix OncoScan). Patients were enrolled on INT-0133, P9754, AOST0331 and APEC14B1 from 1993-2024. Amplifications of *MYC, CCNE1*, *CDK4*, and the 6p21.1 locus, as well as chromosome 6, 8, 12, and 19 ploidy were assessed. Gene amplification was defined as the ratio of gene to chromosome copies (e.g. *MYC* CN/chr8 CN) $>$ 2.0. The primary outcome was occurrence of event-free survival (EFS) event. Patients were matched on metastatic status and follow-up time. Univariate conditional logistic regression models were fit for each genetic feature to obtain the odds ratio (OR) of EFS event associated with amplification (95% confidence interval (CI)) and to conduct one-sided tests for the null hypothesis OR £ 1 at the 5% level. **Results:** Sixty-five case-control pairs for *MYC, CDK4*, and 6p21.1, and 63 for *CCNE1* were analyzed. *MYC* amplification was estimated to have a 1.87-fold increase in odds of EFS event (95% CI: 0.79, 4.42; p = 0.08). *CDK4* amplification was associated with a 5-fold increase in odds of event (95% CI: 1.10, 22.82; p = 0.02). Neither amplification of 6p21.1 or *CCNE1* were associated with increased odds of event, with ORs of 1.33 (95% CI 0.56, 3.16; p = 0.26) and 0.73 (95% CI: 0.29, 1.81; p = 0.25), respectively. **Conclusions:** *MYC* amplification may be associated with increased odds of EFS event in this cooperative group cohort. Though the result did not reach statistical significance, this finding aligns with prior studies demonstrating increased EFS-event risk for patients with *MYC* amplification. While our selection of a ratio cut point $>$ 2.0 to define amplification was informed by prior studies, the optimal cut point has not been determined and cut points may be assay dependent. Although *CDK4* amplification appears associated with increased odds of event, confidence in this finding is limited by a sparse-data bias, due to a low number of control patients with *CDK4* amplification. Future analyses will explore *MYC* and *CDK4* copy number ratio as a continuous variable and assessing the relationship between additional genomic features and EFS events in this population. Research Sponsor: Children's Oncology Group.

A phase I dose-escalation study to assess the oncolytic virus VCN-01 safety and efficacy in refractory retinoblastoma patients. First Author: Jaume Català-Mora, Hospital Sant Joan de Deu, Barcelona, Esplugues De Llobregat. Barcelona, Spain

Background: Preclinical work demonstrated antitumor activity of VCN-01 (oncolytic adenovirus targeting the E2F pathway and expressing hyaluronidase) for retinoblastoma. We report this first-in-children study aiming to assess its safety and efficacy. **Methods:** Patients with intraocular retinoblastoma who failed conservative therapy facing imminent enucleation were eligible for this phase I, dose-escalation study (NCT03284268) with two dose levels of VCN-01 intravitreal injection (2E+9 vp/eye per dose for the first patient) and 2E+10 vp/eye dose in two doses every two weeks for the remaining 8. Dose limiting toxicity (DLT) was defined as $\geq$ grade IV ocular toxicity or $\geq$ grade III systemic toxicity according to CTCAEv04. Response assessed by RB-RECIST criteria and toxicity were evaluated at day 42 of the first injection. **Results:** Thirteen patients (4 screening failures) were enrolled. Out of the 9 treated patients, five had bilateral retinoblastoma. There was no DLT. 7/9 patients experienced adverse reactions. being uveitis the most common (7/9 patients, G3 in four). From the second patient onwards, all patients received pre-emptive oral and/or topical steroids to prevent uveitis. Uveitis was improved or resolved at day 42 in 7 patients. One patient with G3 uveitis did not receive the second dose because of medical decision and also experienced glaucoma requiring treatment. No systemic toxicities occurred. VCN-01 caused reversible changes in electroretinograms due to turbidity. Viral particles were not found in the healthy retina in enucleated eyes. No VCN-01 genomes in peripheral blood were detected in any case. At 42 days of the first injection, 5 patients achieved partial response, 3 stable disease and one progressive disease. Subsequent eye-conservative treatment was administered to 5 patients and 3 eyes are preserved with vision (follow-up 12-49 months). The remaining 6 eyes were enucleated because of refractory tumor. No extraocular relapse occurred. **Conclusions:** VCN01 was safe, being uveitis the most common adverse effect. VCN-01 did not cause retinal toxicity. The response in these heavily pre-treated eyes was encouraging. Clinical trial information: NCT03284268. Research Sponsor: None.

Multi-omics evaluation of relapsed pediatric cancers: What information do these sequential analyses yield? First Author: Caroline Bellavance, Département de Pédiatrie, CHUS, Université de Sherbrooke, Sherbrooke, QC, Canada

Background: While cure rates for children with cancer have significantly improved, relapses remain a challenge, requiring deeper understanding to address them. Nowadays, genomic analyses are widely used at diagnosis and in relapse settings, becoming a standard-of-care in pediatric. The aim of this study is to describe the genomic evolution of relapsed pediatric tumors in search of clonal selection and pathway identification. We also want to assess the clinical value of these new data obtained in relapsed tumors. **Methods:** This is a retrospective analysis from canadian pediatric oncology precision medicine projects. We selected patients aged $<$ 30 years with sequencing data available at diagnosis and relapse. Clinical and genomic data were collected, and each patient was paired with a non-relapsed patient. The incidences of genomic alterations were compared in the two populations and for each patient. For patients who relapsed, patient-adjusted longitudinal mixed models assessed differentially expressed genes at relapse vs diagnosis. Gene set enrichment analyses were performed, using GLMMSeq results, to study metabolic pathways that undergo significant dysregulation over time ($p < 0.05$). Electronic surveys were sent to the treating physicians of relapsed patients. **Results:** A total of 45 patients with 1 or more relapses were compared with 44 patients without relapse. Longitudinal analysis was performed on 35 relapsed patients. Our population has a median age of 10 y.o., a majority had leukemia (47 %) or sarcoma (31%). Among relapsed patients, the mutational burden at diagnosis was 0.82 mut/MB and 1.21 mut/MB at first relapse, compared with 0.47 mut/MB in non-relapsed patients (p = 0.02). 33% of relapsed patients had or acquired a TP53 alteration, compared with 16% without relapse (p = 0.084). MAPK pathway alterations were more prevalent among relapsed patients (p = 0.004). Longitudinal analyses showed enrichment in MAPK pathway at relapse. Other pathways were also significantly enriched at relapse (Wnt, TP53, TNFa, TGFb), while immune pathways (immunoglobulin/lymphocyte complex and activation) were downregulated. Although, 45% of clinicians considered that genomic analysis at relapse was useful, only 18% actually integrated the genomic data into clinical decisions due to better options available than targeted therapies. Indeed, when targeted therapies were used as proposed, it was mostly for a 2nd or 3rd relapse and for sarcoma. **Conclusions:** This study describes the evolution of the genomic landscape, showing an enrichment in mutation and pathways, and increased mutational burden in relapsed pediatric tumors. Longitudinal differential analyses brought more information about genomic evolution than the usual genomic reports sent to clinicians. Overall, the analyses performed are useful for clinicians, and a small subset of patients benefited from this information to guide therapies. Research Sponsor: None.

Efficacy, safety and pharmacokinetics (PK) of zurletrectinib, a next-generation pan-TRK inhibitor, in pediatric and adolescent patients (pts) with NTRK fusion-positive (NTRK+) solid tumors. First Author: Yizhuo Zhang, Sun Yat-sen University Cancer Center; State Key Laboratory of Oncology in South China; Collaborative Innovation Center for Cancer Medicine, Guangzhou, Guangdong, China

Background: NTRK gene fusions are significant oncogenic drivers in pediatric tumors (e.g. infantile fibrosarcoma). Zurletrectinib is a highly selective next-generation TRK inhibitor. Preclinical data of zurletrectinib showed strong activity against resistant mutations, e.g., G595R. Promising efficacy was observed in a phase I/II clinical trial (NCT04685226). The pivotal phase II clinical trial (NCT05745623) is currently ongoing. Here we report an integrated analysis by combining pediatric and adolescent pts from the two clinical trials. **Methods:** Eligible pts with locally advanced or metastatic solid tumor harboring NTRK fusions, who failed from standard of care or for whom there was currently no effective therapy were included in the efficacy analysis. Adolescent pts (12-18 years) received zurletrectinib tablet at fixed dose, and pediatric pts ($<$ 12 years) received zurletrectinib orally disintegrating tablet (ODT) based on body surface area (BSA). The primary endpoint was confirmed objective response rate (ORR) per independent review committee (IRC). Tumor responses were assessed by IRC and investigators per RECSIT1.1 and RANO (BM) criteria. Treatment-emergent adverse events (TEAEs) were evaluated and graded according to CTCAE v5.0. **Results:** As of 23 Nov 2024, 18 pts in total were enrolled, including 8 pediatric pts and 10 adolescent pts. Median age was 5.0 (range: 3-9) and 13.5 (range: 12-15) respectively. ECOG performance status was between 0-1. Among the 18 pts, 6 TRK inhibitor treatment-naïve pts with central lab confirmed NTRK+ were efficacy evaluable. The confirmed ORR assessed by IRC was 100% (95% CI 54.1, 100.0). All of the pts achieved partial response (PR) at the 1st tumor assessment and maintained the remission as of the cutoff date. Median time to response were 1.0 month (95% CI: 0.99, NE) in adolescent pts and 0.9 (95% CI: 0.89, NE) month in pediatric pts. It is worth noting that one pediatric patient who progressed on prior first-generation TRK inhibitor achieved complete response after receiving zurletrectinib. The most common treatment related adverse events (TRAEs) were ALT increased (n = 8) and anemia (n = 6), the majority of which were Gr 1 or 2. There were no TRAEs leading to dose reduction or discontinuation, and no serious TRAEs were reported. PK results indicated that zurletrectinib PK profiles in pediatrics and adolescents at the recommended phase 2 dose (RP2D) were similar to that in adults. **Conclusions:** The integrated analysis demonstrated that zurletrectinib had significant efficacy and good safety profile in pediatric and adolescent pts with NTRK+ solid tumors. Zurletrectinib also showed the potential to overcome the resistance to 1st generation TRK inhibitors. These findings support zurletrectinib is a better treatment option for NTRK+ pediatric and adolescent pts. Clinical trial information: NCT04685226. Research Sponsor: Beijing InnoCare Pharma Tech Co., Ltd, Beijing, China.

Phase I study of mitoxantrone hydrochloride liposome in relapsed and refractory pediatric tumors. First Author: Junting Huang, Sun Yat-sen University Cancer Center; State Key Laboratory of Oncology in South China; Collaborative Innovation Center for Cancer Medicine, Guangzhou, Guangdong, China

Background: Compared with solvent-based mitoxantrone, mitoxantrone hydrochloride liposome has been found to reduce bone marrow toxicity. This open-label, single-arm phase I clinical trial was designed to evaluate the safety and efficacy of mitoxantrone hydrochloride liposome monotherapy in the treatment of pediatric tumors. **Methods:** To explore the maximum tolerated dose (MTD) of mitoxantrone liposome in pediatric cancer patients, using a "3+3" design, patients received three dose levels (16mg/m^2, 20mg/m^2, 24mg/m^2, d1) of mitoxantrone hydrochloride liposome monotherapy every 3 weeks. Patients were observed for dose-limiting toxicity (DLT) during the first cycle. The primary endpoint was MTD, and the secondary endpoints included objective response rate (ORR) and disease control rate (DCR), DLT, adverse events (AE), etc. **Results:** From October 2022 to September 2023, total of 7 pediatric cancer patients were enrolled and completed treatment, of which 6 patients received 16mg/m^2 and 1 patient received 20mg/m^2 mitoxantrone liposome monotherapy. The median age of the patients was 13.0 years (range: 8.0, 17.0). The tumor types included soft tissue sarcoma, hepatoblastoma, T-cell lymphoma, etc. The median number of treatment cycles was 2.0 (range: 1.0, 6.0). 1 patient (16mg/m^2 dose group) developed DLT, which was a grade 3 febrile neutropenia lasting more than 7 days after G-CSF. All patients could be evaluated for toxicity, and 5 patients could be evaluated for efficacy based on imaging findings. The AE of all grades with high incidence ($\geq$50%) were white blood cell decreased (85.7%), anemia (71.4%), neutrophil count decreased (71.4%), platelet count decreased (57.1%), and anorexia (57.1%), respectively. The overall safety was acceptable. Six patients (85.7%) discontinued treatment early, of which 3 (42.9%) were due to disease progression confirmed by imaging, and 3 (42.9%) were due to limited efficacy considered by the investigators. The overall ORR and DCR were 20% (95%CI: 0.5%-71.6%) and 40% (95%CI :5.3%-85.3%), respectively. After the observation of 7 patients, the investigators thought that the efficacy of mitoxantrone liposome monotherapy was not as expected, and the study protocol was revised to continue the study of mitoxantrone liposome combined therapy. **Conclusions:** Mitoxantrone liposome has an acceptable safety profile in pediatric cancer patients, but the preliminary efficacy is not up to expectations, and further studies on combination therapy are needed. Clinical trial information: NCT05620862. Research Sponsor: CSPC Ouyi Pharmaceutical Co., Ltd.

Updated efficacy and safety of entrectinib in children with extracranial solid or primary central nervous system (CNS) tumors harboring *ROS1* fusions. First Author: Ami V. Desai, University of Chicago Medical Center, Chicago, IL

Background: Entrectinib is a TRK and ROS1 inhibitor that has shown rapid and durable responses in children with *NTRK1/2/3* or *ROS1* fusion-positive (fp) extracranial solid or primary CNS tumors in an integrated analysis of the STARTRK-NG (NCT02650401), TAPISTRY (NCT04589845) and STARTRK-2 (NCT02568267) trials. These data led to FDA and EMA approval of entrectinib in pediatric patients $>$ 1 month with NTRK fp tumors. Here we present updated data on pediatric patients with ROS1 fp tumors based on the trials listed above to further describe the efficacy and safety of entrectinib in this population. **Methods:** Eligible pts were TRK/ROS1 inhibitor-naïve, $<$ 18 years old, with locally advanced/metastatic extracranial solid or primary CNS tumors, with measurable or evaluable-only disease. All pts who received $\geq$1 daily dose of oral entrectinib are included in the safety-evaluable population. Pts who had a ROS1 fusion and were followed for $\geq$6 months are included in the ROS1 efficacy-evaluable population. Pts received entrectinib until disease progression, unacceptable toxicity, or consent withdrawal. Tumor responses were confirmed by blinded independent central review (BICR) per RECIST v1.1 or RANO criteria. Primary endpoint: confirmed objective response rate (ORR) per BICR. Key secondary endpoints: ORR in pts with baseline measurable disease per BICR; duration of confirmed response (DoR); time to confirmed response (TTR); clinical benefit rate (CBR); progression-free survival (PFS); overall survival (OS); safety. **Results:** At clinical cut-off (16 July 2024), of the 113 safety-evaluable pts, there were 26 pts in the *ROS1* efficacy-evaluable cohort. ORR was 69.2% (95% CI 48.2, 85.7). Median TTR was 1.84 months. Median OS was not evaluable. Median duration of survival follow-up was 29.4 months (range 1–80). Efficacy outcomes are shown in the table. The most common related adverse events were weight gain (37.2%), anemia (36.3%), and AST increase (26.5%). Related fracture events occurred in 23% of pts. **Conclusions:** Entrectinib yielded rapid and durable responses in pediatric pts with *ROS1* fp extracranial solid or primary CNS tumors. The safety profile of entrectinib was consistent with previous reports. Clinical trial information: NCT02650401; NCT04589845; NCT02568267. Research Sponsor: F. Hoffmann-La Roche Ltd.

Efficacy	*ROS1* (N=26)
Confirmed ORR*, N, % [95% CI]	18, 69.2 [48.2- 85.7]
Complete response	4, 15.4 [4.4- 34.9]
Partial response	14, 53.8 [33.4- 73.4]
Median confirmed DoR*, months (95% CI)	NE (16.2- NE)
Median TTR*, months (range)	1.84 (1.6- 4.0)
CBR*, % (95% CI)	84.6 (65.1- 95.6)
Median PFS*, months (95% CI)	NE (21.8- NE)
Median OS, months (95% CI)	NE (NE- NE)

A phase 1 trial of the FACT inhibitor CBL0137 in pediatric patients with relapsed or refractory solid and CNS tumors: A report from the Children's Oncology Group study PEPN2111. First Author: David Simon Ziegler, Kids Cancer Centre, Sydney Children's Hospital, Sydney, NSW, Australia

Background: CBL0137 is a novel agent that targets the FAcilitates Chromatin Transcription complex (FACT), a histone chaperone that regulates chromatin remodeling during transcription, replication, and DNA repair. CBL0137 has been shown to have anti-tumor activity in multiple preclinical models of pediatric cancer. We report the phase 1 trial of CBL0137 in children with relapsed or refractory solid tumors including central nervous system (CNS) tumors or lymphoma (NCT04870944). **Methods:** Patients (age 12 months to 21 years) with relapsed/refractory solid tumors, central nervous system tumors or lymphoma were eligible. In the dose escalation phase, a rolling-six design was used to evaluate CBL0137 administered intravenously (IV) once per week on Days 1 and 8 of a 21-day cycle. The starting dose was 400 mg/m^2, with escalation to the adult phase 2 dose (RP2D) of 540 mg/m^2. The maximum tolerated dose (MTD) was determined based on cycle 1 dose limiting toxicity (DLT) using Common Toxicity Criteria for Adverse Events (v5). Pharmacokinetics (PK) and cytokine analyses were performed during cycle 1. Seven additional patients ($<$ 18 years old) were accrued to a PK expansion cohort at the RP2D. **Results:** Sixteen patients were enrolled; 14 were evaluable for DLT assessment (12 at 400mg/m^2 [6 in dose escalation and 6 in PK expansion] and 2 at 540mg/m^2). The median (range) age was 10 (4-20) years. Diagnoses included high grade glioma (n = 6), osteosarcoma (n = 5), ependymoma (n = 2), neuroblastoma, hepatoblastoma and Burkitt's lymphoma (1 each). One of 12 evaluable patients treated at 400 mg/m^2 experienced a DLT: Grade 3 photosensitivity. At 540 mg/m^2, the two evaluable patients both had fever and dose limiting Grade 3 hypotension. Non-dose limiting Grade 3-4 toxicities included anemia, lymphopenia, neutropenia, thrombocytopenia, hypokalemia, anorexia, photosensitivity and fever. For both dose levels, a total of 12 patients were reported to have at least one episode of Grades 1-3 fever and/or Grade 1 cytokine release syndrome (CRS). PK parameters (mean$\pm$SD) for CBL0137 (400 mg/m^2) were T_{max}= 0.7 $\pm$ 0.5 h, C_{max}= 1310 $\pm$ 417 ng/mL, and $AUC_{0\text{-}24h}$ = 15300 $\pm$ 6790 h·ng/mL. Given the unexpected toxicities of fever, hypotension, and CRS, cytokine samples were collected in patients enrolled in the PK expansion cohort; all had Grade 1 CRS and significantly elevated levels of both IL-10 (adj p = 0.001) and IL-1RA (adj p $<$ 0.001) at 24 hours vs pre-infusion. **Conclusions:** The RP2D and MTD of CBL0137 in children and adolescents with solid or CNS tumors is 400mg/m^2 IV weekly on Days 1 and 8 of 21-day cycles. CBL0137 leads to immune activation, with cytokine elevation and the possibility of CRS, an unexpected toxicity not previously reported in adults. A Phase 2 cohort in patients with Diffuse Midline Glioma is ongoing and includes further assessment of immune activation. Clinical trial information: NCT04870944. Research Sponsor: Cookies for Kids' Cancer; National Cancer Institute; UM1CA228823.

Factors associated with survival following relapse of high-risk neuroblastoma: A study from the International Neuroblastoma Risk Group (INRG) Data Commons. First Author: Daniel A. Morgenstern, The Hospital for Sick Children, Toronto, ON, Canada

Background: Outcomes for high-risk neuroblastoma (HR-NBL) following relapse are poor, although there is a paucity of data on overall survival post-relapse (OSPR) in the contemporary era. Prognostic factors associated with OSPR across all neuroblastoma risk groups (INSS stage, MYCN status and time to first relapse) have previously been described. Here we present an analysis focussed specifically on HR-NBL. **Methods:** We conducted a retrospective analysis using INRG Data Commons including HR-NBL patients diagnosed $\geq$1985 with relapse/progression $\leq$2022. HR-NBL was defined as age $\geq$547days at diagnosis with INRGSS M; or INRGSS L2 MYCN-amplified disease. The final cohort excluded patients without relapse/progression and with death as first event. Primary endpoint was OSPR, with Kaplan-Meier estimates of survival and sub-group comparisons using log-rank tests. **Results:** Of the 25,245 NBL patients in the INRG Data Commons, 4045 were included in the final analysis. The majority had INRGSS M disease (96%) and were $<$ 5 years at diagnosis (74%), with MYCN amplification in 36% of those with available data. OSPR was 22$\pm$0.7% at 2 years and 8$\pm$0.4% at 5 years, with median OSPR 0.76 years (95% CI: 0.73-0.82). OSPR improved over time; for example, 2-year OSPR was 16+/-2.8% for patients diagnosed 1985-1989 vs 32%$\pm$2.8% for 2015-2019 ($p < 0.0001$). Across the whole cohort, patients with a diagnosis of NBL (vs nodular ganglioneuroblastoma), greater number of involved metastatic compartments (MSI) or elevated LDH at diagnosis, tumors with MYCN amplification, higher MKI, 1p LOH and presence of ALK mutation had statistically significantly worse OSPR than respective counterparts. OSPR for INRGG M was significantly better than for INRGSS L2. Serum ferritin, tumor grade and ploidy were not associated with OSPR, while 11q LOH and age showed non-proportional hazards, with patients aged $\geq$5 years at diagnosis having a better early OSPR but poorer long-term outcome than those $<$ 5 years. **Conclusions:** In this, the largest analysis of patients with relapsed HR-NBL, multiple factors at diagnosis were associated with OSPR, emphasising the importance of tumor biology and disease burden. The finding of improved OSPR for INRG M vs L2 is unexpected but may relate to MYCN amplification. Further analyses will focus on changes in prognostic factors over time, non-proportional hazards and the impact of upfront and relapse treatment paradigms on OSPR and prognostic factors. Research Sponsor: Garron Family Cancer Centre.

Whole genome-based circulating tumor DNA analysis as an ultrasensitive biomarker in pediatric sarcomas. First Author: Claire Johns, Stanford, Palo Alto, CA

Background: Disease monitoring in pediatric sarcomas relies on invasive surgical biopsies and radiologic imaging, which often trail disease activity. Circulating tumor DNA (ctDNA) is an attractive potential biomarker, but studies in pediatric sarcomas have reported low detection rates by tracking copy number alterations or recurrent genetic alterations. We aim to establish a personalized ctDNA pipeline in pediatric sarcomas based on identification of tumor-specific single nucleotide variants (SNVs) from whole genome sequencing (WGS) to enhance ctDNA detection. **Methods:** Patients $<$ 25 years old with new or relapsed sarcoma treated at our institution are eligible to enroll in our study, which is ongoing. Plasma is collected at imaging response evaluations. Matched tumor and germline DNA are collected at baseline and undergo paired WGS to identify tumor-specific SNVs, and personalized hybrid capture panels are designed to track up to 5000 mutations per patient. Cell-free DNA from each time point is analyzed with CAncer Personalized Profiling by deep Sequencing (CAPP-Seq) using duplex sequencing to minimize the background error rate and maximize sensitivity. **Results:** This approach was piloted in 8 pediatric patients with osteosarcoma (5), Ewings sarcoma (2), and rhabdomyosarcoma (1). A median of 619 tumor-derived SNVs (range 160-4937) were tracked per patient. ctDNA was detected in all patients at baseline with mean allele fractions ranging from 0.000937-27.1. Table 1 summarizes characteristics, number of SNVs tracked, and mean allele fraction for each patient. Seven patients had longitudinal ctDNA samples available for analysis. In all patients, ctDNA broadly correlated with radiologic response with ctDNA becoming undetectable in patients with an imaging response and ctDNA remaining detectable in patients who experienced progression. One patient achieved initial remission with undetectable ctDNA and relapsed with ctDNA re-emergence. **Conclusions:** Personalized whole genome-based ctDNA analysis may improve ctDNA detection in pediatric sarcomas. In this pilot, ctDNA was detected at baseline in 8/8 patients, and ctDNA levels correlated with treatment response on imaging. A personalized approach for ctDNA detection in pediatric sarcomas has the potential to aid in disease monitoring and treatment selection. Research Sponsor: Conquer Cancer, the ASCO Foundation; Stanford Maternal and Child Health Research Institute; Dianne Taube Family Foundation.

Patient characteristics and baseline ctDNA allele fraction.

Disease	New (N) v Relapsed/ Refractory (R)	Localized (L) v Metastatic (M)	Sex (M, F)	Age (years)	SNVs (n)	Baseline ctDNA Mean Allele fraction
Osteosarcoma	N	L	M	17	692	0.25

A phase 2 study of sirolimus in combination with metronomic chemotherapy (CHOAnome) in children with recurrent and/or refractory solid and CNS tumors. First Author: Kathryn S. Sutton, Aflac Cancer and Blood Disorders Center, Children's Healthcare of Atlanta, Emory University School of Medicine, Atlanta, GA

Background: Outcomes for recurrent and/or refractory (R/R) solid and central nervous system (CNS) tumors remain poor. Sirolimus, an mTOR inhibitor, has both antiproliferative and antiangiogenic effects, and the mTOR pathway is activated in many cancers. Low-dose metronomic chemotherapy also decreases neovascularization and has demonstrated activity in many pediatric tumors. We previously conducted a phase 1 trial establishing the dose (2 mg/m^2), safety and tolerability of sirolimus in combination with metronomic chemotherapy. The current study is a prospective, multi-institutional phase 2 trial to determine the objective response rate (ORR) in children with R/R solid and CNS tumors treated with this regimen (NCT02574728); herein we report the results of the solid tumor stratum. **Methods:** Patients aged 12 months to 30 years with R/R extracranial solid tumors were eligible. Patients were required to have measurable disease and no known curative therapeutic options. Treatment consisted of continuous sirolimus (2 mg/m^2/dose PO daily), celecoxib (100 mg PO BID), and oral etoposide (50 mg/m^2/day; max: 100 mg) alternating every 21 days with oral cyclophosphamide (2.5 mg/kg/day; max: 100 mg) in 42-day cycles. Sirolimus was dose-adjusted to maintain a serum trough concentration of 10-15 ng/ml. Response was determined using Response Evaluation Criteria in Solid Tumors (RECIST) v1.1. Enrollment proceeded using a Fleming's two-stage design based on best overall response (BOR), requiring 2 objective disease status determinations. **Results:** Twenty-four solid tumor patients were enrolled; 20/24 were evaluable for response. Median age was 14.6 years (range: 2.5–20.5); 9 (45%) were female. Diagnoses included desmoplastic small round cell tumor (DSRCT; n = 3), osteosarcoma (n = 4), Wilms tumor (n = 2), neuroblastoma (n = 5), and one each of Ewing sarcoma, rhabdomyosarcoma, CIC-rearranged sarcoma, clear cell sarcoma-like tumor of the GI tract (CCST), juvenile xanthogranuloma (JXG), and hemangiopericytoma. Median number of cycles was 2 (range: 1-13). Best response after any cycle was partial response (PR) in 2 (CCST and JXG), stable disease (SD) in 8, and progressive disease (PD) in 10 for an objective response rate of 10%. BOR was PR in 2 (10%), SD in 5 (25%), PD in 11 (55%), and unknown in 2 (10%). Median PFS was 3.6 months (range: 1.0-26.2) and median OS was 15.5 months (range: 1.0-55.4). One-year PFS was 26.2% [95% confidence interval (CI): 11.9-57.8%) with 1-year OS of 59.6% (95% CI: 35.1-77.4%). Six patients had $\geq$SD for $\geq$6 months [CCST (n = 1), DSRCT (n = 1), JXG (n = 1), hemangiopericytoma (n = 1), and neuroblastoma (n = 2)]. **Conclusions:** The combination of sirolimus with metronomic chemotherapy showed limited activity in patients with R/R solid tumors, although prolonged disease stabilization was seen across multiple histologies consistent with a metronomic approach. Clinical trial information: NCT02574728. Research Sponsor: Cannonball Kids' Cancer Foundation; Hyundai Hope on Wheels; Carter Samuel Martin Innovative Therapy Research Fund.

Association of neurocognitive impairment and financial hardship in adult survivors of childhood cancer: A report from the Childhood Cancer Survivor Study (CCSS). First Author: Daniel J. Zheng, Children's Hospital of Philadelphia, Philadelphia, PA

Background: Adult survivors of childhood cancer are at high risk for financial hardship due to the cumulative lifetime costs of cancer-directed therapy and chronic health conditions. Whether neurocognitive impairment increases the risk for financial hardship is unknown. **Methods:** Childhood cancer survivors ($\geq$ 5-year survivors, diagnosed $<$ 21 years of age between 1970-1999) enrolled in CCSS completed a validated self-report Neurocognitive Questionnaire (NCQ) in 2014 and a subsequent financial hardship survey (age $\geq$ 26 at survey completion) 3 years later. The NCQ measured neurocognitive impairment in four domains: (1) memory; (2) task efficiency; (3) organization; (4) emotional regulation. NCQ was the exposure and operationalized as the number of impaired domains (0-4); in each domain, impairment was defined as a Z-score $>$90th percentile. Financial hardship outcomes were measured in behavioral (e.g., delaying care due to cost), material (e.g., high out-of-pocket costs), and psychological (e.g., worry about financial situation) domains, as well as two discrete outcomes of debt collection and bankruptcy. Multivariable linear and logistic regressions were used to analyze associations adjusting for age, sex, and race/ethnicity. **Results:** 3023 survivors completed the NCQ (mean age 38.8, SD=8.6 years) and a subsequent financial hardship survey (mean age 41.5, SD=8.7 years). 13.9%, 8.1%, 6.0%, and 2.6% of survivors had neurocognitive impairments in 1-4 domains, respectively. Individuals with NCQ impairment had significantly higher mean standardized scores across all three financial hardship domains than those without NCQ impairments (Table). Each ordinal increase in the number of impaired NCQ domains was associated with a higher mean standardized score for both behavioral and material financial hardship. Individuals with impairments in all four NCQ domains were more likely to be sent to debt collection (54% vs. 25%, OR=3.82, 95% CI: 2.27-6.43) and file for bankruptcy protection (21% vs. 8%, OR=2.81, 95% CI: 1.53-5.17) compared to those without impairments. **Conclusions:** Cancer survivors with neurocognitive impairment are particularly vulnerable to financial hardship. This survivor population should be specifically assessed for these outcomes and offered support to prevent and mitigate financial challenges. Research Sponsor: Childhood Cancer Survivor Study; National Cancer Institute; CA21765, C. Roberts, Principal Investigator; American Lebanese-Syrian Associated Charities (ALSAC).

Standardized mean differences (SMD) of each financial hardship domain by number of NCQ impairments compared to no NCQ impairments.

Number of NCQ domains impaired	Behavioral Domain SMD (95% CI)	Material Domain SMD (95% CI)	Psychological Domain SMD (95% CI)
1	0.21 (0.11-0.31)	0.20 (0.10-0.29)	0.41 (0.31-0.50)
2	0.39 (0.27-0.51)	0.32 (0.20-0.44)	0.38 (0.25-0.50)
3	0.48 (0.34-0.63)	0.35 (0.20-0.49)	0.44 (0.30-0.58)
4	0.72 (0.51-0.93)	0.72 (0.52-0.94)	0.74 (0.53-0.94)

Psychologic distress amongst adolescent and young adult cancer survivors' and parents. First Author: Kaille Meguiar, Vanderbilt University Medical Center, Nashville, TN

Background: Increasing survival in adolescent and young adult (AYA) cancer patients has led to a growing population at risk for poor psychological outcomes. We sought to identify risk factors for the development of psychologic distress and post-traumatic stress (PTS) in AYA survivors and their parents. **Methods:** In a single-institution prospective cohort study, survivors ages 10-25 years old completed a self-report review of systems (ROS) and psychosocial surveys at initial and follow up visits, including the Youth (YSR) or Adult Self Report (ASR) assessing psychologic distress and the Impact of Events Scale (IES) assessing PTS. Parents of patients ages 10-18 years completed the Childhood Behavior Checklist (CBCL) assessing their child's psychologic distress. Parents completed the Beck Anxiety (BAI) and Depression (BDI) Index and IES assessing their personal anxiety, depression, and PTS. Psychologic distress and PTS were defined dichotomously with an internalizing problems T-score $\geq$ 60 on YSR/ASR/CBCL and IES $\geq$ 24, respectively. Psychologic distress and PTS were further analyzed as continuous variables in multivariable linear regression models with age, diagnosis, gender, time from end of therapy (EOT), substance use, sexual dysfunction, ROS, and therapy intensity. Spearman correlation coefficients were computed to assess relationships between patient and parent scores. **Results:** The study enrolled 135 patients and 72 parents, of which 37 were parents of 10-18-year-olds. Median age of patients at diagnosis was 15 years and median time from EOT was 3.2 years. 50% were female, 65% had a hematologic malignancy, and 92% were white. 20% of patients reported psychologic distress. 17% of patients and 17% of parents reported PTS. 10% and 13% of parents reported at least moderate anxiety and depression, respectively. In multivariable regression analyses, psychologic distress was associated with a higher number of patient-reported systems (Slope estimate = 2.98, $p < 0.01$) and shorter time since EOT (-0.45, p = 0.03). PTS was associated with a higher number of patient-reported system (1.46-fold, $p < 0.01$). Multivariable regression analyses in parent data showed parent-reported psychologic distress of patient was associated with a higher number of patient-reported systems (6.01, p = 0.03). Positive correlations were seen between parent-reported psychologic distress of patient and patient self-reported psychologic distress (R = 0.58, $p < 0.01$) and also with patient self-reported PTS (R = 0.51, $p < 0.01$). Parent reported psychologic distress of patient was positively correlated with parent self-reported anxiety (R = 0.45, p = 0.01) and also with parent self-reported PTS (R = 0.42, p = 0.02). **Conclusions:** A meaningful minority of survivors and parents face psychologic distress and PTS. A larger study is ongoing to expand upon our preliminary findings and examine the trajectory of psychologic distress and PTS in survivorship. Research Sponsor: NIH/NIGMS; T32GM108554.

10057 Poster Session

Longitudinal associations between chronic health condition burden and financial hardship among adult survivors of childhood cancer: A report from the Childhood Cancer Survivor study (CCSS). First Author: Tara Suntum, MedStar Georgetown University Hospital, Washington, DC

Background: Childhood cancer survivors experience a large burden of chronic health conditions (CHCs) with the progression of these conditions facilitating potential economic burden. This study examined the association between CHC progression and financial hardship in adult survivors of childhood cancer. **Methods:** The study included CCSS participants diagnosed with pediatric cancer (1970–1999) who survived $>$ 5 years post-diagnosis and were $\geq$26 years old at the assessment of financial burden. Participants completed surveys (2017-2019) assessing three financial hardship domains: behavioral, material, and psychological. CHCs were self-reported at baseline and on up to 4 follow-ups. CHC severity was graded using CTCAE v4.03. To estimate the impact of multiple CHCs, a severity score was calculated based on published methods (PMID: 17595271) accounting for the frequency and grade of conditions. Notable CHC burden was defined as any CHC above low severity grade. Multivariable logistic regression evaluated associations of CHC burden with financial hardship adjusting for age at diagnosis, attained age, sex, insurance, personal income, education, marital status, smoking status, and body mass index. Additional analyses examined whether neighborhood deprivation using the Area Deprivation Index (ADI) (range 0-100) modified the relationship between CHC burden and financial hardship. **Results:** Among 3,638 evaluable participants, the prevalence of notable CHC burden was 66%, material hardship 16%, psychological hardship 26%, and behavioral hardship 21%. Survivors with very high CHC burden had 2.6-fold (95%CI 1.6-4.1) higher odds of material and 1.6-fold (95%CI 1.0-2.4) higher odds of psychological hardship vs. those with low CHC burden. Survivors who progressed to moderate, high, or very high CHC burden had 1.7-fold (95%CI 1.2-2.5) higher odds of material hardship and 1.6-fold (95%CI 1.1-2.2) higher odds of psychological hardship vs. those with persistent low CHC burden. For survivors living in more deprived neighborhoods (ADI$\geq$50), having notable CHC burden was associated with 2.5-fold (95% CI 1.5-4.3) higher odds of material hardship vs. those without notable CHC burden. For survivors living in less deprived neighborhoods (ADI $<$ 50), having notable CHC burden was associated with 1.5-fold (95%CI 1.1-2.2) higher odds of psychological hardship and 1.6-fold (95%CI 1.1-2.1) higher odds of behavioral hardship vs. those without notable CHC burden. **Conclusions:** Longitudinal CHC burden shows strong temporal associations with material and psychological financial hardship. Neighborhood deprivation is associated with financial hardship, beyond individual sociodemographic factors. Multi-level interventions will be crucial to address financial hardship in survivors who develop CHCs earlier than peers. Research Sponsor: National Cancer Institute; U24 CA055727.

Treatment and lifestyle profiles of healthy aging survivors: A report from the Childhood Cancer Survivor Study. First Author: Timothy James Daeeun Ohlsen, Department of Pediatrics, Seattle Children's Hospital, University of Washington, Seattle, WA

Background: Survivors of childhood cancer are at elevated risk for adverse health outcomes, but many maintain excellent health throughout adulthood. We sought to characterize the trajectories of, and examine factors associated with, healthy aging across the lifespan. **Methods:** We longitudinally surveyed $\geq$5 y cancer survivors (18-64 y) and sibling controls enrolled in the Childhood Cancer Survivor Study. "Healthy aging" was defined by 1) having a cumulative number of severe or life-threatening (i.e., grade 3+) chronic health conditions (CHCs) less than or equal to the mean of same age, same sex sibling controls; and 2) having no functional impairment or activity limitations. We then examined prevalences of healthy aging and its 2 component domains across survivor age groups ($<$ 30, 30-39, 40-49, $\geq$50 y). Multivariable logistic regression models adjusted for demographic, treatment, and lifestyle factors at cohort entry estimated risk factors for healthy aging among survivors. **Results:** We analyzed 17,263 survivors (median age 39 y, IQR 32-46) and 3,378 siblings. Among all sibling age/sex groups, mean grade 3+ CHC counts were $<$ 1. Of survivors, 53.4% (95% CI 52.7-54.2) had no Grade 3+ CHC, and 71.4% (95% CI 70.7-72.1) reported no functional impairment. Overall, 45.0% (95% CI 44.2-45.7) of survivors met criteria for healthy aging, but this prevalence decreased with age (Table). In multivariable analysis, treatment factors associated with lower odds of healthy aging included anthracycline dose ($\geq$250 mg/m^2 vs none: OR 0.60, 95% CI 0.52-0.69), alkylator dose ($\geq$8 g/m^2 vs none: OR 0.76, 95% CI 0.67-0.86), and stem cell transplant (OR 0.60, 95% CI 0.41-0.89). High doses of radiation to any site were also associated with less healthy aging (e.g., $\geq$30 Gy to brain vs none: OR 0.22, 95% CI 0.19-0.26). Baseline physical activity $>$ 180 min/week was associated with healthy aging (vs $<$ 180 min: OR 1.23, 95% CI 1.11-1.37). Underweight, overweight, and obese baseline BMIs had lower odds of healthy aging compared with normal BMI (ORs 0.54 to 0.82, each $p < 0.05$). Survivors treated in more recent decades were more likely to experience healthy aging (1990s vs 1970s: OR 1.26, 95% CI 1.06-1.50) even after adjusting for attained age. **Conclusions:** Among childhood cancer survivors, the prevalence of healthy aging declines with age but has improved in more recent treatment eras. Higher levels of exercise and normal BMI at baseline were associated with subsequent healthy aging, suggesting that the trajectory of aging could be improved through targeted interventions. US population-level costs and cost-savings associated with long-term follow-up (LTFU) screening for survivors of childhood cancer. First Author: Matthew J. Ehrhardt, St. Jude Children's Research Hospital, Memphis, TN

Background: Children's Oncology Group's (COG) LTFU Guideline adherence is poor. We evaluated the impact of universal payer coverage on patient costs associated with adherence to COG-directed cardiomyopathy (CM), breast (BC), and colorectal cancer (CRC) screening. **Methods:** We reviewed coverage guidelines for Medicare, Medicaid, and commercial plans for COG screening for exposure-based CM (echocardiogram [echo] every 2-5 yrs based on cumulative chest radiation (RT) and anthracyclines), BC (yearly mammography [MAM] and magnetic resonance imaging [MRI] beginning at age 25 or 8 yrs from chest RT), and CRC (colonoscopy [COL] every 5 yrs or multitarget stool DNA [MTSD] every 3 yrs, starting 5 yrs from abdominopelvic RT or age 30). The eligible US population was estimated from SEER and American Cancer Society cancer survival rates. Cost of screening was derived from the Center for Medicare & Medicaid Services (CMS) and of lifetime treatment from published data. Net costs vs. benefits (in US $) were calculated, assuming 100% adherence, as the sum of cost-savings (i.e., treatment costs averted) and monetary value of quality-adjusted life-yrs (QALYs) gained minus costs (e.g., screening, false positives). **Results:** Screening coverage varied by payer (Table). BC screening for all US survivors with prior chest RT (n = 42,847) yielded a net benefit ranging from $0.5 to $3.4 billion, with patients paying 19.3% of costs. Among 138,702 survivors at-risk of CRC, net benefit from COL and MTSD was $5.7 and 5.0 billion. Patients nationally bore 0% of MTSD but 60% of COL costs. Among 218,322 at-risk of CM, costs exceeded cost-savings by $1.7 billion when using the median echo cost by payer but yielded a $400 million benefit when using the average cost of CMS and the lowest commercial plan. Patients bore 90% of CM costs. **Conclusions:** Screening for CM, BC, and CRC per the COG guidelines results in substantial cost savings and benefits. However, as adherence is $<$ 100% due to copay, inadequate coverage, and low provider awareness, interventions and policies focused on boosting adherence could yield cost savings to the health system and reduce disease burden in this population. Research Sponsor: None.

Food insecurity, dietary quality, and cardiovascular risk in early childhood cancer survivors. First Author: Rahela Aziz-Bose, Dana-Farber/Boston Children's Cancer and Blood Disorders Center, Boston, MA

Background: Childhood cancer survivors (CCS) experience cardiovascular (CV) mortality 7 times higher than the general population. Low-income and Black CCS experience significantly higher all-cause and CV mortality than peers. Food insecurity, a modifiable CV risk factor associated with lower dietary quality, has not been investigated as a potential driver of adverse CCS CV outcomes. We characterized and assessed associations between food insecurity, dietary quality, and CV risk conditions in a prospective cohort of early CCS. **Methods:** Children< 18 years with a hematologic, solid, or central nervous system malignancy < 12 months from completion of cancer-directed therapy were recruited at a quaternary academic pediatric cancer center. Parents/guardians completed a single-timepoint survey including validated measures of food insecurity and dietary quality. Clinical CV risk (systolic or diastolic blood pressure $\geq 95^{th}$ percentile, body mass index $\geq 85^{th}$ percentile, dyslipidemia, or impaired glucose tolerance) and therapeutic CV risk (receipt of anthracycline, chest radiation, or total body irradiation) was abstracted from the medical record. Descriptive statistics summarized dietary quality and prevalence of food insecurity. A t-test compared associations between food security status and dietary quality, followed by multivariable linear regression adjusted for age, sex, race/ethnicity, income, and diagnosis type. Logistic regression compared associations between food security status and presence of clinical CV risk conditions. **Results:** Of 135 eligible participants, 119 (88%) consented to participation and 115 (97%) completed surveys, with no missing food security or dietary data. Participants were a mean age 6.5 years and mean 4.8 months from end of therapy. Twenty-seven percent (n = 31, 95% CI: 19-36%) of participants lived in food-insecure households. Mean child dietary quality was 27.6 (SD 5.3) on a 52-point scale (higher scores reflect higher quality, US adult mean score 35.0). Dietary quality was significantly lower for participants in food-insecure households compared to food-secure households on univariate analysis (25.9 vs 28.2, p = 0.04); in multivariable analyses, this difference was no longer significant. Among the subcohort (n = 97) consented to medical record abstraction, 84% (n = 81) had a CV risk factor (47% [n = 38] clinical conditions, 26% [n = 21] therapeutic exposures, and 27% [n = 22] both). Frequency of clinical CV risk conditions did not differ between children with and without food insecurity (58% vs 63%, p = 0.61). **Conclusions:** One in four children in early cancer survivorship lives with food insecurity. These children concurrently experience multiple CV risk factors and suboptimal dietary quality. Interventions targeting food insecurity and other modifiable CV risk factors are urgently needed to mitigate CV late effects and advance equity in survivorship outcomes. Risk assessment and development of a machine learning–based prediction model for survival in patients with medulloblastoma. First Author: Yu Su, Capital Medical University, Beijing, China

Background: While clinical risk factors have long guided medulloblastoma (MB) treatment, the significance of genetic events in therapeutic strategies has not been fully elucidated. We aimed to explore whether molecular risk categories could inform management by analyzing long-term follow-up profiles, and concurrently to establish and validate an explainable prediction model for MB based on machine learning (ML) approaches, and to assess its prognostic implications in patients. **Methods:** A multicenter cohort of 729 patients from 2001 to 2023 was enrolled as a discovery cohort. Data from 511 patients from international MB consortia were used to validate. Multivariate survival analyses assessed the associations between radiotherapy dose and survival by different molecular risk stratifications which integrated clinical and genetic events, followed by training and internal and external validation of models. The area under the receiver-operating-characteristic curve (AUROC) and decision curve analysis (DCA) were used to compare the predictive performance of six ML models. The SHapley Additive exPlanation method was used to explain the final model. **Results:** Fifteen-year OS and DFS rates were 64.1% (95% CI, 57.9%-71.0%) and 59.1% (95% CI, 53.2%-65.5%) for clinical average-risk group (n = 554), and 55.9% (95% CI, 44.4%-70.2%) and 60.6% (95% CI, 51.9%-70.7%) for clinical high-risk group (n = 175), respectively. Within the high-risk stratification of SHH-MB, higher posterior fossa tumor bed (PFTB) total dose (≥ 55.8 Gy) combined with reduced craniospinal irradiation (CSI) dose (23.4 ~ < 30.6 Gy) was associated with better prognosis. In Gr.3-MB, MYC amplification (activation), as a high-risk marker of dissemination, indicated that CSI dose should be escalated to high intensity (36.0 Gy, p = 0.03) for survival benefits. In the model of Gr.4-MB, CDK6 activation well stratified patients, with 10-year OS of 71.0% (95% CI, 54.0%-93.5%) for average-risk and 52.1% (95% CI, 39.5%-68.8%) for high-risk group. The XGBoost method demonstrated the most optimal predictive efficacy among the six ML models, as evidenced by the training set AUROC of 0.75 (95% CI 0.70-0.80) for 5-year survival rates, 0.75 (0.69-0.80) for 10-year survival rates, and 0.80 (0.72-0.87) for 15-year survival rates in all patients. The final model could accurately predict survival rates in both internal and external validations, and has been deployed through a free, publicly available online software interface. **Conclusions:** The molecular risk stratification was suggested to potentially guide risk-adapted radiotherapy. Except that 36.0 Gy CSI dose is warranted for Gr.3-MB with MYC amplification, CSI reduction is recommended. Furthermore, this study, based on clinical and molecular information, constructs an available survival prediction tool for MB patients. Retinoblastoma patient outcomes in the contemporary era: The RIVERBOAT Consortium. First Author: Murali M. Chintagumpala, Texas Children's Cancer and Hematology Center, Baylor College of Medicine, Houston, TX

Background: Retinoblastoma (RB) is the most common childhood eye tumor. Intraocular RB cure rates approach 100%. Therefore, treatment now focuses on globe salvage and preserving functional vision. The Research into Visual Endpoints and RB Health Outcomes After Treatment (RIVERBOAT) consortium was established to examine patient outcomes in the transitional era from systemic to intraocular therapy. **Methods:** Patients with RB treated at 13 North American centers from 2008-2022 were identified. Medical record abstraction was performed for disease presentation, visual acuity, treatment, globe salvage and functional outcome. Enrollment on the study included submission of retrospective data and prospective data on newly diagnosed patients as well as retrospective data from chart reviews. **Results:** 830 patients (68% white race, 77% non-Hispanic ethnicity) were enrolled. In 420 of these, data was limited to chart review. Median age at diagnosis of the 830 patients (1165 eyes) was 1 year (0 - 16.3) and at enrollment was 7.8 years (0 - 28.6). 60% had unilateral disease and the eye group distribution (International Intraocular Retinoblastoma Classification) was 10% A, 16% B, 12% C, 31% D, 27% E, and 4% unknown (UK). Of the 1165 affected eyes, major treatment modalities included primary enucleation (15%), systemic chemotherapy (SC) (36%), intraarterial chemotherapy (IAC) (10%), SC followed by IAC in 9%, and intravitreal chemotherapy in combination in 6%. SC only was used in 55-59% of those with A-C eyes compared to 29% of D eyes. IAC only was used in 20% of D eyes and 16% of C eyes. Secondary enucleation occurred in 151 eyes (14%): 63/416 (15%) of SC; 34/120 (28%) of IAC; 25/106 (24%) of SC followed by IAC; 29/523 (6%) other treatments. The overall globe salvage rate was 86%. Second malignancies occurred in 5, metastatic disease in 8 and pineoblastoma in 3 patients. Eleven patients died of RB (1%). Visual acuity after treatment was reported in 229 eyes: 106 (eye group 24 A, 37 B, 22 C, 19 D, 3 E, 1 UK) had normal vision (20/20-20/40). 38 eyes, (6 A, 11 B, 4 C, 10 D, 5 E, 2 UK) had moderate vision loss (> 20/40 – 20/70). Twenty-five eyes (5 B, 2 C, 16 D, 2 E) had low vision (> 20/70 < 20/200), and 60 eyes (12 B, 7 C, 32 D, 8 E, 1 UK) were legally blind (>20/200). In those treated with IAC only, normal vision was found in 30% of eyes, moderate vision loss in 22%, low vision in 13%, and legal blindness in 35%. In those treated with SC only, normal vision was noted in 53% of eyes, moderate vision loss in 11%, low vision in 11%, and legal blindness in 25%. In those treated with SC followed by IAC, normal vision was reported in 32%, moderate vision in 26%, low vision in 5% and legal blindness in 37%. **Conclusions:** We demonstrate the significant benefits witnessed by the evolution of RB therapy. Cure rates remain high, with a very low incidence of second malignancies, metastatic disease or trilateral RB. Eye salvage rate was excellent, avoiding low vision or legal blindness in two-thirds of the patients. Research Sponsor: None.

Genome-wide association study of neurocognitive outcomes among childhood cancer survivors. First Author: Jennifer N. French, St. Jude Children's Research Hospital, Memphis, TN

Background: Long-term survivors of childhood cancer experience heightened risk of late effects, with about 40% developing cognitive impairment. Established risk factors include cranial radiation and specific chemotherapies. Variability in treatment-related outcomes has been associated with genetic factors, though prior studies examined targeted pathways and not whole genome approaches. **Methods:** Participants included 4,077 childhood cancer survivors with whole genome sequencing and direct neurocognitive testing from the St. Jude Lifetime Cohort Study (SJLIFE). The mean (standard deviation) age at primary cancer diagnosis was 7.8 (5.7) years, and 28.5 (10.3) years at neurocognitive testing; 52.3% were male; 78.9% were Non-Hispanic White. Linear regression evaluated associations between common genetic variants (minor allele frequency, MAF≥1%) and 20 neurocognitive measures (as age-adjusted Z-scores). Analyses were adjusted for sex, age at primary childhood cancer diagnosis, age at neurocognitive testing, cumulative doses of high-dose methotrexate, intrathecal methotrexate, anthracyclines and cranial radiation, and genetic ancestry . Loci with $P \leq 5x10^{-8}$ were considered genome-wide significant and evaluated in stratified analysis by genetic ancestry and treatment exposures. **Results:** 21 SNPs met genome-wide significance for associations with ≥1 neurocognitive measure, 9 SNPs with a MAF ≥1% in EUR (n = 3,312) and AFR (n = 636) survivors. All 9 SNPs had 1.1-3.6 times larger effect sizes in AFR compared to EUR. The biggest differences in ancestry groups were seen when stratifying analyses by anthracycline exposure. An intronic variant in *ERG*, rs1309269486, had a 2.0-times larger effect on motor speed in exposed EUR (β = -0.70; P= $2.9x10^{-6}$) compared to unexposed EUR (β = -0.35; P= 0.039). In AFR, rs1309269486 was only associated with motor speed in unexposed survivors (β = -1.33; P= $2.9x10^{-3}$), with a 3.8-times greater effect size compared to unexposed EUR. *ERG* has been shown to play a role in neurogenesis. Another intronic variant in *P2RY12*, rs1755678683, also showed a 1.8-times larger effect on attention span in exposed EUR (β = -0.68; P= $5.9x10^{-4}$) than unexposed EUR (β = -0.38; P= 0.035). However, it was associated with attention span in only unexposed AFR (β = -1.28; P= $2.1x10^{-3}$), showing 3.4-times greater effect than in unexposed EUR. *P2RY12* plays a role in microglia function, neuroinflammation, and neurodegeneration. An intronic variant in *COL15A1*, rs1837227843, was associated with working memory in exposed EUR (β = -0.47; P= $5.3x10^{-7}$) and unexposed AFR (β = -0.58; P= $4.9x10^{-3}$). While *COL15A1* is highly expressed in many brain tissues, previous associations with neurocognition have not been established. **Conclusions:** These findings highlight the independent and combined role (with treatment) of genetics and genetic ancestry in adverse neurocognitive impairment among survivors of childhood cancer. Accelerated aging among long-term survivors of childhood cancer: A report from the Childhood Cancer Survivor Study (CCSS). First Author: AnnaLynn Williams, University of Rochester School of Medicine and Dentistry, Rochester, NY

Background: Cross-sectional studies have suggested childhood cancer survivors demonstrate a pattern of functional limitations and morbidity consistent with premature aging, but cannot confirm if aging is accelerated relative to peers without cancer. We used longitudinal data to characterize aging using a Deficit Accumulation Index (DAI) which examines the accumulation of multiple aging-related deficits. **Methods:** We included 5+ year survivors of childhood cancer (N=21,856; at entry mean age 26.7 [SD 6.1], 18.7 [4.7] years post diagnosis) and siblings (N=4,628, mean age 29.1 [7.1]) from the CCSS, a longitudinal prospective cohort study. Participants completed questionnaires at up to four timepoints (mean[SD] follow-up 9.5[8.9] years), with DAI scores generated as the proportion of deficits out of 30 items related to aging, including chronic conditions (e.g. hearing loss, hypertension), psychosocial and physical function, and activities of daily living. The total score range is 0 to 1; and a moderate clinically meaningful difference is 0.02. As survivors completed multiple surveys at varying intervals, attained age was used as the time scale. Linear mixed models compared DAI in survivors to siblings with an attained age*survivor interaction term to determine if DAI was increasing faster in survivors, adjusted for the first DAI score, age at first DAI and sex. Similar models examined DAI changes associated with treatments among survivors. **Results:** The overall adjusted mean [95%CI] DAI was 0.195[0.194, 0.196] for survivors and 0.179[0.177,0.180] for siblings ($p<0.001$). Survivors experienced more rapid increase in DAI over time compared to siblings ($p<0.001$). For example, at age 20 there was no difference in DAI between survivors and siblings, however the mean difference [95%CI] in DAI between survivors and siblings steadily increased with age to 0.011[0.009, 0.013] at 30 years, 0.024[0.022, 0.026] at 40 years, and 0.038[0.035, 0.040] at 50 years; p's<0.001 (Table). Survivors who received abdominal, cranial or chest radiation experienced more rapid increase in DAI over time compared to those who did not (p's<0.001). Survivors who received platinum agents or neurosurgery also experienced a more rapid increase in DAI over time (p's<0.001). **Conclusions:** Our data confirm survivors of childhood cancer experience significant age acceleration relative to peers. Given the ease of measuring DAI using self-reported data, this tool may be used to routinely monitor survivors and identify those at risk for adverse aging-related outcomes so that we may intervene and mitigate their accelerated aging trajectory. Cardiovascular risk factor control and risk of future cardiovascular events in survivors of childhood cancer: A report from the St. Jude Lifetime cohort. First Author: Stephanie B. Dixon, St. Jude Children's Research Hospital, Memphis, TN

Background: Modifiable cardiovascular risk factors (CVRFs; hypertension, diabetes, dyslipidemia) contribute to the excess health-related death in long-term survivors of childhood cancer. However, whether control of CVRFs reduces the risk of major adverse cardiovascular events (MACE) in survivors is not known. **Methods:** Prevalence of hypertension (HTN), diabetes (DM) and LDL cholesterol elevation (LDL) was assessed via in-person assessments in 5+ year survivors ≥18 years old in the St. Jude Lifetime Cohort. Based on ACC/AHA primary prevention guideline recommendations, sub-optimal CVRF control was defined as blood pressure ≥140/90 mmHg, hemoglobin A1c ≥7.0%, and LDL ≥130 mg/dl. MACE was defined as new onset cardiomyopathy, myocardial infarction, stroke and/or cardiovascular death. Piecewise exponential models estimated the multivariable adjusted relative risk (RR) with 95% confidence intervals (CI) for MACE among survivors according to degree of CVRF control. Models were adjusted for sociodemographic factors, physical activity, smoking status, chronic kidney disease, and cancer treatment exposures (anthracycline chemotherapy, chest and/or brain irradiation). **Results:** Among 4876 adult survivors of childhood cancer, 36.1% had HTN, 8.4% DM and 56.5% elevated LDL at first assessment (mean age 28.6 years, standard deviation 9.1). One-third of survivors (33.5%) had at least one sub-optimally controlled CVRF. Among those with HTN, DM or LDL, 30%, 33% and 52% were sub-optimally controlled, respectively. In multivariable models, sub-optimal LDL control was associated with a > 8-fold higher risk of MACE compared to those with no LDL elevation (RR 8.4, CI 4.2 – 19.3; Table). This was more than twice the risk observed in those with well-controlled LDL compared to no LDL elevation (RR 4.0, CI 1.9 – 9.4; p-value <0.001). Similarly, sub-optimal DM control vs never having DM was associated with increased MACE risk (RR 3.4, CI 1.8 – 6.1) with twice the risk in those with sub-optimal control compared to well-controlled DM (p = 0.05; RR well-controlled DM vs no DM 1.6, CI 0.9 – 2.8). HTN, compared to no HTN, was associated with a 3 to 4-fold increase in risk of subsequent MACE, regardless of degree of control. **Conclusions:** Survivors of childhood cancer had a high prevalence of sub-optimally controlled CVRFs that was associated with an increased MACE risk. Optimal control of CVRFs among adult survivors of childhood cancer may reduce the risk of MACE. These findings motivate an intervention trial in intensive CVRF control. Research Sponsor: U.S. National Cancer Institute; U01 CA195547; U.S. National Cancer Institute; P30 CA21765; American Lebanese-Syrian Associated Charities (ALSAC).

CVRF Control	RR of MACE (95% CI)	P-value comparing RR
LDL elevation		
Sub-optimal LDL vs no LDL elevation	**8.4 (4.2 – 19.3)**	**<0.001**
Controlled LDL vs no LDL elevation	**4.0 (1.9 – 9.4)**	
Diabetes		
Sub-optimal DM vs no DM	**3.4 (1.8 – 6.1)**	**0.05**
Controlled DM vs no DM	1.6 (0.9 – 2.8)	
Hypertension		
Sub-optimal HTN vs no HTN	**3.9 (2.2 – 7.0)**	0.28
Controlled HTN vs no HTN	**3.0 (1.9 – 4.8)**

Breast cancer recurrence and mortality among survivors of childhood cancer: A report from the Childhood Cancer Survivor Study (CCSS). First Author: Lucie Marie Turcotte, University of Minnesota Medical School, Minneapolis, MN

Background: Survivors of childhood cancer are at high risk for developing subsequent breast cancer (BC). However, BC recurrence risk and survival after BC recurrence has not been evaluated in survivors of childhood cancer. **Methods:** Analyses included female 5-year survivors participating in CCSS with pathology-ascertained breast carcinomas (in situ or invasive) diagnosed from 1981-2016 at age ≥18y. BC treatment was evaluated against chronological period-specific National Comprehensive Cancer Network guidelines for primary BC. Recurrent BC cumulative incidence was estimated treating death as a competing risk among survivors and females with first primary BC (controls) matched one-to-one by demographics and first BC clinical characteristics including diagnosis age/year, histology and race/ethnicity (206 pairs with complete data). Among survivors and controls with recurrent BC, all-cause mortality was evaluated with cumulative incidence with time at risk starting at relapse and hazard ratios from multivariable Cox regression models adjusted for age and calendar year of recurrence and race/ethnicity. **Results:** Among the 431 childhood cancer survivors with subsequent BC (median diagnosis age: 40 years, IQR: 35-44), 68 developed recurrent BC. Compared with matched controls, survivors had similar 10-year BC recurrence risk (survivors: 14%, 95% CI: 9-20% versus controls: 12%, 95% CI: 9-18%; P=0.52). Among survivors with BC recurrence, Hodgkin lymphoma was the predominant primary cancer diagnosis (63%) and first subsequent BCs were largely early stage (stage 0: 8%; stage I/II: 69%) and estrogen (71%) or progesterone (80%) receptor positive. Most (84%) received first BC treatment following national guidelines for primary BC. However, nearly half (47%) underwent bilateral mastectomies (81% occurring before recurrence) and most received chest radiotherapy (86%) or anthracycline chemotherapy (69%) for either their primary childhood cancer or first subsequent BC. A total of 48 survivors died after BC recurrence, mostly related to BC (83%) or cardiovascular causes (11%). Following recurrence, the 10-year overall mortality probability was significantly higher among survivors (89%, 95% CI: 61-97%) than controls (42%, 95% CI: 18-58%; P=0.0025) and survivors had an adjusted 2.6-fold (95% CI: 1.05-6.49) greater risk of death. **Conclusions:** Although the risk for BC recurrence among childhood cancer survivors with subsequent BC is similar to females with primary BC, this vulnerable population faces substantially greater mortality risk after recurrence. Future studies to identify early predictors of subsequent BC and BC recurrence among survivors are needed to reduce mortality risk. Financial hardship and non-adherence to lifestyle and surveillance recommendations in adult survivors of childhood cancer: A report from the Childhood Cancer Survivor Study (CCSS). First Author: Neel S. Bhatt, Fred Hutchinson Cancer Center, Seattle, WA

Background: The association between different aspects of medical financial hardship and non-adherence to healthy lifestyle recommendations and surveillance for subsequent neoplasms (SN) and cardiomyopathy in long-term survivors of childhood cancer is unknown. **Methods:** A randomly selected subset of participants in the CCSS completed a financial hardship survey and a follow-up survey assessing lifestyle behaviors and adherence to recommended surveillance. Presence of financial hardship was determined by affirmative response to ≥1 item in material (e.g., high out-of-pocket costs), behavioral (e.g., delaying care due to cost), or psychological (e.g., worry about financial situation) hardship domains. Outcomes included "not meeting physical activity guidelines" (< 9 metabolic-equivalent-of-task-hour/week moderate to vigorous activity), "problematic drinking" (> 7 drinks/week or > 3 drinks/day [women], > 14 drinks/week or > 4 drinks/day [men]), current smoker, unhealthy BMI (< 18.5 or ≥30 kg/m^2), and non-adherence to surveillance for breast, colorectal, and/or skin cancer, and cardiomyopathy screening according to the Children's Oncology Group guidelines. Logistic regression models, adjusted for age at the most recent survey, sex, race/ethnicity, education, and chronic health conditions, examined the association of material, behavioral, and psychological hardship with healthy lifestyle and surveillance outcomes. **Results:** A total of 3,322 survivors, at a median of 34.4 (range:19.7-51.4) years from diagnosis and 41 (20-69) years of age at the most recent survey were included. Presence of material hardship alone was associated with higher risk of not meeting physical activity guidelines (odds ratio 1.6, 95% CI 1.2-2.1) and unhealthy BMI (1.4, 1.1-1.8). Presence of both material and behavioral (1.8, 1.2-2.6) or material and psychological (1.8, 1.4-2.4) hardships further increased the risk for unhealthy BMI. Presence of all 3 hardship domains was associated with higher risk of unhealthy BMI (2.2, 1.8-2.7). Behavioral hardship (2.2, 1.1-4.6) and psychological hardship (3.9, 2.4-6.4) alone were associated with higher risk of being a current smoker at time of follow-up, with presence of both further increasing the risk for smoking (4.1, 2.3-7.3). Presence of psychological hardship alone was associated with higher non-adherence to cardiomyopathy screening (1.3, 1.0-1.8) among those at high risk. Associations between hardship and SN surveillance were not significant. **Conclusions:** Financial hardship is associated with non-adherence to healthy lifestyle and recommended screening for cardiomyopathy among adult survivors of childhood cancer. Findings underscore the need for strategies to identify and mitigate financial hardship and improve adherence to recommended lifestyle and surveillance. Research Sponsor: National Cancer Institute; U24 CA55727.

Assessment of smartwatch-based electrocardiogram (ECG) abnormality detection among childhood cancer survivors. First Author: Ibrahim Karabayir, Wake Forest School of Medicine, Winston-Salem, NC

Background: Childhood cancer survivors (CCS), exposed to cardiotoxic cancer therapies, are at lifelong risk for premature cardiovascular disease. However, adherence to guideline recommended screening is low later in life, long after cancer treatment. Novel wearable technologies offer a potential low-cost, easy screening method for arrythmias in CCS, including AF, bradycardia, and tachycardia. However, their utility in population level screening for CCS is unknown. **Methods:** We collected paired single lead smartwatch with FDA cleared ECG functionality and 12-lead 10 second ECGs from adult participants in the St. Jude Lifetime Cohort Study (SJLIFE) who were treated for their primary cancer 1962-2012 and survived ≥5 years. Participants completed an in-person comprehensive examination including a standard 10 second 12-lead ECG recording as well as single lead rhythms were collected using a smartwatch. The smartwatch provided automated annotations including sinus rhythm, AF, bradycardia (HR<60 bpm), tachycardia (HR>100 bpm), and inconclusive rhythm. We compared the smartwatch generated statements to reference diagnostic statements generated by GE MUSE system. **Results:** There were 598 same day ECG pairs in 580 participants (83% White, 14% Black, 50% male, and mean age(SD) 37(10) years). The mean(SD) times between smartwatch and reference ECG recordings were 32(50) minutes. The heart rate from reference ECG and smartwatch ECG had a Pearson Correlation of r=0.85 (p<0.001). The smartwatch ECGs presented statistically significantly (p<0.001) higher heart rates compared to reference ECGs with mean heart rate difference (95% confidence interval) of 1.2 (0.5-1.8) beats per minute. Standard 12-lead ECGs processed by GE MUSE annotations included 478 (80%) sinus rhythm and 120 (20%) as 'no sinus rhythm' with 1 (0.2%) AF, 57 (9.5%) sinus bradycardia, 18 (3.2%) sinus tachycardia and 28 (6.4%) other rhythms. The smartwatch assigned sinus rhythm to 590 (98.7%) of these ECGs. The detailed rhythm annotations between reference ECG and smartwatch ECGs are summarized in Table 1. The smartwatch detected only 3.5% (2 of 57) of reference bradycardia, none of the 18 reference tachycardia and 1 AF event. Overall, among 120 ECGs labelled as 'no sinus rhythm' by the reference device, only 3 (2.6%) of them were also labeled as 'no sinus rhythm' by the smartwatch. **Conclusions:** The smartwatch considered in this study produces heart rate that is not clinically different than heart rate calculated by a reference 12-lead ECG. However, the ECG abnormalities identified by reference ECGs were typically missed by the smartwatch. Research Sponsor: National Cancer Institute; R01CA261834.

Comparison of GE MUSE and smartwatch ECG statements.

		Smartwatch Statements

Predicting valvular heart disease in adult survivors of childhood cancer: A report from the Childhood Cancer Survivor Study (CCSS) and St. Jude Lifetime Cohort (SJLIFE). First Author: Daniel A. Mulrooney, St. Jude Children's Research Hospital, Memphis, TN

Background: Radiotherapy (RT)-related valvular heart disease (VHD) is an understudied late toxicity of childhood cancer therapy. We aimed to define the risk of VHD with clinical data available at 5 and 20 years from cancer diagnosis. **Methods:** Mean heart RT doses were estimated for participants of the CCSS and SJLIFE cohorts treated with RT. Two piecewise exponential regression prediction models were developed in the CCSS, from entry into survivorship (5 years post cancer diagnosis) and 20 years post diagnosis (inclusive of age- and lifestyle-acquired risk factors), to assess subsequent risk of developing severe/life-threatening/fatal VHD (≥ grade 3 Common Terminology Criteria for Adverse Events [CTCAE]) by age 50 years. Models were validated among clinically assessed SJLIFE survivors. **Results:** Among 18,807 CCSS participants [mean age (±standard deviation) at diagnosis = 8.1 (5.8) years and 40 (11.1) at assessment] including 9,998 treated with RT, 164 (0.9%) reported VHD after cohort entry. Of those ≥20 years post diagnosis (n = 16,618) [7.9 (5.8) years at diagnosis; 42.5 (9.6) at assessment] 138 (0.8%) reported VHD. In SJLIFE, 44 (1.0%) of 4,388 survivors, including 2,103 treated with RT, and 35 (1.4%) of 2,423 ≥20-year survivors had VHD (mean ages at diagnosis and assessment: 7.8 [5.7] and 32 [12] years; 7.6 (5.5) and 38.7 (9.2) years, respectively). Prediction performance at age 50 years was good for both models [areas under the receiver operating characteristic curves 0.84 (95% CI 0.79-0.89) and 0.87 (95% CI 0.81-0.91)]. For each 10 Gy of heart RT, the rate of VHD increased approximately 2.5-fold (Table). Acquired risk factors, except glucose intolerance, further increased the risk, marginally for hypertension, significantly (p < 0.05) for obesity (RR 1.7 95% CI 1.0-2.8) and dyslipidemia (RR 2.3 95% CI 1.3-4.0). **Conclusions:** In the first study to develop validated risk prediction models for VHD in survivors of childhood cancer, mean heart RT dose and acquired factors significantly increased the risk, suggesting opportunities for intervention. Research Sponsor: U.S. National Institutes of Health; R01CA261750; U.S. National Institutes of Health; U24 CA55727; U.S. National Institutes of Health; U01 CA195547; American Lebanese Syrian Associated Charities (ALSAC).

Characteristics and concomitant congenital abnormalities among newborns with cancer: A population level analysis. First Author: Sergio Hernandez-Llamas, DHR Health Internal Medicine, Edinburg, TX

Background: Congenital cancers are rare, occurring in 223 per million infants annually. Neuroblastoma, leukemia, and CNS tumors are most common. Up to one-third of cases involve genetic predispositions, emphasizing the need to understand developmental abnormalities for improved surveillance, prognosis, and targeted therapies. **Methods:** A retrospective population-based cohort study was conducted utilizing the Texas Inpatient Public Use Data File (TIPUDF) from 2016 to 2023. The target population consisted of all hospitalizations with Newborn in the source of admission column of the TIPUDF. Hospitalizations discharged more than one year after birth were excluded from the study. The primary exposure was a diagnosis of cancer identified using International Classification of Diseases, Tenth Revisions, Clinical Modification (ICD-10-CM) codes selected from diagnosis chapter NEO: Neoplasms and beginning with C. Outcome variables were selected from diagnosis chapters MAL: Congenital Malformations, Deformations and Chromosomal Abnormalities and PNL: Certain Conditions Originating in the Perinatal Period. Continuous variables are summarized as mean and standard deviation (SD) categorical variables are summarized as counts and percentages. Fisher's exact test and t-tests assessed group differences, with the standardized mean difference (SMD) used as an effect size. **Results:** Out of the 2,906,295 newborn admissions in the TIPUDF from 2016-2023, 136 had a diagnosis of cancer. Compared to newborn admission without cancer, newborn admissions with cancer were more often male (62.5% vs 51.0%). Compared to newborns without cancer, newborns with cancer were associated with higher rates of congenital malformations, deformations and chromosomal abnormalities including atrial septal defects (38.2% vs 1.7%, SMD = 1.0256, p < 0.0001), anomalies of the aorta (1.6% vs 39.7%, p < 0.0001), undescended testicles (0.5% vs 2.9%, SMD = 0.1932, p < 0.0037), ventricular septal defects (15.4% vs 0.7%, SMD = 0.5647, p < 0.0001), Atresia and stenosis of urethra and bladder neck (2.2% vs 0.0%, SMD = 0.2119, p < 0.0001), Cleft lip/palate (2.2% vs 0.1%, SMD = 0.1935, p = 0.0009), anomalies of ureter (1.5% vs 0.0%, SMD = 0.1695, p < 0.0003). Newborns with cancer were more frequently affected by maternal conditions and complications including polyhydramnios (2.9% vs 0.2 %, SMD = 0.2260, p < 0.0001) and maternal infectious and parasitic diseases (7.4% vs 2.6%, SMD = 0.2193, p = 0.0032). **Conclusions:** Congenital cancers are rare but closely linked to congenital abnormalities and maternal complications, emphasizing the importance of early detection and tailored care. Future studies should explore underlying mechanisms and design effective surveillance strategies to enhance early diagnosis and outcomes. Research Sponsor: None.

10072 Poster Session

Evaluating survivorship-related communication gaps to develop a community health worker-led intervention for Hispanic/Latino young adult childhood cancer survivors and their families. First Author: Stephanie M. Smith, Division of Hematology, Oncology, Stem Cell Transplantation & Regenerative Medicine, Department of Pediatrics, Stanford University School of Medicine, Palo Alto, CA

Background: Open communication among young adult childhood cancer survivors (YA-CCS), parents, and clinicians helps YA-CCS understand their cancer history, health risks, and survivorship care needs. However, Hispanic/Latino (H/L) YA-CCS families who prefer a language other than English face significant communication barriers during clinical encounters with English speaking clinicians. As part of an ongoing study aimed at developing an intervention to facilitate family-centered communication, we report here on interviews conducted with H/L YA-CCS and their parents. **Methods:** We held small group and individual interviews in English and Spanish with H/L YA-CCS (ages 18-25, ≥5 years post-diagnosis) and separately with parents of H/L YA-CCS. Transcripts were analyzed qualitatively using thematic analysis in Dedoose software. Participants were recruited through our collaboration with a community-based organization (CBO) and in a pediatric oncology clinic. Using a structured human-centered design process, we assembled a design team of community partners to ideate and prototype an intervention. **Results:** Ten YA-CCS (5 female, 5 male; all bilingual) and 10 parents (all female; Spanish-language preferred) participated, representing 13 families. YA-CCS were median age (min-max) 20.5 (18-25) years and 9 (6-15) years post-diagnosis. YA-CCS described knowledge gaps due to being excluded from parent-clinician conversations during treatment and ongoing avoidance of cancer discussions within families due to emotional burden. Many YA-CCS and parents shared that yearly survivorship clinic visits evoke stress, nervousness, and a sense of being unprepared, often leaving them overwhelmed. Some linked hesitancy to discuss cancer or ask questions during visits to their cultural norms. Guided by these insights, we leveraged our community-clinic partnership to co-develop an intervention to facilitate family-centered communication. In 3 design workshop sessions, CBO staff designed an early prototype for a "pre- and post-visit preparation" communication intervention, in which a community health worker meets with each YA-CCS-parent dyad before and after a survivorship clinic visit to help elicit questions, clarify topics, and debrief action items. **Conclusions:** Effective triadic communication is essential to bridge gaps in cancer survivorship care among H/L YA-CCS. Listening directly to H/L YA-CCS and parents identified communication barriers that are being addressed in the development of a culturally and linguistically tailored intervention to support families affected by cancer. Interviews and the intervention design process are ongoing and updated data will be presented at the meeting. Research Sponsor: Conquer Cancer, the ASCO Foundation; National Institutes of Health, National Cancer Institute; 1K08CA285829-01.

Development of a pediatric oncology financial toxicity outcome measure with content and face validity: The Parent-Reported Instrument of Costs and Experiences with financial toxicity (PRICE) measure. First Author: Timothy James Daeeun Ohlsen, Department of Pediatrics, Seattle Children's Hospital, University of Washington, Seattle, WA

Background: Cancer treatment often leads to adverse financial consequences for patients and families (i.e., financial toxicity, FT). There is no validated measure to quantify FT in pediatric cancer settings, limiting research in this area. **Methods:** We applied a stepwise approach to measure development consistent with ISPOR guidelines. First, we conducted qualitative concept elicitation interviews with family caregivers of children treated for cancer, 3-24 months following diagnosis. Second, we drafted de novo survey items guided by salient domains and aspects of FT from the interviews. Items were reviewed by a multi-institutional panel of experts in oncology and/or FT-related research, who provided numeric ratings of item relevance for aggregation into content validity index (CVI) scores. Experts also provided free text feedback on clarity and content. Items with CVI $<$ 0.75 were removed or revised by a consensus-based process. The revised item list was organized into a preliminary measure and forward and back translated into Spanish. Finally, we pretested items with a new cohort of caregivers in English and Spanish, through iterative rounds of language-concordant cognitive interviews (3-4 per round). Between each round, we reviewed and revised the survey to optimize comprehension, decision and response processes, and flow. **Results:** Concept elicitation with 21 caregivers (86% mothers, 47% college-educated, 14% in Spanish) led to the creation of 56 initial survey items across 5 domains of FT: increased household spending, diminished income, household material hardship, psychological distress related to finances, and behaviors in response to FT. The expert panel (n = 11) consisted of 5 providers, 2 clinical social workers, 2 nurse researchers, and 2 non-clinician researchers, with 6 members external to the study institution. CVI was $<$ 0.75 for 13 items; 11 of these were removed and 2 were revised based on free text feedback. Of 43 items with CVI $\geq$0.75, 9 were removed based on feedback and/or overlap with more highly rated items. Cognitive interviews were held with 19 caregivers (15 in English, 4 in Spanish; 74% mothers, 53% college educated) over 5 iterative rounds. The 36 remaining items were revised and/or removed, and ultimately organized into 16 questions, one of which was added during this phase based on caregiver feedback. In the final round of interviews, participants reported no concerns with content, clarity, or organization in either language. **Conclusions:** We developed a novel outcome measure with content and face validity to assess FT specifically in pediatric oncology settings. Next steps consist of field testing to evaluate the measure's psychometric properties and other dimensions of validity. Potential future applications include use as a study endpoint and/or clinical screening tool. Research Sponsor: Conquer Cancer, the ASCO Foundation.

TPS10074 **Poster Session**

A phase 1/2, open-label study evaluating the efficacy, safety, and pharmacokinetics of luveltamab tazevibulin in infants and children < 12 years of age with *CBFA2T3::GLIS2* acute myeloid leukemia. First Author: Sarah K Tasian, Children's Hospital of Philadelphia, Philadelphia, PA

Background: *CBFA2T3::GLIS2*-rearranged acute myeloid leukemia (AML) is a rare subtype of AML occurring exclusively in very young children and is associated with poor prognosis ($<$ 15% 5-year event-free survival [EFS]) with best-available multi-agent chemotherapy. Luveltamab tazevibulin (luvelta) is an anti–FRα-targeting antibody-drug conjugate with a stable cleavable linker and a 3-aminophenyl hemiasterlin warhead (DAR = 4), which induces cytotoxic and immunologic cell death. *CBFA2T3::GLIS2* AML uniquely expresses high cell surface levels of the FRα, suggesting that FRα-targeted therapies may be effective. Preclinical studies have demonstrated that treatment with luvelta can result in leukemia clearance. Preliminary safety and efficacy data from 25 children with relapsed/refractory *CBFA2T3::GLIS2* AML treated with luvelta via compassionate use are promising [Williams, et al, BLOOD 2023, 142 (1): 4295]. **Methods:** This registration-enabling phase 1/2 study (clinicaltrials.gov NCT06679582) will investigate the pharmacokinetics, safety and preliminary efficacy of Luvelta in relapsed or refractory children with *CBFA2T3::GLIS2* AML and $\geq$5% bone marrow (BM) involvement by morphology. The *CBFA2T3::GLIS2* fusion will be confirmed at Foundation Medicine by next generation sequencing (NGS). The trial will open in up to 35 centers across US, Europe, Canada and Australia and is actively enrolling. The initial part of the trial will test luvelta monotherapy at 3.5 mg/kg or 4.3 mg/kg administered IV every 2 weeks in a 28-day cycle. Bayesian sequential monitoring is used for safety monitoring. The study committees will review the data to identify the recommended phase 2 dose of luvelta which will then be tested in the second part of the trial. Children who achieve BM morphological complete response (CR) may proceed to allogeneic hematopoietic stem cell transplantation (HSCT) or continue single-agent luvelta for up to 2 years at the investigators' discretion. Patients without CR after 2 cycles of luvelta monotherapy may add chemotherapy (cytarabine +/- fludarabine or azacytidine) in cycle 3 and beyond. Post-HSCT maintenance therapy with luvelta monotherapy is also allowed for up to 2 years. The primary endpoint is morphologic CR defined as $<$ 5% AML blasts in BM with absolute neutrophil recovery to $>$ 1000 and platelets $>$ 100,000 and absence of extramedullary disease. Secondary endpoints include PK levels and assessment of anti-drug antibody formation, safety, EFS and overall survival. Rates of measurable residual disease-negative CR and FRα antigen levels pre- and post-luvelta will also be explored. Clinical trial information: NCT06679582. Research Sponsor: None.

TPS10075 **Poster Session**

Phase 1/2 study of zilovertamab vedotin in pediatric and young adult hematologic malignancies or solid tumors (LIGHTBEAM-U01A). First Author: Hyoung Jin Kang, Seoul National University College of Medicine, Seoul National University Cancer Research Institute, Seoul National University Children's Hospital, Seoul, South Korea

Background: ROR1 is an oncofetal protein expressed in various blood and solid cancers. Zilovertamab vedotin (ZV) is an antibody-drug conjugate comprising a monoclonal antibody against ROR1, a proteolytically cleavable linker, and monomethyl auristatin E. LIGHTBEAM-U01A (NCT06395103) is a single-arm, open-label, phase 1/2 basket study designed to evaluate ZV in 4 disease cohorts: pediatric B-cell acute lymphoblastic leukemia (B-ALL), pediatric diffuse large B-cell lymphoma (DLBCL)/Burkitt lymphoma, pediatric neuroblastoma, and pediatric or young adult Ewing sarcoma. **Methods:** Pediatric participants (pts) are aged 0 to $<$ 18 years; young adults are aged 18-25 years. Pts must have a confirmed diagnosis of B-ALL or DLBCL/Burkitt lymphoma per WHO criteria that has relapsed after $\geq$2 prior lines of therapy, or histologically confirmed neuroblastoma or Ewing Sarcoma that is refractory to frontline therapy. Pts with B-ALL must have $\geq$5% bone marrow blasts (M2 or M3), pts with DLBCL/Burkitt lymphoma must have radiographically measurable disease per IPNHL response criteria, and pts with neuroblastoma or Ewing sarcoma must have measurable disease per RECIST v1.1 (or MIBG-avid evaluable neuroblastoma). Pts aged $\leq$16 years must have a Lansky play-performance scale $\geq$50, pts aged $>$ 16 to $<$ 18 years must have a Karnofsky performance status of $\geq$50, and pts aged $\geq$18 years must have an ECOG performance status of 0 or 1. The study consists of 2 parts: dose escalation and confirmation (part 1) and efficacy expansion (part 2). Part 1 will enroll 3-12 pts per dose level. Also, $\geq$3 pts will be enrolled in 2 age groups: 1 to $<$ 6 years and 6 to $<$ 18 years. Pts will receive ZV at a starting dose of 2 mg/kg IV Q3W, escalating to 2.25 and 2.5 mg/kg or de-escalating to 1.75 mg/kg per a modified toxicity probability interval design-2. In part 2, eligibility will be expanded to $\geq$6 months for all cohorts and $\leq$25 years for Ewing sarcoma (if adequate safety and tolerability are shown, eligibility will expand to age 0 to $<$ 6 months). In part 2, 10 pts will be enrolled in each cohort and will receive ZV at the preliminary RP2D determined in part 1. Disease assessments for pts with DLBCL/Burkitt lymphoma, neuroblastoma, or Ewing sarcoma will be performed Q8W for 6 months, then Q12W through 24 months, then Q24W through 5 years, then annually. Disease assessments for B-ALL will be performed at the end of each treatment cycle, at 6 months, at 1 year, then annually. Adverse events (AEs) will be monitored $\leq$30 days after last dose of study treatment (90 days for serious AEs; 30 days if new anticancer therapy is initiated) and will be graded per NCI CTCAE v5.0. Primary end points are safety and objective response rate. Secondary end points are pharmacokinetics, immunogenicity, duration of response, and eligibility for transplant/CAR-T therapy for pts with B-ALL or DLBCL/Burkitt lymphoma. Approximately 50-90 pts will be enrolled. Recruitment is underway. Clinical trial information: NCT06395103. Research Sponsor: Merck Sharp & Dohme LLC, a subsidiary of Merck & Co., Inc., Rahway, NJ, USA.

10500 Oral Abstract Session

Sensitivity of age and family history (FH) criteria for determining pancreatic cancer (PC) surveillance (PCS) eligibility among individuals with hereditary PC risk. First Author: Asaf Maoz, Dana-Farber Cancer Institute/Mass General Brigham/Harvard Medical School, Boston, MA

Background: PCS for individuals with pathogenic/likely pathogenic germline variants (PGVs) predisposing to PC is associated with earlier stage at diagnosis (dx) and improved survival, compared to historical controls. For those with such PGVs, PCS eligibility is determined based on FH of PC and age (age ≥30 years for those with *STK11* PGVs; age ≥40 for *CDKN2A*; age ≥50 for other PC risk genes [Table 1]; or 10 years before the youngest PC in the family). For PGV carriers (apart from *CDKN2A/STK11*), guidelines have required a FH of PC in ≥1 first-/second-degree relatives (FDR/SDR) for PCS eligibility. Limited data have evaluated the sensitivity of these criteria in determining which high-risk individuals benefit from PCS. **Methods:** We evaluated the sensitivity of age and FH criteria for PCS in the Myriad Collaborative Research Registry (MCRR). Individuals who were diagnosed with PC and underwent germline genetic testing were included. To determine the number of PGV carriers who would have been eligible for PCS at the time of their PC dx, FH of cancer and personal cancer history were ascertained from data contained in MCRR at the time of germline testing. **Results:** Among 11,248 PC patients who underwent germline testing, 55.5% were female and 59.2% were non-Hispanic White/European. The mean age at PC dx was 64.6 years. PGVs predisposing to PC were detected in 969 (8.6%) individuals [Table 1], of whom 224 (23.1%) met gene-specific PCS criteria. Of the 969, 829 (85.6%) met gene-specific *age criteria* for PCS. Of the 931 individuals with PGVs in genes requiring FH, only 208 (22.2%) fulfilled *FH criteria* for PCS. **Conclusions:** Most individuals with PC who harbor PGVs in PC susceptibility genes would not have met gene-specific age/FH criteria for PCS. FH of PC has particularly poor sensitivity in identifying PGV carriers who go on to develop PC, supporting recent removal of this criterion from NCCN guidelines for *BRCA2/ATM*. Validation in a clinic-based cohort is ongoing. These data suggest that FH of PC should not be used to determine which PGV carriers are eligible for PCS. Research Sponsor: Betsy Rowe and Family.

10501 Oral Abstract Session

A prospective study of whole-body MRI (WBMRI) as part of a multimodality screening program for individuals with Li-Fraumeni syndrome (LFS). First Author: Asaf Maoz, Dana-Farber Cancer Institute/Mass General Brigham/Harvard Medical School, Boston, MA

Background: Individuals with LFS are at risk for developing cancer in multiple organs and therefore require a multimodal cancer screening program. We assessed the performance of annual WBMRI in early cancer detection for individuals with LFS. **Methods:** Individuals with a germline pathogenic or likely pathogenic variant in the *TP53* gene (defined as LFS) and without cancer diagnosed or treated in the preceding 6 months were eligible to undergo annual non-contrast WBMRI. Clinical findings on WBMRI, follow-up studies, and biopsies were prospectively assessed. Cancer incidence during the study period and up to 18 months after WBMRI was evaluated. **Results:** 162 eligible participants (pts) with LFS (127 adult, 35 pediatric) underwent a total of 477 WBMRIs; 119 (73%) underwent 3 or more. Median age at enrollment was 37 years; 75% of pts were female. Classic or Chompret diagnostic criteria for LFS were met for 66% (84/127) of adult and 77% (27/35) of pediatric pts. Follow-up studies for findings on WBMRI were pursued for 61.4% (78/127) of adult and 34.3% (12/35) of pediatric pts. Biopsies were performed without complication in 18% (29/162) of pts with 39.5% of 38 biopsies confirming a cancer diagnosis. The percentage of pts requiring follow-up studies or biopsies decreased with consecutive WBMRIs (Table 1). During the study period, 37 cancers were diagnosed in 33 pts (27 adults, 6 children); 26 of these pts were alive at the time of data cut off. Fifteen of 37 cancers (40.5%) were asymptomatic cancers diagnosed by WBMRI; 86% (13/15) of these (in 12 patients) were localized and treated with curative intent, including 3 lung cancers and 4 pelvic/abdominal sarcomas. Ten of these 12 pts remain alive at the time of last follow-up. The 22 cancers not diagnosed on WBMRI included five sarcomas, and one each of adrenocortical, lung, thyroid and renal cell carcinoma as well as cancers not likely to be detected on WBMRI (4 breast/chest wall, 3 endoluminal, 3 hematologic, and 3 metastatic recurrences). **Conclusions:** Annual WBMRI contributes substantially to detection of asymptomatic localized cancers among individuals with LFS but interval cancers remain common. Our study highlights limitations of WBMRI and the need for further research to enhance early detection and interception of cancer in LFS. The eREACH study: A randomized study of an eHEALTH delivery alternative for cancer genetic testing for hereditary predisposition in patients with metastatic cancers. First Author: Angela R. Bradbury, University of Pennsylvania, Philadelphia, PA

Background: With FDA approval of targeted therapies in patients with germline *BRCA1/2*-related advanced cancers there is a need to evaluate efficient and effective delivery models for germline cancer genetic testing. **Methods:** eREACH is a 4 arm non-inferiority study where traditional standard-of-care pre-test (visit 1) and post-test (visit 2) counseling delivered by a genetic counselor (GC) are replaced with a patient-centered eHealth (digital) intervention in patients with advanced or metastatic cancer. GC visits were offered by telehealth in the home. Arms include: A (GC/GC), B (GC/digital), C (digital/GC) and D (digital/digital). Those assigned to a digital visit could request a visit with a GC if preferred. Surveys were completed at baseline (T0), after visit 1 (T1), visit 2 (T2) and 6 months (T3). Primary non-inferiority outcomes are change in knowledge and anxiety (T0-T1, T0-T2). Secondary outcomes include uptake of testing, depression, cancer specific distress, responses to testing and satisfaction. We used an intention-to-treat approach (ITT) and as-treated approach (secondary). We used ANOVAs and chi-squared tests for hypothesis testing. For non-inferiority testing, we had additional rules based on the magnitude and sign of effects. **Results:** 229 participants were recruited from 14 states through Penn Medicine, community sites and social media, with 56-60 per arm.Participants were 35-91 YO (mean 67 YO),and37% were male, 17% were non-white and 43% had less than a college education. 70% were from academic sites, 21% from community sites and 9% from social media. Cancer types were: 52% breast, 26% prostate, 18% pancreatic, and 5% ovary. 173 (76%) of patients completed testing (12% had a positive result, 12% had a VUS). In our primary ITT analyses, we met the non-inferiority threshold for all primary and secondary outcomes except for knowledge (T0-T2) and uptake of testing. Increases in knowledge (T0-T2) were greater in Arms A-C as compared to Arm D, although differences were small (averages +2.03-2.54 v +1.23). Uptake of visit 1 was lower in the digital arms (A: 94.7%, B: 92.7% v. C: 76.7%, D: 82.5%), although uptake of testing after visit 1 met non-inferiority. 20% assigned to Arm C and 11% assigned to Arm D requested a GC. As-treated non-inferiority analyses were similar to the ITT results. **Conclusions:** Offering patient-centered digital delivery models with one digital visit and one visit with a genetic counselor is non-inferior to two visits with a genetic counselor for patients with metastatic cancer. Reminders, outreach or completion of digital platforms in clinic could address differences in uptake. The fully digital model may be associated with small differences in knowledge gain, although the clinical significance may be small., and longitudinal data could help inform the appropriateness of the fully digital model. 10503 Oral Abstract Session

Feasibility of Pap-derived ctDNA for detection of sporadic and Lynch-associated endometrial cancer. First Author: Alicia Latham, Memorial Sloan Kettering Cancer Center, New York, NY

Background: Patients (pts) with Lynch Syndrome (LS) have high risk of endometrial cancer (EC) and are recommended risk-reducing hysterectomy (RR-Hys/BSO) due to lack of effective screening. As plasma-derived circulating tumor DNA (plasma-ctDNA) lacks adequate sensitivity in EC, we sought to evaluate Pap-derived ctDNA (Pap-ctDNA) as a novel, non-invasive assay for EC detection. **Methods:** Plasma-ctDNA and Pap-ctDNA were obtained from pts with EC undergoing surgery or LS undergoing RR-Hys/BSO under an IRB-approved protocol. Paired tumor/normal sequencing of ECs was compared to genomic findings from plasma-ctDNA and Pap-ctDNA. Somatic variants in plasma and Pap samples were genotyped using matched tumor tissue, with average allele frequency (VAF) calculated. Tumors were assessed for MSI and/or MMRD via MSISensor or IHC. In LS pts, pathology for precursor lesions was assessed. **Results:** 19 pts (16 EC, 3 LS) underwent prospective collection of 42 samples (20 plasma, 22 Pap). 56% of ECs were low-grade endometrioid and 81% early-stage (I/II) (Table). 12.5% of ECs were MMRD due to MLH1 hypermethylation. Median yield of Pap-ctDNA was higher than plasma-ctDNA (91ng vs. 19.5ng; p=0.0004). 94% of ECs had mutations covered within target regions of both assays, with mutations detected in 93% of Pap-ctDNA, but only 33% of plasma-ctDNA. In pts with mutations detected in both assays, median VAF was higher in Pap-ctDNA vs. plasma-ctDNA in all 5 cases (Table; p=0.012). Among the 13 pts with early-stage EC, 92% of Pap-ctDNA vs 23% of plasma-ctDNA were positive. Of 3 LS pts, one had a focus of MMRD atypical hyperplasia concordant with germline MMR mutation; plasma and Pap-ctDNA were negative. **Conclusions:** Pap-ctDNA from EC pts results in higher ctDNA yield than plasma-based testing. Tumor mutations were detected in >90% of Pap-ctDNA even in early-stage EC, versus only 23% of plasma-ctDNA samples. Pap-ctDNA for early-detection of EC is feasible and is a promising tool for average and high-risk individuals with potential applicability in other neoplasms. Research Sponsor: Society of Memorial Sloan Kettering Cancer Center.

10504 Oral Abstract Session

Gene-specific outcomes in patients with Lynch syndrome treated by immune checkpoint blockade for advanced cancer. First Author: Violaine Randrian, Memorial Sloan Kettering Cancer Center, New York, NY

Background: Lynch syndrome (LS), caused by germline pathogenic variants (gPVs) in DNA mismatch repair genes (*MLH1, MSH2, MSH6, PMS2*), is characterized by microsatellite instability (MSI)/mismatch repair deficiency (MMRd) of associated tumors. The impact of the underlying gPV on the prognosis of LS patients with advanced cancer receiving ICB has not been elucidated. **Methods:** Consecutive cancer-affected LS pts consented to tumor-normal DNA sequencing via MSK-IMPACT (NCT01775072), from 01/2014-01/2024 with advanced solid tumors and receiving ≥1 ICB dose were identified. In cases of multiple cancers, only the first one was considered. MSI and MMRd was assessed via NGS-derived MSISensor score or IHC staining, respectively. Radiological response rates and survival were assessed. **Results:** Among 186 LS patients, 132 had an ICB treated advanced tumor with the following prevalence of gPV: *MSH2* 41% (N=54), *MLH1* 28% (N=37), *PMS2* 17% (N=23), and *MSH6* 14% (N=18). The most represented tumor types were colorectal (35%, N=46), urothelial (14%, N=18), pancreatic/biliary (13%, N=17), upper gastro-intestinal (11%, N=15), endometrial (11%, N=15). Objective response rate was 58%, including 35% with radiological complete response (CR) with higher CR rates in g*MLH1* and g*MSH2* patients (Table). Median follow-up was 53 months [range:0.3-116.3]. Median overall survival (mOS) / Progression free survival (mPFS) were significantly prolonged in *non-gPMS2* patients vs. g*PMS2* patients (Table). MMR IHC was available for 107 (80%) tumors identifying 88% (n=94) as MMRd and 12% (n=13) as MMRp tumors. 69% (9/13) of MMRp tumors were in *PMS2* patients with 8 being both MMRp and MSS suggesting a sporadic origin rather than LS-related cancer. Stratifying by MMRd and MSI status, mOS was similar in patients with MMRd/MSI and MMRd/MSS tumors (109 months vs not reached (NR); HR=0.86; 95%CI [0.35-2.13]), but significantly diminished in in pts with MMRp as compared to MMRd tumors (20 vs 109 months, HR=0.27; 95%CI [0.77-0.96]). In g*PMS2* patients with MMRd tumors, median OS was 27.7 months. **Conclusions:** ICB treatment results in high CR rates in LS patients. The shorter mOS amongst LS patients with *gPMS2* compared to other LS genes is partially explained by the higher prevalence of sporadic MMRp tumors. Even in the context of an MMRd tumor, patients with g*PMS2* have worse outcomes than LS patients with other gPVs. 10505 Oral Abstract Session

Phase Ib study of a plasmid DNA–based immunotherapy encoding the hTERT, PSMA, and WT1 (INO-5401) +/- IL12 (INO-9012) followed by electroporation in cancer patients and healthy individuals with *BRCA1/2* mutations. First Author: Susan M. Domchek, Abramson Cancer Center, Penn Medicine, Philadelphia, PA

Background: Pathogenic variants in *BRCA1/2* increase the risk of breast, ovarian, pancreatic and prostate cancer. Non-surgical risk-reduction strategies are needed. We evaluated an immunological approach for cancer interception via a DNA plasmid vaccine. INO-5401 is a recombinant plasmid-derived DNA based immunotherapy encoding 3 tumor-associated antigens: human telomerase reverse transcriptase (hTERT), prostate specific membrane antigen (PSMA), and Wilms Tumor-1 (WT1). INO-9012 is a DNA plasmid encoding IL-12 deployed as an immune adjuvant. Previous studies have shown that INO-5401 in combination with INO-9012 administered via intramuscular (IM) injection followed by electroporation (EP) with CELLECTRA is both immunogenic and tolerable in cancer patients and may lead to efficacy. **Methods:** The primary objective of NCT04367675 is to evaluate the safety of INO-5401 +/- INO-9012 followed by EP in individuals with *BRCA1/2*. Cohort A included adults with prior localized cancer, no evidence of disease (N = 16); Cohort B, healthy individuals with no prior cancer (goal N = 28). Eligibility: ECOG performance status 0-1, normal ECG, and adequate bone marrow, hepatic, and renal function. Treatment: INO-5401 9 mg IM followed by EP (Arm 1) and INO-5401 9 mg in combination with INO-9012 1 mg IM. followed by EP (Arm 2) on Day 1, and weeks 4, 8, 12. Subjects are assessed at the time of therapy, 2 weeks after each therapy and then every 16 weeks for 2 years. Secondary endpoints (not reported here) include evaluation of immune response. **Results:** 42 of 44 planned subjects are enrolled and have received >1 vaccine (N = 24 *BRCA2*; N = 15 *BRCA1*, N = 3 *BRCA1* and *BRCA2*). All doses will be administered by June 2025 and safety data during administration will be complete. In Cohort A, 17 women, 1 man were treated (median age of 52 [range 39-75]). In Cohort B (healthy individuals), 14 women, 12 men were treated (median age of 48 [range 31-69]). 148 doses have been given. One patient received only 1 vaccine due to treatment-related Grade 1 hematoma. Treatment-related AEs were seen in 95% of subjects, largely grade 1 injection site reactions. AEs seen in > 25% are as below. Grade 3 AEs were seen in 6 (15%), including urticaria (N = 1), vasovagal reaction (N = 1), and hypertension (N = 4), none of which were treatment-related. **Conclusions:** Administration ofa recombinant plasmid-derived DNA based immunotherapy encoding hTERT, PSMA and WT1, +/- IL12, followed by electroporation is feasible and safe in individuals with *BRCA1/2*, including healthy individuals with no prior cancer. The most common AEs are injection site reactions, all of which were Grade 1/2. Clinical trial information: NCT04367675. Research Sponsor: Inovio Pharmaceuticals.

CTCAE Term	Grade 1	Grade 2	Frequency
Pain	N=26	N=3	72.5% (N=29)
Bruising	N=26	N=0	65.0% (N=26)
Swelling	N=19	N=0	47.5% (N=19)
Redness	N=14	N=0	35.0% (N=14)
Injection Site Reaction	N=11	N=2	32.5% (N=13)

10506 Oral Abstract Session

Menopausal hormone therapy after a diagnosis of breast cancer in women with a *BRCA* pathogenic variant and risk of death. First Author: Joanne Kotsopoulos, Women's College Hospital, Toronto, ON, Canada

Background: Use of menopausal hormone therapy (MHT) is contraindicated for women with a personal history of breast cancer. This topic is of importance among women with a pathogenic or likely pathogenic variant (mutation) in *BRCA1* or *BRCA2* given their tendency to develop early onset disease as well as the recommendation to undergo oophorectomy prior to natural menopause. **Methods:** We conducted a prospective analysis of MHT use following breast cancer in *BRCA* carriers and the risk of death. The study included *BRCA* carriers with a diagnosis of breast cancer, no history of another cancer, no prior MHT use, and who were enrolled in a longitudinal study. Women who initiated MHT after their diagnosis were matched to women who did not use MHT on year of birth, age of diagnosis, and treatments received – resulting in 183 matched pairs. We followed women from the date of first MHT use in the exposed and the matched date in the unexposed. Cox proportional hazards was used to estimate the hazard ratio (HR) and 95% confidence intervals (CI) for the risk of death associated with MHT use. **Results:** Among the 183 MHT users, 53 (29%) used a local MHT and 130 (71%) used a systemic MHT. After 6.0 years of follow-up (range 0.01-22.7); there were 9 (4.9%) deaths in the MHT group vs. 22 deaths (12%) in the no MHT group (P = 0.01). The corresponding number of breast cancer deaths were 6 (3.3%) vs. 16 (8.7%) (P = 0.03). The HR for all-cause mortality was 0.31 (95%CI 0.14-0.69; P = 0.004) and for breast cancer-specific mortality was 0.27 (95%CI 0.10-0.70; P = 0.007). The corresponding risk estimates for all-cause death by invasiveness were 0.25 (95%CI 0.11-0.61; P = 0.002) and 0.54 (95%CI 0.07-4.02; P = 0.54) for invasive disease and DCIS, respectively. All-cause mortality with use of systemic MHT was 0.27 (95%CI 0.11-0.67; P = 0.005) and was 0.19 (95%CI 0.03-1.45; P = 0.11) for local MHT. Compared to never HRT use, the HR for E-alone was 0.35 (0.12-1.02; P = 0.05) and was 0.58 (95%CI 0.08-4.29; P = 0.59) for E+P. Subgroup analyses by formulation, gene mutation and tumour pathology are on-going. **Conclusions:** Although based on small strata, the preliminary findings are suggestive of no increased risk of death with MHT use after *BRCA*-breast cancer and may offer an opportunity to improve quality of life in this unique population. Replication in larger datasets are needed. Research Sponsor: Breast Cancer Canada.

10507 Oral Abstract Session

Glucagon-like peptide-1 receptor agonists and incidence of obesity-related cancer in adults with diabetes: A target-trial emulation study. First Author: Lucas A. Mavromatis, NYU Grossman School of Medicine, New York, NY

Background: Obesity is a major risk factor for cancer development. However, whether glucagon-like peptide-1 receptor agonists (GLP-1RAs), a class of diabetes medication which causes weight loss, reduce cancer incidence is unknown. This study investigated whether GLP-1RAs reduce the risk of obesity-related cancer in adults with diabetes and obesity compared to dipeptidyl peptidase-4 inhibitors (DPP-4is), a weight-neutral class of diabetes medication. **Methods:** 85,015 adult patients from 43 U.S. health systems with a body mass index ≥ 30 kg/m2 and a diagnosis of diabetes, who newly initiated a GLP-1RA or DPP-4i between 2013 and 2023 were included. Patients prescribed GLP-1RAs (mean age, 56.8 years) were matched 1:1 on propensity score for GLP-1RA prescription and prescription year with patients prescribed DPP-4is (mean age, 56.8 years). Obesity-related cancer incidence was compared between groups. **Results:** Over a mean follow-up of 3.9 years, there was a lower risk of obesity-related cancers (adjusted HR, 0.93; 95% CI, 0.88-0.98; P=0.005) and all-cause death (adjusted HR, 0.92; 95% CI 0.87-0.97; P=0.001) associated with GLP-1RA use versus DPP-4i use. Assessments of cancer subtypes showed protective associations between GLP-1RA use and colon and rectal cancers. **Conclusions:** GLP-1RAs were associated with a lower risk of obesity-related cancer compared with DPP-4is in a large, real-world cohort of patients with diabetes and obesity. Future studies should prospectively assess the role of GLP-1RAs in cancer prevention. Research Sponsor: National Institute of Diabetes and Digestive and Kidney Diseases of the National Institutes of Health; R01 DK115534 to MEG; National Institute of Diabetes and Digestive and Kidney Diseases of the National Institutes of Health; K24 HL155861 to MEG; National Institute of Diabetes and Digestive and Kidney Diseases of the National Institutes of Health; K01 DK121825 to JS.

Adjusted hazard ratios of incidence of composite obesity-related cancer and all-cause death in propensity-matched patients prescribed GLP-1RAs versus DPP-4is (n=85,015 pairs).

Outcome	Sex	Events/$N_{at\ risk}$ (GLP-1RA)	Events/$N_{at\ risk}$ (DPP-4i)	HR (GLP-1RA/DPP-4i)	P	$P_{interaction}$
Obesity-related cancer (composite)	Overall	2,501/85,015 (2.9%)	2,671/85,015 (3.1%)	0.93; 95% CI, 0.88-0.98	0.005	NA
Obesity-related cancer (composite)	Female	1,754/44,762 (3.9%)	1,898/45,182 (4.2%)	0.92; 95% CI, 0.86-0.98	0.01	0.63
Obesity-related cancer (composite)	Male	747/40,253 (1.9%)	773/39,833 (1.9%)	0.95; 95% CI, 0.86-1.05	0.29	0.63
All-cause death	Overall	2,783/85,015 (3.3%)	2,961/85,015 (3.5%)	0.92; 95% CI, 0.87-0.97	0.001	NA
All-cause death	Female	1,219/44,762 (2.7%)	1,514/45,182 (3.4%)	0.80; 95% CI, 0.74-0.86	<0.001	<0.001
All-cause death	Male	1,564/40,253 (3.9%)	1,447/39,833 (3.6%)	1.04, 95% CI, 0.96-1.11	0.34	<0.001

Adjusted hazards ratios calculated using Cox regression represent ratios of the incidence of composite obesity-related cancer and all-cause death in matched pairs of patients prescribed GLP-1RA versus DPP-4i over average follow-up durations of 3.8 years (GLP-1RA) and 3.9 years (DPP-4i). Results of sex-stratified and sex interaction analyses are also displayed. The threshold for statistical significance is P<0.05.

10508 Oral Abstract Session

Association of glucagon-like peptide 1 receptor agonists with cancer risk in obesity adults with and without diabetes: A target trial emulation study. First Author: Hao Dai, Department of Health Outcomes and Biomedical Informatics, University of Florida, Gainesville, FL

Background: The use of glucagon-like peptide 1 receptor agonists (GLP-1RAs) has substantially expended given their remarkable benefits in managing obesity. Yet, their impact on long-term cancer risk remains unclear, with existing real-world evidence being limited and yielding conflicting results. **Methods:** This retrospective cohort study followed a target trial emulation design using 2014–2024 OneFlorida+ electronic health records (EHR) data. Adults (≥18 years) eligible for anti-obesity medications (AOMs) and without a cancer history were included. We compared GLP-RA users vs. non-users, with 1:1 propensity score matching applied to balance baseline factors between the two groups. The primary outcomes include the incidence of 16 obesity-associated cancers (liver, thyroid, pancreatic, bladder, colorectal, lung, kidney, breast, endometrial, meningioma, esophageal adenocarcinoma, gallbladder, upper stomach, ovarian, multiple myeloma, and prostate), assessed over a follow-up period of up to 10 years. Cox proportional hazards models were used to calculate hazard ratios (HRs) and 95% confidence intervals (CIs), and cumulative incidences were estimated using Kaplan-Meier analyses. **Results:** After matching, 43,317 GLP-1RA users were compared with 43,315 non-users. The incidence rates of the 16 cancers were 20.5 versus 23.6 per 1,000 person-years, respectively, indicating a significantly lower overall cancer risk among GLP-1RA users (HR, 0.83 [95% CI, 0.76–0.91]) compared to non-users. In particular, GLP-1RA use was associated with a reduced risk of endometrial cancer (HR, 0.75 [95% CI, 0.57–0.99]), ovarian cancer (HR, 0.53 [95% CI, 0.29–0.96]), meningioma (HR, 0.69 [95% CI, 0.48–0.97]), and esophageal adenocarcinoma (HR, 0.34 [95% CI, 0.12–0.94]). However, GLP-1RA users showed a trend toward an increased risk of kidney cancer (HR, 1.38 [95% CI, 0.99–1.93]), particularly among the younger adults (≤65 years) and overweight patients (BMI 27–29.9). **Conclusions:** In this large cohort of real-world obesity population with and without diabetes, GLP-1RA use was associated with an overall reduction in obesity-related cancer risk, as well as lower risks of several specific cancers. However, a potential elevated risk of kidney cancer, especially in younger or moderately obese individuals, highlights the need for targeted surveillance and longer-term follow-up to clarify the underlying mechanisms and clinical implications of these findings. Association between type of BRCA1/2 pathogenic/likely pathogenic variants and outcome in young patients with breast cancer: Results from an international cohort study. First Author: Angela Toss, University of Modena and Reggio Emilia, Modena, Italy

Background: Pathogenic/likely pathogenic variants (P/LPVs) in the *BRCA1 or BRCA2* genes significantly increase the risk of developing breast cancer (BC) and other malignancies, with distinct clinicopathologic features depending on the gene involved. However, the clinical implications of the type of P/LPVs within *BRCA1* or *BRCA2* genes remain to be elucidated. **Methods:** The BRCA BCY Collaboration (NCT03673306) is an international, multicenter, hospital-based, retrospective cohort study that included *BRCA* carriers diagnosed with invasive BC at the age of ≤40 years between January 2000 and December 2020. In this analysis, only patients with detailed available information on P/LPVs in the BRCA genes were included. Clinicopathologic features and survival outcomes (disease-free survival [DFS] and overall survival [OS]) were investigated according to P/LPV types (insertion-deletion mutations [INDEL] *vs* single nucleotide variants [SNV] *vs* copy number variations [CNV]; truncating *vs* non-truncating P/LPVs; frameshift *vs* nonsense *vs* splicing *vs* missense P/LPVs). **Results:** Out of 5660 patients from 109 centers worldwide, 3294 were eligible for the present analysis (2080 *BRCA1* and 1214 *BRCA2*). Overall, 61.3% of patients carried INDEL, 32.7% SNV and 6.0% CNV; 76.5% of patients exhibited truncating P/LPVs and 8.4% non-truncating P/LPVs (15.1% not classifiable). Frameshift mutations were the most common (60.3%), followed by nonsense (21.2%), splicing (9.6%), and missense (8.4%) P/LPVs. In both *BRCA1* and *BRCA2* carriers, no statistically significant differences in baseline clinicopathologic variables and P/LPV types were observed except for fewer patients with nodal involvement among CNV of BRCA2. Median follow-up was 7.9 (IQR 4.5-12.9) years. No association between the type of P/LPV in both *BRCA1* and *BRCA2* carriers and DFS was observed, except for better DFS in patients with missense variants of *BRCA2* gene. Compared to patients with non-truncating variants, patients with truncating variants in *BRCA1* had a shorter OS (HR 2.00; 95%CI 1.17-3.41). Albeit not statistically significant, a numerically worse OS was observed among *BRCA2* patients with truncating P/LPVs (HR 6.27 95% CI 0.86-45.87). In *BRCA1* carriers, compared to patients with frameshift P/LPVs, those with missense variants were associated with better OS (HR 0.48 95%CI 0.28-0.84 for missense). In *BRCA2* carriers, similar results were observed. **Conclusions:** In this global cohort of young BRCA carriers with BC, truncating P/LPVs were associated with poorer prognosis, and missense P/LPVs with improved prognosis. This study advances our understanding of the influence of specific types of *BRCA1/2* P/LPVs on BC characteristics and outcomes, potentially suggesting more personalized prevention strategies and treatment approaches. Clinical trial information: NCT03673306. Research Sponsor: None.

10510 Clinical Science Symposium

Germline pathogenic variants in cancer predisposition genes and overall survival of women with breast cancer. First Author: Siddhartha Yadav, Mayo Clinic, Rochester, MN

Background: The impact of germline pathogenic or likely pathogenic variants (PVs) in cancer predisposition genes on overall survival (OS) after breast cancer diagnosis is not well defined. In particular, unbiased OS estimates from population-based studies accounting for clinical subtypes of breast cancer (based on ER, PR, and HER2 status) and for genes other than *BRCA1/2* are lacking. **Methods:** The study included 25,168 prospectively followed women with locoregional invasive breast cancer within the population-based CARRIERS study. Germline sequencing using a custom multigene amplicon-based panel was performed to identify PVs. OS was compared between germline PV carriers in *ATM, BRCA1, BRCA2, CHEK2* and *PALB2* and non-carriers (negative for germline PVs in 13 known breast cancer predisposition genes) for each clinical subtype of breast cancer from the time of breast cancer diagnosis to death or last follow up in a multivariable Cox proportional hazard regression analysis adjusting for age at diagnosis, race/ethnicity, histology, TNM stage, type of surgery, use of adjuvant radiation, chemotherapy and endocrine agents. **Results:** Among 25,168 women with breast cancer, germline PVs in one of the five breast cancer predisposition genes were detected in 5.8% of the women [*ATM*: 0.8%, *BRCA1*: 1.3%, *BRCA2:* 1.6%, *CHEK2*: 1.5%, and *PALB2*: 0.6%]. Among women with ER+ breast cancer, compared to non-carriers, a significantly worse OS was noted for *BRCA1* (Hazard Ratio (HR): 1.8, 95% Confidence Interval (CI): 1.1 – 3.0, p=0.02) and *BRCA2* (HR: 1.8, 95%CI: 1.4 – 2.4, p<0.001), but not for *ATM* (HR: 1.2, 95%CI: 0.8 – 1.7, p=0.40) or *CHEK2* (HR:1.0, 95%CI: 0.8 – 1.3, p=1.0) PV carriers. Worse OS was noted in *PALB2* PV carriers with ER+ breast cancer (HR:1.5, 95%CI: 0.9 – 2.2, p=0.09), although it did not reach statistical significance. Similar HR estimates for OS as with ER+ breast cancer were observed in women with ER+/HER2- breast cancer for *BRCA1*, *BRCA2* and *PALB2* PV carriers, but only *BRCA2* results were statistically significant. Among women with ER-negative breast cancer, compared to non-carriers, a significant difference in OS was not observed for PV carriers in *ATM* (HR: 0.8, 95%CI: 0.4 – 1.8, p=0.63), *BRCA1* (HR:1.2, 95%CI: 0.8 – 1.7, p=0.35), *BRCA2* (HR: 0.8, 95%CI: 0.5 – 1.2, p=0.29), *CHEK2* (HR: 0.7, 95%CI: 0.3 – 1.4), or *PALB2* (HR: 0.9, 95%CI: 0.5 -1.7, p=0.78). **Conclusions:** The suggestive differences in OS by ER status of the tumor in *BRCA1* and *BRCA2* PV carriers warrant further investigation of underlying tumor biology and assessment of endocrine sensitivity of breast cancer in germline PV carriers. Research Sponsor: None.

10511 Clinical Science Symposium

Cancer risk of pathogenic germline variants among 164,774 adult cancers. First Author: Jie Liu, Washington University School of Medicine, St. Louis, MO

Background: Pathogenic germline variants (PGV) in cancer-predisposition genes influence the development of many cancer types but our understanding of cancer risks in PGV carriers remains underexplored. This study aims to further characterize the spectrum of cancers associated with PGVs and factors contributing to the development of multiple primary cancers among PGV carriers. **Methods:** A case-control analysis of 61,453 cancer cases and 366,709 controls in the UK Biobank (UKBB) was performed to test for the associations between risks of 43 solid tumor types and PGVs in 237 cancer predisposition genes. We evaluated each association according to the ClinGen Gene-Disease Validity framework and categorized those with moderate or less evidence as novel. An independent validation cohort of 103,321 cases 340,786 controls from All of Us, Mass General Brigham Biobank, TCGA, Memorial Sloan Kettering IMPACT, and a case-control study of ovarian cancer was used to replicate novel associations. **Results:** We identified 51 novel associations between solid tumor development and PGVs in the UKBB. Out of these, 32 were also significantly associated (p<0.05) in our validation cohorts (Table 1). Among PGV carriers in the UKBB, 16% had one primary malignancy and 2% had two or more. Across most PGV carriers, we observed higher risks of multiple primary cancers compared to single primary cancers. Using cox proportional hazards models, we found that PGV carriers with a personal history of cancer showed a higher hazard ratio of second cancer compared to healthy controls, particularly among those diagnosed with the first cancer earlier in life. The association between PGVs and second cancer remained significant in case-only analysis limited to cancer survivors and adjusted for primary tumor type suggesting this was not explained by shared risk factors. **Conclusions:** These findings expand our understanding of spectrum of cancer risks associated with predisposition genes and highlight that PGV carriers are at high risk of developing multiple primary cancers. In addition to family history, personal history of cancer should be considered for tailored cancer screening in genetically predisposed individuals. Research Sponsor: None.

Interactions between polygenic variants and clinical factors as predictors of breast cancer risk in the UK Biobank. First Author: Timothy Simmons, Myriad Genetics, Inc., Salt Lake City, UT

Background: Polygenic risk scores (PRSs) combine information from single-nucleotide polymorphisms (SNPs) across the genome to explain substantial genetic breast cancer (BC) susceptibility. Previous studies have demonstrated that a multiple-ancestry PRS (MA-385) based on 56 ancestry-informative and 329 BC-associated SNPs is accurate for diverse populations and ranks among the most important known factors affecting the risk of BC development. However, medical guidelines call for more evidence before endorsing the clinical use of PRS, including studies to evaluate possible interactions of SNPs with environmental and hormonal risk factors. Here, we use longitudinal outcomes from the UK Biobank (UKB) to explore interactions of MA-385 and the five most informative individual BC-associated SNPs with the widely used Tyrer-Cuzick (TC) risk model and individual TC risk factors. **Methods:** The study cohort included 197,509 female UKB participants with no history of cancer at the time of study enrollment. We used Cox proportional hazards models to test associations of MA-385, individual BC SNPs, TC, and individual TC risk factors with BC outcomes. Effect modification of MA-385 and individual SNPs by clinical risk factors was evaluated by including interaction terms in the models. All models were adjusted for age at UKB enrollment and 10 principal components. Hazard ratios (HRs) and 95% confidence intervals (CIs) are reported per standard deviation, and significance tests were performed using two-sided p-values based on likelihood-ratio test statistics. **Results:** After a median follow-up of 11.8 years, 7,419 (3.8%) participants were diagnosed with BC.In a model including both MA-385 and TC, MA-385 was a significantly better predictor of BC development (HR = 1.56; 95% CI 1.53-1.60, p= 3.2 x 10^{-329}) over the TC model (HR = 1.21; 95% CI 1.18-1.23; p= 5.4 x 10^{-69}). We found no evidence of interaction between MA-385 and TC (p= 0.31), nor between individual SNPs and TC. After Bonferroni adjustment for multiple testing (102 tests), we found no evidence of interaction between MA-385 or individual SNPs with clinical TC factors. The strongest evidence for interaction was found between a BC SNP on chromosome 2 (rs13387042) and age at UKB enrollment (unadjusted p= 0.002; Bonferroni adjusted p= 0.23). **Conclusions:** In a longitudinal analysis of UKB, MA-385 was a highly significant predictor of BC risk and substantially improved prediction over TC. In contrast, interactions of MA-385, and individual BC SNPs, with TC and individual clinical factors in the TC model were not statistically significant. Clinical TC factors have minimal, if any, impact on the strength of the association between MA-385 and BC. These results may help to alleviate concerns expressed in guidelines that SNPs interact with environmental or hormonal risk factors. Research Sponsor: Myriad Genetics.

10513 Rapid Oral Abstract Session

Association of an ancestry-specific variant near the *ESR1* gene with cancer risk and breast density in women of self-reported Hispanic ancestry. First Author: Elisha Hughes, Myriad Genetics, Inc., Salt Lake City, UT

Background: A single-nucleotide polymorphism (SNP), rs140068132, located in the 6q25 region near the *ESR1* gene, is common in self-reported Hispanic women but rare or absent in other populations. Previous studies have shown that rs140068132 is associated with a significantly reduced risk of breast cancer (BC) and may be particularly protective against triple-negative BC (TNBC). Further research suggests that rs140068132 may be linked to lower breast density. However, existing studies have been small, yielding imprecise estimates, and potential associations with cancers beyond BC remain unknown. **Methods:** We examined associations of rs140068132 with BC, TNBC, ovarian cancer (OC), endometrial cancer (EC), and BI-RADS breast density in a consecutive cohort of self-reported Hispanic women referred for hereditary cancer testing with a multigene panel. Cancer associations of rs140068132 were estimated as odds ratios (ORs), with 95% confidence intervals (CIs), from multivariable logistic regression models adjusted for personal/family cancer history, genetic ancestry, and age. We used Fisher's Exact Test to determine whether homozygous rs140068132 carriers had lower BI-RADS breast density than heterozygous or non-carriers. P-values are reported as two-sided. **Results:** Among 55,463 Hispanic women, 9,304 (16.8%) were affected by BC, 998 (1.8%) by TNBC, 1,520 (2.7%) by OC, and 1,616 (2.9%) by EC. 2,053 women were unaffected and had breast density assessment. 9,665 (17.4%) women were heterozygous for rs140068132, and 629 (1.1%) were homozygous. Consistent with previous studies, we found a highly significant protective effect per allele of rs140068132 for overall BC (OR 0.64; 95% CI 0.60-0.69; p= 6.1 x 10^{-37}) and TNBC (OR 0.53; 95% CI 0.44-0.64; p= 7.4 x 10^{-11}). This finding translates to an overall BC risk reduction of 1.6-fold for heterozygous and 2.4-fold for homozygous carriers compared to non-carriers. TNBC risk was reduced by 1.9-fold for heterozygous and 3.6-fold for homozygous carriers compared to non-carriers. Homozygous rs140068132 carriers were more than 3 times less likely to have high (heterogeneously or extremely dense) breast density compared to heterozygous or non-carriers (OR 3.30; 95% CI 1.22-10.35; p= 0.0095). rs140068132 was not associated with risk of OC (OR 0.98; 95% CI 0.86-1.11; p= 0.77) or EC (OR 1.08; 95% CI 0.96-1.21; p= 0.23). **Conclusions:** We present findings from the largest study to date on cancer risks associated with rs140068132. Our research indicates that rs140068132 does not substantially affect the risk of OC or EC. We confirmed previous reports of significantly reduced risk of BC, particularly TNBC, among carriers of rs140068132, and we provided precise estimates of the ORs per allele. These findings have important implications for genetic risk assessment and may guide personalized BC prevention and treatment strategies. Research Sponsor: Myriad Genetics.

Association between allostatic load and breast radiomic features among diverse women undergoing screening mammography. First Author: Sara Wallam, Columbia University Irving Medical Center, New York, NY

Background: Allostatic load (AL), an indicator of chronic physiologic stress, is associated with increased breast cancer incidence and all-cause mortality in patients diagnosed with breast cancer. Mammographic density (MD) is a well-established breast cancer risk factor. We developed a deep learning, specifically convolutional neural network (CNN)-based, mammographic evaluation, which is a more accurate predictor of breast cancer risk than MD, particularly among Black and Hispanic women. We evaluated the relationship between AL and CNN risk score in a cohort of racially/ethnically diverse women undergoing breast cancer screening. **Methods:** We conducted a retrospective cohort study of women aged 35-74 years, without a personal history of breast cancer, with available clinical data to calculate AL score and mammograms for CNN analysis (output = risk score from 0-1), who underwent screening mammography at Columbia University Irving Medical Center (CUIMC) in New York, NY from 2014-2018. We extracted data on demographics, MD (BIRADS A-D), laboratory values, vital signs, and body mass index (BMI) from the electronic health record (EHR). We calculated AL score using biometrics from 4 physiologic systems: cardiovascular (heart rate, systolic and diastolic blood pressure), metabolic (BMI, blood glucose, albumin, alkaline phosphatase), renal (creatinine, blood urea nitrogen), and immune (white blood cell count). AL scores ranged from 0 to 10, and patients received one point for each lab value out of the reference range. High AL was defined as an AL score above the median for the overall cohort. Multivariable logistic regression analyses were conducted to evaluate the association between high AL and demographic factors, breast cancer risk factors, and CNN risk score. **Results:** Among 9,798 evaluable women, mean age was 57.0 (standard deviation [SD], 9.5), including 24.7% non-Hispanic White, 9.6% non-Hispanic Black, 36.1% Hispanic, and 4.0% Asian women. Median AL score was 3. In multivariable analyses, high AL was associated with older age (odds ratio [OR] =1.03, 95% confidence interval [CI]=1.02-1.03). Compared to non-Hispanic White women, Black and Hispanic women had increased odds of having high AL (OR= 2.62, 95% CI = 2.23-3.08 and OR = 2.12, 95% CI =1.90-2.37, respectively). MD was inversely associated with high AL, and there was no significant association between CNN risk score and AL. **Conclusions:** In this cohort of diverse women undergoing screening mammography, we observed a significant association between high AL and older age and Black and Hispanic race/ethnicity. However, MD was inversely associated with high AL, likely due to higher BMI, and CNN risk score was not associated with AL. Future studies should evaluate the association between novel breast radiomic features and genetic and hormonal biomarkers of breast cancer risk. Disparities in cancer screening and preventive care access among LGBTQ+ populations: A cross-sectional analysis. First Author: Manas Pustake, Texas Tech University Health Science Center, El Paso, TX

Background: The incidence and outcomes of certain health conditions, particularly cancers, can vary significantly across different sexual orientation groups, often influenced by disparities in healthcare access and preventive service utilization. Previous research indicates that sexual minorities may face barriers to appropriate healthcare, increasing the importance of understanding how these disparities manifest in preventive health behaviors, such as cancer screenings. This study aims to identify these differences in preventive care among different sexual orientation groups. **Methods:** The study utilized the Behavioral Risk Factor Surveillance System (BRFSS), an annual nationwide survey collecting health-related data from approximately 400,000 U.S. adults, as the primary data source. The data was cleaned for missing cases. The study population included respondents who completed the optional Sexual Orientation and Gender Identity (SOGI) module, while excluding those with missing data on key variables such as sexual orientation, gender identity, and cancer screening. Descriptive statistics were generated from the database to characterize the study population and examine distributions across different demographic and health behavior variables. Statistical analyses were performed to assess associations between sexual orientation and various cancer screening behaviors. **Results:** The final analysis included 278,519 cases, with demographic characteristics presented in Table. Disparities in educational attainment were observed across sexual orientation groups, with straight individuals representing the largest group across all education levels. A significant association was found between sexual orientation and mammogram screening (p=0.001; Fisher's Exact Test), with higher screening rates among straight respondents (851 yes vs. 144 no) compared to gay, bisexual, and other groups. No significant associations were found for cervical cancer screening (p=0.818) or sigmoidoscopy utilization (p=0.818). Mammogram screening varies by sexual orientation, while other preventive practices show uniform utilization across groups. **Conclusions:** The findings highlight significant disparities in mammogram screening among LGBTQ+ individuals, with no such gaps in cervical cancer screening or sigmoidoscopy. These results call for targeted interventions to enhance mammogram uptake in LGBTQ+ communities. Research Sponsor: None.

Distribution of sexual orientation groups among different races.

Race/Ethnicity	Gay	Straight (Not Gay)	Bisexual	Something Else	Total

Risk patterns for second primary malignancies among human papillomavirus (HPV)–associated first primary cancer survivors in the United States. First Author: Pragati Gole Advani, Roswell Park Cancer Institute, Buffalo, NY

Background: Previous studies have shown an increased risk of second primary malignancies (SPMs) among human papillomavirus (HPV)-associated first primary cancer (FPC) survivors; however, this has not been comprehensively examined by cancer site and patient's sex. We utilized a large population-based database to examine disparities in SPM risk by site of HPV-associated first and second cancers. **Methods:** From 17 United States population-based Surveillance, Epidemiology and End Results (SEER) program cancer registry areas, we identified 124,802 ≥12-month survivors of HPV-associated invasive FPCs (including oropharynx, anus, vulva, vagina, cervix and penis) diagnosed between 2000-2021. Standardized incidence ratios (SIRs) and accompanying 95% confidence intervals (CIs) quantified SPM risk by cancer site compared with the general population. Excess SPM risks were calculated based on SIRs and excess absolute risks (EARs) per 10,000 person-years at risk (PYR). **Results:** Overall, we observed 13,431 SPMs after HPV-associated FPCs representing a 1.6-fold significantly increased risk (95% Confidence Interval [CI] = 1.61-1.67) compared to the general population and an excess of 68 cases per 10,000 PYR. All index HPV-associated FPCs showed statistically significant increased SPM risk compared to the general population. SIRs varied significantly by FPC site with female survivors of vulvar, oropharyngeal and vaginal cancers resulting in higher SPM risk (SIR_{vulva}= 2.46; CI = 2.33-2.58; EAR = 166, $SIR_{oropharynx\text{-}female}$= 2.02; CI = 1.90-2.14; EAR = 121 and SIR_{vagina}= 1.81; CI = 1.56-2.08; EAR = 96) compared to other sites ($p < 0.001$). Analyses by patient's sex revealed significantly increased SPM risk among female survivors of oropharyngeal cancer compared to the males ($SIR_{oropharynx\text{-}male}$= 1.66; CI = 1.61-1.70; $p < 0.01$) but not after anal cancer ($p > 0.05$). Results from SPM site specific analyses revealed significantly higher SIRs for second solid cancers compared to hematological malignancies ($SIR_{solidSPM}$= 1.69; CI = 1.66-1.72; $SIR_{hematSPM}$= 1.03; CI = 0.96-1.11; $p < 0.001$). Among the solid SPMs, the risk of developing a HPV-associated SPM was significantly higher than that of developing a non-HPV-associated SPM ($SIR_{HPV\text{-}SPM}$= 8.89; CI = 8.59-9.21 versus $SIR_{non\text{-}HPV\text{-}SPM}$= 1.33; CI = 1.30-1.35; p-heterogeneity < 0.001); and the difference was more pronounced in females than the males. Strikingly increased SIRs were observed for penile (SIR = 17.61), vulvar (SIR = 27.83) and vaginal (SIR = 32.09) SPMs. **Conclusions:** Using a large-scale population-based data, we observed remarkable similarity in SPM risk by FPC site suggesting a potential role of shared HPV-associated etiology between the two malignancies. SPMs have emerged as an important challenge for cancer survivors, therefore, further research to understand drivers of the observed patterns is warranted. Research Sponsor: None.
