2025 ASCO Annual Meeting Abstracts

Guide to Abstracts

Letter From the Editor

The *2025 ASCO Annual Meeting Abstracts* (a supplement to *Journal of Clinical Oncology*) is an enduring record of the more than 3,000 abstracts selected by the ASCO Scientific Program Committee for presentation as part of the ASCO Annual Meeting.

Publication-only abstracts are included in the online supplement to the June 1 issue of *Journal of Clinical Oncology* at ASCOPubs.org. Abstracts can be also accessed online through ASCO Meeting Experience (meetings.asco.org). Online abstracts include the full list of abstract authors and their disclosure information. All abstracts carry *Journal of Clinical Oncology* citations, for example:

J Clin Oncol 43:16s, 2025 (suppl; abstr 500).

Should you have any questions or comments about this publication, I encourage you to provide feedback by contacting abstracts@asco.org.

Sincerely,

Ryan D. Gentzler, MD, MS
ASCO Meeting Abstracts Editor, Journal of Clinical Oncology

Yara Abdou, MD
ASCO Meeting Abstracts Associate Editor, Journal of Clinical Oncology

ASCO Abstracts Policy

Public Release of Abstracts

The 2025 ASCO Annual Meeting Abstracts were publicly released by ASCO at 5:00 PM EDT on Thursday, May 22, 2025. Abstracts are publicly available online at asco.org/abstracts. Late-Breaking Abstracts, which include all Plenary Abstracts, will be publicly released according to the following schedule:

- Late-Breaking Abstracts presented in a scientific presentation on Friday, May 30, will be publicly released Friday, May 30, at 8:00 AM EDT.
- Late-Breaking Abstracts presented in a scientific presentation on Saturday, May 31, will be publicly released Saturday, May 31, at 8:00 AM EDT.
- Late-Breaking Abstracts presented in a scientific presentation on Sunday, June 1, will be publicly released Sunday, June 1, at 8:00 AM EDT.
- Late-Breaking Abstracts presented in a scientific presentation on Monday, June 2, will be publicly released Monday, June 2, at 8:00 AM EDT.
- Late-Breaking Abstracts presented in a scientific presentation on Tuesday, June 3, will be publicly released Tuesday, June 3, at 8:00 AM EDT.

In the unlikely event that ASCO publicly releases an abstract in advance of the scheduled time, the release will be publicly announced on https://www.asco.org/annual-meeting/abstracts-presentations/abstract-policies-embargoes-exceptions/embargo-abstract-release.

Conflict of Interest Disclosure

All financial relationships reported by contributors to this activity are provided to learners prior to the start of the activity. During planning and development of the activity, relevant financial relationships were mitigated for all contributors. Relationships are considered self-held and compensated unless otherwise noted (I = Immediate family member; Inst = My Institution). Disclosures are submitted per the ASCO Policy for Relationships with Companies.

LBA1 **Plenary Session**

Randomized trial of standard chemotherapy alone or combined with atezolizumab as adjuvant therapy for patients with stage III deficient DNA mismatch repair (dMMR) colon cancer (Alliance A021502; ATOMIC). First Author: Frank A. Sinicrope, Mayo Clinic Rochester, Rochester, MN

The full, final text of this abstract will be available at meetings.asco.org on the day of presentation and in the online supplement to the June 10, 2025, issue of the *Journal of Clinical Oncology*.

LBA2 **Plenary Session**

NIVOPOSTOP (GORTEC 2018-01): A phase III randomized trial of adjuvant nivolumab added to radio-chemotherapy in patients with resected head and neck squamous cell carcinoma at high risk of relapse. First Author: Jean Bourhis, CHUV, Bâtiment Hospitalier, Lausanne, Switzerland

The full, final text of this abstract will be available at meetings.asco.org on the day of presentation and in the online supplement to the June 10, 2025, issue of the *Journal of Clinical Oncology*.

LBA3 **Plenary Session**

Results from VERIFY, a phase 3, double-blind, placebo (PBO)-controlled study of rusfertide for treatment of polycythemia vera (PV). First Author: Andrew Tucker Kuykendall, Moffitt Cancer Center, Tampa, FL

The full, final text of this abstract will be available at meetings.asco.org on the day of presentation and in the online supplement to the June 10, 2025, issue of the *Journal of Clinical Oncology*.

LBA4 **Plenary Session**

Camizestrant + CDK4/6 inhibitor (CDK4/6i) for the treatment of emergent *ESR1* mutations during first-line (1L) endocrine-based therapy (ET) and ahead of disease progression in patients (pts) with HR+/HER2– advanced breast cancer (ABC): Phase 3, double-blind ctDNA-guided SERENA-6 trial. First Author: Nicholas C. Turner, Royal Marsden Hospital, London, United Kingdom

The full, final text of this abstract will be available at meetings.asco.org on the day of presentation and in the online supplement to the June 10, 2025, issue of the *Journal of Clinical Oncology*.

LBA5 **Plenary Session**

Event-free survival (EFS) in MATTERHORN: A randomized, phase 3 study of durvalumab plus 5-fluorouracil, leucovorin, oxaliplatin and docetaxel chemotherapy (FLOT) in resectable gastric/gastroesophageal junction cancer (GC/GEJC). First Author: Yelena Y. Janjigian, Gastrointestinal Oncology Service, Memorial Sloan Kettering Cancer Center, New York, NY

The full, final text of this abstract will be available at meetings.asco.org on the day of presentation and in the online supplement to the June 10, 2025, issue of the *Journal of Clinical Oncology*.

100 Clinical Science Symposium

Performance evaluation of a reflex blood-based methylated ctDNA multi-cancer early detection test in individuals with obesity. First Author: Dax Kurbegov, Sarah Cannon Research Institute, Nashville, TN

Background: Obesity increases risk of 13 distinct cancers, most without screening programs, and collectively representing 40% of all annual US cancer diagnoses.With recent CDC data (2023) showing that obesity rates exceed 35% in 23 U.S. states, multi-cancer early detection (MCED) testing represents a unique opportunity to address a critical screening gap in this population. In this case-control study, we examined the performance of a reflex blood-based ctDNA methylation MCED test in individuals with obesity (BMI $\geq$ 30 kg/m^2), evaluating cancer-specific intrinsic accuracy (sensitivity) and positive predictive value (PPV). **Methods:** We analyzed peripheral blood samples (NCT05435066) from individuals with obesity, including 424 treatment-naïve cancer patients and 458 non-cancer controls, using a reflex test by Harbinger Health. The test system consists of a primary methylome profiling test optimized for high sensitivity (rule-out), followed by a confirmatory reflex analysis utilizing an expanded methylation panel designed to achieve high PPV (rule-in) and tissue of origin (TOO) classification. Test performance metrics were derived using 10-fold cross-validation with patient-level stratification. Overall cancer incidence in the obese population was estimated at 1.6%. Prospective PPV for each TOO readout was calculated using cancer-specific intrinsic accuracy estimated from the case-control study in combination with incidence values. **Results:** In this cohort (mean age 57.1 $\pm$ 13.4 years; 63.3% female; 67.8% White; 22.4%, Black or African American), the test achieved an overall 29.7% (95CI, 25.3-34.6) correct-TOO sensitivity (66.1% false negative, 4.2% incorrect TOO) at 98.9% (95CI, 97.6-99.6) specificity and 98.9% negative predictive value (95CI, 98.85,99.0). Among a subset of cancers associated with obesity, TOO-specific PPVs were: hepatobiliary (HB: liver, biliary duct; 100%; 95CI, ND), CRC (87.5; 95CI, 61.1-96.9), upper gastrointestinal (UGI; 81.8; CI95, 48.6-95.5), uterine (66.7%; 95CI, 26.5-91.7), pancreaticobiliary (PB: pancreas, gallbladder; 17.6%; 95CI 3.1-59.0). Corresponding cancer group sensitivities (early stage, I-II) were: HB 50.0 (35.1), CRC 51.9 (28.6), UGI 40.9 (9.1), uterine 8.5 (3.8), PB 56.5 (25.0). In a modeled cohort of 100,000 tested individuals, the expected TOO readout counts (correct case-type odds) were: 23 for HB (23:0), 60 for CRC (7:1), 42 for UGI (9:2), 23 for uterine (2:1), 279 for PB (1:5). **Conclusions:** Inindividuals with obesity at increased risk for multiple cancers, especially those lacking established screening guidelines, the reflex ctDNA methylation MCED test demonstrated clinically meaningful PPV and early-stage sensitivity for each cancer type. These results warrant prospective validation to assess the test's clinical validity and utility in early-stage cancer detection in this high-risk population. Research Sponsor: None.

101 Clinical Science Symposium

Prognostic significance of blood-based multi-cancer detection in circulating tumor DNA (ctDNA): 5-year outcomes analysis. First Author: Robert Charles Swanton, Cancer Evolution and Genome Instability Laboratory, The Francis Crick Institute, London, United Kingdom

Background: In the case-control Circulating Cell-free Genome Atlas (CCGA) study (NCT02889978), a multi-cancer early detection (MCED) test was developed that uses next-generation sequencing to detect a cancer signal shared across $>$ 50 cancer types using ctDNA in blood. The concentration of ctDNA in blood is associated with cancer aggressiveness and prognosis. Previous analysis of participant outcomes in the second (cross-validation) CCGA substudy evaluated the prognostic value of cancer signal detection by an early version of the MCED test with 3-year follow-up. Participants with confirmed cancer and no cancer signal detected (NCSD) MCED test result had better 3-year survival than those with a cancer signal detected (CSD). In the present analysis, we evaluated the prognostic value of cancer signal detection by a refined version of the MCED test in the third (validation) CCGA substudy (CCGA3) using an updated statistical methodology with 5-year follow-up, a typical timeframe for cancer-survivor status. **Methods:** Participant blood samples collected during CCGA3 were analyzed using the MCED test. Participants with confirmed cancer were followed for up to 5 years and their overall survival stratified by cancer signal detection (CSD/NCSD). Observed survival was compared to the expected survival of a reference population calculated using Surveillance, Epidemiology, and End Results (SEER) data matched to the distribution of age, sex, cancer type, and stage in each signal detection group. A one-sample proportional hazard model was used to assess differences between observed and expected survival based on cancer signal detection status. **Results:** Follow-up data were available for 2475/2513 (99%) of participants with stageable, invasive cancer. Of these, 792 (32%) died during follow-up, 673/792 (85%) of whom had a CSD; of the 1683 (67%) participants alive at follow-up, 579/1683 (35%) had a CSD. Overall observed survival rates of both groups were higher than the expected survival rates based on SEER data matched for known clinical factors (43% vs 40% [CSD]; 88% vs 81% [NCSD]). Observed vs expected survival rates for participants with: stage I cancer were 66% vs 71% (CSD) and 90% vs 85% (NCSD); stage II cancer were 64% vs 67% (CSD) and 92% vs 83% (NCSD); stage III cancer were 48% vs 42% (CSD) and 79% vs 66% (NCSD); stage IV cancer were 22% vs 16% (CSD) and 56% vs 32% (NCSD). Overall HR for NCSD vs CSD across all stages was 0.60 (95% CI: 0.50-0.72; P = 6.18e-09). HRs for signal detection group vs SEER reference populations were $<$ 1 at all stages with NCSD; with CSD, HRs were $<$ 1 at stages III and IV and $\geq$1 at stages I and II. **Conclusions:** In CCGA3, 5-year follow-up confirmed that while CSD was associated with hazard of death, early-stage cases had long-term survival close to expected rates. These results suggest that a CSD MCED test result may inform prognosis and urgency of treatment. Clinical trial information: NCT02889978. Research Sponsor: GRAIL, Inc.

102 Clinical Science Symposium

A phase 1 study of intracerebroventricular (ICV) delivery of bivalent chimeric antigen receptor (CAR) T-cells targeting EGFR and IL13Ra2 in patients with recurrent glioblastoma (rGBM). First Author: Stephen Joseph Bagley, University of Pennsylvania, Philadelphia, PA

Background: Outcomes in patients with rGBM are poor, with historical median overall survival (OS) of 6-9 months. Here we report the results from the dose exploration phase of a phase 1 trial investigating ICV-delivered, bivalent CAR T-cells targeting EGFR epitope 806 and IL13Rα2 in rGBM. **Methods:** Patients with EGFR-amplified GBM that was recurrent/progressive following front-line radiotherapy were enrolled using a 3+3 design (dose levels: 5.0 x 10^6, 1.0 x 10^7, and 2.5 x 10^7 cells). Patients underwent surgery for (1) maximal safe resection and confirmation of viable tumor and (2) Ommaya reservoir placement. Post-operatively, patients received a single ICV dose of CART-EGFR-IL13Rα2 cells without lymphodepleting chemotherapy. Primary endpoints included dose-limiting toxicity (DLT) and determination of the maximum tolerated dose (MTD). Secondary endpoints included objective radiographic response, progression-free survival (PFS), and OS. Serial CSF samples were analyzed for CAR T-cell pharmacokinetics and single-cell RNA sequencing (scRNAseq). **Results:** Eighteen patientsreceived CART-EGFR-IL13Rα2 cells (n=6 per dose level). Median age was 57, 15 (83%) were male, 13 (72%) had MGMT unmethylated tumors, and 7 (39%) had $>$1 prior relapse. One DLT (grade 3 lethargy/fatigue) was observed at the MTD (2.5 x 10^7 cells). Acute neurotoxicity related to CAR T-cells occurred in all patients. Using immune effector cell-associated neurotoxicity syndrome (ICANS) grading, 10 of 18 patients (56%) experienced grade 3 neurotoxicity; none had grade 4-5 neurotoxicity. Using tumor-inflammation associated neurotoxicity (TIAN) grading, 2 of 18 patients (11%) had grade 3 and 1 patient (6%) had grade 4 neurotoxicity. Grade 1-2 fever occurred in all patients. Eleven of 13 patients (85%) with measurable disease at time of CAR T-cell infusion experienced tumor shrinkage, ranging from 1-62% reductions (median 35%, IQR 12 – 39%) in target lesions and with one confirmed partial response by modified RANO criteria. PFS and OS continue to mature and will be presented. CAR T-cell expansion in CSF was robust with a dose-response relationship observed. The CAR transgene remained detectable in CSF and blood 12 months post-CART infusion in a patient experiencing durable stable disease lasting for 17 months (ongoing at data cut-off). In patients undergoing repeat resection following treatment, CART-EGFR-IL13Rα2 cell infusion markedly increased the number of tumor-infiltrating lymphocytes. scRNAseq in post-treatment CSF revealed higher cytotoxicity and exhaustion scores in CD8+ CAR T-cells as compared to the infusion product, indicative of target cell engagement. **Conclusions:** ICV delivery of CART-EGFR-IL13Rα2 is feasible and appears safe. CART-EGFR-IL13Rα2 cells are bioactive and exhibit an encouraging early efficacy signal in rGBM. Clinical trial information: NCT05168423. Research Sponsor: Kite Pharma (a Gilead company).

103 Clinical Science Symposium

Neoadjuvant biomarker trial of pepinemab to enhance nivolumab or ipilimumab activity in resectable head and neck cancer. First Author: Conor Ernst Steuer, Emory University, Atlanta, GA

Background: Neoadjuvant treatment with immune checkpoint blockade (ICB) improves clinical benefit in patients with multiple types of cancers. Window of opportunity studies permit integrated assessments of safety and efficacy, including biomarker assessments of treatment effects and mechanisms of resistance in the tumor microenvironment. SEMA4D blocking antibody, pepinemab (pepi), has been reported to overcome resistance mechanisms including immune exclusion and myeloid suppression in preclinical and clinical studies. We conducted a neoadjuvant integrated biomarker study (NCT03690986) to evaluate the effect of pepi alone and in combination with ICB on the immune profile in the tumor and blood of patients with resectable head and neck squamous cell carcinoma (HNSCC). **Methods:** Patients were randomized to receive one dose of either pepi alone, pepi/ipilimumab (ipi), pepi/nivolumab (nivo), ipi, nivo (n = 6 patients/group), or no treatment (n = 4); followed by surgery within days 17-36. The primary objective is biomarker assessments; clinical endpoints include pathologic response (pMR), safety, surgical delays, RFS, and OS. Analysis of pretreatment and surgically resected tissue and blood to evaluate spatial distribution of tumor and immune populations employed high dimensional 36+ multiplex IHC and 32-color flow cytometry. Biomarker results were stratified by demographic and clinical outcome measures. **Results:** Thirty-four patients were enrolled (median age 63 (58-69); 70.6% male; 79.4% OC, 20.6% OP; 82.4% HPV/p16 Neg). All patients proceeded to surgery without delay; no additional or unexpected TRAEs were observed in pepi combinations; 9/10 patients who experienced TRAEs were Grade 1-2. Biomarker analysis was stratified by HPV status due to vast difference between highly infiltrated HPV+ compared to immunologically cold HPV- TME. Among 24 available HPV-resected tumors,an increase in the number of intratumoral tertiary lymphoid structures (TLS) was observed in pepinemab containing cohorts, whereas B cells lined the tumor edge and were generally excluded from tumor bed in cohorts lacking pepinemab. A significant increase in density of mature TLS (including CD21+ follicular DC and CD23+ germinal center B cells) was observed in patients treated with pepi+nivo compared with pepi or nivo alone and untreated patients. This finding was unexpected, as mature TLS are generally rare in poorly immunogenic HPV-negative HNSCC. Clinical assessments of pathologic response and RFS are being analyzed. **Conclusions:** Neoadjuvant treatment with pepi enhanced the density and maturity of TLS deep within the tumor which was most prominent in combination with nivo notably in HPV-negative disease. Pepi represents a novel strategy to boost tumor immunity and organization of functional TLS to overcome limitations of ICB in HPV- HNSCC. Clinical trial information: NCT03690986. Research Sponsor: Winship Cancer Institute of Emory University, Atlanta, GA.

104 Clinical Science Symposium

Efficacy and safety of IBI363 monotherapy or in combination with bevacizumab in patients with advanced colorectal cancer. First Author: Zhenyu Lin, Cancer Center, Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, China

Background: The prognosis of patients (pts) with microsatellite stable/proficient mismatch repair (MSS/pMMR) colorectal cancer (CRC) who failed standard chemotherapy is poor, highlighting a significant unmet need. No immune-oncology therapy has succeeded in this indication due to the "cold" tumor nature. IBI363 is a PD-1/IL-2$^{\alpha\text{-bias}}$ bispecific antibody fusion protein that blocks PD-1 and stimulates tumor-specific T cells that could potentially turn "cold" tumors into "hot" tumors. **Methods:** The analysis of efficacy and safety data were from 68 pts treated with IBI363 monotherapy and 73 pts treated with IBI363 plus bevacizumab (beva), respectively. Eligible pts were locally advanced unresectable or metastatic CRC who failed or were intolerant to the standard treatment. Data cutoff date was Dec 6, 2024. **Results:** A total of 68 pts and 73 pts (None were confirmed as microsatellite instability-high/deficient mismatch repair [MSI-H/dMMR]; MSS/pMMR: 86.8% and 90.4%; unknown microsatellite/MMR status: 13.2% and 9.6%; liver metastases: 61.8% and 54.8%; *KRAS/NRAS* mutations: 42.6% and 41.1%; previous treatment lines ≥ 3: 63.2% and 53.4%; previous immunotherapy: 27.9% and 16.4%) were treated with IBI363 monotherapy (0.1 mg/kg to 3 mg/kg every week [QW], every 2 weeks [Q2W] or every 3 weeks [Q3W]) and IBI363 plus beva (0.6 or 1 mg/kg Q2W, 1.5, 2 or 3 mg/kg Q3W, plus beva 5 mg/kg Q2W or 7.5 mg/kg Q3W), respectively. Median follow-up time was 11.8 months (range: 0.4–22.5) for monotherapy and 5.1 months (range: 1.2–14.9) for combination. In efficacy-evaluable pts (n = 63 for monotherapy and n = 68 for combination), the objective response rate (ORR) was 12.7% (95% confidence interval [CI]: 5.6–23.5) and 23.5% (95% CI: 14.1–35.4). The median duration of response was 7.5 months (95% CI: 1.2–19.6) for monotherapy and not mature for combination. The median OS was 16.1 months (95% CI: 10.1–not reached) for monotherapy and not mature for combination. Especially, in pts without liver metastasis who received the combination therapy (n = 31), the ORR was 38.7% (95% CI: 21.9–57.8), the DCR was 83.9% (95% CI: 66.3–94.6), and median PFS was 9.6 months (95% CI: 4.1–12.2). Grade ≥ 3 treatment-related adverse events were reported in 16 (23.5%) pts with monotherapy and 22 (30.1%) pts with combination. Arthralgia, rash, and thyroid disorders were commonly reported immune-related adverse events. **Conclusions:** IBI363 monotherapy demonstrated prolonged overall survival in pts with advanced CRC compared to historic data of standard of care. IBI363 plus beva showed even more encouraging efficacy with acceptable safety and warrants further development. Clinical trial information: NCT05460767. Research Sponsor: None.

105 Clinical Science Symposium

Safety and efficacy of ABBV-706, a seizure-related homolog protein 6 (SEZ6)–targeting antibody-drug conjugate, in high-grade neuroendocrine neoplasms. First Author: Alissa Jamie Cooper, Department of Thoracic Oncology, Memorial Sloan Kettering Cancer Center, New York, NY

Background: SEZ6 is a potential neuroendocrine lineage marker that is expressed in small cell lung cancer (SCLC) and high-grade neuroendocrine neoplasms (NENs). NENs have a significant unmet need for novel effective targeted therapies. ABBV-706, a unique antibody-drug conjugate comprising a SEZ6-directed antibody conjugated to a potent topoisomerase 1 inhibitor payload, is being evaluated in a phase 1 study (NCT05599984) in patients (pts) with advanced solid tumors. Preliminary results from ABBV-706 monotherapy dose escalation showed a manageable safety profile with promising efficacy in SCLC and NENs (*J Clin Oncol* 2024;42[suppl 16]: abs 3001). Herein, updated safety and efficacy of ABBV-706 monotherapy in NENs are presented. **Methods:** Pts (≥18 yr) with relapsed/refractory high-grade NENs (well-differentiated grade [G] 3 neuroendocrine tumors [G3 NETs] and poorly differentiated neuroendocrine carcinomas [NECs]), atypical lung carcinoid, and medullary thyroid cancer (MTC) were enrolled in dose-escalation and -expansion cohorts of a phase 1, open-label study. Pts received ABBV-706 monotherapy IV at 1.3–3.5 mg/kg once every 3 weeks. Primary study objectives are assessment of safety, PK, and efficacy. SEZ6 expression is evaluated retrospectively. **Results:** As of Aug 27, 2024, 191 pts were enrolled overall, including 64 with NENs. In the NEN cohort, median age was 63 yr (range 33–86) and pts had received a median of 3 (range 1–8) prior therapies. NEN histologies were large cell NEC (LCNEC; 22%, n=14), gastro-enteropancreatic NEC (GEPNEC; 19%, n=12), MTC (9%, n=6), neuroendocrine prostate carcinoma (NEPC; 8%, n=5), G3 NETs (8%, n=5), and other NECs (34%, n=22). The safety profile for ABBV-706 was similar across NEN subtypes and aligned with the entire study population. For the overall study population, TEAEs occurred in 184 (96%) pts and G≥3 in 134 (70%). Most frequent hematologic TEAEs were anemia (58%; G≥3: 45%), neutropenia (44%; G≥3: 33%), and thrombocytopenia (35%; G≥3: 21%). Most frequent nonhematologic TEAEs were fatigue (45%; G≥3: 3%) and nausea (38%; G≥3: 2%). Unadjudicated pneumonitis/interstitial lung disease rate was 4% (G≥3 in 2 pts). For the entire NEN cohort, the objective response rate (ORR) was 31.3% (20/64) and the clinical benefit rate was 92.2% (59/64). ORR by NEN type was: LCNEC, 28.6% (4/14); GEPNEC, 16.7% (2/12); NEPC, 60.0% (3/5); G3 NET, 60% (3/5); MTC, 16.7% (1/6); other NEC, 31.8% (7/22). The median duration of response was 5.59 mo (95% CI: 4.24, not estimable) and median progression-free survival was 6.80 mo (95% CI: 5.45, 7.75). Correlation analysis of efficacy with SEZ6 expression is ongoing. **Conclusions:** ABBV-706 showed preliminary efficacy in several high-grade NENs with a high unmet need, supporting its further development in specific subtypes. Clinical trial information: NCT05599984. Research Sponsor: AbbVie Inc.; n/a

106 Clinical Science Symposium

Phase 1 study of SHR-1826, a c-MET–directed antibody-drug-conjugate (ADC), in advanced solid tumors. First Author: Yang Zhang, Sun Yat-sen University Cancer Center, Guangzhou, China

Background: MET alterations are key drivers of diverse oncogenic processes, including tumor invasion, growth, and metastasis, and are associated with poor prognosis. SHR-1826 is a novel ADC of a humanized c-MET-directed IgG2 monoclonal antibody attached to a topoisomerase I inhibitor payload via a tetrapeptide-based cleavable linker. We conducted a multi-center, first-in-human, phase 1 trial of SHR-1826 in advanced solid tumors, and here report preliminary results from the dose-escalation and expansion portions. **Methods:** Patients (pts) with advanced solid tumors harboring MET alterations (overexpression, amplification, or activating mutation) who had failed standard therapy or no available standard therapy, were enrolled. The study consisted of dose-escalation (i3+3 design), dose-expansion and efficacy-expansion phases, during which pts received SHR-1826 at 2.2–6.0 mg/kg, Q3W, iv. Primary objectives were to assess safety and tolerability. **Results:** As of Dec.5, 2024, 116 pts were enrolled and treated (NSCLC/CRC/GC/PC, n=72/32/10/2; median age, 59.2 yrs; ECOG PS 1, 87.9%; ≥3 lines of prior therapy, 44.0%; median c-MET H-score, 163 [range 9-300]). During dose-escalation, 1 DLT was observed at 6.0 mg/kg (grade 3 febrile neutropenia). Grade ≥3 TRAEs were reported in 56 (48.3%) pts, with the most common being decreased neutrophil count (32.8%), decreased white blood cell count (22.4%), anaemia (13.8%), and decreased platelet count (11.2%). Interstitial lung disease occurred in 3 (2.6%; grade 1-2, n=2; grade 3, n=1) pts. 2 (1.7%) pts discontinued treatment due to TRAE. There were no treatment-related deaths. Among 58 evaluable pts with NSCLC, ORR was 39.7% (95% CI 27.0–53.4) and DCR was 94.8% (95% CI 85.6–98.9; Table 1); response was observed across a range of c-MET expression levels, and in both *EGFR*-mutated and wild-type tumors. Median duration of response was not reached, with 21 of 23 responses ongoing. In all 72 NSCLC pts, median progression-free survival was 6.8 mo (95% CI 4.5–7.2). **Conclusions:** SHR-1826 demonstrated a manageable safety profile in pts with heavily pretreated advanced solid tumors. Promising anti-cancer activity was observed in MET-altered NSCLC, warranting further investigation in this population. Clinical trial information: NCT06094556. Research Sponsor: Jiangsu Hengrui Pharmaceuticals Co., Ltd.

107 Clinical Science Symposium

Phase 1 trial of SHR-A2102, a nectin-4–directed antibody drug conjugate (ADC), in advanced solid tumors. First Author: Runbo Zhong, Shanghai Chest Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai, China

Background: Nectin-4 is a cell adhesion molecule that is highly expressed in a wide variety of cancers and is associated with poor prognosis. SHR-A2102 is a novel ADC consisting of a fully humanized Nectin-4–directed monoclonal antibody, bound to topoisomerase I inhibitor payload via a cleavable linker. We conducted a multi-center, phase 1 trial to evaluate SHR-A2102 in advanced solid tumors. **Methods:** Patients (pts) with Nectin-4 positive, locally advanced unresectable or metastatic solid tumors were enrolled. The study included dose-escalation (D-ESC), dose-expansion (D-EXP) and efficacy-expansion (E-EXP) phases. SHR-A2102 was given IV at 2–10 mg/kg, Q3W during D-ESC, and at 6 mg/kg and 8 mg/kg Q3W during D-EXP and E-EXP. The primary objectives were to assess safety and tolerability. **Results:** As of Dec. 20, 2024,369 pts were enrolled and treated (median age, 59 y; ECOG PS 1, 85.6%; ≥2 lines of prior therapy, 64.0%). During D-ESC, DLT occurred in 1 pt (10 mg/kg; grade 4 decreased platelet count). Overall, grade ≥3 TRAEs occurred in 167 (45.3%) pts, with the most common (≥3%) being decreased neutrophil count (25.5%), decreased white blood cell count (16.3%), anaemia (11.7%), decreased lymphocyte count (8.7%), decreased platelet count (4.9%), asthenia (3.5%) and nausea (3.3%). 2 (0.5%) pts discontinued treatment due to TRAE. ILD occurred in 1 (0.3%; grade 3) pt. In 304 evaluable pts for response, ORR was 35.2% (95% CI 29.8-40.9) and DCR was 84.2% (95% CI 79.6-88.1). As of data cutoff, 146 (39.6%) pts had disease progression or died; median PFS was 4.7 mo (95% CI 4.3-5.6). Efficacy in selected tumor types is shown in Table. **Conclusions:** SHR-A2102 demonstrated a manageable safety profile and promising activity across a variety of pretreated advanced solid tumors. Multiple trials are ongoing to further assess SHR-A2102 both as monotherapy and in combination therapy for solid tumors. Clinical trial information: NCT05701709. Research Sponsor: Jiangsu Hengrui Pharmaceuticals.

De-escalated neoadjuvant taxane plus trastuzumab and pertuzumab with or without carboplatin in HER2-positive early breast cancer (neoCARHP): A multicentre, open-label, randomised, phase 3 trial. First Author: Hong-Fei Gao, Department of Breast Cancer, Cancer Center, Guangdong Provincial People's Hospital (Guangdong Academy of Medical Sciences), Southern Medical University, Guangzhou, China

The full, final text of this abstract will be available at meetings.asco.org on the day of presentation and in the online supplement to the June 10, 2025, issue of the *Journal of Clinical Oncology*.

501 **Oral Abstract Session**

Predicting pathologic complete response (pCR) from clinicopathologic variables and HER2DX genomic test in stage II/III HER2+ breast cancer treated with taxane, trastuzumab, and pertuzumab (THP): Secondary results from the EA1181/CompassHER2 pCR trial. First Author: Nadine M. Tung, Beth Israel Deaconess Medical Center, Boston, MA

Background: EA1181 (NCT04266249) is a single-arm trial of neoadjuvant THP for patients with clinical anatomic stage II/III HER2+ breast cancer; patients with cT4 or cN3 disease were excluded . Assessing the primary endpoint, 3-year recurrence-free survival in patients with a pCR (ypT0/Tis, ypN0), requires longer follow-up. Here, we present results for the secondary objective of pCR rate and its relation to clinicopathologic factors and the HER2DX pCR likelihood score (Reveal Genomics) derived from gene expression and clinical features. **Methods:** Patients received 4 cycles of trastuzumab and pertuzumab (HP) with weekly paclitaxel (12 weeks) or docetaxel (q3w x 4), followed by surgery. Clinicopathologic features were assessed for all patients and HER2DX pCR score (stratified by ER status) was determined using the diagnostic biopsy in a representative subset of study participants. **Results:** 2175 patients were enrolled. Median age was 55 years (range 22-88 years); 58% had clinical stage IIA, 33% stage IIB, and 9% stage III. 45% had nodal involvement (mostly cN1). 781 tumors were HER2+/ER- and 1394 HER2+/ER+ (locally tested). 2141 patients started THP, for whom the pCR rate was 44% overall, 63.7% in HER2+/ER- and 32.4% in HER2+/ER+ tumors. Disease progressed during THP in 16 patients (0.7%). The pCR rate varied inversely to the proportion of cells staining for ER among patients with HER2+/ER+ breast cancer: 1-10%+, 62.5%; 11-69%, 51.6%; ≥70%, 22.5% ($p < 0.001$). The pCR rate was significantly associated with higher grade, especially in HER2+/ER+ disease. T and N stage did not significantly affect pCR rate. Among 569 patients assessed for the HER2DX pCR score, the pCR rate was significantly greater for patients with a higher vs lower score, regardless of ER status (Table). Further correlations and interactions will be presented. **Conclusions:** Neoadjuvant THP resulted in pCR in nearly two-thirds of pts with clinical stage II/III HER2+/ER- and in one-third with HER2+/ER+ breast cancer. There was no association with clinical stage. Lower ER expression and higher grade were associated with higher pCR rates. The HER2DX pCR score was a significant predictor of pCR, regardless of ER status. Clinical trial information: NCT04266249. Research Sponsor: National Cancer Institute; Breast Cancer Research Foundation; Susan G. Komen for the Cure.

502 **Oral Abstract Session**

Prediction of survival after de-escalated neoadjuvant therapy in HER2+ early breast cancer: A pooled analysis of three WSG trials. First Author: Monika Karla Graeser, West German Study Group and Ev. Hospital Bethesda, Breast Center Niederrhein, Moenchengladbach, Germany and Department of Gynecology, University Medical Center Hamburg, Hamburg, Germany

Background: Current treatment de-escalation strategies in HER2+ early breast cancer (eBC) aim to mitigate acute and late toxicities by reducing or entirely omitting systemic chemotherapy (sCTx). We analyzed the outcomes and investigated predictors of survival in three randomized de-escalation trials investigating short (12-week) neoadjuvant treatments (NAT) with and without sCTx (paclitaxel, pac) in HER2+ eBC. **Methods:** In total, 713 patients (pts) were analyzed. WSG-ADAPT-HR-/HER2+ (NCT01817452) compared trastuzumab and pertuzumab (T + P, n=92) vs. T +P + pac (n=42); WSG-ADAPT-HR+/HER2+ (NCT01779206) compared trastuzumab emtansine (T-DM1, n=118) vs. T-DM1 + standard endocrine therapy (ET, n=125) vs. T + ET (n=129); WSG-TP-II (NCT03272477) compared neoadjuvant/adjuvant T + P + ET (n=100) vs. T + P + pac (n=107). Omission of further sCTx was allowed in pts with pathological complete response (pCR, ypT0/is ypN0); sCTx was mandatory for non-pCR pts. pCR was the primary endpoint of each trial; survival was a secondary endpoint. Kaplan-Meier method and Cox regression were applied for survival analysis. **Results:** Median follow-up of 60.7 months was available for 713 pts (sCTx: n=149; sCTx-free NAT: n=564). 395 tumors (55%) were cT2-4, 414 (58%) were grade 3, and 223 pts (31%) were clinically node-positive. Ten (7%) and 74 (13%) pts had iDFS events, 8 (5%) and 51 (9%) had dDFS events, and 6 (4%) and 34 (6%) pts died in the sCTx and sCTx-free NAT groups, respectively. In the sCTx and sCTx-free NAT groups, the respective 5-year survival rates were 98% (95%CI 93, 99) and 97% (95%CI 95, 98) for OS (HR 0.88; 95%CI 0.36, 2.11; p=0.775) and 96% (95%CI 91, 98) and 88% (95%CI 85, 91) for iDFS (HR 0.56; 95%CI 0.29, 1.08; p=0.083). 95 (66%) and 171 (31%) pts had a pCR after sCTx and sCTx-free NAT, respectively. iDFS events occurred in 5 (5%) pts with pCR and 5 (10%) without pCR after sCTx and in 14 (8%) with pCR and 59 (16%) pts without pCR after sCTx-free NAT. 5-year iDFS rates in pts with pCR were 98% (95%CI 91, 99) after sCTx and 94% (95%CI 89, 97) after sCTx-free NAT (HR 0.76; 95%CI 0.27, 2.14; p=0.609). In univariate analysis, iDFS was associated with pCR (HR 0.18; 95%CI 0.04, 0.77) in the sCTx group and with cT (3-4 vs 1: HR 2.54; 95%CI 1.22, 5.28) and cN stage (cN+ vs cN-: HR 2.27; 95%CI 1.44, 3.58), grade (3 vs 1-2: HR 1.79; 95%CI 0.86, 3.74) and pCR (HR 0.47; 95%CI 0.26; 0.84) in the sCTx-free NAT group. Detailed subgroup analyses including the impact of standard chemotherapy on outcome will be presented at the meeting. **Conclusions:** This pooled analysis demonstrates that de-escalation trials in HER2+ eBC are feasible and safe for patients. 12× weekly paclitaxel + HER2 blockade is an effective and well-tolerated regimen with excellent 5-year survival. The favorable survival after pCR to sCTx-free NAT lays the groundwork for further de-escalation strategies, such as the currently ongoing WSG-ADAPT-HER2-IV evaluating T-DXd as NAT. Clinical trial information: NCT01817452, NCT01779206, NCT03272477. Research Sponsor: None.

503 **Oral Abstract Session**

Comparison of marking techniques for target lymph nodes in 2,596 patients with node-positive breast cancer treated with neoadjuvant chemotherapy: Results from the prospective multicenter AXSANA/EUBREAST-03/AGO-B-053 study (NCT04373655). First Author: Maggie Banys-Paluchowski, Department of Obstetrics and Gynecology, University Hospital of Schleswig Holstein, Campus Lübeck, Lübeck, Germany

Background: Surgical axillary staging in patients with node-positive (cN+) breast cancer scheduled for neoadjuvant chemotherapy (NACT) varies significantly, and includes axillary lymph node dissection (ALND), sentinel lymph node biopsy (SLNB), targeted axillary dissection (TAD), and target lymph node biopsy (TLNB). SLNB/TAD/TLNB aim at reducing surgical morbidity without loosing staging accuracy. Comparative data on marking techniques for TAD/TLNB are limited. Here, different marking techniques from the largest available international prospective cohort are critically evaluated. **Methods:** AXSANA is an ongoing cohort study investigating oncological and patient-reported outcomes after different axillary procedures in cN+ breast cancer treated with NACT. In the present analysis, the subgroup of patients receiving marking of their TLN is selected, and detection and removal rates are analyzed. The entire dataset is continuously and systematically monitored for data quality assurance. **Results:** 6,129 patients from 291 sites in 26 countries were included between June 2020 and January 6th, 2025. Of these, 2,596 had ≥ 1 TLN marked before NACT and had completed surgery at time of analysis. The mean number of suspicious nodes at diagnosis was 1.9 (≥ 4 in 13.4%). 2,484 patients (95.7%) received a minimally invasive biopsy of ≥ 1 node. TLN marking was performed using a clip in 2,003 patients (77.2%), a magnetic seed in 287 (11.1%), carbon ink in 192 (7.4%), radar marker in 119 (4.6%), radioactive seed in 18 (0.7%), radiofrequency identification device (RFID) in 12 (0.5%) or other methods in 2 (0.1%). > 1 type of marker was placed in 36 patients (1.4%). 1 TLN was marked in 2,427 patients (93.5%), followed by 2 TLNs in 138 (5.3%) and ≥ 3 in 27 patients (1%). The mean number of marked TLNs was highest if carbon ink was used (mean 1.21), followed by clip (1.07), magnetic seed (1.06) and radar marker (1.04); no patient received > 1 radioactive seed/RFID. 1,895 patients (73.0%) achieved ycN0 status. Targeted removal of the TLN was planned in 2,100 patients (80.9%): 2,076 (80.0%) were scheduled for a TAD and 24 (0.9%) for a TLNB. TLN was detected and removed during TAD/TLNB in 1,915 patients (91.2%). TLN detection rate was highest in patients whose TLNs were marked with probe-guided techniques (96.6%; radioactive seed: 100%, magnetic seed: 96.9%, radar marker: 96.1%, RFID: 90%), followed by carbon (94.9%) and clip (89.6%; $p < 0.001$). TAD/TLNB removed a median number of 3 nodes (mean 4.1, SD 2.77; carbon: median 4, mean 4.29, SD 3.52, probe-guided: median 3, mean 3.82, SD 2.63, clip: median 3, mean 4.15, SD 2.75). **Conclusions:** This large prospective analysis of patients with initially cN+ breast cancer receiving NACT demonstrates that probe-guided markers provide superior TLN detection rates. Clinical trial information: NCT04373655. Research Sponsor: AGO-B; AWOgyn; Claudia von Schilling Foundation for Breast Cancer Research; Ehmann Foundation Savognin; EndoMag; Merit Medical; Mammotome.

504 Oral Abstract Session

Predicting nodal burden after neoadjuvant chemotherapy (NAC) with circulating tumor (ct)DNA for surgical planning: Results from the I-SPY2 trial. First Author: Rita Mukhtar, Division of Surgical Oncology, Department of Surgery, University of California, San Francisco, San Francisco, CA

Background: Axillary surgery in breast cancer is used for staging and therapeutic purposes, but axillary lymph node dissection (ALND) confers high risk of complications including lymphedema. Accordingly, trials have focused on right-sizing axillary surgery, with options ranging from complete omission of surgery, sentinel lymph node (SLN) surgery, targeted axillary dissection (TAD), or ALND. Identifying a biomarker to reliably predict nodal burden would facilitate accurate selection of surgical management. We evaluated whether the presence or absence of ctDNA in the blood pre and post NAC is associated with residual nodal burden. **Methods:** I-SPY2 is a prospective, multicenter NAC trial for patients with clinical stage II-III high-risk breast cancer. Patients are randomized to novel NAC agents, with pathologic complete response being the primary endpoint. As part of the trial, serial ctDNA is assessed with a highly sensitive tumor-informed assay using up to 16 patient-specific tumor mutations (Signatera) at baseline, 3 weeks, 12 weeks, and post-NAC. We determined whether ctDNA positivity or negativity post-NAC, and the change in ctDNA status baseline/post-NAC (-/-, -/+, +/+, +/-) are associated with ypN category (N0, N1, N2). **Results:** ctDNA status was available post-NAC in 495 patients and change in ctDNA status from baseline was available in 493. At baseline, ctDNA was detected in 160/220 (72.3%) cN0 patients and 227/273 (83.2%) cN+ patients (p=0.006). Post-NAC, ctDNA was detected in 11/220 (5%) cN0 patients and 34/273 (12.5%) cN+ patients (p=0.004). While baseline ctDNA status was not associated with ypN category, there was a significant association between post-NAC ctDNA status and ypN category. For ctDNA + patients post-NAC, 33.3% were ypN0, 31.1% were ypN1, and 35.6% were ypN2 at surgery; in contrast, for ctDNA - patients post-NAC, 67.1% were ypN0, 23.1% were ypN1, and 9.8% were ypN2 ($p<0.0001$). Dynamic ctDNA changes were also associated with ypN category, with significantly more ypN0 patients among ctDNA -/- or ctDNA +/- cases, and more ypN2 patients in those who did not clear ctDNA (+/+) (p=0.0001, Table). **Conclusions:** To our knowledge this is the first study to demonstrate a significant relationship between ctDNA and ypN category, which has important surgical implications. CtDNA negativity was associated with low likelihood of ypN2 disease, making these patients excellent candidates for SLN surgery or TAD. Ongoing analyses will incorporate receptor subtype and timing of clearance of ctDNA. CtDNA in breast cancer may help tailor surgical management of the axilla, potentially reducing patient morbidity without compromising prognostic information. Research Sponsor: None.

ctDNA baseline/post-NAC	ypN0 (n=317)	ypN1 (n=116)	ypN2 (n=60)
ctDNA -/- (n=105)	72.4%	19.1%	8.6%
ctDNA -/+ (n=1)	0.0%	100.0%	0.0%

505 Oral Abstract Session

15-year outcomes for women with premenopausal hormone receptor-positive early breast cancer (BC) in the SOFT and TEXT trials assessing benefits from adjuvant exemestane (E) + ovarian function suppression (OFS) or tamoxifen (T)+OFS. First Author: Prudence A. Francis, Peter MacCallum Cancer Centre, Melbourne, Australia

Background: Long-term follow-up of the SOFT and TEXT randomized trials has shown persistent reduction of recurrence from inclusion of OFS in adjuvant endocrine therapy, and clinically meaningful improvement in overall survival (OS) among patients at higher baseline risk of recurrence. We report a final update after a median follow-up of 15y in SOFT and 16.6y in TEXT. **Methods:** SOFT and TEXT enrolled premenopausal women with HR+ early BC from November 2003 to April 2011 (2660 in TEXT, 3047 in SOFT intention-to-treat populations). TEXT randomized women within 12 weeks of surgery to 5y E+OFS vs T+OFS; chemotherapy (CT) was optional and concurrent with OFS. SOFT randomized women to 5y E+OFS vs T+OFS vs T alone, within 12 weeks of surgery if no CT planned, or within 8 months of completing (neo)adjuvant CT. Both trials were stratified by CT use. The primary endpoint was disease free survival (DFS) which included invasive local, regional, distant and contralateral breast events, second non-breast malignancies and deaths. Secondary endpoints included invasive breast cancer-free interval (BCFI), distant recurrence free interval (DRFI) and OS. 20y data collection was completed in Q4'2024: 80% of surviving patients had final follow-up during or subsequent to 2020, for 70% it was during 2023-2024. 15y Kaplan-Meier estimates and hazard ratios (HR) with 95% CIs are reported. **Results:** There were 815 DFS events and 388 deaths reported in SOFT; and 669 DFS events and 325 deaths in TEXT. In SOFT, a moderate DFS benefit of T+OFS vs T (HR 0.85; 0.72-1.00) persisted, however 1/6 DFS events were not BC related; BCFI benefit was HR 0.82 (0.69-0.98). E+OFS vs T further reduced DFS events (HR 0.73; 0.61-0.86). The 15y DFS in SOFT was 67.0% for T, 70.5% for T+OFS and 73.5% for E+OFS. There were consistent but non-significant decreased hazards of death for T+OFS vs T (HR 0.87; 0.68-1.10) and E+OFS vs T (HR 0.85; 0.67-1.08). 15y OS was 85.3%, 86.7%, 86.9% respectively. For the TEXT+SOFT combined analysis of E+OFS vs T+OFS (n=2346 vs 2344) DFS, BCFI and DRFI continued as significantly improved for E+OFS over T+OFS. 15y DFS was 74.9% vs 71.3% (HR 0.82; 0.73-0.92). 15y OS was 87.8% vs 87.0% (HR 0.94; 0.80-1.11) respectively. 15y estimates by CT use are tabulated. **Conclusions:** The high level 15y final results of the SOFT and TEXT confirm a role for OFS- and aromatase inhibitor-containing adjuvant endocrine therapy for premenopausal women. Analysis is ongoing. Clinical trial information: NCT00066690 (SOFT) and NCT00066703 (TEXT). Research Sponsor: ETOP IBCSG Partners Foundation, BCRF, US NCI, Pfizer, Ipsen, et al have supported long-termfollow-up of the trials.

506 Oral Abstract Session

Updated survival outcomes and predictors of benefit from ovarian function suppression in premenopausal women with hormone-receptor–positive breast cancer: Results from the ASTRRA trial. First Author: Jai Min Ryu, Division of Breast Surgery, Department of Surgery, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, South Korea

Background: The ASTRRA trial previously demonstrated that adding ovarian function suppression (OFS) to tamoxifen (TAM) showed consistent disease free survival (DFS) benefit at 8-yr follow-up analysis in premenopausal women with hormone-receptor (HR)–positive breast cancer who remain premenopausal or resume menstruation after chemotherapy. Here, we aimed to update the survival outcomes and identify patients most likely to benefit from OFS to tailor clinical decision-making. **Methods:** A total of 1,282 premenopausal women were randomized 1:1 to receive either 5 years of TAM alone (TAM-only) or 5 years of TAM with OFS for 2 years (TAM + OFS). The primary endpoint was DFS, and the secondary endpoint was overall survival (OS). For the HER2-negative cohort, a composite risk score (range: 0–5) for breast cancer-free interval (BCFI) was calculated based on tumor size, nodal status, and tumor grade using a Cox regression model. The impact of OFS was analyzed by composite risk score and stratified by age. The events for BCFI were defined as local, regional, or distant recurrence; invasive contralateral breast cancer; or death resulting from breast cancer as the first event. **Results:** With a median follow-up of 117.6 months, the 10-year DFS rate was 83.7% in the TAM + OFS group compared to 75.9% in the TAM-only group (hazard ratio [HR], 0.68; 95% CI, 0.53-0.87). Meanwhile, there were no significant differences in 10-year OS: 94.6% in the TAM + OFS vs. 93.2% in the TAM-only group (HR, 0.79; 95% CI, 0.50-1.27). In the 776 patients with HER2-negative breast cancer, there were no significant differences in the distribution of age group (P = .320), tumor size (P = .572), lymph node status (P = .577), or histologic grade (P = .249) between TAM + OFS and TAM-only groups. Worse 10-year BCFI was significantly associated with younger age ($<$ 40 vs. 40-45 years, P = .026), larger tumor size ($\geq$ 2cm vs. $<$ 2cm, $P < .001$), lymph node positivity (positive vs. negative, $P < .001$), and aggressive histologic grade (III vs. II vs. I, P = .006), respectively. Among patients with a high composite risk score (4–5, n = 282, 36.3% of the HER2-negative cohort), the 10-year BCFI was significantly improved with OFS: 76.6% in the TAM + OFS group vs. 65.7% in the TAM-only group (HR, 0.62; 95% CI, 0.40–0.98). This benefit was particularly pronounced in patients aged 40–45 years. **Conclusions:** We demonstrated the consistent benefit of adding OFS for 2 years to TAM in improving 10-year DFS. In patients with HR-positive/HER2-negative breast cancer and a high composite risk score, the addition of TAM plus OFS resulted in a 10.9% improvement in the 10-year BCFI, suggesting this approach may be beneficial, especially for those aged 40-45 years. Clinical trial information: NCT00912548. 507 Oral Abstract Session

The impact of ovarian function suppression with adjuvant endocrine therapy on survival outcomes in young germline *BRCA* mutation carriers with breast cancer: Secondary analysis of an international cohort study. First Author: Paola Zagami, UNC Lineberger Comprehensive Cancer Center/University of Milan/European institute of Oncology IRCSS (IEO), Chapel Hill, NC

Background: In young women with hormone receptor-positive (HR+) breast cancer (BC), ovarian function suppression (OFS) has been shown to improve outcomes when combined with adjuvant endocrine therapy (ET). However, limited evidence exists on its efficacy in germline *BRCA (gBRCA)* carriers. Here we investigated the association between OFS plus ET and outcomes in the largest global cohort of young g*BRCA* carriers with BC. **Methods:** The BRCA BCY Collaboration (NCT03673306) is an international, multicenter, hospital-based, retrospective cohort study of women harboring germline *BRCA1/2* pathogenic/likely pathogenic variants, diagnosed between 2000 and 2020 with stage I-III invasive BC at age of $\leq$ 40 years. The analysis included patients with HR+ BC and available data on ET and OFS. The OFS group included patients treated with luteinizing hormone-releasing hormone agonists (LHRHa) and/or bilateral risk-reducing salpingo-oophorectomy (RRSO) within 1 year of BC diagnosis. Outcome analyses included disease-free survival (DFS), BC-free interval (BCFI) and overall survival (OS). Cox proportional hazard models, stratified for country, year of diagnosis, nodal status, and surgery type and adjusted for RRSO and bilateral risk-reducing mastectomy (time-dependent), were used to explore the association between OFS use (vs non-use) and outcomes. Sensitivity analysis explored OFS as time-dependent covariate. To address immortal time bias, an additional Cox model accounted for left truncation, considering differences in time to *BRCA* testing. **Results:** Among 5,660 patients from 109 centers, 1,865 patients with HR+ BC were included, of whom 1,071 (57%) received OFS plus ET (35% with an aromatase inhibitor [AI], 65% with tamoxifen [tam])and 794 (43%) received tam alone. Patients receiving OFS were more likely to have node-positive disease (56% vs 47%), receive treatment in recent years (36% vs 17%), undergo mastectomy (70% vs 57%) and be tested for g*BRCA* at diagnosis (46% vs 30%). With a median follow-up of 7.8 years (IQR 4.6-12.1), OFS combined with ET was associated with significantly improved DFS (adjusted HR [aHR] 0.79, 95% CI 0.66-0.94), BCFI (aHR 0.74, 95% CI 0.61-0.89) and OS (aHR 0.66, 95% CI 0.50-0.88) over tam alone. Sensitivity analysis using OFS as a time-dependent factor yielded consistent results. No significant interactions were observed between OFS use and specific g*BRCA* mutations or HER2 status. Sub-analyses by type of ET (OFS + AI vs. OFS + tam vs. tam alone) will be presented at the conference. **Conclusions:** In this global cohort of young *BRCA* mutation carriers, OFS combined with ET was associated with improved DFS, BCFI and OS versus tam without OFS. These findings support the consideration of OFS as a key component of adjuvant therapy in this population. Research Sponsor: None.

508 **Oral Abstract Session**

Efficacy and safety of elinzanetant for vasomotor symptoms associated with adjuvant endocrine therapy: Phase 3 OASIS 4 trial. First Author: Fatima Cardoso, ABC Global Alliance, Lisbon, Portugal

Background: Vasomotor symptoms (VMS) associated with adjuvant endocrine therapy (AET) impact quality of life and decrease treatment adherence, worsening breast cancer outcomes. There are few effective treatment options and none approved for this indication. **Methods:** The 52-week randomized phase 3 trial OASIS 4 (NCT05587296) evaluated the safety and efficacy of elinzanetant (EZN), a dual neurokinin-1 and -3 receptor antagonist, in women aged 18–70 years being treated for, or at high risk of developing, hormone receptor-positive (HR+) breast cancer and experiencing ≥35 moderate-to-severe VMS/week associated with AET. Women were randomized 2:1 to receive once-daily EZN 120 mg for 52 weeks or placebo (P) for 12 weeks followed by EZN for 40 weeks. Primary endpoints were mean change in moderate-to-severe VMS frequency from baseline to weeks 4 and 12 analyzed using mixed model with repeated measures (one-sided p-values). Secondary endpoints were mean changes from baseline in moderate-to-severe VMS frequency to week 1 and moderate-to-severe VMS severity to weeks 4 and 12. Treatment-emergent adverse events (TEAEs) were reported throughout the study. **Results:** Mean (standard deviation [SD]) baseline daily VMS frequency was 11.4 (6.9) in the EZN group (n=316) and 11.5 (6.4) in the P group (n=157). Reductions from baseline in VMS frequency were observed from week 1 (EZN: -4.0 [5.1]; P: -1.8 [3.8]). At week 4, mean (SD) VMS frequency reduced by -6.5 (6.1) with EZN and -3.0 (5.0) with P, with statistical significance between EZN and P (least squares [LS] mean difference [95% confidence interval (CI)]: -3.5 [-4.4, -2.6]; $p<0.0001$). At week 12, reductions in VMS frequency were -7.8 (6.2) with EZN and -4.2 (6.1) with P, with statistical significance between EZN and P (LS mean difference [95% CI]: -3.4 [-4.2, -2.5]; $p<0.0001$). Reductions in VMS severity were greater with EZN vs. P (week 4: -0.7 [0.6]; -0.4 [0.4], week 12: -1.0 [0.7]; -0.5 [0.6]). During the placebo-controlled period, 220 (69.8%) and 98 (62.0%) patients reported TEAEs in the EZN and P groups, respectively. Somnolence, fatigue, and diarrhea were more frequently reported with EZN (Table). Fewer TEAEs were reported in both groups during weeks 13–52. **Conclusions:** EZN was efficacious with a fast onset and well tolerated for the treatment of VMS associated with AET. TEAE frequency was as expected for this type of trial. Adequate VMS management can improve adherence to AET and, therefore, improve cancer outcomes and quality of life. Clinical trial information: NCT05587296. Research Sponsor: Bayer.

n (%)	EZN Week 1–12 n=315	P Week 1–12 n=158	Total EZN Week 1–52 N=465
Any TEAE	220 (69.8%)	98 (62.0%)	368 (79.1%)

NRG-BR003: A randomized phase III trial comparing doxorubicin plus cyclophosphamide followed by weekly paclitaxel with or without carboplatin for node-positive or high-risk node-negative TNBC. First Author: Vicente Valero, The University of Texas MD Anderson Cancer Center, Houston, TX

The full, final text of this abstract will be available at meetings.asco.org on the day of presentation and in the online supplement to the June 10, 2025, issue of the *Journal of Clinical Oncology*.

510 **Rapid Oral Abstract Session**

Prospective randomized phase II trial to assess the efficacy and safety of neo-adjuvant olaparib/carboplatin (OC) in comparison to docetaxel/epirubicin/cyclophosphamide (TAC) in patients with early triple-negative breast cancer (TNBC) with homologous recombination deficiency (HRD): Primary results from the ABCSG 45 trial. First Author: Christian F. Singer, Department of Obstetrics and Gynecology and Center for Breast Health, Comprehensive Cancer Center, Medical University of Vienna and Austrian Breast and Colorectal Cancer Study Group, Vienna, Austria

Background: Carboplatin-based regimen are effective in patients (pts) with eTNBC, and olaparib improves the outcome of pts with *BRCA1/2* pathogenic variants (PV), but the safety / efficacy of OC co-treatment in HRD-positive TNBC is unknown. ABCSG 45 (EU CT 2024-512821-10) is a prospective multicenter phase II study investigating the efficacy and tolerability of OC compared to conventional chemotherapy in HRD-positive eTNBC. **Methods:** Pts with HRD (Myriad genetics)-positive eTNBC were randomized to 6 cycles of olaparib (100 mg bid, days 4-16) / carboplatin (AUC 5) q3w, or 6 cycles of docetaxel/epirubicin/cyclophosphamide (75/50/500) q3w (TAC). In an initial dose-finding phase, 100 mg bid was identified as olaparib combination dose. Stratification factors were tumoral *BRCA1/2* and menopausal status. Primary endpoint was centrally assessed residual cancer burden (RCB), pCR and QoL were secondary endpoints. Planned sample size was 90 pts, randomized 1:1 to achieve 80% power (two-sided alpha=0.05) to detect a RCB 0/I difference of 31%. Differences between treatment arms were assessed with a two-sided Cochran Mantel-Haenszel test using stratification factors. Pre-defined subgroup analysis was performed with logistic regression. **Results:** A total of 90 pts (OC: n=46; TAC: n=44), of whom 42 (47%) were *BRCA1/2* PV carriers, were randomized between November 2019 and December 2023. Median age was 50.5 years (range 27.0-80.0). 40% had cT1, 55.6% cT2, and 4.4% cT3/4 tumors, and 60% of pts were clinically N0. 94.4% of tumors were G3, and Ki67 was >60% in 71.1%. Overall, the RCB0/I rate with OC was 52.2% vs. 70.5% with TAC (stratified risk difference = -18.8% (95%CI: -39.6% to 2.0%); p=0.068). In pts with *BRCA1/2* PV, RCB0/I rates were comparable: 77.3% (OC) vs. 65.0% (TAC), while in 47 pts with *BRCA1/2* wild type (WT), OC was significantly less effective: RCB0/I of 29.2% vs 73.9% in TAC (interaction p=0.008). pCR was achieved in 47.8% (OC) vs 59.1% (TAC; p=0.231). In pts with a *BRCA1/2* PV, OC resulted in 77.3% pCR rate, vs. TAC 65.0%, in *BRCA1/2 WT* pts pCR was achieved by 20.8% (OC) vs. 56.5% (TAC) (interaction p=0.021). OC treatment resulted in more ≥ grade 3 hematologic toxicities with 30% vs 3% thrombocytopenia and 43% vs 18% neutropenia but caused fewer non-hematological toxicities. **Conclusions:** In this prospective randomized study in HRD-positive TNBC, 6 cycles of TAC resulted in strikingly high RCB0/I and pCR rates, independent of *BRCA1/2* status. 6 cycles of OC achieved a pCR rate of >77% in BRCA1/2 PV but were less effective in pts with *BRCA1/2* WT disease. These results may help to optimize neoadjuvant treatment strategies in TNBC. This research was conducted with support from AstraZeneca Austria GmbH. Clinical trial information: 2024-512821-10. Research Sponsor: None.

A phase 2 study of response-guided neoadjuvant sacituzumab govitecan and pembrolizumab (SG/P) in patients with early-stage triple-negative breast cancer: Results from the NeoSTAR trial. First Author: Rachel Occhiogrosso Abelman, Massachusetts General Hospital Cancer Center, Harvard Medical School, Boston, MA

Background: Sacituzumab govitecan (SG) is a TROP-2 directed antibody-drug conjugate (ADC) approved for metastatic triple negative breast cancer (TNBC). Pembrolizumab (P), an anti-programmed death 1 monoclonal antibody, is approved for early-stage TNBC and metastatic PD-L1 positive TNBC. However, safety and efficacy of SG+P in early TNBC is not known. We published results of Arm A1 investigating neoadjuvant SG monotherapy in early TNBC (Spring et al. Annals of Onc 2024). Here we present results from Arm A2 of the NeoSTAR study investigating the combination of neoadjuvant SG + P in early-stage TNBC (NCT04230109). **Methods:** Patients (pts) with early TNBC (tumor size ≥2 cm or node positive) with no prior treatment were eligible. Pts received SG at starting dose of 10mg/kg on days 1,8 of a 21-day cycle for 4 cycles with P 200 mg given on day 1 of each cycle. After trial regimen, pts underwent imaging to determine residual radiographic disease per RECIST v1.1. A biopsy was performed if residual disease (RD) was suspected. Additional neoadjuvant chemotherapy (ANACT) was at discretion of the treating physician prior to definitive surgery. The primary objective was rate of pathologic complete response (pCR) with neoadjuvant SG/P. Secondary objectives included need for ANACT, radiographic response (RR), safety and tolerability (adverse events [AEs] per CTCAE v5.0) and event-free survival. A Simon two-stage design and standard descriptive statistics were utilized, including 95% binomial confidence intervals for all rates estimated. **Results:** From 5/19/23-8/13/24, 50 pts were enrolled (median age: 57 years, range 23-77). Clinical anatomic stage was II in 48 pts (96%) and III in 2 pts (4%). 64% of pts were node negative at diagnosis. 44 pts (88%) completed the trial regimen (5 pts had toxicity, 1 pt progressed on treatment). In interim analysis, 5/15 had pCR and so the remaining 35 were enrolled. The pCR rate per protocol (pts with pCR at surgery directly after SG/P without ANCT) was 16/50 (34%, 95% CI 19.5-46.7). The RR rate (complete CR or partial response PR) was 66% (95% CI 50-78%), 30% CR and 36% PR. Of 26 pts who received ANACT, 9 experienced pCR (2 biopsy-confirmed RD, 6 negative or non-diagnostic RD biopsy, 1 no biopsy). Overall, 25 (50%, 95% CI 35.5-64.5) pts had pCR at surgery. Of 5 pts with pathogenic BRCA mutations, 3 (60%) had pCR after SG/P, and 1 pt had pCR after ANACT. 20 pts (40%) had grade 3 or higher AEs. The most common AEs were nausea (28, 56%), alopecia (26, 52%), fatigue (23, 46%), and diarrhea (22, 44%). Dose reductions of SG occurred in 4 pts (8%). Updated survival and biomarker data will be presented at the meeting. **Conclusions:** In the first trial to investigate the SG/P combination in early TNBC, 34% of pts had pCR. Additional research is needed to determine the optimal duration and sequence of neoadjuvant SG/P and chemotherapy for pts with TNBC. Clinical trial information: NCT04230109. Research Sponsor: None.

512 Rapid Oral Abstract Session

The Promise study: A presurgical randomized clinical trial of CE/BZA vs placebo in postmenopausal women with ductal carcinoma in situ. First Author: Swati Kulkarni, Northwestern University Feinberg School of Medicine, Chicago, IL

Background: Conjugated estrogen/bazedoxifene (CE/BZA), the first tissue selective estrogen complex, was developed as an alternative to combination estrogen and progesterone therapy to treat hot flashes and osteoporosis. Preclinical studies found that CE/BZA reduced mammary ductal proliferation and increased expression of anti-tumorigenic markers in breast stroma. Our study aimed to determine if a pre-surgical window-of-opportunity intervention with CE/BZA in women with ductal carcinoma in situ (DCIS) had a protective effect on the duct epithelium and stroma of DCIS lesions without impacting quality of life. Differences between CE/BZA and placebo arms for the primary endpoint, change in Ki-67 protein expression, and quality-of-life endpoints are reported here. **Methods:** This multicenter, randomized, double-blind placebo-controlled Phase 2 trial was conducted between 9/19/17 and 8/21/24. Postmenopausal women with estrogen receptor positive (ER+) DCIS undergoing surgery were randomized to CE 0.45 mg /BZA 20 mg or placebo for 28 +/-7 days. Percentage of nuclei staining for Ki-67 was evaluated on slides from the baseline core biopsy and surgical specimen. Changes were compared between arms using the two-sample t-test, while changes within arms were analyzed using paired t-test. Analyses were done on log2 scale to satisfy the normality assumption. The Breast Cancer Prevention Trial Eight Symptom Scale (BESS) and Menopause-Specific Quality of Life (MENQOL) surveys were self-administered by patients before and after the intervention. Wilcoxon's signed-rank and rank-sum tests were used to perform within- and between-arm comparisons, respectively. **Results:** Of the 171 patients consented,141 enrolled, and 117 completed the study. Ninety-four patients (46= CE/BZA, 48=placebo) took >80% of the medication and had Ki-67 evaluated at baseline and post-intervention. The BESS and MENQOL surveys were completed by 100 and 108 patients, and 125 patients were evaluated for toxicity. The mean absolute change in Ki-67 was -5.62 (SD=10.2; p=0.003) in the CE/BZA arm and -1.07 (SD=10.8; p=0.6) in the placebo arm, with a greater reduction in CE/BZA arm (p=0.016). There was no difference between arms in the BESS score across all 8 domains or in the MENQOL score. However, within each arm, vasomotor symptoms decreased in the CE/BZA arm (p=0.002) but not in the placebo arm (p=0.4). No grade > 3 treatment related adverse events were reported. **Conclusions:** In this prospective randomized clinical trial, CE/BZA significantly reduced epithelial proliferation in ER+ DCIS with no impact on quality of life compared to placebo. These results support consideration that CE/BZA is a safe option to manage menopausal symptoms for women concerned about their risk of developing breast cancer, and provide supportive evidence that CE/BZA may reduce the risk of developing invasive breast cancer. Clinical trial information: NCT02694809. Research Sponsor: U.S. National Institutes of Health; 1R01CA218436-01.

513 Rapid Oral Abstract Session

The WinPro trial: A window of opportunity study of endocrine therapy with and without prometrium in postmenopausal women with early stage hormone receptor-positive breast cancer. First Author: Lucy Haggstrom, St Vincent's Hospital Sydney and University of New South Wales, Sydney, NSW, Australia

Background: Preclinical evidence has shown that progesterone is a tumour suppressor in estrogen receptor positive (ER+) breast cancer. Prometrium is bioidentical to human progesterone, currently used for treating menopausal symptoms. **Methods:** The WinPro trial is a randomised, multi-centre, phase 2, window of opportunity trial of preoperative endocrine therapy in post-menopausal women with early-stage, ER+, progesterone receptor (PR) +, HER2- breast cancer. Patients (pts) were randomised 1:1:1 to letrozole (let) 2.5mg daily, letrozole 2.5mg daily + prometrium (pro) 300mg daily, or tamoxifen (tam) 20mg daily + prometrium 300mg daily for 11-17 days before surgery. The primary endpoint was the percent proportional reduction in Ki67 between biopsy and surgery ('Ki67 suppression') in let vs let + pro in the per protocol population. Other endpoints were safety, changes in ER, PR and androgen receptor (AR) via immunohistochemistry (IHC) and H-scores, spatial transcriptomics and RNA sequencing. **Results:** From Feb 2018 to June 2024,244 pts were enrolled across 6 Australian sites. 239 pts were randomised to let (n=78, 32.6%), let + pro (n=79, 33.1%), and tam + pro (n=82, 34.3%). 189 pts completed per protocol: let (n=66, 34.9%, let + pro (n=64, 33.9%), and tam + pro (n=59, 31.2%). Baseline characteristics were well balanced across arms. There was no significant difference in Ki67 suppression between let (88.2%) vs let + pro (89.2%) (p = 0.4). Ki67 suppression appeared inferior with tam + pro (61.5%). Treatments were well tolerated, with hot flushes less frequent in let + pro (13.3%) vs let (22.4%) or tam + pro (20.5%). IHC analyses showed no change in ER% after treatment, a decrease in PR% after treatment with let and let + pro, and a decrease in AR% after treatment in all groups. H-score, spatial transcriptomics, RNA sequencing and PAM50 analyses are underway. **Conclusions:** The WinPro trial showed that the addition of pro to let in post-menopausal women with ER+, PR+, HER2- breast cancer was safe, reduced hot flushes and led to similar reduction in Ki67 as let alone. Ongoing translational analyses are underway which will examine the changes in gene expression in malignant, immune and stromal cells at sub-cellular resolution and provide further insight into the mechanisms of response and resistance to endocrine therapy. Clinical trial information: ACTRN12618000928213. Research Sponsor: Cancer Council New South Wales; National Health and Medical Research Council, Australian Government; Besins Healthcare.

514 Rapid Oral Abstract Session

Early results of the French multicenter, randomized SHARE trial comparing whole breast irradiation versus accelerated partial breast irradiation in postmenopausal women with early-stage low risk breast cancer: Analysis of toxicity and cosmetic outcomes. First Author: Yazid Belkacemi, AP-HP, Department of Radiation Oncology and Henri Mondor Breast Center, Henri Mondor University Hospital, University of Paris Est Creteil (UPEC), Paris, France

Background: Locoregional management of early stage breast cancer (BC) has evolved from maximal tolerable to minimal effective therapies. Significant advancements in radiation therapy (RT), such as limited target volumes and hypofractionation, have led to accelerated partial breast irradiation (APBI). This study reports on toxicity and cosmetic outcomes of APBI in post-menopausal women with unifocal pT1-N0-M0 invasive BC. **Methods:** The SHARE trial (NCT01247233) is a non-inferiority, multicenter, randomized trial comparing local control of APBI versus Whole Breast Irradiation (WBI). Eligible patients were postmenopausal women over 50 years who had lumpectomy with surgical margins > 2mm. Only patients who had at least 4-5 clips placed in the tumor bed during surgery were eligible. Patients were randomized to receive either WBI (50Gy in 25 fractions (fr) with optional 16Gy-boost or 40Gy in 15 fr, or 42.5Gy in 16fr) or APBI (38.5Gy or 40Gy in 10fr twice daily). Primary endpoint was local recurrence. Secondary endpoints included grade >2 toxicity (NCI-CTCAE-v4) and cosmetic outcomes (good/excellent versus intermediate/poor) evaluated by both patients and doctors, over the follow-up time. We estimated the cumulative incidences (CI) using the Kalbfleisch-Prentice method due to competing events, and cause-specific Hazard Ratios (cs-$HR_{APBI/WBI}$) from Cox models adjusted on stratification factors. **Results:** Among 1006 patients (503 per arm) enrolled between December-2010 and July-2015, with a median follow-up of 5.8 years, 28 deaths and 11 local recurrences were reported. The risk of severe toxicity appeared significantly reduced in the APBI-arm when considering all type of toxicity (cs-$HR_{APBI/WBI}$=0.74, [95%-CI: 0.61-0.89], p=0.001; 3-year CI=45% [41-49] in WBI vs 36% [32-40] in APBI), or only breast skin toxicity (cs-HR=0.55 [0.44-0.70], p<0.001; 3-year CI=36% [32-40] vs 21% [18-25], respectively). Conversely, for non skin breast toxicities, WBI was less toxic: cs-$HR_{APBI/WBI}$=2.06 (1.49-2.86), p<0.001). We observed no significant difference of patient-reported cosmetic results: cs-$HR_{APBI/WBI}$=1.08 (0.85-1.37), p=0.54. Findings were similar for doctor-evaluated results. Rib fractures incidence was nearly double in APBI compared to WBI. **Conclusions:** The SHARE trial showed that APBI is associated with reduced severe and skin-related toxicities compared to WBI, with no significant difference in cosmetic outcomes. Conversely, WBI was less toxic concerning non-skin breast toxicity, mainly breast fibrosis. The question that currently remains open on a practical level is how to consider APBI in the context of the widespread adoption of the "Fast Forward" regimen for patients at low risk of recurrence. Dalpiciclib (Dalp) plus endocrine therapy (ET) as adjuvant treatment for HR+/HER2− early breast cancer (BC): The randomized, phase 3, DAWNA-A trial. First Author: Zhi-Ming Shao, Fudan University Shanghai Cancer Center, Shanghai, China

Background: Dalp, a potent CDK4/6 inhibitor, has demonstrated significant improvements in PFS when combined with ET in both first-line and later-line settings for HR+/HER2− advanced BC. We conducted a randomized, double-blind, phase 3 trial (DAWNA-A) to further evaluate Dalp with ET as adjuvant therapy for high-risk, early HR+/HER2− BC and here present findings from the pre-specified first interim analysis (IA1). **Methods:** Women aged 18-75 y, with stage II-III, HR+/HER2− BC, who had completed definitive local therapy (surgery and/or radiotherapy) and had pathologically confirmed ipsilateral axillary lymph node involvement, were enrolled. Patients (pts) were randomized (1:1) to receive oral Dalp (125 mg QD; 3-wk on/1-wk off, for 2 y) + ET (letrozole 2.5 mg/anastrozole 1 mg/tamoxifen 10 mg/toremifene 60 mg QD, for 5 y) or placebo + ET. Pre/perimenopausal pts received LHRH agonists (perimenopausal use at investigator's discretion). Stratification factors were menopausal status (pre/peri vs post), clinical stage (II vs III), number of involved nodes (<4 vs ≥4), and adjuvant chemo (y vs n). The primary endpoint was invasive disease-free survival (iDFS). IA1 was pre-planned at ~254 iDFS events (~50% of total expected). As of Oct 25, 2024, 268 iDFS events occurred and IA1 was performed; the actual superiority boundary was a 1-sided p <0.00205 (Lan-DeMets [O'Brien-Fleming] boundary). **Results:** Between Apr. 30, 2021 and Jul. 19, 2024, 5274 pts were randomized (Dalp, n=2640; placebo, n=2634). As of data cutoff, median follow-up was 20.3 mo (range 0.0–41.9). Dalp + ET significantly prolonged iDFS vs placebo + ET (HR 0.56, 95% CI 0.43–0.71; 1-sided p <0.0001); iDFS benefits with Dalp were generally consistent across stratification factors and other baseline subgroups. DFS and distant DFS (DDFS) also favored Dalp + ET over placebo + ET (Table). TRAEs led to discontinuation of Dalp in 2.1% of treated pts in Dalp arm and of placebo in 0.8% in placebo arm. Tr-SAE occurred in 3.7% and 1.5%, respectively. There was no death due to TRAEs. **Conclusions:** Addition of Dalp to ET as adjuvant treatment significantly improved iDFS, with a tolerable safety profile. These data support the use of Dalp for treating HR+/HER2- early BC. Clinical trial information: NCT04842617. Research Sponsor: Jiangsu Hengrui Pharmaceuticals Co., Ltd.

516 Rapid Oral Abstract Session

Efficacy and safety of ribociclib (RIB) + nonsteroidal aromatase inhibitor (NSAI) in NATALEE: Analysis across menopausal status and age. First Author: Kevin Kalinsky, Winship Cancer Institute at Emory University, Atlanta, GA

Background: The NATALEE trial demonstrated significant invasive disease–free survival benefit with RIB + NSAI vs NSAI alone in patients (pts) with stage II/III HR+/HER2− early breast cancer (EBC) at high risk of recurrence. Here, we report outcomes by menopausal status and age. **Methods:** Pts were treated with RIB + NSAI or NSAI alone in NATALEE; premenopausal (PreM) women also received goserelin. Men were excluded from this analysis. Efficacy, safety, and quality of life were analyzed by menopausal status (assessed at randomization or start of adjuvant endocrine therapy, whichever was first) and age (PreM [<40 y, ≥40 y]; postmenopausal [PostM; <60 y, ≥60 y]). Data cutoff was April 29, 2024. **Results:** A greater portion of PreM vs PostM pts had ECOG performance status 0 (86.8% vs 80.1%), Ki-67 >20% (39.9% vs 34.4%), N1-N3 nodal stage (63.4% vs 56.9%), and T3/T4 tumors (28.7% vs 24.0%) at diagnosis. There was consistent treatment benefit with RIB + NSAI vs NSAI alone across groups and ages (median follow-up, 44.2 months) (Table). Fewer PreM pts discontinued RIB due to AEs vs PostM (16.1% vs 22.9%); reductions due to AEs were similar (22.4% vs 23.6%). Of pts who discontinued due to AEs, more PreM pts did so without a dose reduction vs PostM (75.4% vs 67.5%). Within menopausal groups, fewer pts in the younger cohorts discontinued RIB due to AEs (Table). Alanine aminotransferase elevation was the most common AE leading to discontinuation in the PreM (6.2%) and PostM groups (8.0%). Time to deterioration in global and physical functioning scales of the EORTC QLQ-C30 was similar between treatment arms for all subgroups. **Conclusions:** RIB + NSAIprovides treatment benefit to a broad range of pts with stage II/III HR+/HER2− EBC across menopausal status and age. In younger PreM pts, who typically have more aggressive disease characteristics, treatment favored RIB + NSAI, and these pts were least likely to discontinue RIB due to AEs. Clinical trial information: NCT03701334. Research Sponsor: None.

The TRADE study: A phase 2 trial to assess the tolerability of abemaciclib dose escalation in early-stage HR+/HER2- breast cancer. First Author: Erica L. Mayer, Medical Oncology, Dana-Farber Cancer Institute, Harvard Medical School, Boston, MA

Background: The CDK4/6 inhibitor abemaciclib (abema) is approved with adjuvant endocrine therapy (ET) for high-risk node positive hormone receptor positive (HR+) HER2- breast cancer. This regimen reduces cancer recurrence, yet therapy may be complicated by toxicity, limiting patient (pts) ability to maintain dose or continue medication. In the phase III monarchE study, 25.8% of pts discontinued abema early for reasons other than recurrence, 18.5% for adverse events (AEs), and 43.6% required dose reduction. Experiences with other targeted therapies suggest initial dose escalation may reduce toxicity and discontinuation. TRADE is a prospective, single-arm, phase 2 study evaluating whether a dose-escalation strategy of adjuvant abema improves drug tolerability. **Methods:** Eligible pts had node-positive HR+/HER2- breast cancer and were candidates for adjuvant abema with ET. All pts started abema at 50 mg BID for 2 weeks (wks), escalated to 100 mg BID for 2 wks, then escalated to final dose of 150 mg BID onwards. Escalation required absence of ongoing grade 3/4 or persistent grade 2 toxicity; anti-diarrheal medication was used as needed. The primary endpoint, measured at 12 wks, was a composite rate of discontinuation of abema for any reason or inability to reach or maintain the 150 mg dose. Based on assumptions from monarchE, the experimental hypothesis was that a dose-escalation schedule of abema would significantly reduce rate of the composite primary endpoint at 12 wks from 40%. **Results:** 90 pts enrolled, 89 evaluable for the primary endpoint (1 progression before 12 wks). Median age was 58 [range 24-78], 4% were Black, 3% were Hispanic. 48% had stage II disease, 52% had stage III, all received AI, 14% concurrent OFS. The study achieved the predefined primary endpoint with 26 pts (29.2%; 90% CI [21.3-38.2]; p=0.046) meeting the composite endpoint at 12 wks: 6 (6.7%) for early discontinuation (3 [3.4%] for toxicity), 8 (9.0%) for inability to reach 150 mg, and 12 (13.5%) for dose reduction from 150 mg. The most frequent >grade 2 treatment related AEs by 12 wks were neutropenia (23.3%), diarrhea (22.2%), and fatigue (20%). Rates of clinically significant diarrhea (> grade 2) within 0-4, 4-8, and 8-12 wks were 5.6%, 14.6%, 15.3%, in contrast to rates from monarchE of 20.5%, 12.1%, 7.3% in the same periods. **Conclusions:** The TRADE study is a positive trial meeting its primary endpoint. Use of an adjuvant abema dose escalation strategy allowed a greater number of pts (70.8%) to reach and maintain the 150 mg dose at 12 wks than in monarchE. Early discontinuation was infrequent, and 93.3% were continuing therapy at 12 wks. Reduced incidence and severity of clinically important toxicity such as diarrhea was observed. This dosing strategy could be considered when initiating adjuvant abemaciclib. Further follow-up will assess long-term tolerability, dosing maintenance beyond 12 wks, and correlative analyses. Clinical trial information: NCT06001762. Research Sponsor: Lilly.

Impact of chemotherapy on financial toxicity in African-American breast cancer patients: Early findings from the navigator-assisted hypofractionation (NAVAH) phase I clinical trial. First Author: Maya J. Stephens, Medical College of Georgia, Augusta, GA

Background: With the rising cost of chemotherapy, the financial toxicity (FT) of systemic therapy can substantially impair patient quality of life. FT is also associated with various socioeconomic factors, one being race. Patients of African American race often bear the worst burden of cancer treatment-related FT, with a 40% increased mortality from breast cancer. The degree to which chemotherapy prior to radiation therapy (RT) impacts FT has yet to be formally quantified. We report early FT findings among African American breast cancer patients prior to receipt of adjuvant RT on the ongoing Navigator-Assisted Hypofractionation (NAVAH) Phase I clinical trial (ClinicalTrials.gov ID: NCT05978232) to assess the impact of chemotherapy on FT. **Methods:** African-American breast cancer patients undergoing RT were eligible if age 18+ with pathologically confirmed breast cancer following resection. As part of the trial, patients were assisted by a patient navigator during and after treatment. FT was measured using the validated 12-item COmprehensive Score for financial Toxicity-Functional Assessment of Chronic Illness Therapy (COST-FACIT) survey instrument. COST-FACIT scoring was used to find FT in patients before receipt of RT. Values from 26-44 represent Grade 0 FT (none), values from 14-25 represent mild Grade 1 FT (mild), values from 1-13 represent Grade 2 FT (moderate), and values of 0 represent Grade 3 FT (severe). The chi-square test was used to identify statistically significant differences ($p < 0.05$) between patients who received chemotherapy versus no chemotherapy prior to receipt of RT. **Results:** The first 32 enrolled patients completing the pre-RT COST-FACIT survey were evaluated. 53% of patients underwent chemotherapy before RT. Mild to moderate FT was apparent in 56% of patients. The mean and median COST-FACIT score (range 4.4-39) was 25 (+/- 10.4). 78% of patients who experienced some level of FT underwent chemotherapy and 22% of patients experiencing FT did not receive chemotherapy ($p = 0.0015$). Of patients who did not experience FT, 21% received chemotherapy and 79% of patients did not. In total, 82% of patients who underwent chemotherapy before RT reported mild to moderate FT. Grade 3 FT was not observed. **Conclusions:** The NAVAH study is the first to objectively compare FT among patients receiving chemotherapy before RT for early-stage breast cancer. Our findings indicate that more than 80% of patients who underwent chemotherapy experienced FT. Approximately 1 in 5 patients not experiencing FT received chemotherapy. The findings indicate that chemotherapy plays a significant role in patient quality of life, highlighting a subsection of patients who may benefit from proactive financial assistance to reduce the detrimental effect of FT on their livelihood. Out-of-pocket cost modeling of EUROPA trial arms for adjuvant breast cancer therapy: Five days of radiation versus five years of antiestrogen therapy. First Author: Ena Chinedum Oboh, The George Washington University School of Medicine and Health Sciences, Washington, DC

Background: Optimal adjuvant therapy following breast-conserving surgery in adults with low-risk, early-stage breast cancer remains uncertain. Cost and financial toxicity remain significant concerns for breast cancer patients. There is limited granular analysis of the role of insurance in the aggregate cost of five fractions of adjuvant radiotherapy (RT) versus adjuvant endocrine therapy (ET), as is being explored in the EUROPA Phase III trial. This study aims to disaggregate costs, estimate out-of-pocket (OOP) expenses by insurance plan, and increase transparency to better inform treatment decisions. **Methods:** Treatment protocols were aligned with the EUROPA trial arms. For our financial model, we used five-fraction RT and ET prescribed over 5 years, with follow-up after two years (consistent with EUROPA trial results) and five years (full duration of prescribed antiestrogen therapy). OOP costs, deductibles, and copays/coinsurance were calculated using Medicaid, Original Medicare, Medigap Plan G, and Medicare Part D plans. Data sources included medicare.gov, medicaid.oh.gov, aarpmedicareplans.com, and the CMS physician fee schedule. Price estimates reflect actual insurance plan costs rather than claims data. The model assumes a Medicare- and/or Medicaid-eligible patient aged ≥ 70 years with early-stage estrogen-receptor positive breast cancer after breast-conserving surgery. **Results:** Original Medicare beneficiaries face estimated OOP treatment costs of $1,049.06 for adjuvant ET at 24 months and $2,130.25 at five years. For five-fraction RT, the estimated OOP costs are $1,490.93 at 24 months and $2,320.12 at five years. Medigap Plan G beneficiaries incur lower OOP expenses: $682 for adjuvant ET at 24 months and $1,705 at five years, and $514 at 24 months and $1,285 at five years for five-fraction RT. In contrast, Medicaid beneficiaries have no OOP expenses for either treatment option, as Medicaid fully covers all treatments. **Conclusions:** The EUROPA trial highlights HRQOL outcomes at 24 months for endocrine therapy versus radiotherapy in women aged 70+ with luminal A-like early breast cancer. This cost analysis, based on actual cost estimates, provides a clear comparison of OOP expenses across Medicaid and Medicare plans. While RT has higher upfront OOP costs at 24 months under Original Medicare, the cost difference narrows over five years, with RT incurring slightly higher cumulative costs. This reflects RT's one-time nature versus the ongoing costs of ET, which more than doubles over the same period. Medigap Plan G beneficiaries experience significantly reduced OOP costs, favoring RT further at five years, while Medicaid eliminates OOP costs entirely for either treatment, ensuring equitable access to both options. These findings support the initial EUROPA trial results favoring RT over ET for HRQOL and treatment-related toxicity. Research Sponsor: None.

Impact of body mass index (BMI) on efficacy and safety of abemaciclib in breast cancer patients (pts) treated in the monarchE trial. First Author: Christine Desmedt, Laboratory for Translational Breast Cancer Research, KU Leuven, Leuven, Belgium

Background: Two years (yrs) of adjuvant abemaciclib + endocrine therapy (ET) resulted in sustained improvement in invasive disease-free survival (IDFS HR=0.68, 5 yrs rates: 84% abemaciclib + ET vs 76% ET, 8% absolute benefit) in pts with hormone receptor positive, human epidermal growth factor receptor 2 negative, node-positive, high-risk early breast cancer (EBC). Obesity is an established factor influencing the biology and prognosis of breast cancer; however, the specific impact on treatment (tx) outcomes remains uncertain. Here we report efficacy and safety by BMI in monarchE. **Methods:** Pts were randomized 1:1 to receive ET for at least 5 yrs +/- abemaciclib for 2 yrs. Groups were defined by baseline BMI (kg/m^2): as obese ($\geq$30), overweight (25$<$30), and non-overweight ($<$25). IDFS/DRFS in each group was assessed using Kaplan-Meier method and unstratified Cox model. Safety was summarized by subgroup. **Results:** 1507 pts (27%) were obese, 1762 (32%) were overweight, and 2227 (41%) were non-overweight. Most obese pts were postmenopausal (67%), received aromatase inhibitor as first ET (75%) and a substantial proportion (47%) had $\geq$4 comorbidities, vs 60%, 69%, 34% among overweight pts and 47%, 63%, 30% among non-overweight, respectively. Pts $\geq$65 yrs constituted 18%, 17% and 12% of these groups. Disease characteristics were balanced across BMI groups. A consistent tx benefit in IDFS was observed with the addition of abemaciclib to ET across all 3 BMI groups: obese (HR = 0.67, 95% CI: 0.53, 0.85), overweight (HR = 0.73, 95% CI: 0.58, 0.91), and non-overweight (HR = 0.68, 95% CI: 0.55, 0.83), with an interaction p-value of 0.858. 5yr IDFS rates in the ET arm were lowest in obese pts (74%) and similar for overweight and non-overweight pts (77% in each). In the abemaciclib + ET arm, absolute improvements in IDFS were 8.8%, 5.8% and 7.9% across each respective BMI group. Similar findings were observed for DRFS. Obese pts had fewer grade$\geq$3 (G$\geq$3) neutropenia, and related dose hold/reductions. Despite higher G$\geq$3 diarrhea in obese pts, related dose reductions and discontinuations were similar in all 3 groups. G$\geq$3 ALT elevations were low in all groups. Serious AEs (SAEs) were more common in obese pts, across tx arms (Table). **Conclusions:** In pts with high-risk EBC, adjuvant abemaciclib + ET showed consistent and clinically meaningful tx benefit across BMI subgroups, along with a manageable safety profile. Additional analyses are planned to adjust for the impact of confounding factors such as comorbidities. Clinical trial information: NCT03155997. Research Sponsor: Eli Lilly and Company.

The effect of endocrine therapy omission on survival in ER-negative PR-low (1–10%) early-stage breast cancer treated with chemotherapy. First Author: Shawn Michael Doss, Medical College of Georgia, Augusta, GA

Background: The effect of endocrine therapy omission on outcomes in breast cancer (BC) with low progesterone receptor (PR) expression (1–10%) is unknown. Previously, omitting adjuvant endocrine therapy in estrogen receptor (ER)-low (1–10%) BC was associated with worse survival (1), but whether this is also true for PR 1–10% (PR-low) BC has not been studied. We analyzed outcomes for omission of endocrine therapy in patients with ER-negative PR-low stage I–III BC who received chemotherapy. **Methods:** We identified 46,704 patients from the National Cancer Database (diagnosed 2018–2020) with PR 1–10% stage I–III BC, of whom 3651 (7.8%) were ER-negative. Of these, 2,915 (79.8%) received chemotherapy. After excluding incomplete data for covariates, 2,796 remained for analysis. Cox proportional hazards models were used to analyze overall survival (OS). Multivariate Cox regression and propensity score matching were performed to account for confounding by age, stage, comorbidity score, HER2 status, year of diagnosis, and grade. This study protocol was developed and reviewed by oncology faculty prior to implementation. **Results:** Of the final cohort of 2,796 ER-negative PR-low BC patients, 73.6% were HER2-negative and 85.0% were high grade. Stage distribution was 34.8% stage I, 43.6% stage II, and 21.6% stage III. Endocrine therapy was omitted in 2,051 (73.4%). OS was 93.9% (95% CI 93.0–94.9%) at 2 years and 86.1% (95% CI 84.3–87.9%) at 4 years, with 267 total deaths. In the univariate (unadjusted) analysis, omission of endocrine therapy was associated with worse 4-year OS (hazard ratio [HR] 1.84, 95% CI 1.34–2.53, p$<$0.001). In the multivariate (adjusted) analysis, the HR was 1.72 (95% CI 1.25–2.37, p$<$0.001). Interaction testing for endocrine therapy and HER2 status was not significant. To account for possible pandemic impacts on OS, a sensitivity analysis of 2,639 patients (after excluding those who did not survive six months beyond definitive surgery) was performed and yielded a HR of 1.50 (95% CI 1.08–2.10, p=0.016). After propensity score matching of 1,490 ER-negative PR-low BC patients (matched by age, stage, comorbidity score, HER2 status, year of diagnosis, and grade), omission of endocrine therapy was still associated with worse 4-year OS (HR 1.63, 95% CI: 1.12–2.36, p=0.010). In contrast, omission of endocrine therapy in matched ER-negative PR-negative (instead of PR-low) BC patients was not associated with worse OS (HR 1.12, 95% CI: 0.92–1.37, p=0.27). **Conclusions:** In ER-negative PR-low (1–10%) early-stage BC treated with chemotherapy, omission of endocrine therapy may be associated with worse overall survival, suggesting that endocrine therapy could improve survival in ER-negative BC patients even with only low (1–10%) PR expression. Further investigation is recommended as this retrospective study design cannot establish causality. 1. Choong, 2024, *JCO*. Research Sponsor: None.

Practice patterns related to ovarian function suppression in the SWOG S2010 clinical trial of young women with breast cancer. First Author: Norah Lynn Henry, University of Michigan Medical School, Ann Arbor, MI

Background: Addition of ovarian function suppression (OFS) to adjuvant endocrine therapy (ET) improves disease free survival for young patients at high risk of breast cancer recurrence. SWOG S2010, an ongoing clinical trial that has completed enrollment, is examining the benefit of active symptom monitoring for improving 18-month persistence with ET plus OFS. Because data are currently limited on the use of OFS and endocrine therapy in routine practice, this report of S2010 enrollees describes practice patterns related to the prescription of ET for young patients starting OFS plus ET for treatment of stage 1-3 hormone receptor-positive breast cancer. **Methods:** We characterized the baseline demographic, clinical, and pathologic data from the pre- and perimenopausal patients starting OFS plus ET for treatment of breast cancer enrolled in S2010 using descriptive statistics. **Results:** Of the 557 participants enrolled on S2010, median age was 44.5 years (range 23.5-57.1), 25% were Hispanic, 6% Black, 6% Asian, and 76% White. In addition, 39% were not college graduates, 9% were uninsured, and 58% worked full time. Most patients were overweight (34%) or obese (39%). Planned ET was aromatase inhibitor (AI) therapy for 423 (76%) and tamoxifen for 134 (26%). For OFS, 425 (80%) received GnRHa injections, 33 (6%) underwent bilateral salpingo-oophorectomy, and 74 (14%) had chemotherapy-induced ovarian failure (CIOF). Of the 32 (43%) participants with CIOF who were under the age of 45, 12 (38%) were planning to receive AI therapy without concomitant GnRHa therapy. There were 294 participants (55%) with anatomic stage 1 ER-positive breast cancer, of whom 127 (43%) did not receive chemotherapy. Of the 174 participants (33%) with anatomic stage 2 disease, 32 (18%) did not receive chemotherapy. **Conclusions:** Most participants on this clinical trial received GnRHa therapy as their method for OFS, and an AI for their endocrine therapy. We found that a small number of patients under the age of 45 with CIOF did not receive GnRHa therapy and planned to start AI therapy, even though such patients are at high risk of recovery of ovarian function. Additionally, approximately one-quarter of trial participants appeared to have low risk disease based on non-receipt of chemotherapy and anatomic Stage 1, despite NCCN guidance recommending that OFS be reserved for patients with higher risk features. These findings suggest that additional education about the optimal use of OFS in young women with hormone receptor-positive breast cancer may be warranted. Clinical trial information: NCT05568472. Beyond the 5-year mark: Adherence to and continuation of extended adjuvant endocrine therapy in non-metastatic breast cancer patients. First Author: Jenny Wei, Department of Hematology-Oncology, Kaiser Permanente San Francisco, San Francisco, CA

Background: Extending adjuvant endocrine therapy (AET) beyond five years has been shown to be beneficial for women with non-metastatic, hormone-responsive breast cancer. While many studies have examined adherence to (taking medication according to prescribed regimen) and continuation of (taking medication for prescribed duration) AET, most have focused on the first five years of use and data beyond that period are lacking. To address this knowledge gap, we conducted a large retrospective cohort study to determine adherence to and continuation of AET beyond the first 5 years among a cohort of non-metastatic breast cancer patients treated in a community setting. **Methods:** We estimated adherence to and continuation of extended AET (tamoxifen or aromatase inhibitor) among 13,675 women at Kaiser Permanente Northern California (KPNC), an integrated healthcare system caring for approximately 4.5 million members. The cohort consisted of women diagnosed with Stage I-III, estrogen receptor positive (ER+) breast cancer and were treated at KPNC from 2008 to 2017. Adherence was defined as medication possession ratio $>$80% for each 12-month period during follow-up. Continuation was defined as time to last pill possession date before a 180-day gap of AET and was based on the Kaplan-Meier estimator. Both adherence and continuation were examined for the 10-year period after initiation. **Results:** Of the 13,675 eligible women who initiated AET, 81% were 50 years or older, 61% were white and 76% had an Elixhauser Comorbidity Score of 2 or less. Most women had Stage I or II breast cancer (90.9%) that was progesterone receptor positive (79%) and HER2 negative (84%). We observed a gradual decline in adherence to AET each year from 79% in year 1 to 60% in year 5, followed by a dramatic drop to 23% in year 6. After year 6, annual adherence again dropped gradually and was 10% in year 10. Median AET continuation time was 5.1 years. Similarly, there was also a striking decline in AET continuation between year 5 and 6, with 52% continuing AET to the end of year 5 and 20% continuing to the end of year 6. Only 4.5% of the cohort continued to the end of year 10. **Conclusions:** We observed a substantial drop in both adherence to and continuation of AET following year 5 into year 6 with only 4.5% of the cohort continuing to the end of year 10. This period may represent an opportunity for intervention to improve use of extended AET. Future studies are needed to identify factors affecting adherence to and continuation with extended AET. Research Sponsor: None.

Impact of initial chemotherapy dosing on subsequent dosing patterns and treatment completion in early-stage breast cancer. First Author: Maria Jose Monroy Iglesias, Memorial Sloan Kettering Cancer Center, New York, NY

Background: While breast cancer treatment guidelines provide dosing recommendations, some patients do not receive the full expected dose at outset. Preemptive dose reduction, often due to toxicity concerns, may influence subsequent reductions or early discontinuation. The impact of initial dose reductions on subsequent care delivery remains unclear. **Methods:** The Optimal Breast Cancer Chemotherapy Dosing (OBCD) study is a cohort of 34,109 women diagnosed with stage I-IIIA breast cancer at two U.S. integrated healthcare systems between 2004-2019. We examined associations between first-cycle dose proportion (FCDP), categorized as ≥95%, 90-95%, 85-90%, <85%, with average relative dose intensity (ARDI) categories and early discontinuation. Adjusted prevalence ratios (aPRs) were estimated using generalized linear models of the Poisson family to evaluate associations between FCDP (≥95% vs. <95%) and the likelihood of further dose reductions (based on ARDI) and early discontinuation. Analyses were performed overall and stratified by age, body mass index (BMI), and Charlson comorbidity index (CCI), as older age and comorbidities, including obesity, are linked to higher risk of dose reductions. **Results:** Among 9,724 women receiving adjuvant chemotherapy, 66% of those with FCDP ≥95% remained fully dosed throughout treatment. In contrast, 46% of patients in both the 90–95% and 85–90% FCDP groups stayed in the same category. The highest likelihood of early discontinuation was seen in patients with FCDP <85% (19%) compared to 13% in the FCDP ≥95% group (p <0.01). Multivariable analyses showed that women with FCDP <95% were more likely to experience further dose reductions (aPR 1.34; 95%CI 1.21-1.49), than those with FCDP ≥95%; but interactions with BMI, CCI, or age were not statistically significant. However, the associations between FCDP and early discontinuation (aPR 1.29; 95%CI 1.11-1.50) varied by BMI (p-interaction 0.02) and age (p-interaction 0.03). A lower FCDP was positively associated with early discontinuation in women with BMI 25-30kg/m^2 (aPR 1.62; 95%CI 1.27-2.07) and BMI 30-35kg/m^2 (aPR 1.50; 95%CI 1.16-1.94), but no association was observed for BMI <25 or >35 kg/m^2. Patients aged ≤49 years (aPR 1.84; 95% CI 1.39–2.45) and 50–64 years (aPR 1.25; 95% CI 1.07–1.46) with FCDP <95% were more likely to discontinue early, with no association observed in older adults. **Conclusions:** Women with breast cancer who have FCDP <95% are more likely to experience further dose reductions, regardless of age, BMI, or CCI, suggesting that initiating treatment with reduced doses may not prevent subsequent reductions. Early discontinuation was more likely among patients with FCDP <95%, particularly those with BMI 25–30 or 30–35 kg/m² or younger age. These findings may reflect frailty, treatment intolerance, or patient preferences. Understanding the drivers of these decisions is key to guide strategies that balance toxicity concerns with maintaining adequate dosing to reduce treatment cessation in at-risk groups. Chemotherapy (CT) declination among patients with early-stage hormone receptor positive breast cancer (BC) and high Oncotype DX recurrence scores (RS). First Author: Inimfon Jackson, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Among patients with hormone receptor positive, HER2-negative (HR+/HER2-) BC, the 21-gene Oncotype DX assay is both prognostic of recurrence risk and predictive of CT benefit. However, some patients decline CT despite their physician's recommendations. We investigated the factors associated with CT declination and its impact on overall survival (OS) among patients with early-stage HR+/HER2- BC and high RS. **Methods:** Patients (≥18 years) diagnosed with HR+/HER2- BC from 2018-2021, with pathologic (p) T1-T3, pN0-N1 disease and RS >25, were identified in the National Cancer Database. Multivariable logistic regression was used to examine the factors associated with CT declination. Furthermore, multivariable Cox proportional hazards regression was used to evaluate the association between CT declination and OS based on a propensity score matched 1:5 cohort using year of diagnosis, age, race/ethnicity, pT and pN. **Results:** Among 23,416 patients with early-stage HR+/HER2- BC and RS >25, 74.3% were non-Hispanic White (NHW) and 12.1% were Black. Overall, 2601 (11.1%) patients declined CT despite physician recommendation (median RS of 30). Among those declining CT, 15.8% also declined endocrine therapy. On univariate analysis, CT declination was associated with older age, Black race and lobular histology. After adjustment, each unit increase in RS was associated with lower odds of CT declination (aOR=0.97; 95%CI 0.96–0.97). A more recent year of diagnosis was associated with lower odds of CT declination while older age and Black race (aOR=1.33; 95%CI 1.17–1.51) were associated with higher odds. Additionally, patients on Medicaid (aOR=1.66; 95%CI 1.40–1.97) and Medicare (aOR=1.29; 95%CI 1.12–1.48) had higher odds of declination compared to those on private insurance. Having pN1 disease was associated with lower odds of declination than pN0 disease (aOR=0.74; 95% 0.66–0.83). There was no association between comorbidity and declination. Notably, CT declination was associated with an increased risk of death after a median follow-up of 3 years (aHR=1.28; 95%CI 1.02–1.61) among 10,909 matched patients. Sensitivity analyses among patients with RS >30 showed similar results. **Conclusions:** Though prospective studies have demonstrated the benefit of CT among patients with high RS, 11% of patients declined CT. We observed a decrease in CT declination over time, as well as with increasing RS. Of note, Black patients, and those on Medicaid or Medicare were more likely to decline chemotherapy. CT declination was associated with worse OS. While the reasons for treatment declination are multifactorial, research is needed to understand the underlying disparities and work toward improving cancer care delivery. Research Sponsor: Susan G. Komen Foundation; SAC220221; The Breast Cancer Research Foundation; 23-190.

526 Poster Session

Treatment-related neutropenia as a predictor of response to adjuvant palbociclib in the PALLAS trial (ABCSG-42/AFT-05/BIG-14-13/PrE0109). First Author: Kristina Fanucci, Dana-Farber Cancer Institute, Boston, MA

Background: The PALLAS trial (NCT02513394) investigated the efficacy of the addition of palbociclib (palbo) to standard adjuvant endocrine therapy (ET) to reduce breast cancer recurrence. Previous analyses of this trial have not shown significant benefit of combination palbo+ET over ET alone. Given prior data showing that extent of neutropenia is associated with response to palbo and other cell cycle-specific therapies, we evaluated whether extent of neutropenia could identify responders to palbo in the adjuvant setting. **Methods:** PALLAS is a global, open-label, phase III trial that randomized patients (pts) with stage II-III hormone-receptor positive, HER2-negative breast cancer to receive ET for ≥5 years with or without standard-dose palbo for 2 years in 28-day cycles. The primary endpoint is invasive disease-free survival (iDFS). For this exploratory analysis, the palbo population was classified into pts with treatment-emergent high-grade neutropenia (HGN) with maximum grade ≥3 (absolute neutrophil count <1000), or low-grade/no neutropenia (LGN) with maximum grade <2; these groups were compared to each other and to the ET alone group for 5-year iDFS outcomes. Logistic regression examined individual baseline characteristics associated with HGN during the first 3 cycles within the palbo group. Impact of HGN during the first 3, 6, and 12 cycles on iDFS was tested using univariate and multivariable landmark Cox regression. **Results:** The safety population included 5736 pts, 2840 allocated to palbo+ET, 2896 to ET alone. Prior publications reported no new safety signals, low rates of serious infection, and no grade 5 treatment-related events. The palbo+ET group consisted of 1006 (35.4%) LGN and 1834 (64.6%) HGN. 5-year iDFS results are shown in the table. Pts who received palbo+ET and developed HGN by the end of cycle 6 had significantly improved 5-year iDFS compared to those who received ET alone (p=0.04), which remained statistically significant when adjusting for body mass index (BMI), prior chemotherapy, and race. Multivariable logistic regression showed lower BMI, prior chemotherapy, Asian race, and prior mastectomy were significantly associated with HGN (all p<0.05). **Conclusions:** In this exploratory analysis of the phase III PALLAS adjuvant trial, addition of palbo to ET appeared to be superior to ET alone in pts who developed HGN in the first 6 cycles of treatment but not in those who had LGN. These findings are consistent with observations in the metastatic setting suggesting that neutropenia could be a useful biomarker for palbo concentration and efficacy. Clinical trial information: NCT02513394. Research Sponsor: Pfizer.

Maximum grade neutropenia measured at end of cycle:	5-year iDFS

Real-world (RW) analysis of characteristics and risk of recurrence (ROR) in Black patients (pts) with HR+/HER2− early breast cancer (EBC) eligible for NATALEE. First Author: Yara Abdou, Division of Oncology, Lineberger Comprehensive Cancer Center, The University of North Carolina at Chapel Hill, Chapel Hill, NC

Background: The NATALEE trial showed statistically significant and clinically meaningful invasive disease–free survival benefit with ribociclib + nonsteroidal aromatase inhibitor (NSAI) vs NSAI alone in pts with stage II/III HR+/HER2− EBC at high ROR that deepened even after all pts were off ribociclib. Prior RW analyses have shown clinically meaningful ROR at 5 y despite endocrine therapy (ET) among NATALEE-eligible pts. TAILORx and RxPONDER reported racial disparities in recurrence and outcomes; however, further understanding of characteristics and unmet needs in Black pts is needed. This RW analysis describes pt characteristics and outcomes among Black pts eligible for NATALEE and receiving ET. **Methods:** Data from the US Flatiron Health EHR-derived deidentified database (2011-2023) were used. Selection criteria included pts aged ≥18 y with anatomical stage I-III (AJCC) HR+/HER2− EBC who had primary tumor surgical resection and started adjuvant ET. Pt characteristics and treatment patterns were analyzed in Black vs White pts eligible for NATALEE. ET (any) adherence was defined as proportion of days covered ≥80%. Recurrence-free survival (RFS), distant recurrence–free survival (DRFS), and overall survival (OS) were assessed descriptively and using multivariate Cox regression analysis. **Results:** A total of7481 pts met selection criteria. Overall, 41.2% (242/588) of Black and 33.0% (1697/5142) of White pts met NATALEE eligibility criteria. Compared with White pts, Black pts were younger (median age, 59 y vs 62 y) and more likely to be premenopausal (29.3% vs 23.8%), have anatomical stage III disease (35.1% vs 25.7%), more extensive nodal involvement (19.8% N0, 54.1% N1, 14.0% N2, and 7.0% N3 vs 24.0% N0, 53.3% N1, 11.3% N2, and 6.2% N3), higher use of Medicaid (13.2% vs 3.6%), lower socioeconomic status (lowest socioeconomic status quintile, 33.9% vs 11.4%), higher obesity (body mass index ≥30, 52.9% vs 38.4%), and lower ET adherence (3 y ET adherence: 57.0% vs 65.2%; 5 y ET adherence: 48.3% vs 56.2%). Five-y RFS, DRFS, and OS rates were 74.3%, 77.6%, and 85.0%, respectively, in Black pts and 83.2%, 84.5%, and 90.9% in White pts. Compared to White pts, Black pts had worse RFS (hazard ratio, 1.5; *P*=0.0045), DRFS (hazard ratio, 1.4; *P*=0.0272), and OS (hazard ratio, 1.7; *P*=0.0023) after adjusting for age, menopausal status, body mass index, tumor size and grade, nodal status, chemotherapy use, and socioeconomic status index. **Conclusions:** In a RW dataset of pts eligible for adjuvant ribociclib based on NATALEE inclusion criteria, Black pts had a higher recurrence risk and worse survival compared with White pts, underscoring the opportunity to improve outcomes and address racial disparities in Black pts with HR+/HER2− EBC. Real-world patterns of Oncotype DX (O-Dx) testing and chemotherapy (CT) use among patients with early-stage, hormone receptor−positive (HR+) breast cancer (BC). First Author: Marija Sullivan, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: O-Dx, a 21-gene assay, has transformed the management of patients with early-stage, HR+, HER2-negative (HER2-) BC by guiding personalized treatment decisions regarding adjuvant CT. However, real-world patterns of CT use based on recurrence score (RS) remain a topic of interest. Using a large, hospital-based database, we evaluated testing patterns, factors associated with O-Dx testing, and examined predictors of CT use among patients by RS. **Methods:** Patients ≥18 years with early-stage, HR+/HER2- BC diagnosed from 2018-2021 who underwent surgery and had pT1-T3, pN0-N1 disease were identified in the National Cancer Database. Descriptive analyses were used to compare baseline sociodemographic, clinical and treatment characteristics by receipt of O-Dx testing. Multivariable logistic regression was used to examine factors associated with receipt of O-Dx testing and predictors of CT use, stratified by RS into 0-10 (low risk), 11-25 (intermediate risk) and > 25 (high risk). **Results:** Of 319,771 patients with early-stage, HR+/HER2- BC, 54% (172,491) received O-Dx testing. Median age was 61 among those who received testing and 65 among those who did not. Black (aOR = 0.93; 95%CI 0.90–0.95) and Hispanic patients (aOR = 0.89; 95%CI 0.86–0.92) were less likely to receive testing than White patients. Compared to private insurance, those on Medicare (aOR = 0.93; 95%CI 0.91–0.95), Medicaid (aOR = 0.89; 95%CI 0.86–0.92), or no insurance (aOR = 0.91; 95%CI 0.85–0.98) had lower odds of O-Dx testing. While older age, higher comorbidity scores and pN1 disease were associated with lower odds of testing, recent year of diagnosis, pT2 disease, lobular histology, higher grade and treatment in academic facilities were linked to higher odds of testing. Overall, 16% (51,213) of patients received CT. Of those, 17.3% did not have an O-Dx test, while 76% of those who received CT and testing had RS > 25. 4.2% of patients aged 18-49 years received CT despite RS 0-10. Among patients without a test, being Black (aOR = 1.19; 95%CI 1.12–1.26) or Hispanic (aOR = 1.08; 95%CI 1.01–1.16) was associated with higher odds of receiving CT. Black patients with RS > 25 (aOR = 0.84; 95%CI 0.76–0.93) were less likely to receive CT than White patients. Larger tumors, pN1 disease and higher-grade tumors were associated with greater odds of CT receipt while older age at diagnosis and lobular histology were associated with lower odds regardless of RS. **Conclusions:** O-Dx testing has been increasingly incorporated into clinical practice. Our findings highlight disparities in the receipt of O-Dx testing and CT use, particularly according to RS. Black patients who did not undergo O-Dx testing were more likely to receive CT, while those with RS > 25 were less likely to receive CT. Further research is needed to explore physician and patient decision-making regarding O-Dx testing and adjuvant CT. Research Sponsor: Susan G. Komen; SAC220221; Breast Cancer Research Foundation (BCRF); 23-190.

Estrogen receptor expression in residual breast cancer following neoadjuvant chemotherapy. First Author: Sarah K. Premji, Mayo Clinic, Rochester, MN

Background: Neoadjuvant chemotherapy (NAC) is commonly administered to patients (pts) with estrogen receptor alpha (ER) negative (immunohistochemistry [IHC] 0%) and ER-low (IHC 1-10%) breast cancer (BC). For pts without pathological complete response (pCR), ER expression may differ between baseline and residual BC following NAC. We previously demonstrated adjuvant endocrine therapy (ET) omission in ER-low early-stage BC was associated with significantly worse overall survival (OS); however, this effect was restricted to pts with residual BC following NAC and those with higher baseline ER levels (IHC 6-10%) (Choong et al., ASCO 2024). Here, we assessed how often ER was expressed in residual invasive BC for pts treated with NAC for ER-negative and ER-low BC. **Methods:** Weidentified pts with pre-treatment (tx) ER-negative and ER-low (regardless of HER2 expression) stage I-III BC treated with NAC who underwent BC surgery at Mayo Clinic Rochester between 2009 and 2023. ER IHC was performed in a CAP/CLIA laboratory. We evaluated ER expression in residual invasive BC for pts without pCR. The percent of pts with a post-tx change in ER status was estimated and reported with 95% Wilson confidence intervals. **Results:** 955 pts (838 [88%] pre-tx ER-negative; 117 [12%] pre-tx ER-low) met inclusion criteria, of whom 69% had HER2-negative and 31% HER2-positive BC. The median age at diagnosis was 52 (range: 24-86). 496 (52%) had residual BC. Residual BC was more common in HER2-negative versus (vs) positive tumors (56% vs 42%, p < 0.001) but did not differ significantly by ER status (ER-negative 51% vs ER-low 57%, p = 0.22). Of those with residual BC, 277/496 (56%) had ER re-testing. Rates of ER re-testing did not vary for pre-tx ER-negative vs -low (57% vs 51%, p = 0.37) but were significantly lower for HER2-positive vs HER2-negative tumors (39% vs 62%, p < 0.001). Among those with post-tx testing, 31/277 (11%, 95% CI: 8-15%) had an increase in ER expression from pretreatment levels (defined as ER IHC < 1% to either 1-10% or > 10%; or ER IHC 1-10% to > 10%). In these 31 pts, the original NAC was for either TNBC (21/31; 68%) or HER2+ BC (10/31; 32%). In pts with pre-tx ER-negative BC, 27/243 (11%, 95% CI: 8-16%) had ER expression in the residual BC including 14/243 (6%, 95% CI: 3-9%) with ER > 10% and 13/243 (5%, 95% CI: 3-9%) with ER 1-10%. For pts with baseline ER-low BC, 4/34 (12%, 95% CI: 5-27%) had ER > 10% in the residual BC. Among the 31 pts where ER increased following NAC, 21/31 (68%) received adjuvant ET, including 17/18 if ER was > 10% in the residual disease and 4/13 in those with ER 1-10%. **Conclusions:** In pts treated with NAC for ER-negative or ER-low BC not achieving pCR, we identified higher ER expression in the residual breast cancer in > 10% of pts. Given that omission of ET in ER-low BC with residual cancer following NAC is associated with worse survival, repeat biomarker testing should be considered in those without pCR, and ET individualized according to ER expression. Research Sponsor: None.

Molecular and immune profiling of breast cancer from pregnancy to postpartum: Insights into the tumour-immune landscape during breastfeeding from GEICAM EMBARCAM study. First Author: Regina Peña-Enriquez, Instituto Maimónides de Investigación Biomédica de Cordoba (IMIBIC)-Hospital Universitario Reina Sofia, Universidad de Cordoba, Córdoba, Spain

Background: Breast cancer (BC) is the most common malignancy among young women of childbearing age, with a rising incidence in this population. Pregnancy-associated breast cancer (PABC) is an aggressive entity linked to poor prognosis and elevated metastatic risk. Despite advances in BC research, the impact of pregnancy, breastfeeding, and postpartum mammary gland remodeling on tumor biology remains unclear, highlighting the need to explore their interaction with the tumor microenvironment for novel therapies. **Methods:** A gene expression and immune cell profiling analysis was conducted using the nCounter Breast Cancer 360 panel (NanoString) and CIBERSORTx (Newman 2019, Nat Biotechnol) on FFPE tumor samples from GEICAM/2017-07 EMBARCAM study (NCT04603820) PABC patients during the gestation (PABC_GS, n=21), breastfeeding (PABC_BF, n=21), and first-year postpartum (not during lactation period, PABC_FY, n=15) vs non-PABC tumours (n=49). Differential expression analysis per gene and biological signature was performed using the *limma* package. P-values were adjusted with the Benjamini-Yekutieli false discovery rate (FDR) method. Additionally, the LM22 matrix from CIBERSORTx was employed to quantify 22 immune cell types from normalized NanoString data. Statistical significance was set at 5%. **Results:** PABC clinical subtypes were 46% HR-positive/HER2-negative, 21% HER2-positive, and 33% triple-negative. Differential gene expression analysis identified similar significant enrichment pathways across all PABC groups compared to non-PABC: DNA repair-related signatures (HRD, BRCAness, BC p53) and BC proliferation (adj p<0.05), along with higher CDK4 expression and genomic risk (p<0.05). Conversely, key regulatory pathways such as apoptosis, TGF-Beta, and PD-L1 were downregulated (adj p<0.05). Nonetheless, it is noteworthy that the PABC_BF group showed a unique profile marked by increased immune activity and cell abundance (cytotoxic cells, CD8 T cells, T-reg, cytotoxicity), elevated SOX2 expression (adj p<0.05) and inflammatory chemokines levels (p<0.01) compared to non-PABC. The CIBERSORTx analysis supported these findings, demonstrating a significantly higher abundance of several immune cells in PABC_BF, remarkably CD8+ T-cells and T-regs, compared to all other groups (p<0.05). **Conclusions:** This GEICAM EMBARCAM sub-study reveals that PABC tumors display aggressive molecular features across all subtypes, contributing to poor prognosis. Notably, the breastfeeding-associated subset (PABC_BF) exhibits a highly active tumor-immune microenvironment with robust immune cell infiltration and inflammatory signalling, highlighting potential for targeted immunotherapy. These findings underscore the need for further clinical research to optimize immune-based strategies in PABC patients' management. Clinical trial information: NCT04603820. Research Sponsor: Instituto de Salud Carlos III (PI18/00817 and PI22/00969).; Fundacion Le Cado.

Prospective decision impact study of the Breast Cancer Index: Results from the BCI Registry study. First Author: Tara B. Sanft, Yale University, New Haven, CT

Background: The Breast Cancer Index (BCI) is a validated gene expression assay that provides an individualized risk of late distant recurrence and predicts the likelihood of benefit from extended endocrine therapy (EET) in HR+ early-stage breast cancer. The objective of this analysis was to assess the influence of BCI on clinical decision-making regarding EET. **Methods:** The BCI Registry study is a prospective, multi-institutional study investigating the long-term clinical outcome, decision impact, and quality of life in HR+ breast cancer patients receiving BCI testing as part of routine clinical care. Physicians and patients completed pre- and post-BCI test questionnaires to assess physician decision-making; physician confidence; and patient preferences and concerns for EET. Pre- and post-BCI responses were compared using McNemar's test and the Wilcoxon signed rank test. The BCI Registry Study is registered on ClinicalTrials.gov under NCT04875351. **Results:** In the current analysis,pre- and post-BCI testing questionnaires were completed for 2850 physicians and 2832 patients. 88.6% of patients were postmenopausal, 76.5% N0, 73.0% T1, 53.5% G2, and 13.0% HER2-positive. Following BCI testing, physicians changed treatment recommendations for EET in 41.2% (1175/2850) of patients (p<0.001). In cases where physicians recommended EET prior to BCI testing, 49.8% (775/1555) changed their recommendation to not treat with EET, while 31.2% (400/1280) of those who did not recommend EET prior to BCI testing changed their recommendation in favor of EET. Following BCI testing, 43.9% (1250/2850) of physicians felt more confident in their recommendation (p<0.001) and 43.2% (1223/2832) of patients felt more comfortable with their EET decision (p<0.001). The percentage of physicians having high confidence levels (confident or strongly confident) increased from 63.6% (N=1813) pre-BCI testing to 88.2% (N=2515) post-BCI testing. The percentage of physicians having low confidence levels (not at all confident, not confident, or ambivalent) decreased from 33.1% (N=943) pre-BCI testing to 11.0%(N=313) post-BCI testing. In BCI (H/I)-Low patients, 48.9% (868/1776) showed a decreased preference for EET (p<0.001). In BCI (H/I)-High patients, 34.6% (365/1056) showed an increased EET preference (p<0.001). After BCI testing, significantly more patients were less concerned about cost (23.9%, p<0.001), drug safety (25.7%, p<0.001), and EET benefit (30.9%, p<0.001). No significant change in concern regarding side-effects was observed (p=0.58). **Conclusions:** Incorporating BCI into clinical practice resulted in significant changes in physician recommendations for EET, while at the same time increasing physician confidence. Knowledge of the BCI result improved patient preference, satisfaction and reduced patient concerns regarding cost, drug safety and benefit of EET. Research Sponsor: None.

HER2DX prognostic value in older patients with HER2-positive early breast cancer: A correlative analysis from the RESPECT phase III trial. First Author: Kazuki Nozawa, Department of Advanced Clinical Research and Development, Nagoya City University, Graduate School of Medical Sciences, Nagoya, Japan

Background: HER2DX, the first multigene assay specifically designed for HER2+ breast cancer, has demonstrated potential to guide treatment decisions. However, its validation in the context of de-escalated chemotherapy regimens, including trastuzumab monotherapy, in older patients remains limited. In the RESPECT trial (NCT01104935, JCO 2020), 1-year of trastuzumab monotherapy was shown to be a clinically meaningful adjuvant option compared to de-escalated chemotherapy and trastuzumab in older patients with HER2+ early breast cancer. This exploratory analysis of HER2DX within the RESPECT trial (Trans-RESPECT study) aimed to evaluate the assay's prognostic value. **Methods:** The RESPECT Phase III trial enrolled patients aged 70–80 years with stage I–IIIA HER2+ early breast cancer. Participants were randomized to receive trastuzumab monotherapy (H group) or trastuzumab plus chemotherapy (H+CT group). Chemotherapy regimens included paclitaxel monotherapy (35.1%), anthracycline/cyclophosphamide alone (22.9%), CMF (19.8%), docetaxel monotherapy (14.5%), or docetaxel-carboplatin (3.1%). Risk stratification into HER2DX low- or high-risk groups used both the standard 50 cutoff (scale 1-99) and an exploratory 32 cutoff, previously reported in the APT trial (Tolaney et al., Lancet Oncol, 2023). The primary endpoint was relapse-free survival (RFS), with secondary endpoints including overall survival (OS). **Results:** Among 275 patients in the RESPECT trial, 154 tumors (56.0%) were profiled using HER2DX (H group: 74; H+CT group: 80). Baseline characteristics of the profiled cohort mirrored those of the overall trial population. Most patients (92.9%) had a performance status of 0, 28.6% were older than 75 years, 53.2% were HR-negative, 80.5% had node-negative disease, and the majority had pT1c (41.6%) or pT2 (44.8%) tumors. Using the HER2DX 50 cutoff, 40 patients (26.0%) were classified as high risk, and 114 (74.0%) as low risk. RFS was higher in the HER2DX low-risk group compared to the high-risk group (hazard ratio [HR] = 2.02, 95% CI: 0.97–4.19), with 5-year RFS rates of 92% and 77%, respectively. OS was also superior in the HER2DX low-risk group (HR = 2.74, 95% CI: 1.18–6.36), with 5-year OS rates of 97% and 84%. Using the HER2DX 32 cutoff, 81 patients (52.6%) were classified as high risk, and 73 (47.4%) as low risk. In the H group, 3- and 5-year RFS were 97% and 94% in the low-risk group, compared to 87% and 81% in the high-risk group. In the H+CT group, 3- and 5-year RFS were 95% and 95% in the low-risk group, compared to 93% and 83% in the high-risk group. **Conclusions:** The HER2DX genomic risk score demonstrates prognostic value in older patients with HER2+ early breast cancer, including those treated with trastuzumab monotherapy. This assay may aid in identifying patients suitable for treatment de-escalation strategies. Additional analyses will be presented at the conference. Clinical trial information: NCT01104935. Research Sponsor: Chugai Pharmaceutical Co., Ltd.

The difference of clinical and molecular characteristics between HR-positive/HER2-positive and HR-negative/HER2-positive early breast cancer: A secondary analysis of 11 clinical trials. First Author: Hongmei Zheng, Department of Breast Surgery, Hubei Cancer Hospital, Tongji Medical College, Huazhong University of Science and Technology; Hubei Provincial Clinical Research Center for Breast Cancer, and Wuhan Clinical Research Center for Breast Cancer, Wuhan, China

Background: HER2+ early breast cancer (EBC) are treated as an identical cluster of patients in clinical practice. However, the various status of hormone receptor (HR) leads to different outcomes. We aimed to clarify the difference of clinical and molecular characteristics between HR+/HER2+ and HR-/HER2+ EBC. **Methods:** This secondary analysis assessed pathologically complete response (PCR) and disease free survial (DFS) among HR+/HER2+ and HR-/HER2+ EBC patients enrolled in the 11 clinical trials. These studies included 16866 HER2+ EBC patients, with available immunohistochemistry and/or in situ hybridization results. There are five neoadjuvant trials (TRYPHAENA, Kristine, Neosphere, BERENICE and Peony) and six adjuvant trials (HERA, HannaH, Aphinity, Katherine, PrefHer and SafeHer). The primary endpoints of the trials were PCR, DFS, overall preference proportions and adverse event rates. Kaplan–Meier approach and Cox proportional hazards model were applied to estimate the association of treatment strategies with PCR and DFS among HR+ and HR- populations. The 11 trials were all registered with ClinicalTrials.gov, number NCT00976989, NCT02131064, NCT00545688, NCT02132949, NCT02586025, NCT00045032, NCT00950300, NCT01358877, NCT01772472, NCT01401166 and NCT01566721. **Results:** In the16866 HER2+ EBC patients, except for PrefHer and SafeHer trials, which has no information about HR status, there are 13801 patients with HR details, of which, HR+ 8004 (58.0%) and HR- 5713 (41.4%). In HER2+ EBC, the various status of HR leads to different outcomes. Our study revealed an interesting phenomenon that compared to HR-/HER2+ EBC, HR+/HER2+ EBC has a lower pCR rate. However, trials from adjuvant therapy studies suggested HR+/HER2+ EBC has a longer DFS, which is not consistent with other subtype patterns. The pCR rate is a near-term indicator that visualizes the response rate to a particular treatment, and the DFS is a distant indicator that reflects the overall biological behavior of the individual. The HR+/HER2+ EBC, despite its low pCR rate, potentially improves its long-term DFS due to the addition of adjuvant endocrine therapy postoperatively. **Conclusions:** Compared to HR-/HER2+ EBC, HR+/HER2+ patients has a lower pCR rate, but has a longer DFS, which deserve further exploration. Research Sponsor: None.

The stratification of the HER2+ early breast cancer patients according to HR status in the 11 clinical trials.

Trial	Total, n	HR+, n(%)	HR-, n(%)	Unknown, n

Patterns of early and late recurrence across breast cancer subtypes in the CCTGMA.32 trial. First Author: Ana Elisa Lohmann, University of Western Ontario, London, ON, Canada

Background: An ongoing constant risk of recurrence out to 20 years is well established in hormone receptor positive breast cancer (BC) less so in other BC subtypes. This study aims to describe patters of early ($\leq$ 5 years of BC diagnosis) and late recurrence ($>$ 5 years of BC diagnosis) across immunohistochemically defined BC subtypes - luminal (ER/PgR+HER2-), triple negative (TN: ER/PgR/HER2-) and HER2+ (any ER/PgR) in CCTGMA.32 (NCT01101438) which investigated metformin vs placebo in patients enrolled 2010-2013. **Methods:** 3649 patients with high-risk non-metastatic BC were enrolled and followed for first locoregional and distant recurrence, new primary cancers and death. Annual rates of these events were calculated in each BC subtype and averaged for early (years 0-5) and late (after 5 years) post randomization. **Results:** In luminal (n = 2104), TN (n = 925), HER2+ (n = 620) BC the median follow-ups were 96.2 (range 0.2 to 120.7), 94.5 (0.03 to 120.5), 95.2 months (0.03 to 119.8), respectively. Patterns of events varied across subtypes and early vs late. In luminal BC, the early vs late annual invasive cancer event rates (ICERs) was 3.04 vs. 2.31 % (late rate 0.76 of early rate). The annual early vs late rates of distant recurrence (DR) were 2.33 vs 1.72% (late rate 0.74 of early rate). Bone was the most common site of DR both early and late. In the TN BC, the early vs late annual ICERs were 4.6 and 1.21% (late rate 0.35 of early rate). Annual early vs late DR rates were 3.09 vs. 0.20 % (late rate 0.28 of early rate). Visceral metastases (lung, liver, CNS) were most common early. In HER2+, early vs late annual ICERs were 2.93 vs 1.47% (late rate 0.50 of early rate). Annual early vs late DR rates were 2.25 vs 0.71% (late rate 0.32 of early rate). Bone and visceral metastases were common early. CNS was rare after 5 years in all BC subtypes. Second primary cancers (new BC and non-primary BC) were frequent across BC subtypes, with no fall-off over time; they were responsible for the majority of late events in TN and HER2+ BC. **Conclusions:** In luminal BC, risk of late ICER remains high (annual rate about three-quarters of early rate), while risk of late events was lower in TN and HER2+BC (late rates one quarter to one-third of early rates). Risk of second primary cancers did not decrease over time, and second primaries were the most frequent late events in TN and HER2+BC. Clinical trial information: NCT01101438. Real-world evidence of PARPi-related MDS/AML risk in breast cancer patients: An international collaborative network analysis. First Author: Michela Palleschi, IRCCS Istituto Romagnolo per lo Studio dei Tumori (IRST) "Dino Amadori", Meldola, Italy

Background: Poly (ADP-ribose) polymerase (PARP) inhibitors have emerged as a significant therapeutic advance in breast cancer treatment. However, concerns about therapy-related myeloid neoplasms, specifically myelodysplastic syndrome (MDS) and acute myeloid leukemia (AML), necessitate thorough investigation of their safety profile in real-world settings. **Methods:** Using the TriNetX Global Collaborative Network, we conducted a retrospective analysis comparing breast cancer patients treated with PARP inhibitors (PARPi) versus conventional chemotherapy only (anthracyclines and taxanes). Our primary analysis utilized propensity score matching (1,702 patients per group) accounting for age and race, to evaluate the risk of developing MDS/AML. Hazard ratio (HR) was used to compare the incidence of MDS/AML between the matched cohorts. Secondary analyses included an unmatched Cox proportional hazards model in a larger cohort (1,826 vs 36,257 patients), comparison between different PARP inhibitors, and assessment of mortality risk factors. **Results:** In the propensity score-matched analysis, PARPi treated patients demonstrated a statistically significant higher risk of developing MDS/AML versus chemotherapy only cohort (16 cases versus 10, HR=5.25; 95% CI: 1.96-13.92; p$<$0.0001). Treatment patterns differed notably, with PARPi-treated patients receiving more carboplatin (HR=1.73; 95% CI: 1.42-2.10) but less anthracycline therapy (HR=0.25; 95% CI: 0.20-0.31). The unmatched Cox regression analysis confirmed these findings with a higher risk of developing AML/MSD in the PARPi cohort (HR=3.47; 95% CI: 1.87-6.27) and identified age (HR=1.03; 95% CI: 1.02-1.05) and platinum therapy (HR=2.12; 95% CI: 1.26-3.59) as independent risk factors. Within the triple negative group, the data remains statistically significant (HR=3.14; 95% CI: 1.459-6.757). No significant differences in MDS/AML risk were observed between olaparib and talazoparib. While mortality was comparable between groups, prior platinum exposure emerged as a significant mortality risk factor (HR=2.39; 95% CI: 1.09-5.09). **Conclusions:** Our findings indicate a significantly increased risk of therapy-related myeloid neoplasms with PARP inhibitor treatment compared to conventional chemotherapy, particularly in the context of previous platinum exposure in breast cancer patients. These results underscore the importance of careful patient selection and monitoring during PARP inhibitor therapy, while highlighting the need for extended follow-up studies to fully characterize long-term safety profiles. Extended endocrine therapy after 5 years of adjuvant LHRH-agonist in premenopausal patients with node-positive hormone receptor (HR)-positive early breast cancer. First Author: Carmine Valenza, Division of Early Drug Development, European Institute of Oncology IRCCS, University of Milan, Milan, Italy

Background: There is no evidence regarding the benefit of extended endocrine therapy (eET) beyond 5 years of adjuvant treatment with LHRH agonists (LHRHa) in premenopausal women with node-positive, HR-positive early breast cancer (eBC). **Methods:** We conducted a retrospective study on two prospectively maintained datasets (Young Women Study and IEO Breast Cancer Dataset) to evaluate the clinical benefit of eET in women who had completed 5 years of adjuvant LHRHa, remained premenopausal, and had no evidence of distant or locoregional recurrence. This study included <40y women at diagnosis (between 2006 and 2016) with node-positive HR+ eBC, with ductal, lobular, or mixed histological subtypes, receiving or not eET (tamoxifen monotherapy or LHRHa+tamoxifen/aromatase inhibitor [AI]). The primary endpoint was the invasive breast cancer-free survival (IBCFS), calculated from the 5th year of endocrine therapy (ET) and adjusted for dataset, age at diagnosis, histotype, stage, disease subtype, type of adjuvant chemotherapy and ET received. **Results:** 503 patients were included (see Table): 287 received eET for a median duration of 3.6 years (Interquartile Range: 2.1–5.0). At a median follow-up of 7.05 years (calculated from the 5th year of ET), 50 and 72 IBCFS events occurred in the eET and non-eET groups, respectively. The adjusted Hazard Ratio (HR) for IBCFS comparing the eET to the non-eET group was 0.60 (95% CI,0.41-0.88; p<0.001). For distant recurrence or death, 28 and 46 events occurred, respectively, and the adjusted HR for distant disease free-survival was 0.43 (95% CI, 0.27-0.71). Among patients receiving eET, the adjusted HR for IBCFS comparing tamoxifen monotherapy (n=137) with LHRHa+tamoxifen/AI (n=150) was 0.75 (95% CI, 0.41-1.38). **Conclusions:** Extending endocrine therapy beyond five years of LHRHa treatment resulted in significantly higher IBCFS and distant metastasis free-survival. Larger prospective studies are required to confirm this finding and determine the most effective eET strategy. Research Sponsor: None.

Patterns in male and female breast cancer care: A comparative analysis of stage at presentation, treatment, and survival in the Veterans Health Administration. First Author: Ariana Naaseh, Washington University in St. Louis School of Medicine, St. Louis, MO

Background: Male breast cancer (MBC) is a rare disease that is often managed using treatment protocols derived from female breast cancer (FBC). Given its rarity, limited large-scale national cohort data exists to inform clinical treatment decisions for MBC. This study aims to compare contemporary treatment trends and survival outcomes for MBC and FBC within the Veterans Health Administration (VHA). **Methods:** We conducted a retrospective cohort study of patients diagnosed with MBC and FBC between 2000 and 2022 using national data from the VHA Cancer Cube registry. Demographics, tumor characteristics, treatment (surgery, chemotherapy, hormone therapy, and radiation), and survival were compared between MBC and FBC patients. Descriptive statistics and chi-square tests compared the cohorts. Kaplan-Meier methods and Cox proportional hazards regression model were utilized to examine overall survival (OS). **Results:** Of the 14,018 total patients who met inclusion criteria, only 13.9% (n=1952) were males. MBC patients were significantly more likely to get diagnosed at an older age (MBC 68.8 vs. FBC 60.0 years; p≤0.001) and present with stage III or IV disease (25.8% vs. 12.9%; p<0.001). Compared to FBC patients, MBC patients had significantly higher rates of receiving hormone therapy (56.8% vs. 51.6%; p<0.001) and lower rates of chemotherapy (34.3% vs. 37.4%; p=0.007), radiation (21.2% vs. 47.3%; p <0.001), and surgery (92.1% vs 93.0%; p=0.01). MBC patients were significantly less likely to undergo breast-conserving surgery (BCS) (11.2% vs. 52.0%; p <0.001) than FBC patients. In a Cox proportional hazard model including age and stratified by stage, MBC patients had reduced OS (6.9 vs. 19.0 years; p<0.001) and higher risk-adjusted hazard of all-cause mortality (adjusted hazard ratio 1.40, 95% CI 1.30-1.49). OS for MBC was lower than FBC across all stages (Table). **Conclusions:** Our national cohort study is the largest series of patients with MBC and FBC in the VHA population to date. We demonstrate that MBC patients present with advanced-stage cancer, are less likely to receive aggressive treatments, are less likely to undergo BCS, and have reduced OS across all stages, compared to FBC patients. Our findings highlight the need for further research to optimize outcomes of MBC patients. Research Sponsor: National Cancer Institute; T32CA009621.

Racial differences in the prognostic value of Oncotype (RS) and MammaPrint (MP) in postmenopausal, estrogen receptor (ER)–positive, node-negative (N0) breast cancer (BC) patients with low genomic risk: A National Cancer Database (NCDB) study. First Author: Prashanth Ashok Kumar, George Washington University Medical Faculty Associates, Washington, DC

Background: Postmenopausal patients with ER+, HER2 negative, N0 BC often rely on genomic testing, such as RS or MP, to determine the benefit of chemotherapy. However, the prognostic value of RS, particularly among ethnic minority patients, remains uncertain. **Methods:** We utilized the 2021 NCDB to include postmenopausal female BC patients aged >50 years. Inclusion criteria were ER+, HER2-negative patients with, stage T1-4, N0, RS <26, or MP low risk. Patients were stratified by race, Caucasian (W) and African American (AA). Univariate analysis was performed to evaluate patient and tumor characteristics. Five-year overall survival (OS) rates were constructed using Kaplan-Meier (KM) product limit estimation. Unadjusted and covariate adjusted associations between race and OS were evaluated using Cox proportional hazard (PH) regression. Associations between race and OS among subgroups were similarly evaluated to highlight disparities and trends within the population. Hazard ratios (HRs; AA: W), 95% confidence intervals (CIs) and p-values are reported. **Results:** 96,411 patients had an RS<26 [W- 89,105 (92.42%) AA-7,306(7.58%)] and 3,146 had MP low [W-2,929(93.1%) AA-217(6.9%)]. Over 93% of patients in both groups received endocrine therapy, ~75% underwent partial mastectomy and radiation, and 7% received chemotherapy. Significant racial differences in tumor size and grade were observed in the RS group: T1 tumors (AA: 75% vs. W: 78%), T2 tumors (AA: 23% vs. W: 20%, p<0.001), G1 (AA: 29% vs. W: 34%), and G3 (AA: 13% vs. W: 9.3%, p<0.001), but these differences were not seen in the MP group. At 5 years, survival for RS <26 was 95.5% (AA) vs. 97.1% (W), and for MP low, 96% (AA) vs. 96.7% (W). The adjusted HR for RS <26 showed worse outcomes for AA (HR: 1.2, 95% CI 1.1–1.31, p<0.001), especially in younger patients, grades 1–2 tumors, T1 stage, partial mastectomy and low income. For MP low, the HR was not significant (HR: 1.08, 95% CI 0.59–1.97, p=0.8). **Conclusions:** Our analysis shows that among ER+, HER2- N0 cohort with RS <26, AA patients have a 20% increase in the risk of death compared to W patients, after adjusting for patient- and tumor-related factors. In contrast, no survival disparities were observed in the MP low-risk group. These findings suggest that RS may not be fully prognostic for AA patients even when accounting for clinic-pathologic risk factors. Study limitations include its retrospective design, potential biases, and incomplete consideration of biological and socioeconomic factors. Research Sponsor: None.

The impact of racial and socioeconomic disparities on radiation therapy delays in breast cancer patients: A National Cancer Database analysis. First Author: Mehmet Murat Zerey, Miami Cancer Institute, Baptist Health South Florida, Miami, FL

Background: Despite advancements in breast cancer (BC) treatment, significant disparities in outcomes persist in the United States. Timely initiation of adjuvant radiation therapy (RT) is crucial, as delays are associated with increased recurrence. Using the National Cancer Database (NCDB), this study provides a larger-scale analysis of racial and ethnic (R/E) disparities, examining the role of socioeconomic (SE) factors, including education and income, on RT delays and overall survival (OS) differences. **Methods:** A retrospective analysis was conducted using data from the NCDB. The study included female patients (pts) ≥18 years with stage I-III BC diagnosed between 2004 and 2020. Pts who received chemotherapy were excluded. Pts were categorized by R/E into four groups: White (W), Black (B), Hispanic (H), and Other (O). SE variables, including income and education, were stratified into quartiles (Q1–Q4) as defined by the NCDB. A delay in RT initiation was defined as starting treatment more than 3 months (mos) after surgery. Kaplan-Meier (KM) analysis with the log-rank test was used to compare OS across groups. Cox proportional hazards regression was performed to estimate hazard ratios (HR) and assess the impact of income and education on delays in RT and survival outcomes. **Results:** A total of 395,328 female BC pts were included in the analysis. The median age of the cohort was 65. Most were W (85.2%), followed by B (7.4%), H (4.0%), and O (3.5%). Almost all pts had stage I (81.6%) BC. The majority of patients were in the highest (Q4) income and education quartiles (40.2% and 45.6% respectively). Higher RT delays (> 3 mos) were observed in B (11.07%) and H (11.38%) compared to W (5.31%), (p < 0.001). Pts in the lowest income and education quartiles (Q1) experienced delays more frequently (8.02% and 9.29%, respectively) compared to those in Q4 (5.72% and 5.27%, respectively p < 0.001). KM survival analysis revealed significant differences in OS for delayed RT, with median survival of 218 mos for 0–3 mos, 211 mos for 3–6 mos, and 209 mos for > 6 mos (p < 0.001). KM survival analysis also demonstrated worse survival for pts in Q1 income and education compared to Q4 (p < 0.001). Cox proportional hazards model, when adjusted for clinical, R/E and SE factors revealed that pts in Q1 for income (HR = 1.411, p < 0.001) and education (HR: 1.036, p < 0.001) had a significantly higher risk of mortality compared to Q4. **Conclusions:** This study highlights significant R/E and SE disparities in timely RT initiation and survival outcomes among BC pts. B, H, and pts with lower S/E status experienced greater RT delays, emphasizing the critical need for targeted interventions to address delays in care and improve equity in cancer treatment. Association between chemotherapy use and clinical outcomes in young BRCA carriers with T1N0 breast cancer: Results from an international cohort study. First Author: Filipa Lynce, Dana-Farber Cancer Institute, Boston, MA

Background: Systemic treatment decisions for young BRCA carriers with small node-negative breast cancers present unique challenges due to limited evidence on the benefits of chemotherapy in this setting. This study evaluated chemotherapy use and survival outcomes among these patients. **Methods:** The BRCA BCY collaboration (NCT03673306) is an international, multicenter, hospital-based, retrospective cohort study that included carriers of germline pathogenic variants in *BRCA1/2* diagnosed with invasive breast cancer at the age of ≤40 years between January 2000 and December 2020. Among patients diagnosed with T1N0 disease, survival outcomes - disease-free survival (DFS) and overall survival (OS) defined from breast cancer diagnosis - were compared between patients who received chemotherapy and those who did not, using multivariate Cox models adjusted for propensity score (including age at diagnosis, histology, grade, country and year of diagnosis) and risk-reducing surgeries (bilateral risk-reducing mastectomy (RRM) and/or risk-reducing salpingo-oophorectomy (RRSO)), and accounting for the delayed entry at the time of BRCA testing (i.e. left truncation). Subgroup analyses were performed according to tumor subtype (HR+/HER2- vs triple negative breast cancer (TNBC)). **Results:** Out of 5660 from 109 centers, 1280 patients had T1N0 breast cancer: T1mic (n = 14, 1.1%), T1a (n = 92, 7.2%), T1b (n = 303, 23.7%), T1c (n = 778, 60.8%), and T1 size unknown (n = 93, 7.3%). Most patients received chemotherapy (80%), although use was less frequent over time. Among patients who received chemotherapy, the majority were treated with an anthracycline-containing regimen (83.6%) and in the adjuvant setting (85.7%). Patients who received chemotherapy were younger and more likely to have high grade, TNBC or larger tumors compared to those who did not. The median follow-up was 8.7 years (IQR 5.0-13.4 years), during which 428 had DFS events including second primary breast cancer (n = 174), locoregional (n = 130), distant relapse (n = 65), second primary non breast cancer (n = 53), and 88 had died. Overall, 8-year DFS was 69.4%. In multivariate analysis, no significant differences in DFS or OS were observed between patients who received chemotherapy and those who did not (DFS HR = 0.92, 95% CI 0.65-1.31; OS HR = 0.68, 95% CI 0.37-1.24). No significant difference in 8-year DFS was observed between patients with HR+/HER2- breast cancer (n = 474) treated with or without chemotherapy (HR 0.91: 95% CI 0.59-1.43), or between patients with TNBC (n = 637) treated with or without chemotherapy (HR 0.84: 95% CI 0.46-1.53). **Conclusions:** In this global study of young BRCA carriers with T1N0 breast cancer, chemotherapy was not associated with better DFS or OS overall. However, these patients remain at high risk of events and warrant investigation of additional risk-reduction strategies. Research Sponsor: None.

Long-term outcomes of patients with HER2-positive invasive lobular carcinoma in the ALTTO trial (BIG 2-06/NCCTG N063D [Alliance]). First Author: Guilherme Nader Marta, Medical Oncology, Dana-Farber Cancer Institute, Harvard Medical School, Boston, MA

Background: Invasive lobular carcinoma (ILC) is the second most common histologic subtype of breast cancer (BC), representing 10–15% of cases. HER2 overexpression is rare in ILC, and there is limited data on the clinical characteristics and outcomes of patients (pts) with HER2-positive (HER2+) ILC treated with adjuvant trastuzumab. This study aims to investigate the prognostic value of ILC histology in this setting. **Methods:** ALTTO was a multicenter, randomized phase III trial evaluating the efficacy of trastuzumab, lapatinib, their sequence, or combination as adjuvant therapy in pts with HER2+ early BC. Pts with pure ILC or invasive BC of no special type (NST) who were enrolled in trastuzumab-containing arms of the ALTTO trial were included in this analysis. Central pathology review confirmed histologic subtype and was used for classification, while local pathology was used when centralized review was unavailable (USA and China). Survival outcomes, including disease-free survival (DFS), and overall survival (OS) were evaluated using Kaplan-Meier method and multivariate Cox regression adjusted for prognostic factors. Patterns of relapse were analyzed and compared across histological subtypes. Time to distant recurrence (TTDR) and time to CNS recurrence were summarized using cumulative incidence functions. **Results:** Among pts in the trastuzumab-containing arms (N = 6281), 84.4% underwent central pathology review, with a concordance rate of 67.4% for ILC diagnosis. A total of 61 pts with pure ILC (1.0% of the cohort) and 5981 pts with NST were included in the analysis. Pts with ILC were older (mean 54.8 vs. 50.9 years; p=0.002), more likely White (95.1% vs. 68.8%; p<0.001), and postmenopausal (72.1% vs. 56.3%; p=0.01). The proportion of pts with ILC (vs NST) was higher in Europe (67.2% vs 53.7%) and lower in Asia-Pacific (8.2% vs 30.6%) (p<0.001). A significantly higher proportion of ILC (vs NST) were hormone receptor-positive (80.3% vs. 57.4%; p<0.001), Grade 1-2 (51.7% vs. 39.3%; p=0.05). At a median follow-up of 9.8 years (IQR 6.9-10.0), no significant differences in DFS (hazard ratio [HR] 1.14, 95% CI 0.66-1.97; adjusted HR [aHR] 1.33,0.77–2.31), OS (HR 0.96, 0.43-2.15; aHR 1.09, 0.48–2.44), or TTDR (HR 1.67, 0.91–3.05) were observed between ILC and NST. Central nervous system (CNS) relapses were more frequent in ILC (13.6% at 10y, 95% CI 7.1–26.1%) than in NST (5.0%, 4.5–5.7%), with an HR of 3.14 (1.52–6.48) for CNS recurrences in ILC when compared to NST. **Conclusions:** Long-term outcomes were comparable between ILC and NST in HER2+ early BC treated with trastuzumab-containing regimens. The higher incidence of CNS metastases in ILC highlights its unique relapse pattern, necessitating further investigation to optimize treatment. High discordance between central and local pathology emphasizes the need for standardized histological review in trials and treatment decisions. Clinical trial information: NCT00490139. Cost-effectiveness of HER2/neu 655 genotyping in managing trastuzumab-induced cardiotoxicity risk in HER2-positive breast cancer patients. First Author: Isabel Blancas, Hospital Universitario Clínico San Cecilio / Medicine Department, Granada University / Instituto de Investigación Biosanitaria de Granada (ibs Granada), Granada, Spain

Background: Trastuzumab has significantly improved survival in HER2-positive breast cancer patients. However, around 20% of patients experience cardiotoxicity. Cardiotoxicity has been defined as a ≥10% drop in left ventricular ejection fraction (LVEF) or LVEF <50%, or the appearance of clinical cardiac insufficiency. The HER2/neu 655 A>G polymorphism has been linked to cardiotoxicity risk. This study evaluates the cost-effectiveness of HER2/neu 655 genotyping. **Methods:** Eighty-eight HER2-positive breast cancer patients treated for early disease with trastuzumab were retrospectively analyzed. All were genotyped for HER2/neu 655 A>G (AA: n=53, AG: n=32, GG: n=3). LVEF was monitored by echocardiography or isotopic ventriculography at baseline and regular intervals. Cardiotoxicity was defined as above. Logistic regression adjusting for hormonal status and anthracycline use estimated the association between genotype and cardiotoxicity. Cost data from the Andalusian Regional Health Service included diagnostic tests, cardiology visits, pharmacologic therapy, and hospitalizations. **Results:** Among the 53 patients with the AA genotype, 3.7% experienced a decrease in LVEF, while 9.4% developed clinical symptoms. For the AG genotype (32 patients), 9.3% showed an LVEF reduction, and 28.1% presented clinical symptoms. In the GG genotype group (3 patients), 1 patient (33.3%) developed clinical symptoms. AG carriers had a significantly higher risk of cardiotoxicity than AA patients (OR adjusted for hormonal status and anthracycline treatment =4.42; p=0.037). HER2/neu 655 A>G genotyping costs €38. Asymptomatic LVEF reductions usually required 3 cardiology visits including echocardiography (€121.05 each), and one year of pharmacological treatment (carvedilol and/or enalapril therapy; €84.72 total). Cardiac insufficiency costs range from €2,992.61 (grade 1) to €9,363.56 (grade 4). **Conclusions:** HER2/neu 655 genotyping is cost-effective for identifying patients at higher risk of trastuzumab-induced cardiotoxicity. The low cost of genotyping is outweighed by the potential savings in preventing severe cardiac events. Genotype-driven monitoring and proactive cardiac and targeted cardiovascular risk management in AG carriers could reduce both the incidence and severity of cardiotoxicity. Research Sponsor: None.

Neuromorphological effects of simultaneous exercise during neo-/adjuvant chemotherapy in breast cancer patients: The Exercise Cancer and Cognition (ECCO) study. First Author: David Kiesl, Ordensklinikum Linz - Elisabethinen, Linz, Austria

Background: Cancer-Related Cognitive Impairment (CRCI) is commonly experienced by breast cancer patients, often linked to chemotherapy. It manifests as deficits in learning, memory, reaction time, and concentration, with the hippocampus—a critical region for cognitive and affective functions—playing a central role. The hippocampus retains neurogenesis potential throughout life, with physical exercise shown to enhance hippocampal volume and memory function. High-intensity exercise appears to have superior cognitive benefits compared to moderate aerobic activity. The ECCO study aimed to assess the neuropsychological and brain morphological effects of high-intensity interval training (HIIT) in breast cancer patients, focusing here on imaging data subanalysis. **Methods:** The ECCO-study was designed as monocentric two-armed 1:1 randomized controlled trial (RCT), including a 12-month intervention group and a control group. Patients in the intervention group were instructed to perform strength- and low-intensity endurance training at least once a week at home according to the American College of Sports Medicine (ACSM) recommendations and to complete a supervised high-intensity interval training (HIIT) once a week at our health center. Patients in the control group were advised physical activity recommendations according to the World Health Organsiation (WHO). Participants randomized to the control arm received usual care and physical activity recommendations have been given according to usual standards. The volume measurements of the brain were performed with an automatic segmentation tool FreeSurfer version 7.4. The FreeSurfer algorithm performs an automatic segmentation of subcortical volumes and reconstructs the cortex after the elimination of non-brain tissue. **Results:** MRI data were available at baseline and after 12 months for a total of 67 patients diagnosed with breast cancer. Randomized into an intervention arm (n = 35) and control arm (n = 32). The groups were comparable in all demographic factors such as age, BMI and VO2max. There were no statistically significant changes ($p < 0.05$) in the volumes between the baseline measurement and the 12-months-follow-up measurement. Other brain areas also showed no significant ($p < 0.05$) alterations between baseline and follow-up. No differences were found in the volume change between the exercise group and the control group. **Conclusions:** This analysis of the ECCO study revealed that there were no significant changes in hippocampal volume or in the more precise categorization into its subfields in either the intervention or control group of breast cancer patients. Contrary to hypotheses suggested in the literature, it was shown that breast cancer therapy does not lead to morphological changes in the hippocampus, indicating that CRCI is not based on morphological damage. Clinical trial information: NCT04789187. Research Sponsor: Verein zur Forschungsförderung der Krebshilfe OÖ.

Effect of a multidisciplinary intervention based on a supervised training program on cardiovascular risk and quality of life in early stage breast cancer patients. First Author: Maria Torrente, Hospital Universitario Puerta de Hierro-Majadahonda, Madrid, Spain

Background: There is growing evidence that physical activity can enhance cancer care. Exercise programs have been shown to help manage treatment side effects, improve functional outcomes, enhance overall quality of life, and reduce fatigue. Additionally, obesity and cardiovascular disease are among the most common comorbidities in breast cancer survivors. However, despite these benefits, exercise is still not widely prescribed to oncology patients. A multidisciplinary approach involving various healthcare professionals is crucial to ensuring that exercise interventions are tailored to individual needs. Our study aims to determine whether a 12-week exercise intervention can improve physical fitness and reduce cardiovascular risk in patients with early-stage breast cancer after completing oncologic treatment. For the first time, impact is assessed by measuring cardiorespiratory fitness (VO_2 max) and muscle strength, including range of motion, speed, and power. **Methods:** A total of 75 women with histologically confirmed Stage I-III primary breast cancer who have recently completed all cancer-related treatments were included. Through computer-generated simple randomization, participants were assigned to resistance training (RTG; two sessions/week for 12 weeks) or control (CG; general physical activity guidelines recommendations). Outcomes were evaluated at baseline and week 12. Muscular strength (including range of motion, speed, and power) was the primary outcome. Secondary outcomes included cardiorespiratory fitness (measured by VO_2 max-*maximum* rate of oxygen consumption attainable during exercise), cancer-related fatigue and HRQoL. All participants had Performance status 0 or 1 and completed the EUROQOL-5D 5L and EORTC-QLQ-C30 QoL online survey. **Results:** The expected number of 75 patients was enroled in the study (mean age 55.9 $\pm$ 7.4 years, all female). Patients assigned to the intervention had a significant positive change in HRQoL total score [mean difference 3.8; 95% confidence interval (CI) 0.2; 7.3; P = .038], body mass index [mean difference -0.7 kg/m2 (95% CI -1.3; -0.1); P = .022], muscle strength [mean difference 2.5 (95% CI 0.1; 5); P = .044; effect size 0.39], and cardiorespiratory fitness (VO2 max) [mean difference 2.7 (95% CI 0.8; 4.6); P = .007]. No significant changes were observed in the control group between week 0 and 12. **Conclusions:** This 12-week supervised exercise-based programme improved HRQoL, body mass index, muscle strength, range of motion, and power in loads while notably enhancing cardiorespiratory fitness. Integrating exercise into standard healthcare practice can significantly improve patient's quality of life and reduce cardiovascular risk. Research Sponsor: SPANISH SOCIETY OF MEDICAL ONCOLOGY.

Survival impact of adjuvant chemotherapy regimens for small (T1mi/a/b), node-negative (pN0), triple-negative breast cancer (TNBC). First Author: Kai Conrad Cecil Johnson, The Ohio State University - James Comprehensive Cancer Center, Columbus, OH

Background: While triple negative breast cancer (TNBC) represents an aggressive subtype of breast cancer worldwide, clinically low-risk cases are still encountered. When managing such cases, questions remain regarding the true added benefit of adjuvant chemotherapy on survival outcomes given the absence of dedicated prospective trials for this population. Additionally, in the event that systemic therapy is pursued for these patients, it remains unclear whether anthracycline-containing treatments lead to improved long-term outcomes. **Methods:** Given the rarity of stage 1 triple negative breast cancer, we extracted recurrence & survival data from within the ASCO-developed CancerLinQ database to perform an in-depth retrospective analysis involving women with small (pT1mi/a/b), node-negative (pN0), TNBC who underwent curative breast surgery and were diagnosed between the years 2002-2023. For the adjuvant chemotherapy recipients, only those who received a regimen of either taxane chemotherapy plus cyclophosphamide (TC) or an anthracycline & cyclophosphamide combined followed by taxane chemotherapy (AC-T) were included in this study. Our co-primary objectives were to compare the invasive recurrence-free survival (iRFS) and overall survival (OS) of patients who received adjuvant TC or AC-T versus those receiving locoregional therapy alone. Our secondary outcome included an iRFS comparison between AC-T, TC, & locoregional therapy. Clinicopathologic variables were compared with appropriate tests for the categorical and continuous variables. **Results:** Among the 159 patients identified with T1mi/a/b N0 TNBC who met inclusion criteria, 42 had undergone locoregional therapy alone, 77 had received TC chemotherapy, and 40 received AC-T. Baseline demographics found that the locoregional group had a higher proportion of T1mi/a vs T1b patients ($p < 0.001$) & a higher average age ($p < 0.002$). No differences were seen between groups in terms of germline mutations (BRCA1, BRCA1, PALB2, CHEK2, & ATM), tumor grade, lymphovascular invasion, surgery type, race, ethnicity, or average body-mass index. After a median follow up period of 57.2 months overall, we found there was a significant benefit in both iRFS (HR 2.52, 95% CI 1.1-5.83, p = 0.025) & OS (HR 6.95, 95% CI 1.62-29.79, p = 0.0027) for those who received adjuvant chemotherapy (TC or AC-T) compared to locoregional therapy alone. The 5-year iRFS was 89.9% with AC-T, 77.1% with TC, & 69.1% with locoregional therapy, whereas the 5-year OS was 96.9%, 96.3%, 85.8%, respectively. **Conclusions:** These findings suggest that a recurrence & survival benefit is seen with the application of adjuvant chemotherapy, even among this clinically low-risk population. However, whether it needs to be AC-T or TC appears less significant. Research Sponsor: None.

Obesity, chemotherapy dosing, and toxicity: Results from the Optimal Breast Cancer Chemotherapy Dosing study. First Author: Elizabeth Kantor, Memorial Sloan Kettering Cancer Center, New York, NY

Background: ASCO guidelines state that most cytotoxic drugs should be dosed according to full body surface area (BSA) without limiting the dose on the basis of obesity. This approach is supported by a lack of evidence to suggest that patients with obesity, when fully-dosed, experience higher risk of toxicity. Indeed, historical evidence suggests that obese, fully-dosed patients may experience lower risk of neutropenia than normal weight patients. However, questions remain regarding the representativeness of historical trial data on which this evidence is based. We examined this issue in the Optimal Breast Cancer Chemotherapy Dosing (OBCD) Study. **Methods:** The OBCD Study is a real-world cohort of 34,109 women diagnosed with stage I-IIIA breast cancer at Kaiser Permanente Northern California and Kaiser Permanente Washington between 2004-2019. Among women receiving the full dose of chemotherapy at treatment initiation ($\geq$90% of intended dose, n = 7,644), we examined risk of toxicities in women with obesity (BMI $\geq$30 kg/m^2) compared to non-obese women (BMI 18.5-$<$ 30 kg/m^2). We examined hematologic (neutropenia, anemia, thrombocytopenia) and non-hematologic (nephrotoxicity, hepatotoxicity, neuropathy, and cardiotoxicity) toxicities. Hazard ratios (HR) and 95% confidence intervals (CI) were calculated using Cox proportional hazards regression, adjusted for covariates including prevalent comorbid conditions. Secondary analyses examined associations pertaining to specific BMI groups and also stratified by administration schedule (standard vs dose-dense). **Results:** Fully-dosed patients with obesity experienced lower risk of neutropenia (HR: 0.80; 95% CI: 0.73-0.88) and any hematologic toxicity (HR: 0.83; 95% CI: 0.75-0.91) but increased risk of neuropathy (HR: 1.34; 95% CI: 1.18-1.52), cardiotoxicity (HR: 2.30; 95% CI: 1.13-4.67), and non-hematologic toxicities overall (HR: 1.31; 95% CI: 1.15-1.48). The strength of these associations increased with increasing BMI category. The inverse association between obesity and hematologic toxicity was evident for standard administration schedules (HR: 0.54; 95% CI: 0.45-0.66) but not dose-dense schedules. However, the positive association between obesity and non-hematologic toxicities persisted regardless of administration schedule. **Conclusions:** Women with obesity given the full BSA-determined chemotherapy dose are less likely to experience neutropenia than fully-dosed non-obese women. Importantly, this holds among patients with more severe obesity, but not when restricted to newer dose-dense administration schedules. Findings also suggest that fully-dosed patients with obesity may experience higher risks for neuropathy and cardiotoxicity. These findings highlight the importance of better understanding the risks and benefits of dosing strategies as treatments and patient populations continue to evolve. Clinical outcomes of patients with stage I triple-negative breast cancer (TNBC) treated with or without chemotherapy: The Mayo Clinic experience. First Author: Sumeet Kumar Yadav, Mayo Clinic Health System, Mankato, MN

Background: TNBC is associated with higher risk of recurrence and poorer survival rates than other breast cancer subtypes. For node-positive TNBC or tumors larger than 0.5 cm, chemotherapy is generally recommended. For stage I TNBC, the benefit from chemotherapy, the optimal regimen, and whether to administer it in the neoadjuvant versus adjuvant setting remain controversial. Here, we report the treatment patterns and clinical outcomes of patients with stage I TNBC treated at Mayo Clinic. **Methods:** Using the Mayo Clinic Tumor Registry data, we identified patients with stage I TNBC treated between 2010 and 2021. We used the pathologic tumor (T) category for patients treated with upfront surgery and the clinical T category for patients receiving neoadjuvant chemotherapy. We used the Kaplan-Meier method and log-rank test to compare recurrence-free survival (RFS) according to treatment groups, measured from the day of surgery. RFS was reported at a median follow-up of 3.9, 6.2, and 7.3 years for patients who received chemotherapy neoadjuvantly, adjuvantly, and surgery alone with no chemotherapy, respectively. **Results:** A total of 602 patients with Stage I TNBC were included, with a median age of 62 years. 290 (48%) underwent upfront surgery followed by adjuvant chemotherapy (pT1a: 2%, pT1b: 25%, pT1c: 74%), 127 (21%) received neoadjuvant chemotherapy followed by surgery (cT1a: 2%, cT1b: 11%, cT1c: 87%), and 185 (31%) underwent primary surgery without any chemotherapy (pT1mi/T1a: 33%, pT1b: 32%, pT1c: 35%). Most patients treated with neoadjuvant therapy received anthracycline/cyclophosphamide + taxane (70%), while most patients treated in the adjuvant setting received a non-anthracycline containing regimen (60%). The 5-year RFS was 96% (95% CI: 93-100%) for patients who received chemotherapy neoadjuvantly, 95% (95% CI: 92-98%) for those who received chemotherapy adjuvantly, and 85% (95% CI: 80-91%) for those treated with surgery alone and no chemotherapy ($P < 0.0001$). 71 (56%) of the 127 patients who received neoadjuvant therapy achieved a pCR, with only 1 RFS event (at 14 months) in that group, compared to 4 RFS events among those not achieving pCR (at 12, 20, 28 and 75 months, respectively). Among patients not receiving chemotherapy (either adjuvantly or neoadjuvantly), the 5-year RFS rates were 94% for pT1mi/T1a, 92% for pT1b and 72% for pT1c (T1mi/a/b vs T1c, $P = 0.009$). **Conclusions:** In this large cohort of stage I TNBC, patients who received chemotherapy (adjuvantly or neoadjuvantly) had better 5-year RFS compared with those treated with locoregional therapy only. Among patients receiving chemotherapy, 5-year RFS was nearly identical regardless of whether chemotherapy was administered before or after surgery. Interestingly, patients undergoing upfront surgery were more likely to receive an anthracycline-sparing chemotherapy regimen. Clinical validation of a multi-modal Ataraxis AI platform for recurrence prediction in early-stage breast cancer across multiple patient cohorts. First Author: Jan Witowski, Ataraxis AI, New York, NY

Background: Breast cancer (BC) treatment selection is traditionally guided by clinical characteristics. However, as clinical characteristics cannot capture the complexity of a disease, genomic tools have been developed. Recent advances in artificial intelligence (AI) have allowed pathology imaging to be used to build more accurate and comprehensive prognostic/predictive models. In this study, we validated an AI test, powered by a pan-cancer histopathology foundation model, that integrates digital pathology images with clinical variables to predict breast cancer recurrence. **Methods:** The Ataraxis AI prognostic model (ATX) was developed using 4,659 stage I-III BC patients from 10 distinct cohorts. Ataraxis AI platform first extracts novel morphological features from digitized H&E slides using a pre-trained AI foundation model. These morphological features are then integrated with common clinical characteristics, such as TNM staging, ER/PR/HER2 status, age at diagnosis, or lobular or ductal histology to generate a risk score between 0 and 1. We evaluated ATX on 3,502 patients from 5 external cohorts, including 858 patients with available Oncotype DX (ODX) scores. The primary endpoint of this study was disease-free interval (DFI), defined as the time until first recurrence, with deaths prior to recurrence censored. **Results:** Across 3,502 patients spanning five validation cohorts, ATX accurately predicted DFI with a C-index of 0.71 [0.68-0.75] and hazard ratio (HR) of 3.63 [3.02-4.37, $p < 0.01$], computed for every 0.2 unit increase in the test score. Compared to ODX (n = 858), the ATX was more accurate, achieving a C-index of 0.67 [0.61-0.74] versus 0.61 [0.49-0.73]. Additionally, ATX added independent prognostic information to ODX in a multivariate analysis (HR: 3.11 [1.91-5.09, $p < 0.01$]). ATX demonstrated robust accuracy in TNBC (n = 230, C-index: 0.71 [0.62-0.81], HR: 3.81 [2.35-6.17, p = 0.02]) and HER2+ (n = 353, C-index: 0.67 [0.55-0.80], HR: 2.22 [0.99-5.01, p = 0.05]) groups. **Conclusions:** (1) ATX is predictive of breast cancer recurrence, (2) ATX improves upon the accuracy of ODX, (3) ATX demonstrates robust performance in all main BC subtypes. Research Sponsor: Ataraxis AI.

ATX evaluated across 5 cohorts individually and pooled, for both Harrell's C-index and hazard ratio.

Cohort	N	C-index	HR
Karmanos	168	0.62 [0.49-0.75]	3.82 [1.33-10.98, p=0.01]

Pathologic complete response to neoadjuvant chemotherapy in early-stage male breast cancer across molecular subtypes and racial/ethnic groups. First Author: Jincong Q. Freeman, Department of Public Health Sciences, The University of Chicago, Chicago, IL

Background: Male breast cancer (mBC) accounts for ~1.0% of all breast cancers in the U.S. Neoadjuvant chemotherapy (NACT) is often used to downsize locally advanced tumors and/or allow for lumpectomy in early-stage breast cancer. However, data on pathologic complete response (pCR) after NACT in mBC is scarce. This study aimed to explore how pCR in male patients with early-stage breast cancer differed by molecular subtype and by race/ethnicity. **Methods:** This retrospective study analyzed data from the 2004-2021 U.S. National Cancer Database registry. Patients were eligible if they were male sex, aged ≥18 years, diagnosed with stage I-III disease, and underwent NACT. pCR (achieved/did not achieve) was defined as ypT0/TisypN0. Molecular subtypes included HR+/HER2−, HR+/HER2+, HR−/HER2+, and TNBC. Racial/ethnic groups included Asian or Pacific Islander, Black, Hispanic, White, and Other. We performed multivariable logistic regression, adjusting for age, race/ethnicity, molecular subtype, clinical T/N, and tumor grade. **Results:** Of 1428 patients, the mean age was 58.5 years (SD=12.8); 69.3% identified as White, followed by 18.8% as Black, 6.2% as Hispanic, 3.4% as Asian or Pacific Islander, and 2.4% as Other. Most (87.2%) patients had invasive ductal carcinoma. 51.3% were HR+/HER2−, 31.9% were HR+/HER2+, 11.7% were TNBC, and 5.1% were HR−/HER2+. Overall, the rate of pCR was 10.9%. Patients with HR−/HER2+ tumors achieved the highest pCR rate (37.3%) compared to 33.8% with TNBC, 14.9% with HR+/HER+, and only 3.7% with HR+/HER2− tumors ($p<.001$). The pCR rate trended higher in Asian or Pacific Islander (14.6%) or Hispanic (13.6%) patients than in Black (11.2%), White (10.4%), or Other (8.8%) patients, though not statistically significant ($p=.728$). On multivariable regression analysis, patients with HR+/HER2+ (adjusted odds ratio [aOR] 3.89, 95% CI: 2.24-6.76; $p<.001$), TNBC (aOR 8.80, 95% CI: 4.76-16.28; $p<.001$), or HR−/HER2+ (aOR 13.45, 95% CI: 6.40-28.28; $p<.001$) tumors had greater odds of having achieved pCR than those with HR+/HER2− tumors. No significant differences in odds of pCR by race/ethnicity were found. Additionally, older age (aOR 0.84 [per 10-year increase], 95% CI: 0.72-0.98; $p=.026$) and grade 1/2 (*vs* grade 3) tumors (aOR 0.39, 95% CI: 0.25-0.60; $p<.001$) were associated with lower odds of pCR. **Conclusions:** In early-stage mBC, the post-NACT pCR rate varied significantly across molecular subtypes, with the lowest rate in HR+/HER2− tumors, mirroring patterns observed in female breast cancer in the neoadjuvant setting. pCR rates were similar by race/ethnicity but lower among patients who were older or had low-grade tumors. These data suggest pCR dependence on tumor biology and could help neoadjuvant treatment selection to achieve optimal outcomes for early-stage mBC. Future research could investigate survival outcomes by pCR in this mBC population. Research Sponsor: National Institute on Aging; T32AG000243; Susan G. Komen Breast Cancer Foundation; TREND21675016.

Artificial intelligence (AI) based spatial assessment of tumor-infiltrating lymphocytes (TIL) and pathologic complete response in early HER2+ breast cancer (BC): Secondary analysis of NSABP B-41. First Author: Ilana Schlam, Dana-Farber Cancer Institute, Boston, MA

Background: Manual quantitative assessment of stromal TILs has shown promise as a biomarker in HER2+ BC. We present an AI-powered single-cell TIL assessment. **Methods:** Manual TIL assessment was completed per guidelines. Zero-shot, AI-powered pipeline (Case45) was used to analyze tumor microenvironment (TME) from H&E slides, focusing on TILs and their spatial interplay with cancer cells. The algorithm identified all cells, deriving three metrics: pct_lymphocyte (lymphocytes/total cells), AI_TIL (adjacent-tumor lymphocyte to stromal cell ratio), hotspot_immune (normalized fraction of immune cell aggregates in relation to cancer/tissue). Spearman correlation coefficients evaluated correlations; logistic regression models assessed the relationship between TIL measurements and pCR, with and without gene expression adjustments. AUC assessed predictive performance, and univariate Cox models examined TILs' association with event-free survival (EFS). **Results:** Our analyses included tumors of 262 patients with early-stage HER2+ BC, 67% estrogen receptor (ER) positive, 51% positive lymph nodes. Poor histologic grade ($p<0.001$), non-luminal (p=0.006), and ER- tumors (p=0.003) were associated with higher manual TILs. Manual TILs were moderately associated with pct_lymphocyte (r= 0.34) and AI_TIL (r= 0.43). Perthe table, manual TILs were positively associated with pCR, the association was numerically stronger in ER- tumors (Interaction p=0.38). pct_lymphocyte and AI_TIL were positively associated with pCR, regardless of ER status. hotspot_immune was strongly associated with pCR (OR=1.26 for all, 1.29 in ER-, 1.22 in ER+, $p=<0.001$). TILs and *ESR1 and ERBB2* provided complementary prognostic utility in pCR in trastuzumab-treated patients (AUC: 0.699-0.757). Among all subjects, there was no association between manual TILs and EFS (p=0.2); there was a marginal association between AI_TIL and EFS (p=0.06). **Conclusions:** The spatial characterization of TILs using an AI-powered tool shows promise as a prognostic biomarker in both HER2+/ER+ and HER2+/ER- BC, manual TIL assessment is prognostic in HER2+/ER- BC. The assessment of immune aggregates appears to be highly predictive of pCR. Further validation through prospective-retrospective studies, focused on the spatial immune heterogeneity in the TME, is required before integrating these biomarkers into routine clinical practice. Clinical trial information: NCT00486668. Research Sponsor: BCRF; BCRF 21-156.

Ultrasensitive circulating tumor DNA (ctDNA) detection for prognostication in triple-negative breast cancer (TNBC) post-neoadjuvant chemotherapy (NAC). First Author: Luc Cabel, Institut Curie, Paris and Saint-Cloud, France

Background: NAC +/- immune checkpoint inhibitors is the standard of care for most early-stage TNBC patients. After NAC and breast surgery, adjuvant treatment decisions rely on pathological complete response (pCR) status, which does not inform on the presence of distant micrometastases. Blood-based assays for ctDNA enable non-invasive monitoring of residual disease levels at sensitivities down to 1 part-per-million (PPM). We report the prognostic value of ultrasensitive ctDNA detection during NAC in patients with TNBC. **Methods:** Early-stage TNBC patients treated with NAC in the SCANDARE prospective study were evaluated for ctDNA before, during, after NAC/pre-surgery and during post-surgical follow-up. Plasma ctDNA was profiled using NeXT Personal (Personalis), an ultrasensitive tumor-informed MRD assay that tracks up to 1,800 patient tumor-specific variants based on whole genome sequencing to attain sensitivity down to 1-3 PPM with >99.9% specificity. **Results:** Plasma ctDNA was analyzed for 279 samples from 84 TNBC patients (Stage I: 2%, II: 77%, III: 20%), of whom 35 (42%) achieved pCR after NAC. After a median follow-up of 53 months, 16 patients (19%) developed distant metastases, and 18 patients (21%) died. ctDNA was detected before NAC in all 82 patients with an available sample (median=3461 PPM, IQR: 1168-22078), with pretreatment levels in the ultrasensitive range (<100 PPM) in 12%. Most ctDNA detections during (51%) and post-NAC (55%) were <100 PPM. Patients with rates of early on-treatment ctDNA reduction faster than the median, or clearance, had significantly improved distant relapse-free interval (DRFI, log-rank $P=7.7x10^{-3}$) and overall survival (OS, log-rank $P=7.9x10^{-3}$). Patients with post-NAC, pre-surgery ctDNA clearance had significantly improved DRFI (log-rank $P=3.5x10^{-7}$) and OS (log-rank $P=1.4x10^{-11}$), and were enriched for pCR (59% vs 9%, OR=13.9, 95% CI [2.8,137.2], Fisher's exact $P=1.4x10^{-4}$). Multivariable Cox models including pCR and ctDNA detection post-NAC, pre-surgery performed significantly better than models including only pCR for predicting DRFI (LRT $P=8.0x10^{-4}$) and OS (LRT $P=6.6x10^{-4}$). ctDNA detection significantly stratified survival outcomes among patients without pCR (DRFI HR=8.2, 95% CI [1.8,37.0], Cox $P=6x10^{-3}$), with 60% of ctDNA-positive patients developing distant metastases vs 10% of ctDNA-negative patients. During follow-up, all plasma samples from non-relapsing patients were ctDNA-negative. In relapsed patients, ctDNA was detected in 95% of samples collected at relapse or tumor progression. **Conclusions:** Ultrasensitive ctDNA detection informs on the outcome of early TNBC treated by NAC, independently of pCR status. These results, obtained with samples taken post-NAC but before-surgery warrant investigating the benefit of implementing ctDNA detection in an interventional setting. Association of immune, proliferation gene signatures and stromal tumor infiltrating lymphocytes (sTILs) with outcomes in patients with stage I triple-negative breast cancer (TNBC). First Author: Paolo Tarantino, Dana-Farber Cancer Institute, Boston, MA

Background: Approximately one third of all TNBC diagnoses are stage 1. No validated biomarker is routinely utilized to guide treatment at this early stage. **Methods:** Samples from patients with stage I TNBC or ER-low (1-10%) breast cancer undergoing surgery at Dana-Farber/Brigham Cancer Center between 2016 and 2021 were identified. The 10-gene Core Immune Gene (CIG) signature and the 4-gene proliferation signature (both part of the TNBC-DX tool) were derived from extracted RNA. Central evaluation of sTILs was conducted at Dana-Farber, with 5% and 20% used as thresholds. All markers were tested for prediction of recurrence free survival (RFS) using the Kaplan-Meier method. **Results:** We identified 253 patients with stage I TNBC (n=218) or ER-low tumors (n=35) treated at Dana-Farber. Median age was 61 (31 – 85), most tumors were ductal (89%), high-grade (73%), 48% were >1 cm and 65% received chemotherapy. 5-year RFS in the overall cohort was 86.8%, with numerical variation by tumor size (T1a 100%, T1b 93.8%, T1c 81.7%, p=0.26). Gene signatures and sTILs were obtained for 117 and 123 patients, respectively (both for 110 patients), with their association with outcomes described in Table 1. Median follow-up was 3 years. A total of 20/117 patients (17.1%) had medium-high CIG score, with none experiencing RFS events prior to year 5. Similarly, no recurrence was observed prior to year 5 in 29 patients (24.8%) at the upper CIG quartile (vs 83-88% 5-year RFS in other quartiles). Worse outcomes were seen among patients in the upper quartile of proliferation (5-year RFS 83%, vs 88-100% in other quartiles). Overall, 33/123 patients (26.8%) had high sTILs (>20%) and experienced the highest 5-year RFS (97%, vs 78% if low sTILs). OS data will be presented. **Conclusions:** High expression of the 10-gene CIG immune signature or high sTILs are associated with numerically improved outcomes in patients with stage I TNBC that did not reach statistical significance, warranting further study as prognostic tools. Research Sponsor: None.

3- and 5-year recurrence free survival (RFS) according to gene signatures and sTILs. P values were obtained via Cox proportional hazard models.

Association of ImPrintTN signature with survival outcomes by race in basal-type triple negative breast cancer (TNBC): FLEX registry analysis. First Author: Priyanka Sharma, University of Kansas Medical Center, Westwood, KS

Background: ImPrintTN is a triple negative breast cancer (TNBC) immune classifier signature that has been associated with pathological complete response (pCR) to immunotherapy (IO) plus chemotherapy in ISPY2. Real Word data (RWD) from FLEX was utilized to assess the association of ImPrintTN with self-reported race and its impact on clinical outcomes in early stage TNBC. **Methods:** Patients (pts) enrolled in the FLEX (NCT03053193) trial diagnosed with early-stage TNBC and BluePrint Basal molecular subtype with available survival data, who self-identified as Black or White, were eligible for this analysis. ImPrintTN results (+/-) were acquired through whole transcriptome profiling. Chi-squared and Fisher's exact tests assessed differences in clinical characteristics. Association of pCR outcomes and ImPrintTN+/- were tested by binary logistic regression. Recurrence-free survival (RFS) was compared between race and ImPrintTN+/- using Kaplan-Meier estimates and log rank tests. Cox proportional hazards model was used to analyze the association of ImPrintTN, race, and clinical features with RFS. **Results:** Among 279 eligible patients with early stage Basal TNBC, 23.7% were Black, 76.3% were White, 27.7% had node positive disease, 49.8% received neoadjuvant therapy, 47.3% adjuvant therapy, 2.5% IO, and median follow-up was 3 years. 56.6% of pts were ImPrintTN+, similarly distributed by race (Black: 60.6%, White: 55.4%, p=0.761). Among pts treated with neoadjuvant therapy (n=139) no significant differences in pCR rates were observed by race (Black: 26.5%; White: 35.2%; p=0.46). However, a higher pCR rate was achieved in ImPrintTN+ vs ImPrintTN- cancers (39.3% vs 22.0%; OR=2.29, 95% CI [1.04-5.08]; p=0.039). The 3-year RFS was similar for Black (82.5%) and White (83.5%; p=0.91) pts. Significantly improved 3-year RFS was associated with ImPrintTN+ (87.9%) compared to ImPrintTN- (77.5%; p=0.01). Among ImPrintTN+, RFS was similar for Black (89.7%) and White (87.3%; p=0.30) pts. However, ImPrintTN- observed a trend towards lower 3-year RFS in Black (71.1%) compared with White (79.2%; p=0.24) pts. In a multivariate model, RFS probability was significantly associated with ImPrintTN (ImPrintTN+ vs ImPrintTN-: HR= 0.41, 95% CI [0.22-0.75]; p=0.004) and nodal status (LN+ vs LN-: HR= 2.98, 95% CI [1.66-5.37,]; p<0.001), while race and neo/adjuvant therapy were not. **Conclusions:** The analysis found that 56.6% of Basal TNBCs in the FLEX trial were ImPrintTN+, with similar proportions observed among Black and White pts. ImPrintTN status was prognostic for both pCR and RFS in TNBC and was associated with significantly improved RFS across racial groups. However, the negative prognostic impact of ImPrintTN- appeared more pronounced among Black compared with White pts. Ongoing research is focused on exploring biological differences within the ImPrintTN- subgroup by race. Clinical trial information: NCT03053193. Research Sponsor: Agendia, Inc.

Real-world (rw) ctDNA testing trends and associated outcomes in patients (pts) with early stage breast cancer (EBC). First Author: Erin Fidyk, Flatiron Health, New York, NY

Background: Emerging evidence from prospective studies underscores the prognostic potential of ctDNA to inform risk stratification and clinical decision-making in EBC (stage I-III). However, its use and correlation with outcomes in routine clinical practice remains less understood. We describe tumor-informed ctDNA testing trends and the association of test results with recurrence risk among pts with EBC in the rw setting. **Methods:** Pts with an EBC diagnosis (dx) after 1/1/2018 who had documented HR/HER2 status at initial dx, surgery, and ≥1 commercial ctDNA test in the early stage setting were selected using machine learning models from the Flatiron Health US-nationwide EHR-derived, deidentified, longitudinal database of >750 000 pts with BC (data cutoff 8/31/2024). ctDNA positivity (ctDNA+) was defined as having ≥1 positive test in EBC. Baseline characteristics were stratified by EBC subtype and ctDNA status. To examine the association of ctDNA status with recurrence, unadjusted Kaplan-Meier (KM) plots and adjusted Cox proportional hazards models were performed to assess recurrence-free survival among ctDNA-tested pts, controlling for age, race/ethnicity, stage, ECOG status, dx year, insurance status, practice type, and neoadjuvant/adjuvant treatment. Recurrence was indexed to surgery date and defined as locoregional or metastatic recurrence or death. **Results:** In a cohort of 195 279 pts with EBC, 14 496 ctDNA tests were performed in 4639 pts (median 2 per pt) with most in stage I (43.3%) and II (37.1%). Testing prevalence was highest in HR-/HER2- (4.9%), followed by HR-/HER2+ (3.5%), HR+/HER2+ (2.9%), and HR+/HER2- (1.9%). Testing increased from 1.6% (n = 450) of EBC pts dx in 2020 to 4.25% (n = 1278) in 2023 with a decrease in median time to first test pre- and post-2022 (35 vs 8 months respectively). Among tested pts, 921 (19.9%) had ≥1 positive test and were more likely to be younger (58 vs 64 years) and have stage III disease compared to non-tested pts. ctDNA+ patients had a worse 3-year overall survival (OS) as well as a strong association with recurrence (Table). **Conclusions:** In the largest rw study of ctDNA testing in EBC to date, pts with ctDNA+ disease across all subtypes were more likely to recur, highlighting the potential prognostic value of ctDNA testing to inform pt counseling, monitoring and treatment strategies. These rw results, coupled with findings from prospective randomized trials, support the case for ctDNA+ as a distinct risk category in the management of EBC. Research Sponsor: Flatiron Health, Inc.

Association of genetic predisposition to low-grade systemic inflammation with cancer-related fatigue in women receiving chemotherapy for non-metastatic breast cancer in URCC07012 and URCC10055. First Author: Ayo Olowofela, Department of Radiation Oncology, Medical College of Wisconsin, Milwaukee, WI

Background: Cancer-related fatigue (CRF) is reported by ~75% of patients receiving chemotherapy for breast cancer. CRF has been linked to inflammation. Chronic, low grade systemic inflammation is a polygenic trait, and a polygenic risk score for inflammation (iPRS) might be associated with risk of CRF. **Methods:** Using data from the UK Biobank,we developed an iPRS using the INFLA-score, a composite measure of serum C-reactive protein, white-cell count, platelet count, and neutrophil-lymphocyte ratio. The iPRS was evaluated for association with CRF among women with non-metastatic breast cancer enrolled in one of two completed multi-site clinical trials of the University of Rochester Cancer Center NCI Community Oncology Research Program (NCORP) Research Base. CRF was measured before and after standard-of-care chemotherapy using the Multidimensional Fatigue Symptom Inventory-Short Form (MFSI-SF). Linear regression evaluated the change in MFSI-SF score from pre- to post-chemotherapy; logistic regression evaluated a binary outcome of any vs no worsening of scores. Analyses were adjusted for patient and treatment factors. **Results:** The NCORP cohort included 802 women who received chemotherapy (anthracycline-based = 51.8%; previous surgery = 85.0%) at a median age of 55 years (range = 22 to 81). There was an increase in MFSI in 55% of the women, with a mean increase of 8 (range=-64 to 71) from prechemotherapy (mean=8, range = -24 to 83) to post-chemotherapy (mean=15.3, range = -24 - 88), indicating an overall increase in CRF. The iPRS was associated with a significant decrease in MFSI-SF (β=-3.29; 95%CI=-6.25 to -0.34; *P*=0.029; covariate-adjusted β=-2.71; 95%CI=-5.50 to 0.08; *P*=0.057) and lower odds of worsening CRF (OR=0.66; 95%CI=0.47-0.93; *P*=0.016; covariate-adjusted OR=0.67; 95%CI=0.47 to 0.96; *P*=0.029). The negative relationship between the iPRS and change in CRF was partially explained by the finding that women with an iPRS in the highest quartile have worse pre-chemotherapy MFSI-SF scores (β=4.33; 95%CI=0.23 to 8.43; *P*=0.038). **Conclusions:** Women with genetic predisposition to low-grade systemic inflammation, indicated by a higher iPRS, have worse CRF pre-chemotherapy that does not worsen, and may improve, over the course of treatment while women with a lower iPRS have less CRF pre-chemotherapy and are at greatest risk of developing new or worsening CRF during treatment. If validated, the iPRS could identify patients in need of supportive care interventions to reduce CRF. This work was supported by the National Institutes of Health National Cancer Institute Contract No. HHSN261201500003I, Task Order No. HHSN261000039 and by UG1CA189961, URCC NCORP Research Base. Assessment of ovarian function suppression (OFS)-containing adjuvant endocrine therapy in premenopausal women by Breast Cancer Index. First Author: Ruth O'Regan, University of Rochester, Rochester, NY

Background: Breast Cancer Index (BCI) previously identified that premenopausal patients with *HOXB13/IL17BR* ratio (H/I)-Low tumors derived greater benefit than BCI(H/I)-High tumors from OFS-containing adjuvant endocrine therapy vs tamoxifen alone in the Suppression of Ovarian Function Trial (SOFT). This translational study of the Tamoxifen and Exemestane Trial (TEXT) was conducted to assess the predictive benefit of BCI (H/I) from exemestane (E) plus OFS over tamoxifen (T) plus OFS and validate the prognostic performance of BCI. **Methods:** Blinded BCI testing was performed in all available tumor samples from patients enrolled in TEXT, of which 1782 of 2660 had BCI successfully assessed and BCI categories assigned per established clinical cutpoints. Primary endpoints were breast cancer–free interval (BCFI) for predictive and distant recurrence–free interval (DRFI) for prognostic analyses. Per pre-specified SAP, a secondary analysis of predictive benefit combined the two OFS arms common to TEXT and SOFT (2896 of 4690 patients); clinicopathologic subgroup analyses were conducted in the combined TEXT+SOFT cohort. Cox proportional hazards models, stratified by chemotherapy use and nodal status, that included treatment assignment, BCI(H/I) status, and interaction term were used to assess BCI predictive performance by testing for treatment-by-BCI(H/I) interaction. The median follow-up was 13 years. **Results:** Among TEXT patients, 58% had BCI(H/I)-Low tumors.Patients with BCI (H/I)-Low tumors exhibited a 6.6% absolute benefit in 12-year BCFI (HR=0.61 [95% CI, 0.44-0.85]) for E+OFS versus T+OFS while those with BCI(H/I)-High tumors had an 6.3% absolute benefit (HR=0.78 [95% CI, 0.57-1.07]) (P-interaction = 0.29). Results were consistent in the combined TEXT+SOFT cohort and adjusting for clinicopathological variables. Clinical subgroup analyses consistently showed benefit of E+OFS vs T+OFS for BCI(H/I)-Low tumors, and more variable relative treatment effects among BCI(H/I)-High tumors, including by age. Post-hoc exploratory time-varying estimates suggested the treatment-by-BCI relationships may differ in years 0-5 vs >5 years. BCI and BCIN+ as continuous indices were prognostic for distant recurrence in N0 (P = 0.0004) and N1 (P < 0.0001) cancers. The 12-year DRFI was 96.3%, 90.3% and 84.9% for BCI-low, intermediate and high-risk N0 cancers, respectively. **Conclusions:** BCI was confirmed as prognostic in premenopausal women with HR+ early breast cancer enrolled in TEXT. BCI(H/I) status did not clearly predict differential benefit from E+OFS vs T+OFS. The TEXT results complement the prior results from SOFT, indicating premenopausal patients with BCI(H/I)-Low tumors benefit from more intensive endocrine therapy. Dynamic changes in circulating tumor DNA among Taiwanese early breast cancer patients undergoing upfront surgery: Results from the VGH-TAYLOR study. First Author: Chi-Cheng Huang, Taipei Veterans Genreal Hospital, Taipei City, Taiwan

Background: Circulating tumor DNA (ctDNA) has emerged as a promising prognostic marker in breast cancer. Post-treatment ctDNA detection is associated with increased recurrence risk and reduced long-term survival. This study evaluated dynamic ctDNA changes in early breast cancer patients with distinct immunohistochemical (IHC) subtypes. **Methods:** Liquid biopsies were performed using the Oncomine Breast cfDNA Assay v2. Samples were collected at baseline (pre-surgery, visit 1), after adjuvant therapy (visit 2), and every six months thereafter (visit 3 and subsequent visits) for patients in the upfront surgery (Group 1A) arm of the VGH-TAYLOR study. Pre-operative and follow-up ctDNA detectability and its impact on recurrence-free survival (RFS) were evaluated. **Results:** A total of 577 early breast cancer patients with at least one ctDNA test were analyzed; the majority (74%, n=425) were hormone receptor (HR)-positive/human epidermal growth factor receptor 2 (HER2)-negative. Among 500 pre-operative samples, ctDNA was detected in 24% (n=121) of patients, with *TP53* (21%, n=106) and *PIK3CA* (6%, n=28) being the most prevalent mutations. During follow-up (visit 2 and later), ctDNA was detected in only 3% (n=13) of patients; all harbored *TP53* mutations, with one case also exhibiting an *ERBB3* mutation. All patients with detectable follow-up ctDNA had also tested positive pre-operatively (Table 1). Five-year RFS was 94% in the ctDNA-positive group (n=121) and 95% in the ctDNA-negative group (n=319). Among HR-negative/HER2-positive and HR-negative/HER2-negative subtypes, ctDNA positivity was associated with numerically worse RFS (90% vs. 94% and 88% vs. 89%, respectively). **Conclusions:** Following surgery and adjuvant therapy, most pre-operative ctDNA-positive cases became undetectable (89%, 108/121). Although ctDNA positivity showed a trend toward compromised RFS, particularly in HR-negative/HER2-positive and HR-negative/HER2-negative subtypes with *TP53* mutations, the high clearance rate of pre-surgery ctDNA positivity warrants longer follow-up to fully evaluate its prognostic value and the impact of liquid biopsy in early breast cancer. Clinical trial information: NCT04626440. Research Sponsor: Yonglin HealthCare Foundation.

Dynamic changes of circulating tumor DNA before surgery and after treatment across immunohistochemical subtypes among early breast cancer.

Subtype	Pre-surgery ctDNA positive	Post-treatment/follow-up ctDNA positive
HR+/HER2+	26%(9/35)	0%(0/35)
HR+/HER2-	22.8%(84/369)	1.9%(7/369)
HR-/HER2+	25%(7/28)	7.1%(2/28)
HR-/HER2-	30.8%(20/65)	6.2%(4/65)

HR: hormone receptor, HER2: human epidermal growth factor receptor II, ctDNA: circulating tumor DNA.

Impact of germline *BRCA* status on clinical outcomes of patients with HR+/HER2- early breast cancer. First Author: Antonio Marra, Division of Early Drug Development for Innovative Therapies, European Institute of Oncology IRCCS, Milan, Italy

Background: Germline pathogenic variants (PVs) in the *BRCA1* and *BRCA2* (g*BRCA1/2*) genes increase the risk for breast cancer (BC) development.The prognostic significance of *gBRCA1/2* in patients with hormone receptor-positive/HER2-negative (HR+/HER2) early BC is still controversial. **Methods:** This cohort study derived from a prospectively-maintained institutional database of all consecutive patients with BC who underwent germline testing, including *BRCA1*, *BRCA2* and *PALB2*, at the European Institute of Oncology (May 2002-Jan 2024). The study population comprised patients with stage I-III HR+/HER2- (estrogen receptor expression >1%) invasive BC who underwent surgery and (neo)adjuvant treatment, as endocrine therapy (ET) +/- chemotherapy (CT) (Jan 2000-Dec 2022). Primary endpoints were distant relapse-free interval (DRFI) and invasive disease-free survival (iDFS) by STEEP 2.0. Univariate and multivariate Cox proportional-hazard models were employed for survival analyses, with left-truncated models to account for the time from BC diagnosis to germline testing. **Results:** A total of 1,730 patients were included in the analyses, with 52 (3%) *BRCA1*, 180 (10%) *BRCA2*, and 9 (0.5%) *PALB2* PV carriers. Compared to non-carriers, patients with *gBRCA*1/2 and *gPALB2* PVs were younger (median age: 39 vs 42 yrs, p<.001), had advanced disease stage (stage II-III: 71% vs 58%, p<.001), higher tumor grade (G3: 54% vs 26%, p<.001) and Ki-67 expression (median: 26% vs 20%, p<.001). Patients with *gBRCA*1/2 and *gPALB2* PVs were also more likely to receive neoadjuvant (13% vs 6%, p<.001) and/or adjuvant CT (56% vs 36%, p<.001) and mastectomy (56% vs 45%, p=.002). All patients received adjuvant ET, as tamoxifen or aromatase inhibitor +/- GnRH analogue. No patient received adjuvant olaparib or CDK4/6 inhibitor. At a median follow-up of 9.7 (IQR 6-13.9) years, 335 (19%) patients experienced local relapse, 316 (18%) distant metastasis, and 124 (7.2%) died due to BC. At multivariate analyses, *gBRCA2* P/LPVs were independently associated with shorter DRFI (HR 1.46, 95%CI 1.04–2.06, p=.028) and iDFS (HR 1.34, 95 CI 1.01–1.78, p=.045), regardless of stage, nodal status, (neo)adjuvant CT, type of surgery and adjuvant ET, whereas *gBRCA1* were not. Exploratory analyses showed that among 232 *gBRCA1/2* carriers, 47 (20%) and 96 (41%) were eligible for adjuvant olaparib or abemaciclib therapy per OlympiA and monarchE criteria, respectively, with 37 (16%) eligible for both therapies. Additional analyses to unravel interaction of *gBRCA* status with adjuvant treatment are underway. **Conclusions:** Patients with HR+/HER2- early BC harboring *gBRCA2* PVs had a significantly increased risk of recurrence, with a potentially distinct impact of *BRCA2* vs *BRCA1*. Only a small proportion of this population currently qualify to adjuvant treatment escalation with targeted therapies, underscoring the need of expanding the therapeutic options in this setting. Cadence of circulating tumor DNA (ctDNA) testing for molecular surveillance in early-stage breast cancer (eBC). First Author: Marla Lipsyc-Sharf, UCLA Health Jonsson Comprehensive Cancer Center, Los Angeles, CA

Background: Post-surgical detection of molecular residual disease (MRD) via plasma ctDNA testing is strongly associated with recurrence of eBC. Our prior real-world data suggests that adjuvant MRD testing impacts clinical care for most patients (pts) with positive ctDNA (ctDNA+) results. Ongoing trials are studying whether adjuvant ctDNA testing improves eBC outcomes. While serial testing is known to improve MRD detection rates, the optimal cadence of testing is unknown. Here, we investigated the role of timing, cadence, and quantitative results of real-world ctDNA testing on detection of clinical recurrence of eBC. **Methods:** We identified eBC pts with available recurrence-free survival data who had adjuvant plasma MRD testing via a clinically validated, personalized, tumor-informed mPCR-NGS ctDNA test (Signatera, Natera, Inc.). All tests were ordered in the United States in the real-world clinical setting between 2019-2024; clinical records were reviewed. The cumulative incidence of clinical recurrence after each ctDNA test was used to calculate negative predictive value (NPV) for recurrence within 3, 6, 12, 18, 24, and 30 months (mo) post-test. ctDNA levels at different timepoints prior to recurrence were analyzed separately by ER and HER2 status. **Results:** For 819 pts with stage I-III eBC (ER+/HER2-: 249, HER2+: 68, triple-negative [TNBC]: 502), there were 4689 total plasma samples obtained in the adjuvant setting (median 5.7 time points per patient). Median time of first adjuvant ctDNA testing was 7 mo after surgery (range: 0.1-214.9). Median follow-up was 18.1 mo (range: 0.7-239.4). For pts with ER+/HER2- tumors, median time to first test was 14.6 mo (range: 0.3-214.9) versus 16.1 mo (range: 0.3-151.8) in HER2+ and 7.1 mo (range: 0.1-178.8) in TNBC. Among pts with multiple adjuvant ctDNA tests, median interval between tests was 2.8 mo (consistent across subtypes). For ER+ and TNBC tumors NPV (95%CI) gradually decreased over time from 99.5% (98.8-99.8) and 99.7% (99.2-99.9) at 3 mo to 97.7% (96.7-98.4) and 97.8% (96.6-98.5) at 30 mo, respectively. Among ctDNA+ TNBC pts, quantitative ctDNA levels were higher among those who recurred < 3 mo after a +ctDNA test than those with recurrence in 3-6 mo; median ctDNA levels were lowest in pts who recurred > 6 mos after a ctDNA+ test (median [range], 2.7 [0.03-1089.6] vs 2.0 [0.1-15.3] vs 0.3 [0.3-1.7] MTM/mL, p = 0.0041 and p = 0.0071, respectively). This trend was less pronounced in ER+HER2- disease between pts who relapsed < 6 mo, 6-9 mo, and > 9 mo after a ctDNA+ test (median [range], 11.6 [0.26-299.4] vs 4.5 [0.2-27.0] vs 3.8 [2.3-124.5] MTM/mL, p = 0.5, p = 0.8). **Conclusions:** The data from this real-world analysis of tumor-informed ctDNA testing in pts with eBC during surveillance demonstrate a high NPV for both ER+ and TNBC disease. These data guide future prospective ctDNA-guided studies aimed at therapeutic interception to improve clinical outcomes. Research Sponsor: Conquer Cancer, the ASCO Foundation; Natera, Inc.

Association of lifestyle factors and pathological characteristics in patients with early breast cancer and overweight/obesity: Results from the Breast Cancer Weight Loss (BWEL) trial. First Author: Caterina Sposetti, Dana-Farber Cancer Institute, Boston, MA

Background: Obesity and other lifestyle factors are associated with breast cancer (BC) risk and outcomes. These relationships appear to vary in pre- vs postmenopausal women. Here we explore associations between pathological features, diet quality and physical activity (PA) in patients (pts) with BC enrolled in the BWEL (Alliance for Clinical Trials in Oncology A011401) trial, stratifying for menopausal status. **Methods:** BWEL is a phase III trial evaluating the impact of a weight loss intervention on disease outcomes in 3180 pts with stage II-III HER2– BC and body mass index ≥27 kg/m^2. The first 542 BWEL pts underwent assessment of PA (7-Day PA Recall) and diet (24-hour Diet Recall) at enrollment. Healthy Eating Index 2020 (HEI) score (0-100, higher value = healthier diet) and minutes/week (min/wk) of moderate/vigorous PA (MVPA) were calculated. Estrogen receptor (ER) and progesterone receptor (PR) expression level (%) were abstracted from pathology reports. Analyses of links between HEI score, MVPA min/wk, % ER/PR, stratified by menopausal status, were conducted using t-tests; differential associations by menopausal status used linear regression models with interaction term. **Results:** In 523 pts with available pathology data, 76.5% had ER/PR+ BC, 56.2% were postmenopausal. Median HEI score was 50.1 (range 18.1-96.4), median MVPA min/wk was 0 (range 0-630), median time from diagnosis to enrollment was 10.0 months (range 2.4-13.1). In postmenopausal pts, higher diet quality was linked to increased % ER and PR (HEI above vs below median, mean % ER 78.0 vs 66.1, p=0.012; mean % PR 57.7 vs 43.1, p=0.004). The relationship between HEI score and % ER/PR differed significantly by menopausal status (interaction term of menopausal status and % ER: p=0.006; and % PR: p=0.012); there were no significant associations between HEI scores and % ER/PR in premenopausal pts. There were no significant associations between PA and % ER/PR. **Conclusions:** Healthier diet was associated with higher % ER and PR in postmenopausal pts with BC, but no relationship was seen in premenopausal pts. These data suggest that lifestyle factors may influence BC pathologic features related to outcomes in older women. Association of infiltration of hematopoietic stem cells (HSC) with cell proliferation and patient survival in breast cancer. First Author: Masanori Oshi, Roswell Park Comprehensive Cancer Center, Buffalo, NY

Background: HSCs, also known as blood stem cells, are self-renewable cells that can develop into all types of blood cells. They are found in bone marrow and peripheral blood. However, the clinical relevance of HSCs in the BC TME remains unknown.To elucidate the clinical significance of HSC infiltration in the tumor microenvironment (TME) of breast cancer (BC). **Methods:** In silico analyses were conducted on 5,176 BC patients, including large independent cohorts; The Sweden Cancerome Analysis Network-Breast (SCAN-B) and the Molecular Taxonomy of Breast Cancer International Consortium (METABRIC), as well as multiple single-cell sequenced cohorts. HSC were identified through the xCell algorithm, and patients with high HSC levels were defined as those with HSC expression above the median in each cohort. **Results:** Fraction of HSCs ranged from 0.04-0.50% of all cells in BC TME by single cell transcriptome analyses. HSC infiltration was not correlated with its lineage cells, common myeloid progenitor cells and common lymphoid progenitor cells, but was associated with high infiltration of dendritic cells and stromal-related cells and low infiltration of Myeloid-related cells; M1-macrophages, and eosinophils, and lymphoid-related cells; Th1 cells, Tregs, NK T cells, and memory B cells. HSC high BC enriched TGF-β signaling, myogenesis, coagulation, and angiogenesis gene sets. On the other hand, all the cell proliferation-related gene sets in Hallmark collection; E2F targets, G2M checkpoint, MYC targets-v2, and mitotic spindle, enriched to low HSC BC, and HSC infiltration was significantly lower in high histological grade BC and in Ki67 high expression BC. HSC high patients were significantly associated with better overall survival compared to low patients in ER+/HER2- (both $p<0.02$), but not in TNBC in both cohorts. Interestingly, there was no survival difference by HSC infiltration in ER+/HER2- when neoadjuvant chemotherapy (NAC) was used. Together with our finding that HSC in the TME markedly reduced by NAC, we cannot help but speculate that the loss of HSCs by NAC may have contributed to lose their benefit in patient prognosis. Lastly, high levels of HSC were associated with significantly lower risk of lung metastasis and better survival, but not with brain and bone metastases. **Conclusions:** This is the first report that quantified HSCs using transcriptome in TME and demonstrated that they are rare, associated inversely with cell proliferation and with better survival in ER+/HER2- BC patients. Survival benefit of HSC infiltration was lost with NAC that reduce its infiltration. HSC high BC was associated with lower risk of lung metastasis and with better survival, but not with brain nor bone metastasis. Research Sponsor: National institutes of healthes.

MRI-based radiomic signature and its association with genomic complexity in breast tumor heterogeneity. First Author: Joonoh Lim, Inocras Inc., San Diego, CA

Background: Breast cancer is inherently heterogeneous, posing challenges for effective treatment. Uncovering the relationship between imaging features and genomic profiles could improve patient stratification. In this study, we evaluated whether radiomic features can capture the underlying genomic complexity of breast tumors, potentially offering a non-invasive means to better characterize tumor heterogeneity. **Methods:** We analyzed 284 breast cancer patients using an integrated radiogenomic approach. MRI-derived radiomics features were extracted and clustered using unsupervised learning methods, resulting in 12 distinct clusters. We then analyzed these clusters against matched whole-genome sequencing and transcriptome data, focusing on heterogeneity-related radiomics features. Clustering was performed using dynamic tree cutting after hierarchical clustering of 10 principal components derived from 214 radiomic features. **Results:** We identified distinct patterns of tumor heterogeneity among the 12 identified clusters, named according to descending cluster size (range: 10-46). Clusters 9, 4, and 3 exhibited the highest homogeneity (in that order), with cluster 9 being the most homogeneous overall. Cluster 12, 11, 8, 7, and 5 showed varying degrees of heterogeneity, while clusters 1 and 2 were moderately heterogeneous. Cluster 1-3 were HER2-enriched (PAM50). Clusters 1 and 2 together had *ERBB2* amplifications (33%; Fisher's exact test, $P = 0.056$), whereas cluster 3 was HER2-positive (IHC) without amplifications. Cluster 1 leaned toward the basal-like subtype, while 3 leaned toward luminal A. Cluster 2 was enriched in luminal B (50%; $P = 0.012$). Cluster 1-3 were distinguishable by their degree of radiomics-quantified heterogeneity. Cluster 4 was enriched in high *Myc* expression (17%; $P = 0.059$). Cluster 5 was enriched in whole-genome-based HRD (40%; $P = 0.01$) and basal-like (52%; $P = 0.001$). Cluster 6 was deprived of *TP53* mutations (37%; $P = 0.04$), had low tumor mutational burden, and was characterized by small volume but higher surface-volume ratio, suggesting irregular shape. Cluster 8 was enriched in *PIK3CA* mutations (60%, $P = 0.046$), cluster 10 was enriched in *CHEK2* mutations (9%; $P = 0.039$), cluster 11 showed high *TERT* (40%, $P = 0.005$) and *CDKN2A* (40%; $P = 0.048$) expression, cluster 12 was predominantly post-menopausal (80%; $P = 0.47$), and both clusters 10 and 12 exhibited low *ESR1* expression (20%; $P = 0.035$). **Conclusions:** This comprehensive radiogenomic analysis demonstrates that MRI-based radiomics features can effectively capture tumor heterogeneity patterns that correlate with specific genomic alterations in breast cancer. The identification of 12 distinct clusters, each with characteristic genomic features, provides new insights into the biological basis of tumor heterogeneity, potentially opening new avenues for breast cancer subtyping. Pregnancy-associated breast cancer: Tumor infiltrating lymphocytes TILting the balance? First Author: Carsten F.J. Bakhuis, University Medical Center Utrecht, Utrecht, Netherlands

Background: Pregnancy-Associated Breast Cancer (PABC), which includes breast cancer diagnosed during pregnancy (PrBC) or postpartum (PPBC), is often more aggressive and diagnosed at more advanced stage compared to breast cancer in non-pregnant young women. The aggressive tumor growth in PABC may be influenced by the maternal shift towards immunotolerance during pregnancy, aimed at safely harboring the semi-allogenic fetus. Potentially, this shift allows cancer cells to evade immune detection. In recent years, the importance of stromal tumor-infiltrating lymphocytes (sTILs) as a marker of the anti-cancer immune response has become evident. Given the aforementioned relevance of immunotolerance in PABC development, we have evaluated the presence and prognostic importance of sTILs in PrBC and PPBC patients in this most extensive study to date. **Methods:** We assessed tumor tissues from the Dutch Pregnancy-Associated Breast Cancer Cohort, which includes PrBC and PPBC (≤1 year postpartum) patients diagnosed between 1988 and 2022. Whole slide images (H&E) of tumors from 200 patients were uniformly reviewed, and sTILs were scored according to international guidelines. Given the lack of previous sTIL cutoffs for PABC, a data-driven approach was chosen. **Results:** Our initial analysis revealed a clear survival benefit for a sTIL score of at least 20%. Therefore, our PrBC/PPBC patient group was divided into a "Low sTILs" ($<$ 20%, n = 153) and a "High sTILs" (≥20%, n = 47) group. High sTIL scores were associated with a higher histologic grade (89% grade III versus 73% in the low sTIL group, p = 0.043) and more frequent triple negativity (68% versus 43%, p = 0.021) Despite this more aggressive histopathology, higher sTILs were associated with a significantly better 5-year overall survival (OS) probability (94% versus 69%, $p < 0.001$). In a multivariable analysis, correcting for disease stage, intrinsic subtype and tumor grade, high sTIL scores remained a strong prognostic indicator in PABC (HR 7.3, 95% CI 2.24 – 23.9). In a subgroup analysis for triple negative disease only (n = 93), patients with a high sTIL score (n = 30) showed a better 5-year OS probability (93% versus 60%, p = 0.002), which also persisted in a multivariable analysis (HR 4.7, 95% CI 1.4 – 15.7). **Conclusions:** Despite the immunotolerance in pregnancy, this study demonstrates the presence and prognostic importance of sTILs in PABC. Importantly, patients with high sTILs (≥20%) had a markedly better prognosis despite having more aggressive disease characteristics, regardless of subtype. Therefore, sTILs may be an important prognostic indicator and may aid in selecting patients to forgo adjuvant systemic therapy, especially during pregnancy. Effect of allostatic load and measures of segregation on cancer detection and false positive rate after screening mammography. First Author: Niam Abeysiriwardena, Massachusetts General Hospital, Boston, MA

Background: Allostatic load (AL), a cumulative stress measure and residential segregation (MRSs) have been associated with breast cancer (BC) outcomes. We assess the association of AL and MRSs on breast screening outcomes. **Methods:** From the Mass General Brigham Biobank, we retrospectively identify women aged ≥40, who underwent screening mammography from Jan 1, 2021 to Dec 31, 2021. We collected age, self-reported race/ethnicity, and zip code. Five MRSs were computed: Dissimilarity, Isolation (BI), Delta Index, Absolute Centralization, and Spatial Proximity. To compute AL, we assessed cardiovascular, metabolic, immune and renal lab values. AL was assigned one point for each lab value in the worst quartile and summed. We assessed any false positive (FP) and cancer diagnoses within 12 months after the index screen. Multiple imputation was performed for missing covariates. Multivariable logistic regression models were constructed to assess age, race, AL, and each MRSs association with cancer detection and FP rates. Rubin's rules were applied to estimate overall odds ratios (OR), confidence intervals (CI), and p-values for all covariates. **Results:** Of 13,754 women assessed, 1.2% (n=169) women received a cancer diagnosis. Most of the women were White (87.6%), 2.6% Asian, 5.3% Black; 1.5% self-identified as Hispanic; mean age, 64.4±11.3SD. Each point increase in AL increased the risk of cancer detection after screening mammography by 15% (OR=1.15,95% CI[1.06, 1.25],p=0.001). No association was detected between each MRS and cancer detection (all p>0.22). BI, the expected proportion of neighbors belonging to the same group, was associated with FP rate, with BI > 0.6 increasing the odds of FPs (OR=2.80[1.13-6.92],p=0.026). After adjusting for AL and MRSs, age and race were not significantly associated with cancer detection, but 5-year changes in age were associated with lower FP rate (OR=0.82[0.80, 0.84],p<0.001). **Conclusions:** AL was associated with an increased risk of cancer detection after screening mammography after adjusting for age, race, and MRSs. The MRS BI above 0.6 was associated with an increased false positive rate. Further work is needed to confirm these observations. Clinical Relevance Statement: AL and MRS (i.e., BIS) may represent potential biomarkers for personalized mammographic screening for BC. Research Sponsor: None.

Prognostic value of systemic inflammation in early-stage breast cancer in the CANTO cohort (SIM-CANTO). First Author: Julia Dixon-Douglas, Peter MacCallum Cancer Centre, Hobart, Australia

Background: The importance of host anti-tumor immunity in early-stage breast cancer (eBC) is now well recognised. Neutrophil / lymphocyte ratio (NLR) is a peripheral blood-based measure of systemic inflammation and immune status that has been associated with prognosis in other tumour types.We aimed to evaluate the prognostic value of NLR in a large prospective cohort of eBC. **Methods:** Patients with eBC (stage I-III) in the national French CANTO (NCT01993498) cohort with baseline peripheral blood counts (obtained after diagnosis and before any eBC treatment, including surgery) were included, regardless of systemic (neo)adjuvant therapy. The independent variable of interest was baseline NLR assessed as a continuous variable. Outcomes included invasive- and distant-disease-free survival (iDFS, DDFS) and overall survival (OS). We performed univariable analysis followed by multivariable Cox regression models sequentially adjusting for age, biologic subtype, TNM stage and treatment. Main analyses were conducted in the overall cohort, while additional analyses explored the role of NLR in subtypes (ER+/HER2-, HER2+, TNBC). For a cohort of patients receiving neoadjuvant therapy we tested the impact of NLR or pCR using Wilcoxon test. Sensitivity analyses used NLR as a categorical variable (using median NLR as cutoff to define high vs low NLR). **Results:** Overall, 10 470 patients were included. Median follow-up was 6.7 years (5.1 – 8.5). The median age at diagnosis was 56.4 years. Most (78%) of patients had stage I/II eBC, 77% ER+/HER2-, 13% HER2+ and 9% TNBC. The median NLR was 2.03. In the univariate analysis, there was a significant association between increasing NLR and worse DDFS in the overall cohort (HR: 1.1, p = 0.004; 95% CI:1.1 – 1.16) and in the ER+/HER2- cohort (HR: 1.1; p = 0.03; 95%CI:1.1 – 1.2). In a model adjusted by age and biologic subtype, NLR showed significant associations with DDFS (HR 1.07; p = 0.04) in the global cohort, but these associations did not maintain significance after further adjustment for TNM stage and treatment. Similarly, in the ER+/HER2- cohort, NLR was significantly associated with DDFS when adjusted for age (HR 1.08; p = 0.02), which was no longer significant after adjusting for TNM stage. No statistically significant differences were observed across other subtypes for DDFS, iDFS or OS, nor for pCR in the neoadjuvant cohort. Sensitivity analysis showed consistent results, in particular low NLR was significantly associated with improved DDFS (HR: 0.8, p = 0.03; 95%CI: 0.7 – 0.9) in the ER+/HER2- subgroup. **Conclusions:** Systemic inflammation, as measured by baseline NLR, was associated with significantly shorter DDFS in the overall CANTO cohort and in the ER+/HER2- subgroup in univariable and age- adjusted analysis. However, this association disappeared after adjustment for known clinicopathologic prognostic characteristics. Research Sponsor: None.

Exploring tumor genomics and clinical outcomes in in adolescent and young adult (AYA) breast cancer. First Author: Faris Tamimi, King Hussein Cancer Center, Amman, Jordan

Background: Breast cancer in adolescents and young adults (AYAs, defined as individuals aged 39 or younger) often exhibits aggressive biological behavior and distinct clinical patterns compared to older patients. This research investigates the somatic mutations and clinical features that distinguish AYA breast cancer, aiming to uncover unique genomic and prognostic characteristics. **Methods:** We analyzed data from the METABRIC cohort using cBioPortal, focusing on 173 genes sequenced from 2,509 breast cancer cases. The dataset included information on copy number variations, gene expression, and long-term clinical outcomes. Tumor characteristics, mutation frequencies, and relapse-free survival (RFS) outcomes were compared between AYAs and older patients. Statistical methods employed included Chi-square tests for categorical data, Wilcoxon Rank-Sum tests for medians, and Cox regression for survival analysis. The 10 most commonly altered genes across the dataset were examined. **Results:** Of 2,498 patients included in the analysis, 143 were AYAs (5.7%) and 2,355 were older patients (94.3%). Compared to older patients, AYAs demonstrated: Lower ER-positive rates (37.8% vs. 74.9%), Higher ER-/HER2- subtype prevalence (25.2% vs. 11.6%), Greater lymph node positivity (52.4% vs. 41.3%), and Worse Nottingham Prognostic Index scores (median 5.04 vs. 4.04). Genomic analysis revealed significantly higher TP53 mutation frequencies in AYAs (58.9% vs. 33.2%, p < 0.01) and lower PIK3CA alterations (28.1% vs. 42.1%, p < 0.01). Other significantly altered genes in AYAs included TG, TRPS1, CASC8, POU5F1B, MYC, CASC11, NDRG1, and LINC02912. However, stratification by receptor subtypes (ER-/HER2-, ER+/HER2-, HER2+) showed no significant differences in TP53 or PIK3CA alterations between AYAs and older patients. AYA status (< 40 years) was associated with worse recurrence-free survival (RFS) in univariable analysis and remained a significant predictor in multivariable analysis, adjusting for ER status, HER2 status, and nodal involvement (HR: 1.33, 95% CI: 1.00–1.77, p = 0.048). **Conclusions:** AYA breast cancer is marked by distinct genomic and clinical features, including higher TP53 mutation rates, lower PIK3CA mutation rates, more aggressive subtypes such as ER-/HER2-. While some genomic differences are less pronounced within biomarker-matched subgroups, AYAs remain at higher risk for recurrence. These findings highlight the urgent need for age-specific therapeutic strategies to improve outcomes in this population. Research Sponsor: None.

Gene alteration event frequency by age group (AYA versus >39 years).

Gene	AYA	>39	p-Value	q-Value
TP53	58.90% (86/146)	33.16% (780/2352)	<0.001	<0.001
PIK3CA	28.08% (41/146)	42.05% (989/2352)	<0.001	0.0442
TG	35.62% (52/146)	23.72% (558/2352)	<0.01	0.0645
NDRG1	29.45% (43/146)	19.56% (460/2352)	<0.01	0.126

Global trends and regional disparities in young-onset breast cancer: Age-specific patterns from 1990 to 2021. First Author: Muzamil Khan, The George Washington University School of Medicine and Health Sciences, Washington, DC

Background: Young-onset breast cancer (YOBC), defined as breast cancer in women under 40, is a growing global health concern with unique biological and clinical implications. Analyzing its patterns and distribution is essential for developing effective healthcare strategies and ensuring efficient resource allocation. **Methods:** Data on incidence, prevalence, mortality, and morbidity indicators (DALYs, YLD, and YLL rates per 100,000) were obtained from the Global Burden of Disease (GBD) 2021 database for women under 40 from 1990 to 2021. The dataset, covering 204 countries, was stratified into five age groups: 35–39, 30–34, 25–29, 20–24, and < 20 years. Linear regression was used to calculate average annual percent change (AAPC) and 95% confidence intervals (CI) for each indicator and age group. Statistical significance was set at p < 0.05. **Results:** Between 1990 and 2021, YOBC accounted for 16,783,674 deaths globally. Incidence increased across all age groups, with the largest increases in women under 30. AAPC for incidence was 2.27 (95% CI: 2.21–2.33) in those under 20, 2.18 (95% CI: 2.11–2.24) for ages 20–24, and 1.60 (95% CI: 1.51–1.70) for ages 25–29 (all p < 0.0001). Prevalence showed similar increases: 2.35 (95% CI: 2.29–2.41), 2.24 (95% CI: 2.18–2.30), and 1.64 (95% CI: 1.54–1.73), respectively (all p < 0.0001). Mortality AAPCs were 1.54 (95% CI: 1.46–1.61) for under 20, 1.35 (95% CI: 1.23–1.46) for ages 20–24, and 0.68 (95% CI: 0.59–0.76) for ages 25–29, while older cohorts saw declines, including -0.38 (95% CI: -0.53 to -0.23, p < 0.0001) for ages 35–39. DALYs also increased in younger groups, with AAPCs of 1.56 (95% CI: 1.49–1.63) for under 20 and 1.37 (95% CI: 1.26–1.48) for ages 20–24 but declined in older cohorts. Regionally, Turkey had the highest AAPCs across metrics, Malawi had the highest incidence and YLL for those under 20, and Zimbabwe, Yemen, and Lesotho reported the highest incidence, prevalence, YLL, and DALY. In contrast, Ukraine, Mariana Island and Armenia experienced the greatest declines in incidence, prevalence, YLL, and DALY. **Conclusions:** The global burden of YOBC has risen sharply, especially in the youngest cohorts (< 20 and 20–24 years), with significant increases in low- and middle-income regions like Turkey, Sub-Saharan Africa, and the Middle East. Age-specific interventions, early detection, and preventive measures are needed to address the growing YOBC rates. Research Sponsor: None.

Interferon signaling and outcomes in triple-negative breast cancer (TNBC) in FinXX, CALGB 40603 (Alliance) and real-world clinico-genomic data. First Author: Saranya Chumsri, Mayo Clinic Florida, Jacksonville, FL

Background: Several studies established the prognostic role of both the amount and locations of tumor-infiltrating lymphocytes (TILs) in TNBC. Three distinct immunotypes were described based on the amount and locations of TILs: immune enriched (IN), immune excluded, and immune desert. Using single-cell spatial transcriptomic analysis in the Mayo Clinic TNBC cohort, our previous studies showed the central role of interferon (IFN) signaling in IN phenotype. Herein, we evaluated the association between IFN and outcomes in TNBC in 3 independent datasets. **Methods:** NanoString IO360 was performed in 114 samples from FinXX (NCT00114816) to generate 22-gene IFNα and 33-gene IFNγ signatures. RNA sequencing was performed in 388 samples from CALGB 40603 (NCT00861705). 3038 TNBC samples were tested by WTS (NovaSeq; Caris Life Sciences, Phoenix, AZ). Median values were used as cut-offs for high vs low IFNγ RNA expression and 18-gene IFNγ signature scores. Caris Life Science CODEai was used to evaluate real-world overall survival (OS) obtained from insurance claims and calculated from tissue collection to last contact using Kaplan-Meier estimates. Chi-square, Mann-Whitney U, ANOVA, and Cox regression were used. **Results:** A high 22-gene IFNα signature score was associated with significantly improved recurrence-free survival (RFS) in FinXX (hazard ratio [HR] 0.32, 95% confidence interval [CI] 0.14-0.74, p 0.007) and OS (HR 0.28, 95%CI 0.12-0.66, p 0.003). Similar findings were observed with 33-gene IFNγ signature with significant improvement in RFS (HR 0.21, 95%CI 0.09-0.51, p $<$ 0.001) and OS (HR 0.18, 95%CI 0.08-0.44, p $<$ 0.001). Furthermore, in CALGB 40603, both IFNα and IFNγ scores were positively associated with pathologic complete response (pCR: IFNα p 0.019 and IFNγ p 0.007) and residual cancer burden (RCB: IFNα p 0.044 and IFNγ p 0.013). Using the Caris data platform to further validate, we identified 2899 TNBC patients (pts) with genomic and clinical outcome data. High IFNγ expression was associated with significant improvement in OS (25.95 vs 17.43 months; HR 0.65, 95% CI 0.59 – 0.72, p $<$ 0.001). Similarly, pts with high IFNγ signature scores had significant improvement in median OS (25.79 vs 16.22 months; HR 0.66, 95% CI 0.6 – 0.73, p $<$ 0.001). **Conclusions:** This study underscores the pivotal role of IFN signaling in TNBC. High IFNα and IFNγ signatures were consistently associated with improved RFS, OS, higher pCR rates, and lower RCB across clinical trial cohorts and real-world data. These findings signify IFN signaling as a potential key biomarker and therapeutic target in TNBC. MHC class I expression and outcomes in breast cancer in the real-world clinico-genomic data and the FinXX trial. First Author: Yi Liu, Department of Quantitative Health Sciences, Mayo Clinic, Phoenix, AZ

Background: Major histocompatibility complex class I (MHC I) plays a critical role in immune surveillance by binding peptides derived from intracellular proteins and presenting them on the cell surface for recognition by CD8+ T cells. Loss or downregulation of MHC I expression has been identified as a key mechanism of immune evasion in cancers. Here, we evaluated MHC I expression and outcomes in all subtypes of breast cancer (BC). **Methods:** 9,038 BC samples were analyzed via NGS (592-gene panel, NextSeq; WES/WTS, NovaSeq; Caris Life Sciences, Phoenix, AZ), including triple-negative BC (TNBC) 3,038, HER2-positive (HER2+) 1,082, and hormone receptor-positive (HR+HER2-) 4,918. Immune cell fractions were estimated using WTS deconvolution (Quantiseq). MHC I (*HLA-A*/*HLA-B*/*HLA-C*)-high (H) and -low (L) were classified by RNA expression above or below the 25th percentile. Real-world overall survival (OS) was derived from insurance claims and calculated from tissue collection to last contact using Kaplan-Meier. NanoString IO360 was performed in 114 samples from the FinXX trial (NCT00114816). Statistical significance was assessed using chi-square, Mann-Whitney U, ANOVA, and Cox regression with multiple comparison adjustments (q$<$.05). **Results:** TNBC had higher expression of *HLA-A* and *HLA-B* (median TPM: 169 and 191) compared to HER2+ (146.6 and 170, q$<$0.05) and HR+HER2- (141.7 and 157.5, q$<$0.05). However, there was no significant difference in *HLA-C* expression across 3 BC subtypes. In TNBC, MHC I-H tumors had higher frequencies of PD-L1 positivity (66.2% vs. 13.1%) as well as higher infiltration of B cells (4.5% vs. 3.2%), M1 macrophages (5% vs. 1.5%), M2 macrophages (4% vs. 2.1%), Tregs (2.8% vs. 0.8%), $CD8^+$ T cells (1.8% vs. 0%), dendritic cells (3.2% vs. 2.8%), higher T-cell inflamed score (137 vs. -144), and IFN*g* score (0.02 vs. -0.49) compared to MHC I-L TNBC (all q$<$.05). MHC I-H TNBC was associated with significant improvement in median OS (30.1 vs. 15.2 months, HR 0.55, 95% CI 0.46-0.65, p$<$0.0001). However, this survival difference was not observed in patients with MHC I-H vs. MHC I-L in HER2+ (HR 1.04, 95% CI 0.74-1.47, p = 0.81) and HR+HER2- (HR 0.87, 95% CI 0.75-1.02, p= 0.09) BC subtypes. We further validated the MHC I expression in the FinXX trial. Similarly, patients with MHC I-H had significant improvement in recurrence-free survival (HR 0.27, 95%CI 0.11-0.66, p = 0.002) and OS (HR 0.23, 95% CI 0.09-0.57, p = 0.0005) compared to MHC I-L. **Conclusions:** Our findings demonstrate that higher MHC I expression is associated with higher immune infiltration and improved outcomes in TNBC but not in HER2+ or HR+HER2- BC subtypes. These results suggest that MHC I expression plays a critical role in the tumor microenvironment of TNBC. Future studies are needed to evaluate the prognostic value and potential therapeutic target of MHC I in TNBC. Support: Breast Cancer Research Foundation, Bankhead Coley, W81XWH-18-1-0564. Impact of HER2 low status on pathologic response after neoadjuvant chemotherapy in TNBC: A large scale retrospective cohort study. First Author: Julia Tchou, University of Pennsylvania, Philadelphia, PA

Background: HER2 low status, defined as HER2 1+ or HER2 2+ and nonamplified by in-situ hybridization, has demonstrated the ability to identify a population of patients with triple-negative disease who benefit from trastuzumab deruxtecan in the metastatic setting. The implications of HER2 low status in the early-stage setting is unclear. This study evaluated whether HER2 low status impacts rates of pathologic complete response in response to neoadjuvant chemotherapy (NAC). **Methods:** Using the national cancer database (NCDB), patients with clinically invasive non-metastatic breast cancer between 2010-2021 were retrospectively identified (n=1,926,979). Patients with unknown receptor status or who did not have triple negative breast cancer (n=1,755,897) and those who did not have surgery (n=9,849) were excluded. Clinicopathologic, treatment, and outcome variables were compared using chi-square and anova tests. Subgroup analysis was performed among patients who received NAC and had available pathologic response results. Multivariable binary logistic regression was performed to assess clinical variables associated with pCR after NAC. Cox proportional hazards model was performed to assess clinical variables associated with overall survival (OS) in TNBC receiving NAC. **Results:** Of the 161,233 individuals eligible for analysis, 79,268 (49.4%) had HER2 low disease. The proportion of HER2 0, HER2 1+ and HER2 2+/ish negative (HER2 2+) were 50.6, 34.8, and 14.6% respectively. Overall, 49,994 (31%) individuals received NAC with an overall pCR rate of 42.9%. The pCR rate was significantly lower in those with HER2 2+/ish negative compared to those with HER2 0 TNBC at 39.9 vs. 44.2%, p $<$0.001. On multivariable analysis, HER2 1+ status trended towards a lower likelihood of pCR R 0.95, 95% CI 0.91-1.00, p=0.06) while HER2 2+/ish negative status was significantly associated with a lower likelihood of pCR (OR 0.87, 95% CI 0.82-0.94, p$<$0.001) compared to HER2 0 disease. Cox proportional hazards model analysis demonstrated that the strongest clinical factor for worse OS was non-pCR with HR 3.76, 95% CI 3.48 – 4.05, p$<$0.001 while neither HER2 1+ or HER2 2+/ish negative was associated with worse OS. **Conclusions:** In this analysis, tumors that were HER2 2+/ish negative were associated with a significantly lower pCR rate after NAC compared with HER2 0 tumors. This is the first large-scale study to demonstrate that HER2 low status may be prognostically unfavorable in early-stage TNBC. Examination of novel neoadjuvant therapeutic approaches tailored based on HER2 status including trastuzumab deruxtecan may be warranted to improve pCR rates and outcomes in patients with HER2-low early-stage breast cancer. Research Sponsor: None.

Reframing hormone-positive DCIS management: Effects of adjuvant therapies and surgical extent on any invasive recurrence. First Author: Thomas O'Keefe, University of California, San Francisco, San Francisco, CA

Background: The treatment of DCIS is still primarily informed by trials that are now decades old. We have learned since then that only invasive subsequent events, not in situ ones, increase a woman's risk of eventual metastasis and breast cancer mortality, and may necessitate more aggressive systemic treatment. This suggests a need for the reassessment of the impact of adjuvant therapies. **Methods:** Women diagnosed with a first breast cancer of unilateral hormone positive DCIS undergoing breast conserving surgery were identified in the Surveillance, Epidemiology and End Results Program registry. Propensity-matching was performed between treatment groups using age, race, lesion size and grade. Competing risks methods were used to estimate the cumulative incidence of any invasive event at 10 years and subdistribution hazard ratios (sHRs) were calculated from multivariate models adjusting for the same covariates used for matching. **Results:** A total of 14,189 patients diagnosed from 2007 to 2011 were eligible for matching, among whom 900 (6.3%) suffered a subsequent invasive event.A cohort was developed by matching from the smallest treatment group, lumpectomy with endocrine therapy. There were 2,996 matched patients, among whom 511 (17.1%) had an invasive subsequent event. Adjuvant endocrine therapy was associated with reduced risk of any invasive event (sHR=0.38, p$<$0.001) compared to patients undergoing lumpectomy without adjuvant therapy. Radiotherapy alone was not associated with reduced risk (sHR=1.03, p=0.81): it was associated with reduced risk of an ipsilateral invasive event (sHR=0.65, p=0.006) but an increased risk of a contralateral invasive event (sHR=1.50, p=0.01). In subgroup analyses, lumpectomy with radiation therapy was noted to be non-significantly associated with increased risk of any invasive disease in patients younger than 60 years (sHR=1.38, p=0.053) and with decreased risk in patients 60 years or older (sHR=0.79, p=0.12). **Conclusions:** Our results suggest that endocrine therapy may confer the greatest risk reduction to the development of any subsequent invasive recurrences, and whole-breast radiotherapy may be associated with increased risk for younger women. The risk posed by DCIS as a high-risk marker may outweigh its risk as a premalignant lesion. Research Sponsor: None.

Impact of postmastectomy radiotherapy on health-related quality of life and safety in breast cancer patients undergoing breast reconstruction: A multi-center cross-sectional study (Reborn-02). First Author: Hirohito Seki, Department of Breast Surgery, Kyorin University School of Medicine, Tokyo, Japan

Background: Postmastectomy radiotherapy (PMRT) is the standard treatment for improving the prognosis of patients with high-risk breast cancer. Expanded indications for breast reconstruction (BR) will likely increase the number of patients undergoing BR who require PMRT, but combining BR with PMRT raises concerns about complications and aesthetics. Evaluating the impact of PMRT on the health-related quality of life (HR-QOL) in Japanese patients is essential for shared decision-making (SDM). This study assessed differences in postoperative HR-QOL and complications between patients who underwent BR with or without PMRT. **Methods:** We conducted a multicenter cross-sectional study using a questionnaire survey of patients with primary breast cancer who underwent BR between January 2008 and December 2022 at participating institutions, which was approved by the respective institutional review boards. We used the Japanese version of the BREAST-Q questionnaire and questions on patient backgrounds. **Results:** We included 1078 patients with primary breast cancer. The questionnaire response rate was 77.0% (830/1078). The non-PMRT and PMRT groups comprised 616 and 214 patients, respectively. The PMRT group had higher rates of axillary lymph node dissection (11.7% vs. 52.4%; $P<0.001$), adjuvant hormonal therapy (67.2% vs. 90.6%; $P<0.001$), and perioperative chemotherapy (31.8% vs. 84.0%; $P<0.001$) than the non-PMRT group. Moreover, the overall complication rate (45.3% vs. 76.2%, $P<0.001$) and the rates of dermatitis (9.9 vs. 48.1%; $P < 0.001$), skin necrosis (2.9 vs. 9.8%; $P<0.001$), breast asymmetry (17.0% vs. 24.3%; P=0.002), capsular contracture (4.9 vs. 16.4%; $P<0.001$), and lymphedema of the upper limb (1.1% vs. 7.5%; $P<0.001$) were higher in the PMRT group. Multivariate analysis revealed PMRT as an independent risk factor for dermatitis, skin necrosis, and capsular contracture. In the BREAST-Q assessment, the PMRT group showed lower satisfaction with the breast (55 vs. 49; $P<0.001$), and with physical (85 vs. 76; $P<0.001$), psychosocial (55 vs. 49; $P<0.001$), and sexual well-being (36 vs. 34; P=0.021) than the non-PMRT group. Multiple regression analysis revealed PMRT as an independent factor associated with low BREAST-Q scores for breast satisfaction and physical and psychosocial well-being in patients with BR. **Conclusions:** This is the first large-scale, multi-institutional study to use patient-reported outcomes to assess the effects of PMRT on HR-QOL in Japanese patients with breast cancer who underwent BR. PMRT was associated with an increased risk of complications and decreased HR-QOL in patients with BR. Of note, these findings do not negate the role of PMRT in patients undergoing BR, but highlight the importance of SDM based on realistic HR-QOL expectations after breast reconstruction surgery with PMRT. Research Sponsor: None.

Development and validation of prediction models for 5-year and 10-year ipsilateral breast tumor recurrence after breast-conserving surgery. First Author: Yasuaki Sagara, Department of Breast Surgical Oncology, Social Medical Corporation Hakuaikai Sagara Hospital, Kagoshima, Japan

Background: Ipsilateral breast tumor recurrence (IBTR) remains a critical concern for patients undergoing breast-conserving surgery (BCS). Reliable prediction tools for IBTR risk can support personalized surgical strategies and adjuvant treatment decisions, especially in the era of evolving systemic therapies. This study aimed to develop and validate prediction models for 5-year and 10-year IBTR. **Methods:** This multi-center retrospective cohort study included 10,089 women who underwent partial mastectomy for invasive breast cancer between 2008 and 2017. Cases involving conversion to mastectomy, use of neoadjuvant chemotherapy, bilateral/multiple cancers, or missing key data were excluded. Prediction models were developed using Cox proportional hazards regression and validated via bootstrap resampling. Model performance was assessed using Harrell's C-index, Brier scores, calibration plots, and goodness-of-fit tests. The cumulative incidence of IBTR, which served as the baseline for the prediction model, was calculated using the Fine and Gray model, treating death as a competing risk. **Results:** The median age of patients was 55 years [interquartile range (IQR): 46–65]. During a median follow-up of 8.9 years (IQR: 6.4–10.8), IBTR occurred in 292 patients (3.1%). The initial model, based on variables from Sanghani et al. (JCO 2010), achieved a Harrell's C-index of 0.70. Incorporating hormonal receptor status, HER2 status, radiotherapy, and targeted therapy as predictors reduced the C-index to 0.60, despite their clinical relevance. Importantly, the inclusion of these factors improved calibration, demonstrating better alignment between predicted and observed IBTR probabilities. The final Cox model exhibited strong clinical and statistical robustness ($p < 0.001$), providing individualized IBTR risk estimates. Cox-Snell residual analysis confirmed goodness-of-fit, with the cumulative hazard closely following the 45-degree line up to 0.3, indicating reliable model performance for observed events. While hazard ratios (HRs) for chemotherapy and radiotherapy were consistent with results of EBCTCG meta-analyses (MA), HR for endocrine therapy was lower than reported in MA. Consequently, HRs from MA were adopted to account for treatment effects in our prediction model. **Conclusions:** We have developed and validated a new prediction model for 5-year and 10-year IBTR using Cox regression and bootstrap methods. A web-based tool is under development to enable individualized risk assessment and treatment planning. Future research will focus on external validation and the integration of genetic and novel therapeutic data to enhance model robustness and clinical utility. Research Sponsor: Japanese Breast Cancer Society.

Regional node recurrence after sentinel lymph node biopsy for ycN0 patients treated with primary chemotherapy in cT1-3N1M0 breast cancer (second report from SHARE study). First Author: Shigeru Imoto, Kyorin University, Mitaka, Japan

Background: Axillary management after sentinel lymph node biopsy (SLNB) is still debated for clinically node-positive breast cancer (BC) patients treated with neoadjuvant chemotherapy (NAC). The Japanese Society for Sentinel Node Navigation Surgery conducted a prospective non-randomized phase 2 study (SHARE study, UMIN000030558). False-negative rate (FNR) as the primary endpoint was reported at ASCO2023. In brief, it was 11.5% (90% confidence interval, 5.5% and 20.5%). When multimodal imaging, 1 nodal metastasis, multiple tracers, multiple sentinel lymph nodes were considered for subset analysis, the FNR was 12.1%, 9.1%, 11.1%, and 10.6%, respectively. Here we report a short-term prognosis of ycN0 BC patients. **Methods:** Clinical T1-3N1M0 BC was eligible. Nodal metastasis was histologically confirmed. In case of ycN0 BC, SLNB was planned and lymphatic mapping depended on each institutional practice. In cases of pN0(sn), pN0(i+)(sn) and pN1mi(sn), SLNB followed by lymph node sampling (LNS) had been allowed instead of axillary lymph node dissection (ALND). **Results:** Between February 2018 and May 2021, 185 patients from 19 institutes were registered. Twenty-seven cases were excluded by protocol deviation, non-ycN0 or withdrawal of SLNB. Among the 158 ycN0 cases, sentinel lymph nodes were detected in 153 cases. The median age was 52 years old. Clinical stage was IIA in 40 cases, IIB in 105 and IIIA in 8. Luminal subtype classified by ER, PR and HER2 expression was found in 60 cases, HER2 in 34, Luminal-HER2 in 35 and triple-negative in 24. SLNB alone was performed in 37 cases, SLNB and LNS in 72 and SLNB followed by ALND in 44. Regional nodal irradiation was planned in 63 cases. At the median follow-up of 24 months, 13 cases relapsed and 5 died of BC. Regional node recurrence-free survival rate at 2 years after surgery, disease-free survival rate and overall survival rate were 98.6%, 92.6% and 97.3%, respectively. **Conclusions:** SLNB-guided axillary management is feasible and safe in ycN0 BC after NAC. Clinical trial information: 000030558. Research Sponsor: The Japanese Society for Sentinel Node Navigation Surgery.

Preoperative axillary US and MRI in early-stage breast cancer: Potential to prevent unnecessary axillary surgery. First Author: Xin Wang, West China Hospital (China), Chengdu, China

Background: Recent studies, including the INSEMA and SOUND trials, have demonstrated that omitting sentinel lymph node (SLN) biopsy does not adversely affect survival outcomes. Notably, patients with positive axillary findings on ultrasound (US) tended to show more extensive axillary nodal metastasis on final histopathological examination. Thus, we aimed to focused on the advanced utility of preoperative axillary US and Magnetic Resonance Imaging (MRI) in preventing unnecessary axillary surgery in a large series of patients with early-stage breast cancer treated with both breast surgery and SLN biopsy. **Methods:** Between January 2012 to December 2023, a total of 7879 patients who underwent breast surgery for clinical T1–2/N0 cancers and SLN biopsy with or without axillary lymph node dissection were included. Preoperative axillary US and MRI findings were compared with clinical-pathologic variables, considering the presence of SLN metastasis. Patients with positive results routinely underwent US-guided fine needle aspiration biopsy (FNAB), and negative FNAB results were also considered. Multivariate logistic regression analysis was used to identify factors associated with SLN metastasis. **Results:** A total of 7879 eligible patients (47.48% with clinical T1 cancer and 52.52% with T2 cancer) were included in our study. Among them, 2048 (25.99%) had positive SLN biopsy, and 1971 (25.02%) underwent axillary lymph node dissection due to positive SLN biopsy. Patients with SLN metastasis were younger and had a higher frequency of positive axillary findings on US and MRI, as well as clinical T2 stage ($P<0.05$). At multivariate analysis, positive axilla at US (P =0.001), positive axilla at MRI (P =0.02), clinical T2 stage (P =0.004), grade 3 (P =0.004) and lymphovascular invasion (P=0.001) were significantly associated with SLN metastasis. The number of nodal metastases increase with increasing tumor size. Among 3595 (45.06%) patients with negative axilla at US and MRI and clinical T1 stage cancer, 698 (8.75%) had SLN metastasis. For these people, the median follow-up was 73.6 months. The estimated 5-year invasive disease–free survival rate was 96.8%, while the 5-year overall survival rate was 98.6%. The analysis of the first primary-outcome events (occurrence or recurrence of invasive disease or death from any cause), showed apparent differences between the positive axilla at US and MRI and clinical T1 stage cancer group and negative axilla at US and MRI and clinical T1 stage cancer group in the incidence of recurrence (4.7% vs. 3.2%) and death (2.0% vs. 1.4%). **Conclusions:** Preoperative axillary US and MRI results, along with clinical T stage are significant predictors of SLN metastasis in patients with early-stage breast cancer. The results of this study suggest that preoperative axillary US and MRI can help select patients at minimal risk of SLN metastasis, for whom axillary surgery could be omitted. Use of local estrogen therapy among breast cancer patients in SEER-MHOS database. First Author: Olivia Mitchel, University of Arizona- College of Medicine Tucson, Tucson, AZ

Background: Anti-hormonal therapy with tamoxifen or aromatase inhibitors is a key component in the treatment of hormone receptor-positive breast cancers. One of the adverse effects of this type of therapy is genitourinary syndrome of menopause, which may be treated with vaginal estrogen. It remains unclear whether local vaginal estrogen use carries any increased risk of recurrence or mortality in patients with a history of breast cancer. This has led to conflicting advice in the clinical setting and potentially unnecessary avoidance of hormone-based products that could possibly provide women symptomatic relief. Further exploration of the relationship between local estrogen therapy and breast cancer outcomes is warranted. **Methods:** A retrospective cohort study of 18,620 female breast cancer patients $\geq$ 65 years of age diagnosed between 2010-2017 in the SEER-MHOS registry was performed, comparing the breast cancer patients who used local vaginal estrogen (n=800) to those who did not (n=17,820), to assess whether local vaginal estrogen exposure was associated with any difference in overall survival as a primary outcome. Breast cancer specific survival was analyzed as a secondary outcome. Missing data was excluded by complete case analysis. Wilcoxon rank-sum tests were performed to compare continuous variables, Chi-square tests to compare categorical variables, Kaplan-Meier estimation to summarize overall survival, and sub-distribution hazard regression was performed to evaluate breast cancer specific survival by group. Multivariate regression models controlled for age, race, cancer stage, treatment (i.e. surgery, radiation, anti-hormonal therapy), and year of diagnosis. The research protocol was approved by our Scientific Review Committee and submitted for IRB approval. **Results:** There was a statistically significant increase in overall survival (HR=0.56, $p<0.0001$) as well as breast cancer-specific survival (HR=0.53, p=0.014) among breast cancer patients who used vaginal estrogen compared to those who did not. Among those who used vaginal estrogen, there was a statistically significant increase in overall survival for those with a duration of use >7 years (median duration of use) compared to those with a duration of use <7 years (HR=0.01, $p<0.0001$). Subset analysis restricted to patients with hormone positive breast cancer showed a statistically significant increase in overall survival for those who used vaginal estrogen compared to those who did not (HR=0.62, p=0.0007), and a nonsignificant increase in breast cancer specific survival (HR=0.62, p=0.08). **Conclusions:** The use of vaginal estrogen among this SEER-MHOS cohort of breast cancer patients showed improved survival outcomes. These findings add to a rising contemporary paradigm shift that local hormone therapy is not associated with increased risk to overall or breast cancer specific survival, which has important clinical implications. Efficacy and safety of post-mastectomy radiation therapy for patients with breast cancer after breast reconstruction: A retrospective multicenter cohort study (Reborn-03). First Author: Wakako Tsuji, Department of Breast Surgery, Shiga General Hospital, Moriyama Shiga, Japan

Background: A cornerstone of multidisciplinary treatment for breast cancer, breast reconstruction has recently been extended to high-risk patients with breast cancer who require post-mastectomy radiation therapy (PMRT). PMRT reduces the 10-year risk of locoregional recurrence; however, its association with postoperative complications remains unclear. This study aimed to evaluate the efficacy and safety of PMRT in patients with high-risk breast cancer who underwent breast reconstruction. **Methods:** This retrospective cohort study included patients with high-risk breast cancer who underwent immediate or delayed breast reconstruction after mastectomy between 2008 and 2018. High-risk patients were defined as those with positive axillary lymph nodes, clinical tumor size of >5 cm, chest wall invasion, or skin invasion. Patient data were collected from participating institutions and analyzed retrospectively. **Results:** Of the 1,138 patients, 427 (37.5%) underwent PMRT and 711 (62.5%) did not. The median age at surgery was 46 years (range, 23–76years), and the median follow-up period was 8 years. The number of patients meeting more than two high-risk criteria was 149 (23.9%) and 81 (11.4%) in the PMRT and non-PMRT cohorts, respectively. Breast reconstruction using silicone breast implants (SBI) was performed in 70% and 71.4% of patients in the PMRT and non-PMRT cohorts, respectively. The locoregional recurrence rates were 7.7% and 12.7% in the PMRT and non-PMRT cohorts, respectively (P=0.034). Multivariate analysis revealed that PMRT was an independent predictive factor for reducing locoregional recurrence ($P<0.001$) (Table 1). Complications occurred in 130 patients (30.4%) in the PMRT cohort and 168 (23.6%) in the non-PMRT cohort (P=0.016). The reoperation rates due to complications were 46 (35.4%) in the PMRT cohort and 61 (36.3%) in the non-PMRT cohort (P = 0.100). In the PMRT cohort, 62 patients (14.5%) experienced grade 2 radiation-induced dermatitis, and three patients (0.7%) developed grade 2 radiation-induced pneumonia. **Conclusions:** Although the incidence of adverse events was slightly higher in the PMRT cohort, the reoperation rates due to complications were comparable between the cohorts. PMRT is a safe and effective modality that provides substantial benefits for locoregional recurrence reduction in patients with high-risk breast cancer undergoing breast reconstruction. Research Sponsor: None.

Multivariate analysis for locoregional recurrence in patients with high-risk breast cancer who underwent breast reconstruction.

Factors	Hazard ratio	95% Confidence interval	P-value
PMRT	0.40	0.251-0.623	<0.001
Neoadjuvant therapy	3.43	2.29-5.12	<0.001
pT (>5 cm)	1.95	1.25-3.03	0.003
Surgical margin	1.96	1.01-3.81	0.047

Implications for sentinel lymph node biopsy (SLNB) omission in patients with early-stage node-negative HR+/HER2- breast cancer undergoing mastectomy. First Author: Jennifer Hechao Chen, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: The SOUND and INSEMA trials demonstrated non-inferiority of SLNB omission in HR+/HER2- early-stage breast cancer (BC) patients with negative axillary ultrasound (AUS) undergoing breast conserving therapy (BCT). However, it remains unclear if this approach may be applied to patients receiving mastectomy. We evaluated outcomes in a similar patient population receiving BCT versus mastectomy. **Methods:** Using an institutional database (2010-2023), we identified patients with cT1N0M0 HR+/HER2- unifocal invasive ductal carcinoma with negative AUS who underwent upfront BCT (breast conserving surgery + Radiation therapy [RT]) or mastectomy +/- RT. All patients underwent SLNB. Clinicopathologic and treatment characteristics were compared by surgery type as well as clinical outcomes. **Results:** Among 1,506 patients, median age was 59 years (IQR 51-67), and 80% were postmenopausal. BCT was performed in 78.2% (n=1,178) while 21.8% (n=328) underwent mastectomy. Patients who underwent mastectomy were more likely to be younger, premenopausal, with larger and higher grade tumors (Table). SLN positivity rate was 7.7% with no significant differences by surgery type (7.6% vs 8.2%, p=0.684). Only 4 (1.2%) and 2 (0.2%) patients had pN2 disease in the mastectomy and BCT cohorts, respectively. More patients undergoing mastectomy had axillary lymph node dissection compared to patients undergoing BCT (6.96% vs 0.3%, $p<0.001$). Among mastectomy patients, 10.1% received RT with higher rates in node-positive patients (52.9% vs 5.1%, $p<0.0001$). Similarly, chemotherapy use was higher among node-positive mastectomy patients (76.5% vs 22.5%, p=0.0001). Among SLN-positive postmenopausal patients with 21-gene recurrence score (RS) <25, chemotherapy use was 16.6% (2/12) after BCT and 0% (0/4) after mastectomy. When RS was >26, chemotherapy use was 60% (27/45) after BCT and 85.7% (12/14) after mastectomy. Median follow up was 25.3 months (IQR 13.2-58.9). There were 3 (0.2%) axillary recurrences with 2 recurrences after mastectomy (1 of whom received RT). There were 7 (0.46%) distant recurrences, with 2 following mastectomy. **Conclusions:** Among patients with cT1N0M0 HR+/HER2- invasive ductal carcinoma with negative AUS, positive SLNs were identified in 7.7% with only 0.46% having pN2 disease. Low axillary and distant recurrence rates were observed regardless of surgery type. However, given that nodal status impacts RT use among mastectomy patients, further research investigating omission of SLNB in this cohort is warranted. Research Sponsor: None.

Serial circulating tumor DNA (ctDNA) monitoring in early-stage, HR+/HER2-, invasive lobular carcinoma (ILC) of the breast and impact on clinical outcomes. First Author: Julia Foldi, University of Pittsburgh Medical Center (UPMC), Pittsburgh, PA

Background: ILC accounts for ~10-15% of breast cancer (BC) cases in the US with difficult-to-diagnose patterns of metastasis. Loss of E-cadherin (*CDH1*) is the pathognomic feature of ILC. Tumor-informed ctDNA assays detect molecular residual disease in patients who completed definitive therapy for early-stage BC. However, little is known about the ctDNA dynamics and its prognostic relevance in ILC specifically. Here, we assessed actionable genomic alterations and correlated ctDNA dynamics with clinical outcomes in patients with HR+/HER2- ILC. **Methods:** We utilized Natera's proprietary real-world database linked to commercially available claims data and commercial ctDNA testing via a clinically validated, personalized, tumor-informed mPCR-NGS ctDNA assay (Signatera, Natera, Inc.) to identify patients with early-stage, HR+/HER2- ILC. Tumors with *CDH1* truncated alterations from tumor whole exome sequencing were categorized as ILC. HR+/HER2- tumors were categorized using treatment regimens from insurance claim codes. Targetable alterations in *PIK3CA*, *AKT*, *PTEN*, *BRCA1*, *BRCA2*, *ESR1*, NF1, and *ERBB2* were assessed. ctDNA positivity rates and distant recurrence-free survival (DRFS) were evaluated using longitudinal ctDNA status (ctDNA + or -). The timing of ctDNA+ after primary BC surgery was divided into two categories: <2 years (y) and >2y. **Results:** 430 patients with early-stage HR+/HER2- ILC and ctDNA testing were identified. The most common targetable alterations co-mutated with *CDH1* were in *PIK3CA* (54.4%), *AKT1* (5.1%), *NF1* (4.9%), and *ERBB2* (4.6%). The first ctDNA test was performed on 258 (59.3%) and 172 (39.5%) patients within or after 2y surgery, respectively. Of 430 patients, 88 (20.2%) had >1 ctDNA+ test. A ctDNA+ result was reported in 31/258 (12%) and in 57/172 (33.1%) patients with testing within or after 2y surgery, respectively. Longitudinal ctDNA+ was associated with DRFS based on distant secondary malignant neoplasm claim codes. Among patients with a ctDNA- test within 2y, only 2.83% (6/212) presented a DRFS event compared to 48% (12/25) of ctDNA-+ cases (Odds ratio 31, p-value=1.42E-9). In patients with a ctDNA- test after 2y, only 2.06% (2/95) presented a DRFS event compared to 37.5% (9/24) of ctDNA+ cases (Odds ratio 27, p-value=4.92E-6). **Conclusions:** To our knowledge, this is the first large-scale analysis of the landscape of targetable genomic alterations and matching longitudinal ctDNA and outcomes in patients with early-stage, HR+/HER2- ILC. We find that *PIK3CA* is most frequently co-mutated with *CDH1*, and a comparison with the *CDH1* wildtype cohort will be presented. These data provide insights into the ability of ctDNA to detect recurrence earlier, including sites associated with challenges in the interpretation of imaging results in the early-stage ILC setting. TROP2 overexpression as predictor of outcome in patients with early triple-negative breast cancer. Exploratory analysis from the GEICAM_CIBOMA trial. First Author: Federico Gustavo Rojo Todo, Hospital Universitario Fundación Jiménez Díaz; CIBERONC-ISCCIII; GEICAM Spanish Breast Cancer Group, Barcelona, Spain

Background: Antibody-drug conjugates (ADCs) have emerged as a promising therapeutic strategy for triple-negative breast cancer (TNBC), a subtype with limited treatment options and poor prognosis. Understanding the biological and prognostic/predictive implications of biomarkers for these ADCs could help refine appropriate adjuvant treatment for high-risk TNBC. TROP2-targeted ADC sacituzumab govitecan has demonstrated significant improvements in progression-free and overall survival in clinical trials involving the advanced TNBC setting. We sought to explore the prognostic/predictive value of TROP2 expression by immunohistochemistry (IHC) in early TNBC patients (pts) from the GEICAM_CIBOMA trial (NCT00130533). **Methods:** We evaluated TROP2 expression by IHC using an anti-TROP2 monoclonal antibody (clone ERP20043, Abcam) in tumors from a subset of 70 TNBC pts included in the trial. These patients received either 6 months therapy with capecitabine (n=35) or observation (n=35) after receiving standard (neo)adjuvant chemotherapy (trial recruitment between 2006 and 2011). Semi-quantitative Histoscore (H-score) was estimated to consider the following TROP2 expression categories: H-score 0 to $<$100: TROP2 low; H-score 100-200: TROP2 medium; H-score $\geq$200: TROP2 high. Median TROP2 H-score was also explored for pts categorization. Cox regression models were assessed to predict DRFS (primary endpoint), DFS and OS (secondary endpoints). Multivariate models were adjusted for confounding factors, including histological grade, stage, chemotherapy regimen, and treatment. **Results:** The TROP2 H-score median value was 165. Medium/high TROP2 expression (H-score $\geq$100) was observed in 27 (77%) pts treated with capecitabine, and 25 (71%) in the observation group. Higher TROP2 expression was associated with higher histological grade (p=0.032). Medium/high TROP2 expression significantly associated with better DRFS (univariate analysis, HR=0.41; 95%CI 0.19-0.90; p=0.026; multivariate analysis, HR=0.24; 95% CI 0.10-0.60; p=0.002). This prognostic value was confirmed at DFS (multivariate analysis, HR=0.33; 95%CI 0.14-0.77; p=0.010) and OS (multivariate analysis, HR=0.29; 95%CI 0.11-0.76; p=0.011). High TROP2 expression by median value (H-score $\geq$165) was also associated with better clinical outcome (DRFS univariate analysis, HR=0.43; 95%CI 0.19-0.97; p=0.041; multivariate analysis, HR=0.44; 95%CI 0.19-1.02; p=0.057). TROP2 expression categorization did not demonstrate predictive value of capecitabine benefit (DRFS interaction with treatment, p=0.852). **Conclusions:** In this GEICAM_CIBOMA trial sub-study, TROP2 overexpression by IHC was observed in 74% of the analyzed cases and significantly associated with better clinical outcome in early TNBC pts, in terms of DRFS, DFS, and OS. Clinical trial information: NCT00130533. Research Sponsor: Sociedad Española de Oncologia Medica SEOM (SEOM/FECMA Grant 2022).

Disparities in demographics and outcomes of breast cancer in females undergoing mastectomy in rural vs. urban teaching centers. First Author: Harkaran Shergill, Maulana Azad Medical College, New Delhi, India

Background: Breast cancer (BC) sensitization, awareness, and increased screening have led to significant improvements in prevention, management, and survival rates over the last three decades. Recent reports have shown that the use of prophylactic and therapeutic mastectomy is on the rise. Previous studies have revealed healthcare disparities between rural (RC) and urban teaching centers (UTC), which may influence outcomes. In this retrospective study, we propose to explore the presence of similar disparities among BC patients undergoing mastectomy in rural hospitals vs. UTC. **Methods:** For this study, we extracted procedures of mastectomy among BC females through the hospitalization records of the National Inpatient Sample (NIS). We stratified our sample into procedures performed at RC and UTC. Procedural and postprocedural complications were compared through multivariable regression models. **Results:** We studied 75915 BC patients who underwent mastectomy between 2016 and 2022. Around 93.2% of our sample involved procedures performed at UTC, with 6.8% conducted at RC. Procedures at RC involved an older group(mean age 66.18 years vs. 57.19 years, $p < 0.01$), with a higher Charlson Comorbidity Index (CCI) score(mean score 3.79 vs. 3.53, $p < 0.01$). An estimated 91.6% of all procedures were performed on an elective basis(88.8% of rural and 91.9% of UTC, $p < 0.01$). Metastasis was present in 25.5% of all cases (25.4% of UTC and 25.8% of rural cases, p = 0.591). Mastectomies performed at RC had higher odds of bleeding (aOR 1.170, 95% CI 1.075-1.272, $p < 0.01$), sepsis (aOR 2.163, 95% CI 1.557-3.004, $p < 0.01$), postprocedural respiratory failure (PPRF) (aOR 2.667, 95% CI 1.479-4.808, $p < 0.01$), need for mechanical ventilation (MV) (aOR 2.732, 95% CI 1.845-4.046, $p < 0.01$), ischemic stroke (aOR 5.073, 95% CI 2.884-8.922, $p < 0.01$), and cardiac arrest (aOR 8.443, 95% CI 4.861-14.666, $p < 0.01$). Acute kidney injury events were similar (aOR 1.160, 95% CI 0.945-1.423, p = 0.155). The odds of all-cause death were higher among RC procedures (aOR 5.401, 95% CI 3.456-8.442, $p < 0.01$). **Conclusions:** The findings of this study have significant implications for healthcare policies. BC patients undergoing mastectomy in rural areas were significantly older and had a higher CCI score. Moreover, rural procedures reported higher risks of bleeding, sepsis, stroke, cardiac arrests, PPRF, MV use, and death. These results highlight the need for additional studies to establish the causes of these disparities, which may reflect the need for improving healthcare services in rural areas. Furthermore, encouraging RC to set up review protocols on their adverse events through Ishikawa diagrams may help identify probable healthcare inequities compared to UTC, which can then be remedied. This research has the potential to influence policy changes that could improve outcomes for rural BC patients. Research Sponsor: None.

Changes in the degree of satisfaction and quality of life in breast cancer patients who are candidates for breast conservation but opted for mastectomy: A single-center prospective study. First Author: Changhoon Lee, Department of Surgery, Seoul National University Hospital, Seoul National University College of Medicine, Seoul, South Korea

Background: Randomized trials have shown that breast-conserving surgery (BCS) and total mastectomy (TM) provide comparable survival outcomes for early breast cancer patients. Consequently, the choice of surgery is now considered a preference-based shared decision-making process. While studies have examined quality of life (QoL) in TM and BCS patients, it remains unclear how choosing TM over BCS affects postoperative QoL and satisfaction. This single-center prospective trial investigated the longitudinal impact of TM on QoL and satisfaction in the BCS-eligible patients who voluntarily opted for TM. **Methods:** We prospectively screened newly diagnosed breast cancer patients who are eligible for BCS based on the preoperative clinical assessment between Nov 2021 and June 2024 at Seoul National University Hospital. Patients were allowed to choose between TM and BCS through the shared decision-making process, and were enrolled according to the selected surgical method. A series of surveys were conducted using the BREAST-Q questionnaire and Decision Regret Scale (DRS) before and between 6-24months following surgery and then compared the results between two groups. **Results:** A total of 68 patients were enrolled; 28 opted for TM, and 40 underwent BCS, with two patients lost to follow-up in the TM group. The TM group was significantly older than the BCS group (57.92 vs. 51.43 years, p=0.015), and had larger preoperative tumor sizes (25.77mm vs. 17.88mm, p=0.001). Postoperatively, satisfaction with the breast (62.0 vs. 53.3, p=0.013) and physical well-being (chest) (83.9 vs. 77.5, p=0.004) decreased significantly. Satisfaction with the breast was significantly lower in the TM group compared to BCS (62.7 vs. 38.7, $p<0.001$). Psychosocial well-being (80.3 vs. 58.1, $p<0.001$), sexual well-being (55.3 vs. 24.2, $p<0.001$), and physical well-being (80.9 vs. 72.9, p=0.043) were all lower in the TM group. When comparing pre- and postoperative scores, the TM group experienced greater declines in breast satisfaction (-1.38 vs. -21.34, p=0.007), psychosocial well-being (5.71 vs. -8.40, p=0.004), and sexual well-being (1.55 vs. -17.83, p=0.004). The TM group also had significantly higher DRS scores (21.92 vs. 13.52, p=0.036), indicating greater regret. **Conclusions:** Our data demonstrates that patients who opted for TM over BCS for their breast cancer surgery may experience more profound decline in QoL and higher degree of regret after their surgery. These findings should be incorporated into the shared decision-making process when choosing optimal surgical treatment in early breast cancer patients who are eligible for BCS. Research Sponsor: None.

Bilateral mastectomy and breast cancer morality for invasive lobular carcinoma: A SEER-based study. First Author: Richa Jaiswal, Women's College Hospital, University of Toronto, Toronto, ON, Canada

Background: Many women with unilateral breast cancer opt for bilateral mastectomy. While removing the unaffected contralateral breast lowers the risk of second primary cancers, there is no benefit on breast cancer mortality. Studies have not investigated whether this holds true for invasive lobular carcinoma (ILC). To estimate the 20-year risk of breast cancer mortality in women with stage I-III unilateral ILC and compare survival outcomes between unilateral lumpectomy, unilateral mastectomy and bilateral mastectomy. **Methods:** This retrospective cohort study used the Surveillance, Epidemiology, and End Results (SEER) database to identify women diagnosed with unilateral invasive lobular carcinoma (ILC) between 2000 and 2020. The cohort was followed for up to 20 years to assess contralateral breast cancer and breast cancer-specific survival. We estimated crude mortality rates, 20-year cumulative breast cancer mortality, and hazard ratios by surgical treatment group. Kaplan-Meier was used for cumulative risk, and Cox proportional hazards models for unadjusted and adjusted hazard ratios with 95% confidence intervals. P-values < 0.05 were considered significant. **Results:** We identified 58,861 women with unilateral ILC. Of which, 34,561 (59%) had lumpectomy, 18,894 (32%) had unilateral mastectomy, and 5406 (9.1%) had bilateral mastectomy. The mean age (in years) was 64 $\pm$11 for unilateral lumpectomy, 62 $\pm$13 for unilateral mastectomy, and 57$\pm$11 for bilateral mastectomy ($p < 0.0001$). The mean tumour size was smallest in the lumpectomy group (1.9$\pm$1.5 cm) compared with 3.6$\pm$ 3 cm in both unilateral and bilateral mastectomy groups ($p < 0.0001$). The 20-year cumulative invasive contralateral breast cancer risk was 7.3% for lumpectomy, 7.5% for unilateral mastectomy, and 0.3% for bilateral mastectomy. The 20-year cumulative breast cancer mortality was 13.4% in the lumpectomy group, 30.2% in unilateral mastectomy group and 24.3% in bilateral mastectomy group. However, after adjusting for demographic, clinical, and treatment variables, we observed no difference in breast cancer mortality rates among unilateral mastectomy patients versus lumpectomy patients (adjusted hazard ratio [aHR], 1.01; 95% CI, 0.94–1.08), and a statistically significant reduction in breast cancer mortality rates among bilateral mastectomy patients compared to lumpectomy patients (aHR, 0.90; 95% CI, 0.82–1.00; p value 0.04). **Conclusions:** In this cohort of invasive lobular breast cancer, bilateral mastectomy patients had a significantly lower risk of contralateral breast cancer and, after adjusting for differences in the surgical treatment groups, had a 10% lower rate of breast cancer mortality as compared to lumpectomy patients. Research Sponsor: None.

Evaluating the outcome of cardiovascular risk factors in breast cancer patients. First Author: Michelle Koifman, The Brooklyn Hospital Center, Brooklyn, NY

Background: Breast cancer patients are at increased risk of cardiovascular disease due to factors such as treatment-related toxicity and shared comorbidities. This study analyzes demographics and outcomes of cardiovascular risk factors in hospitalized breast cancer patients using nationwide data to guide improved care strategies. **Methods:** We used the National Inpatient Sample Database (2016 to 2020) to perform the analysis. ICD-10 codes were used to make the primary diagnosis of patients with breast cancer admitted to hospitals, and secondary diagnosis of various cardiac risk factors. We used the chi-square test and the student's T-test to analyze categorical and continuous variables. Multivariable regression analysis was used to adjust for confounders and calculate adjusted odds ratio (aOR). Statistical significance was set at $p < 0.05$. **Results:** A total of 855394 patients were detected with primary diagnosis of breast cancer. Out of them, 11% had coronary artery disease (CAD), 13% had congestive heart failure (CHF), 6% had atrial fibrillation, 1% had ventricular arrhythmias and 0.06% had endocarditis. The prevalence of cardiac risk factors was mostly in older adults. The mean age of patients with CAD and CHF was 73 years, atrial fibrillation was 75 years, ventricular arrhythmias was 69 years and endocarditis was 71 years. The mortality was found to be higher in patients with cardiac risk factors as well. The patients with coronary artery disease had aOR of 1.9 (p-value 0.02), congestive heart failure had 1.3 (p-value <0.001), atrial fibrillation had aOR 1.1 (p-value 0.001), for ventricular arrhythmias was 3 (p-value <0.001) and for endocarditis was 1.4 (p-value 0.3). **Conclusions:** Breast cancer patients with cardiovascular risk factors experience significantly higher mortality rates compared to those without. These findings emphasize the need for early cardiovascular risk assessment and proactive management in breast cancer patients to improve outcomes and reduce complications. Research Sponsor: None.

Outcomes of cardiovascular disease in breast cancer patients.

Mortality	With Cardiac Risk Factors	Without Cardiac Risk Factors	Adjusted Odds Ratio	Adjusted Odds Ratio
Coronary Artery Disease	4.7%	4.5%	1.9	0.02
Congestive Heart Failure	6.6%	4.3%	1.3	<0.001
Atrial Fibrillation	5.5%	4.5%	1.1	0.01
Ventricular arrhythmias	12%	4.5%	3.0	<0.001
Endocarditis	6.6%	4.6%	1.4	0.3

Gene expression signatures (GES) derived from digital histology to predict pathologic complete response (pCR) to neoadjuvant chemotherapy (CT) in ISPY2 and other trial/real world cohorts. First Author: Frederick Matthew Howard, University of Chicago, Chicago, IL

Background: GES predictive of response to therapy across multiple breast cancer subtypes are commercially available or in development. Deep learning models can predict GES from digital histology, and may serve as a lower-cost alternative immediately available at the time of biopsy. **Methods:** Transformer-based models trained to predict 38 distinct breast cancer signatures from pathology (all with Pearson correlation > 0.5 versus true GES) were previously developed using cases from The Cancer Genome Atlas. These models were applied to digital H&E from pre-treatment biopsies from HER2- cases treated with CT or CT + immunotherapy (IO) from the ISPY2 trial. The histology-derived GES most predictive of pCR in ISPY2 (as per area under the ROC curve [AUROC]) was tested in two external neoadjuvant cohorts - a subset of a trial from Yale of durvalumab + CT (NCT02489448) with TIL annotations, and patients receiving standard of care CT at University of Chicago. AUROC significance was assessed with 1000x bootstrapping, with Benjamini Hochberg correction applied in ISPY2 to account for testing multiple GES models. Tertiles of predicted expression calculated in ISPY2 defined groups with low, medium, and high likelihood of pCR; these cutoffs were tested in the external cohorts. **Results:** Accuracy for pCR prediction was tested in 578 patients from seven arms of ISPY2 – with breakdown by treatment and hormone receptor (HR) status shown in Table. A histology model for a GES defined by estrogen regulated genes (Oh et al, JCO 2006) – including proliferation, apoptosis, and interferon-response genes – predicted pCR with the highest AUROC (0.794) in ISPY2, and outperformed a logistic regression fit on grade, HR status, and tumor / nodal stage (AUROC 0.705, p for comparison 0.0001). Tertiles of predicted expression for this GES (computed in ISPY2) identified groups with low / high pCR rates which were robust to treatment, HR status, and consistent in validation cohorts (Table). This digital signature (AUROC 0.737) compared favorably to pathologist TIL annotation (AUROC 0.664) from the external Yale cohort. An explainability tool demonstrated that patterns of lymphocytic infiltrate and poor differentiation contributed to high signature predictions from histology. **Conclusions:** A digital histology-derived GES consistently identifies patients at low / high likelihood of pCR with neoadjuvant CT or CT + IO, and may improve treatment personalization. Research Sponsor: National Cancer Institute/U.S. National Institutes of Health.

Subgroup	n	AUROC	p	% pCR (low expression)	% pCR (mid expression)	% pCR (high expression)

Neoadjuvant penpulimab combined with taxanes and carboplatin in triple-negative breast cancer: A single-arm, open-label, multi-center phase II clinical study (neoTAPPL). First Author: Wenting Yan, Department of Breast and Thyroid Surgery, Southwest Hospital, Army Medical University; Key Laboratory of Minimally Invasive Surgery and Precision Treatment for Breast Cancer of Chongqing Municipal Health Commission, Chongqing, China

Background: The integration of immunotherapy with neoadjuvant chemotherapy has been shown to enhance pathologic complete response (pCR) and survival outcomes in patients with triple-negative breast cancer (TNBC). Nonetheless, additional research is required to ascertain the optimal neoadjuvant regimen. Here we present a prospective phase II NeoTAPPL trial in which evaluated the efficacy and safety of penpulimab (anti-PD-1 antibody) in combination with taxanes and carboplatin for TNBC patients. **Methods:** In this open-label, multi-center phase II study, patients with untreated, histologically confirmed TNBC in stage II-III were enrolled. Patients received 6 cycles of neoadjuvant therapy with penpulimab (200 mg, d1, q3w) plus taxanes (docetaxel 75 mg/m^2 or nab-paclitaxel 260 mg/m^2, d1, q3w) and carboplatin (AUC=6, d1, q3w). Patients who either completed or discontinued the neoadjuvant treatment would undergo breast surgery. Adjuvant chemotherapy and immunotherapy were at the discretion of the treating physician, and radiation therapy was per standard of care. The primary endpoint was the rate of pCR based on the definition of ypT0/Tis ypN0. Secondary endpoints included residual cancer burden (RCB), event free survival (EFS), overall survival (OS), adverse events (AE), and immune response biomarkers. **Results:** 50 patients were enrolled, among which 37 patients received neoadjuvant treatment and underwent breast surgery. The median age was 51 years (range, 32-72). 33 (89.2%) patients had stage II breast cancer at diagnosis. 21 of the 37 patients achieved pCR (56.7%; 95% CI, 40.9%-71.3%), and 29 patients achieved RCB 0-1 (78.4%; 95% CI, 62.8%-88.6%). The ORR and DCR were 86.5% (95% CI, 72.0%-94.1%) and 91.9% (95% CI, 78.7%-97.2%), respectively. Subgroup analysis showed that 60.6% (20/33) patients with stage II had achieved pCR, 25% (1/4) patients with stage III reached this outcome. The pCR rate was 56.5% (13/23) in patients with negative lymph nodes, and 57.1% (8/14) in those with positive lymph nodes. Treatment-emergent adverse events (TEAEs) of any grade occurred in all 37 pts, in which 20 (54.1%) were grade ≥3. The most common grade ≥3 TEAEs were neutropenia (43.2%), leukopenia (24.3%), anemia (21.6%), and thrombocytopenia (18.9%). 15 patients (40.5%) experienced immune related adverse events (irAEs), all of which were hypothyroidism. **Conclusions:** In this trial, we demonstrated that an anthracycline-free neoadjuvant regimen consisting of penpulimab, carboplatin and taxanes in TNBC showed promising antitumor efficacy and manageable safety profile. The study is still ongoing. Clinical trial information: ChiCTR2300071925. Neoadjuvant low-dose carboplatin and docetaxel in combination with toripalimab for early or locally advanced triple-negative breast cancer (NeoTOP): A single-arm phase 2 trial. First Author: Jun Tang, Sun Yat-sen University Cancer Center, Guangzhou, China

Background: Neoadjuvant immunotherapy combined with chemotherapy improves the rate of pathological complete response (pCR) and prognosis of triple-negative breast cancer (TNBC). However, chemo-immunotherapy treatment is frequently associated with adverse events, resulting in dose reduction and delays. Approaches to deescalate chemo-immunotherapy without compromising outcomes for TNBC patients are needed. Evidence suggests that low-dose carboplatin potentiates the anti-tumor effect of PD-1 inhibitors through many mechanisms. The NeoTOP trial aimed to assess the efficacy and safety of low-dose carboplatin and docetaxel in combination with toripalimab as neoadjuvant therapy for early or locally advanced TNBC. **Methods:** This is a single-arm, open-label, phase 2 trial. Patients with untreated stage IIA-IIIC TNBC were enrolled. Eligible patients received carboplatin (AUC=4), docetaxel (75 mg/m^2) and toripalimab (240 mg), every 21 days for a total of 6 cycles. Toripalimab (240mg, every 3 weeks) continued post-operatively for a further 11 cycles. The primary endpoint was the rate of pCR (ypT0/Tis ypN0). The secondary endpoints included safety, objective response rate (ORR), residual cancer burden (RCB) rate, event-free survival and overall survival. This study used Simon's two-stage design. **Results:** From January 2022 to September 2024, 51 patients were enrolled. Among them, 29 patients (56.9%) had stage II, and 22 (43.1%) had stage III. Four patients prematurely discontinued study treatment due to adverse events (three patients) or tumor progression (one patient), including two discontinued toripalimab only and two discontinued both toripalimab and chemotherapy. One of the four patients who discontinued treatment achieved a pCR when proceeding to surgery. One patient achieved clinical CR after neoadjuvant therapy and refused to receive surgery. After surgery, pCR in both breast and lymph nodes was achieved in 29 of 50 patients, resulting in a pCR rate of 58.0%. For all the 51 patients who received at least one dose of neoadjuvant therapy, the ORR was 90.2%. The proportions of RCB-0, RCB-1, RCB-2, and RCB-3 were 58%, 12%, 22%, and 8%. All 51 (100%) patients reported any grade of treatment-related adverse events (TRAEs). Grade ≥3 TRAEs occurred in 23 (45.1%) patients. Serious adverse events were reported in 5 (9.8%) patients. The regimen was well tolerated, and no new toxicity signals were noted. **Conclusions:** The combination of low-dose carboplatin, docetaxel, and toripalimab showed promising efficacy and manageable safety, suggesting the feasibility of this regimen in the neoadjuvant setting for TNBC. Further randomized phase III trials are warranted. Clinical trial information: NCT06618014. Research Sponsor: None.

Post-treatment MRI to predict pathological complete response in triple-negative breast cancer following neoadjuvant chemoimmunotherapy. First Author: Toulsie Ramtohul, Institut Curie, Paris, Ile de France, France

Background: Neoadjuvant chemoimmunotherapy (NACI) has significantly improved pathological complete response (pCR) rates in early-stage triple-negative breast cancer (TNBC). However, the predictive accuracy of post-treatment MRI for pCR remains unexplored. Our objective was to assess the performance of post-treatment MRI in predicting pCR in TNBC patients treated with NACI. **Methods:** In this prospective, multicenter study (August 2021–June 2024), women with early-stage TNBC were recruited from three centers. Post-treatment dynamic contrast-enhanced (DCE) MRI data were analyzed across multiple vendors. The predictive performance of radiological complete response (rCR) on MRI for pCR was evaluated using the area under the curve (AUC) of receiver operating characteristics. A multivariable logistic regression model incorporating rCR, nodal involvement, and Ki-67 levels was developed and validated. For patients with residual enhancement, a radiomics score was generated using first-order and shape-based features. **Results:** The study included 175 women in a training set from centers #1 (mean age 49 ± 11 years) and 84 in an external test set from centers #2 and #3 (mean age 52 ± 12 years). MRI rCR achieved an AUC of 0.83 (95% CI: 0.75–0.92) for pCR prediction. A combined model with rCR, nodal status, and Ki-67 levels yielded an AUC of 0.88 (95% CI: 0.81–0.96) in the test set. Among patients with rCR, no nodal involvement, and Ki-67 >30%, the false-positive rate was 3.6% and 3.5% in the training and test sets, respectively, with all cases limited to Residual Cancer Burden-I. For patients with residual enhancement, a model incorporating a radiomics score and lesion count achieved an AUC of 0.80 (95% CI: 0.69–0.90). **Conclusions:** Post-treatment MRI effectively predicts pCR in early-stage TNBC after NACI, suggesting its potential role in identifying candidates for breast cancer surgery omission trials. Research Sponsor: Institut Curie.

Accuracy of rCR for predicting pCR.

Set	Subgroup	Sensitivity (%)	Specificity (%)	PPV (%)	NPV (%)	F1 score (%)
Training	N0 and Ki-67>30%	81 (54/67) [71,90]	86 (12/14) [67, 99]	96 (54/56) [92, 99]	48 (12/25) [28, 68]	88
External test	N0 and Ki-67>30%	82 (28/34) [70, 95]	92 (11/12) [76, 99]	97 (28/29) [90, 99]	65 (11/17) [42, 87]	89

Note-Unless otherwise specified, the data are presented as percentages, with the numbers of participants in parentheses and 95% CIs in brackets; pCR = pathological complete response; PPV = positive predictive value; NPV = negative predictive value.

Efficacy and safety of neoadjuvant TQB2102 in women with locally advanced or early HER2-positive breast cancer: A randomized, open-label, multi-centre phase 2 trial. First Author: Junjie Li, Shanghai Cancer Center, Shanghai, China

Background: Standard neoadjuvant regimens for HER2-positive breast cancer include trastuzumab and pertuzumab combined with chemotherapy, and the efficacy and safety of third-generation HER2-direted antibody-drug conjugate (ADC) is unknown. TQB2102 is an anti-HER2 antibody-drug conjugate that targets two non-overlapping epitopes of HER2 (ECD2 and ECD4). It consists of a humanized HER2 IgG1 bispecific antibody conjugated to a topoisomerase I inhibitor via a cleavable linker, and the DAR value is 6. **Methods:** This open-label, randomized, multi-centre phase 2 study enrolled HER2-positive patients aged 18-75 years with stage II–III disease. Patients were randomly assigned to receive neoadjuvant TQB2102 6mg/kg every 3 weeks for 6 cycles or for 8 cycles. The primary endpoint was pathological complete response (pCR). Safety was analysed in patients who received at least one dose of study medication. **Results:** Between 05 February 2024 and 24 Sep 2024, we randomly assigned 52 patients to neoadjuvant TQB2102 6 cycles (Arm A, n=26), 8 cycles (Arm B, n=26). The baseline characteristics were well balanced; approximately 50% of the patients were hormone receptor (HR)-positive, and 63% of the patients were stage III. The pCR rate was 57.7% in Arm A (95%CI 36.9%-76.7%), 76.9% in TQB2102 Arm B (95%CI 56.3%-91%). In patients with HR positive disease, the pCR rate was 53.8% in Arm A and 58.3% in Arm B; in patients with HR negative disease, the pCR rate was 61.5% and 92.9%. Grade 3 or higher adverse events occurred 23.1% in Arm A, and 30.8% in 8 Arm B, 7.69% with increased alanine aminotransferase and aspartate transferase. Dose reduction rate and discontinuation was 3.8% and 19.2% in Arm A, 3.8% and 23.1% in Arm B, and no treatment-related deaths occurred. **Conclusions:** This is the first study to report the efficacy and safety of third-generation duel-HER2-directed ADC in the neoadjuvant setting for HER2-positive breast cancer. TQB2102 is highly efficient and well tolerated. Clinical trial information: NCT06198751. Research Sponsor: None.

Early on-treatment (on-Rx) tumor volume reduction (TVR) to predict response to the KEYNOTE-522 (KN-522) regimen in early stage triple negative breast cancer (TNBC). First Author: Clinton Yam, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Monitoring clinical response by breast ultrasound (US) during neoadjuvant therapy is considered standard of care. We previously demonstrated that suboptimal on-Rx TVR after neoadjuvant doxorubicin and cyclophosphamide (AC) predicts non-pCR after sequential taxane-based chemo. However, it is unknown if on-Rx TVR has the similar predictive value in pts receiving the KN-522 chemo-immunotherapy regimen. **Methods:** Pts with early stage TNBC planned to receive the KN-522 regimen were enrolled on the prospective ARTEMIS trial (NCT02276443). Breast US was performed at baseline and after 6 weeks of paclitaxel + carboplatin + pembrolizumab. TVR was defined as the percent reduction of tumor volumes calculated using 3 perpendicular measurements of the index breast lesion. Pathological complete response (pCR) was defined as ypT0/isN0. Logistic regression was used to examine associations between covariates and pCR. Receiver operating characteristic (ROC) analyses were utilized to assess the predictive value of TVR and determine an optimal TVR threshold. **Results:** 150 pts were included. Clinicopathological characteristics are described in Table 1. The pCR rate was 63%. In uni- and multi-variable analyses, TVR was the only covariate to demonstrate statistically significant association with pCR (aOR:1.9 per 10% TVR, p<0.001). In ROC analyses, the area under the ROC curve (AUC-ROC) was 0.74 (95% CI: 0.66-0.82). TVR>50%, selected based on the Youden index, predicted pCR with the following performance characteristics: positive predictive value: 73%; negative predictive value: 79%; sensitivity: 94%; specificity: 41%. **Conclusions:** Early on-Rx TVR by breast US outperforms clinicopathological covariates in the prediction of pCR in pts with TNBC receiving the KN-522 regimen and should be leveraged for risk stratification and design of response-adapted neoadjuvant clinical trials for pts with TNBC. Clinical trial information: NCT022766443. Research Sponsor: Conquer Cancer, the ASCO Foundation; 12238.

Use of artificial intelligence (AI)–powered spatial analysis to predict pathologic complete response (pCR) in HR+ HER2- breast cancer (BC) patients treated with neoadjuvant chemotherapy (NAC). First Author: Dae-Won Lee, Seoul National University Hospital, Seoul, South Korea

Background: In the KEYNOTE(KN)-756 study, adding pembrolizumab to NAC increased pCR in high-risk HR+ HER2- BC. There is an unmet need to discover who will benefit from adding immune checkpoint inhibitors (ICIs). This study aims to investigate the role of pCR in HR+ HER2- BC and to identify whether AI-powered TIL analysis could predict pCR in patients treated with NAC without ICIs. **Methods:** This is a single-center study conducted in Seoul National University Hospital, Korea. H&E whole-slide images (WSIs) of archival breast tumor tissues at diagnosis were analyzed by Lunit SCOPE IO, an AI-powered spatial TIL analyzer. Tumors with a high proportion of area with high intratumoral TIL were classified as immune-inflamed, those with a high proportion of area with low intratumoral but high stromal TIL as immune-excluded, and the remaining as immune-desert. Recurrence risk prediction AI model was trained and validated on independent 1,552 H&E WSIs to predict OncotypeDx score. Patients with histologic grade 3 and tumor size ≥2 cm with node-positive status, or tumor size ≥5 cm were classified as those eligible for KN-756 study. **Results:** A total of 425 BC patients who were treated with NAC without ICIs between January 2015 and October 2018 were included. The median age was 47 (range 24-80), 67.1% had stage III disease, 93.6% had node-positive disease, and 23.5% were eligible for KN-756 study. pCR was achieved in 57 (13.4%) patients and was higher in patients with whom were eligible for KN-756 study (20% vs 11.4%, p= 0.041). Patients who achieved pCR had better 5-year event free survival (EFS, 92.9% vs 77.7%, p= 0.010). AI-powered spatial analysis was performed in 340 patients. There were 125 (36.8%) with immune-desert tumor, 138 (40.6%) with immune-excluded tumor, and 77 (22.6%) with immune-inflamed tumor. Patients with inflamed tumor had higher pCR rate compared to those with immune-excluded or immune-desert in the whole population (Table) and in patients not eligible for KN-756 study (25.6% vs 11.9% vs 5.7%, p = 0.013). Patients with inflamed or excluded tumor had better EFS compared to desert group (80.9% vs 71.2%, p = 0.0275). In addition, recurrence prediction model showed that those who were predicted to have OncotypeDx score ≥ 26 had higher pCR rate (18.2% vs 4.3%, p= 0.002). **Conclusions:** Achieving pCR was associated with favorable EFS in HR+ HER2- patients treated with NAC. Patients with immunogenic tumor microenvironment had higher pCR rate and better EFS. Investigating the role of immune checkpoint inhibitors according to tumor microenvironment may be promising. Research Sponsor: None.

SHR-A1811 as neoadjuvant therapy for HR-positive, HER2-low breast cancer: A single-arm, phase II clinical study. First Author: Zhenzhen Liu, Department of Breast Disease, Henan Breast Cancer Center, The Affiliated Cancer Hospital of Zhengzhou University & Henan Cancer Hospital, Zhengzhou, China

Background: Human Epidermal Growth Factor Receptor (HER2)-low breast cancer accounts for approximately 55% of all breast cancer cases, and it is more prevalent in hormone receptor-positive (HR+) breast cancer. Recent breakthroughs in anti-HER2 antibody-drug conjugates (ADCs) have revolutionized the therapeutic landscape for breast cancer treatment, particularly for HER2-low breast cancer. SHR-A1811 is an anti-HER2 ADC and has demonstrated acceptable tolerability and encouraging antitumor activity in HER2-low advanced breast cancer. Therefore, we conducted the phase 2 trial to investigate the efficacy and safety of SHR-A1811 as a neoadjuvant treatment in patients with HR+/HER2-low breast cancer. **Methods:** This is an open-label, two-stage, phase II clinical trial. In the first stage, 35 participants will be enrolled, and if at least 18 participants achieve an objective response rate (ORR), the trial will proceed to the second stage, enrolling an additional 31 subjects. Eligible patients are women aged 18-70 years; treatment-naive; histologically confirmed invasive breast cancer stage cT2-3/N0-2M0; HR+/HER2-low, and the expression of Ki-67 exceeds 14%. Eligible patients receive SHR-A1811 as neoadjuvant therapy. SHR-A1811 is administered intravenously at a dose of 6.4 mg/kg once every three weeks for a total of eight cycles. The primary endpoint is ORR. Secondary endpoints include safety, residual cancer burden (RCB) 0-1, and pathologic complete response (pCR). **Results:** A total of 66 patients enrolled in this study. The median age was 49 years, with 84.8% (56/66) aged $\geq$ 40 years. Of all patients, 66.7% (44/66) were premenopausal, 66.7% (44/66) had node-positive disease, 86.4% (57/66) had stage II, 13.6% (9/66) had stage IIIA, and 74.2% (49/66) had HER2 expression of IHC 2+/FISH-, while 25.8% (17/66) were IHC 1+. In the modified intention-to-treat population (mITT, patients who received at least one cycle of study treatment and at least one post-baseline MRI assessment), 81.5% (53/65) of patients achieved an ORR, and two patients achieved a pathological complete response, resulting in a pCR rate of 3.1% (2/65). Additionally, the proportion of patients with RCB 0 or RCB I was 9.3% (6/65). 97% (64/66) of patients experienced at least one treatment-related adverse event (TRAE). Grade 3 or higher TRAEs occurred in 39.4% (26/66) of patients, with the most prevalent being neutropenia (27.3%, 18/66), leukopenia (16.7%, 11/66), and anemia (13.6%, 9/66). No interstitial lung disease (ILD) and treatment-related deaths were reported. **Conclusions:** As a neoadjuvant treatment, SHR-A1811 achieves a significant improvement in ORR and brings both pCR and RCB 0-I benefits in patients with HR+/HER2-low breast cancer. These outcomes support further exploration of SHR-A1811 in this patient population. Clinical trial information: NCT05911958. Research Sponsor: None.

Computational pathology-informed immune biomarker for trastuzumab benefit in HER2+ breast cancer: Validation in NSABP B-41 clinical trial. First Author: Satvika Bharadwaj, Wallace H. Coulter Department of Biomedical Engineering, Emory University and Georgia Institute of Technology, Atlanta, GA

Background: Trastuzumab, a targeted therapy, considerably improves survival outcomes in HER2+ breast cancer patients (pts). However, identifying pts most likely to benefit from trastuzumab and those who might avoid it, remains a challenge. Data from the NSABP B-41 randomized clinical trial which evaluated lapatinib-containing regimens against trastuzumab, each given concurrently with chemotherapy in the neoadjuvant setting, holds potential for computational pathology to uncover treatment response patterns. In this study, we present DeSTIL (Density and Spatial Architecture of Tumor Infiltrating Lymphocytes [TILs]), a predictive biomarker derived from Hematoxylin and Eosin (H&E) images, to evaluate the immune microenvironment and identify HER2+ pts that benefit from trastuzumab. **Methods:** Digitized and quality-controlled H&E slides from HER2+ pts in The Cancer Genome Atlas (TCGA; n=175) were used to develop DeSTIL and was independently validated on NSABP B-41 (n=221) pts. Following nuclei segmentation, TILs were identified, and their density and spatial architecture features were quantified. A lasso-regularized Cox proportional hazards model was used to select features and compute a continuous DeSTIL risk score, which was then dichotomized at the median into DeSTIL-positive and DeSTIL-negative groups in the training set. The locked model was validated on NSABP B-41 to predict event-free survival (EFS) in pts receiving neoadjuvant chemotherapy with trastuzumab, lapatinib, or a combination of trastuzumab and lapatinib. Within the DeSTIL-stratified groups, treatment-specific progression was analyzed to evaluate the potential benefit of trastuzumab-based therapies. **Results:** Among 221 HER2+ pts from the NSABP B-41 trial, 61 pts (28%) were classified as DeSTIL-positive and 160 (72%) as DeSTIL-negative, based on the median training threshold. DeSTIL-positive pts demonstrated a significant benefit with the trastuzumab-alone arm compared to the combination regimen (HR=0.09, 95% CI=0.01-0.77, p=0.0061) (interaction term p=0.024) and against lapatinib plus the combination regimen (HR = 0.11, 95% CI = 0.01-0.9, p = 0.01) (interaction term p = 0.05). In contrast, no significant benefit was observed in DeSTIL-negative pts when comparing trastuzumab to the combination regimen (HR=1.33, 95% CI=0.47-3.75, p=0.5840) or to lapatinib plus the combination regimen (HR=1.01, 95% CI=0.45-2.30, p=0.9701). **Conclusions:** DeSTIL, a biomarker based on the density and spatial architecture of TILs, may help identify HER2+ pts more likely to benefit from trastuzumab. Further validation through prospective trials is warranted. Additionally, this biomarker offers a practical framework for comparing HER2-targeted therapies, with the potential to minimize unnecessary treatments, reducing associated cardiotoxicity and financial burden. Exploration of the new classification of hormone receptor-positive breast cancer: Based on the genomic landscape of 2111 early to mid-stage Asian patients. First Author: Cuiyun Zhang, The Affiliated Cancer Hospital of Zhengzhou University and Henan Cancer Hospital, Zhengzhou, China

Background: The molecular classification of breast cancer using omics data has led to varied prognoses; however, with the increase of targeted therapy options, current classifications may not adequately guide treatment strategies. **Methods:** This study analyzed 2,111 HR^+ Asian breast cancer patients using next-generation sequencing of 1,021 genes for targeted therapy classification. **Results:** The majority of patients had invasive ductal carcinoma (67.0%) and were at stages 0 to III (89.6%), with 29.7% being HER2 positive. Variations were widespread, with SNV/Indel mutations found in 99.4% and CNV detected in 44.6% of the samples, respectively. The key signaling pathways, including PAM, RTK/RAS, DDR, and TP53, each showed a prevalence of 50% or higher and co-existed. Interestingly, 76.1% of patients had actionable mutations, predominantly in the PAM (54.8%), RTK/RAS (22.2%), and DDR (11.7%) pathways, which were found to be mutually exclusive ($p < 0.01$). Subsequently, Patients were categorized into two groups, C and M, based on CNV presence, revealing significant differences in the prevalence of actionable genes and pathways. The C group stood out for its high prevalence of PAM (43.7%) and HER2 (38.4%), while the M group exhibited prominence in PAM (64.1%) and DDR (15.0%). Notably, responses to neoadjuvant treatment (NAT) varied as well, with higher pCR rates (51.9% vs. 22.1%, $p < 0.001$) for the combination of chemotherapy and HER2-targeted therapy (Chemo + HP) and lower pCR rates (6.0% vs. 15.2%, p = 0.017) for chemotherapy alone (Chemo) observed in the C group compared to those in the M group. Additionally, subsequent subgroup analyses based on actionable signaling pathways between the two groups showed similar patterns, with the $C\text{-}HER2^+$ subgroup having the highest pCR rate (64.1%) for Chemo + HP and $M\text{-}PAM^-\text{-}DDR^-$ subgroup showing the highest pCR rate (21.5%) for Chemo. Besides, clinical characteristics among the various groups and subgroups showed differences. For instance, the $M\text{-}PAM^-\text{-}DDR^+$ subgroup had an earlier onset ($p < 0.001$) and included more premenopausal individuals (p=0.034), along with higher ER and PR expression ($p < 0.001$) and lower Ki-67 levels ($p < 0.001$). Multivariate logistic regression analysis identified HER2 amplification, PR negativity, and TP53 mutation as independent risk factors for the efficacy of Chemo + HP NAT. **Conclusions:** The study suggested that classifying breast cancer patients based on CNVs and actionable pathways may enhance neoadjuvant pCR rates. This underscored the potential implications for expanding neoadjuvant treatment strategies and facilitating tailored precision treatment options based on distinct molecular profiles and therapy responses. Research Sponsor: None.

Analysis of event-free survival (EFS) of stromal tumor infiltrating lymphocytes (sTILs), PD-L1 expression, and their early dynamics in the NeoTRIP trial. First Author: Giampaolo Bianchini, Università Vita-Salute San Raffaele, Milan, Italy

Background: We demonstrated that pre-treatment sTILs and PD-L1, and on treatment sTILs but not PD-L1 were associated with pathological Complete Response (pCR) to neoadjuvant therapy in patients (pts) with triple-negative breast cancer (TNBC) enrolled in NeoTRIP (NCT02620280) trial (Bianchini G ESMO 2020). Here we assess the association between the same biomarkers and EFS. **Methods:** NeoTRIP randomized 280 pts to nab-paclitaxel/carbo for 8 cycles (CT) or with atezolizumab (CT/A). As Per-Protocol Population, 258 pts were evaluable for EFS, the primary endpoint of the study.We collected samples at baseline (n=258/258; 100%) and on Day 1 Cycle 2 (D1C2) (n=230/258; 89.2%]. We centrally assessed sTILs (cut-off $\geq$30% to be considered high) and PD-L1 expression (SP142) on immune cells (IC) (IC$\geq$1% considered positive). Association with EFS was investigated. Imaging mass cytometry (IMC) (Wang Nature 2023) was used to investigate the biology linked to PD-L1 dynamic over-expression. **Results:** Median follow-up was 54 months. Pre-treatment high sTILs and PD-L1+ were associated with lower risk of recurrence in CT arm (HR 0.35 [0.12-0.99], p=0.049 and HR 0.31 [0.15-0.64], p=0.001, respectively). In CT/A arm neither pre-treatment marker was significantly associate with EFS. At D1C2 in CT arm, high sTILs but not PD-L1+ was significantly associated with lower risk of recurrence (HR 0.34 [0.15-0.81], p=0.015 and HR 0.65 [0.28-1.48], p=0.30, respectively). In CT/A arm both high sTILs and PD-L1+ were strongly associated with lower risk of recurrence (HR 0.23 [0.07-0.78], p=0.019 and HR 0.25 [0.11-0.57], p=0.001, respectively). Only in CT/A arm, on-treatment PD-L1 provided prognostic information independent of baseline biomarkers, on-treatment sTILs and pCR (adjHR = 0.25 [0.11-0.58], p=0.001). In patients with baseline PD-L1- tumors and paired D1C2 samples (n=87), conversion from PD-L1- to on-treatment PD-L1 positivity occurred in 64.3% and 17.8% in CT/A and CT arms, respectively ($p= 7.39x10^{-6}$). The tumors converted to PD-L1+ status were significantly associated with better outcome in CT/A arm (HR 0.23 [0.08-0.68], p=0.008) but not in CT arm (HR 0.82 [0.24-2.85], p=0.76). Notably, in CT/A arm, patients with baseline PD-L1- tumors had similarly low pCR rate regardless of PD-L1 status on D1C2 (20% and 25.9% in PD-L1- and PD-L1+ D1C2 groups, respectively). The IMC results for the biological characterization of tumors with induction of PD-L1+ will be presented. **Conclusions:** In NeoTRIP on-treatment high sTILs (both CT and CT/A arms) and PD-L1 positivity (only in CT/A arm) were significantly associated with lower risk of recurrence independently of pCR and baseline biomarkers. The findings suggest up-regulation of PD-L1 as new candidate pharmacodynamic biomarker of benefit from atezolizumab. Whether this observation hold also for pembrolizumab remain to be defined. Long-term outcomes in triple-negative breast cancers (TNBC) treated with talimogene laherparepvec (TVEC) in combination with neoadjuvant chemotherapy (NACT). First Author: Hatem Hussein Soliman, H. Lee Moffitt Cancer Center and Research Institute, Tampa, FL

Background: TVEC is an engineered herpes simplex oncolytic virus (HSV OV) approved for the treatment of melanoma. We published a phase 1/2 trial combining TVEC with NACT in early stage TNBC demonstrating increased pathologic complete response (pCR) compared to expected rates with NACT. We are presenting updated long term follow up data on this cohort of both phase 1 and 2 evaluable patients. **Methods:** Stage II-III TNBC pts were enrolled into a single arm, optimal phase 1/2 trial with TVEC (10^6 PFU 1st dose then 10^8 PFU x 4 doses) weeks 1,4,6,8,10 + weekly paclitaxel (80mg/m2) IV x 12, followed by dose dense AC (doxorubicin/cyclophosphamide 60/600 mg/m2) IV q2weeks x 4 alone (wT-AC) given preoperatively. Primary endpoint was pCR rate. Secondary endpoints included 5 year disease free survival/overall survival rates (DFSR/OSR), safety, immune correlates. **Results:** Forty six patients were enrolled at Moffitt (5/2018 – 4/2020) and evaluable for response and outcomes. Study demographics: median age 49 (27-66), 69.5% White, 13% Black, 13% Hispanic, clinical stage II 80% and III 20%, node + 45%. The pCR rate for the phase 1/2 cohort was 45.6% (95% CI 30.9-60.9). Additionally, 10 patients had residual cancer burden (RCB) 1 responses (associated w/ favorable outcomes) 21.7% (95% CI 10.9-36.3%). At median follow up of 70 months (range 17-98), six patients have had a breast cancer recurrence DFSR=86.9% (95% CI 73.7-95.0) and four patients died OSR=91.3% (95% CI 79.2-97.6). DFSR in pCR group = 95.2% (95% CI 76.1 – 99.9) and non-pCR group = 80% (95% CI 59.3 – 93.1%). All but one of the recurrences occurred in patients with non-PCR responses (RCB 2-3) to TVEC+NACT. Clinical stages at presentation for patients with recurrences were 5 stage II and 1 stage III. No patients had any HSV reactivation or autoimmunity events during the post study surveillance period. Greater immune enrichment of B and T cell subsets in pCR vs. non-pCR tumors was observed during TVEC treatment. **Conclusions:** To our knowledge, this is the first report on longer term outcomes for early TNBC treated with OV. TVEC plus wT-AC demonstrates promising long term outcomes when compared to the more intensive KEYNOTE 522 checkpoint regimen. Additional investigation of oncolytic viruses administered during NACT for TNBC is warranted to confirm this benefit. Clinical trial information: NCT02779855. Research Sponsor: Amgen.

Neoadjuvant cadonilimab (anti-PD-1/CTLA-4 bispecific antibody) plus chemotherapy in early or locally advanced triple-negative breast cancer: A single-arm phase II trial (CABIN study). First Author: Tao Wu, Changde Hospital, Xiangya School of Medicine, Central South University, Changde, China

Background: Neoadjuvant chemotherapy for triple-negative breast cancer (TNBC) can improve surgical outcomes; however, many patients fail to achieve pathological complete response (pCR). Immune checkpoint inhibitors (ICIs) targeting PD-1/PD-L1 show promise, but responses are limited. This phase II trial evaluates cadonilimab (AK104), a bispecific PD-1/CTLA-4 antibody, combined with nab-paclitaxel and carboplatin in neoadjuvant TNBC to improve pCR rates and assess safety. **Methods:** This phase II, single-arm trial enrolled patients aged 18-75 with treatment-naïve, stage IA-IIIC triple-negative breast cancer (TNBC). Patients received cadonilimab (10 mg/kg) plus nab-paclitaxel (260 mg/m²) and carboplatin (AUC 4) every 3 weeks for six cycles, followed by surgery within 4 weeks. Biopsy specimens were collected before treatment for whole-exome sequencing. The primary endpoint was total pathological complete response (tpCR) rate (ypT0/is ypN0). Secondary endpoints included objective response rate (ORR), disease control rate (DCR), disease-free survival (DFS), event-free survival (EFS), overall survival (OS), and safety. **Results:** A total of 29 patients were enrolled from January 31, 2023, to January 20, 2025. The median age was 53 years, and 11 patients (37.9%) were premenopausal. The majority had positive nodal involvement (75.9%) and stage III (51.7%) disease. of the 29 patients, 19 (65.5%, 95% CI: 45.7-82.1) achieved total pathological complete response (tpCR), and 21 (72.4%, 95% CI: 52.8-87.3) achieved breast pCR (bpCR). Tumor downstaging occurred in 89.7% (T) and 62.1% (N) of patients. Radiological assessments showed an objective response rate (ORR) of 93.1% (95% CI: 77.2-99.2) and a disease control rate (DCR) of 100%. All patients experienced at least one treatment-related adverse event (TRAEs), with 51.7% having grade 3/4 events, most commonly neutropenia (37.9%), platelet count decrease (19.2%), and leukopenia (17.2%). Serious TRAEs occurred in 6.9%. Immune-related adverse events (irAEs) of any grade occurred in 14 (48.0%) patients, while those of grade $\geq$ 3 occurred in only one patient (3.4%). The most common irAE was hypothyroidism (44.8%, 13/29), all were grade 1 or 2. Notably, patients with *TASOR2* or *MST1R* mutation demonstrated a significantly lower pCR rate (both *P*=0.041). Additionally, *CCND1* amplification showed a non-significant negative trend with the pCR rate (*P*=0.051). **Conclusions:** The combination of cadonilimab, nab-paclitaxel, and carboplatin in neoadjuvant treatment for stage IA-IIIC TNBC showed promising efficacy, with high response rates and significant tumor downstaging, particularly in stage III patients. The regimen was well tolerated with manageable adverse events, supporting its further investigation as a potential neoadjuvant treatment for TNBC. Clinical trial information: ChiCTR2200067005. Research Sponsor: None.

Biomarkers of neoadjuvant dalpiciclib in patients with operable HER2-negative luminal B breast cancer in the DANCER trial. First Author: Yunxiang Zhou, Department of Breast Surgery and Oncology, The Second Affiliated Hospital of Zhejiang University School of Medicine, Hangzhou, China

Background: DANCER (NCT05640778) was a circulating tumor DNA (ctDNA)-directed, single-arm, phase II trial investigating the clinical activity of dalpiciclib combined with aromatase inhibitors as a neoadjuvant regimen for operable human epidermal growth factor receptor 2 (HER2)-negative luminal B breast cancer. Although a high complete cell cycle arrest (CCCA) rate (primary endpoint) of 86.7% (26/30) was achieved at 2 weeks (T1), some patients showed suboptimal clinical responses after neoadjuvant therapy. This underscores the importance of identifying biomarkers predictive of response to CDK4/6 inhibitors. **Methods:** Plasma samples collected at baseline (T0), T1, mid-therapy (T2), surgery (S), and postoperatively (PO) underwent ctDNA and Olink proteomic analyses. Tumor tissues obtained at T0, T1, and S were assessed for somatic variation profiling, immunohistochemical markers and MammaPrint index. Patients achieving CCCA at both T1 and S with a concurrent objective response by MRI at S were classified as Good Responders (GRs, *n* = 15); others were Moderate Responders (MRs, *n* = 15). **Results:** The baseline clinicopathological features of the patients were balanced between the GR and MR groups. Compared to MRs, the GRs at S exhibited significantly lower residual cancer burden (RCB) scores, preoperative endocrine prognostic index (PEPI) scores, histological tumor grades, Ki67 expressions, and CA153 levels. Additionally, GRs demonstrated significantly higher Miller-Payne grades, tumor-infiltrating lymphocyte levels, and tumor shrinkage rates. In terms of biomarkers, GRs had a higher rate of ctDNA clearance at and prior to T2 (100.0% vs 54.5%; $p = 0.045$), as well as higher levels of plasma CCL4 ($p = 0.029$), plasma CCL19 ($p = 0.020$), immunohistochemical pRb ($p = 0.044$), and immunohistochemical CDK4 ($p = 0.034$). Furthermore, *GSTM1* demonstrated a significant shift in its copy number pattern after treatment at S, with five previously detected baseline deletions no longer being identified and five de novo amplifications emerging ($p = 0.007$). Lack of early ctDNA clearance was also significantly associated with RCB class of III and PEPI score of $\geq$ 4. Besides, MammaPrint high-risk patients showed a significant increase in RCB and PEPI scores vs. low-risk patients. **Conclusions:** Patients with operable HER2-negative luminal B breast cancer who exhibit early ctDNA clearance, MammaPrint low-risk status, *GSTM1* deletion, increased pRb/CDK4 expression, and higher plasma CCL4/CCL19 levels may derive substantial benefit from neoadjuvant dalpiciclib therapy. Clinical trial information: NCT05640778. Research Sponsor: National Natural Science Foundation of China; the Key Research and Development Program of Zhejiang Province.

Patient outcomes in WSG-ADAPT according to NATALEE and MonarchE risk criteria. First Author: Oleg Gluz, West German Study Group and Ev. Hospital Bethesda, Breast Center Niederrhein, Moenchengladbach, Germany and University Hospital Cologne, Cologne, Germany

Background: In HR+/HER2- high-risk early breast cancer (eBC), abemaciclib and ribociclib improve the efficacy of standard endocrine treatment (ET), as shown in MonarchE (abemaciclib) and NATALEE (ribociclib). However, the absolute benefit varies according to prognostic factors. We analyzed the outcome of prognostic groups based on MonarchE and/or NATALEE inclusion criteria in the WSG-ADAPT trial considering Recurrence Score (RS, OncotypeDx) and Ki-67 response after preoperative ET. **Methods:** In WSG-ADAPT (NCT01779206), patients (pts) with clinically high-risk HR+/HER2- eBC (cT2-4 or cN+ or G3 or Ki67 $\geq$ 15%) initially received a 3-week standard ET before surgery or sequential biopsy. Pts with c/pN2-3 or G3 with Ki67 $>$ 40% were randomized directly to chemotherapy (CT trial) evaluating (neo)adjuvant 4 $\times$ paclitaxel q2w vs. 8 $\times$ nab-paclitaxel q1w, followed by epirubicin + cyclophosphamide q2w, followed by ET. pN0-1 pts with RS 0-11 or RS 12-25 with ET-response (central $Ki67_{postET} \leq$ 10%) received ET alone (ET trial); RS 12-25 pts without ET-response entered CT trial. Pts with N1-3 or T3 or T2, N0 with either Ki-67 $\geq$ 20% or G3 or RS $>$ 25 were classified as NATALEE high-risk, pts with N2-3 or N1 with either T3-4 or G3 or Ki-67 $\geq$ 20% were classified as MonarchE high-risk. **Results:** In the WSG-ADAPT ET trial, 303 (14.2%) and 784 (36.7%) of 2135 pts were classified as MonarchE and NATALEE high-risk, respectively. In the CT trial, 963 (43.2%) and 1572 (70.5%) of 2230 pts were classified as MonarchE and NATALEE high-risk. After 60 months of median follow-up, both high-risk vs. low-risk classifications were highly prognostic for iDFS and dDFS in ET and CT trials. However, low-risk pts (by both classifications) in the ET trial had 5-y iDFS and dDFS of 94.7% and 96.4%, respectively, vs. 90.1% and 93.6% for high-risk by just NATALEE but not by MonarchE criteria (p = n.s.) and vs. 88.3% and 88.9% in both NATALEE and MonarchE high-risk pts ($p < 0.001$). In the ET-only cohort, survival outcomes were similar between pN0 and pN1 pts at high-risk by NATALEE but not by MonarchE criteria (5-y iDFS of 87.7% vs. 90.2%; p = n.s. and 5-y dDFS of 91.7% vs. 91.9%; p = n.s.). In the CT trial, 5-y iDFS and dDFS rates were 93.9% and 94.9%, respectively, for NATALEE low-risk pts vs. 84.7% and 87.0% for high-risk by NATALEE but not by MonarchE criteria and vs. 77.7% and 79.6% for MonarchE high-risk pts. **Conclusions:** Among 4365 pts in the WSG-ADAPT trial, subgroups classified as high-risk by NATALEE and MonarchE criteria had poor outcomes. However, N0-1 pts who were high-risk by NATALEE but not MonarchE criteria and pts with RS $\leq$ 25 and/or ET response had only slightly inferior outcomes compared to low-risk pts with ET therapy alone. Assuming a hazard ratio of 0.7 for a ribociclib effect, as shown in NATALEE, an absolute benefit of approx. 2% fewer dDFS events after 5 years can be assumed in this group based on the WSG-ADAPT experience. Shared decision-making will be key in this intermediate-risk group. Clinical trial information: NCT01779206. Research Sponsor: Genomic Health (Exact Science); Celgene; Amgen; Allgemeine Ortskrankenkasse.

Racial disparities in clinical outcomes of early-stage triple-negative breast cancer treated with neoadjuvant chemoimmunotherapy: Insights from the NCDB. First Author: Zunairah Shah, Roswell Park Comprehensive Cancer Center, Buffalo, NY

Background: Triple-negative breast cancer (TNBC) is an aggressive breast cancer (BC) subtype, and Black patients (pts) with TNBC have worse survival outcomes after neoadjuvant chemotherapy, likely due to biological and socioeconomic factors. Neoadjuvant immune checkpoint inhibitors combined with chemotherapy, i.e. neoadjuvant chemoimmunotherapy (NACI) have improved pCR rates and overall survival (OS), but its efficacy by race is unclear. This study evaluates racial disparities in clinical outcomes for pts with early-stage TNBC treated with NACI, aiming to address this critical gap. **Methods:** We analyzed the National Cancer Database (NCDB) for pts with stage II/III TNBC treated with NACI from 2019 to 2022. Primary outcomes included pCR and OS, which were analyzed with race using univariate and multivariable logistic regression and Cox proportional hazards models, while adjusting for clinicopathologic variables (age, stage, grade, comorbidities (Charlson-Deyo Comorbidity Classification) and socioeconomic factors (residence (rural/urban area), insurance, income). P value $\leq$0.05 was considered statistically significant. **Results:** A total of 5,137 pts were included. Median age was 51 years (range:39-63); 69.9% were White, 20.5% Black, 9.6% Other, 49.3% had stage II and 50.7% had stage III TNBC. Median follow up was 26.6 months (3.3-61.9), pCR was achieved in 76.5% pts, (White: 77%, Black: 74%, Other: 76%; p = 0.113). Pts achieving pCR had significantly higher 3-year OS (92% vs 72%, p$<$0.001) and 5-year OS (84% vs 56%, p$<$0.001) compared to those without pCR. Racial disparities in survival were observed, with 3-year OS of 88%, 84%, and 85% (p $<$0.05) and 5-year OS of 83%, 77%, and 85% for White, Black, and Others, respectively (p$<$0.05). After adjusting for covariates, Black pts had a trend toward lower likelihood of pCR compared to White pts although not statistically significant (odds ratio (OR) 0.76 [95% CI: 0.54–1.07]. The factors independently associated with worse OS were residence in rural areas (HR 1.79 [95% CI: 1.00–3.19], p = 0.05), tumors $\geq$10 cm (HR 1.92 [95% CI: 1.21–3.06], p = 0.006), stage III disease (HR 1.91[95% CI: 1.47–2.49], p $<$ 0.001) and Black vs. White group (HR 1.42 [95% CI: 1.10–1.84], p = 0.007). **Conclusions:** Black pts with TNBC receiving NACI have worse OS than White pts, possibly due in part to social, structural, or biological determinants of health. Further research is needed to investigate personalized treatment strategies that address the unique challenges Black pts face in achieving long-term survival and improving overall prognosis. Research Sponsor: None.

Survival rates and hazard ratios by race.

Race	3-year survival rate (%)	5-year survival rate (%)	Hazard ratio
White	88%	83%	1.00
Black	84%	77%	1.42 [95% CI 1.10–1.84]
Other race	85%	85%	1.19 [95% CI 0.82–1.74]

Outcomes of neoadjuvant endocrine therapy (NAET) versus neoadjuvant chemotherapy (NAC) in stage II-III invasive lobular carcinoma (ILC). First Author: Jason A. Mouabbi, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: ILC is a distinct subtype of breast cancer, accounting for up to 15% of cases, and is characterized by unique clinical and pathological features. ILC often yield poor responses to NAC. Case reports suggest that NAET yields favorable outcomes in ILC. However, no large-scale study has evaluated the impact of NAET in ILC patients. This is the first large study that aims to compare the outcomes of NAC versus NAET in stage II/III ILC. **Methods:** A retrospective analysis was performed on patients treated at MD Anderson Cancer Center with a diagnosis of anatomical stage II-III estrogen receptor-positive (ER+) HER2-ve ILC in our prospectively collected and curated electronic database. Data collected included demographics, receptor status (ER, PR, HER2), treatments received, clinical anatomic and pathologic stage, type of surgery, surgical pathology outcomes, and recurrence. Endpoints included pathologic complete response (pCR), modified Preoperative Endocrine Prognostic Index (mPEPI) score 0, endocrine therapy responsiveness (ETR; Ki67 $\leq$10%), rates of axillary downstaging (from node positive to negative), rate of lumpectomy, rate of axillary lymph node dissection (ALND), and 10-year distant recurrence-free survival (10y DRFS). For DFRS, NAC patients were compared to NAET patients who did not receive adjuvant chemotherapy (ACT). Univariate analysis identified variables associated with outcomes, and multivariate logistic regression was planned for significant factors (p $<$ 0.05). **Results:** We analyzed 611 patients among who the median age was 55 (range 30–91), with 77% White, 8.5% Hispanic, and 8.1% Black. 65% were postmenopausal and all patients received adjuvant ET. 509 (80%) received NAC, and 102 (20%) received NAET. Among NAET patients, 83% received a non-steroidal AI, while 98% of NAC patients received anthracycline-containing regimens. pCR was achieved in 13 NAC patients (2.5%) and 2 NAET patients (1.9%). mPEPI score 0 was attained by 10 NAET patients (9.8%), and the ETR rate was 83%. Axillary downstaging occurred in 11% of NAC patients and 5% of NAET patients. Rates of lumpectomy (17.1% in NAC vs. 17.6% in NAET) and axillary lymph node dissection (ALND) (68.6% in NAC vs. 62.6% in NAET) were comparable between the groups. With a median follow-up of 85 months, 10y DRFS was 55% for NAC and 65% for NAET (HR 0.57, 95% CI 0.33–0.98, P = 0.02). Univariate analysis for DRFS revealed no significant associations with age, race, or initial stage (all p $>$ 0.05), precluding multivariate analysis. **Conclusions:** This large-scale analysis highlights the limited efficacy of NAC in ILC, with minimal pCR rates. NAET yields promising results, including superior 10y DRFS. These findings underscore the potential of NAET as a viable neoadjuvant option for patients with stage II/III ER+ ILC. Research Sponsor: None.

604 Poster Session

Serum estradiol (sE2) levels in premenopausal (PreM) women receiving neoadjuvant ovarian function suppression (OFS) with the oral SERD amcenestrant, alone, or in combination with letrozole or abemaciclib in the I-SPY2 Endocrine Optimization Pilot (EOP). First Author: Jo Chien, University of California, San Francisco, San Francisco, CA

Background: The addition of OFS to standard endocrine therapy (ET) improves iDFS for preM women with early-stage hormone receptor positive (HR+) breast cancer (BC). Incomplete OFS occurs in a subset of women, the long-term clinical significance of which is unclear. This study evaluates local sE2 levels in preM women receiving OFS with an oral SERD in the neoadjuvant (NA) setting. **Methods:** The EOP is a I-SPY2 sub-study investigating NA endocrine-based strategies in pts with HR+ HER2- Stage 2/3 BC predicted to have lower benefit from chemotherapy. Pts were randomized to oral amcenestrant 200 mg/d, alone or in combination with either letrozole 2.5 mg/d or abemaciclib 150 mg bid. Additional pts were randomized to a standard of care (SOC) arm consisting of an aromatase inhibitor. All PreM pts received OFS with monthly GnRHa up to 2 wks prior to C1D1 of study therapy. Pts were treated for 6 months prior to surgery. sE2 levels were collected locally prior to each GnRHa injection. Tumor Ki67 was assessed at 3 weeks and surgery, and associated with sE2 level. Statistical significance was determined using a two-sided Student's t-test and a significance level 0.05. **Results:** Between 5/2021-8/2022, 74 pts were enrolled to an amcenestrant containing arm, 40 of whom were preM. 38/40 pts had at least one local sE2 level measured in follow up. Of these 38 pts (median age 45 years), 37 suppressed sE2 into the postmenopausal (postM) range at one or more follow-up timepoints. Of the 37 pts that completely suppressed into the postM range, 6 pts had sE2 levels rebound into the preM range (mean 319 pg/mL, range 20-848 pg/mL) with peak sE2 levels occurring at a median of 12 weeks from C1D1. One pt never suppressed to the postM range (peak sE2 1227 pg/mL) and was found to have an ovarian cyst after 3 months on amcenestrant, requiring surgery. One additional pt had multiple ovarian cysts (sE2 84 pg/mL). Median age of the 7 pts who had sE2 rebound was 43 years. There was no significant difference in Ki67 at 3 weeks and surgery between pts whose sE2 levels remained suppressed (median Ki67 2.0%) compared to those whose estradiol rebounded into the preM range or never suppressed (median Ki67 1.5%). In the 5 pts whose sE2 rebounded to $>$ 200 pg/mL, all pts had tumor Ki67 $<$ 10% at 3 weeks and surgery. Between 12/2022 and 8/2023, 20 pts were enrolled to AI +/- OFS and 11 pts were preM. Of the 11 preM pts, all pts suppressed sE2 to the postM range. No SOC patients had sE2 levels rebound into the preM range. **Conclusions:** In this study of neoadjuvant oral SERD with monthly OFS, 7/38 (18.4%) preM pts had sE2 levels remain or rebound into the preM range. sE2 levels did not appear to impact Ki67 suppression on NA ET. Work up for ovarian cysts should be considered in pts with symptoms, or significantly elevated or persistent sE2 levels. Clinical trial information: NCT01042379. Research Sponsor: Quantum Leap Healthcare Collaborative.

605 Poster Session

Molecular insights into HR+/HER2+ early-stage breast cancer: Neoadjuvant therapy responses by MammaPrint and BluePrint genomic subtypes. First Author: Laila Samiian, Baptist MD Anderson Cancer Center, Jacksonville, FL

Background: Clinical HER2+ (cHER2+) early breast cancer (EBC) represents 15-20% of invasive EBC and is typically treated with Neoadjuvant HER2-targeted therapy (NHT) combined with chemotherapy, regardless of ER status. NBRST and I-SPY2 trials showed varied NHT responses in cHER2+ tumors based on genomically-defined molecular subtypes, emphasizing the importance of understanding tumor biology. Genomic assays MammaPrint (MP) and BluePrint (BP) predict therapy response and inform treatment decisions. Here, we explored the biological pathways underlying differential NHT response in triple positive (HR+HER2+) tumors using whole transcriptome analysis (WTA). **Methods:** Patients with HR+/HER2+ early-stage breast cancer treated with NHT (N = 720) were included from FLEX (NCT03053193). MP classified tumors as UltraLow (UL), Low, High 1, or High 2 Risk, while BP categorized them as Luminal A, Luminal B, HER2, or Basal. Differences in clinical characteristics and pathological complete response (pCR) rates were assessed by Chi-Square or Fisher's exact tests and proportional Z-test, respectively. Differential gene expression (DGE) analysis of WT profiles was performed between tumors with and without pCR, using limma package in R, followed by pathway enrichment analysis in Metascape. **Results:** Among 720 HR+/HER2+ EBCs, MP classified 19 (2.6%) as UL, 107 (14.9%) as Low, 385 (53.5%) as High 1, and 209 (29.0%) as High 2. BP classified 120 (16.7%) as Luminal A, 307 (42.6%) as Luminal B, 278 (38.6%) as HER2, and 15 (2.1%) as Basal. Compared to other BP subtypes (Luminal A/B), BP HER2 tumors were associated with younger age (54 vs 60, p $<$ 0.001), premenopausal status (p = 0.002), higher grade (G3: 54.7%, p $<$ 0.001), and T3 tumors (10.7% vs 3-4%, p $<$ 0.001). pCR rates with NHT were higher in BP HER2 tumors compared to Luminal A/B tumors (n = 41, 61.2% vs n = 18, 26.5%, respectively, p $<$ 0.001). WTA of BP HER2 tumors with pCR showed 23 genes with 2-fold change (not statistically significant after correction), 20 of which were upregulated and associated with regulation of bone morphogenic protein encoding genes and increased cell-substrate/cell matrix adhesion, compared to tumors that had residual disease. **Conclusions:** These data show heterogeneity within HR+/HER2+ tumors, with approximately 60% genomically reclassified as non-HER2-type by BP. Consistent with I-SPY2, BP HER2 cancers showed higher pCR rates than Luminal A/B, suggesting that additional therapeutic strategies are needed to increase the pCR rates in these cancers. Although WTA in BP HER2 tumors with and without pCR identified DGE, the findings were not statistically significant. Future analyses of WTA in larger numbers of BP subtypes within the HR+ HER2+ EBC patients who are being enrolled on the FLEX trial may elucidate the biology of the cancers with pCR vs non-pCR. Clinical trial information: NCT03053193. Research Sponsor: Agendia, Inc.

Results of the prospective randomized controlled trial VOG-01: Neoadjuvant endocrine therapy ribociclib + fulvestrant + GnRH-a versus chemotherapy 4 AC + 4 T for early HR+/HER2-negative breast cancer in premenopausal patients. First Author: Rashida Orlova, Saint Petersburg State University, Saint Petersburg, Russian Federation

Background: CDK4/6 inhibitors are used to treat HR+/HER2- metastatic breast cancer in combination with endocrine therapy. However, there is still a lack of evidence about combined endocrine therapy in neoadjuvant setting. VOG-01 is a phase II randomized trial that evaluated the effects of combination ribociclib plus fulvestrant and GnRH-a as neoadjuvant therapy in premenopausal patients. **Methods:** Premenopausal women with HR+/HER2-negative stage II-III were randomly assigned to Fulvestrant (500 mg on the 1st, 15th, 28th days of the first cycle, then once every 28 days), Triptorelin (3.75 mg every 28 days) and Ribociclib (600 mg daily, 3 weeks/4) during 16-24 weeks (NET), or Doxorubicin 60 mg/m2 + Cyclophosphamide 600 mg/m2 x4 21-day courses followed by Docetaxel 75 mg/m2 x4 21-day courses (NCT). Primary endpoint was objective response rate. Secondary endpoints were pathological response rate (RCB), frequency of breast-conserving surgery, severity of adverse events and the quality of life (EORTC QLQ-C30). **Results:** Eighty two patients were recruited. The objective response rate was 83% in the NET and 71% in the NCT (p = 0.2). Complete pathological response (RCB 0) was in 2 cases (5%) in the NET and in 4 cases (10%) in the NCT; RCB I was in 1 case (2.6%) in the NCT and did not occur in the NET; RCB II - 55% in the NET and 62% in the NCT, RCB III was in 40% and 26% respectively. Breast-conserving surgery were not so common in both groups: 37% in the NET and 32% in the NCT (p=0.5). Severe adverse events (CTCAE ver 5 G3-4) were 66% in the NET and 87% in NCT ($p < 0.019$). Quality of life significantly decreased during NCT compared with NET: the total score was 75.7 ± 22.2, 42.0 ± 19.7, 66.3 ± 12.9 in NCT at visits on 1-12-24- weeks and 76.4 ± 20, 70.7 ± 25.4, 76.1 ± 20.5 in NET at the same visits ($p < 0.05$). **Conclusions:** For the first time randomised trial comparing NET and NCT was conducted in premenopausal women with HR+/HER2-early breast cancer. NET was not inferior to standard NCT in terms of objective response rate, complete or pronounced pathological response rate and breast-conserving surgery. At the same time it was associated with a lower severity of adverse events and increased quality of life. Nevertheless new treatment approach requires confirmation of its effectiveness in large studies. Clinical trial information: NCT04753177. Research Sponsor: None.

HER2DX genomic test in HER2-positive breast cancer treated with 15 weeks of neoadjuvant paclitaxel, trastuzumab, and pertuzumab (THP): Final analysis from the BiOnHER clinical trial. First Author: Bartomeu Fullana Grimalt, Avinguda de la Granvia de l'Hospitalet, 199-203, L'hospitalet De Llobregat, Barcelona, Spain

Background: HER2DX is a 27-gene genomic assay providing prognostic and predictive insights in early-stage HER2-positive (HER2+) breast cancer. Although widely validated, less data exists for its performance in THP beyond the DAPHNe trial (JAMA Oncol 2023), which included 80 patients (pts). This study aimed to validate HER2DX for predicting pathological complete response (pCR) with THP and compare its performance to hormone receptor (HR) status. **Methods:** HER2DX (Reveal Genomics) was centrally evaluated on all tumor biopsies from the BiOnHER trial (NCT05912062), where pts with stage I-III HER2-positive breast cancer received 15 weeks of neoadjuvant THP at the Catalan Institute of Oncology. Biopsies were collected at pre-treatment baseline (D1) and day 8 (D8) after an HP loading dose but before initiating paclitaxel. HER2DX pCR group cutoffs were based on predefined thresholds for HER2DX low-, medium-, and high groups. Logistic regression and receiver-operating characteristic (ROC) curve analyses were used for statistical evaluation. The primary objective was to assess HER2DX pCR score for predicting pCR (ypT0/isN0). Secondary objectives included evaluating HER2DX performance by HR status, baseline TILs/Ki67, and additional insights from D8 data. **Results:** HER2DX was successfully evaluated in all 83 enrolled patients. The cohort included 65.1% T2 tumors, 62.7% cN0 status, 69.9% stage II disease, and 67.5% HR-positive tumors. The overall pCR rate was 45.8% (95% CI, 34.9–57.0%), and the ypT1miN0 rate was 54.2%. HER2DX pCR score was significantly associated with pCR (odds ratio [OR] = 5.26, $P < 0.001$), with an AUC of 0.835. Patients were categorized into 35.0% low, 37.5% medium, and 27.5% high HER2DX pCR score groups, with pCR rates of 13.3% (95% CI, 4.4–31.6%), 51.6% (95% CI, 33.4–69.4%), and 81.8% (95% CI, 59.0–94.0%), respectively. Among HR-negative tumors, pCR rates were 78.6% for high-pCR and 0.0% for low-pCR groups, while in HR-positive tumors, pCR rates were 87.5% and 13.8%, respectively. HR status alone was associated with pCR (OR = 0.125, P = 0.006) but lost significance in multivariable analysis including HER2DX. Baseline Ki67 (median: 35.0%) and TILs (median: 8.0%) were not associated with pCR. While D8 data offered biological insights, it did not improve predictive performance beyond baseline HER2DX. **Conclusions:** HER2DX is a robust predictor of pCR following neoadjuvant THP in stage I-III HER2-positive breast cancer, outperforming HR status. Baseline TILs and Ki67 were not predictive of pCR, and HER2DX D8 data did not improve predictive performance. Clinical trial information: NCT05912062. Research Sponsor: Instituto de Salud Carlos III (ISCIII); FIS PI20/00544.

Outcomes of elderly patients with early-stage triple-negative breast cancer treated with the KEYNOTE-522 regimen. First Author: Renata Colombo Bonadio, Instituto D'Or de Pesquisa e Ensino (IDOR), São Paulo, Brazil

Background: The KEYNOTE-522 regimen (neoadjuvant pembrolizumab combined with a four-drug chemotherapy backbone, followed by adjuvant pembrolizumab) is a standard of care for stage II-III triple-negative breast cancer (TNBC). However, the median age of TNBC diagnosis is 40–50 years, and elderly patients (pts) are underrepresented in clinical trials. **Methods:** The effectiveness and safety of the KEYNOTE-522 regimen were evaluated in patients aged ≥65 years (y) in the Neo-Real/GBECAM-0123 trial, a real-world, multicenter study conducted across ten institutions since July 2020. Pathological complete response (pCR) was assessed as the primary endpoint. Patients < 65y served as the control group. **Results:** Of the 413 pts included in the study, 45 (10.9%) were aged ≥65y. Compared to younger patients, elderly pts exhibited a higher proportion of special histological types (15.6% vs 6.8%, P = 0.055), lower-grade tumors (grade 1–2: 35.5% vs 13.6%, P = 0.001), lower Ki-67 index (< 50%: 46.7% vs 16.6%, P < 0.001), and fewer germline BRCA1/2 mutations (2.2% vs 13%, P = 0.039). The majority of patients in both groups had stage II disease (77.8% vs 69.3%, P = 0.574). Elderly pts were less likely to receive dose-dense anthracycline and cyclophosphamide (AC) (44.4% vs 55.4%, P = 0.027). Patients aged ≥ 65y had lower pCR rates compared to those < 65y (46.3% vs 64%; univariate logistic regression: OR 0.48, 95%CI 0.25–0.93, P = 0.030). However, this difference was not significant in multivariable analysis adjusted for histological type, tumor grade, Ki-67 index, BRCA status, and AC schedule (OR 1.80, 95% CI 0.74–4.37, P = 0.188). Elderly pts experienced significantly higher rates of safety concerns (Table 1). **Conclusions:** TNBC in elderly pts appears to have distinct biological characteristics, which may contribute to lower pCR rates with the KEYNOTE-522 regimen. Additionally, the higher incidence of safety issues in this population underscores the importance of personalized treatment strategies and careful patient selection. Further studies focused on elderly pts with TNBC are needed. Research Sponsor: None.

Safety outcomes of elderly patients treated with KN522 regimen.

	≥ 65y	< 65y	P

Early adverse symptoms to predict response to treatment among patients in the I-SPY trial. First Author: Amrita Basu, University of California, San Francisco, San Francisco, CA

Background: The adverse event (AE) landscape in oncology is changing due to the introduction of immunotherapy and antibody drug conjugates. These AEs come with both short and long-term symptoms that significantly impact patient quality of life. Monitoring for early onset of symptoms could optimize therapy for a particular patient, maximizing potential efficacy while mitigating toxicity. It is also possible that some toxicities are directly associated with drug sensitivity. We sought to identify symptoms associated with pathologic complete response (pCR) using patient-reported outcomes (PROs) in early-stage high-risk breast cancer patients. **Methods:** Our study population included 288 stage II/III high-risk breast cancer patients enrolled on the I-SPY2 trial from 2021-2024, who received novel neoadjuvant therapies ± standard paclitaxel. pCR was assigned if tumor was absent in breast and nodes at surgery following neoadjuvant treatment. Patients (n = 288, pCR rate = 29%, 89% administered immunotherapy) were sent electronic PROs. 33 patient-reported AEs were measured using NCI's Patient Reported Outcomes - Common Terminology Criteria for Adverse Events (PRO-CTCAE). Each symptom was evaluated using severity, frequency, and interference on a Likert Scale. Presence of early PRO symptoms (cycles 1-3 of treatment) were binarized (at least one of moderate or greater), and odds ratios were computed with pCR as outcome. To assess whether higher grade AEs were enriched in patients that achieved a pCR, we also performed the Wilcoxan rank sum test using maximum (worst) symptom severity. **Results:** Of 288 patients included in our analysis (median age = 48 years, range = 20-78), 203 (70.5%) were White, 17 (5.9%) were Asian, 33 (11.5%) were Black or African American, and 35 (12.2%) were Hispanic. PRO analysis revealed that patients that had moderate to severe muscle pain (27% vs 10% OR = 3.15, $p < 0.05$), joint pain (22% vs 8% OR = 3.23, $p < 0.05$), headache (27% vs 12.5% OR = 2.59, $p < 0.05$), or mouth/throat sores (16% vs 5% OR = 3.56, $p < 0.05$) within weeks 1-3 had higher odds of achieving a pCR. When we looked at maximum severity between weeks 1-3, patients that achieved a PCR had higher grade muscle pain (p = 0.04), heart palpitations (p = 0.035), and significantly lower grade numbness and tingling (p = 0.002). Beyond 6 weeks, associations were weaker or insignificant. **Conclusions:** Our study utilizes an analysis framework that was able to determine sentinel symptoms such as muscle and joint pain, mouth/throat sores and palpitations as early as weeks 1-3 associated with increased efficacy. This may suggest an early immune reaction in patients that eventually respond favorably to treatment. Our work can help provide earlier proactive monitoring to mitigate toxicities, treatment redirection if needed, and a potential symptom-based early understanding to personalize treatment efficacy. A similar analysis is underway to predict immune related AEs. Clinical trial information: NCT01042379. Research Sponsor: National Cancer Institute.

Automated prediction of response to neoadjuvant chemotherapy from digitized H&E slides of pre-treatment core needle biopsies in INFORM (TBCRC 031) patients with low stromal TILs. First Author: Stuart J. Schnitt, Brigham and Women's Hospital, Boston, MA

Background: We previously performed anautomated analysis of whole slide images (WSI) of H&E-stained pre-treatment core needle biopsies (CNBs) from patients (pts) enrolled in the INFORM phase II trial of neoadjuvant cisplatin vs doxorubicin-cyclophosphamide in HER2-negative germline *BRCA* carriers. That analysis demonstrated that a digital biomarker of complex immune response (CmbI) which combines immune heterogeneity index (IHI), proliferative, and cell cycle G1/S deregulation signatures, was significantly predictive of response (RCB 0,1) to neoadjuvant chemotherapy (NAC) in all pts, in sub-cohorts including TNBC, and in both therapy arms. Further, a lower IHI, indicating less heterogeneity of stromal tumor infiltrating lymphocytes (sTIL), was predictive of a better response to NAC (RCB 0,1), whereas a higher IHI, indicating greater heterogeneity of sTIL was associated with a worse response (RCB 2,3). The predictive performance of IHI alone was modest compared to CmbI but superior to sTIL. High sTIL is associated with favorable prognosis for NAC, especially in TNBC. However, the impact of heterogeneity of immune cell distribution on NAC response, particularly in those with low sTIL is unknown. The current study evaluated if IHI could augment sTIL assessment by identifying NAC responders in patients with tumors demonstrating low sTIL. **Methods:** CNBs scanned at 40x on a Hamamatsu Nanozoomer scanner were evaluated using the 4D QPOR platform to generate IHI as a continuous index. Among 88 QPOR analyzable pts, 85 had sTIL scores available from prior visual pathologic review. Tumors with low sTIL ($<$ 30%, a previously documented clinically significant cut-off),were further stratified into low vs high IHI using median IHI for the population as the cut-off. We then determined the relationship between IHI and likelihood of response to NAC (RCB 0,1) in the overall cohort, and in the TNBC and ER low ($<$ 10%) sub cohorts. The analysis was also performed using the median sTIL cut-off $<$ 20% previously used in INFORM. **Results:** Low IHI was significantly predictive of NAC response (RCB 0,1) in low sTIL pts in the overall cohort (N = 64, OR = 4.75; 95% CI1.50, 16.21), p = 0.005, PPV = 70%) and in the ER low sub cohort (N = 46, OR = 4.04;95% CI 1.04-17.38, p = 0.04, PPV = 72%). IHI was modestly predictive in the low sTIL pts in TNBC sub cohort (N = 41, OR = 4.28 (0.99, 20.77), p = 0.03, PPV = 71%) but not predictive in high sTIL pts ($<$ 1/3 pts in each subgroup). For sTIL $<$ 20%, IHI had stronger predictive ability in all pts (N = 64, OR = 7.63 (1.83, 40.09), p = 0.0016, PPV = 80%). **Conclusions:** Heterogeneity of immune cell distribution determined by computational analysis of WSI of pre-treatment CNB of patients with germline BRCA mutations and HER2-negative cancers in the INFORM trial improves response prediction to NAC in patients with low baseline sTIL as determined by visual analysis. Research Sponsor: None.

I-SPY2 endocrine optimization pilot (EOP): Neoadjuvant lasofoxifene (Laso) in molecularly selected patients with hormone receptor positive (HR+)/HER2 negative (HER2-) stage 2/3 breast cancer (BC). First Author: Mei Wei, Huntsman Cancer Institute, University of Utah, Salt Lake City, UT

Background: EOP, an I-SPY2 sub-study, evaluates the tolerability and activity of novel endocrine strategies in stage 2/3 breast cancer (BC) patients (pts) predicted to have lower chemotherapy benefit. Laso, a selective estrogen receptor modulator (SERM), has shown favorable toxicity profile and activity in HR+/HER2- endocrine-resistant metastatic BC. **Methods:** Pts with Stage 2/3 HR+/HER2-, MammaPrint (MP) low risk BC were enrolled. Pts with MP High1 BC were included if clinically node-negative. Pts received oral laso 5 mg daily for six 28-day cycles. Laso was continued until the day prior to surgery. Premenopausal pts received ovarian function suppression (OFS) starting C2D1. The primary endpoint was feasibility ($>$75% of patients completing $>$75% study therapy). Baseline (T0), 3-wk (T1) biopsies, and the surgical specimen (T3) was assessed centrally for Ki-67. Breast MRI functional tumor volume (FTV) was performed at T0, T1, 12 weeks (T2), and pre-operatively (T3). Blood was collected for tumor informed ctDNA at T0, T1, T2, T3. Advance event (AE) was assessed using CTCAE V5. **Results:** From 3/2023 to 5/2024, 20 pts were enrolled. Median age 50.5 years, 50% premenopausal, and 1 male pt. 60% cN0, 80% MP low-risk signature. 18 (90%) pts completed $>$75% study therapy. Two pts discontinued treatment due to pt preference. Median Ki67 at T0 was 14.7%. At T1, 87.5% of pts remained or suppressed Ki67 to $<$10% and 37.5% suppressed to $<$2.7%. Ki67 at T1 was similar between pre-and postmenopausal pts despite OFS (Table). The median MRI FTV was 8.4 cc at T0, and 3.4 cc at T3. Median % FTV reduction from T0 to T3 was -47.5%. 2/20 pts (10%) achieved a modified PEPI score of 0. No patients achieved completed pathological response. Of the 16 pts with RCB results, 2 (12.5%) RCB-1, 6 (37.5%) RCB-2, 8 (50%) RCB-3 disease. 14 pts had ctDNA available at T0. 4/14 were ctDNA+ at T0, 2 of whom became ctDNA negative, and 2 remained ctDNA+. 10/14 pts were ctDNA negative at T0, 8 of whom remained negative, 2 became positive at T1 then cleared. All AEs were grade(G) 1 except 1 pt with G2 hot flashes. Most common AEs include hot flashes (85%), constipation (50%), fatigue (50%), and nausea (35%). One pt had G3 hypersensitivity and hypertension, both unrelated to therapy. **Conclusions:** Neoadjuvant laso demonstrates a favorable AE profile and promising anti-tumor activity in suppressing 3-wk Ki67 and MRI FTV change in pts with HR+ HER2-negative early BC. Ki67 suppression in premenopausal pts was seen in the absence of OFS. Clinical trial information: NCT01042379. Research Sponsor: NIH PO1-CA210961.

Ki67 expression at pre-treatment, and 3-wk time point.

	All Patients (n=20)	Premenopausal (n=10)	Postmenopausal (n=9)
Median Ki67 expression			
Baseline	10.0%	12.5%	10.0%
3-wk	5.1%	3.0%	6.0%
Number of pts with Ki67 expression <10% at 3-wk	87.5%[1]	87.5%	85.7%
Number of pts with Ki67 expression <2.7% at 3-wk	37.5%	50%	28.6%

Verification of the BREASTEST assay in an Australian population: A novel liquid biopsy assay measuring lipid biomarkers for early-stage breast cancer screening. First Author: David Speakman, BreastScreen Victoria, Melbourne, VIC, Australia

Background: Women with dense breasts are at higher risk of developing breast cancer however there is no agreement on how to screen these women, despite mandatory density reporting becoming more prevalent. Currently available image-based, population level breast screening modalities have poor sensitivity in these women. Likewise, the positive predictive value of imaging is reduced due to a higher false positive rate/recall rate compared to that of women with less dense breasts. Liquid biopsy approaches do not suffer from imaging-dependent challenges with density and provide a promising option in this population. We have discovered a novel liquid biopsy assay using a lipidomic discovery platform by combining liquid chromatography tandem mass spectrometry (LC-MS/MS) and machine learning. The BREASTEST assay is intended to complement standard of care screening and address gaps in the current screening paradigm. **Methods:** This study was conducted to verify the performance of the BREASTEST assay in an Australian population (n = 720). This verification study was an observational case-control study that prospectively recruited women with breast cancer (n = 275) or without (n = 446) across 10 clinical sites over a 34-month period. A primary imaging modality was identified for each subject and a binary classification was assigned to the outcome of this imaging (normal/suspicious) to enable comparison to, and combination with, the BREASTEST assay. An assay with a high sensitivity has utility as a rule-out test and would complement population-based imaging (high specificity). Therefore, the assay was designed to achieve a sensitivity of 0.90. The combined specificity of imaging with the assay was calculated to estimate the clinical benefit BREASTEST could bring in ruling-out women without breast cancer. A safe de-escalation rate was also calculated in this study to assess the potential reduction in unnecessary further assessment if this assay was added to standard imaging. **Results:** The utility of the BREASTEST assay was observed when results were combined with primary imaging data in the study cohort. Across all imaging modalities and breast densities, the assay improved the combined specificity in 45–75-year-old women by +6.1% (0.712, 0.773) and had a safe de-escalation rate of 21.0%. Highlighting the potential benefit to women with dense breasts, in women aged 30-49 years with breast density category D the combined specificity was +14.7% (0.585, 0.732) and safe de-escalation rate of 37.5%. The BREASTEST assay alone obtained a sensitivity of 0.90, specificity of 0.369 with an AUC of 0.743. **Conclusions:** The performance and utility of the BREASTEST assay was verified in this study in an Australian population. It has highlighted the potential of this assay in the workup of women with breast conditions, in particular women with dense breasts. Research Sponsor: BCAL Diagnostics.

TPS615 **Poster Session**

A phase III trial evaluating addition of adjuvant chemotherapy to ovarian function suppression + endocrine therapy in premenopausal women with pN0-1, HR+/HER2- breast cancer (BC) and oncotype recurrence score (RS) ≤25 (OFSET): NRG-BR009. First Author: Eleftherios P. Mamounas, NSABP and AdventHealth Cancer Institute, Orlando, FL

Background: The TAILORx and RxPONDER trials demonstrated that RS identifies many postmenopausal pts with node-neg and node-pos BC and RS $\leq$25, who do not benefit from addition of ACT to endocrine therapy (ET). Both trials also showed that certain subsets of premenopausal pts (node-neg/high clinical risk/RS 16-20, node-neg/RS 21-25, and node-pos/RS $\leq$25) benefited from adding ACT to ET. Most premenopausal pts in these trials did not receive ovarian function suppression (OFS) as part of their ET regimen. Given the observed benefit from OFS in high-risk premenopausal pts with HR+/HER2- BC in the SOFT/TEXT trials, many questioned whether all or part of the observed ACT benefit in the TAILORx/RxPONDER trials may have been the result of chemotherapy-induced OFS. To address this question, we developed OFSET, a phase III, multicenter clinical trial comparing OFS+ET *v* ACT+OFS+ET. **Methods:** We hypothesize that addition of ACT to OFS+ET is superior to OFS+ET in improving invasive breast cancer-free survival (IBCFS) among premenopausal, early-stage BC pts with HR+/HER2- tumors, and a 21-gene RS between 16-25 (for pN0 pts) and 0-25 (for pN1 pts). Secondary objectives include invasive disease-free survival, overall survival, distant recurrence-free interval, breast cancer-free interval, and health-related quality of life (HRQOL). Pts must be node-neg with RS 16-20 (plus high clinical risk), or RS 21-25, or have 1-3 positive nodes with RS $\leq$25. Stratification is by nodal status/RS status (pN0 RS 16-25 *v* pN1 RS 0-15 and pN1 RS 16-25), intent to receive CDK4/6 inhibitor (yes; no), and age (18-39 *v* $\geq$40). Pts are randomized after surgery to either OFS+ET or ACT+OFS+ET*v* ET is an aromatase inhibitor (AI). Choice is per investigator discretion; tamoxifen is allowed if AI is not tolerated or if OFS is incomplete. Radiotherapy will be administered per investigator discretion per protocol guidelines. The HRQOL sub-study will assess differences in severe menopausal symptoms, measured by the FACT ESS-19 score between arms, as well as increased pain severity (PROMIS). Blood and tumor specimens will be collected for future research. Accrual of 3,960 pts is anticipated to be completed in 7 yrs, 7 mos. Per NSABP B-28 and RxPONDER data, 5yr IBCFS of pN1 pts on the ACT+OFS+ET arm is estimated at 92.3%. Based on TAILORx data, 5yr IBCFS of pN0 pts on the ACT arm is ~95%. Assuming 56% of pts to be pN0 and 44% pN1, and a 0.5% annual loss-to-follow-up rate, the definitive analyses to detect a hazard ratio: 0.75 with ACT+OFS+ET *v* OFS+ET, with one-sided α of 0.025 and 80% power, will require 380 IBCFS events, expected to occur~11 yrs after study initiation. OFSETwas activated Aug 2023. As of 1-6-25, accrual is: 188/3,960. NCT #: NCT05879926. Support: U10CA180868, -80822, UG1CA189867, U24CA196067. Clinical trial information: NCT05879926. TPS616 **Poster Session**

A phase 3, randomized study of adjuvant sacituzumab tirumotecan plus pembrolizumab vs treatment of physician's choice in participants with triple-negative breast cancer who received neoadjuvant therapy and did not achieve a pathologic complete response at surgery. First Author: Heather L. McArthur, UT Southwestern Medical Center, Dallas, TX

Background: Trophoblast cell surface antigen 2 (TROP2) expression is higher in triple-negative breast cancer (TNBC) vs other breast cancer subtypes, and high expression is associated with poor prognosis. Sacituzumab tirumotecan (sac-TMT; also known as MK-2870/SKB264) is a novel antibody-drug conjugate composed of anti-TROP2 antibody coupled to a cytotoxic belotecan derivative via a novel linker (average drug/antibody ratio, 7.4). In a prior phase 3 study (OptiTROP-Breast01), sac-TMT alone improved PFS (HR, 0.31; 95% CI, 0.22-0.45; $P < 0.00001$) and OS (HR, 0.53; 95% CI, 0.36-0.78; $P = 0.0005$) vs chemotherapy in participants with heavily pretreated advanced TNBC. The current standard of care (SOC) for patients with newly diagnosed, high-risk, early-stage TNBC is neoadjuvant pembrolizumab + chemotherapy followed by adjuvant pembrolizumab after surgery. Patients who do not achieve a pathologic complete response (pCR) with the current SOC have higher rates of recurrence and mortality vs patients who achieve pCR. This study (NCT06393374) evaluates adjuvant sac-TMT + pembrolizumab vs treatment of physician's choice (TPC; pembrolizumab ± capecitabine) in participants with TNBC who received neoadjuvant therapy and did not achieve pCR at surgery. **Methods:** This phase 3, multicenter, open-label study is enrolling participants ≥18 years old with centrally confirmed TNBC per most recent American Society of Clinical Oncology/College of American Pathologists guidelines. Participants have non-pCR after ≥5 cycles of neoadjuvant pembrolizumab + chemotherapy, including ≥1 cycle of anthracycline-based neoadjuvant therapy. Participants must provide tissue from the surgical specimen for central TROP2 assessment and be able to continue on adjuvant pembrolizumab. Randomization must be conducted ≤12 weeks from surgical resection (window may be extended in consult with sponsor). Participants are randomized 1:1 to pembrolizumab 400 mg Q6W for 5 doses + sac-TMT 4 mg/kg Q2W for 12 doses or TPC with pembrolizumab 400 mg Q6W for 5 doses ± capecitabine 1000-1250 mg/m^2 BID on days 1-14 and days 22-35 every 42 days for 4 cycles until completion of therapy or disease recurrence, unacceptable toxicity, or withdrawal. Randomization is stratified by residual tumor and lymph node status, TROP2 expression, and intention to use capecitabine. Primary endpoint is invasive disease-free survival. Secondary endpoints are OS, distant recurrence-free survival, patient-reported outcomes, and safety. Enrollment began Q2 2024. Clinical trial information: NCT06393374. Research Sponsor: Merck Sharp & Dohme LLC, a subsidiary of Merck & Co., Inc., Rahway, NJ, USA.

TPS617 **Poster Session**

Adjuvant WIDER: A phase 3b trial of ribociclib (RIB) + endocrine therapy (ET) as adjuvant treatment (tx) in a close-to-clinical-practice patient (pt) population with HR+/HER2− early breast cancer (EBC). First Author: Stephanie L. Graff, Brown University Health Cancer Institute, The Warren Alpert Medical School of Brown University, Providence, RI

Background: The phase 3 NATALEE trial met its primary endpoint with significant invasive disease–free survival benefit with RIB + ET vs ET alone in a broad pt population with stage II/III HR+/HER2− EBC, sustained with additional follow-up at 44.2 months (hazard ratio, 0.715). The Adjuvant WIDER trial will evaluate RIB + ET in an HR+/HER2− EBC pt population that reflects pts seen in clinical practice as it has wider eligibility criteria, including an additional focus on enrolling minority pts underrepresented in NATALEE. Given the unmet need in pts with Stage II/III EBC, the results of this trial will complement existing data on benefits of RIB + ET. **Methods:** This phase 3b, multicenter, open-label, single-arm trial will evaluate, with early involvement of key pt advocacy groups, the efficacy and safety of adjuvant RIB + ET in a close-to-clinical-practice pt population with HR+/HER2− EBC. Eligible women and men aged ≥18 years with an ECOG PS of 0 to 2 and anatomic stage II/III disease (AJCC 8th ed), with additional criteria for stage IIA disease (N1 or N0 with grade 3, or grade 2 with Ki-67 ≥20% or high genomic risk), will be included. Pts will receive RIB (400 mg/d; 3 wk on/1 wk off) + ET (letrozole 2.5 mg/d, anastrozole 1 mg/d, or exemestane 25 mg/d) for 36 months, followed by ET alone as SOC per investigator's clinical judgment. Pre/perimenopausal women and men will receive goserelin 3.6 mg or leuprolide 3.75 mg/4 wk. Switching between ETs during study tx will be allowed in cases of unmanageable toxicity. Pts may have received (neo)adjuvant ET if initiated ≤36 months prior to enrollment. The number of pts with prior ET between 12 and 36 months will be capped at ≈30%; this cap will not be applicable to Black or African American pts. For pts with prior ET >12 months, restaging is recommended. Pts with prior CDK4/6i tx (except RIB) in the adjuvant setting for ≤6 months who discontinued due to toxicity can be included. Study tx may be held ≤28 days (or longer on agreement) to recover from RIB-related toxicity before restarting. If indicated, pts must have completed radiotherapy or chemotherapy before screening. Key exclusion criteria are distant metastases and/or recurrence and clinically significant, uncontrolled heart disease at screening. The primary endpoint is investigator-assessed invasive breast cancer–free survival rate at 3 years per STEEP v2.0 criteria. Secondary endpoints include invasive disease–free survival, distant disease–free survival, distant relapse–free survival, recurrence–free interval, overall survival, quality of life, and safety. Exploratory endpoints will assess subsequent antineoplastic tx, potential mechanisms of RIB benefit/resistance to RIB + ET, and RIB efficacy/safety in Black pts. Estimated enrollment is 1400 pts globally. Recruitment is ongoing. Clinical trial information: NCT05827081. Research Sponsor: Novartis Pharmaceuticals Corporation.

TPS618 **Poster Session**

Phase III study to evaluate the efficacy and safety of GLSI-100 (GP2 + GM-CSF) in breast cancer patients with residual disease or high-risk PCR after both neo-adjuvant and postoperative adjuvant anti-HER2 therapy: Flamingo-01. First Author: Snehal Patel, Greenwich LifeSciences, Stafford, TX

Background: GP2 is a biologic nine amino acid peptide of the HER2/*neu* protein delivered in combination with Granulocyte-Macrophage Colony Stimulating Factor (GM-CSF) that stimulates an immune response targeting HER2/neu expressing cancers, the combination known as GLSI-100. Of the 146 patients that have been treated with GLSI-100 over 4 clinical trials, GLSI-100 was well-tolerated and no serious adverse events observed were considered related to the immunotherapy. **Methods:** This Phase III trial is a prospective, randomized, double-blinded, multi-center study. After 1 year of trastuzumab-based therapy, 6 intradermal injections of GLSI-100 or placebo will be administered over the first 6 months and 5 subsequent boosters will be administered over the next 2.5 years. The participant duration of the trial will be 3 years treatment plus 1 additional year follow-up. Study Size – Interim Analysis: Approximately 498 patients will be enrolled. To detect a hazard ratio of 0.3 in invasive breast cancer free survival (IBCFS), 28 events will be required. An interim analysis for superiority and futility will be conducted when at least 14 events have occurred. This sample size provides 80% power if the annual rate of events in placebo patients is 2.4% or greater. Up to 250 non-HLA-A*02 subjects will be enrolled in an open-label arm. Eligibility Criteria: The patient population is defined by these key eligibility criteria: 1) HER2/neu positive and HLA-A*02, 2) Residual disease or High risk pCR (Stage III at presentation) post neo-adjuvant therapy, 3) Exclude Stage IV, and 4) Completed at least 90% of planned trastuzumab-based therapy. Trial Objectives: The trial objectives are to: 1) Determine if GP2 therapy increases IBCFS, 2) Assess the safety profile of GP2, and 3) Monitor immunologic responses to treatment and assess relationship to efficacy and safety. Study Status: The study is actively recruiting and enrolling patients in the US and Europe at up to 150 sites. Contact Information: Greenwich LifeSciences, Inc., Stafford, TX; Email: Flamingo-01@greenwichlifesciences.com; Website: greenwichlifesciences.com Funding: This trial is supported by Greenwich LifeSciences. Clinical trial information: NCT05232916. Research Sponsor: None.

TPS619 **Poster Session**

ELEGANT: Elacestrant versus standard endocrine therapy (ET) in women and men with node-positive, estrogen receptor-positive (ER+), HER2-negative (HER2-), early breast cancer (eBC) with high risk of recurrence in a global, multicenter, randomized, open-label phase 3 study. First Author: Aditya Bardia, UCLA Health Jonsson Comprehensive Cancer Center, Los Angeles, CA

Background: Adjuvant ET is the standard of care (SOC) for treating ER+/HER2- eBC. Despite advances to optimize adjuvant treatment in high-risk ER+/HER2- eBC, there continues to be a risk of local and metastatic (incurable) recurrence that persists, and new therapies with desirable safety profiles are warranted. Elacestrant is a next-generation oral SERD that provides a novel mechanism of action that has shown both SERD (degradative) and SERM (partial agonist) activity that differs from currently available adjuvant ET (Wardell, ERC 2015). In the EMERALD trial, elacestrant significantly prolonged PFS vs SOC ET in the overall population (HR 0.70; 95% CI 0.55-0.88; P=0.0018) and in patients with *ESR1*-mut tumors (HR 0.55; 95% CI 0.39-0.77; P=0.0005) (Bidard, JCO 2022). In patients with *ESR1*-mut tumors who received prior ET+CDK4/6i ≥12 mo, mPFS with elacestrant was 8.6 vs 1.9 mo with SOC ET (Bardia, CCR 2024). In a preoperative, window of opportunity ER+/HER2- eBC trial (SOLTI-1905-ELIPSE), elacestrant was associated with complete cell cycle arrest (defined as Ki67<2.7%) rate of 27% and a statistically significant mean change from baseline, shifting tumor biology toward a more endocrine-sensitive and less proliferative tumor phenotype (Vidal, CCR 2025). Given that elacestrant demonstrated efficacy in mBC regardless of *ESR1*-mut status relative to SOC ET and has shown biologic activity in eBC, it is hypothesized that elacestrant can prolong invasive breast cancer-free survival (IBCFS) in patients with high-risk eBC who received prior adjuvant ET±CDK4/6i. **Methods:** ELEGANT (NCT06492616) is a global, multicenter, open-label phase 3 study designed to evaluate elacestrant vs SOC ET (AI or tamoxifen) in patients with eBC and a high risk of recurrence. Patients will be randomized 1:1 to continue SOC ET or to elacestrant for a duration of 5 yrs. Eligible patients are women or men with ER+/HER2− node-positive eBC who have completed 24-60 mo of adjuvant ET±CDK4/6i and have ECOG PS ≤1. Patients who received a prior CDK4/6i or a PARP inhibitor must have already completed or discontinued these treatments. Pre/perimenopausal women and men will be administered a LHRH agonist. Exclusion criteria include inflammatory breast cancer, history of prior invasive breast cancer, and >6 mo continuous interruption of prior SOC adjuvant ET or discontinuation of adjuvant ET >6 mo prior to randomization. The primary endpoint is IBCFS. Key secondary endpoints include distant relapse-free survival, overall survival, invasive disease-free survival, safety, patient-reported outcomes-quality of life, and pharmacokinetics. Status: Planned enrollment is 4,220 patients; recruitment is ongoing. Clinical trial information: NCT06492616. Research Sponsor: Menarini Group.

TPS620 **Poster Session**

EORTC-2129-BCG: Elacestrant for treating ER+/HER2- breast cancer patients with ctDNA relapse (TREAT ctDNA). First Author: Michail Ignatiadis, Breast Medical Oncology Clinic, Institut Jules Bordet, Université Libre de Bruxelles (ULB), Hôpital Universitaire de Bruxelles (HUB), Brussels, Belgium

Background: (Neo)adjuvant systemic treatment, with chemotherapy and/or endocrine therapy (ET), substantially reduces the recurrence rates of estrogen receptor positive (ER+) human epidermal growth factor receptor 2 negative (HER2-) early-stage breast cancer (BC). However, recurrences still occur up to 20 years after diagnosis. Circulating tumor DNA (ctDNA) has emerged as a useful biomarker for surveillance in several solid tumors. ctDNA-based detection of molecular recurrence could allow the start of effective therapies before the clinical evidence of metastases. Elacestrant, a selective ER degrader, approved in the advanced setting of ER+/HER2- ESR1-mutated BC following progression on a CDK4/6-inhibitor, could be used at the time of ctDNA-based molecular relapse to delay or prevent the clinical manifestation of distant metastasis. **Methods:** TREAT ctDNA is an European Organisation for Research and Treatment of Cancer (EORTC)-led intergroup international, multicentre, randomised, open label, superiority phase III trial to evaluate adjuvant elacestrant vs standard ET in patients with ER+/HER2- BC. The study comprises a screening and a randomised phase based on ctDNA status using a clinically-validated, tumor-informed molecular residual disease ctDNA assay (Signatera). Screening phase: 1960 patients with intermediate to high-risk stage II or III ER+/HER2- BC on medium to long duration ET will be screened for a ctDNA-based molecular relapse every 6 months. Randomised phase: 220 ctDNA-positive patients without imaging evidence of recurrence will be randomised 1:1 between continuing current ET versus switching to elacestrant for a duration of at least 7 years of ET in total. Participants will undergo intensive follow-up for 3 years with computed tomography and bone scans, in addition to the standard annual breast imaging. The primary endpoint of the study is distant metastasis free survival and secondary endpoints are invasive disease-free survival, relapse-free survival, overall survival, safety and quality of life. Recruitment started in December 2023 in Belgium, is open in 12 countries at 74 sites and anticipates up to 120 enrolling sites in 2025. Overall study status and databases status will be periodically reviewed by the IDMC. Clinical trial identification: EU trial number 2022-501453-36-00. NCT05512364. Study conducted under the Breast International Group (BIG) umbrella. Collaborative groups: GIM, CTI, SUCCESS, SOLTI, HeCOG, HORG, BOOG, SweBCG and ETOP-IBCSG. Clinical trial information: 2022-501453-36-00. Research Sponsor: BERLIN-CHEMIEAG MENARINI from Germany.

TPS621 **Poster Session**

The SURVIVE study: Standard surveillance vs. intensified liquid biopsy-based surveillance in early breast cancer survivors. First Author: Henning Schäffler, Department of Gynecology and Obstetrics, University Hospital Ulm, Ulm, Germany

Background: Current breast cancer (BC) follow-up relies on clinical examinations and breast imaging, as studies from the 1980s demonstrated no survival benefit from distant metastasis screening. However, with advancements in treatment strategies and the diagnostic potential of liquid biopsies, this approach warrants re-evaluation. To enable pre-symptomatic detection of distant relapse, we propose assessing a liquid biopsy-guided surveillance strategy incorporating tumor markers (CA 27.29, CA 125, CEA), circulating tumor cells (CTCs), and circulating tumor DNA (ctDNA). **Methods:** The SURVIVE study (NCT05658172) is the first large-scale, multicenter, partially double-blinded randomized controlled trial comparing intensified and standard surveillance in 3,500 survivors of medium- to high-risk early breast cancer (eBC). All subtypes are eligible. High risk includes (neo-)adjuvant chemotherapy, tumor size $>$50 mm, positive lymph nodes ($\geq$pN1mi), or high grade ($\geq$G3). Patients are randomized 1:1 to standard or liquid biopsy-guided intensified follow-up. Primary therapy (surgery, adjuvant chemo- or radiotherapy) completion is required, while adjuvant endocrine, antibody, or targeted therapy is permitted. Enrollment is allowed up to 24 months post-primary therapy for TNBC/HER2+ eBC and 60 months for HR+/HER2- eBC. In both arms, guideline-based follow-up is performed, with additional blood samples collected longitudinally (years 1–3 every 3 months; years 4–5 every 6 months). In the intervention arm, these samples are analyzed for tumor markers, CTCs, and ctDNA (RaDaR assay). Abnormal findings indicating minimal residual disease (MRD) trigger full staging. Recurrence is treated per national guidelines. In the case of M0 status, liquid biopsy testing and staging continue, with the option for inclusion in interventional trials, if applicable. The study is recruiting, with the first patient enrolled in December 2022. By January 2025, 812 patients were randomized across 78 centers. Final enrollment is scheduled for 2026 but may occur earlier due to accelerated recruitment. Statistics: The two primary objectives are to evaluate the lead time effect obtained by liquid biopsy marker testing in the intensified follow-up arm and to test whether intensified, liquid biopsy-guided surveillance improves overall survival (OS) compared to standard follow-up. OS will be analyzed in the ITT population using Kaplan-Meier and Cox regression, while the lead-time effect is assessed descriptively. Secondary endpoints include IDFS, DDFS, DRFS, BCSS, and QoL as well as biomarker sensitivities and specificities obtained in the intensified follow-up arm. Aims: We aim to determine whether liquid biopsy-guided follow-up enables earlier, sensitive, and specific detection of distant (oligo-)metastases, facilitating timely intervention and improving OS. Clinical trial information: NCT05658172. Research Sponsor: German Federal Ministry of Education and Research.

TPS622 **Poster Session**

The SURVIVE HERoes study: Targeting molecular relapse in breast cancer—A secondary adjuvant intervention study of trastuzumab deruxtecan versus SOC treatment in patients with HER2-positive or HER2-low early breast cancer and ctDNA positivity after primary therapy. First Author: Kerstin Pfister, Department of Gynecology and Obstetrics, University Hospital Ulm, Ulm, Germany

Background: Current research on circulating tumor DNA (ctDNA) in the adjuvant setting of early breast cancer (eBC) underscores its strong prognostic significance. Patients who are ctDNA-positive but show no radiological signs of relapse (i.e., molecular relapse) exhibit reduced disease-free and overall survival. Secondary adjuvant intervention studies represent an innovative and promising therapeutic approach. **Methods:** We introduce SURVIVE HERoes (NCT06643585), a phase III randomized clinical trial comparing the potent antibody-drug conjugate trastuzumab deruxtecan to standard of care (SoC) in patients with HER2-positive or HER2-low eBC and molecular residual or recurrent disease (ctDNA-positive, cM0) following primary therapy. Patients tested positive for ctDNA in a tumor-informed approach are eligible, if staging examinations do not show any residual or recurrent cancer. Participants are randomized in a 2:1 ratio to receive trastuzumab deruxtecan (+ endocrine therapy for HR+ patients) or SoC therapy. Stratification factors include hormonal receptor status (positive versus negative) and HER2 status (positive versus low). The primary endpoint is ctDNA clearance rate after 12 months of therapeutic intervention. Secondary endpoints include relapse-free survival, overall survival, safety, and quality of life (QoL). The trial will enroll a total of 180 participants across 50 centers in Germany. Staging examinations and ctDNA assessments will be performed at regular intervals. The study is accompanied by a comprehensive translational research program. Recruitment began in January 2025 and is anticipated to continue until 2030. Discussion: Treating ctDNA-positive patients without radiographic evidence of recurrence is a novel therapeutic strategy. If SURVIVE HERoes and similar studies targeting minimal residual disease (MRD) yield positive results, they could pave the way for a new molecularly driven individualized treatment approach aimed at achieving cure by liquid biopsy triggered early intervention in this new therapeutic window of pre-symptomatic MRD. Clinical trial information: NCT06643585. Research Sponsor: Astra Zeneca.

TPS623 **Poster Session**

Short-term pre-operative durvalumab (MEDI 4736) in early small triple-negative breast cancer patients (POP-Durva). First Author: Joana M. Ribeiro, Gustave Roussy, Department of Medical Oncology, IHU-National PRecISion Medicine Center in Oncology, France, Villejuif, France

Background: Pathological response to neoadjuvant immune checkpoint inhibitors (ICI) is associated with excellent survival in several tumor types. In Stage II-III triple negative breast cancer (TNBC), neoadjuvant anti-PD-(L)1 with chemotherapy improves pathological complete response (pCR) and reduces recurrence. In Stage I TNBC, (neo)adjuvant chemotherapy remains standard of care. Exceptional responses to ICI in TNBC have been observed, suggesting a subgroup of Stage I TNBC could be treated with ICI alone; however, biomarkers to select patients are lacking. **Methods:** Trial Design: POP-Durva (NCT05215106) is a prospective, single-arm phase II trial evaluating pCR after two doses of durvalumab in Stage I TNBC. Patients with untreated clinical stage I ($\leq$2cm, N0) TNBC (ER $<$ 10%, PR $<$ 10%, HER-2 non-amplified) with sTIL of $\geq$ 5% will be included. Study treatment consists of two doses of durvalumab 10mg/kg IV, on D1 and D15. On completion of study treatment, patients will undergo breast US and will proceed to surgery, or standard neoadjuvant treatment, per physician preference. Fresh tissue biopsy and Formalin-Fixed Paraffin-Embedded (FFPE) will be collected at screening, on D22 or at surgery; blood will be collected for PBMC and ctDNA at screening, D1, D15 and on D22; faecal specimen collection will occur at baseline and at end of treatment (for microbiota analysis). Trial Endpoints: The primary endpoint is pCR (ypT0/is ypN0). In patients who proceed directly to surgery following durvalumab, pCR will be assessed at surgery. Patients with residual invasive disease at the D22 biopsy who receive further neoadjuvant therapy will be considered non-pCR for the primary endpoint. With an expected pCR rate of 20%, a sample size of 195 patients provides a 95% confidence interval of a precision of 6.2%. The secondary objectives are ORR and safety. The key exploratory objective is to identify biomarkers of response to ICI. Spectral cytometry, single-cell RNA and TCR sequencing will be performed to describe on-treatment immune cell dynamics and to identify mechanisms of response to ICI monotherapy. Imaging-mass cytometry will characterise tumour-immune cell spatial interactions. Microbiome profiles will be correlated with response. 4 sites in France are actively recruiting; as of 27/01/2025, 35 patients have been treated. Clinical trial information: NCT05215106. Research Sponsor: None.

TPS624 **Poster Session**

RECAST (Re-Evaluating Conditions for Active Surveillance Suitability as Treatment) for DCIS: Clinical trial in progress. First Author: Ruolin Lorraine Jiang, University of California, San Francisco, San Francisco, CA

Background: Ductal Carcinoma In Situ (DCIS) is a condition where cancerous cells are confined to the breast ducts. The standard of care is surgery, either breast conservation and radiation or mastectomy. Data from the COMET study in hormone receptor-positive (HR+) DCIS demonstrates that active surveillance (AS) is a safe alternative for initial treatment. Starting with endocrine risk-reducing therapy first may assist in identifying candidates for risk reduction vs. focal surgical removal. The RECAST (Re-Evaluating Conditions for Active Surveillance Suitability as Treatment) study re-orders the treatment, starting with endocrine risk reduction, and uses serial imaging to assess treatment response to predict who can safely proceed with AS and endocrine therapy. Imaging response markers are tested to predict the success of endocrine therapy. Several novel endocrine treatments are tested. The trial gives patients a window of opportunity to evaluate the impact of endocrine therapy based on their imaging characteristics to explore alternatives to surgery. Rather than being randomly assigned to surgery or AS, all patients start with AS and serve as their own control. **Methods:** Women are screened for and randomized to 1 of 4 endocrine treatments, one of which is the standard of care endocrine therapy (choice of tamoxifen, baby tamoxifen, or an aromatase inhibitor is left to patient and physician discretion); MRIs are conducted at baseline, 3 and 6 months and semiquantitative imaging determines suitability for AS. Patients on AS are eligible to continue treatment for 3 years. Follow-up consists of an MRI alternating with a mammogram every 6 months. Quality of life (QOL) is measured using PROMIS and the FACT-ES composite scores. *Eligibility:* All patients with a diagnosis of HR+ DCIS (any grade), defined as $>$ 50% ER+ or PR+ on immunohistochemistry *Exclusion*: Presence of invasive disease, pregnancy or active breastfeeding, history of deep vein thrombosis. Patients with a solid mass on MRI must have a repeated biopsy *Primary objectives:* To determine whether novel endocrine therapy increases the fraction of patients who are suitable for long-term AS and how medications are tolerated compared to standard endocrine treatment *Primary endpoints:* QOL and fraction of patients who meet criteria for remaining on AS after 6 months based on MRI *Secondary endpoints:* Biomarkers of response and resistance *Progress to date:* RECAST activated on 01/22/2024. Currently,12 sites in the US are open to enrollment. 28 are in the process of activation. There are 22 patients accrued with 6 in screening. RECAST is an important next step in elucidating the factors that predict the success of AS and provide a framework for understanding endocrine resistance in the HR+ DCIS population. Clinical trial information: NCT06075953. Research Sponsor: Quantum Leap Healthcare Collaborative.

TPS625 **Poster Session**

NRG-BR007: A phase III trial evaluating de-escalation of breast radiation (DEBRA) following breast-conserving surgery of stage 1, HR+, HER2-, RS ≤18 breast cancer. First Author: Julia R. White, University of Kansas Medical Center Comprehensive Cancer Center, Kansas City, KS

Background: Approximately 50% of newly diagnosed invasive breast cancers are stage 1, with the majority being ER/PR-positive, HER2-negative. Genomic assays such as the Oncotype DX have identified patients (pts) with reduced risk of distant metastasis and without benefit from chemotherapy added to endocrine therapy (ET), freeing them from excess toxicity. Genomic assays are also recognized as prognostic for in-breast recurrence (IBR) after breast-conserving surgery (BCS) and could similarly allow de-escalation of adjuvant radiotherapy (RT). Reducing overtreatment is of interest to pts, providers, and payers. **Methods:** We hypothesize that BCS alone is non-inferior to BCS plus RT for IBR and breast preservation in women intending ET for stage 1 invasive breast cancer (ER and/or PR-positive, HER2-negative with an Oncotype DX Recurrence Score [RS] of $\leq$18). Stratification is by age ($<$60; $\geq$60), tumor size ($\leq$1 cm; $>$1-2cm), and RS ($\leq$11, $>$11-18/MammaPrint Low). Pts are randomized post-BCS to Arm 1 with breast RT using standard methods (moderate or ultra hypo- or conventional-fractionated whole breast RT with/without boost, or APBI) with $\geq$5 yrs of ET (tamoxifen or AI) or Arm 2 with $\geq$5 yrs of ET (tamoxifen or AI) alone. The specific regimen of ET in both arms is at the treating physician's discretion. Eligible pts are stage 1: pT1 ($\leq$2 cm), pN0, age $\geq$50 to $<$70 yrs, s/p BCS with negative margins (no ink on tumor), s/p axillary nodal staging (SNB or ALND), ER and/or PR-positive (ASCO/CAP), HER2-negative (ASCO/CAP), and Oncotype DX RS $\leq$18 (diagnostic core biopsy or resected specimen). A "low risk" MammaPrint is permissible if completed as part of usual care prior to screening. Primary endpoint is IBR (invasive breast cancer or DCIS). Secondary endpoints are breast conservation rate, invasive in-breast recurrence, relapse-free interval, distant disease-free survival, overall survival, patient-reported breast pain, patient-reported worry about recurrence, and adherence to ET. We assume a clinically acceptable difference in IBR of 4% at 10 yrs to judge omission of RT as non-inferior (10-yr event-free survival for RT group is 95.6% *v* 91.6% for the omission-of-RT group). BR007 is powered to detect non-inferiority with 80% power and a one-sided α=0.025, assuming that there would be a ramp-up in accrual in the first two years (leveling off in Yrs 3-5); 1,670 pts (835 per arm) are required for randomization. Conservative loss to follow-up is 1%/yr. Some T1a pts screened may have Oncotype DX scores $>$18, making them ineligible for the study. In the accrual process, 1,714 pts will be required to register to ensure that our final randomized cohort is 1,670 pts. As of 1-6-2025: 1,168/1,670 pts have been randomly assigned, and 1,294 screened. Support: U10 CA180868, -180822, UG1 CA189867. Clinical trial information: NCT04852887. Research Sponsor: National Cancer Institute; U10 CA180868; National Cancer Institute; UG1CA189867; National Cancer Institute; UG1 CA189867.

TPS627 **Poster Session**

MELODY: A prospective non-interventional multicenter cohort study to evaluate different imaging-guided methods for localization of malignant breast lesions (EUBREAST-4/iBRA-NET/AGO-B-062, NCT 05559411). First Author: Maggie Banys-Paluchowski, Department of Obstetrics and Gynecology, University Hospital of Schleswig Holstein, Campus Lübeck, Lübeck, Germany

Background: In the last decades, the proportion of breast cancer patients receiving breast-conserving surgery has increased, reaching 70-80% in developed countries. In case of non-palpable lesions, surgical excision requires some form of breast localization. While wire-guided localization has long been considered gold standard, it carries several limitations, including logistical difficulties, the potential for displacement and patient discomfort, and re-excision rates reaching 21% (in DCIS up to 30%). Other techniques (radioactive seed or radio-occult lesion localization, intraoperative ultrasound, magnetic, radiofrequency, and radar localization) have been developed with the aim of overcoming these disadvantages. However, comparative data on the rates of successful lesion removal, negative margins, and re-operations are limited. In most studies, the patient perspective, addressing e.g. discomfort and pain, has not been evaluated. The aim of MELODY (MEthods for LOcalization of Different types of breast lesions) is to evaluate different imaging-guided localization methods with regard to oncological safety, patient-reported outcomes, surgeon and radiologist satisfaction and economic impact. **Methods:** The EUBREAST and the iBRA-NET have initiated the MELODY study to assess breast localization techniques and devices from several perspectives (NCT05559411, http://eubreast.org/melody). MELODY is a prospective intergroup cohort study which enrolls female and male patients. planned for breast-conserving surgery with imaging-guided localization for invasive breast cancer or DCIS. Multiple or bilateral lesions and neoadjuvant chemotherapy are allowed. Primary outcomes are: 1) Intended target lesion and/or marker removal, independent of margin status on final histopathology, and 2) Negative resection margin rates at first surgery. Secondary outcomes are, among others: rates of second surgery and secondary mastectomy, Resection Ratio (defined as actual resection volume divided by the calculated optimum specimen volume), duration of surgery, marker dislocation rates, rates of marker placement or localization failure, patient-reported outcomes, rates of "lost markers", radiologist and surgeon satisfaction, and health economic evaluation of the different techniques. Target accrual is 7,416 patients. Enrollment started in January 2023. Until 24 January 2025, 3938 patients from 20 countries were enrolled in the study. The study is expected to complete patient enrollment in year 2026. The study will be conducted in 30 countries and is supported by the Oncoplastic Breast Consortium (OPBC), AWOgyn, AGO-B, SENATURK, the American Society of Breast Surgeons (ASBS) and the Korean Breast Cancer Study Group (KBCSG). Clinical trial information: NCT05559411. Research Sponsor: None.

TPS628 **Poster Session**

Radiation omission in patients with clinically node-negative breast cancer undergoing lumpectomy (ROSALIE). First Author: Elena Parvez, McMaster University, Hamilton, ON, Canada

Background: Currently, the standard of care for patients undergoing neoadjuvant chemotherapy (NAC) and breast conserving surgery (BCS) is adjuvant radiation (RT). However, high rates of pathologic complete response (pCR) after NAC have raised questions regarding the necessity of WBRT in these cases. A meta-analysis of 9 German NAC trials demonstrated a 5-year locoregional recurrence (LRR) of only 4% in patients with pCR who underwent BCS with radiation therapy. Data from two large National Surgical Adjuvant Breast and Bowel Project (NSABP) neoadjuvant trials (B.18 and B.27) demonstrated a local recurrence risk of 5.1% at 10 years (2.5% at 5 years) in patients $>$50 years with node negative breast cancer who had a pCR and were treated with BCS and RT. With such low rates of recurrence, we postulated that the absolute benefit that RT can offer is limited. Radiation therapy is not without side effects, which include both short-term and long-term toxicity. As such, a trial of de-escalation of RT is warranted. **Methods:** This study is a prospective, multi-center, single arm cohort study of omission of WBRT following BCS in patients with a pCR following NAC. Eligible and consenting female patients with newly diagnosed T1-3 node negative breast cancer age $>$50 years with no clinical evidence of distant metastatic disease, who have been treated with NAC, BCS and axillary staging surgery with final pathology demonstrating a pCR (ypT0N0) will be enrolled to the study and followed. Negative lymph node involvement at initial presentation must be documented by imaging (US or MRI), fine needle aspiration (FNA) or core needle biopsy. Marker clip must have been placed in the tumour bed prior to or during neoadjuvant chemotherapy when the tumour can still be identified. Study participants will not receive adjuvant RT, the current standard of care. Study participants will be followed and assessed for local recurrence, regional recurrence, distant recurrence, DFS and OS. Any additional breast cancer treatments received by the participant for the first recurrence event including repeat BCS, mastectomy, additional systemic therapy and radiation therapy (RT) will be documented. The primary outcome is ipsilateral breast tumour recurrence (IBTR) at median 5-year follow-up. A local recurrence of 5% without RT was felt to be acceptable. Based on a postulated 5-year IBTR risk of 3.0%, 4 years of accrual plus an additional 3 years of follow-up, a 90% two-sided CI for a postulated LR rate of 3.0% at 5 years would have an upper bound of $<$5% with 300 patients. To account for a 5% potential loss to follow-up and 10% receiving RT contrary to protocol, a sample size of 352 patients will be required. The trial opened in March 2024. Clinical trial information: NCT05866458. Research Sponsor: Canadian Institutes of Health Research (CIHR).

TPS629 **Poster Session**

HERTHENA-Breast03: A phase 2, randomized, open-label study evaluating neoadjuvant patritumab deruxtecan + pembrolizumab before or after pembrolizumab + chemotherapy for early-stage TNBC or HR-low+/HER2− breast cancer. First Author: Joyce O'Shaughnessy, Baylor University Medical Center, Texas Oncology, Dallas, TX and Sarah Cannon Research Institute, Dallas, TX

Background: The standard of care for patients with high-risk, early-stage TNBC is neoadjuvant pembrolizumab (pembro) + chemotherapy followed by adjuvant pembro. Patients with HR-low+/HER2− breast cancer may also be treated per recommendations for TNBC. There is a need for improved neoadjuvant therapy to increase the rate of pCR, as patients who do not achieve pCR have a high risk of recurrence, and to reduce risk of long-term toxicities associated with cyclophosphamide and anthracyclines. HER3 is frequently expressed in breast cancer and implicated in drug resistance. Patritumab deruxtecan (HER3-DXd) is an antibody-drug conjugate comprising a fully human anti-HER3 IgG1 monoclonal antibody linked to a topoisomerase I inhibitor (DXd) via a stable tetrapeptide-based linker that is selectively cleaved within tumor cells. This phase 2 study (NCT06797635) will evaluate neoadjuvant HER3-DXd + pembro before or after carboplatin + paclitaxel + pembro for early-stage TNBC or HR-low+/HER2− breast cancer. **Methods:** Eligible participants (pts) are adults (≥18 y) with untreated, locally advanced nonmetastatic (AJCC stage cT1c, N1–N2 or cT2–cT4, N0–N2) TNBC or HR-low+/HER2− breast cancer. Pts (N ≥10 and ≤30) in part 1 of the study (safety lead-in) will receive neoadjuvant HER3-DXd + pembro followed by carboplatin + paclitaxel + pembro (Table) then surgery. DLT evaluation and dose finding for HER3-DXd (three dose levels of 5.6 mg/kg Q3W, 4.8 mg/kg Q3W and 3.2 mg/kg Q3W) during cycle 1 of neoadjuvant HER3-DXd + pembro will be performed in part 1 to determine an acceptable dose of HER3-DXd for part 2. Pts (N ~342) in part 2 will be randomly assigned 1:1:1 to arm A, B or C (Table) for neoadjuvant treatment. Randomization will be stratified by cancer type (TNBC vs HR-low+/HER2−) and, in the TNBC subgroup, PD-L1 status (combined positive score ≥10 vs <10), overall stage (II vs III) and HER3 expression (low vs high). After neoadjuvant treatment, pts will undergo surgery (with postoperative radiotherapy if clinically indicated) and receive adjuvant pembro 400 mg Q6W for 5 cycles. Pts with residual disease may receive additional adjuvant treatment of physician's choice. Primary endpoints are safety (part 1 and 2) and pCR (ypT0/Tis ypN0) (part 2). Enrollment is ongoing. Clinical trial information: NCT06797635. Research Sponsor: Merck Sharp & Dohme LLC, a subsidiary of Merck & Co., Inc., Rahway, NJ, USA (MSD). This study is part of a collaboration between MSD and Daiichi Sankyo, Inc.

	Neoadjuvant cycles 1-4	Neoadjuvant cycles 5-8
Part 1 Arm A	HER3-DXd 5.6 or 4.8 or 3.2 mg/kg Q3W + pembro[a]	Carboplatin[b] + paclitaxel[c] + pembro[a]
Part 2 Arm A	HER3-DXd (selected dose from Part 1) + pembro[a]	Carboplatin[b]+ paclitaxel[c] + pembro[a]
Part 2 Arm B	Carboplatin[b] + paclitaxel[c] + pembro[a]	HER3-DXd (selected dose from Part 1) + pembro[a]
Part 2 Arm C	Carboplatin[b] + paclitaxel[c] + pembro[a]	Doxorubicin[d] OR epirubicin[e] + cyclophosphamide[f] + pembro[a]

[a]200 mg Q3W; [b]AUC 1.5 mg/mL/min QW; [c]80 mg/m^2 QW; [d]60 mg/m^2 Q3W; [e]90 mg/m^2 Q3W; [f]600 mg/m^2 Q3W.

TPS630 **Poster Session**

Eliminating breast surgery for triple negative or HR-/HER2+ breast cancer patients with clinical complete response to combined neoadjuvant chemotherapy and neoadjuvant radiotherapy: A multicenter, phase 2 trial (EBCS). First Author: Zhengjun Yang, Tianjin Medical University Cancer Institute and Hospital, Tianjin, China

Background: Recent advancements in immunotherapy and targeted therapies have significantly improved pathological complete response (pCR) rates in patients with triple-negative breast cancer (TNBC) and HER2-positive breast cancer undergoing neoadjuvant chemotherapy. The combination of neoadjuvant chemotherapy with radiotherapy may further enhance pCR rates through synergistic effects, prompting a reevaluation of traditional surgical approaches. The Sound trial demonstrated that omitting sentinel lymph node biopsy in node-negative patients is safe and feasible, supporting further de-escalation of surgical interventions. For patients achieving pCR, the necessity of breast and axillary surgery is increasingly questioned, given the potential to reduce surgical morbidity without compromising outcomes. Our study investigates whether omitting surgery in patients with pCR confirmed by vacuum-assisted core biopsy (VACB) yields non-inferior 5-year event-free survival (EFS) compared to standard surgery. **Methods:** This multicenter, phase 2 trial enrolls patients aged ≥18 years with untreated cT1-2 N0 M0 TNBC or HER2-positive breast cancer and ECOG 0-1. Patients receive four cycles of TCb (HP)* neoadjuvant chemotherapy, followed by neoadjuvantradiotherapy starting from the fifth cycle (50 Gy in 25 fractions + 14 Gy boost in 7 fractions). The TCb (HP)* regimen is tailored based on tumor subtype: triple-negative patients receive TCb (nab-paclitaxel + carboplatin) with or without immunotherapy (pembrolizumab), while HER2-positive patients receive TCbHP (nab-paclitaxel + carboplatin + trastuzumab and pertuzumab) regimens. After six cycles, patients undergo MRI. If MRI suggests complete clinical response (cCR), VACB of the primary lesion is performed under ultrasound/stereotactic guidance (6 cores, 7-10 G needle). If no residual tumor or atypical cells are found, breast and axillary surgery are omitted. Patients receive indicated immunotherapy/targeted therapy and are followed every 6 months for 5 years. The primary endpoint is 5-year EFS. Secondary endpoints include breast pCR rate (bpCR: ypT0), overall survival (OS), patient-reported outcomes (PROs), and safety. TheThis trial is designed to determine whether the 5-year EFS of patients who avoid breast surgery after pCR confirmed by VACB is non-inferior to that of patients who undergo standard breast surgery with confirmed pCR. Based on a 90.3% 5-year EFS in pCR patients (cT1-2N0 TNBC/HER2+), the trial uses a one-sided test (non-inferiority margin: 5%; power: 80%; α: 0.1) to determine if omitting surgery is non-inferior. 185 patients are needed to omit surgery. Assuming 80% pCR and 10% dropout, 256 participants will be enrolled. The trail is actively recruiting. Clinical trial information: NCT06498154. Research Sponsor: None.

TPS631 **Poster Session**

A randomized trial of trastuzumab deruxtecan and biology-driven selection of neoadjuvant treatment for HER2-positive breast cancer (ARIADNE). First Author: Alexios Matikas, Karolinska Institutet and Karolinska University Hospital, Stockholm, Sweden

Background: Neoadjuvant therapy is the standard of care for the treatment of non-metastatic HER2-positive breast cancer. Studies on first generation antibody-drug conjugates (ADC) such as trastuzumab emtansine (T-DM1) showed equal or slightly lesser efficacy than chemotherapy combined with dual HER2 blockade. Trastuzumab deruxtecan (T-DXd) is a next generation ADC approved for the treatment of metastatic HER2-positive breast cancer, with greatly improved efficacy compared with T-DM1. **Methods:** ARIADNE is an academic, international, open label, randomized, comparative phase IIB trial, actively enrolling in Sweden (ten sites) and in Norway (seven sites), with sites in Belgium (three), Netherlands (one) and Italy (three) activating during Q2 2025. A total of 370 patients with non-metastatic HER2-positive primary breast cancer and an indication for neoadjuvant therapy will be offered inclusion and randomized 1:1 to receive either i) a taxane, carboplatin, trastuzumab and pertuzumab for three cycles or ii) T-DXd for three cycles. Further treatment is based on the PAM50-defined intrinsic molecular subtype from a pretreatment biopsy: HER2-enriched (approximately 65%) patients continue with the same treatment for three more cycles. Estrogen receptor (ER) positive and luminal (approximately 25%) patients receive trastuzumab and pertuzumab for three cycles, combined with letrozole and ribociclib for two cycles. Finally, ER-negative and luminal or basal-like (approximately 10%) patients either continue with the same treatment for three additional cycles in case of radiologic complete response, or they receive four cycles of dose-dense epirubicin and cyclophosphamide in case of lack of complete response. The primary endpoint of ARIADNE is locally assessed rate of pathologic complete response (pCR) in patients with molecularly HER2-enriched tumors, defined as ypT0/Tis, ypN0, as determined by a pathologist blinded to treatment assignment (intention-to-treat analysis). Key secondary endpoints are rates of complete radiologic response at three cycles; rates of pCR in the other two molecular groups and in the two groups of the initial randomization; event-free survival, defined as the time from randomization to disease progression, locoregional or distant recurrence, contralateral breast cancer, other cancer, or death due to any cause. Tissue and plasma samples are collected at baseline, during treatment and surgery, as well as during follow-up. The first patient was randomized on 26th October 2023; 46 patients had been enrolled to the study until January 2025. Clinical trial information: NCT05900206. Research Sponsor: None.

TPS632 **Poster Session**

OPERETTA: A phase II study evaluating neoadjuvant and adjuvant olaparib plus pembrolizumab following platinum-based chemotherapy plus pembrolizumab for germline BRCA mutated triple negative breast cancer. First Author: Yuko Takahashi, Department of Breast and Endocrine Surgery, Okayama University Hospital, Okayama, Japan

Background: Triple negative breast cancer (TNBC) remains the most challenging phenotype of breast cancer. There is still an unmet clinical need for improving the fine-tuning of indications for targeted treatments in this population. In TNBC, the frequency of germline BRCA (gBRCA) 1/2 mutations was reported to be up to 19.5%. This has led to promising clinical strategies based on poly adenosine diphosphate (ADP)-ribose polymerase inhibitors that inhibit single-stranded DNA damage repair and/or modified chemotherapy approaches targeting the DNA damage response, using platinum-based regimens. Based on the results of the OlympiA and KEYNOTE522 study, the adjuvant treatment with olaparib for gBRCAm and neoadjuvant and adjuvant pembrolizumab for patients with a high risk of recurrence TNBC has been treatment options as the standard of care. We hypothesize that neoadjuvant and adjuvant combination treatment with olaparib and pembrolizumab following combination treatment with platinum-based chemotherapy and pembrolizumab would synergistically increase the anti-tumor effect through the enhancement of immunogenicity and DNA damage in patients with gBRCA mutated breast cancer. **Methods:** OPERETTA is a multicentered, prospective single-arm phase II feasibility study of patients treated with neoadjuvant olaparib plus pembrolizumab following platinum-based chemotherapy plus pembrolizumab in gBRCA 1/2 mutated TNBC. The patients with stage IIA-IIIB TNBC known as gBRCA 1/2 mutated will be registered. The primary objective is the pCR rate defined as the absence of residual invasive disease in the breast and axilla. The secondary objectives include additional efficacy measures (i.e., Residual Cancer Burden [RCB] 0/1rate, 3 years overall survival [3y-OS], 3 years event-free survivals [3y-EFS]), and safety. The estimated sample size using Simon's two-stage design, with a null hypothesis of a 45% pCR rate and an alternative hypothesis of 70%, was calculated. Given a significance level of 0.1 and 80% power, the design allows a maximum of 23 patients to be included. Eligible patients will be received combination treatment with paclitaxel (80 mg/m2 qw), carboplatin (AUC 1.5 qw or AUC 5 q3w), and pembrolizumab (200mg q3w) for first 12 weeks followed by olaparib (300mg BID) with pembrolizumab (200mg q3w) for another 12 weeks as neoadjuvant treatment. Breast/axillary surgery and radiotherapy are recommended per standard of care. After surgery, the combination of olaparib plus pembrolizumab will be continued for another 27 weeks as adjuvant treatment. This study is recruiting in Japan, and 2 patients are enrolled as of January 2025. This study is part of the West Japan Oncology Group (WJOG) breast cancer study group: WJOG14020B. Clinical trial information: NCT05485766. Research Sponsor: Merck; AMED.

Vepdegestrant, a PROTAC estrogen receptor (ER) degrader, vs fulvestrant in ER-positive/human epidermal growth factor receptor 2 (HER2)—negative advanced breast cancer: Results of the global, randomized, phase 3 VERITAC-2 study. First Author: Erika P. Hamilton, Breast Cancer Research Program, Sarah Cannon Research Institute, Nashville, TN

The full, final text of this abstract will be available at meetings.asco.org on the day of presentation and in the online supplement to the June 10, 2025, issue of the *Journal of Clinical Oncology*.

1001 **Oral Abstract Session**

Patient-reported outcomes (PROs) in patients with ER+, HER2- advanced breast cancer (ABC) treated with imlunestrant, investigator's choice standard endocrine therapy, or imlunestrant + abemaciclib: Results from the phase III EMBER-3 trial. First Author: Giuseppe Curigliano, Istituto Europeo di Oncologia, IRCCS, University of Milano, Milano, Italy

Background: Imlunestrant (imlu) is a next-generation, brain-penetrant, oral selective estrogen receptor degrader. The EMBER-3 trial, in patients (pts) with ER+, HER2- ABC who had disease progression on or after aromatase inhibitor-based therapy, showed significant progression free survival (PFS) improvement with imlu vs standard therapy (SOC, fulvestrant or exemestane) in pts with *ESR1* mutations (*ESR1*m), and with imlunestrant+abemaciclib (imlu+abema) vs imlu in all pts, regardless of *ESR1*m. Exploratory PRO analyses are presented here. **Methods:** EORTC QLQ-C30 was administered at baseline (BL) and every 8 weeks until treatment discontinuation. Prespecified QLQ-C30 analysis used a longitudinal mixed model for repeated measures to calculate mean change from BL in pts with BL and $\geq$1 post-BL score. PRO-CTCAE (diarrhea frequency) was administered weekly, reporting 0 (never) to 4 (almost constantly). PRO-CTCAE (injection site reaction [ISR]) was administered to fulvestrant recipients weekly for 2 weeks post-injection, reporting yes/no (pain, swelling, redness). Descriptive analysis was used for PRO-CTCAE. **Results:** In pts with *ESR1*m, imlu monotherapy was associated with many improved or maintained EORTC QLQ-C30 scores, whereas scores with SOC were declined or maintained. Specifically, pts with *ESR1*m on imlu had improved global health status (GHS)/quality of life (QOL) and physical function (PF) scores, while scores with SOC declined (mean change differences between treatments: 9.9 [0.1, 19.7] and 6.2 [-0.8, 13.1], respectively). These PRO findings mirror the PFS findings in this group. In the overall population, GHS/QOL scores declined similarly with imlu vs SOC (mean change differences: 0.5 [-4.7, 5.7]), while PF scores were maintained with imlu vs a slight decline with SOC (mean change difference: 2.5 [-1.1, 6.1]). Most fulvestrant recipients (72%) reported ISR at any time while on treatment, with a mean of 31% during the first week of the first 6 cycles. Imlu+abema vs imlu showed broadly similar declines in all pts, with minimal mean change differences in GHS/QOL and PF scores (0.8 [-7.4, 5.9]; -2.2 [-6.6, 2.2], respectively). Pts reported similarly low rates of "frequent" or "almost constant" diarrhea with imlu (3%) and SOC (2%) and higher rates with imlu+abema (22%). **Conclusions:** PROs from EMBER-3 demonstrated that patients with *ESR1*m had better GHS/QOL and PF with imlu vs SOC, mirroring efficacy results. While the frequency of CTCAE defined ISRs was low, the high rate of PRO-CTCAE ISR demonstrates that this clinically relevant adverse event is underappreciated by physicians. Additionally, all pts had generally comparable GHS/QOL and PF with imlu+abema vs imlu. Overall, these results support the efficacy and safety of imlu compared to existing SOC. Clinical trial information: NCT04975308. Research Sponsor: Eli Lilly and Company, Indianapolis, IN, USA.

1003 **Oral Abstract Session**

INAVO120: Phase III trial final overall survival (OS) analysis of first-line inavolisib (INAVO)/placebo (PBO) + palbociclib (PALBO) + fulvestrant (FULV) in patients (pts) with *PIK3CA*-mutated, hormone receptor-positive (HR+), HER2-negative (HER2−), endocrine-resistant advanced breast cancer (aBC). First Author: Nicholas C. Turner, Royal Marsden Hospital and Institute of Cancer, London, United Kingdom

Background: INAVO, a highly potent and selective PI3Kα inhibitor that also promotes mutated p110α degradation, is FDA-approved in combination with PALBO + FULV for *PIK3CA*-mutated, HR+, HER2−, endocrine-resistant aBC, based on the primary analysis of INAVO120 (NCT04191499), which showed a statistically significant and clinically meaningful investigator-assessed progression-free survival (INV-PFS) benefit in the INAVO arm vs. the PBO arm (hazard ratio 0.43; 95% confidence interval [CI] = 0.32–0.59; $p < 0.0001$). At that analysis, interim OS results were immature. Here we report the final OS analysis, including updated efficacy and safety. **Methods:** Pts received INAVO (9 mg orally once daily [PO QD]; Days 1–28 of each 28-day cycle)/PBO + PALBO (125 mg PO QD; Days 1–21 of each cycle) + FULV (500 mg intramuscularly; Cycle 1 Days 1 and 15 then every ~4 weeks). OS and objective response rate (ORR) were formally tested; updated INV-PFS and safety analyses are descriptive. **Results:** Data cut-off was Nov 15, 2024, at 34.2 months (mo) of median follow-up. Median OS was 34.0 mo (95% CI = 28.4–44.8) in the INAVO arm and 27.0 mo (95% CI = 22.8–38.7) in the PBO arm (stratified hazard ratio 0.67; 95% CI = 0.48–0.94; p = 0.0190 [boundary = 0.0469]). The OS benefit was consistent across key subgroups. The survival probability at 6, 12, 18, 24, and 30 mo was 96.8%, 87.0%, 74.3%, 65.8%, and 56.5% in the INAVO arm and 90.1%, 76.7%, 67.2%, 56.3%, and 46.3% in the PBO arm. ORR was 62.7% (95% CI = 54.8–70.2) and 28.0% (95% CI = 21.3–35.6), respectively ($p < 0.0001$). Median time to chemotherapy (TTC) was 35.6 mo (95% CI = 25.4–not reached) in the INAVO arm and 12.6 mo (95% CI = 10.4–16.1) in the PBO arm (stratified hazard ratio 0.43; 95% CI = 0.30–0.60). Updated median INV-PFS was 17.2 mo (95% CI = 11.6–22.2) in the INAVO arm and 7.3 mo (95% CI = 5.9–9.2) in the PBO arm (stratified hazard ratio 0.42; 95% CI = 0.32–0.55), with landmark analyses supporting durable benefit. 90.7% of pts in the INAVO arm and 84.7% in the PBO arm had grade 3/4 adverse events (AEs); there were no new grade 5 AEs; 63.4% and 13.5% experienced any-grade hyperglycemia (grouped term); and AEs led to INAVO and PBO discontinuation in 6.8% and 0.6% of pts, respectively. **Conclusions:** INAVO + PALBO + FULV demonstrated a statistically significant and clinically meaningful OS benefit compared with PBO + PALBO + FULV. Improvement in INV-PFS was maintained during longer follow-up, along with a substantial and statistically significant improvement in ORR. TTC was also substantially delayed (by ~2 years) by the addition of INAVO to PALBO + FULV. With longer exposure to INAVO, no new safety signals, nor changes in the safety profile, were noted, supporting good tolerability (reflected in low discontinuation due to AEs). Clinical trial information: NCT04191499. Research Sponsor: F. Hoffmann-La Roche Ltd; The authors acknowledge the Memorial Sloan Kettering Cancer Center support grant (P30 CA008748).

1004 **Oral Abstract Session**

Phase I/Ib study of inavolisib (INAVO) alone and in combination with endocrine therapy ± palbociclib (PALBO) in patients (pts) with *PIK3CA*-mutated, hormone receptor−positive, HER2-negative locally advanced/metastatic breast cancer (HR+, HER2− LA/mBC): Analysis of hyperglycemia (HG) in prediabetic/obese pts. First Author: Mafalda Oliveira, Vall d'Hebron University Hospital and Vall d'Hebron Institute of Oncology (VHIO), Barcelona, Spain

Background: INAVO, a highly potent and selective PI3Kα inhibitor that also promotes degradation of mutated p110α, is approved by the FDA in combination with PALBO + fulvestrant (FULV) for *PIK3CA*-mutated, HR+, HER2−, endocrine-resistant advanced BC. HG is a common on-target side effect of PI3K inhibitors. There are limited data for PI3K inhibitors in prediabetic/obese pts. Data from prediabetic/obese pts with HR+, HER2− LA/mBC treated with INAVO from a Phase I/Ib study (GO39374; NCT03006172) are reported here. **Methods:** Adults $\geq$ 18 years of age received INAVO alone (Arm A), + letrozole (LET) + PALBO (Arm B), + LET (Arm C), + FULV (Arm D), + FULV + PALBO (Arm E), or + FULV + PALBO + primary prophylactic metformin (Arm F). Data are reported across all arms unless indicated. Pts with baseline risk factors for HG were defined by HbA_{1c} $\geq$5.7%, fasting blood glucose $\geq$ 100 mg/dL, or body mass index $\geq$ 30 kg/m^2. Adverse events (AEs) were reported using NCI-CTCAE v4, which utilizes fasting laboratory glucose values for HG severity grading, rather than clinical interventions used in v5. **Results:** Clinical cut-off was Jan 1, 2024. From190 pts treated, 110 (57.9%) were prediabetic/obese; their median time on INAVO was 222 days (range, 7 to 2,152) and mean cumulative dose intensity was 91.8%. Most prediabetic/obese pts discontinued INAVO due to progressive disease (82 [74.5%]); six (5.5%) discontinued INAVO due to an AE (one due to HG). HG was reported in 80.9% of prediabetic/obese pts (grade 3–4: 34.5%). In pts with two risk factors, 87.9% reported HG (grade 3–4: 39.4%). Among pts with HG, median time to onset was 14 days (range, 1 to 1,674) and 86.0% of events resolved by clinical cut-off. Median time to improvement or resolution of first worst grade $\geq$ 2 event was 8 days (range, 1 to 64). INAVO dose interruptions, reductions, and discontinuations due to HG were reported in 41.8%, 13.6%, and 0.9% of pts, respectively. The most common anti-HG medications were metformin (52.7%; biguanide; concomitant use in Arm F excluded), empagliflozin (25.5%; SGLT-2 inhibitor), sitagliptin (22.7%; DPP-4 inhibitor), and pioglitazone (13.6%; thiazolidinedione); insulin was used in 8.2% of pts. Median time to metformin start (excluding Arm F) was 14 days (range, 1 to 1,710); the median start dose was 1,000 mg total daily; and the highest daily start dose was 2,000 mg. More than one anti-HG medication was often needed. **Conclusions:** A high proportion of prediabetic/obese pts were included in GO39374. In most of these pts, HG was manageable with dose interruptions and oral anti-HG medications, most commonly metformin. Data support the use of INAVO in prediabetic/obese pts; further investigation of INAVO in pts with diabetes is warranted. Clinical trial information: NCT03006172. Research Sponsor: Genentech, Inc.; The authors acknowledge the Memorial Sloan Kettering Cancer Center support grant (P30 CA008748).

A double-blind placebo controlled randomized phase III trial of fulvestrant and ipatasertib as treatment for advanced HER2-negative and estrogen receptor positive (ER+) breast cancer following progression on first line CDK 4/6 inhibitor and aromatase inhibitor: The CCTG/BCT MA.40/FINER study (NCT04650581). First Author: Stephen K. L. Chia, BC Cancer Agency, Vancouver, BC, Canada

The full, final text of this abstract will be available at meetings.asco.org on the day of presentation and in the online supplement to the June 10, 2025, issue of the *Journal of Clinical Oncology*.

1007 **Oral Abstract Session**

Phase III of oral paclitaxel (DHP107) vs intravenous paclitaxel in HER2-negative recurrent or metastatic breast cancer (mBC): Primary analysis of a multinational optimal trial (NCT03315364). First Author: Sung-Bae Kim, Asan Medical Center, University of Ulsan College of Medicine, Seoul, South Korea

Background: DHP107 is a novel oral formulation of paclitaxel that is approved in South Korea and China for the treatment of gastric cancer. DHP107 had encouraging monotherapy anti-tumor activity with objective response rate (ORR) of 55% and median progression free survival (PFS) of 8.9 months (Mo) as first-line therapy in 31 patients with HER2 negative metastatic breast cancer (mBC) in the OPTIMAL phase II study (Kim *Ther Adv Med Oncol* 2021). The first primary analysis is reported herein. **Methods:** This phase III, open-label, randomized, controlled trial evaluated the non-inferiority of DHP107 to intravenous (IV) paclitaxel in mBC, with non-inferiority margin of 1.33. Patients (Pts) had received one or more lines of endocrine-based therapy and no chemotherapy for mBC. Pts from Korea, China, and Europe were randomized 1:1 to receive either DHP107 (200 mg/m² orally, twice daily) or IV paclitaxel (80 mg/m² weekly). The primary endpoint was investigator-assessed PFS. Secondary endpoints included overall survival (OS), ORR, disease control rate (DCR), quality of life (QoL), and safety. **Results:** With the median follow-up of 38.8 Mo, the median age of the pts was 56 years. Of the 549 pts who underwent randomization, 481 pts had hormone receptor positive (HR+) disease and 68 pts had triple negative disease. Among all pts, DHP107 demonstrated non-inferiority to IV paclitaxel in PFS (mPFS: 10.02 vs. 8.54 Mo; HR 0.869, 95% CI 0.707–1.068). OS was comparable between groups (mOS: 32.95 vs. 32.46 Mo; HR 0.979, 95% CI 0.769–1.246). Among HR+HER2-pts, the mPFS was 10.74 Mo in the DHP107 arm, and 9.07 Mo in IV paclitaxel arm (HR 0.869, 95% CI 0.700-1.080). QoL outcomes showed no significant differences. ORR (45.8% vs. 39.7%) ad DCR (93.5% vs. 86.4%) were higher in the DHP107 group. DHP107 was associated with lower incidences of peripheral neuropathy (37.91% vs. 48.29%), hypersensitivity reactions, musculoskeletal and connective tissue disorders, and injection/infusion related reactions compared to IV paclitaxel. Neutropenia was the most common toxicity in both groups, occurring more frequently in the DHP107 group (81.6% vs. 59.3%) with higher rates of Gr≥3,4 neutropenia (67.15% vs. 29.66%), and febrile neutropenia (6.14% vs. 0.76%), but no grade 5 events were reported. Gastrointestinal toxicities were more frequent in the DHP107 group but were predominately Gr1. In this study, discontinuation rate due to AEs were comparable (12.27% vs. 8.75%, p=0.2081) and AEs leading to death occurred rarely in both groups (1.08% vs. 1.90%). **Conclusions:** DHP107 demonstrated comparable efficacy to IV paclitaxel with tolerable and manageable toxicity. These results establish DHP107 as an effective, convenient alternative to IV paclitaxel for patients with HER2-negative mBC, supporting its potential role in routine clinical practice. Clinical trial information: NCT03315364. Research Sponsor: DAEWHA PHARM. CO., LTD.

Circulating tumor DNA, pathologic response after neoadjuvant therapy, and survival: First results from TBCRC 040 (the PREDICT-DNA trial). First Author: Natasha Hunter, University of Washington, Seattle, WA

Background: Patients with Stage II/III breast cancer that overexpresses the human epidermal growth factor-2 (HER2+) or is triple-negative (TNBC) generally receive upfront neoadjuvant therapy (NAT) before definitive surgery. Pathologic complete response (pCR) after NAT is associated with improved survival but a small proportion of patients remain at risk for recurrence. Circulating tumor DNA (ctDNA) in patients whose primary tumors have detectable mutations could improve the identification of patients who remain at risk after NAT. **Methods:** The Pathologic Response Evaluation and Detection In Circulating Tumor-DNA (PREDICT-DNA) trial was a prospective, multi-center study aimed at validating ctDNA as a biomarker for treatment response in Stage II/III HER2+ or TNBC. The primary aim was to determine the negative predictive value (NPV) of ctDNA for residual disease following NAT; secondary aims included five-year invasive disease-free survival (IDFS), which were fit to a Cox proportional hazards model. Mutations were identified from tumor tissue; ctDNA was then analyzed in pre- and post-NAT blood and compared with surgical pathology. Proposed sample size was 229 patients based on simulation to control expected half-width of a confidence interval on NPV to be ≤15% when NPV=90%. The Personalis NeXT Personal ctDNA assay was centrally performed. **Results:** 228 participants were enrolled in 24 sites between 2016 and 2018. 53% had TNBC, and 47% had HER2+ disease. 92.2% (n=166/180) had detectable ctDNA at baseline, and 46% of patients had pCR (42% TNBC, 50% HER2+). 54% of all post-NAT ctDNA detections were in the ultrasensitive range below 100 PPM. Among 112 subjects with undetectable ctDNA prior to surgery, 45 were found to have residual disease resulting in an NPV of 60% (CI 0.51-0.69). Patients with TNBC and detectable ctDNA prior to surgery were approximately 12 times more likely to experience a recurrence regardless of pCR (HR 12.8 [95% CI: 2.3-71.5]). See Table describing landmark IDFS analyses after surgery. **Conclusions:** While lack of ctDNA detection after NAT and before surgery did not predict pCR, initial analysis of predefined secondary objectives suggest that ctDNA-negative patients before surgery have excellent prognosis regardless of pCR, particularly if TNBC. This suggests that ctDNA may be a better biomarker for long term clinical outcomes than pCR. Further correlations and interactions will be presented. Clinical trial information: NCT02743910. Circulating tumor (ct)DNA monitoring of ER+/HER2- high-risk breast cancer during adjuvant endocrine therapy. First Author: Lajos Pusztai, Yale Cancer Center, Yale School of Medicine, New Haven, CT

Background: ctDNA monitoring during adjuvant endocrine therapy is an opportunity to detect molecular relapse before clinically apparent recurrence. ctDNA positivity rates, dynamics and the frequency of asymptomatic imaging-detectable metastatic disease at the time of ctDNA detection remain unknown in high-risk ER+/HER2- BCs. We present ctDNA results from a prospective, multicenter, randomized ctDNA interventional trial, DARE (NCT04567420). **Methods:** Patients receiving adjuvant endocrine therapy for >6 months but <7 years, with either recurrence risk >15% (PREDICT, RSPC, CTS5), >4 positive axillary lymph nodes, (primary tumor >5 cm, or 1-3 positive nodes with grade 3 histology, or >3 cm tumor, or high molecular risk (Oncotype Dx RS >26, MammaPrint high risk, EndoPredict >4, Prosigna score >60) were eligible for ctDNA surveillance with the Signatera assay (Natera, Inc.) every 6 months. ctDNA+ patients had systemic staging with imaging and if there was no evidence of metastatic disease patients were randomized to switching to fulvestrant + palbociclib (Arm A) or to continuation of adjuvant therapy (Arm B). Negative predictive value (NPV) was calculated for recurrence in the screening group after each ctDNA- test. In randomized patients, early ctDNA dynamics were correlated with recurrence-free survival (RFS) and ctDNA clearance rates were calculated by trial arm. **Results:** 552 patients had tissue sent for assay design; 494 had ctDNA results; 52 failed WES and/or had incomplete tumor/normal/blood sets; 6 had pending reports. Among patients not randomized, 432 were ctDNA-, of these N=43 had one time point and 389 had >2 ctDNA- result, overall median screening time 27.4 months (0-45.5), 4 ctDNA- patients had recurrence (NPV 100% at 6 months and 99% at 12 months post-testing). Forty patients were randomized, 34 had post-randomization ctDNA result. Randomization rates were 53% and 76% for patients who tested ctDNA-positive on the first screening (N=19) versus those who turned positive in follow up testing (N=15). At any time post-randomization, ctDNA clearance rates were 63% (10/16) in Arm A and 22% (4/18) in Arm B. Among randomized patients, 6 of 9 patients with increased ctDNA levels from the pre-randomization to the 3-month on-treatment recurred (median time to recurrence 4.8 months, range: 3.3-24.3), among those with a decrease in ctDNA post-treatment only 1 of 6 experienced recurrence at 10.3 months (HR: 5.3, 95% CI: 1.1-53, p=0.04). **Conclusions:** This study demonstrates the ability of ctDNA to identify breast cancer patients at high risk of relapse for randomization in a prospective, multicenter, randomized clinical trial. Patients with serially ctDNA- results during surveillance had 99% RFS after a median f/u of 27.4 months. Interim analysis revealed higher clearance rates in Arm A compared to patients randomized to Arm B. Early on treatment ctDNA dynamics is prognostic of patient outcomes. Clinical trial information: NCT04567420. Research Sponsor: Pfizer; Natera Inc.

1011 Clinical Science Symposium

Circulating tumor DNA (ctDNA) dynamics as a predictor of treatment response in metastatic breast cancer (mBC). First Author: Pedram Razavi, Memorial Sloan Kettering Cancer Center, New York, NY

Background: ctDNA testing has emerged as a prognostic and predictive biomarker in the management of mBC. However, the relationship between ctDNA trends and real-world treatment outcomes has yet to be fully characterized. Here, we utilized a claims database to evaluate the association between ctDNA trends and the time to next treatment (TTNT) in patients with mBC. **Methods:** We utilized Natera's proprietary real-world database linked to commercially available claims data to identify patients who received treatment for mBC and had ctDNA testing performed commercially using a clinically validated, personalized, tumor-informed mPCR-NGS ctDNA assay (Signatera™, Natera, Inc.). Insurance claim codes for treatment regimens were used to determine BC receptor subtype and therapy dates. Treatment lines were included in the analysis if a ctDNA test result was available within 4 weeks before treatment initiation (T1) and a subsequent ctDNA test result was available 2-6 weeks after treatment initiation (T2). TTNT was calculated as the time from initiation of the first treatment to the subsequent treatment. T1 to T2 ctDNA dynamics were analyzed using the Student's t-test and were categorized as favorable (persistently negative, ctDNA-clearance, ctDNA-decrease) or unfavorable (ctDNA-negative to positive, ctDNA-increase). **Results:** A total of 7,222 treatment lines were assessed for duration of treatment and corresponding ctDNA dynamics, including3,117 lines (N=2,362 patients) for HR+/HER2- mBC, 3,717 lines (N=1,943 patients) for HER2+ mBC, and 888 lines (N=605 patients) for TNBC. Of these, 448 treatment lines met the inclusion criteria for ctDNA analysis. In HER2+ breast cancer, TTNT across 226 treatment lines was significantly longer in patients with favorable ctDNA dynamics (6.7 [3.18–10.3] months) relative to unfavorable dynamics (2.7 [1.4–5.1] months; $p<0.0001$). Among patients with HR+/HER2- mBC, TTNT across 156 treatment lines was longer in those with favorable ctDNA dynamics (median [Q1, Q3]: 7.51 [3.72–11.57] months) compared to unfavorable dynamics (5.02 [1.8–9.84] months; p=0.052). A similar trend was observed in TNBC, where TTNT across 66 treatment lines was longer with favorable ctDNA dynamics (6.03 [2.89–10.07] months) compared to unfavorable dynamics (2.7 [1.16–5.89] months; p=0.381), though this was not statistically significant. **Conclusions:** Early on-treatment ctDNA dynamics, assessed within the first 6 weeks of therapy, was associated with TTNT in a real-world ctDNA monitoring setting across different mBC subtypes and therapeutic regimens. An early rise in ctDNA levels correlated with the shortest TTNT, whereas ctDNA clearance was associated with the longest TTNT intervals. These findings highlight the potential of serial ctDNA testing in mBC for monitoring treatment response and informing clinical decisions. Research Sponsor: None.

1012 Clinical Science Symposium

Assessment of ctDNA somatic homologous recombination deficiency (HRD) in triple-negative breast cancer (TNBC) from SWOG S1416 trial. First Author: Shane R. Stecklein, University of Kansas Medical Center, Kansas City, KS

Background: HRD is observed in up to two-thirds of g*BRCA*-wildtype TNBC. S1416 (NCT02595905) showed that addition of a PARP inhibitor (veliparib) to cisplatin improved progression-free survival (PFS) in *gBRCA*-wildtype metastatic TNBC (mTNBC) with HRD phenotype ("*BRCA*-like"). In this study, we sought to evaluate concordance between circulating tumor DNA (ctDNA)-based detection of somatic homologous recombination repair (sHRR) alterations and tumor-based HRD and to assess if sHRR deficiency (sHRR+) was associated with benefit from veliparib in g*BRCA*-wild type mTNBC in SWOG S1416. **Methods:** S1416 enrolled patients with mTNBC who had received ≤ 1 line of prior therapy and randomized them to cisplatin plus veliparib or placebo. Central *gBRCA1/2* testing classified patients as *gBRCA*-mutated or -wildtype. An *a priori* defined biomarker panel classified *gBRCA*-wildtype patients into *BRCA*-like (HRD+) and non-*BRCA*-like (HRD-) groups. A third group with *gBRCA*-wildtype, but without tissue BRCA classification was also included. Pre-treatment and progression plasma samples were utilized for assessment of sHRR status. ctDNA was analyzed using the Guardant OMNI next-generation sequencing platform. sHRR+ was defined by detectable somatic alterations (SNVs, INDELs, fusions with a functional impact notation of deleterious, and/or CNVs with a functional characterization of homozygous deletion) in a 24 gene panel. **Results:** Among *N*=213 g*BRCA*-wildtype patients with evaluable pre-treatment blood samples, 25% were sHRR+. Among sHRR+ patients, alterations in *CHEK2* (18%), *BRCA1* (17%), *BARD1* (8%), *ATM* (7%), *BAP1* (7%), *CDK12* (7%), *NBN* (7%), *BRCA2* (5%), and *FANCA* (5%) accounted for 80% of sHRR alterations. Most sHRR+ patients (91%) had alterations in only one of 24 genes, suggesting mutual exclusivity of homologous recombination pathway alterations in ctDNA. sHRR+ status was numerically higher in *BRCA*-like compared to non-*BRCA*-like tumors or unclassified tumors (32% vs. 20% vs. 20%, respectively; *P*=0.12). Among *n*=98 patients with availability of evaluable pre-treatment and progression samples, 31% were sHRR+ at baseline and 28% were sHRR+ at progression. Numerically, conversion from sHRR+ to sHRR- was more common than conversion from sHRR- to sHRR+ (30% vs. 9%, respectively). sHRR was not prognostic for PFS (median 4.3 (sHRR+) vs. 4.1 (sHRR-) months, respectively; *P*=0.30) nor predictive of benefit from veliparib (*P*=0.40). **Conclusions:** One-fourth of *gBRCA*-wildtype mTNBC patients have ctDNA sHRR alterations, and there is incomplete overlap between tumor- and ctDNA-assessed HRD. ctDNA sHRR alterations were mostly mutually exclusive. Approximately one-third of patients with baseline sHRR+ converted to sHRR- at time of progression while receiving DNA damaging chemotherapy. sHRR was not prognostic and did not predict benefit from veliparib in S1416. Research Sponsor: NIH/NCI/NCTN; U10CA180888; NIH/NCI/NCTN; U10CA180819.

1013 Oral Abstract Session

Exploratory biomarker analysis of trastuzumab deruxtecan (T-DXd) vs physician's choice of chemotherapy (TPC) in HER2-low/ultralow, hormone receptor–positive (HR+) metastatic breast cancer (mBC) in DESTINY-Breast06 (DB-06). First Author: Rebecca Alexandra Dent, National Cancer Centre Singapore, Singapore, Singapore

Background: DB-06 (NCT04494425), a Phase 3, randomized, open-label study, demonstrated a clinically meaningful progression-free survival (PFS; 13.2 vs 8.1 months [hazard ratio: 0.64]) benefit with T-DXd vs TPC (capecitabine, nab-paclitaxel, or paclitaxel) in patients with HR+, HER2-low (immunohistochemistry [IHC] 1+ or IHC 2+ / in situ hybridization–negative) or -ultralow (IHC 0 with membrane staining) mBC after $\geq$1 endocrine-based therapy (primary data cutoff: March 18, 2024). Here, we report an exploratory circulating tumor DNA (ctDNA) analysis based on baseline genomic status. **Methods:** Baseline ctDNA profiling in blood samples was assessed via Guardant OMNI 500-gene liquid biopsy assay. In total, 625 patients had evaluable ctDNA samples and putative tumor content, and comprised the biomarker evaluable population (BEP) presented herein. Baseline characteristics and efficacy outcomes were evaluated in key genomic subgroups (PI3K pathway, *ESR1*m, *BRCA1/2*m), including confirmed objective response rate (cORR) and PFS, both by blinded independent central review. **Results:** Genomic alterations were observed in 45.0% (PI3K pathway, n=281), 51.5% (*ESR1*m, n=322), and 7.7% (*BRCA1/2*m, n=48) of patients. The median PFS (mPFS) for each mutational subgroup was 13.2 (T-DXd) and 7.1 (TPC) months (PI3K pathway), 11.3 (T-DXd) and 7.0 (TPC) months (*ESR1*m), and 21.4 (T-DXd) and 5.6 (TPC) months (*BRCA1/2*m). T-DXd improved PFS and cORR outcomes compared with TPC across all mutational subgroups reported (Table). **Conclusions:** In this exploratory ctDNA analysis, T-DXd demonstrated a greater clinical benefit vs TPC regardless of PI3K pathway, *ESR1*, or *BRCA1/2* mutation. Clinical trial information: NCT04494425. Research Sponsor: AstraZeneca; Daiichi Sankyo.

BEP (N=625) subgroup (n=T-DXd/TPC)	T-DXd cORR, %	TPC cORR, %	T-DXd mPFS, mo*	TPC mPFS, mo*	PFS hazard ratio

Square brackets = 95% CIs (based on the Clopper-Pearson [cORR] or Brookmeyer-Crowley method [PFS]). PFS hazard ratios and CIs based on Cox proportional hazards model with no stratification factors, and ties handled by Efron approach. A hazard ratio <1 favors T-DXd vs TPC. No formal testing of significance was performed; *Number of PFS events: 89 (T-DXd) and 92 (TPC) in the PI3K pathway group, 115 (T-DXd) and 107 (TPC) in the *ESR1*m group, and 7 (T-DXd) and 23 (TPC) in the *BRCA1/2*m group; †includes *AKT*m, *PIK3CA*m, and *PTEN*m; CI, confidence interval; m, mutation; mo, months; NE, non-evaluable.

1014 Rapid Oral Abstract Session

Use of artificial intelligence–assistance software for HER2-low and HER2-ultralow IHC interpretation training to improve diagnostic accuracy of pathologists and expand patients' eligibility for HER2-targeted treatment. First Author: David Mulder, Mindpeak GmbH, Hamburg, Germany

Background: The advent of HER2-targeted antibody-drug conjugates and the introduction of HER2-low and HER2-ultralow diagnostic categories have made precise HER2 IHC assessment crucial for optimal breast cancer treatment. However, reproducible and accurate HER2 IHC scoring, particularly in cases with low level of HER2 expression, remains challenging. Many patients with HER2-low or HER2-ultralow expression risk being misclassified as HER2 null, potentially missing access to effective HER2 targeted therapies. Artificial intelligence (AI) assisted HER2 assessment may improve pathologists' diagnostic accuracy and concordance during interpretation training, especially in challenging cases with minimal membrane staining. **Methods:** A training platform for AI-supported digital HER2 IHC assessment of breast cancer samples was developed for pathologists. A total of 105 pathologists from 10 countries participated in masterclass sessions, assessing 20 digital HER2 IHC-stained breast cancer cases both without and with AI assistance. Cases assigned ground-truth IHC scores by a central reference center, were divided into three exams: A (n = 5), B (n = 7), and C (n = 8). The masterclasses consisted of: (1) Exam A, (2) a lecture on HER2 IHC scoring, (3) Exam B, (4) discussion of results from Exams A and B, and (5) AI-assisted Exam C. The AI software was used for decision support only for Exam C. The HER2 IHC scoring followed ASCO/CAP 2023 guidelines, adapted to include the HER2-ultralow (IHC 0 with membrane staining) and HER2 null (IHC 0 with no membrane staining), and provided individual tumor cell classifications for explainability. **Results:** Across 1,940 readings, pathologists achieved an average agreement of 76.3% with reference scores without AI (Exams A+B), compared to 89.6% with AI-assistance (Exam C). For HER2 clinical categories (null, ultralow, low, positive) accuracy improved from 66.7% without AI to 88.5% with AI. Misclassification of HER2-ultralow cases as HER2 null occurred in 29.5% of readings without AI but decreased to 4.0% with AI assistance. **Conclusions:** AI-assisted training improved pathologists' accuracy in HER2 IHC scoring by 13.3%, compared to central reference scores. Furthermore, AI reduced the misclassification of HER2-low and HER2-ultralow cases as HER2 null by 25.5%, potentially enabling more patients to access HER2-targeted therapies. These findings highlight the value of AI systems in biomarker interpretation training, providing pathologists with enhanced decision-making tools at the individual cell level and improving diagnostic precision in HER2 IHC interpretation. Research Sponsor: AstraZeneca.

1015 Rapid Oral Abstract Session

Treatment rechallenge after trastuzumab-deruxtecan–related interstitial lung disease: A multi-institution cohort study. First Author: Kelsey H. Natsuhara, University of California, San Francisco Helen Diller Family Comprehensive Cancer Center, San Francisco, CA

Background: T-DXd is an antibody-drug conjugate approved for advanced HER2+/low/ultra-low breast cancer and multiple other solid tumors. T-DXd carries a rare but serious risk of ILD (incidence 12-15%), requiring frequent imaging and symptom evaluation. For > grade (G) 2 ILD, guidelines recommend permanent drug discontinuation. For asymptomatic G1 ILD, drug is held with the option for rechallenge (RC) if imaging findings resolve. Limited data exist on outcomes of RC after ILD in diverse real-world patients (pts). **Methods:** In this multi-center retrospective study, we analyzed pts with T-DXd related ILD treated from 2017-2024. Pts with ILD were identified via chart/ICD code review. Adjudication of T-DXd related ILD was based on treating providers' assessment and graded via CTCAE v5. We collected pt demographics, T-DXd and steroid dosing, imaging results, and outcomes after RC. Statistical analysis was performed using Wilcoxon rank sum and Fisher's exact tests. **Results:** Four centers treated 712 pts with T-DXd, with a 9.1% rate of any grade ILD (n=65). One other center reported only RC data in 18 pts with ILD. In total, 47 pts were RC; 38 after G1 ILD (81%), 9 after G2. Median (med) time to initial ILD was 145 days (d) after 1st dose (interquartile range [IQR] 78-205). Demographics for pts RC are shown in the table. Among 50 pts with G1 ILD, including pts not RC, 28/50 (56%) received steroids for a med of 36d (IQR 27-79). Radiographic improvement was seen at a med of 24d (IQR 19-63) for pts treated with steroids vs 82d (IQR 48-94) without ($p<0.01$); and a med of 35d (IQR 22-82) for pts RC vs 81d (IQR 68-105) for pts not RC (p=0.01). Among pts with G1 ILD, 38/50 (76%) were RC at a med of 42d (IQR 36-57) from last dose; 23/38 (61%) were dose reduced. After RC, pts remained on T-DXd for a med of 215d (IQR 60-334); 10/38 (26%) developed recurrent ILD (7-G1, 2-G2, 1-G3) at a med of 211d (IQR 47-273) from RC. No statistically significant differences were seen between ILD onset, time to RC, or demographics for pts with recurrent ILD vs not. Of the 9 pts RC after G2 ILD, T-DXd was continued for a med of 129d (IQR 49-171); 2/9 (22%) developed recurrent ILD (1-G2, 1-G3). No G5 toxicity was seen with RC. **Conclusions:** In this multi-center study, high RC rates were seen after G1 ILD with long duration of clinical benefit. Pts treated with steroids had faster radiographic ILD improvement, highlighting the importance of early steroid use. Among pts RC after G1 ILD, recurrent ILD rates were low, with the majority G1 and no G5 events. Notably, 9 pts with G2 ILD were RC, with a similar rate of recurrent ILD; this must be interpreted cautiously. Our large cohort data further supports the safety of T-DXd RC in diverse real-world settings. Research Sponsor: None.

Phase IB and II study of ribociclib with trastuzumab plus endocrine therapy in HR+/HER2+ advanced breast cancer patients: Korean Cancer Study Group BR 18-2 MINI trial. First Author: Joohyuk Sohn, Division of Medical Oncology, Department of Internal Medicine, Yonsei Cancer Center, Yonsei University College of Medicine, Seoul, South Korea

Background: In HER2+ advanced breast cancer (ABC), standard treatment has been anti-HER2 therapy with chemotherapy, regardless of hormone receptor status. While prior studies support the use of CDK4/6 inhibitors with anti-HER2 and endocrine therapy in pretreated HR+/HER2+ ABC, data on their first line use without chemotherapy are limited. This study investigates ribociclib, trastuzumab, and letrozole as a first-line combination in HR+/HER2+ ABC. **Methods:** This multicenter, single-arm, prospective trial was conducted across 17 academic institutions in South Korea (NCT03913234). Eligible patients were HR+/HER2+ ABC with no prior systemic therapy for metastatic disease. The Phase IB study used a 3+3 design to determine the recommended Phase II dose (RPIID) of ribociclib with fixed doses of letrozole (2.5 mg QD) and trastuzumab (8 mg/kg loading, then 6 mg/kg every 3 weeks). The Phase II trial evaluated efficacy and safety at the RPIID. The primary endpoint was progression-free survival (PFS), targeting an improvement from 8 to 12 months. Secondary endpoints included overall survival (OS), objective response rate (ORR), duration of response (DOR), and safety. PAM50 testing assessed correlations between intrinsic subtype and treatment efficacy. **Results:** Phase IB (n = 13) identified the RPIID as ribociclib 600 mg QD, with one dose-limiting toxicity (Grade 3 ALT elevation) at 400 mg. In Phase II, 77 patients were enrolled, with a median age of 61 years (range 31–85), 18.2% (14/77) premenopausal, 66.2% (51/77) HER2 IHC 3+ and recurrent disease in 64.9% (50/77). 66.2% (51/77) had visceral metastases. At a median follow-up of 15.8 months (95% CI: 12.9-19.1) months, the median PFS was 30.4 months (95% CI: 19.6–NA), meeting the primary endpoint. The median OS was not reached. The ORR was 61.1%, including 3 complete and 41 partial responses, with a DOR of 11.8 months (95% CI: 7.6-13.4). Common adverse events included neutropenia (66.7%), pruritus (24.4%), and nausea (22.2%). There was a death reported due to aortic aneurysm. PAM50 analysis in 75 patients (phase IB/II) showed no significant correlation between intrinsic subtype and efficacy. **Conclusions:** Ribociclib, trastuzumab, and letrozole as first-line therapy in HR+/HER2+ ABC demonstrated a median PFS of 30.4 months with a manageable safety profile, supporting its potential as a chemotherapy-free option. Clinical trial information: NCT03913234. Research Sponsor: None.

1017 Rapid Oral Abstract Session

HER2-ADC trastuzumab rezetecan (SHR-A1811) in HER2-positive breast cancer with brain metastases: Update results from REIN trial. First Author: Min Yan, Department of Breast Disease, Henan Breast Cancer Center, The Affiliated Cancer Hospital of Zhengzhou University & Henan Cancer Hospital, Zhengzhou, China

Background: HER2-directed antibody-drug conjugates (ADCs) have been demonstrated to be of intracranial activity in patients with HER2+ breast cancer (BC) with brain metastases (BM). Our prospective, non-randomized phase 2 trial (NCT05769010) aimed to assess the feasibility of SHR-A1811, a novel HER2-target ADC, with or without other anti-tumor agents in HER2-expressing BCBM. Here we report the data of SHR-A1811 combined with bevacizumab in HER2+ BCBM, and update the results of SHR-A1811 in HER2+ BCBM (preliminary ORR data of the first 25 patients in Arm 1 has been published at 2024 ASCO), presenting the efficacy and safety of SHR-A1811 alone or in combination in the treatment of HER2+ BCBM. **Methods:** Patients with HER2-positive or -low BC with at least one radiotherapy-naïve measurable intracranial lesion were eligible for our trial. The patients with HER2+ disease enrolled in Arm 1 received SHR-A1811 6.4 mg/kg every 3 weeks, while those in Arm 3 were assigned to SHR-A1811 4.8 mg/kg and bevacizumab 15 mg/kg every 3 weeks until disease progression, unaccepted toxicity, or no further benefit. The primary endpoint was the intracranial overall response rate (ORR-IC) per RANO-BM. **Results:** Between March 30, 2023, and June 3, 2024, 58 patients were enrolled in Arm 1 (n = 33) and Arm 3 (n = 25). Among these, 56 patients (96.6%) had received anti-HER2 therapy previously, and the median number of prior systemic therapies in advanced setting was 2 (range: 0-9). 54 patients received at least one efficacy assessment and the confirmed ORR-IC in Arm 1 and Arm 3 were 84.4% (27/32) and 72.7% (16/22) respectively, which were numerically identical to the overall ORR in each arm, and all patients achieved intracranial disease control. As of December 31, 2024, the median PFS of Arm 1 was 13.2 (95% CI: 10.0-15.4) months, while the median PFS of Arm 3 was not mature. 78.8% (26/33) of patients in Arm 1 and 48.0% (12/25) in Arm 3 experienced treatment-related adverse events (TRAEs) of grade 3 or 4, and the frequencies of grade 4 TRAEs were 36.4% and 4% respectively. The grade 3/4 TRAEs that occurred in more than one patient included decreased neutrophil counts (Arm 1 / Arm 3: 69.7% / 36.0%), decreased leucocyte counts (51.5% / 16.0%), decreased platelet counts (30.3% / 0%), anemia (21.2% / 8.0%), decreased lymphocyte counts (21.2% / 0%), and nausea (6.1% / 0%). **Conclusions:** Our findings showed that SHR-A1811 6.4 mg/kg solely or SHR-A1811 4.8 mg/kg combined with bevacizumab both can attain high intracranial remission rates, while the lower-dose combination regimen might exhibit a better safety profile. The long-term outcomes will continue to be followed up. Clinical trial information: NCT05769010. Research Sponsor: None.

1018 Rapid Oral Abstract Session

A phase II clinical study of adebrelimab and bevacizumab combined with cisplatin/carboplatin in triple-negative breast cancer patients with brain metastases. First Author: Ting Li, Department of Breast and Urologic Medical Oncology, Fudan University Shanghai Cancer Center, Shanghai, China

Background: Brain metastases (BMs) of triple-negative breast cancer (TNBC) is a lethal disease often associated with a limited life span of approximately 6 months and local therapy is usually the first treatment choice due to lack of effective anti-tumor agents. Here reported a triplet, anti-PD-L1 (Adebrelimab, SHR-1316), bevacizumab plus cisplatin/carboplatin in BMs of triple negative breast cancer. **Methods:** This is a single center, single-arm, phase II clinical trial involving triple-negative breast cancer patients with active brain metastases. A total of 35 participants were administered a triplet treatment consisting of Adebrelimab, bevacizumab and cisplatin/carboplatin. Prior use of bevacizumab or anti-PD-1/PD-L1 was not allowed. Prior use of platinum was allowed only in cases with platinum-sensitive disease. The primary endpoint was the objective response rate in the central nervous system (CNS-ORR), and the secondary endpoints included the clinical benefit rate in CNS (CNS-CBR), progression-free survival (PFS), overall survival (OS), the first progression site and safety. **Results:** The data cutoff for this analysis was on December 20, 2024. A total of 35 patients enrolled in this study from August 2020 to October 2024. Among all patients, 42.9% (15/35) had neurological symptoms at baseline, and 80% (28/35) had not received any local treatment for their brain metastases. The median number of previous lines of therapy for metastatic disease was 2 (range 0-4), with 40% (14/35) patients having received a prior platinum agent. In the intention-to-treat population,which comprised patients who received at least one cycle of study treatment, the CNS-ORR was 77.1% (27/35), with 5 complete responses (CR), 22 partial responses (PR) and the confirmed CNS-ORR was 71.4%(25/35). Among the 23 patients who progressed, the brain was the site of first progression in 69.6% (16/23) of patients. The median PFS was 7.6 months (95%CI, 5.7-11.5), while CNS-PFS was 10 months (95%CI, 7.4-12.6), and median OS was 16 months (95%CI, 11.7 to not reached). Treatment-related adverse events (TRAEs) were reported in 100% (35/35) of patients, with the incidence of grade≥3 TRAEs being 48.6% (17/35), including neutropenia (8.6%, 3/35) and platelet count decreased (8.6%, 3/35). Adebrelimab related serious adverse events (SAEs) occurred in one patient (facial nerve disorder), no treatment-related deaths were reported. **Conclusions:** The triplet treatment of anti-PD-L1 Adebrelimab, bevacizumab and cisplatin/carboplatin, was the first regimen demonstrating a high intracranial anti-tumor activity, a prolonged CNS-PFS and OS with a good safety profile. Warranting further investigation in this highly aggressive disease. Clinical trial information: NCT04303988. Research Sponsor: None.

1019 Rapid Oral Abstract Session

Sacituzumab tirumotecan (sac-TMT) as first-line treatment for unresectable locally advanced/metastatic triple-negative breast cancer (a/mTNBC): Initial results from the phase II OptiTROP-Breast05 study. First Author: Yongmei Yin, Department of Oncology, the First Affiliated Hospital of Nanjing Medical University, Nanjing, China

Background: TROP2 (trophoblast cell surface antigen 2) is highly expressed in TNBC and associated with poor survival. Sac-TMT (MK-2870/SKB264) is a TROP2 ADC developed with a novel linker to conjugate the payload, a belotecan-derivative topoisomerase I inhibitor. It is approved in China for pts with a/mTNBC who have received at least two prior chemotherapies, including one for metastatic disease. The Phase II OptiTROP-Breast05 study (NCT05445908) evaluated sac-TMT as first-line treatment for pts with a/mTNBC. The study also explored the impact of PD-L1 combined positive score (CPS) status. Pts with CPS $<$ 10 (PD-L1-negative, IHC 22C3 pharmDx) have limited treatment options, representing a critical unmet need. **Methods:** Pts with a/mTNBC who had not received prior treatment for advanced disease were enrolled, regardless of PD-L1 or TROP2 status, to receive sac-TMT at 5 mg/kg Q2W until disease progression or unacceptable toxicity. For pts with recurrent TNBC, a disease-free interval (DFI) of at least 6 months was required for eligibility. Tumor assessment was performed every 6 weeks per RECIST v1.1 as assessed by investigator. **Results:** As of 18 Nov 2024, a total of 41 pts (median age 55 yrs; 43.9% ECOG PS 1; 78.0% PD-L1 CPS $<$ 10) were enrolled; 61.0% of pts had visceral metastases at baseline, 29.3% of pts had de novo metastasis, 19.5% of pts had a DFI of 6-12 months (mos), and 51.2% of pts had a DFI $>$ 12 mos. The median follow-up was 18.6 mo. The objective response rate (ORR) was 70.7% (29/41, 3 unconfirmed PR) and the disease control rate (DCR) was 92.7%. Median duration of response (mDoR) was 12.2 mo, while the median progression-free survival (mPFS) was 13.4 mo, and the 12-mo PFS rate was 64.6% (95% CI: 45.0%, 78.7%). Among the 32 pts with PD-L1 CPS $<$ 10, the ORR was 71.9% (23/32, 3 unconfirmed PR) and the DCR was 93.8%. The mPFS in this subgroup was 13.1 mo, with a 12-mo PFS rate 59.1% (95% CI: 37.1%, 75.7%). Treatment-related adverse events (TRAEs) of grade 3 or higher occurred in 63.4% of pts. The most common $\geq$ grade 3 TRAEs (occurred in $\geq$5% of pts) were neutrophil count decreased (46.3%), WBC count decreased (34.1%), anemia (12.2%), stomatitis (9.8%), lymphocyte count decreased (7.3%) and fatigue (7.3%). No treatment-related deaths occurred, and there were no reports of neuropathy or interstitial lung disease/pneumonitis. **Conclusions:** Sac-TMT demonstrated promising anti-tumor activity with a manageable safety profile as a first-line treatment for pts with a/mTNBC, independent of the PD-L1 status. A Phase 3 study comparing sac-TMT vs investigator's choice of chemotherapy in first-line PD-L1-negative (CPS $<$ 10) a/mTNBC is currently underway (NCT06279364). Clinical trial information: NCT05445908. Research Sponsor: Sichuan Kelun-Biotech Biopharmaceutical Co., Ltd.

1020 Rapid Oral Abstract Session

Dose optimization of PF-07248144, a first-in-class KAT6 inhibitor, in patients (pts) with ER+/HER2− metastatic breast cancer (mBC): Results from phase 1 study to support the recommended phase 3 dose (RP3D). First Author: Patricia LoRusso, Yale School of Medicine, New Haven, CT

Background: PF-07248144 is a selective catalytic inhibitor of KAT6, a histone lysine acetyltransferase. To inform the RP3D, we evaluated two pharmacokinetically distinguishable doses of PF-07248144 in combination with fulvestrant (FUL) from a phase 1 study in ER+/HER2− mBC in a dose expansion phase. **Methods:** Pts with ER+/HER2− mBC after prior CDK4/6i and endocrine therapy (ET) received PF-07248144 at recommended doses for expansion (RDEs) of 5 mg QD alone, 5 mg QD plus FUL, or 1 mg QD plus FUL (N = 107) and were followed up (at least 6 months across all cohorts) to assess for safety and efficacy. Primary objective wassafety/tolerability per CTCAE 5.0 and RDE selection. Other objectives included antitumor activity per RECIST 1.1, PK, PD, and predictive biomarkers. **Results:** 5 mg QD was identified as the RDE for both PF-07248144 monotherapy (35 pts treated) and FUL combination (43 pts treated) based on safety, PK, PD, and antitumor activity. 1 mg PF-07248144 plus FUL (29 pts treated) was selected as the lower RDE based on a distinguishable PK and safety profile while achieving maximal blood and tumor PD marker reduction and efficacious concentrations supported by preclinical models. As of Oct 11, 2024, a total of 107 pts were treated at RDEs. Baseline pt characteristics from the two RDEs plus FUL were comparable. All pts received prior CDK4/6i and ET in the metastatic setting. Positive dose-response relationships were identified for both safety (neutropenia) and efficacy (objective response rate [ORR]) endpoints. At 5 mg and 1 mg doses plus FUL, the most common treatment-related adverse event (TRAE) was dysgeusia (G1+G2: 83.7% vs 89.7%). The most common G$\geq$3 TRAE was neutropenia (G3: 39.5% vs 20.7%; G4: 7.0% vs 0.0%). The neutropenia was reversible and manageable with dose modifications. No febrile neutropenia was observed. The safety profile of 5 mg PF-07248144 monotherapy was consistent with 5 mg RDE plus FUL. No events of pneumonitis were reported in the 107 pts treated. For FUL plus 5 mg and 1 mg PF-07248144, ORR was 37.2% (95% CI: 23.0–53.3) vs 24.1% (10.3–43.5); median duration of response was 15.8 mos (9.2–not estimable [NE]) vs 4.6 mos (3.4–NE); clinical benefit rate was 55.8% (39.9−70.9) vs 37.9% (20.7–57.7). With median duration of follow-up 21.9 mos and 11.0 mos for pts receiving FUL plus 5 mg and 1 mg PF-07248144, the median progression-free survival was 10.7 mos (95% CI: 5.3−13.8) vs 3.6 mos (1.8–5.6), respectively. **Conclusions:** Based on a thorough benefit–risk assessment of two pharmacokinetically distinguishable doses with sufficient number of pts and follow up, 5 mg QD PF-07248144 was identified as the optimal dose in combination with FUL with acceptable safety and encouraging activity. A pivotal phase 3 trial is planned to address the high unmet medical need in ER+/HER2− mBC after progression on CDK4/6i plus ET. Clinical trial information: NCT04606446. Research Sponsor: Pfizer Inc.

1021 Rapid Oral Abstract Session

Phase II study of trastuzumab-pkrb plus gedatolisib in patients with HER2-positive metastatic breast cancer who progressed after 2 or more HER2-directed chemotherapies (KM-10A/KCSG BR18-13). First Author: Ju Won Kim, Korea University Anam Hospital, Seoul, South Korea

Background: The prognosis of patients with HER2 positive metastatic breast cancer (MBC) has dramatically improved with the advent of HER2-targeted therapy. However, resistance to anti-HER2 therapies remains inevitable. Aberrations in the PI3K-AKT-mTOR pathway are recognized as a key mechanism of resistance to HER2 directed therapies. This study is a multicenter, prospective, single-arm, phase II study to evaluate the antitumor activity and safety of trastuzumab-pkrb plus gedatolisib in patients with HER2 positive MBC who progressed after 2 or more HER2 directed chemotherapy. **Methods:** The primary endpoint was the overall response rate (ORR), assumed to be 25% with a type I error rate of 0.05 and a power of 0.9. Although the target enrollment was 62 patients, the study was prematurely terminated after 44 patients due to the drug supply issue of gedatolisib. Patients with HER2-positive MBC and PI3K pathway genomic aberrations, identified via tumor-targeted sequencing or cfDNA analysis, were enrolled after disease progression on at least two HER2-directed therapies. The treatment regimen included trastuzumab-pkrb and gedatolisib. Safety and efficacy outcomes were evaluated, with a data cutoff of December 31, 2024. **Results:** Primary efficacy and safety data were evaluable in 44 patients. The median age was 59 years (range: 28-72), and the median number of prior palliative treatment lines was 4 (range: 2-10). Genomic aberrations included mutations kinase domain (26 patients), helical domain (11), amplification (1) of *PIK3CA*, deletion of *PTEN* (2), and other mutations (4). Among the 44 evaluable patients, the best overall responses were complete response (CR) in 2 patients (4.5%), partial response (PR) in 17 (38.6%), stable disease (SD) in 19 (43.2%), progressive disease (PD) in 5 (11.4%), and non-evaluable (NE) in 1 (2.3%), resulting in an objective response rate (ORR) of 43.2% and a disease control rate (DCR) of 86.4%. The median progression-free survival (mPFS) was 5.8 months. After a median follow-up of 32.5 months, 22 deaths were recorded, and 19 patients were alive. The median overall survival (mOS) after study enrollment was 18.4 months. Common treatment-related adverse events (TRAEs) included oral mucositis (32.3%; 4.1% $\geq$ grade 3) and skin reactions (14.1%; 1.8% $\geq$ grade 3). Hyperglycemia was reported in 6.8% (0.5% $\geq$ grade 3). No fatal adverse event related to trial medications were reported. **Conclusions:** In this phase II study, the combination of trastuzumab-pkrb and gedatolisib demonstrated a 43.2% response rate with manageable toxicity in patients with HER2 positive MBC and *PIK3CA* mutations. A translational research study focused on the analysis of cfDNA and PBMC is currently being planned. Clinical trial information: NCT03698383. Research Sponsor: Korea Health Industry Development Institute; HI17C2206.

1022 Poster Session

Longitudinal tissue analysis and correlation of microenvironmental changes with combined immunotherapy and targeted therapy response in metastatic breast cancer. First Author: Jieqiong Liu, Yat-sen Memorial Hospital of Sun Yat-sen University, Guangzhou, China

Background: The ability to interrogate changes within the tumor microenvironment before, during and following therapeutic intervention could yield important understanding of treatment response and causes for disease progression.Here we conducted a multicenter phase II clinical trial (NCT04521179) examining the effect of a novel CTLA-4/PD-L1 bispecific (KN046) antibody in combination with a a novel anti-HER2 bispecific (KN026) antibody in treatment resistant metastatic breast cancer. Our on-going trial demonstrated that in advanced HER2-positive breast cancer (HER2+ BC) patients, who have progressed after prior anti-HER2 combinational therapies, the objective response rate (ORR) of this chemo-free therapy of KN026 in combination of KN046 was about 47.2% (95% CI: 30.4-64.5). To explore the underlying mechanism of this regimen, we collected tumor specimens from patients before and after receiving this combinational treatment for emerging multimodal molecular analyses ("Multi-omics") to provide an in-depth description of the tumor immune microenvironment and its correlation with treatment response. **Methods:** We performed matched pre- and on-treatment investigative biopsies on index tumors and performed single-cell RNA sequencing (scRNA-seq) and single-cell T cell receptor sequencing (scTCR-seq) analysis. **Results:** We performed comprehensive scRNA-seq on tumor biopsies obtained from a total of 17 patients that evaluable for overall response. Among them, 13 patients had two biopsies taken, and four patients had one biopsy collected either before or during treatment. Single-cell RNA and T cell receptor sequencing from 334,183 cells from site-matched tumors reveal significant temporal shift of various immune cell populations and phenotypes within the tumor microenvironment associated with treatment responses. In-depth analysis of subpopulations revealed that $CD8^+$ T cells are activated in responsive patients during treatment, and T_{REG} cells, one of $CD4^+$ T cell subtypes, are activated in non-responsive patients after therapy. Moreover, we also found that combined-therapy activates cDCs and induces an inflammation shift in Mϕs of responsive patients. **Conclusions:** We identified that regulatory T cells are activated while effector T cells, natural killer cells, and dendritic cells were significantly depleted in non-responding tumors. The immune response in responsive patients was effectively enhanced, whereas in nonresponsive patients, it was significantly diminished. And higher baseline levels of Mϕs were associated with therapeutic resistance. These results support that longitudinal analysis of tumor microenvironment to generate multi-omics data that can lead to rich insight disease process and to provide clinical value in evaluating treatment responses. Clinical trial information: NCT04521179. Research Sponsor: Guangdong Science and Technology Department (2023B1212060013, 2022B1515020100, 2022A1515012238); the Natural Science Foundation of China (82273033, 82072924, 82072906).

1023 Poster Session

Zongertinib in HER2-altered breast cancer: Preclinical activity and preliminary results from a phase Ia dose-escalation study. First Author: David Berz, Valkyrie Clinical Trials, Inc., Los Angeles, CA

Background: Preclinical studies have demonstrated that zongertinib, an irreversible TKI, selectively and potently inhibits oncogenic HER2 in a variety of cancer models. An ongoing Phase (Ph) Ia/Ib dose escalation/expansion trial (NCT04886804) has demonstrated preliminary clinical activity of zongertinib across a range of HER2-driven solid tumors. Here we present comparative preclinical data for zongertinib in breast cancer (BC) cell lines and cell line-derived xenograft (CDX) models, as well as clinical data from patients (pts) with HER2-driven BC who received zongertinib during Phase Ia dose escalation. **Methods:** Cell proliferation assays were undertaken in *HER2*-amplified BC cell lines (relative copy numbers ranging from 3.2–10.1) exposed to serial dilutions of zongertinib and tucatinib. Antitumor activity of zongertinib (5–40 mg/kg QD) *in vivo* was assessed in three *HER2*-amplified BC CDX models. Ph Ia of the trial enrolled pts with confirmed HER2 alterations (mutations, amplification or overexpression) who had exhausted all other treatment (Tx) options. In Ph Ia, zongertinib was administered at 15–150 mg BID or 60–360 mg QD in 21-day cycles. Primary endpoints were maximum tolerated dose (MTD) and dose-limiting toxicities (DLTs). Efficacy (objective response, OR) was evaluated as a secondary endpoint using RECIST v1.1. **Results:** Zongertinib inhibited tumor cell growth *in vitro* with greater potency (4.5–16.4-fold) than tucatinib (zongertinib IC_{50}: 2.6–40.6 nM; tucatinib IC_{50}: 13.2–664.0 nM). In mice, zongertinib was well tolerated and led to a dose-dependent inhibition of BC tumor growth, with tumor regressions at higher doses ($\geq$ 20 mg/kg QD). As of August 29, 2024, 121 pts had been treated in the Ph Ia trial. Two DLTs occurred during the MTD evaluation period; the MTD was not reached. Treatment-related adverse events (TRAEs; all/grade $\geq$3) occurred in 82.6%/12.4% of pts; the confirmed OR rate was 31.4% across all doses and tumor types. In total, 15 pts with Stage IV BC (HER2 overexpression/amplification: n = 10; *HER2* mutations: n = 4; both: n = 1) received zongertinib (100 mg BID: n = 1; 240–360 mg QD: n = 14). Most were white (60.0%) and had an ECOG PS of 1 (66.7%). Mean (standard deviation, SD) age was 58.1 (7.4) years. Mean (SD) Tx duration was 4.0 (3.4) months. TRAEs (any/grade $\geq$3) occurred in 93.3%/0.0% of pts. In pts with BC, the confirmed OR rate was 26.7% (4 partial responses). The confirmed disease control rate was 73.3%. Regardless of confirmation, the OR rate was 46.5%. At the time of data cut-off, 2 pts with responses were still on treatment, and an additional 3 patients had a response lasting longer than 4 months. **Conclusions:** Zongertinib potently inhibits HER2-driven BC growth in preclinical models *in vitro* and *in vivo*. Preliminary Ph Ia data indicate that zongertinib has encouraging clinical activity and manageable safety in pts with advanced, HER2-driven BC. Clinical trial information: NCT04886804. Research Sponsor: Boehringer Ingelheim.

Transcriptomic analysis of HER2 expression in metastatic breast cancer: Insights from a UAE patient cohort. First Author: Rachel Su Jen Wong, Department of Haematology-Oncology, National University Cancer Institute, Singapore, Singapore

Background: HER2-low metastatic breast cancer (mBC) has emerged as a clinically significant subgroup since approval of trastuzumab deruxtecan. However, its relevance as a distinct subtype remains debated. We aimed to identify HER2-related gene signatures, examine the molecular characteristics of HER2-low mBC, and investigate the potential for classifying HER2-low mBC into subgroups with profiles resembling either HER2-positive (HER2+) or HER2-negative (HER2-) mBC. **Methods:** We performed differential gene expression (DGE) analysis using the TCGA-BRCA dataset, comparing HER2+ and HER2- samples to identify a 17-gene HER2 expression signature. The findings were validated on archival samples from a UAE clinical center, where DGE analysis was repeated to compare HER2+ and HER2-zero mBC. HER2-low samples were then classified into two subsets; positive-like and zero-like based on their HER2 signature gene expression level. Lastly, Gene Set Enrichment Analysis (GSEA) was conducted to evaluate the molecular characteristics of these subsets. **Results:** In the TCGA-BRCA dataset (n = 409; median age 59 years, range 26–90), 20.5% of samples were HER2+, and 79.5% were HER2-. DGE analysis identified a 17-gene HER2 signature that effectively separated HER2+ and HER2- mBC. These 17 genes including GSDMB, ERBB2, and MED1, are associated with HER2 expression. In the UAE cohort (n = 69; median age 52 years, range 24–84), comprising 7.25% HER2+, 60.87% HER2-low, and 31.88% HER2-zero mBC, 7 genes (GSDMB, GRB7, ERBB2, STARD3, PGAP3, MIEN1, TCAP) from the 17-gene HER2 signature were similarly upregulated in the HER2+ samples. We observed an increasing trend in HER2 signature expression across the groups, from HER2-zero to HER2-low and then HER2+ mBC showing the highest expression. This trend was supported by separation across HER2 status with gene-level expression, Gene Set Variation Analysis scores and Principal Component Analysis (PCA). Next, HER2-low mBC were classified into two distinct subgroups based on distance-to-centroid approach with PCA. Based on distance to HER2+ and HER2-zero centroids, HER2-low mBC were classified into positive-like and zero-like subgroups respectively. Separation of the positive-like and zero-like samples were observed with DGE analysis and expression of the HER2 signature genes. GSEA of HER2-low positive-like samples indicate increased activation of ERBB2 oncogenic pathway and suppression of gene sets involved in immune-mediated pathways compared to HER2-low zero-like mBC. **Conclusions:** This study reveals the potential utility of transcriptomic HER2 signature to characterize HER2-related molecular features in mBC, revealing a gradient of HER2 signature expression across HER2+, HER2-low, and HER2-zero. Identification of suppressed immune-mediated pathways in HER2-low positive-like mBC suggests combination with immune mediators as potential treatment strategy. Research Sponsor: None.

1025 Poster Session

Phase I summary of the C406 (CART) efficacy and safety for an HER-2–positive breast cancer population. First Author: Meili Sun, Department of Oncology, Jinan Central Hospital, Shandong University, Jinan, China

Background: C406 is a chimeric antigen receptor (CAR) modified autologous T cell, which is a CART targeting HER-2. Here we present the breast cancer results in Phase 1 study. **Methods:** This phase 1 trial to evaluate the safety and efficacy of chimeric antigen receptor (CAR) modified autologous T cells (C406) for pts with Her2-positive recurrent or refractory breast cancer. C406 is administered intravenously at a fixed dose. Response was evaluated by RECIST v.1.1 every 4 weeks. **Results:** As of Jan 18, 2025, 8 (F) breast cancer pts have received C406 at doses of $3*10^7$/kg (n = 6), $1*10^8$/kg (n = 2). Two patients in the $3*10^7$/kg -dose group received the second transfusion. Overall, the median age was 59 years, the median number of priortreatment lines was 3.125 and the median number of anti-HER-2 treatment lines was 2. The histological type was invasive breast cainoma, 7 cases of ductal carcinoma and 1 case of mucous carcinoma. These breast cancer hormone receptor types include ER+/PR+, ER-/PR-, and ER+/PR-. Cyclophosphamide combined with fludarabine was the regimen for lymphocyte clearance in all patients. Among them, 1 patient did not receive bridging therapy. Bridging treatment options for other patients were as follows, attillizumab bridging therapy (n = 1), albumin-bound paclitaxel combined with carboplatin and attillizumab (n = 1), albumin-bound paclitaxel combined with Attillizumab (n = 2), gemcitabine combined with attillizumab (n = 1), Albumin-bound paclitaxel + epirubicin + cyclophosphamide + Attilizumab + local radiotherapy (n = 1), docetaxel + Attilizumab + local radiotherapy (n = 1). Among the 8 pts having imaging tumor assessment, the DCR was 75%, which includes 0 partial responses (PR), 6 stable disease (SD), and 2 progressive disease (PD) according to RECIST v1.1. Among the 6 SD pts, 1 pt's progression-free survival (PFS) is 8 months. All the 8 pts experienced a treatment related adverse events (TRAEs). The most common TRAEs included white blood cell count decrease (100%, 8/8), neutrophil count decrease (100%, 8/8), lymphocyte count decrease (100%, 8/8) and cytokine release syndrome (25%, 2/8). No TRAE leading to discontinuation and death. **Conclusions:** C406 therapy showed an acceptable safety profile anti-tumor activity for advanced HER-2 positive breast cancer, but the antitumor activity needs to be further explored. Clinical trial information: ChiCTR2500096093. Research Sponsor: None.

Decoding HER2 dynamics: Exploring HER2 expression across a real-world breast cancer cohort. First Author: Michelle Green, Labcorp, Durham, NC

Background: HER2 expression in breast cancer (BC) has evolved from a binary scoring system to a continuum-based approach, driven by the therapeutic benefits of trastuzumab deruxtecan (T-DXd) in patients with HER2-Low tumors. Our understanding of HER2 expression is complicated by several factors, including tumor heterogeneity, altered expression as tumors progress, and variations in assay technique and scoring. Here we describe HER2 expression patterns in a large cohort of patients with BC, including a subset with longitudinal results. **Methods:** HER2 expression levels were determined by IHC using the VENTANA 4B5 antibody. HER2 copy number and HER2/CEP17 ratios were determined using a validated dual-probe ISH assay. Tumors were retrospectively identified as HER2-Zero (IHC 0), HER2-Low (IHC 1+ or 2+ with negative ISH) or HER2-positive (IHC3+ or IHC2+ with positive ISH) based on the established IHC and ISH values scored at the time of reporting (Apr 2013 to Nov 2024). Estrogen and progesterone receptor (HR) levels were determined using validated IHC assays. All testing was performed in a CAP/CLIA accredited referral laboratory. Tumor histology, specimen collection site (CS), and patient demographics were abstracted from test requisition forms. Results are descriptive and presented in aggregate. **Results:** A total of 30,023 BC specimens from 27,055 patients were included in the analysis. Most patients were female (99%; 26,687) with a median age at testing of 63.5 years. Among HER2-Low specimens, 87% were HR-positive (HR+) and 13% were HR-negative/HR-Low (ER IHC $<$ 10%). Longitudinal specimens were available for 1,267 patients with a median of 77 days between collection dates. 69% (869) of longitudinal specimens demonstrated the same level of HER2 expression, including in 69% (597/868) of cases where both specimens were collected from breast and 69% (203/294) of cases where the first specimen was collected from breast and the second was collected from another site. Among 398 patients who had HER2 expression levels changes, 46% went from HER2-Low to HER2-Zero and 33% went from HER2-Zero to HER2-Low. **Conclusions:** HER2-Low status is common in BC, especially among HR-positive cases.HER2 expression status changed between longitudinal specimens in 31% of patients, which may inform therapeutic eligibility. This reaffirms current guidelines recommending a biopsy at first distant recurrence and suggests that serial biopsies might be helpful in detecting HER2 expression in an originally HER2-Zero tumor. Research Sponsor: None.

Longitudinal HER2 expression levels changes.

HER2 Expression Level Change	Both CSs Breast	Breast to Other CS	Other CS combinations	Total
Positive to Low	27	3	3	33
Positive to Zero	5	2	1	8
Low to Positive	23	6	3	32
Low to Zero	116	51	17	184
Zero to Positive	6	3		9
Zero to Low	94	26	12	132
No Change (Positive)	71	32	7	110

A phase Ib/IIa study of BAT8010+BAT1006, an anti-HER2 monoclonal antibody-exatecan conjugate combined with an ADCC-enhanced HER2 mAb in patients with advanced solid tumors. First Author: Shusen Wang, Sun Yat-sen University Cancer Center, Guangzhou, China

Background: BAT8010 is an ADC argeting HER2, while BAT1006 is a humanized monoclonal antibody targeting another epitope of HER2, with ADCC enhancement activity via completely devoid of fucose. This study investigates the combination of BAT8010 and BAT1006 in patients with advanced solid tumors. **Methods:** Patients in this open-label, multicenter clinical trial received BAT8010 +BAT1006 on day 1 of a 21-day cycle until intolerable or disease progression occurred. The study objectives included assessing tolerability, safety, pharmacokinetic characteristics, immunogenicity, and preliminary efficacy. **Results:** As of January 15, 2025, 20 patients with metastatic breast cancer (mBC, n=14) and gastric cancer (GC, n=6) were enrolled in three cohorts: BAT8010 (2.1mg/kg) + BAT1006, BAT8010 (2.4mg/kg) + BAT1006 and BAT8010 (2.7mg/kg) + BAT1006, with BAT1006 fixed at 15 mg/kg. HER2 positivity on tumor tissue was categorized as IHC2+/FISH+ or IHC3+. Two dose-limiting toxicity (grade 4 thrombocytopenia and neutropenia) were reported in the BAT8010 (2.7mg/kg) + BAT1006 group. The maximum tolerated dose was determined to be BAT8010 (2.4mg/kg) + BAT1006, and expansion studies have been proceeded at this dose. Safety: Among the 20 patients who received at least one dose of BAT8010 + BAT1006, 17/20 (85%) reported at least one treatment-emergent adverse events (TEAEs). The most common TEAEs (≥5%) included neutropenia, leukopenia, nausea, thrombocytopenia and anemia. Most TEAEs were Grade 1 or 2; however, 55% of the patients experienced Grade 3 or greater AEs, including neutropenia 7/20 (35%), thrombocytopenia 5/20 (20%), infusion-related reaction 1/20 (5%) and febrile neutropenia1/20 (5%). The infusion-related reaction was mild, and one subject discontinued the study treatment due to TEAEs. No cases of interstitial lung disease (ILD)/pneumonitis were reported. Efficacy: Fourteen mBC patients were recruited across the dose cohorts: BAT8010 (2.1 mg/kg)+BAT1006 (n=3), BAT8010 (2.4 mg/kg)+BAT1006 (n=7) and BAT8010 (2.7 mg/kg)+BAT1006 (n=4). Most had previously undergone 3-7 lines of systemic treatments, including trastuzumab and HER2 ADC regimens. Six GC patients were included in the BAT8010 2.4mg/kg + BAT1006 (n=4) and BAT8010 2.7mg/kg + BAT1006 (n=2) cohort. Sixteen patients had at least one tumor assessment, yielding an ORR of 43.7% (7/16) and a DCR of 87.5% (14/16). Among the 12 mBC patients, the ORR is 50% (6/12) with a DCR of 91.66% (11/12), including one CR. In the 4 GC patients, the ORR was 25% (1/4) with a DCR of 75% (3/4). **Conclusions:** The combination of BAT8010 and BAT1006 was well-tolerated, with manageable toxicity, and demonstrated promising preliminary antitumor activity in metastatic breast cancer and gastric cancer. Dose expansion studies are ongoing to further detect the safety and efficacy in these population. Clinical trial information: CTR20241120. Research Sponsor: None.

JSKN003, a biparatopic HER2-targeting ADC, in heavily pretreated HER2-positive breast cancer: A pooled analysis of early-phase studies. First Author: Yiqun Du, Department of Medical Oncology, Fudan University Shanghai Cancer Center, Shanghai, China

Background: JSKN003 is a biparatopic HER2-targeting antibody-drug conjugate (ADC) conjugated to a topoisomerase I inhibitor (TOP1i) via a tetrapeptide linker, designed to enhance serum stability and anti-tumor activity. The efficacy and safety of JSKN003 in advanced ovarian cancer and other solid tumors have been highlighted in previous reports, and this analysis provides updated insights into its performance in HER2-positive breast cancer. **Methods:** JSKN003-101 is a dose-escalation and -expansion study in Australia, and JSKN003-102 is a phase I/II study in China, both involving patients with advanced solid tumors. A pooled analysis was performed to assess its efficacy and safety in HER2-positive advanced breast cancer. **Results:** As of November 29, 2024, the median follow-up duration was 3.52 months (range: 2.99-3.71). A total of 71 patients with HER2-positive breast cancer were enrolled, with the majority receiving 6.3 mg/kg or 8.4 mg/kg doses. The median age was 54 years (range: 32-79), with 78.9% ECOG 1. All patients had stage IV disease, with 76.1% having visceral metastases. All patients had prior anti-HER2 therapy, including 87.3% with prior ADCs or TKIs, and 56.3% having ≥3 prior lines. Among 62 evaluable patients, 56 were T-DXd naïve. In these 56 patients, the overall response rate (ORR) was 67.9% (95%CI: 54-79.7), and the disease control rate (DCR) was 94.6% (95%CI: 85.1-98.9). In the RP2D subgroup (6.3mg/kg, n = 30), the ORR was 70.0% (95%CI:50.6-85.3). Of 6 patients with prior T-DXd exposure, 1 achieved a partial response (PR), 3 had stable disease (SD), and tumor shrinkage was observed in 3. Both median progression-free survival (PFS) and median overall survival (OS) were immature. Treatment-related adverse events (TRAEs) ≥Grade 3 occurred in 11.3% of patients, and serious adverse events (SAEs) in 9.9%, with 2 drug-related. No TRAEs led to death or treatment discontinuation. The most common TRAEs (≥20%) included nausea, elevated liver enzymes, vomiting, decreased appetite, fatigue, diarrhea, and anemia. No≥Grade 3 neutropenia was observed. Grade ≥3 anemia and decreased platelet count were each reported in 1 patient (1.4%), both being Grade 3. Interstitial lung disease (ILD) occurred in three patients (4.2%), all Grade 1-2, with no Grade ≥3 events. **Conclusions:** JSKN003 demonstrated promising efficacy and manageable safety in heavily pretreated HER2-positive breast cancer, including T-DXd-experienced patients. The biparatopic HER2 antibody design likely enhanced its binding efficiency and contributed to the observed clinical benefit. These findings support the planned Phase 3 trial to further evaluate its therapeutic potential. Clinical trial information: NCT05494918; NCT05744427. Research Sponsor: Jiangsu Alphamab Biopharmaceuticals Co., Ltd.

IBI354 (anti-HER2 antibody-drug conjugate [ADC]) in patients (pts) with HER2-positive breast cancer (BC) and other solid tumors: Updates from a phase 1 study. First Author: Charlotte Rose Lemech, Scientia Clinical Research, Randwick, Australia

Background: HER2 has been established as an important therapeutic target for BC. IBI354 consists of trastuzumab (anti-HER2 antibody) conjugated to a camptothecin derivative. In a global, multicenter, phase 1 study, IBI354 was well tolerated and showed promising efficacy in BC and other solid tumors (2024 ESMO 345MO/720MO/576P). Here, we report updated safety and efficacy of IBI354. **Methods:** Eligible pts with advanced solid tumors who had failed or were intolerant to standard treatment were enrolled. Positive HER2 was defined as immunohistochemistry (IHC) 2+/in situ hybridization (ISH)+ or IHC 3+. IBI354 was administered intravenously at 6-15 mg/kg Q3W or Q2W. Primary endpoint was safety. Secondary endpoints were objective response rate (ORR), disease control rate (DCR), duration of response (DoR) and progress-free survival (PFS) assessed by investigators per RECIST v1.1 and overall survival (OS). **Results:** As of Nov 12, 2024, a total of 368 pts with solid tumors were enrolled in China and Australia (females: 89.4%, median age: 56.0 years [range: 27-82], ECOG PS 1: 75.0%). Median follow-up time was 11.3 months (range: 5-19). Median treatment duration was 25.0 weeks (range: 3.1-63.3) and 124 (33.7%) pts remain on treatment. Treatment-related adverse events (TRAEs) occurred in 331 (89.9%) pts while ≥grade 3 (G3) TRAEs occurred in 93 (25.3%) pts. Most common TRAEs included white blood cell count decreased (48.6%, with 7.1% ≥G3), anemia (46.7%, with 4.9% ≥G3), nausea (46.2%, with 0.8% ≥G3) and neutrophil count decreased (38.3%, with 9.8% ≥G3). Interstitial lung disease occurred in 8 (2.2%) pts (5 treatment-related and 3 treatment-unrelated, all G1-2). TRAEs led to dose reduction in 5 (1.4%) pts and treatment discontinuation in 4 (1.1%) pts. No TRAE led to death. Efficacy was evaluable in 88 pts with HER2-positive BC (stage IV: 97.7%; prior systemic therapy regimens≥5: 65.9%; IHC 2+/ISH+: 19.3%, IHC 3+: 80.7%). The overall confirmed ORR was 58.0% (95% CI: 47.0-68.4) and DCR was 90.9% (95% CI: 82.9-96.0). Among 51 pts with confirmed responses, median DoR was not reached (events rate: 19.6%) and 12-month DoR rate of 71.8% (95% CI: 52.9-84.2). Median PFS was not reached with events rate of 37.5%. Median OS was not reached with events rate of 5.7% and 9-month OS rate of 96.2% (95% CI: 88.7-98.8). **Conclusions:** IBI354 continues to demonstrate favorable safety profiles with no new safety signals. Encouraging efficacy was observed in HER2-positive BC. Clinical trial information: NCT05636215. Research Sponsor: Innovent Biologics (Suzhou) Co., Ltd.

Efficacy of tucatinib, trastuzumab, and capecitabine (TTC) following trastuzumab-deruxtecan (T-DXd) in HER2-positive metastatic breast cancer (MBC): Updated results and subgroup analyses from the UNICANCER multicenter retrospective cohort. First Author: Jean-Sebastien Frenel, Institut de Cancerologie de L'Ouest, Saint-Herblain, France

Background: T-DXd is the standard second-line treatment for HER2-positive MBC with TTC being the preferred third-line option. However, the efficacy of TTC following T-DXd remains unclear. Here, we provide an updated and subgroup analysis of a French cohort comprising 101 patients who received TTC after T-DXd. **Methods:** We conducted a retrospective study across 12 French comprehensive cancer centers, including patients with HER2-positive MBC treated with TTC after T-DXd exposure. The primary endpoint was progression-free survival (PFS), while secondary endpoints included overall survival (OS) and time to next treatment (TTNT). **Results:** A total of 101 patients who initiated TTC between August 2020 and December 2022 were included in the analysis. The median age was 56.4 years (range: 30.8–84.8). Patients had received a median of 4 prior MBC therapies (range: 2–15), which included pertuzumab (81%) and T-DM1 (93%). 82 patients (81%) experienced progression on T-DXd, while 19 discontinued due to toxicity or other reasons. The data cutoff date was December 1, 2024. For the whole population, with a median follow-up of 29.6 months (95% CI [26.0–34.0]), the median PFS was 4.7 months (95% CI [3.9–5.8]), the median TTNT was 5.2 months (95% CI [4.5–6.6]), and the median OS was 13.9 months (95% CI [12.4–19.0]). For the 86 patients who initiated TTC immediately after T-DXd, the median PFS and TTNT were 5.2 months (95% CI [4.4–6.4]) and 5.5 months (95% CI [4.7–7.2]), respectively. HR+ disease was identified in 71.3% (n=72) of the cohort, with 84.7% receiving TTC immediately post-T-DXd. With a median follow-up of 29.6 months (95% CI [25.1–NR]), the HR+ population had a median PFS of 4.1 months (95% CI [3.5–5.6]) and a median OS of 13.4 months (95% CI [12.3–19.0]). The median TTNT was 4.7 months (95% CI [4.0–6.3]). Among the 65 RECIST-evaluable HR+ patients, best response included progressive disease in 40%, stable disease in 29%, partial response in 29%, and complete response in 2%. With a median follow-up of 29.3 months (95% CI [26.0–NR]), the HR- population had a median PFS of 5.8 months (95% CI [4.4–10.5]) and a median OS of 17.5 months (95% CI [10.6–22.9]). The median TTNT was 6.0 months (95% CI [4.9–10.7]). Among the 24 RECIST-evaluable HR- patients, best response included progressive disease in 25%, stable disease in 38%, partial response in 33%, and complete response in 4%. **Conclusions:** This large retrospective cohort with extended follow-up highlights the efficacy of TTC in HER2-positive MBC patients previously treated with T-DXd. These findings support the role of TTC as a viable treatment option post-T-DXd and provide insights for optimizing therapeutic strategies in this setting. Research Sponsor: None.

1031 Poster Session

Eribulin plus pyrotinib In trastuzumab-resistant HER2-positive advanced breast cancer: A single-arm, multicenter phase II trial (EPIC trial). First Author: Zhenchuan Song, Fourth Hospital of Hebei Medical University, Shijiazhuang, China, Shijiazhuang, China

Background: This study (ChiCTR2000038832) aimed to evaluate the efficacy and safety of combining eribulin with pyrotinib in patients with advanced HER2-positive breast cancer who had developed resistance to trastuzumab. These patients typically face a poor clinical prognosis, and evidence-based guidance for treatment decisions remains limited. **Methods:** Eligible patients were those with pathologically confirmed HER2-positive metastatic breast cancer, an Eastern Cooperative Oncology Group (ECOG) performance status of 0 or 1, and prior treatment with trastuzumab and taxanes. Participants received oral pyrotinib (400 mg once daily) and intravenous eribulin (1.4 mg/m² on days 1 and 8 of each 21-day cycle) for up to six cycles. Pyrotinib was continued until disease progression or intolerable toxicity. The primary endpoint was progression-free survival (PFS). The secondary endpoints include the objective response rate (ORR), disease control rate (DCR), duration of response (DoR), overall survival (OS), and safety. **Results:** Between February 2021 and September 2023, 30 patients were enrolled, with a median age of 57 years (range: 30–76). All had received prior trastuzumab and taxane therapies. As of November 30, 2024, the median follow-up was 20.1 months. Disease progression or death occurred in 15 patients, and the median PFS was 13.73 months (95% confidence interval [CI]: 11.1–14.8). The 12-month PFS rate was 61.7% (95% CI: 44.2%–86.0%). The 12-month OS rate was 75.3% (95% CI: 66.2%–84.4%). The objective response rate (ORR) was 53.3% (16/30), and the disease control rate (DCR) was 80.0% (24/30). Median overall survival was not reached. Common adverse events (AEs) of any grade occurring in > 15% of patients included diarrhea (40%), nausea (20%), anorexia (16%), and vomiting (16%), with grade 3 diarrhea reported in 3% of patients. No treatment-related deaths were observed. **Conclusions:** The combination of eribulin and pyrotinib shows promise as a therapeutic option for patients with HER2-positive advanced breast cancer resistant to trastuzumab. While advancements in anti-HER2 therapies continue, further studies are needed to address unresolved challenges in this clinical context. Clinical trial information: ChiCTR2000038832. Research Sponsor: None.

Quantitative pre-treatment assessment of trastuzumab deruxtecan (T-DXd) antibody target (HER2) and payload target (topoisomerase 1, Topo1) to predict outcomes in metastatic breast cancer (MBC). First Author: Paolo Tarantino, Dana-Farber Cancer Institute, Boston, MA

Background: The antitumor activity of T-DXd for MBC is sub-optimally predicted by HER2 immunohistochemistry (IHC). We evaluated novel assays to quantify the expression of T-DXd antibody and payload targets and their association with outcomes. **Methods:** We retrieved pre-treatment FFPE tumor samples for patients (pts) with MBC receiving T-DXd at Dana-Farber Cancer Institute between 2017 and 2023. Patients were categorized by HER2 IHC status at start of T-DXd. The RPPA-based protein assessment of HER2 and Topo1 was performed in a CLIA lab after laser capture microdissection enrichment of tumor epithelium. The HER2DX standardized assay was performed after RNA extraction. We evaluated the association of each marker, continuously and by tertiles/quartiles, with time to next treatment (TTNT) with T-DXd. Cox proportional hazards models were utilized to estimate hazard ratios and log-rank test p-values were reported. The Kaplan-Meier method was used to calculate median estimates. **Results:** HER2DX and RPPA testing were conducted for 41 (25 with HER2+, 16 with HER2- MBC) and 38 pts (24 with HER2+, 14 with HER2- MBC), respectively.Both HER2DX and RPPA HER2 quantitative testing significantly predicted outcomes with T-DXd (Table). The HER2DX HER2 amplicon mRNA signature was significantly associated with TTNT with T-DXd (p=0.001), including when divided into tertiles, with a range of 4.7 months in the lowest vs 12.03 months in the highest tertile (p=0.02). Similarly, the RPPA-based HER2 protein expression was significantly associated with TTNT when divided into quartiles (p=0.02). Pre-treatment Topo1 protein expression was significantly associated with outcomes in pts with HER2-negative MBC (n=14), with higher expression of TOPO1 associated with worse TTNT with T-DXd (p=0.04). **Conclusions:** Higher pre-treatment HER2 mRNA signature (HER2DX) and protein (RPPA) expression predicted improved outcomes with T-DXd for MBC, whereas higher Topo1 expression was associated with worse outcomes with T-DXd among pts with HER2- MBC. Research Sponsor: Terri Brodeur Breast Cancer Foundation; Saverin Award; Susan G. Komen Breast Cancer Foundation; Breast Cancer Research Foundation.

Efficacy and safety results of TQB2930, a HER2-targeted bispecific antibody combined with chemotherapy in patients with HER2-positive breast cancer (BC) previously treated with ≥2 line treatments: Results from a phase 1b/2 study. First Author: Qingyuan Zhang, Breast Department, Harbin Medical University Cancer Hospital, Harbin, China

Background: TQB2930 is a HER2-targeted bispecific antibody designed to bind two distinct HER2 epitopes: the extracellular domain 4 (ECD4), and the extracellular domain 2 (ECD2). In an ongoing phase 1b/2 clinical trial, TQB2930 has demonstrated favorable tolerability alongside durable responses in patients with heavily pretreated metastatic HER2-positive BC. In this context, Cohort 4 of the trial was designed to evaluate the safety and efficacy of TQB2930 in combination with chemotherapy for patients with HER2-positive BC who had received at least two prior lines of treatment. **Methods:** Cohort 4 enrolled patients aged ≥18 years with recurrent or metastatic HER2-positive BC who had undergone at least two prior systemic therapies. Patients with stable brain metastases were permitted. All enrolled patients received TQB2930 intravenously at a dose of 30 mg/kg every three weeks (Q3W), administered in combination with one of four investigator-selected chemotherapies (capecitabine, eribulin, gemcitabine, or vinorelbine). The primary endpoint was the overall response rate (ORR), while secondary endpoints encompassed disease control rate (DCR), progression-free survival (PFS), overall survival (OS), safety, and immunogenicity. **Results:** As of December 15, 2024, 55 patients (pts) had been treated with TQB2930 combined with chemotherapy. The median follow-up duration was 4.14 months (95% CI: 3.55–4.31). Out of 52 patients evaluable for efficacy, the ORR was 48.1% (25/52), with 88.5% (46/52) experiencing a reduction in target lesion size. Among patients who had progressed on prior T-DM1 therapy, the ORR was 36.8% (7/19), whereas patients who had failed other HER2-ADC therapies exhibited an ORR of 50% (8/16), including RC48, DS-8201, and so on. Notably, the median PFS and OS had not yet been reached, while the 6-month PFS rate was estimated at 71%. Grade ≥3 TRAEs were primarily hematological, encompassing decreased white blood cell count, neutropenia, thrombocytopenia, and infusion-related reactions. Importantly, there were no grade ≥3 cardiac toxicities, and the incidence of sinus bradycardia or QT interval prolongation was < 3%. **Conclusions:** The combination of TQB2930 with chemotherapy demonstrates encouraging antitumor efficacy and an acceptable safety profile in patients with HER2-positive BC who have undergone at least two prior lines of treatment. These results support the potential of TQB2930 as a novel therapeutic strategy for HER2-positive BC and underscore the need for further clinical exploration. This study was funded by Chia Tai Tianqing Pharmaceutical Group Nanjing Shunxin Pharmaceutical Co., Ltd. Clinical trial information: NCT06202261. Association of germline homologous recombination deficiency mutations with HER2 status conversion from negative to positive following neoadjuvant chemotherapy in breast cancer. First Author: Colin P. Bergstrom, Stanford University School of Medicine, Stanford, CA

Background: Neoadjuvant therapy (NT) is well established in breast cancer management, with subsequent adjuvant therapy guided by biomarker status and tumor response. While rare, biomarker status can change post-NT. The mechanisms driving conversion and optimal treatment strategies remain unclear. This study aimed to investigate clinicopathological characteristics, including germline mutations, in patients who underwent HER2 status conversion from negative to positive (N-P) after NT. **Methods:** Patients treated with NT for breast cancer between 2012 and 2023 were retrospectively identified from the Stanford STRIDE database. Clinicopathological features, including demographics, genetic data, treatment history, pathological characteristics, and recurrence, were collected through chart review. ER, PR, and HER2 status were assessed using immunohistochemistry (IHC) and fluorescence in-situ hybridization (FISH), with HER2 interpretation following ASCO/CAP guidelines relevant at the time of testing. Per institutional policy, both IHC and FISH were routinely performed for HER2 assessment. **Results:** A total of 28 patients with HER2 status change were identified; 26 (93%) were female and 2 (7%) male, with a median diagnosis age of 47 years (IQR 39–58). Most patients were ER-positive (N=24, 86%) at diagnosis. Among 25 patients who underwent germline testing, 56% harbored mutations in homologous recombination deficiency genes, including BRCA2 (5, 20%), BRIP1 (4, 16%), PALB2 (2, 8%), ATM (2, 8%), and BRCA1 (1, 4%). Post-NT, patients were classified into HER2 groups: 36% (10/28) in Group 1, 46% (13/28) in Group 1b (HER2 low amplified with HER2/cell <6 and ratio >2), 14% (4/28) in Group 3, and 4% (1/28) in Group 4. Adjuvant HER2-directed therapy was administered to 24 patients (89%): trastuzumab in 8 (29%), trastuzumab and pertuzumab in 12 (43%), and trastuzumab emtansine in 4 (14%); 4 patients (14%) did not receive adjuvant HER2 therapy. Recurrence occurred in 8 patients (29%), including 3 with germline mutations. One non-mutated case involved discordant HER2-positive recurrence with ipsilateral in-breast recurrence and liver metastases, testing HER2-positive by FISH despite IHC 0. **Conclusions:** This study highlights that a majority of patients who underwent HER2 status conversion after NT harbored homologous recombination deficiency mutations, suggesting a potential mechanistic basis. Furthermore, while 85.8% of patients received adjuvant HER2-directed therapy, the rarity of HER2-positive recurrences underscores the potential for overtreatment. Further studies are needed to elucidate the mechanisms of HER2 status conversion from negative to positive after NAT which will improve the efficacy of treatment strategies and patient outcomes. Recurrence risk prediction model in HER2-positive early breast cancer after HER2-targeted therapy. First Author: Qingyao Shang, National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China

Background: HER2-positive breast cancer patients treated with adjuvant targeted therapy, including trastuzumab or pertuzumab have demonstrated improved outcomes. However, a part of patients still experience recurrence despite targeted therapy. This study aims to develop a time-dependent model to predict recurrence risk in HER2-positive early breast cancer patients following targeted therapy, utilizing data from the APHINITY trial. **Methods:** The APHINITY trial included two arms: trastuzumab-only arm (n = 2,400) and trastuzumab + pertuzumab dual-target therapy arm (n = 2,404). Each group was randomly divided into training (70%) and validation (30%) cohorts, resulting in 3,363 patients in the training set and 1,441 patients in the validation set. The Cox proportional hazards model and two machine learning models, Random Survival Forest (RSF) and XGBoost (XGB), were used to predict invasive disease-free survival. Model performance was evaluated using Harrell`s C-index and area under the curve (AUC). **Results:** After selecting clinical variables provided by the APHINITY trial, 12 variables were included in the model training. The predictive performance of Cox model, RSF and XGB machine learning models was assessed. Among them, the RSF model demonstrated the best predictive effectiveness. In the training set, the RSF model achieved a C-index of 0.66, with AUCs of 0.78 for 1-year recurrence risk, 0.70 for 3-year recurrence risk, and 0.66 for 5-year recurrence risk. In the validation set, the RSF model achieved a C-index of 0.68, with AUCs of 0.79 for 1-year recurrence risk, 0.73 for 3-year recurrence risk, and 0.71 for 5-year recurrence risk. The XGB model performed slightly worse than RSF, and the machine learning methods significantly outperformed the Cox model. **Conclusions:** In this study, a time-dependent recurrence prediction model was established based on large-sample randomized controlled trial, demonstrating a favourable short-term recurrence prediction effect, which can serve as a clinical decision assistant for screening patients at high risk of recurrence for intensified adjuvant therapy or follow-up monitoring. 1036 Rapid Oral Abstract Session

Racial and ethnic disparities in clinical outcomes of HER2-positive metastatic breast cancer treated with antibody-drug conjugates: A TriNetX real-world evidence study. First Author: Zunairah Shah, Roswell Park Comprehensive Cancer Center, Buffalo, NY

Background: HER2-positive breast cancer (HER2+ BC) is an aggressive BC subtype driven by overexpression of the human epidermal growth factor receptor 2 (HER2). Antibody drug conjugates (ADCs), such as trastuzumab deruxtecan (T-DXd) and ado-trastuzumab emtansine (T-DM1), both approved for metastatic HER2+ BC, have significantly improved survival in this population. However, racial and ethnic disparities in outcomes with ADCs remain unclear. **Methods:** De-identified data from TriNetX, a global federated health research network, were analyzed for patients with metastatic HER2+ BC receiving HER2-directed ADCs. Kaplan-Meier analysis assessed overall survival. Statistical comparisons of survival rates between groups were made using log-rank tests. Propensity matching was used to adjust for age, comorbidities and lines of treatment. Two-sided P $\leq$0.05 was used to determine statistical significance. **Results:** A total 7,462 patients were included in this analysis. The median age was 56.2 years (range: 43-69), 68% were Non-Hispanic White (NHW), 17% Black, 5% Asian, and 10% Hispanic. 4,774 pts received TDM-1, 1,547 received T-DXd, and 1,141 received both. 37.6% patients treated with TDM-1 and 64.3% treated with T-DXd received $>$2 lines of prior therapy. Overall, the survival rate was 96% at 1 year, 89.3% at 3 years, and 83.7% at 5 years. At 3 years, the survival varied significantly by race: 90.3% in NHWs, 87.1% in Black, 92.9% in Asians, and 91.3% in Hispanics (p $<$ 0.001). Similar differences extended to 5 years: NHW 85.0%, Black 80.9%, Asian 89.5%, Hispanic 86.7% (p$<$0.001) (Table). Among patients receiving T-DM1, the 3-year survival rate was 71.9%, compared to 45.7% in the T-DXd cohort (p$<$0.05). After adjusting for age and comorbidities, there was no difference in survival between patients who received T-DXd and TDM1 (not including who received both) (HR 2.55 (95% CI: 2.20–2.96; p = 0.75). **Conclusions:** Our study shows better outcomes with use of ADCs in heavily pretreated metastatic HER2-BC, with 83.7% of patients surviving beyond 5 years. However, significant racial disparities were observed, with Asian patients showing the highest survival while Black patients had the poorest survival which could be due to multi-level factors. Future studies are needed to understand the underlying mechanisms behind this racial disparity in outcomes with HER2-directed ADCs to inform strategies to improve patient outcomes. Research Sponsor: None.

Survival rates and hazard ratios by race.

Race	3-year survival probability (%)	5-year survival probability (%)	Hazard Ratio
NHW	89.60	83.96	1.00
Black	86.90	80.30	1.33 (95% CI: 1.26–1.40)
Asian	92.26	88.92	0.69 (95% CI: 0.6–0.75)
Hispanic	91.20	86.27	0.89 (95% CI: 0.83–0.95)

NHW (Non-Hispanic White).

Characterization of the immune microenvironment and spatial phenotypes across HER2 subtypes in advanced or metastatic breast cancer. First Author: Ayse A. Koksoy, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Breast cancer is defined by HER2 and hormone receptors (HR) status, which influence the clinical outcomes. HER2-positive has been traditionally defined as HER2 overexpression on immunohistochemistry (IHC score of 3+) or 2+ and *ERBB2* amplification on *in situ* hybridization (ISH). HER2^{low} (IHC 1+ or 2+ and non-amplified ISH) accounts for nearly half of tumors. There is a paucity of data regarding immune subpopulations and spatial phenotypes in HER2 subtypes. We have investigated the characteristics of tumor immune microenvironment contexture across HER2 groups (HER2$^+$ vs HER2^{low} vs HER2$^-$ (0 by IHC)) focusing tumor infiltrating lymphocytes (TIL) and on immune cell dynamics, including the distribution and spatial proximity to tumor cells to potentially inform treatment selection. **Methods:** Formalin-fixed paraffin-embedded (FFPE) samples of patients with metastatic breast cancer who had HER2 IHC/ISH testing according to ASCO-CAP guidelines were stained and analyzed using an 8-plex immunofluorescence (mIF) panel (CD3, CD8, CD69, FOXP3, Ki67, PD-L1, PD1, PanCK). For neighborhood analysis, samples with an area $>$ 2 mm^2 and a phenotypes density with $>$ 2 cells/mm² were considered. A novel spatial analysis method was used to quantify the Euclidian distance between tumor cells and surrounding immune cell populations. The clustering coefficient was used to determine the connectivity of immune cell node neighbors. These findings were analyzed in relation to the clinical characteristics. **Results:** Tumor and stromal compartment analysis was done on 44 FFPE samples (10 HER2$^-$, 19 HER2^{low}, and 15 HER2$^+$) with 84% collected from metastatic sites. HER2 status was not significantly associated HR status or overall TIL infiltration into the tumor compartment. The dominant TIL subset identified was non-regulatory CD3+ T cells as defined as CD3$^+$/FOXP3$^-$/CD8$^-$. HER2$^-$ samples were more associated with lack of PD-L1 expression on intratumoral myeloid cells and PD-L1 low expression on tumor cells as compared with HER2^{low} and HER2$^+$ (p = 0.06). For spatial analysis, 33 samples (6 HER2$^-$, 16 HER2^{low} and 11 HER2$^+$) were considered. Macrophages and proliferating tumor cells were more abundant in HER2$^-$ samples than HER2^{low} or HER2$^+$ (p = 0.006 and p-0.027, respectively). Median distances from tumor cells to macrophages and T_{regs} were shorter in HER2$^-$ cases compared to HER2I^{ow} (p $<$ 0.001). Although the clustering coefficient were similar between HER2 groups, HER2^{low} group clustered mostly around macrophages while HER2$^+$ group preferred cytotoxic T cells (CD8$^+$). **Conclusions:** The spatial organization and density of immune cells in the HER2^{low} and HER2$^+$ breast cancer microenvironment may provide insight into prognosis and guide therapeutic approaches for combination therapies and HER2-targeted immunotherapies. Risk of radiation necrosis with concurrent antibody-drug conjugates and radiotherapy in HER2-positive breast cancer with brain metastases: A meta-analysis. First Author: Zouina Sarfraz, Miami Cancer Institute, Baptist Health South Florida, Miami, FL

Background: Antibody-drug conjugates (ADCs) have transformed the outcomes of HER2-positive breast cancer (BC), particularly in patients with brain metastases (BM) due to the use of ADCs like trastuzumab emtansine (T-DM1) and trastuzumab deruxtecan (T-DXd), which have demonstrated intracranial efficacy. Radiotherapy (RT), especially stereotactic radiosurgery (SRS), remains a cornerstone for BM management. However, combining ADCs with RT may increase the risk of symptomatic radiation necrosis (SRN). This meta-analysis evaluates SRN outcomes in patients receiving concurrent (C-ADC) versus non-concurrent ADCs with RT (NC-ADC). **Methods:** A systematic search was performed in January 2025 across PubMed, Cochrane, and conference proceedings from ASCO, SNO, ESMO, and SABCS. Eligible studies included randomized controlled trials and cohort studies (CS) of C-ADC and NC-ADC in HER2-positive BC patients with BM. Studies reporting SRN rates or related outcomes were included. A random-effects model was used to calculate pooled proportions and risk ratios (RR) with 95% confidence intervals (CIs). Heterogeneity across studies was assessed using the I² statistic, with values of 0–25% considered low, 26–50% moderate, and greater than 50% high. **Results:** Out of 884 studies screened, 9 CS (N = 421) were included. The median age was 56.3 years (IQR: 49.8–57). Patients receiving prior intracranial RT was 41.28%, 19.28% underwent SRS, and 19.58% received prior whole brain radiotherapy (WBRT). The median time of C-ADC was 8.75 days (IQR: 8.0–18.0) and NC-ADC was 273.5 days (IQR: 225.75–327.75). The pooled proportion of SRN in the C-ADC group was 19.5% (95% CI: 9.2%–29.8%; I² = 39.19%, τ^2 = 0.0061, P = 0.1382) indicating moderate heterogeneity. NC-ADC group experienced a pooled SRN proportion of 6.9% (95% CI: 2.5%–11.2%; I² = 51.98%, τ^2 = 0.0014, P = 0.0089), signifying high heterogeneity. The pooled RR showed a significantly increased SRN risk in the C-ADC group (RR = 2.726, 95% CI: 1.454–5.109, P = 0.002). Heterogeneity for the pooled RR was negligible (I² = 0.0%, Q = 0.20, P = 0.977), indicating consistent findings across studies. **Conclusions:** C-ADC is associated with a significantly higher risk of SRN. This risk is concerning but must be balanced against potential improvements in local control and efficacy outcomes. Prospective studies are needed to optimize treatment schedule and sequences to minimize toxicity and optimize survival. Research Sponsor: None.

Meta-analytical findings.

Analysis/Measure	Effect Size	95% CI	I²	P-Value	Notes
Pooled Proportion (Overall)	0.110	0.050–0.169	76.53%	0.0003	High heterogeneity (τ^2=0.0047)
C-ADC Proportion	0.195	0.092–0.298	39.19%	0.0002	Moderate heterogeneity (τ^2=0.0061)
NC-ADC Proportion	0.069	0.025–0.112	51.98%	0.0021	High heterogeneity (τ^2=0.0014)
Risk Ratio (C-ADC vs. NC-ADC)	2.726	1.454–5.109	0.0%	0.002	No heterogeneity (τ^2=0.0000)

1040 Poster Session

Molecular and clinical insights of trastuzumab deruxtecan efficacy in advanced breast cancer (aBC). First Author: Elias Bou Farhat, Brigham and Women's Hospital, Boston, MA

Background: In aBC, trastuzumab deruxtecan (T-DXd) has demonstrated efficacy in HER2-positive, HER2-low, and HER2-ultralow disease subtypes. However, the impact of molecular markers on treatment outcomes requires further investigation, particularly in the context of HER2 status across biopsies, genetic alterations, and the tumor micro-environment (TME). **Methods:** We retrospectively analyzed 477 patients (pts) with aBC (DFCI = 369; Yale = 108) treated with T-DXd. HER2 immunohistochemistry (IHC) discordance was defined as a shift in HER2 status across the last two tumor samples prior to T-DXd (HER2 0 to 1, 2, or 3+ or vice versa). Concordance was defined as consistent HER2-0, HER2-low (1 or 2+) or HER2 3+ across samples. Outcomes included time-to-next treatment (TTNT) and overall survival (OS); multivariable Cox proportional hazards models were performed. Targeted tumor sequencing was conducted on 163 pts with aBC treated with T-DXd. TME analysis of 97 patients used machine learning on H&E slides to classify tumors as inflamed, desert, or altered. **Results:** Pts with discordant HER2 (n = 118, 25%) showed similar outcomes to those with concordant HER2-0 (n = 32) expression, both of which had significantly worse OS and TTNT compared to concordant HER2-low (both 1 or 2+) (n = 202) or HER2-3+ (n = 111) tumors (Table). *PTEN* mutations (mut; n=13) were associated with significantly shorter TTNT. *ERBB2* amplifications or gains (n= 31) correlated with improved outcomes. CDK12 deletions or loss (n = 14) were linked to poorer TTNT (Table). *PTEN* mut and *ERBB2* amplifications were predictive of outcomes with T-DXd, as neither alteration was associated with TTNT in pts receiving non-T-DXd first-line systemic therapy. Tumors with inflamed TME had the worst outcomes, followed by deserts and altered TMEs (Table). **Conclusions:** We identify favorable biomarkers of T-DXd efficacy in aBC, including concordant HER2-low or HER2-3+ status, absence of PTEN mut, and an altered or desert TME. These findings require validation to refine treatment strategies across HER2-driven malignancies. Research Sponsor: None.

	OS T-DXd: HR (95% CI)	p/q-value	TTNT T-DXd: HR (95% CI)	p/q-value	TTNT 1st Line: HR (95% CI)	p/q-value

Transcriptomic biomarkers of therapeutic response to antibody-drug conjugates in metastatic breast cancer: A comprehensive multi-center study. First Author: Samer Alkassis, UCLA Health Jonsson Comprehensive Cancer Center, Los Angeles, CA

Background: The three antibody-drug conjugates (ADCs) — sacituzumab govitecan (SG), trastuzumab deruxtecan (T-DXd), and trastuzumab emtansine (T-DM1) — that are FDA-approved for treatment of metastatic breast cancer (MBC) have markedly improved patient outcomes. However, most patients with MBC treated with ADCs ultimately have disease progression via either primary or acquired ADC resistance. Here, we characterized the transcriptomic profile of drug efflux genes in MBC prior to ADC treatment (tx) to elucidate biomarkers of response and resistance to SG, T-Dxd, and T-DM1. **Methods:** We analyzed the transcriptomic tumor profile of six drug efflux pump genes (*ABCB1*, *ABCC1-4*, *ABCG2*) generated from pre-tx biopsies collected from patients with MBC (N = 453; 36% TNBC, 26% HR+/HER2-, 20.5% HER2+, 19% NOS) 1 year prior to or up to 15 days post-tx with SG (n = 204), T-DXd (n = 178), or T-DM1 (n = 71). RNA-sequencing data were generated and processed with the Tempus xR assay. The correlation between duration of treatment (DoT) and gene expression was tested for all genes of interest using Pearson's correlation coefficient. Cox proportional hazards models with risk set adjustment were used to test for associations between pre-tx gene expression and overall survival (OS), where gene expression was modeled as a continuous linear predictor. The proportional hazards assumption for OS was tested, and Cox modeling results were omitted when evidence of non-proportional hazards was detected. Given the exploratory nature of the analyses, all p-values are uncorrected and nominal statistical significance was set at $p < 0.05$. **Results:** This diverse cohort had a median age of 52 and a range of races (55% White, 14% Black, 7.1% Other, 24% Unknown). Median DoT across all patients was 130 days. Higher expression of drug efflux pump genes was associated with shorter DoT for T-DXd (*ABCB1*: -0.290, p = 0.017; *ABCC1*: -0.274, p = 0.025). Additionally, higher expression of *ABCB1* was associated with worse OS for T-DXd (HR: 1.30, 95% CI: 1.10 - 1.53, p = 0.002). In the SG cohort, no significant associations between efflux pump expression and DoT were found, but higher pre-tx *ABCC1* and *ABCC4* gene expression was associated with worse OS (HR: 1.34, 95% CI: 1.02-1.75, p = 0.034; HR:1.19, 95%CI: 1.00-1.41, p = 0.042). In the T-DM1 cohort, no significant associations were found between efflux pump gene expression and DoT or OS. **Conclusions:** Multi-modal analysis identified drug efflux pump gene expression as a potential biomarker of resistance, primarily to T-DXd. These findings should be further validated, and combinatorial clinical trial strategies may be explored. Research Sponsor: Tempus AI, Inc.

Integrating dynamic analysis of serial ctDNA testing to enhance diagnostic and prognostic assessments in patients with metastatic breast cancer. First Author: Qiang Zhang, Department of Medicine, Division of Hematology and Oncology, CTC Core Facility, Robert H. Lurie Comprehensive Cancer Center, Northwestern University, Chicago, IL

Background: The monitoring of circulating tumor DNA (ctDNA) in patient with metastatic breast cancer (MBC) plays a critical role in predicting therapy resistance, metastasis, and prognosis. Our previous studies have highlighted the importance of dynamic ctDNA analysis correlated with treatment resistance and prognosis in MBC (ASCO 2022 (#1057), AACR 2023 (#1031), and CCR Zhang Q., 2024). Here, we report that multivariable analysis of ctDNA mutations including P53, Myc, and BRAF, provides a significantly greater prognostic impact on survival. **Methods:** This study included 391 MBC patients who received systemic treatment between 2016 and 2022 (IRB-approved non-interventional trial, NU16B06) at the Robert H. Lurie Cancer Center, Northwestern University. Blood samples (15 ml each) were collected from patients at 3 time points: before treatment, and 3 and 6 months after treatment. Plasma ctDNA was analyzed by Guardant 360 using NGS for a 74-gene panel. The median follow-up was 26.6 months since enrollment. Causal Inference-Ensemble Learning was used for statistical analyses. **Results:** Among 391 patients (54.4% Luminal-like, 17.7% HER2-positive, 27.9% Triple-negative), the most common ctDNA mutations were $TP53^{Mut}$ (160 patients, 40.92%), $PIK3CA^{Mut}$ (39 patients, 29.4%), and Myc^{Mut} (53 patients, 13.55%) at any time point. Other notable mutations included $HER2^{Mut}$ (49 patients, 12.5%), $FGFR1^{Mut}$ (45 patients, 11.5%), $PTEN^{Mut}$ (39 patients, 9.9%), and $BRAF^{Mut}$ (35 patients, 8.95%). Less frequent mutations were $FGFR2^{Mut}$ (13 patients, 3.3%), $MAPK^{Mut}$ (8 patients, 2.0%), $BRCA1^{Mut}$ (20 patients, 5.1%), $BRCA2^{Mut}$ (17 patients, 4.3%), and $CDH1^{Mut}$ (21 patients, 5.37%). Patients in mutation groups showed significantly shorter median overall survival (OS) compared to wild-type groups: $TP53^{Mut}$ vs $TP53^{WT}$, Hazard Ratio (HR) = 1.91 (P = 0.0002); Myc^{Mut} vs Myc^{WT}, HR = 3.24 ($P < 0.0001$); and $BRAF^{Mut}$ vs $BRAF^{WT}$, HR = 2.45 (P = 0.007). No significant correlations were found between other gene mutations and OS. Analysis of multiple ctDNA mutations (TP53, Myc, and BRAF) revealed significant prognostic differences. Cohort 1 (no mutations, 231 patients) had a significantly longer median OS of 32.2 months compared to 20.5 months in cohort 2 (at least one mutation, 119 patients) and 15.3 months in cohort 3 (two or more mutations, 59 patients). Cohort 3 exhibited the worst prognosis compared to both cohort 1 and cohort 2 (Chi-square = 13.3, P = 0.0003). These findings suggest that combined analysis of ctDNA mutations enhances the ability to predict prognosis. **Conclusions:** In this study, we identified multiple ctDNA mutations during long-term follow-up, which are associated with prognosis. The synergy of multivariable analysis of ctDNA mutations during treatment enhances the role of single ctDNA alterations in monitoring metastatic prognosis, thereby supporting clinical decision-making. Research Sponsor: Robert H Lurie Cancer Center, Northwestern University.

***TP53* genomic alterations including targetable *TP53* Y220C mutation in clinically advanced breast cancer.** First Author: Nicole Casasanta, Yale Cancer Center, Yale School of Medicine, New Haven, CT

Background: Recent studies demonstrating the ability of drugs such as Rezatapopt to target the *TP53* Y220C mutation motivated us to assess the *TP53* mutation landscape in clinically advanced breast cancer (CABC). **Methods:** FFPE blocks of 23,760 CABC were analyzed by hybrid capture-based comprehensive genomic profiling that evaluated broad types of genomic alterations (GA) including mutations, amplifications, deletions, and fusions. MSI-high (MSI-H) status, tumor mutational burden (TMB), genomic ancestry, mutational signature, and homologous recombination deficiency signature (HRDsig) were determined from sequencing data. PD-L1 expression was determined by IHC (Dako 22C3, TPS scoring system). GA were compared using Fisher's exact test with the Benjamini-Hochberg multiplicity adjustment. **Results:** Among analyzed cases of CABC, 12,653 (53%) had *TP53* GA and 254 (1.1%) were the Y220C mutation. When compared with *TP53* wild type (wt) cases, *TP53* GA group were younger (56 vs 60 years; $p < .0001$) and had a higher median GA (6 vs 5; $p < .0001$). Both *TP53* Y220C group (15.7% vs 11.2%; not significant [NS]) and *TP53* non-Y220C group (18.3% vs 11.2%; $p < .0001$) were more frequently of African genetic ancestry than *TP53*wt group. The *TP53* non-Y220C had significantly less European (*TP53* non-Y220C: 65.2% vs 74.7%; $p < .0001$) genetic ancestries. MSI-H was rare in all groups, but slightly higher in *TP53* Y220C than *TP53*wt cases (1.7% vs 0.3%; p = .036). Median TMB was low for all groups (range 2.41-2.61; NS). An APOBEC genomic signature was more common in *TP53* non-Y220C mutant than *TP53*wt (6.2% vs 5.0%; p = .0002) but not in *TP53* Y220C (4.3% vs 5.0%; NS). GA more frequent in *TP53* Y220C and non-Y220C groups versus *TP53*wt included *BRCA1*, *ERBB2*, *PTEN*, and *RB1*. GA more frequent in the *TP53*wt group included *BRCA2*, *CCND1*, *CDH1*, *ESR1*, and *PIK3CA*. More *TP53* Y220C than *TP53* non-Y220C mutant cancers had *CDH1* mutations (6.3% vs 2.8%; NS) suggesting the Y220C GA may be more frequent in lobular carcinomas. **Conclusions:** *TP53* Y220C is a relatively rare event in CABC. The *TP53* mutant group was associated with GA in tumor suppressor genes, including *BRCA1*, *PTEN*, and *RB1*, whereas the *TP53*wt group was associated with GA in pathways associated with endocrine resistance, including *PIK3CA* and *ESR1*. Comprehensive results of ESG401, a TROP2-targeting ADC: Updated phase 1 analysis in advanced solid tumors. First Author: Fei Ma, Cancer Hospital Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China

Background: ESG401 is a novel ADC comprising a humanized anti-TROP2 IgG1 monoclonal antibody conjugated to the Topoisomerase I inhibitor SN-38 via a stable cleavable linker. ESG401-101 is a phase 1, open-label, dose-escalation (1a) and dose-expansion(1b) study evaluating the safety and antitumor activity of ESG401 in advanced solid tumors. This report summarizes the comprehensive phase 1 results. **Methods:** Patients (pts) aged 18–75 years with locally advanced/metastatic solid tumors received ESG401 until unacceptable toxicity, progressive disease, or consent withdrawal. Phase 1a results (n = 40) have been reported previously. Phase Ib comprised three parallel cohorts: late-stage TNBC, late-stage HR+/HER2-, and first-line TNBC. **Results:** As of Oct 23, 2024, 156 pts were enrolled at 13 sites across China (40 in 1a; 116 in 1b). Most pts had metastatic HR+/HER2-BC (n = 65; median prior lines: 3; range: 1–10), followed by late-line TNBC (n = 47; median prior lines: 3; range: 1–12), first-line TNBC (n = 40), HER2+BC (n = 2), and one case each of endometrial cancer (EC) and adenoid cystic carcinoma (ACC). All pts had distant metastases at baseline; 13%, 57%, and 54% had brain, liver, and lung metastases, respectively. ESG401 demonstrated efficacy in pts with solid tumor(Table), including those with brain metastases. The safety profile remained consistent with no new or unexpected signals. The most common any-grade TEAEs were leukopenia, neutropenia, anemia, nausea, and vomiting. Grade ≥3 TRAEs were primarily neutropenia and leukopenia, none leading to permanent discontinuation. TRAEs led to delayed dosing, dose reduction, and discontinuation in 38.5%, 7.1%, and 2.6% of pts, respectively. **Conclusions:** ESG401 demonstrated favorable safety and efficacy benefits due to its enhanced linker, showing good safety and promising antitumor activity in advanced solid tumors across settings. These results warrant further clinical investigation. Clinical trial information: NCT04892342. Research Sponsor: Shanghai Escugen Biotechnology Co., Ltd.

Effect of ERBB2 activating mutations on enhanced internalization and activity of trastuzumab deruxtecan in HER2-non-amplified metastatic breast cancer. First Author: Nicholas Mai, Memorial Sloan Kettering Cancer Center, New York, NY

Background: Trastuzumab Deruxtecan (T-DXd) is a HER2-targeting antibody drug conjugate approved for the treatment of HER2 low metastatic breast cancer (MBC). Whether HER2 activating mutations define a distinct clinical subset within HER2 low MBC is unknown. Here we present a single institution retrospective study of patients treated with T-DXd and report real world progression free survival (PFS), in patients with mutant vs. wild type (wt) HER2. We further modeled the impact of various HER2 mutations on T-DXd internalization and activity preclinically to characterize mechanistic and mutation-specific differences. **Methods:** All patients who had received T-DXd for HER2-low and HER2-null MBC at Memorial Sloan Kettering Cancer Center were eligible for inclusion. Clinicopathologic data were abstracted from patient records. PFS was determined clinically and calculated using the Kaplan-Meier method. Univariable and multivariable associations between PFS and patient characteristics were assessed using Cox-proportional hazards models. *ERBB2* mutations were modeled in breast cell lines and examined for kinetics of fluorescence-labeled T-DXd cell internalization and potency of T-DXd antitumor effects. **Results:** We found 278 patients who received T-DXd for HER2 non-amplified MBC. Thirty-one had triple negative breast cancer and 247 had estrogen receptor positive MBC. Median age was 59 and TDXd was the median 6th line of systemic treatment for MBC. Median PFS for all patients was 6.97 months (95%CI 5.73-8.4). *ERBB2* mutations were found in 23 (8.2%) patients on genomic sequencing via MSK-IMPACT. Among mutations, 20 were known oncogenic mutations per OncoKB (eg D769Y, L755S, S310F, V777L), while 3 were variants of unknown significance (L35R, P378L, R1169K). *ERBB2* activating mutations were significantly associated with prolonged T-DXd PFS; median 6.28 months in the wt population vs 10.58 months with an *ERBB2* mutation (HR 0.55, 95%CI 0.31-0.98, p = 0.04). After adjusting for age, treatment line, and ER status, *ERBB2* mutations were independently associated with longer PFS. Among patients with *ERBB2* activating mutations, 9 had HER2 IHC 0 disease, while the remaining 14 were at least HER2 IHC 1+. There was no statistically significant difference in PFS between patients with HER2 IHC 0 vs 1+ (HR 1.74, 95%CI 0.53-5.7, p = 0.35) among those with *ERBB2* mutations. Finally, expression of the most common *ERBB2* mutants in MCF10A cells lead to more rapid internalization of labeled TDX-d into cells and lower IC50 for inhibition of proliferation. **Conclusions:** *ERBB2* activating mutations are associated with longer T-DXd PFS in HER2-non-amplified MBC, even when HER2 IHC was 0, likely due to enhanced ADC internalization. The data imply that *ERBB2* mutant breast cancers may be uniquely sensitive to T-DXd, independent of HER2 expression levels. 1046 Poster Session

Differences in genomic profiles, targeted treatment use, and overall survival in patients with metastatic breast cancer by Area Deprivation Index. First Author: Emily L. Podany, Washington University in St. Louis, St. Louis, MO

Background: We previously showed racial differences in circulating tumor DNA (ctDNA) profiles and PI3K inhibitor (PI3Ki) use in patients (pts) with metastatic breast cancer (mBC); however, these findings may be influenced by socioeconomic disadvantage. A validated measure to explore this is the Neighborhood Atlas Area Deprivation Index (ADI, Kind et al NEJM 2018), which includes 17 measures of neighborhood disadvantage such as poverty, employment, and education. We sought to determine differences in genomic profiles, PI3Ki use, and overall survival (OS) in pts with mBC by ADI. **Methods:** This retrospective cohort study analyzed 1127 pts with mBC and ctDNA testing using the Guardant360 assay who were treated at Washington University in St. Louis (N = 634), Massachusetts General Hospital (N = 313), Weill Cornell (N = 109), and Northwestern University (N = 71). 9-digit zip codes were converted into national ADI ranks (0-100) divided into high deprivation (HDep, rank ≥60) and low deprivation (LDep, rank < 60) groups based on prior studies. Multivariate models were designed to determine genomic and prognostic differences by ADI. Pts with *PIK3CA* mutations were evaluated by ADI and use of PI3Ki in the second line or beyond, either through clinical trial enrollment or after FDA approval. OS from time of first ctDNA test was stratified by ADI and self-reported race. **Results:** The cohort included 165 Black pts (14.6%) and 335 pts (29.7%) from HDep zip codes. Black pts were more likely to be from HDep areas (Odds ratio [OR] 3.82, 95% confidence interval [CI] 2.62-5.57, P < 0.001). There were no differences in mBC subtype between ADI groups. Pts with HR+ HER2- mBC in the HDep group were significantly less likely to receive PI3Ki vs LDep (8/46, 17.4% vs 33/90, 36.7%, P = 0.02) despite equal incidence of *PIK3CA* mutations. Pts in the HDep group were more likely to have *TP53* single nucleotide variants (snv) (OR 1.58, 95% CI 1.18-2.10, P = 0.002) and less likely to have *AKT1* snv (OR 0.29, 95% CI 0.11-0.80, P = 0.017). Among pts in the HDep group, worse prognosis was seen in pts who self-identified as Black (hazard ratio [HR]1.51, 95% CI 1.02-2.25, P = 0.04), had *PIK3CA* snv (HR 1.73, 95% CI 1.23-2.44, P = 0.002), or *TP53* snv (HR 1.56, 95% CI 1.12-2.17, P = 0.009). Median OS was significantly shorter in the HDep vs LDep group (24 months [mos] vs 28 mos, P = 0.04) and significantly lower for Black pts in the HDep vs Black pts with LDep or White pts with HDep or LDep (15 mos vs 25-28 mos, P = 0.02). **Conclusions:** In this multi-institutional cohort, we identified significant disparities in the use of PI3Ki in HDep neighborhoods and higher rates of *TP53* snv, which are associated with aggressive tumor biology. Pts with mBC in HDep areas, especially Black pts, had shorter OS. Further research is needed to validate these findings, determine the root causes of these disparities, and implement change to achieve equity in precision medicine use. Research Sponsor: None.

Dissecting primary endocrine resistance through ctDNA profiling of a hybrid real-world and clinical trial dataset in hormone receptor-positive, HER2-negative (HR+/HER2-) metastatic breast cancer (MBC). First Author: Lorenzo Gerratana, Department of Medical Oncology, Centro di Riferimento Oncologico di Aviano (CRO), IRCCS, Aviano, Italy

Background: New targeted therapies, including novel endocrine agents and antibody drug conjugates, are revolutionizing the treatment of HR+/HER2- metastatic breast cancer (MBC). However, questions surrounding primary and secondary endocrine resistance (R1 and R2, respectively) still hinder the development of personalized treatment strategies. This study aimed to investigate R1 by leveraging liquid biopsy in a hybrid real-world and clinical trial dataset. **Methods:** This study used the nationwide (US-based) deidentified Flatiron Health-Foundation Medicine MBC clinicogenomic database (FH-FMI CGDB), comprising data originated from ~280 US cancer clinics (~800 sites of care), and analyzed a cohort of 855 patients (pts) profiled through the FoundationOne Liquid CDx NGS panel, combining it with the first 65 pts enrolled in the GIM-24-PalboBP study (NCT04318223). R1 was defined as 1-line PFS of < 6 months. A 1:3 Propensity Score Matching was applied to balance key factors (i.e. age, ECOG performance status, visceral, lymph node, multiple metastasis, type of CDK6/4i). Pathogenic alterations with a > 10% prevalence were tested singularly and according to oncogenic pathways based on Sanchez-Vega F et al, Cell. 2018. Associations between ctDNA alterations, R1, and R2 were assessed using logistic regression, while prognosis was evaluated through Cox regression. **Results:** A set of 528 pts (respectively 132 and 396 for R1 and R2) was selected from the original cohort of 855 pts. Top detected alterations were PIK3CA SNV (46%), TP53 SNV (33%) and ESR1 SNV (24%). R1 was associated with TP53 SNV (OR = 2.30, P < 0.001), CCND1, FGF19, FGF3 and FGF4 CNVs (respectively OR = 1.75, P = 0.018; OR = 1.62, P = 0.044; OR = 1.80, P = 0.015; OR = 1.73, P = 0.024). On the other hand, ESR1 SNV was associated with R2 (OR = 0.47, P = 0.005). CCND1, FGF19, FGF3 and FGF4 CNVs were significantly co-occurring (P < 0.001) and located in the chromosome (chr) 11q13.3 region. In multivariable analysis, TP53 SNV, ESR1 SNV and chr11q13.3 CNV maintained their association with R1 (respectively OR = 2.22, P < 0.001; OR = 0.47, P = 0.006 and OR = 1.94, P = 0.006). Pathway analysis was consistent, showing a significant association between R1 and SNVs in the P53 and in the ER pathways (respectively OR = 1.92, P = 0.002; OR = 0.58, P = 0.024) and CNVs in the cell cycle pathway (OR = 2.18, P = 0.001). No differences were observed for 2-line (PFS2) across R1 and R2 (median PFS2 8.89 vs 8.03 months P = 0.589). Chemotherapy was prevalent in the R1 group (35% vs 15%). Within pts receiving 2-line endocrine therapy, TP53 SNV was the only prognostic factor in R1 (HR = 2.02, P = 0.008), while SNVs in TP53 and ESR1 had an impact on PFS2 in R2 (respectively HR = 1.50, P = 0.003 and HR = 1.45, P = 0.008). **Conclusions:** This study confirms TP53 and ESR1 as key factors for R1 and R2, respectively, with ESR1 showing a prognostic impact on PFS2 in R2 only. Additionally, chr11q13.3 emerges as a new candidate region for R1. These results provide critical data for both decision making and 2-line clinical trial design. Research Sponsor: None.

Genomic alterations (GAs) associated with durability of benefit from trastuzumab deruxtecan (T-DXd), trastuzumab emtansine (T-DM1) and sacituzumab govitecan (SG) in metastatic breast cancer (MBC). First Author: Tess A. O'Meara, Dana-Farber Cancer Institute, Boston, MA

Background: Predictive biomarkers are needed to guide use of T-DXd, T-DM1 and SG in MBC. We used real-world comprehensive genomic profiling (CGP) of tumor tissue and circulating tumor DNA (ctDNA) to describe pre- and post-treatment somatic GAs in patients receiving these antibody-drug conjugates (ADCs) and evaluated the predictive value of *ERBB2* amplification (*ERBB2*amp) in MBC treated with T-DXd and T-DM1. **Methods:** MBC patients with FoundationOne CDx or FoundationOne Liquid CDx who received T-DXd, T-DM1 or SG monotherapy were included. Clinical data originated from 280 cancer clinics (~800 sites of care) between 1/2011-4/2024 included in the US-wide deidentified Flatiron Health-Foundation Medicine MBC clinicogenomic database. For each ADC and MBC subtype, we characterized the GA profile of pre-ADC samples. Pre- and post-treatment GAs were then compared by chi-square, adjusted for multiple comparisons. For patients who received T-DXd or T-DM1, time to next treatment (TTNT) was compared between patients with or without *ERBB2*amp by tissue CGP by Cox models, adjusted for age, ECOG status, HR status, and line of therapy. **Results:** We identified 1,177 pre-ADC samples (n = 972 tissue, n = 205 liquid biopsy; T-DXd n = 492, T-DM1 n = 167, SG n = 518). *TP53* (59.7%), *PIK3CA* (34.4%), and *ERBB2* (20.6%) were most commonly altered across all samples. Median TTNT for T-DXd in HER2+ MBC (n = 106) was 16.6 mo; *ERBB2* alterations were present in 84.6% of cases above the median vs 47.5% below. Median TTNT for cases with somatic *BRCA1/2* mutations (n = 6) was 8.48 mo vs 18 mo for *BRCA1/2* wildtype. Formal statistical analyses of baseline GAs and associations with TTNT on each ADC will be presented at the conference. GAs in *ATM* (24% vs 3.7%, $p < 0.0001$), *GNAS* (6% vs 2%, $p < 0.0001$), *EGFR* (4% vs 0.2%, $p < 0.01$) and *ERCC4* (2% vs 0, p = 0.02) were more prevalent in samples post-T-DXd (n = 50, 15 tissue/35 liquid) vs pre-T-DXd (n = 492, 378 tissue/114 liquid). GAs in *ERCC4* (3.3% vs. 0, p = 0.001) were more prevalent in samples post-SG (n = 60, 31 tissue/29 liquid) vs pre-SG (n = 518, 439 tissue/79 liquid). HER2+ MBC with *ERBB2*amp by CGP (n = 54) had more favorable TTNT on T-DXd vs non-amplified HER2+ (n = 30; 22.5 vs 6.4 mo, HR 0.10, 95% CI 0.04-0.24, $p < 0.0001$). HER2-low MBC with *ERBB2*amp by CGP (n = 6) had more favorable TTNT on T-DXd vs non-amplified HER2-low (n = 263; NR vs 7.4 mo, HR 0.22, 95% CI 0.05-0.90, p = 0.035). HER2+ MBC with *ERBB2*amp by CGP (n = 102) had more favorable TTNT on T-DM1 vs non-amplified HER2+ (n = 45; 8.3 vs 2.6 mo, HR 0.50, 95% CI 0.33-0.75, $p < 0.001$). **Conclusions:** This real-world analysis provides insight into baseline GAs and associations with TTNT on T-DXd, T-DM1 and SG in MBC as well as GAs that emerge on treatment. *ERBB2*amp by CGP carried additional predictive value to IHC/FISH HER2 status in both HER2+ and HER2-low MBC treated with T-DXd and HER2+ MBC treated with T-DM1. Research Sponsor: None.

Macroscale genomic alterations in histomolecular invasive lobular carcinoma compared to other breast cancer subtypes. First Author: Jason A. Mouabbi, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Although invasive lobular carcinoma (ILC) is often classified as a separate breast cancer (BC) subtype with distinct molecular features, options for diagnosis and treatment remain similar to other BCs. Using an integrated histomolecular approach to classify 617 BC samples into either histomolecular ILC (hmILC) or histomolecular no special type (hmNST) subsets, we compared their macroscale genomic alterations to describe biological traits of the ILC BC subtype, which may lead to improved approaches in BC therapies. **Methods:** A total of 617 BC FFPE samples were subject to whole-exome and bulk RNA sequencing analysis. hmILC subset was defined based on CDH1 truncation/deletion or low CDH1 expression (z-score $< -2.5\times$MAD), while all other samples were classified as hmNST. Copy number variations (CNVs) were assessed using Sequenza to detect recurrent amplifications/gains and deletions; homologous recombination deficiency (HRD) scores were calculated based on large-scale state transitions and loss-of-heterozygosity events; tumor mutational burden (TMB) scores were evaluated as percent of mutations per megabase; and mutational signatures were deconvoluted using maftools R package. **Results:** Genome-wide CNV analysis revealed distinct patterns in hmILC compared to hmNST. hmILC showed hallmark deletions at regions harboring *CDH1* (16q), while gains were observed significantly more frequently at regions harboring *FCGR3A* (1q) compared to hmNST. Elevated APOBEC activation signature expression was found in 32% hmILC vs. 19% hmNST samples (p = 0.002, chi-squared test). HRD-positive cases were less frequent in the hmILC subset (25%) compared to hmNST (42%) (p = 0.001). In contrast, hmILC tumors more frequently demonstrated high TMB scores compared to hmNST (10% vs. 2%, p = 0.0003). Moreover, TMB-positive hmILC samples were mostly HRD-negative.Genetic alterations in genes like *FANCA*, *FANCD2* and *PALB2* were more frequently enriched in hmILC tumors compared to hmNST ($p < 0.1$). Furthermore, hmILC subset with high HRD scores frequently harbored additional DNA repair gene mutations (e.g., *BRCA2*) compared to the subset with low HRD scores (p = 0.02). **Conclusions:** This study revealed macroscale genomic alterations, such as unique CNV patterns, altered distributions of HRD- and TMB-positive cases and increased APOBEC-driven mutational processes, in the hmILC BC subset. These distinct genomic architectures highlight the need for innovative trials using inhibitors of DNA repair and related pathways for hmILC BC patients, particularly in those with high HRD-high tumors. Landscape analysis of proteins in the development of breast cancer brain metastasis. First Author: Dongyan Xu, The Second Affiliated Hospital, Zhejiang University School of Medicine, Hangzhou, China

Background: Breast cancer brain metastasis(BCBM) is a major cause of mortality in advanced breast cancer patients, and treatment options are limited. In this project, we investigated the proteomic landscape of primary breast cancer and brain metastasis. **Methods:** We conducted high-throughput proteomic analysis on primary and brain metastatic breast cancer tissues surgically resected from 21 patients. Following screening and sample processing using pressure cycle technology (PCT) for peptide extraction, we used the data-independent acquisition (DIA) mass spectrometry (MS) method to acquire the data. Additionally, we used biological function assays, co-culture experiments, and transcriptome sequencing analysis to further investigate the differentially expressed proteins. **Results:** Patients were mostly in clinical stage II, with two excluded from analysis due to no surgery. Breast cancer classifications included 47.6% HER2+/HR-, 28.6% HER2+/HR+, 9% HER2-/HR+, and 14.3% TNBC. All patients received chemotherapy, with 57% undergoing neoadjuvant therapy and 12 receiving targeted therapy (all with trastuzumab). A total of 9430 protein groups were identified, with 692 showing differential expression in BCBM. Notably upregulated proteins included CRYAB, GFAP, STXBP1 and significantly downregulated proteins included CACNA1A, AOC3, PMP2, OGN. Most differentially expressed proteins were involved in extracellular matrix (ECM) and cell-cell interactions, with collagen family proteins (e.g., COL14A1, COL22A1) playing key roles in BCBM. HER2+ BCBM was associated with ECM pathways, while TNBC impacted the immune microenvironment. Regardless of the subtype, we identified 11 proteins that collectively contribute to the development of BCBM, including CRYAB, ATP6V0A1, HLA-DQB1, TPM2, SERPINB9, NFATC2, GRAP, ALDH1L2, DHRS4L2, SEPTIN1 and SAMHD1. We found that high ACOX1 and low KRT9/KRT14 expression were linked to poor prognosis in BCBM. Analyzing whether patients had undergone targeted therapy, we found that resistance might be acquired through the oxidative phosphorylation pathway, promoting brain metastasis in HER2+ breast cancer. Interestingly, CRYAB expression was prominent across all subtypes of BCBM and targeted therapy groups, suggesting it may serve as an essential biomarker for BCBM. We have confirmed that CRYAB can promote the proliferation and migration of HER2+BCBM, and preliminarily verified that CRYAB is closely related to immune infiltration through CXCL5, CXCL8 and CCL3 in tumor microenvironment, which may promote the occurrence of HER2+BCBM by affecting the NF-κB pathway. **Conclusions:** Leveraging high-throughput proteomics, we present a detailed analysis that elucidates the biological processes involved in developing and progressing BCBM from multiple angles. This work offers new directions for early prediction, treatment, and prognosis of BCBM in clinical practice. Research Sponsor: National Natural Science Foundation of China; 81602716.

Evaluation of tumor immune microenvironment in Hispanic and African American breast cancer. First Author: Robert Hsu, Norris Comprehensive Cancer Center, University of Southern California, Los Angeles, CA

Background: Hispanics or Latinos (HL) and African Americans or Black (AA) have a higher prevalence of advanced-stage breast cancer (BC) at diagnosis compared to Non-Hispanic Whites (NHW). To understand the role of immune system, we evaluated the tumor immune microenvironment (TIME) by race/ethnicity among HL, AA, and NHW BC patients. **Methods:** 15544BC samples were tested by NGS (592, NextSeq; WES, NovaSeq) and WTS (NovaSeq; Caris Life Sciences, Phoenix, AZ). Race/ethnicity data is self-reported. Immune cell were estimated using WTS deconvolution (Quantiseq). Gene expression profiles were analyzed for T-cell inflammation score (TIS) and interferon-gamma (IFN-gamma) score. Real-world overall survival (OS) was obtained from insurance claims and calculated from date of tumor biopsy to last contact using Kaplan-Meier estimates. Statistical significance was determined by chi-square and Mann-Whitney U test with *p*-values adjusted for multiple comparisons ($q < .05$). **Results:** 7170 NHW (35.3%, N = 2528) biopsied (bx) from primary breast cancer (pBC), 64.7% (N = 4642) metastatic bx (mBC), 1,508 AA (pBC 39.3% N = 592, mBC 60.7% N = 916), and 1,754 HL (pBC 44.1% N = 774, mBC 55.9% N = 980) cases were included. By subtype, there were 1,956 (60.4% NHW, 20.7% NHB, 18.9% HL) TNBC, 3425 HR+/HER2- (72.6% NHW, 11.9% NHB, 15.6% HL), and 694 HER2+ (64.6% NHW, 15.7% NHB, 19.7% HL). Across all cases, AA (20.5%) and HL (20.4%) had greater incidence (%) of PD-L1+ cases versus (vs) NHW (17.4%), all $q < .05$. TMB-High (³10 mut/Mb) was similar in NHW (11.5%), AA (10.8%), and HL (10.9%). AA tumors had lower median % cell infiltration of M2-like macrophages (M2 $M\varphi$), B cells, and neutrophils vs NHW (Table). HL had a lower fraction of M2 $M\varphi$ and higher CD8+ T cells (Table). AA had lower TIS (-8 vs 1, p = .02) while HL had lower IFN-gamma (-0.38 vs. -0.35, $q < .05$) vs NHW. By subtype, AA had lower neutrophils (4% vs 4.3%) and increased DC fractions (3.1% vs 2.8%) in TNBC vs NHW, all $q < .05$; no significant changes seen in HL vs NHW. AA had worse mOS than NHW overall (31.8 vs 36.8 months (mo)), HR 1.1, 95% CI 1 – 1.2, p = < .01), in pBC (40.3 vs 49.9 mo, HR 1.3, 95% CI 1.1 – 1.5, p = < .01), but not mBC (27.4 vs 29.1 mo, HR 1, p = 0.2). HL had similar mOS vs NHW overall (37.4 vs 36.8 mo, HR 0.9, p = 0.9) and in mBC (29.1 vs 31 mo, HR 0.96, p = 0.4), but worse mOS in pBC (44.7 vs 50.0 mo, HR 1.1, 95% CI 1 – 1.3, p = .01). **Conclusions:** Our study shows worse mOS in AA and HL pBC cases vs NHW, possibly from a less inflamed TIME in AA and HL and lower fraction of neutrophils and M2 $M\varphi$ despite higher % of PD-L1+. Targeting $M\varphi$ and CD8+ T cells and converting cold to hot TIME may lessen race/ethnic disparities, especially in early-stage BC. Research Sponsor: None.

Circulating tumor DNA (ctDNA)-based minimal residual disease (MRD) measured by Guardant Reveal in patients (pts) with HER2-positive (HER2+) metastatic breast cancer (mBC) with long-term disease control on first-line trastuzumab-pertuzumab. First Author: Antonio Llombart-Cussac, Hospital Arnau Vilanova - Lliria, FISABIO, Valencia, Spain

Background: The CLEOPATRA and PERUSE trials established the combination of a taxane with the antiHER2 monoclonal antibodies trastuzumab and pertuzumab (HP) as the gold standard first-line treatment for HER2+ mBC. In both studies, the progression events reached a plateau after 4 years and up to 30% of pts remained long-term progression-free, hypothesizing HP maintenance can be safely discontinued. We therefore evaluated whether epigenomic-based ctDNA MRD analysis can potentially identify pts with a higher chance of permanent remission. PRE-PHENIX is a multi-center observational study that explores the prevalence of MRD measured by Guardant Reveal in HER2+ mBC pts on long-term first-line HP maintenance. **Methods:** A total of 40 pts with HER2+ mBC on first-line treatment with HP maintenance for a minimum of 4 years were included. Confirmation of no progressive disease by CT or PET-scan in the last 3 months previous to study entry was mandatory. Plasma samples were analysed using Guardant Reveal powered by the Guardant Infinity platform, a tissue-free epigenomic assay interrogating differentially methylated regions of DNA optimized to detect breast cancer DNA from normal cell-free DNA. Two ctDNA tests were performed on each patient within a 6 – 12-week interval. Additionally, 11 pts with confirmed disease progression on antiHER2 therapy for mBC were included as case controls. The primary objective was to establish the prevalence of positive MRD in both populations and the agreement between the two tests for the Long-Term responders. **Results:** Median age was 63.2 years (range 30.8 – 84.4). The median duration of first-line HP treatment was 6.9 years (range 4.2 - 11.1). At diagnosis, 26 pts (65%) presented with "de novo" mBC and 20 (50%) had visceral disease. The last radiological evaluation categorized 6 pts (15%) as having stable disease (SD), 2 pts (5%) with partial response (PR), and 32 pts (80%) with complete response (CR). Among the 11 pts with confirmed progression, 2 presented exclusive Central Nervous System (CNS) disease. Guardant Reveal identified MRD in 4 long-term responders (10%), 3 out of 6 pts (50%) with SD, 1 of 2 pts (50%) with PR, and no MRD among the 32 pts with CR. A perfect agreement was observed between the two tests (Kappa-index of 1). Ten out of the 11 pts (91%) with disease progression had MRD, including the two with exclusive CNS involvement. **Conclusions:** Our study demonstrates clinically significant performance of a tissue-free MRD test, Guardant Reveal, as a potential non-invasive monitoring tool to guide de-escalation strategies in pts HER2+ mBC pts with long-term remissions on HP treatment. A prospective study (PHENIX) to guide HP interruption by ctDNA monitoring is planned. This study was funded by a Fundación Contigo full grant (Spain) and Guardant Health. Research Sponsor: None.

Antibody drug conjugates treatment response score (ADC TRS) for sequencing trastuzuamb deruxtecan (T-DXd) and sacituzumab govitecan (SG) in advanced breast cancer (aBC). First Author: Andi Cani, University of Michigan Medical School, Rogel Cancer Center, Ann Arbor, MI

Background: T-DXd, targeting HER2, is approved in hormone receptor positive or negative (HR+/-) HER2-low (1-2+ by immunohistochemistry [IHC]) and HR+/HER2-ultralow (0+ with membrane staining) aBC. SG, targeting TROP2, is approved in HR+/HER2 negative [-; < 3+ by IHC] and triple negative BC (TNBC; HR-/HER2-). Given limitations in determining IHC 0-1+ status and lack of predictive biomarkers, biomarkers for sequencing these ADCs in those with HER2- aBC are needed. Recently, Thomas et al. reported the discovery of ADC TRS—a generalized model combining individual ADC target expression, proliferation, and adhesion to predict multi-ADC target/tumor type clinical benefit—as well as validation of SG and T-DXd TRS models (tuned by pan-tumor response rates) by a qRT-PCR based clinical trial assay (CTA; Strata Select ADC [SSA]) for predicting clinical benefit of first ADC (SG or T-DXd) in those with HER2- aBC (ASCO 2024 #3140; AACR 2025 #1014). Here, we evaluated ADC target expression and T-DXd/SG TRS status from SSA validation cohort HER2- BC patients stratified by clinical HR/HER2 IHC status. **Methods:** Adults with aBC from an observational trial (NCT03061305) with valid FFPE tumor tissue results from SSA validation cohort testing were included. aBC types were determined by HR/HER2 IHC results (by ASCO/CAP scoring), with those HER2 3+ or *HER2* amplified (by Strata Select testing) considered HER2+. ADC target component expression (*HER2* or *TROP2;* pan-tumor scaled absolute expression) and T-DXd and SG TRS statuses (+ associated with more clinical benefit) by SSA were compared by IHC defined aBC types. **Results:** 230 patients with aBC from SSA validation testing were included (median age 58 yrs, 40% self-reported non-European;180 with definitive aBC type [see Table for distribution]). *HER2* expression was significantly increased vs. *TROP2* in HER2+ and HR+/HER2 aBC, and did not significantly differ in those with TNBC (see Table). Across all patients, 42%, 30%, 27% and 0.4% were T-DXd/SG TRS +/+, -/-, +/- and -/+, respectively. Results were similar in those with HER2 IHC 0+ (n = 37, median *HER2* vs. *TROP2* = 2.2 vs. 2.3, p = 0.51; 8% and 3% T-DXd/SG TRS +/- and -/+, respectively. **Conclusions:** Pan-tumor optimized, validated ADC TRS models support sequencing T-DXd before SG in nearly all patients with advanced HER2- BC, including those with TNBC and HER2 0+ IHC. Prospective evaluation of the CTA is warranted. Research Sponsor: Strata Oncology.

ADC target expression (*HER2* or *TROP2*) and T-DXd | SG TRS status by SSA in BC patients.

					T-DXd/SG TRS Status

Estrogen receptor (ER) expression on circulating tumor cells (CTCs) and cell free DNA (cfDNA) mutational landscape in the PACE randomized phase II study. First Author: Carolina Reduzzi, Weill Cornell Medicine, New York, NY

Background: The PACE (NCT03147287) randomized phase II trial investigates CDK4/6 inhibition beyond progression in combination with endocrine treatment, with or without PD-L1 inhibition, in hormone receptor-positive (HR+)/HER2- metastatic breast cancer (MBC) (Mayer et al 2024). We previously reported that cfDNA alterations and CTC number correlated with survival and treatment response (Jeselsohn et al 2024; Gerratana et al ASCO 2023). Here we investigated ER expression on CTCs in relation to the cfDNA mutational landscape. **Methods:** Samples were collected at baseline. CTC enumeration and ER protein expression on CTCs (by immunofluorescence) was evaluated with the CellSearch and the ACCEPT software. Samples were classified as CTC^{high} or CTC^{low} (cutoff ≥5 CTC/sample). CTC^{high} samples were defined ER+ if >15% CTCs/sample expressed ER to ensure good inter-group stratification. Concurrently, cfDNA was analyzed with the Guardant360 assay. Only pathogenic single nucleotide (snv) and copy number variations (cnv) with ≥3% prevalence were included and categorized into oncogenic pathways (Sanchez-Vega et al 2018). Differences in distribution across CTC groups were tested through Chi-squared and Fisher's test. **Results:** From 220 enrolled patients, 167 were evaluable for ER on CTCs. Of these, 91 were CTC^{low}, 30 were CTC^{high}/ER-, and 46 CTC^{high}/ER+. *ESR1* mutations were more common in CTC^{high} /ER+ samples, while CTC^{high}/ER- samples had higher incidence of alterations in *SMAD4*, *PIK3CA*, *BRAF* and *CDK4* compared to the other 2 groups (Table 1). CTC^{high}/ER- had also higher mutant allele frequency compared to CTC^{high} /ER+ and CTC^{low} (MAF > 3% in 73% vs 54% and 31%, respectively, p < 0.001). CTC^{low} samples had overall lower cfDNA alteration incidence. Similarly, alterations in the ER pathway were more frequent in samples with CTC^{high} /ER+, whereas alterations in PI3K, cell cycle and P53 pathways were more common in CTC^{high}/ER- samples. Alterations in the RTK/RAS/RAF pathway were more common in CTC^{high} samples (23% and 28% for ER- and ER+ vs 9.9% for CTC^{low}, p = 0.017). Similar results were observed with a 10% threshold. **Conclusions:** Distinct cfDNA alterations were identified based on ER expression in CTCs in HR+/HER2- MBC. Integrating CTC enumeration and cfDNA profiling may help elucidate resistance mechanisms, identify actionable targets, and predict benefit from continued CDK4/6 inhibition beyond progression. Research Sponsor: Pfizer; Merck KGaA; CrossRef Funder ID: 10.13039/100009945.

Overall survival in patients with HR+/HER2- advanced or metastatic breast cancer treated with a cyclin-dependent kinase 4/6 inhibitor plus an aromatase inhibitor: A US Food and Drug Administration pooled analysis. First Author: Jennifer Gao, Oncology Center of Excellence, U.S. Food and Drug Administration, Silver Spring, MD

Background: Cyclin-dependent kinase 4/6 inhibitors (CDKI) are FDA-approved for use in combination with aromatase inhibitors (AI) for the treatment of patients with hormone receptor-positive (HR+), human epidermal growth factor receptor 2-negative (HER2-), advanced or metastatic breast cancer (MBC) as initial (1L) endocrine-based therapy. We have previously reported the pooled analyses of the benefit in progression-free survival of adding CDKI to AI, and here report the pooled overall survival (OS) results for adults treated with CDKI + AI for 1L HR+/HER2- MBC. **Methods:** We pooled individual patient data (N=2252) from 4 randomized trials (MONALEESA-2 & 7, MONARCH-3, PALOMA-2) of a CDKI (abemaciclib, palbociclib, ribociclib) or placebo + AI in adults with 1L HR+/HER2- MBC. OS was defined as time from randomization to death from any cause and was a key secondary endpoint in all 4 trials. Not all 4 trials reached OS statistical significance, but all OS hazard ratios of the individual trials were <1. The median OS was estimated using Kaplan-Meier methods, and hazard ratios with 95% confidence intervals (CI) were estimated using Cox regression models. Analyses were prespecified, with patients analyzed collectively and by various clinicopathological subgroups of interest. **Results:** Overall results in all patients and various clinicopathologic subgroups of interest are shown (Table). **Conclusions:** In this descriptive exploratory pooled analysis, the addition of a CDKI to AI suggested an association with an OS benefit for this class of drugs used as a component of 1L endocrine-based therapy for adults with HR+/HER2- MBC. Additional research is needed to determine which subgroup of patients may benefit more or less of the addition of a CDKI to AI. Research Sponsor: None.

Prospective cohort study of palbociclib in HR+/HER2- metastatic breast cancer in Japan. First Author: Takashi Ishikawa, Department of Breast Surgical Oncology, Tokyo Medical University, Tokyo, Japan

Background: The combination of palbociclib (PAL) with an aromatase inhibitor or fulvestrant has been shown to improve progression-free survival (PFS) in hormone receptor (HR)-positive and human epidermal growth factor receptor (HER2)-negative metastatic breast cancer. However, the addition of PAL to endocrine therapy increases toxicity and cost compared to endocrine therapy alone. In addition, PAL treatment may affect the efficacy of subsequent treatments, as its benefit in terms of overall survival (OS) has not yet been demonstrated. Therefore, it is crucial to prospectively evaluate whether PAL can improve clinical outcomes and quality of life (QoL) for patients in a real-world setting. **Methods:** A prospective observational study of PAL is planned in three cohorts (A, B, and C) categorized by line of endocrine treatment (1st, 2nd, or 3rd or later line) for post-menopausal metastatic or unresectable breast cancer. The primary endpoint is PFS in each line of treatment. For cohort B, PFS2 is defined as time from initiation of first-line therapy for metastatic disease. Based on the results of the PALOMA-2 and -3 studies, the planned sample size was set at 700 cases with confidence intervals: 340 in cohort A, 200 in cohort B and 130 in cohort C. Secondary endpoints include OS, clinical benefit rate, time to chemotherapy, adverse events (AEs), patient-reported outcomes and health-related quality of life, which will also be evaluated during follow-up. This study aims to determine whether the efficacy, safety and QoL outcomes of PAL treatment in daily clinical practice are comparable to those observed in clinical trials, and whether PAL affects the efficacy and safety of subsequent treatments. This report presents PFS results from each cohort. An exploratory analysis of OS rates from the start of 1st-line therapy for metastatic disease is also reported. **Results:** A total of 700 patients were enrolled from April 2019 to January 2023. After excluding cases with contraindications, the final cohort distribution was as follows: 246 in cohort A, 282 in cohort B, and 65 in cohort C. The median PFS was 25.8 months (95% CI: 21.4) for cohort A, 18.0 months (95% CI: 14.0-22.7) for cohort B, and 12.0 months (95% CI: 7.7-17.4) for cohort C. The median PFS2 for cohort B was 57.9 months (95% CI: 45.2-65.1). The 3-year OS rates for cohorts A and B from the start of 1st-line metastatic therapy were 76.3% and 93.1%, respectively. **Conclusions:** The PFS result for the 1st-line cohort (Cohort A) was nearly equivalent to the 24.8 months observed in PALOMA-2, while the 2nd-line cohort (Cohort B) showed markedly better results than the 9.5 months reported in PALOMA-3. Although the background of each cohort needs to be further investigated, the PFS2 result of Cohort B was excellent and the subsequent 3-year OS of this cohort was satisfactory. Based on these results, the use of PAL in the 2nd line setting may be clinically acceptable. Clinical trial information: UMIN000035863. Research Sponsor: Pfizer Inc.

1057 Poster Session

Results of a phase 1 study of vosilasarm (EP0062), a first-in-class oral selective androgen receptor modulator (SARM) in patients with advanced or metastatic AR+/ER+/HER-2- breast cancer. First Author: Hyo S. Han, H. Lee Moffitt Cancer Center and Research Institute, Tampa, FL

Background: Vosilasarm (EP0062) is an oral, nonsteroidal, Selective Androgen Receptor Modulator (SARM). Initially developed under the code RAD140, EP0062 has been reformulated with markedly improved bioavailability and pharmacokinetics. Preclinically, vosilasarm has been shown to act as a potent tissue-selective AR agonist, suppressing growth and proliferation of multiple AR+/ER+/HER-2- breast cancer cell lines and patient-derived xenograft models, as monotherapy or in combination with standard of care (SoC) regimens (Clin Can Res 2017 23(24); SABCS 2019 P5-05-01). Here we report results from the dose finding and optimization cohorts of an ongoing phase 1/2 study (NCT05573126) in patients (pts) with advanced AR+/ER+/HER-2- breast cancer. **Methods:** The study recruited post-menopausal women with locally advanced or metastatic AR+/ ER+/HER-2- breast cancer, $\geq$ 18 years of age, with endocrine sensitive disease. AR+ defined as $\geq$ 10% AR nuclei staining by IHC. Primary objectives were to evaluate safety and determine the optimal dose for evaluation in future combination cohorts. Other endpoints included PK, ORR, DOR, CBR $\geq$6 months and genomic analysis (biopsy- or ctDNA-based NGS). **Results:** A total of 20 pts (Median age 59.5 y, PS 0/1 [70/30%]) were treated across 4 dose cohorts: 20mg QD (n = 2), 10mg BID (n = 10), 10mg QD (n = 5), 15mg BID (n = 3). The 10mg BID cohort was expanded for dose optimization. All pts received prior CDK4/6i and AI and/or SERD with a median of 4 prior lines (in any setting). CtDNA analysis showed genomic heterogeneity at baseline, with ESR1 mutations (8/19 pts) and TP53 mutations (9/19 pts) the most frequent. No DLTs were observed. 89% of all TEAEs were G1 or G2 with most common being increase in LFTs (55% of pts), nausea (40% of pts) and anemia (25% of pts). The LFT increases were transient, asymptomatic and generally occurred in cycle 1, with 2 pts requiring a dose interruption followed by reduction. Most common $\geq$ G3 TEAEs were ALT increase in 4 pts (20%). No treatment related deaths were observed. 19 pts were evaluable for efficacy. For 11/ 19 (58%) pts the best response was stable disease. 4/19 (21%) pts had clinical benefit with CBR $\geq$6 mo, corresponding with marked suppression of CA15-3 in 5/19 (26%) patients. Vosilasarm has a favorable PK profile with good bioavailability and no accumulation. Full data will be reported. 10 mg BID was selected as the optimal dose for Phase 2. **Conclusions:** Vosilasarm has promising clinical benefit, safety and tolerability in this heterogeneous, heavily pre-treated population. This confirms the potential of vosilasarm, a first in class SARM, as a new treatment strategy for AR+/ ER+/ HER-2- breast cancer. The study is continuing with evaluation of vosilasarm in combination with SoC therapies including oral SERD, mTOR inhibitor and CDK4/6 inhibitors. Clinical trial information: NCT05573126. Research Sponsor: Ellipses Pharma.

Impact of BMI on CDK4/6 inhibitors efficacy and safety in advanced breast cancer: Results from a propensity score matched study—CAMELIA. First Author: Min Tian, Department of Oncology, the First Affiliated Hospital of Nanjing Medical University, Nanjing, China

Background: Body mass index (BMI) is strongly associated with the development and progression of breast cancer. Despite the widespread use of cyclin-dependent kinase (CDK) 4/6 inhibitors combined with endocrine therapy (ET) in hormone receptor (HR)-positive advanced breast cancer, the effect of BMI on therapeutic outcomes remains poorly understood. **Methods:** Patients aged ≥18 years with advanced HR-positive breast cancer who received CDK4/6 inhibitors at six hospitals in China were included. 588 patients admitted between December 2016 and December 2024 were evaluated. Patients were categorized into two groups based on BMI: Group 1 (BMI < 25.0 kg/m²) and Group 2 (BMI ≥ 25.0 kg/m²). Propensity score matching with a 3:1 ratio was performed, resulting in 452 patients included in the final analysis. The median follow-up duration was 21.53 months. Progression-free survival (PFS) and overall survival (OS) across BMI categories were compared using Kaplan-Meier (KM) curves and log-rank test. Univariate and multivariate cox regression analyses were performed to assess the impact of baseline clinical factors on PFS. **Results:** Of 452 patients, 339 (66.7%) were in Group 1, 113 (33.3%) were in Group 2 at baseline. The KM analysis revealed that patients with BMI ≥ 25 kg/m² had a significantly longer PFS compared to those with BMI < 25 kg/m². The median PFS was 16.77 months (95% CI: 12.86–20.67) in Group 1, versus 12.93 months (95% CI: 11.38–14.49) in Group 2 (p = 0.036, HR 0.737, 95% CI: 0.554–0.981). However, no significant difference in OS was observed between the two groups (Group 1: 55.6 months vs. Group 2: not reached, p = 0.949, HR 1.015, 95% CI: 0.637–1.618). Univariate and multivariate cox regression analyses identified BMI, lymph node, liver, bone, and brain metastasis are independent prognostic factors for the entire cohort. Subgroup analyses revealed that BMI ≥25 kg/m² was associated with improved survival in patients aged < 60 years, Eastern Cooperative Oncology Group (ECOG) performance status ≥ 1, with lung metastases, received ≥ 1 line of chemotherapy, and received ≥2 lines of CDK4/6 inhibitors. While Group 1 demonstrated a higher overall response rate (ORR) (30.4% vs. 26.5%, p = 0.476), Group 2 had a higher disease control rate (DCR) (87.0% vs. 91.2%, p = 0.314), though neither reached statistical significance. No significant differences were found in the incidence of grade 3/4 hematologic adverse events (AEs) (36.9% vs. 31.5%, p = 0.460) or non-hematologic AEs (17.1% vs. 14.4%, p = 0.605). **Conclusions:** In this study, overweight patients (BMI ≥ 25 kg/m²) with metastatic breast cancer may benefit more from CDK4/6 inhibitors. Moreover, similar adverse events were observed across BMI groups. These findings suggest that BMI could serve as a key predictor of CDK4/6 inhibitors treatment response, providing valuable insights for personalized therapeutic strategies in metastatic breast cancer. Clinical utility of [^{18}F]fluoroestradiol (FES) PET/CT to guide second-line treatment decision in patients with ER-positive HER2-negative metastatic breast cancer progressing on first-line endocrine therapy. First Author: Hannah M. Linden, University of Washington, Seattle, WA

Background: Second line treatment options for patients with ER+/HER2- metastatic breast cancer (MBC) after progression on 1st line endocrine therapy (ET) continue to expand with novel endocrine agents (oral SERDs) and combination therapies (PIK3CA/AKTi, CDKi). However, short median PFS reported in clinical trials show that many patients do not benefit from 2nd line ET. Identifying endocrine-resistant MBC at time of progression on 1st line ET can help place patients on potentially more effective non-ET options (e.g., chemotherapy / antibody-drug conjugates). FES PET/CT has been approved for clinical use in the U.S. and allows whole-body evaluation of ER expression in MBC. Difference in FES uptake across lesions may reflect ER loss/downregulation, a mechanism of endocrine resistance. Goal of this clinical trial was to evaluate the impact of FES PET/CT results on 2nd line therapeutic management decisions. **Methods:** In this multicenter trial in the U.S. [NCT05068726], patients with progression of ER+/HER2- MBC on 1st line ET were prospectively enrolled to undergo FES PET/CT in addition to standard of care (SOC) imaging (CT + bone scan / FDG PET/CT). Treating oncologists completed questionnaires before and after FES PET/CT, detailing therapeutic management plans plus their confidence in the plans. FES PET/CT scans were compared with SOC imaging to assess FES uptake in MBC lesions. An FES uptake score (number of FES-positive lesions divided by total number of lesions per patient) was calculated to evaluate ER expression heterogeneity by central blinded image evaluation. **Results:** 45 patients underwent FES PET/CT. FES PET/CT results led to a change in therapeutic management in 17/45 patients (37.8%; 95% CI 23.8% - 53.5%). Revised management plan was ET in 5/17 and non-ET in 12/17 patients. FES uptake score was 1 (all lesions FES-positive) in 14/45 patients and < 1 (with FES-negative lesions, indicating ER expression heterogeneity) in 31/45 patients. Of 14 patients with FES uptake score of 1, 11 received 2nd line ET. Of 31 patients with FES uptake score < 1, 15 were treated with ET and 16 with non-ET, based on guidelines suggesting that an FES-negative lesion is predictive of lack of endocrine response. FES PET/CT results led to 25/45 patients avoiding additional tests (20 biopsies, 5 scans) and 7/45 patients receiving further testing (4 biopsies, 1 scan, 2 other). Treating oncologist's confidence in 2nd line treatment decision (measured in n = 45 on 10-point scale with 10 being fully confident) increased on average with 2 points from 6.6 (SD = 1.7) pre-FES PET/CT to 8.6 (SD = 1.8) post-FES PET/CT. **Conclusions:** FES PET/CT is a clinically useful tool in the post-first line ER+/HER2- MBC setting. FES PET/CT results led to a change in management in 37.8% of patients and increased oncologist's confidence in 2nd line treatment decision. Clinical trial information: NCT05068726. Research Sponsor: Zionexa SAS, a GE HealthCare Company.

Imlunestrant with or without abemaciclib in advanced breast cancer (ABC): Safety analyses from the phase III EMBER-3 trial. First Author: Joyce O'Shaughnessy, Baylor University Medical Center, Texas Oncology, Dallas, TX and Sarah Cannon Research Institute, Dallas, TX

Background: Imlunestrant is a next-generation, brain-penetrant, oral SERD. The EMBER-3 trial (NCT04975308) in patients with ER+, HER2- ABC and disease progression on/after aromatase inhibitor therapy showed significant progression-free survival improvement with imlunestrant (imlu; 400 mg once daily [QD]) over standard therapy (SOC, fulvestrant or exemestane) among patients with *ESR1* mutations, as well as with imlunestrant+abemaciclib (imlu [400 mg QD] + abema [150 mg twice daily]) over imlu in all patients regardless of *ESR1* mutation status. Detailed safety analyses are presented. **Methods:** The safety population included all patients who received at least one dose of study treatment. Analyses included incidence, severity (CTCAE v 5.0), management, and outcomes of common treatment-emergent adverse events (TEAEs). **Results:** Safety analyses included 859 patients: imlu (n=327), SOC (n=324), and imlu+abema (n=208). Incidence of any (imlu: 83%; SOC: 84%; imlu+abema: 98%), ≥ grade 3 TEAEs (imlu: 17%; SOC: 21%; imlu+abema: 49%), and serious AEs (SAEs; imlu: 10%; SOC 12%; imlu+abema: 17%) were similar between imlu and SOC arms and higher in the combination arm. Most common any-grade AEs with imlu were diarrhea (21%), nausea (17%), and fatigue (23%) and with imlu+abema were diarrhea (86%), nausea (49%), and neutropenia (48%); majority were grade 1 AEs. Incidence of elevated transaminases (any%/≥G3%: 16/1 and 20/5), VTE (1/0 and 3/1), ILD (1/0 and 2/0), bradycardia (2/0 and 1/0), and photopsia (0/0 and 0/0) were relatively low or not observed with imlu and imlu+abema, respectively. Dose reduction rates were 2% with imlu and 39% with imlu+abema, and discontinuation rates due to AEs were low (4% and 6%, respectively). The table characterizes the most commonly observed AEs. Further details will be presented. **Conclusions:** Imlunestrant had a favorable safety profile, similar to SOC, with mostly grade 1 AEs. Safety of imlunestrant + abemaciclib was consistent with the known abemaciclib profile, without additive toxicity. AEs were manageable with supportive medications and/or dose adjustments, resulting in few discontinuations in all arms. Imlunestrant, as monotherapy or in combination with abemaciclib, provides a safe, tolerable, all-oral targeted therapy option for patients with ER+, HER2- ABC. Clinical trial information: NCT04975308. Research Sponsor: Eli Lilly and Company.

Giredestrant (G) with atezolizumab (ATEZO), and/or abemaciclib (ABEMA) in patients (pts) with ER+/HER2− locally advanced/metastatic breast cancer (LA/mBC): Interim analysis (IA) from the phase I/II MORPHEUS Breast Cancer study. First Author: Mafalda Oliveira, Vall d'Hebron University Hospital, Barcelona, Spain

Background: Endocrine therapy (ET) + a cyclin-dependent kinase 4/6 inhibitor (CDK4/6i) is a therapeutic mainstay for first-line treatment (tx) of ER+ mBC, but selection of effective ET combinations after progression remains a challenge. G is a highly potent, non-steroidal, oral (PO), selective ER antagonist and degrader shown to be well tolerated and to achieve robust ER occupancy. Immune checkpoint inhibition has shown a trend towards activity in a number of ER+ BC studies. Additionally, ABEMA (a CDK4/6i) has immunomodulatory activity, making its inclusion a compelling therapeutic approach. Here, we present a 24-week IA of the G + ATEZO ± ABEMA arms and a 22-week IA of the G + ABEMA arm from MORPHEUS BC (NCT04802759). **Methods:** Eligible pts had ER+, HER2− LA/mBC and had received prior tx with a CDK4/6i and 1–2 lines of ET. Pts were randomized to G (30 mg PO QD) alone (previously reported), G + ATEZO (840 mg IV Q2W), G + ATEZO + ABEMA (150 mg PO BID), or G + ABEMA until loss of clinical benefit/ unacceptable toxicity. Investigational drug doses were identical across all arms. Primary endpoints were safety and objective response rate (ORR). Exploratory analyses included evaluation of circulating tumor DNA alterations and tumor gene expression using RNAseq. **Results:** As of Apr 24, 2024, 15 pts in the G + ATEZO arm, 30 in the G + ATEZO + ABEMA arm and, as of Jan 9, 2023, 15 in the G + ABEMA arm, were efficacy/safety evaluable. Many pts had prior fulvestrant (60%, 43%, and 27%, respectively) and prior CDK4/6i duration ≥12 mo (73%, 77%, and 53%). Safety data are shown in the Table. In the triplet arm, the most common grade ≥3 adverse event (AE) was neutropenia/neutrophil count decreased (20%). No grade 5 AEs were reported. Confirmed ORR (all partial responses) were 20%, 33%, and 7% in the G + ATEZO, G + ATEZO + ABEMA, and the G + ABEMA arms, respectively. 7/9 confirmed responses (in *ESR1*-evaluable pts) in the G + ATEZO + ABEMA arm were in pts with *ESR1*-mutated disease. Data with longer follow-up, including progression-free survival, detailed safety, and exploratory biomarker analyses, will be presented. **Conclusions:** The combinations of G + ATEZO, G + ATEZO + ABEMA, and G + ABEMA were tolerable, with no unexpected safety signals including no high-grade interstitial lung disease/ pneumonitis and low rates of high-grade liver toxicity. Clinical activity was observed, with a trend towards improved ORR with G + ATEZO + ABEMA, particularly in tumors with *ESR1* mutations. Clinical trial information: NCT04802759. Research Sponsor: F. Hoffmann-La Roche Ltd.

Phase Ib study of inavolisib (INAVO) + weekly paclitaxel (wP) in patients (pts) with locally advanced/metastatic (LA/m) incurable solid tumors: Safety, pharmacokinetics (PK), and preliminary antitumor activity. First Author: Seock-Ah Im, Seoul National University College of Medicine, Cancer Research Institute, Seoul National University, Seoul, South Korea

Background: wP is commonly used for treating solid tumors as a single agent or in combination with targeted agents. However, it has an unfavorable benefit–risk profile when given with pan-PI3K inhibitors or alpelisib. INAVO, a potent and selective PI3Kα inhibitor that also promotes mutated p110α degradation, was FDA approved in combination with palbociclib + fulvestrant for hormone receptor-positive, HER2-negative (HR+, HER2−), endocrine-resistant advanced breast cancer (BC) following recurrence on/after completing adjuvant endocrine therapy. We report data from INAVO + wP in pts with LA/m solid tumors from a Phase Ib study (CO42800; ISRCTN45319897). **Methods:** Eligible pts had progressed after standard systemic therapy. In part 1 (dose-escalation phase; 3+3 design), pts with LA/m incurable solid tumors received INAVO 6 mg/9 mg orally daily (PO QD) + wP (80 mg/m^2). In part 2 (dose-expansion phase), pts with LA/m incurable *PIK3CA*-mutated solid tumors (triple-negative BC [TNBC]; HR+, HER2− BC; others) received INAVO 9 mg PO QD (recommended dose from part 1) + wP. Primary endpoint: Safety/tolerability in parts 1 and 2. Secondary endpoints: Preliminary antitumor activity in part 2 (only TNBC and HR+, HER2− BC data are available); PK in parts 1 and 2. **Results:** Of 66 pts enrolled (parts 1 and 2), four received no treatment and eight were still on treatment at clinical cutoff (Oct 11, 2024). Reasons for study discontinuation were per protocol study completion (56.1%), death (16.7%), pt withdrawal (9.1%), loss to follow-up (1.5%), and other (4.5%). There were no dose-limiting toxicities. In safety-evaluable pts (n = 62), grade 3, 4, and 5 adverse events (AEs) occurred in 59.7%, 3.2%, and 0% of pts, respectively. One pt discontinued INAVO due to AEs; INAVO dose modifications (reduction/interruption) due to AEs occurred in 61.3% of pts. The most common AEs (> 10% of pts) were diarrhea (61.3%), hyperglycemia (51.6%), and anemia (45.2%). Neutropenia (24.2%) and diarrhea (8.1%) were the most common grade 3–4 AEs. Serious AEs occurred in 30.6% of pts (mostly single AEs in individual pts, and unrelated to study treatment).In part 2, confirmed overall response rate in pts with TNBC (n = 20) was 50.0% and in pts with HR+, HER2− BC (n = 19) it was 36.8%. Median duration of confirmed response was 7.4 mo (95% confidence interval 5.2, 11.5) and 12.8 mo (3.7, not evaluable), respectively; median progression-free survival, 7.0 mo (3.5, 9.3) and 7.4 mo (6.2, 14.7). PK of INAVO and wP at Cycle 1, Day 15 were comparable to historic data. **Conclusions:** In CO42800, INAVO + wP was well tolerated in pts with LA/m solid tumors, including those with a *PIK3CA* mutation, with no new safety signals or drug–drug interactions observed. Encouraging preliminary antitumor activity shown in pts with HR+, HER2− BC or TNBC supports further investigation. Clinical trial information: ISRCTN45319897. Research Sponsor: Genentech, Inc.

PARPi effectiveness after CDK4/6i in *BRCA1*- and *BRCA2*-associated HR+/ HER2- advanced breast cancer: Results from the multicenter real-world PAMBRACA study. First Author: Emma Zattarin, University of Modena, Modena, MO, Italy

Background: Poly(adenosine diphosphate–ribose) polymerase inhibitors (PARPi) are the paramount of personalized therapy for *BRCA1* and *BRCA2* pathogenic/likely pathogenic variant (P/LPV) carriers with hormone receptor-positive (HR+)/HER2-negative (HER2-) advanced breast cancer (aBC). Nevertheless, data on the efficacy of PARPi following cyclin-dependent kinase 4/6 inhibitors (CDK4/6i) combined with endocrine therapy (ET) are limited. **Methods:** The PAMBRACA study is a multicenter, hospital-based, retrospective-prospective cohort study enrolling *BRCA1* and *BRCA2*-P/LPV carriers with HR+/HER2- aBC treated with ET+CDK4/6i and/or PARPi. In this analysis, the real-world Progression-Free Survivals (rwPFS) of ET+CDK4/6i and subsequent lines were evaluated through Kaplan-Meier method and compared with the log-rank test. Median follow-up was calculated using the reverse Kaplan-Meier method. Multivariate Cox regression model was used to adjust the association between treatment regimens and rwPFS for clinically relevant variables. **Results:** We included12 *BRCA1* and 57 *BRCA2*-P/LPV carriers who were diagnosed with HR+/HER2- aBC between January 1998 and December 2023 in six Italian Institutions. All the patients (pt) received CDK4/6i+ET for aBC (85.5% as first line, 7.2% as second line, 7.3% as third or subsequent line). At CDK4/6i starting, median age was 45 years (range 28-80); 52.2% of pts had visceral metastases and 17.4% had *de novo* aBC. Median follow-up was 39.5 months (mo). Among pts treated with CDK4/6i as first or second line, median rwPFS was 15.1 mo (95%CI 11.8-18.5) and 3.1 mo (95%CI 2.1-NA), respectively. Among the 49 patients who progressed to first or second-line CDK4/6i, 17 (34.7%) received a PARPi as first line post-CDK4/6i, 12 (24.5%) a monochemotherapy (monoCT), 8 (16.3%) an ET (+/- everolimus), 8 (16.3%) a polychemotherapy (polyCT) and 4 (8.2%) died without receiving a subsequent line. No significant differences in clinicopathological characteristics were observed among the treatment groups, except for the number of metastatic sites (<3 vs >3), which was higher for pts receiving mono/polyCT (p = 0.053). PARPi treatment was associated with significantly higher median rwPFS (13 mo vs 4.5 mo for monoCT vs 3 mo for ET vs 6 mo for polyCT, $p < 0.001$), also after adjusting for the number of metastatic sites [for PARPi vs other lines, adjusted hazard ratio (aHR) 0.20, 95%CI 0.09-0.49, $p < 0.001$]. 17 pts received PARPi as later treatment lines, which were independently associated with lower median rwPFS vs PARPi as first post-CDK4/6i line (6 vs 13 mo, aHR 2.81, 95%CI 1.15-6.90, p = 0.024). **Conclusions:** AfterCDK4/6i+ET, PARPi were independently associated with longer rwPFS compared to other systemic therapies in *BRCA1* and *BRCA2*-P/LPV carriers with HR+/HER2- aBC. Earlier PARPi use after CDK4/6i was associated with greater clinical benefit. Research Sponsor: None.

1064 Poster Session

A phase I/IIa study to evaluate the tolerability, safety, pharmacokinetics and efficacy of ecuriclib (BPI-1178) alone in advanced solid tumors and in combination with endocrine therapy for advanced or recurrent HR+/HER2- breast cancer. First Author: Yiqun Du, Phase I Cinical Trial Center, Fudan University Shanghai Cancer Center, Shanghai, China

Background: Ecuriclib (BPI-1178) is a new cyclin-dependent kinases (CDKs) 2/4/6 inhibitor, which has shown strong inhibition on the expression of CDK2/4/6 in pre-clinical studies. This first-in-human phase I/IIa study aimed to assess the preliminary efficacy, safety and tolerability of ecuriclib monotherapy for advanced solid tumors or in combination with endocrine therapy (ET) for HR+/HER2- advanced breast cancer (ABC). **Methods:** Patients with advanced solid tumors included in phase I received ecuriclib alone at doses of 25~500 mg in a 3+3 dose-escalation or expansion manner. Phase IIa consisted of two cohorts, A and B. Cohort A included patients with HR+/HER2- ABC who had progressed after ET receiving ecuriclib in combination with fulvestrant, and treatment-naive patients with HR+/HER2- ABC in cohort B were treated with ecuriclib in combination with letrozole. All patients administered ecuriclib with either intermittent (21 days on, 7 days off) or continuous (28 days on) dosing schedule in a 28-day cycle until disease progression, unacceptable toxicity, etc. Safety was assessed as per CTCAE 5.0. Efficacy endpoints included confirmed objective response rate (ORR), disease control rate (DCR), progression-free survival (PFS), etc. assessed by investigators per RECIST 1.1. **Results:** As of August 9, 2024, a total of 129 patients have been enrolled. And 33 patients were enrolled in Phase I study. No DLT was observed. In Phase IIa Cohort A, 70 patients were enrolled and in which 64 patients were evaluable for efficacy. 26 patients were enrolled into cohort B with 25 efficacy-evaluable patients. In Cohort A, the top three treatment related adverse events (TRAEs) of grade $\geq$ 3 were neutrophil count decreased (35.7%), white blood cell count decreased (14.3%), and hypertriglyceridemia (14.3%) while in Cohort B those were neutrophil count decreased (23.3%), hypertriglyceridemia (16.7%), alanine aminotransferase increased (10.0%), and white blood cell count decreased (10.0%). No TRAE leading to permanent discontinuation or death occurred in this trial. **Conclusions:** Ecuriclib in combination with ET demonstrated promising efficacy and manageable safety profile in patients with HR+/HER2- ABC. Clinical trial information: NCT04282031. Research Sponsor: Beta Pharma (Suzhou) Co., Ltd.

Quantifying the clinical impact of tissue reflex testing for liquid biopsy *ESR1* mutation–negative cases with low ctDNA tumor fraction (TF) in HR(+) HER2(-) breast cancer. First Author: Jing Du, Yale School of Medicine, New Haven, CT

Background: *ESR1* mutations (*ESR1*mut) commonly drive acquired resistance to estrogen deprivation by aromatase inhibitors, a first-line standard of care for HR(+)HER2(-) metastatic breast cancer (MBC). We previously published that approximately 63% of patients with HR(+)HER2(-) MBC at progression have a liquid biopsy (LBx) negative for *ESR1*mut. The absence of an *ESR1*mut may either accurately reflect the tumor genotype (true negative) or represent a false negative due to insufficient ctDNA shedding, with the risk of missing an actionable mutation. Among these patients, 40% exhibit a high ctDNA TF $\geq$1% (informative negative), while 60% have a low ctDNA TF $<$ 1% (indeterminate negative). This suggests that up to 38% of all patients with HR(+)HER2(-) MBC in this context could potentially benefit from reflex tissue biopsy (TBx) for *ESR1*mut in cases deemed indeterminate negative by LBx due to low ctDNA shedding. The goal of this study is to determine the rate of *ESR1*mut detection in a new TBx after an indeterminate negative result from FoundationOne Liquid CDx (F1LCDx). **Methods:** This study included a cohort of patients with BC who underwent tissue and liquid Foundation Medicine comprehensive genomic profiling (CGP) within an interval of up to 90 days during routine clinical care. Clinical data of a subset of patients with confirmed HR(+)HER2(-) MBC was obtained from the US-wide deidentified Flatiron Health-Foundation Medicine MBC clinicogenomic database (CGDB). The data originated from ~280 cancer clinics (~800 sites of care) between 01/2014-09/2024. False negative rate (FNR) and positive percent agreement (PPA) for *ESR1*mut detection were calculated with tissue CGP as reference. **Results:** A total of 522 BC patients underwent TBx and LBx. Among these, 229 (43.9%) had ctDNA TF $<$ 1%. Without accounting for TF, the overall FNR for *ESR1*mut was 6.3% and the PPA was 67.1%. In LBx with TF $\geq$1%, the FNR for *ESR1*mut was 0.9% and PPA was 96.0%. In contrast, for TF $<$ 1% samples, the FNR was 12.0% and the PPA 25.7%. 101 patients were included in the CGDB and had a confirmed HR(+)HER2(-) MBC, in which 56 (55.4%) had LBx with ctDNA TF $<$ 1%. The overall FNR for *ESR1*mut in this subset of patients was 9.5% and the PPA was 61.9%. In LBx with TF $\geq$1%, the FNR was 0% and PPA was 100%. And for TF $<$ 1%, the FNR was 15.1% and PPA 20.0%. **Conclusions:** BC patients with informative negative *ESR1*mut (defined as LBx *ESR1*mut negative with TF $\geq$1%) are unlikely to have *ESR1*mut detected on tissue CGP testing. However, patients with indeterminate negative *ESR1*mut (defined as LBx *ESR1*mut negative with TF $<$ 1%), 12-15% were found to be false negatives. This suggests that approximately 5% of all HR(+)HER2(-) MBC patients with *ESR1*mut could be missed without reflex testing with a TBx. ctDNA TF levels offer critical guidance in deciding when a reflex to tissue is warranted, ensuring accurate treatment. Thymidine kinase activity (TKa) as independent predictor of outcome in metastatic breast cancer (MBC) patients in the GEICAM/2013-02 PEARL trial. First Author: Angel Guerrero, Instituto Valenciano de Oncología (IVO). GEICAM Spanish Breast Cancer Group, Valencia, Spain

Background: TKa is a proliferation biomarker measurable in blood via the DiviTum™ TKa assay. Levels of TKa before and during treatment can provide prognostic, predictive and monitoring information in MBC. The PEARL trial (NCT02028507) was a phase III, multicenter, open-label, randomized study that compared endocrine therapy (ET) + CDK4/6 inhibitor Palbociclib (Palbo) vs. Capecitabine (Cape) in aromatase inhibitor-resistant HR+/HER2- MBC patients (pts). ET + Palbo did not improve median progression-free survival (mPFS 17.8 vs. 17.3 months (m.), p = 0.9) or overall survival (mOS 31.1 vs. 32.8 m., p = 0.5) over Cape. We explored whether TKa levels could predict better response to ET + Palbo vs Cape. **Methods:** Plasma from 555 pts (92%) was collected at baseline (BL) and on treatment (C1D15, C2D15). 1129 samples were analyzed using the DiviTum TKa assay (FDA approved/CE labelled, Biovica, Sweden). Cutoffs: 250/400 DiviTum units of Activity (DuA) for BL, 50 DuA or fold change (C1,C2/BL) $>$ 2 for on-treatment. The Kaplan-Meier method estimated median PFS and OS. Adjusted hazard ratio (HR) with 95% confidence interval (CI) were calculated using Cox proportional hazards regression model, considering relevant prognostic clinical variables. **Results:** BL TKa $\leq$ 250 DuA predicted better mPFS (11.4 vs. 4.04 m., aHR 2.1; 95% CI 1.7-2.6, p $<$ 0.0001) and mOS (38.47 vs. 17.31 m., aHR 3.2; 95% CI 2.45-4.19, p $<$ 0.0001) regardless of therapy. After starting therapy, Cape and ET + Palbo elicited distinct TKa responses due to their different mechanisms. At C1, C2, pts on Cape had higher mTKa vs ET + Palbo (448 vs. 28 DuA, p $<$ 0.0001). In the CT arm, an increase of TKa at C1 or C2 greater than 2-fold from BL predicted for better mPFS (13.04. vs. 6.34 m., aHR 0.59; 95% CI 0.43-0.81, p = 0.0013) and mOS (39.26 vs. 23.23 m., aHR 0.31; 95% CI 0.2-0.5, p $<$ 0.0001). In the ET + Palbo arm, a TKa at C1 or C2 $>$ 50 DuA predicted a shorter mPFS (3.68 v 11.27 m, aHR 2.81; 95% CI 2.08-3.8, p $<$ 0.0001) and mOS (18.73 vs. 45.11 m., aHR 3.44; 95%CI 2.34-5.06, p $<$ 0.0001). Similar results are observed regardless of BL TKa value. Exploring a BL TKa $>$ 400 DuA demonstrated a better response to Cape compared to ET+ Palbo, despite overall very poor outcomes: mPFS 4.04 m on Cape vs 2.01 on ET + Palbo, (aHR 1.72; 95% CI 1.14-2.59, p $<$ 0.0096), and showed a similar trend in mOS, 15.4 m on Cape vs 14.6m on ET+Palbo, (aHR 1.29 95% CI 0.84-1.99, p = 0.24). **Conclusions:** These data demonstrate that CT vs a CDK4/6 inhibitor influence TKa response differently, and the direction and magnitude of the TKa response can predict for benefit to a specific therapy. The original PEARL study analysis showed no outcome differences between Cape vs ET + Palbo in HR+/HER2- MBC pts, however assessment of TKa before and during therapy identified which patients had the highest probability of responding. Utilization of TKa as a predictive biomarker may allow for better personalized treatment selection. Clinical trial information: NCT02028507. Research Sponsor: None.

Prognostic role of estrogen receptor (ER) expression in breast cancer (BC) metastases and its dynamics from primary to metastatic disease: Results from a large multicentric cohort of patients with phenotypically stable ER+(≥10%)/HER2- BC. First Author: Federica Miglietta, University of Padova Oncology 2 Unit, Istituto Oncologico Veneto IRCCS, Padova, Italy, Italy

Background: ER expression is one of the main determinants of prognosis in patients (pts) with BC. Phenotypic conversion from ER+ (ER$>$=10%)/HER2- primary BC towards ER$<$10%/HER2- advanced BC has a well-known negative impact on outcome. However, in the specific context of phenotypically stable ER+/HER2- BC, the prognostic impact of ER expression in metastases or ER dynamics during disease evolution, remains largely understudied. **Methods:** We enrolled pts with advanced BC undergoing biopsy of a metastatic site. ER+ was defined as ER$>$=10%. ER expression was evaluated both as continuous and categorical variable (categories: 10-30%, 30-50%, 50-100%). Overall survival (OS) was the primary study endpoint. Cox multivariable models included covariates associated with OS in univariate analysis. **Results:** Among 1114 pts, 410 had ER+/HER2- phenotype in both primary and metastatic tumor specimens. In this subgroup, ER expression (both continuous and categoric) in metastases had significant prognostic value: for each 10% lower ER expression, the risk of death increased by 6.7% (p=0.011). Pts with ER 10-30% had significantly worse OS than those with ER 50-100% (HR 0.62, p=0.023), and numerically shorter than ER 30-50% (HR 0.51, p=0.063). The table shows the evolution of ER categories from primary BC to metastases. ER expression dynamics also had prognostic impact. Regarding continuous ER expression changes in paired primary vs. metastatic BC, each 10% ER increase corresponded to 5.9% decrease in the risk of death (p=0.008). Pts whose tumors showed an increased ER expression from 10-30% to 50-100% had the most favorable outcome overall, with better OS compared to pts with persistently low ER levels (HR 6.73, p=0.002), or to pts with decreased ER expression in metastases - particularly pts whose ER levels dropped from 50-100% to 10-30% (HR 2.89, p=014). These pts also had superior OS when compared to pts with persistently high ER levels (HR 2.08, p=0.043). The prognostic impact was preserved at the multivariate analysis (including age, grade, visceral/non-visceral disease, biopsy site). **Conclusions:** Intratumor ER expression and dynamics may in part explain the prognostic heterogeneity of pts with ER+/HER2- stable phenotype from primary to advanced BC. Pts with lower ER levels in metastases are prognostically disadvantaged. Dynamic changes in ER expression provide additional insights beyond those captured by single-point assessment. Interestingly, pts whose tumors shifted from ER 10–30% to ER 50–100% showed the most favorable prognosis, even outperforming those with consistently high ER levels. Research Sponsor: None.

SIM0270 in combination with palbociclib in patients with ER+/ HER2- advanced breast cancer: The phase Ib study. First Author: Jiong Wu, Fudan University Shanghai Cancer Center, Shanghai, China

Background: SIM0270 is a highly potent oral selective estrogen receptor degrader (SERD) which has shown ER degradation and robust antitumor activity across variety of preclinical models. Here, we present results of SIM0270 combined with palbociclib cohort(dose escalation and dose expansion) from Phase I study in patients with ER+/ HER2- advanced breast cancer (NCT05293964). **Methods:** Patients with ER+/HER2- advanced breast cancer were enrolled. The key inclusion criteria for dose escalation and dose expansion were the same as follows: ≥ 1 prior endocrine therapy (ET) with disease recurrence/ progression while being treated with adjuvant ET for ≥ 24 months and/or first line ET for ≥ 6 months in advanced setting; ≤2 prior chemotherapies in advanced setting; and prior fulvestrant was allowed. A Bayesian Optimal Interval design (BOIN) was adopted for dose escalation. The key endpoint of dose escalation was dose limiting toxicities (DLT), and the key endpoints of dose expansion included safety and tolerability, pharmacokinetics (PK) and efficacy. **Results:** As of December 26, 2024, 44 patients were enrolled including 12 from dose escalation and 32 from dose expansion, with a median follow up of 11.8 months. No DLT was reported in dose escalation. In total, 38 patients (86.4%) had visceral disease, and 8 patients (18.2%) had ESR1 mutation at baseline. 22 patients (50%) received prior endocrine therapy in the advanced setting, of which, 15 patients (34.1%) had aromatase inhibitor (AI), 12 patients (27.3%) had fulvestrant. 13 patients (29.5%) received prior chemotherapy in the advanced setting.The most common treatment emerged adverse events (TEAEs) were white blood cell count decreased (95.5%) and neutropenia (95.5%). Sinus bradycardia was reported in 77.3% (34/44) of the patients, 85.3% (29/34) were grade 1 (asymptomatic) requiring no dose modification. Grade 3/4 treatment-related AEs (TRAEs) occurred in 77.3% of the patients with most commonly reported events including neutropenia (70.5%) and white blood cell count decreased (40.9%). No fatal AEs were reported. TRAEs led to dose reduction were reported in 38.6% for palbociclib and 9.1% for SIM0270. No TRAEs led to treatment discontinuation. And 24 patients remain on study treatment. In the response evaluable patients, confirmed overall response rate (ORR) was 41.5% (17/41) and clinical benefit rate (CBR, defined as complete response, partial response or stable disease ≥ 24 weeks) was 82.5% (33/40). Median progression free survival (PFS) was not reached (NR). In patients with ESR1 mutation at baseline, ORR and CBR were 87.5% (7/8) and 100% (8/8), respectively. **Conclusions:** SIM0270 in combination with palbociclib showed acceptable safety and tolerability, promising clinical activity in patients with ER+/HER2- advanced breast cancer. Clinical trial information: NCT05293964. Research Sponsor: Simcere Zaiming Pharmaceutical Co., Ltd.

First-line (1L) ribociclib (RIB) + endocrine therapy (ET) vs combination chemotherapy (combo CT) in clinically aggressive hormone receptor (HR)+/HER2− advanced breast cancer (ABC): A subgroup analysis of patients (pts) with or without liver metastases (mets) from RIGHT Choice. First Author: Nagi S. El Saghir, American University of Beirut Medical Center, Beirut, Lebanon

Background: The phase II RIGHT Choice trial reported a statistically significant progression-free survival (PFS) benefit at the primary prespecified analysis and a 9-month (mo) benefit at the final analysis with 1L RIB + ET over combo CT in pts with clinically aggressive HR+/HER2− ABC. As liver mets in ABC indicate a worse prognosis, an analysis by liver mets status was performed (data cutoff: May 10th, 2023). **Methods:** Pre- and perimenopausal women (N = 222) with no prior systemic therapy for clinically aggressive HR+/HER2− ABC were randomized 1:1 to receive RIB + letrozole or anastrozole + goserelin or physician's choice of combo CT. Enrolled pts had ABC for which combo CT was clinically indicated by physician's judgment. **Results:** In total, 107 (RIB + ET, n = 54; combo CT, n = 53) and 115 (RIB + ET, n = 58; combo CT, n = 57) pts presented with or without liver mets, respectively. Pts with liver mets had PFS of 18.3 vs 12.7 mo and median time to treatment failure (mTTF) of 13.2 vs 8.3 mo with RIB + ET vs combo CT, respectively (Table). A clinical benefit rate (CBR) of 77.8% vs 67.9%, overall response rate (ORR) of 64.8% vs 60.4%, and median time to response (mTTR) of 6.4 vs 3.0 mo were seen in the RIB vs CT arm, respectively. Pts without liver mets had PFS of 25.2 vs 15.4 mo and mTTF of 24.0 vs 10.1 mo in the RIB vs CT arm, respectively, and similar CBR, ORR, and TTR regardless of treatment (tx). No new safety signals were observed in pts with liver mets. A numerically longer median time to deterioration (mTTD) in FACT-B total score was seen with RIB + ET vs combo CT in pts with and without liver mets. **Conclusions:** This analysis from RIGHT Choice showed similar clinically meaningful efficacy and quality-of-life benefits and no new safety signals for RIB + ET vs combo CT between pts with and without liver mets. These results support the 1L use of RIB + ET in pts with clinically aggressive HR+/HER2− ABC even in the presence of liver mets. Clinical trial information: NCT03839823. Research Sponsor: Novartis Pharmaceuticals Corporation.

Elacestrant (Ela) combinations with ribociclib (Ribo) and everolimus (Eve) in patients (pts) with ER+/HER2- locally advanced or metastatic breast cancer (mBC): Update from ELEVATE, a phase (Ph) 1b/2, open-label, umbrella study. First Author: Hope S. Rugo, University of California, San Francisco Helen Diller Family Comprehensive Cancer Center, San Francisco, CA

Background: Progression of ER+/HER2- mBC on 1L endocrine therapy (ET) + CDK4/6i is associated with several mechanisms of resistance that impact efficacy and subsequent therapy. Treatment options include endocrine monotherapy, continuing ET+CDK4/6i, or PI3K/AKT/mTOR pathway–ET combination regimens. Acquired *ESR1* mutations emerge in up to 50% of patients and continuing SOC ET is limited by resistance to ET due to these mutations. Several trials have shown improved mPFS with the addition of Eve: 3.6-6.8 mo (Cook 2021, Vasseur 2024) or switch in CDK4/6i: 5.3 mo (Kalinsky 2023). In the Ph 3 EMERALD trial, single-agent Ela significantly improved PFS vs SOC ET (*ESR1*-mut tumors HR 0.55; 95% CI 0.39-0.77; P=0.0005; all pts HR 0.70; 95% CI 0.55-0.88; P=0.0018) with manageable safety in pts with ER+/HER2- mBC who had prior ET+CDK4/6i (Bidard 2022). This analysis reports updated safety and preliminary efficacy for Ela in combination with Ribo or Eve. **Methods:** ELEVATE evaluates Ela in combination with everolimus (Eve), alpelisib (Alp), capivasertib (Capi), ribociclib (Ribo), palbociclib (Palbo), or abemaciclib (Abema) to address different resistance mechanisms. Pts with ER+/HER2- mBC and 1-2L of prior ET are eligible regardless of *ESR1*-mut status. Objectives are to identify the RP2D (Ph 1b) and evaluate PFS (Ph 2) with each combination. **Results:** Elacestrant combinations with Ribo or Eve showed safety consistent with the known profiles of each drug + SOC ET. The most common AEs (≥30%) with Ela + Ribo (n=32) from Ph 1b were neutropenia (38%; 25% ≥Gr3) and nausea (31%; 0 ≥Gr3). The most common AEs for Ela + Eve (n=72) from Ph 1b + Ph 2 were nausea (54%; 6% ≥Gr3), diarrhea (43%; 7% ≥Gr3), stomatitis (38%; 3% ≥Gr3), and fatigue (32%; 6% ≥Gr3). Median PFS for Ela + Ribo was 7.2 months, while for Ela + Eve was 8.5 months. Table 1 summarizes mPFS from Ph 1b in efficacy-evaluable pts who received prior ET+CDK4/6i, as of Dec 2024. Updated data will be presented. **Conclusions:** Elacestrant plus Ribo or Eve demonstrates promising Ph 1b efficacy in pts with ER+/HER2- mBC with progressive disease after ET+CDK4/6i in all patients. Ela 345 mg + Ribo 400 mg QD was determined as the RP2D. Previously, Ela 345 mg + Eve 7.5 mg was identified as the RP2D. Elacestrant has the potential to become an ET backbone for various targeted agents, offering an all-oral treatment regimen in pts with ER+/HER2- mBC, delaying chemo or ADC-based regimens. Clinical trial information: NCT05563220. Research Sponsor: None.

Differential genomic landscape of estrogen receptor (ER)-low versus ER-positive (ER+) and ER-negative (ER-) metastatic breast cancer (MBC). First Author: Chiara Corti, Dana-Farber Cancer Institute, Boston, MA

Background: Guidelines define ER+ breast cancer (BC) as ≥1% tumor nuclei staining positive by IHC. Data on managing ER-low tumors (1–10% ER staining) is limited, with mixed evidence suggesting outcomes similar to ER- but a higher risk of death with adjuvant endocrine therapy (ET) omission. We aimed to examine the genomic landscape of ER-low MBC compared to ER+ and ER-. **Methods:** This retrospective study included consecutive patients (pts) with MBC who consented to clinicopathologic data collection and genomic profiling (OncoPanel) on tumor samples with matched ER IHC through the EMBRACE (Ending Metastatic Breast Cancer for Everyone) program. For multiple sequencing timepoints, the first was analyzed. SNVs, CNVs and TMB were compared among ER groups. Genes altered in > 3% of pts were analyzed for ER status association, with Benjamini-Hochberg adjusted p < 0.2 subjected to Holm-corrected pairwise testing. **Results:** Between 10/2000-12/2020, 1199 pts were identified:48 ER-low, 797 ER+, and 354 ER-. Median age at diagnosis was 63.8 (34.8-86.8), 64.4 (30.8-96.3), and 62.6 (30.3-92.7) years for ER-low, ER+, and ER- groups, respectively. De novo stage IV disease was observed in 8.3% (4/48) of ER-low, 27.0% (215/797) of ER+, and 17.2% (61/354) of ER- cases. Overall, 801/1199 (66.8%) had metastatic and 398/1199 (33.2%) had primary samples sequenced. 27/48 ER-low (56.3%), 451/797 ER+ (56.6%), and 73/354 ER- (20.6%) pts received ET before sequencing. CDK4/6i were administered in 8/48 ER-low (16.7%), 107/797 ER+ (13.4%), and 5/354 ER- (1.4%) pts prior to sequencing. The most clinically relevant genomic alterations are shown in the Table. *TP53* mutations (mts) were more frequent in ER-low vs ER+ BC, and not significantly different between ER-low and ER- tumors. *PIK3CA* and *CDH1* alterations were more frequent in ER-low than ER- BC, with no significant difference compared to ER+. *AKT1* and *RB1* alterations were significantly higher in ER-low vs ER+ BC. *ESR1* mts were not significantly different between ER+ and ER-low BC. Median TMB was higher in ER-low vs ER+ cases, without significant differences between ER-low and ER- cases. **Conclusions:** ER-low BC has a distinct genomic profile, with high *TP53* mts (similar to ER-) and frequent PI3K pathway alterations (typical of ER+). Ongoing analyses of clinicopathologic features and survival across ER-low, ER+, and ER- cohorts will be presented. Research Sponsor: Terri Brodeur Breast Cancer Foundation; The Benderson Family Fund; NIH/NCI grant; 1P50CA168504.

Molecular and prognostic convergence of HR+/HER2− metastatic breast cancer (MBC) to a TNBC-like profile: Insights from circulating tumor DNA (ctDNA)-based genomic analysis across treatment lines. First Author: Lorenzo Foffano, Universita degli Studi di Udine, Udine, Italy

Background: While the transition to a triple negative (TNBC)-like profile represents a recognized mechanism of treatment resistance for hormone receptor-positive, HER2-negative (HR+/HER2-) MBC, the molecular mechanisms of this phenomenon remain largely unknown. This analysis investigated the genomic and prognostic differences between HR+/HER2− and TNBC across treatment lines through ctDNA profiling analysis **Methods:** This retrospective study analyzed a multi-institutional cohort of 1071 patients (pts) with HER2 negative MBC and ctDNA testing with the Guardant360 NGS panel within a large academic consortium (PMAC). HR and HER2 status were defined based on the most recent biopsy, pts with ER-low profile (ER $<$ 10% regardless of PR status) were excluded. Associations across single nucleotide and copy number variations (SNVs and CNVs), HR+/HER2− and TNBC subtypes across treatment lines were tested by multinomial logistic regression (MLR) in terms of Relative Risk Ratio (RRR). The impact of prognosis was evaluated through Cox regression for overall survival (OS), defined from time of baseline ctDNA collection. **Results:** There were 827 pts with HR+/HER2- MBC (77.2%) and 244 pts with TNBC (22.8%). Multivariable MLR, designed with first line HR+/HER2- as the reference, investigated genomic alterations across treatment lines. In second line, *ESR1* SNVs (RRR 7.34, p $<$ 0.001) and *EGFR* CNVs (RRR 0.15, p = 0.01) were significantly associated with HR+/HER2-, while *TP53* SNVs had a higher prevalence in TNBC (RRR 2.71, p = 0.009). In third line, *ESR1* SNVs were significantly enriched in HR+/HER2- (RRR 5.44, p $<$ 0.001), while *TP53* SNVs emerged for TNBC (RRR 5.26, p $<$ 0.001). From fourth line onward ($\geq$ 4L), *ESR1* SNVs (RRR 8.09, p $<$ 0.001), *TP53* SNVs (RRR 1.81, p = 0.022) and *PIK3CA* CNVs (RRR 5.93, p = 0.003) showed higher prevalence in HR+/HER2- relative to first line HR+/HER2-, while *TP53* SNVs were also associated with TNBC (RRR 10.43, p $<$ 0.001). Compared to TNBC, HR+/HER2− had a favorable prognostic impact in terms of OS in first (HR 0.32, p $<$ 0.001), second (HR 0.35, p $<$ 0.001) and third line (HR 0.37, p $<$ 0.001). However, in $\geq$ 4L, no significant differences emerged (HR 0.79, p = 0.282), with similar results observed with respect to TNBC across all lines (HR 1.01, p = 0.929). *MYC* CNVs had an unfavorable prognostic role for both HR+/HER2− $\geq$4L (HR 2.41, p = 0.004) and TNBC in all lines (HR 2.14, p = 0.014). **Conclusions:** Our study suggests a dynamic molecular evolution of HR+/HER2− MBC, with a progressive acquisition of molecular and prognostic features compatible with a TNBC-like profile and loss of endocrine sensitivity. These findings highlight the need for comprehensive biological characterization of this subtype across treatment lines to better understand its evolution under therapeutic pressure and consequently adapt treatments. Ultrasensitive ctDNA monitoring during CDK4/6 inhibitor therapy for metastatic breast cancer. First Author: Julia Ah-Reum An, Memorial Sloan Kettering Cancer Center, New York, NY

Background: The combination of CDK4/6 inhibitor (CDK4/6i) and endocrine therapy (ET) is the standard first-line treatment for patients with hormone receptor-positive/HER2-negative (HR+/HER2-) metastatic breast cancer (MBC). However, it exhibits highly variable efficacy, with some cancers progressing within 3–6 months while many others achieve durable and potentially indefinite complete responses (CRs). While pharmacologic strategies to escalate or deescalate this therapy exist, diagnostic tools to identify the patients who would benefit from each approach are needed. Ultrasenstive ctDNA offers the potential to assess disease burden dynamically and with more precision. In this study, we evaluate the validity of an ultrasensitive assay capable of detecting ctDNA levels in the parts per million range for monitoring patients with HR+/HER2- MBC. **Methods:** Patients from the MSK-LINC prospective ctDNA monitoring study, who received CDK4/6i+ET for HR+/HER2- MBC were included in the study. MRD monitoring was performed using personalized tumor-informed panels designed from whole genome sequencing (WGS) of matched tumor and normal specimens to identify up to 2,000 somatic alterations for each patient using the Precise MRD assay (Myriad Genetics). Results were reported as an overall ctDNA detection status and a quantitative tumor fraction. **Results:** 29 patients with HR+/HER2- MBC (8 *de novo*, 21 recurrent) were included in this ongoing study. The median progression-free survival (PFS) was 48.8 months (range 2.6 – 78.5) with 17/29 of patients experiencing disease progression. ctDNA panels were successfully designed for all cases, and 140/146 (95.9%) plasma samples passed QC. All pre-treatment samples had detectable ctDNA with a median tumor fraction of 1.4% (range 0.00093%, 14.0%). An early decrease in ctDNA levels, $>$ 50% reduction from baseline or levels $<$ 0.01% in the second sample collected within 3 months, was significantly associated with longer PFS (p $<$ 0.001). We focused on 7 patients who achieved radiographic CR all with PFS $>$ 3y. Notably, 3 patients had continued to have ultra low levels of ctDNA (median: 0.0086%, range 0.00032%, 0.11%), indicating stable viable micrometastatic disease below the threshold of imaging, effectively controlled by treatment. In contrast, 4 patients also achieved molecular CR (mCR) defined as sustained undetectable ctDNA suggesting that metastatic disease was either eradicated or rendered dormant without significant cell turnover. **Conclusions:** Ultrasensitive ctDNA monitoring is a promising tool for monitoring disease burden and treatment response. Our results highlight the ability of ctDNA to distinguish between stable molecular disease vs. mCR, highlighting the potential of ctDNA as a biomarker for tailoring treatment strategies in patients who achieve outstanding clinical responses. Effectiveness comparison of palbociclib, ribociclib and abemaciclib in patients with HR+/HER2- aBC: Updated results from the real-world, Italian study PALMARES-2. First Author: Claudio Vernieri, Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy

Background: The Cyclin Dependent Kinase 4/6 inhibitors (CDK4/6i) Palbociclib (P), Ribociclib (R) and Abemaciclib (A) combined with Endocrine Therapy (ET) are the standard 1st line therapy for patients (pts) with Hormone Receptor positive, Human Epidermal growth factor Receptor 2-negative, advanced Breast Cancer (HR+/HER2- aBC). However, based on conflicting results of large real-world (RW) studies (Vernieri C et al. Abstr 1014, ASCO 2024; Rugo H et al. PS2-03, SABCS 2024), it remains unclear whether P, R and A are similarly effective. **Methods:** PALMARES-2 is a multicenter, observational Italian RW study comparing the effectiveness of 1st line P, R or A in female pts with HR+/HER2- aBC. The primary endpoint is overall survival (OS); RW progression-free survival (rwPFS) and time to chemotherapy (TTC) are secondary endpoints. rwPFS, TTC and OS were defined as the time between 1st line ET+CDK4/6i initiation and disease progression/death, initiation of 1st chemotherapy line/death, or patient death, respectively. We used Inverse Probability of Treatment Weighting (IPTW) to balance 14 prognostic covariates related to patients (age, ECOG PS, menopausal status), tumor biology (ER, PgR, HER2, Ki67, grading, histology, endocrine sensitivity/resistance/*de novo* metastatic) and metastatic sites (liver, bone, lung, serosal) in P, R and A cohorts. Effectiveness comparisons were reported as adjusted Hazard Ratio (aHR) and 95% confidence interval (CI). **Results:** With a cutoff date of Jan 10th, 2025, we enrolled 3598 pts, of whom 1392 (38.7%), 1408 (39.1%) or 798 (22.2%) received P, R or A, respectively. Pts receiving A were more likely to have endocrine-resistant disease, liver metastases and lower PgR expression, and less likely to have *de novo* metastatic disease (p $<$ 0.001). Median follow-up was shorter in R/A cohorts (31.8/29.6 months) than in the P cohort (52.4 months). Median rwPFS, TTC and OS in the whole population were 26.1, 39.4 and 67.1 months, respectively. After IPTW adjustment, R and A were associated with better rwPFS and TTC when compared to P, while only R was associated with better OS (Table). R and A did not show significant rwPTS, TTC or OS differences (Table). **Conclusions:** The three CDK4/6i have different effectiveness in HR+/HER2- aBC pts. Longer follow-up of PALMARES-2 study and more pts/events in the A cohort are needed to perform definitive OS comparisons between P, R and A. Research Sponsor: None.

1075 Poster Session

Use of baseline plasma circulating tumor DNA (ctDNA) to predict duration of endocrine therapy (ET) and CDK4/6 inhibitor (CDK4/6i) therapy (tx) and to analyze intrinsic vs acquired endocrine resistance. First Author: Pietro De Placido, Dana-Farber Cancer Institute, Boston, MA

Background: ET + CDK4/6i is standard-of-care for patients (pts) with hormone receptor-positive/HER2-negative (HR+/HER2-) metastatic breast cancer (MBC). We aimed to identify predictors ET + CDK4/6i tx duration and to compare genomic profiles in pts with intrinsic vs acquired resistance. **Methods:** Plasma samples were collected from pts with HR+/HER2- MBC enrolled in the EMBRACE cohort study who had plasma collection within 3 months (mo) prior to CDK4/6i initiation to 14 days after initiation. The primary outcome was duration of ET+CDK4/6i tx, defined as time from tx initiation to end of tx. Intrinsic resistance was defined as pts with tx duration $<$ 180 days. Plasma samples were analyzed using the Guardant360 assay, which includes genotyping of $>$ 700 genes and tumor fraction (TF) score. TF was estimated by normalizing cancer-specific differentially methylated regions with matched control regions in each sample. The predictive value of baseline TF (0 vs $>$ 0) was tested using a Cox regression model including age, line of tx, and liver metastases. For comparison of pts with intrinsic vs acquired resistance, analysis was limited to samples with TF $>$1% to minimize the impact of variation in tumor shed. Gene frequency between intrinsic and acquired resistance samples were compared using q-tests(q $<$ 0.25). **Results:** A total of 188 pts were included. Median age at MBC diagnosis was 57.5 yrs. ET+CDK4/6i was given in the first-line (1L) in 115 pts, second-line (2L) in 37 pts, and $>$ 2L in 36 pts. Of 167 pts, TF was undetectable (TF = 0) in 19 (11%) and detectable (TF $>$ 0) in 148 (89%). In Cox regression, baseline TF (p = 0.001), line of tx (n = 0.002), and presence of liver metastasis (p = 0.014), but not age, were predictors of duration of tx. Median duration of tx was 44.6 mo in pts with baseline TF = 0 vs. 5.8 mo in pts with baseline TF $>$ 0 (HR 0.28, 95% CI 0.14-0.56). Similar results were found when restricting the analysis to those receiving tx in the 1L or 2L. There were notable differences in the frequency of ESR1 (63% vs 48%), CDH1 (38% vs 18%), PTEN (21% vs 9%), RB1 (32% vs 20%), and CDKN2A (20% vs 5%) alterations in pts with intrinsic vs acquired resistance, though these did not reach statistical significance in the setting of small sample size. ESR1 fusions were seen in 14% (8/56) pts with intrinsic resistance vs 7% (3/44) pts with acquired resistance. Among pts with intrinsic resistance, ERBB2 copy number loss was present in 7(13%) (6 het loss, 1 homozygous deletion), RB1 copy number loss in 10 (18%) (all het loss), and CDKN2A copy number loss in 9(16%) (7 het loss, 2 homozygous deletions). **Conclusions:** Baseline TF in ctDNA is highly predictive of time on ET+CDK4/6i tx in pts with HR+/HER2- MBC. Baseline genomic profiles differ qualitatively between pts with intrinsic vs acquired resistance. If validated, baseline plasma may provide a valuable tool in tx selection. 1076 Poster Session

Comparing clinical benefit of trastuzumab deruxtecan (T-DXd) and sacituzumab govitecan (SG) in a large cohort of HER2-negative metastatic breast cancer (MBC). First Author: George W. Sledge Jr., Caris Life Sciences, Phoenix, AZ

Background: T-DXd and SG are antibody-drug conjugates (ADCs) increasingly used in HER2-negative BC, however, there are insufficient data to guide ADC sequencing and use in tumors of various HER2 expression levels. **Methods:** A total of 4033 HER2 negative MBC treated with SG or T-DXd that underwent tumor profiling at Caris Life Sciences (Phoenix, AZ) were studied. HER2 low (Her2-L), ultra low (Her2-UL) and null (Her2-N) were tested by IHC and CISH. Hormone receptor status (HR+/-) was tested by ER and PR IHC. Real-world clinical data were obtained from insurance claims. Time on treatment (TOT) was determined as the interval from start to end of the ADCs. Cox proportional hazards model was used for hazard ratio (HR) and log-rank for p values. **Results:** Overall, 1444 (36%) were treated with T-DXd but not SG (T-only) while 1808 (45%) with SG but not T-DXd (S-only). HR+ cases comprise 64% of T-only and 24% of S-only cohorts; 75% and 68% of T-only and S-only tumors were taken from metastatic sites. As expected, HER2-L, HER2-UL and HER2-N cohorts treated with T-DXd had decreased TOT (4.8 months (m), 4.1m and 3.5m, p< .001) while HER2 status had no impact on SG TOT (3.0m, 2.8m and 3.4m). Interestingly, even in HER2-N group, T-only showed a borderline better TOT than S-only (Table, p=.053); this effect was significant in HR+ HER2-N subset but not significant in HR- HER2-N. Similarly, in HER2-UL and L, T-DXd TOT was significantly longer than SG TOT; when further stratified by HR status, the effect was highly significant in HR+ and not seen in HR- cohorts. In cohorts crossed over from one ADC to another, patients treated with T-DXd first (N=420) or SG first (N=361) showed no TOT difference (10.4m vs. 10.8m, p= .4); although the HER2-N subset had moderate preference of SG first (11.5m vs. 8.5m, HR=0.66 [0.52-0.84], p< .001, while TOT were similar in HER2-UL (HR=0.93, p=.7) and HER2-L (HR=1.04, p=.7) groups. **Conclusions:** We report outcome from a large real world dataset and demonstrate that T-DXd shows statically significant improved outcome in HR+ tumors across HER2 subgroups while in TNBC, both agents exhibit comparable benefit. In patients treated with both ADC's, SG first showed preferred outcome in HER2-N group but not in HER2-UL or L. We provide important insight on clinical benefit of the two widely used ADCs in breast cancer and warrants further validation in independent cohorts. Research Sponsor: None.

Steroid receptor expression and overall survival in breast cancer patients with ER+ bone metastasis: A retrospective review. First Author: Anthony Michael Rossi, University of Arizona College of Medicine, Tucson, AZ

Background: Endocrine therapy (ET) resistance is common in estrogen receptor-positive (ER+) metastatic breast cancer (BC), where bone metastases (BMET) are usually the first sign of spread. ER signaling and ET effects can depend on other steroid hormones receptors (SHRs), such as progesterone receptors (PR) and androgen receptors (AR). However, the roles of these receptors in ER+ BC BMET are underexplored. To address this gap, PR and AR protein expression in HER2-/ER+ BMET and associations with overall survival (OS) were examined. **Methods:** In a retrospective analysis on BC BMET samples analyzed at Caris Life Sciences, n = 2038 HER2- BMETS were identified by immunohistochemistry (IHC) (≤1+intensity or ≤10% staining, or 2+ & > 10% with CISH-null reflex test). HER2- ER+ (by IHC, ≥1+ & ≥1%) BMETs ("ER+ BMET" n = 1700; 84.5% of total) were then examined for prevalence of IHC+ SHR expression (PR: ≥1+ & ≥1%; AR: ≥1+ & ≥10%) and associated pathogenic/likely pathogenic *ESR1* or *PIK3CA*gene mutations (mut). Associations of SHR status with clinical outcomes were tested by inferring OS from biopsy collection or start of therapy to last contact. **Results:** Most ER+ BMET expressed PR (59.3%) or AR (87.1%). Only 9.4% of PR+/ER+ BMET were AR-null, while 38.2% of AR+/ER+ BMET were PR-null. Overall, "triple positive" (AR+/PR+/ER+) BMET comprised the largest group (53.7%), followed by PR-null AR+/ER+ BMET (33.2%). AR-null ER+ BMET with (5.6%) or without PR (7.3%) were less common. AR+ status was associated with better outcomes for ER+ BMET patients (pts) with longest OS for "triple positive", while "loss" of PR was associated with shorter OS (Cox proportional hazards ratio (HR) = 1.37, p < 0.0001). AR-null status was associated with worse OS compared to "triple positive" regardless of PR status (AR-/PR- HR = 1.66, p < 0.001; AR-/PR+ HR = 1.85, p < 0.0001). In ER+ BMET with *ESR1mut* (16.3%), OS for triple positive tumors, which were more prevalent (74.0%) due to increased PR expression, was reduced (HR = 1.92, p < 0.0001 vs *ESR1wt*). For *PIK3CA*, "loss" of PR abrogates benefits associated with AR+ status only in *PIK3CAmut* pts (48.7%) with patterns between SHR groups otherwise maintained. Among ER+ BMET pts who received aromatase inhibitors or fulvestrant, AR+ status was associated with the best OS, regardless of PR status, where treatment was associated with significantly longer OS (vs no treatment) across SHR groups, except in PR+/AR-null. For ER+ BMET pts treated with CDK4/6 inhibitors, OS was highest in the "triple positive" cohort, with onlyAR+ SHR groups demonstrating improved OS with treatment. **Conclusions:** Based on this analysis, AR expression is more prognostic of OS than PR, regardless of treatment, in pts with ER+ BC BMETs, with "triple positive" BMETs generally associated with the best OS. Research on SHRs as mediators vs biomarkers of risk in ER+ BC BMETs is needed to provide direction for possible therapeutic targeting. Research Sponsor: None.

Evaluating accuracy and concordance of pathologists and the utility of AI assistance software for digital HER2 IHC assessment in breast cancer including HER2-ultralow scoring: An international multicenter observational study. First Author: Gabriela Acosta Haab, Pathology Department, Maria Curie Hospital, Buenos Aires, Argentina

Background: The emergence of novel therapeutic agents demonstrating improved progression-free survival (PFS) and overall survival (OS) in breast cancer patients with low HER2 expression underscores the need for accurate and reproducible HER2 status assessment. However, challenges such as subjective interpretation of immunohistochemistry (IHC) staining and variability in assay quality hinder diagnostic consistency. AI-based decision support software could enhance diagnostic accuracy and reproducibility. To date, systematic evaluation of pathologist performance in scoring low HER2 expression, as well as the role of AI assistance, remains limited in real-world, multicenter settings. **Methods:** Six academic centers from different countries provided digital HER2 IHC-stained breast cancer images (n = 728) generated with five whole-slide scanner models and one microscope camera. In a two-arm observational study, consensus ground truth (GT) scores were established by two expert pathologists per center without AI assistance. Subsequently, two additional pathologists (scorers) evaluated each case both without and with AI support. Scoring followed ASCO/CAP 2023 HER2 interpretation guidelines, with an additional subclassification of IHC 0 cases into "null" (IHC 0 with no staining) and "ultralow" (IHC 0 with membrane staining). **Results:** For the HER2-low decision range, AI software alone achieved 91.0% accuracy in distinguishing HER2 0 from 1+/2+/3+ scores against GT. Across the four categories, AI achieved 80.3% accuracy compared to 77.6% for scorers alone and 81.4% with AI assistance. AI support improved inter-reader agreement from 73.5% to 86.4%. When the HER2 ultralow category was included, AI assistance increased scorers' average accuracy across all classes from 70.4% to 74.7% and boosted inter-reader agreement from 65.6% to 80.6%. For differentiating HER2 null from HER2 ultralow, AI improved scorers' accuracy from 68.6% to 77.9%, resulting in 40% more cases being classified as HER2 ultralow and 65% reduction in the number of incorrectly scored HER2 null cases. **Conclusions:** This first international multicenter study on HER2 IHC diagnosis, including HER2 ultralow scoring highlights the challenges faced by pathologists and the significant benefits of AI decision-support systems in real-world settings. AI assistance improved pathologist concordance and accuracy, particularly at the HER2 null vs. ultralow boundary, reducing diagnostic errors. Incorporating AI into routine clinical diagnostics has the potential to optimize treatment selection for breast cancer patients. Research Sponsor: AstraZeneca.

Elacestrant combinations in patients (pts) with ER+/HER2- locally advanced or metastatic breast cancer (mBC): Safety update from ELEVATE, a phase (Ph) 1b/2, open-label, umbrella study. First Author: Nancy Chan, NYU Langone Health, New York, NY

Background: Tumors develop resistance following 1L endocrine therapy (ET) + CDK4/6i in ER+/HER2- mBC. Elacestrant (Ela) significantly improved PFS vs standard-of-care (SOC) ET (*ESR1*-mut tumors HR 0.55; 95% CI 0.39-0.77; P=0.0005; all pts HR 0.70; 95% CI 0.55-0.88; P=0.0018) with a manageable safety profile for pts with ER+/HER2- mBC and prior ET+CDK4/6i (Bidard 2022). ELEVATE (NCT05563220) evaluates Ela in combination with everolimus (Eve), alpelisib (Alp), capivasertib (Capi), ribociclib (Ribo), palbociclib (Palbo), or abemaciclib (Abema) to address different resistance mechanisms. Prior analyses have demonstrated safety consistent with the known profiles of each agent in combination with SOC ET. Ph 1b safety and efficacy evaluations reported the RP2D and antitumor activity with the following combinations: Ela + Eve (RP2D: Ela 345 mg QD + Eve 7.5 mg QD) and Ela + Abema (RP2D: Ela 345 mg QD + Abema 150 mg BID)(Ciruelos ESMO 2024, Rugo ESMO 2024). Ela 345 mg + Palbo 125 mg was determined as the RP2D (Rugo SABCS 2024). Herein, we report updated safety that includes additional pts/dose levels, and longer observation time for Ela in different combinations. **Methods:** Eligible pts have ER+/HER2- mBC and 1-2L of prior ET regardless of *ESR1*-mut status. Objectives are to determine the RP2D (Ph 1b) and evaluate PFS (Ph 2) with each combination. **Results:** Table 1 reports the most common all-grade AEs from Ph 1b (Ribo, Alp, Capi combinations) and Ph 1b + Ph 2 (Eve combination) as of Dec 2024. Ela 345 mg + Ribo 400 mg QD was identified as the RP2D. Updated data will be presented. **Conclusions:** Elacestrant combinations continue to demonstrate safety consistent with the known profiles of each drug + SOC ET without increased risk of associated AEs. Elacestrant has the potential to become an ET backbone for multiple targeted agents, providing an all-oral treatment option in pts with ER+/HER2- mBC, delaying chemo or ADC-based regimens. Clinical trial information: NCT05563220. Research Sponsor: None.

Enhancing precision oncology for Haitian breast cancer patients through deep learning-enabled computational pathology tools. First Author: Rebecca Henderson, University of Alabama at Birmingham, Birmingham, FL

Background: While early-stage breast cancer is often curable in high-resource settings, mortality-to-incidence ratios remain unacceptably high for women in lower- and middle-income countries (LMIC). This disparity is due to an inability within LMICs for patients to access basic cancer diagnostics (e.g., IHC). Consequently, there is a major need to develop innovative approaches for the cancer diagnostic-therapeutic pipeline to deliver high-quality care for LMIC patients. To this end, deep learning (DL) has shown considerable promise in identifying clinically relevant biology within histopathology (H&E). Therefore, we have curated an unprecedented dataset of H&E whole slide images (WSIs) and tissue-matched estrogen receptor (ER) status for 5500 breast cancer slides from Zanmi Lasante (Haiti). **Methods:** Using The Cancer Genome Atlas (TCGA) breast cancer and Haitian datasets, we trained a DL-enabled tool, using H&E WSIs, to predict ER status for each patient. As the TCGA dataset predominantly comprises patients of European ancestry, we assessed whether a TCGA-trained model would generalize to Haitian patients. After WSI processing and feature extraction, attention-based weakly supervised multiple instance learning was used to train a classification model. To assess performance, both the TCGA and Zanmi Lasante datasets were split into training (70%), validation (15%), and testing (15%) sets, and the results were compared across both patient populations. **Results:** Using the TCGA dataset (2100 H&E WSIs), we trained an ER classification model. This model demonstrated a performance of an area under receiver operating characteristic (AUROC) of 0.92 on the "held-out" TCGA test set, but only an AUROC of 0.71 on the Haitian "held-out" test set for ER status prediction. This drop in model performance, or domain shift, is consistent with known biological differences between breast cancers enriched in Black women compared to those in Caucasian women. Notably, pre-training our model on the TCGA dataset and then fine-tuning on a portion of the Haitian training set (2800 WSIs) substantially improved predictive performance to an AUROC of 0.85 on the Haiti test set. **Conclusions:** This study illustrates the potential of DL to advance precision oncology in low-resource settings and highlights the need for adequate training data from LMIC patients. We anticipate tools from this work will be deployed for use in Haitian breast cancer patients to inform precision-based use of endocrine therapies. Research Sponsor: None.

Cell-free circulating chromatin profiling for epigenomic characterization of mechanisms of response and resistance to sacituzumab govitecan in breast cancer. First Author: Ana Christina Garrido-Castro, Dana-Farber Cancer Institute, Boston, MA

Background: The efficacy of sacituzumab govitecan (SG), a TROP2-directed antibody-drug conjugate (ADC), in hormone receptor-positive/HER2-negative (HR+/HER2-) metastatic breast cancer (mBC) has been demonstrated, yet biomarkers predicting response and resistance remain an unmet clinical need. We applied a novel multimodal epigenomic liquid biopsy assay to characterize tumor-specific transcriptional activation of relevant genes of interest and resistance mechanisms in the phase 2 SACI-IO HR+ trial (NCT04448886). **Methods:** Baseline plasma samples were collected from patients (pts) with HR+/HER2- mBC enrolled in SACI-IO HR+, which compared SG alone to SG combined with pembrolizumab (SG-pembro). Genome-wide signals from promoters, enhancers and DNA methylation were profiled from 1 mL of plasma from 95 pts, of which 80 met the assay quality control thresholds and ctDNA metrics required for downstream analysis (ctDNA $\geq$ 0.5%, N_{SG}= 42, $N_{SG\text{-}pembro}$= 38). We used epigenomic and RNA-seq datasets from 23 breast cancer cell lines to train a model to predict *TROP2* expression ($r = 0.66$, $P < 0.01$) and tested for association with progression free survival (PFS). We used Gene Set Variation Analysis to score samples for HALLMARK gene set activities using gene-proximal epigenomic signals and tested for independent association of those activities with PFS via CoxPH models, with baseline ctDNA fraction included as a known prognostic covariate. Statistical significance was determined based on improved model fit compared to ctDNA alone. **Results:** Compared to healthy donors, plasma from trial pts was enriched for breast cancer specific signatures such as estrogen response and hedgehog signaling (FDR $<$ 0.05), highlighting the ability of the liquid biopsy platform to extract tumor specific signal. Baseline ctDNA fraction was prognostic in both treatment arms (Hazard Ratio $[HR]_{SG}$= 0.38, $P < 0.01$; $HR_{SG\text{-}pembro}$= 0.28, $P < 0.01$). Conversely, predicted *TROP2* expression was not associated with PFS in either treatment arm. In the SG arm, higher activity of pathways such as epithelial to mesenchymal transition and Wnt signaling were associated with shorter PFS (FDR $<$ 0.1), highlighting potential mechanisms of resistance. Gene signatures related to cell cycle such as mitotic spindle and E2F targets were associated with longer PFS (FDR $<$ 0.1). The above pathway associations with PFS were not statistically significant in the SG-pembro arm. **Conclusions:** This study demonstrates the feasibility of a multimodal epigenomic liquid biopsy platform for non-invasive characterization of therapeutic response and resistance to SG with or without pembrolizumab in HR+/HER2- mBC. By providing real-time insight into transcriptional regulation, this approach may improve patient stratification and guide ADC treatment strategies. Clinical trial information: NCT04448886. Treatment patterns in HR+/HER2- metastatic breast cancer (MBC) with co-occurring *PIK3CA* and *ESR1* mutations. First Author: Jimmitti Teysir, Memorial Sloan Kettering Cancer Center, New York, NY

Background: *PIK3CA* and *ESR1* mutations co-occur in 12-15% of patients with HR+/HER2- MBC. While FDA-approved PI3K inhibitors (PI3Ki) and selective estrogen receptor degraders (SERDs) have advanced care for patients with biomarkers, treatment outcomes and optimal sequencing in those with co-occurring mutations remain unclear. **Methods:** We conducted a retrospective analysis of patients with HR+/HER2- MBC and co-occurring *PIK3CA* and *ESR1* mutations treated at Memorial Sloan Kettering (MSK) between 2010 and 2024. Mutations were identified via MSK-IMPACT (tumor tissue) and MSK-ACCESS (ctDNA), with additional genomic data integrated from Guardant and Foundation One. Clinical and treatment data, including PI3Ki (alpelisib, inavolisib or investigational agents) and/or SERDs (fulvestrant or oral agents) were abstracted. Median progression-free survival (mPFS) was assessed in patients with mutations identified prior to therapy initiation. **Results:** 3,166 patients with HR+/HER2- MBC were identified, including 1,444 (46%) with *PIK3CA* mutations, 664 (21%) with *ESR1* mutations and 243 (8%) with co-occurring mutations. After excluding 26 patients with incomplete records or concurrent malignancies, the final cohort included 217 patients (7%), with 206 having MSK-IMPACT, 58 MSK-ACCESS, 49 Guardant, and 3 FoundationOne data. Of 217 patients, 77 (36%) received a PI3Ki after a median of 4 prior lines (range: 1–16), with 68 (88%) having prior CDK 4/6i. Single-agent SERD was administered to 46 patients (21%) after a median of 3 prior lines (range: 2–18), including 34 (74%) with prior CDK 4/6i. 8 patients received PI3Ki followed by SERD, and 7 received SERD followed by PI3Ki, either consecutively or with intervening treatments. The mPFS was 7.1 m with PI3Ki (95% CI: 4.6–9.3) and 4.0 m with single-agent SERD (95% CI: 3.4–9.8). In the SERD cohort, earlier line of treatment (1–2 vs. 3+; HR 0.29, 95% CI 0.09–0.90) and liver metastasis (HR 3.42, 95% CI 1.10–10.6) were independently associated with PFS. CDK 4/6i duration $\geq$12 m in the SERD cohort was associated with improved mPFS in stratified analysis (9.8 vs. 2.7 m; log-rank p = 0.002). For patients treated with PI3Ki followed by SERD (n = 8), mPFS1 was 8.9 m (95% CI: 5.6, NE) and mPFS2 was 6.0 m (95% CI: 2.3, NE). SERD to PI3Ki (n = 7) yielded a mPFS1 of 3.4 m (95% CI: 1.8, NE) and mPFS2 of 10.0 m (95% CI: 1.6, NE). **Conclusions:** Prior CDK4/6i $\geq$ 12 m in patients with co-occurring mutations treated with a SERD was associated with significantly improved PFS, potentially reflecting a conditioning effect of prior therapy. The total PFS (PFS1 + PFS2) in patients treated with sequential targeted therapies was similar; however, small sample sizes and potential confounders in this retrospective cohort limit definitive interpretations. Larger prospective studies are needed to determine optimal sequencing strategies. Research Sponsor: None.

Targeting PARP-1 in ER-positive endocrine-resistant breast cancer. First Author: Azzurra Zicarelli, University of Chicago, Chicago, IL

Background: Resistance to endocrine therapy (ET) in breast cancer (BC) patients is frequently associated with acquired ESR1 gene mutations like the Y537S, which triggers a constitutive estrogen receptor (ERα) activation. Therefore, the identification of novel therapeutic strategies is crucial for the management of ER-positive, ET-resistant BC. In this context, PARP1 poly(ADP-ribose) polymerase 1 (PARP-1) has emerged as a promising therapeutic target, based on its involvement in the regulation of oxidative DNA damage in BC cells. **Methods:** Data from the METABRIC dataset were used to assess the clinical relevance of PARP-1 in ER-positive BC patients. As experimental models, MCF7 and T47D BC cell lines expressing ERα wild type (wt) or Y537S mutation were used. PARP-1 regulation was investigated by western blotting, immunofluorescence, and chromatin immunoprecipitation (ChIP) assays. Gene expression, promoter assays, and chromatin immunoprecipitation sequencing (ChIP-seq) studies allowed us to analyze the transcriptional activity mediated by ERα. Cell cycle, proliferation and colony formation experiments as well as *in vivo* studies were performed to evaluate the biological effects of the PARP-1 inhibitor niraparib. **Results:** We observed that the up-regulation of PARP-1 upon exposure to 17β-estradiol (E_2) occurs through ERα in BC cells expressing either ERα wt or Y537S mutation. Moreover, we assessed that the transcriptional activity of ERα relies on PARP-1, as demonstrated by the ability of nirabarib to prevent the transactivation of ERα and the regulation of ERα target genes. In addition, niraparib halted the proliferation and cycle progression of BC cells expressing either ERα wt or Y537S mutation. Of note, niraparib suppressed primary tumor growth in xenograft tumors derived from ERα Y537S mutated MCF7 cells. **Conclusions:** Our data suggest that crosstalk between PARP-1 and ERα is involved in the proliferative responses of ERα wt or Y537S mutated BC cells. Therefore, targeting PARP-1 could provide a promising strategy to overcome the ET resistance of BC cells. Research Sponsor: None.

Racial and ethnic differences in biomarker testing for targetable alterations among patients with HR+ HER2- metastatic breast cancer (mBC). First Author: Catherine Keane, Flatiron Health, New York, NY

Background: In recent years novel therapies have been approved for patients (pts) with mBC and *ESR1*, *AKT1*, *PTEN*, *PIK3CA*, and *gBRCA* alterations. Given limited evidence on which patients are receiving standard of care, this study assessed racial and ethnic inequities in biomarker testing and the role of social determinants of health (SDOH) in explaining potential inequities. **Methods:** This study leveraged the US nationwide Flatiron Health electronic health record (EHR)-derived, deidentified database of > 750 000 pts with BC. Adult female pts diagnosed (dx) with HR+ HER2- mBC between 1/1/2011, and 4/30/2024, with a geocodeable address were included. Testing rates for alterations in *ESR1*, *PIK3CA*, *AKT1*, *PTEN*, and *gBRCA* were measured over time from mBC dx using variables extracted from unstructured clinician documentation in the EHR using machine learning. Fine and Grey models accounting for competing risks were used to estimate subdistribution hazard ratios (HR) and 95% confidence intervals (CI) for biomarker access. Models were adjusted for covariates including age, stage, ECOG status, and dx year, followed by practice setting and area-level SDOH factors (ie, English language proficiency, residential segregation, vehicle ownership, urbanicity, and residence in medically underserved areas). **Results:** The cohort included 36 316 pts (61.5% non-Latinx [NL]-White, 6.1% Latinx, 9.7% NL-Black, 1.9% NL-Asian, and 20.8% NL-Other/Unknown). Overall, Asian, Black, and Latinx pts were less likely than White pts to undergo biomarker testing (adjusted HR [95% CI]: Latinx, 0.88 [0.82-0.95]; NL-Black, 0.87 [0.82-0.93]; NL-Asian, 0.87 [0.76-0.98]). Racial/ethnic inequities in overall biomarker testing were partially explained by SDOH factors. Specifically, the White-Latinx inequity in testing was mediated by residential segregation ie, association attenuated towards the null (mediated HR [95% CI], 0.94 [0.87-1.02]), limited English proficiency (0.92 [0.85-1.00]), and lack of vehicle ownership (0.91 [0.84-0.98]). Compared with White pts, NL-Black pts were less likely to be tested for *ESR1* (HR [95% CI], 0.86 [0.77-0.95]) and *PIK3CA* (0.86 [0.80-0.92]). Latinx pts were less likely to be tested for *PIK3CA* (0.87 [0.80-0.95]) and this inequity was mediated by residential segregation (0.96 [0.87-1.05]) and limited English proficiency (0.92 [0.84-1.00]). **Conclusions:** Asian, Black, and Latinx pts were generally less likely than their White counterparts to receive biomarker testing after a mBC dx, especially for *PIK3CA* and *ESR1*. SDOH factors explained some of these biomarker testing inequities. Equitable access to biomarker testing should be prioritized to ensure patients have access to the most effective therapies. Future research should examine whether racial/ethnic inequities in biomarker testing are associated with inequities in treatment and outcomes. Research Sponsor: Flatiron Health.

Therapeutic impact of novel agents in patients with stage IV de novo HR+ve/Her2-ve breast cancer: Results from a real world dataset. First Author: Shaheenah S. Dawood, Mediclinic City Hospital, Dubai, United Arab Emirates

Background: The objective of this retrospective analysis was to look at the therapeutic impact of CDK4/6i and novel agents among pts with stage IV Denovo HR+ve/HER2-ve breast cancer (BC). **Methods:** We utilized a federated network of de-identified health data representing approximately 165 million pt lives available through the TriNetX Research Network. We identified 41,843 pts with HR+ve/HER2-ve stage IV Denovo BC treated diagnosed between Jan 2005 - Jan 2025. Propensity score matching analysis by age and site of metastases was carried out. OS was computed using the Kaplan Meier product limit method. The index event is the date of diagnosis. **Results:** 8,541(20.4%) received a CDK4/6i. Among pts treated with CDK4/6i 1,396(16.3%), 6,169 (72.2%) and 2,157 (25.2%) pts received Ribo, Palbo and Abema respectively. Over time there has been a significant decrease in use of palbocilcib with significant increase in use of abema and ribo. Median OS was similar between Ribo and Abema(HR 0.88; 95%CI (0.75,1.04) p=0.14). Compared to pts receiving palbo median OS was signficantly better among pts receiving abema (HR 0.77; 95%CI (0.69,0.85) p<0.0001) or ribociclib (HR 0.69; 95%CI (0.60,0.81) p<0.0001).628 pts received more than one CDK4/6i. (152 palbo + ribo, 118 ribo + abema, 368 abema+ palbo). 5-year OS was 63.9% and 70.4%(HR 1.37; 95%CI 1.06,1.77) respectively among pts who received 1 vs >1 CDK4/6i. Among patients treated with CDK4/6i, OS was significantly longer among pts who received elacestrant vs those who did not (HR 0.401; 95%CI (0.215,0.745). 228 pts treated with a CDK4/6i received an antibody drug conjugate (ADC). Median time to use of an ADC was 45m. 5yr OS was 75.8% vs 58.7% among those who did and did not receive an ADC respectively (HR 0.45, 95%0.30,0.67). 5yr OS was 76.2% vs 52.7% among those who did and did not receive Trastuzumab deruxtecan respectively (HR 0.37, 95%0.19,0.70). 5yr OS was 76.2% vs 60.4% among those who did and did not receive Sacituzumab govetican respectively (HR 0.40, 95%0.25,0.65). **Conclusions:** Among pts with stage IV Denovo HR+ve/HER2-ve BC treated with a CDK4/6i using a CDK4/6i beyond progression is an option. Novel agents such as oral SERDS and ADCs are also associated with improved prognostic outcome in the real world setting. Research Sponsor: None.

Updated efficacy of mutant-selective PI3Kα inhibitor RLY-2608 in combination with fulvestrant in patients with *PIK3CA*-mutant HR+HER2- advanced breast cancer: ReDiscover trial. First Author: Sarah L. Sammons, Dana-Farber Cancer Institute, Boston, MA

Background: Oncogenic *PIK3CA* mutations constitutively activate PI3Kα and drive approximately 40% of HR+HER2- breast cancer (BC); however, the toxicity (hyperglycemia, rash, diarrhea, stomatitis) of non-selective inhibitors (i) limits their tolerability and efficacy. RLY-2608 is the first oral, pan-mutant-selective, allosteric PI3Kαi designed to overcome these limitations. We report efficacy and safety of RLY-2608 + standard-dose fulvestrant (F) in pts with *PIK3CA*-mutant, HR+HER2- BC treated in the FIH study, ReDiscover (NCT05216432). **Methods:** Previously treated adult pts with advanced HR+HER2- BC and *PIK3CA* mutation per local assessment were eligible. Pts were eligible to enroll with measurable or non-measurable disease. Key objectives were investigator-assessed efficacy per RECIST 1.1 and adverse events (AEs) per CTCAE v5.0. **Results:** As of 4NOV24, safety was assessed in 118 pts treated across RLY-2608 doses 100-1000 mg BID, and efficacy in the 52 pts without detectable *PTEN/AKT* co-alterations treated at the RP2D (600 mg BID). All pts received prior endocrine therapy and CDK4/6i with 48% having ≥ 2 prior systemic therapies for advanced disease including 56% with prior F/SERD and 25% with prior chemotherapy or antibody-drug conjugate. Median follow-up was approximately 9.5 months. The RP2D provided exposure in the target therapeutic range and rapid clearance of mutant *PIK3CA* ctDNA. 31/52 pts had measurable disease with 26/31 (83.9%) achieving disease control, 23/31 (74.2%) experiencing radiographic tumor reduction and 12/31 achieving an objective response (38.7%, 95% CI 21.8-57.8) with median time-to-response 8 weeks. mPFS was 9.2 months (95% CI 5.8,18.4) across all 52 RP2D pts, and 11.4 months (95% CI 7.2-NR) in 32 pts receiving RLY-2608 at the RP2D as 2L treatment. Treatment-related AEs (TRAEs) were generally low-grade, manageable and reversible, most commonly hyperglycemia (42.4% any grade; 2.5% Gr 3), nausea (41.5%; 0.8% Gr 3), fatigue (40.7%; 8.5% Gr 3), creatinine increased (34.7%; 0.8% Gr 3), and diarrhea (30.5%; 1.7% Gr 3). There were no grade 4/5 TRAE; and severe, off-target stomatitis and rash were absent or rare. **Conclusions:** RLY-2608 demonstrates favorable safety/tolerability along with highly encouraging PFS observed across *PIK3CA* genotypes in pts with advanced *PIK3CA*-mutant HR+HER2- BC previously exposed to CDK4/6i. These data validate RLY-2608 as the first allosteric pan-mutant selective PI3Kαi and support advancing RLY-2608 + F to pivotal testing, which is planned for later this year. Clinical trial information: NCT05216432. Research Sponsor: Relay Therapeutics.

Impact of body weight and body composition on survival and toxicities in patients receiving CDK4/6 inhibitors for ER+/HER2- metastatic breast cancer. First Author: Jorge Avila, Montefiore Medical Center, Bronx, NY

Background: Body composition influences treatment outcomes and adverse events in many oncologic conditions including metastatic breast cancer (mBC). The objective of our study was to evaluate the impact of body composition measures on progression-free survival (PFS) and adverse events in patients treated with cyclin-dependent kinase 4/6 (CDK4/6) inhibitors for estrogen receptor-positive (ER+)/HER2- mBC. **Methods:** A single institution retrospective analysis of 207 patients treated with CDK4/6 inhibitors was conducted. Baseline body weight and body composition measures (total fat, visceral fat, subcutaneous fat, skeletal muscle area, skeletal muscle density and muscular adiposity) were analyzed. PFS was evaluated using Cox proportional hazard models, and logistic regression was used to evaluate the relationship between these variables and adverse events. Early changes in body composition were defined as variations in muscle or fat compartments within 3 months. Low muscle quality was defined as muscle power index value of 1 to 2 Standard Deviations below the normal range. **Results:** The median age of our cohort was 61 years, with 77% of patients being postmenopausal and 46% identifying themselves as Black. Most patients received palbociclib (76%), followed by abemaciclib (14%) and ribociclib (10%) as part of their treatment. Median BMI was 27.97 kg/m2, with 36% being classified as obese. Sarcopenia was present in 18% of our patients, and 71% had low muscle quality. Higher BMI (HR, 0.96; 95% CI, 0.93-0.99; p 0.01), obesity (HR, 0.60; 95% CI, 0.42-0.86; p = 0.01) and weight (HR, 0.99; 95% CI, 0.98-0.99; p = 0.01) were significantly associated with improved PFS. Modest but statistically significant associations with PFS were observed for total fat (HR 0.99; 95% CI 0.98-0.99; p = 0.01) and subcutaneous fat (HR, 0.99; 95% CI, 0.98-0.99; p = 0.01); however, this was not the case for visceral fat and muscle adiposity. There was no significant association between body muscle compartment distribution (including sarcopenia) and PFS. Early changes in skeletal muscle density were associated with improved PFS (HR, 0.95; 95% CI, 0.91-0.99; p = 0.01), while sarcopenia and low muscle quality were not significant predictors. Grade 3/4 hematologic toxicities were associated with lower muscle area (p = 0.02), but no significant association between fat compartments and adverse events was found. **Conclusions:** Obesity is associated with improved survival outcomes in patients receiving CKD4/6 inhibitors for ER+/HER2- mBC; furthermore, this effect is driven by subcutaneous fat. Early changes in skeletal density during CDK4/6 inhibitors treatment is a potential predictor of improved outcomes. Muscle area is a potential predictor of treatment toxicities. Our findings suggest that body composition plays an important role in outcomes and adverse events in this group of patients. Research Sponsor: None.

1088 Poster Session

Phase 1 trial of exercise as first-line therapy for hormone receptor (HR)–positive advanced breast cancer (TBCRC 054). First Author: Neil M. Iyengar, Memorial Sloan Kettering Cancer Center, New York, NY

Background: Observational studies show post-diagnosis exercise is associated with reduced risk of cancer death in patients with HR-positive breast cancer. We conducted a phase 1a dose-finding trial of exercise therapy as first-line treatment for HR-positive advanced breast cancer (TBCRC 054). **Methods:** This multicenter trial was conducted using a patient-centric, decentralized platform (NCT03988595). Non-exercising patients receiving first line endocrine plus CDK4/6 inhibitor therapy were allocated using an adaptive continual reassessment design to one of four escalated exercise therapy dose levels (range: 90 to 300 min/week) of individualized, moderate-intensity treadmill walking for 6 consecutive months. The trial was later amended to add a fifth dose level of 375 min/week and to allow dose cohort backfilling. Exercise therapy sessions were conducted remotely in patient's homes with real-time monitoring. The primary objective was to identify the recommended phase 2 dose (RP2D) as determined by feasibility and preliminary clinical efficacy. Feasibility was evaluated by relative exercise dose intensity (REDI). A dose level was considered feasible if ≥70% of patients achieved a REDI ≥75%. One-year progression free survival (PFS) rates were assessed by the Kaplan-Meier method. **Results:** Fifty-four women (median age 53 [46 to 63] years) were enrolled between August 2019 and April 2024; 23 (43%) had visceral metastases, 43 (80%) received an aromatase inhibitor, 11 (20%) received fulvestrant, and 53 (98%) received a CDK4/6 inhibitor. The proportion of patients with REDI ≥75% in each dose level was: 90 min/week (n = 10): 80%, 150 min/week (n = 10): 60%, 225 min/week (n = 11): 82%, 300 min/week (n = 13): 62%, and 375 min/week (n = 10): 40%. Among the two feasible dose levels (90, 225 min/week), 1-year PFS rate was 70% (95% CI, 47% to 100%) in the 90 min/week dose level and 91% (95% CI 75% to 100%) in the 225 min/week dose level. No serious adverse events were observed. Overall, 225 min/week (~ 45 minutes per treatment at 5 times weekly) was selected as the RP2D. **Conclusions:** This multicenter phase 1 trial showed that exercise therapy doses of 90 and 225 min/week are feasible and safe in patients receiving first line endocrine-based therapy. These data also support the rationale for a phase 2 trial testing the preliminary clinical efficacy of exercise at the RP2D of 225 min/week in HR-positive advanced breast cancer. Clinical trial information: NCT03988595. Research Sponsor: National Cancer Institute; R01CA235711.

Pulmonary toxicities in patients (pts) with metastatic breast cancer (mBC) treated with trastuzumab deruxtecan (T-DXd): The Mayo Clinic Enterprise Experience, updated. First Author: Jenna Elizabeth Hoppenworth, Mayo Clinic, Rochester, MN

Background: T-DXd has become an important treatment option in mBC and other malignancies. Interstitial lung disease/pneumonitis (ILD) occurred in 10-14% of pts in the DESTINY-Breast trials (0-2% G5 ILD), and with potential lower incidence/severity in earlier line settings (Krop et al, ASCO 2023). We previously reported the Mayo Clinic Rochester, MN experience with T-DXd related ILD in mBC (Hoppenworth et al, ASCO 2024). Here, we expand the data to include patients treated at all locations of the Mayo Clinic Enterprise. **Methods:** We retrospectively identified pts with mBC who received ≥1 dose of T-DXd across the Mayo Clinic enterprise (Rochester, MN; Mayo Clinic Health System locations in MN/WI; Scottsdale, AZ; and Jacksonville, FL) between July 2022-December 2023. Demographic, mBC characteristics, and pulmonary clinical variables were abstracted from the clinical records. Data were summarized using descriptive statistics. Diagnosis of ILD was determined by treating clinicians, and severity was approximated to CTCAE V5 based on clinical documentation. **Results:** 252 pts with mBC received T-DXd during the study period. The majority were Caucasian (86%) and female (99%) with a median age of 63. 91 pts (36%) were current/formers smokers and 97 (39%) had prior pulmonary comorbidities. The majority had HER2 low (155, 62%) and HR positive (164, 65%) mBC. 35 (14%) developed any grade ILD [G1: 6 (17%), G2: 13 (37%), G3: 3 (8.6%), G4: 3 (8.6%), G5: 10 (29%)], with 15 (43%) presenting with ≥G3. 29 (83%) presented with at least 1 symptom (cough or SOB). Among those with previous pulmonary toxicity, 4 (33%) had previous pneumonitis in the ILD cohort. The median prior lines of all therapies (including endocrine therapy) were 5, with a median of 3 prior lines of chemotherapy in both the ILD (range 1-13) and non-ILD cohorts (range 1-13). Median onset to any grade ILD was 7 cycles. 20 pts (57%) received steroids for ILD. 14 (40%) had a bronchoscopy, all had a CT chest, 16 (46%) were hospitalized, 7 (20%) were intubated and 1 (3%) had a lung biopsy. Pts with G5 ILD had a median of 3 lines of chemo and a median of 8 cycles prior to onset of ILD, compared to 3 lines of chemo and a median of 7 cycles for those with G1-4 ILD. G5 pts were all Caucasian females, 5 were former smokers, 5 were non-smokers, 1 had a history of pneumonitis. T-DXd was rechallenged in 4 pts (G1-2 ILD) without ILD recurrence. **Conclusions:** In this retrospective case series,14% of pts treated with T-DXd experienced any grade ILD (4% G5) which is in alignment with the rate observed in the pivotal DESTINY-Breast trials, though with higher rates of G5 toxicity. Among those with ILD, increased lines of therapy were not associated with increased risk. Further research is needed to correlate risk. Research Sponsor: None.

1090 Poster Session

Preliminary efficacy and safety of TQB2102 in patients with HER2 low-expressing recurrent/metastatic breast cancer: Results from a phase 1b study. First Author: Shusen Wang, Department of Medical Oncology, Sun Yat-Sen University Cancer Center; State Key Laboratory of Oncology in South China; Collaborative Innovation Center for Cancer Medicine, Guangzhou, China

Background: TQB2102 is a novel antibody-drug conjugate (ADC) comprised of a recombinant humanized anti-HER2 bispecific antibody that simultaneously binds to two distinct HER2 epitopes (ECD4 and ECD2), an enzyme-cleavable linker, and a DNA topoisomerase I inhibitor payload. This study aims to evaluate the efficacy and safety of TQB2102 for patients (pts) with HER2-expressing relapsed/metastatic breast cancer. **Methods:** This 1b phase, open-label, multicenter, randomized trial was divided into two cohorts: Pts in cohort 1 were HER2 low-expressing breast cancer and in cohort 2 were HER2 positive BC, all pts were refractory or intolerant to standard therapy. In cohort 1, HER2 low-expressing pts were randomly assigned to receive TQB2102 monotherapy at a dose of 6.0 mg/kg (Q3W, IV) or 7.5 mg/kg (Q3W, IV). The primary endpoint was ORR per RECIST v1.1, and the secondary endpoints were PFS, DCR and safety etc. **Results:** 73 HER2 low-expressing female pts were randomized to receive at least one dose of TQB2102 6mg/kg (n = 37) or 7.5mg/kg (n = 36), the median age was 53. All pts had received chemotherapy in the metastatic setting, and hormone receptor positive pts (n = 50) also had received prior CDK4/6 inhibitors. In cohort 1, pts had undergone a median of 4 prior treatment lines (range: 1-10) in the metastatic setting, the median prior lines of chemotherapy therapies were 2 (range: 1-5), and 12.3% (n = 9) pts had received prior ADCs. As of data cutoff on Nov 1, 2024, median follow-up time was 7.16 months. ORR was 53.4% (39/73) in cohort 1, and the ORR of 7.5mg/kg (58.3%) was better relative to 6.0mg/kg (48.7%). Objective responses were observed in subgroups with HR positive pts (27/50, ORR 54.0%), HR negative pts (12/23, ORR 52.2%); of which the ORR of 7.5mg/kg with HR+ and HR- was 66.7% (14/21) and 46.7% (7/15), respectively. For HER2 low-expressing pts who received prior ADC therapies, the ORR was 44.4% (4/9). In cohort 1, DCR was 86.3% (63/73, among 6 pts was not available), and median PFS was not yet mature. TRAEs were reported in 71 (97.3%) HER2 low-expressing pts. Grade≥3 TRAEs and serious TRAEs were reported in 30 (41.1%), 13 (17.8%) pts, respectively. The main TRAEs were neutropenia, leukopenia, anemia, nausea, vomiting. The common TRAEs and grade ≥3 TRAEs occurred similarly at both doses, with hematologic toxicities such as anemia were slightly higher at 7.5mg/kg than at 6.0mgkg, but all were tolerable. No Interstitial lung disease was reported in cohort 1 pts. **Conclusions:** TQB2102 was well-tolerated and showed promising antitumor activity in heavily pretreated HER2 low-expressing recurrent/metastatic breast cancer pts. The recommended phase 3 dose of TQB2102 in HER2 low-expressing r/m BC was 7.5 mg/kg Q3W. A phase III trial to evaluate the efficacy and safety of TQB2102 versus investigator-selected chemotherapy in HER2 low-expressing r/m BC is currently ongoing (NCT06561607). Clinical trial information: NCT06115902. Research Sponsor: None.

Standard-dose vs fixed-dose capecitabine in patients with advanced gastrointestinal and metastatic breast cancer. First Author: Nanuli Gvazava, The University of Kansas Cancer Center, Westwood, KS

Background: Capecitabine at the FDA-approved standard dose (SD) of 1250 mg/m² twice daily for 14 days with a 7-day break, has significant toxicities. We conducted a randomized trial comparing SD and fixed dose (FD) Capecitabine 1500 mg twice daily, 7 days on, 7 days off in patients with metastatic breast cancer (MBC) and advanced gastrointestinal (GI) cancers. We previously reported that in MBC cohort progression-free survival and overall survival were similar, and FD had significantly lower toxicities. We now present time to treatment failure (TTF) and toxicity in MBC and GI cohorts. **Methods:** Patients with MBC or advanced GI cancers (colorectal, small bowel, gastroesophageal, pancreatic and bile duct) with any prior lines of therapy were randomized 1:1 to either FD-7/7 or SD-14/7. Post hoc analysis was performed to determine TTF, and landmark analysis was performed for Freedom from Treatment Failure (FFTF). Capecitabine-related toxicities [diarrhea, hand foot syndrome (HFS) and stomatitis] were solicited and graded at each visit. **Results:** 182 patients were enrolled (N=93 FD, N=89 SD) of which 153 had MBC and 29 had an advanced GI cancer. Median TTF was 4.92 months (3.02, 5.93) in FD arm, and 3.11 months (2.49, 3.90) in SD arm (log rank p=0.0111). Landmark analysis of FFTF is shown in Table 1. At 24 months, the FFTF in the FD arm was 15.6%, while in the SD arm it was 2.5% (p=0.0054). Grade 2 and higher toxicities were more common in SD compared to FD, including HFS, diarrhea, and stomatitis (Table 1) **Conclusions:** Fixed-dose capecitabine at 1500 mg twice daily for 7 days on and 7 days off demonstrates a longer time to treatment failure compared to the standard FDA-approved dosing in patients with MBC and advanced GI cancers and is associated with significantly lower toxicities. Clinical trial information: NCT02595320. Research Sponsor: None.

Landmark freedom from treatment failure at 12, 24 and 36 months; solicited adverse events.

Limited changes in the CNS immune microenvironment in patients with breast cancer metastasis and capturing these changes using machine learning. First Author: Andrew Ip, John Theurer Cancer Center, Hackensack University Medical Center, Hackensack, NJ

Background: Metastasis of breast cancer to the central nervous system (CNS) is common, especially in triple negative and HER2-positive tumors. The CNS is considered immune specialized and likely the brain and brain-border immune microenvironment creates a sanctuary site for breast cancer CNS metastasis. A better understanding of the immune microenvironment may allow for better utilization of immunotherapy to treat CNS metastasis. Toward this goal, we evaluated the cellular transcriptomic profile of cerebrospinal fluid (CSF) cells and compared between patients with documented metastatic tumor by cell-free DNA (cfDNA) testing of the CSF fluid (cfCSF-Pos) and patients without evidence of cfDNA metastasis (cfCSF-Neg) (Charifa et al., https://doi.org/10.1016/j.jlb.2024.100281). **Methods:** RNA was extracted from the CSF cells of 63 cfCSF-Pos patients and 93 cfCSF-Neg patients. The RNA was sequenced and quantified using a targeted RNA panel of 1600 genes by next generation sequencing (NGS). We used two thirds of the samples for training a machine learning (ML) system and one third for testing. The ML system uses Bayesian statistics with k-fold cross-validation (with k = 12) to first rank the top biomarkers distinguishing CSF-Pos from CSF-Neg samples. Then Random Forest was used to distinguish between the two classes using the top ranked biomarkers. **Results:** cfCSF-Neg contains mainly T-cells with median CD2:CD22 RNA ratio of 70.07 (range 0.01-14820). This was not significantly different (p = 0.19) from cfCSF-Pos cases (median: 41.31, range: 0.4-10172). The ratio of CD4:CD8A in cfCSF-Neg (median: 4.89, range: 0.47-2522) was also not significantly different (p = 0.31) from that in cfCSF-Pos cases (median: 5.0, range: 0.29-48). While significant variation in the levels of T- and B-cells is noted within each group, there was no significant difference in the individual cell population (T-cells, B-cells, plasma cells, natural killer cells, neutrophils, monocytes, or dendritic cells) overall after adjusting for multiple testing. Despite this lack of difference in cell populations, the testing set showed that cfCSF-Pos patients can be readily distinguished from cfCSF-Neg patients with AUC of 0.886 (CI: 0.797-0.976) using 30 top genes selected by ML. Except for KRT8 and KRT19, the majority of the top genes selected by the ML algorithm suggests modulation of T-cell activation including but not limited to TBX21, CD3D, CD5, IKZF3, NFATC2, and INPP5D. **Conclusions:** The data suggest the CNS remains immunologically specialized with modulating the adaptive immune response in the setting of breast cancer metastasis. Significant modulation in the CSF T-cells suggests selective targeting with immunotherapy may prove beneficial with the potential for active monitoring using this combination CSF cellular and cfDNA approach. Research Sponsor: None.

A phase II study to evaluate the safety and efficacy of BB-1701 in subjects with HER2 expression locally advanced/metastatic breast cancer previously treated with HER2-ADC containing TOP-I inhibitor. First Author: Xiaoxiang Guan, The First Affiliated Hospital of Nanjing Medical University, Nanjing, China

Background: BB-1701 is an HER2-targeting antibody-drug conjugate (ADC) containing eribulin. In phase I study, BB-1701 had shown promising antitumor activity in breast cancer (BC) patients with HER2 high/low expression and manageable safety profile. Currently, there are no approved treatment options for metastatic BC patients with high/low expression who have received HER2-ADC containing TOP-I inhibitor, especially for trastuzumab deruxtecan. We report the preliminary efficacy and safety results from the ongoing phase 2 study of BB-1701 in advanced or metastatic breast cancer patients with HER2 expression previously treated with HER2-ADC containing TOP-I inhibitor. **Methods:** Patients enrolled were $\geq$18 years of age; had confirmed locally advanced/metastatic HER2 expressing breast cancer; disease progression after previous HER2-targeting ADC (containing TOP-I inhibitor) therapy; an ECOG PS $<$ 2; and measurable lesion(s) (per RECIST v1.1). HER2 expression was confirmed by IHC before patient enrollment. BB-1701 is administered at 1.6 mg/kg Q3W. **Results:** As of 28 January 2025, 23 patients with HER2 high/low-expressing breast cancer have been enrolled and treated. Median age is 51 years, all patients are female, and 26.1%/73.9% patients have ECOG PS 0/1. The median number of prior systemic therapy lines was 4.0, 21.7%/78.3% HER2 status are high expression/low expression. All patients experienced at least one treatment-emergent adverse events (TEAEs). The most common ($\geq$10%) all grade TEAES are neutrophil count decreased, platelet count decreased, Aspartate aminotransferase increased, and white blood cell count decreased. One grade 3 TEAEs is peripheral neuropathy, and another grade 3 TEAE is neutrophil count decreased. There has been no grade 4 or grade 5 events as of data cut-off date. One treatment emergent serious adverse event is peripheral neuropathy. Of the 23 patients, 14 were evaluable for efficacy. Among 14 evaluated patients, 4 patients achieved partial response (PR) and 9 patients had stable disease (SD), with disease control rate (DCR) of 92.8%. Among 3 HER2 high-expressing patients who were previously treated with trastuzumab deruxtecan, 1 patient achieved PR and 2 patients had SD with DCR of 100.0%. Among 8 HER2 low-expressioning (IHC 1+) patients, 3 patients achieved PR (2 patients received prior trastuzumab deruxtecan and 1 patient received prior SHR-A1811) and 4 patients had SD with DCR of 87.5%. More data will be presented at the ASCO meeting. **Conclusions:** BB-1701 shows promising antitumor activity and a manageable safety profile in HER2 expressing breast cancer patients who had previously been treated with HER2-ADC (containing TOP-I inhibitor). Clinical trial information: CTR20241422. Clinical trial information: CTR20241422. Research Sponsor: None.

Results of a phase I study of alpelisib and sacituzumab govitecan (SG) in patients with HER2-negative metastatic breast cancer (MBC). First Author: Priyanka Sharma, University of Kansas Medical Center, Westwood, KS

Background: Sacituzumab govitecan (TROP2-directed antibody drug conjugate, ADC) is effective in treatment of pretreated HER2-negative MBC. PI3K is the most frequently altered pathway in breast cancer. This phase I trial investigated the combination of SG plus alpelisib (oral α-specific PI3K inhibitor) in HER2-negative MBC. **Methods:** Eligible patients had HER2-negative MBC and had received $\geq$1 prior line of chemotherapy in the advanced or neo/adjuvant setting and had not received prior PI3K/AKT inhibitor. The study was 3+3 dose escalation design: dose level 1: alpelisib 250 mg+SG 8 mg/kg; dose level 2: alpelisib 250 mg+SG 10 mg/kg; dose level 3: alpelisib 300 mg+SG 10 mg/kg. Alpelisib was dosed PO daily and SG IV, D1 and 8 every 21 days. Antidiarrheal prophylaxis was utilized for the first two cycles. Primary endpoint was recommended phase 2 dose (RP2D). Additional endpoints included adverse events (AEs), objective response rate (ORR), progression-free survival (PFS), and pharmacokinetics. **Results:** 12 patients were enrolled between 2022-2024 (dose level 1: N = 3, dose level 2: N = 6, dose level 3: N = 3). 7/12 (58%) had triple-negative breast cancer (TNBC), and 5/12 (42%) had hormone receptor (HR)-positive disease. All patients had visceral disease. 8/12 (67%) had $\geq$1 prior metastatic chemotherapy; 4/12 (33%) had prior immunotherapy; 3/12 (25%) had prior ADC. One dose-limiting toxicity (hyperbilirubinemia) was observed at dose level 2. RP2D was alpelisib 300 mg + SG 10 mg/kg. The most frequent grade $\geq$3 treatment-related AEs were electrolyte imbalance (G3 17%, G4 17%), neutropenia (G3 33%, G4 0%), diarrhea (G3 17%, G4 0%), and hyperglycemia (G3 8%, G4 8%). There were no G5 AEs. Pharmacokinetics of SG and its metabolites were consistent with previous reports. Among 11 patients evaluable for response, ORR was 36% (4/11) (complete response [CR] = 1, partial response [PR] = 3) and clinical benefit rate (CR + PR + stable disease $>$ 24 weeks) was 64% (7/11). ORR in TNBC was 50% and in HR-positive disease was 20%. Among patients with prior ADC, ORR was 33% and clinical benefit rate was 67%. Three of four patients with ORR had response lasting $>$ 6 months, with median duration of response of 14.9 (range 3.2 to 28.1) months. Median PFS was 5.7 months. Tumor and serial ctDNA analysis are ongoing. **Conclusions:** Combination of SG + alpelisib was feasible, with manageable side effects. The toxicity profile of the combination was consistent with the known safety profiles of the two agents. This combination demonstrated encouraging efficacy in HER2-negative MBC, with prolonged duration of responses, and warrants further evaluation in larger studies. Clinical trial information: NCT05143229. Research Sponsor: Novartis; Gilead Sciences.

Assessing the impact of scalp cooling in patients receiving trastuzumab deruxtecan for metastatic breast cancer. First Author: Elahe Salehi, Dana-Farber Cancer Institute, Boston, MA

Background: Outcomes for patients (pts) with metastatic breast cancer (MBC) have improved with novel antibody drug conjugates like trastuzumab deruxtecan (T-DXd). While T-DXd has been associated with increased risk of alopecia, there are limited data describing the efficacy of scalp cooling in preventing alopecia and improving quality of life among pts receiving T-DXd. **Methods:** This prospective, phase II study enrolled pts with MBC without alopecia at baseline who were initiating treatment with T-DXd; pts elected to participate in a scalp cooling (SC) arm with the Paxman scalp cooling system or a non-SC arm. The primary endpoint was hair loss, defined as locally assessed CTCAE v5.0 grade $\geq$1 alopecia occurring at C3D1, C5D1, or end of treatment (EOT), whichever occurred first. The impact of SC on quality of life (QOL) was assessed using the Chemotherapy-Induced Alopecia Distress Scale (CADS) and body image scale (BIS) at baseline, C3D1, C5D1, and EOT. The study aimed to enroll 20 pts per arm to provide at least 80% power to detect a 28% decrease in hair loss rate between the SC vs non-SC arms (8% vs 36%) using a difference in proportions test (one-sided type I error 10%). **Results:** A total of 40 evaluable pts were enrolled: 20 in SC arm and 20 in non-SC arm. Median age was 61 (33-77); 2 (5%) were Black, 2 (5%) were Hispanic. Twenty-eight (70%) pts had hormone receptor positive disease, 11 (27.5%) HER2+, 2 (5.0%) triple-negative. Thirty-five (87.5%) had prior chemotherapy for MBC; median prior lines was 1 [range: 0-5]. 27 (67.5%) had prior endocrine therapy, 28 (70.0%) had prior CDK4/6 inhibition; 7 (17.5%) had prior use of SC. Thirty-three (82.5%) pts (18 [90%] in SC arm, 15 [75%] in non-SC arm) experienced $>$grade 1 alopecia, with similar rates observed in both arms (p = 0.41). Grade 2 alopecia was the main reason (45%) for SC discontinuation. Median time to G2 alopecia was 2.76 months (95% CI: 1.64-NA) in SC arm and 4.60 months (95% CI: 2.53, NA) in non-SC arm (p = 0.8). Median CADS scores trended upward from baseline to EOT (Baseline: 3.50; C3: 7.22; C5: 9.00; EOT: 11.5) in the SC arm and were more variable in the non-SC arm (baseline: 3.00; C3: 5.00; C5: 2.56; EOT: 6.50); median BIS scores trended upward in both the SC (baseline: 3.00; C3: 8.00; C5: 9.00; EOT: 11.5) and non-SC arms (baseline: 3.00; C3: 5.00; C5: 5.00; EOT: 9.00), with no statistically significant difference. **Conclusions:** In this prospective phase II trial, the use of SC with T-DXd did not show a benefit in hair preservation vs no SC. QOL analysis was not significantly different for those receiving SC vs no SC. Small sample size and lack of randomization may limit interpretation of results. Further work is planned to investigate strategies to improve efficacy of SC with ADCs. Clinical trial information: NCT04986579. Research Sponsor: AstraZeneca and Daiichi Sankyo; Paxman Scalp Cooling; Friends of Dana-Farber.

Bria-IMT + checkpoint inhibitor: Phase I/II survival results compared to benchmark trials in metastatic breast cancer. First Author: Saranya Chumsri, Mayo Clinic Florida, Jacksonville, FL

Background: Bria-IMT is a combination immunotherapy consisting of allogeneic whole cell cancer vaccine (SV-BR-1-GM) administered w/ immune checkpoint inhibitor (CPI). SV-BR-1-GM breast cancer cells are engineered to directly stimulate anti tumor immunity via expression of tumor associated antigens and secretion of GM-CSF to enhance dendritic cell activation. Addition of CPI potentiates SV-BR-1-GM to overcome the immune suppressive tumor microenvironment. **Methods:** This Ph I/randomized Ph II study evaluated the Bria-IMT regimen in pts w/ metastatic breast cancer; CTX (300 mg/m²) on day -2/-3, SV-BR-1-GM and CPI on Day 0, w/ low dose peg interferon α at inoculation sites on day 2 ($\pm$1) . Phase II pts were randomized 1:1 to receive CPI at cycle 1 or cycle 2. Two SV-BR-1-GM formulations (w/ vs w/o IFNγ incubation) were evaluated. Biomarkers included cancer-associated macrophage-like cells, circulating tumor cells, PD-L1 scores, and delayed-type hypersensitivity skin tests. **Results:** 54 pts (22 Ph I, 32 Ph II) enrolled; 11 received pembrolizumab, 44 retifanlimab (1 crossover). 33 (61%) pts were ER+/PR+/HER2-, 18 (33%) TNBC, 3 (6%) HER2+. Median OS, PFS, ORR, and CBR were evaluated against two pivotal Ph 3 trials, ASCENT[1] (SG in TNBC) and TROPiCS-02[2] (SG in HR+/HER2- MBC) (see Table 1). In randomized pts, C1 vs C2 CPI had PFS (3.7 vs 3.2 mos, P=0.09) and OS (11.4 vs 7.4 mos, P=0.19). Pts receiving Ph 3 formulation (w/o IFNγ; N=37) had greater PFS (3.6 vs 2.6 mos, P=0.01) and OS (13.4 vs 6.9 mos, P=0.01). Bria-IMT was well tolerated w/ no Tx related D/Cs. **Conclusions:** The Bria-IMT Ph 3 formulation cohort OS was comparable to ASCENT and TROPiCS-02 (13.43 vs 11.8, 14.4 mos), exceeding TPC arms (6.9, 11.2 mos). CBR (61%) compared favorably to ASCENT (40%) and TROPiCS-02 (34%); ORR (14%) matched or exceeded TPC arms (4%, 14%). These outcomes were observed in a more heavily pretreated population, demonstrating Bria-IMT's clinical activity. Randomized Ph 2 results suggest efficacy and safety in heavily pretreated MBC, w/ no significant OS difference between C1 and C2 CPI initiation and 22% of pts still in active survival follow up. Superior outcomes w/ the Ph 3 formulation support its continued evaluation. A randomized Ph 3 trial is ongoing, comparing Bria-IMT vs treatment of physician's choice (NCT06072612). Clinical trial information: NCT03328026. Research Sponsor: BriaCell Therapeutics Corp.

Trial (Cohort)	Age (Median, Range)	Prior Therapies (Median)	OS (Median, mos)	PFS (Median, mos)	ORR (%)	CBR (%)
Bria-IMT (Overall Cohort)	61 (38-81)	6 (2-13)	9.9 (1.8-30.3)	3.6	10%	55%
Bria-IMT (Ph 3 Formulation)	62 (44-80)	6 (2-13)	13.43 (1.8-30.3)	3.6 (1.8-16.5)	14%	61%
ASCENT (SG)	54 (27-82)	4 (2-17)	11.8	4.8	31%	40%
ASCENT (TPC)	53 (27-81)	4 (2-14)	6.9	1.7	4%	8%
TROPiCS-02 (SG)	57 (49-65)	3	14.4	5.5	21%	34%
TROPiCS-02 (TPC)	55 (48-63)	3	11.2	4	14%	22%

1097 Poster Session

First-line durvalumab plus chemotherapy with or without oleclumab for locally advanced or metastatic triple-negative breast cancer: SYNERGY overall survival and circulating tumor DNA analysis. First Author: Elisa Agostinetto, Université Libre de Bruxelles (ULB), Hôpital Universitaire de Bruxelles (HUB), Institut Jules Bordet,, Brussels, Belgium

Background: SYNERGY (NCT03616886) is a randomized, investigator-initiated, phase I/II trial testing if targeting the immunosuppressive adenosine pathway with the anti-CD73 antibody oleclumab, plus the anti-PD-L1 durvalumab and chemotherapy, enhances antitumor activity in untreated locally advanced or metastatic triple-negative breast cancer (TNBC). Here, we report the overall survival (OS) and circulating tumor DNA (ctDNA) analysis. **Methods:** 133 patients received weekly carboplatin and paclitaxel x12 plus durvalumab, with (arm A) or without (arm B) oleclumab (6 in phase I, 63 in arm A, 64 in arm B). Maintenance with durvalumab +/- oleclumab was continued until disease progression or unacceptable toxicity. The primary endpoint was clinical benefit rate at week 24 (previously reported, Nat Commun. 2023;14(1):7018). Secondary endpoints included OS and progression-free survival (PFS). Exploratory endpoint included ctDNA analysis. Circulating cell free DNA (cfDNA) was extracted from 343 plasma samples collected at baseline (n = 128), week 3 (n = 122), and week 13 (n = 93). For ctDNA detection, we performed low-coverage genome-wide sequencing of cfDNA from the above-mentioned samples and from 55 plasma samples from healthy donors to correct a possible batch effect. **Results:** Data cut-off was September 13, 2024, with a median follow-up of 21.7 months. Median OS was not significantly different between arms: 25.1 vs. 20.9 months in arm A vs. B, respectively; HR 0.97 (95%CI 0.63-1.50, p = 0.90). The updated median PFS showed similar PFS: 4.8 vs. 5.4 months in arm A vs. B, respectively; HR 1.22, (95%CI 0.84-1.78, p = 0.29). Among the 343 plasma samples analyzed, ctDNA detection declined from 77% at baseline to 46% at week 3, to 18% at week 13. At any timepoint, CtDNA detection was significantly associated with worse PFS and OS (Table). Twelve patients across both arms exhibited exceptional long responses, without progressive disease and still receiving the study treatment at data cutoff; all exceptional responders evaluable for ctDNA analysis had ctDNA clearance. **Conclusions:** Theaddition of oleclumab to chemo-immunotherapy did not improve PFS or OS in advanced TNBC. However, a subgroup of patients experienced exceptional long-lasting response, indicating potential benefit in selected cases. CtDNA detection was strongly associated with poorer outcomes at all timepoints, underscoring its potential as a biomarker in this disease/setting. Clinical trial information: NCT03616886. Research Sponsor: AstraZeneca.

Timepoint	ctDNA detection	mPFS (95% CI)*	P value	mOS (95% CI)*	P value

Multiomic profiling of LRRC15 in triple negative breast cancer (TNBC). First Author: Dan Morgenstern Kaplan, University of Miami/Jackson Memorial Hospital, Miami, FL

Background: Leucine-rich repeat-containing protein 15 (*LRRC15)* has emerged as a potential biomarker and therapeutic target for various cancers due to its high expression in cancer-associated fibroblasts (CAFs) and role in tumor progression. High LRRC15 expression is associated with poor prognosis in TNBC. This study aims to define the multiomic profile of *LRRC15* in TNBC. **Methods:** 3,038 TNBC samples were analyzed via Next-Generation Sequencing (592, NextSeq; Whole Exome Sequencing, NovaSeq) and Whole Transcriptome Sequencing (NovaSeq; Caris Life Sciences, AZ). Immune cell fractions were estimated using WTS deconvolution (Quantiseq). Stromal cell abundance in the tumor microenvironment (TME) was estimated from RNA expression profiles using MCP Counter. *LRRC15*-high (H) and -low (L) tumors were classified by RNA expression above or below the 25th percentile. Real-world overall survival (OS) and treatment-related survival were derived from insurance claims and calculated from tissue collection or treatment initiation to last contact using Kaplan-Meier. Statistical significance was assessed using chi-square and Mann-Whitney U tests with multiple comparison adjustments ($q < .05$). **Results:** *LRRC15*-H TNBC tumors had higher frequency of *PIK3CA* (25.9% vs 16.8), PIK3R1 (6.2% vs 1.6%), PTEN (11.3% vs 5.8%), but lower frequency of *RB1* (7.8% vs 12.1%) and *KMT2D* (2% vs 4.4%) compared to *LRRC15*-L, all $q < 0.05$. *LRRC15*-H had higher PD-L1 positivity (32.3% vs 24.5%, $q < 0.05$). Analysis of immune cells showed *LRRC15*-H TNBC had higher infiltration of B cells (4.2% vs 3.5%), M1 macrophages (4.3% vs 2%), M2 macrophages (4% vs 2.5%), Tregs (1.9% vs 1.1%), neutrophils (4.9% vs 3.9%), $CD8^+$ T cells (0.4% vs 0.1%), but lower dendritic cells (2.5% vs 3%), all $q < 0.05$. *LRRC15*-H tumors had greater abundance of CAFs (575.6 vs 93.78, 6.14 fold change (FC)) and endothelial cells (7.3 vs 3.7, 1.97 FC), all $q < 0.05$. *LRRC15*-H had higher T-cell inflamed score (71.5 vs -77) and *IFNg* score (-0.14 vs -1.72), all $q < 0.05$. *LRRC15*-H tumors had higher expression of immune checkpoint genes (*CD274, PDCD1, PDCD1LG2, CTLA4, LAG3, HAVCR2, FOXP3, IDO1, TNFSF14, TIGIT, BTLA, CEACAM1, CD47, CD80, CD86, CD160, CD274*; FC 1.2-2.5, $q < 0.05$). *LRRC15*-H was associated with better OS (mOS: 24.7 vs 13.6 months; HR 0.61, 95% CI 0.53-0.7, $p < 0.001$). Post-pembrolizumab survival was longer for *LRRC15*-H patients (mOS: 27.2 vs 19.4 months; HR 0.61, 95% CI 0.42-0.89, p = 0.01). **Conclusions:** *LRRC15*-H TNBC exhibited better outcomes with pembrolizumab, likely due to higher immune cell fractions and increased CAFs. These findings highlight TNBC heterogeneity and position *LRRC15* as a potential biomarker for tumor stratification, a possible adverse prognostic biomarker and a positive predictive biomarker. Ongoing phase I trials targeting LRRC15 show promise. Combining *LRRC15*-targeted therapies with immunotherapy may improve TNBC outcomes, warranting further validation in breast cancer models. Research Sponsor: None.

1099 Poster Session

Acute circulating tumor DNA dynamics during and after infusional therapy initiation. First Author: Briana To, The Ohio State University Comprehensive Cancer Center, Columbus, OH

Background: For patients with advanced breast cancer, the proportion of tumor-derived DNA in circulation ('tumor fraction'/TF) has been shown to be prognostic. There is evidence that early change in TF may correlate with response to therapy, potentially providing a rapid, minimally-invasive predictive biomarker. However, there is little known regarding TF dynamics during and in the hours immediately after infusion of targeted or cytotoxic therapies, including whether there is a 'surge' in ctDNA corresponding to acute cell death. We hypothesized that tracking TF change peri-infusion would provide insight regarding acute ctDNA dynamics. **Methods:** Banked plasma samples were derived from a phase 1b trial of HSP90 inhibitor onalespib with paclitaxel in patients with advanced triple negative breast cancer. Plasma was collected during the first cycle of therapy on study pre-infusion, end-of-infusion (EOI), then 0.5/1/2/4/6/8/24 hours post-infusion for 1) onalespib alone (day -7); 2) paclitaxel alone 7 days later (day 1); 3) onalespib+paclitaxel 7 days later (day 8) for a total of maximum 26 time points per patient. 317 samples from 14 patients underwent shallow whole genome sequencing (sWGS) and TF determination. The objective was to evaluate change in TF from pre-infusion to 6-hours and 24-hours post-infusion. Exploratory objectives included association of TF dynamics with progression-free survival (PFS) and overall survival (OS). **Results:** 313/317 (98.7%) of available plasma samples completed sWGS. Of these, 104/313 (33.2%) were collected on onalespib alone, 114/313 on paclitaxel alone (36.4%), and 95/313 (30.4%) on onalespib+paclitaxel. For the co-primary objectives, there was a significant decline in TF from pre-infusion to 6 hours for paclitaxel alone (Wilcoxon signed rank p = 0.03) but no significant change for onalespib alone/onalespib+paclitaxel or from pre-infusion to 24 hours for any treatment group (all Wilcoxon signed rank $p > 0.05$). There was a significant decline in TF from pre-infusion day -7 (median TF 16%) to 24 hours after C1D8 (median TF 6.5%, Wilcoxon signed rank p = 0.004). Baseline TF≥20% was associated with significantly worse PFS (log-rank p = 0.002) with a trend toward worse OS (log-rank p = 0.067) but categorization of TF change using ctDNA-RECIST was not associated with significant differences in PFS or OS. **Conclusions:** In this study of > 300 plasma timepoints during the first cycle of treatment on a phase Ib clinical trial, there was no significant 'surge' in ctDNA TF within minutes to 24 hours of infusion of onalespib, paclitaxel or both in combination. However, there was a significant decline in TF over the first full cycle of therapy. This suggests that despite ctDNA half-life of minutes-to-hours, consistent change in TF may not be detectable for days or weeks, providing important insight in the design of studies evaluating ctDNA change as a minimally-invasive biomarker. Research Sponsor: None.

A phase 1b study of Plk1 inhibitor onvansertib in combination with paclitaxel in metastatic triple-negative breast cancer (mTNBC) patients. First Author: Antonio Giordano, Dana-Farber Cancer Institute, Harvard Medical School, Boston, MA

Background: TNBC represents 15-20% of all breast cancer and is characterized by a more aggressive clinical course compared to other subtypes with response rate < 10% after 2-3 lines of chemotherapy. Onvansertib is an oral polo-like kinase 1 (PLK1) ATP-competitive inhibitor with preclinical data showing synergy when combined with paclitaxel (P) in TNBC models. Here, we report safety and outcome data for subjects enrolled in a phase 1b clinical trial of onvansertib and P for patients (pts) with mTNBC. **Methods:** Eligible pts received escalating doses of onvansertib, studied using a Bayesian Optimal Interval (BOIN) design, with a fixed dose of P to determine the maximum tolerated dose and recommended phase 2 dose (RP2D) of onvansertib. The primary objective was the characterization of dose-limiting toxicity (DLT). Onvansertib was tested at 9, 12, and 18 mg/m² dose levels (DL). Onvansertib was administered orally, once daily for 21 consecutive days, followed by 7 days off; P was administered intravenously at 80 mg/m^2 once on days 1, 8, and 15 of every 28-day cycle. Exploratory objectives included pharmacokinetic (PK) and circulating tumor DNA analyses. **Results:** 17 pts enrolled from September 2022 to August 2024. Median line of chemotherapy for mTNBC was 3 (range 1-11), 14/17 pts received prior taxane, 7/17 immunotherapy (IO), and 13/17 a prior antibody drug conjugate (ADC). There were 3 pts enrolled at DL0 (9 mg/m²), 4 at DL1 (12 mg/m²), and 10 at DL2 (18 mg/m²). One pt in DL2 remains on treatment, and 16 are off study (11 pts discontinued due to disease progression (PD) per RECIST 1.1; 3 due to clinical PD; 1 due to unacceptable toxicity; 1 death unrelated to the study drug). DLTs were observed in 0/3 pts at DL0, 1/4 (25%) at DL1, and 3/10 (30%) at DL2. Common adverse events were anemia (47% ≥ Grade 2, 12% Grade 3), decreased neutrophil count (47% ≥ Grade 2, 24% Grade 3-4), and fatigue (24% ≥ Grade 2, 6% Grade 3). Best responses included 24% partial response (PR, 2/4 confirmed) and 24% stable disease (2/4 SD ≥ 12 weeks) (Table 1). All 4 responders were treated in DL2 (18mg/m^2), 3/4 pts received prior P (2/4 in mTNBC setting) and IO (all in mTNBC), 2/4 received an ADC. The RP2D of onvansertib in combination with P is 18 mg/m². PKs and other biomarkers will be presented. **Conclusions:** The combination of onvansertib and P demonstrated a safe toxicity profile and promising clinical activity in pretreated mTNBC pts and warrant further exploration of the combination at the RP2D. Clinical trial information: NCT05383196. Research Sponsor: METAVIVOR; Cardiff Oncology.

Camrelizumab plus nab-paclitaxel and cisplatin as first-line treatment for metastatic triple-negative breast cancer: A prospective, single-arm, open-label phase II trial. First Author: Biyun Wang, Department of Medical Oncology, Fudan University Shanghai Cancer Center, Shanghai, China

Background: Platinum-based chemotherapy plays an important role in the treatment of TNBC. Our previous research has demonstrated the superiority of nab-paclitaxel/cisplatin (AP) regimen as the initial treatment for metastatic TNBC(mTNBC; *Xichun Hu, 2020ESMO)*. Camrelizumab is a humanized monoclonal antibody against PD-1. Herein, we conducted this prospective, single arm, open-label phase II study to evaluate the efficacy and safety of camrelizumab in combination with AP regimen as the first-line treatment of mTNBC (NCT04537286). **Methods:** Patients with untreated mTNBC received camrelizumab (200 mg D1), nab-paclitaxel (125 mg/m^2 D1,D8) and cisplatin (75 mg/m^2 D1) intravenously every 3 weeks until disease progression or intolerable toxicity. The primary endpoint was progression-free survival (PFS). Secondary endpoints included objective response rate (ORR), disease control rate (DCR),overall survival (OS) and safety. Exploratory analyses included immunohistochemistry and RNA sequencing of archival tumour samples. **Results:** A total of 90 patients were enrolled. Overall, median age was 51 years; 46.7% of patients had three or more metastatic sites; 78.9% of patients had visceral involvement; 82.2% of patients had taxanes exposure. As of data cutoff (July 10th 2024), median duration of follow-up was 18.1 months. Median PFS was 11.8 (95%CI 10.1-13.6) months and median OS was 27.1 (95%CI 22.1-33.6) months. ORR was 71.1% and DCR was 86.7%. Median time to response was 1.5 months. TRAEs were reported in all patients while grade 3-4 TRAE occurred in 55.6% patients, including neutropenia (34.4%), leukemia (24.4%), and anemia (10.0%). irAEs were reported in 57.8% patients, including RCCEP (45.5%), rash (11.1%), pneumonitis (10.0%), while grade 3-4 irAEs only occurred in 4.4% patients. Three-months landmark analyses showed that patients with irAE have significantly longer OS than those without (29.3 vs. 22.1 months, *P* = 0.018). Exploratory analyses demonstrated that patients with PDL1 CPS ≥10 had significantly longer PFS (13.7 vs 11.4 months, *P* = 0.039). Patients with high TILs had significantly longer OS (23.1 vs.10.3 months, *P* = 0.003). The proportion of PDL1 positive (CPS ≥1) patients was 81.8% in basal compared to 0% in non-basal subtype (*P* = 0.023). Hallmark pathway analysis showed that the activation of DNA repair pathway (HR,11.6, 95%CI 2.4-55.7, *P* = 0.002) and MYC target pathway (HR,7.4,95%CI 1.9-28.2, *P* = 0.004) was significantly associated with shorter PFS, while the activation of KRAS signaling (HR,3.2, 95%CI 1.1-9.7, *P* = 0.035) was significantly associated with worse OS. **Conclusions:** Camrelizumab plus AP as first-line treatment in patients with mTNBC demonstrated satisfying efficacy with manageable toxicity. Randomized controlled trial is warranted in the future. Clinical trial information: NCT04537286. Research Sponsor: None.

Safety and efficacy of the anti-TROP2 antibody-drug conjugate (ADC) IBI130 in patients (pts) with advanced triple-negative breast cancer (TNBC) and other solid tumors: Results from the phase 1 study. First Author: Fan Wu, Fujian Cancer Hospital, Fuzhou, China

Background: TROP2 is a promising therapeutic target in various solid tumors. IBI130 is composed of an anti-TROP2 antibody conjugated to the camptothecin derivative NT1. Herein, we report the multi-regional, first-in-human, phase 1 study of IBI130. **Methods:** Eligible pts with unresectable locally advanced or metastatic solid tumors who failed or intolerant to standard treatment were enrolled. The study included dose escalation and dose expansion. IBI130 was intravenously administered at 1/2/4/6/8/10/12 mg/kg Q3W during dose escalation, which was guided by modified continuous reassessment method (mCRM) according to Bayesian logistic regression model (BLRM) and escalation with overdose control (EWOC) principle. Primary endpoint was safety. Secondary endpoint was efficacy assessed by investigator per RECIST v1.1 including objective response rate (ORR), disease control rate (DCR), duration of response (DoR) and progression-free survival (PFS). **Results:** As of Dec 15, 2024, 71 pts were enrolled from China and Australia (median age: 60 years [range: 30-81], female: 85.9%, Caucasian: 16.9%, ECOG PS 1: 48.6%; prior lines of anticancer treatment≥2: 63.8%). Median follow-up of the study was 4.6 months (range: 0.8-9.7). No dose-limiting toxicity (DLT) was observed across all dose levels during dose escalation (n = 18). Median treatment duration was 18 weeks (range: 3-45) with 40 (56.3%) pts still on treatment. Treatment-emergent adverse events (TEAEs) occurred in 68 (95.8%, with 90.1% treatment-related adverse events [TRAEs]) pts including grade 3 (G3) events in 17 (23.9%, with 15.5% TRAEs) pts. No grade 4-5 events occurred. Common TEAEs (≥30%) were stomatitis (52.1%, with 9.9% G3), nausea (31.0%, with 2.8% G3) and rash (31.0%, with 1.4% G3). Interstitial lung disease occurred in 1 pt (1.4%, G1). Only 1 pt (1.4%) had G3 lymphocyte count decreased. Other ≥G3 hematological toxicities were not observed. TRAEs led to dose reduction in 5 (7.0%) pts and treatment discontinuation in 1 (1.4%) pts. Efficacy of IBI130 was evaluable in 30 pts with TNBC treated at 4/6/8/10 mg/kg (all stage IV, and 96.7% had failed or were intolerant to taxanes). The overall ORR was 50.0% (95% CI: 31.3-68.7) and DCR was 83.3% (95% CI: 65.3-94.4). As for different dose levels, ORR and DCR were 40.0% (95% CI: 5.3-85.3) and 60.0% (95% CI: 14.7-94.7) for 4 mg/kg (n = 5), 40.0% (95% CI: 5.3-85.3) and 80.0% (95% CI: 28.4-99.5) for 6 mg/kg (n = 5), 50.0% (95% CI: 18.7-81.3) and 100% (95% CI: 69.2-100.0) for 8 mg/kg (n = 10), 60.0% (95% CI: 26.2-87.8) and 80.0% (95% CI: 44.4-97.5) for 10 mg/kg (n = 10). DoR and PFS data were not mature as of the cutoff date. **Conclusions:** IBI130 was well tolerated featured by superiority of hematological safety, and encouraging efficacy of IBI130 was observed in advanced TNBC, supporting its potential as a best-in-class TROP2 ADC. Clinical trial information: NCT05923008. Research Sponsor: Innovent Biologics (Suzhou) Co., Ltd.

1103 Poster Session

SHR-A1811 plus adebrelimab in unresectable or metastatic triple-negative breast cancer: Results from a phase 1b/2 expansion cohort. First Author: Yan Liang, The First Affiliated Hospital of Nanjing Medical University, Nanjing, China

Background: SHR-A1811 is a novel HER2-directed antibody-drug conjugate with promising antitumor activity in breast cancer (BC), yielding a confirmed objective response rate (ORR) of 79.4% in HER2 positive BC, 60.9% in HER2 low-expressing BC, and 52.0% in triple-negative BC (TNBC) as monotherapy. We evaluated SHR-A1811 in combination with adebrelimab (anti-PD-L1 antibody), pyrotinib (irreversible, pan-HER receptor tyrosine kinase inhibitor), pertuzumab, or albumin-bound paclitaxel in unresectable or metastatic breast cancer in an open-label, dose-finding and efficacy expansion phase 1b/2 study. Here, we report the safety and efficacy results of the SHR-A1811 plus adebrelimab cohort. **Methods:** Patients (pts) with unresectable or metastatic TNBC and ≥1 line of prior treatment received intravenous SHR-A1811 at an escalating dose of 4.8 mg/kg and 5.6 mg/kg Q3W, in combination with adebrelimab (1200 mg Q3W) in phase 1b part. In phase 2 part, TNBC pts with no systematic antitumor therapy in the recurrent or metastatic setting were treated with SHR-A1811 at 4.8 mg/kg Q3W plus adebrelimab. Primary endpoints were safety and ORR. The data cutoff date was Nov 30, 2024. **Results:** Fifty TNBC pts were enrolled in total. In phase 1b, 8 pts were enrolled and treated. No DLT was observed. The confirmed ORR was 66.7% (2/3) and 60.0% (3/5) in the 4.8 mg/kg and 5.6 mg/kg dose group, respectively. In phase 2, 42 treatment naive TNBC pts were enrolled. 13 (31.0%) pts had ≥3 metastases sites, 22 (52.4%) pts were HER2-low (IHC 2+/ISH- or IHC 1+)/ultra-low (IHC 0-1), 20 (47.6%) pts were HER2-nul (IHC 0), and 30 (71.4%) pts were PD-L1-positive (CPS ≥1). At the time of data cutoff, the median follow-up time was 4.6 mo (range, 0.2-10.4). Among efficacy evaluable TNBC pts, the overall ORR was 66.7% (26/39) (Table). ORR was 77.8% (21/27) in the PD-L1-positive subgroup. The 6-month PFS rate was 86.2%. SHR-A1811 plus adebrelimab was well tolerated with no new safety concerns identified. Treatment-emergent adverse events of grade ≥3 occurred in 26 (61.9%) out of 42 pts in phase 2, with decreased neutrophil count (45.2%), decreased white blood cell count (33.3%), and decreased lymphocyte count (9.5%) being the most common. **Conclusions:** SHR-A1811 plus adebrelimab had a good safety and tolerability profile. The combination showed encouraging antitumor activity in unresectable or metastatic TNBC, irrespective of HER2 or PD-L1 expression status. Clinical trial information: NCT05353361. Research Sponsor: Jiangsu Hengrui Pharmaceuticals.

Phase 2 preliminary efficacy summary[1].

	SHR-A1811 4.8 mg/kg + adebrelimab		
	CPS ≥1 (N = 30)	CPS <1 (N = 12)	Total (N = 42)
ORR, Overall[2]	21/27 (77.8)	5/12 (41.7)	26/39 (66.7)
HER2-low/-ultralow	11/13 (84.6)	4/9 (44.4)	15/22 (68.2)
HER2-nul	10/14 (71.4)	1/3 (33.3)	11/17 (64.7)
6-mo PFS rate, % (95% CI)	88.9 (43.3, 98.4)	78.8 (38.1, 94.3)	86.2 (60.7, 95.7)

[1]HER2 and PD-L1 results were based on central lab assessment.

ETER901: A randomized, open-label, phase III trial of anlotinib in combination with anti-PD-L1 antibody benmelstobart (TQB2450) versus nab-paclitaxel in first-line treatment of recurrent or metastatic triple-negative breast cancer. First Author: Jiayu Wang, National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China

Background: Recurrent or metastatic triple-negative breast cancer (TNBC) represents an aggressive malignancy with unfavorable prognoses. Benmelstobart (TQB2450) is a humanized monoclonal antibody targeting PD-L1, and anlotinib (ALTN) is an anti-angiogenic oral multi-target tyrosine kinase inhibitor. Herein, we present the findings of a randomized, open-label, phase 3 study comparing the combination of benmelstobart plus ALTN with nab-paclitaxel as first-line treatments for patients (pts) with recurrent or metastatic TNBC. **Methods:** In this phase 3 trial, patients with previously untreated stage IV or recurrent/metastatic TNBC were randomly allocated in a 1:1 ratio. One group received 1200 mg of intravenous benmelstobart on day 1, along with 12 mg of oral ALTN from days 1 to 14, following a 3-week cycle. The other group was administered 100 mg/m² of intravenous nab-paclitaxel on days 1, 8, and 15 within a 4-week cycle. Randomization was stratified based on whether patients had received neoadjuvant or adjuvant taxane therapy and the presence or absence of liver or brain metastases at baseline. The primary endpoint was progression-free survival (PFS), evaluated by the blinded independent central review by RECIST version 1.1. **Results:** The initial plan was to enroll 332 pts in this trial. However, due to the COVID-19 pandemic, the enrollment process was delayed, and recruitment was terminated in January 2023. Eventually, 147 pts were randomized (with a median follow-up of 14 months), among whom 75 were assigned to the benmelstobart plus ALTN group and 72 to the nab-paclitaxel group. In the intention-to-treat analysis, as assessed by the investigators, the median PFS was 7.85 months for the benmelstobart plus ALTN combination, in contrast to 5.55 months for nab-paclitaxel (hazard ratio, 0.70; 95% confidence interval, 0.46 to 1.06; P = 0.1687). The median overall survival was 35.81 months for study group and 21.03 months for control group (hazard ratio, 0.78; 95% confidence interval, 0.49 to 1.24; P = 0.2625). Grade ≥3 drug-related adverse events occurred in 56.5% of the patients in the study group and 36.6% in the control group. The most prevalent grade ≥3 adverse events in the study group were hypertension (28.0%) and hypertriglyceridemia (13.3%). **Conclusions:** The combination of benmelstobart plus ALNT might extend both progression-free survival and overall survival in the first-line treatment of patients with recurrent or metastatic TNBC. The adverse events were in line with the previously established safety profiles of each individual agent. (Funded by Chia Tai Tianqing Pharmaceutical Group Co., Ltd. ClinicalTrials.gov number, NCT04405505). Clinical trial information: NCT04405505. Research Sponsor: Chia Tai Tianqing Pharmaceutical Group Co., Ltd.

Clinical, sociodemographic, and facility-related determinants of immunotherapy use in metastatic triple-negative breast cancer. First Author: Ismail Ajjawi, Yale School of Medicine, New Haven, CT

Background: Immunotherapy has emerged as a promising treatment option for metastatic triple-negative breast cancer (mTNBC), yet the factors influencing its adoption remain poorly understood. This study investigates the clinical, sociodemographic, and facility-related determinants of immunotherapy use in patients with mTNBC from 2015 to 2020, utilizing data from the National Cancer Database (NCDB). **Methods:** We conducted a retrospective cohort study of mTNBC patients from the NCDB between 2015 and 2020, categorizing them into two groups: those who received immunotherapy and those who did not. Patients were excluded if they had missing data on key variables such as immunotherapy receipt and clinical characteristics (e.g., tumor stage, subtype). Univariable and multivariable logistic regression analyses were performed to identify factors influencing immunotherapy adoption. The impact of immunotherapy on overall survival was assessed using Cox proportional hazards regression analysis. Overall survival between the two groups was compared using the log-rank test. **Results:** A total of 1,887 mTNBC patients were included in the study: 1,656 (87.8%) did not receive immunotherapy, and 232 (12.2%) received immunotherapy. Multivariable logistic regression identified several factors associated with immunotherapy use. Later year of diagnosis (2018-2020: OR 5.35, $p < 0.001$) and academic facilities (OR 1.43, p = 0.044) were positively associated with immunotherapy use. In contrast, older age (71+: OR 0.49, p = 0.019), facilities in rural areas (OR 0.43, p = 0.042), Black race (OR 0.73, p = 0.039), Hispanic ethnicity (OR 0.53, p = 0.026), and higher Charlson comorbidity scores (OR 0.31, p = 0.035 for scores ≥2) were associated with a lower likelihood of receiving immunotherapy. Insurance status did not significantly influence immunotherapy use. Log-rank test showed that patients receiving immunotherapy had significantly improved survival compared to those who did not (Figure 1). The median survival for patients receiving immunotherapy was 2.21 years (95% CI: 1.80–2.96), compared to 1.01 years (95% CI: 0.93–1.11) for those not receiving immunotherapy (log-rank $p < 0.001$). Cox regression analysis showed that immunotherapy use was associated with a significantly reduced risk of death (HR 0.59, 95% CI: 0.46–0.77, $p < 0.001$). **Conclusions:** Immunotherapy use in mTNBC has increased in recent years, with clinical, sociodemographic, and facility-related factors influencing its adoption. Patients receiving immunotherapy had significantly better survival outcomes. Our findings highlight the importance of addressing disparities in access to immunotherapy, particularly related to race, age, ethnicity, and comorbidity burden, to ensure equitable treatment and outcomes for all mTNBC patients. Research Sponsor: None.

1106 Poster Session

Chemokines as predictive biomarkers for immune checkpoint inhibitor (ICI) efficacy in triple negative breast cancer (TNBC). First Author: Shipra Gandhi, Roswell Park Comprehensive Cancer Center, Buffalo, NY

Background: TNBC, although an aggressive breast cancer (BC) subtype, is highly immunogenic and the only BC subtype where the ICI pembrolizumab is approved. However, predictive biomarkers for pembrolizumab benefit are limited. The chemokines *CXCL9* and *CXCL10* attract $CD8^+$ T cells into the tumor microenvironment (TME) and are associated with chemotherapy benefit, but little is known about their role in prediciting pembrolizumab benefit in TNBC. We investigated the association of *CXCL9*, *CXCL10* and their cognate receptor *CXCR3* with TME and ICI efficacy. **Methods:** 3,038 TNBC samples were analyzed via NGS (592-gene panel, NextSeq; WES/WTS, NovaSeq; Caris Life Sciences, Phoenix, AZ). Tumor mutational burden (TMB) totaled somatic mutations per tumor (high > 10 mt/MB). Immune cell fractions were estimated using WTS deconvolution (Quantiseq). *CXCL9*/*CXCL10*/*CXCR3*-high (H) and -low (L) tumors were classified by RNA expression above or below the 50th percentile. Real-world overall survival (OS) was derived from insurance claims and calculated from start of pembrolizumab to last contact using Kaplan-Meier. Statistical significance was assessed using chi-square and Mann-Whitney U with multiple comparison adjustments ($q < .05$). **Results:** TNBC expressed higher levels of *CXCL9* and *CXCL10* (median (TPM): 5.3 and 14.7) compared to N = 1,082 HER2+ (4.8 and 10.3, $p < 0.05$) and N = 4,918 HR+HER2- (2.7 and 7, $q < .05$) BC. *CXCR3* expression was higher in TNBC compared to HR+HER2- (1.9 vs 1.7, $q < .05$), but no difference when compared to HER2+ (1.9 vs 2, q = 0.97) BC. *CXCL9*/*CXCL10*/*CXCR3*-H TNBC had higher median OS post pembrolizumab [*CXCL9*-H vs -L: 26.5 vs 15.7 months (mo), HR: 0.65 (95% CI 0.5-0.84); *CXCL10*-H vs -L: 26.0 vs 20.6 mo, HR 0.74 (0.57-0.95); *CXCR3*-H vs -L: 32.6 vs 18.3 mo, HR 0.68 (0.52-0.88), all $p < 0.05$]. *CXCL9*-H, *CXCL10*-H and *CXCR3*-H had higher PD-L1 positivity (22C3), TMB high, higher T cell inflamed score, *TP53* mutations, elevated B and $CD8^+$T cells infiltration, but not neutrophils, and higher expression of immune checkpoint genes (Table). **Conclusions:** High *CXCL9*/*CXCL10*/*CXCR3* expression is associated with longer survival in patients with TNBC post pembrolizumab, and characterized by an immune-enriched TME. Further investigation is needed to evaluate this chemokine axis in TNBC and its potential as a therapeutic target to enhance ICI efficacy. Research Sponsor: NIH (NCATS, NCI); K08CA279766-01A1.

Comprehensive molecular and immune characterization of adrenergic stress-signaling receptor *ADRB2* in triple negative breast cancer (TNBC). First Author: Sachin Kumar Deshmukh, Caris Life Sciences, Phoenix, AZ

Background: Chronic stress-mediated β2-adrenergic receptor (β2-AR) signaling promotes tumor growth via immunosuppression in the tumor microenvironment (TME) in preclinical models. Blockade of β2-AR has shown higher survival benefit in patients with TNBC in observational studies compared to other breast cancer (BC) subtypes. However, the molecular and immunological features associated with *ADRB2* (gene for β2-AR) gene expression in TNBC are unknown, prompting this investigation. **Methods:** 3,038 TNBC samples were analyzed via NGS (592-gene panel, NextSeq; WES/WTS, NovaSeq; Caris Life Sciences, Phoenix, AZ). Immune cell fractions were calculated by deconvolution of WTS: Quantiseq. TNBC *ADRB2*-high(H) and *ADRB2*-low(L) RNA expression were classified as above or below the 50^{th} percentile, respectively. Real-world overall survival (OS) was obtained from insurance claims and calculated from tissue collection to last contact using Kaplan-Meier estimates. Statistical significance was assessed using chi-square and Mann-Whitney U tests with multiple comparison adjustments ($q < 0.05$). **Results:** *ADRB2* gene expression was lowest in TNBC (median (TPM: 1.6) compared to N = 453 HR-HER2+ (1.9), N = 629 HR+HER2+ (2.0) and N = 4,918 HR+HER2- (2.2) BC (all $q < 0.05$). African American or Black patients (N = 670) had lower expression of *ADRB2* compared to European American or White (N = 1,412) TNBC patients (1.3 vs 1.7, $q < 0.05$). *ADRB2*-H TNBC had higher mutation frequency of *PIK3CA* (21% vs 15.4%), *CDH1* (7% vs 3.5%), *NF1* (8% vs 4%), *AKT1* (3.5% vs 2.1%), but lower frequency of *TP53* (81.6% vs 87.5%), *NOTCH1* (2.5% vs 4.5%) and *NOTCH3* (4.4% vs 11.7%) compared to *ADRB2*-L, all $q < 0.05$. *ADRB2*-H had greater PD-L1 (22C3) positivity (39.1% vs 30.2%, $q < 0.05$), higher % of B cells (4.5 vs 3.4), M1 Mφ (3.4 vs 2.8), M2 Mφ (3.9 vs 2.2), Tregs (2.2 vs 1.3), NK cells (3.1 vs 2.6), DC (3.1 vs 2.9), $CD8^+$ T cells (0.9 vs 0.2), all $q < 0.05$. *ADRB2*-H TNBC had higher T-cell inflamed score (95 vs -80), *IFNγ* score (-0.23 vs -0.37), MAPK activation score (-0.46 vs -1.7), all $q < 0.05$; and higher expression of immune checkpoint genes (*CD274, PDCD1, PDCD1LG2, CTLA4, LAG3, HAVCR2, FOXP3, IDO1, TNFSF14, TIGIT, BTLA, CEACAM1, CD47, CD274*; fold change: 1.6-3.7, all $q < 0.05$). *ADRB2*-H tumors had higher expression of genes related to inflammatory response, IFNγ response, IL6-JAK-STAT3 signaling (normalized enrichment score (NES): 1.9 – 2.1), while *ADRB2*-L had enrichment of MYC targets V1, MYC targets V2, E2F targets and G2M checkpoint (NES: 2.5 – 4.2), all FDR < 0.01. *ADRB2*-H TNBC had better OS (mOS: 23.6 vs 18.6 months; HR 0.81, 95% CI 0.73-0.89, $p < 0.0001$) compared to *ADRB2*-L. **Conclusions:** High *ADRB2* expression in TNBC is associated with better survival and an immune enriched TME, elevated immune checkpoints and other targetable vulnerabilities. Future studies are needed to investigate *ADRB2* as a potential stress biomarker and therapeutic target. Research Sponsor: NIH (NCATS and NCI); K08CA279766-01A1.

Enhanced efficacy of inavolisib combined with anti-PD-1 or anti-HER2 antibody in treating brain metastases from breast cancer. First Author: Jian-Li Zhao, Sun Yat-sen Memorial Hospital, Sun Yat-Sen University, Guangzhou, China

Background: The PI3K/AKT/mTOR signaling pathway is a crucial regulatory pathway involved in cell proliferation, survival, migration, and metabolism. This dysregulation can occur through various mechanisms, such as PIK3CA gene mutations and PTEN gene loss. The research of PI3K inhibitors has made significant progress in the treatment of ER-positive and HER2-negative breast cancer. Alpelisib is the only approved PI3K inhibitor for treating PIK3CA mutation-positive breast cancer. The SOLAR-1 trial demonstrated that Alpelisib combined with endocrine therapy significantly prolongs progression-free survival in these patients. However, despite improving PFS, the side effects of PI3K inhibitors pose limitations on their widespread application. Consequently, researchers are exploring next-generation PI3K inhibitors with improved safety and efficacy. Inavolisib is a novel, highly selective PI3Kα inhibitor that shows better tolerability and safety compared to existing PI3K inhibitors and has demonstrated promising antitumor effects in clinical trials. Building on this, our study aims to identify the optimal treatment regimen combining Inavolisib with various breast cancer therapies to effectively target brain metastases. **Methods:** We established a brain metastasis model in C57BL/6 mice by intracardiac injection of control (triple-negative) and hHER2+ Py8119 breast cancer cells. In addition to the Inavolisib monotherapy and vehicle control groups, Inavolisib was combined with a PD-1 antibody or albumin-bound paclitaxel in the triple-negative model. In the HER2+ model, Inavolisib was combined with Tucatinib, trastuzumab, or SHR-A1811 (an ADC drug targeting HER2). We monitored changes in body weight and survival rates in each group and assessed brain metastasis using IVIS small animal in vivo imaging. **Results:** In the triple-negative model, Inavolisib monotherapy or its combination with albumin-bound paclitaxel reduced intracranial tumor size but did not significantly extend mouse survival. Conversely, the combination of Inavolisib and PD-1 antibody significantly prolonged overall survival in triple-negative breast cancer mice. In the HER2+ breast cancer model, all three combination therapies reduced tumor burden and extended survival compared to monotherapy. However, overall, the combination with trastuzumab achieved unexpectedly good results, which were comparable to SHR-A1811 and superior to Tucatinib. **Conclusions:** Our findings suggest that the combination of the PI3K inhibitor Inavolisib with anti-PD-1 or anti-HER2 antibody therapy may offer an effective strategy for treating brain metastases in breast cancer. This discovery provides new insights and possibilities for improving treatment options in breast cancer brain metastasis. Further research is needed to validate the efficacy and safety of this combination therapy. Research Sponsor: None.

Efficacy and safety of RC48-ADC in triple-negative breast cancer subtypes: FUSCC-TNBC-umbrella trial results. First Author: Yin Liu, Fudan University Shanghai Cancer Center, Shanghai, China

Background: RC48-ADC is a novel HER2-targeting antibody-drug conjugate. This study evaluated RC48-ADC in pretreated triple-negative breast cancer (TNBC) patients with low HER2 expression, stratified by AR status. **Methods:** In this phase Ib/II trial, pretreated metastatic TNBC patients with low HER2 expression were enrolled: RL group (LAR subtype, n=20) and RO group (non-LAR subtype, n=20). All received RC48-ADC 2.0 mg/kg intravenously every 2 weeks. Primary endpoint: objective response rate (ORR). Secondary endpoints: progression-free survival (PFS), overall survival (OS), disease control rate (DCR), and safety. **Results:** 40 heavily pretreated patients were enrolled (median 2 previous lines, range 1-7). In the overall population, best ORR was 35.0% (confirmed ORR: 32.5%), DCR 47.5%, median PFS 4.0 months. RL group showed better outcomes: best ORR 45.0% vs 25.0%, confirmed ORR 40.0% vs 25.0%, DCR 50.0% vs 45.0%, median PFS 4.9 vs 3.1 months. Median OS was not reached in RL group vs 16.6 months in RO group. Most common treatment-related adverse events (TRAEs) were AST increased (70% vs 40%) and ALT increased (65% vs 20%), mostly grade 1-2. Peripheral neuropathy occurred in 15% (RL) and 10% (RO) patients. Hematologic toxicities were mild. No treatment-related deaths occurred. **Conclusions:** RC48-ADC showed promising antitumor activity with manageable safety in pretreated TNBC patients with low HER2 expression, particularly in LAR subtype. The 35.0% ORR in heavily pretreated TNBC warrants further investigation in biomarker-selected populations. Clinical trial information: NCT03805399. Research Sponsor: None.

Artificial Intelligence-based tumor microenvironment and PD-L1 analysis using digital pathology to predict pembrolizumab response in metastatic triple-negative breast cancer. First Author: Jee Hung Kim, Division of Medical Oncology, Department of Internal Medicine, Gangnam Severance Hospital, Yonsei University College of Medicine, Seoul, NA, South Korea

Background: The combination of pembrolizumab and chemotherapy improves survival in programmed death ligand 1 (PD-L1) positive metastatic triple-negative breast cancer (mTNBC). However, responses vary even among PD-L1 positive, and predictive biomarkers remain undefined. This study investigates the predictive biomarkers to pembrolizumab through digital pathology and artificial intelligence (AI)-based tumor microenvironment (TME) and PD-L1 analysis. **Methods:** We retrospectively analyzed 53 PD-L1 positive, mTNBC patients treated with pembrolizumab at Gangnam Severance Hospital (2017–2024). PD-L1 positivity was defined as a combined positive score (CPS) $\geq$ 10. Immune phenotypes and immune cell density in both tumor and stroma were analyzed in 67 H&E images using Lunit SCOPE IO, an AI-powered whole slide image analyzer. PD-L1 CPS was analyzed in paired PD-L1 staining images by both Lunit uIHCv2 analyzer and pathologists. Samples were categorized as pre-(pre) or post-treatment (post). Pre-samples were collected before any therapy exposure, while post-samples were obtained after recurrence following neo/adjuvant therapy. These features were analyzed for their association with pembrolizumab response and clinical outcome. **Results:** With a median follow-up of 13.2 months, the median age was 53 years, and 16 patients (22.5%) were *de novo* stage IV TNBC. AI-assessed PD-L1 positivity was seen in 52.2% (35/67) of cases, compared to 74.6% (50/67) by pathologist. Overall, AI-based PD-L1 positive cases had a median progression-free survival (mPFS) of 8.8 months (mo) vs 6.7 mo in PD-L1 negative (p = 0.028), while pathologist-reported cases showed 7.9 mo vs 6.3 mo, respectively (p = 0.17). AI-based PD-L1 positivity in pre-samples was associated with better PFS with pembrolizumab (mPFS 7.7 mo vs 4.4mo, HR 0.32, p = 0.014), while post-samples showed no significant association (mPFS 7.3 mo vs 6.4mo, HR 0.69, p = 0.4). Notably, post-samples (50.0%) had a higher proportion of cases with AI-based CPS $\geq$ 10 compared to pre-samples (36.4%), primarily driven by increased PD-L1-expressing macrophages, as revealed by AI-based cell composition analysis (22.7% vs 7.7%, p = 0.0007). When categorized by AI-based immune phenotype, notable differences were seen between pre/post-samples despite PD-L1 positivity. Post-samples showed a higher prevalence of the immune-desert phenotype, reflecting significant changes in the TME following prior therapy exposure (40.0% vs 20.0%, p = 0.06). **Conclusions:** This study highlights the role of the TME and PD-L1 assessed by AI in predicting pembrolizumab response in mTNBC. While PD-L1 positivity in pre-samples was associated with outcome, PD-L1 positivity in post-samples showed limited association with PFS, potentially influenced by immune desert phenotype and increased PD-L1-expressing macrophages. Research Sponsor: None.

Geographic access to triple negative breast cancer (TNBC) clinical trials: Are trials located near Black women? First Author: Laura Burns Amin, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Despite recent treatment advances, TNBC has a poor prognosis relative to other breast cancer subtypes. Black women in the U.S. are more likely to be diagnosed with TNBC, are diagnosed at more advanced stages, and have higher mortality even after controlling for socioeconomic variables than women of other races. Although clinical trials are essential to improving TNBC treatment, Black women are underrepresented. We investigated the geographic availability of TNBC clinical trials for Black women in the U.S. to elucidate potential trial access limitations. **Methods:** All trials registered on ClinicalTrials.gov as of 9/30/2024 were queried (N= 510,397). Phase II and III interventional treatment trials in active status in the U.S. including "breast" in the title or disease variable (n =449) were considered. We narrowed results to TNBC trials through keyword searches of title and disease variables (e.g., TNBC, HER2 negative and hormone receptor negative). We tabulated the number of trials per county and supplemented with 5-year population estimates (2018-2022) and county adjacency data from the U.S. Census Bureau to evaluate for geographic and demographic differences in TNBC trial availability. **Results:** We identified 108 active TNBC trials (58 metastatic [54%], 50 nonmetastatic [46%]), including 87 Phase II (81%) and 21 Phase III (19%). There were 1,230 U.S. study sites, of which 217 had one active TNBC trial (18%), 529 had 2-4 trials (43%), and 484 had $\geq$5 trials (39%). Most sites had metastatic and nonmetastatic offerings (700, 57%) while 450 sites had only non-metastatic trials (37%) and 80 had only metastatic trials (7%). State-level differences in trial availability were observed (see Table). For example, 37% of Black and 34% of non-Black women 18+ in Alabama had no TNBC trials in their or neighboring counties while all women 18+ in nine states had a trial available in at least a neighboring county. **Conclusions:** A geographical analysis of active Phase II and III therapeutic TNBC clinical trials found uneven trial availability across the country. Most study sites had $<$ 5 TNBC trials available; a third of sites had no metastatic trials, suggesting that many women may have difficulty finding an applicable trial even when near to a site. On a national scale, distance does not appear to be a primary reason for disparities in TNBC trial participation for Black and non-Black women. Nevertheless, millions of women live in areas without any trials, therefore expanding geographic reach is a necessary but insufficient approach to improve access. Research Sponsor: None.

Category (Number of Counties)	Black women 18+ in millions (%)	Non-Black women 18+ in millions (%)	Total in millions (%)
Counties with trial (748)	14 (82%)	88 (77%)	102 (78%)
Trials only in adjacent county (1452)	2 (12%)	21 (18%)	22 (17%)
No trials in county nor adjacently (944)	1 (6%)	6 (5%)	7 (5%)
Total (3144)	17 (100%)	115 (100%)	131 (100%)

Immunotherapy vs. chemotherapy run-in followed by pembrolizumab plus nab-paclitaxel in metastatic triple negative breast cancer (mTNBC): Results from a phase II study. First Author: Alessandro Leal, Perlmutter Cancer Center, NYU Langone Health, New York, NY

Background: Pembrolizumab (pembro) with chemotherapy has shown survival benefit in PD-L1+ (CPS10+) mTNBC, but many responses are not durable, and patients with PD-L1 negative/low tumors do not benefit from the combination. Data from GeparNuevo and TONIC suggest that induction therapy can remodel the tumor immune environment and improve responses. We have conducted a trial with two run-in cohorts and mandatory serial tissue and blood collections in 50 mTNBC patients, comparing pembro vs. nab-paclitaxel (nab-P). **Methods:** Single-arm, single institution phase II study (NCT02752685) to evaluate safety and clinical activity of nab-P+pembro in PD-L1 unselected mTNBC, 0-2 prior lines of chemotherapy allowed. Patients (n = 50) were enrolled sequentially into two cohorts: chemotherapy run-in (cTNBC, nab-P before nab-P+pembro) and immunotherapy run-in (iTNBC, pembro before nab-P+pembro). Serial tumor biopsies assessed by IHC (Dako 22C3), quantitative multiplex immunofluorescence (qMIF), and gene expression (NanoString). Overall response rates assessed using irRECIST. Tumoral T- and myeloid-cell phenotypes, peripheral lymphocyte-to-neutrophil ratio (LNR), and monocyte-to-lymphocyte ratio (MLR) were correlated with overall response rate (ORR) and survival outcomes. **Results:** 50 patients enrolled and completed treatment, for 80% of patients: treatment was 1L for metastatic disease. Median follow-up is 19.9 months, clinical results for cTNBC and iTNBC cohorts shown in table. Across both cohorts higher LNR was associated with improved OS (R= 0.37, p= 0.0075), conversely, higher MLR was associated with poorer OS (R= -0.46, p= 0.00087). Tumor immune cell subpopulations showed no significant differences between iTNBC and cTNBC at baseline. Analyses of on-treatment samples will be presented at the meeting. PD-L1 expression, while not different at baseline, remained unchanged in cTNBC but increased significantly in iTNBC ($p < 0.02$), possibly reflecting pembrolizumab-driven immune modulation. With the caveat of comparing sequential cohorts, the iTNBC cohort showed a trend for higher ORR (47% vs. 23%, p= 0.08) and longer median PFS (8.4 vs. 5.5 months, HR = 0.68, 95%CI: 0.37-1.24), with significantly longer OS (25.8 vs. 18 months, HR = 0.50, 95%CI: 0.26-0.98, p = 0.043) compared to cTNBC. **Conclusions:** Timing of pembro administration may influence PD-L1 expression and clinical outcomes in mTNBC. We show that the immunotherapy run-in strategy converts more PD-L1-negative/low into PD-L1-positive tumors, possibly rendering more patients eligible for chemoimmunotherapy and improving outcomes. Clinical trial information: NCT02752685. Research Sponsor: Merck & Co., Inc.

	cTNBC (n=30)	iTNBC (n=20)

Trop2-targeted PET/CT with ^{68}Ga-MY6349 for the diagnosis of primary and metastatic breast cancer and evaluation towards patient stratification in Trop2-targeted ADCs. First Author: Liang Zhao, The First Affiliated Hospital of Xiamen University, Xiamen, China

Background: Trop2-targeted ADCs have demonstrated promising efficacy and have been approved in patients with HR+HER2- and triple-negative breast cancer (TNBC). However, not all patients within these subtypes benefit equally from such treatment, highlighting the urgent need for developing tools for patient selection and stratification. We have previously developed a novel PET/CT imaging agent (^{68}Ga-MY6349) that specifically targets Trop2, which has shown high specificity for Trop2 in preclinical and clinical studies (DOI: 10.1172/JCI185408). **Methods:** This study enrolled patients with newly diagnosed or previously treated breast cancer at the First Affiliated Hospital of Xiamen University between January 2024 and December 2024. All patients underwent paired ^{18}F-FDG PET/CT and ^{68}Ga-MY6349 PET/CT imaging. SUVmax derived from the two PET/CT modalities and pathological results were recorded to evaluate the tumor uptake pattern and lesion detectability of the two imaging modalities. **Results:** A total of 61 patients were prospectively enrolled, including 7 true-negative and 54 true-positive cases. Among the 562 true-positive lesions, ^{68}Ga-MY6349 uptake (SUVmax) was significantly associated with breast cancer subtypes ($P<0.001$, Kruskal-Wallis H=34.9). SUVmax values were highest in HR+/HER2- [7.2 (4.4–9.4)], followed by TNBC [5.2 (3.8–6.4)], HER2+ [4.8 (1.7–7.4)], and HR+/HER2+ [3.3 (2.1–8.1)]. In HR+/HER2- subtypes, ^{68}Ga-MY6349 demonstrated significantly higher uptake compared to ^{18}F-FDG [7.2 (4.4–9.4) vs. 3.6 (2.3–5.5), $P<0.001$]. However, no significant difference regarding tumor uptake was observed in other subtypes. In 27 patients with HR+/HER2- subtypes, ^{18}F-FDG PET/CT detected 139/208 lesions (missing 2 primary, 40 visceral and bone metastases, and 27 lymph node metastases), while ^{68}Ga-MY6349 PET/CT detected 202/208 lesions (missing 1 visceral and bone metastasis and 5 lymph node metastases). Interestingly, among 215 lesions in 16 TNBC patients, ^{18}F-FDG PET/CT detected 206 metastatic lesions (missing 9 lymph node metastases), whereas ^{68}Ga-MY6349 PET/CT detected all lesions. For HER2+ (7 patients with 74 lesions) and HR+/HER2+ (4 patients with 65 lesions) subtypes, the two tracers exhibited comparable lesion detectability. **Conclusions:** ^{68}Ga-MY6349 PET/CT demonstrated superior uptake and greater lesion detectability compared to ^{18}F-FDG PET/CT in patients with HR+/HER2- breast cancer. The high uptake of ^{68}Ga-MY6349 in HR+/HER2- and TNBC lesions may partially explain the favorable clinical outcomes observed with Trop2-targeted ADCs in these subtypes, suggesting its potential role for patient selection and stratification for Trop2-targeted therapies. However, the observed heterogeneity in uptake warrants further investigation to clarify its applications across different patient populations. Clinical trial information: NCT06188468. Research Sponsor: None.

1114 Poster Session

Comprehensive characterization of interleukin-enhanced factor 2 (ILF2) in triple-negative breast cancer (TNBC). First Author: Matias Alberto Bustos, Saint John's Cancer Institute at Providence Saint John's Health Center, Santa Monica, CA

Background: While treatment and management of TNBC has improved, there is a need for novel prognostic biomarkers to better inform outcomes and guide therapeutic options. *ILF2* is a poorly characterized protein with pleiotropic functions that is highly expressed in TNBC. Here we evaluated the associations of *ILF2* with 1) genomic and transcriptomic data, 2) tumor microenvironment (TME), and 3) clinical outcomes in TNBC. **Methods:** 15,544 breast cancer (BC) samples, including 3,038 TNBC, were tested by NGS (592, NextSeq; WES, NovaSeq) and WTS (NovaSeq; Caris Life Sciences, Phoenix, AZ). *ILF2*-high (H) and *ILF2*-low(L) TNBC were defined by respective quartiles. Immune cell fractions were estimated by WTS deconvolution (Quantiseq). Real world overall survival (OS) was obtained from insurance claims and calculated from tissue collection to last contact using Kaplan-Meier estimates. Statistical significance was determined by chi-square, Fisher's exact, and Mann-Whitney U test with p-values adjustments ($q < .05$). **Results:** *ILF2* expression (median Log2(TPM+1) was higher (all $q < .05$) in key subgroups: ductal compared to lobular carcinoma (6.4 vs 6.0); primary compared to metastatic BC (6.4 vs 6.3); African American compared to White (6.4 vs 6.3); basal compared to luminal A, luminal B, HER2 PAM50 subtypes (6.9 vs 5.8, 6.3, 6.3); and TNBC compared to HR+HER2+, HR-HER2+, HR+HER2- subtypes (6.7 vs 6.3, 6.4, 6.2). Biopsied tissues from primary TNBC (pTNBC) and metastatic TNBC (mTNBC) patients were stratified into *ILF2*-H and *ILF2*-L groups. In both mTNBC and pTNBC, *ILF2*-H groups had 1) higher percentage of young patients (age < 50) (pTNBC: 35.5% vs 19.8%; mTNBC: 28.1% vs 17.3%; all $q < .05$); 2) higher mutation frequency of *TP53* (pTNBC: 94.5% vs 79.6%; mTNBC: 92.4% vs 74.4%), but lower frequencies for *PIK3CA* (pTNBC: 5.1% vs 23.4%, mTNBC: 8.8% vs 27.4%), *CDH1* (pTNBC: *0.8% vs 6.1%;* mTNBC: 2.8% vs 12.2%; all $q < .05$); 3) higher infiltration of NK cells (pTNBC: 3% vs 2.6%; mTNBC: 2.8% vs 2.6%), but lower infiltration of M2 Mφ (pTNBC: 2.5% vs 3.3%; mTNBC: 2.6% vs 3.2%) and Tregs (pTNBC: 1.5% vs 1.9%; mTNBC: 1.4% vs 1.7%; all $q < .05$); 4) higher expression levels of immune checkpoint (*CD274, PDCD1LG2, CTLA4, LAG3, HAVCR2, FOXP3, IDO1, CD276*, FC: 1.2-3.1; all $q < .05$), stem cell genes (*CD44, NANOG, POU5F1, KLF4, ALDH1A1*, FC: 1.4-2.4; all $q < .05$), and drug efflux genes (*ABCC3, ABCC11, ABCC2, ABCB1, ABCG2, ABCC1*, FC: 1.1-4.5; all $q < .05$) compared to *ILF2*-L group. In pTNBC, *ILF2*-H had significantly shorter OS vs *ILF2*-L group (22.3 vs 28.9 months, HR 1.2 [95% CI 1-1.5], p = .03), but no significant differences were observed between mTNBC *ILF2* groups (HR 1.1 [95% CI 0.93-1.3], p = .2). **Conclusions:** *ILF2*-H TNBC patients showed differential genomic and transcriptomic alterations that relate to therapy resistance, immune suppressive TME, and shorter OS. Further studies are warranted to validate the effects of *ILF2* upregulation on therapeutic efficacy. Research Sponsor: The Fashion Footwear Association of New York (FFANY) Foundation; None.

Concurrent GLP1R-agonist use with chemoimmunotherapy for early-stage triple-negative breast cancer. First Author: Bethania Santos, UT Southwestern Medical Center, Dallas, TX

Background: Glucagon-like peptide-1 receptor agonists (GLP-1RAs) have emerged as a key class of drugs for treating type 2 diabetes mellitus (DM2) and obesity. GLP-1 is rapidly degraded by DPP4, which led to the development of DPP4 inhibitors (DPP4i). Prior work has shown GLP-1R in tumor cells activates key growth signaling and GLP-1RA likely dampen inflammation. This suggests that GLP-1R activation may influence response rates to chemoimmunotherapy. This study aims to investigate the impact of GLP-1RAs and DPP4i (GLP1 drugs) exposure on pathological complete response (pCR) rates for patients with early-stage triple negative breast cancer (TNBC) receiving neoadjuvant chemoimmunotherapy. **Methods:** Patients with early-stage TNBC diagnosed between July 1, 2021, and December 31, 2023, who received the KEYNOTE-522 regimen were identified at three institutions. Patients using GLP-1RAs and DPP4i at breast cancer diagnosis and throughout the neoadjuvant period, alone or with other diabetes medications, were included. Those who started or discontinued GLP-1 drugs during chemoimmunotherapy were excluded. Group comparisons were made using Chi-square and two-sample t-tests. Human TNBCs were analyzed by IHC and CosMx 6000-plex spatial transcriptomics. **Results:** Among 343 patients, 7.5% were using GLP-1 drugs. The pCR rate among patients exposed to GLP-1 drugs was 30.8% compared to 64.4% in those not exposed (p = 0.001). For patients using other classes of DM2 medications (n = 46), the pCR rate was 65.2%, while for those not taking any DM2 medications (n = 271), the pCR rate was 64.2%. In univariate analysis, patients exposed to GLP-1 drugs were significantly older than non-exposed (median age: 60 vs. 51 years; p = 0.009), had a higher BMI (35.0 vs. 28.9 kg/m²; p = 0.002), and had higher rates of DM2, hypertension, and hyperlipidemia. In multivariate analysis, only age was associated with pCR (OR: 0.97, 95% CI: 0.96-0.99, p = 0.007). When comparing patients taking GLP-1 drugs with those using other DM2 medications, no significant differences were observed regarding age, BMI, or clinical T or N stage. To evaluate tumor-intrinsic factors that may influence treatment response, we examined TNBC specimens (n = 84) and identified GLP-1 receptor expression in tumor cells in 35.7% of cases and in the tumor microenvironment in 60.7% of cases. A spatial transcriptomics atlas of GLP-1 drug-exposed tumors (469,029 cells) provides evidence of GLP-1 pathway activity in both malignant and non-malignant cells of the tumor microenvironment. **Conclusions:** We observed significantly lower pCR rate among patients taking GLP1 drugs during neoadjuvant chemotherapy for TNBC. These effects were not observed with other diabetic medications. Detection of GLP1R expression in TNBC specimens indicates there may be direct and indirect effects of agonists to the GLP1 pathway on chemoimmunotherapy response rates. Research Sponsor: None.

HAI-score, an objective HER2 artificial intelligence method for accurate H-score estimation from IHC-stained breast cancer samples. First Author: Sahar Almahfouz Nasser, Emory University, Atlanta, GA

Background: Accurate HER2 assessment is essential for breast cancer (BC) treatment, as it directs targeted therapy decisions and predicts patient prognosis. While immunohistochemistry (IHC) is widely used, its manual scoring is susceptible to inter-observer variability. RNAscope, an RNA in situ hybridization (ISH)-based technique, has shown to have a strong correlation with HER2 protein levels and has outperformed AQUA, a high-throughput quantitative immunofluorescence imaging system, in detecting HER2-low cases. However, RNAscope is constrained by its higher cost and technical complexity compared to IHC staining assays. To address this, we propose the HAI-Score, an objective, robust, accessible, non-tissue disruptive, and fast Artificial Intelligence method for evaluating the H-score from IHC images, validated using RNAscope values. **Methods:** The dataset comprises 526 tissue microarray (TMA) cores for RNAscope and IHC evaluations. The dataset includes 100 commercially available BC cores (from TissueArray.Com) and 426 cores from 243 patients at MD Anderson Cancer Center. We digitized TMA cores stained with HercepTest (Dako) (S1 dataset, n=566) and Ventana Pathway 4B5 (Roche) (S2 dataset, n=580) assays. Half of the images were randomly allocated for training and the remaining half were used for validation. A computer vision algorithm detects cell membranes using a specially designed image filter based on domain knowledge. Different visual features were then extracted from these detected cell membranes, including perimeter, normalized area, Feret diameter, fractal dimension, porosity, and staining intensities. These features were used to train a neural network to predict the HAI-Score. The ground truth was defined as HER2 RNA levels measured by RNAscope. We evaluated the HAI-Score accuracy by correlating it (Pearson, R^2) with RNA values and compared it to correlations from AHSQ (a state-of-the-art deep learning model), an expert pathologist, and FDA-approved HER2 IHC assays (HercepTest, Ventana PATHWAY). **Results:** HAI-Score yielded a correlation of 0.85 and an R^2 value of 0.711 on the testing dataset, which includes images from both the S1 and S2. This performance surpassed AHSQ, the H-score by a breast pathologist, and the scores of two FDA assays with RNA values (Table 1). **Conclusions:** HAI-Score provides an objective alternative to evaluate HER2 expression. It is strongly correlated with HER2 RNA levels and was superior to evaluations by an experienced breast pathologist. Following additional independent multi-site validation, HAI-Score could enable treatment personalization, optimize better surgical planning, and reduce overtreatment. Impact of HER2-ultralow heterogeneity and optimal threshold on trastuzumab deruxtecan (T-DXd) efficacy in metastatic breast cancer: A national multicenter cohort study (HEROIC). First Author: Yutian Zou, Sun Yat-sen University Cancer Center, Guangzhou, China

Background: Trastuzumab deruxtecan (T-DXd) has been approved for patients (pts) with HER2-ultralow metastatic breast cancer (MBC). HER2 discordance commonly occurs between primary and metastatic lesions within the same patient; however, its incidence remains unknown in the HER2-ultralow era. Additionally, there is still controversy about which specimen to use to determine HER2-ultralow status and optimal threshold to guide T-DXd therapy. **Methods:** This national, multicenter cohort study included MBC pts treated with T-DXd (5.4 mg/kg) with HER2 status available for both primary tumors and matched metastases between January 2020 and October 2024 (NCT06551220). HER2 status was determined according to the DB-06 protocol. Pts were divided into three cohorts based on HER2 discordance patterns: cohort 1 (HER2-positive/low/ultralow in both primary and metastases), cohort 2 (HER2-positive/low/ultralow in primary and HER2-null in metastases), and cohort 3 (HER2-null in primary and HER2-positive/low/ultralow in metastases). Endpoints included progression-free survival (PFS), overall survival (OS), objective response rate (ORR), disease control rate, and clinical benefit rate. **Results:** From 24 centers nationwide, 3546 pts met the criteria and were included. The incidence of HER2 discordance between primary and matched metastases has changed across eras of HER2-positivity definitions: HER2-positive era (9.8%, K = 0.78), HER2-low era (25.0%, K = 0.39), and HER2-ultralow era (20.2%, K = 0.16). Among T-DXd-treated pts (n = 1052), a higher response rate was observed in cohort 1 (ORR = 55.7%) and cohort 3 (ORR = 53.1%) compared to cohort 2 (ORR = 13.0%). ORR is positively correlated with HER2 expression if metastatic lesions are used as the examined tissue (positive 62.9%, low 49.8%, ultralow 47.0%, null 13.0%). However, the correlation between ORR and HER2 expression is not significant when primary lesions were examined (positive 57.8%, low 41.5%, ultralow 54.4%, null 53.1%). Additionally, cohort 1 (mPFS = 11.6 mo, mOS = 30.7 mo) and cohort 3 (mPFS = 10.9 mo, mOS = 18.4 mo) exhibited significantly superior PFS and OS compared to cohort 2 (mPFS = 6.1 mo, mOS = 12.3 mo). Faint incomplete membrane staining percentage $\geq$5% in metastatic lesion was the best threshold to distinguish PFS (HR = 0.54, P= 0.02; mPFS, 11.4 vs 8.6 mo) and ORR (OR = 4.00, P= 0.01; 60% vs 27%) among HER2-ultralow MBC treated with T-DXd. **Conclusions:** A high HER2-ultralow discordance rate was observed between primary tumors and matched metastases. HER2 status in metastatic specimens more accurately predicts T-DXd efficacy compared to primary specimens. A staining threshold of $\geq$5% tumor cells in metastatic lesions may optimize T-DXd treatment in HER2-ultralow MBC. Therefore, re-evaluating HER2 status in metastatic lesions is recommended for T-DXd treatment decision. Research Sponsor: None.

Opioid use disorder among females with breast cancer: A comprehensive analysis of prevalence in the United States and associated factors. First Author: Aneri Sanepara, Pandit Deendayal Upadhyay Medical College, Rajkot, Gujarat, India

Background: Patients with breast cancer (BC) are frequently prescribed opioids for pain management, placing them at risk of opioid use disorder (OUD). This study analyzes the prevalence of OUD and identifies factors contributing to its risk among BC patients in the United States. **Methods:** We conducted a retrospective analysis using the National Inpatient Sample (NIS) database, a Healthcare Cost and Utilization Project (HCUP) component. Females with BC were identified through ICD-10 codes. The Cochran-Armitage trend test assessed OUD prevalence trends from 2016 to 2022. Multivariable regression models estimated the impact of multiple patient demographics and comorbidities on the presence of OUD. **Results:** Among 1,189,884 females aged$\geq$18 with BC, 2.3% (27,500) had OUD. The mean age of OUD patients was 58.38 years, compared to 64.46 years in the non-OUD cohort. OUD prevalence was highest in those aged 18–50 years (3.8%), followed by 51–60 years (3.0%), and lowest in those $>$ 60 years (1.7%). Between 2016 and 2020, OUD prevalence increased from 1.9% to 2.8%, followed by a decline to 2.4% in 2022 (p-trend $<$ 0.01). Factors that were linked with higher OUD involved patients with neoplasm-related pain(NRP)(aOR 5.718, 95% CI 5.549-5.893, $p < 0.01$), on palliative care (aOR 1.397, 95% CI 1.353-1.443, $p < 0.001$), with metastasis (aOR 1.573, 95% CI 1.526-1.621, $p < 0.01$), depression (aOR 1.447, 95% CI 1.400-1.495, $p < 0.01$), bipolar disorder (aOR 2.173, 95% CI 2.038-2.317, $p < 0.01$), suicidality (aOR 3.228, 95% CI 2.938-3.546, $p < 0.01$), and anxiety (aOR 1.617, 95% CI 1.572-1.664, $p < 0.01$). Moreover, substance use such as cocaine (aOR 5.252, 95% CI 4.708-5.859, $p < 0.01$) and amphetamine (aOR 3.948, 95% CI 3.443-4.527, $p < 0.01$) was also associated with higher odds, while cannabis users (aOR 0.876, 95% CI 0.793-0.968, $p < 0.01$) had lower odds of OUD. Our study further found racial disparities, with reduced odds among Blacks (vs Whites, aOR 0.933, 95% CI 0.901-0.967, $p < 0.01$) and Hispanics (vs.Whites, aOR 0.866, 95% CI 0.827-0.906, $p < 0.01$). Socio-economic differences were also noted, with lower odds among those of the 26th-50th (vs. 0-25th, aOR 0.932, 95% CI 0.9-0.966, $p < 0.01$), 51st-75th (vs. 0-25th, aOR 0.951, 95% CI 0.918-0.986, $p < 0.01$), and 76th-100th (vs. 0-25th, aOR 0.916, 95% CI 0.882-0.951, $p < 0.01$) household income quartiles. **Conclusions:** This study showcases the significant prevalence and impact of OUD among BC patients, identifying socioeconomic and racial disparities, and key risk factors such as NRP, psychiatric comorbidities, and concurrent substance use, like cocaine and amphetamines. Interestingly, cannabis use was associated with a lower risk of OUD, which may reflect its role as an alternative pain management strategy. Overall, this study suggests the need to adopt crucial preventative measures against OUD in patients exhibiting these characteristics. Research Sponsor: None.

Treatment patterns, genomic characteristics, and outcomes among patients with metastatic lobular breast cancer. First Author: Sherry Shen, Memorial Sloan Kettering Cancer Center, New York, NY

Background: Invasive lobular carcinoma (ILC) is characterized by loss of E-cadherin expression and accounts for 10-15% of breast cancer diagnoses. ILC differs from the more common invasive carcinoma of no special type in the pattern of metastatic spread and genomic characteristics; however, clinicopathologic characteristics among patients with metastatic ILC are not well described. Here, we present comprehensive treatment, genomic, and outcome data in a large single-center cohort of patients with metastatic ILC. **Methods:** Patients were identified for inclusion in this retrospective study if they had ILC histology on early-stage breast biopsy/surgical pathology and/or *CDH1* mutation on metastatic site biopsy; all patients were required to have MSK-IMPACT somatic next generation sequencing (NGS) data available. Clinicopathologic characteristics were abstracted from the EMR. The Kaplan-Meier method was used to estimate overall survival (OS). The log-rank test was used to compare OS by ILC subtype and by genetic mutations. Wilcoxon rank sum test and Kruskal-Wallis test were used to compare number of treatment lines by receptor status. **Results:** 654 patients were included, of whom 99.8% were female, 89% were white, and 96% non-Hispanic. 438 (67%) had recurrent disease whereas 212 (33%) had *de novo* metastatic disease. Among 307 with ILC histologic subtype data available, 139 (45%) had classic type, 65 (21%) had pleomorphic, 45 (15%) had mixed, and 58 (19%) had other ILC subtypes. 454 (87%) had hormone receptor-positive (HR+) disease, 45 (9.1%) had HER2+ disease, and 50 (9.5%) had triple negative disease at metastatic diagnosis. In the total cohort, median number of treatment lines for metastatic disease was 4 (IQR 2-7) and median number of chemotherapies was 2 (IQR 1-3). In the HR+ cohort, median number of endocrine therapies was 2 (IQR 1-3). Among patients with genomic data from a biopsy obtained within 2 months of metastatic diagnosis, 79% had a *CDH1* mutation, 48% had a *PIK3CA* mutation, 5.6% had an *AKT1* mutation, 11% had a *PTEN* mutation, 9.3% had an *ESR1* mutation, 17% had a *HER2* mutation, and median tumor mutation burden (TMB) was 4 (IQR 3-7); 17% had TMB ^{3}10. Median OS in the total cohort was 4.4 years (95%CI 4.1-4.8). OS did not differ significantly by ILC subtype (p= 0.8). OS differed significantly by *CDH1* mutation status (wt 5.3 years, 95%CI 4.1-6.6; mut 3.7 years, 95%CI 3.5-4.2, p= 0.01), *PIK3CA* status (wt 4.6 years, 95%CI 4.0-5.8; mut 3.4 years, 95%CI 3.1-3.9, $p<$ 0.001), and *PTEN* status (wt 4.2 years, 95%CI 3.7-4.5; mut 3.4 years, 95%CI 2.2-4.3, p= 0.008). OS did not differ significantly by *HER2*, *AKT1*, or *ESR1* mutation status. **Conclusions:** In a large single-center cohort of patients with metastatic ILC, OS did not vary by ILC subtype, but did differ significantly by *CDH1, PIK3CA,* and *PTEN* mutation status. This underscores the prognostic importance of NGS in metastatic ILC. Research Sponsor: None.

TPS1120 **Poster Session**

A phase III randomized trial of radiotherapy optimization for low-risk HER2-positive breast cancer (HERO): NRG-BR008. First Author: Lior Zvi Braunstein, Memorial Sloan Kettering Cancer Center, New York, NY

Background: Breast radiotherapy (RT) is the standard of care for patients with early-stage breast cancer (BC) who undergo breast-conserving surgery (BCS). However, the magnitude of benefit of RT is less clear in BCS patients with low-risk disease who receive effective systemic therapy. Among patients with early-stage HER2-positive (HER2+) BC, 10-year locoregional recurrence has been reported as low as 1.5% following BCS, adjuvant chemotherapy and HER2-targeted therapy, and RT. Given these exceedingly favorable outcomes, with the addition of HER2-directed therapy, we seek to evaluate the feasibility of omitting RT among patients with early-stage HER2+ BC following BCS and appropriate systemic therapy. **Methods:** This is a phase III randomized trial for patients ≥18 years with early-stage, node-negative, HER2+ (IHC/FISH) BC treated with BCS with negative margins and sentinel lymph node biopsy or axillary dissection. Patients undergoing primary surgery must have pathologic T1-2 (≤3 cm) N0 disease, whereas patients receiving neoadjuvant therapy must have clinical T1-2 (with radiographically T≤5 cm) N0 disease and exhibit a pathologic complete response (ypT0N0) at surgery (residual DCIS [ypTis] spanning ≤1 cm is permitted, and surgical margins are negative for DCIS). All patients must receive cytotoxic chemotherapy and HER2-targeted therapy, either in the adjuvant or neoadjuvant setting. Stratification is by age (<60; ≥60), tumor size (≤1 cm; >1 cm), estrogen-receptor status (positive; negative), and systemic therapy sequencing (adjuvant *v* neoadjuvant). Patients will be randomized to standard breast RT in addition to continuation of trastuzumab to complete one year of treatment (Arm 1), or trastuzumab alone (Arm 2). Endocrine therapy will be recommended for patients with hormone-receptor-positive tumors. The primary endpoint is the recurrence-free interval (RFI). Secondary endpoints include time to ipsilateral breast recurrence, locoregional recurrence, disease-free survival, and overall survival, in addition to the 7-year ipsilateral breast recurrence rate among those not receiving RT. A health-related quality of life sub-study will assess differences in patient-reported breast pain and worry. We estimate a 7-year RFI of 97.5% with RT and allow for a clinically acceptable decrement of 3.63% without RT (7-year RFI of 93.87%; HR 2.5) to establish omission of RT as non-inferior. NRG-BR008 aims to enroll 1,300 patients over 7.25 years, yielding 80% power to detect the non-inferiority of RT omission with a one-sided α=0.05. We expect to observe the required 38 RFI events within 4.5 years of additional follow-up. The NRG-BR008/HERO trial opened to accrual in March 2023. Accrual is 64/1,300 as of 1/23/24. NCT #: NCT05705401. Support: U10 CA180868, -180822, UG1 CA189867, U24 CA196067. Clinical trial information: NCT05705401. IND.241: A Canadian Cancer Trials Group liquid-biopsy informed platform trial to evaluate treatment in CDK4/6-inhibitor resistant ER+/HER2- metastatic breast. First Author: David W. Cescon, Princess Margaret Cancer Centre/UHN, Toronto, ON, Canada

Background: The combination of a CDK4/6 inhibitor + endocrine therapy (CDK4/6i+ET) is standard first-line systemic treatment for patients with ER+/HER2-negative metastatic breast cancer (MBC). Beyond this initial therapy, there are numerous therapeutic agents available/ in development for subsequent lines of treatment. Circulating tumor DNA (ctDNA) via liquid biopsy is a promising, non-invasive approach for blood-based tumor genotyping, patient stratification and response assessment with the potential to enhance biomarker-driven strategies and aid in development of new therapeutics. **Methods:** IND.241 is a master protocol platform design consisting of independent substudies monitoring patients with ER+/HER2- MBC prior to progression (PD) on CDK4/6i+ET and investigating novel agents or drug combinations in 2nd/3rd lines after progression on CDK4/6i+ET. The primary objective of the novel drug/combination substudies is to centrally interrogate ctDNA (Tempus xF+, a 523-gene liquid biopsy panel) and evaluate whether biomarker selection improves ORR or CBR as assessed by RECIST 1.1. Secondary objectives include safety and toxicity profile for each drug/combination, PFS, and OS. The monitoring substudy (Substudy A) enrolls patients currently on CDK4/6i+ET treatment and aims to characterize the molecular profile, clinical features, and ctDNA dynamics of acquired resistance. This platform trial enables creation and maintenance of a tissue and data bank including clinical data, genomics, and radiomics from all substudies to evaluate surrogates of treatment outcomes and potential biomarkers of response, resistance, and disease progression. Patients with specific biomarkers detected in ctDNA will be enrolled into corresponding biomarker positive cohorts of substudies. Patients with no substudy-specific biomarkers are randomized to biomarker negative cohorts of available substudies. Treatment substudies follow a 2-stage design. Currently, the monitoring substudy A is actively accruing. Substudy B is evaluating lunresertib (PKMYT1 inhibitor) + gemcitabine in patients +/-CCNE1 overexpression / amplification. Substudy C is evaluating niraparib (PARP inhibitor) + fulvestrant (ET) in patients +/- alterations in BRCA1/2 (germline/somatic) or PALB2 (germline). These latter two substudies have now closed to accrual, with efficacy and safety evaluation ongoing. Substudy D, which has recently been added, is evaluating lunresertib + camonsertib (ATR inhibitor) in patients +/- CCNE1 overexpression/amplification, FBXW7 or PPP2R1A alterations. Additional substudies are in development for inclusion in this platform trial. Clinical trial information: NCT05601440. Research Sponsor: Repare Therapeutics; GSK.

Phase II study evaluating 68Ga-FAPI PET uptake heterogeneity as a predictor of T-DXd treatment response in HER2-positive breast cancer brain metastases. First Author: Biyun Wang, Department of Medical Oncology, Fudan University Shanghai Cancer Center, Shanghai, China

Background: Breast cancer is a leading cause of metastasis to the central nervous system (CNS). Approximately 30% of patients with HER2-positive breast cancer develop brain metastases, which are associated with a poor prognosis and limited treatment options. T-DXd has shown promise in treating brain metastases from HER2-positive breast cancer. However, up to 10% patients showed brain metastasis progression at the initial evaluation of treatment and may require radiotherapy or neurosurgery immediately. Identifying predictors of treatment response and determining the timing for local therapy intervention is crucial for personalized medicine. Heterogeneity in tumor metabolism, as assessed by (68Ga)–labeled fibroblast-activation protein inhibitor (68Ga-FAPI) PET-CT which displays the activity of cancer-associated fibroblasts (CAFs) in the tumor microenvironment, with good sensitivity and specificity in brain metastasis imaging, may serve as a biomarker for treatment response. This study aims to investigate the predictive value of 68Ga-FAPI PET uptake heterogeneity for T-DXd treatment response in HER2-positive breast cancer brain metastases. **Methods:** This open-label, single-center, phase II clinical trial will investigate the heterogeneity of brain metastasis and analyze the difference between stable and active brain metastasis evaluated by 68Ga-FAPI uptake in HER2-positive MBC. Patients with HER2-positive metastatic breast cancer and confirmed brain metastases by MRI were enrolled; at least one measurable intracranial lesion (≥ 1.0 cm) that has not previously been treated with radiation. Radiotherapy or neurosurgery is allowed with an interval ≥ 4 weeks. Patients will receive T-DXd treatment and undergo 68Ga-FAPI PET-CT scans before and after two cycles of treatment. The primary endpoint is the difference in baseline heterogeneity index by 68Ga-FAPI PET-CT between cerebral lesions achieving ORR and those that do not. Secondary endpoints include 68Ga-FAPI PET-CT value changes (SUVmax, SUVmean) at baseline and after treatment; difference in baseline heterogeneity index for PFS, CBR and OS; difference of baseline heterogeneity index, SUVmax and SUVmean between active or stable brain metastasis; 68Ga-FAPI PET-CT value changes (heterogeneity index, SUVmax, SUVmean) at baseline and 2 cycles after T-DXd treatment of whole body metastasis lesions. The study plans to enroll 50 patients and is actively enrolling. Clinical trial information: NCT06797622. Research Sponsor: CSCO-LingHang Oncology Research Foundation (Y-2022HER2AZQN-0378).

SOLTI-2201 ACROSS-TROP2 trial: A phase II study to identify predictive biomarkers of sacituzumab govitecan benefit and to understand resistance mechanisms in HR+/HER2- advanced or metastatic breast cancer. First Author: Eva Maria Ciruelos, University Hospital 12 de Octubre/ SOLTI Cancer Research Group, Madrid, Spain

Background: Sacituzumab Govitecan (SG) is a TROP2-directed antibody-drug conjugate (ADC) linked to a topoisomerase I inhibitor via a hydrolysable CL2A linker. It is approved for the treatment of metastatic triple-negative breast cancer (mTNBC) patients who have undergone at least two prior systemic therapies, including one for advanced disease, and of hormone receptor-positive (HR+)/HER2-negative metastatic breast cancer (mBC) patients after endocrine therapy (ET) and two systemic treatments. Currently, no biomarkers, including TROP2 protein expression, have been identified to predict SG response, highlighting the need to explore biomarkers of efficacy and to identify key resistance mechanisms to the drug. The ACROSS-TROP2 study aims to address this unmet medical need. **Methods:** ACROSS-TROP2 (NCT06236269) is a phase II, open-label, single-arm trial investigating SG in HR+/HER2-negative mBC patients. The study initially planned to enroll 50 pre- or post-menopausal female or male participants who progressed during or after treatment with CDK4/6 inhibitors and received up to one prior chemotherapy or ADC regimen for metastatic disease. Due to high recruitment rates and promising findings demonstrating ADC benefits in earlier treatment lines (Bardia et al., NEJM 2024), a protocol amendment was introduced to expand the sample size to 100 patients. Participants will receive SG at 10 mg/kg via IV infusion on Days 1 and 8 of each 21-day cycle until disease progression (PD). Fresh tumor biopsies will be obtained at baseline, after 2–3 weeks of treatment (C2D1), and at PD. The primary endpoint is to measure changes in the CelTIL score—a composite of tumor cellularity and tumor-infiltrating lymphocytes—between baseline and C2D1 biopsies, as CelTIL is associated with long-term efficacy. Secondary endpoints include overall response rate, progression-free survival, duration of response, time to response, safety, and tolerability. Correlative analyses of molecular markers in tissue and blood will be conducted to correlate biological findings (e.g., CelTIL, Ki67, TROP2, PD-1/PD-L1, PAM50) with clinicopathological data, evaluate the predictive value of early dynamic changes in ctDNA, identify genomic alterations linked to treatment response and resistance, and explore changes from baseline to PD to identify mechanisms of resistance. A paired t-test will assess whether the mean change in CelTIL score is statistically different from zero. The study has been approved in Spain and is actively enrolling participants at 10 sites within the SOLTI network. Previously presented at ESMO Breast 2024, FPN: 265TiP, Eva Ciruelos et al. - Reused with permission. Clinical trial information: NCT06236269. Research Sponsor: None.

TPS1124 **Poster Session**

LITESPARK-029: A phase 2, randomized, open-label study of belzutifan plus fulvestrant in participants with estrogen receptor–positive, HER2-negative unresectable locally advanced or metastatic breast cancer after progression on previous endocrine therapy. First Author: Bora Lim, Department of Breast Medical Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Endocrine-based therapy (ET), with or without cyclin-dependent kinase 4/6 inhibitors (CDK4/6i), prolongs PFS and OS in participants (pts) with metastatic hormone receptor–positive (HR+) and human epidermal growth factor receptor 2–negative (HER2–) breast cancer. After PD on first-line therapy, next-line therapy options provide limited PFS gains, in part due to resistance mechanisms (eg, hyperactive FOXA1). The transcription factor hypoxia-inducible factor 2α (HIF-2α), a major target of FOXA1, regulates key components of angiogenesis and subsequent development of metastasis. Preclinical studies show suppression of tumor growth with an HIF-2α antagonist, particularly when combined with fulvestrant. Belzutifan, an HIF-2α inhibitor, is approved for the treatment of pts with advanced renal cell carcinoma following a PD-(L)1 inhibitor and vascular endothelial growth factor tyrosine kinase inhibitor. LITESPARK-029 (NCT06428396) evaluates belzutifan + fulvestrant vs everolimus + fulvestrant or exemestane in pts with estrogen receptor–positive (ER+)/HER2– unresectable locally advanced or metastatic breast cancer. **Methods:** This phase 2, randomized, active-controlled, open-label, multicenter study is enrolling pts ($\geq$18 y) with locally confirmed ER+/HER2– unresectable, locally advanced or metastatic disease who have had radiographic PD on $\geq$12 mo of ET + CDK4/6i therapy in the noncurative setting or received $\geq$2 lines of ET in the noncurative setting including CDK4/6i where the CDK4/6i was discontinued due to intolerance (not due to progression). Pts must also be eligible for additional ET with everolimus plus either fulvestrant or exemestane per local investigator assessment, have an ECOG PS of 0 or 1, and provide a new or recent core biopsy for central determination of ER and HER2 status. Prior treatment with chemotherapy, antibody-drug conjugates, or PARP inhibitors in the noncurative setting is prohibited. Pts are randomized 1:1 to receive oral belzutifan 120 mg once daily + fulvestrant 500 mg on days 1 and 15 of cycle 1 and on day 1 of all subsequent 28-day cycles or oral everolimus 10 mg once daily + fulvestrant (as above) or oral exemestane 25 mg once daily until PD or unacceptable toxicity. Randomization is stratified by treatment with prior ET + CDK4/6i therapy ($<$ 18 mo duration before PD vs $\geq$18 mo duration before PD or no PD). Tumor imaging is performed at screening, Q8W from randomization through week 56, and Q12W thereafter. The primary endpoint is PFS per RECIST v1.1 by blinded independent central review (BICR). Secondary endpoints include PFS rate per RECIST v1.1 by BICR at 6 and 12 mo, OS, ORR per RECIST v1.1 by BICR, clinical benefit (CR, PR, or stable disease for $\geq$24 weeks), and safety. The study start date was July 2024. Clinical trial information: NCT06428396. Research Sponsor: Merck Sharp & Dohme LLC, a subsidiary of Merck & Co., Inc., Rahway, NJ, USA.

TPS1125 **Poster Session**

ALISertib in combination with endocrine therapy in patients with hormone receptor-positive (HR+), HER2-negative (HER2–) recurrent or metastatic breast cancer: The phase 2 ALISCA-Breast1 study. First Author: Pooja Prem Advani, Mayo Clinic, Jacksonville, FL

Background: Despite the many available treatments for patients (pts) with HR+, HER2– recurrent/metastatic breast cancer (MBC), optimal treatment after progression on CDK4/6 inhibitors (CDK4/6i) is unclear. One possible CDK4/6i resistance mechanism is increased expression of Aurora kinase A (AURKA), a key mitosis regulator associated with poor prognosis. Further implicated in CDK 4/6i resistance, high c-Myc or RB1 loss of function (LOF) are associated with transcriptional co-regulation or synthetic lethality, respectively, with AURKA. Alisertib is a highly selective, reversible, ATP-competitive, orally administered, small-molecule AURKA inhibitor with antiproliferative activity in HR+ BC-derived cell lines and BC xenograft models. Models with elevated AURKA or c-Myc expression, or RB1 LOF show greater alisertib sensitivity. Alisertib had activity in phase 1 and 2 trials, including objective response rates (ORRs) of 19.6–20% and median progression-free survival (PFS) of 5.4–5.6 months alone or with fulvestrant in pts with HR+/HER2–, endocrine-resistant MBC. The most common treatment-related grade $\geq$3 adverse events (AEs) were neutropenia, anemia, and leukopenia. **Methods:** ALISCA-Breast1 (NCT06369285) is a randomized phase 2 study. Primary objective: to determine the optimal alisertib dose administered with endocrine therapy (ET) based on AEs and serious AEs per CTCAE v5.0 and efficacy (ORR, duration of response, disease-control rate, PFS, overall survival). Secondary objectives: to identify biomarkers of efficacy and alisertib pharmacokinetics (PK). Key inclusion criteria: $\geq$18 years; ECOG performance status 0 or 1; confirmed HR+, HER2–, recurrent/metastatic breast adenocarcinoma not amenable to curative therapy; available tumor tissue for biomarker analyses; progression on or after $\geq$2 prior ET lines in recurrent/metastatic setting; prior CDK4/6i with ET in recurrent/metastatic setting. Key exclusion criteria: prior chemotherapy in recurrent/metastatic setting; prior AURKA-specific or pan-Aurora-targeted agents; unstable brain metastases. Eligible pts will be randomized 1:1:1 to alisertib 30 mg, 40 mg, or 50 mg orally twice daily on days 1—3, 8–10, and 15–17 every 28 days, plus physician's choice of anastrozole, letrozole, exemestane, fulvestrant, or tamoxifen not previously used in recurrent/metastatic setting or progressed upon in adjuvant setting; $\leq$50 pts will be enrolled per arm in the USA and Europe. All pts will undergo sparse PK sampling. Tumor tissue will be centrally assessed for biomarkers, including *RB1, MYC, TP53, ESR1,* PI3K/AKT pathway, *HER2* and *AURKA* genomic alterations/expression levels. The study will determine the optimal alisertib dose to combine with ET and may identify biomarker(s) defining pts with the greatest benefit from alisertib-based therapy. Clinical trial information: NCT06369285. Research Sponsor: Puma Biotechnology Inc.

TPS1126 **Poster Session**

Integrating gene signatures to guide HR+/HER2- MBC therapy in a diverse cohort (INSIGHT). First Author: Sonya A. Reid, Vanderbilt-Ingram Cancer Center, Vanderbilt University Medical Center, Nashville, TN

Background: Black women with breast cancer (BC) have a 40% higher mortality rate compared to Non-Hispanic White (NHW) women. Worse outcomes have been observed among Black women with hormone receptor positive (HR+), human epidermal growth factor receptor 2 negative (HER2-) BC despite comparable systemic therapies. Gene expression profiling has been used in early-stage BC to provide prognostic and predictive information beyond standard immunohistochemical classifications. BluePrint, an 80-gene molecular subtype signature, and MammaPrint (Agendia), a 70-gene risk of distant recurrence signature, further classify HR+/HER2- BC into luminal A, luminal B, HER2-enriched, and basal-type tumors. Non-Luminal A (Luminal B, HER2-enriched, and Basal-type) tumors are more aggressive and are associated with worse survival compared to Luminal A tumors. Our preliminary data demonstrate that non-Luminal A tumors are overrepresented in Black women (11% Black vs. 5% White). The role of molecular subtyping in guiding therapy for patients with HR+/HER- MBC is not defined. Retrospective studies have shown that non-Luminal A HR+/HER2- tumors derive less benefit from endocrine therapy (ET). We hypothesize that patients with non-Luminal A, HR+/HER2- MBC progressing on ET +/- CDK4/6 inhibition derive more benefit from chemotherapy than ET in the second line. Furthermore, the impact of the intervention will be more pronounced in Black women compared to NHW women. INSIGHT is a randomized phase II study evaluating the anti-tumor effect of capecitabine versus physician's choice ET as second line for patients with non-Luminal A HR+/HER2- MBC (NCT05693766). **Methods:** In this study, patients progressing on 1st line ET +/- a CDK4/6i are enrolled. Archival primary or metastatic tumor samples are analyzed using MammaPrint and BluePrint. Patients with non-Luminal A tumors are randomized (1:1) to receive physician's choice ET versus capecitabine, stratified by molecular subtype and race. Disease assessments are performed every three months. The primary endpoint is progression free survival (PFS). Secondary endpoints include overall response rate, clinical benefit rate, overall survival, and patient reported outcomes. The study has 80% power to detect a minimal hazard ratio of 0.5 in 5-year PFS with one-sided α = 0.05. Exploratory correlative studies are planned. This trial enriches for racial/ethnic minority patients through collaborations with the University of Texas Southwestern and the University of Alabama at Birmingham, health systems that serve large minority populations. Seven of the 64 planned patients have been enrolled. Clinical trial information: NCT05693766. Research Sponsor: Susan G. Komen.

TPS1127 **Poster Session**

ELCIN: Elacestrant in women and men with CDK4/6 inhibitor (CDK4/6i)-naïve estrogen receptor-positive (ER+), HER2-negative (HER2-) metastatic breast cancer (mBC)—An open-label multicenter phase 2 study. First Author: Virginia G. Kaklamani, University of Texas Health Science Center at San Antonio, San Antonio, TX

Background: Endocrine therapy (ET) plus a CDK4/6i is the mainstay treatment in first-line ER+/HER2- mBC; however, a subset of patients are unable to tolerate CDK4/6i, and resistance to ET emerges. Intrinsic resistance mechanisms include alterations in the PI3K/AKT/mTOR or cell cycle pathways; acquired resistance mechanisms include estrogen receptor gene 1 mutations (*ESR1*-mut), which emerge in up to 50% of patients during prolonged aromatase inhibitor therapy in mBC. In the phase 3 EMERALD trial, elacestrant significantly prolonged PFS vs standard-of-care (SOC) ET and was associated with a manageable safety profile in patients with ER+/HER2- mBC previously treated with ET+CDK4/6i, leading to its approval as the first clinically available oral SERD. Elacestrant significantly reduced the risk of progression or death vs SOC ET by 30% in the overall population (HR 0.70; 95% CI 0.55-0.88; P=0.002) and by 45% in patients with *ESR1*-mut tumors (HR 0.55; 95% CI 0.39-0.77; P=0.0005) [Bidard, 2022]. Preclinical studies demonstrated that elacestrant is equally active in both in vitro and in vivo models of ER+/HER2- breast cancer, regardless of prior exposure to CDK4/6i. Based on preclinical models and clinical efficacy data, elacestrant may improve clinical outcomes in CDK4/6i-naïve patients and provide a convenient all-oral treatment option if combined with CDK4/6i. The ELCIN trial will evaluate efficacy and safety of elacestrant in patients with ER+/HER2- mBC who received prior ET and no prior CDK4/6i in the metastatic setting. **Methods:** ELCIN (NCT05596409) is an open-label, multicenter, single-arm phase 2 trial. Eligible patients are women or men with ER+/HER2— mBC who received 1-2 lines of prior ET and no prior CDK4/6i or chemo in the metastatic setting. Patients must have measurable disease per RECIST v1.1 or a mainly lytic bone lesion (for bone disease only), ECOG PS $\leq$1, adequate bone marrow and organ function, and no active or newly diagnosed CNS metastases or visceral crisis. Patients will receive elacestrant 345 mg once daily. The primary objective is investigator-assessed PFS. Secondary objectives are ORR, DoR, CBR, OS, PROs-QoL, and safety. Exploratory objectives include elacestrant efficacy according to *ESR1*-mut status, changes in biomarkers, including allele mutation frequencies (cfNAs), and relationship between efficacy endpoints. Status: ELCIN has a planned sample size of 60 patients; recruitment is ongoing worldwide. Clinical trial information: NCT05596409. Research Sponsor: Menarini Group.

TPS1128 **Poster Session**

SIMRISE: A randomized phase III trial evaluating SIM0270 in combination with everolimus versus treatment of physician's choice in patients with ER+/HER2- advanced breast cancer, previously treated with CDK4/6 inhibitors. First Author: Jiong Wu, Fudan University Shanghai Cancer Center, Shanghai, China

Background: CDK4/6 inhibitors (CDK4/6i) in combination with endocrine therapy (ET) have demonstrated sustained benefits in the first-line treatment of HR+/HER2- advanced breast cancer(aBC). However, effective ET options are limited for patients who progressed after the treatment of ET in combination with CDK4/6i. SIM0270 in combination with everolimus exhibited promising anti-tumor activities in a Phase I study. **Methods:** SIMRISE is an ongoing randomized, open label, Phase III trial designed to evaluate SIM0270 in combination with everolimus versus the treatment of physician's choice (TPC) for patients with ER+/HER2- aBC progressed on previous ET and CDK4/6i. A total of 460 patients will be enrolled across approximately 50 sites in China. Patients are randomized in a 1:1 ratio to receive either SIM0270 + everolimus or TPC (exemestane + everolimus or fulvestrant). Stratification factors include: visceral metastasis (yes or no); prior fulvestrant (yes or no); baseline ESR1 status (mutation detected or not detected). Key eligibility criteria include: ER+/HER2- aBC patients having measurable disease per RECIST 1.1 or bone only disease with at least one predominant lytic bone lesion or mixed lytic-blastic lesion; postmenopausal women and pre-/perimenopausal women or men receiving luteotropic hormone releasing hormone agonist(LHRHa) therapy per local prescribing information; patients must have received at least one line and no more than two lines of ET; recurrence while on or within 12 months of completion of adjuvant ET for $\geq$24 months is considered as first-line ET, or first line ET in advanced setting for $\geq$6 months. Patients must have previously received CDK4/6i combined with ET for $\geq$6 months; one line chemotherapy for aBC is allowed. The Primary endpoint is progression-free survival (PFS) as assessed by blinded independent review committee (BIRC). The secondary endpoints include PFS (assessed by investigators), overall survival (OS), objective response rate (ORR), duration of response (DoR), clinical benefit rate (CBR), time to progression (TTP), safety, pharmacokinetics (PK) and patients-reported outcomes (PRO). The analysis of primary endpoint will use a stratified log-rank test at an overall of 0.05 significance level (two-sided). Futility analyses are planned, and an independent data monitoring committee will be in place. Clinical trial information: NCT06680921. Research Sponsor: Simcere Zaiming Pharmaceutical Co., Ltd.

TPS1129 **Poster Session**

ADELA: A double-blind, placebo-controlled, randomized phase 3 trial of elacestrant (ELA) + everolimus (EVE) versus ELA + placebo (PBO) in ER+/HER2- advanced breast cancer (aBC) patients with *ESR1*-mutated tumors progressing on endocrine therapy (ET) + CDK4/6i. First Author: Antonio Llombart-Cussac, Medica Scientia Innovation Research (MEDSIR), Hospital Arnau de Vilanova, FISABIO, Translational Oncology Group, Universidad Cardenal Herrera-CEU, Alfara Del Patriarca, Spain

Background: ET+CDK4/6i is standard-of-care (SOC) in 1L ER+/HER2- aBC; however, tumors eventually develop resistance. Constitutive activation in the PI3K/AKT/mTOR pathway can contribute to endocrine resistance in breast cancer. *ESR1* mutations are a common type of acquired resistance that emerges in 40-50% of patients in the metastatic setting after prolonged aromatase inhibitor exposure. There is an unmet need for novel therapeutic approaches to overcome resistance mechanisms and improve outcomes in patients with ER+/HER2- aBC with *ESR1*-mutated tumors progressing after ET+CDK4/6i. ELA is a next-generation oral SERD that binds to ER-alpha, inducing its degradation. In EMERALD, ELA improved PFS vs SOC ET in patients with *ESR1*-mutated tumors (HR 0.55; 95% CI 0.39-0.77; P=0.0005) [Bidard 2022]. Differences were notable among patients who received prior ET+CDK4/6i $\geq$12 mo; median PFS with ELA was 8.6 mo vs 1.9 mo with SOC ET (HR 0.41; 95% CI 0.26-0.63) [Bardia 2024]. Crosstalk between ER and PI3K/AKT/mTOR pathways provides a rationale for evaluating ELA+EVE (a mTORC1 inhibitor). In ELEVATE phase 1b (NCT05563220), ELA+EVE demonstrated ORR 22% and CBR at 24 weeks 72% in patients with ER+/HER2- aBC progressing after ET+CDK4/6i; ELA 345 mg + EVE 7.5 mg was identified as the RP2D [Rugo ESMO 2024]. Safety was consistent with the known profile of EVE+SOC ET. ADELA compares ELA+EVE vs ELA+PBO in ER+/HER2- aBC patients with *ESR1*-mutated tumors progressing on ET+CDK4/6i. **Methods:** ADELA (NCT06382948) is an international, multicenter, double-blind, placebo-controlled phase 3 trial. Eligible patients are adults ($\geq$18 yrs) with ER+/HER2- aBC and *ESR1*-mutated tumors, previously treated with 1-2 lines of ET for aBC, and evidence of disease progression on prior ET+CDK4/6i for aBC after $\geq$6 mo. Patients receiving CDK4/6i-based adjuvant therapy are eligible (disease progression must be confirmed after $\geq$12 mo of treatment but $<$12 mo following CDK4/6i completion). Other criteria include adequate organ function and ECOG PS 0-1. Exclusion criteria include prior chemotherapy for aBC and active uncontrolled/symptomatic brain metastasis. Patients will be randomized 1:1 to 28-d cycles of ELA 345 mg + EVE 7.5 mg QD or ELA 345 mg + PBO QD until disease progression or unacceptable toxicity. Patients will receive dexamethasone mouthwash during the first 8 wks. Stratification factors are presence of visceral metastases (yes vs no) and duration of prior CDK4/6i ($\geq$12 mo vs $<$12 mo). The primary objective will be to evaluate PFS based on blinded independent review committee. Secondary endpoints include investigator-assessed PFS, OS, ORR, CBR, DoR, TTR, best percentage change in tumor burden, safety, and HRQoL. Status: Planned enrollment is 240 patients; recruitment is ongoing. Clinical trial information: NCT06382948. Research Sponsor: Menarini Group.

TPS1130 **Poster Session**

Dauntless-1, a phase 2 clinical trial to evaluate PMD-026, a first-in-class pan-RSK inhibitor, combined with fulvestrant to overcome resistance to CDK4/6 inhibitors in advanced or metastatic HR+/HER2- breast cancer. First Author: Sandra Elaine Dunn, Phoenix Molecular Designs, Vancouver, BC, Canada

Background: Resistance to CDK4/6 inhibitors (CDK4/6i) is common for many patients with HR+/HER2- advanced or metastatic breast cancer, therefore new strategies are urgently needed to overcome this challenge. Ribosomal S6 kinases (RSK1-4) are implicated in breast cancer growth and resistance, and they are activated by the PI3K and MAPK pathways, which are linked to CDK4/6i resistance. As a convergence point of these pathways, RSK drives resistance by promoting the G2/M phase of the cell cycle and bypassing G1/S control. Inhibiting RSK with PMD-026, a first-in-class oral small molecule inhibitor, halts G2/M progression and blocks growth in CDK4/6i-resistant models, including those cross-resistant to abemaciclib and palbociclib. RSK also complexes with estrogen receptor alpha (ERα), enhancing transcription and tumor growth. PMD-026 disrupts this interaction, showing activity in both ESR1 wild-type and mutant HR+/HER2- models, making it a promising partner for endocrine therapies. It synergizes with fulvestrant and oral SERDs, achieving significant growth inhibition in preclinical models, including a 7000-fold improvement with fulvestrant in soft agar assays. Nuclear translocation of RSK is a key driver of breast cancer in mice and serves as a biomarker for RSK signalling activity. In the Phase 1/1b monotherapy study, PMD-026 was generally well-tolerated, and it reduced the risk of progression or death in patients by 93% in a subset of RSK2 high metastatic breast cancer patients. **Methods:** Dauntless-1 is a Phase 2a study for locally advanced or metastatic HR+/HER2- breast cancer patients previously treated with a CDK4/6i in combination with endocrine therapy (NCT04115306). It is designed to prospectively enroll RSK2+ ($\geq$50% nuclear staining with $\geq$2+ staining intensity) patients to evaluate PMD-026 in combination fulvestrant. Fulvestrant will be dosed per the package insert (500 mg IM, Day 1 and 15 of the first 28-day cycle, then Day 1 of every cycle thereafter) in combination with PMD-026 at the RP2D (200 mg, PO, Q12h), determined in the dose-finding portion of the study. The combination regimen will have a safety lead-in cohort of 6 patients. The SRC will review the safety data after the sixth patient has been treated for at least 28 days. If determined to be safe, up to 14 additional patients will receive the combination for a total of 20 patients. A Bayesian safety monitoring rule will be used to evaluate the rate of DLTs during expansion. Primary objectives will be safety, pharmacokinetics, and progression free survival. Secondary objectives include duration of response, overall response and overall survival. Exploratory objectives will evaluate PMD-026 in the context of mutations (ESR1, PIK3CA, AKT1, p53, KRAS) at baseline using ctDNA. Clinical trial information: NCT04115306. Research Sponsor: None.

TPS1131 **Poster Session**

OPERA-01: A randomized, open-label, phase 3 study of palazestrant (OP-1250) monotherapy vs standard-of-care for ER+, HER2- advanced or metastatic breast cancer patients after endocrine therapy and CDK4/6 inhibitors. First Author: Barbara Pistilli, Breast Cancer Unit, Gustave Roussy, Villejuif, France

Background: Endocrine therapy(ET) resistance is a major challenge in treating estrogen receptor-positive (ER+), human epidermal growth factor receptor 2-negative (HER2–) metastatic breast cancer (MBC); estrogen receptor (ESR1) mutations are an important mechanism of resistance. The standard of care (SOC) first-line treatment for ER+, HER2– MBC is ET plus a cyclin-dependent kinase 4/6 inhibitor (CDK4/6i). Despite the benefit of ET and CDK4/6i, disease progression and acquired resistance to the combination remain a challenge. Novel, more effective ETs that can overcome resistance are needed to improve outcomes and delay time to chemotherapy. Palazestrant (OP-1250) is a novel oral, complete estrogen receptor antagonist (CERAN) and selective ER degrader (SERD) that acts by blocking both transcriptional activation function domains, AF1 and AF2, regardless of ESR1 mutation status. As monotherapy, palazestrant showed a tolerable safety profile, favorable pharmacokinetics and encouraging antitumor efficacy in heavily-pretreated patients during phase 1/2 studies, regardless of *ESR1* mutation status (NCT04505826; Lin et al. ESMO 2023 MO382). **Methods:** OPERA-01 (NCT06016738) is a multicenter, randomized, open-label, phase 3 clinical trial comparing the efficacy and safety of palazestrant as a single agent to SOC ET (fulvestrant, anastrozole, letrozole, or exemestane) in patients with ER+, HER2– MBC that relapsed or progressed on 1-2 prior lines of ET, including a CDK4/6i. Adult patients are eligible with a diagnosis of evaluable ER+, HER2– inoperable locally advanced or MBC and an Eastern Cooperative Oncology Group performance status of 0 or 1. Prior treatments must include 1 or 2 prior lines of ET with the last ET duration of $\geq$6 months; must have received and have disease progression on CDK4/6i with ET for MBC. Prior chemotherapy for MBC is not allowed. The study included a dose selection phase, where participants were randomized to 90 mg qd or 120 mg qd palazestrant or SOC; enrollment in this phase is complete. After the dose selection of palazestrant, the study will continue with the selected dose compared to SOC ET at a 1:1 randomization. Overall, 510 patients will be randomized to palazestrant or SOC ET during the study. The primary endpoint of progression-free survival will be assessed by blinded independent central review in patients with and without *ESR1* mutations (dual primary endpoint). Secondary endpoints include overall survival, antitumor activity (objective response rate, clinical benefit rate, and duration of response), safety, exposure and patient-reported outcomes in patients with and without *ESR1* mutations. Study recruitment began in November 2023. Clinical trial information: NCT06016738. Research Sponsor: Olema Oncology.

TPS1132 **Poster Session**

Immunologic targeting of native and mutated ESR1 receptor for treatment of hormone receptor expressing metastatic breast cancer. First Author: Aixa Elena Soyano Muller, H. Lee Moffitt Cancer Center and Research Institute, Tampa, FL

Background: Hormone receptor positive (HR+) HER2 negative metastatic breast cancer (MBC) remains a difficult clinical problem. Endocrine therapies have remained the mainstay of therapy for decades and despite combination with targeted agents and development of novel targeted therapies, the 5-year survival rate of MBC remains low. Resistance to ET can occur due to the development of point mutations in the estrogen receptor alpha type I (ESR1), which constitutively activates the receptor, making it resistant to anti-estrogen. We produced a peptide library of the entire wild type (WT) ESR1 and identified four promiscuous peptide epitopes that routinely drive a CD4 Th1 response in healthy donors and breast cancer patients. Additionally, we created overlapping peptides around each known ESR1 mutation site and pulsed them on type I polarized dendritic cells (DC1) also resulting in an increased CD4 Th1 response. We hypothesize that ER alpha receptor can serve as a target for the immune response and ESR1 mutations that develop in HR+ breast cancer patients can be utilized as a neoantigen that will drive CD4 Th1 responses and antibodies that can be developed as an immune based therapy for patients with HR+ MBC. Combining DC1 vaccination with novel endocrine therapies such as Elacestrant, we expect an increase in ESR1 degradation and enhanced antigen presentation leading to an expanded immune and clinical response. **Methods:** In this open pilot study, up to 18 patients with HR+ HER2 negative, ESR1 mutated MBC with measurable or evaluable disease will be enrolled to determine the feasibility and safety of the combination of DC1 vaccines and Elacestrant. Prior use of elacestrant is exclusionary. Eligible patients will undergo apheresis of peripheral blood to collect and create DC1 vaccines. DC1 will be pulsed with ESR1 WT and mutated peptides. Patients will be injected in their groin nodes (or accessible tumor if available) weekly with these pulsed DC1 (20-50 million) for eight consecutive weeks. They will alternate between WT ESR1 DC1s and mutated ESR1 DC1s. Patients will receive combination of DC1 vaccinations and Elacestrant at 345 mg orally daily concurrently during vaccination and continued after. After the initial vaccination series, patients will undergo radiological assessment of their disease, and if no evidence of progression they will receive booster DC1s every four weeks x 3 doses. The primary objective of this pilot study is safety and feasibility. Secondary objectives include preliminary efficacy, biomarkers assessment, safety and patient reported outcomes. Tumor tissue and blood samples will be collected for correlative analyses including ctDNA and changes in variant allele frequency of ESR1 during treatment. The study is open at H. Lee Moffitt Cancer Center. Clinical trial information: NCT06691035. Research Sponsor: V Foundation.

Adaptive designed eniluracil + capecitabine phase 2 trial in advanced or metastatic breast cancer patients. First Author: David Young, Processa Pharmaceuticals, Inc., Hanover, MD

Background: Ethynyl-uracil (eniluracil or 6422), an irreversible inhibitor of the dihydropyrimidine dehydrogenase enzyme that metabolizes 5-FU to catabolites, eliminates the formation of 5-FU catabolites and catabolite side effects while exposing cancer cells to more 5-FU and more cancer killing 5-FU anabolites. The combination of a single 40 mg day 1 dose of 6422 followed by Day 2 Capecitabine (6422+Cap) on a 7 day on + 7 day off schedule (7+7) of Capecitabine (Cap) is being evaluated. The dose of Cap used in 6422+Cap will be approximately 15% of the therapeutic dose of Cap used in clinical practice for breast cancer. A Phase 1B study in patients with refractory gastrointestinal (GI) cancer has been completed. The Maximum Tolerated Dose of Cap in 6422+Cap was determined to be 225 mg BID. The Recommended Phase 2 Dose Range of Cap in 6422+Cap was determined to be from 75 mg BID to 225 mg BID. based on the FDA's Optimal Design Guidance and Project Optimus initiative to define the dose-response relationship for both safety and efficacy. Since FDA believed that determining the optimal dosage regimen following the Principles of Project Optimus would be extremely difficult for 6422+Cap in GI cancer given the standard combination chemotherapeutic treatments, the target population was changed to breast cancer patients. FDA also determined that a Phase 1B study in breast cancer would not be required given the GI cancer Phase 1B data. **Methods:** Several Project Optimus focused Phase 2 designs were evaluated. Based on guidance from the FDA, an adaptive, 3 arm, 30 patients/arm, phase 2, open-labelled, randomized trial was selected which would compare 2 regimens of 6422+Cap vs. standard dose of Cap alone. The study would initially enroll patients into 2 treatment arms. The 2 arms are: a 1000 mg/m2 BID monotherapy Cap control group and a 6422+Cap regimen of 40 mg on day 1 followed by day 2 Cap dose of 150 mg BID on 7+7 schedule. Upon completing the enrollment and evaluation of 9-10 patients in each of the first 2 arms, an interim analysis will be conducted to determine the Cap dose to be used in the 6422+Cap 3rd arm. Depending on the interim results, Cap dose in the 3rd arm will either be increased to 225 mg BID or decreased to 75 mg BID. Patients with triple-negative or HR positive/HER2 negative, advanced or metastatic breast cancer are eligible for the study. Patients should have measurable disease in accordance with RECIST 1.1. Patients with stable brain metastases are eligible. The primary endpoint of the study is Objective Response Rate. This will be assessed based on the null hypothesis that the endpoint in each 6422+Cap arm is less than or equal to the monotherapy arm. Additionally, safety will be assessed by the incidence and severity of adverse events across treatment groups. The pharmacokinetics of Cap, 5-FU, and the FBAL catabolite will be evaluated using population PK analysis. Currently 3 patients have been enrolled in the study. Clinical trial information: NCT06568692. Research Sponsor: Processa Pharmaceuticals Inc.

TPS1134 **Poster Session**

DATO-Base: A phase II study of DATOpotamab deruxtecan for patients with breast cancer brain metastases or leptomeningeal disease. First Author: Paolo Tarantino, Dana-Farber Cancer Institute, Boston, MA

Background: Approximately half of patients with metastatic TNBC and one fifth of those with estrogen receptor (ER)+/HER2-negative metastatic breast cancer (MBC) eventually develop breast cancer brain metastases (BCBM), with an adverse prognostic effect. Intracranially penetrant systemic therapies in HER2-negative MBC are very limited. In this setting, antibody-drug conjugates (ADCs) have shown promise, with impressive intracranial activity observed with trastuzumab deruxtecan. Datopotamab deruxtecan (Dato-DXd) is a novel anti-Trop2 ADC with robust antitumor activity in HER2-negative MBC. In the TROPION-Breast01 phase 3 trial, Dato-DXd outperformed chemotherapy for ER+/HER2-negative MBC, and promising early-phase data was also reported in triple-negative MBC. Preclinical data in tumor models found favorable intracranial penetration for Dato-DXd, and encouraging clinical data were reported in patients with lung cancer brain metastases. Based on the relevant unmet need and the promising preclinical and clinical data seen with Dato-DXd, there is a strong rationale in testing Dato-DXd for patients with HER2-negative MBC and BCBM or leptomeningeal disease (LMD). **Methods:** DATO-Base is an ongoing, open label, multicenter, investigator-initiated phase II trial for patients with HER2-negative MBC with active BCBM and/or LMD. Eligible participants are women and men with HER2-negative active (newly diagnosed/untreated or treated/progressive) brain metastases or LMD. Patients are enrolled in one of three cohorts: Cohort A (n = 24) for HR+/HER2-negative BCBM; Cohort B (n = 24) for triple-negative BCBM; Cohort C (n = 10) for HER2-negative LMD (any ER status). Patients in Cohort A require prior treatment with at least one line of endocrine treatment in the metastatic setting; no prior treatment is required for Cohorts B and C. Prior treatment with approved or investigational ADCs is allowed. Participants receive Dato-DXd 6 mg/kg IV on day 1 of each 21-day cycle until progression, unacceptable toxicity, withdrawn consent, noncompliance, or death. The primary endpoint for Cohorts A and B is intracranial objective response rate per RANO-BM criteria. Patients in each cohort will be enrolled based upon Simon two-stage designs: if $\geq$1/9 patients respond, a total of 24 patients will be enrolled. Cohort C is exploratory, with description of overall survival and exploratory endpoints. Blood and cerebrospinal fluid is being collected at baseline, C2D2, and at progression for translational studies. The trial was activated in December 2023, with enrollment ongoing. Clinical trial information: NCT06176261. Research Sponsor: None.

TPS1135 **Poster Session**

The efficacy and safety of eutideron, etoposide, and bevacizumab in patients with brain metastases from breast cancer. First Author: Bishal Tiwari, Nassau University Medical Center, East Meadow, NY

Background: Brain metastases (BM) from breast cancer (BC) are a significant therapeutic challenge, with limited systemic treatment options capable of crossing the blood-brain barrier (BBB). Median overall survival (OS) ranges from 4 to 16 months, influenced by molecular subtype and treatment modality. Triple-negative and HER2-positive subtypes are associated with higher BM incidence. There is a crucial need to explore systemic therapies that address both intracranial and extracranial disease. Eutideron, a novel small-molecule inhibitor with robust CNS penetration, has demonstrated activity against metastatic BC models involving the brain. Early clinical studies suggest its efficacy in advanced BC, with intracranial activity and manageable toxicity. Combining eutideron with etoposide, a cytotoxic agent, and bevacizumab, an anti-VEGF monoclonal antibody, may enhance therapeutic outcomes. Bevacizumab, known for reducing BM-associated edema and improving quality of life, has shown promise in combination regimens but has not been evaluated alongside eutideron and etoposide. This Phase II trial investigates this novel three-drug regimen in patients with recurrent BC and measurable BM. **Methods:** This open-label, single-arm Phase II trial evaluates the efficacy and safety of eutideron, etoposide, and bevacizumab in female patients aged $\geq$18 years with recurrent metastatic BC and measurable BM. Eligible patients had an ECOG performance status of 0–2, life expectancy $\geq$12 weeks, and progressed untreated or previously treated BM not requiring immediate local treatment. Baseline brain MRIs confirmed at least one measurable CNS lesion per RANO-BM criteria. The treatment regimen includes eutideron (30 mg/m²/day, IV, Days 1–5 of a 21-day cycle), etoposide (30 mg/m²/day, IV, Days 1–3 of a 21-day cycle), and bevacizumab (10 mg/kg, IV, Days 1 and 21 of each cycle). After 4–6 cycles, responders continued bevacizumab maintenance until progression or intolerable toxicity.Primary endpoint: CNS Objective Response Rate (CNS-ORR) per RANO-BM. Secondary endpoints: CNS Clinical Benefit Rate, CNS Progression-Free Survival, Overall Survival, and systemic ORR by RECIST 1.1. Safety was monitored using CTCAE v5.0. The trial, targeting 43 patients across Chinese centers, aims to inform future strategies for BC patients with BM. Clinical trial information: NCT05781633. Research Sponsor: None.

TPS1136 **Poster Session**

Trial in progress: A study of Bria-OTS cellular immunotherapy in metastatic recurrent breast cancer. First Author: Neal Shiv Chawla, Sarcoma Oncology Center, Santa Monica, CA

Background: Metastatic breast cancer is almost always fatal. Objectives: Primary: To evaluate the safety of BC1 cell line immunotherapy in patients with advanced late-stage metastatic breast cancer; Secondary: To evaluate the tumor response to BC1 cellular immunotherapy; Exploratory: To evaluate progression-free (PFS) and overall survival (OS); To evaluate the immune responses elicited by BC1 cellular immunotherapy; To evaluate patient and tumor characteristics that may be predictive of responses to HLA-matched cellular immunotherapy; To evaluate time to subsequent therapy; and To evaluate PFS 2 on subsequent therapy. **Methods:** Study Population: Patients with metastatic recurrent breast cancer after progression on prior therapies. Key Inclusion Criteria: Histologically-confirmed metastatic breast cancer after failure of standard therapies; $\geq$18 years old; Expected survival of $>$4 months; Adequate performance status (ECOG $\leq$2); Adequate hematologic and organ function; Clinically stable with resolution of toxicities from previous treatment to baseline with the exception of alopecia. Key Exclusion Criteria: Concurrent anti-cancer treatment or concurrent cancer; Anti-cancer treatment within 3 weeks of first treatment; History of hypersensitivity to study therapies; New York Heart Association stage 3-4 cardiac disease; Moderate-severe pleural or pericardial effusion; Pregnant or nursing; HIV+; Known immunodeficiency or ongoing treatment with immunosuppressive therapy $>$10 mg/day prednisone equivalent; Severe psychiatric or other clinically progressive major medical problems. Study Design: This is an open-label study. Phase 1: BC1 cell line alone; Phase 2, Bria-OTS regimen with check point inhibitor (CPI). Phase 1: Patient 1: 20 million cells BC1 intradermally q2 wks x 8 wks (4 doses); Patient 2: 40 million cells of BC1; Patient 3: 60 million cells BC1. If no DLT with BC1 monotherapy, the combinational phase of the study will begin with BC1 and the Bria-OTS regimen q3 wks + CPI. During the Phase 1 combination and Phase 2 expansion phases, all patients will be treated with BC1 cells as part of the Bria-OTS regimen, which includes cyclophosphamide 300 mg/m^2 2-3 days prior to BC1 cell inoculation, and concurrent peg-interferon 0.6 mcg s.c. on the day of BC1 cell inoculation. Imaging studies: At screening, after monotherapy phase, before combination phase, and q9 weeks thereafter for 6 months, then q12 weeks. Patients who had PD but with clinical benefit may continue treatment. Subjects will continue to be followed for time on subsequent therapy (PFS2) and survival q3 mos. for 2 years. The phase 1 monotherapy part of the study has enrolled and treated 3 patients. Clinical trial information: NCT06471673. Research Sponsor: BriaCell Therapeutics Corp.

TPS1137 **Poster Session**

Trial in progress: ENCORE—Multicenter prospective registry of sequential antibody drug conjugates (ADCs) in HER2 negative metastatic breast cancer (MBC) (TBCRC-067). First Author: Laura Ann Huppert, University of California San Francisco, San Francisco, CA

Background: Antibody-drug conjugates (ADCs) have demonstrated substantial improvement in progression free survival (PFS) and overall survival (OS) in phase III clinical trials in patients with metastatic triple negative breast cancer (mTNBC) and hormone receptor positive/HER2-negative (HR+/HER2-) metastatic breast cancer (MBC), offering an effective new treatment strategy. Several outstanding questions impact the use of these drugs clinically, and prospective real-world data is needed. First, it is important to understand the safety and efficacy of these agents in a real-world population with diverse patient characteristics. Second, it is critical to understand the safety and efficacy of these ADCs in sequence. Third, it is essential to identify biomarkers that can help clarify mechanisms of response and resistance to ADCs, which may inform future sequencing and treatment strategies. **Methods:** This is a multicenter prospective registry study of patients with HER2-negative MBC who are treated with sequential ADCs per standard of care (SOC) with the goal to understand the safety and efficacy of sequential ADCs in a real-world setting (NCT06774027). A total of 100 participants with HER2-negative MBC will be enrolled in this study, either prior to starting their first ADC per SOC (cohort 1 = HR+/HER2-; cohort 2 = mTNBC) or prior to starting their second ADC per SOC (cohort 3 = HR+/HER2-; cohort 4 = mTNBC). The dual primary endpoints are real-world progression free survival (rwPFS) of ADC1 and rwPFS of ADC2. Secondary endpoints include overall response rate (ORR), duration of response (DOR), best overall response (BOR), disease control rate (DCR), and real-world overall survival (rwOS), and safety for each ADC. Exploratory endpoints include translational correlates of response/resistance to ADCs (e.g., circulating tumor DNA, circulating tumor cells, and tissue spatial correlates) and patient-reported outcomes (PROs). rwPFS and rwOS will be estimated by the Kaplan-Meier method. Statistics will be descriptive. Enrollment to start in the first quarter of 2025. Clinical trial information: NCT06774027. Research Sponsor: Gilead.

TPS1138 **Poster Session**

Update on phase III pivotal trial of Bria-IMT + CPI vs physician's choice in advanced metastatic breast cancer (BRIA-ABC). First Author: Saranya Chumsri, Mayo Clinic Florida, Jacksonville, FL

Background: The SV-BR-1-GM breast cancer cell line activates anti-tumor immunity by expressing tumor associated antigens and secreting GM-CSF which enhances dendritic cell activation and promotes adaptive (T-cell mediated) and innate (dendritic and NK cell) immune responses. The cells are also engineered to optimize immune recognition through pt specific HLA antigen matching. SV-BR-1-GM acts through direct antigen presentation and CD4+ T-cell activation and, when combined w/ checkpoint inhibitors (CPIs), has demonstrated clinical benefit in 54 heavily pretreated metastatic breast cancer (MBC) pts. In pts w/ disease progression following CPI therapy, similar or improved progression free survival (PFS) compared to their prior treatment regimen. Disease control following antibody drug conjugates was observed in 40%of pts. Clinical benefit was seen in 5 out of 8 pts w/ untreated intracranial metastases. CD8+ Immuno-PET imaging suggests systemic activation, w/ increased CD8+ tumor infiltrating lymphocytes at both primary and metastatic tumor sites, as well as lymphoid organs. Optimized sequencing of CPI w/ SV-BR-1-GM and its latest phase 3 formulation have shown enhanced clinical outcomes, including improved overall survival (OS) (median 13.4 mos), PFS (3.6 mos), and clinical benefit rate (CBR; 61%).These findings have informed refinements to the ongoing pivotal, registration enabling Phase 3 trial, designed to optimize pt selection and treatment sequencing strategies. **Methods:** This ongoing multicenter, randomized, open label Phase 3 trial evaluates Bria-IMT + CPI vs. Treatment of Physician's Choice (TPC) in MBC pts lacking approved curative therapies. Pts are randomized 1:1:1 to Bria-IMT + CPI, TPC, or Bria-IMT monotherapy (discontinued after 150 enrollments to prioritize combination arms). The Bria-IMT regimen consists of: Day -2: Cyclophosphamide 300 mg/m², Day 0: 20M irradiated SV-BR-1-GM cells, Day 2/3: 0.1 mcg pegylated α interferon at each inoculation site. CPI infusion is administered Day -3 to 3. Cycles q3w. TPC regimens follow site specific SOC. Imaging q6w (first 2 cycles), then q8w. Eligibility includes all MBC subtypes, including CNS mets, and permits prior CPI therapy ($>$21 days pre-treatment). There will be 100 sites across the U.S., Canada, and ex-North America w/ an enrollment target of 404. The trial is currently active at 59 sites with 217 sub investigators. To date, 67 pts screened: 46 randomized (median age 56 yrs [34–83], median 6 [2–13] prior lines of therapy. The primary endpoint is OS, with an interim analysis at 144 events targeting a hazard ratio of 0.6. Secondary endpoints: PFS, overall response rate, CBR, CNS event free survival, and TWiST. Safety analyses ongoing; pt reported outcomes assess subjective treatment impact. Clinical trial information: NCT03328026. Research Sponsor: BriaCell Therapeutics Corp.

TPS1139 **Poster Session**

Efficacy and safety of disitamab vedotin in combination with RC148 versus albumin-bound paclitaxel ± toripalimab for patients with HR-negative HER2-low-expressing unresectable locally advanced or metastatic breast cancer: An open-label, randomized, controlled phase II study. First Author: Jiayu Wang, Cancer Hospital, Chinese Academy of Medical Sciences, Beijing, China

Background: Patients (pts) with hormone receptor (HR)-negative and HER2-low-expressing (defined as IHC 1+, or IHC 2+/ISH-) advanced breast cancer have poor prognosis and more effective treatment options are needed. Disitamab vedotin (DV) is a novel humanized anti-HER2 antibody conjugated with monomethyl auristatin E (MMAE) via a cleavable linker. DV alone or in combination with a PD-1 inhibitor showed encouraging antitumor activities with manageable safety in pts with HER2-low-expressing (IHC 1+, or IHC 2+/ISH-) advanced or metastatic breast cancer, gastric cancer and other solid tumors (Wang J., et al., *Cancer Commun*, 2024; Wang Y., et al., *eClinicalMedicine*, 2024). RC148 is a bispecific monoclonal antibody directed against programmed death receptor-1 and vascular endothelial growth factor receptor. DV+RC148 combination is expected to exert a synergistic antitumor effect by improving the tumor immune microenvironment. We aim to evaluate the efficacy and safety of DV plus RC148 versus albumin-bound paclitaxel $\pm$ toripalimab in pts with HR-negative HER2-low-expressing advanced breast cancer in this randomized phase II trial (NCT06642545). **Methods:** The key eligibility criteria are pts aged 18 years or older with unresectable stage III or stage IV breast cancer, negative HR status, low HER2 expression (defined as IHC1+, or IHC2+/ISH-), no previous chemotherapy for locally recurrent or metastatic disease, and no disease recurrence within 6 months after treatment completion (within 12 months if using taxanes) if with radical treatment. Pts who previously received anti-HER2 therapy or immunotherapy are excluded (except pts receiving neoadjuvant/adjuvant PD-[L]1 inhibitors 12 months prior to recurrence or progression). Pts will be randomized (stratified by PD-L1 expression status: positive or negative) in a ratio of 1:1 to receive DV (2.0 mg/kg) plus RC148 (20 mg/kg) intravenously once every two weeks or to receive albumin-bound paclitaxel (125 mg/m^2 day 1 and day 8) $\pm$ toripalimab (240 mg day 1) intravenously every three weeks until occurrence of disease progression or intolerable toxicity. The primary endpoint is objective response rate (ORR) in all pts per investigator's assessment according to RECIST v1.1. The secondary endpoints are ORR in the PD-L1-positive pts; investigator-assessed progression-free survival, disease control rate, duration of response, and overall survival in all pts and the PD-L1-positive pts. This study was initiated in August 2024. Clinical trial information: NCT06642545. Research Sponsor: RemeGen Co., Ltd.

TPS1140 **Poster Session**

A phase II trial to assess the impact of β2 adrenergic receptor (β2-AR) blockade in metastatic triple negative breast cancer (mTNBC). First Author: Shipra Gandhi, Roswell Park Comprehensive Cancer Center, Buffalo, NY

Background: In PD-L1+ mTNBC patients (pts), the standard of care treatment is chemotherapy and pembrolizumab (P) in the first-line setting. Our group and others have demonstrated that chronic β2-AR signaling suppresses $CD8^+$ cytotoxic T lymphocytes (CTL) function, drives their exhaustion, and increases the number of immunosuppressive myeloid-derived suppressor cells (MDSCs) and regulatory T cells (Tregs) in the tumor microenvironment (TME), thus supporting tumor proliferation. Consequently, abrogation of β-AR signaling using the pan β-blocker propranolol or $\beta\text{-AR}^{-/-}$ knockout mice increased the intratumoral frequency of CTLs and elevated the CTL:Treg ratio (Bucsek et al. Cancer Res. 2017; PMID: 28819022). Similarly, mouse tumor models also demonstrated decreased exhaustion markers (PD1, TIM3, LAG3) on CTLs when β-AR was blocked, via propranolol (Qiao G et al. Cancer Immunol Res. 2021, PMID: 33762351). Confirming this phenomenon, we have shown, in a prospective clinical trial in metastatic melanoma, that β-AR blockade with propranolol significantly increased response to P with an objective response rate (ORR) of 78%, as opposed to 30-40% with P alone (Gandhi et al. Clin Cancer Res 2021, PMID: 33127652). Moreover, clinical β-AR blockade was associated with higher immune infiltration in the TME (Hiller JG, Clin Cancer Res 2020, PMID: 31754048). Therefore, we hypothesize that using propranolol with chemotherapy and P should improve response for pts with newly metastatic PD-L1+ TNBC. **Methods:** This is a phase II single-arm, non-randomized multi-center study. Pts are women ≥18 yrs with PD-L1+ mTNBC, who will receive propranolol, chemotherapy (paclitaxel, nab-paclitaxel, gemcitabine-carboplatin) and P in the upfront setting: chemotherapy on days 1, 8 and P on day 1 every 3 weeks in addition to propranolol 30 mg BID, with intra-pt propranolol dose-escalation by 10 mg BID weekly to a total of 80 mg BID as tolerated by blood pressure and heart rate as natural biomarkers for dose. Treatment will continue until disease progression per RECIST. The primary endpoint is ORR, defined as complete or partial response. The secondary endpoint is safety, 6-month progression-free and overall survival. As an exploratory endpoint, changes in TME and blood immune markers will be assessed. In stage 1, n1=23 evaluable pts will be enrolled. If ≥ 13/23 responses are observed, then the study will continue to enroll another n2=14 pts for a total of n=37, otherwise will be suspended for futility. If ≥ 24/37 responses are observed, then the proposed therapy will be considered promising. Pre- and 6-week post-treatment tumor biopsies and blood samples will be analyzed for changes in stress-induced biomarkers (epinephrine, norepinephrine, and frequency of CTL, MDSC, Treg) and exhaustion markers (PD1, TIM3, LAG3). The study is currently open and has accrued one patient. Clinical trial information: NCT05741164. Research Sponsor: NIH (NCI).

TPS1141 **Poster Session**

Emiltatug ledadotin (Emi-Le): A B7-H4-directed dolasynthen antibody-drug conjugate (ADC) being investigated in phase 1 dose expansion in patients with triple negative breast cancer who received at least one prior topoisomarase-1 inhibitor ADC. First Author: Hyo S. Han, H. Lee Moffitt Cancer Center and Research Institute, Tampa, FL

Background: Breast cancer is the leading cause of cancer death for women worldwide, with triple-negative breast cancer (TNBC) considered one of the more aggressive breast cancers, accounting for ~15% of all cases. Unfortunately, there remains an unmet medical need for effective and well-tolerated treatments for advanced/metastatic TNBC; in heavily pretreated patients, standard-of-care single-agent chemotherapy has limited efficacy, with response rates of ~5%, PFS ~7 weeks. Emiltatug ledadotin (Emi-Le; XMT-1660) is a B7-H4-directed Dolasynthen ADC designed with a precise, target-optimized drug-to-antibody ratio (DAR 6) and a proprietary auristatin F-HPA microtubule inhibitor payload with controlled bystander effect. The FDA has granted Emi-Le two Fast Track designations for the treatment of adult patients with breast cancer, including patients with TNBC who have previously been treated with topoisomerase-1 inhibitor (topo-1) ADCs. Initial dose escalation clinical data from the ongoing Phase 1 trial at doses ranging from 38.1-67.4 mg/m2 per cycle demonstrated a 23% confirmed response rate in patients with B7-H4 high TNBC who were heavily pretreated all of whom received at least one prior topo-1 ADC. **Methods:** Based on encouraging clinical activity and tolerability data in the initial dose escalation data, the expansion portion (EXP) of the Phase 1 trial has been initiated and is actively enrolling patients. EXP has a Simon 2-stage design and will evaluate two doses in patients with advanced/metastatic TNBC who have received 1-4 prior lines of systemic therapy, including at least one topo-1 ADC. Patients will be evaluated for B7-H4 expression prospectively by IHC and will be stratified into B7-H4 TPS “high” and B7-H4 TPS “low” cohorts. The first EXP dose is 67.4 mg/m2 Q4W. Dose exploration is ongoing to identify a potential second higher EXP dose. The protocol includes the option for multiple additional indications, including HR+/HER2- breast cancer, endometrial cancer, ovarian cancer, and ACC-1. Clinical trial information: NCT05377996. Research Sponsor: Mersana Therapeutics.

TPS1142 **Poster Session**

TBCRC 058: A randomized phase II study of enzalutamide, enzalutamide with mifepristone, and treatment of physician’s choice in patients with androgen receptor-positive metastatic triple-negative or estrogen receptor-low breast cancer (NCT06099769). First Author: Tiffany A. Traina, Memorial Sloan Kettering Cancer Center, New York, NY

Background: Triple-negative breast cancer (TNBC) refers to a heterogenous group of breast cancers (BC) that lack expression of ER, PR, and HER2. Despite recent advances with immunotherapy (IO) and antibody-drug conjugates (ADCs), TNBC remains the most aggressive subtype, characterized by a high risk of recurrence and a short overall survival in the metastatic setting. BCs with low levels of ER and PR expression (1-10%) clinically behave like TNBC, and clinical management follows the TNBC treatment (tx) paradigm. We and others have identified a subset of ER/PR/HER2 negative breast cancers (BC) that express the androgen receptor (AR). Enzalutamide (enza), an AR-antagonist, has demonstrated activity in AR+ metastatic TNBC (Traina et al, JCO 2018). Activation of the glucocorticoid receptor (GR) has been implicated as a mechanism of resistance to AR inhibition in prostate and BC (Kach et al, Sci Transl Med 2015). Advanced TNBC remains an area of unmet need, particularly in patients who are ineligible for or progress following a checkpoint inhibitor. This randomized study will evaluate the efficacy of enza or enza plus the GR antagonist mifepristone (mif) as compared to physician’s choice chemotherapy (TPC). **Methods:** This is a randomized phase II trial; 201 patients (pts) will be randomized 1:1:1 to enza, enza with mif, or TPC (carboplatin, paclitaxel, eribulin, or capecitabine). The primary endpoint (endpt) is progression free survival (PFS), and the trial is designed to test the hypothesis that PFS in the pooled enzalutamide arms is superior to TPC; there is 80% power to detect a hazard ratio (HR) of 0.70, corresponding to increase in PFS from 3.5 months (mos) with TPC to 5.0 mos with enza-based tx. Secondary endpts include pairwise comparisons of PFS among the 3 arms and evaluation of response rate, clinical benefit rate, duration of response, overall survival, safety/toxicity, and patient-reported outcomes by arm. Exploratory endpts include correlation of tumor and circulating markers (constitutively active AR variants in circulating tumor cells and circulating tumor cell DNA) with tx response. Eligible pts must have: ECOG 0-2, metastatic ER/PR low or negative, HER2 0-2+ (FISH not amplified) (BC), measurable or evaluable disease (dz) per RECIST v1.1, < 3 prior lines of chemotx, any # prior endocrine txs, no prior anti-AR tx or CYP17 inhibition, no prior mif. Pts with PD-L1+ BC must have received prior IO if not contraindicated. Tumors must have AR >10%, normal organ function, no history of brain mets. As of 1/23/25, 11 of 201 pts have begun protocol-specified tx. Clinical trial information: NCT06099769. Research Sponsor: Breast Cancer Research Foundation; TBCRC; Astellas; Corcept; The TaTa Sisterhood Foundation; Pfizer.

TPS1143 **Poster Session**

AXALAP: Phase Ib study of axatilimab in combination with olaparib in *BRCA1/2* and *PALB2*-associated metastatic HER2-negative breast cancer (BC). First Author: Filipa Lynce, Dana-Farber Cancer Institute, Boston, MA

Background: Poly(ADP-ribose) polymerase (PARP) inhibitors (PARPi) have revolutionized the treatment of patients (pts) with germline *BRCA1/2* (gBRCA)-associated HER2-negative BC. However, resistance eventually occurs in almost all pts. Tumor-associated macrophages (TAMs), a key component of the BC tumor microenvironment, are highly immunosuppressive and associated with poor clinical outcomes. In preclinical immunocompetent models of BRCA-associated BC, PARP inhibition induces suppressive CSF-1R+ TAMs, contributing to resistance, so that combining anti-CSF-1R therapy with PARPi significantly enhances progression free survival (PFS) compared to PARPi monotherapy (190d vs 92d). Axatilimab (SNDX-6352; Ab969.g2), a humanized IgG4 monoclonal antibody targeting CSF-1R, reduces TAMs, potentially slowing tumor growth and enhancing anti-tumor immunity. In the Phase I SNDX-6352-0502 study for advanced solid tumors, axatilimab showed tolerability at the highest dose (6 mg/kg), with biomarker modulation observed at doses as low as 1 mg/kg. Axatilimab is FDA-approved for chronic graft-versus-host disease (cGVHD). **Methods:** AXALAP (NCT06488378) is a non-randomized open-label, proof-of-concept phase 1 study designed to evaluate axatilimab 1mg/kg or 3mg/kg every 2 weeks in combination with olaparib 300 mg twice daily in pts with somatic or germline *BRCA1/2*- and *PALB2*-associated HER2-negative metastatic BC. Patients must be PARPi naïve, or have not progressed on prior PARPi, and have received up to 2 prior lines of chemotherapy for metastatic disease. Pts will receive a two-week lead-in of olaparib monotherapy, followed by combined olaparib and axatilimab. Pts will undergo mandatory tumor biopsies pre-treatment, after the 2-week olaparib lead-in, and after 2 cycles of olaparib/axatilimab, with an optional biopsy at time-of-progression. Primary objectives are to establish the maximum tolerated dose (MTD) and recommended phase 2 dose and to assess the safety and tolerability of axatilimab and olaparib. Secondary objectives include assessment of changes in CSF-1R+ CD163+ macrophage levels after olaparib monotherapy and after 2 cycles of combination treatment at the MTD; to determine the objective response rate and the median PFS of the combination per RECIST 1.1 criteria. The MTD will be determined by Bayesian Optimal Interval (BOIN) design. Pts will be treated in cohorts of 3 with a maximum of 10 at each dose. If the MTD is identified as 3mg/kg, we will complete enrollment of 10 pts at 1 mg/kg to assess biological effectiveness and clinical efficacy of the lower dose. We expect to treat up to 20 pts, who will receive study treatment until development of unacceptable toxicity or disease progression. Enrollment began on 5/2024 at Dana-Farber Cancer Institute and the trial will also open at Beth Israel Deaconess Medical Center and Mayo Clinic-Rochester. Clinical trial information: NCT03604692. Research Sponsor: Incyte; U.S. National Institutes of Health; U.S. National Institutes of Health.

1500 Oral Abstract Session

Pharmacist-led medication reconciliation televisit (MRT) for phase 1 oncology clinical trials: A telemedicine model. First Author: Sarah O'Neill, Massachusetts General Hospital Cancer Center, Boston, MA

Background: Accurate medication reconciliation is critical in oncology trials to mitigate drug-drug interactions (DDIs), address eligibility and enhance patient safety. Cancer patients often experience polypharmacy (≥5 medications), increasing the risk of additive toxicities when investigational agents are introduced. Medication lists in Electronic Medical Records (EMRs) are often incomplete or outdated, complicating eligibility evaluations. To streamline screening for Phase 1 trials, a pharmacist-led medication reconciliation televisit (MRT) model was implemented to improve baseline medication list accuracy and reduce in-clinic time. **Methods:** From December 2022 to January 2025, one MRT was scheduled for each patient screening for Phase 1 trials (≥18 years, English-speaking or with interpreter support), after trial consent but before registration. Pharmacists reviewed EMRs and dispense histories, then conducted structured phone interviews with patients to review prescription (RX), over-the-counter (OTC), herbal and cannabis product usage, including name, strength, dose, frequency, start dates, indications and ingredients. Inactive medications were discontinued, allergies were updated, patient concerns and medication details were documented in the EMR. **Results:** A total of 525 MRTs across 82 trials had a median turnaround time of 2 days. Patients (median age 61 years) reported a median of 12 medications (range 2–41) and a median total time spent of 45 minutes (range 5–330) including documentation. 4.8% of patients required interpreter support. Primary cancer types (12 total) included gastrointestinal (32%), breast (20%) and head and neck (11%). Table 1 summarizes MRTs April 2024 and later which captured additional data: 64% required an EMR-prompted outside source reconciliation, 32% modified allergies, a median of 3 medications were added (range 0–37), 2 were changed (range 0-13), 3 were discontinued (range 0-18) and the median call time was 18 minutes. **Conclusions:** Pharmacist-led MRTs provided substantial value for investigators and research nurses, enabling them to focus on patient care. Flexible scheduling of remote MRTs supported presence of caregivers and medications, reducing list omissions and hospital chair time for patients. Sponsors and study teams gained more accurate baseline records, lowering the risk of unknown prohibited medications. This scalable telemedicine model offers potential for broader use in oncology trials, improving efficiency and patient safety. Research Sponsor: None.

1501 Oral Abstract Session

Remote clinical pharmacist impact on reducing total cost of care in Enhancing Oncology Model—enrolled oncology practices. First Author: Daniel Kendzierski, McKesson Specialty Health, The US Oncology Network, The Woodlands, TX

Background: The national cost of cancer care is estimated to exceed $245 billion by 2030, primarily due to the high cost of cancer drugs. The Enhancing Oncology Model (EOM) is a voluntary 6-month, 2-sided, risk-based payment model implemented by the Centers for Medicare and Medicaid Services (CMS) to improve cancer care while simultaneously reducing the total cost of care (TCOC). The US Oncology Network (The Network) comprises approximately 50% of all providers participating in EOM nationwide across twelve practice sites. In The Network, drug costs represented an average of 63% of a patient's TCOC. This study aims to demonstrate the impact of a pharmacist in reducing TCOC in the EOM model. **Methods:** Medication initiatives were clinically evaluated and adopted at an individual practice level and included: monoclonal antibody (moAB) dose rounding, pembrolizumab dose banding, biosimilar therapeutic interchange (TIC) to preferred products, use of a preferred PD-1 agent in metastatic NSCLC, decreased upfront usage of long-acting growth factor (GF) in metastatic cancer, and preferred use of zoledronic acid over alternatives. ClinReview pharmacists (CRP) remotely reviewed oncology treatment orders for cost-savings opportunities. CRPs updated eligible treatments per practice protocols or reviewed with the treating oncologist. Interventions were submitted by the CRP into a tracking system and marked as an EOM-related intervention. TCOC reduction was calculated using the difference between the CMS allowable for the original treatment ordered and the new order. **Results:** From July 1, 2023, to December 31, 2024, seven CRPs within five of The Network's EOM participating practices evaluated over 5,600 patients for medication initiatives. A total of 1,271 interventions were identified, with 1,180 accepted. The sum of TCOC reduction amounted to 8,982,235. Further breakdown of each initiative and average TCOC reduction per intervention are shown in Table 1. In addition to the six initiatives, the CRP contributed an additional 1,201,326 in medication savings associated with drug selection. **Conclusions:** CRP's medication initiatives within The Network's EOM participation reduced TCOC by nearly $9 million across five practices. Key initiatives such as pembrolizumab dose banding and preferred use of zoledronic acid were the largest contributors. These findings demonstrate the potential for pharmacist-driven interventions to lower costs and drive the success of value-based care models in oncology practices. Research Sponsor: None.

EOM Initiative	n (%)	TCOC Reduction, $	Average TCOC Reduction per intervention, $
moAB dose rounding	443 (35)	1,537,273	3,470
Pembrolizumab dose banding	106 (8)	1,962,105	18,510
TIC	356 (28)	1,510,945	4,244
Preferred PD-1 agent for NSCLC	26 (2)	153,117	5,889
Decrease GF use	37 (3)	109,822	2,968
Zoledronic acid use	181 (14)	2,157,895	11,992

1502 Oral Abstract Session

Video-based genetic counseling to reduce physician workload and enhance consulter understanding: A prospective randomized clinical trial. First Author: Georg Pfeiler, Department of Obstetrics and Gynecology and Center for Breast Health, Comprehensive Cancer Center, Medical University of Vienna and Austrian Breast and Colorectal Cancer Study Group, Vienna, Austria

Background: Genetic counseling is an essential part of germline genetic testing, which is reccomended for use of PARP inhibitors in breast cancer treatment. Despite its importance, only about 40-60% of breast cancer patients receive genetic counseling. A video tool has been developed to provide genetic counseling, aiming to reduce the physician's workload and improve the patient's understanding. **Methods:** Advice seekers at increased risk for hereditary breast and ovarian cancer as well as breast and ovarian cancer patients were included in the trial. They were randomly assigned 1:1 to either standard of care (physician only, PO) or video based followed by physician genetic counseling (VPO). A 15-minute video tool was created for VPO participants, who watched it on an iPad and answered 6 comprehension questions online. The physician then clarified any misunderstood topics. In both groups, counseling time was measured from conversation start to blood donation. Afterwards, participants completed a questionnaire with 9 comprehension questions (16 points total). Data analysis included Bernard's and Pearson's tests for categorical data, Kendall's test for correlations, and ordinal logistic regression for multivariable analysis. **Results:** A total of 110 participants with a median age of 47 years were randomized into two groups: PO counseling (55 participants, 50%) and VPO counseling (55 participants, 50%). Among them, 29% (32 participants) received therapeutic counseling for breast/ovarian cancer, while 71% (78 participants) received predictive counseling with no cancer diagnosis. Participant characteristics were well balanced between groups, with no significant differences in age, indication for counseling, sex (90% female), level of education, or German-speaking proficiency. Participants reported their sources of genetics knowledge as previous knowledge (30%) and physician counseling (70%) in the PO group, and as previous knowledge (20%), physician counseling (30%), and the video tool (45%) in the VPO group. The video significantly improved comprehension scores from 62.5% (10 points, PO group) to 81.3% (13 points,VPO group) ($p < 0.0001$). Additionally, the video tool significantly reduced the time physicians spent on counseling from 6.6 minutes to 2.4 minutes ($p < 0.0001$). According to the logistic regression model, both the level of education (estimate -1.34, $p = 0.002$) and German language comprehension level (estimate 1.62, $p = 0.001$) significantly influenced the genetic counseling comprehension score. **Conclusions:** In this prospective randomized trial, video genetic counseling improved comprehension and reduced physician counseling time. The genetic video tool, which can be translated into various languages, facilitates genetic counseling by decreasing the workload for physicians, which may increase the genetic counseling rate in the clinic. Research Sponsor: None.

1503 Oral Abstract Session

Electronic patient-reported outcome-based weight management versus usual care during induction chemotherapy followed by concurrent chemoradiotherapy in nasopharyngeal carcinoma: A phase II randomized controlled trial. First Author: Qiu-Yan Chen, Department of Nasopharyngeal Carcinoma, Sun Yat-Sen University Cancer Centre, Guangzhou, China

Background: Nearly almost patients with nasopharyngeal carcinoma (NPC) experience weight loss (WL) and malnutrition during treatment. However, effective patients' weight management remains a challenge, as no standardized approach currently exists. This study aimed to evaluate the feasibility and efficacy of an electronic patient-reported outcome (ePRO) based weight management in mitigating WL and malnutrition in patients with locally advanced NPC (LA-NPC) receiving induction chemotherapy (IC) followed by concurrent chemoradiotherapy (CCRT). **Methods:** In this phase II randomized controlled trial, eligible patients aged 18 to 70 years with stage III-IVa (AJCC ^{8}th) NPC were randomly assigned in a 1:1 ratio to either ePRO-based weight management (ePRO group) or usual care (UC group). Body weight, NRS2002, PG-SGA, EORTC QLQ-C30 and hematological indicators were collected at six timepoints during treatment. Patients in ePRO group used the ePRO weight management system (ePRO-WMS). When predefined e-alert were triggered (e.g., WL $>$ 5%), the MDT promptly communicated and responded with patients. Patients in UC group did not use the ePRO-WMS and had no e-alerts. The primary outcome was the proportion of patients experiencing WL $>$ 10% at one month after completing CCRT (Post-1m). The secondary outcomes included WL $>$ 10% and WL $>$ 20% at the end of CCRT (W7-CCRT), as well as comparisons of NRS2002, PG-SGA, EORTC QLQ-C30, and hematological indicators. WL was compared using the χ^2 test, while other secondary outcomes were analyzed with linear mixed-effects models (ClinicalTrials.gov, NCT05834712). **Results:** From May 2022 to August 2023, 112 patients were enrolled in each group (76.8% male, 86.6% with ≥ junior high school education). 110 patients (UC group) and 109 patients (ePRO group) completed IC+CCRT. Among ePRO group, 107 patients successfully completed the ePRO-WMS, generating 561 e-alerts. Compared to UC group, ePRO group had significantly fewer patients with WL $>$ 10% at Post-1m (37.5% *vs.* 57.1%, $P = 0.003$) and W7-CCRT (22.3% *vs.* 38.4%, $P < 0.001$). Additionally, ePRO group showed improved nutritional status (Retinol Binding Protein, 38.3 *vs.* 34.8, $P = 0.011$) and quality of life. Notably, reductions in inflammation (C-reactive protein, 10.4 *vs.* 15.9, $P = 0.027$) and immune suppression ($CD4^+CD25^+$ regulatory T cells, 20.1 *vs.* 22.2, $P = 0.034$) were also observed. No significant differences were found between groups for acute adverse and progression-free survival (median follow-up time: 16 months). However, 2 cases of nasopharyngeal necrosis were observed in the UC group during follow-up. **Conclusions:** Compared to usual care, ePRO-based weight management in LA-NPC patients mitigated weight loss, alleviated inflammation, and significantly improved nutritional status and quality of life. Clinical trial information: NCT05834712. Research Sponsor: None.

1504 Oral Abstract Session

A novel virtual reality supportive care intervention (BMT-VR) for patients undergoing hematopoietic stem cell transplantation (HSCT): A pilot randomized clinical trial. First Author: Hermioni L. Amonoo, Department of Supportive Oncology, Dana-Farber Cancer Institute; Department of Psychiatry, Mass General Brigham; Harvard Medical School, Boston, MA

Background: Patients with hematologic malignancies undergoing HSCT experience immense physical and psychological symptom burden during their extended transplant hospitalization. Interventions that help manage patients' psychological distress and improve their quality of life (QOL) during this inpatient stay are limited. Virtual reality (VR), with its three-dimension capabilities for user engagement, offers a novel delivery modality for scalable, targeted, and patient-centered supportive care interventions aiming to address the persistent unmet psychosocial needs of these patients. **Methods:** We conducted a pilot randomized clinical trial (RCT) of a VR supportive care intervention (BMT-VR). Patients undergoing HSCT were randomly assigned to BMT-VR or usual care during their 3-4-week hospitalization. BMT-VR consisted of five self-directed modules addressing 1) supportive psychoeducation and managing expectations during HSCT; 2) effective coping; and 3) acceptance and gratitude while dealing with uncertainty. The primary endpoint was feasibility ($\geq$60% of eligible patients enrolling, and $\geq$60% of BMT-VR participants completing $\geq$3/5 modules). To assess BMT-VR's acceptability, we used the System Usability Scale ($>$ 80 = excellent acceptability). We assessed psychological distress (Hospital Anxiety and Depression Scale), QOL (Functional Assessment of Cancer Therapy-BMT), post-traumatic stress symptoms (PTSD-Checklist), coping (Measure of Current Status-A), and self-efficacy (Cancer Self-Efficacy Scale) at baseline (i.e., 3 days post-HSCT) and 4-, 12-, and 24-weeks post-HSCT. We used analysis of covariance (ANCOVA) to explore the preliminary effects of BMT-VR on outcomes. **Results:** We enrolled 58.3% (81/139) of eligible patients (BMT-VR (n = 40); usual care (n = 41)) with a mean age of 57.9 (SD = 14.7) and 51.9% women. 74.4% of BMT-VR participants completed $\geq$3/5 modules and 65.1% completed 5/5 modules, with median acceptability score = 81.2. At 4-weeks, BMT-VR vs. usual care participants reported improved anxiety (5.3 vs. 3.6, P = 0.016), QOL (108.2 vs. 96.8, P = 0.014), coping (36.6 vs. 32.4, P = 0.023), and self-efficacy (144.6 vs. 131.9, P = 0.019). Although BMT-VR vs. usual care participants reported sustained improvements in QOL (B = 3.8, P = 0.002), coping (B = 1.8, P = 0.011), and self-efficacy (B = 4.5, P = 0.017), BMT-VR effects became more pronounced for depression (B = -0.5, P $<$ 0.001), and PTSD (B = -1.7, P $<$ 0.001) symptoms longitudinally across all time points. **Conclusions:** A novel VR-delivered supportive care intervention tailored to the psychosocial needs of HSCT recipients is feasible and acceptable and demonstrated preliminary efficacy for improving psychological distress and QOL. A subsequent multi-site RCT will evaluate BMT-VR's efficacy for improving outcomes in diverse HSCT settings. Clinical trial information: NCT05629676. Research Sponsor: Doris Duke Charitable Foundation; Clinician Scientist Development Award; National Cancer Institute; K08CA251654.

1505 Oral Abstract Session

Geriatric assessment and management with a question prompt list using a web-based application to reduce treatment toxicity in older patients with cancer: A randomized controlled trial (J-SUPPORT 2101 study). First Author: Ayumu Matsuoka, Division of Survivorship Research, National Cancer Center Institute for Cancer Control, National Cancer Center, Tokyo, Japan

Background: Older adults with cancer experience aging-related physical, psychosocial and cognitive challenges that require comprehensive communication with their oncologists. Geriatric assessment (GA) can assess these aging-related problems and guide management. Communication support may further facilitate the implementation of GA-guided management (GAM). We report secondary outcomes of a single-blind, parallel-group, multicenter, randomized controlled trial evaluating the efficacy of a program combining GAM recommendations and communication support to facilitate aging-related communication between older Japanese patients with cancer and their oncologists. **Methods:** This study included patients aged $\geq$70 years with advanced or recurrent gastrointestinal cancers who were scheduled to receive first- or second-line systemic therapy and had impairment in at least one GA domain as assessed with a web-based application at baseline. In the intervention group, GAM recommendations and a question prompt list were given to patients by trained intervention providers to be shared with their oncologists at the first outpatient visit after randomization. During 5 months after the initial intervention, the implementation of the GAM recommendations was reviewed monthly by the intervention providers with the patients and their oncologists. The control group received usual care. Secondary outcomes included the incidence of grade 3-5 adverse events (National Cancer Institute Common Terminology Criteria for Adverse Events, ver. 5.0), dose modifications, early treatment discontinuation, unplanned hospital utilization during 3 months, overall survival rate at 6 months, and health-related quality of life and patient satisfaction at 3 and 6 months. **Results:** Between September 2021 and September 2023, 215 patients (99 women, 116 men; median age 75 [range 70-88] years) were randomized (n=108/107 in the intervention/control group). No differences were found between the groups in patient background characteristics. The incidence of any grade 3-5 adverse event was significantly lower in the intervention group than in the control group (50.9% vs. 66.4%, P$<$0.05); the incidence of hematologic toxicities was significantly reduced (37.0% vs 55.1%, P$<$0.01), while that of non-hematologic toxicities remained similar (29.6% vs 36.4%, P=0.31). Early treatment discontinuation was also significantly lower in the intervention group than in the control group (26.9% vs. 43.0%, P$<$0.05). No significances were found in other secondary outcomes including overall survival rate at 6 months (77.7% vs 78.7%, P=0.88) **Conclusions:** Our program combining GAM recommendations with communication support significantly reduced severe treatment toxicity without compromising survival in older patients with cancer. Clinical trial information: UMIN000045428. Research Sponsor: Japan Agency for Medical Research and Development.

1506 Oral Abstract Session

A technology-enabled clinical trial program's impact on patient screening and trial enrollment in 2024. First Author: Samantha Mallahan, Tempus AI, Inc., Chicago, IL

Background: Typical workflows for clinical trial start-up and screening are time- and resource-intensive. The Tempus AI TIME program offers a novel clinical trial solution, collaborating with clinical sites to increase trial access and alleviate site burden by streamlining study activation and screening methods. **Methods:** The TIME program consists of an algorithmic trial screening platform (TApp), team of oncology nurses, diverse trial portfolio, and rapid study activation processes. Patient-level clinical information is centralized within the TIME database and includes structured and unstructured data generated from Electronic Medical Record integration, next generation sequencing results, and natural language processing models. The TApp used this data combined with trial eligibility criteria to algorithmically match patients to TIME trials. TApp searches were triggered by changes to study criteria and/or updates to clinical data. Algorithmic matches were filtered based on site capabilities, site interest in the trial, and trial lookback criteria, which defined the required recency of a patient's latest clinical document or encounter. Qualifying matches were then reviewed by a Tempus nurse and sent to sites if confirmed eligible. Trial activations followed TIME's streamlined operational methods using a pre-negotiated rate card for site reimbursement of all clinical trial activities, standardized clinical trial agreement, and central IRB. Trials could be activated prospectively before the first eligible patient was identified, or in a "just-in-time" (JIT) manner if a patient was ready to consent. Data collected included TIME network information, TApp and nurse screening results, activation timelines, and enrollments across all active TIME sites and trials from 01/01/2024 - 12/31/2024. **Results:** During 2024, the TIME network consisted of 87 sites (79 Community, 8 Academic) and 98 trials. The TApp completed 1,323,259,353 searches across 1,281,676 patients resulting in 2,251,505 potential TApp trial matches. After applying site capability and trial lookback filters, TIME nurses screened 35,912 of these matches with 5,034 confirmed. These matches led to 186 activations (82 JIT, 104 prospective) and 573 consents. **Conclusions:** The Tempus AI TIME program facilitated the screening of 1.28M+ patients for over 95 clinical trials, averaging 1.57 consents per day over 1 year. Future trial matching strategies should utilize algorithmic screening and rapid activation processes to improve patient access and trial success. Research Sponsor: Tempus AI, Inc.

Effect of human-AI teams on oncology prescreening: Final analysis of a randomized trial. First Author: Ravi Bharat Parikh, Emory University, Atlanta, GA

Background: Eligibility assessment for oncology clinical trials – "prescreening" – relies on manual review of unstructured clinical notes, which is error-prone and time-consuming. Artificial intelligence (AI) language models that merge deep learning with oncologist-derived rules (neurosymbolic AI) can enhance prescreening by automating eligibility extraction from longitudinal electronic health records (EHRs), yet real-world evaluations are limited. We compared the accuracy and efficiency of traditional vs. AI-augmented (Human+AI) prescreening. **Methods:** In this randomized non-inferiority trial, two research coordinators (RCs) abstracted 12 common trial eligibility criteria from complete EHRs from patients with advanced non-small cell lung cancer (NSCLC) or colorectal cancer (CrC) treated in a community oncology practice. Before the trial, gold-standard abstraction was performed by 3 independent oncologist reviewers. Charts were randomized in blocks of 20 to be viewed alone (Human-alone) or augmented by a pretrained neurosymbolic model (Human+AI) in a paired design, such that each RC reviewed each patient chart. The primary aim was to evaluate noninferiority (margin ±5%) and subsequent superiority of chart-level accuracy (proportion of correctly abstracted elements per chart relative to gold standard) between Human+AI vs. Human-alone. Secondary outcomes were criterion-level accuracy (proportion of correctly abstracted elements across charts for each eligibility criterion), and efficiency (median abstraction time per chart). Paired t-tests and Wilcoxon rank-sum tests assessed differences between Human+AI vs. Human-alone. We descriptively compared accuracy of both arms vs. the AI algorithm (AI-alone). **Results:** Among 356 charts (196 NSCLC, 160 CrC), Human+AI had noninferior and superior accuracy than Human-alone (76.1% vs. 71.5%, $p < 0.001$); both Human arms were superior to AI-alone (59.9%). Human+AI had greatest criterion-level accuracy for 7 of 12 criteria. Efficiency was similar between Human arms (32.1 vs. 31.8 min, p = 0.51). **Conclusions:** AI-augmented prescreening was more accurate than RC or AI prescreening alone. Human+AI teaming most improved accuracy for biomarker, staging, and response criteria. While Human+AI did not save time, efficiency gains may be realized as RCs become more familiar with AI eligibility models. AI language models can enhance CRC prescreening and identification of trial-eligible patients. Clinical trial information: NCT06561217. Research Sponsor: Mendel AI.

Disparities in pediatric oncology outcomes in the occupied Palestinian territories: A retrospective study from Augusta Victoria Hospital. First Author: Ru'a Rimawi, Dana-Farber Cancer Institute, Boston, MA

Background: Childhood cancer survival rates exceed 80% in high-income countries, but over 80% of the global burden occurs in low- and middle-income countries, where survival rates are significantly lower. The occupied Palestinian territories (OPT)—comprising the West Bank, Gaza, and East Jerusalem—face additional and location-specific challenges, including political instability, movement restrictions, and fragmented healthcare, that would be expected to further negatively impact care. The aim of our study is to report on outcomes of children treated at the only specialized pediatric oncology cancer center, Augusta Victoria Hospital (AVH), located in East Jerusalem. **Methods:** This was a retrospective IRB approved study conducted by Dana-Farber Cancer Institute and AVH. Chart review was performed to obtain diagnoses, treatments and outcomes of all pediatric oncology patients with histologically confirmed cancer admitted at AVH from January 2018 to June 2024. **Results:** A total of 424 patients were included, with a median age at diagnosis of 6.95 years (IQR, 3.35–11.2). Of these, 51.2% were male. Patients resided in the West Bank (51.2%), Gaza (43.4%), and East Jerusalem (3.8%). The median diagnostic delay, defined as date of symptom onset to date of diagnosis, was 24.5 days (IQR, 10-45), with significant variation by gender (males: 30 days; females: 20 days, p = 0.018), age group (<5 years: 14 days; ≥5 years: 30 days, p = 0.003), and oncology diagnosis (leukemia: 14 days, lymphoma and solid tumors: 30 days, p = 0.014). Treatment delays, defined as the time form diagnosis to treatment initiation, was 14 days (IQR, 4-30), with the shortest duration for leukemia (2 days) and the longest for solid tumors (30 days, p = 0.008). There were no significant differences in time to treatment by region. The majority of patients lost to follow-up were living in Gaza (15/21, 71%). Among the 13% deaths, 15.4% were treatment-related, primarily due to infection, and most of these treatment-related deaths (65%) occurred in patients living in Gaza. The 3-year overall survival (OS) rate was 76.31%, and event-free survival (EFS) rate was 62.36%. Gaza patients had the lowest 3-year EFS rate (37.12%) compared to the West Bank (70.37%) and East Jerusalem (77.78%; $p < 0.0001$). **Conclusions:** This study is the first to report on outcomes of pediatric oncology patients treated at the only specialized center in the OPT. Males and patients older than 5 years experienced longer diagnostic delays, while patients with solid tumors faced treatment delays 15 times longer than those with leukemia. Gaza patients had higher lost to follow-up rates and treatment-related deaths with significantly inferior EFS. Research Sponsor: None.

1510 Clinical Science Symposium

Analysis of evidence in NCCN harmonized guidelines for sub-Saharan Africa. First Author: Scott Swartz, Department of Medicine, University of California, San Francisco, San Francisco, CA

Background: The National Comprehensive Cancer Network (NCCN) Harmonized Guidelines for Sub-Saharan Africa (SSA) have emerged as leading cancer treatment guidelines in SSA. The NCCN-SSA guidelines, derived by adapting NCCN guidelines for the SSA context, offer standardized recommendations to guide cancer care and shape policy in SSA. This study examines the evidence cited in support of the NCCN-SSA guidelines, with a focus on population characteristics and generalizability to SSA. **Methods:** Two reviewers independently examined the NCCN-SSA guidelines for the eight most common cancers in SSA to identify all studies cited in support of treatment/management recommendations. Study selection discrepancies were resolved by discussion. Full-text articles were reviewed and data on age, sex, race, and recruitment geography were abstracted. Descriptive analyses were performed using R statistical software. **Results:** Overall, 4,589 citations were reviewed, and 2,938 (64.0%) studies with individual-level data were included, representing >10.4 million study participants. Of the 2,061 studies reporting geographic information (70%), 50 (2.4%) recruited in SSA; of these, 39 (83.0%) recruited from South Africa. Three studies (0.2%) recruited exclusively in SSA. Most studies (95.3%) recruited exclusively from high or upper-middle income countries. Only 29.2% of studies with race data included >10% Black study participants. **Conclusions:** Most studies cited in the NCCN-SSA guidelines were conducted in high-income countries outside SSA. A small minority of all study participants were Black. Our findings underscore potential limitations in the generalizability of the NCCN-SSA guidelines to SSA and highlight a pressing need to generate and incorporate context-specific data to guide care and inform policy. Research Sponsor: UCSF Helen Diller Family Comprehensive Cancer Center.

1511 Clinical Science Symposium

Integrated health system for resolving breast cancer screening actions: Multicenter randomized clinical study—Itaberaí randomized trial, ReBEC, RBR-39vm2nd. First Author: Ruffo Freitas-Junior, CORA – Advanced Center for Diagnosis of Breast Diseases Federal University of Goias, Goiania, Goias, Brazil

Background: The ITABERAÍ Project involves an intervention through training of Community Health Workers (CHW), based on evidence from clinical breast examinations (CBE) screening. It is a randomized, prospective, phase III, multicenter clinical study. The target population is divided into a Control Group (CG) and an Intervention Group (IG), where the CG receives the Brazilian Ministry of Health's (MS) recommendations for breast cancer screening, The IG, in addition to the MS recommendations, receives the CBE. Among the stages of the project are the training of CHW and the development of tools for data collection. Objective: This study aims to evaluate the functioning of the integrated system as a tool for the resolution of breast cancer screening actions, according to the ITABERAÍ Project. **Methods:** Information stored in the integrated system database developed for the project, from 2022 to 2024, was analyzed. The system comprises a set of services and applications that integrates actions from the registration of participants to the diagnosis and treatment of altered cases. It involves the integration of the App Rosa with the Web System (RosaWatch). The App Rosa was created for exclusive use by the CHW to collect data from participants who agree to participate in the study, while RosaWatch is for use by the Family Health Team (FHT), specialist doctors, nurse navigators, and researchers, and was created to collect information on the follow-up of altered cases. To evaluate the functioning of the system, data on the completeness of the information stored according to the Study Group and the follow-up of cancer cases were checked. **Results:** At the end of 3 years of project implementation, data from 3,670 randomized women were reported, of which 92% (3,359) were active in the project, out of this 1,780 (53%) in the CG and 1,579 (47%) in the IG ($p < 0.05$). Regarding the completeness of the information, by the end of 2024, it was found that 2,984 (88.8%) had consistent data. Stratifying by year of data collection, a significant increase in completeness was observed: in 2022, of the 425 records, 278 (65%) were compliant; in 2023, of the 2,255 records, 2,117 (94%) were compliant; and in 2024, of the 679 records, 654 (96%) were compliant. During the study period, 3,143 breast exams were performed by the CHW of the IG, with 594 (19%) altered cases. Of these, after screening at the Family Health Units (ESF), 90 (15%) participants received care from a specialist doctor (mastologist), and 10 had a confirmed breast cancer. In the CG, ESF doctors referred 33 women for specialist consultations, and six diagnoses were confirmed. **Conclusion:** The integrated system proved to be effective in monitoring the actions of the ITABERAÍ Project. Additionally, it contributed to the adherence of the CHW and the quality standard of the information, facilitating better data monitoring. Clinical trial information: RBR-39vm2nd. Research Sponsor: None.

Anesthesia type during surgery for treatment of biologically aggressive cancers: Results of the GA-CARES randomized, multicenter trial. First Author: Elliott Bennett Guerrero, Stony Brook University School of Medicine, Stony Brook, NY

The full, final text of this abstract will be available at meetings.asco.org on the day of presentation and in the online supplement to the June 10, 2025, issue of the *Journal of Clinical Oncology*.

1513 **Rapid Oral Abstract Session**

General practitioner-led vs surgeon-led colon cancer survivorship care: A randomized clinical trial. First Author: Julien Vos, Amsterdam UMC, Amsterdam, Netherlands

Background: The role of general practitioners (GPs) in providing survivorship care for cancer patients remains debated. In 2015, the randomized I CARE trial was initiated to evaluate the impact of GP-led vs. surgeon-led survivorship care on quality of life (QoL) and assess the effect of the eHealth application Oncokompas. An interim analysis after 12 months revealed no clinically relevant differences in QoL changes. However, patients continued to have follow-up consultations for up to 60 months after treatment. This study addressed the long-term QoL outcomes of the trial. **Methods:** The I CARE trial was a pragmatic, 2x2 factorial, open-label, randomized controlled trial. The trial was conducted in 8 hospitals and 225 general practices across the Netherlands. The trial included patients who underwent primary surgical treatment for stage I-III colon cancer or rectosigmoid carcinoma, and who were eligible for routine follow-up according to national guidelines. Inclusion lasted from March 26, 2015, to Nov 21, 2018. Patients were randomized using variable block randomization, stratified by age and tumor stage, into four groups (1:1:1:1): usual surgeon-led care, surgeon-led care with Oncokompas, GP-led care, and GP-led care with Oncokompas. The primary outcome was QoL at 5 years, as measured by the change from baseline in the EORTC QLQ-C30 summary score (range 0-100). Generic and disease-specific QoL were measured at baseline, 3, 6, and 12 months, and annually up to 60 months post-treatment. Differences in QoL changes were analyzed using piecewise linear mixed-effects models with a knot at 24 months to capture potential deviations in QoL recovery. A 10-point difference was considered clinically relevant (superiority design with α = 0.05, power of 80%, and 15% dropout). The trial is registered with the Netherlands Trial Register (NTR4860). **Results:** In total 303 patients were enrolled; 79 were randomized to surgeon-led care, 83 to surgeon-led care with Oncokompas, 73 to GP-led care, and 68 to GP-led care with Oncokompas. Patients were male (67%) with a mean age of 68.0 years (SD 8.4). Of the 151 patients assigned to Oncokompas, 51 (36%) reported using the app at least once in the first year. Baseline QoL was high in all groups. No clinically meaningful differences in QoL were observed between GP-led and surgeon-led groups at 24 months (difference of -0.5 [95% CI -1.6 to 0.5]) and 60 months (-0.01 [-0.8 to 0.8]). Oncokompas also had no meaningful effect (difference of 0.8 [0.0 to 1.6] at 60 months). **Conclusions:** In this pragmatic, randomized controlled trial conducted in the Netherlands, GP-led survivorship care did not improve long-term QoL compared to traditional surgeon-led care among non-metastatic colorectal cancer survivors. Due to low usage rates, the impact of Oncokompas is inconclusive. Survivorship care models can be tailored to fit individual preferences. Clinical trial information: NTR4860. Research Sponsor: Dutch Cancer Society; grant BMA 5954.

1514 **Rapid Oral Abstract Session**

Effect of post-discharge symptom monitoring on hospital readmissions: A randomized trial. First Author: Robert Michael Daly, Memorial Sloan Kettering Cancer Center, New York, NY

Background: There is growing interest to improve patient care transitions from hospital to home and to prevent readmissions but effective interventions are lacking. **Methods:** We conducted a randomized clinical trial among patients with cancer discharged after an unplanned hospital admission at a specialty cancer center. Hospitalized patients on medical oncology services were randomized at discharge to receive either a digital symptom monitoring and management intervention or to usual care. Patients randomized to the intervention received a daily electronic symptom assessment for 10 days post-discharge, consisting of 9 common symptoms from the National Cancer Institute Patient Reported Outcomes version of the Common Terminology Criteria for Adverse Events and an open-ended question to allow for patients to provide further symptom context and for two-way engagement with their clinical team. Patients also received customized self-management education delivered through the patient portal based on their reported symptoms. Primary oncologists received alerts through the portal for moderate and severe symptoms. Usual care consisted of symptom monitoring at the discretion of the primary clinical team, generally comprising an oncologist and an office practice nurse. The primary outcome was the 30-day readmission rate, analyzed using cumulative incidence functions and Gray's test with death as a competing risk. Secondary endpoints included 90-day readmission rate and 30-day emergency room visit without admission rate. **Results:** Between 04/19 and 09/19/2024, 1,713 patients were randomized with median age 66 years (range: 19 – 99), 66% white, 12% African American, 11% Asian, and 11% Hispanic with 53% female. The most common cancer diagnoses were gastrointestinal (26%), thoracic (11%), genitourinary (10%), gynecologic (10%), leukemia (9%), and lymphoma (9%). In the intervention group, the most frequently reported moderate and severe symptoms were fatigue and pain. The two arms had roughly similar proportions of patients who died before a hospital readmission. The 30-day readmission rate was 30% in the intervention group compared to 37% in the usual care group (p = 0.001). The decrease in readmission rate was maintained at 90 days (45% vs. 52%, p = 0.002). Emergency room visits without admission at 30 days were also lower in the intervention group (12% vs. 17%, p = 0.007). **Conclusions:** Digital post-discharge symptom monitoring and customized patient self-management education for 10 days post discharge reduced hospital readmissions in patients with cancer. Further research is necessary to identify the precise mechanisms that contribute to the success of this intervention. Research Sponsor: National Cancer Institute; Emerson Collective Digital Oncology Care.

SNF-CLIMEDIN: A HECOG prospective randomized trial of digital support and intervention in patients with advanced non-small cell lung cancer (NSCLC)—Final results. First Author: Paris A. Kosmidis, Department of Medical Oncology, Hygeia Hospital, Athens, Greece

Background: This trial aims to investigate the feasibility and effectiveness of online digital intervention to NSCLC patients in terms of adverse events (AEs), quality of life (QoL), cost, and the interrelation with clinical and molecular characteristics. **Methods:** This prospective randomized trial recruited 200 advanced NSCLC patients (3/22-10/23). Final analysis was undertaken in 12/24. All had NGS tissue analysis for 161 genes, and received standard treatment (predominantly immuno-chemotherapy). Through the CareAcross online platform, they received information about their disease and treatment, and periodically reported any of the 22 preplanned AEs. Patients were randomized 1:1 in the Intervention (A) and Control (B) arm; patients in arm A received digitally, additionally, evidence-based guidance for the reported AEs. The study was designed to assess AE improvement (measured per patient as reduction of AEs reported at last contact, compared to those previously reported) and QoL. EQ5D-5L scores were collected. Patient-case level hospitalization data were collected and costs were estimated based on reimbursed cost as defined by the Ministry of Health. Results were correlated with patients' clinical and molecular characteristics. **Results:** Clinical and molecular characteristics will be presented during ASCO Congress. Comparing arms A vs B: ORR: 42.1% vs 41.7%; Median PFS: 11m (8.0-15) vs 10m (7.0-13), 1-year PFS: 43% (31%-54%) vs 42% (31%-53%) (p = 0.4). Median OS: 15m (12-20) vs 16m (12-21), 1-year OS: 59% (48%-68%) for both arms (p = 0.9). PFS and OS were improved for those with best responses ($p < 0.001$). Patients with EGFR mutations had better OS (p = 0.05). The most common AEs reported in both arms were fatigue, cough, anorexia, nausea. More AEs were reported online vs to clinicians (89% vs 68% of patients; $p < 0.01$). Baseline EQ5D-5L was similar for both arms; when compared with data at best response, Anxiety/Depression showed the biggest difference in improvement for arm A vs B. Among the 22 AEs, 17 improved more in arm A, 1 improved equally, and 4 improved more in Arm B. The comparative improvements of rash and stomatitis in arm A vs B were statistically significant (p = 0.0073 & p = 0.0447). The mean hospitalization cost (arm A vs B, in Euros) was 455.4 (95%CI: 91.9-941.5) vs 779.5 (346.6-1328.5) ($p < 0.001$); the mean diagnostics cost was 20.3 (0.5-50.8) vs 73.3 (1.3-186.1) ($p < 0.001$). **Conclusions:** Digital oncology is feasible, cost-effective by reducing hospitalizations and tends to improve QoL (especially anxiety and depression) and most AEs of NSCLC patients regardless of clinical and molecular status. Patients report, digitally, more informative AEs for clinical and research analysis. Through the digital transformation of healthcare, digital oncology can be a complementary tool to the Oncology team and warrants further exploration. Clinical trial information: NCT05372081. Research Sponsor: Stavros Niarchos Foundation.

1516 Rapid Oral Abstract Session

Breast cancer diagnosis, management, and outcomes in transgender, nonbinary, and gender-diverse individuals: A multicenter cohort. First Author: Chandler Scott Cortina, Division of Surgical Oncology, Department of Surgery, Medical College of Wisconsin & MCW Cancer Center, Milwaukee, WI

Background: Paucity of data on breast cancer (BC) in transgender, nonbinary, and gender-diverse (TGD) individuals leads to suboptimal screening and treatment algorithms. We developed a national multicenter retrospective cohort to describe demographic, clinicopathologic, and treatment characteristics of TGD individuals with BC and report outcomes. **Methods:** The cohort included TGD persons age ≥18yrs with stage 0–IV BC treated at 22 US centers from 1990–2023. Demographic and clinicopathologic characteristics were evaluated and compared to BC patients in the SEER 2016–21 dataset. Wilcoxon rank sum tests, χ^2 tests, and KM analysis were used to compare variables and estimate 5-yr BC-specific survival (BCSS). **Results:** 112 TGD persons with 113 BCs were included. Median age at diagnosis was 42.5yrs (IQR 36.5–51), 92.9% were female sex at birth (FSAB), 73.2% were NH-White, and 38.4% used gender-affirming hormones pre-BC. Of those FSAB (n=104), 61.5% were premenopausal and 11.5% had undergone gender-affirming top surgery (GATS) pre-BC. Most BCs (51.8%) were self-detected, 27.7% were screen-detected (48.2% underwent screening pre-BC), 13.4% were incidentally found on GATS pathology, 3.6% were provider-detected, and 2.7% were incidentally found on other imaging. Of 84 (75%) tested patients, 16/84 (19%) had a pathogenic germline variant, with *BRCA2* (25%) and *BRCA1* (18.8%) being most common. Most tumors were HR+ (85.7%) and early stage (25.7% DCIS and 45.1% stage I). Regarding local treatment, most (61.6%) underwent mastectomy, with 63.8% omitting reconstruction; after lumpectomy, 29% omitted radiation (RT). 41.1% received systemic chemotherapy and while endocrine therapy (ET) was recommended for 79, only 81% (64/79) received ET. There was no difference in surgery type (p = 0.22) or ET receipt (p = 0.32) by SAB. Compared to patients in SEER (N = 401,311), the TGD cohort was younger (median age 42.5 *vs* 62yrs), more frequently NH-White (75.2% *vs* 65.1%), more often had PR+ disease (79.5% *vs* 70.7%), and had a higher proportion of males (MSAB) (7.1% *vs* 0.8%) (p <0.01 for all); but there was no difference in disease stage (p = 0.39). At 38 months median follow-up: 12 (10.7%) had a locoregional recurrence (LRR), and 2 died of metastatic BC. 5-yr BCSS probability was 96.2% (95% CI 85.3–99.0%). **Conclusions:** The first multicenter cohort study of TGD individuals with BC identified they were younger and had a higher proportion MSAB compared to BC patients in SEER. Most tumors were self-detected, and the pathogenic germline variant rate was high – suggesting a possible role for earlier screening in high-risk TGD persons regardless of SAB. The elevated LRR rate along with low ET and RT uptake indicates opportunities to improve adherence to guideline concordant care. Findings underscore the necessity for prospective research to inform gender-inclusive evidence-based BC screening and treatment guidelines. Research Sponsor: National Cancer Institute.

Inclusion of people living with HIV in Food and Drug Administration (FDA) oncology pivotal registration trials from 2020 to 2024. First Author: Alberto Giovanni Leone, Department of Oncology and National Centre for HIV Malignancy, Chelsea and Westminster Hospital, London, United Kingdom

Background: People living with HIV (PLWH) have an increased risk of developing cancers compared to the population without HIV, with cancer being the leading cause of death for this population in high-income countries. Previous research by the ASCO-led HIV working group found only 11% of clinical trials supporting FDA cancer therapy approvals from 2010-2014 allowed for inclusion of PLWH, leading to clinical uncertainty in the efficacy-safety profile of new cancer treatments in this group. To address this gap, ASCO (2017) and FDA (2020) issued guidelines encouraging inclusion of PLWH in cancer clinical trials. To explore their impact, we examined inclusion of PLWH in pivotal cancer trials post-guidelines release. **Methods:** We reviewed all new FDA-approved indications of the past five years (Jan/2020-Nov/2024). For each new approval, two authors independently assessed the inclusion/exclusion criteria outlined in the primary protocol of each pivotal trial. We analyzed data on the FDA label, cancer type, therapeutic modality, inclusion/exclusion criteria, sponsor, and the protocol (version 1) publication date. **Results:** We identified 244 new therapy indications, based on supporting data from 259 pivotal clinical trials. 27% of trials permitted inclusion of PLWH. Pivotal trials for hematological cancers, compared to solid cancers, were significantly more likely to exclude PLWH [unadjusted Odds Ratio (OR) 3.15, 95% confidence interval (CI): 1.51-6.56; p=0.0012]. Pivotal trials of immunomodulatory agents were significantly more likely (OR 3.87, 95% CI: 1.91–7.83; p<0.0001) to exclude PLWH compared to other cancer therapies. The inclusion rate was 10.3% for AIDS-defining cancers and 29.8% for non-AIDS-defining cancers. Trials funded only by industry were significantly more likely (OR 2.80, 95% CI: 1.36-5.77; p=0.0078) to exclude PLWH, compared to non-industry funded trials. Inclusion rate of PLWH was higher in protocols published after 2020 (39.1%) compared to those before (26.3%). **Conclusions:** Our analysis indicates an improvement in the inclusion of PLWH in oncology pivotal trials following ASCO and FDA guidance. However, nearly three out of four pivotal cancer trials continue to exclude PLWH. This highlights an unmet need, resulting in uncertainty for healthcare professionals regarding the safety and clinical utility of new cancer treatments in PLWH. Additional strategies must be considered to address this disparity. Research Sponsor: None.

Rates of PLWH inclusion in oncology pivotal trials.

	Include PLWH (%)
Total (n=259)	27.4
Solid Cancers (185)	33
Haematological malignancies (74)	13.5
Immunomodulatory agents (89)	12.4
Other agents*(170)	35.3
Industry-funded (223)	24.2
Non-industry funded (36)	47.2
AIDS-Defining Cancers (30)	10
Non-AIDS Defining Cancers (45)	29.8

*Chemotherapy, targeted therapy, drug-antibody conjugates, hormone therapy, radionuclide therapy.

1518 Rapid Oral Abstract Session

Economic modelling to inform pricing for LMICs of immune checkpoint inhibitors in advanced PD-L1-high non-small cell lung cancer. First Author: Giulia Segafredo, Medicines Patent Pool, Genève, Switzerland

Background: Lung cancer is the most common cancer and cause of cancer death, encompassing for 16.8% of all cancer-related deaths worldwide. Anti-PD(L)1 Immune Checkpoint Inhibitors (ICIs) as monotherapy currently represent the standard of care (SoC) for advanced Non-Small Cell Lung Cancer with high (≥50%) PD-L1 expression in high-income countries. Despite their efficacy, ICIs remain largely inaccessible in low- and middle-income countries (LMICs), with affordability being a significant barrier. Providing evidence on cost-effective (CE) price ranges for ICIs in LMICs is critical for global health policymakers to devise strategies to enhance access. **Methods:** A partitioned-survival model was used to estimate CE price targets for three ICIs (atezolizumab, cemiplimab, and pembrolizumab) as single agents compared to platinum-based combination chemotherapy (current SoC in several LMICs). Treatment duration was assumed of up to 35 cycles or until disease progression. Cost-effectiveness thresholds were set at 1, 2, and 3 times the gross domestic product (GDP) per capita per quality-adjusted life year (QALY) gained. Case studies were modelled in two LMICs (India and South Africa – not all ICIs were registered in both countries) to determine the maximum price at which ICIs would be CE from the perspective of publicly-funded health systems. Primary efficacy data were sourced from phase III clinical trials (KEYNOTE-024, IMpower110, and EMPOWER-Lung 1), and country-specific data were collected through interviews with key technical stakeholders. Values were reported in USD for 2023. **Results:** The analysis determined that the maximum acquisition costs for ICIs to be cost-effective at 1-, 2-, and 3-times GDP per capita in India and South Africa, range from $14.20 to $648.00 per cycle per patient. Current reference prices would require discounts of up to 93.3% to meet the 3 GDP threshold. Dose-optimization strategies such as low-dose and vial sharing were identified as feasible and evidence-based approaches to achieve partial price reduction (sensitivity analysis will be provided). **Conclusions:** To make ICIs cost-effective in LMICs, significant discounts from current reference prices are needed. Similar price reductions (up 93%) have been achieved for other monoclonal antibodies, such as trastuzumab, in India and South Africa, also driven by the availability and uptake of quality-assured biosimilars. A comprehensive approach, combining accelerated biosimilar availability, also leveraging voluntary licensing and technology transfer, with dose and treatment-duration optimization strategies could help achieve target price levels and improve accessibility. Research Sponsor: Medicines Patent Pool.

Country	WTP threshold (xGDP)	Pembrolizumab	Atezolizumab	Cemiplimab
India	1	$72.6	$74.2	$66.5
	2	$199.7	$166.9	$181.5
	3	$308.6	$259.6	$300.0
South Africa	1	$51.5	$53.1	$14.2
	2	$349.9	$289.0	$314.7
	3	$648.2	$525.0	$615.2

1519 Rapid Oral Abstract Session

Association of court-documented major adverse financial events before cancer diagnosis and mortality risk in the US. First Author: Robin Yabroff, Surveillance and Health Equity Science, American Cancer Society, Atlanta, GA

Background: Cancer diagnosis is associated with increased risk of financial hardship in the US. This study examined the associations of court-documented major adverse financial events (AFEs) of bankruptcies, liens, and evictions prior to cancer diagnosis and risks of all-cause and cancer-specific mortality. **Methods:** Individuals aged 21 to 69 years diagnosed with common cancer types, including bladder, female breast, colorectal, kidney, lung and bronchus, oral cavity/pharynx, or prostate cancers or melanoma during 2014-2015 were identified from the SEER population-based registries for Seattle, Louisiana, and Georgia. Registry data were linked with LexisNexis consumer data to identify history of court-documented AFEs of bankruptcies, liens, and evictions. Vital status and cause of death were examined through December 31, 2021. The association of pre-diagnosis AFEs and risk all-cause and cancer-specific mortality was assessed with separate multivariable Cox proportional hazards models for each survival outcome, stratified by cancer site. Models were adjusted for stage, age, race and ethnicity, marital status, registry, registry-specific income categories, and the interaction between income and registry. **Results:** Of 58,796 individuals diagnosed with one of the 8 selected cancers, 21,694 (36.9%) had a pre-diagnosis AFE and there were 16,714 deaths (28.4%) during the study period between 2014 and 2021. Pre-diagnosis AFEs were associated with higher risk of all-cause mortality for individuals diagnosed with female breast (hazard ratio (HR): 1.18; 95% confidence interval (CI): 1.09-1.28), colorectal (HR: 1.14; 95% CI: 1.06-1.23), oral cavity/pharynx (HR: 1.14; 95% CI: 1.06-1.23) and prostate (HR: 1.33; 95%CI: 1.20-1.47) cancer and early- and late-stage melanoma (HR: 2.23; 95% CI: 1.89-2.99 and HR:1.34; 95% CI:1.01-1.80, respectively), in adjusted models. Pre-diagnosis AFEs were also associated with significantly higher risk of cancer-specific mortality for these five cancers. **Conclusions:** Court-documented AFEs of pre-diagnosis bankruptcy, lien, or eviction was associated with increased risk of all-cause and cancer-specific mortality for multiple cancer types in this study using a novel SEER cancer registry-LexisNexis consumer data linkage. The association of pre-diagnosis AFEs and mortality risk underscores lasting adverse consequences of patient financial vulnerability prior to incurring high out-of-pocket costs of cancer treatment. Our findings are especially timely, with growing efforts by health care providers to screen and address patient health-related social needs as part of comprehensive oncology care. Research Sponsor: None.

1520 Rapid Oral Abstract Session

Effect of broad-based genomic sequencing on survival outcomes in advanced non-small cell lung cancer: A national cohort study, 2011-2023. First Author: Patricia Mae Garcia Santos, Division of Health Services, Outcomes, and Policy, Department of Radiation Oncology, Winship Cancer Institute, Emory University, Atlanta, GA

Background: Use of broad-based genomic sequencing (BGS) for advanced non-small cell lung cancer (aNSCLC) is rising. While older studies have found no survival benefit with BGS, its impact on survival outcomes in the era of modern targeted therapy is unknown. **Methods:** In this retrospective cohort study, the 2011-2023 Flatiron Health Database—a nationally representative database of electronic health records from > 280 US cancer clinics—was queried for patients with Stage IIIB-IV NSCLC who received at least one line of systemic therapy with ≥12 months follow-up. Primary exposure was receipt of BGS vs. "Focused" biomarker testing (i.e., *ALK* FISH, *EGFR* PCR) within 90 days of first- and second-line therapy start. To address baseline confounding, we used 1:1 nearest-neighbor propensity score matching based on age at initial diagnosis, sex, self-reported race/ethnicity, histology (squamous vs. non-squamous), insurance status, smoking status, ECOG performance status, practice type (academic vs. community), stage at diagnosis, advanced diagnosis year, and practice rate of BGS. Adjusted Cox proportional hazards models compared median progression-free survival (mPFS) and median overall survival (mOS) between groups. Sensitivity analyses adjusted for biomarker status and used an instrumental variable approach. **Results:** Our initial unmatched cohort consisted of 35,060 patients (BGS, *n* = 14,192; Focused, *n* = 20,868; 52% female, 3.5% Asian, 9.3% Black, 3.8% Hispanic, 79% community practice). In the propensity-matched first-line therapy cohort (BGS vs. Focused, *n* = 10,008 in each group; all standardized mean differences < 0.1), BGS was associated with greater mPFS (6.4 vs. 6.0 months; adjusted HR [95%CI], 0.96 [0.92-1.0], $p = 0.046$) and mOS (16 vs. 14 months; 0.91 [0.86-0.95], $p < 0.001$). Sensitivity analyses were consistent with primary results. Patients receiving BGS had higher rates of *ALK/EGFR* positivity (18% vs. 13%) and receipt of targeted therapy (20% vs. 17%). Upon adjustment for biomarker status, however, BGS remained associated with improved OS (1.01 [0.88-0.98], $p = 0.004$) but not PFS (0.98 [0.94-1.03], $p = 0.4$). In the propensity-matched second-line therapy cohort, no associations between BGS and survival outcomes were observed. **Conclusions:** This is the first national analysis of survival outcomes in aNSCLC to demonstrate a survival benefit with BGS. These findings support guideline endorsement and payer coverage of BGS prior to 1st line therapy. Research Sponsor: None.

1521 Poster Session

Financial toxicity and drivers of delayed care among cancer survivors across the lifespan. First Author: Justine Po, Keck School of Medicine of University of Southern California, Los Angeles, CA

Background: Financial toxicity has been increasingly recognized as a cause of poor outcomes among cancer survivors. Cancer survivors have been shown to face greater healthcare access and affordability issues than the general population, and available evidence suggests that adolescent/young adult (AYA) cancer survivors may face especially high financial toxicity. However, existing research is limited by small sample sizes and methodological constraints. Understanding age-specific healthcare barriers could inform targeted interventions to improve outcomes for cancer survivors across the lifespan. **Methods:** Participants aged 18 and older were enrolled with informed consent in the All of Us Research Program, an NIH database integrating multiple health information sources. Included participants were cancer survivors who had available data for age, sex and other demographics. Cancer diagnoses were identified using ICD and SNOMED codes. Survey data were used to assess outcomes of financial toxicity and drivers of delayed care, as well as covariates of race, ethnicity, income, education, marital and insurance status. As all participants were insured, insurance status was dropped from the final models. Age groups were coded as 18-39, 40-49, 50-64, 65-74 and 75+. Statistical analysis was conducted using logistic regression by age group, adjusted for covariates. **Results:** 15,637 cancer survivors were included for analysis, including 1,090 participants aged 18-39 and 2,104 participants over age 75. Compared to 18-39 year olds, odds of being unable to afford specialist care decreased with age: [40-49] OR = 0.57 ($p = 0.01$), [50-64] OR = 0.18 ($p < 0.0001$), [65-74] OR = 0.07 ($p < 0.0001$), [75+] OR = 0.006 ($p < 0.0001$). Results were similar for primary care, with more extreme effect sizes. Causes of delayed care differed by age group. 18-39 year olds were more likely to report elderly caregiving responsibilities and inability to get time off work as drivers of delayed care, while 40-49 year olds were more likely to report difficulties accessing child care as a driver (OR = 5.25, $p < 0.0001$). Older cancer patients were also more likely than AYAs to report lack of transportation access as a cause of delayed care ([65-74] OR = 2.33, $p < 0.0001$). **Conclusions:** To date, this study represents the largest and most comprehensive analysis of healthcare barriers among cancer survivors across the lifespan. Targeted interventions based on the most significant barriers by age group may more effectively improve healthcare access and outcomes for all ages. Our results support that AYA cancer survivors may benefit most from financial support, elderly care resources and medical notes to facilitate time off work. By comparison, expanding childcare support may be most important for increasing access among those aged 40-49. Among older cancer survivors, ensuring reliable transportation presents the greatest opportunity for improving healthcare access. Research Sponsor: National Institutes of Health, Office of the Director.

1522 Poster Session

Spillover effects of Medicaid expansion on insurance coverage, diagnosis, and survival among low-income elderly patients with cancer. First Author: Kewei Sylvia Shi, American Cancer Society, Atlanta, GA

Background: Medicaid expansion under the Affordable Care Act is associated with increased health insurance coverage and improved outcomes among patients with cancer < 65 years. Although not the target population, individuals ≥65 years may also benefit from Medicaid expansion through "welcome mat" effects, referring to the indirect increase in Medicaid enrollment from increased public awareness and streamlined enrollment procedures. This study examines the associations of Medicaid expansion with Medicaid coverage, stage at diagnosis, and survival among cancer patients ≥65 years. **Methods:** Using the National Cancer Database, we identified patients ≥65 years newly diagnosed with cancer between 2010-2022 residing in areas with median household income below 200% of the federal poverty level. We applied a quasi-experimental difference-in-differences design, with multivariable linear probability models to compare the changes in the percentage of dual-eligible or Medicaid-only coverage, stage at diagnosis, and two-year survival post (vs. pre) Medicaid expansion in expansion states compared with non-expansion states. **Results:** A total of 1,468,116 patients with cancer were identified, with 885,671 patients from expansion states and 582,445 patients from non-expansion states. After adjusting for sociodemographic characteristics, the percentage of patients with dual or Medicaid-only coverage increased from 10.27% to 11.33% in expansion states and decreased from 9.4% to 8.11% in non-expansion states, resulting in a net increase of 1.34 percentage points (ppt, 95% confidence interval [CI]: 1.12, 1.56) associated with Medicaid expansion. Differences were more pronounced among patients with stage III-IV cancers, females, non-Hispanic Black, metropolitan residents, and those with ≥2 comorbidities. The percentage of early-stage (I/II) cancer diagnoses decreased more in non-expansion states (49.82% to 47.19%) than in expansion states (47.63% to 46.06%), resulting in a net increase of 0.96 ppt (95% CI: 0.58, 1.34). The protective effects of Medicaid expansion were stronger for late-stage (III/IV) non-small cell lung and uterine cancers, as well as early-stage thyroid and bladder cancers. Two-year overall survival rates increased from 58.86% to 62.39% in expansion states and from 59.18% to 62.55% in non-expansion states, leading to a net increase of 0.95 ppt (95% CI: 0.61, 1.29). Improvements were most notable for prostate, lung, kidney, and bladder cancers. **Conclusions:** Medicaid expansion was associated with an increase in Medicaid coverage, early-stage cancer diagnoses, and improved two-year survival among patients diagnosed with cancer ≥65 years. Findings underscore the spillover benefits of Medicaid expansion in supporting low-income elderly populations and the importance of indirect benefits when evaluating Medicaid expansion's broader impact. Research Sponsor: None.

1523 Poster Session

Bolstering access to clinical trials: Sociodemographic characteristics of patients enrolled in interventional clinical trials within a large, NCORP-designated community oncology practice setting. First Author: Meera Vimala Ragavan, Kaiser Permanente San Francisco Medical Center, San Francisco, CA

Background: Access to clinical trials is an important aspect of cancer care given rapidly changing treatment paradigms.Most patients with cancer including those belonging to racial/ethnic minoritized groups are treated in community oncology settings, but only a minority (< 5%) of these patients are enrolled on clinical trials. Barriers to trial enrollment in community oncology settings have been well described at the patient, provider, and system levels. The National Cancer Institute Community Oncology Program (NCORP) aims to address these barriers- and improve equity in trial enrollment- by providing support and infrastructure for community oncology practices to conduct clinical trials. Kaiser Permanente Northern California (KPNC) is a large integrated health system comprising thirty cancer trial sites and is part of the Kaiser Permanente NCORP, one of the largest NCORP-designated sites. In this study, we compared sociodemographic characteristics of patients enrolled in interventional trials with the overall cancer population within KPNC. **Methods:** We evaluated all patients enrolled on interventional cancer clinical trials within KPNC between 1/1/2015-12/31/2022. We abstracted demographic and clinical characteristics from the KPNC cancer registry. We compared characteristics to the incident cancer population diagnosed over the study period across KPNC. We used Pearson chi squared tests (categorical), binomial tests (binary) and one-sample t tests (continuous) to compare sociodemographic characteristics. **Results:** We identified 1,341 patients who were enrolled onto interventional clinical trials and compared them to 97,764 patients diagnosed with cancer over the study period. Patients enrolled on interventional trials were younger (mean age 60.2 vs 62.9 years, $p < 0.001$), more likely to have Stage IV disease (22.7% vs 11.2%, $p < 0.001$), more likely to reside in high-socioeconomic status neighborhoods (27.7 vs 23.8%, $p < 0.001$), and less likely to speak a language other than English (4.7 vs 7.1%, $p < 0.001$). There were no differences in race, ethnicity or sex distributions between the trial population and overall population. **Conclusions:** Across a large NCORP-designated community oncology trials program, the racial and ethnic makeup of patients enrolled on trials was similar to the broader cancer population within KPNC. These findings suggest that the trial infrastructure provided by NCORP may surmount the structural barriers that drive low access to trials among racial/ethnic minorities. Small differences in enrollment based on age, language and socioeconomic factors persisted. Efforts to bolster clinical trial portfolios in community oncology settings may address existing barriers to enrollment. Integrating collaborative care in oncology: Improving quality of life and mental health for patients with cancer. First Author: Kyle N. Lavin, University of North Carolina at Chapel Hill, Chapel Hill, NC

Background: In the U.S., 22 million patients with cancer face unmet behavioral health needs, contributing to up to $245B in preventable healthcare costs. These unique challenges stem from physical, emotional, practical, and relational stressors associated with their cancer journey. Collaborative care, an evidenced based model that integrates behavioral health into medical settings, has been shown to improve access, outcomes, and reduce overall healthcare costs in primary care. Cerula Care offers a virtual collaborative care model that seamlessly integrates with oncology practices to improve quality of life and behavioral health outcomes. The team includes a Consulting Psychiatrist, Behavioral Health Care Manager, and Behavioral Health Coach working in coordination with oncology teams. **Methods:** This study analyzed data from 127 patients with cancer enrolled in Cerula Care's 12-week virtual care program between 1/31/24 and 8/31/24. Behavioral health outcomes, including anxiety (GAD-7), depressive symptoms (PHQ-9), and quality of life (FACT), were assessed monthly. Analyses focused on baseline to two-month outcomes due to limited sample sizes beyond two months (many patients were still in earlier stages of the program). Correlations and paired t-tests were conducted to evaluate changes in outcomes. **Results:** Of the 127 patients enrolled, mean age was 57.1 years (range: 28–78), 83.5% were female, 52.8% identified as White, 33.9% Black or African American, 0.8% Asian, and 3.1% other races. Breast cancer was the most common diagnosis (52.8%), followed by lung, colorectal, pancreatic, and ovarian cancers. Behavioral health outcomes from baseline to month 2 are shown in the table. **Conclusions:** Within just two months of care, Cerula Care significantly improved depressive symptoms and anxiety, as well as quality of life for cancer patients. Notably, improvements in quality of life were correlated with minority status, highlighting the program's potential to reduce disparities in cancer care. By integrating behavioral health into oncology treatment, this model demonstrates a scalable, impactful solution to enhance patient outcomes. Future research should focus on long-term sustainability, cost-effectiveness, and broader implementation across diverse oncology settings. Research Sponsor: None.

Behavioral health outcomes from baseline to month 2.

Outcome	Measure	Sample Size (n)	Change	Statistical Significance (p-value)
Depressive Symptoms	PHQ-9 Score	50	↓ 4.47 points	**p < .001**
Anxiety Levels	GAD-7 Score	52	↓ 2.06 points	**p = .007**
Quality of Life	FACT Score	N/A	**Improved,** especially in racial minority patients	**r = .439, p = .017**

From food deserts to clinical trial deserts: Challenges in access to breast cancer trials. First Author: Rachel Ann Sachs, Robert Wood Johnson Medical School, New Brunswick, NJ

Background: Patients who live in food deserts have high mortality rates from breast cancer and stand to benefit from participating in research studies, yet they may face complex barriers to doing so. This study explores the relationship between living in a food desert and breast cancer clinical trial enrollment and assesses the contribution of transportation barriers and distance. **Methods:** The national Vizient Clinical Database (which includes 98% of academic and 1,000 community hospitals) was queried for women treated for breast cancer between January 2022 and June 2024. Patients who traveled $>$ 4 hours to get to treatment were excluded ("destination care"). The outcome of interest was participation in a clinical trial. A "clinical trial desert" was defined as $>$ 2 hour driving time to the nearest hospital enrolling patients in clinical trials. Multivariable analysis evaluated the association between living in a level 1 (most severe) USDA food desert census tract, a clinical trial desert, a census tract with high transportation vulnerability (households with limited access to a car or public transit), and breast cancer clinical trial participation. Interaction analysis was performed between food desert and clinical trial desert status. **Results:** Of 1,317,269 patients, 103,790 (7.9%) lived in a food desert, and 22,779 (1.7%) participated in a clinical trial. Patients living in a food desert comprised 6.2% of patients enrolled in a trial vs 7.9% of patients not enrolled, $p < .0001$. 41.0% of patients living in a food desert also resided in a clinical trial desert. On multivariable analysis, living in a food desert was associated with decreased odds of trial participation (aOR 0.87, 95% CI 0.82-0.92, $p < .0001$), as was living in a clinical trial desert (aOR 0.89, 95% CI 0.84-0.94, $p < .0001$), and living in the most vulnerable quartile for neighborhood transportation (aOR 0.89, 95% CI 0.85-0.93, $p < .0001$; ref: least vulnerable). Medicaid insurance also decreased the odds of enrollment (aOR 0.84, 95% CI 0.80-0.89, $p < .0001$; ref: private). Conversely, receiving care at an academic hospital increased the odds of enrollment (aOR 2.98, 95% CI 2.62-3.15, $p < .0001$; ref community hospital). Living in both a food desert and a clinical trial desert decreased the odds of clinical trial participation by 27% (aOR 0.73, 95% CI 0.70-0.76, $p < .0001$) compared to 19% if living in a food desert alone (aOR 0.81, 95% CI 0.78-0.84, $p < .0001$); $p < .0001$ for interaction. **Conclusions:** Neighborhood transportation barriers, clinical trial deserts, and food deserts all independently confer a similar lower likelihood of participation in a clinical trial. Living in a clinical trial desert compounds the negative impact of living in a food desert alone, further taxing already disadvantaged populations. Interventions such as patient navigation, food banks, and opening clinical trials near communities experiencing food insecurity may mitigate these challenges. Research Sponsor: None.

Low-dose anti-PD-(L)1 inhibitor strategies: A systematic review. First Author: Pablo Jiménez Labaig, Head and Neck Unit, The Royal Marsden NHS Foundation Trust, London, United Kingdom

Background: Immune checkpoint inhibitors (ICIs) targeting the PD-(L)1 pathway have revolutionized cancer therapy, but their high costs significantly limit accessibility, particularly in low- and middle-income countries (LMICs). Low-dose regimens may offer a viable solution to this challenge. This systematic review analysed study designs, dosing strategies, clinical outcomes, and potential cost savings of low-dose ICIs. **Methods:** A PRISMA/EQUATOR compliant systematic search of WebOfScience, Cochrane Central Register of Clinical Trials, ASCO and ESMO conference databases was conducted until October 10th, 2024. Studies investigating reduced-dose anti-PD(L)1 from those FDA/EMA-approved regimens were included. Data were categorized by dose and country income level. **Results:** From 1,751 records, 25 studies (4 clinical trials, 21 observational studies) involving 1,793 participants met inclusion criteria, with 1,202 receiving low-dose ICIs. Two studies used non-inferiority designs, and 21 evaluated participants across multiple treatment lines. The population had a median age of 53.1 years (range 19–84), 26% female, 88% with advanced disease, and 9% ECOG $\geq$2. Most studies were conducted in Asia (81.4%, n = 1,459), with head and neck (22.8%, n = 409) and non-small cell lung cancers (17.3%, n = 311) being most studied. 48% studies were from LMICs, 44% from high-income countries (HIC), and 8% from upper middle-income countries (UMIC). India contributed the most (studies, *k*= 12, 839 participants). Nivo (*k*= 21), pembro (*k*= 6) and atezo (*k*= 1) were assessed. The most common regimens were Nivo40mg Q2W (*k*= 7), Nivo20mg Q3W (*k*= 6) and Nivo20mg Q2W (*k*= 5) [Table 1]. A radiological response rate between 5-75% was noted when low-dose ICI was used as monotherapy (*k*= 10). High variability in participant selection and interventions restricts further conclusions about efficacy and safety. The median projected savings were 83.3% (25–99.40%), with $\geq$70% savings in half of the studies. **Conclusions:** This review described the use of low-dose anti-PD(L)1 drugs, especially in healthcare settings with limited resources, highlighting radiological responses observed with monotherapy. Non-inferiority or near-equivalence randomized clinical trials will be helpful in establishing their clinical validity. Research Sponsor: None.

Characterizing transportation need and missed visits among patients receiving radiotherapy. First Author: Kathleen Cui, University of California, San Francisco, San Francisco, CA

Background: Patients with cancer receiving radiotherapy (RT) are vulnerable to treatment interruptions, which affect oncologic outcomes. To prioritize program development for improved RT access, we aimed to characterize transportation need via standardized department screening and its association with missed RT visits. **Methods:** We prospectively identified a cohort of 552 consecutive patients with cancer who received RT at a single academic institution between September 2023 and March 2024, during which a quality improvement program for standardized transportation needs screening was implemented. Missed RT visits were determined computationally and counted if a patient did not arrive for a scheduled RT visit; these missed visits may have been due to pre-planned reasons, unplanned hospital admissions, or other logistical causes. Clinical data were extracted from the electronic medical record system. Univariable and multivariable logistic regression analyses were used to determine associations between demographic variables and transportation need. Fisher's exact test was used to compare missed RT visits between patients with varying social needs. **Results:** Median age was 66 years (IQR: 53.75-74). Most patients were English-speaking (85.1%), male (54%), and white (51.8%). Common planned transportation modes were driving (76.2%) and public transit (8%), as well as Veterans Affairs transportation, rideshare, and taxi. Of all patients, 26.4% missed $\geq$1 RT visit and 19.9% reported transportation need. Overall, 39.1% versus 23.3% of patients with versus without transportation need missed $\geq$1 RT visit ($p = 0.001$). Other social needs were found among 17.6% of patients, the most common being housing (80.3%). Of those with transportation need, 45.5% had additional social needs. Frequency of missed RT visits were similar between patients with sole transportation need (41.7%) and those with additional social needs (39.1%) ($p = 0.563$). On univariable analysis, there was increased transportation need among patients identifying as Asian (OR = 1.87, 95% CI 1.05-3.27, $p = 0.030$), Latinx (OR = 3.14, 95% CI 1.74-5.63, $p < 0.001$), unknown/declined race/ethnicity (OR = 2.84, 95% CI 1.29-5.99, $p = 0.007$), non-English speaking (OR = 3.01, 95% CI 1.80-4.98, $p < 0.001$), with Medicaid insurance (OR = 3.61, 95% CI 1.94-6.71, $p < 0.001$), and with Medicare insurance (OR = 1.81, 95% CI 1.11-2.97, $p = 0.019$). On multivariable analysis, Latinx (OR = 2.18, 95% CI 1.02-4.52, $p = 0.040$) and Medicaid versus private insurance (OR = 2.28, 95% CI 1.12-4.61, $p = 0.022$) were independent predictors of transportation need. **Conclusions:** Our findings support the utility of transportation screening as a tool for anticipating and providing resources to minimize missed RT treatments. Future initiatives toward improving RT access may benefit from proactive assessment and support of social needs, including but not limited to transportation. Research Sponsor: None.

Disparities in breast cancer screening for the Brazilian Unified Health System (SUS): A warning of the need to change public policies. First Author: Ruffo Freitas-Junior, CORA – Advanced Center for Diagnosis of Breast Diseases Federal University of Goias, Goiania, Goias, Brazil

Background: Breast cancer is the most prevalent form of cancer in Brazilian women, contributing significantly to cancer-related mortality, particularly when diagnosed at advanced stages. Public policies of the Ministry of Health have been not changed for the last 2 decades. **Methods:** This ecological, temporal series study evaluated breast cancer screening coverage, clinical staging, and the time from diagnosis to treatment initiation in women of 40-49, 50-69 and 70 years of age in Brazil as a whole, its geographical regions, and states between 2013 and 2022. The data were extracted from databases of the Unified Health System (DATASUS). **Results:** There was a decreasing trend in screening coverage for the 40-49-year age group between 2013 and 2020 (APC = -10.79; $p < 0.001$), followed by stability in 2020-2022. Rates for the 50-69-year group remained stable, while coverage fell for women 70 years of age (APC = -6.27; $p < 0.001$) between 2013 and 2022. Cases of advanced stages at diagnosis tended to increase in all age groups: 40-49 (APC = 1.71; $p < 0.001$), 50-69 (APC = 1.43; $p < 0.001$) and 70 years (APC = 1.82; p = 0.001). Breast cancer screening coverage was low for all the age groups and all geographical regions, with lower rates found for the 40-49 and 70-year age groups. The poorest coverage was in the north, northeast and Midwestof the country, revealing regional disparities. The proportion of cases diagnosed at advanced stages (III/IV) increased,particularly in younger women (40-49 years) and the elderly (70 years). Time from diagnosis to treatment initiationexceeded 60 days in > 50% of cases in all age groups, with an increasing trend in women of 50-69 (APC = 1.27; $p < 0.001$) and 70 years of age (APC = 1.83; $p < 0.001$). **Conclusions:** This study highlightsthe urgent need for public policies to increase breast cancer screening coverage beyond the 50-69-year age group, and to guarantee equitable access to early diagnosis and timely treatment, particularly in less affluent areas. Dealing with these disparities is crucial to improving breast cancer outcomes in Brazil. Research Sponsor: None.

Differences in insurance status among Asian Americans with cancer: A disaggregated analysis by ethnic subgroup. First Author: Lilac Nguyen, Memorial Sloan Kettering Cancer Center, New York, NY

Background: Asian Americans, the fastest-growing racial/ethnic group in the U.S., experience significant variation in barriers to cancer care access, yet most research treats them as a monolithic group. Insurance is crucial for accessing cancer care, but limited data exist on non-insurance rates among Asian Americans. This study investigates the heterogeneity in insurance status across Asian American subgroups in the context of common cancers. **Methods:** We analyzed data from the National Cancer Database (NCDB), and focused on breast, prostate, and non-small-cell lung cancers among patients under 65. Insurance status was dichotomized as non-insured/Medicaid versus private/government/Medicare/other, and binary logistic regression was used to calculate odds ratios (ORs) for insurance status by Asian American subgroups. **Results:** There were 2,161,947 patients with breast cancer, 603,172 with lung cancer, and 964,423 with prostate cancer. We found significant heterogeneity in insurance status among Asian American subgroups; such heterogeneity was mirrored across the three most common cancer types. Consistently, Japanese Americans were less likely to be uninsured or have Medicaid than White Americans (4.5%, 2.5%, and 12.2%, for patients with breast, prostate, and lung cancer, respectively, among Japanese-Americans vs. 10.2%, 5.5%, and 20.7% among White Americans, (odds ratio 0.54(95% CI: 0.47-0.61) for breast, 0.55(0.37-0.83) for prostate, 0.72(0.56-0.91) for lung), while every other Asian subgroup was significantly more likely to be uninsured or have Medicaid than White Americans (OR range 1.24 to 7.23 for breast, 1.25 to 10.42 for prostate, 1.12 to 6.39 for lung, all p-values <0.05 except for Laotians, Hmongs, and Thai with prostate cancer). Pakistani Americans were the group most likely to be uninsured or on Medicaid among patients with breast cancer (OR 7.22 (6.17-8.46) and prostate cancer (OR 10.41 (7.08-15.33) and were the second-most likely subgroup among patients with lung cancer (OR 4.82 (3.21-7.23). Hmong and Kampuchean were among the top three groups with breast or lung cancer who were uninsured or on Medicaid. **Conclusions:** Significant heterogeneity exists in insurance coverage among Asian American subgroups, which highlights the diversity of disparities Asian American patients face; these findings call into question the model minority myth, as every other Asian American subgroup besides Japanese-American was significantly less likely to be insured than White Americans. Asian American patients have broad differences in histories, social determinants of health, and barriers to accessing care, which may merit differentially targeted health interventions among certain subgroups. Breast cancer screening mammography among transgender and gender diverse (TGD) individuals: A nationwide study of >10,000 TGD individuals. First Author: Elizabeth Jane Cathcart-Rake, Mayo Clinic, Rochester, MN

Background: Regular breast cancer screening reduces mortality. The American College of Radiology (ACR) recommends annual screening mammography for asymptomatic, average risk 1) transgender and gender diverse (TGD) men (individuals assigned female sex at birth but identify as men) age 40+ and with residual breast tissue and 2) TGD women (individuals assigned male sex at birth but identify as women) age 40+ and on gender-affirming hormone therapy for 5+ years. This nationwide study investigated screening mammography in TGD individuals. **Methods:** Four cohorts were identified with complex algorithms of medical and pharmacy data in the OptumLabs Data Warehouse, a longitudinal, administrative insurance claims database that includes patients with commercial insurance and Medicare Advantage: 1) TGD men, 2) TGD women, 3) individuals with gender dysphoria not meeting other TGD criteria (NMOT), and 4) cisgender women – all of whom met ACR screening criteria. The primary endpoint was the percentage of individuals with high adherence, defined as completing >75% of recommended screenings; comparisons were made across the cohorts (Chi-square test). Multivariable logistic regression was used to compare adherence between TGD men and cisgender women with adjustment for demographics and with 1:4 matching (on race/ethnicity, age group, year of healthcare plan enrollment, and duration of follow-up). **Results:** 10,478 TGD individuals (3,778 TGD men; 1,294 TGD women; and 5,406 with gender dysphoria NMOT) and 6,218,369 cisgender women were identified. For TGD men, TGD women, individuals with gender dysphoria NMOT, and cisgender women, high adherence was observed in 41.1% (95% confidence interval (CI): 39.5, 42.6%); 7.4% (95% CI: 6.0, 8.8%); 11.9% (95% CI: 11.0, 12.7%); and 38.3% (95% CI: 38.3, 38.4%), respectively, $p < 0.0001$. No screening ever in these same populations was observed in 23.6% (95% CI: 22.2, 24.9%); 81.3% (95% CI: 79.2, 83.4%), 72.8% (95% CI: 71.6, 74%), and 35.9% (95% CI: 35.8, 35.9%), respectively, $p < 0.0001$. When TGD men were matched and compared to 15,112 cisgender women, a differential association was observed between gender and high adherence by age group ($p < 0.0001$); compared to cisgender women, the likelihood of high adherence in TGD men ages 40-49 (n = 2,472), 50-59 (n = 852), 60-69 (n = 320), and 70+ (n = 134) were as follows: odds ratios (OR's): 1.38 (95% CI: 1.28, 1.50), $p < 0.0001$; 1.57 (95% CI: 1.35, 1.81), $p < 0.0001$; 0.812 (95% CI: 0.619, 1.065), p = 0.1316; and 1.277 (95% CI 0.835, 1.951), p = 0.2595, respectively. **Conclusions:** This study found that TGD men manifest relatively high adherence to screening mammography, whereas TGD women and individuals with gender dysphoria NMOT manifest low adherence. Future research should focus on improving breast cancer screening in these underserved populations. Implementation of an academic precision oncology service in a community setting. First Author: Junlone Moy, Eshelman School of Pharmacy, The University of North Carolina at Chapel Hill, Chapel Hill, NC

Background: Implementation of precision oncology (PO) in community practice remains challenging due to insufficient resources to order and interpret genomic test results. In 2023, our PO program (located at an academic hub) partnered with a community site to optimize clinical workflows around molecular testing and to provide documented expert review of testing results. To date, the service has reviewed over 150 cases. We undertook a retrospective review to determine the impact of our intervention on the rates of next generation sequencing (NGS) ordered at this site. **Methods:** Patients with visits to the community cancer center between 1/2022 and 7/2024 were screened for inclusion (n = 900). Eligible patients had an advanced/metastatic solid tumor and were managed at the community site. Patients were placed in the historical or interventional cohort based on the date that their cancer became advanced/metastatic relative to the service implementation (1/1/2023). Due to a historical lack of genomic data integration within the EHR, evaluation of NGS results and subsequent treatment required manual chart review. The study was approved by the IRB of the University of North Carolina. **Results:** We identified 109 historical patients and 76 interventional patients who met eligibility. NSCLC patients comprised the majority of the population (27%), followed by prostate (12%), breast (10%), and colon (7%) cancers. We observed a significantly increased rate of NGS testing in solid tumors after implementation of the service (40.4% versus 57.9% before and after, p = 0.0192). The rate of NGS testing within 30 days of diagnosis of advanced/metastatic disease also improved in the interventional cohort (21.1% versus 36.8%, p = 0.0187). The median time from first clinic visit to results was 20.5 days in those who were testing in the historical cohort versus 10.5 days in the interventional cohort. RNA transcriptome sequencing was used more frequently in the interventional cohort (40.9% versus 6.8%, p = 0.0003). **Conclusions:** Utilization of a PO program at an academic hub to support NGS testing at a community site resulted in increased testing rates and more timely access to results in advanced cancer patients. Although limited by sample size, the data emphasizes a continued need for infrastructure to support the application of PO in community settings. Research Sponsor: None.

	Historical *(Prior to 1/1/2023)*	Interventional *(After 1/1/2023)*	P-value
Rate of NGS testing in all patients	44/109 (40.4%)	44/76 (57.9%)	**0.0192**
Rate of NGS testing within 30 days of diagnosis	23/109 (21.1%)	28/76 (36.8%)	**0.0187**
Rate of NGS testing in NSCLC	15/24 (62.5%)	22/26 (84.6%)	0.109
Rate of blood-only NGS testing in those with results	27/44 (61.4%)	19/44 (43.2%)	0.0896
Rate of genome-informed therapy (all patients)	5/109 (4.6%)	8/76 (10.5%)	0.121
Rate of genome-informed therapy (NSCLC)	1/24 (4.2%)	4/26 (15.4%)	0.3508
Median time from clinic visit to NGS testing results	20.5 days	10.5 days	–––

Development and fairness assessment of machine learning models for predicting 30-day readmission after lung cancer surgery. First Author: Atulya Aman Khosla, Department of Internal Medicine, William Beaumont University Hospital, Royal Oak, MI

Background: Predicting post-surgical readmissions is essential for improving patient outcomes and reducing healthcare costs. While machine learning (ML) models offer high predictive accuracy, they may perpetuate healthcare disparities if not rigorously evaluated for algorithmic bias. In this study, we examine the limitations of ML-based readmission prediction models, highlighting how bias can persist despite strong performance metrics. We also explore the impact of integrating fairness constraints to mitigate these disparities, ensuring equitable clinical decision-making across racial and ethnic groups. **Methods:** We analyzed National Surgical Quality Improvement Program (NSQIP) data (2016–2020) for 23,843 lung cancer surgery patients. Multiple ML models were developed using demographic, clinical, and laboratory variables. Model performance was assessed using standard accuracy metrics alongside fairness evaluations, including Demographic Parity and Equalized Odds, to measure disparities across racial groups. **Results:** The cohort had 56.5% females; 66.4% of cases belonged to the White race, 6.3% were Black, and 2.9% belonged to the Hispanic ethnicity. The median [Q1, Q3] was 69.0 [62.0, 74.0] years, and the overall readmission rate was 7.5%. The median operation time was higher among readmitted cases (171 minutes vs. 157.0; $p < 0.001$). However, there was no clinically significant difference between median [Q1, Q3] LOS between the two groups (4.0 [2.0, 6.0] vs. 4.0 [3.0, 7.0]; $p < 0.001$). The best-performing model (CatBoost) achieved high accuracy but showed disparities in prediction rates across racial groups (Demographic Parity Difference: 0.030, Equalized Odds Difference: 0.333) since the model disproportionately flagged Hispanic patients for readmission risk while potentially under-identifying risk in other groups. Significant predictors included operative time, preoperative sodium (139 vs. 140 mmol/L, $p < 0.001$), and COPD status (33.8% vs. 25.3%, $p < 0.001$). After implementing fairness constraints, the model maintained strong predictive performance while reducing demographic disparities, with selection rates balancing across racial groups (range: 0.51%-3.50%). **Conclusions:** Despite their high accuracy, ML models for predicting post-surgical readmissions can reinforce existing healthcare disparities. Our findings underscore the importance of fairness-aware modeling to mitigate bias, ensuring equitable clinical decision support. While fairness constraints improved demographic balance, residual disparities persisted, highlighting the need for ongoing scrutiny when deploying AI in clinical settings. This study emphasizes the critical need for continuous fairness evaluation in medical AI applications to prevent unintentional harm to vulnerable patient populations. Research Sponsor: None.

Fall risk assessment by QTUG device in geriatric cancer patients on chemotherapy at a tertiary care hospital. First Author: Tilak Tvsvgk, Command Hospital (AF), Bengaluru, India

Background: Age-related changes, such as declines in muscle strength, balance, and coordination, are exacerbated by cancer and its treatments elevating the risk of falls. Cancer chemotherapy often lead to adverse effects which can increase fall risk. The consequences of falls in older cancer patients can be severe impacting the recovery process. The aim of the study was to estimate the baseline fall risk and frailty in geriatric patients and comparing the same after 03 cycles of chemotherapy and correlate the factors contributing to the increased risk. **Methods:** A prospective observational study enrolling elderly cancer patients, who are not bed-bound or using a limb prosthesis were enrolled. Patients with brain/spinal cord tumours were excluded. Fall risk assessment was done using the Kinesis Q-TUG device. Based on the scores the patients were classified into low-risk, moderate-risk and high-risk of falls. The fall risk assessment was repeated after three cycles of chemotherapy. **Results:** A total of 94 males and 122 females (n = 216) patients, 25% of whom were more than 70 yrs of age were enrolled. Overall the females were associated with higher fall risk and frailty compared to males. The combined fall risk estimates at baseline and post 3 cycles did not reveal a significant fall risk increase, however the timed-up-and-go (TUG) times were significantly lower post 3 cycles [Table-1]. The average stride length, stride velocity did not show any significant difference but the number of steps to turn increased post 3 cycles. Though the frailty did not show a significant difference, the correlation between fall risk and frailty showed a significant positive correlation (r = -0.91). **Conclusions:** While there was a slight increase in fall risk and frailty among geriatric cancer patients undergoing chemotherapy, these changes were not statistically significant. However, the decline in mobility underscores the adverse effects of chemotherapy on functional performance. The strong correlation between fall risk and frailty emphasizes the need for assessments and targeted interventions to mitigate fall risks. With increasing number of older adults with cancer, the findings advocate for enhanced monitoring and early management strategies to improve safety and outcomes for elderly cancer patients. Research Sponsor: None.

APP-first as a strategy to increase new patient access and treatment of patients with gastrointestinal malignancies within a cancer center. First Author: Amalia Stefanou, H. Lee Moffitt Cancer Center and Research Institute, Tampa, FL

Background: Quality cancer care depends on timely and efficient evaluation of patients to determine next steps in treatment. To support this goal, we implemented a care delivery model where advanced practice providers (APP) were tasked with seeing new patients as an entry into the system, with a goal of completing testing and referrals prior to a subsequent visit with a surgical oncologist. **Methods:** A retrospective review was performed focusing on four hepatobiliary and pancreatic surgeons and their corresponding APP teams. The *APP-First* program was deployed in 2021. The purpose was to increase capacity and best prepare the patient's work-up prior to an appointment with the surgeon to facilitate treatment initiation. We compared NPs during two distinct time periods, before (7/2018-6/2020) and after (7/2022-6/2024) implementation of *APP First*. The primary outcome, impact on access, was determined by change in the number of NP seen by the group, and the secondary outcomes were number and proportion of patients receiving treatment at our institution. Patients were excluded if time to care was > 180 days or they received non-GI related care. Changes in outcomes of interest before and after implementation of the program were compared by Chi-square with significance set at p = 0.05. **Results:** A total of 2585 NPs were seen during the study period with 1797 beginning treatment at our facility (69.5%). During the pre-intervention period 1091 NPs were seen by the group, including 277 (25.5%) initially evaluated by an APP. Following the model implementation, 1494 NPs were seen, 915 (61.2%) by an APP and 579 (38.8%) by an MD ($p < 0.001$). There was no change in percent of NPs choosing to pursue care at our institution (68.7% vs 68.7%, p = 0.970), however after implementation, patients were more likely to be scheduled for operations after their initial visit (11.4% vs 14.3%, p = 0.031). **Conclusions:** Implementation *APP-first* led to increased NPs capacity translating into a 36.9% higher volume of NPs seen, without change in patient satisfaction as demonstrated by an unchanged percentage of patients choosing treatment at our institution. The established workflow within this model facilitated expedited care, resulting in higher proportion of patients treated and an increase in the number and proportion of patients receiving surgery. These data support the implementation of delivery of care models leveraging the role of APPs in a well-integrated system, with overall improved capacity, access, and treatment for patients with cancer. Gender, place of death, and racial disparities in the reporting odds ratio of cardiovascular disease burden in leukemia across age groups (15–85) in the U.S.: A CDC WONDER disproportionality analysis. First Author: Tehmasp Mirza, Shalamar Medical and Dental College, Lahore, Pakistan

Background: Leukemia, a hematologic malignancy, often coexists with cardiovascular disease (CVD), worsening outcomes due to shared risk factors like diabetes, hypertension, and smoking. Despite CVD's known impact on leukemia mortality, research on demographic and geographic disparities remains limited. This study examines disparities in the Reporting Odds Ratio (ROR) of CVD burden among leukemia deaths across age, gender, place of death, and race/ethnicity using CDC WONDER data (1999–2020). **Methods:** A disproportionality analysis of CDC WONDER death certificate data for U.S. adults (15–85) was conducted. Records were grouped into four variables: leukemia deaths with CVD (A), leukemia deaths (B), CVD deaths (C), and all deaths (D). RORs were calculated as (A/B) / (C/D) and stratified by gender, race/ethnicity, urbanization, and place of death. Age groups were categorized into 15–24, 25–64, and 65+ years. Joinpoint regression was used to compute annual percentage change (APC) and average annual percentage change (AAPC) to identify trends. **Results:** Analysis of 22 years of data revealed disparities in RORs across demographics. The 15–24 age group had the highest ROR for males (2.51) and females (1.59), indicating a greater CVD burden in leukemia deaths than all-cause mortality. Middle-aged (25–64) and older adults (65+) had lower RORs (<1), suggesting a reduced CVD-leukemia burden in these groups. Trends: The young female cohort showed a sharp ROR decline (2018–2020, APC: -22.02%; 95% CI -36.00 to -1.23; p=0.039), while the elderly male cohort (85+) had a steady rise (APC: 6.93%; 95% CI 1.74–9.24; p<0.0001). Place of Death: Medical facilities had the highest CVD burden in leukemia deaths, especially in younger cohorts (15–24; ROR: 1.47). Hospice facilities had the lowest RORs across age groups. The "Other/Unknown" category had an outlier ROR of 4.81 in the youngest cohort, suggesting data limitations. Race/Ethnicity: Hispanics had the highest ROR (2.64) in the 15–24 age group, followed by Asians (2.21). In middle and older age groups, RORs declined for all races. Hispanics (65–74) showed an increasing ROR trend (AAPC: 0.92%; 95% CI 0.45–1.36; p=0.002). **Conclusions:** Significant disparities exist in CVD burden among leukemia deaths, with younger cohorts, males, Hispanics, and patients in medical facilities showing the highest RORs. These findings highlight the need for targeted cardio-oncology strategies to address CVD risk in leukemia patients. Further research on chemotherapy-related cardiotoxicity and healthcare disparities is crucial to reducing inequities and improving outcomes. Research Sponsor: None.

Oncofertility practice patterns in NCCN cancer centers after the overturn of *Roe v. Wade*. First Author: Nikita V. Baclig, University of California Los Angeles, Los Angeles, CA

Background: The Supreme Court decision of *Dobbs v. Jackson* to overturn *Roe v. Wade* gave states authority to regulate reproductive health. This has led to concerns about access to assisted reproductive technologies used in oncofertility. The impact of this legal climate on oncofertility practices remains unknown. This study aims to understand how academic cancer centers across the United States have experienced changes in oncofertility care in a post-*Roe* world. **Methods:** In collaboration with the National Comprehensive Cancer Network (NCCN) Best Practices Committee, a survey was developed to evaluate changes in oncofertility access and utilization in the 2 years since the *Dobbs* decision. In July 2024, the survey was sent to NCCN Member Institutions, which represent 23 states with varied post-*Roe* protections for reproductive care. The survey responses were de-identified for analysis. Questions were both multiple choice and free response. **Results:** The survey was sent to 33 NCCN Member Institutions and yielded 24 responses (72.7%). A majority (83.3%) indicated that reproductive care was a moderate-high priority for their cancer center. Most (62.5%) reported an increase in the number of cancer patients receiving fertility preservation. According to the Center for Reproductive Rights, 13 institutions are in states that have restricted reproductive rights since the *Dobbs* decision. However, only 4 (16.7%) survey respondents reported that reproductive health laws had become more restrictive. The remaining reported that laws had not changed, were less restrictive, or abstained (83.3%). All 4 respondents who indicated more restrictive laws reported moderate-high priority placed on reproductive care and half reported an increase in cancer patients receiving fertility care. In the states that reported no or neutral change (n=14, 58.3%) or less restrictive laws (n=5, 20.8%), most (68.4%) reported an increase in patients receiving fertility care. One respondent who indicated more restrictive laws reported a decrease in resources for fertility care. Many centers have prioritized oncofertility by developing oncofertility programs, assigning fertility navigators, and creating electronic health record-assisted referral alerts and clinical pathways. **Conclusions:** Large academic NCCN Member Institutions, most in states with no change or less restrictive reproductive laws since the *Dobbs* decision, reported an increase in number of patients who accessed fertility care. Additional studies will clarify whether this reflects underlying trends or increased fertility care due to a fear of limited future access. Only a minority of the institutions in restrictive states responded to the survey and most who did reported similar or improved access to oncofertility care. The lack of response from restrictive states needs to be examined further as it may reflect concerns about oncofertility care in the new political landscape. Research Sponsor: None.

Trade-off preferences in older adults with newly diagnosed acute myeloid leukemia. First Author: Kah Poh Loh, University of Rochester Medical Center, Rochester, NY

Background: Treatment decisions for older adults with acute myeloid leukemia (AML) are highly preference-sensitive, requiring a balance between survival and other important outcomes such as toxicities and quality of life (QoL). Understanding patients' trade-off preferences is critical for guiding personalized treatment planning. We examined the trade-off preferences of older adults newly diagnosed with AML and factors influencing these preferences. **Methods:** We collected data from two clinical trials evaluating an AML communication tool. Older adults completed questionnaires at diagnosis assessing trade-offs between survival and two key outcomes: a) maintaining QoL and b) treatment-related toxicities (nausea/vomiting, bedbound status, assistance with daily activities, worsening memory, and confusion). The survival-QoL trade-off was categorized as agree vs. disagree. Trade-offs for treatment-related toxicities were scored from 0 to 5, with higher scores indicating a greater willingness to endure toxicities for survival. We used binary logistic regression to identify factors associated with survival-QoL trade-off, while ordinal logistic regression was used for survival-toxicity trade-off. **Results:** We included 95 older patients with newly diagnosed AML; mean age was 73.7 (SD 7.6), 38% female, and 94% White. Approximately 37% received intensive and 54% received lower-intensity treatment. Only 15% prioritized survival over maintaining QoL, 39% neutral, and 46% prioritize maintaining QoL over survival (Table). Over 60% would decline treatments leading to confusion, and 45% would avoid treatments causing bedbound status. On multivariable analyses, patients enrolled with a caregiver had a significantly higher odds of prioritizing survival over QoL [Odds Ratio (OR): 5.92, p=0.04]. Employed patients were more likely to endure treatment-related toxicities for survival compared to those who were unemployed, retired or homemaker (OR: 7.76, $p<0.01$). **Conclusions:** Trade-off preferences among older adults with AML vary widely and are influenced by caregiving support and employment status. Actively eliciting these preferences is essential to align treatment decisions with individual patient values. Research Sponsor: Conquer Cancer Foundation Walther Cancer Foundation; American Cancer Society.

Preferences of older adults with AML.

I would like to try treatments for my cancer if they could help me live longer, even if it is very likely they would	Agree/ Strongly agree	Neutral	Disagree/ Strongly disagree
Have high level of side effects (e.g., nausea/vomiting)	60%	24%	16%
Make me require more assistance from family and friends with completing daily activities (e.g., shopping, managing money)	53%	22%	25%
Make me bedbound and unable to use the bathroom without assistance	35%	20%	45%
Make my memory worse	29%	29%	40%
Cause me to become confused often so that I am not aware of my surroundings	15%	23%	61%
Living longer is more important to me than maintaining my quality of life	15%	39%	46%

OP-35: Does a tool designed to measure potentially preventable chemotherapy toxicities do so effectively? First Author: Ryan W. Huey, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: OP-35 is a measure developed by the National Quality Foundation that the Center for Medicare and Medicaid Services (CMS) uses to evaluate the quality of care for patients undergoing outpatient chemotherapy treatment. Launched in 2021, it was intended to measure rates of potentially preventable complications of chemotherapy treatment. The tool assesses the rate of emergency department visits and admissions (EDV/A) visits for patients receiving outpatient intravenous (IV) systemic anti-cancer therapy (SACT) and defines potentially preventable by the presence of $\geq$1 of 10 diagnoses: anemia, dehydration, diarrhea, emesis, fever, nausea, neutropenia, pain, pneumonia, or sepsis. However, it is unknown if these diagnoses track truly preventable visits and therefore if it is a valid measure of quality. **Methods:** We conducted a retrospective review of patients who received outpatient IV SACT (the denominator for OP-35) at the University of Texas MD Anderson Cancer Center between January 2023 and December 2023. All patients who had an EDV/A were assessed to understand the primary and secondary diagnoses associated with their encounters. **Results:** The total number of patients included in the population who received outpatient IV SACT was 10,353. Of these, 2,401 (23.2%) had an EDV/A within 30 days of receiving outpatient IV SACT. Of patients with an EDV/A, 67% of patients had one EDV/A, 21% had 2, and 12% had $\geq$3. The most common diagnosis groups were pain (83%), anemia (69%), nausea (44%), and fever (35%). 82% of patients had more than one qualifying diagnosis. For 68%, the qualifying diagnosis was a secondary diagnosis. Of patients with a qualifying EDV/A, only 15% did not have a qualifying OP-35 diagnosis. **Conclusions:** While OP-35 was designed to measure potentially preventable chemotherapy-related complications, the exclusion of relatively few patients among those with an EDV/A suggests that a significant proportion of qualifying events may not truly be preventable. The qualifying diagnosis list may need to be tailored to exclude non-preventable admissions. This would improve the metric's specificity and validity as measure of care-quality. Future work should clarify which diagnoses lead to misclassification of non-preventable EDV/As. Research Sponsor: None.

Patients with qualifying EDV/A		N = 2,401
Type of Cancer	Solid Malignancy	2,020 (84%)*

Qualitative findings from providers and patients for planning implementation of screening clinical breast examination in Soweto, South Africa. First Author: Daniel O'Neil, Yale Cancer Center, Yale University, New Haven, CT

Background: Over 50% of South African women with breast cancer (BC) are diagnosed at stages III & IV. To inform an Implementation Mapping process to design strategies for implementing screening clinical breast exam (CBE) in primary care facilities in Soweto, South Africa, we gathered qualitative data from local primary care providers and patients on barriers to CBE and possible implementation approaches. **Methods:** We conducted semi-structured interviews with administrators, nurses, doctors, and community health workers (CHWs) and focus groups with women potentially eligible for screening CBE at four Soweto primary care facilities that do not offer BC screening. Our discussion guide explored BC screening perceptions among both groups. We also asked providers for recommendations about how to best implement a future CBE screening program, and we asked patients about factors that would motivate them to participate in such a program. We analyzed transcripts deductively in parallel with data collection. We organized themes using the Consolidated Framework for Implementation Research (CFIR). To support Implementation Mapping's emphasis on addressing the needs of individual stakeholders, our analysis focused on the CFIR Individuals domain and Characteristics subdomain taken from the COM-B system. **Results:** We analyzed 27 interviews with 8 administrators, 1 medical officer, 14 nurses, 3 CHWs, and 1 clerk, and 4 focus groups with 23 total women. Providers (*i.e.,* deliverers) and patients (*i.e.,* recipients) alike expressed enthusiasm for CBE's potential to decrease BC mortality and morbidity. Both groups also cited CBE's potential to overcome and counteract patients' limited knowledge of breast health and BC symptoms. The primary barrier to CBE, according to both groups, is the high patient volume at public facilities. Providers described staff shortages limiting opportunity to perform CBE and patients cited long wait times as a barrier to pursuing "extra" services. Providers often recommended hiring new personnel designated for CBE screening. Patients suggested various approaches to expanding access, such as screening in both the clinic and community, opportunistic screening while patients wait for other clinic services, and walk-in access for "screening only" visits. Patients also emphasized the need to improve trust in the clinics and their staff. Regarding educational outreach, providers focused on expert-delivered teaching in both the clinic and community. Patients valued experts but also recommended engaging BC survivors and other community members to promote screening through word-of-mouth. **Conclusions:** Soweto's primary-care clinicians and patients expressed enthusiasm for the health benefits of BC screening, but successful implementation must address barriers faced by both groups, including long clinic wait times and personnel shortages. Research Sponsor: National Cancer Institute.

Development of an early sepsis treatment-decision algorithm in children and adolescents with cancer in a middle-income country: Results from a multinational modified Delphi consensus. First Author: Paula Aristizabal, Division of Hematology/Oncology, Department of Pediatrics, University of California San Diego and Rady Children's Hospital-San Diego and University of California San Diego Moores Cancer Center, San Diego, CA

Background: Despite global efforts, striking childhood cancer survival gaps between low- and middle-income countries (LMIC) and high-income countries persist. Based on data from the Colombian childhood cancer clinical outcomes surveillance system, VIGICANCER, sepsis accounts for approximately 90% of all preventable deaths. In response, we developed a consensus-based Treatment-Decision Algorithm (TDA) for early sepsis detection and treatment, adapted to the local context and balancing optimal clinical management and resource utilization. **Methods:** We used RAND/UCLA Delphi method (preparatory phase, literature review, rating) to consult experts on the appropriateness of the proposed risk/alert definitions, critical steps, evidence-based interventions, and decision-making trees in the adapted TDA. Consensus involved: a) Pilot anonymous voting on a 22-statement online survey (5-point Likert scale, open-ended questions); b) Reading/rating in a hybrid meeting (in-person/virtual); and c) Voting on statements where consensus was not reached. Consensus was defined as: ≥70%, strong; 51%-69%, moderate; ≤50%, no consensus. **Results:** Preparatory phase and literature review: A multinational (Colombia, Mexico, US), interprofessional panel of 19 members, including from pediatric cancer centers and academic societies (oncology, emergency medicine, hospital medicine, critical care, infectious diseases, nursing) ensured geographic and resource representation. A Colombian internal expert taskforce (n = 6) completed a comprehensive literature review, met biweekly, and developed the *Colombian Protocol for Early Sepsis Detection in Children with Cancer* and accompanying TDA with 3 domains: sepsis screening, sepsis huddle, and early treatment. Consensus results: a)Pilot(n = 19 members), strong agreement was obtained for 81% of statements in one round; b) Reading/rating (n = 8 members), strong agreement was reached in 90% of statements after two rounds; and c) Voting on statements without consensus (n = 11 members, online), moderate agreement was reached in 100% of statements (2) in one round. **Conclusions:** Through collaborative consensus, we successfully developed an evidence-based, user-friendly TDA for early sepsis detection and treatment, tailored to resource-constrained settings. The diverse, interprofessional panel facilitated contextual adaptations of the TDA. The proposed TDA provides clinicians serving children with cancer in Colombia with an easy-to-follow TDA that is clear, exhaustive, and suitable for adaptation to individual local settings. Next steps involve applying improvement science methodology to implement the TDA in Colombia and Mexico and evaluating its predictive value for prompt sepsis detection in children with cancer, contributing to reduction of survival gaps in LMIC. Research Sponsor: None.

Impact of the eSyM symptom monitoring program on nurse telephone encounters across six cancer centers. First Author: Michael J. Hassett, Dana-Farber Cancer Institute, Boston, MA

Background: After developing an ePRO-based, EHR-integrated symptom monitoring program (eSyM) and implementing it across 6 health systems, we found lower odds of acute care utilization among those who used eSyM to report symptoms. Facilitating communication between patients and clinicians is a potentially important mechanism by which symptom monitoring programs may improve outcomes. We measured the association between eSyM deployment, symptom reporting and severe symptom reporting on the frequency and number of nurse telephone encounters (TELs). **Methods:** eSyM was deployed in a stepped wedge RCT from 2018-2023 for adults who started chemotherapy (CHEM) or were discharged following surgery (SURG) for a suspected or confirmed GI, GYN or thoracic cancer. We analyzed three cohorts: 1) for all patients, we compared those treated before vs. after eSyM deployment; 2) for post-deployment patients (eSyM eligible), we compared those who did vs. did not report symptoms within 30 days of first eSyM prompt; and 3) for symptom reporters (eSyM users), we compared those who did vs. did not report severe symptoms. Outcomes of interest were the proportion of patients with at least one TEL and total number of TELs within 30 days of first eSyM prompt. Poisson regression was used to estimate the number of TELs within 30 days accounting for cancer and treatment type, as well as age, gender, and other factors. **Results:** In total, 18,830 patients were and 21,112 were not exposed to eSyM (median age 64, 66% female). Among eligible patients, 8,298 (44%) reported symptoms within 30 days. Among eSyM users, 3,666 (44%) reported one or more severe symptoms within 30 days. The proportion of patients with TELs and the number of TELs per patient are below (Table). In regression analyses, there were more TELs within 30 days after eSyM deployment (SURG 0.09 [95%CI 0.07-0.11; P < .0001], CHEM 0.26 [95% CI 0.23-0.28; P < .0001]) and among severe symptom reporters (SURG 0.42 [95%CI 0.38-0.45; P < .0001], CHEM 0.43 [95% CI 0.38-0.48; P < .0001]). **Conclusions:** eSyM exposure and reporting severe symptoms were associated with a greater likelihood and larger number of TELs, supporting nurse intervention as a mediator of the association between ePRO monitoring and clinical outcomes. Future studies should explore the impacts of ePRO systems on nursing workload and health system costs. Clinical trial information: NCT03850912. Research Sponsor: National Cancer Instiute; 1UM1CA233080-01.

Cohort	Treatment	% patients reporting within 30 days, P value			Mean number of TELs among those with at least one TEL (SD), P value

Cost and resource utilisation for liquid biopsy vs tissue biopsy genotyping in advanced NSCLC: A micro-costing model. First Author: David O'Reilly, Beaumont RCSI Cancer Centre, Dublin, Ireland

Background: For patients with advanced non-small cell lung cancer, tumour genotyping identifies actionable variants that inform targeted therapeutic choices, that improve outcomes. Liquid biopsy genotyping (LBG) is a non-invasive approach to tissue biopsy genotyping (TBG) that reduces turnaround, avoids repeat tissue biopsy, and can identify additional actionable variants. However, despite these benefits, patient access to LBG is not universal in a range of healthcare systems. While others have developed models evaluating the cost-effectiveness of LBG, these have are limited by assumptions regarding frequency of oncogenic variants and treatment utilisation. We utilised a micro-costing model (MCM) to quantify the cost/resources of LBG and TBG in a prospective trial (*PLAN;* ClinicalTrials.gov Identifier: NCT05542485) aimed at investigating the feasibility of LBG in a tertiary cancer centre. **Methods:** A deterministic MCM was developed to enumerate the cost to generate a genomics report for both LBG and TBG in NSCLC. Capital costs were calculated based on up-front investment and annual depreciation/maintenance. Costs of consumables and staff time associated with each procedure was sourced from relevant hospital departments (e.g. Medical Physics) and evaluated for accuracy by a health economist and medical oncologist. We calculated the cost of sample acquisition (endobronchial ultrasound-guided biopsy or phlebotomy), processing, and genotyping for both LBG and TBG, from patients enrolled on the *PLAN* study (n = 100) between 08/2023-07/2024. Finally, we performed an exploratory analysis investigating potential reduction in staff time associated with automated library preparation, using currently available technology. **Results:** We identified that TBG requires more staff time (€534 vs €330), capital investment (€326 vs €16), and consumables (€1544 vs €788), resulting in an overall increased cost, compared with LBG (€2404 vs €1135). Automation of library preparation would reduce staff time required for LBG (Reduced to €191; 33% reduction) with less of an impact on TBG (Reduced to €485; 10% reduction). This difference was due to the increased wet-lab time with LBG and greater staff time for sample acquisition in TBG vs LBG (€298 vs €8). Finally, in the *PLAN* study, LBG resulted in cancellation of 12 repeat tissue biopsies, resulting in further savings. **Conclusions:** LBG is a cheaper alternative to TBG. Our data indicates LBG saves cost in the areas of healthcare staffing and capital infrastructure with further savings made through avoidance of repeat tissue biopsies. Thus, the resources required for LBG and TBG are different and should be considered in service planning for tumour types such as NSCLC in which genotyping is standard-of-care. Clinical trial information: NCT05542485. Research Sponsor: AstraZeneca; Amgen; Novartis; Irish Cancer Society; Charitable Infirmary Charitable Trust.

Impact of a collaborative care-based symptom intervention model on chemotherapy adherence in patients with breast cancer. First Author: Michael H. Storandt, Mayo Clinic, Rochester, MN

Background: Treatment toxicity may limit the ability of cancer patients to receive all recommended cycles of therapy. Four to six cycles of docetaxel plus cyclophosphamide (TC) is a common adjuvant chemotherapy regimen for early-stage breast cancer. We assessed the impact of routine collection of patient-reported outcomes (PROs), coupled with a collaborative care model-based symptom management intervention, on the number of cycles of TC received by patients with breast cancer. **Methods:** The Enhanced, EHR-facilitated Cancer Symptom Control (E2C2) trial was a cluster-randomized, pragmatic clinical trial, conducted between March 2019 and January 2023 at Mayo Clinic Rochester and within the Mayo Clinic Health System in Minnesota and Wisconsin. Patients regularly reported the severity of 6 SPPADE symptoms (Sleep deficit, Pain, Physical function impairment, Anxiety, Depression, and Energy deficit/fatigue) on 11-point numerical rating scales. Each symptom score was interpreted as none to mild (0-3), moderate (4-6), or severe (7-10). The E2C2 intervention included symptom management education modules, clinician decision support aids, and the option to discuss severe symptoms with a nurse, physical therapist, or social worker. Patients with breast cancer who received at least one cycle of TC were included in this analysis. We compared the number of cycles of docetaxel and cyclophosphamide completed by patients in the control condition versus those in the intervention condition. **Results:** We identified 198 patients with breast cancer who received TC during the control condition and 128 who received TC during the intervention condition. Median age was 61.3 years in the control group and 60.3 years in the intervention group, and 94% and 95% were white, respectively. Those receiving treatment during the control condition, on average, completed 3.53 cycles of docetaxel, while those receiving TC during the intervention condition completed 3.77 cycles (p = 0.014). Seventy-eight percent in the control group completed at least 4 cycles of docetaxel, compared to 84% in the intervention group. Those receiving TC during the control condition completed an average of 3.71 cycles of cyclophosphamide, compared to 3.78 cycles in the intervention condition (p = 0.231). Eighty-four percent of patients in the control group and 86% in the intervention group completed at least 4 cycles of cyclophosphamide. **Conclusions:** Routine PRO surveillance, coupled with guideline-based collaborative care interventions, was associated with completion of a greater number of cycles of docetaxel. These findings suggest that routine symptom surveillance and management may enhance the docetaxel tolerance profile and improve treatment adherence in patients with early-stage breast cancer, allowing for delivery of an optimized treatment course. Research Sponsor: NCI of the National Institutes of Health; UM1CA233033 (PI Cheville, Mayo Clinic, Rochester, MN).

1544 Poster Session

Successful accrual of a cluster randomized controlled trial (RCT) comparing an educationally enhanced genomic tumor board (EGTB) intervention to usual practice (S2108CD, NCT# 05455606). First Author: Meghna S. Trivedi, Herbert Irving Comprehensive Cancer Center, Columbia University Medical Center, New York, NY

Background: Observational studies show genomic tumor boards (GTBs) can enhance clinician knowledge and application of genomic tumor test (GTT) results. An RCT is needed to evaluate the impact of GTBs on treatment and outcomes. Conducting such a trial requires physician engagement and recruitment of an unbiased study population over a short period of time due to rapid changes in cancer genomics. S2108CD prospectively evaluates the impact of an educationally enhanced GTB (EGTB) intervention through a cluster RCT design across rural and community oncology practices in the United States. **Methods:** Recruitment Centers (RCs) were selected from the NCI Community Oncology Research Program (NCORP) with a focus on rural and minority/underserved (RMU) sites and cluster randomized 1:1 to EGTB intervention (virtual GTB and physician educational materials) versus usual practice (UP). Oncologists and their patients with advanced solid tumors who had GTT ordered were enrolled. The primary aim is to compare the proportion of patients receiving evidence-based genome informed therapy by arm. Here, we describe accrual and baseline characteristics of the RCs and the enrolled physicians and patients. **Results:** Between 8/2022 and 11/2024, 18 RCs were randomized to UP versus EGTB intervention. A median of 5 clinics (range, 1-13) comprised each RC. Six RCs were classified as RMU in each arm (n = 12). Overall, 121 physicians registered to the study and they registered 1284 patients (median 47.5 patients/month), of which 983 (77%) were registered at RMU RCs. In the UP arm, 614 patients and 61 physicians registered, and in the EGTB arm, 670 patients and 60 physicians registered (demographics of registered patients in table; unknown race/ethnicity [3%] not shown), meeting accrual goal within target timeframe. The 3 most common patient neoplasms were lung, mediastinal and pleural (n = 352, 27.4%), gastrointestinal (n = 344, 26.8%), and breast (n = 152, 11.8%). **Conclusions:** Timely accrual to S2108CD demonstrates the feasibility of conducting a cluster RCT to evaluate an EGTB intervention. There was high participation of RMU sites with a study population reflecting cancer types relevant for GTT; however, there were fewer than anticipated non-White and Hispanic patients registered. Study endpoint data are currently maturing. The final analysis of S2108CD will be conducted and reported in 2026. Clinical trial information: NCT05455606. Research Sponsor: NIH/NCI/NCORP; UG1CA189974; The Hope Foundation for Cancer Research.

Patient characteristic		Overall (N=1284, %)	UP (N=614, %)	EGTB (N=670, %)
Age, median (range)		67.7 (20.3, 96.7)	67.6 (20.3, 96.7)	67.7 (22.4, 94.2)
Sex	Female	646 (50)	325 (53)	321 (48)

Electronic patient-reported outcomes with vital sign monitoring versus usual care during trastuzumab deruxtecan treatment for metastatic breast cancer: Updated results from the PRO-DUCE study. First Author: Yuichiro Kikawa, Department of Breast Surgery, Kansai Medical University Hospital, Hirakata, Japan

Background: The PRO-DUCE study (jRCTs031200387), a multicenter, randomized controlled study, evaluated the impact of ePRO plus body temperature (BT)/SpO_2 monitoring (ePROm) vs.usual care (UC) on the quality of life (QoL) for patients (pts) with HER2-positive metastatic breast cancer (MBC) treated with T-DXd. The primary results presented at ASCO 2024 showed that at week 24, ePROm demonstrated better results for global health status (GHS) vs. UC. Based on recent studies showing that symptom monitoring and alert notifications via ePROs could improve pt QoL and overall survival (OS), we consider the effects of long-term QoL scores and OS. **Methods:** The pts population was observed from March 1, 2021, to February 29, 2024 (data cutoff date: May 20, 2024). We randomized pts with HER2-positive MBC eligible for T-DXd to the ePROm or UC group. ePROm involved weekly reporting of symptoms based on PRO-CTCAE and daily monitoring of BT and SpO_2 reports via a smartphone at home. If any reported symptoms exceeded the predetermined thresholds, an email alert was sent to the medical staff; the ePRO data were then reviewed, and, if necessary, a phone consultation was provided. Endpoints in this updated analysis included QoL scores and cancer-related fatigue beyond week 24 using the EORTC QLQ-C30 (C30) and EORTC QLQ-FA12 (FA12), OS, and safety. **Results:** Between March 2021 and January 2023, 111 pts were enrolled (ePROm: 56; UC: 55). Throughout the observation period, 1045 alert notifications were generated, of which 279 were considered necessary to contact pts and 231 telephone counseling was conducted by healthcare providers (response rate: 82.8%). Throughout 48 weeks, the PRO-CTCAE response rate was $>$ 89% in the ePROm group. The number of evaluable pts at 48 weeks was 37 in the ePROm and 41 in the UC group. At week 48, changes in GHS from baseline in the ePROm and UC groups were -3.7$\pm$18.6 and -12.7$\pm$23.8, and those in FA12 total score were -4.9$\pm$14.3 and 8.1$\pm$16.4, respectively. The median OS was 24.5 months (95% CI: 21.8, not reached) in the ePROm group with a median follow-up duration of 18.3 months, whereas in the UC group, the median OS was not reached (95% CI: 20.7, not reached) with a median follow-up duration of 18.1 months [HR = 1.39; 95% CI: 0.75, 2.59]. The majority of any-grade treatment-emergent adverse event using CTCAE were reported in a higher proportion of pts in the ePROm group than in the UC group during the observation period. Interstitial lung disease incidence was similar in both groups (7.4% in ePROm group vs. 9.3% in UC group), with all cases being grade 1. **Conclusions:** Long-term findings from the PRO-DUCE study demonstrated that QoL observed at week 24 in the ePROm group was maintained over time. While there was no difference in OS, these findings might support the integration of ePROm in clinical practice to optimize QoL for pts receiving T-DXd. Clinical trial information: jRCTs031200387. Research Sponsor: Daiichi Sankyo.

Advancing equity and collaboration in a dedicated young onset cancer clinic: A prospective study. First Author: Ilit Turgeman, Lin Medical Center, Haifa, Israel

Background: Coordinated young onset cancer (YOC) clinics improve patient experience and access to supportive services. However, geographic and ethnic disparities hinder equitable representation and outcomes. This study describes the design and impact of a YOC clinic serving a socioeconomically diverse population. **Methods:** A YOC clinic was established at a peripheral cancer center for patients aged 18-49, staffed with an oncologist, nurse, and social worker. Tailored referrals were facilitated to designated psychosocial and integrative services. Monthly team meetings and biweekly patient support activities were implemented. Data on demographics, cancer characteristics, coping styles (BASIC-Ph model), anxiety and depression (HADS-A/D), referral patterns and satisfaction were prospectively collected and analyzed across ethnic and clinical subgroups. **Results:** From 6/2022 - 4/2023, 104 patients enrolled (mean age 38; 76% female; 62.4% Jewish, 34.7% Arab). Most were married (63.5%), had children (81.4%), unemployed (72.3%), with up to high school education (50.7%). Most (76%) were on active treatment and 38% had metastatic disease. Breast cancer was most common (46.2%), followed by gastrointestinal and thoracic malignancies. Family cancer history (61.5%) actionable somatic (25%) and germline (6.7%) alterations were noted. Referrals were most frequent for integrative medicine (50%), genetics (41.3%), psychology, occupational therapy, with adherence rates of 88%. Ethnic and cancer-type variations in referral patterns were observed, but high uptake was consistent. HADS-A correlated with lack of exercise and HADS-D with unemployment and non-metastatic disease ($p < 0.05$). Females tended more to belief-based coping, males favored imagination, academics employed cognitive strategies, alcohol use to affect and cannabis to imagination ($p < 0.05$), while those with advanced cancer preferred physical coping (p = 0.82). HADS-A correlated with psychology referrals (M = 9.78 vs. 6.86, p = 0.013), belief-based coping to spirituality, social coping to physiotherapy and nutrition ($p < 0.05$). Social coping and sexuality services were less utilized in ethnic minorities and those on active treatment. Nearly all (94.2%) had no prior support group yet satisfaction was high (mean 5/5) with patients citing community, supportive services and side effect management as key benefits. **Conclusions:** A structured, multidisciplinary YOC clinic leverages existing services to enhance collaboration, equity, and access to tailored resources, meeting the unique needs of diverse young cancer patients. Beyond addressing disparities, this model fosters a sense of community among patients, promoting engagement with supportive services that may enhance treatment outcomes. Sharing this approach globally may inspire broader adoption of YOC clinics to benefit underserved populations and advance cancer care equity. Research Sponsor: None.

1547 Poster Session

Automated conversational artificial intelligence (AI) for outpatient malignant bowel obstruction (MBO) symptom monitoring. First Author: Ainhoa Madariaga, Hospital Universitario 12 de Octubre, Madrid, Spain

Background: MBO is a severe complication of advanced cancer. A Canadian ambulatory MBO program with nurse-led proactive call management demonstrated reduced hospitalization rates and improved survival. To overcome resource limitations, a smartphone app was developed, achieving 65% adherence. Building on this foundation, automated phone calls offer a promising approach to enhance adherence and improve symptom monitoring. **Methods:** We conducted a prospective pilot study at a tertiary Spanish hospital to remotely monitor MBO signs and symptoms using a conversational AI-based platform (Lola-Tucuvi). Patients (pts) with cancer with an active MBO or at risk of developing it (per PMMBO criteria) were enrolled. Automated, interactive phone calls were performed by the platform (Lola) weekly or biweekly. Lola performed structured MBO symptom assessments utilizing advanced natural language processing and AI algorithms, to analyze responses in real time. Alerts were generated for moderate or severe symptoms, which were flagged on a dashboard. Nurses contacted pts based on alerts. The primary objective was feasibility measured by adherence (% of answered calls), with a hypothesized adherence of $\geq$65% considered optimal. **Results:** From January 2024 to January 2025, 54 pts were enrolled, with 25 still active at the time of analysis. Median age was 60 years (range 29-86), and 96% of pts are female. Type of tumors included gynecologic (87%) and gastrointestinal (13%). All pts were on systemic therapy: chemotherapy (50%), immunotherapy (24%), ADC (15%), targeted (11%). Median prior lines of therapy were 2 (1-6), and 41% (22/54) of pts had an active MBO prior to enrollment. Lola performed 716 phone calls and 645 were answered, with an adherence of 90%. This resulted in an estimated 183.2 hours of nursing call time saved. Median time on the program was 117 days (7-356), and pts received a median of 14 calls. Of answered calls, the 36% (234/645) generated alerts, with 44% classified as severe. Most frequent severe and moderate alerts were constipation and abdominal pain, respectively. Nurses acted on 73% (171/234) of the alerts, providing interventions such as dietary modifications, medication adjustments, clinical or emergency assessments. During follow-up in the program 31.5% (17/54) of pts had $\geq$1 active MBO and 18.5% (10/54) required admissions for MBO. Feedback was received from 26 pts, indicating a high satisfaction (4.6/5), and 96% would recommend the use of Lola. **Conclusions:** This conversational AI platform demonstrated excellent feasibility with 90% adherence, higher than prior app-based solutions. It effectively monitored MBO symptoms, enabling timely clinical interventions and enhancing patient engagement. These results highlight the potential of AI-driven remote monitoring system to improve outcomes in cancer care. Further validation through randomized studies is warranted. Research Sponsor: Spanish Society of Medical Oncology (SEOM).

Oncologists' perspectives on challenges using chemotherapy, immune checkpoint inhibitors, and targeted kinase inhibitors for metastatic cancer. First Author: Christine M. Veenstra, University of Michigan, Ann Arbor, MI

Background: Compared to cytotoxic chemotherapies, the standard of care for metastatic cancers for decades, use of immune checkpoint inhibitors (ICI) and targeted kinase inhibitors (TKI) has rapidly expanded with evolving indications for patients with advanced disease. We evaluated oncologists' report of challenges to using each type of therapy and associations between challenges and oncology practice resources. **Methods:** From 2023-24 we surveyed 824 medical oncologists, identified using SEER registry data, in Georgia and Los Angeles. We asked oncologists about challenges to using chemotherapy, ICIs and TKIs for the treatment of metastatic cancer. We also asked about resources available at their practice, including administrative and clinical support staff, financial counselors, dedicated pharmacists, social workers, genetic counselors, and interpreters. We generated descriptive statistics of challenges and assessed bivariate associations between challenges and practice resources. **Results:** We present results for a preliminary sample (N = 370). The Table shows the proportion of oncologists who endorsed each challenge. Compared to cytotoxic chemotherapy, oncologists were more likely to endorse moderate to big challenges using ICIs and TKIs related to insurance approval/prior authorization, co-pay assistance and out-of-pocket costs, as well as keeping up with clinical guidelines and familiarity with dosing and side effects; symptom management was more likely to be a moderate to big problem for chemotherapy and TKIs than for ICIs (all $p < 0.01$). Challenges with insurance approval/prior authorization, co-pay assistance, and out-of-pocket costs were associated with the availability of administrative and clinical support staff, dedicated pharmacists, and social workers (all $p < 0.05$). Challenges with symptom management were associated with the availability of clinical support staff and dedicated pharmacists (all $p < 0.05$). **Conclusions:** Oncologists endorsed more challenges using ICIs and TKIs compared to cytotoxic chemotherapy in the treatment of metastatic cancer. TKIs were associated with the most challenges, including problems keeping up with clinical guidelines and familiarity with dosing and side effects for nearly 20% of respondents. It is reassuring that many practice resources exist to help address these challenges. Oncologists may benefit from more educational resources—particularly related to TKIs—in their practices. Research Sponsor: National Cancer Institute; CA251464.

Oncologist-reported challenges.

	% reporting moderate to big challenge			
	Cytotoxic chemotherapy	ICI	TKI	P
Obtaining insurance approval/prior authorization	13	26	35	<0.01
Obtaining co-pay assistance for patients	19	27	43	<0.01
Out-of-pocket costs to patients	25	42	66	<0.01
Symptom management	50	17	43	<0.01
Keeping up with clinical guidelines	7	14	19	<0.01
Familiarity with dosing and side effects	6	7	17	<0.01

Improving access to cancer screening through national telehealth-based lung and colorectal cancer screening programs. First Author: Deanna Brockman, Color Health, Burlingame, CA

Background: Access to routine cancer screening remains a significant barrier to early detection, especially among historically underserved populations. However, little is known about how virtual care can improve access to cancer services. Color and the American Cancer Society (ACS) collaborated to develop two community-based, telemedicine programs for national colorectal and lung cancer screening. Here we evaluate the impact of these programs in expanding access. **Methods:** The Colorectal Cancer (CRC) Screening Program (launched in June 2025) provides at-home fecal immunochemical tests (FIT) to eligible individuals aged 45-75 years. Kits are distributed through federally qualified health centers and other community locations. The Lung Cancer Screening Program (launched in November 2023) offers eligible individuals access to scheduling support for low-dose screening CTs based on ACS guidelines. Both programs leverage a virtual-first approach: patients provide health history information for a cancer risk assessment through an online platform where they can also access educational resources and schedule appointments with physicians to discuss cancer risk (note: screening eligibility is determined based on self-report). Care advocates provide personalized support, including step-by-step guidance on completing tests, navigating screening guidelines, and coordinating follow-up care. **Results:** Across both cancer screening programs (n = 548), participants were predominantly female (CRC: 62.0%; lung: 62.9%) and had similar average ages (CRC: 50.3 years, range 18-90; lung: 53.9 years, range 18-81). In the CRC screening program, 397 participants picked up or requested kits, with the highest demand in California (10.1%), Texas (9.1%), and Florida (7.1%). In total, 126 participants were eligible and activated a kit; participant ineligibility was largely due to already being up-to-date with screening (29.1%) or age (28.5%). Of the 94 completed tests, 4 (4.3%) were abnormal results. In the lung cancer screening program, 71 participants (47%) across 28 states met ACS eligibility criteria; the remaining participants were ineligible due to age (21.1%), less than 20-pack year smoking history (25.4%), no smoking history (25.4%), or a combination of age and smoking history (28.2%). A total of 17 participants (23.9%) subsequently completed a lung CT. Average time to appointment was 29 days (range 9-93), and all appointments were located within 11 miles of the participant's preferred location. Clinically significant findings included Lung-RADS 3 or 4 nodules (29.4%, n = 5) and other incidental findings requiring follow-up care. **Conclusions:** These results illustrate how targeted, community-based approaches can bridge critical gaps in cancer screening by simplifying logistics, reducing costs, and providing tailored support through virtual and community-based solutions. Current treatment patterns for early breast cancer among healthcare professionals and concordance with expert recommendations: Analysis of an online interactive decision support tool. First Author: Timothy Quill, Clinical Care Options, Reston, VA

Background: The treatment paradigm for HER2-negative early breast cancer (EBC) now includes pembrolizumab and targeted therapies such as olaparib, abemaciclib, and most recently, ribociclib in the adjuvant setting for eligible patients. Here, we assess current intended treatment patterns among healthcare professionals (HCPs) for EBC and compare them with those of experts using an online Interactive Decision Support Tool (IDST). **Methods:** We developed an online IDST in July 2024 with input from 5 breast cancer experts providing therapy recommendations for 12 unique patient case scenarios based on presentation characteristics including disease subtype, disease burden, treatment history, *BRCA* mutation status, and risk of recurrence. HCPs entered specific patient characteristics to define a case along with their intended management for that case. The IDST then showed each expert's recommendation for that case scenario and asked the HCPs if the recommendations affected their intended approach. Here, we report a comparison of the expert recommendations and HCP-selected therapy for different EBC case scenarios. **Results:** Between August 2024 and January 2025, 140 HCPs entered 182 cases. Among the 138 HCPs who indicated their treatment plan, plans were concordant with experts for 59% of the cases. Of note, the 5 experts showed complete concordance in their treatment recommendations for all 12 unique case scenarios. Concordance with the experts was higher among HCP treatment plans for cases of hormone receptor–positive (HR+)/HER2-negative (HER2-) cases compared with triple-negative cases (65% vs 49%). High concordance was seen for HR+/HER2- cases receiving adjuvant AI with *BRCA* WT and high risk of recurrence per the monarchE trial criteria (86%; n = 37) with lower concordance for this setting without a high risk of recurrence (65%, n = 26) with HCPs often choosing endocrine therapy plus a CDK4/6 inhibitor. In the setting of TNBC, HCPs entered cases predominantly related to adjuvant therapy after neoadjuvant chemotherapy plus pembrolizumab (n = 44). Among cases without a pathologic CR in this setting (n = 29), concordance was 50% with or 54% without a pathologic germline *BRCA* variant, respectively. Among TNBC cases with a pathologic CR in this setting (n = 15), concordance was 40% with overtreatment by HCPs evident in 33% of cases. HCPs indicated that expert recommendations changed their intended treatment in 28 of 84 (33%) cases and confirmed their choice in 45 of 84 cases (53%). **Conclusions:** These data suggest ongoing challenges with incorporating pembrolizumab and the newest targeted therapies into adjuvant treatment plans for high-risk EBC, particularly TNBC. Continued education and development of resources for HCPs, including online IDSTs, may be increasingly important as the treatment of high-risk EBC continues to evolve. Research Sponsor: None.

Evaluation of longitudinal image-derived AI prognostication as a predictor of overall survival (OS) in a phase 3 advanced non-small cell lung cancer (aNSCLC) trial. First Author: Javier Montalt-Tordera, Bayer, Sant Joan Despi, Spain

Background: Confidently anticipating an overall survival (OS) benefit in cancer care and therapeutic research is a defining challenge. AI tools may offer longitudinal measurements that predict OS differences objectively from existing data. Longitudinal imaging-based prognostication (IPRO-Δ), a fully automated deep learning system, was independently trained on real-world imaging data to predict survival from pairs of longitudinal computed tomography (CT) scans. **Methods:** We retrospectively assessed and compared how IPRO-Δ and percent change in RECIST sum of longest diameters (ΔSLD) predicted OS from 165 pairs of baseline and week 13 CT scans acquired in NExUS (NCT00449033), a phase 3 randomized controlled trial evaluating chemotherapy in combination with either sorafenib or placebo for first-line treatment of subjects with aNSCLC. The two study arms did not show a difference in OS and were combined for this analysis. To examine the association of IPRO-Δ and ΔSLD with OS, we measured the concordance index (c-index) and the standardized hazard ratios (HRs, change in risk for a one-standard-deviation increase in the marker). We also report median OS (mOS) for patients with partial response (PR, *n* = 60), stable disease (SD, *n* = 83) and progressive disease (PD, *n* = 22) at week 13, as defined by RECIST 1.1 guidelines (zero patients had a complete response). To explore the stratification potential of IPRO-Δ, we also define equivalent strata by ordering patients by their IPRO-Δ score and maintaining the same proportions (e.g., the top 60 patients by IPRO-Δ would be IPRO-PR, while the bottom 22 patients would be IPRO-PD), and report the mOS for these strata. **Results:** For the combined trial arms, median OS was 10.9 months (95% CI: 8.6 – 13.6), 108 (65.4%) were male, and 145 (87.9%) were diagnosed as stage IV. Table 1 reports the c-index, HR and stratified mOS values for both survival markers. **Conclusions:** At week 13 in NExUS, IPRO-Δ predicted OS differences significantly better than ΔSLD. Future work will explore how IPRO-Δ could serve as the basis for a surrogate endpoint in aNSCLC trials. Research Sponsor: None.

Summary of association of IPRO-Δ and ΔSLD with OS.

	IPRO-Δ @ Week 13 (95% CI)	ΔSLD @ Week 13 (95% CI)	*p*-value
C-Index	0.654 (0.604 – 0.713)	0.543 (0.495 – 0.599)	<0.01
HR (1SD)	1.72 (1.38 – 2.15)	1.14 (0.94 – 1.38)	<0.01
OS (months, PR / SD / PD or IPRO equivalent)	16.5 / 10.9 / 5.7	12.5 / 12.3 / 4.6	-

Real-world side effects of targeted therapies: High-throughput association studies leveraging the CancerLinq Discovery lung cancer database. First Author: Joseph Vento, Department of Internal Medicine, Division of Hematology and Oncology, UT Southwestern, Dallas, TX

Background: Targeted therapies have unique side effect profiles distinct from other cancer drugs. Challenges of collecting generalizable toxicity data on these medications include the self-reporting infrastructure of existing post-market surveillance databases, as well as the infrequent use of many of these drugs by single cancer centers. The CancerLinQ Discovery (CLQD) database synthesizes deidentified electronic health record (EHR) data from millions of U.S. cancer patients. Diagnosis codes in this database can be used to study treatment side effects. **Methods:** We developed high-precision phenotyping algorithms to identify non-small cell lung cancer (NSCLC) patients receiving targeted therapies in the CLQD database. We then performed phenome-wide association studies (PheWAS) comparing new diagnosis codes in patients receiving each targeted therapy to new codes in patients receiving chemotherapy or immunotherapy. Codes with significant associations were compared to toxicity data reported in clinical trials and the FDA Adverse Event Reporting System (FAERS) database. **Results:** We identified 5,278 NSCLC patients who received targeted therapies with the latest CLQD data pull in 2022. For each of the 18 targeted therapies with five or more patients in the database, descriptive statistics and two PheWAS analyses are reported: one for diagnosis codes relative to chemotherapy, and one relative to immunotherapy. These analyses identified significant associations corresponding to known toxicity profiles as well as potentially underreported side effects. **Conclusions:** This high-throughput framework augments the characterization of side effect profiles for existing targeted therapies and can proactively monitor for toxicity signals as novel therapies and treatment indications emerge. The importance of collecting real-world data across institutions is highlighted in the ability to find clinically relevant associations even in targeted therapies directed against rare mutations. Research Sponsor: National Library of Medicine.

Transforming oncology clinical trial matching through multi-agent AI and an oncology-specific knowledge graph: A prospective evaluation in 3,800 patients. First Author: Arturo Loaiza-Bonilla, St. Luke's University Health Network, Easton, PA

Background: Clinical trial enrollment in oncology is often hampered by the manual, time-intensive process of matching patients to trials with highly specific eligibility criteria. Advances in artificial intelligence (AI)—particularly multi-agent large language models (LLMs) and oncology-specific knowledge networks—hold promise for streamlining this workflow and minimizing human labor. This abstract presents a prospective evaluation of an AI platform that automates medical data extraction, leverages an oncology-specific knowledge graph, and provides real-time trial recommendations, demonstrating a significant reduction in staff effort while maintaining high clinical accuracy. **Methods:** Multi-Agent AI & Oncology Knowledge Graph 1. OncoAgents: Specialized LLMs (data extraction, eligibility, trial matching), collaborating to outperform generic or zero-shot AI. 2. OncoGraph: Domain-specific knowledge graph uniting patient data, molecular profiles, and clinical guidelines for context-aware matching. 3. OncoRecommend: Real-time engine processing new data, trials, and guidelines, delivering rapid, relevant suggestions. 4. OncoSet: Expert-curated dataset (>2,000 patient records, 14,000+ trials, 50+ tumor subtypes) ensuring robust AI performance. Prospective Analysis (Jan–Dec 2024): Cohort: 3,804 patients (ECOG 0–2) with metastatic/progressing malignancies seeking trial options. Data Extraction: 157,367 pages (~86.5M tokens) processed for tumor type, stage, treatment lines, and biomarkers. Trial Matching: Automated application of inclusion/exclusion criteria; oncologists validated AI-generated matches. Efficiency: Manual matching for large cohorts can require thousands of hours; this AI approach condensed it to ~1 hour of expert review. **Results:** 1. Screening & Identification: 3,804 patients screened; 23,912 trials identified; 17,912 confirmed after expert review. 2. Time-to-Recommendation: Under one week from screening to final recommendations via real-time AI prioritization. 3. Performance Metrics: Sensitivity (Recall): 0.8375, Specificity: 0.8359, Precision: 0.8121, F1 Score: 0.8246. Demonstrates advantages over zero-shot or frontier GPT-based models. 4. GPT Comparison: Extraction Accuracy: 80.29% vs up to 63.15% (GPT-4o); Trial Matching Accuracy: 82.06% vs 47.00% (GPT-4o). **Conclusions:** This multi-agent AI platform, underpinned by an oncology-specific knowledge graph, significantly boosts efficiency and accuracy in oncological trial matching. By cutting manual workloads from thousands of hours to near-automated speeds, recommendations allow for just-in-time, decentralized and patient-centric trial activation. Ongoing enhancements—such as deeper biomarker integration, expanded knowledge graph coverage, and seamless EHR interoperability—promise further gains in personalized oncology care. Breath-based VOC analysis leveraging canine olfaction for multi-cancer detection: Insights from a 1000-sample study. First Author: Akash Kulgod, Dognosis, Inc., Bangalore, India

Background: Volatile organic compound (VOC) analysis is a validated approach for identifying disease-specific metabolic alterations through exhaled breath. The non-invasive and low-cost nature of breath sample collection makes it particularly suitable for large-scale cancer screening in resource-limited settings, such as those commonly found in the Global South. Canine olfaction has been demonstrated in prior controlled studies to detect VOCs with high accuracy across a range of pathologies, including malignancies. This study evaluates the performance of trained biomedical detection dogs in identifying multiple cancer types using VOC analysis and examines the integration of neurobehavioral data to support real-world diagnostic applications. **Methods:** A retrospective case-control study was conducted involving 1000 participants across three clinical sites in Hubli, India. Exhaled breath samples (n = 105 cancer-positive, n = 895 healthy controls) were collected using standardized protocols designed to maintain VOC integrity. Trained biomedical detection dogs analyzed these samples, with their behavioral responses recorded via motion sensors, video data, and electroencephalography (EEG) systems. A consensus-based decision framework was implemented to account for variability among individual dogs. Preliminary machine learning models were trained using the recorded neurobehavioral data to evaluate their potential for augmenting detection accuracy; however, these models remain in the validation phase. **Results:** The detection system demonstrated a sensitivity of 96% and a specificity of 100% across multiple cancer types in the test set, including oral, breast, esophageal, and cervical cancers. Sensitivity for early-stage cancers was 85%. The consensus-based approach among dogs enhanced reliability and minimized individual variability. Preliminary analysis of neurobehavioral data indicates potential for machine learning applications to refine diagnostic interpretation. **Conclusions:** Breath-based VOC analysis combined with canine olfaction demonstrates high accuracy in multi-cancer detection, including early-stage cancers. Its suitability for non-invasive and low-cost implementation, particularly in resource-constrained settings like the Global South, highlights its potential for addressing disparities in cancer screening access. Future research will focus on validating machine learning models and comparing the system's performance with existing diagnostic standards to further support global scalability and clinical adoption. PRESCIENTai, an AI-based digital histopathological image signature for risk of late distant recurrence and extended endocrine therapy (EET) benefit in hormone receptor–positive breast cancer. First Author: Eleftherios P. Mamounas, NSABP and AdventHealth Cancer Institute, Orlando, FL

Background: A subset of patients (pts) with hormone receptor-positive (HR+) breast cancer (BC) experiences late distant recurrence (DR) and is more likely to benefit from EET. Clinical practice guidelines recommend use of genomic assays such as Breast Cancer Index (BCI) to identify these pts. We developed an updated AI-based digital histopathological risk score model to predict risk of late DR and extended letrozole therapy (ELT) benefit in this population. **Methods:** The AI model, PRESCIENTai, was trained on eligible samples (N = 2,271) from the National Surgical Adjuvant Breast and Bowel Project (NSABP) B-42 cohort, which randomized postmenopausal women with HR+ BC who were disease-free after 5 yrs of endocrine therapy (aromatase inhibitor (AI) or tamoxifen followed by AI) to either 5 yrs of letrozole or placebo. A transformer-based end-to-end deep learning model predicted risk score from H&E whole-slide images (WSI) in conjunction with clinical information (age at randomization, surgery type, node status, prior use of tamoxifen, race, lowest bone mineral density T-score, HER2 status). CTransPath was used for feature extraction from WSI tiles. 5-fold cross validation was performed with data split into training, validation, and test sets (60:20:20). The risk score threshold was defined by the 50% quantile of the training set for each fold. Cox regression and Kaplan-Meier analysis evaluated late DR and ELT benefit in high- and low-risk pts. **Results:** Hazard ratio (HR) was computed for DR in low- vs. high-risk pts [HR = 0.198 (95% CI: 0.124, 0.317); $p < 0.001$], with absolute difference of 7.61% in 10-yr DR (1.84% vs. 9.46%). High-risk pts experienced greater ELT benefit over placebo (HR = 0.622; 95% CI: 0.416–0.929; $p = 0.02$) than low-risk pts (HR = 0.727; 95% CI: 0.305–1.733; $p = 0.471$), with 10-yr absolute benefit of 3.74% vs. 0.66%. Even among node(+) pts, PRESCIENTai identified greater ELT benefit for high-risk pts (HR = 0.521; 95% CI: 0.329–0.827; $p = 0.006$) than low-risk pts (HR = 0.53; 95% CI: 0.048-5.905, $p = 0.606$), with 10-yr absolute benefit of 6.66% vs. 1.89%. ELT benefit was also observed for high-risk pts in other clinical subgroups such as age ≤60 years and prior tamoxifen. However, p-interaction for ELT benefit in high- vs. low-risk groups was not significant for all pts ($p = 0.791$) or node(+) pts ($p = 0.889$). **Conclusions:** This novel digital signature predicts risk of late DR in pts with HR+ BC. Although absolute ELT benefit was greater in high- vs. low-risk pts, the treatment by risk score interaction was not statistically significant. This is, to our knowledge, the first AI model to predict long-term outcomes in pts with HR+, early BC using a single slide image and clinical information. Successful validation in additional pt cohorts will confirm the clinical utility of PRESCIENTai for prediction of late DR risk and EET benefit. Computational pathology to predict docetaxel benefit for high-risk localized prostate cancer in NRG/RTOG 0521 (NCT00288080). First Author: Sebastian R. Medina, Wallace H. Coulter Department of Biomedical Engineering at Georgia Tech and Emory University, Atlanta, GA

Background: The benefit of adding docetaxel (DTX) to standard of care (SOC) for high-risk localized prostate cancer remains debated. The NRG/RTOG 0521 randomized phase III trial demonstrated that docetaxel, when added to SOC—comprising radiotherapy (RT) and long-term androgen deprivation therapy (ADT)—improved overall survival (OS). However, while RTOG 0521 demonstrated improved OS with DTX, the observed improvement did not meet the predetermined threshold for clinical significance, leaving the role of DTX intensification uncertain. Enhanced stratification methods are needed to identify aggressive disease phenotypes and guide patient selection for adjuvant chemotherapy. This study aims to develop and validate a computational AI derived pathology image classifier (APIC) to quantify the tumor-immune microenvironment from diagnostic biopsy specimens and predict DTX benefit in patients from the NRG/RTOG 0521 trial. **Methods:** The study included patients with available high-quality biopsy images from the NRG/RTOG 0521 trial. Primary outcome was OS, median follow-up was 5.7 years. After segmenting nuclei and identifying lymphocytes, we derived features that captured immune-tumor spatial patterns and nuclear diversity in the tumor microenvironment to construct APIC. DTX benefit was evaluated using Cox proportional hazards models with interaction terms, log-rank tests and Kaplan-Meier analyses by comparing OS between treatment arms within APIC-stratified groups. **Results:** Among NRG/RTOG 0521 trial participants, 350 patients had evaluable quality biopsy slide images. Half of the SOC (RT+ADT) arm was used for training (84 patients), and 266 patients were used for validation (SOC: 85 patients, and SOC+DTX arm: 181 patients). DTX significantly improved OS in APIC-positive (n = 119, 45%) patients (HR = 0.49, 95% CI: 0.26-0.92, p = 0.023) but not in APIC-negative (n = 147, 55%) patients (HR = 1.17, 95% CI: 0.59-2.3, p = 0.66). APIC-positive patients derived 22% 10-year OS benefit (95% CI: 1.7%-41.6%) from DTX. The 10-year OS was 74% in the DTX arm compared to 52% with RT and ADT alone in the APIC-positive group. A significant interaction (p = 0.024) was observed between APIC status and treatment. **Conclusions:** We validated APIC as a predictive biomarker for DTX benefit in high-risk localized prostate cancer patients from NRG/RTOG 0521, identifying a subset who achieved significant survival improvement from treatment intensification – a benefit not reached in the unselected trial population. Further investigation is warranted to evaluate APIC's predictive potential of DTX intensification in metastatic disease settings. Use of a large language model (LLM) for pan-cancer automated detection of anti-cancer therapy toxicities and translational toxicity research. First Author: Ziad Bakouny, Memorial Sloan Kettering Cancer Center, New York, NY

Background: Understanding why patients develop adverse events to anti-cancer therapies and predicting the occurrence of these toxicities has lagged behind tumor response biomarker development. This critical gap is primarily due to limited availability of large-scale curated toxicity data. Here, we leverage advances in natural language processing (*Jee J et al., Nature, 2024*), pooled clinical trial data, and associated germline sequencing to detect adverse event data and determine clinical and genomic correlates. **Methods:** We utilized the Llama 3.1 LLM to automatically annotate patient adverse event data for 5 of the most common anti-cancer therapy related adverse events (adrenal insufficiency, hyperthyroidism, hypothyroidism, colitis, and pneumonitis). To validate LLM predictions at the patient-level, we used a pooled institutional dataset with gold standard prospectively collected adverse event data from 1,754 patients with solid tumors across 675 individual clinical trials. We further validated the LLM predictions at the clinical note-level using a subset of 100 manually curated notes. We evaluated note-level and patient-level predictions using sensitivity and specificity. Patient-level time-to-adverse event development predictions were evaluated using Pearson R^2 coefficients. Common Terminology Criteria for Adverse Events v 5.0 was used for toxicity definitions. **Results:** The patients' average age (standard deviation) was 61.6 (14.5) years and 836 (47.7%) were female. The most common cancers were non-small cell lung cancer (N= 194, 11.1%), soft tissue sarcoma (N=171, 9.7%), breast cancer (N= 155, 8.8%), and melanoma (N=129, 7.4%). 44 (2.5%) patients had adrenal insufficiency, 88 colitis (5.0%), 253 hypothyroidism (14.4%), 66 hyperthyroidism (4.4%), and 146 pneumonitis (8.3%). Among 1258 patients with complete systemic therapy information available, 422 (33.5%) were treated with immunotherapy and 563 (44.8%) with chemotherapy. The performance metrics for LLM predictions at the note and patient levels are summarized in the table. **Conclusions:** We demonstrate the ability of an LLM to accurately annotate anti-cancer therapy toxicity data across a large number of patients. This approach is scalable to other toxicities and promises to spur adverse event research. Clinical and genomic correlates of anti-cancer therapy adverse events, using data from all patients with solid tumors with MSK-IMPACT data, will also be presented at the meeting. Research Sponsor: National Cancer Institute; T32CA009512-35; National Cancer Institute; P30-CA008748.

Performance metrics for LLM model.

Toxicity	Note-level (N= 100 notes)		Patient-level (N= 1,754 patients)		
	Sensitivity	Specificity	Sensitivity	Specificity	R^2
Adrenal insufficiency	100.0%	97.8%	97.7%	94.7%	98.2%
Colitis	66.7%	99.0%	94.3%	80.4%	89.2%
Hyperthyroidism	57.1%	100.0%	74.0%	91.4%	98.7%
Hypothyroidism	100.0%	88.9%	88.1%	74.0%	96.1%
Pneumonitis	76.9%	97.7%	98.6%	70.1%	83.9%

Association of deep learning CT response assessment and interpretable components with overall survival in advanced NSCLC: Validation in a trial of sasanlimab and a real-world dataset. First Author: Chiharu Sako, Onc.AI, San Carlos, CA

Background: Identifying advanced non–small cell lung cancer (aNSCLC) patients who derive long-term benefit from immune checkpoint inhibitors (ICIs) remains a significant challenge. Radiomic analyses, particularly leveraging deep learning, hold promise for improving prognostic accuracy beyond tumor size metrics. We developed serialCTRS, a novel biomarker using deep learning to quantify thoracic CT changes from baseline to 3 months post-treatment, predicting overall survival (OS) in patients receiving PD-(L)1 inhibitors. **Methods:** SerialCTRS was previously trained and validated on a multi-institutional Real-World Dataset (RWD) (training: 1,171 aNSCLC patients, 14,424 CT scans; validation: 612 patients; Sako et al. SITC, 2024). For this study, we retrospectively validated serialCTRS in two distinct cohorts of aNSCLC patients: (1) a clinical trial (N = 52) treated with the PD-1 inhibitor sasanlimab in the second or later line and (2) a fully blinded RWD from Baylor Scott & White Health system (N = 147), an institution not used for training. The pipeline—spanning image quality control, preprocessing, feature extraction, and survival modeling—operated without manual annotations. To enhance interpretability, we developed 3D submodels for prognostic signals related to (i) tumor burden, (ii) body composition, and (iii) lung vasculature. Predictive performance was compared to RECIST 1.1 using concordance index (c-index) and ROC-AUC for 24-month OS (OS24 AUC). **Results:** SerialCTRS outperformed RECIST in OS prediction and remained a significant predictor after multivariate adjustments with other known predictors including age, sex, PD-L1 TPS, and NLR across both validation cohorts. In the sasanlimab cohort, serialCTRS achieved a c-index of 0.77, surpassing RECIST (0.72), with an OS24 AUC of 0.86 (95% CI: 0.74–0.98). In the Baylor cohort, serialCTRS demonstrated a c-index of 0.68 vs. RECIST (0.62) and an OS24 AUC of 0.76 (0.67–0.86). Submodels targeting individual components achieved c-indices of 0.65 (tumor burden), 0.61 (body composition), and 0.61 (vasculature) in the sasanlimab cohort, and 0.63, 0.61, and 0.59, respectively, in the Baylor cohort. Combining the submodels improved c-indices to 0.69 (sasanlimab) and 0.66 (Baylor), demonstrating complementary signal among radiographic features. **Conclusions:** SerialCTRS outperformed RECIST 1.1 in predicting OS in independent clinical trial and RWD datasets. Interpretable submodels highlighted the prognostic value of tumor burden, body composition, and vasculature changes. SerialCTRS offers a promising tool for personalizing therapy and accelerating drug development in aNSCLC, with a fully automated pipeline for robust and scalable clinical use. Future work will focus on larger, more diverse cohorts to validate utility in guiding precision oncology. Research Sponsor: None.

Computational pathology to predict docetaxel benefit in patients with metastatic hormone-sensitive prostate cancer from the CHAARTED trial (ECOG-ACRIN E3805). First Author: Sebastian R. Medina, Wallace H. Coulter Department of Biomedical Engineering at Georgia Tech and Emory University, Atlanta, GA

Background: The CHAARTED trial demonstrated the efficacy of early docetaxel (DTX) in combination with androgen deprivation therapy (ADT) for metastatic hormone-sensitive prostate cancer (mHSPC), particularly in patients (pts) with high volume (HV) disease. Volume of metastases has been shown to assist pts selection, however more precise biomarkers are needed to select pts that might benefit from early DTX, especially in low volume (LV) metastasis. We aim to validate a computational AI pathology image classifier (APIC), that quantifies the tumor-immune microenvironment from biopsy images to predict DTX benefit in pts from the CHAARTED trial. **Methods:** The study included a subset of pts from CHAARTED for whom high-quality biopsy images were available. Outcomes were defined as overall survival (OS) and time to castration resistance (CRPC). After segmenting nuclei and identifying lymphocytes, we derived features that captured immune-tumor spatial patterns and nuclear diversity to construct APIC and stratify patients into positive or negative groups. DTX benefit was evaluated using Cox proportional hazards with interaction terms, log-rank tests and Kaplan-Meier analyses by comparing endpoint estimates between treatment arms within APIC-stratified groups. **Results:** Among CHAARTED trial pts, we analyzed H&E images that met quality control and excluded prostatectomies (N = 286/790, 36.2%). Half of the ADT arm was used for training (78 pts), and 208 pts were used for validation (ADT = 77, DTX = 131). Among these, 118 pts (56%) were classified as APIC-positive and 90 pts (44%) as APIC-negative. In APIC-positive, DTX significantly improved OS (HR = 0.52 [95% CI: 0.31–0.85], p = 0.0075, interaction $p < 0.05$) and delayed time to CRPC (HR = 0.48 [95% CI: 0.33–0.71], p = 0.00019, interaction $p < 0.05$). APIC-positive pts who received DTX derived a 24.3% higher 5-year OS and remained castration-sensitive 21.8% longer than those who received ADT alone. In APIC-negative pts, no prolongation effects of OS or time to CRPC were observed from the addition of DTX. APIC was able to identify pts benefiting from DTX in the HV group for OS (HR = 0.43 [95%CI: 0.24-0.77], p = 0.0035), and in both HV (HR = 0.50 [95%CI: 0.31-0.79], p = 0.0027) and LV (HR = 0.42 [95%CI: 0.20-0.91], p = 0.023) groups for time to CRPC. While CHAARTED showed modest CRPC delay in LV pts and no clear OS benefit, APIC identified a subset of LV pts who derived substantial CRPC delay from DTX. **Conclusions:** We validated APIC as a predictive biomarker for DTX benefit in mHSPC pts from CHAARTED. Notably, in unselected pts with LV disease where the benefit of DTX is less, APIC identified an LV subset who derived significant delayed progression to CRPC from adding DTX to ADT. This work, validated in the context of ADT alone, warrants investigation alongside androgen receptor axis-targeted agents. Frailty in motion: How Fitbit data reflects patients with cancers' functional status in the All-of-Us database. First Author: Kenan Najjar, Carle Illinois College of Medicine, Champaign, IL

Background: Frailty is a vital determinant of outcomes in adults with cancer, leading to heightened toxicity, morbidity, and reduced survival. Despite its significance, comprehensive frailty assessment remains constrained by time, resources, and knowledge. Deficit-based frailty indices (FIs) require extensive surveys, limiting real-world use. Wearable devices (e.g., Fitbit) that track daily steps offer a straightforward measure of physical function, yet their associations with FIs are uncertain in oncology. Leveraging the All of Us Research Program (Controlled Tier Dataset Version 7), one of the most diverse NIH resources, we examined the association between steps and the validated All of Us Frailty Index (AoU-FI) [Wong et al. *J Gerontol A Biol Sci Med Sci.* 2023]. We hypothesized that higher step counts would correspond to lower (fitter) AoU-FI scores. **Methods:** We identified adults $\geq$50 years old with cancer and 3–7 days of Fitbit data between 2017–2025. The AoU-FI comprises 33 deficits encompassing lifestyle, comorbidities, overall health, and healthcare access. Frailty was categorized as Fit (< 0.15), Pre-Frail (0.15–0.25), or Frail (> 0.25). Scores were matched with wearable data $\pm$ 30 days; outliers (< 300 or $> 20{,}000$ steps/day) and records missing $\geq$20% of FI items were excluded. Demographics (age, sex, race/ethnicity) and cancer diagnoses were documented. Mean step counts were compared via t-tests. A linear regression assessed the step–frailty link, and a multivariable logistic model for discerning Fit vs Pre-Frail or Frail (age$\geq$65, male, $>$ one cancer) employed normalized step counts (per 1,000). **Results:** Among 361 participants (mean age 65.7$\pm$7.8; 66.8% female; 92.5% White; 97.5% non-Hispanic/Latino), 86.2% had one cancer (skin 55.7%, breast 24.8%, prostate 9.9%). Frailty categories were 44.0% Fit, 40.4% Pre-Frail, and 15.5% Frail. Mean steps declined with increasing frailty (Fit vs. Pre-Frail 8,136$\pm$3,251 vs. 7,067$\pm$3,598; p = 0.007; vs. Frail 5,486$\pm$3,623; $p < 0.0001$). A linear regression confirmed an inverse link between frailty and steps. (slope = -7.38×10^{-6}; $p < 0.0001$). Adjusted analysis showed steps remained highly significant (OR = 1.14, 95% CI: 1.07–1.21, $p < 0.0001$), whereas gender, $>$ one cancer, and age$\geq$65 were not. **Conclusions:** All-of-Us is designed to represent many populations, and our sample showed older adults adopting wearable technologies, highlighting their potential for clinical use. However, the sample was primarily White individuals with skin cancer, reflecting coverage gaps in wearable data across the cancer population. Step counts strongly correlated with fitness, supporting wearable-based functional assessment in oncology. Chronological age did not correlate with frailty, aligning with guidelines prioritizing holistic assessments. Future efforts should integrate broader populations, minute-level metrics, and cancer and treatment information to refine frailty classification as recruitment grows. Research Sponsor: "The All of Us Research Program is supported by the National Institutes of Health, Office of the Director. The program would not be possible without the partnership of its participants."

DeepSeal: Empowering clinical researchers to analyze clinicogenomic data with an intuitive chat-based interface. First Author: Gaurav Sharma, Ocean Genomics, Pittsburgh, PA

Background: Traditional clinicogenomic analysis workflows in oncology require substantial bioinformatics expertise and custom coding, creating a bottleneck where clinical researchers must rely on analysts for data interpretation. This dependency hinders hypothesis development, exploration and discovery, as researchers cannot directly interact with their data in real-time. DeepSeal addresses these challenges by providing a user-friendly, chat-based interface that enables immediate analysis of clinicogenomic data and seamless generation of results, empowering clinical researchers to independently explore and validate hypotheses. **Methods:** DeepSeal, an integration of a large language model with clinical and molecular databases and bioinformatics tools, was evaluated by replicating the findings of Riaz et al. (Cell, 2017), in advanced melanoma patients treated with nivolumab. Through natural language prompts, DeepSeal performed multiple analyses including differential gene expression analysis and Gene Set Enrichment Analysis (GSEA) to generate comprehensive molecular profiles of responders versus non-responders and to identify molecular signatures associated with treatment response. **Results:** DeepSeal successfully replicated the key findings of Riaz et al., identifying significant differential expression of immune-related genes in treatment responders. GSEA executed through DeepSeal's chat interface further revealed enrichment of immune-related pathways critical for response, including B cell activation (GO:0042113), T cell activation (GO:0042110), and regulation of adaptive immune response (GO:0002819). The chat interface enabled rapid hypothesis testing and visualization generation, with analyses completed in minutes without the need for programming expertise. **Conclusions:** DeepSeal demonstrates the feasibility of enabling clinical researchers to independently analyze complex clinicogenomic data through natural language interaction. By successfully replicating and validating findings from Riaz et al., it generates reliable insights without programming expertise, offering a transformative approach to accelerate translational research. This removal of technical barriers between researchers and their data has the potential to substantially speed hypothesis testing and discovery in oncology, ultimately enhancing the pathway from molecular insights to improved patient care. Virtual oncology collaborative tumor board using multiple artificial intelligence agents. First Author: Jiasheng Wang, Comprehensive Cancer Center & James Solove Research Inst., The Ohio State University Medical Center, Columbus, OH

Background: Clinical guidelines are complex documents with tables and figures. Finding specific answers to questions within these guidelines can be challenging and time-consuming. Current AI tools often struggle to extract information from these PDF guidelines. To address this, we developed a novel system that uses a group of artificial intelligence (AI) agents, where each agent is designed to perform a distinct job, like finding information, reading documents, or summarizing findings. These agents communicate with each other to analyze complex clinical guidelines, working as a team to answer physician questions like trained oncologists discussing cases in a tumor board environment. **Methods:** Publicly available PDF guidelines published by the ASCO from Jan 2021 to Dec 2024 were acquired. A three-agent framework was constructed using the AutoGen platform, comprising a Coordinator Agent, a PDF Viewer Agent, and a Reviewer Agent. The Coordinator Agent selects the appropriate guideline based on a user's question; the PDF Viewer Agent extracts information from the selected guideline file, and the Reviewer Agent generates a summary of the findings answering the original question. The agents were powered by Anthropic's Claude 3.5 Sonnet. The primary objective of the study was to evaluate the platform's accuracy in selecting the relevant guideline based on user questions and in subsequently answering those questions accurately. **Results:** A total of 34 ASCO guidelines were obtained, covering a range of cancer types: breast (15), GI (4), head and neck (4), thoracic (4), neuro-oncology (3), GU (2), melanoma (1), and gynecologic (1). One hundred question-answer pairs were created by board-certified oncologists based on these guidelines to evaluate the system's performance. It's important to note that these answers were based directly on the information in the guidelines and may not always reflect the most current clinical knowledge, thus serving as a rigorous test of the framework's ability to adhere to the provided documents. Our multi-agent framework achieved a 93% accuracy rate in matching user questions with the correct guideline and answered 88% of the questions accurately. Comparatively, when the same questions were evaluated using OpenAI's GPT-4o (ChatGPT) and Claude 3.5 Sonnet without the multi-agent framework, the accuracy was significantly lower at 48% and 49%, respectively. The total computational cost of processing all questions using the multi-agent framework was 13.44 USD. The complete code, dataset, and detailed results are publicly accessible at https://github.com/jwang-580/ASCO_guideline_agents. **Conclusions:** This study demonstrates that a collaborative AI agent system can accurately provide answers from clinical guidelines that is more accurate than ChatGPT and similar software. Our results suggest a promising way to develop more effective AI tools for clinicians to use in their practice. Research Sponsor: None.

Comparison of artificial intelligence to expert physician assessments of real-world oncology cases. First Author: Olivia Main, NYU Perlmutter Cancer Center, NYU Grossman Long Island School of Medicine, Mineola, NY

Background: Artificial intelligence (AI) is increasingly being incorporated into the oncology field as a tool to support clinical decisions. AI tools such as ChatgGPT or OpenEvidence provide responses to user-generated queries, whereas some institutions or companies such as Primum, Inc, offer consultations with actual experts who provide personalized responses to clinician-submitted real-world cases. However, the value of AI tools to augment expert consultations continues to evolve. We report results of a study comparing AI versus expert oncologists' responses to 107 real-world hematology/oncology cases. **Methods:** Among 107 cases, inquiries included lymphomas (30), myeloma (24), leukemias (11), myeloid disorders (10), as well as classical hematology (32), assessed among 20 experts. Responses to de-identified cases submitted by practicing clinicians to Primum (www.primum.co) between June 2022-July 2023 were compared to GPT-4 responses (openai.com/chatgpt). The instructional prompt to GPT-4 was, "You are an expert oncologist conversing with another oncologist as a peer. You prefer to rely on guidelines and data published in reputable medical journals when responding." Five expert faculty at our institution adjudicated the blinded comparative responses, including their preference, quality and practical value scores, and prediction of which response was AI generated. Comparison of scores was by t-test to generate P-values between expert and AI groups, and Pearson correlation was used for comparisons between adjudication scores. **Results:** Expert responses were preferred by $>$ 50% of adjudicators in 75% of cases (deviation $\pm$25%). Randomized AI responses were correctly identified 90% of the time. Mean expert vs AI scores (Likert scale 0-4) for quality (2.0 vs 2.1, P = 0.9) and practical value (2.1 vs 2.1, P = 0.9) were equivalent. Interestingly, AI responses were preferred in 46% (n = 15) of classical hematology and 31% (n = 9) of lymphoma cases, largely due to being more concise. However there was no concordance between high practical value scores and disease subtype for either group. **Conclusions:** : Expert physician responses were preferred over AI responses for most of the cases based on the level of detail presented, suggesting an implicit value of personalized responses compared to AI. Results showed no significant differences in quality or practical utility between AI generated responses and those from experts, reflecting a similarity in the information extracted from standardized guidelines, and potentially adding value of AI in supporting clinical decision making. Our findings are limited by the broad coverage of hematologic conditions for which experts and guidelines vary. Overall, these data suggest that while AI can supplement knowledge of management paradigms by providing basic management strategies, at present it cannot replace personalized expert consultation in clinical practice. Evaluating fairness and mitigating bias in models predicting financial toxicity among patients with genitourinary cancers. First Author: Atulya Aman Khosla, Department of Internal Medicine, William Beaumont University Hospital, Royal Oak, MI

Background: Financial toxicity, the economic burden patients face from healthcare expenses, is a growing concern in cancer care. Recognizing the high costs of diagnosis and treatment of genitourinary (GU) cancers, this study aims to (1) comprehensively characterize the socioeconomic, demographic, and care-related factors associated with financial toxicity in patients with GU cancers, and (2) evaluate bias in the predictive model developed using these patient factors. **Methods:** The 2019–2022 Medical Expenditure Panel Survey (MEPS) data was used to identify patients with GU cancers. MEPS captures utilization, frequency, cost, and payment sources of U.S. health services alongside health insurance coverage characteristics and accessibility in the workforce. Financial toxicity was defined as patient-reported difficulties paying medical bills, high out-of-pocket expenses ($>$ 10% of total income), and high self-pay ratios ($>$ 20% of total healthcare expenditure). Predictive modeling was performed using logistic regression using age, sex, race/ethnicity, income, insurance status, and expenditure-related predictors. To address potential algorithmic bias, Fairlearn's *ThresholdOptimizer, a postprocessing algorithm,* was applied to this predictive model, adjusting predictions to ensure equalized odds across racial groups. Performance metrics, including accuracy, precision, and recall, were evaluated overall and by racial group. **Results:** Overall, we identified 1131 patients with GU cancers (weighted *n* = 11,723,024) in the MEPS data; median age 72 yrs; sex 93.4% male; 71.6% White, 18.3% Black, 6.5% Hispanic, and 3.5% Other. 22.2% of patients reported financial toxicity with a median [Q1, Q3] total healthcare expenditure of $2,645.0 [$898.5, $5328.0] vs. $503.5 [$171.0, $1286.8]. Logistic regression achieved an overall accuracy of 95%, with a precision of 97% and recall of 77% for financial toxicity cases. Fairness metrics of the unadjusted predictions revealed bias to specific communities with lower recall for Black (46.2%) and Other Races (33.3%) compared to Hispanic (75.0%) and White (90.4%) patients. After threshold optimization, recall improved to 61.5% for Black and 50% for Other Races, while Hispanic (84.6%) and White (100%) patients maintained high performance. However, disparities persisted, as evidenced by an equalized odds difference of 0.21. **Conclusions:** This study underscores the critical need for responsible development of predictive models impacting cancer care. Our findings show that a bias-correcting postprocessing algorithm can be an essential tool since it can be applied to existing models without requiring retraining; however, these algorithms do not represent a definitive solution since this model's underlying bias persists, highlighting the need to ensure models learn from fair data sets that are representative of the US population. Machine learning model to forecast patient availability for oncology clinical trials. First Author: Rajeev Kulkarni, ConcertAI, Cambridge, MA

Background: Automating eligibility criteria assessment for oncology clinical trials is an emerging application of machine learning (ML). However, machine learning applications to predict patient availability – the likelihood of a patient beginning a new treatment (time to next treatment) in a prespecified time window – are not well described. We used a large clinicogenomic database of patients diagnosed with solid cancer indications to train ML model to predict patient availability for clinical trials. **Methods:** This was a retrospective study based on data drawn from the ConcertAI Oncology Research database, enriched by key variables derived from unstructured data. Line of therapy was derived from expert rules applied to structured medications data. Our cohort consisted of patients with confirmed diagnosis of solid cancers without a second malignancy. Patient follow-up period started on the date of diagnosis of metastasis and ended on the earlier of last date of activity / date of death. Random observation date was set between start and end dates to label patients. Patients administered a new treatment after the random observation date were labelled evet, else censored (no new treatment began). Label date is start of new treatment and end dates for event & censored cases respectively. The time to event (TTE) was defined as the duration between the random observation and the label dates. In the event cases, this duration is the time to next treatment (TTNT). Over 2000 features based on variables broadly grouped as tumor-specific biomarkers (PTEN, KRAS, etc.), ECOG, staging, disease status, medications, and imaging (evidence of image, not report) were employed to build multiple ML models. Temporal validation of the models was performed by setting up a simulated index date and predicting the probability of patient beginning a new treatment within 60 days of the simulated index date. Patients receiving new treatment within the 60 days were true positives. **Results:** TTE models were trained on a cohort comprised of 90K patients across 12 cancer indications with 54% patients starting a new treatment. Median age and overall survival (OS) of the cohort was 73 years and 703 days respectively. Temporal validation was performed on 25K patients with similar demographics/OS and 58% patients starting new treatment. Multiple ML methods were used to train models, with boosted gradient model demonstrating highest c-index of 0.73 based on 87 features. Temporal validation demonstrated AUC and weighted F1 of 87% and 67% respectively. True positive cases were assigned high predicted probability in 75% of the cases. **Conclusions:** AI models supporting 12 solid cancer indications accurately predicted patient availability. These models can be integrated into real-time clinical workflows alongside patient eligibility models to provide clinicians and patients visibility in ascertaining a patient's likelihood of being eligible for a clinical trial. Research Sponsor: None.

Magnetic resonance imaging (MRI) radiomics as predictor of clinical outcomes to neoadjuvant immunotherapy in patients with muscle invasive bladder cancer undergoing radical cystectomy. First Author: Andrea Necchi, IRCCS San Raffaele Hospital, Vita-Salute San Raffaele University, Milan, Italy

Background: Muscle-invasive bladder carcinoma (MIBC) is a deadly disease, for which we pioneered the use of neoadjuvant immune-checkpoint inhibitors (ICI) in a clinical trial (PURE-01, NCT02736266) testing 3 cycles of neoadjuvant pembrolizumab before radical cystectomy (RC). The objective of this study is to assess the ability of radiomic features extracted from a robust MRI processing pipeline to predict the pathological response to neoadjuvant pembrolizumab. **Methods:** A total of 120 patients (pts) with MIBC (102M/18 F), with median age of 68 years, a clinical stage T2N0 (n = 53; 44%) or T3-4N0 (n = 67; 56%), who were enrolled in PURE-01 study were analyzed. Patients had matched pre- and post-ICI MRIs, and tumors were segmented on both T2w images by GU radiologists. The MRI signal intensities were standardized by N4-bias field correction and robust z-scores. IBSI-compatible pyCERR software was used to extract radiomics features. A total of 289 radiomic features, including shape, first-order statistics, and higher-order textures, were analyzed for associations with pathological complete response (pCR at RC). An additional association was also investigated for major response groups, i.e., CR and partial response (PR, i.e. downstaging to ypT$\leq$1N0) versus no response (NR). We employed Elastic Net, a machine learning technique that blends the strengths of Lasso and Ridge regression and is particularly effective for datasets with many correlated features such as in our study. The endpoint was modeled by training Elastic Net logistic regression models separately for pre- and post-ICI MRI features, as well as clinical T-stage. Models were evaluated on a 30% held-out test set using ROC curves (AUC). **Results:** For pCR, the best-performing model included four post-ICI MRI features: shape (flatness) and texture features from Gray Level Co-occurrence Matrix (GLCM: homogeneity, sum average, and sum entropy), and had a test AUC of 0.83 (95%CI: 0.66 - 0.99). Separate models fit on pre-ICI MRI features selected two important pre-ICI MRI features: shape (surface-to-volume ratio) and first order (robust mean absolute deviation), but the overall performance was lower than post-ICI models (test AUC 0.66; 95%CI: 0.42 - 0.89). For major response assessment, the best-performing model included two post-ICI MRI features: shape (flatness) and texture (GLCM sum average) and had a test AUC of 0.92 (95%CI: 0.8-1.0). **Conclusions:** This is one of the first machine learning models using MRI radiomics to predict neoadjuvant immunotherapy response in pts with MIBC. These results could be instrumental for improving the way we can predict the pathological response in these pts. Clinical trial information: NCT02736266. Research Sponsor: Associazione Italiana per la Ricerca sul Cancro (AIRC); IG 27746.

Acoustic biomarkers and AI: Transforming NSCLC detection and personalized care. First Author: Chiara Giangregorio, Department of Electronics, Information and Bioengineering, Politecnico di Milano, Milan, Italy

Background: Implementing a mass screening program for lung cancer using low-dose chest CT presents significant challenges, including financial constraints and concerns about radiation exposure. Nonetheless, recent evidence reveals that lung cancer is not limited to smokers, as it also affects non-smoker populations who are currently excluded from existing screening programs. As part of the I3LUNG study (NCT05537922), we investigated the use of AI-based forced cough analysis as a non-invasive approach to distinguish NSCLC patients undergoing immunotherapy (IO) from healthy individuals. Additionally, we examined whether cough features could differentiate patients based on their baseline clinical features. **Methods:** Machine Learning-based preprocessing isolated meaningful cough events and extracted 39 acoustic features from the time and frequency domains. To reduce redundancy and improve model performance, highly correlated features ($>$ 85%) were eliminated. Support Vector Machines (SVM) and Deep Learning (DL) models were then employed to distinguish NSCLC patients from healthy controls. Additional statistical analyses of acoustic features were conducted on cough recordings from patients to evaluate differences based on smoking status (current, former, or never smokers) using the Kruskal-Wallis test with Benjamini-Hochberg post-hoc correction. Similarly, differences based on the presence or absence of lung metastases were assessed using the Mann-Whitney test. **Results:** A total of 200 individuals were enrolled in the study, including 91 stage IIIB-IV NSCLC patients undergoing IO and 109 healthy controls. Cough recordings were analyzed, with the SVM model achieving an accuracy of 82% and a specificity of 92% on the test set. The DL model demonstrated superior performance, with an accuracy of 95% and a specificity of 100%. Significant differences were observed in the peak-to-root-mean-square value ratio and cough duration among smokers (current, former, or never), with P-values of 0.026 and 0.042, respectively. Furthermore, spectral features - including centroid, rolloff, spread, kurtosis, bandwidth, and flatness - differed significantly between patients with and without lung metastases ($P < 0.01$). **Conclusions:** These findings highlight the potential of cough as a valuable digital biomarker for NSCLC diagnosis. The tool's high sensitivity facilitates the effective identification of individuals at risk for lung cancer, while its exceptional specificity makes it a promising initial screening method, efficiently triaging positive cases for follow-up chest CT scans. Future studies should validate these results on larger cohorts. Moreover, the correlation of specific cough features with smoking status and the presence of lung metastases suggests that this tool could extend beyond screening to monitoring disease progression over time. Research Sponsor: HorizonEurope; Grant agreement ID: 101057695.

Real-time AI-based computer-aided detection/diagnosis (AI-CAD) for breast ultrasound: A prospective, multicenter, multinational study. First Author: Jeeyeon Elizabeth Lee, Department of Surgery, Kyungpook National University Chilgok Hospital, School of Medicine, Kyungpook National University, Daegu, South Korea

Background: To evaluate the effectiveness of a real-time AI-based computer-aided detection/diagnosis (AI-CAD) system as a diagnostic decision support tool for breast ultrasound in a real-world clinical setting, conducted as a prospective, multicenter, and multinational study. **Methods:** From May to December 2024, a total of 75 patients undergoing breast ultrasound were enrolled in a prospective study conducted in Korea (n = 38) and Hong Kong (n = 37). In this study, six experts operated a real-time AI-CAD system (CadAI-B, BeamWorks Inc., Korea) on a tablet PC connected to a handheld ultrasound device during breast ultrasound examinations. Image and clinical data were collected from patients with established ground truth through follow-up, biopsy, or surgery. The AI-CAD system highlights suspicious areas during scanning to assist physicians in detecting breast cancer and supports big data-driven differential diagnosis by providing BI-RADS categories and malignancy scores (0–100%) when the user freezes the image. The diagnostic performance of experts and the real-time AI-CAD system was evaluated using the area under the receiver operating characteristic curve (AUC), along with sensitivity and specificity. **Results:** The analysis included 75 patients (mean age 55 years, IQR 46–66) with 24 malignancies (32.0%), 45 benign lesions (60.0%), and 6 normal cases (8.0%). The mean breast mass size was 1.2 cm ($\pm$1.0 cm): benign 0.8 cm ($\pm$0.7 cm), malignant 1.8 cm ($\pm$1.3 cm). The BI-RADS category distribution was as follows: for experts—category 1 (4.0%), 2 (21.3%), 3 (24.0%), 4a (16.0%), 4b (18.7%), 4c (4.0%), 5 (12.0%); and for AI-CAD—category 1 (32.0%), 2 (5.3%), 3 (9.3%), 4a (17.3%), 4b (21.3%), 4c (13.3%), 5 (1.3%). The overall diagnostic performance of experts and AI-CAD, as AUCs calculated by BI-RADS, were 0.801 and 0.751, respectively (P = .679). The sensitivity and specificity were 91.7% (22/24) and 68.6% (35/51) in experts and 87.5% (21/24) and 57.8% (32/51) in AI-CAD, respectively (P = .481). **Conclusions:** In this real-world clinical study conducted across multiple centers and countries, CadAI-B demonstrated performance comparable to that of experts and showed its potential as a valuable diagnostic tool. Clinical trial information: NCT06622967. Research Sponsor: None.

Cancer patients' messages about radiology/pathology reports: Insights for AI. First Author: Susan Chimonas, Memorial Sloan Kettering Cancer Center, New York, NY

Background: Cancer patients often use portals to view results prior to discussing with physicians, leading to messages with questions or concerns.[1] These messages vary widely in content and urgency, creating challenges for healthcare providers to respond effectively.[2] Categorizing and triaging these messages through AI-enhanced tools could streamline communication and improve patient care and satisfaction. **Methods:** This study assessed common themes in 1 week (April 1-8, 2023) of patients' portal messages about "rapidly read" pathology and radiology reports (viewed by patients within 6 hours of posting to the portal, as a proxy for viewing before discussing with physicians) at Memorial Sloan Kettering Cancer Center in New York City. **Results:** Five notable themes emerged across a total of 48 messages about rapidly read radiology and pathology results: Interpretation (24/48, 50%): Half of the messages contained questions like, *"What does this mean?"* Patients sought explanations of pathology and radiology findings, reflecting a need for clear, accessible interpretations. Implications (14/48, 29%): With questions like, *"What are the next steps?"* patients often asked how findings might alter treatment plans, highlighting a need for guidance on the care implications of their reports. Concern (5/48, 10%): Some patients expressed worry or pessimism about pathology and radiology reports: *"I am very worried"* and *"Maybe it's time to give up."* Such statements indicated a need for supportive communication. Relief (3/48, 6%): In other messages, patients shared positive emotions regarding favorable results – *"It is a huge weight off my mind."* These responses offer clinicians opportunities to reinforce patient satisfaction. Errors/Omissions (3/48, 6%): Occasionally, patients perceived errors or omissions in their reports – *"The radiologist totally misread the size of the lesion"* – which impacted their trust in the information. Addressing these concerns promptly can help strengthen the patient-provider relationship. **Conclusions:** This novel study highlights opportunities for AI-enhanced tools to triage messages and facilitate timely, effective responses. This study found common themes in patients' diverse questions about rapidly read pathology and radiology reports. By implementing AI to categorize and triage message patterns, providers could support patients more efficiently. Methods in development could be used to classify the message content.[3] For instance, AI-driven natural language processing tools could recognize queries related to "What does this mean?" and offer clear, accessible explanations of medical terms. Similarly, AI could be trained to flag high-priority messages based on distress signals, ensuring that these messages are addressed swiftly. Implementing such AI-based solutions could help meet patients' immediate needs while they await conversations with their providers. Research Sponsor: None.

Analysis of a large language model-based system versus manual review in clinical data abstraction and deduction from real-world medical records of patients with melanoma for clinical trial eligibility assessment. First Author: Christine Vecchio, Cleveland Clinic Taussig Cancer Institute, Cleveland, OH

Background: Manual chart review (MCR) is the gold standard for assessment of information from electronic medical records (EMRs) for clinical trial eligibility. However, this method is labor-intensive, prone to error, and limited in scalability with high volumes of unstructured EMR data. Large language models (LLMs), have shown promise in natural language understanding, and automating chart review and abstraction would significantly improve efficiency and accuracy in data review for clinical research. In this evaluation project, we compared the performance of Synapsis LLM, a medically-specialized LLM, with medical professionals at answering questions tied to eligibility criteria of relevant clinical trials, by reading clinical notes of patients with melanoma. **Methods:** We conducted a comparative analysis using records of randomly selected patients with melanoma from the Cleveland Clinic. Two parallel processes were assessed: (1) MCR conducted by a melanoma and an oncology specialized research nurse (2) Automated chart review using the Synapsis LLM. Both processes ran on two cohorts: Cohort (A) consisting of 25 EMRs that were posed 23 eligibility questions each, and Cohort (B) consisting of 25 different EMRs, posed 22 eligibility questions each. In total, there were 1,125 questions answered by each of the research nurses as well as Synapsis AI. The questions addressed focused on melanoma-specific clinical characteristics, including but not limited to treatment approaches, related surgical procedures, imaging findings, and genetic testing. Performance metrics included accuracy of answers to the questions, and time required to complete the abstraction process. Discrepancies between the responses of the two research nurses and the LLM were analyzed in comparison to the established ground truth, which was determined through a consensus review by physicians to ensure the validity and reliability of the results. **Results:** Synapsis LLM performed the task with 95.73% accuracy in 2.5 minutes while the melanoma specialized nurse responded with 95.11% accuracy in 427 minutes. The oncology specialized research nurse's accuracy was 88.09%, and the tasks was completed in 540 min. The comparison demonstrated significant time savings and medical-grade accuracy for the application of this LLM-based technology compared to manual methods. **Conclusions:** This is the first project that compares an LLM-based system vs research nurses in deducing clinical characteristics from patients' EMRs for clinical trial eligibility. Synapsis LLM accurately completed the abstraction process, outperforming in accuracy and time the clinical personnel. This study highlights the potential of LLMs like Synapsis AI in scalable clinical research applications that currently rely solely on MCR. Research Sponsor: None.

Leveraging AI to enhance symptom capture and reduced hospitalizations. First Author: Arman Koul, Cancer Center, Stanford Healthcare, Stanford, CA

Background: Unplanned hospitalizations and ED visits for cancer patients impose significant morbidity, financial costs, and reduced quality-of-life. Efficient resource allocation in oncology care requires proactive strategies to identify patients at high risk for preventable admissions, optimizing bed availability and outpatient management. CMS classifies acute care utilization (ACU), hospital stays or ED visits, within 30 days of chemotherapy for certain conditions, as "preventable" under OP-35, emphasizing the need for better risk stratification. By leveraging artificial intelligence (AI) including machine learning and large language models (LLM), predictive models can analyze the electronic health record (EHR) to identify patients who may benefit from early outpatient interventions. This study leverages AI to assess preventable admissions and quantify the benefits of proactive management, enhancing patient outcomes and care efficiency in oncology. **Methods:** This study analyzed data from 18,187 patients across a multisite cancer center to develop predictive models for ACU within 30 days of any systemic therapy following OP-35 criteria. Models incorporated structured data and clinical notes using LLMs. Using 2010–2019 data for training and 2020–2024 for validation, XGBoost and Random Forest models were developed to maximize sensitivity while maintaining acceptable specificity. Estimates of preventable hospital bed days were modeled to evaluate the impact of AI-driven risk stratification and targeted interventions on hospital resource utilization. **Results:** The 30-day hospital visit prediction model demonstrated strong performance, with the XGBoost algorithm achieving an AUROC of 0.84 (95% CI: 0.83–0.86). Incorporating later therapy lines improved accuracy by accounting for the complexity of advanced disease. A threshold was set to prioritize sensitivity for identifying high-risk patients while maintaining specificity to minimize unnecessary interventions. Model implementation was estimated to prevent 22% of hospital visits when paired with timely intervention, saving 1,160 of the 5,370 bed days observed in the 2021–2024 cohort. **Conclusions:** This study underscores the potential of AI-driven prediction models to enhance precision oncology by identifying patients at risk for unplanned hospital visits following systemic cancer therapy—a critical quality indicator impacting patient outcomes, healthcare costs, and operational efficiency. By incorporating multi-line therapy data and leveraging advanced modeling techniques, the approach effectively captures disease progression and personalized treatment histories. Utilizing LLMs to structure fragmented data across care systems addresses a prevalent challenge in oncology. Accurate risk prediction of hospitalization facilitates proactive interventions, improves care coordination, reduces bed occupancy, and supports informed decision-making, ensuring timely and targeted support for high-risk patients. The role of healthcare system distrust in shaping patients' attitudes and beliefs of artificial intelligence (AI) use in oncology. First Author: Marco Santos Teles, Memorial Sloan Kettering Cancer Center, New York, NY

Background: AI offers significant potential to improve cancer care, yet little is known about patients' attitudes and beliefs around its use and which factors influence acceptance of this new technology. Distrust in healthcare is increasingly prevalent and may hinder patient perceptions of innovations such as AI. This study aimed to evaluate the relationship between healthcare system distrust and acceptance of AI in oncology. **Methods:** We conducted a cross-sectional survey study with patients at an urban academic cancer center. We developed an 8-item AI Patient Acceptance scale, where patients rated their comfort with AI in different aspects of oncologic care (e.g. diagnosis, treatment planning) on a 5-point Likert scale (range 8-40, higher scores indicate greater comfort; Cronbach's α = 0.94). The survey also included a 10-item Health Care System Distrust (HCSD) scale (range of 10-50, higher scores indicate greater distrust). Multiple linear regression was performed to evaluate the association between HCSD and AI Patient Acceptance scores, adjusted for demographic and clinical factors. **Results:** Of 383 patients approached, 330 (86%) participated. Among these, 49.4% were age 65 or older, 55.9% male, 68.1% non-Hispanic white, 77.4% had a college degree or more. The most common tumor types reported were prostate (34.5%) and breast (26.4%) cancer, with 70.6% currently receiving treatment. Patients were most comfortable with AI use in cancer screening (80.2% somewhat or very comfortable), and supportive care applications, such as exercise (78.2%) and diet (74.8%). They were least comfortable with AI use to assist with diagnosis (70.4%) and other clinical decision-making applications, including treatment planning (64.8%) and prognosis (61.5%). Higher levels of distrust measured by the HCSD scale were negatively associated with the AI Patient Acceptance scale scores after adjusting for co-variates (B = -0.263, p = 0.002). Younger patients (age $<$ 65) were more likely to report lower scores on the AI acceptance scale (B = -1.996, p = 0.021), while sex, race/ethnicity, and education level were not associated with AI acceptance. **Conclusions:** Higher distrust in the healthcare system is associated with lower acceptance of AI in cancer care. As we integrate new technologies like AI into oncology, mitigating distrust in the medical community will be essential to ensure patient-centered implementation. Research Sponsor: None.

Cross-sectional study on the impact of receiving potentially sensitive test results online on the emotional health of patients with breast cancer. First Author: Anezka Carvalho Rubin de Celis Ferrari, Hospital Sirio Libanês, São Paulo, Brazil

Background: Internet has changed the way people communicate. In healthcare, patients have now easy access to their test results online; however, this has been particularly challenging in oncology because of potentially sensitive results present in imaging and pathology reports and tumor markers. In breast cancer, survival rates have improved significantly and more people are getting screened regularly. Providing online access to test results to patients may have ambiguous outcomes, such as increasing their engagement, but also their anxiety levels. This study aims to investigate associations between online access to potentially sensitive test results and effects on the emotional health of patients with breast cancer, particularly for symptoms of anxiety and depression. **Methods:** We conducted a cross-sectional study with 385 patients who had been diagnosed with breast cancer in the past 5 years. Participants completed a printed questionnaire on their approach to receiving test results (whether or not they accessed the results online), their feelings of anxiety about the results, and validated questionnaires assessing symptoms of anxiety (GAD-7) and depression (PHQ-9). Descriptive data analysis was performed using simple and cross tabulations for qualitative variables and measures such as mean, median, mode and standard deviation for quantitative variables. The normality of the data was checked using the Shapiro-Wilk test, while associations between qualitative variables were assessed using the Pearson chi-square test or Fisher's exact test. The significance level was set at 5%, using SPSS software version 22.0. **Results:** Partial results presented here include 329 patients, representing 85.45% of the total sample. A statistically significant association was found between the habit of accessing test results online and higher levels of anxiety ($p < 0.05$). Patients with positive screening for anxiety on GAD-7 reported greater anxiety while waiting for results ($p < 0.05$), while no such association was found for depression. In addition, online access to results showed a significant association with education level ($p < 0.05$) and patient age ($p < 0.05$), with younger patients and those with a higher level of education showing a greater propensity for this practice. However, no significant associations were found between tumor stage (early vs. metastatic) or time from diagnosis and the perception of anxiety ($p > 0.05$). **Conclusions:** There is an apparent association between the habit of receiving test results online and anxiety levels in patients with breast cancer. The recruitment is now complete, and results of the entire cohort will be available for presentation. Research Sponsor: None.

Utilization and impact of a digital care platform on cancer patients in India. First Author: Vamshi Krishna Muddu, AIG Hospitals, Hyderabad, India

Background: Cancer patients experience complex symptoms and treatment-related side effects that impair quality of life (QoL) and increase healthcare utilization. Digital health tools have the potential to improve symptom management and patient outcomes by facilitating real-time communication and support, especially for patients with limited access to immediate care. This study aimed to assess the usability and impact of a digital cancer care platform (Alivius) among Indian cancer patients, their primary caregivers, and care teams. **Methods:** We conducted a prospective, interventional, real-world study at a single tertiary cancer center in India from Jan 30, 2024, to Jun 11, 2024. We enrolled 100 cancer patients aged 18–80 years who had access to a smart phone, can read English, had a confirmed cancer diagnosis and had undergone at least one cycle of chemotherapy or radiotherapy. Patients were asked to communicate their symptoms and concerns to the care team and got health education materials for their disease. Primary endpoints included the Monthly Active Users (MAU) and Net Promoter Score (NPS) a metric used to measure customer loyalty and satisfaction by asking customers how likely they are to recommend a company or product. Secondary endpoints included the number of chat interactions, patient-logged symptoms, and use of educational content. Data were collected through in-app user activity and user feedback surveys. Descriptive statistics summarized the data with chi-square test for categorical variables and t-tests or non-parametric tests for continuous variables. **Results:** Out of 100 registered patients (mean age 58.7 $\pm$ 12.5 years; 61% male), the majority had gastrointestinal (55%) and genitourinary (18%) cancers. 66 caregivers participated in survey, with 84.8% being immediate family members. Average MAU during the study period was 58. The NPS for recommending the hospital and the digital application was 30.9 and 32.4 respectively, indicating positive user perception. User engagement was high during the study period: 85% accessed educational content, 82% updated health status, and 78% tracked mood. A total of 2,825 app activities were recorded, including 888 health status updates and 436 chat interactions. 507 side effects alerts generated, 29.5% were high severity, primarily related to tiredness and fatigue (29.2%), gastrointestinal issues (27.2%), and pain (17.5%). Customer Satisfaction Score (CSAT) was 50 and 48.5 among care teams (Doctors & Nurses) and patients, respectively. The app facilitated real-time communication between patients, caregivers, and care teams. **Conclusions:** Digital platform demonstrated high user engagement and positive perceptions among both the patients and their caregivers. The app effectively facilitated communication, symptom tracking, and management of treatment side effects. Patient centered digital platforms hold promise for improving cancer care support. Biologically interpretable pathomics-driven transformer model with self-supervised training for outcome prediction of immunotherapy in non-small cell lung cancer. First Author: Butuo Li, Shandong Cancer Hospital and Institute, Shandong First Medical University and Shandong Academy of Medical Science, China Institution or Organization, Jinan, China

Background: Only a subset of non-small cell lung cancer (NSCLC) patients experiences durable benefit from immune checkpoint inhibitors (ICIs), and precise biomarkers remain scarce. Meanwhile, computational pathology, based on digital pathology, has led to significant advancements in NSCLC prognosis prediction. Yet limited generalization and interpretation remain critical challenges in current clinical practice. Self-supervised learning, pretrained on unlabeled data to comprehensively capture underlying biological information in pathological images, may enable expandable, interpretable pathomics models for outcome prediction of ICIs. **Methods:** H&E-stained slides from pan-cancer patients were digitized as whole slide images (WSIs), then segmented for preprocessing. A self-supervised foundation model (patho-GPT) were performed to extract WSI features, and further fine-tuned for outcome prediction of immunotherapy in NSCLC with progression-free survival (PFS) labels. Its performance was evaluated by accuracy, sensitivity, specificity, and AUC in internal and external validation. Patients were classified as immunotherapy-resistant (R) or immunotherapy-sensitive (S), and ROC/survival curves were generated. The model was also tested in an operable cohort on neoadjuvant immunotherapy. Finally, single-cell RNA (scRNA) sequencing analyses were performed to provide biological insights. **Results:** A total of 13770 whole slide images (WSIs) from 6589 patients were included to construct the self-supervised patho-GPT model, which utilizes a context encoder, target encoder, and predictor based on the Vision Transformer architecture. There were 771 WSIs from 511 NSCLC patients receiving immunotherapy, labeled using 5.23 months as the cut-off value. All patients were divided into training and validation sets at a 7:3 ratio. For downstream outcome prediction of immunotherapy, the weight of patho-GPT was fine-tuned in the training set, and performance was evaluated in internal and independent external validation sets. The accuracy was 0.828 (AUC 0.774) in the internal set and 0.758 (AUC 0.752) externally. Survival analyses showed the model's risk group was significantly associated with survival after immunotherapy. In contrast, the ViT-ViT model using initial weights achieved 0.677 accuracy (AUC 0.547) in the external set, which was significantly inferior. ScRNA sequencing and differential analysis between R and S groups were performed, and a high level of H1.2hi Teffs was found in R, linked to dysfunction of cytotoxicity-related genes and immune pathways. **Conclusions:** The self-supervised patho-GPT can be used for the accurate prediction of immunotherapy outcome, with well generalization and biological interpretation. Artificial intelligence based music therapy intervention in cancer patients undergoing chemotherapy in oncology day care (MUSICC). First Author: Sujith Kumar Mullapally, Apollo Proton Cancer Centre, Chennai, India

Background: Studies on the role of music therapy for improving the quality of life of cancer patients are scarce. Artificial intelligence (AI) is being increasingly utilised in healthcare universally. Echo Care ©DigiNxtHlt Solutions leverages AI technology multi-class neural networks to make personalised recommendations by learning continuously from patients' usage and interactions. We aim to study impact of this AI based music therapy in health-related quality of life (HR-QOL) in cancer patients undergoing chemotherapy. **Methods:** A pilot interventional study for 50 consecutive cancer patients being administered chemotherapy at daycare facility was conducted. After informed consent, each patient underwent assessments during chemotherapy on week 1, week 3 and week 6. Vitals assessment, FACT G7 and HADS assessment was done at baseline, 3rd week and 6th week.30 minutes experience of sounds rendered by "echo Care" AI based application ©DigiNxtHlt Solutions was provided at each session of chemotherapy at 1st week, 3rd week and 6th week. Vitals were checked on admission to daycare unit followed by HR-QOL assessments which were done on digital platform by patients using unique ID and password. After completing the FACT G7 and HADS assessment, option was given to select from multiple music modules generated by AI based on data entered by patients. Once they completed the 30min session, post session vitals were measured. Qualitative feedback also was collected. The primary objective was quality of life as defined by FACT G7/ HADS scores and secondary endpoint was change in physiological vital parameters at baseline, 3 weeks, 6 weeks. Statistical analysis done by SPSS version 22.0. **Results:** A total of 50 patients were enrolled for the study during study period from March 2023 to Dec 2024. Mean HADS score for depression was 10.2 +/-4 and for anxiety was 7.5 +/- 3. 40% patients had high HADS score for anxiety. 18% had high HADS score for depression.50% of patients had improvement in HADS score for anxiety and depression whereas 50% did not have much change in their scores. Mean FACT-G7 score is 13.5+/-2 with majority having value less than 16 (70%). From qualitative feedback, 25% reported "very satisfied", whereas 75% reported to be "satisfied" with music intervention. 54% patients felt less anxious, 50% had calming effect and masking of pain, 37.5% felt mood elevation, positivity and closer to their family. 30% patients felt muscle relaxing effect. 37.5% felt sleepy during music session with 25% not feeling any change in them during the sessions. **Conclusions:** Artificial intelligence-based music therapy intervention in cancer patient undergoing chemotherapy shows promising results in terms of health-related quality of life, satisfaction and experience and can be offered to cancer patients as a non-pharmacological intervention to improve their quality of life during their treatment. Clinical trial information: CTRI/2023/03/050509. Research Sponsor: None.

A randomized, controlled pilot trial of a neuromodulatory digital therapeutic for individuals with breast cancer. First Author: Samantha Adler, Click Therapeutics, Inc, New York City, NY

Background: Fatigue, pain, and mood symptoms are common side effects of cancer therapy and cancer patients. Frontoparietal circuitry has been implicated in chemotherapy-induced cognitive impairment as well as post-treatment fatigue. We hypothesized that a smartphone-based multimodal multistable bias modification (MMBM) intervention could improve fatigue, mood, and pain-related attentional biases in breast cancer patients by correcting the neurocircuitry alterations caused by uncertainty stress induced by cancer diagnosis, as well as alterations resulting from chemotherapy, correcting frontoparietal circuitry changes resulting from cancer or its treatment. **Methods:** A randomized, single-blinded exploratory study in patients with breast cancer (n = 81) was conducted. Participants were randomized 1:1 to an active MMBM app or a control app and instructed to use it for 7 minutes daily over 4 weeks. Clinical endpoints included PROMIS-29+2, Brief Pain Inventory (BPI), and Pain Catastrophizing Scale (PCS). Feasibility and acceptability of app usage were also evaluated. **Results:** The MMBM app group showed significant improvements over control in PROMIS-29 fatigue (-3.4, $p < 0.05$), depressive symptoms (-2.8, $p < 0.05$), and symptoms of anxiety (-3.0, $p < 0.05$) domains. There were also several pain measures that showed significant improvement over time in the MMBM group, but not the control group, such as the PROMIS-29 pain intensity measure (-0.9, $p < 0.001$), the BPI average pain intensity (-0.7, $p < 0.001$) and current pain intensity (-0.7, $p < 0.01$), and the PCS total score (-3.3, $p < 0.01$). **Conclusions:** This study provides preliminary evidence that the MMBM intervention may alleviate fatigue and mood-related symptoms in breast cancer patients, with potential for improving pain-related symptoms as well. These findings underscore the potential of digital neuromodulation as an innovative approach to enhance the quality of life of patients with complex conditions, specifically breast cancer. Clinical trial information: NCT06136923. Research Sponsor: None.

Exploring social determinants of health and immunotherapy utilization in patients with stage III non-small cell lung cancer following definitive chemoradiation. First Author: Chaewon Hwang, Beth Israel Deaconess Medical Center, Boston, MA

Background: Since the approval of immunotherapy (IO) for maintenance therapy in stage III non-small cell lung cancer (NSCLC) in 2018, its use has expanded rapidly. This study aimed to evaluate patterns of IO use among diverse patient populations who received definitive chemoradiation (CRT) followed by adjuvant IO for stage III NSCLC. **Methods:** A retrospective analysis was performed using the National Cancer Database for patients $\geq$ 18 years old with stage III NSCLC diagnosed between 2018 to 2021. Patients receiving $\geq$ 60 Gy of radiation in $\geq$ 30 fractions and IO delivered 50-150 days from starting CRT were included. Patients who underwent surgery were excluded. Social determinants of health included race, ethnicity, insurance, treatment site, Charlson-Deyo comorbidity index (CCI), high school graduation rate (HSGR; lowest, low, mid, high per US Census data), income (categorized similarly to HSGR), sex, and age. Odds ratios (OR) were calculated for IO use. Logistic regression analyses were performed for each variable followed by multivariable analysis with statistically significant factors ($P < 0.05$). IRB exemption was granted. **Results:** 25,746 patients were included: 21,848 White, 3,236 Black, 558 Asian, and 104 Native American. 620 were Hispanic. On univariate analysis, the following were predictive of IO receipt: Black vs White race (OR 0.86, $P < 0.001$), Hispanic vs non-Hispanic ethnicity (0.72, $P < 0.001$), Medicare or other governmental insurance vs private (OR 0.94, P = 0.037 and 0.85, P = 0.034), CCI 1 or 2 vs 0 (1.11, $P < 0.001$ and 1.13, P = 0.005), community site vs academic/research center (0.88, P = 0.007), lowest and low vs high HSGR (0.78, $P < 0.001$ and 0.87, $P < 0.001$), lowest vs high income (0.90, P = 0.005), female vs male sex (1.06, P = 0.028), and age (-0.88%/year, $P < 0.001$). On multivariate analyses, Black patients were 3.3% less likely to receive IO than White patients (0.88, $P < 0.001$). Hispanic patients were 8.2% less likely to receive IO than non-Hispanic patients (0.72, $P < 0.001$). Medicare insurance (0.93, P = 0.012) and treatment at community sites (0.86, P = 0.002) were associated with reduced IO use. Patients from areas with lower HSGR were less likely to receive IO than those with the highest HSGR (lowest: 0.75, $P < 0.001$; low: 0.83, $P < 0.001$; mid 0.91, P = 0.039). Higher CCI (CCI 1: 1.12, $P < 0.001$; CCI 2: 1.13, P = 0.004; CCI 3: 1.10, P = 0.046), lower income (lowest: 1.11, P = 0.048; low: 1.10, P = 0.041; mid: 1.10, P = 0.025), and female sex (1.05, P = 0.048) were associated with increased IO use. **Conclusions:** This study highlights disparities in IO use following CRT for stage III NSCLC patients. Black race, Hispanic ethnicity, Medicare or governmental insurance, treatment at community sites, and lower education were associated with decreased IO use. These findings emphasize the need for strategies to ensure equitable access to advanced cancer therapies. Research Sponsor: None.

Food insecurity and disparities in mental health symptoms and severity among breast cancer survivors. First Author: Kent Schechter, Ben May Department for Cancer Research, The University of Chicago, Chicago, IL

Background: Breast cancer survivors (BCS) often experience mental health challenges during survivorship. Food insecurity is a growing public health concern in the US, which may exacerbate the challenges faced by BCS. However, little is known about the associations between food insecurity and mental health symptoms and severity among BCS. **Methods:** We conducted a secondary analysis of the 2022 National Health Interview Survey that used stratified clustering sampling to interview US adults aged ≥18. This study was limited to women with a breast cancer history. Food insecurity (secure/insecure) was measured using a 10-item questionnaire assessing past 30-day household food situations. Ever having anxiety was self-reported (yes/no), and the severity level in the past 2 weeks was examined using the 7-item Generalized Anxiety Disorder scale. Women reported ever having a depressive symptom (yes/no), and the 8-item Patient Health Questionnaire depression scale was used to evaluate the severity level in the past 2 weeks. We compared weighted percentages using Rao-Scott Chi-squared tests and computed *P*-trends using the Cochran-Armitage test. We performed weighted logistic regression to estimate adjusted odds ratios (AOR). All analyses accounted for survey weights. **Results:** We obtained an unweighted sample of 644 BCS (weighted sample 4,234,520). Overall, 7.6% experienced food insecurity. BCS who were food insecure were younger than those secure (mean age 61 vs 69 years; $P<.002$). Black (20.4%) or Hispanic (24.3%) BCS were more likely than White BCS (4.7%) to experience food insecurity ($P<.001$). BCS who were food insecure reported a higher percentage of depression than those secure (52.9% [95% CI: 35.5-70.3%] vs 24.4% [95% CI: 20.2-28.6%]; $P<.001$). The proportion of anxiety was higher among BCS who were food insecure than those secure (45.4% [95% CI: 27.7-63.1%] vs 19.8% [95% CI: 16.0-23.6%]; $P<.001$). After controlling for demographic and socioeconomic factors, BCS who were food insecure had greater odds of depression (AOR 3.19, 95% CI: 1.42-7.17) or anxiety (AOR 3.14, 95% CI: 1.34-7.34) than those secure. Compared with BCS who were food secure, those insecure were more likely to experience moderate (26.0% vs 6.0%) or severe (7.5% vs 0.6%) depression (*P*-trend$<.001$), as well as moderate (6.4% vs 4.4%) or severe (14.5% vs 1.3%) anxiety (*P*-trend$<.001$). BCS who were food insecure also reported a higher proportion of forgoing mental health counseling due to cost than those secure (6.8% vs 1.5%; $P=.02$). **Conclusions:** Our findings highlight food insecurity prevalence and associated disparities in mental health symptoms and severity among BCS. Interventions and policies, e.g., food pantries/meals programs and nutrition assistance, are needed to address food insecurity. Cancer centers should also consider routine mental health screening and offer proper services to reduce racial disparities among BCS. Research Sponsor: National Institute on Aging; T32AG000243; Susan G. Komen Breast Cancer Foundation; TREND21675016.

Real world treatment patterns and outcomes in metastatic EGFR mutation–positive NSCLC patients: A retrospective study from a tertiary care cancer center in India. First Author: Jyothis P. Jose, MVR Cancer Centre & Research Institute, Calicut, India

Background: Lung cancer is the leading cause of cancer related mortality worldwide with Non small lung cancer (NSCLC) constituting the majority of cases. EGFR mutations, predominantly exon 19 and Exon 21 L858R are actionable targets in approximately 25-30% Indian patients. Third generation EGFR tyrosine kinase inhibitors have set new benchmarks in the treatment of metastatic EGFR mutation positive NSCLC. However real world adoption in India faces significant barriers including financial constraints and healthcare disparities. **Methods:** Our objective was to evaluate whether patients with EGFR mutation positive metastatic NSCLC receiving the standard of care treatment and analyze demographic, clinical and molecular characteristics of EGFR mutation positive lung cancer patients treated at our center and compare treatment patterns and survival outcomes with national and global data. This retrospective study analyzed 894 stage 4 NSCLC patients treated between 2018-2023 of these 252 (28.1%) were EGFR mutation positive. Data on EGFR types, treatment modalities and survival outcomes were collected and analyzed. Kaplan Meir survival analysis was performed to estimate progression free survival (PFS) and overall survival (OS). **Results:** First line Osimertinib was median OS was 30 months and PFS was 20 months. The standard of care at that time received by 13.5% only. Other TKI alone (Gefitinib, Erlotinib and Afatinib) median OS was 21 months while PFS was 12 months. Other TKI with chemotherapy median OS 27 months and PFS was 18 months. Mutation specific outcomes showed exon 19 deletions had better overall survival 27 months PFS 16 months compared to Exon 21 L858R (OS 16; PFS 11 months). T790M were identified in 71% patients progressing after first line treatment. Second line osimertinib achieved a median PFS of 9.5 months. **Conclusions:** Despite the efficacy of osimertinib demonstrated in global trials, its adoption was limited to 13.5% of eligible patients in this cohort due to economic barriers. These findings emphasize the urgent need for systemic interventions to improve access to advanced therapies in India. Policymakers and healthcare systems must address these gaps through measures like government subsidies, expanded insurance coverage and cost effective diagnostic platforms to ensure equitable access to precision oncology in resource limited settings. Research Sponsor: None.

Racial disparities in oncology clinical trials by absolute neutrophil count eligibility criteria: A single center retrospective analysis. First Author: Arvind Suresh, Department of Medicine, University of California San Francisco, San Francisco, CA

Background: Black individuals have been historically underrepresented in clinical trials. The Duffy-null phenotype leads to clinically insignificant lower absolute neutrophil counts (ANC) and is found in 66% of non-Hispanic Blacks (NHB) and < 1% non-Hispanic Whites (NHW) in the United States. Although the ANC lower limit of normal for Duffy-null individuals is estimated to be 1,210/μL, little is known about the impact of ANC criteria on racial underrepresentation in clinical trial eligibility and enrollment. **Methods:** We conducted a single-center retrospective study of patients newly diagnosed with five cancers (lung, breast, prostate, colorectal, non-Hodgkin lymphoma) between 1988-2024. Baseline organ function data (Hgb, ANC, platelets, AST, ALT, creatinine, and bilirubin) were compared between NHB and NHW. We also identified ANC thresholds above which eligibility proportions differ between NHB and NHW. **Results:** We identified 23,854 patients. 14,585 had available baseline lab data within one year prior to starting anti-cancer therapy. The table lists the percentage of NHW and NHB who meet ANC eligibility criteria at thresholds of 1,000, 1,500, and 2,000/μL. Among patients with breast cancer, the median ANC was 3,500 for NHB and 3,890 for NHW (p = 0.63) and fewer NHB were eligible at all ANC thresholds of 1,500/μL or greater (94.5% NHB vs 97.2% NHW, p = 0.03). For those with prostate cancer, the median ANC was 3,780 for NHB and 4,450 for NHW (p = 0.03) and significantly fewer NHB were eligible at all ANC thresholds of 1,400/μL or greater (97.6% NHB vs 99.6% NHW, p = 0.04). For those with non-Hodgkin lymphoma (NHL), the median ANC was 4,260 for NHB and 4,020 for NHW (p = 0.34) and significantly fewer NHB were eligible at all ANC thresholds of 1,600/μL or greater (90.4% NHB vs 97.1% NHW, p = 0.008). Patients with lung cancer (ANC NHB 4,820 vs NHW 4,920; p = 0.85) and colorectal cancer (ANC NHB 3,930 vs NHW 4,150; p = 0.27) did not have significant ANC eligibility differences between NHB and NHW. No significant differences were found for other baseline labs. **Conclusions:** Our findings provide further evidence that ANC criteria may contribute to differences in clinical trial eligibility between NHB and NHW for breast cancer, prostate cancer, and NHL. Further work is needed to identify optimal cutoffs for each disease group. Limitations include lack of Duffy status for most patients and race is an imperfect approximation. Future clinical trials should proactively address these differences by using ANC eligibility criteria based on Duffy phenotyping. Research Sponsor: UCSF Department of Epidemiology and Biostatistics.

Factors associated with receipt of surveillance breast MRI among racially/ethnically diverse women with a personal history of breast cancer. First Author: Preeti Kakani, Columbia University Irving Medical Center, New York, NY

Background: Surveillance breast imaging among breast cancer (BC) survivors is recommended for early detection of local recurrence or contralateral BC. Breast MRI is increasingly used as a screening modality given its heightened sensitivity compared to mammography, and in 2018, the American College of Radiology released guidelines recommending supplemental breast MRI among women diagnosed with BC under age 50 or with dense breasts. We investigated demographic and clinical factors associated with receipt of surveillance breast MRI among women with a personal history of BC. **Methods:** We conducted a retrospective cohort study of women with stage 0-III BC between January 2018-June 2023 at Columbia University Irving Medical Center in New York, NY. We excluded women with bilateral mastectomies. The primary outcome was receipt of at least one breast MRI > 1 year after initial diagnosis. Data from the electronic health record included age at diagnosis, race/ethnicity, primary language, health insurance, first degree family history of BC, germline genetic testing results, stage at diagnosis, mammographic density (MD), and BC treatments (surgery, radiation, chemotherapy, and hormonal therapy). We performed multivariable logistic regression to assess factors associated with receipt of surveillance breast MRI. **Results:** Among 1,990 evaluable patients, mean age was 59.7 years (SD 12.2), and the cohort included 14% non-Hispanic Black, 33% Hispanic, and 6% Asian women. About 22% of women were diagnosed before age 50, 53% had dense breasts (BIRADS C-D), and 18% received at least one surveillance breast MRI > 1 year after diagnosis. On adjusted analysis, younger age at diagnosis, higher MD, first-degree family history of BC, receipt of germline genetic testing, and having a germline pathogenic variant were associated with receipt of breast MRI. Compared to non-Hispanic White women, Hispanic and non-Hispanic Black women had lower odds of receiving breast MRI (odds ratio [OR] = 0.44, 95% confidence interval [CI] = 0.31-0.63 and OR = 0.57, 95% CI = 0.38-0.86, respectively). However, compared to patients with commercial insurance, those with Medicaid were more likely to undergo breast MRI (OR = 1.57, 95% CI = 1.10-2.25). Results were similar when restricting the analysis to those diagnosed before age 50 or with dense breasts. **Conclusions:** Hispanic and non-Hispanic Black women with BC were less likely to receive surveillance breast MRI than their non-Hispanic White counterparts. Also, as patients with Medicaid were more likely to undergo breast MRI than those with commercial insurance, there may be varying health insurance coverage for breast MRI. These results highlight the need for more standardized guidelines surrounding surveillance breast MRI among BC survivors, which may inform public health initiatives aimed at promoting equitable breast imaging practices in this population. Meeting enrollment targets in IMbrave152/SKYSCRAPER-14, a global phase 3 study in patients with unresectable hepatocellular carcinoma (HCC). First Author: Christopher Cotter, Genentech, Inc., South San Francisco, CA

Background: The FDA has released guidance that the patient population in clinical studies should be representative of the intended-use population and the epidemiology of the disease, particularly in terms of race and ethnicity. IMbrave152/SKYSCRAPER-14 (NCT05904886) is a global phase 3 trial in patients with HCC, a disease with a globally high Asian and African prevalence, and which significantly impacts underrepresented (including Black and Hispanic) patients in the USA. Enrollment goals (by race/ethnicity), as well as operational and protocol-driven tactics to meet those goals, were implemented for IMbrave152. As of January 2, 2025, the targets for Black and Hispanic patients were met. **Methods:** Global recruitment began on September 14, 2023. Operational tactics included: feasibility questions about the ability to recruit underrepresented populations; utilization of internal and external databases to identify sites that could enroll underrepresented patients; incorporation of patient input; and enhanced patient-support services to facilitate recruitment and retention. Protocol-driven tactics included: modifying inclusion and exclusion criteria (considering race/ethnicity); streamlining study assessments; flexibility to use decentralized processes; and inclusion of an Africa Extension Cohort, which allowed for the recruitment of patients in Africa beyond the intent-to-treat population. **Results:** As of January 2, 2025, the randomized, global population included 8% Black and 14% Hispanic patients (US recruitment included 16% Black and 19% Hispanic patients), exceeding other global HCC studies, which recruited 2% or fewer Black patients and 11% or fewer Hispanic patients. Only two out of seven phase 3 studies in recent years have reported on Hispanic patient recruitment. **Conclusions:** IMbrave152 recruited the highest percentage of Black and Hispanic patients to date in a global phase 3 HCC study. These results demonstrate that recruitment of an underrepresented population is feasible if operational and protocol-driven tactics are utilized. Clinical trial information: NCT05904886. Intervention adherence, engagement and tool utilization in the breast cancer weight loss (BWEL) trial by race and ethnicity (Alliance A011401). First Author: Ashley Odai-Afotey, Dana-Farber Cancer Institute, Boston, MA

Background: Black and Hispanic breast cancer (BC) survivors have a higher prevalence of obesity and experience less success with weight loss interventions (WLI) than White BC survivors. The BWEL trial (Alliance A011401; NCT02750826) is a phase III randomized trial evaluating the impact of a 2-year telephone-based WLI on invasive disease-free survival in participants (pts) with stage II-III HER2-negative BC and a BMI $\geq$ 27 kg/m^2. At 12-months, the WLI induced significant weight loss across demographic factors, including race and ethnicity. However, Black and Hispanic pts lost less weight and completed fewer calls than White pts. Here, we evaluate intervention adherence, engagement and tool utilization in BWEL pts by race and ethnicity. **Methods:** BWEL randomized pts to a WLI plus health education (HE) or HE alone. WLI pts received semi-structured telephone-based health coaching, delivered in English or Spanish, and received an activity monitor and wireless scale. Pts self-reported race and ethnicity. Mean values for call duration, call density (time to complete the initial 12-week intensive intervention phase), intervention attrition, and frequency of Fitbit use and weight tracking over 12-months were compared by race and ethnicity, comparing least squares means with Tukey-Kramer adjustment for multiple comparisons with adjusted p-values. **Results:** Of 3181 pts randomized to the study between 08/2016 and 02/2021, 1591 pts were allocated to the WLI arm. 80.5% of pts were White, 12.8% Black, and 7.1% Hispanic. Average BMI was 34.5 ($\pm$5.7) kg/m2. Compared to White pts, Black pts had fewer days of Fitbit usage (113.6 vs. 159.8, p$<$0.0001) and weight tracking (77.9 vs. 135.6 days, p$<$ 0.0001). Hispanic pts had fewer days of Fitbit usage (108.8 vs. 154.9, p= 0.001) and weight tracking (87 vs. 129.5 days, p=0.0002) compared to non-Hispanic pts. There were no differences in attrition rate, average call duration, or call density by race or ethnicity. **Conclusions:** In a phase III WLI trial, engagement with tools designed to support weight loss was significantly lower in Black and Hispanic pts. Future work is needed to explore ways to enhance engagement and improve weight loss outcomes for racial and ethnic minority pts. Breast cancer optimal care timeframes for culturally and linguistically diverse populations and First Nations People: A regional centre experience in Australia. First Author: Matthew Hon, Townsville University Hospital, Douglas, QLD, Australia

Background: Culturally and linguistically diverse (CALD) populations and First Nations People are at-risk communities who face unique challenges in cancer diagnosis and management resulting in inequities. Optimal Care Pathways (OCP) established by Cancer Council Australia aim to address these disparities. The Breast cancer OCP outlines an integrated model of care with optimal timeframes such as time from general practitioner (GP) referral to specialist surgical review, time from decision to treat to surgery or neoadjuvant chemotherapy (NAC), and time from completion of NAC to surgery. **Methods:** Retrospective data was collected for all CALD (migrant from non-English speaking country and/or primary language identified as not English) and First Nations patients diagnosed with breast cancer treated at a regional centre in Australia (Townsville University Hospital) from 2018 – 2022. A comparison cohort (control) of consecutive non-CALD, non-First Nations patients was included. Data collected included patient demographics, tumour characteristics, stage, and identified timeframes which were compared with OCP. **Results:** 133 patients were included with 43 CALD (32%), 41 First Nations (31%) and 50 control (37%). CALD and First Nations cohorts had higher rates of stage IV disease at diagnosis (12 v 15%) compared to control cohort (0%). They were also more likely to be diagnosed via emergency department admission (CALD 16 v First Nations 7%) compared to control cohort (0%) suggesting later presentation. Of those referred through OCP defined GP pathway, a similar percentage were reviewed by specialist surgeon within optimal 2-week timeframe in all groups (CALD 47%; First Nations 39%; control 44%). Median time from decision to treat to surgery were longer in CALD versus control groups (19 v 13 days; p = 0.03), and in First Nations versus control groups (22 v 13 days; p = 0.02). Less CALD (89%, n = 24) and First Nations (82%, n = 18) patients underwent surgery within optimal 5-week timeframe compared to control (98%, n = 40). Similarly, median time from decision to treat to NAC were longer in CALD versus control groups (19 v 14 days; p = 0.05), and First Nations versus control groups (20 v 14 days; p = 0.03). Most patients (91%, n = 29) commenced NAC within optimal 4-week timeframe; 2 CALD and 1 First Nations patients did not. Median time from completion of NAC to surgery was longer in CALD versus control groups (29 v 24 days; p = 0.15), and in First Nations versus control groups (35 v 24 days; p = 0.04). Of those who recieved NAC, 100% CALD (n = 9), 69% First Nations (n = 9), and 89% control (n = 8) patients underwent surgery within optimal 4-week timeframe. **Conclusions:** Achievement of key OCP timeframes was lower in both CALD populations and First Nations People. Strategies need to be further developed to address the delays and health outcome disparities in these vulnerable cohorts. Research Sponsor: None.

Continuous financial toxicity screening in community oncology. First Author: Thomas Gregory Knight, Atrium Health Levine Cancer Institute, Wake Forest University School of Medicine, Charlotte, NC

Background: Financial Toxicity (FT) has been repeatedly linked with adverse cancer clinical outcomes. However, screening practices vary widely, especially in community settings where $<$ 50% routinely proactively engage patients to discuss care costs. This quality improvement pilot examined the feasibility and impact of continuous FT screening in a community-based clinical practice. **Methods:** Using PDSA methodology, an electronic distress screening (EDS) tool was implemented at each visit at two rural oncology practices. Evidence of FT was defined as answering "yes" to the question "Do you have insurance/financial problems or concerns?" The EDS tool would automatically email the financial navigation (FN) team on "yes" response and patients were contacted by FN within 48 hours. Contact was attempted at least 3 additional times if unable to be reached. Four successive monthly PDSA cycles ran from April to July 2024. In addition to demographic trends, success metrics were: % of screened patients with FT; % of FT patients new to the FN team; number and types of resolutions of FT concerns; and satisfaction and feasibility survey of clinical teams and patients. **Results:** In the 4-month study,1071 patients were screened using the EDS tool: 169 (16%) affirmed FT. Of those with FT concerns, 140 (83%) were new to FN. The FN team provided a primary resolution to 85 patients of 169 (50%) who alerted. Of the remainder, 45 (27%) could not be contacted after multiple attempts and 39 (23%) reported clicking in error. Primary resolutions included: Charity Care Program Referral (36%), Financial Teaching (29%), Billing Changes (11%), Social Work Referral (9%), Medication Assistance (6%), and Marketplace Insurance Obtained (5%). The patients receiving FN services were majority female (75%) and between 35 and 64 yo (57%). The most prevalent cancer types were Blood/Marrow (35%) and Breast (31%). 66% were white, 24% African American, and 14% Hispanic. Payors included 40% commercial insurance, 31% Medicare, 19% Medicaid, and 9% other. Geographically, 62% of patients resided in rural areas, 24% suburban, and 4% urban. Patient satisfaction with FN was high across all categories; 55% agreed or strongly agreed that FN services helped lower stress about bills. Scores were highest for "FN cared about my concerns and needs" (69%); "would recommend it to others in need" (63%); and "information from FN was clear and easy to understand" (61%). The clinic teams survey in participating locations felt the EDS screening tool was feasible in their practice environment (67%) and reported they felt routine FT screening was useful for patients (67%) (n=9). **Conclusions:** Structured implementation of routine FT screening with an EDS tool in a rural, oncology community practice is feasible with high patient and clinical team satisfaction and may allow for earlier identification of at-risk patients. Future directions include screening questionnaire refinements and expansion to other clinical sites. Research Sponsor: None.

Socioeconomic- and insurance-based inequities in Oncotype DX testing and score-guided treatment. First Author: Courtney Williams, University of Alabama at Birmingham, Birmingham, AL

Background: Personalized approaches to breast cancer treatment are increasingly guided by expensive, lab-based genomic testing like Oncotype DX (ODX) Breast Recurrence Score Test.Little is known about how socioeconomic and insurance status may affect utilization of ODX testing and subsequent ODX score-guided treatment. **Methods:** This retrospective cohort study included women diagnosed with an early-stage, HR+/HER2- breast cancer from 2011-2023 within the nationwide Flatiron Health electronic health record-derived deidentified database. Socioeconomic status was measured by the Yost index, a census block-level measure of neighborhood deprivation. Insurance status was captured at time of diagnosis. Utilization of ODX testing was compared descriptively. Likelihood of receiving adjuvant chemotherapy by neighborhood deprivation or insurance status was estimated using relative risk, predicted probabilities, and 95% confidence intervals from adjusted Poisson models with robust variance estimates. Analyses were stratified by age due to differing recurrence risk score categorizations. ODX scores indicating low or low/medium recurrence risk suggests chemotherapeutic benefit will likely not outweigh risk of side effects, while scores indicating medium or high recurrence risk suggests chemotherapeutic benefit will likely outweigh risk of side effects. **Results:** Of 4,367 patients eligible for ODX testing, mean diagnosis age was 62 years (SD 12), 77% were white, 69% had stage I cancer, 8% had ≥1 comorbidity, 48% were commercially insured, and 30% lived in a highly deprived neighborhood. Compared to those without, patients with an ODX test (46%, n = 2,026) were more often white (81% vs. 74%), commercially insured (51% vs. 45%), or lived in a neighborhood of low deprivation (73% vs. 67%). For patients aged ≤50 with ODX testing (n = 370), 51%, 25%, 12%, and 12% had low, low/medium, medium, and high recurrence risk. Of those with low recurrence risk, patients who resided in neighborhoods of low vs. high deprivation had 9% higher probability of receiving potentially inappropriate overtreatment with adjuvant chemotherapy (15%, 95% CI 10-25% vs. 6%, 95% CI 2-24%). Of those with low/medium recurrence risk, publicly vs. commercially insured patients were 2.7x more likely to receive adjuvant chemotherapy (RR 2.71, 95% CI 1.00-7.39). For patients aged > 50 with ODX testing (n = 1,656), 83% and 17% had low and high recurrence risk. Of those with high recurrence risk, patients who resided in neighborhoods of high vs. low deprivation were 18% less likely to receive recommended adjuvant chemotherapy, suggesting undertreatment (RR 0.82, 95% CI 0.67-1.00). **Conclusions:** Socioeconomic- and insurance-based inequities, including both overtreatment and undertreatment, were observed in this national cohort of women with early stage breast cancer eligible for ODX testing, indicating opportunities to increase care quality. Empowering minority patients: A tailored education initiative for clinical trial awareness in thoracic oncology. First Author: Tadana Angelica Vazquez Rothschuh, Ponce Health Sciences University, Ponce, PR, Puerto Rico

Background: Minority populations are underrepresented in clinical trials. Underrepresentation stems from multiple barriers that include restrictive eligibility criteria, systemic inequities, and patient-related factors. Effective educational interventions are needed to address barriers toward increasing minority patient understanding and participation in clinical trials. Despite their potential, video-based, culturally tailored interventions for minority patient education on clinical trials remain understudied and underutilized. **Methods:** We developed 3 brief (<5 min) culturally tailored educational videos about clinical trials in thoracic oncology for Black (English) and Hispanic/Latino patients (English and Spanish). Patients completed pre- and immediate post-video surveys to assess knowledge about, attitudes toward, and willingness to participate in clinical trials. Inclusion criteria included age ≥18 years, diagnosis of stage I-IV lung cancer, ECOG performance status 0-2, self-identification as Black or Hispanic/Latino, proficiency in English or Spanish, and access to an electronic device. Feasibility was measured by participant recruitment rates, completion of pre-and post-video surveys, and video acceptability via self-reported satisfaction. **Results:** Between April and September 2024, 54 patients were approached, and 30 (56%) were successfully enrolled (Table). Among those approached, 4 were ineligible, and 20 declined participation. All enrolled patients completed the pre- and post-video surveys. Over 90% reported high satisfaction with the videos. The total knowledge score increased significantly following the intervention ($p < .001$). For specific items, significant improvements were observed in understanding pre-clinical studies (p = .012), placebo use (p = .001), and clinical trial registration (p = .012). After the videos, over 90% of patients believed that clinical trials are useful and play an important role in developing new drugs and improving lung cancer outcomes. Potential barriers were observed in ~50% of patients, including concerns with informed-consent language, randomization, costs, and healthcare team communication style. There was a significant increase in willingness to participate in a clinical trial after watching the educational videos (p=.04). **Conclusions:** Our culturally tailored, patient-centered educational videos on clinical trials in thoracic oncology were both feasible and well-accepted. Future studies should explore whether such interventions can increase minority patient enrollment in therapeutic clinical trials. Development of a culturally tailored educational tool designed to increase access to somatic testing among Black men with metastatic prostate cancer (mPCa). First Author: Christopher Johns, University of California, San Francisco, San Francisco, CA

Background: Somatic testing (ST), also known as molecular profiling, has become increasingly important for therapy selection in men with mPCa. Interventions targeting known racial inequities in the use of ST are lacking. Our objective was to design a culturally tailored educational tool to augment patient education with the ultimate goal of increasing equitable access to ST for Black patients with mPCa. **Methods:** We used principles of human-centered design to develop a ST educational tool. We first designed a prototype with key stakeholders, then conducted a qualitative study of Black patients with mPCa at three sites – a tertiary care academic center, a VA medical center, and a safety net oncology clinic. Trained interviewers conducted semi-structured interviews to explore patients' perceptions of ST and elicit feedback about the educational tool until data saturation was met. Based on this feedback, we iteratively revised the tool. Interviews were transcribed, and two coders qualitatively analyzed transcripts using the COM-B framework to identify barriers/facilitators of tool use. **Results:** For the initial prototype, four physicians, one genetic counselor, and two patients contributed to the design of a 7-min video of a Black oncologist with informative animations followed by a text-based decision aid. We approached 18 patients, of whom 11 (61%) consented to review the tool then complete the interview. All participants expressed a positive perception of the tool and comprehension of the information. Tool facilitators included 1) trust in the tool, 2) actionability of the tool's content, and 3) appreciation for a Black physician featured in the video. Barriers included 1) difficulty navigating the electronic interface, 2) negative emotions from reflection on their cancer diagnosis or racial inequities, 3) too much information in the decision aid, particularly about biopsy risks and testing costs, and 4) content concerns on risks associated with ST/biopsy. For participants' perceptions of ST, facilitators included 1) desire to learn more about mPCa and 2) motivation to improve their health, their family's health, or the health of the Black community. Barriers included 1) misinformation about ST and mPCa, 2) difficulty accessing affordable healthcare, 3) mistrust of the healthcare system due to prior negative experiences, and 4) belief that mPCa and its treatments are emasculating. Overall, 10/11 patients reported planning to either discuss ST with their oncologist (7/11) or obtain ST (5/11). **Conclusions:** We successfully designed an educational tool for pre-test education about ST for Black men with mPCa. This educational tool was well received and may have contributed to PCa patients further pursuing somatic testing. Further evaluation of the feasibility, acceptability, and efficacy of this educational tool is warranted. Research Sponsor: Prostate Cancer Foundation.

Comparative analysis of demographics and outcomes in young versus average onset hospitalized gastrointestinal cancer patients in New York State. First Author: Mrinalini Ramesh, University at Buffalo, Buffalo, NY

Background: Recent studies have shown an increasing incidence of gastrointestinal (GI) cancers among young patients. This study investigates clinical outcomes and healthcare utilization among young (< 50) versus average onset (≥50) GI cancer patients admitted to hospitals in New York State (NYS). **Methods:** We performed a retrospective analysis using the Statewide Planning and Research Cooperative System (SPARCS) database from 2009 to 2022. Patients were divided into two groups: young-onset GI cancer patients (YOGIC, < 50 years) and average-onset GI cancer patients (AOGIC, ≥50 years). GI cancers included anal, biliary tract, colorectal, esophageal, gallbladder, liver, pancreatic, peritoneal, small intestine, and stomach cancers. The study population was further stratified by demographic and clinical characteristics. All variables were compared using the Kruskal-Wallis test or Fisher's exact test, along with multivariate linear and logistic regression in RStudio version 4.4.2, with a significance level of $p \leq 0.05$. Clinical characteristics, including severity of illness and risk of mortality, were defined using the All Patient Refined (APR) grading system. **Results:** A total of 256,924 patients were identified (26,071 YOGIC and 230,853 AOGIC) with a primary admitting diagnosis of a GI cancer from 2009 to 2022. The AOGIC group had a higher proportion of white and female patients, whereas the YOGIC group included a higher proportion of black and male patients ($p < 0.001$). Anal, peritoneal, and stomach cancers were more prevalent in YOGIC, while pancreatic and esophageal cancers were more common among AOGIC ($p < 0.001$). AOGIC patients were more likely to have extreme (13% vs. 9.7%) or major (39% vs. 32%) severity of illness compared to YOGIC ($p < 0.001$). However, the median total cost of stay for YOGIC was significantly higher than that for AOGIC ($21,421 vs. $19,658 respectively, $p < 0.001$). YOGIC patients were more likely to undergo procedures during hospitalization (95%) compared to AOGIC (93%) ($p < 0.001$). YOGIC patients were more likely to be discharged home (66%) vs. AOGIC (48%) ($p < 0.001$). Longer hospital stays were associated with patients diagnosed with esophageal, peritoneal, and stomach cancers ($p < 0.001$) versus the reference group (anal cancer), and in AOGIC [log fold-change 0.029 (95% CI: 0.021-0.038), $p < 0.001$]. Despite a higher mortality risk in AOGIC, mortality rates decreased faster over the study period [OR 0.97 (95% CI: 0.96-0.98), $p < 0.001$]. **Conclusions:** AOGIC patients experience a higher risk for mortality and longer hospital stays. However, YOGIC patients undergo further procedural interventions and have been found to have higher inpatient admission costs. Policies focused on earlier outpatient interventions may alleviate the burden on inpatient care. Research Sponsor: This work was supported by funding from the National Cancer Institute. The study's design and decision to publish were independent of any involvement from the funding sources.

Assessing the effects of financial toxicity on quality of life among hematopoietic stem cell transplantation recipients. First Author: Grace Ann Hanvey, Mayo Clinic, Rochester, MN

Background: "Financial toxicity" refers to the financial burden imposed by treatment costs on individuals with cancer, constituting a major barrier to achieving equitable cancer outcomes. Recent literature increasingly demonstrates the detrimental impacts of financial toxicity on quality of life (QOL) among individuals with cancer, including individuals who have undergone hematopoietic stem cell transplantation (HSCT). This study evaluates associations among treatment cost burden and various aspects of QOL following HSCT. **Methods:** Seven hundred one HSCT recipients completed a survey examining their biopsychosocial health one year following transplant. The survey included the Functional Assessment of Cancer Therapy – Bone Marrow Transplantation (FACT-BMT), a multifactorial measure of QOL specific to this population. Treatment cost burden endorsement was measured on a 5-item Likert scale. Hierarchical regression models were developed to assess the incremental effects of demographic characteristics (i.e., Block 1), clinical predictors (Block 2), and cost burden (Block 3) on physical, emotional, social, functional, BMT-specific, general, and composite QOL outcomes. **Results:** Significant model improvement was observed with the addition of clinical factors ($\Delta F(2,650) = 20.28$, $p < .001$), and subsequently, treatment cost burden ($\Delta F(1,649) = 110.29$, $p < .001$). In the final model, higher cost burden was associated with poorer physical ($\beta = -0.323$, $p < .001$), emotional ($\beta = -0.301$, $p < .001$), social ($\beta = -0.250$, $p < .001$), functional ($\beta = -0.317$, $p < .001$), BMT-specific ($\beta = -0.341$, $p < .001$), general ($\beta = -0.377$, $p < .001$), and composite QOL ($\beta = -0.381$, $p < .001$). Poorer performance score was associated with each QOL indicator ($p < .001$), with allogeneic transplant type associated with poorer functional ($\beta = -0.001$, $p = .002$), but higher emotional ($\beta = 0.118$, $p = .002$), wellbeing. Older age ($\beta = 0.113$, $p = .003$) and female sex predicted higher ($\beta = 0.183$, $p < .001$), while Hispanic ethnicity predicted poorer ($\beta = -0.095$, $p = .010$), social wellbeing. Female sex was associated with poorer QOL specific to BMT concerns ($\beta = -0.118$, $p = .001$). **Conclusions:** Higher treatment cost burden is associated with poorer overall QOL and its physical, emotional, social, functional, and BMT-specific components one year following HSCT, after controlling for demographic and clinical characteristics. This reflects a critical barrier to equitable cancer care, suggesting that financial toxicity may perpetuate preexisting inequities in QOL, treatment, disease, and survival outcomes that disproportionately impact the underserved. Future research should prioritize 1) better understanding relationships among complex indicators of financial toxicity, QOL, and their underpinning mechanisms and 2) developing solutions to mitigate financial toxicity of HSCT and overall cancer care. Early post-operative opioid fills after cancer-directed surgery among Medicare beneficiaries by race and ethnicity. First Author: Ashley Odai-Afotey, Dana-Farber Cancer Institute, Boston, MA

Background: Post-operative pain is often underestimated and undertreated. Researchers have shown that Black patients receive fewer opioids than White patients across multiple settings and conditions; however, little is known about whether post-operative opioid prescribing for cancer-directed surgery differs by race and ethnicity. We characterized racial and ethnic differences in opioid fills among Medicare beneficiaries undergoing cancer-directed surgery. **Methods:** Using 100% Medicare data for fee-for-service beneficiaries enrolled in parts A, B, and D, we identified episodes of cancer-directed surgeries from 2012-2021 among adults who survived > 30d after surgery and were discharged home. We used Part D claims to identify opioid prescriptions filled in the 30d after outpatient surgeries and the 30d after hospital discharge for inpatient surgeries, overall and among non-Hispanic White (NHW), Black (NHB), Hispanic, and Asian patients. **Results:** Among 981,702 surgical episodes (mean age 73 [SD 8] years, 36% male), 83% were NHW, 8% NHB, 4% Hispanic and 2% Asian patients. Most surgeries were for breast (38%), colorectal (15%), prostate (13%), or lung (10%) cancers. Most (67%) patients with surgical episodes had an opioid fill within 30d, with a mean dose of 246 morphine milligram equivalents (MMEs) in the first prescription, and a mean total dose of 360 MMEs filled within 30d of surgery or discharge. On average, patients filled 1.4 opioid prescriptions, with a mean of 9-days' supply in the 30d after surgery or discharge. NHB patients had the highest rate of opioid prescription, doses, and days' supply; Asian patients had the lowest rate of opioid prescriptions, doses, and days' supply (Table). Findings among Hispanic patients mirrored NHW patients. **Conclusions:** Among Medicare beneficiaries undergoing cancer-directed surgeries in 2012-2021, two-thirds of surgical episodes were associated with an opioid fill. In contrast to prior studies of opioid fills among cancer patients, we observed the highest opioid fills among Black patients. Future work is needed to understand the association of time and patient, physician, and healthcare factors on post-operative opioid prescribing and to understand the association of opioid prescribing with pain control. Disaggregating Asian American and Pacific Islander subgroups to evaluate disparities in breast cancer characteristics and outcomes. First Author: Shawn Michael Doss, Medical College of Georgia, Augusta, GA

Background: When Asian American and Pacific Islander (AAPI) subgroups are aggregated under the labels "AAPI" or "Asian," subgroup-specific differences in breast cancer (BC) presentation and outcomes may be masked. Potential overlooked disparities among these diverse groups remain understudied. We analyzed BC characteristics and outcomes among regional AAPI subgroups. **Methods:** From the National Cancer Database (2009–2020), we identified patients diagnosed with stage I–IV BC, excluding patients missing race or stage. Multivariate logistic regression examined odds of advanced stage (III–IV), high-grade histology, and triple-negative BC (TNBC) at diagnosis. Multivariate Cox regression assessed three-year overall survival (OS). Age, comorbidity index, diagnosis year, and zip code income quartile were analyzed to account for confounding. **Results:** Of 1,956,145 total patients, there were 61,731 pooled AAPI patients, comprised of East Asian (n=23,643), South Asian (n=13,642), Southeast Asian (n=19,000), and Pacific Islander (PI) (n=5,446) subgroups. Non-Hispanic White (NHW) (n=1,639,814) served as the reference group. Compared to NHW, pooled AAPI had higher odds of advanced stage (adjusted odds ratio [aOR] 1.09; 95% CI 1.07–1.12; p<0.001) and high-grade histology (aOR 1.21; 95% CI 1.17–1.25; p<0.001). There was no difference in odds of TNBC (0.98; 0.92–1.03; p=0.41). Despite this, AAPI had better three-year OS (hazard ratio [HR] 0.79 (0.76–0.82; p<0.001). Compared to NHW, each AAPI subgroup had higher odds of high-grade histology and better OS except for PIs, who had similar odds of both. South Asians and Southeast Asians had higher odds of advanced stage (aOR 1.27; 1.21–1.34; p<0.001 and 1.22; 1.17–1.27; p<0.001, respectively), while East Asians had lower odds (0.86; 0.83–0.90; p<0.001). South Asians showed increased odds of TNBC (aOR 1.11; 1.00–1.23; p=0.04), whereas Southeast Asians (0.82; 0.73–0.91; p<0.001) and PIs (0.81; 0.66–0.98; p=0.036) showed lower odds. **Conclusions:** Disaggregating AAPI subgroup data is necessary to understand disparities in BC among these heterogenous populations. Further studies are warranted to evaluate disparities in healthcare delivery and its efficacy in these subgroups. Research Sponsor: None.

Breast cancer characteristics by AAPI and subgroup.

	Advanced Stage (aOR, 95% CI)	High-Grade (aOR, 95% CI)	TNBC (aOR, 95% CI)	Three-Year OS (HR, 95% CI)

The development of the cost of cancer in 31 European countries. First Author: Andrea Manzano, IHE, Stockholm, Sweden

Background: The estimated number of new cancer cases in Europe has risen from 2.6 million in 1995 to 4.1 million in 2022. Around every fourth death is due to cancer, yet survival rates have been improving due to advances in early detection, diagnosis, and treatment. The implications of these epidemiological changes and medical advances for the overall cost of cancer are not well documented. **Methods:** This cost-of-illness study estimated the direct and indirect costs of cancer across 31 European countries (the EU-27 countries, plus Iceland, Norway, Switzerland, and the UK) from 1995 to 2023. For direct costs, information on cancer-specific health expenditure was searched for all countries and combined with data from Eurostat and the OECD. Extrapolations were made for countries with missing information. For indirect costs, productivity losses due to premature mortality were calculated using mortality data from the World Health Organization, Eurostat, and the Office for National Statistics, combined with labor market data from Eurostat. Productivity loss due to morbidity were estimated using data from prior studies and changes in population structure. The human-capital approach was employed to calculate indirect costs. Total costs, costs per capita, and costs per new case were estimated for Europe as a whole and for each individual country. **Results:** Between 1995 and 2023, the combined direct and indirect costs of cancer across all countries increased by 43% from EUR 159 billion to EUR 228 billion (all figures adjusted to 2023 prices). Direct costs grew by 135%, from EUR 62 to EUR 146 billion, while indirect costs, which fell below direct costs after 2005, decreased by 16% from EUR 97 to EUR 82 billion. The decline in indirect costs reflects a reduction in potential years of working life lost due to premature mortality of working-age patients. Direct costs of cancer accounted for 4-8% of total health expenditures in all countries, with modest increases over time in some but not all countries. Per capita costs for all countries combined rose by 35% from EUR 313 to 423. However, there was a seven-fold difference between countries in 2023 ranging from around EUR 150 in Bulgaria and Romania to EUR 1,011 in Switzerland. This disparity represents a reduction from the twelve-fold difference observed in 1995. The cost per new cancer case remained relatively stable in Europe as whole at around EUR 78,000 between 1995 and 2010, before declining slightly to EUR 72,000 in 2015 and stabilizing thereafter. **Conclusions:** The societal cost of cancer in Europe has been steadily increasing. The growing number of cancer patients is spurring this development, rather than changes in cost per patient, which has remained mostly stable for nearly 30 years. Although the direct costs of cancer have risen the most, this has been partially offset by reductions in indirect costs. Changes in indirect costs and epidemiological trends should be considered in debates about the rising costs of cancer. Trends in female breast cancer among adolescent and young adults in Southeast Asia. First Author: Jenny Chen, Memorial Sloan Kettering Cancer Center, New York, NY

Background: Breast cancer is the leading cancer among women globally and poses a growing public health challenge, particularly in adolescents and young adults (AYAs), defined as individuals aged 15–39 years. In Southeast Asia (SEA), rising breast cancer rates among AYAs are compounded by unique biological, socioeconomic, and healthcare barriers, including late-stage diagnosis and limited access to screening and treatment. However, regional data on incidence and mortality trends remain scarce. This study aims to analyze temporal trends in AYA breast cancer incidence and mortality across 11 SEA countries from 1990 to 2021 using data from the Global Burden of Disease (GBD) database. **Methods:** We extracted breast cancer incidence and mortality data for AYAs in SEA from the GBD database (1990–2021) for Brunei, Cambodia, Indonesia, Lao PDR, Malaysia, Myanmar, the Philippines, Singapore, Thailand, Timor-Leste, and Vietnam. Age-standardized rates (ASRs) were calculated, and temporal trends were evaluated using Estimated Annual Percent Change (EAPC) based on log-linear regression. **Results:** Breast cancer incidence among AYAs increased significantly across SEA from 1990 to 2021. Thailand reported the highest ASR in 2021 (11.78 per 100,000) and the most pronounced rise in incidence (EAPC 4.06). Significant increases were also observed in Vietnam (EAPC 2.92), Cambodia (2.63), and Laos (2.57). Mortality trends were heterogeneous: Singapore achieved a significant decline (EAPC -2.00), attributed to advancements in early detection and treatment, while Thailand, Indonesia, Vietnam, and Cambodia experienced rising mortality rates. In 2021, the highest mortality rates were recorded in Myanmar (2.54 per 100,000), Thailand (2.36 per 100,000), and the Philippines (2.17 per 100,000). **Conclusions:** The growing burden of AYA breast cancer in SEA reflects a combination of epidemiologic transitions, socio-economic shifts, and regional healthcare disparities. Rising incidence is linked to changes in reproductive behavior, lifestyle factors, and urbanization, while increased mortality highlights gaps in healthcare access and screening infrastructure. Urgent public health interventions tailored to AYA populations are needed to enhance early detection, improve treatment accessibility, and address disparities across SEA. Regional collaboration and investments in healthcare systems are critical to mitigating the growing burden of breast cancer among AYAs in this dynamic region. Research Sponsor: None.

The impact of race on the association between structural racism and the quality of non-small cell lung cancer (NSCLC). First Author: Jacquelyne Janean Gaddy, Yale School of Medicine, New Haven, CT

Background: Structural racism encompasses multiple intricate systems that generate and reinforce inequities amongst minoritized communities. Given the complexities associated with measuring structural racism, we sought to evaluate the relationship between structural racism and racial inequities amongst Black and White patients with NSCLC using an established structural racism index. **Methods:** We conducted a retrospective analysis using Surveillance, Epidemiology, and End Results -Medicare data. Outcomes were: localized stage at diagnosis, stage appropriate evaluation and treatment, and 2-year survival. We used the County Structural Racism (CSR) index, which assesses racial inequity within counties across various domains including criminal justice, education, employment, housing, and health care. We categorized counties into quintiles of the CSR index and estimated multivariable mixed effects logistic regression models to determine the adjusted association between structural racism and each outcome. We included interaction terms between patient race (Black versus White) and CSR to determine whether structural racism moderates the association between patient race and outcomes. We used the results of the regression models to calculate the adjusted predicted probabilities of each outcome across strata of patient race and CSR quintile. **Results:** The cohort included 54,344 individuals (10.3% Black, 89.7% White) diagnosed with NSCLC from 2013-2019. When compared to White patients, Black patients were less likely to be diagnosed at a localized stage (30.9% vs 38.4%), undergo stage appropriate evaluation and treatment (20.3% vs 28.0%), and survive two years after diagnosis (29.2% vs 37.3%) (all $p < 0.001$). Black patients were more likely to live in counties with higher structural racism (8.2% of the population in lowest quintile vs 19.2% in highest quintile). We did not find a clear association between structural racism and our outcomes. However, we did find that patient race moderated the association between structural racism and two-year survival. Specifically, Black patients in areas in the lowest quintile of structural racism had a predicted probability of two-year survival of 28.3% (95% CI, 25.2-31.4) compared to 31.1% (95% CI, 29.8-32.4) amongst White patients, a difference of 2.8% ($p = 0.08$). In areas with the highest structural racism, Black patients had an even more pronounced reduction in the probability of two-year survival (27.4%, 95% CI, 24.6-30.2 vs. 37.5, 95% CI, 34.9-40.1 for White patients), resulting in a disparity of 10.1% ($p < 0.001$). **Conclusions:** Increased structural racism exacerbates the racial disparity in two-year survival experienced by Black patients with NSCLC. Research Sponsor: R01MD017569.

1599 Poster Session

30 year trends in racial disparities for early stage lung cancer treatment. First Author: Olivia Frances Lynch, Yale School of Medicine, New Haven, CT

Background: Racial disparities in lung cancer treatment have been recognized for over 30 years. Our prior work showed that among Medicare beneficiaries diagnosed during 1992-2002, Black patients were less likely to receive curative therapy than White patients. As treatment approaches have evolved and increased attention has been paid to healthcare disparities, it is unclear whether this pattern has changed over time. We assessed temporal trends in racial disparities in receipt of curative therapy from 2005 to 2019, and compared findings to estimates from over 25 years earlier. **Methods:** Using the SEER-Medicare data linkage, we conducted a retrospective cohort study of Medicare fee for service beneficiaries diagnosed with stage I-II NSCLC during 3 time intervals: 2005-07, 2011-13, and 2017-19. Consistent with the prior study, we restricted the sample to Non-Latinx Black and Non-Latinx White patients. Curative therapy was defined as either surgery and/or radiation within 6 months of diagnosis. In our prior study, curative treatment was limited to surgery, as radiation was rarely used as curative therapy at that time. We performed multivariable logistic regression with receipt of any curative therapy as our outcome, controlling for sociodemographic and clinical covariates. We included a time*race interaction to evaluate whether receipt of treatment differed by race over time, and calculated the predicted probability of treatment across time and race group. **Results:** We identified 28,287 patients (7.5% Black) for study inclusion. Black and White patients were similar across most demographic variables; however, Black patients were more likely to have ≥3 comorbidities and to have been hospitalized in the year prior to diagnosis. Overall, receipt of curative therapy was lower among Black patients (69.9%) compared to White patients (83.3%) throughout the study period and across all time intervals (Table). In adjusted analyses, Black patients were less likely to receive curative treatment in all 3 time intervals, with a Black-White difference of -17.6% in 2005-07, -14.2% in 2011-13, and -9.7% in 2017-19 (p-value for time*race interaction = < 0.001). Compared to the 1992-94 and 2000-02 time intervals from the prior study where Black-White difference in receipt of treatment was -11.8% and -14.4% respectively, disparities have persisted. **Conclusions:** Racial disparities in receipt of curative treatment for early stage lung cancer in Medicare beneficiaries have persisted 30 years, with minimal improvement. Research Sponsor: None.

Receipt of curative treatment by race and time period, adjusted.

At-risk cancer genetic syndrome identification (ARCAGEN-ID): Novel EHR integrated system to overcome disparities in identification and testing for cancer genetic syndromes. First Author: Vinit Singh, Roswell Park Comprehensive Cancer Center, Buffalo, NY

Background: Identifying individuals at-risk for a hereditary cancer syndrome (HCS) is crucial to prevent cancer deaths. While there are established guidelines for genetic testing, less than 30% eligible individuals are tested, with consistently worse rates among underserved. The complexity of guidelines and providers' unconscious bias contribute to these disparities. This project aimed to enhance the identification and testing of at-risk individuals, focusing on underserved populations. **Methods:** NCCN/ACMG criteria for genetic testing were translated into three distinct rule-based conditional logic statements in the EHR. A total of 218 rules that serially evaluate each aspect of an individual criteria, and together roll up into a logic statement of "at-risk for HCS. The rules evaluate personal and/or family history, determine age at onset, and categorize family relationships. A proof-of-concept automated outreach initiative was developed that allowed patients to opt into genetic testing after an informational video was watched was developed. Relevant data were extracted and compared using chi-square test. **Results:** Out of 1.3 million individuals, ARCAGEN-ID identified 59,377 (4.8%) at-risk of an HCS. Of those, 47,000 (79.2%) had not been previously evaluated: 43,051 (79.3%) at-risk for Breast, Ovarian, Pancreas, Prostate related mutation; 3,308 (70.2%) at-risk for Lynch syndrome, and 1,144 (80.5%) at-risk for other HCSs. Among previously identified individuals, 2,340 (18.9%) had a pathogenic variant (PV). Compared to overall population in health system, ARCAGEN group had a higher proportion of female (82% vs 55%, $p < 0.01$), White (78% vs 65%, $p < 0.01$) and non-Hispanic (89% vs 84%, $p < 0.01$) individuals, and had less often Medicaid (16.7% vs 28%, $p < 0.01$). Within ARCAGEN, comparing previously identified individuals with newly identified ones, the latter were significantly more often male (19.9 vs 11.13%, $p < 0.01$), younger (≤45y) (33.6% vs 27.2%, $p < 0.01$), Non-White (22.9& vs 20.5%, $p < 0.01$), and more often on Medicaid (31.5% vs 13%, $p < 0.01$). For the pilot, 126/504 outreached individuals (25%) viewed the video and completed a questionnaire. 43/504 (8.5%) pursued testing, and 7 (16%) had a PV. A total of 7% had prior testing not recorded in discrete fields; 2% declined testing; and 6% sought genetic counseling prior to testing. A higher proportion of African American (AA) individuals opted for testing through this strategy (11%) compared to the overall percentage of this population that was outreached (6%, $p = 0.05$). **Conclusions:** Through this automated system, we were able to identify more non-White individuals and add more Medicaid-insured individuals for testing. Uptake after outreach was higher among AA. Thus, a system like ARCAGEN can help overcome disparities in HCS identification without a relevant increase in resources. Research Sponsor: None.

Clinical implications and prevalence of benign ethnic neutropenia (BEN) in breast cancer patients of Middle Eastern ethnicity. First Author: Shruti Prem Sudha, Bahrain Oncology Center, Muharraq, Bahrain

Background: Benign ethnic neutropenia (BEN) commonly affects patients of African and Middle-Eastern descent and is not a true neutropenic state. Patients with BEN have the Duffy-null phenotype on red cells and Duffy phenotyping has been used as a surrogate marker for diagnosis. There is evidence that cancer patients with BEN are not at increased risk of infection with chemotherapy. The primary aim of this study was to assess the prevalence of BEN among breast cancer patients in Bahrain using Duffy antigen phenotyping on red cells. The secondary aims were to study treatment delays and infectious complications in BEN patients. **Methods:** We conducted this retrospective study after obtaining IRB approval. We reviewed records of 493 consecutive breast cancer patients treated in our setting from January 2018 to January 2024. We included patients with neutropenia at presentation (defined as having an absolute neutrophil count [ANC] of $< 1.5 \times 10^3/\mu L$). Patients with Duffy-null phenotype and no identifiable secondary causes of neutropenia were presumed to have BEN. Clinical details studied included drug, and family history, treatment interruptions for neutropenia, filgrastim responsiveness, and episodes of febrile neutropenia. Overall survival (OS) and progression-free survival (PFS) estimation using the Kaplan-Meier method and Cox regression analysis of prognostic factors were performed using R software version 4.2.0. **Results:** Of 493 patients, 72 (14.6%) had a presumed diagnosis of BEN. The median age at presentation was 45 yrs, and the median follow-up duration was 3.6 yrs. 13% patients had metastatic disease at presentation and 11% had triple-negative breast cancer (TNBC). The median ANC at diagnosis was $1.2 \times 10^3/\mu L$ (range $0.4–2.1 \times 10^3/\mu L$). The 4-yr OS was 95% (95% CI, 89–100%) and the 4-yr PFS was 75% (95% CI, 63–89%). Treatment was interrupted due to low ANC in 65% of patients, and the median ANC at which treatment was delayed was $0.8 \times 10^3/\mu L$. 89% patients had received filgrastim and all were filgrastim responsive. Only one patient had uncomplicated neutropenic fever. On multivariable analysis, inferior PFS was seen in patients with metastatic disease (HR, 6.2; 95% CI, 2.17–17.9; $p < 0.001$), and TNBC (HR, 7.73; 95% CI 1.79–33.3; p = 0.006). We did not find any effect of treatment delay on the PFS. **Conclusions:** Ethnic neutropenia is prevalent among breast cancer patients in Bahrain. Duffy phenotyping can be used in place of more invasive tests to identify these patients. Treatment delays due to apparent neutropenia are common, however, response to filgrastim is universal, and febrile neutropenia episodes are rarely seen. Since these patients are not at increased risk of infection, larger studies to identify unique neutrophil thresholds for holding chemotherapy in BEN can help avoid compromising therapy. This can have far-reaching implications in populations with a high prevalence of BEN. Research Sponsor: None.

Community-based patient navigation and preventative care among women surviving breast cancer. First Author: Anthony Zisa, Lombardi Comprehensive Cancer Center, Georgetown University Medical Center, Washington, DC

Background: Routine physical exams, mammograms, and Pap smears are essential to long-term follow-up for breast cancer survivors, enabling detection of recurrence and guiding overall health maintenance. Barriers to preventive care adherence over time can be addressed by community-based organizations (CBOs) by providing information and supportive services, including navigation to screening. We studied adherence to preventive care and screening among breast cancer survivors who engaged a national cancer control CBO–examining how sociodemographics, cancer care factors, and quality of life (QoL) were associated with adherence. **Methods:** A secondary data analysis was conducted among N = 777 breast cancer survivors who contacted a CBO for resources, including no-cost patient navigation. Patient-reported outcomes were assessed after 30 days, along with survivorship care planning (SCP) and QoL. An index score was created based upon women's self-reported adherence to receiving routine physical exams, mammograms, and Pap smears at recommended intervals. **Results:** Among survivors, 37% were age < = 46, 19% were non-white, 63% were in a partnered relationship, 23% rated their QoL (general health) as fair/poor, and 47% carried a pathogenic variant in *BRCA*. Medical providers caring for these survivors included primary care physicians (53.6%) and oncology specialists (46.4%). For index scores, 66% were adherent to all 3 recommendations for follow-up, 29% to 2 recommendations, and 6% to < = 1 recommendation. The most adhered to recommendation was a physical exam (97%), and the least was a Pap smear (73%): 88% of survivors reported mammograms at recommended intervals. At the bivariate level, breast cancer survivors who were younger (t, df = 4.59, 711, $p < .001$), non-white, (t, df = -3.27, 267, $p < .001$), in a partnered relationship (t, df = 1.76, 54, $p < .05$), and with better QoL (r = -.09 $p < .01$) were more adherent to guideline-based care. A trend was observed for SCP: survivors who received care summaries (56%), including follow-up instructions (64%), and in written form (45%), were more likely to adhere (r = 0.05, $p < .10$). In a multivariable regression model adjusting for partnership status and SCP, younger survivors (B = 1.13, $p < .001$), who were non-white (B = 1.0, $p < .01$), and with better QoL (B = .09, $p < .05$) were more adherent. **Conclusions:** Survivors can benefit from guideline-based cancer prevention and screening with CBO-led support. Tailored SCP is essential to reinforce life-saving health behaviors and enhance follow-up adherence. Research Sponsor: Centers for Disease Control and Prevention #U58DP005408; #P30CA051008.

Mutation rate differences across populations and association with performance disparities in pathology AI diagnostic models. First Author: Po-Jen Lin, Department of Biomedical Informatics, Harvard Medical School, Boston, MA

Background: Previous studies have established artificial intelligence (AI) algorithms to classify cancer types, providing real-time diagnostic support. In addition, AI models have identified previously unknown pathology patterns associated with cancer genomic profiles. However, these models exhibit variable performance in different demographic groups, and the causes remain largely unknown. To address this challenge, we investigated the relationships between biases in AI diagnostic models and mutation rate disparities across populations and evaluated the efficacy of a fairness-aware contrastive learning (FACL) framework in reducing performance disparities. **Methods:** We obtained whole-slide pathology images, mutation rates of the 5 most frequently mutated genes in each cancer type, age, sex, and race from 9,217 patients in The Cancer Genome Atlas across 10 cancer types. We identified tasks with performance disparities across demographic groups, and employed generalized linear models to quantify the relationship between mutation rates and model bias in each cancer type. We further developed an FACL framework, and evaluated its effectiveness in mitigating these disparities using metrics including differences in accuracy (DIA) and equal opportunity. **Results:** Six genomic profile prediction tasks showed significant performance disparities across population groups (Table). Variations in TP53 mutation are associated with differential error rates in serous UCEC v. nonserous UCEC, mixed IDC v. ILC, LUAD v. LUSC, and GBM v. LGG classification tasks. Differences in CDH1 mutation rates were linked to racial disparity in mixed IDC v. ILC and age discrepancy in IDC v. ILC classification tasks. Our FACL framework mitigated performance disparities across demographic groups in 5 out of 6 tasks where standard AI model exhibited significant bias ($p < 0.05$). **Conclusions:** Biases in AI-driven cancer pathology diagnosis stem from disparities in somatic mutation prevalence across demographic groups. Addressing these biases is critical to ensuring fairness and the global applicability of AI tools. Our findings demonstrate that the FACL-based framework effectively reduces performance disparities, making AI-powered cancer diagnostics more reliable. Research Sponsor: None.

Gentian violet compared with methylene blue for sentinel lymph node biopsy in breast cancer: A retrospective analysis from a resource-limited setting. First Author: Mehwish Mooghal, Cancer Foundation Hospital, Karachi, Pakistan

Background: Sentinel lymph node biopsy (SLNB) minimizes morbidity in breast cancer surgeries compared to axillary lymph node dissection. Standard tracers like vital blue (VB), methylene blue (MB) and radioisotopes (RI) are effective but often costly and logistically challenging in low- and middle-income countries (LMICs). Gentian violet (GV), a low-cost alternative, offers potential for resource-constrained settings. **Methods:** A retrospective cohort study was conducted at Cancer Foundation Hospital Karachi, Pakistan between January 2023 - December 2024. The study included 28 patients with breast cancer who underwent SLNB using GV and RI. Sentinel lymph node (SLN) detection rates, concordance between GV and RI, and safety profiles were assessed. Detection was analyzed across tumor grades, histology, receptor statuses, and neoadjuvant chemotherapy (NACT) status. **Results:** The majority of patients were aged 41–50 years (n = 8) and > 70 years (n = 8) and had a BMI in the range of 21–30. Tumor size analysis revealed that T2 tumors were most common (57.1%, n = 16), followed by T3 tumors (21.4%, n = 6). Neoadjuvant chemotherapy (NACT) was administered to 35.7% (n = 10) of patients and all patients were clinically node-negative (cN0) at diagnosis with no distant metastases. Stage II disease predominated (78.6%, n = 22), and invasive ductal carcinoma (IDC) was the most common type (71.4%, n = 20), and 53.6% (n = 15) of tumors were poorly differentiated (Grade 3). Receptor status analysis showed ER/PR positivity in 64.3% (n = 18) of cases, triple positivity in 21.4% (n = 6), while HER2/neu-positive and triple-negative subtypes each accounted for 7.1% (n = 2). GV successfully identified SLNs in 96.4% of cases, with moderate concordance with RI (Kappa = 0.512). GV identified more nodes in 32.1% of patients, while RI identified more in 14.3%; both identified the same number in 50%. The false-negative rate for GV was low (4.2%). Detection rates were consistent across histological types (e.g., invasive ductal carcinoma: 1.94 nodes by GV vs. RI), tumor grades (Grade 3: 1.78 by both), and receptor statuses (triple-positive cases: ~2.4 nodes by GV vs. 2 by RI), with no significant differences. NACT did not impact SLN detection (p = 0.844). No complications or adverse events related to GV dye were observed intraoperatively or during the postoperative follow-up at days 0, 3–7, and 30. The safety profile of GV dye demonstrated no staining-related complications, dermatitis, tattooing, or skin necrosis. **Conclusions:** Gentian violet is a safe, effective, and affordable alternative to MB/VB for SLNB in breast cancer. It demonstrates high detection rates and a favorable safety profile, making it particularly suitable for LMICs. Broader studies are encouraged to validate these findings and further its clinical adoption. Research Sponsor: No funding received.

Comparison of mobile mammography versus urban hospital-based breast cancer screening. First Author: Carla Zeballos Torrez, Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA

Background: Breast cancer screening via mobile mammography units (MMU) is used to improve access in medically underserved communities. This study aims to evaluate factors associated with site of screening, recall rates and time to diagnostic resolution for MMU vs hospital-based sites. **Methods:** This retrospective study analyzed screening mammography examinations performed in a MMU and at our large, urban hospital sites during overlapping 2-week periods in 2022 and 2023. BI-RADS, recall and cancer detection rates were assessed. For BI-RADS 0 patients, time intervals between screening and diagnostic imaging and, when indicated, between diagnostic imaging and biopsy, were collected. Area of Deprivation Index (ADI), an index of socioeconomic status for communities, was calculated for each patient. Diagnostic resolution was defined as time from screening to completion of diagnostic work-up. Statistical analyses were performed with chi-square, analysis of variance, and Kruskal-Wallis tests. Cox regression analysis was used to assess factors associated with diagnostic resolution. **Results:** In the MMU cohort (n=516) vs the hospital-based cohort (n=2401), more patients identified as Non-Hispanic Black (68% vs 40%, $p < 0.001$), reported no insurance (71% vs 2.1% $p < 0.001$), had no PCP (35% vs 9.8%, $p < 0.001$), and were in the highest ADI percentile (70% vs 27%, $p < 0.001$). Regardless of screening site, most patients with longer time to diagnostic resolution had a higher ADI percentile; 58% of patients with > 80 ADI percentile ($p < 0.001$) had diagnostic resolution in > 60 days. The MMU cohort had a higher recall rate (18.8% vs 9.9%; $p < 0.001$) and trend towards a higher cancer detection rate (13.6 vs 8.7 per 1000 examinations, p = 0.32) than the hospital-based cohort. Among BI-RADS 0 patients (n=333), there were longer delays to diagnostic resolution in the MMU vs the hospital-based cohort (Table 1). Patients with no insurance were less likely to have diagnostic resolution compared to insured patients (HR: 0.43, 95%CI [0.26,0.71], p = 0.001). **Conclusions:** Compared to hospital-based screening, MMU-screened patients experienced longer times to diagnostic resolution and had higher recall rates. Although MMU offers an effective strategy to improve screening access, our study highlights opportunities for improved patient navigation, social work support, and financial assistance to promote more equitable follow-up of abnormal screening mammograms. Radiotherapy utilization at the fourth most populous province in Indonesia: A single centre study. First Author: Vito Filbert Jayalie, Murni Teguh Memorial Hospital, Medan, North Sumatra, Indonesia

Background: Cancer continues to grow as a health burden in Indonesia, with the current cumulative cancer risk at 14.0%. Along with the rising rate of cancer discovery, treatment effectiveness should be constantly improved. This study was conducted to explore the actual radiotherapy utilization rate (aRUR) of the 10 most common cancers at Murni Teguh Memorial Hospital (MTMH), a cancer referral hospital in North Sumatra. **Methods:** This was a retrospective study utilizing MTMH medical records in 2019. Data on the 10 most common cancers in Indonesia (based on GLOBOCAN 2020) were collected. Completed data underwent double filtering and cleaning before analysis with the Statistical Package for the Social Sciences (SPSS) and Microsoft Excel to calculate aRUR. Further elaboration was made to compare with the Collaboration for Cancer Outcomes Research and Evaluation (CCORE) RUR data. **Results:** A total of 3,928 samples were collected with 74% of patients being female; the mean age is 50 (0,6 to 96) years old; 38% of cancer staging reported (6% stage I; 32% stage II; 34% stage III; and 28% stage IV). The most to least common cancers are breast, colon, rectal, nasopharynx, cervix, ovary, leukemia, prostate, lung, and lymphoma. Out of 457 irradiated cases, radiotherapy was most used in breast (36%), nasopharyngeal (23%), and cervical cancer (23%). There was gap between these three cancers' aRUR to their optimal RUR (oRUR) calculated by CCORE (54.4% for cervix; 52% for nasopharynx; 41.27% for rectum). Optimal radiotherapy utilization was reached only for colon and ovarian cancers. **Conclusions:** Our study shows that a gap between aRUR and oRUR was observed for most cancers treated at MTMH. Several factors may contributed to this result, including patient factors, clinical factors, and administrative/bureaucracy factors. Further study is needed to address the cause and to plan any measures to shorten the gap and optimize radiotherapy. Research Sponsor: None.

1607 Poster Session

Rates and predictors of cancer screening in California (CA) prisons. First Author: Christopher Manz, Dana-Farber Cancer Institute, Boston, MA

Background: Cancer is the leading cause of death in state prisons. Patients diagnosed with cancer in prison are more likely to have Stage IV diagnoses and have worse survival. Rates and predictors of cancer screening in prison and the relationship to stage at diagnosis are unknown. **Methods:** This retrospective study evaluated patients incarcerated in CA prisons in 2014-2023 who met screening criteria for breast, cervical, colon, liver and lung cancers during periods tracked by the prison system (Table). Correctional data were used to identify screening-eligible patients incarcerated during the study period, screening eligibility dates, receipt of screening and periods of incarceration. These data were matched to CA cancer registry data from 2014-2021 using name and date of birth; cancers were identified between the start of the tracking period for each cancer and 2021. For each cancer, we calculated the proportion of: patients who ever received cancer screening, time covered by a screening test (sum of non-overlapping time of screening intervals [e.g., 10 years for colonoscopy] divided by time eligible for screening), and patients diagnosed at Stage IV (stratified by ever-receipt of screening prior to diagnosis). Generalized estimating equations models with logit link adjusted for demographic and incarceration characteristics (e.g. incarcerated in the past year) clustered at the prison+yard level were used to determine predictors of receipt of screening for each cancer and the association of ever-receipt of screening with Stage IV diagnosis. **Results:** The study included 83,174 individuals who were 79% male, had a median age of 51 when first eligible for any screening, and were 33% Non-Hispanic White. Rates of ever receiving cancer screening ranged from 43-87%, and mean proportion of time covered ranged from 30-75% (Table). In adjusted models, receipt of outpatient mental health services, higher security level and recent change in prison or primary care clinician were associated with higher screening rates for most cancers. 597 screenable cancers were diagnosed from the start of each screening tracking period through 2021. 17% of cancers were diagnosed as Stage IV. In the adjusted model including all cancers, patients who ever received screening prior to diagnosis were 60% less likely to be diagnosed with Stage IV disease (OR 0.40, 95% CI 0.24-0.69). **Conclusions:** Cancer screening rates in CA prisons are high and may explain why rates of Stage IV diagnoses in CA prisons are comparable to the general population and lower than in other state prisons. Research Sponsor: None.

Implementation of a clinical trial navigation program for cancer patients: Barriers and facilitators identified through stakeholder perspectives. First Author: Milica Paunic, Temerty Faculty of Medicine, University of Toronto, Toronto, ON, Canada

Background: Patient navigation has been highlighted as a solution to improve clinical trial access. The Clinical Trial Navigator (CTN) Program is a Canadian cancer clinical trial navigation program that can be accessed online by patients or healthcare professionals (HCP). Trained individuals search and provide patients and/or oncologists a report of potentially eligible trials for free. Over 550 patients have used the Program since its launch in 2019, but systemic implementation within cancer centers has yet to occur. We aimed to identify facilitators and barriers to implementing the CTN Program in Canadian cancer centers by gathering insights from key stakeholders. **Methods:** Thirty-three 45-minute, virtual, semi-structured interviews were conducted with healthcare/clinical research professionals (CRP; n = 9) and patient-focused stakeholders (n = 24). Interviews were guided by the Consolidated Framework for Implementation Research (CFIR) and analyzed by two independent researchers using thematic analyses with deductive and inductive coding. **Results:** Participants highlighted the importance of patient navigation to address barriers related to the limited availability of clinical trials and difficulty in identifying them, noting that navigation can significantly reduce this workload. *CRP: "We need a program dedicated to look at trials across the board. [The clinical trial unit team] has no time or tools to be able to do this for patients."* Key barriers to implementing navigation were the financial and logistical stressors for patients who may want to enroll onto trials that the navigator finds, particularly when only available in another institution. *HCP: "[Our province] covers only travel for the consultation, so [financing] is a big barrier and needs to be thought through."* Another commonly cited barrier was obtaining the required medical information for the CTN Program to perform high quality clinical trial searches. *Cancer advocacy group leader: "It's got to be very physician structured because [the CTN Program intake form] needs patient records. I'll ask patients what stage they are at and they don't know, so asking them for their medical information [to perform a clinical trial search], they just don't know that."* When the clinical trial search is initiated by patients and the report of potential eligible trials returned to them, patients felt they needed extra support in discussing the report with their oncologist. *Patient: "Every oncologist is different. Some are very easy to talk to...one was extremely difficult...so to have a discussion is very difficult."* **Conclusions:** Our findings provide critical considerations for the successful implementation of the CTN Program in cancer centers across Canada. We have planned program adaptations to address these results and will evaluate changes in uptake and effectiveness of the CTN Program. Research Sponsor: None.

Association of West African ancestry, reproductive factors, and deprivation with incidence of triple-negative breast cancer among Black women in the U.S. First Author: Neha Hippalgaonkar, University of Illinois Chicago, Chicago, IL

Background: Black women have the highest incidence of triple negative breast cancer (TNBC) of any racial or ethnic group in the U.S. The TNBC incidence rate among Black women varies substantially by state of residence (Sung H, et al, JAMA Oncol 2023), and the underlying factors driving state level variation are unknown. Genetic ancestry of West Africans and U.S.-born Black Americans (whose ancestry is primarily admixed West African) is significantly different from East Africans, and approximately 10% of the U.S. Black population identify as African immigrants. We used state level data on the number of Black residents who identify as East African immigrants to estimate the proportion of the Black population in that state with West African ancestry (defined as not East African immigrant), and we conducted a mediation analysis of state TNBC incidence data to investigate whether West African ancestry, reproductive patterns, and socioeconomic deprivation influence the relationship between race and TNBC incidence. **Methods:** We obtained state level TNBC incidence rates for Black women (2011-2021) from the U.S. Cancer Statistics Public Use database. State level data on country of birth from the 2020 U.S. census, rates of breastfeeding and fertility for Black residents, and socioeconomic indicators (the 2015 official poverty measure (OPM) and Multidimensional Deprivation Index (MDI)) were obtained from the U.S. Census Bureau. Correlations between TNBC incidence rates and variables of interest were tested with Spearman's correlation test. Causal mediation analysis of TNBC incidence rate differences was performed by estimating coefficients for direct and indirect effects with linear regression models. We calculated estimates of the proportion mediated with 95% confidence intervals (CI) accounting for a priori confounders and potential effect modification at the state level. **Results:** State TNBC incidence rates among Black residents were inversely correlated with the proportion of residents identifying as East African immigrants ($r = -0.42$, $p = .006$) and the rate of breastfeeding ($r = -0.35$, $p = .03$). There was no correlation with fertility rates, OPM or MDI. In unadjusted analyses, East African immigrant proportion at the state level mediated 15.3% ($p = 0.01$) of the differences in TNBC incidence rates. After adjustment for rates of breastfeeding, fertility, and socioeconomic indicators, East African immigrant proportion was associated with 30.1% ($p = 0.02$) of the difference in TNBC incidence rates for Black women at the state level. **Conclusions:** Proportion of East African immigrants and rate of breastfeeding are inversely correlated with TNBC incidence rates in Black women. These factors transmit a portion of state level differences in TNBC incidence, suggesting that West African ancestry partially mediates the higher incidence of TNBC in Black women. Effects of socioeconomic status on access to next generation sequencing in patients with metastatic breast cancer. First Author: Conchita Martin de Bustamante, UT Southwestern Medical Center, Dallas, TX

Background: Metastatic breast cancer is difficult to treat and a major cause of mortality related to breast cancer. Standard treatment includes therapeutic options that target specific molecular signals and pathways responsible for cancer growth. For metastatic breast cancer, focused next-generation sequencing (NGS) on DNA isolated from the tumor tissue or circulating tumor DNA in the blood has quickly become standard of care to create actionable and personalized treatment plans. In ER+ disease, NGS helps to determine potential second-line therapies. However, these tests are often expensive, limiting their clinical implementation. We hypothesized that limited access to these therapies increases health disparities in clinical oncology. **Methods:** Data from 187 patients with recurrent MBC were obtained from the Dallas Metastatic Breast Cancer Study, a clinical database that was established in 2021 at a single academic medical system to track patient demographics, area deprivation index (ADI), treatments, and other variables. Commercial NGS testing was performed on patient tumor tissue or tumor DNA from blood samples by Tempus and FoundationOne between the years 2014 through 2022. **Results:** Overall, 39% of patients in our dataset received NGS testing. Patients who are not Hispanic/Latino (n=140, OR: 3.99, 95% CI: 1.66-9.61) are 4 times more likely to receive NGS compared to those who are Hispanic/Latino. We then explored whether ADI correlated with access to NGS testing. ADI measures education level, employment, housing quality, and income to rank neighborhoods by SES disadvantage; a higher quartile ADI equates to a greater disadvantage. Our data showed that patients in the lowest quartile ADI are 2.5 times more likely to have NGS testing compared to those in the highest quartile (OR: 2.54, 95% CI 1.07-6.20). To account for different clinical indications for receiving NGS testing, we then looked at NGS trends between tumor molecular subtypes. We observed that ER+ patients were 3 times more likely to have NGS testing compared to ER- patients (n=118, OR: 2.77, 95% CI: 1.45-5.29) and that TNBC patients were less likely to receive NGS testing compared to ER+ patients, however this difference was not significant (n=113, OR: 0.36, 95% CI: 0.13-1.01). In ER+ patient population, we found that Hispanics/Latinos were 79% less likely to undergo NGS testing compared to their non-Hispanic counterparts (n=76, OR: 0.21, 95% CI: 0.06-0.73). **Conclusions:** These results suggest that even in clinically indicated ER+ disease, NGS testing is disproportionately offered to patients with a higher SES, particularly those who are not Hispanic/Latino. Whether these discrepancies stem from the recent adoption of NGS as standard of care or from actual barriers to accessing care should be defined in future studies. However, identifying that these disparities exist promotes awareness for clinicians to offer NGS more broadly. Research Sponsor: None.

Trust and communication among sexual and gender minority (SGM) cancer survivors. First Author: Brandon M. Godinich, Texas Tech Health Science Center El Paso, El Paso, TX

Background: Trust and effective communication in healthcare are essential for delivering high-quality cancer care, especially for marginalized groups like SGM patients. This study examines the differences in trust and communication among LGBTQIA cancer survivors and those without (w/o) a cancer history to inform strategies for improving cancer care equity. **Methods:** Data from the nationally representative Health Information National Trends Survey (HINTS) from 2018-2022 was used to evaluate questions on communication, quality of care, and trust in those who self-identified as homosexual, gay, or lesbian, bisexual, or "something else" for sexual orientation. Two cohorts compared SGM participants with prior cancer diagnosis (survivors) and those w/o cancer. Demographic data included: age, gender, race/ethnicity, education, employment, and household income. Analysis was done in STATA with Chi-squared and T-tests testing between SGM survivors and those w/o cancer and multivariate analysis (MVA) focused on SGM survivors. **Results:** In total, 1,258 SGM participants were included, of which 144 (11.4%) were SGM cancer survivors. SGM survivors were older than those w/o cancer history (median 64 vs. 46, $p < 0.001$) but had no significant differences in employment (25.0% vs. 47.2%) or race (White: 79.9% vs 69.5%; Black 21.9% vs 19.6%) (p = NS). Less than half of SGM survivors (44.9%) reported they always or usually had the chance to ask all of their health-related questions during provider visits, this was better than SGM w/o cancer (36.8%, $p = 0.03$). About a third reported that providers always/usually gave adequate attention to their emotions and feelings (37.2% survivors vs 37.5% w/o cancer, p = NS). Most felt they were always/usually adequately involved in decisions about their health care (82.5% survivors vs 82.0% w/o cancer, p = NS). Only 33.1% SGM survivors rated their overall quality of care as excellent/very good within the past year; this was slightly better than surveyed SGM w/o cancer (24.6%, p = NS). Half of SGM survivors (50.9%) trusted information about cancer from doctors, slightly more than for those w/o cancer (46.2%, p = NS). In a MVA limited to SGM survivors, only education was associated with decreased trust of cancer information from a doctor; those with at least some college (OR = 0.51 95% CI 0.26-0.99, $p = 0.048$) or postgraduate education (OR = 0.36 95%CI 0.14-0.92, $p = 0.034$) had less trust compared to those with a high school degree or less. **Conclusions:** This national study shows that patient-reported overall healthcare to SGM survivors is poor. Less than a third of SGM survivors reported good quality of care and less than half felt providers answered all their questions; only half trusted cancer information from a doctor. Concerningly, those with higher education levels were less likely to trust doctors. Future efforts should focus on ensuring that *all patients* benefit from high quality cancer care and communication. Research Sponsor: None.

Quantifying financial toxicity in oncology: A comprehensive analysis of prescription cost disparities using public data from 2022. First Author: Charishma Bhimineni, Jefferson Einstein Montgomery, East Norriton, PA

Background: Financial toxicity in cancer care poses a significant burden for patients and healthcare systems. This study analyzed public data to evaluate the financial impact of oncology treatments, focusing on factors such as demographics, insurance type, gender disparities, or geographics. **Methods:** The 2022 Medical Expenditure Panel Survey (MEPS) data was analyzed, focusing on antineoplastic and immunologic agents. Cost distributions, payment sources, and financial burden—defined as prescription costs exceeding 20% of annual household income—were assessed across various insurances and demographic groups (age, gender, race, income, and education). Geographic analyses utilized Federal Information Processing Standard (FIPS) state codes. **Results:** The study included 1,379 oncology prescriptions. Prescription costs averaged 1,569 per prescription (median 388), ranging from 19 to 7,208. Annual costs spanned 2,507 (25th percentile) to 26,857 (75th percentile), with a median of 3,561 and a mean of 14,138. Non-prescription medical costs, such as procedures and hospitalizations, had a median of 45,475 and a mean of 47,509, with some exceeding 132,396 annually. Uninsured patients faced the highest average costs (78,439 annually), followed by Medicare patients (67,979). Medicaid patients had the lowest total costs (53,469). VA/TRICARE patients showed moderate costs (56,619) but higher prescription expenses (16,758). Low-income patients faced the greatest financial burden, spending 11.71% of their income on prescriptions, compared to 5.89% for middle-income and 2.66% for high-income patients. Private insurance beneficiaries faced the highest costs (5,500-6,000), particularly among Black and White patients, followed by Medicare (4,500-5,000). Medicaid beneficiaries incurred lower costs (3,500-4,000), while uninsured patients had the lowest mean costs (2,500-3,000), reflecting limited access to comprehensive treatments. Female patients had higher costs for breast and lung cancer treatments. Black and Hispanic patients relied more on Medicaid. Patients with graduate degrees had higher average costs (4,226) than those with a high school education or less (3,707). Geographically, financial burden was highest in the Midwest, moderate in the Northeast, and mixed in coastal and Southern states. **Conclusions:** Significant disparities in financial toxicity exist across demographics, insurance types, and regions. The gap between mean and median costs underscores the disproportionate financial strain faced by some patients. Policy interventions, including expanded insurance coverage, capped out-of-pocket costs, and targeted subsidies, are needed to improve equity and affordability in cancer care. Racial differences in cardiovascular outcomes among cancer patients receiving immune checkpoint inhibitors. First Author: Cho Han Chiang, Department of Medicine, Mount Auburn Hospital, Harvard Medical School, Cambridge, MA

Background: Immune checkpoint inhibitors (ICIs) increase the risk of major adverse cardiovascular events (MACE). We aimed to evaluate disparities in MACE across racial groups. **Methods:** We conducted a propensity score-matched study using the TriNetX Analytics Network database, which includes de-identified data from over 140 healthcare institutions. Adult cancer patients treated with ICIs were included and those with prior MACE were excluded. Patients were grouped into White, Black, Asian, and Hispanic cohorts. The primary outcome was incident MACE, defined as the composite of myocarditis, pericarditis, myocardial infarction, ischemic stroke, heart failure, atrial fibrillation, and venous thromboembolism (VTE) within 12 months of ICI. Matching was performed using variables: age, sex, cancer type, metastatic disease, comorbidities, and cardiovascular medication. **Results:** A total of 58,217 eligible patients were identified, including 44,151 White, 5,876 Black, 5,347 Asian, and 2,843 Hispanic individuals. After matching, cohorts were adequately balanced. Black patients had the highest risk for MACE, with an 18% increased risk compared to White (HR 1.18 [95% CI: 1.06-1.30]) and Hispanic patients (HR 1.18 [95% CI: 1.03-1.35]) and an 80% increased risk compared to Asian patients (HR 1.80 [95% CI: 1.57-1.35]). This increased risk among Black patients appeared to be driven by higher rates of heart failure and VTE. The risks of MACE were similar between White and Hispanic individuals while Asian patients had the lowest risk. **Conclusions:** There were racial differences in immune-related MACE, with Black patients experiencing the highest risk of cardiotoxicity following ICI treatment. Research Sponsor: None.

Hazard ratio for effects of race on cardiovascular outcomes.

	Black vs. White	Black vs. Hispanic	Black vs. Asian	White vs. Asian	White vs. Hispanic	Hispanic vs. Asian
Outcomes	n=5,109 each	n=2,636 each	n=3,095 each	n=2,842 each	n=4,876 each	n=2,157 each
MACE	1.18 (1.06-1.30)	1.18 (1.03-1.35)	1.80 (1.57-2.07)	1.44 (1.28-1.62)	0.98 (0.86-1.12)	1.60 (1.35-1.91)

Impact of sociodemographic factors and Medicaid expansion on postoperative outcomes for glioblastoma, 2004-2021. First Author: Bhav Jain, Stanford University School of Medicine, Stanford, CA

Background: Glioblastoma (GBM), the most aggressive primary brain tumor in adults, has a median survival of ~15 months despite treatment and exhibits significant disparities in care access. Sociodemographic factors and policy interventions, such as Medicaid expansion under the ACA, show potential to mitigate inequities in other cancers. However, their impact on GBM outcomes remains underexplored. **Methods:** Using the National Cancer Database, we conducted a retrospective study of 85,631 GBM patients treated with surgery between 2004 and 2021. Multivariate regression models and Kaplan-Meier survival analyses evaluated associations between sociodemographic factors (e.g., race, income, education, rurality, insurance status) and outcomes, including postoperative hospital stay, 30-day readmission, 90-day mortality, and overall survival. All models adjusted for key clinical (e.g., tumor size, comorbidities, receipt of chemotherapy/radiation therapy) and patient (e.g., age, sex) covariates. A difference-in-differences analysis assessed the effects of Medicaid expansion on these outcomes. **Results:** Regarding postoperative length of hospital stay, disparities were observed by race (Black vs. White β = 1.45 days [1.22–1.68]; Asian American and Pacific Islander [AAPI] vs. White β = 0.86 days [0.50–1.22]), rurality (urban vs. metro β = -0.31 days [-0.47 to -0.15]), insurance status (private vs. uninsured β = -1.10 days [-1.41 to -0.80]), and education (highest vs. lowest quartile β = -0.28 days [-0.48 to -0.09]). Unplanned 30-day hospital readmission rates demonstrated disparities by race (Black vs. White OR = 1.19 [1.04–1.35]), income (highest vs. lowest quartile OR = 0.84 [0.75–0.96]), and education (highest vs. lowest quartile OR = 1.19 [1.05–1.34]). Moreover, 90-day mortality indicated disparities by race (Black vs. White OR = 0.85 [0.77–0.95]; AAPI vs. White OR = 0.64 [0.53–0.77]), income (highest vs. lowest quartile OR = 0.81 [0.74–0.89]), education (highest vs. lowest quartile OR = 1.13 [1.03–1.23]), and insurance status (private vs. uninsured OR = 0.71 [0.62–0.82]). Finally, overall survival demonstrated disparities by race (Black vs. White HR = 0.88 [0.85–0.91]; AAPI vs. White HR = 0.77 [0.73–0.82]), income (highest vs. lowest quartile HR = 0.83 [0.81–0.86]), education (highest vs. lowest quartile HR = 1.12 [1.09–1.15]), rurality (rural vs. metro HR = 1.06 [1.00–1.12]), and insurance status (Medicaid vs. no insurance HR = 1.09 [1.04–1.15]). Medicaid expansion did not significantly impact any outcomes, including overall survival (DID HR = 0.95 [0.84–1.07]). **Conclusions:** Significant sociodemographic disparities persist in GBM postoperative outcomes, with no improvement from Medicaid expansion. Targeted socioeconomic interventions are needed to address inequities in access to specialized neuro-oncological care and improve outcomes for underserved populations. Research Sponsor: None.

1615 Poster Session

Symptom burden, quality of life (QoL), social and behavioral characteristics in young patients (<40 years old) with cancer: A prospective cohort of 7323 patients across 110 sites in France and Belgium. First Author: Kaïssa Ouali, Gustave Roussy, Drug Development Department (DITEP), Villejuif, France

Background: Cancer in individuals under 40 years old is increasingly recognized as a public health concern, characterized by unique etiologies, biology, and clinical behaviors compared to older populations. Young patients may also face specific physical, psychosocial, and socioeconomic challenges that can influence outcomes which are often suboptimally addressed in routine care. Digital health and specifically remote patient monitoring (RPM) offer a way to track and manage these challenges effectively, increasing access to supportive care. **Methods:** Prospective, observational cohort of 7323 adult patients with cancer participating in an RPM pathway across 110 hospitals in France and Belgium between Jun-2022 and Dec-2024. Patients were grouped by age ($<$ 40 vs. $\geq$40). At baseline, demographic, clinical, and social and behavioral data were collected. Longitudinal symptom burden (e.g., anxiety, pain, nausea) was assessed using validated patient-reported outcomes (PRO-CTCAE). High symptom burden was defined as PRO-CTCAE grade $\geq$3. QoL was measured by EORCT QLQ-C30 summary score. Linear mixed models, adjusted for relevant covariates, were used to compare changes in symptom burden over 12 weeks between age groups. **Results:** Younger patients (n = 350 pts $<$ 40 years) were more often female (77 vs 62%, p $<$ 0.001) and with localized disease (55 vs 45%, p $<$ 0.001). The rate of breast, lung, colorectal and pancreatic cancers represented respectively 157%, 27%, 57% and 17% of the proportion in older adults (p $<$ 0.001). Younger patients also presented with more unfavorable social and behavioral characteristics including higher alcohol consumption (26.3 vs. 15.3%, p= 0.005), tobacco consumption (23.2 vs. 13.8%, p $<$ 0.001), unemployment (17.7 vs 7.2%, p $<$ 0.001) and financial insecurity (23.2 vs 10.9%, p $<$ 0.001). Similar QoL was found at baseline (mean [SD] 76.9 [16.8] vs 76.1 [17.0], p = 0.84). Adherence to RPM surveys was lower in the younger group (74 vs 84%, p = 0.001), who took also on average longer to answer (22 vs 10h, p$<$0.001). Younger patients had higher early (week 1 to 3) symptom burden (anxiety 16.7 vs 10.6%, p = 0.001], fatigue [36.1 vs 30.6, p = 0.05], nausea [30.4 vs 18.6%, p $<$ 0.001], anorexia [16.7 vs 10.6, p = 0.004] and performance status decline [26.8 vs 18.7%, p = 0.012). At 12 weeks, symptom burden improved in both groups, and the between-group difference was no longer significant. **Conclusions:** In this large, multi-institutional cohort, younger patients faced unique physical, psychological and behavioral challenges and experienced higher early symptom burden. Interestingly, by 12 weeks, both groups demonstrated symptomatic improvement, with no remaining differential across age groups. These findings suggest that RPM and supportive interventions may help mitigate disparities in symptom burden over time. Research Sponsor: Resilience Care.

1616 Poster Session

Prevalence of and factors associated with financial toxicity among gastrointestinal cancer patients in Pakistan. First Author: Sehar Salim Virani, Aga Khan University Hospital, Karachi, Pakistan

Background: Financial toxicity (FT) impacts cancer care in low- and middle-income countries (LMICs), affecting treatment adherence and quality of life. This study assesses FT prevalence and associated factors among gastrointestinal (GI) cancer patients across distinct healthcare systems in Pakistan. **Methods:** A cross-sectional study was conducted across three tertiary care centers in Karachi: Aga Khan University Hospital (AKUH, private, fee-for-service), Jinnah Postgraduate Medical Center (JPMC, public, free), and Cancer Foundation Hospital (CFH, private-philanthropy, subsidized). FT was assessed using the Urdu version of the Comprehensive Score for Financial Toxicity–Functional Assessment of Chronic Illness Therapy (COST-FACIT). Multivariable negative binomial regression identified factors linked to high FT. **Results:** Of 375 patients, 44.5% were from AKUH, 33.6% from JPMC, and 21.9% from CFH. Mean age was 50.8 $\pm$ 14.4 years, with 62.4% males. Only 8.3% had health insurance, and the median International Wealth Index (IWI) was 79.9 (IQR: 57.1–95.1). Catastrophic healthcare expenditure affected 41.7%. The mean COST-FACIT score was 16.0 $\pm$ 7.4, with 46.1% experiencing mild FT (score: 14–26) and 41.9% moderate FT (score: $\leq$14). Patients delaying or forgoing care had higher FT (p $<$ 0.001). Borrowing money, selling assets, or cutting essential expenses were strongly associated with increased FT (p $<$ 0.001). Patients at AKUH reported higher FT than JPMC (IRR = 0.84, 95% CI: 0.74–0.97). Younger patients (21–50 years) (IRR = 0.66, 95% CI: 0.46–0.95) and those receiving chemotherapy (IRR = 0.89, 95% CI: 0.81–0.98) experienced higher FT. Females (IRR = 1.36, 95% CI: 1.17–1.58) and higher socioeconomic status (IRR = 1.39, 95% CI: 1.06–1.83) were associated with lower FT. **Conclusions:** Nearly 85% of GI cancer patients faced FT. Younger age, male gender, lower socioeconomic status, and systemic therapy were associated with higher FT. Subsidized care, financial support, and institution-specific strategies are critical to mitigating FT in LMIC healthcare systems. Research Sponsor: None.

Patient characteristics and treatment costs across hospitals.

	AKUH	JPMC	CFH
Gender, n (%)			
Male	109 (65.3)	73 (57.9)	52 (63.4)
Female	58 (34.7)	53 (42.1)	30 (36.6)

The effect of a vertically integrated health system on the disparity of socioeconomic status seen in cancer stage at presentation. First Author: Robert Michael Cooper, Kaiser Permanente Los Angeles Medical Center, Los Angeles, CA

Background: Earlier stage of diagnosis may lead to more curable disease and less intensive treatment. Vertically integrated health care systems through screening and integrated care delivery model may provide benefit in identifying cancer patients at earlier stage of disease. **Methods:** We examined an insured Southern California cohort of 503,279 patients diagnosed with invasive cancer between Jan 1 2015 and Dec 31 2020 provided by the state SEER Cancer Registry. Stage at diagnosis provided was SEER summary stage in which patients were defined as having local disease or advanced (regional or metastatic) disease. We used geocoded socioeconomic status, race/ethnicity, and hospital of diagnosis as independent variables. For hospital of diagnosis, patients were divided into those diagnosed in Kaiser Foundation Hospitals or not. The first cohort was for cancers with robust screening programs and included breast, cervical and colon (CBC group). The second cohort was all other cancers (non CBC group). We evaluated each of these groups independently. The prevalence of local disease was determined and multilinear regression was used to determine the adjusted odd ratios of being diagnosed with local disease. **Results:** Compared to patients not diagnosed in Kaiser Foundation hospitals (non KFH), patients diagnosed in Kaiser Foundation hospitals (KFH) were more likely to be diagnosed with local disease. 1.14 (95% Confidence Intervals 1.13, 1.16) for the total cohort. We looked at the adjusted interaction of being diagnosed in KFH for each quintile: Highest SES 1.03 (1.00, 1.07), Upper Middle SES 1.11 (1.08, 1.14), Middle SES 1.21 (1.18, 1.25), Lower-Middle SES 1.25 (1.21, 1.29) and Lowest 1.34 (1.29, 1.38). Compared to patients not diagnosed in Kaiser Foundation hospitals (non KFH), patients diagnosed in Kaiser Foundation hospitals (KFH) were more likely to be diagnosed with local disease in the CBC cohort 1.12 (1.09, 1.16) and in the non CBC cohort 1.16 (1.14, 1.17). **Conclusions:** Vertically integrated health care systems have shown advantages in preventive care. We show that insured patients diagnosed in Kaiser Foundation hospitals present with more localized and less advanced disease than patients diagnosed in non KF hospitals. This advantage was seen in a group of patients with established screening program and was also seen in diseases without screening programs. A sub analysis showed that the advantage more pronounced the lower the SES. How a vertically integrated care delivery system provides these advantages deserves further study. Research Sponsor: None.

Dihydropyrimidine dehydrogenase (DPD) deficiency–related variants among Mexican patients with gastrointestinal (GI) malignancies. First Author: Enrique Soto Pérez de Celis, University of Colorado Anschutz Medical Campus, Aurora, CO

Background: DPD deficiency is the most important risk factor for developing fluoropyrimidine-related adverse events. Genetic variants causing DPD deficiency are found in 6-8% of Caucasian patients. However, there is limited information on their prevalence in underrepresented ethnic groups, such as Hispanics and Latinos, and testing for these variants is not routinely recommended in Latin America. Our goal was to assess the allele frequency of clinically actionable dihydropyrimidine dehydrogenase (*DPYD)* risk variants defined by the Clinical Pharmacogenetics Implementation Consortium (CPIC) and the European Medicines Agency (EMA) among admixed Mexican patients with GI malignancies. **Methods:** Patients with recently diagnosed GI cancer candidates for fluropyrimidine therapy were recruited from a single institution in Mexico City. After providing informed consent, a blood sample and clinical characteristics were collected. We utilized the Illumina Infinium Global Screening Array (GSA)-to genotype 34 DPYD variants, six of which are known to lead to an increased risk of fluoropyrimidine toxicity and are considered clinically actionable. **Results:** Two hundred and eight patients with a mean age of 62 years (SD 13.2) were included. 47% were female. The most common type of cancer was colorectal (38%) followed by pancreas (22%) and biliary tract (18%). DNA samples from 192 patients passed quality control, of which 156 (62%) received fluoropyrimidines during follow-up. Only 2 patients (1%) were heterozygous for actionable *DPYD* intermediate metabolizer risk variant alleles: one with *c.2846A > T (*rs67376798*, D949V)* and one with *c.1129–5923C > G [*rs75017182; HapB3 SNP *c.1236G > A;* rs56038477]. No patients were found to have other CPIC-listed *DPYD* risk variants. Additionally, we investigated the allele frequencies of other 30 *DPYD* variants and observed low-frequency variation (between 0.260 and 0.0032) in rs56038477, rs1801160, rs17376848, rs1801159, rs1801158, rs45589337, rs2297595, rs200562975, and rs1801265. Several of these may be related to decreased DPYD activity and warrant further analysis regarding their impact on adverse drug reactions. **Conclusions:** In contrast with reports from Caucasic populations, we found a very low allele frequency of *DPYD* actionable variants. Our findings highlight the limitation of current pharmacogenomic testing recommendations and panels, which may not be appropriate for admixed ethnic populations such as Hispanics/Latinos due to disparities in representation. There is a need to study the role of other *DPYD* variants in larger patient samples to understand their role in the toxicity risk of admixed populations in Mexico and Latin America, to explore the use of novel techniques such as Next Generation Sequencing, and to investigate the effect of other related genes on toxicity risk. State-level trends and associated disparities in melanoma burden in the United States. First Author: Furkan Bahar, Mount Auburn Hospital/Harvard Medical School, Cambridge, MA

Background: Melanoma, an aggressive skin cancer, poses a significant public health challenge in the United States despite advancements in detection and treatment due to its high mortality. This study analyzes trends in melanoma incidence, mortality, and disease burden in the US from 1990 to 2021. **Methods:** Data on incidence rates (IR), mortality rates (MR), disability-adjusted life years (DALYs), and estimated annual percentage changes (EAPCs) from 1990 to 2021 were extracted from the Global Burden of Disease 2021 database. Regional trends within the US were evaluated to identify state-level patterns and disparities. **Results:** In 2021, melanoma IR in the US was 27.2 per 100,000, far exceeding the global average of 3.8. Between 1990 and 2021, IR increased by 64.8%, compared to a global rise of 28.8%. Among US states, Maine had the highest IR at 37.8 per 100,000, while the District of Columbia reported the lowest IR at 8.3. Alaska showed the largest relative increase (EAPC of 81.5%), while New Jersey was the only state to report a decline in incidence, with an EAPC of -1.6%. The US melanoma mortality rate was 3.0 per 100,000 in 2021, compared to the global rate of 0.78. US mortality increased by 5.5%, while the global mortality rate rose by 25.8%. West Virginia recorded the highest mortality rate at 4.49 per 100,000, whereas the District of Columbia had the lowest rate at 1.20 and the most significant improvement, with an EAPC of -43.5%. In terms of DALYs, the US reported a rate of 79.2 per 100,000 in 2021, significantly higher than the global average of 21.27. Between 1990 and 2021, DALYs in the US declined by 14.4%, contrasting with an 8.5% increase globally. The DALY/incidence ratio in 2021 was 2.9 in the US, compared to 5.6 globally, indicating notable differences in disease burden across populations. Melanoma disproportionately affected males, with an IR of 33.9 per 100,000 compared to 20.7 in females (male-to-female ratio: 1.6). Mortality rates followed a similar pattern, with males experiencing a rate of 4.0 per 100,000 vs. 2.1 for females, consistent with global trends. **Conclusions:** Despite the decrease in DALYs, melanoma incidence and mortality continue to rise in the US, exceeding global averages. Significant disparities persist across states and genders, reflecting the complex interplay of risk factors and behavioral patterns. The lower DALY/incidence ratio in the United States highlights the likely effectiveness of US treatment options in mitigating disease burden per case. Variations among states may also be attributed to differences in ethnic distribution, which influence genetic susceptibility, healthcare access, and prevention efforts. Research Sponsor: None.

Association of allostatic load (AL) and residential segregation with breast biopsy outcomes after screening mammography. First Author: Braelyn Wekwerth, Massachusetts General Hospital, Boston, MA

Background: Allostatic Load (AL) and residential segregation have been associated with the risk of breast cancer (BC). However, the independent effects of AL and measures of residential segregation (MRSs) on cancer detection and the false positive (FP) biopsy rate in a screening mammography population have not yet been assessed. **Methods:** We retrospectively identified women aged ³40 who underwent screening mammography between 1/1/2021-12/31/2021 and subsequent breast biopsy from the Mass General Brigham Biobank. We collected age and self-reported race/ethnicity. Each participant's zip code was geocoded to the corresponding census tract. We computed five MRS indices: Dissimilarity (DD), Isolation (BI), Delta (D), Absolute Centralization (AC), Spatial Proximity (SP). We collected the following biomarkers obtained within two years before the index screen: cardiovascular, metabolic, immunologic, renal lab values. AL was assigned one point for each lab value in the worst quartile and summed (continuous). We collected diagnostic breast imaging and biopsy encounters within 12 months after the index screen. Multiple imputation accounted for missing data. Multivariable logistic regression assessed age, race, AL and each of our MRSs association with cancer detection and FP rates. We applied Rubin's rules to estimate overall odds ratios (OR), confidence intervals (CI), and p-values for all covariates. **Results:** Of the 418 eligible women, 59.6% (N=249) had an FP biopsy, and 66.3% (N=277) had breast cancer, including cases of ductal carcinoma in situ. On average, women were 62 years old (SD=13); 85.6% White. DD was associated with a reduced risk of benign high-risk lesions (OR=0.69, 95% CI:[0.49-0.95]; p=0.025), and homogeneous, affluent census tracts—whether predominantly Black or White—were similarly protective (OR=0.85, 95% CI:[0.72, 0.99]; p=0.041). MRS indices were linked to lower benign high-risk outcomes (e.g. SP, OR=0.53, 95% CI:[0.31, 0.91]; p=0.021). Age and race significantly predicted adverse events (AEs). Older age was consistently associated with increased AEs across all models (OR = 1.09, 95% CI:[1.00, 1.18]). Cancer detection also increased with age (OR = 1.20, 95% CI: [1.10, 1.30]; $p < 0.001$). AL was significantly linked to cancer detection (OR = 1.13, 95% CI:[1.00, 1.28]). **Conclusions:** Some MRSs are associated with cancer detection and high-risk FP. AL remains associated with these cancer and high-risk FP, even accounting for these segregation measures. These factors may contribute to an increased risk of cancer, highlighting the significance of spatial and socioeconomic influences on screening outcomes. Clinical Relevance Statement: AL may serve as a biomarker to enhance biopsy selection following screen-detected mammographic abnormalities, potentially improving cancer detection rates. Racial differences in serious immune-related adverse events among cancer patients receiving immune checkpoint inhibitors. First Author: Cho Han Chiang, Department of Medicine, Mount Auburn Hospital, Harvard Medical School, Cambridge, MA

Background: Immune checkpoint inhibitors (ICIs) are associated with an increased risk of adverse events (irAEs). We aimed to evaluate disparities in serious irAEs among patients from different racial backgrounds. **Methods:** We performed a propensity score-matched study using the TriNetX Analytics Network database, which includes de-identified data from over 140 healthcare institutions. We included adult cancer patients treated with ICIs and grouped patients into White, Black, Asian, and Hispanic cohorts. The outcomes were incident composite irAEs, which included pneumonitis, colitis, thyroiditis, hypophysitis, adrenal insufficiency, Stevens-Johnson syndrome (SJS) / toxic epidermal necrolysis (TEN), and hepatitis within 12 months of ICI. Patients were matched using variables: age, sex, ICI type, cancer type, metastatic disease, and underlying comorbidities. **Results:** We identified 72,501 cancer patients who received ICIs, including 56,937 White, 7,027 Black, 5,623 Asian, and 2,914 Hispanic patients. Cohorts were adequately balanced across covariates after matching. White and Hispanic patients showed similar risks of irAEs, both having approximately 30% higher risk of developing serious irAEs compared with Black and Asian patients. Compared with Black patients, White and Hispanic patients had higher risks of colitis and adrenal insufficiency. Compared with Asian patients, White and Hispanic patients had higher risks of pneumonitis, colitis, and thyroiditis. **Conclusions:** White and Hispanic patients have the highest risks of developing serious irAEs. Further research is needed to explore the underlying causes and develop targeted interventions to mitigate these disparities. Research Sponsor: None.

Hazard ratio for the effects of race on irAEs.

	White vs. Black	White vs. Asian	White vs. Hispanic	Black vs. Asian	Hispanic vs. Black	Hispanic vs. Asian
Outcomes	n=7,207 each	n=5,562 each	n=3,314 each	n=3,839 each	n=2,680 each	n=2,224 each

Survival disparities between patients with breast cancer with and without HIV at Jaramogi Oginga Odinga Teaching and Referral Hospital (JOOTRH). First Author: Harriet Fridah Adhiambo, Kenya Medical Research Institute, Nairobi, Kenya

Background: Breast cancer and HIV/AIDS pose significant public health challenges. Women living with HIV face higher mortality rates when diagnosed with breast cancer than HIV-negative women. Although advancements in treatment have improved survival outcomes, limited evidence exists on the impact of HIV on breast cancer outcomes in low-resource settings. This study examines survival disparities between breast cancer patients with and without HIV. **Methods:** We conducted a retrospective cohort study of breast cancer patients diagnosed at JOOTRH between January 2013 and September 2024. Data from paper-based records included demographics, clinical data and outcomes (survival status). Survival, defined as time from diagnosis to death or last follow-up, accounted for transfer out, death, being alive, or lost to follow-up. Variables with >20% missingness were excluded. Survival disparities by HIV status were estimated using Kaplan-Meier, with mortality relationships analyzed via Cox Proportional Hazards Model. **Results:** Out of 494 breast cancer patients, 101(20%) were HIV+, 219 (44%) had unknown HIV status, and 174(36%) were HIV-. At diagnosis, HIV+ patients were younger (median: 48, [IQR 40–56]) compared to HIV- patients (median: 51, [IQR 40–64], p=0.030) and had a lower median BMI (23.2 vs. 25.4, p=0.008). HIV positive patients had a longer median time to treatment initiation (56 days, IQR 25–127) compared to HIV-negative patients (44 days, IQR 20–94), although the difference was not statistically significant (p=0.4). In this cohort, 12% (60) of patients had died, with a higher mortality rate among HIV+ patients (17%, 17 out of 101) compared to HIV- patients (14%, 24 out of 174), while loss to follow-up was substantial in both groups (43% HIV+ vs. 37% HIV-, p<0.001). The crude 5-year survival probability was 14% lower in HIV+ patients (59%, [95% CI 38 – 91]) than HIV- patients (73%, [61–87]). Survival, adjusted for age, smoking, employment, and cancer stage, did not vary significantly by HIV status (HR for HIV+ vs. HIV-: 1.13, 95% CI: 0.51–2.50, p = 0.8). However, survival was significantly lower among patients with health insurance (HR = 0.35, 95% CI: 0.12–0.97, p = 0.044) and those with > primary/elementary school education (HR: 0.13, 95% CI: 0.02, 0.88, p = 0.037) compared to those with primary education only. Patients who did not receive treatment had a significantly higher mortality risk (HR = 3.52, 95% CI: 1.54–8.04, p = 0.003. **Conclusions:** In this study, breast cancer patients living with HIV had poorer crude 5-year survival probabilities compared to their HIV-negative counterparts, although the adjusted survival did not differ significantly by HIV status. Factors associated with significantly lower survival included lack of treatment, lower education levels, and absence of treatment. These findings underscore the need for targeted interventions to improve breast cancer outcomes among HIV-positive patients, particularly in low-resource settings. Research Sponsor: None.

Association between Geriatric 8 frailty, guideline treatment, treatment adherence, and overall survival in older patients with cancer (PROGNOSIS-G8). First Author: Helena Møgelbjerg Ditzel, Department of Oncology, Odense University Hospital, Odense, Denmark

Background: Frailty is frequent among older adults with cancer and may affect oncologic treatment tolerance. Frailty screening, with tools such as the Geriatric 8 (G8), is recommended to help guide clinical decision-making. While the G8 has been strongly associated with survival, its relationship with treatment adherence remains less clear. This study aimed to evaluate the association between G8-identified frailty and treatment outcomes in a large cohort of older adults with diverse cancer types. **Methods:** This single-center prospective cohort included adults, age ≥70 years, with solid cancers who underwent G8 screening at their initial oncology consultation. Treatment-related outcomes included one-year overall survival, first-line oncologic treatment adherence within 9 months, and whether patients were offered guideline treatment. Guideline treatment was defined as regimens consistent with recommendations from national guidelines for first-line oncologic treatment, allowing add-on protocol treatment, while less-than-guideline treatment referred to regimens not among first choices, often deemed inferior. Adherence to the doctor-patient selected treatment plan was defined as the absence of discontinuations, dose reductions after treatment initiation, or un-administered treatments (i.e., excluding delays). Data on demographics, comorbidity, cancer diagnosis, treatment, and survival were extracted from medical records. Associations between G8 frailty (≤14/17 points) and outcomes were analyzed using multivariate logistic regression and Cox proportional hazards regression, adjusting (adj.) for confounders. **Results:** Among the 1,398 patients screened, 65% were frail. Frailty doubled the risk of death at one year (adj. HR 2.0, 95% CI 1.7-2.4, p < 0.001). Frail patients who adhered to less-than-guideline treatment had a 69% lower mortality risk compared to frail patients unable to adhere to guideline treatment (adj. HR 0.31, 95% CI 0.21-0.47, p < 0.001). Non-frail patients were more likely to adhere to treatment (adj. OR 2.38, 95% CI 1.49-3.81, p < 0.001) and were more often offered guideline treatment (adj. OR 1.98, 95% CI 1.28-3.06, p = 0.002) compared to frail patients. Lastly, when receiving guideline treatment, non-frail patients had significantly better adherence than frail patients (adj. OR 3.08, 95% CI 1.72-5.52, p < 0.001). **Conclusions:** G8 frailty screening effectively identifies older adults at a higher risk of treatment non-adherence and mortality, facilitating tailored treatment approaches. Our findings suggest that frail patients may benefit from initial less-intensive treatments with potential escalation to improve adherence and survival. Implementing G8 screening in routine practice addresses the unique challenges associated with frailty, ensuring more effective, equitable care for at-risk older adults. Prognostic awareness in older adults with metastatic cancer: Secondary analysis of a randomized controlled trial. First Author: Cristiane Decat Bergerot, Oncoclínicas&Co, Sao Paulo, Brazil

Background: Prognostic awareness plays a key role in patient outcomes, particularly among older adults with metastatic cancer. This secondary analysis of a randomized controlled trial (RCT) evaluated the effect of a Geriatric Assessment-guided Intervention (GAIN-S) on patient responses to prognosis items over time between two arms. **Methods:** Eligible participants, aged 65+, diagnosed with metastatic solid cancers, and undergoing treatment across multiple Brazilian states, were randomized 1:1 into two arms. The GAIN-S included a geriatric assessment (GA), which devised tailored treatment based on identified impairments. Patients in the usual care (UC) arm received standard care. Both arms completed the Illness and Prognostic Awareness Impact Questionnaire (PAIS) at baseline (T1) and 12 weeks (T2), assessing Emotional (10 items; range 0-30) and Adaptive (12 items; range 0-36) domains; each rated on a 4-point Likert scale The change in PAIS (T2 - T1) was calculated for each participant in both the GAIN-S and UC arms, and then the mean changes in PAIS between the two arms were compared via independent t-test. **Results:** Eighty-six patients were approached; 80 provided consent (93% enrollment rate). At 12 weeks, the analytic sample included 77 patients. Demographic characteristics were well-balanced between arms, with a mean age of 74.5 years (SD=6.1), primarily female (55.8%), self-identified as White (71.4%), and 50.4% had at least a college education. The most common cancer types were genitourinary (29.9%), breast (24.7%), and gastrointestinal (22.1%). At T1, no significant differences were noted in PAIS between arms. However, there was significant improvement in PAIS Emotional (UC: mean change=-0.26, SD=1.6 vs GAIN-S: mean change=0.87, SD=1.4; P=0.002) and Adaptive (UC: mean change=-0.07, SD=0.6 vs GAIN-S: mean change=0.74, SD=1.7; P=0.008) domains between in the GAIN-S arm (Table). **Conclusions:** This secondary analysis highlights the impact of GA-guided care on improving prognostic awareness in older adults with metastatic cancer. GAIN-S resulted in significant improvements in Emotional and Adaptive domains compared to UC. Tailored interventions addressing the specific needs of older adults with metastatic cancer may enhance understanding of prognosis and improve adaptive responses. Studies are needed to determine whether these differences translate into meaningful improvements in outcomes. Research Sponsor: None.

Impact of GAIN-S intervention on prognostic awareness.

	Change over time			
	Arm 1 (T2-T1) Mean (SD)	Arm 2 (T2-T1) Mean (SD)	Difference Arm 2 - Arm 1 (SE)	p-value
Emotional Domain 10 items (range: 0-30)	-0.263 (1.62)	0.872 (1.44)	**1.135 (0.35)**	**0.002**
Adaptive Domain 12 items (range: 0-36)	-0.079 (0.67)	0.744 (1.73)	**0.823 (0.30)**	**0.008**

National cancer system characteristics and global pan-cancer outcomes. First Author: Edward Christopher Dee, Memorial Sloan Kettering Cancer Center, New York, NY

Background: Approximately 29.9 million cancer cases and 15.3 million deaths are anticipated by 2040 globally. Health systems must invest in cancer system strengthening. A greater understanding of health system factors that can be leveraged to improve cancer control may guide health system planning. Therefore, we conducted a pan-cancer ecological study making use of most recent available national health system metrics for cancer outcomes and health system metrics, spanning the breadth of global income levels across 185 countries. **Methods:** Estimates of age-standardized mortality-to-incidence ratios were derived from GLOBOCAN 2022 for patients with cancer of all ages. Health spending (% of gross domestic product [GDP]), physicians/1000population, nurses and midwives/1000population, surgical workforce/1000population, GDP per capita, Universal Health Coverage Service Coverage Index (UHC index), availability of pathology services, human development index, gender inequality index, radiotherapy centers/1000population, and out-of-pocket expenditure as percentage of current health expenditure were collected. The association between MIR and each metric was evaluated using univariable linear regressions. Metrics with $P < 0.0045$ (Bonferroni corrected) were included in multivariable models. Variation inflation factor allowed exclusion of variables with significant multicollinearity. R2 defined goodness of fit. **Results:** On univariable analysis, all metrics were significantly associated with MIR of cancer ($P < 0.001$ for all). After including metrics significant on univariable analysis and correcting for multicollinearity, the final multivariable model had R2 of 0.8729. Therefore, the following variables were associated with lower (improved) MIR for cancer: 1) nurses/midwives per 1000 population ($\beta = -0.0049$, $P < 0.057$), 2) UHC index ($\beta = -0.0042$, $P < 0.001$), 3) radiotherapy centers per 1000 population ($\beta = -11.21$, $P = 0.072$), and 4) GDP per capita ($\beta = -1.7x10\text{-}6$, $P < 0.001$). On analysis stratified by sex, the following were associated with improved MIR for all cancers among females: 1) UHC index ($\beta = -0.0042$, $P < 0.001$), 2) GDP per capita ($\beta = -9.9x10\text{-}7$, $P = 0.02$), and 3) gender inequality index ($\beta = 0.13$, $P = 0.084$) (R2 0.8699). The following were associated with improved MIR for all cancers among males: 1) nurses/midwives per 1000 population ($\beta = -0.0053$, $P = 0.066$), 2) UHC index ($\beta = -0.0042$, $P < 0.001$), 3) radiotherapy centers per 1000 population ($\beta = -12.37$, $P = 0.076$), 4) GDP per capita ($\beta = -2.31x10\text{-}6$, $P < 0.001$) (R2 0.8485). **Conclusions:** This comprehensive pan-cancer analysis of health system metrics suggests progress towards UHC, strengthening the nursing/midwifery workforce, facilitating access to services such as radiotherapy, and mitigating gender inequality are key priorities in cancer control. These generalizable findings may guide efforts to strengthen cancer systems throughout the world. Validating Navya Earthshot: An AI-enabled point-of-care solution for guideline-adherent treatment planning in a decentralized cancer care model. First Author: Umesh Mahantshetty, Tata Memorial Hospital, Homi Bhabha National Institute, Homi Bhabha Cancer Hospital & Research Centre, Visakhapatnam, India

Background: Adherence to guidelines increases overall survival, globally. In resource-constrained settings, ~ 30% of patients receive undertreatment or overtreatment. Despite significant investment in decentralized cancer care—with tertiary hub centers providing support to non-specialized spoke centers—shortage of oncologists creates a knowledge gap, which may be partially addressed by clinically validated AI solutions. Navya is a clinically validated AI solution for cancer patients in use since 2014 which matches patient-specific data to evidence and generates treatment recommendations vetted via asynchronous expert review. Navya Earthshot is a new, provider facing solution for point of care cancer treatment planning for non-specialized providers, and is built as an AI driven search interface on Navya's validated domain model supporting subspecialized expert opinions in oncology. **Methods:** This multicenter, prospective validation took place at 25 hospitals across India participating in a decentralized cancer care model. All patients with breast, oral and lung cancerbetween January and June 2024 with all decisions (curative and palliative; local and systemic therapies) were included. Navya Earthshot matched input patient data available in the patient medical record with National Cancer Grid (NCG) guidelines, and output evidence based treatment plans at the point of care. The output was shared at each center, and concordance was scored by the tumor board/treating oncologists, as well as by a group of domain experts experienced in analyzing NCG guidelines. **Results:** Navya Earthshot processed 1787 decisions in a decentralized cancer care system, pertaining to 40% (725) breast, 20% (351) oral, 40% (711) lung cancer diagnoses respectively. Patients were well represented with respect to age ($<$ 45 years (23%) and $>$ 45years (77%), and early stage (24%); advanced stage (58%) and incomplete diagnostic workup (18%)). Of the 1787 decisions, Navya Earthshot output referred 27% (478) to hub center tumor boards due to presence of uncommon histologies or scenarios not covered by the NCG guidelines (3rd line therapy etc.). In the remainder 73% (1309) decisions, Navya Earthshot output diagnostic or treatment plans. Of these, 85% (1114/1309) were scored concordant with NCG guidelines, and adopted by the local treating oncologist. The remaining 15% (195) decisions were referred to a hub center for treatment planning. **Conclusions:** Navya Earthshot can improve capacity of oncologists in resource-constrained settings and enhance adherence to guideline-driven care in a decentralized cancer care model. In a majority of cases, this point-of-care solution can improve access to care locally, reduce reliance on tertiary hub centers, and improve patient outcomes, globally. Research Sponsor: None.

Advancing global equity in cancer care: Comparative environmental impacts of radiotherapy in Brazil and the U.S. First Author: Katie Lichter, Department of Radiation Oncology, University of California, San Francisco, San Francisco, CA

Background: Climate change poses a significant threat to global health, necessitating efforts to address the environmental impacts of oncology care, particularly in low- and middle-income countries (LMICs). Radiation therapy is a cornerstone of cancer treatment, yet its delivery often involves high energy consumption and resource use, contributing to environmental degradation and inequities in health outcomes. Despite these challenges, the environmental footprint of radiotherapy in the Global South remains largely unexplored. This study quantifies the environmental impacts of radiotherapy in Brazil, compares these findings to external beam radiation therapy (EBRT) delivery in the U.S., and explores how sustainable practices may promote equity by reducing operational costs and expanding access to radiation therapy in underserved regions. **Methods:** A life cycle assessment (LCA) of EBRT for ten cancer disease sites was conducted at a radiation oncology clinic (Vitta) in Brasília, Brazil, following ISO 14040 and 14044 standardized methodology. Data on medical supplies, equipment usage, building energy consumption, and staff and patient travel from 2018-2023 was analyzed to assess environmental impacts across nine categories, including greenhouse gas emissions, air pollution, and carcinogenic potential. These results were compared with a previously published LCA of EBRT across four U.S. healthcare centers. **Results:** Radiotherapy at Vitta had a lower environmental impact across all categories compared to U.S. centers. Transit-related emissions were the largest contributor at Vitta, though they remained lower than those in the U.S. due to shorter travel distances (median 15 miles/week by public transit at Vitta vs. 48–90 miles/week by car in the U.S.). Vitta's reliance on hydroelectric energy eliminated emissions from building heating and reduced cooling-related emissions to 9.3% of the clinic's total footprint, compared to 74.0% at U.S. sites using mixed-grid electricity and natural gas. However, impacts from medical supplies at Vitta were higher across all categories, reflecting opportunities for resource optimization. **Conclusions:** This study provides novel insights into the environmental impact of radiotherapy in an LMIC context, underscoring the importance of regional differences in care delivery. The reduced environmental footprint at Vitta highlights the value of sustainable practices, such as renewable energy and public transit, in mitigating the health sector's climate impact while reducing operational costs. These findings support the development of adaptable, scalable models for global radiation oncology, particularly in publicly funded and rural clinics, to expand access and promote equity in cancer care. Future research should prioritize environmentally sustainable strategies that align with the unique needs of LMICs and underserved populations. Research Sponsor: None.

Achieving global breast cancer initiative key performance indices for breast cancer patients in Botswana by HIV status. First Author: Tara Friebel-Klingner, Johns Hopkins University, Baltimore, MD

Background: Low- to middle-income countries have disproportionately higher breast cancer (BC) mortality rates, partly due to late-stage diagnosis. In people with HIV (PWH), BC mortality is worse compared to those without HIV. The WHO's Global Breast Cancer Initiative (GBCI) proposes to reduce mortality through 3 identified pillars: (1) health promotion for early detection with at least 60% of invasive BC diagnosed at stage 1 or 2; (2) timely diagnosis, where evaluation, imaging, and pathology are completed within 60 days from first doctor's appointment; and (3) $\geq$80% of patients completing treatment. Few real-world data exist on these key performance indices in PWH. Understanding the influence of clinical and demographic factors associated with achieving the GBCI pillars can inform tailored interventions to increase BC survival. We aimed to assess pillars 1 and 2 in BC patients presenting to a referral hospital in Botswana, by HIV status. **Methods:** This prospective BC cohort included patients $>$18 years, presenting for BC care at Princess Marina Hospital between 2015 and 2023. Patients with unknown HIV status and/or unknown stage were excluded. Pillar 1 was assessed using the cancer stage documented in the medical chart. Pillar 2 was assessed using patient recall of first-contact with health facility and pathology report date. We characterized socioeconomically disadvantaged districts as those with poverty rate $\geq$20% and $<$ 100% of the population living within 5km from a health facility. Descriptive statistics and logistic regression were used. Results were stratified by HIV status. All p-values were two-sided. Data was analyzed using STATA 18.5. **Results:** 655 patients (median age: 51.2, IQR 42.4, 63.4) met eligibility criteria. 212 (31.8%) were PWH and 11 (1.7%) men. 180 (27.1%) attained pillar 1, and 59 (9.3%) attained pillar 2. PWH were younger (48.9 vs. 58.6; $p < 0.001$) and more likely to be single (70.3% vs. 47.3%; < 0.001). There was no significant difference between rates of PWH and those without HIV achieving both pillar 1 (23.1% vs 28.9%, p = 0.12) and pillar 2 (11.4% vs 8.3%, p = 0.2). However, PWH had a significantly shorter interval from first contact with the health facility to completed pathology (11.9 months vs. 20.1 months, p = 0.013). There was no significant difference between residents of socioeconomically disadvantaged districts versus non-residents in achieving pillar 1 (29.7% vs. 27.0%, p = 0.72) or pillar 2 (8.3% vs. 9.3%, p = 0.84). **Conclusions:** Majority of BC patients presenting to the referral hospital in Botswana did not achieve the GBCI pillars 1 and 2. However, PWH had significantly less diagnostic interval, which may be reflective of frequent contact for PWH in established care and may present an opportunity for care integration for PWH. Early detection and patient navigation interventions may potentially help Botswana achieve the WHO's GBCI goals and reduce BC mortality. Disparities in exercise referral practices and barriers among oncologists in public and private institutions in Latin America. First Author: Paulo Gustavo Bergerot, Oncoclínicas&Co, Medica Scientia Innovation Research (MEDSIR), Sao Paulo, Brazil

Background: Exercise offers significant benefit for patients with cancer, improving physical function, quality of life, and treatment-related outcomes. However, barriers such as limited referral practices and insufficient knowledge hinder its integration into care. This study compared referral practices, exercise assessment, and physicians' perceptions in public (PUB) and private institutions (PRI). **Methods:** A cross-sectional survey of 454 physicians from 21 Latin American countries was conducted using a 25-item questionnaire on referral practices, patients' exercise habits, and perceived barriers and facilitators to implementing exercise programs. Descriptive statistics summarized respondent characteristics and adherence to exercise-related practices. Chi-square tests were used to compare differences in referral practices and perceived barriers/facilitators between physicians working in PUB versus PRI institutions. **Results:** Out of 454 participants, most were from PUB (52%), mainly from Mexico (17%), Brazil (12%), and Colombia (10%). In the PRI (48%), Brazil led with 51%, followed by Argentina (18%), and Peru (8%). Female representation was higher in PUB compared to PRI (57% vs. 43%, P = 0.01). Physicians in PUB were less likely than those in PRI to assess exercise habits (53% vs. 18%, P = 0.001), refer patients (72% vs. 36%, P = 0.001), or provide guidance (56% vs. 12%, P = 0.001). Resource limitations were more common in PUB (e.g., no referral location: 86% vs. 70%, P = 0.04). Barriers included treatment side effects (PUB: 66% vs. PRI: 40%, P = 0.001) and lack of knowledge on prescribing exercise (PUB: 63% vs. PRI: 27%, P = 0.001). Physicians in PUB emphasized facilitators like access to qualified professionals (90% vs. 66%, P = 0.001) and personal experience (90% vs. 80%, P = 0.01). **Conclusions:** This study reveals significant disparities in cancer exercise practices between oncologists in public and private institutions across Latin America. Oncologists in public institutions were less likely to assess exercise, refer patients to exercise programs, and provide guidance. They also reported greater barriers, such as treatment side effects and lack of knowledge on exercise prescription and resources. Facilitators such as access to qualified professionals were less prominent in public institutions. These findings highlight the need for targeted interventions to improve exercise integration in cancer care, particularly in resource-limited settings. Research Sponsor: None.

Investigating gender demographics and equity among hematologists. First Author: Florence Broussais, Institut Carnot CALYM, Lyon, France

Background: Despite a substantial number of women in the field of hematology, representation in leadership roles remains inconsistent with ~50% of women among medical graduates in many countries. This survey of hematologists sought to examine gender demographics and explore experiences with professional development including mentorship, involvement in and leadership of clinical trials, and opportunities for career advancement. **Methods:** An international online survey of hematologists was developed collaboratively with the Women in Lymphoma (WiL) global organization in partnership with the HERmatology initiative (AstraZeneca). It was distributed to and by the membership of WiL. All participants were licensed medical practitioners, self-characterized on gender, age, years of practice, country of practice, and seniority of role. Statistical differences between males and females were calculated by pairwise z-tests with a significance level of 90%. **Results:** From October to December 2024, 237 hematologists from 34 countries were surveyed: 182 female and 55 male. The proportion of females to males in hematology practices significantly favored females (53% [51, 56] vs. 47% [44, 49]). Heads of Department (60% [55, 66] vs. 40% [35, 45]) and direct supervisors (59% [54, 64] vs. 41% [36, 46]) were significantly more likely to be male. Females reported serving as Principal Investigator significantly less frequently for industry-sponsored clinical trials over the past 12 months than males (2.1 vs 0.9, $p < 0.1$), but no significant differences as a Site Investigator (3.4 vs 2.4, p = 0.2). No differences were observed in female vs. male participation or leadership in cooperative group / academic clinical trials. There was a trend for fewer female physicians invited to write an article or publication in the past 12 months compared to males (2.7 vs. 4.2, p = 0.15), as well as fewer opportunities to receive public recognition from a senior colleague (1.1 vs. 1.9, p = 0.15). Females overall were significantly less likely to have clinical ($p < 0.1$) or career mentors ($p < 0.1$), but earlier-career females were more likely than later-career females to have both ($p < 0.1$). 'Family or caregiving responsibilities' was the top factor discouraging women from pursuing careers in hematology (86% agreed), followed by a 'Lack of representation of women in leadership positions' (59% agreed). **Conclusions:** Differences were noted between males and females across several career dimensions, including representation in leadership roles, involvement in industry-sponsored clinical trials, and access to mentorship. These results underscore the continued need for systematic efforts to reduce unconscious bias and promote greater diversity within hematology. Providing additional structured support, particularly to boost female leadership in industry-sponsored trials, will help advance gender equity, ultimately benefiting both medical progress and patient outcomes. Research Sponsor: None.

Clinical profiles, patient expectations and outcomes from an integrative oncology clinic in India: A novel integrated model of care in oncology. First Author: Kanakavalli K. Kundury, JSS Academy of Higher Education & Research, Mysuru, India

Background: Integrative approaches are used in Oncology care, often as an auxiliary measure to the Standard of Care (SoC). There is paucity of data regarding Integrated oncology model approach combining alternate systems of medicines like Ayurveda & Siddha, Yoga and Dietary modification recommendations along with SoC . In this study, we present an audit of this novel Integrated oncology model of care provided by online and in-patient consultations at Isha Integrative Oncology Clinic (IIOC), Isha Health Solutions (IH), Coimbatore, India. **Methods:** A clinical audit was conducted for 514 patients who have received care through Integrated oncology consultations (in-person or online) at IIOC from January 2016 to July 2024. This abstract focuses on the statistical analysis of data of the initial 196 consecutive patients based on descriptive data from clinical proformas and follow-up visits for symptomatic response outcomes. Updated data will be presented at the conference. **Results:** Among 196 patients analysed, 99% of patients had online consultations. The median age was 52yrs (7-81yrs) and Male: Female ratio was 1: 1.3. 50% belonged to age group 40-60 yrs whereas 29% were between 60-85 yrs. Most common cancers in males were hematological cancers (20%), prostate cancers (11%), GI cancers (11%) and in females were breast (26%), ovary (10%) and colon (5%). The most common stage was Stage 4 (58%) followed by Stage 3 (40%). Most common symptoms were pain (49%), anorexia (43%), fatigue (42%), lack of sleep and anxiety (39%). Most common side effects of chemotherapy were fatigue (32%), constipation (25%), anorexia/weight loss (25%), pain (16%) etc. Most common expectations were cure/avoid relapse (32%), symptomatic relief (15%), reduction from chemotherapy side effects (11%), integration of Yoga (10%) etc. Only 6% of patients wished to avoid chemotherapy. Integrated oncology model based on complementary systems of medicine (Ayurveda & Siddha), dietary changes and yoga was provided to all patients (100%). After using this model of care, improvement in cancer-related symptoms was reported by 90% of patients and compliance seen in 73% of patients. **Conclusions:** Our study is one of the largest clinical audits in Integrative oncology in published literature. Younger patients and advanced cancer patients more often seek integrative oncology care and main expectation is to achieve better cure rates and symptomatic relief. In this study, all patients were provided a novel integrated oncology model with alternative medicines (Ayurveda & Siddha), yoga, and dietary modifications in addition to their ongoing SoC resulting in good symptomatic relief and high compliance rates. Integrative oncology model incorporating alternative medicine, yoga, and dietary changes can be effectively offered to cancer patients alongside standard treatment. Further prospective studies are warranted. Research Sponsor: None.

How do health concerns present in cancer survivors who require interpreters? Database analysis of a structured survivorship clinic for early-stage cancer. First Author: Lawrence Kasherman, Concord Clinical School, Faculty of Medicine and Health, University of Sydney, Concord, NSW, Australia

Background: Cancer survivors (CS) of Culturally and Linguistically Diverse (CALD) backgrounds face disparities in care. We aimed to compare demographics and health concerns of CALD CS with non-CALD CS following completion of primary treatment. **Methods:** The Sydney Cancer Survivorship Centre (SCSC) database was analyzed to compare baseline differences in demographics and health concerns between early-stage CS of solid tumor or hematologic cancers requiring interpreters (CALD CS) during initial consultations to those who did not (non-CALD CS). Descriptive statistics were used to illustrate distribution by age, gender and tumour type. Survivors completed questionnaires on symptoms, quality of life (QoL), distress, exercise time and were assessed by a psychologist for fear of cancer recurrence (FCR). Univariate analyses were used to determine differences at presentation to the survivorship clinic between CALD and non-CALD groups. **Results:** From September 2013 to April 2024, 939 initial consultations (median 10.9 months from diagnosis) with consenting CS were conducted at SCSC. 15% (n = 137) required interpreters in 21 different languages (Mandarin (n = 48, 35%), Korean (n = 26, 19%) and Cantonese (n = 19, 14%)): 83 (61%) used professional interpreters, 25 (18%) family/friends. CALD CS were more likely to be female (58%), aged 40-64 (51%) and have colorectal cancer (55%). Common symptoms in CALD CS of at least moderate severity included fatigue (39%), numbness (32%), and pain (31%), not significantly different to non-CALD CS. Significantly lower proportions of CALD CS reported trouble concentrating (19 vs 29%, p = 0.023), hot flashes (14 vs 23%, p = 0.017) and problems with sexual function (12 vs 20%, p = 0.032). CALD CS were significantly more likely than non-CALD CS to report less minutes/week doing vigorous (13.2 vs 32.8; $p < 0.001$), moderate (32.3 vs 73.0; $p < 0.001$) and resistance exercise (4.6 vs 18.7; $p < 0.001$), but more light exercise (219.6 vs 115.5; p = 0.041). Mean global FACT-G QoL score for CALD CS was 77.4 (SD 20), with physical (mean 21.4, SD 6) and emotional (mean 17.6, SD 5) domains most impacted; these were not significantly different from non-CALD CS scores. There were no significant differences between groups in mean distress thermometer scores (3.09 vs 3.39/10; p = 0.288), rates of moderate-to-severe distress (36 vs 41%; p = 0.952) or rates of psychologist-assessed moderate-to-severe FCR (19 vs 28%; p = 0.228). **Conclusions:** CALD CS experience similar physical and psychosocial health concerns to non-CALD CS at initial survivorship clinic consultations but are less likely to report issues with sexual function, concentration and hot flashes, and are more likely to exercise less. Future work should focus on longitudinal effects and comparisons over time, with particular focus on addressing cultural sensitivities and increasing exercise intensity. Living beyond cancer: The long-term impact of breast cancer diagnosis on cognitive function. First Author: Cheng Peng, Brigham and Women's Hospital, Boston, MA

Background: While some clinical studies report greater cognitive difficulties in middle-aged women diagnosed with and treated for breast cancer over the short-term, observational studies of older persons, with longer follow-up, found that a history of cancer was associated with lower Alzheimer's disease risk. We estimated the relation of breast cancer and treatment history with cognitive status and rate of decline among older women. We further divided breast cancer survivors by: (1) time since cancer diagnosis (assessing recency), (2) age of cancer onset (reflecting body aging at diagnosis), and (3) stage (capturing disease aggressiveness). To evaluate any overlap in shared or opposing genetic risk, we estimated cognitive status by breast cancer polygenic risk score (PRS). **Methods:** A cognitive sub-study was initiated in 1995-2001 in the Nurses' Health Study, including 1,378 breast cancer survivors and 14,196 cancer-free women. Breast cancer diagnoses were self-reported and confirmed by medical records; treatment was self-reported. Cognitive function was assessed up to 4 times (over a mean of 6.6 years) and combined into 4 outcomes: global composite score, Telephone Interview for Cognitive Status (TICS), verbal memory, and working memory. We used linear models to assess breast cancer history and treatment with cognitive status (averaged across follow-ups). We used mixed-effects models to assess breast cancer history and treatment with rate of cognitive decline. We computed a breast cancer PRS and evaluated cognitive function across quartiles of PRS. **Results:** The mean age of breast cancer diagnosis was 65.4 years, and the mean time between cancer diagnosis and baseline cognitive assessment was 8.6 years. We observed similar distributions of key risk factors for AD between women with and without history of breast cancer, including age, education, depression, and physical activity. No significant differences in global cognitive status were noted comparing women with a history of breast cancer with those who were cancer-free. Associations did not differ by age of cancer onset ($<$ 65 vs. $\geq$65 years), time since diagnosis ($<$ 5 vs. $\geq$5 years), or stage. Genetically predicted breast cancer risk was not associated with the global cognitive status. Women with breast cancer and treated with hormone therapy, chemotherapy, and/or radiation therapy had similar global cognitive status compared to cancer-free women. No significant differences by breast cancer history were observed for TICS, verbal memory, or working memory. Over the modest follow-up time, we observed no significant differences in cognitive decline between women with a history of breast cancer and cancer-free women. **Conclusions:** We observed no association of history of breast cancer or breast cancer treatment with cognitive function status or rate of decline, suggesting there is neither harm nor benefit of breast cancer diagnosis on long-term cognition. Research Sponsor: National Institute on Aging.

Blended survivorship and palliative care for patients with advanced lung cancer receiving targeted therapy: An open pilot. First Author: Laura A. Petrillo, Massachusetts General Hospital, Boston, MA

Background: Targeted therapy improves survival and quality of life for patients with advanced non-small cell lung cancer (NSCLC) with driver alterations. However, advanced NSCLC remains incurable, and the timing of progression on targeted therapy is unpredictable. Thus, many patients live with an abiding, distressing sense of uncertainty. To better support patients with advanced NSCLC receiving targeted therapy, we 1) developed and refined a blended early palliative care and survivorship intervention and 2) conducted an open pilot to further refine the intervention. **Methods:** We conducted a review of evidence and prior palliative care and behavioral health interventions to inform the development of POISE, a structured, supportive care intervention for patients with advanced NSCLC receiving targeted therapy, in which trained palliative care clinicians aim to enhance patient coping with uncertainty, setting lifestyle goals, and prognostic awareness. To refine POISE, we first conducted qualitative interviews with 20 community partners, including patient/caregiver advocates, palliative care clinicians, psychologists, and oncologists. We elicited feedback on POISE intervention content and delivery. We used rapid analysis to analyze interview transcripts and identified themes, with which we finalized POISE (4 monthly one-hour palliative care visits). We then conducted an open pilot study of POISE among 10 patients diagnosed with advanced NSCLC with a targetable mutation (i.e., EGFR, ALK, ROS1 or RET) in the past 6 months who were receiving care at a single academic cancer center. All participants received POISE and completed self-report surveys at baseline and at 12 and 20 weeks. Participants rated their satisfaction with POISE and completed exit interviews at 20 weeks. We used a framework approach to analyze exit interviews and identify themes for further intervention refinement. **Results:** Qualitative interviews highlighted a need to strengthen the POISE clinician training and supervision plan to increase palliative care clinicians' behavior modification therapy skills. We revised the POISE manual to be more flexible to accommodate patient choice in session focus and added a list of community organizations to support ongoing behavior change. With the revised intervention, we then initiated the POISE open pilot. We approached 13 eligible patients, of whom 10 (mean age = 67 years, 5 female, 5 male) consented to participate. Most (8/10) patients completed all 4 sessions and all surveys. All (8/8) patients reported that POISE was helpful and would recommend it to others. In exit interviews, patients suggested incorporating caregivers in sessions and adding a patient-facing workbook to assist with skill acquisition. **Conclusions:** POISE warrants further study in a feasibility pilot randomized controlled trial. Clinical trial information: NCT04900935. Research Sponsor: National Cancer Institute.

Experiences and preferences of cancer survivors across the immunotherapy journey. First Author: Shelley Fuld Nasso, National Coalition for Cancer Survivorship, Silver Spring, MD

Background: Immuno-oncology (IO) drugs are recommended by guidelines for several tumor types and can significantly improve survival in patients with cancer. As patients experience long-term care due to extended survival, it is important to understand the challenges of survivorship and experiences receiving IO. Here, we present IO treatment experiences and preferences for IO based on modes of administration among cancer survivors. **Methods:** A web-based survey was administered to US cancer survivors in the fall of 2024. Patients were recruited via physician referral and were eligible to participate if they were $\geq$ 18 years of age, diagnosed $\geq$ 1 year prior with any solid tumor cancer (any stage), and received IO within the past 5 years. The survey included the Quality of Life-Cancer Survivor (QoL-CS) scale (range 0–10; higher scores indicate better QoL) and a direct preference exercise. The preference exercise asked patients to indicate whether they would prefer IO be administered via subcutaneous (SC) injection or intravenous (IV) infusion and asked patients to rank the influence of common characteristics of each administration on preferences. Study variables were analyzed descriptively. **Results:** The mean (standard deviation [SD]) age of patients (N = 100) was 57.8 (7.2) years; 46% were White and 51% were male. The most common tumor types reported were lung (26%), melanoma (14%), kidney (12%), and colon (10%). Mean (SD) time since cancer diagnosis was 4.1 (2.7) years and mean time since starting IO was 2.4 (1.5) years. Most (72%) patients reported that a typical visit for receiving an infusion lasted between 1–2 hours and most (56%) traveled 30–60 minutes to receive their infusion. Some patients experienced interrupted access to their most recent IO treatment due to transportation delays (24%) and not having someone to accompany them to treatment (24%). The average QoL-CS score was moderate (mean [SD], 5.1 [1.3]) and 57% of patients agreed that IO improved their QoL. Yet, 42% and 48% noted that daily activities and physical health, respectively, were negatively affected by their most recent IO treatment. Most patients (92%) preferred a hypothetical SC injection over IV infusion; the top SC injection characteristics influencing this preference were no need to access the vein with an IV catheter, the amount of time it takes to be administered (described as 5 vs 30 minutes), and the potential for more flexibility in scheduling/location of receiving IO treatment. **Conclusions:** Our study found that IO treatment improved the QoL of most cancer survivors. However, challenges to receiving IO, including the time required for travel and administration, were common. Most patients in our sample would prefer a SC administration of IO over an IV infusion, suggesting that less-invasive modes of administration requiring less time and greater flexibility may present opportunities to improve the patient treatment experience. Research Sponsor: Bristol Myers Squibb.

Health related social needs in an urban academic breast cancer survivorship program. First Author: Mumtu Lalla, Montefiore Einstein Comprehensive Cancer Center, Bronx, NY

Background: Health-related social needs (HRSN) impact cancer care and are associated with late stage at diagnosis (dx), prolonged time to therapy initiation, and poor outcomes. Little data exists regarding long-term impact of cancer dx and therapy on HRSN in late survivorship. We evaluated associations of cancer therapies with HRSN in a diverse cohort of breast cancer (BC) survivors seen in an urban academic medical center. **Methods:** HRSN screening was completed by BC survivors seen in the cancer center survivorship program in 2023. Survivors were 4 or more years (yrs) from dx of Stage 0 to III BC, with all therapy complete (including endocrine therapy) and no evidence of metastasis. HRSN screens were compared with those completed by newly diagnosed (dxed) BC patients (pts) and adult general medical pts. Charts of survivors were reviewed for details of BC dx and treatment [stage, hormone receptor (HR) and HER2 status, type of surgery, and use of chemotherapy, radiation, and endocrine therapy]; as well as demographic data (age, race, ethnicity, insurance status, ZIP code). Neighborhood distress was categorized using Distressed Communities Index (DCI). Associations of clinical and demographic factors with HRSN in BC survivors were evaluated by Chi-Square and ANOVA tests. **Results:** 465 BC survivors [177 (38%) Black, 228 (49%) Hispanic] completed HRSN screening. Median age at assessment was 68 (range 43-98) and at dx was 57 (range 27-89); median time from dx was 11.25 yrs (range 4-35). 63.5% resided in distressed ZIP codes; 26.4% in at-risk ZIP codes. Most common HRSN in survivors completing their first HRSN screen (n = 395) were housing quality (5.3%) and food insecurity (4.8%). BC survivors were less likely to endorse HRSN than newly dxed BC pts (16.7% vs 24.0%, p = 0.03), but had similar HSRN as general medical pts (16.7% vs 14.6%, NS). Among survivors, younger age at BC dx (p = 0.006) and at HRSN screen (p = 0.004) was associated with greater risk of HRSN, with pts dxed prior to 57 almost twice as likely to endorse HRSN as those dxed after 57 (22.7% v 12.6%, p = 0.004). Younger survivors with HRSN were more likely to reside in distressed ZIP codes (p = 0.03). Hispanics seen in new survivorship visits were more likely to endorse HRSN than Hispanics seen in follow-up and than non-Hispanics seen in new or follow-up visits (p = 0.03). Race, insurance status, time from BC dx, stage, HR and HER2 status, extent of surgery, and use of chemotherapy, radiation, or endocrine therapy were not significantly associated with HRSN in survivors. **Conclusions:** In this diverse cohort, late BC survivors had similar HRSN prevalence as general medical pts. Younger age was associated with greater HRSN in survivors, while BC stage, receptor status, and extent of treatment were not. Hispanics presenting for first survivorship visit endorsed greatest HRSN. These findings have implications for interventions targeted to young survivors and for culturally sensitive survivorship care. Research Sponsor: None.

1637 **Poster Session**

Feasibility trial of health coaching-based navigation after breast cancer treatment. First Author: Ruvarashe Rumano, The Ohio State University, Columbus, OH

Background: Following breast cancer diagnosis, 25% of survivors experience psychosocial needs like depression, anxiety, and fear of recurrence. Integrative survivorship support services address these needs, but participation is lower among Black women, who report higher psychosocial distress. Patient navigation has emerged as a strategy to reduce these barriers. This study piloted a navigation-based intervention aimed at improving psychosocial symptom management over 6 months. **Methods:** A single-arm feasibility trial was conducted with Black breast cancer survivors from November 2022-June 2024. Women aged 18+ with non-metastatic breast cancer were recruited. A trained lay navigator provided personalized support and resource facilitation to address psychosocial and healthcare challenges. Interactions were analyzed qualitatively to assess preliminary impact. Surveys administered at baseline and post-intervention included the Life and Longevity after Cancer, Patient Reported Outcomes Measurement Information System, and Breast Cancer Survivorship Experience Survey, with responses measured on a Likert scale. Quantitative data were analyzed descriptively. **Results:** Of 21 Black women who consented (mean age 64), 18 began the study while 3 did not proceed beyond consent. Of these, 44.4% completed all six months, while 61.1% completed three months. Eight participants completed post-surveys. All participants found the study easy to join, 5/8 found its length appropriate, and 6/8 were satisfied with session intervals. All would recommend the program, and 4 preferred in-person sessions. Participants reported confidence in accessing future support programs. Key benefits included managing stress, family stressors, and improving community support. Qualitative analysis of 108 transcripts from 17 participants identified six themes: managing health challenges, communication, emotional well-being, resilience in daily life, program support, and future planning. Survey results showed improvements in well-being and self-efficacy. LILAC scores increased from 52.7 to 63.9, PROMIS physical scores rose from 12.4 to 13.3, and mental scores improved from 13.3 to 15.6. Self-efficacy decreased slightly in BCSES scores from 53.6 to 52.5. **Conclusions:** Among Black breast cancer survivors, 61% completed biweekly sessions during the first 3 months, with a drop in participation after transitioning to monthly sessions. Participants reported benefits in addressing distress and accessing support programs. Future efforts should focus on tailored strategies to enhance engagement and retention. Research Sponsor: OSUCCC Intramural Research Program; Speilman Fund.

Predicting overall survival in adults with cancer in the US using machine learning approaches integrating comprehensive social risk factors. First Author: Yiwang Zhou, St. Jude Children's Research Hospital, Memphis, TN

Background: Adults with cancer in the U.S. face an elevated mortality risk compared to the general population, with social risk factors playing a critical role – particularly among those with comorbidities. However, traditional mortality risk prediction models often focus on treatment exposures and basic demographic factors, overlooking social risk factors. We aim to develop a machine learning (ML) model that integrates comprehensive social risk factors with traditional predictors to predict overall survival for adults with cancer in the U.S. **Methods:** We analyzed data from 6,181 nationally representative adults diagnosed with cancer from the National Health Interview Survey (NHIS; 2013-2014). A total of 74 risk factors, including basic demographics (e.g., age at the survey, sex, marital status, body mass index [BMI]), personal and household socioeconomic status (SES; e.g., education, food insecurity), lifestyle, social support, and health status (e.g., chronic health conditions [CHCs], disability), were included in modeling. The primary endpoint was 5-year overall survival from the survey completion date, with secondary endpoints of 1- and 2-year survival. Death from any cause after the survey was defined as an event, and subjects were censored 5 years post-survey. The sample was randomly split into 70% training and 30% testing. A random survival forest (RSF) model predicted survival. The time-dependent area under the receiver operating characteristic (AUROC) curve and the Brier score (BS) assessed the model performance. Both AUROC and BS range from 0 to 1, with higher AUROC for higher accuracy (discrimination) and lower BS for better alignment between predicted and observed risk (calibration). The Shapley additive explanations (SHAP) values were used to interpret variable importance in the established RSF model. **Results:** The mean age of subjects during the survey was 65.6$\pm$13.8 years, and 40.2% were male. For the established RSF model, the AUROC (mean $\pm$ standard deviation) for predicting 1-, 2-, and 5-year survival was 0.795 $\pm$ 0.026, 0.810 $\pm$ 0.018, and 0.831 $\pm$ 0.011, respectively, reflecting high and improved predictive accuracy over time. The BS for 1-, 2-, and 5-year survival was 0.039 $\pm$ 0.004, 0.065 $\pm$ 0.005, and 0.119 $\pm$ 0.005, respectively, indicating excellent calibration. The top five variables ranked by SHAP values include age at the survey (0.048), use of special equipment due to health problems (0.029), employment status (0.020), number of CHCs (0.016), and BMI (0.015). **Conclusions:** By integrating social risk factors with traditional risk predictors, we developed an ML model that predicts overall survival with high accuracy and excellent calibration for adults with cancer in the U.S. Identifying key risk social factors enables targeted interventions, potentially improving health outcomes and management for the adult cancer population. Research Sponsor: None.

Pioneering cancer survivorship care in Latin America: Early results from the OC sobre VIVER program in Brazil. First Author: Luciana Landeiro, Oncoclínicas&Co, Salvador, Brazil

Background: Cancer survivorship poses a growing challenge, especially in low- and middle-income settings. The OC SobreVIVER program, launched in October, 2020 by the Oncoclínicas Group, addresses survivorship care gaps by providing structured, multidisciplinary care. Initially piloted for breast cancer survivors in two Brazilian units, the program expanded in 2023 to include colorectal and prostate cancer survivors across eight states. This study presents preliminary data. **Methods:** This descriptive, observational study assessed the OC SobreVIVER program's impact on survivorship care. Multidisciplinary consultations involving oncologists, nurses, psychologists, and nutritionists addressed late toxicities, recurrence risk, and quality of life, following international survivorship guidelines. Telehealth and digital tools improved accessibility. Data from July, 2023 to December, 2024 included clinical characteristics, program metrics, and patient-reported satisfaction via EORTC PATSAT 33 and Net Promoter Score (NPS). Descriptive statistics summarized key outcomes. **Results:** From July 2023 to December 2024, the program supported 577 survivors (518 breast, 47 colorectal, 12 prostate) across 11 practices in eight states, with 490 initial consultations, 91 follow-ups, and over 20 support groups conducted.Virtual consultations were available to all patients, enhancing accessibility for underserved regions. Patient-reported satisfaction was high, with 95% of respondents classified as Promoters (scores 9–10) in the NPS, demonstrating strong program loyalty. Based on EORTC PATSAT 33 evaluations, over 80% of respondents rated their medical care experience in the highest satisfaction range (41–50), and over 80% rated their nursing care experience in the highest category (29–35). Minimal dissatisfaction was reported, with less than 2% of responses falling into the lowest satisfaction ranges ($<$ 20 for medical care and $<$ 14 for nursing care). **Conclusions:** The OC SobreVIVER program demonstrates the feasibility of a structured, multidisciplinary survivorship model in a private network across Brazil. Preliminary data highlight its effectiveness in addressing complex survivorship needs, enhancing accessibility through telehealth, and maintaining high satisfaction.This integrated, patient-centric approach ensures continuity of care across physical, social, psychological, spiritual, and nutritional dimensions, fostering a more comprehensive and holistic survivorship experience. Oncology primary care clinics for comprehensive care of high-risk adolescent and young adult (AYA) cancer survivors. First Author: Alique Gabrielle Topalian, University of Cincinnati, Cincinnati, OH

Background: Adolescent and young adult (AYA) cancer survivors experience early development of chronic medical conditions compared to healthy peers. Due to their young age at diagnosis and living decades beyond treatment, they are also at higher risk for second primary malignancies (SPM) and late effects than older adult-onset cancer survivors. Primary care providers are responsible for most long-term care of survivors and many are unfamiliar with the effects of cancer treatment in younger populations. Oncology primary care providers are uniquely positioned to address increased needs of AYA patients because of their additional survivorship expertise. **Methods:** In 2020, the University of Cincinnati Cancer Center established an oncology primary care clinic. An accompanying clinical registry was developed to track patient outcomes longitudinally Electronic medical records of all patients seen between 1/2021 and 1/2025 (n = 901) were extracted and entered in REDCap. Records of AYA cancer survivors, defined as cancer diagnosis between the ages of 18-39, were queried and analyzed (9%, n = 85). **Results:** The patient population's mean age was 36 yrs (range 20-74; std dev = 11.3). Hematologic cancers (37%) were most common followed by breast (13%) and brain (9%). Additionally, 14% were diagnosed with a SPM. Comorbid conditions were prevalent with 60% of patients having cardiovascular disease such as hypertension. Neurologic (46%), endocrine (44%), and psychologic (71%) co-morbidities were also common. Over half of patients were overweight/obese (68%) and many patients were former (19%) or current (7%) smokers. Eligible patients received their recommended cancer screening including breast (82%), colon (60%), and cervical (40%). Due to treatment exposures, 53% of patients were eligible for cardiomyopathy screening and 73% received recommended echocardiograms. A reduced ejection fraction was found in 26% of patients screened. **Conclusions:** Comprehensive primary care services and longitudinal monitoring are imperative in this high-risk population. Oncology primary care provides necessary survivorship-informed care and longitudinal monitoring for early onset comorbidities and SPMs. Tailored education and outreach efforts for providers and patients should address preventative health services needed in this high-risk population. Research Sponsor: None.

Risk and predictors of late second primary malignancies in long-term breast, prostate, colon, and rectal cancer survivors. First Author: Tendai Kwaramba, Department of Medical Oncology, Yale Cancer Center, Yale School of Medicine, New Haven, CT

Background: In older, long-term (5-year) cancer survivors, mortality risks from aging and treatment-related effects may surpass those of their index cancer. Second primary malignancies (SPMs) occurring 5-10 years post-diagnosis are understudied in older patients. This study aims to quantify SPM risk, identify predictors, and describe prevalent SPM sites in older survivors of breast, prostate, colon, and rectal cancer to guide survivorship care. **Methods:** This retrospective cohort study analyzed patients aged 66+ with stage I-III cancer diagnosed between 2003-2011 using the SEER-Medicare database. Eligible patients survived ≥5 years post-diagnosis and had continuous Medicare Parts A & B enrollment from 1 year pre-diagnosis to 1 year post-diagnosis. The primary outcome was late SPMs occurring 5-10 years after index cancer diagnosis. Covariates included demographics, comorbidities, index cancer characteristics, treatment, and early SPMs (diagnosed within 5 years). Least absolute shrinkage and selection operator for variable selection and 5-year restricted mean survival time regression models were used. Cumulative late SPM incidence was calculated with mortality as a competing risk. The prevalence of specific SPMs was calculated as a proportion relative to the total number of SPMs within each cohort, and categorized as hematologic, predominantly screen-detected (breast, prostate, colorectal), or other solid tumors. **Results:** Of the 88,227 long-term survivors included with median age of 73.3 (IQR 69.5-78), 6.2% developed early SPMs and 8.2% (7,231) developed late SPMs. The 5-year cumulative incidence of late SPMs was 8.6%, highest in prostate (9.2%) and lowest in breast (6.7%) cancer survivors. Non-screenable cancers had the highest 5-year risk (6.2%), followed by screen-detected (1.3%) and hematologic malignancies (1.1%). Lung was the most common SPM overall (18.4% of SPMs), including in survivors of breast (21%), rectal (19.2%) and colon (16.5%) cancers, while prostate was most common in rectal cancer survivors (17.0%). Diagnosis of SPM in the early (< 5 years) survivorship cohort was associated with shorter time to a new late SPM, particularly in prostate cancer survivors (RMST Ratio 0.97, 95% CI 0.96-0.98). Treatments and high-risk disease features showed no significant associations with occurrence of late SPMs. **Conclusions:** Late SPMs were diagnosed in 8.6% of older, long-term cancer survivors. Lung cancer was the most common SPM overall. Some screen-detected SPMs, such as prostate were also common which is notable in a population aging out of screening guidelines. Prediction of SPMs was limited by the absence of modifiable risk factors, genetic data, and family history in SEER-Medicare data. Early SPMs were the sole predictor of late SPMs while treatment and index cancer features showed no effect, suggesting other drivers of late SPM development in older survivors. Subtype-specific trends in lung cancer incidence and survival: A SEER analysis (2004–2021). First Author: Shubhank Goyal, University of Texas Rio Grande Valley, Mcallen, TX

Background: Lung cancer remains a leading cause of cancer mortality, with adenocarcinoma, squamous cell carcinoma (SCC), and small cell lung cancer (SCLC) as key subtypes. Advances in early detection (e.g., low-dose CT screening post-2013) and systemic therapies (e.g., targeted agents and immunotherapies [IO], approved 2015 for adenocarcinoma/SCC, 2018 for SCLC) have transformed care. However, links between incidence trends and survival outcomes remain unclear.This study leverages SEER data (2010–2021) to extend prior analyses (Howlader et al. 2000-2017, NEJM 2020) and evaluate subtype-specific trends, focusing on the post-2015 era of IO adoption and updated screening eligibility. **Methods:** Age-adjusted incidence and 3-year relative survival rates for adenocarcinoma, SCC, and SCLC were analyzed using SEER data (2004–2021), stratified by stage. Joinpoint regression identified significant trend changes. Survival shifts >2% annually were temporally linked to key milestones: low-dose CT screening (2013), EGFR/ALK inhibitors (2013), and IO (2015). **Results:** For adenocarcinoma, distant-stage survival rose from 12.8% (2011) to 23.0% (2018), with a sharp +3.1% annual increase in 2018 aligning with immunotherapy adoption. Localized and regional survival improved by 5.3% and 6.5%, respectively, over the study period. These trends probably reflect the combined impact of early detection and systemic therapies. In SCC, localized-stage survival increased from ~56% to ~66% after 2015, driven by earlier detection and reduced late-stage incidence. However, regional and distant-stage survival saw only modest gains (~7%), highlighting limited advancements for advanced disease. SCLC showed the least survival improvements despite declining incidence, largely attributed to reduced smoking. Distant-stage survival stagnated at ~4–6%, while localized-stage survival improved transiently by 17% from 2010 to 2012, likely reflecting temporary improvements in early-stage management. However, overall outcomes for SCLC remain poor, underscoring an urgent need for new therapies. **Conclusions:** Advancements in lung cancer treatment and cancer screening have led to significant survival gains. Adenocarcinoma's distant-stage survival improvements highlight the transformative impact of immunotherapy, while localized SCC gains emphasize the role of early detection and screening. SCLC remains a major challenge, with survival rates stagnating despite a steady decline in incidence. Further innovation in SCLC therapies, along with equitable access to both screening and novel treatments, is crucial to improving outcomes across all lung cancer subtypes. Survival data beyond 2018 for metastatic disease and post-2024 for localized disease (following IO approvals for respective indications) will provide deeper insights into the real-world impact of these therapeutic advancements. Research Sponsor: None.

Telehealth and cancer care delivery: An updated real-world analysis of the impact of telehealth on patient access and treatment utilization at a comprehensive cancer center. First Author: Kelsey H. Natsuhara, University of California, San Francisco Helen Diller Family Comprehensive Cancer Center, San Francisco, CA

Background: Telehealth in oncology (onc) has persisted due to its convenience and potential to improve equitable access to care. Data on telehealth's impact on treatment (tx) access are needed to guide long-term telehealth policies. **Methods:** We identified adult patients (pts) who completed ≥1 medical, surgical, or radiation onc visit with an associated cancer diagnosis at our center from 2017-2019 (pre-telehealth) vs 2021-2023 (post-telehealth). Data from 2020 was excluded, given COVID irregularities. We selected 3 disease groups with varying telehealth use – breast (low), GI (medium), and GU (high) – allowing us to better control for external factors (eg COVID). We compared changes in visit distribution, sociodemographic, and tx patterns within and between disease groups pre- vs post-telehealth using Chi-square and ANOVA tests. Logistic regression analyses identified post-telehealth predictors of receiving tx, including the percentage (%) of in-person (IP) visits per pt. **Results:** We analyzed 109,200 encounters and 26,907 pts pre-telehealth vs 143,159 encounters and 50,168 pts post-telehealth. Pt volume increased in all groups post-telehealth (+99% breast, +55% GI, +104% GU). Post-telehealth, the % of video visits (VVs) increased in breast (1.5% to 28.8%), GI (2.0% to 55.2%), and GU (3.0% to 80.9%). In all groups, the % of pts seen from outside the SF Bay Area decreased (-7.5 breast, -1.4 GI, -6.1 GU). In breast and GU, the % of pts receiving cancer tx decreased (-5.2, -16.0, $p<0.01$), while the % of pts receiving GI tx was stable (-0.9). For infusion tx, predictors of tx receipt included metastatic disease (OR 3.9, 95% CI 3.6-4.2) and higher % of IP medical onc visits (OR 3.6, 95% CI 3.3-3.9); while living outside the Bay Area was negatively associated with infusion tx (OR 0.5, 95% CI 0.4-0.5). For surgery, the % of IP surgical onc visits (OR 0.7, 95% CI 0.6-0.7) and living outside the Bay Area (OR 0.8, 95% CI 0.7-0.9) were negatively associated with tx receipt. For radiation tx, metastatic disease (OR 2.8, 95% CI 2.5-3.1), but not living outside the Bay Area (OR 0.6, 95% CI 0.5-0.7), was associated with tx receipt. The % of IP radiation onc visits was not significant (OR 1.1, 95% CI 1.0-1.4). **Conclusions:** Among 3 disease groups with varying telehealth use, pt volume increased in all groups, while the % of pts receiving tx at our center decreased. This suggests that providers may be providing collaborative care while pts receive care locally. In regression analyses, higher % of IP medical onc visits was positively associated with receiving infusions, highlighting the importance of IP visits during active medical onc tx. However, this was not seen for surgery and radiation tx. For these time-limited interventions, pts seen virtually are still likely to access tx at our center. Further analyses are needed to identify pts and visit types best suited for telehealth. Research Sponsor: Conquer Cancer Foundation Young Investigator Award.

Pilot study of an enhanced telehealth program for patients with prostate cancer. First Author: Erin Mary Bange, Memorial Sloan Kettering Cancer Center, New York, NY

Background: The time required for cancer treatment is considerable. Telehealth (TH) with home monitoring can minimize travel burden but patients' perceptions regarding tradeoffs of clinic visits versus enhanced telehealth (ET) are uncertain. We piloted an ET intervention offering patients on androgen deprivation therapy (ADT) for prostate cancer up to four components of care at home. **Methods:** Prostate cancer patients on ADT were offered participation in 4 at home services: 1) TH oncologist visits; 2) remote BP monitoring (BP); 3) home phlebotomy (HP); and 4) self-injection of ADT or denosumab at home with RN support via TH as needed. Clinicians referred eligible patients and specified frequency of each service. Completion rates were evaluated for each component. Patient perspectives, preferences for subsequent care, and assessments of the feasibility, acceptability, and appropriateness of each component were collected after participation in eligible services at least once over the course of the pilot. Feasibility, acceptability, and appropriateness were measured by validated measures (scores from 1-5). Patient satisfaction with ET was measured using a net promoter score. All results are based on the last completed patient survey. **Results:** Between 6/2023 and 6/2024, 39 patients enrolled in the pilot, the median age was 70 (IQR: 61.5-76.7), 62% were white, and 69% (N = 27) lived with family or a partner. Table 1 shows the %/(N) of patients who chose to participate in each at home component with completion rates at the patient and visit level. 73% (145/198) of remote monitoring failures were due to patient inability to execute the at home task. > 75% of patients reported that each service was convenient and saved time. Most patients reported no problems with completing the visit (TH 89%, BP 89%, HP 91%, injections 67%). Patients were either very likely or somewhat likely to participate again (TH 97%, BP 100%, HP 96%, injections 100%) and the majority preferred ET for future care (TH 79%, BP 79%, HP 87%, injections 100%). 62% (24/39) of patients found at-home visits to be equally or less stressful than in-person care. Patients found each service to be feasible, acceptable, and appropriate (mean score > 4.7 for all services) and gave ET a net promotor score of 79. **Conclusions:** Patients found ET for the management of prostate cancer on ADT to be feasible, acceptable, and appropriate, providing a more patient-centered and convenient alternative to traditional clinic-based care. Future studies will explore scalability and applicability across diverse patient populations and treatment regimens. Impact of telehealth utilization on adherence to endocrine therapies in privately insured breast cancer patients: A claims-based cohort study. First Author: Shaimaa Elshafie, Clinical and Administrative Pharmacy, College of Pharmacy, University of Georgia, Athens, GA

Background: Adherence to endocrine therapies is essential for reducing recurrence and improving survival in breast cancer patients. However, nonadherence remains a significant challenge, particularly among young women. Telehealth has emerged as a promising tool to address barriers to care, yet its impact on long-term adherence to endocrine therapies is poorly understood. This study evaluated the association between telehealth utilization and adherence to endocrine therapies among privately insured women with nonmetastatic breast cancer. **Methods:** Using medical and pharmacy claims data from the Merative MarketScan database, we identified women under 65 years old who were newly diagnosed with nonmetastatic breast cancer in 2018 and were commercially insured for at least one year before diagnosis and five years after initiating endocrine therapy. Telehealth utilization was identified through billing codes, and adherence was measured by the proportion of days covered (PDC) with adherence defined as $\geq$80% prescription coverage. Generalized linear mixed models were used to estimate odds ratios (ORs) and 95% confidence intervals (CIs) while adjusting for relevant patient-level covariates. **Results:** The study cohort included 1,141 patients with the majority (53%) aged 45-54 years and 92% exhibited moderate severity of comorbidities. All patients initiated endocrine therapy in 2018 with 34% receiving tamoxifen, 33% receiving an aromatase inhibitor, and 33% switching between agents during follow-up. Telehealth utilization increased sevenfold during the second year of treatment (coinciding with the COVID-19 pandemic) and peaked in the third year when 48% of patients used telehealth and 2,178 visits were recorded. Adherence rates declined steadily over time: from 75% in the first year to 36% by the fifth year. Patients who utilized telehealth were 58% more likely to be adherent compared to those who did not utilize telehealth (OR = 1.58; 95% CI: 1.31-1.91; $p < 0.0001$). Geographic region, insurance plan type, and endocrine therapy agent were also significant predictors of adherence. **Conclusions:** Telehealth utilization was significantly associated with improved adherence to endocrine therapies among privately insured breast cancer patients. These findings highlight the potential of telehealth to mitigate barriers to long-term treatment adherence. Future research should explore strategies to sustain adherence and evaluate the broader clinical and economic implications of telehealth in this population. Research Sponsor: None.

Comparative effectiveness of delivering early palliative care via video versus in-person on end-of-life outcomes in patients with advanced lung cancer. First Author: Jessica R. Bauman, Fox Chase Cancer Center, Philadelphia, PA

Background: Findings from our prior large-scale comparative effectiveness trial showed the equivalent effect of delivering early palliative care via video versus in-person on quality of life among patients with advanced non-small cell lung cancer (NSCLC). We now report on whether the two care delivery modalities were equivalent with respect to patient-reported communication with clinicians about their end-of-life (EOL) care preferences and hospice utilization. **Methods:** Between 6/14/2018 and 5/4/2023, we enrolled 1250 patients with newly diagnosed advanced NSCLC in a randomized trial of early palliative care across 22 US cancer centers. Patients were randomly assigned to meet with a palliative care clinician every 4 weeks from enrollment through the course of the disease, either via video or in the outpatient clinic. Participants completed self-report surveys at baseline and weeks 12, 24, 36, and 48, including an item asking if they had discussed with their clinicians the care they would want to receive if dying (yes/no); patients' final assessments prior to death or last follow up were analyzed. We reviewed patients' health records to collect data on hospice referral and length of stay. To test the equivalence in these outcomes, we used a binomial generalized linear model with the identity link function (pre-specified equivalence margin of $\pm$8% for patient-reported communication about EOL care) and linear regression (pre-specified equivalence margin of $\pm$6 days for mean length of stay in hospice). P-values were adjusted for multiplicity using a Bonferroni correction. **Results:** Of the 1250 enrolled participants, 888 (71.0%) completed at least one survey post baseline regarding whether they communicated with clinicians about EOL care preferences. Among those, 29.1% of the video group and 26.0% of the in-person group reported "yes," indicating that they recalled such EOL care discussions (difference = 3.1%, 95% CI: -1.8%, 8.1%; p = 0.26 for equivalence). During the course of the trial, 733/1250 (58.6%) patients died, of whom 537/733 (73.3%) were referred to hospice. Mean lengths of hospice stay were 25.3 days for the video group versus 25.1 days for the in-person group (difference = 0.2, 95% CI: -7.0, 7.4; p = 0.46 for equivalence). When excluding outlying patients receiving hospice services $>$ 180 days (n = 13), the mean lengths of hospice stay were 19.1 (video group) versus 19.7 (in-person group) days (difference = -0.6, 95% CI: -4.6, 3.3; p = 0.06 for equivalence). **Conclusions:** Although thresholds were not met to confirm equivalence statistically, the two modalities for delivering early palliative care demonstrate very similar outcomes with respect to patient-clinician communication about EOL care and hospice utilization. These findings provide further evidence of the utility of video visits for providing high quality palliative and EOL care. Clinical trial information: ClinicalTrials.gov Identifier (NCT03375489). Assessing circadian rhythms and chemotherapy safety in remote patients with pancreatic ductal adenocarcinoma (PDAC) using a multidimensional digital platform (MultiDom, NCT04263948). First Author: Francis Albert Lévi, UPR Chronotherapie, Cancers et Transplantation, Université Paris Saclay, Hôpital Paul Brousse ID Isco 13918, Villejuif, France

Background: The disruption of circadian clocks is associated with reduced survival and treatment tolerability in cancer patients (pts). Here, real-time analyses of telemonitored circadian rhythms and electronic Pt-Reported Outcome (ePRO) are integrated within a multidimensional telemonitoring-telecare digital platform that triggers proactive telecare toward improved quality of life (QoL) and treatment safety. **Methods:** The multicentre, interventional, prospective, longitudinal, single-arm study recruited pts receiving mFOLFIRINOX chemotherapy (CT) q2-weeks for pancreatic ductal adenocarcinoma (PDAC). Early warning signals of circadian disruption, body weight loss, and ePROs severity are extracted from real time analysis and graphical displays of (i) continuously telemonitored rest-activity and chest surface temperature (chestemp) rhythms using a chest sensor, and (ii) daily body weight (e-balance), and (iii) daily self-rating of 23 symptoms using a GPRS tablet (MD Anderson Symptoms Inventory, MDASI). Pts participate for 1 week before (baseline) and 6 weeks after 1st CT course. Circadian disruption is defined by an ($I < O$) value $<$ 96%. ($I < O$) is the % accelerations per min In-Bed that are below median accelerations per min Out-of-Bed for 3 days; ($I < O$) range in controls, 97-100%). Automatic alerts are sent via internet for decision of proactive intervention by the oncology team, in case of circadian disruption, chestemp increase by 1.5°C, weight loss $>$ 5%, or MDASI symptom $\geq$ 7. **Results:** From 6/2021 to 7/2024, 58 pts with advanced PDAC were selected (male, 52%), median age, 58 y.o. (range, 33-82); WHO performance status (PS) 0/1/2, 36%/53%/10% of the pts; metastatic sites 0/1/ $>$ 2, 38%/24%/8%; liver metastases, 50%). Early PDAC-related complications prevented platform use in 5 pts. The platform was used by 53 pts during a median of 45.5 days (IQR, 38-50], with $>$ 85% compliance. At baseline, large between-pts differences in circadian rhythms were found for both rest-activity $I < O$ (median [IQR]), 98.4 accelerations/min [95.8-99.6]); range, 75 to 100), and chestemp circadian amplitude (median, 1.1°C [IQR, 0.7-1.4], range, 0.3°C to 2.7°C). Baseline circadian disruption was larger in male pts (56% vs 31%; p = 0.07) and in those with PS 1-2 (47% vs 14%; p = 0.02). Consistently, median chestemp circadian amplitude was less in males compared to females (0.8°C vs 1.3°C, $p < 0.01$) and in pts with PS = 1-2 compared to PS = 0 (0.8°C vs 1.3°C; $p < 0.01$). Maximum toxicities of CT were circadian disruption (100% of the pts), body weight loss $>$ 5% (59%), and MDASI symptom $\geq$7 (46%), without any influence of baseline pt characteristics. **Conclusions:** The use of this multidimensional digital platform combining circadian and other physiology metrics with ePROs was feasible and accepted by the pts. Its implementation seemed to be clinically relevant toward improving the care of remote pts at risk of adverse events. Clinical trial information: 04263948. Research Sponsor: Education and Research Direction of Ramsay-Santé.

Remote physiologic and behavioral monitoring to predict early treatment response in metastatic cancer: High-Definition Oncology study (HDOs) preliminary results. First Author: Leire Paz-Arbaizar, Department of Signal Theory and Communications, University Carlos III, Leganés, Spain

Background: Emerging evidence suggests that behavioral, physiologic or emotional factors may act as real-time indicators of treatment response, with potential as modifiable factors. Advances in remote monitoring technologies provide passive (e.g., heart rate, sleep patterns) and active (e.g., self-reported emotions) data. HDOs collects such data and serial -omics from 300 women with metastatic cancer to identify novel markers, understand disease trajectories and develop a digital twin for individualized care. We present data from 25% accrual. **Methods:** Women receiving first-line treatment for metastatic colorectal, lung, or hormone-positive breast cancer were eligible. Patients continuously wore a smartwatch and used the EB2 App to capture step count (SC), sleep duration (SL), phone usage (PU), time at home (TH), location clusters (LC), mean (MHR) and minimum (mHR) heart rate, mean (MSHR) and minimum (mSHR) sleeping heart rate and sleeping oxygen saturation (SOS). Emotional valence was self-reported from a list of 20 emotions and classified as negative (-1), neutral (0) or positive (+1). Aim 1: to explore the relationship between the variables and response (CB: CR+PR+SD vs. PD) at the first CT scan at day +90 analyzing data from days 1-15 and 75-90 (Mann-Whitney U). Aim 2: to find Response-Associated Behavioral Patterns (RABPs) associated with CB or PD. First, Daily Behavioral Profiles (DBPs) are obtained using unsupervised learning models from $>$ 2 million days of smartwatch and App data (external set). After identifying 256 DBPs with the VQ-VAE model, Latent Dirichlet Allocation defined RABPS based on the frequency and abundance of DBPs per patient. RABPs were compared among classes (response type, age group) using X^2. Bilateral P values $<$ 0.01 were deemed significant. **Results:** from May 2023 to April 2024, 77 female patients (median age 61; 28-80) were accrued (46 Breast, 23 Lung, 8 Colorectal). At first CT, 72 (93.5%) achieved CB while 5 (6.5%) had PD. During days 1-15, CB patients showed lower PU (2.4 vs. 3.9 hours; P = 0.002), TH (18.5 vs. 22 hours; P = 2* $10^{\wedge-7}$), MHR (78 vs. 88 bpm), mHR (59 vs 70 bpm), MSHR (75 vs 88 bpm) mSHR (66 vs 78 bpm) (all Ps $< 10^{\wedge-10}$) and reported more negative EV. The trends persisted in days 76-90 in addition to SC (7235 vs 4038 steps/day; P = 0.00001) and decreased SOS (90.1% vs. 92.6%; P = 1.5*$10^{\wedge-8}$). Six RABPS were identified. Patients $<$ 60 yo displayed more often RABPs 1, 2 and 5 (84% vs. 16%; P = 0.02). RABP1 breast cancer and RABP5 lung cancer patients were more likely to experience PD vs. CB (75% vs. 24%; P = 0.08; and 69% vs.19%, P = 0.07, respectively). **Conclusions:** Behavioral and physiologic data in days 1-15 and 76-90 were strongly associated with treatment response, independent of tumor type, age or treatment. RABPS identifying patients at high risk of PD can be detected, highlighting their value as markers for early intervention. Research Sponsor: None.

Administration of tarlatamab in an outpatient setting utilizing remote patient monitoring: Mayo Clinic experience. First Author: Ashley Potter, Mayo Clinic Rochester, Rochester, MN

Background: Tarlatamab is a bispecific T-cell engager targeting DLL3 that has shown promise as a therapy in small cell lung cancer. Administering tarlatamab requires careful consideration of immune-related adverse events (AE), including cytokine release syndrome (CRS) and immune effector cell-associated neurotoxicity syndrome (ICANS). Prescribing information recommends patients to be monitored for 22-24 hours in an appropriate healthcare setting for cycle 1 (C1), days 1 and 8. At Mayo Clinic in Rochester MN (MCR), tarlatamab is initially administered in a hospital-based outpatient (HBO) setting utilizing an innovative remote patient monitoring system (RPM). In this study, we describe our RPM process and patient outcomes thus far. **Methods:** We retrospectively reviewed records of patients treated with tarlatamab from August through December 2024. All patients received tarlatamab in the HBO setting and were enrolled into RPM for C1, days 1–10. Patients attended daily HBO visits on days 1–3 and 8–10 of C1 and were required to stay within 30 minutes of the hospital with a 24-hour caregiver for 48 hours following infusion days in C1-2. Data on patient characteristics, frequency of RPM alerts, escalations, rate of CRS & ICANS, and need for hospitalizations were reported using descriptive metrics. **Results:** As part of RPM, patients are provided with a kit containing preconnected Bluetooth-enabled devices to measure vital signs (VS), including blood pressure (BP), heart rate (HR), temperature (T), and pulse oximetry (SpO2). The kit also includes a cellular-enabled tablet for electronic ICANS questionnaires, which upload directly into our electronic medical record system. Patients are required to log VS four times daily, monitored in real-time by a centralized virtual RPM nursing (RN) team. Embedded decision trees trigger alerts, prompting the RN team to contact patients and follow care pathways for escalations as needed. Among the 16 patients treated, the median age was 68 years, and the median ECOG PS was 1. During the 10-day RPM period, a total of 2,233 VS entries were recorded. Of these, 88% (14/16) of patients had alerts triggered, with a median of 2 alerts per patient. Alerts were mostly for out-of-range systolic BP (56%), HR (56%), and T (25%), with none for SpO2. The RN team escalated alerts in 50% (8/16) of the patients. Overall, 38% (6/16) of patients were managed entirely in the HBO setting. Among the 63% hospitalized, 56% had CRS limited to grade (G) 2, and 31% had ICANS limited to G3. Two patients were hospitalized for other indications. The mean length of stay was 2.6 days, with no ICU admissions. **Conclusions:** Our experience shows that frequent monitoring required with tarlatamab can be safely and effectively executed in an outpatient setting with the utilization of an RPM system. It can potentially minimize the burden of hospitalizations for patients and the healthcare system. Research Sponsor: None.

Teledermatology-dermoscopy: Expanding access to skin cancer screening to reduce healthcare disparities. First Author: Brenda Santellano, Georgia Cancer Center, Augusta University, Augusta, GA

Background: Skin cancer, the most common malignancy in the United States, continues to rise in incidence. Underserved populations face significant barriers to care, including lack of insurance, language differences, and limited access to specialists. The Augusta Free Dermatology Clinic, a student-run clinic, collaborates with the Teledermatology in Rural Georgia program to address these challenges through store-and-forward (SAF) teledermatology-dermoscopy. This approach involves transmitting dermoscopic images to a dermatologist for remote analysis. Implemented during Community Health Fairs (CHFs), this initiative aims to enhance access to skin cancer screening in underserved communities. **Methods:** Volunteer medical students (MS) from the Medical College of Georgia (MCG) and general physicians underwent training to use a dermatoscope effectively. Trained MS collected brief medical histories and dermoscopic images for SAF referrals during CHFs serving individuals with incomes below 200% of the federal poverty line. Polarized dermoscopic images were captured using iPhones equipped with magnetic dermatoscope attachments and were securely transmitted to a board-certified dermatologist via a teledermatology platform. Dermatological recommendations were provided within one hour and communicated to patients, with Spanish translators facilitating communication. **Results:** Across two CHFs (~8 hours each), 10 MS volunteered in shifts under the supervision of a general physician (n = 1) or dermatology resident (n = 1). A total of 141 patients presented with dermatological concerns, of whom 24 (17.02%) were referred for SAF consultations due to suspicious skin lesions. Among these, 17 (70.83%) had benign lesions, while 7 (29.17%) were identified as potentially malignant and referred for in-person follow-up at the Augusta Free Dermatology Clinic for further evaluation or biopsy. Comprehensive data were available for 112 patients (79.43%), most of whom were female (58.04%, n = 65) and Latino/Hispanic (98.21%, n = 110). The majority were uninsured (73.21%, n = 82), Spanish-speaking (98.21%, n = 110), and required translation services (98.21%, n = 110). Nearly all participants worked in skilled agricultural roles (98.21%, n = 110) and reported a median of two household dependents (range: 0–9). Common diagnoses among follow-up patients included healthy skin (45.54%, n = 51), acne (5.36%, n = 6), melasma (5.36%, n = 6), benign nevi (5.36%, n = 6), dermatitis (4.46%, n = 5), and folliculitis (3.57%, n = 4). Other less common conditions were diagnosed in 30.36% (n = 34) of patients. **Conclusions:** The implementation of teledermatology-dermoscopy at CHFs effectively addressed barriers to dermatological care in underserved populations. This approach demonstrated the potential to improve early detection of skin cancer, facilitate timely care, and reduce healthcare disparities. Research Sponsor: United States Department of Agriculture Rural Utilities Service (USDA).

Patient-reported experience with an immunotherapy telehealth platform. First Author: Robert Michael Daly, Memorial Sloan Kettering Cancer Center, New York, NY

Background: The Making Teleheath Delivery of Cancer Care at Home Effective and Safe for Immunotherapy (MATCHES-IO) intervention seeks to improve the efficiency and patient experience for those treated with single agent pembrolizumab. Because pembrolizumab is administered as an outpatient infusion every 3-weeks, patients require up to 18 clinic visits per year to receive treatment, which is arduous. During the COVID-19 pandemic, the FDA granted accelerated approval for an extended interval dosing administered every 6 weeks, but despite this approval every 3-week dosing remains the standard (65% of prescriptions) as clinicians perceive this schedule enables them to identify and manage toxicity early. Telehealth may be the impetus to change the standard to the more convenient 6-week in person schedule, but evidence is needed. **Methods:** We conducted a single arm pragmatic trial to evaluate the efficiency and patient experience of a telehealth immunotherapy platform (MATCHES-IO) in patients with non-small cell lung, genitourinary, or melanoma cancers receiving single agent pembrolizumab. MATCHES-IO evaluates whether in-person visits for pembrolizumab therapy q6wk (rather than q3wk) with interim telehealth toxicity checks between in-person treatments for the first six months of therapy is more efficient and enhances patient experience relative to the standard q3wk infusion visits. The components of the platform include clinician-patient virtual visits, labs at home, biometric devices at home for vital sign monitoring, and electronic patient-reported outcomes to monitor for common IO-related toxicities. Patient experience was assessed after each MATCHES-IO televisit for up to two televisits. We measured experience with a patient experience survey that included how likely are they to recommend this intervention to similar patients (scale 0-10). **Results:** Between July 2023 and January 2025, 59 patients were enrolled, median age 69 (range 25–85), 81.5% White, 11.1% Black, 7.4% Asian, and 61.1% male. Cancer types included thoracic (50.9% of patients), genitourinary (30.5%), and melanoma (18.6%). 45 patients (76.3%) have completed a MATCHES-IO televisit and completed a patient experience survey. The median score for likelihood to recommend was 10 (range 4-10). 97.8% patients perceived a benefit to the MATCH-IO televisit including saved time (82.2% of respondents), patient convenience (71.1%), convenience for caregiver/family (44.4%), saved money (44.4%), and better monitoring of cancer and treatment (24.4%). 57.8% of patients found the at home visit less stressful than the in-person visit. **Conclusions:** Patients endorsed an enhanced experience with an immunotherapy telehealth platform for extended dosing of pembrolizumab. Further follow-up is needed to confirm these experience findings and determine whether this platform improved efficiency through fewer in-person visits. Outcomes of germline expedited point of care (POC) genetic testing through telehealth in the Veterans Health Administration (VA). First Author: Akiko Chiba, Department of Surgery, Duke University Medical Center, DUMC, Durham, NC

Background: Germline genetic testing is standard of care for treatment planning for several malignancies. To increase access to genetic testing for Veterans, VA developed and disseminated educational materials, laboratory portal access, and templates for ordering and documenting consent and testing in the electronic health record to facilitate POC testing by oncology providers. Here, we describe the outcomes of POC testing. **Methods:** POC tests ordered between 2/24/23-11/18/24 by oncology providers at VA sites or with National TeleOncology (NTO) were identified through the VHA's Corporate Data Warehouse and the VINCI (VA Informatics and Computing Infrastructure) research environment. Pathogenicity of variants was determined by the classification provided by the laboratory. Providers are recommended to use the POC testing for patients actively being treated for the following cancers: metastatic/high risk prostate, breast, ovarian, exocrine pancreatic/ampullary, colon $<$ 50 years of age, medullary thyroid, and pheochromocytoma/paraganglioma. **Results:** POC tests were ordered at 45 different VAs for 1293 patients. Total of 1364 tests were ordered, and 1195 (87.5%) tests were . The tests ordered included 854 (62.6%) curated multigene panel and 510 (37.4%) targeted cancer panels. Demographics are summarized in Table. Among 1382 diagnoses listed as the indication for testing (some patients had multiple), the most common cancer diagnoses were prostate (831, 60.1%), breast (206, 14.9%), and pancreatic (94, 6.8%). Most tests were ordered for patients who met POC indications, but 13.6% of orders were for other indications. A total of 77 (6.4%) patients were found to have pathogenic/likely pathogenic variants (PV) in dominantly inherited cancer predisposition genes. Seventy-one (5.9%) patients had PVs in high/moderate penetrance cancer predisposition genes. **Conclusions:** POC testing is feasible and being widely adopted across the VA. Further work is needed to determine if patients found to have actionable PVs through the POC mechanism have changes in treatment or are referred for follow-up genetic counseling. A significant, minority of tests were ordered for patients with diagnoses not eligible for POC testing. Continued education and support is planned to increase utilization of POC testing in oncology across the VA. Research Sponsor: None.

DIPCAN, a multidimensional approach to precision oncology: Harnessing genomic, clinical, pathological and radiographic data to advance personalized cancer treatment. First Author: Enrique Grande, Department of Medical Oncology, MD Anderson Cancer Center Madrid, Madrid, Spain

Background: Advances in big data analytics and artificial intelligence (AI) are enabling novel approaches to patient classification in oncology. While existing studies often correlate only a few data types, the DIPCAN Study (Digitalisation and Integral Management of Personalised Medicine in CANcer) seeks a comprehensive, integrated analysis combining phenotypic, clinical, pathological, radiomic, and genomic data from patients with metastatic cancer in Spain. DIPCAN aims to deepen insights into cancer's multifactorial nature, driving personalized care and more precise therapeutic strategies. **Methods:** DIPCAN was initiated through a consortium comprising five technology and healthcare SMEs—Genomcore, Quibim, Pangaea Oncology, Artelnics, and Atrys Health—alongside Eurofins Megalab and the non-profit MD Anderson International Foundation Spain. Funding was secured via the Spanish Ministry of Economic Affairs and Digital Transformation under the EU-funded Recovery, Transformation, and Resilience Plan (R&D Missions Program in Artificial Intelligence, File No. MIA.2021.M02.0006). DIPCAN's primary objective is to characterize and map clinical, phenotypic, genomic, and radiomic profiles of metastatic cancer patients across Spain. Secondary goals involve developing Big Data, AI, and machine learning tools to enable multidimensional analysis of these patients. Eligible patients are 18 years or older, have histologically confirmed metastatic solid tumors, a life expectancy exceeding three months, and available tumor material for histological and molecular analyses. Participants consent to undergo a comprehensive set of diagnostic and imaging procedures outlined in the study protocol. If recent tumor tissue ($<$3 years) is unavailable, patients may opt for a current biopsy or liquid biopsy. At no cost, participants receive consultations with oncology and drug development specialists, who document baseline characteristics and compile structured medical histories. Additional diagnostics include bloodwork emphasizing lipid metabolism, digital pathology, extensive NGS sequencing on tissue or blood, and a full-body MRI. All participants receive digital access to their data and a clinical report with tailored recommendations for their physicians. With ethics approval in place, DIPCAN has enrolled 1,500 patients since June 14, 2022. Data collection is ongoing, with anticipated advancements in AI-driven analysis aimed at refining precision oncology approaches for metastatic cancer in Spain. Clinical trial information: 2021.M02.0006. Research Sponsor: European Union; MIA.2021.M02.0006.

TPS1657 **Poster Session**

A pilot single-arm, pragmatic trial in progress of in-home versus in-clinic subcutaneous nivolumab administration through Cancer Care (connected access and remote expertise) Beyond Walls (CCBW) program. First Author: Dina Elantably, Mayo Clinic, Jacksonville, FL

Background: Cancer treatments are traditionally administered in clinical settings, which can isolate patients from their familiar environments and exacerbate physical, psychosocial, and financial burdens. Travel requirements further amplify these challenges, particularly for underserved populations. Studies indicate that patients prefer receiving care at home, and international models have demonstrated the safety of home-delivered chemotherapy since the 1990s; however, no U.S. clinical trial data exists. In response, Mayo Clinic has developed the *Cancer CARE (Connected Access and Remote Expertise) Beyond Walls (CCBW)* program, a distributed cancer care delivery model that expands access to quality cancer care by bringing it to the home environment, providing in-home cancer treatment, lab testing, telemedicine, and community paramedic support. This trial evaluates the safety, acceptability, and impact of home-based subcutaneous (SC) nivolumab (Nivo) administration compared to in-clinic treatment within the CCBW initiative. **Methods:** This open-label, single-arm trial evaluates the impact of SC Nivo administration location—home versus infusion center—on patient reported cancer care experience, patient-preferred treatment location, acceptability, safety, and patient-reported outcomes. Eligible adult patients (ECOG 0-1) receiving IV Nivo for an FDA-approved indication and residing within 75 miles of Mayo Clinic Florida will transition to SC Nivo, receiving two initial in-clinic cycles. If tolerated without injection reactions, four cycles will be administered at home before resuming in-clinic treatment. Exclusion criteria include concurrent investigational/standard treatments or contraindications to immunotherapy. Fifty patients will be enrolled, with an estimated 75% (n=38) providing cancer care ratings after 8 weeks in-clinic and 8 weeks at-home, offering 85% power to detect a mean difference in ratings of 0.50 standard deviations. The primary endpoint is within-patient change in cancer care rating (0–10 scale, CAHPS Cancer Care Survey) comparing 8 weeks of in-clinic vs. at-home care. Secondary endpoints include patient-preferred treatment location, comfort with home injections, safety (grade 3+ adverse events), function (EORTC QLQ-F17), symptoms (PRO-CTCAE), side effect impact (GP5), and healthcare utilization (ER visits, hospitalizations). Cost will be assessed as a tertiary endpoint. The trial has FDA approval (IND #170079), Mayo Clinic IRB approval (#23009663), and ClinicalTrials.gov registration (NCT06265285). Enrollment began in April 2024, with an expected accrual period of 24 months. To date, 10 patients have been enrolled, and final analysis is expected 2.5 years after trial activation. Clinical trial information: NCT06265285. Research Sponsor: BMS; Mayo Clinic.

Trial in progress: Evaluating the effectiveness of Blue-button—A tool for institution-agnostic, EHR-integrated regional automated clinical trial prescreening and matching. First Author: Waddah Arafat, Simmons Comprehensive Cancer Center, University of Texas Southwestern Medical Center, Dallas, TX

Background: Clinical trial enrollment is essential for advancing cancer treatment and improving patient outcomes. Despite the benefits, only 7% of adult cancer patients in the US enroll in clinical trials due to barriers such as limited awareness, the time-intensive nature of manual prescreening and lack of relevant on-site clinical trials. This contributes to insufficient enrollment, causing approximately 20% of trials to fail. Automated prescreening using electronic health records (EHRs) offers a promising solution to streamline trial identification and improve access. This study builds on our published feasibility study (Cancer 2023; doi: 10.1002/cncr.35022) that demonstrated the potential of an open-source clinical trial matching tool, developed in collaboration with ACS CAN and MITRE Corporation, to improve locoregional trial identification for patients. **Methods:** Trial Design: This prospective, randomized, two-arm pilot study is being conducted at two sites: University of Texas Southwestern Medical Center (UTSW), an academic center, and Tampa General Hospital (TGH), a community hospital. Patients are randomized to usual care or an intervention arm utilizing Blue-button, an automated prescreening tool. This SMART-on-FHIR tool automatically extracts deidentified patient data (e.g., cancer type, stage, biomarkers) from the site EHR system and uses them to query external matching services via the FHIR mCODE standard. Using the standard FHIR ResearchStudy resource format, research coordinators review potential trial matches returned within a specified radius of the practice for eligibility and discuss them with patients. At UTSW, this includes prostate, bladder, breast cancer and colon cancer cohorts. At TGH, the trial includes breast, prostate, and colorectal cancers, as well as glioblastoma and multiple myeloma. Statistical Methods:The primary endpoint is the proportion of patients enrolling in trials, comparing intervention and usual care arms. Secondary objectives include evaluating usability, barriers to enrollment, and participant diversity. A total of 1200 patients (600 per arm) will be enrolled, with 81% power to detect a 75% relative increase in enrollment from 9.0% (control) to 15.8% (intervention) at a one-sided alpha of 0.05. Trial Progress:The first phase of the trial addressed institutional approvals, security compliance, and complex server and EHR integrations. The later phase addressed integration of the automated tool into diverse clinical workflows, engagement with site staff and participating patients. Both sites have enrolled approximately 200 patients to date, half on the intervention arm. The final phase will address primary and secondary outcomes as per trial design. Clinical trial information: NCT05885880. Research Sponsor: American Cancer Society Cancer Action Network.

DISCO App: A patient intervention to reduce the financial burden of cancer in a diverse patient population. First Author: Lauren M. Hamel, Karmanos Cancer Center, Wayne State University, Detroit, MI

Background: Financial toxicity, the material and psychological burden of treatment cost, affects up to half of people with cancer and can affect adherence and survival. Financial toxicity is a health equity issue, disproportionately affecting Black patients. Patient education about cost and patient-provider cost discussions are recommended to mitigate financial toxicity but occur infrequently. Our goal is to mitigate financial toxicity through a tailorable education and communication intervention, the DISCO App. The DISCO App was shown to be feasible, acceptable, and preliminarily effective at prompting cost discussions and improving related outcomes in a pilot trial. The aim of the ongoing trial is to test the effectiveness of the DISCO App on short- and longer-term outcomes for Black and White patients with cancer. **Methods:** This study is a longitudinal RCT. Oncologists are eligible if they treat patients with solid tumors at the trial site. Patients of participating oncologists are eligible if they are $\geq$ 18 years of age; identify as Black or White; can read and write in English; have an email address; and were diagnosed with a solid tumor for which systemic therapy is a likely recommended treatment. Strata were created to balance arms by patient race, income, age, and sex. Upon consent, patients are randomized to one usual care arm (1) or one of two intervention arms (2 and 3). All patients are asked to allow one treatment discussion with their oncologist to be video recorded for analysis. Prior to the recording, intervention patients utilize the DISCO App on an iPad. The DISCO App includes a video about treatment costs, ways to manage costs, and the importance of discussing costs with oncologists. Once patients enter their socio-demographic information (e.g., employment, insurance) and any financial concerns, they receive a tailored list of questions to ask their oncologist. Arm 3 patients receive an intervention booster via email two months after the recording. Patients complete measures at baseline, right after the recording, and at 1, 3, 6 and 12 months after the recording. Measures assess outcomes including cost discussions, communication quality, cost knowledge, self-efficacy for cost management, referrals for support, short- and longer-term financial toxicity, and treatment adherence. The patient-oncologist interaction is the unit of analysis and we will use multi-linear models to compare outcomes by arm. We anticipate recruiting up to 15 oncologists and 240 patients. Data collection began in March 2021 and will continue until July 2025. Participants to date include 13 oncologists and 192 patients (116 Black, 76 White). Most patients completed the baseline assessment (n=164), the post-interaction assessment (n=137), and at least 1 follow-up assessment (n=132); 125 treatment discussions have been recorded. The IRB reviewed the trial in December 2024 and approved continuation. Clinical trial information: NCT04766190. Research Sponsor: American Cancer Society; ACS RSG-20-026-01-CPHPS.

TPS1660 **Poster Session**

RACED (Reduction of Cervical Cancer Disparities): The impact of navigators and racial literacy training. First Author: Abna Faustina Sousa Vieira, Instituto do Câncer do Estado de São Paulo, Faculdade Medicina da USP, São Paulo, Brazil

Background: Cervical cancer is the third most prevalent cancer in Brazilian women. Approximately 17,000 new cases are expected for Brazil's 2023-2025 triennium. The complex multimodality treatment of locally advanced cervical cancer (LACC), which relies on platinum-based chemoradiotherapy (CRT) and brachytherapy (BT), in addition due to the significant healthcare demands of patients with cervical cancer, creates challenges for a public-funded health system. The Black population experiences the highest cancer mortality rates compared to the general population, partly due to inequalities in social, economic, political, and health areas spheres. Data showed that, compared to White women, the mean age-adjusted mortality rates according to race/skin color were 27% higher in Black women. Around 60% of Black patients have a cervical cancer diagnosis in locally advanced or advanced stages. The incidence rate among Black women was found to be significantly higher than that of their White counterparts, with a relative risk of incidence nearly 50% higher. This disparity cannot be ignored. **Methods:** Our study is based on Critical Racial Praxis for Public Health. It is inspired by the ACCURE (Accountability for Cancer Care Through Undoing Racism and Equity) initiative trial, composed of 3 anti-racist actions: 1- oncology navigation with racial literacy, 2- real-time medical record alert system, and 3- race-specific feedback. Our intervention, in turn, consists of oncology navigation with racial inequities training and improving interprofessional team knowledge about race and diversity through race-specific feedback. This prospective, single-center, non-randomized clinical trial of anti-racist actions and treatment support will compare prospective patients with a historical control from the same hospital. The primary endpoint is to increase the completion rate of definitive treatment with CRT+BT for 100 patients with IB2 to IVA cervical cancer (convenience sample). The secondary endpoints are to analyze the implementation policy of this strategy and to make an economic assessment of the use of this implementation (we hypothesize that such measures reduce both visits to the emergency room due to toxicity, as well as admissions to wards and ICU). Patient inclusion is expected to begin in March 2025. Nurses are receiving training in oncology navigation and racial literacy in healthcare. As this is a race-conscious trial, the researchers plan to prospectively compare outcomes between the intervention group's Black/Brown and non-Black/Brown populations. In addition, given critical race theory, the research team comprises Black women in creation, design, and throughout the entire study continuum. Clinical trial information: 85819325.0.0000.0068. Research Sponsor: Bristol Myers Squibb Foundation.

TPS1661 **Poster Session**

Practical geriatric assessment (PGA) implementation strategies and correlative evaluations (PACE-70): A hybrid implementation-effectiveness study in 3 community practices. First Author: Gabriel Aleixo, University of Pennsylvania, Philadelphia, PA

Background: The use of a geriatric assessment to inform oncologic care for older persons with cancer is an evidence-based practice that improves patient-clinician communication, reduces treatment-related toxicity, and is recommended by national guidelines. However, the implementation of a geriatric assessment can be time-consuming and burdensome, leading to suboptimal use in clinical practice. Developed and endorsed by the American Society for Clinical Oncology (ASCO), the Practical Geriatric Assessment (PGA) is designed to improve clinical usability and adoption, but its implementation in real-world settings has not been evaluated. The PACE-70 study aims to evaluate PGA implementation and resultant chemotherapy dose modification among older adults with advanced cancer treated in a community setting. An exploratory aim will evaluate how the PGA, body composition and step count monitoring correlate with chemotherapy toxicity and other clinical outcomes. **Methods:** The PACE-70 study is a Type III hybrid implementation-effectiveness study enrolling at three community sites within a large academic health system. Eligible participants will be 70 years or older, have a diagnosis of advanced or metastatic solid malignancy, and be starting a new line of palliative-intent systemic therapy, where the expected prevalence of grade 3 toxicity exceeds 50 percent. The PGA will be administered via the electronic health record (EHR), available for patients to complete independently prior to an initial medical oncology visit, or during the visit with staff assistance. Results from the PGA will be shared automatically with clinical teams via the EHR, including a Best Practice Alert highlighting any identified geriatric impairment(s) and ASCO's recommendation for PGA-adapted care. The primary outcome will be the PGA completion rate. The secondary outcome will be the rate of chemotherapy dose modification among those with any identified geriatric impairment. Clinician perspectives on PGA implementation will be assessed via structured interviews among a sub-sample of participating clinicians. In a subsample of patients consenting to additional data collection, exploratory analyses will examine correlations between the PGA, step counts (measured via FitBit) and body composition (measured via standard abdominal CT scans) with clinical outcomes, including toxicity, hospitalization, and death. PACE-70 will be the first study to report on real-world implementation of the PGA in a multisite community oncology setting. It will provide insights on the facilitators and barriers of the PGA to inform chemotherapy dose modification, as well as its potential predictive value for clinical outcomes. It will lay the foundation for larger trials of effectiveness seeking to encourage PGA implementation and PGA-adapted care. Clinical trial information: pending. Research Sponsor: None.

TPS1662 **Poster Session**

Patient Priorities Care for older breast cancer survivors: A patient-centered approach to improve quality of breast cancer survivorship. First Author: Dana Elena Giza, The University of Texas Health Science Center at Houston, Houston, TX

Background: Older adult breast cancer survivors have higher rates of chronic conditions compared with other cancer survivors and may have a higher treatment burden. High treatment burden is associated with poor quality of life and increased healthcare utilization. Aligning care with patient priorities can reduce the treatment burden during survivorship care. Patient Priorities Care (PPC) is an approach designed to align care around each patient's goals to help decrease treatment burden. Although the PPC approach was previously designed for patients with multiple chronic conditions, we sought feedback from stakeholders, including older patients with a history of breast cancer, to adapt the PPC approach to breast cancer survivorship context. This quality improvement project aims to use PPC and patient's self-defined goals to improve the quality of survivorship care for older adults breast cancer survivors. **Methods:** We are conducting a multicenter, randomized quality improvement project with a hybrid implementation-effectiveness design to evaluate the impact of the adapted PPC approach compared to standard survivorship care on treatment burden and quality of life (NCT06478589). We are recruiting 120 older adult breast cancer survivors from outpatient oncology and primary care clinics. Eligible patients are: (1) $\geq$65 years of age; (2) stage I-III breast cancer, who had finished active breast cancer treatment and are in the first year of survivorship care; (3) have evidence of burdensome care; (4) English-speaking; and (5) able to provide informed consent. Enrollment started in December 2024. Patients are stratified based on treatment burden at baseline; patients with a score of $>$ 15 on the treatment burden questionnaire (TBQ) undergo simple randomization with a 2:1 ratio to either the PPC or standard survivorship care group. The PPC for Breast Cancer Survivorship intervention consists of: (1) a 30-minute priorities identification visit with a facilitator, 2) delivery of a structured patient priorities report to the survivorship care team, 3) survivorship care alignment using the patient's priorities. The primary outcome measures are differences in treatment burden (TBQ) and quality of life (FACT-B) from baseline at 3 to 6 months. Secondary outcomes include goal attainment achievement at 3,6 months for patients in the intervention group and adherence to standard and priorities-based breast cancer survivorship recommendations at 12 months for both groups. Descriptive statistics will be used to report patients' baseline and clinical characteristics. All analysis will be intention to treat. The effect of the intervention on changes (baseline to 3, 6 months) in the TBQ and FAST-B scores using Bayesian analysis. For the goal attainment differences, we will compare the differences in goal ratings from baseline at 3, 6 months within the Patient Priorities Group. Clinical trial information: NCT04513977. Research Sponsor: NIA.

TPS1663 **Poster Session**

Impacting quality of life and pancreatic cancer survivorship through a telehealth intervention. First Author: Vincent Chung, City of Hope, Duarte, CA

Background: Pancreatic cancer patients experience significant debilitating symptoms as a direct or indirect result of disease, treatment, and co-morbidities resulting in higher symptom burden compared to other cancer types. The presence of comorbidities, declines in organ function, and increased need for assistance with daily function complicates the care of older adults with pancreatic cancer. Cancer not only affects the patient but also the entire family, especially the one that assumes the role of the family caregiver (FCG). Robust evidence suggests that survivors with pancreatic cancer and their FCGs experience high symptom burden and reduced quality-of-life (QOL). Despite robust evidence pointing to potential benefits of palliative care, many pancreatic cancer patients never receive any due to the workforce shortage. A scalable method of providing palliative care is needed. **Methods:** We are conducting a randomized pilot study to determine the feasibility, acceptability, and preliminary efficacy of a centrally administered telehealth, self-management survivorship care intervention in patients with pancreatic cancer and their FCGs. Patients within 8 weeks of initiating first line treatment for metastatic disease are eligible. Prior to initiating the intervention sessions, an advanced practice nurse (APRN) will complete separate comprehensive survivor/FCG QOL assessments using baseline surveys. The assessments will focus on QOL needs for survivors/FCGs and will include geriatric assessment for all regardless of age (activities of daily living, physical mobility, falls, social activity limitations, social support). Based on the QOL and geriatric screenings, the Intervention APRN will complete a personalized care plan for the patient, and a personalized self-care plan for the FCG. This provides for tailoring of the care plan to the participant's needs and preferences and will be shared with each participant's oncology care team after session completion. Both care plans will be organized around the four QOL aspects of care (physical, psychological, social, spiritual). Cultural aspects of care are taken into account and integrated appropriately within the four QOL aspects of care. A fully developed intervention resource manual with support reference materials and intervention content are provided to each patient and FCG. The patient and FCG coaching sessions are bi-weekly, centrally administered and separate but parallel to allow participants to freely discuss their QOL needs. Clinical trial information: NCT06524973. Research Sponsor: U.S. Department of Defense.

A prognostic classification system for extent of resection in IDH-mutant grade 2 glioma: A report by the RANO resect group. First Author: Philipp Karschnia, Department of Neurosurgery, Uniklinikum Erlangen, Friedrich-Alexander-University Erlangen-Nuremberg, Erlangen, Germany

Background: The effects of resection in IDH-mutant grade 2 gliomas remain controversial since terminology for extent of resection was inconsistently applied across trials. We aimed to (I) establish a standardized classification system for extent of resection and (II) assess the impact of supramaximal resection on survival in IDH-mutant astrocytomas and 1p19q-codeleted oligodendrogliomas. **Methods:** Patients with newly diagnosed grade 2 IDH-mutant glioma meeting the WHO 2021 criteria were identified across sixteen centers in the USA, Europe, and Asia as part of the RANO *resect* effort. Additional patients from UCSF served for validation. Kaplan-Meier analyses and log-rank tests were applied to calculate survival, and Cox's proportional hazard regression model to adjust for multiple variables (significance level: $p \leq 0.05$). **Results:** We identified 1391 newly diagnosed IDH-mutant gliomas grade 2 between 1993-2024, of which 728 patients (379 astrocytoma, 349 oligodendroglioma) received no adjuvant treatment and allowed to study the effects of resection. Smaller post-operative T2/FLAIR tumor remnants were favorably associated with outcome. We classified those patients according to residual T2/FLAIR tumor volumes: patients with 'maximal T2/FLAIR resection' (class 2; 0-5 cm^3 remnant) had superior progression-free and overall survival compared to 'submaximal T2/FLAIR resection' (class 3; 5-25 cm^3 remnant) or 'minimal T2/FLAIR resection' (class 4; $>$25 cm^3 remnant), with 10-year survival rates of 82.2% *vs*. 75.0% *vs*. 45.6% (respectively; $p = 0.001$). Resection of non-infiltrated structures beyond T2/FLAIR borders provided an additional survival benefit as characterized by a 10-year survival rate of 97.5%; thus defining class 1 'supramaximal T2/FLAIR resection' (HR for OS *vs.* class 2: 0.24, CI 0.1-0.5 / in astrocytoma: 0.26, CI 0.1-0.7 / in oligodendroglioma: 0.21, CI 0.1-0.9). Effects of extensive resection on survival unfolded after 3 years in astrocytomas, whereas survival curves separated after 6-8 years in oligodendrogliomas. The prognostic relevance of the four-tier classification was conserved in a multivariate analysis controlling for clinical markers including pre-operative tumor and 1p19q-codeletion, in subgroups of either astrocytomas or oligodendrogliomas, and in a separate cohort of 586 patients who received adjuvant chemo-/radiotherapy. The prognostic value of the classification was further validated in the external UCSF cohort of 381 grade 2 IDH-mutant gliomas ($p = 0.001$). **Conclusions:** The proposed 'RANO classification for extent of resection' serves as prognostic tool for patient stratification in grade 2 IDH-mutant gliomas. While effects of extensive surgery are evident earlier in astrocytomas, 'supramaximal' resection translates into a survival benefit for both astrocytomas and oligodendrogliomas and should be characterized in clinical trials. Research Sponsor: None.

2002 **Oral Abstract Session**

Final clinical and molecular analysis of the EORTC randomized phase III intergroup CATNON trial on concurrent and adjuvant temozolomide in anaplastic glioma without 1p/19q codeletion: NCT00626990. First Author: Martin J. Van Den Bent, Erasmus MC Cancer Institute, Rotterdam, Netherlands

Background: The 1st and 2nd interim analyses of the CATNON trial on anaplastic glioma (NCT00626990) showed benefit from adjuvant (adj) temozolomide (TMZ) on overall survival (OS) in patients with IDH mutant (mt) tumors, but no benefit of concurrent (conc) TMZ regardless of Isocitrate dehydrogenase 1 and 2 (IDH) mutation (mt) status. We now present the final analysis and the exploratory molecular marker analysis of the study. **Methods:** The 2x2 factorial design phase III CATNON trial randomized 751 adult patients with newly diagnosed non-codeleted anaplastic glioma to either 59.4 Gy radiotherapy (RT) alone; the same RT with concTMZ; the same RT and 12 cycles of adjTMZ or the same RT with both concTMZ and adjTMZ. Methylation status including *MGMT* promoter methylation status were assessed with the Infinium MethylationEPIC Beadchip. IDH mutation (mt) status and glioma specific alterations were assessed with a glioma targeted panel using Agilent SureSelect baits. **Results:** After a median follow-up of 10.9 years and with 499 events observed, in the intent-to-treat population the hazard ratio (HR) for OS adjusted for stratification factors after concTMZ was 0.906 (95%CI 0.760, 1.082; p=0.28) and after adjTMZ 0.647 (95%CI 0.541, 0.773; p $<$0.0001). In 660 patients IDH status could be determined: IDH was mt in 444 tumors and wild type (wt) in 216 tumors. Median OS was 1.7 yrs in patients with IDHwt tumors and 8.5 years in patients with IDHmt tumors. Benefit to TMZ was limited to patients with anaplastic glioma IDHmt of which 199 were still alive (45%). For patients with IDHmt tumors the HR for concTMZ was 0.81 (95% CI 0.63-1.04; p=0.09) and for adjTMZ 0.54 (95% CI 0.42-0.69,p $<$ 0.0001). No benefit was observed of concTMZ in IDHmt glioma patients that also received adjTMZ (HR 0.92 95% CI 0.63-1.36; p=0.69). In patients with IDHmt tumors that had received any TMZ median OS was 10.3 years, the median OS in patients treated with adjTMZ was 12.5 years (95% CI 9.4-15.0; p$<$0.0001). In exploratory analysis, high-copy number Amplification of *PDGFR* and *CDK4*; Homozygous deletion of the *CDKN2A/B* locus, total copy number alterations, methylation subtype (A_IDH vs A_IDH_HG, G-CIMP high versus low, *MGMT*-promoter methylation as determined by methylation arrays) were all associated with outcome but none was predictive for benefit to TMZ. **Conclusions:** Despite more follow-up, concTMZ did not improve OS regardless of IDH status. AdjTMZ increased OS in patients with IDHmt tumors but not in patients with IDHwt tumors. Molecular factors of known prognostic significance for IDHmt 1p/19q intact anaplastic glioma did not predict benefit to TMZ. Median OS in patients with IDHmt glioma having received adjTMZ after RT was 12.5 years. Standard of post-operative care in patients with high grade IDHmt astrocytoma should be RT followed by 12 cycles adjTMZ. Funding Source: MSD. Clinical trial information: NCT00626990. 2003 **Oral Abstract Session**

A phase 2 study of pemigatinib for pre-treated glioblastoma or other gliomas with activating FGFR1-3 alterations: Results from FIGHT-209. First Author: Enrico Franceschi, IRCCS Istituto delle Scienze Neurologiche di Bologna, Bologna, Italy

Background: FGFR genomic alterations occur in approximately 8% of gliomas. Inhibition of FGFR1-3 with pemigatinib showed antitumor activity in a multihistology basket trial (FIGHT-207) in which approximately 10% of participants (pts) had recurrent/progressive FGFR-altered glioblastoma (GBM). We further investigated pemigatinib activity in primary brain tumors by conducting an international, multicenter, single-arm, 2-cohort, phase 2 study specifically in adults with FGFR-altered pretreated gliomas (FIGHT-209; NCT05267106). **Methods:** Pts were enrolled in 2 cohorts: A, histologically or molecularly defined GBM; or B, other gliomas, glioneuronal tumors, and neuronal tumors. Eligible pts had tumors harboring a FGFR1-3 fusion/rearrangement or mutation detected by an accredited laboratory that had recurred/progressed after $\geq$1 prior therapy. Pemigatinib (oral, 13.5 mg on days 1-14/21) was intended to continue until progression by Response Assessment in Neuro-Oncology (RANO) criteria determined by an independent review committee (IRC) or unacceptable toxicity. Efficacy of each cohort was evaluated independently. The primary endpoint was objective response rate (ORR; partial plus complete) per RANO (cohort A), with a goal of $>$ 28%. Key secondary and exploratory endpoints were ORR in cohort B, ORR by investigator assessment, progression-free survival (PFS) by IRC, overall survival (OS), safety, neurologic function by Neurologic Assessment in Neuro-Oncology (NANO), and efficacy correlations with diagnosis and specific FGFR-alterations. **Results:** Between May 2022 and December 2023, 74 pts were enrolled in cohort A and 9 in cohort B. FGFR1-3 fusions/rearrangements were the most common genomic alterations in cohort A (n = 65 [88%]) and in cohort B, FGFR1 mutations (n = 8 [89%]). Pts had a median (range) age of 56 (20-79) years; 60% were male. On September 27, 2024 (data cutoff), 16 pts remained on treatment (cohort A, n = 11 [15%]; cohort B, n = 5 [56%]); 67 discontinued, primarily due to progressive disease (n = 59 [71%]). In cohort A, ORR was 8% (6 partial responses [PR], 0 complete responses [CR]); 21 pts (28%) had stable disease (SD); estimated 6-month PFS rate was 17% (95% CI, 8.7-27.8) and 12-month OS rate 48% (95% CI, 35.6-60.2). In cohort B, the ORR was 22% (1 CR, 1 PR); 3 (33%) SD. Most treatment-emergent adverse events (AEs) were low grade in severity (grade $\geq$3, 36.1%). Hyperphosphatemia, a class effect of FGFR inhibitors, was the most common AE (75%); 6 pts (7%) required dose reduction and 4 pts (5%) discontinued due to AEs. **Conclusions:** ORR did not meet the pre-specified goal of $>$ 28% among pts with GBM harboring pemigatinib-sensitizing FGFR alterations. However, durable disease stabilization was observed, notably in pts with CNS tumors other than GBM, and toxicities were manageable. More mature PFS and OS data will be presented with exploratory molecular correlations. Clinical trial information: NCT05267106. Research Sponsor: Incyte Corporation.

2004 Oral Abstract Session

A phase II study of asandeutertinib (TY-9591) in advanced NSCLC patients with EGFR-positive mutations and brain metastases. First Author: Pu-Yuan Xing, National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College, Beijing Key Laboratory of Clinical Study on Anticancer Molecular Targeted Drugs, Beijing, China

Background: Asandeutertinib (TY-9591), a deuterated osimertinib derivative, is a new central nervous system-active 3rd generation epidermal growth factor receptor tyrosine kinase inhibitor (EGFR-TKI), that can potently and selectively inhibit *EGFR*- sensitizing mutations (EGFRm+) and T790M resistance mutation. The phase I study for asandeutertinib (NCT04204473) showed had a very superior clinical efficacy on the NSCLC with *EGFR* mutations. This phase II study (NCT05146219) aimed to further evaluate the efficacy and safety of asandeutertinib in patients with locally advanced or metastatic EGFRm+ NSCLC with brain metastases (BM). **Methods:** 29 patients were enrolled and received asandeutertinib treatment at a dose of 160 mg once daily. The 27 patients with *EGFR*-sensitizing mutations (19 Del or L858R) did not take any EGFR-TKI previously, while the 2 patients with *EGFR* T790M resistance mutation previously received 1st or 2nd-generation EGFR-TKIs therapy. The primary endpoints were the intracranial objective response rate (iORR) assessed by investigator (INV) per RANO-BM and the extracranial objective response rate (eORR) assessed by INV per the RECIST v1.1. **Results:** At the time of data cutoff at March 21,2024, the median follow-up time was 16.4 months. The confirmed INV-iORR was 93.1% (95% CI: 77.2%-99.2%) (n = 29). The confirmed INV-iORR for those who were treated with asandeutertinib as first line was 92.6% (95% CI : 75.7%-99.1%) (n = 27). The 2 patients with previous EGFR-TKI therapy were intracranial partial response (iPR). The median intracranial duration of response (iDoR) and intracranial progression-free survival (iPFS) were not reached. The 12-month iDoR was 82.8%, and the 12-month iPFS was 96.6%. The median PFS was 13.5 months (95% CI: 12.5-NA) (n = 29) and 15.1 months (95%CI : 12.5 - NA) (n = 27) for those without previous EGFR-TKI therapy. Any intracranial or extracranial progression was evaluated as systemic progression, which may lead to underestimation of the systemic PFS. The mean treatment was 402.9 days (n = 29). 27 (93.1%) patients experienced treatment-related adverse events (TRAEs). The most common TRAEs (≥10%) included decreased white blood cell count, decreased absolute neutrophil count, decreased platelet count, elevated serum creatine phosphokinase, diarrhea, etc (majority grade 1/2). Grade 3 TRAEs occurred in 27.6% patients while no grade 4/5 adverse event. Six serious adverse events were reported by five patients (17.2%), of which two patients (6.9%) were study drug-related. The interstitial lung disease, cardiomyopathy and keratitis were not reported. **Conclusions:** Asandeutertinib is highly effective and well-tolerated in locally advanced or metastatic EGFRm+ NSCLC patients with BM. Pivotal phase II study (NCT05948813) and phase II trials (NCT05382728) are onging. Keywords: TY-9591; Deuterated osimertinib derivative; Brain metastases. Clinical trial information: NCT05146219. Research Sponsor: None.

2005 Oral Abstract Session

Patritumab deruxtecan (HER3-DXd) in active brain metastases (BM) from metastatic breast (mBC) and non–small cell lung cancers (aNSCLC), and leptomeningeal disease (LMD) from advanced solid tumors: Results from the TUXEDO-3 phase II trial. First Author: Matthias Preusser, Division of Oncology, Department of Internal Medicine I, Medical University of Vienna, Vienna, Austria

Background: BM and LMD are common and severe complications of solid cancers with high morbidity, poor prognosis, and limited treatment options. Antibody drug conjugates (ADCs) have shown high intracranial overall response rates (IC-ORR) in HER2-positive mBC and *EGFR*-mutated NSCLC patients (pts). HER3-DXd, an ADC combining an anti-HER3 antibody with a topoisomerase (topo) I inhibitor, has shown promising results in mBC and aNSCLC pts. Since HER3 is highly expressed in aNSCLC and mBC CNS metastases, we hypothesized HER3-DXd may have clinical activity in BM from mBC and aNSCLC pts, and LMD from any solid tumor. **Methods:** TUXEDO-3 (NCT05865990) is an international, multicenter, multicohort, single-arm, phase II trial enrolling pts with BM from mBC (cohort 1), aNSCLC (cohort 2), and LMD from any solid tumor (cohort 3). Key inclusion criteria were: Pts ≥18 years old, histologically documented disease, ECOG PS 0-2, and left ventricular ejection fraction ≥50% in all cohorts; newly diagnosed/progressing BM with ≥1 brain lesions ≥10mm by MRI, and ≥1 line of prior systemic treatment, in cohorts 1 and 2; LMD per EANO-ESMO in cohort 3. Pts received HER3-DXd 5.6 mg/kg IV Q3W until disease progression, unacceptable toxicity or withdrawal for any reason. Primary endpoint was IC-ORR per local investigator according to RANO-BM in cohorts 1 and 2, and 3-month OS in cohort 3. Sample size was based on Simon's two-stage design. Primary endpoint was met if ≥3 IC responses (H0: ≤5%; H1: ≥25%) in cohort 1 and 2; and if ≥3 pts with 3-month OS (H0: ≤5%; H1: ≥25%) in cohort 3. Overall sample size was 60 pts with a target population of 20 pts per cohort. **Results:** Between December 2023 and July 2024, 61 evaluable pts were enrolled from 8 Austrian and Spanish sites. Median age (min; max) was 57.0 (35.0; 75.0), 59.5 (37.0; 72.0) and 51.5 (40.0; 66.0) years in cohorts 1, 2 and 3, respectively. At data cut-off, median follow-up (min; max) was 4.4 (1.4; 10.1), 4.3 (0.2; 11.0) and 3.5 (0.8; 8.6) months in cohorts 1, 2 and 3, respectively. Primary endpoints were met in all three cohorts. In cohort 1, 5/21 (23.8%) pts had IC response irrespective of BC subtype; 2 (40.0%) responders had received previous topo I based ADCs. In cohort 2, 5/20 (25.0%) pts had IC response. In cohort 3, 11/20 (55.0%) pts achieved 3-month OS irrespective of the LMD type. No new signals of toxicity were observed and neurological symptoms, QoL and neurocognitive function remained stable or improved over the treatment period. Tumoral HER3 expression did not correlate with treatment response. **Conclusions:** TUXEDO-3 is the first trial evaluating efficacy and safety of HER3-DXd in pts with BM or LMD. HER3-DXd showed substantial CNS activity in parenchymal metastases and LMD, and may be a potential novel treatment for CNS disease in cancer pts. Clinical trial information: NCT05865990. Research Sponsor: Daiichi Sankyo Company, Limited; Merck Sharp & Dohme LLC, a subsidiary of Merck & Co.

2006 Oral Abstract Session

A phase II study of an anti-telomerase CD4+ T-helper vaccine (UCPVax) with or without temozolomide in newly diagnosed glioblastoma. First Author: Antoine Carpentier, Hôpital Saint-Louis, Paris, France

Background: UCPVax is a therapeutic vaccine designed to stimulate CD4+ helper T cell responses against telomerase (TERT), a protein highly expressed in glioblastoma (GBM). Temozolomide (TMZ), a standard chemotherapeutic agent in the treatment of GBM, has been shown to induce CD4+ T-cell lymphopenia, which could potentially impair the immune response to the vaccine. We conducted a multicenter, 2-cohort, phase IIa study to evaluate the immunogenicity and efficacy of UCPVax, with or without TMZ, as adjuvant therapy in patients with newly diagnosed GBM following chemoradiation. **Methods:** Patients with non-mutated IDH1 glioblastoma (GBM) were enrolled one month after completing concurrent radiotherapy and temozolomide (TMZ). Cohort A received the vaccine alone, without additional TMZ, while Cohort B was treated with both the vaccine and six monthly cycles of TMZ. The primary endpoint was the induction of TERT-specific CD4+ T cell responses, assessed ex vivo using the INF-γ ELISpot assay. Secondary endpoints included epitope spreading, clinical outcomes, and safety. **Results:** Thirty-one GBM patients with unmethylated MGMT status were included in cohort A, and 30 patients (50% with unmethylated MGMT status) were included in cohort B. The vaccine was well tolerated, with no vaccine-related serious adverse events. Vaccine-expanded TERT-specific CD4+ T cells were detectable *ex vivo* in 25/30 (83%) of patients in cohort A (no additional TMZ) and in 18/26 69% of patients in cohort B (treated with additional TMZ). Epitope spreading was induced in 29 out of 55 evaluable patients (52.7%), corresponding to 15/26 (57.7%) in cohort A and 14/29 (48%) in cohort B. Median overall survival (OS) was significantly improved in patients who developed an epitope spread response compared to those who did not (19.3 vs. 12.8 months, P = 0.03). In the 44 patients with measurable disease at the time of inclusion, the radiological response rate (RR) was 34%, including minor responses. In patients who developed epitope spreading after vaccination (n = 22), the RR was 50%, compared to 18.7% in patients without epitope spreading (P = 0.05). Furthermore, tumor-infiltrating lymphocytes against TERT were detected in 3 vaccinated patients who underwent surgery at recurrence. **Conclusions:** UCPVax demonstrated robust immunogenicity, even when co-administered with TMZ, and was associated with improved overall survival (OS) in GBM patients who developed an epitope spreading response. These findings support further clinical investigation of TERT-derived CD4+ helper vaccine in GBM patients. Clinical trial information: NCT04280848. Research Sponsor: French Eastern Interregional Group of Clinical Research and Innovation (GIRCI-Est - APJ2017); Oligocyte.

2007 Oral Abstract Session

INB-200: Phase 1 study of gene-modified autologous gamma-delta (γδ) t cells in newly diagnosed glioblastoma multiforme (GBM) patients receiving maintenance temozolomide (TMZ). First Author: Mina Lobbous, Cleveland Clinic, Cleveland, OH

Background: Recent cell therapy and CAR-T initiatives for GBM have shown initial responses but durability has been disappointing. We developed a novel approach to treat newly diagnosed GBM using innate γδ T cells following forced upregulation of tumor stress-associated targets. **Methods:** We leveraged the TMZ-induced activation of the DNA damage response (DDR) pathway to transiently upregulate NKG2D-L targets on GBM. Co-administration of TMZ chemotherapy with γδ T cells engineered for TMZ resistance by insertion of a methylguanine-DNA methyltransferase (MGMT)-expressing lentivector (DeltEx Drug Resistant Immunotherapy – DRI) enables the targeting of residual GBM cells during the standard-of-care Stupp regimen. A total of 23 patients were enrolled, with 13 treated and (62% male; median age 66 (range: 21-74); 92% IDH-WT, 54% MGMT-unmethylated). Cohorts (C) 1, 2 and 3 received 1, 3 or 6 doses (1×10^7 DRI cells/dose) into the resection cavity with 150 mg/m^2 of IV TMZ on Day (D) 1 of each Stupp regimen maintenance cycle. **Results:** No Dose limiting toxicities (DLTs) were seen nor were occurrences of cytokine release syndrome (CRS) or neurotoxicity (ICANS). Most common adverse events were related to underlying TMZ and Stupp regimen. As of January 24, 2025, median follow-up is 16.9 months (m). The median PFS for patients is 8.3m for those who received a single dose of INB-200, 9.9m for all patients (a 44% increase over the 6.9m mPFS of the Stupp) and 14.0m for patients who received repeated doses, an 102.4% improvement over Stupp and 69% over single dose patients. A patient with IDH mutant tumor remains progression free for almost 44 months and one with MGMT-unmethylated tumor for 18 months. Biopsy specimens from three patients are available with general immune activation having been demonstrated. **Conclusions:** To date all patients had manageable toxicity with outpatient treatment and a continued encouraging trend in longer PFS from treatment with DRI γδ T cells. Clinical trial information: NCT04165941. Research Sponsor: IN8Bio, Inc.

2008 Oral Abstract Session

Immunological correlates from phase I study of CARv3-TEAM-E in patients with recurrent glioblastoma (GBM): INCIPIENT trial. First Author: Bryan D. Choi, Massachusetts General Hospital, Boston, MA

Background: Chimeric Antigen Receptor (CAR) T cells for glioblastoma (GBM) have been limited by the challenge of targeting a single tumor antigen in a heterogeneous disease. To address this barrier, we generated a novel engineered T-cell product (CARv3-TEAM-E) that targets the EGFRvIII antigen while also secreting T-cell-Engaging Antibody Molecules (TEAMs) against wild-type EGFR. **Methods:** The INCIPIENT clinical trial is a first-in-human study of CARv3-TEAM-E in patients with recurrent GBM (NCT05660369). Patients were treated with intraventricular CARv3-TEAM-E T cells (10E6 cells per infusion). A subset of patients were conditioned with lymphodepleting chemotherapy (LDC) consisting of cyclophosphamide and fludarabine. Immune cells were profiled in the cerebrospinal fluid (CSF) and peripheral blood of patients by flow cytometry. **Results:** CAR T cells were detected in the CSF of all patients for an average of 33.6 days (*SD* = 10.33). Granulocytes, NK cells, B cells, and monocytes appeared in the CSF immediately after infusion, decreasing to low levels over the course of several weeks. TEAM-positive T cells persisted in CSF until (median) day 33.6 (*SD* = 10.8) with a range of 21-56 days. CAR T cells were transiently detected in the peripheral blood of 9/10 patients at an average of 14 days (*SD* = 3.5) after infusion. Prior to infusion, CAR T cells were predominantly CD4-positive and remained as such in the CSF over time. Those in the periphery exhibited CD4-to-CD8 polarization. Of patients who received multiple infusions, 3 out of 6 had CAR-positive T cells in the CSF after a second infusion, although their persistence was short-lived and was not detected in the periphery following repeat infusions. LDC increased engraftment of CAR T cells in CSF but not in peripheral blood. Patients with poor CAR persistence demonstrated the development of anti-CARv3-TEAM-E antibodies in the CSF and serum, which increased with reinfusion. **Conclusions:** Following initial infusion, intraventricularly delivered CARv3-TEAM-E T cells were detected in the CSF and peripheral blood in patients with recurrent GBM. Reduced persistence was observed with subsequent infusions. This corresponded with the emergence of anti-CARv3-TEAM-E antibodies in treated patients. Clinical trial information: NCT05660369. Research Sponsor: Gateway for Cancer Research; National Cancer Institute/U.S. National Institutes of Health; 1R01CA294071-01A1.

2009 Clinical Science Symposium

Multicenter trial of microbubble-enhanced transcranial focused ultrasound (MB-FUS) with monthly adjuvant temozolomide for patients with high-grade gliomas. First Author: Graeme Woodworth, University of Maryland School of Medicine, Baltimore, MD

Background: High-grade gliomas (HGGs) have few effective therapies targeting tumor cell recurrence, which remain shielded by blood-brain barrier (BBB). MB-FUS allows for controlled BBB opening (BBBO) enabling localized drug delivery and increased tumor biomarker release into systemic circulation. **Methods:** MR-guided MB-FUS with real-time feedback was evaluated for HGG patients in multicenter phase 1/2 trial (BT008: NCT03551249, NCT03616860) for adverse events (AEs) and feasibility [primary endpoints], efficacy [secondary endpoint], and plasma cell-free DNA (cfDNA) post-procedure [exploratory]. After resection and 6 weeks of chemoradiation, peri-resectional infiltrative regions were targeted with MB-FUS during monthly adjuvant temozolomide cycles (MB-FUS+TMZ). For efficacy, overall survival (OS) and progression-free survival (PFS) were compared with an external cohort, created using restriction and coarsened exact matching (CEM). **Results:** Trial cohort had 34 patients enrolled and evaluated from 5 sites in North America. No serious procedure-related AEs were seen, with the most common AEs being mild, self-resolving. BBBO was seen in 100% of treatments, covering 82% targeted volumes with ≤3mm accuracy. Trial cohort had longer mPFS (univariate 13.5 vs. 9.6 months, multivariate HR 0.62, 95%CI: 0.39-0.99, p=0.048) and mOS (36.4 vs. 19.1 months, multivariate HR 0.50, 95%CI: 0.26-0.95, p=0.036), with treatment effect robust in sensitivity analyses. Disease state correlated closely with longitudinal plasma cfDNA changes. **Conclusions:** MB-FUS+TMZ is a safe and feasible therapeutic approach for HGG, potentially improving survival and enabling longitudinal non-invasive monitoring. Clinical trial information: NCT03551249, NCT03616860. Research Sponsor: Insightec Inc; U.S. National Institutes of Health; R21NS113016.

Leveraging stimulated Raman histology-based cellularity for random forest prediction of glioblastoma recurrence. First Author: Sanjeev Herr, Drexel University College of Medicine, Philadelphia, PA

Background: Glioblastoma is a universally fatal diagnosis with extent of resection being one of the most significant predictors of overall and progression-free survival. Most patients eventually experience recurrence, with sixty percent recurring along the resection cavity. Recent work leveraging Stimulated Raman histology (SRH) and artificial intelligence (AI) has approximated glioma cellularity within the infiltrative margins. It remains unknown if these estimates of glioma burden at the infiltrative margins influence glioblastoma recurrence. This study aims to evaluate a predictive model of focal recurrence in patients with glioblastoma using SRH and AI-generated cellularity scores from tissue samples taken at the resection cavity margins. **Methods:** A multi-center, retrospective cohort study was conducted on patients diagnosed with glioblastoma who underwent resection followed by spatial annotated tissues acquired from the resection cavity margins. Tissues were analyzed using SRH optical imaging, and histopathology analysis was performed using confocal microscopy. Tissue cellularity was measured histologically and by optical imaging. **Results:** Over 400 patients and 2,200 specimens were analyzed, of which a nested subset of 60 patients were selected based on selection criteria. Using preoperative and postoperative imaging, margin samples were determined to be in an area of recurrence (n=58) or nonrecurrence (n=220). Cellularity was significantly higher in the recurrent margin sample group when compared to the nonrecurrent group (p = 0.026), which was further confirmed by a pathologist-determined cellularity score (0-3) that demonstrated similar findings (p = 0.026). Results were validated across three medical centers. Six classifiers were then trained for recurrence prediction. Using nineteen of the most predictive variables, random forests (RF) performed best with an AUC of 0.848. RF screening for the minimum practical number of variables demonstrated an AUC of 0.805 using only FastGlioma, age and extent of resection as variables. **Conclusions:** AI-generated cellularity scores have the potential to predict focal recurrence of glioblastoma, allowing for more tailored approaches to surgical resection and radiotherapy to increase progression-free survival. Research Sponsor: None.

Stereotactic radiation versus hippocampal avoidance whole brain radiation in patients with 5-20 brain metastases: A multicenter, phase 3 randomized trial. First Author: Ayal Aizer, Brigham and Women's Hospital/Dana-Farber Cancer Institute, Boston, MA

Background: Radiation therapy forms the mainstay of management for patients with brain metastases. Published randomized trials have found improved quality of life with stereotactic radiation (SRS/SRT) over whole brain radiation (WBRT) in patients with ≤ 4 brain metastases; comparative trials in patients with >4 brain metastases are lacking. In addition, prior randomized trials have demonstrated the superiority of hippocampal avoidance WBRT (HA-WBRT) over traditional WBRT, but no study has compared SRS/SRT to HA-WBRT. Accordingly, we conducted a multicenter, phase 3 randomized trial comparing SRS/SRT to HA-WBRT in patients with 5-20 brain metastases. **Methods:** Eligible patients were age 18-80 with 5-20 brain metastases secondary to a solid primary other than small cell lung cancer, were naïve to prior brain-directed radiation, and lacked leptomeningeal disease. The primary endpoint was the average of patient-reported symptom severity and interference over the first six months post-baseline relative to baseline, using the MD Anderson Symptom Inventory–Brain Tumor (MDASI-BT) module, a validated instrument assessing 22 symptoms and 6 interference measures integral to quality of life, each scored 0-10 with higher scores indicating greater symptomatology/interference in function. The target effect size was a symptom severity of 0.70, corresponding to 50% of the observed difference between patients with a good (90-100) versus poor (≤80) Karnofsky performance status; with 80% power and a two-sided alpha of 0.05, 196 patients were required. **Results:** Between 4/2017-5/2024, 196 patients enrolled, 98 in each arm. The median number of brain metastases was 14 (IQR 11-18); 25% of patients underwent prior neurosurgical resection. Baseline mean MDASI-BT symptom severity scores were 2.2 (SRS/SRT arm) and 1.9 (HA-WBRT arm), p=0.20; respective interference scores were 3.5 and 3.2 (p=0.40). The average of weighted post-baseline severity and interference scores relative to baseline indicated lower symptomatology/inference in the SRS/SRT arm, meeting the primary endpoint of the study (difference between SRS/SRT and HA-WBRT: -1.06, p<0.001). Averaged post-baseline symptom severity scores minus baseline were -0.03 and 0.59 in the SRS/SRT and HA-WBRT arms, respectively (difference -0.62, with lower symptom severity in the SRS/SRT arm, p<0.001); respective interference estimates were -0.62 and 0.89 (difference -1.50, with lower interference in the SRS/SRT arm, p<0.001). Median survival was 8.3 and 8.5 months in the SRS/SRT and HA-WBRT arms, respectively (p=0.30). **Conclusions:** This phase 3 randomized trial indicates that patients with 5-20 brain metastases experience fewer symptoms and less interference in function after SRS/SRT as opposed to HA-WBRT, without compromise of survival, supporting SRS/SRT as the standard of care in this population. Clinical trial information: NCT03075072. Research Sponsor: Varian.

2012 Rapid Oral Abstract Session

Utidelone in combination with etoposide and bevacizumab in HER2-negative breast cancer patients with brain metastasis: A prospective, single-arm, phase II trial. First Author: Yehui Shi, Tianjin Medical University Cancer Institute and Hospital, Tianjin, China

Background: For advanced HER2 negative breast cancer patients with brain metastasis, systematic therapy has failed to yield satisfied efficacy, although bevacizumab and etoposide have shown some effectiveness as mono- or combination therapy. Novel microtubule inhibitor utidelone demonstrated good efficacy in advanced breast cancer patients in several clinical trials, and was also suggested a capability of blood-brain barrier penetration. Therefore, utidelone in combination with bevacizumab and etoposide would be a promising regimen for HER2 negative breast cancer patients with brain metastasis. **Methods:** Breast cancer patients with brain metastasis were enrolled and Simon's two-stage optimal trial design was used for this trial. If more than 3 out of 13 patients showed central nervous system (CNS) response, 30 more patients would be further enrolled. The acceptable ORR was set to be 40% for the trial. Utidelone (30mg/m^2/day, iv, d1-5), and etoposide (100mg/m^2, iv, d1-3) were concurrently administered with bevacizumab (10mg/kg iv, d1) every 21 days for 6 cycles, followed by maintenance treatment with utidelone and bevacizumab until disease progression or unacceptable toxicity. The primary endpoint is CNS-ORR. Secondary endpoints include CNS-clinical benefit rate (CNS-CBR), CNS-PFS, PFS, and safety. **Results:** 34 female HER2 negative patients were enrolled, including 11 triple negative breast cancer patients and 23 patients of luminal subtype, with a median age of 52 years (range 34-74) and a median treatment lines of three. Five patients had prior brain radiotherapy and 2 patients were previously treated with brain surgery. As of December 2, 2024, the median follow up duration was 11.5 months. The CNS-ORR was 67.6% (23/34), and the CNS-CBR was 88.2% (30/34). The median PFS was 6 months (95% confidence interval [CI], 4.265-7.735). The median CNS-PFS was 15 months (95% CI, 6.760-23.240), with supportive treatment for some of the patients after extracranial progression which included etoposide re-administration, or abraxane, endocrine therapy, radiotherapy and immunotherapy. The major AE was peripheral neuropathy with 8.8% (3/34) of Grade 3, primarily classified as sensory. Most of the treatment-related AEs were grade 1 or 2 and were considered manageable and reversible. **Conclusions:** Utidelone in combination with etoposide and bevacizumab has shown promising anti-tumor activity and manageable toxicity in HER2 negative breast cancer patients with brain metastasis, and a randomized control trial is warrantied. Clinical trial information: NCT05781633. 2013 Rapid Oral Abstract Session

Phase 1 study of HMPL-306, an inhibitor of mutant IDH1/IDH2 (mIDH1/2), in western patients (pts) with advanced mIDH solid tumor, including glioma. First Author: Jordi Rodon Ahnert, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Isocitrate dehydrogenase (IDH) 1 or IDH2 mutations or co-mutations have been associated with various tumors, including glioma. HMPL-306 ('306) is a novel, small-molecule, orally available, highly selective, and potent dual inhibitor of both mIDH1 and mIDH2. This is a phase 1 study of '306 in pts with locally advanced or metastatic solid tumors with mIDH. Here, we report the results of the dose escalation stage. **Methods:** Pts with locally advanced or metastatic solid tumors with any mIDH were enrolled to receive '306 once daily (QD) for 28-day cycles. The mTPI-2 design was used for dose escalation, having explored in 8 successive cohorts (50-400 mg). The study aims to determine the maximum tolerated dose (MTD)/recommended phase 2 dose (RP2D), evaluate safety, tolerability, preliminary efficacy and pharmacokinetics/pharmacodynamics (PK/PD). **Results:** As of Aug 9, 2024, 42 pts were administered '306 across 8 doses (n = 3, 3, 5, 12, 6, 4, 4, 5 in 50, 100, 150, 200, 250, 300, 350, 400 mg QD cohorts, respectively), with 17 (40.5%) lower-grade glioma (LGG, grade 2 and grade 3 glioma) pts, 3 (7.1%) grade 4 glioma pts and 22 (52.4%) non glioma pts. The median age was 55 years, and 25 (59.5%) pts were male. During the dose escalation from 50 mg to 400 mg QD cohort, 1 pt given 250 mg QD experienced a dose-limiting toxicity (DLT) of grade 3 lipase increased. MTD was not reached. 12 (28.6%) pts reported grade $\geq$3 adverse events (AEs), which reported in $\geq$ 2 pts was abdominal pain. Efficacy signals were observed especially in LGG pts, in the efficacy evaluated set (N = 14), objective response rate (ORR) was 7.1%, disease control rate was 100%; in the safety analysis set (N = 17), median progression-free survival (PFS) was 20.5 months (95% confidence interval [CI]; 5.5-not estimable). One grade 2 glioma pt with multiple previous treatment on the 200 mg QD achieved minor response lasting 16.8 months. The ORR of grade 4 glioma pts and non glioma pts were not reached, the disease control rate were 33.3% and 25%, respectively. Drug exposures were dose-proportional from 50 mg to 400 mg. Steady-state with ~5-fold accumulation was reached after ~28 days of repeated daily dosing. In non-glioma pts, 2-HG inhibition plateaued after ~28 days, increasing with dose, reaching ~90% at $\geq$150 mg at C2D1. **Conclusions:** '306 was well-tolerated in pts with mIDH1/2 solid tumors, showing target inhibition and durable responses in LGG. Clinical trial information: NCT04762602. Research Sponsor: HUTCHMED Limited.

2014 Rapid Oral Abstract Session

Vaccination by homologous antigenic loading with DOC1021 as adjuvant therapy for glioblastoma: Phase I clinical trial results. First Author: Joseph Georges, Banner University Medical Center, Phoenix, AZ

Background: Glioblastoma is a devastating tumor for which median overall survival (mOS) remains 14-18 months despite aggressive standard of care (SOC) treatment. Clinical studies of dendritic cell (DC) vaccination for GBM have shown promise but have been largely inconclusive. DC homologous antigenic loading leverages p38MAPK and mTORC1 signaling cascades to initiate cDC1-like skewing of monocyte-derived DC, leading to potent downstream induction of tissue-homing cytolytic memory effector T cells. Here we report results of a completed phase I study for glioblastoma (IDH-wt). **Methods:** This clinical trial evaluated autologous DC vaccine DOC1021 prepared from mobilized peripheral blood mononuclear cells (PBMC), loaded with autologous tumor lysate and amplified tumor mRNA, and administered bilaterally near deep cervical lymph nodes. Three courses of vaccine every 2 weeks plus weekly peg-IFN were administered after completion of chemoradiation. Four dose levels from 3.5 x 10^6 to 3.6 x 10^7 total vaccine cells were tested. Patients with subtotal resection or tumor progression prior to vaccination were not excluded. **Results:** Sixteen newly diagnosed patients completed treatment, median age 61 years (range 47-73), 94% MGMT unmethylated, 25% subtotal resected. OS at 12-months was 88% compared to expected ~60% for SOC and 5 patients are still alive at 19-30 months of follow-up. Two recurrent glioblastoma patients were also treated and survived for 10-12 months. Most common AEs were mild flu-like symptoms and injection-site reactions, and there were no dose limiting toxicities. Analysis of post-vaccination PBMC indicated expansion of $CD4^+$ (13/13 patients) and $CD8^+$ (11/13) central memory T-cell compartments ($p < 0.00006$ and $p < 0.003$, respectively) as well as expansion of $CD8^+CD127^+$ MPECs (12/13; $p < 0.002$). Among 3/3 patients analyzed by spatial transcriptomics, intense $CD25^+$ foci correlating with co-expression of effector memory T-cell and migratory microglial markers were observed in post-vaccination but not pre-vaccination samples. For 8 patients who were observed rather than re-operated for worsening T1-weighted signal on MRI in the 23 weeks after vaccination, signal gradually resolved and GBM-specific mOS is not yet reached compared to 15.1 months for 8 patients who received reoperation despite comparable clinical characteristics, suggesting an immune-reactive microenvironment manifesting as pseudo-progression. **Conclusions:** DOC1021 combined with SOC is safe and potentially efficacious in this challenging population that included subtotal resections, pre-treatment progression and 15/16 MGMT unmethylated. A randomized phase II trial is being launched including criteria to avoid early re-operation for enhancing T1-weighted signal that may be pseudo-progression. Clinical trial information: NCT04552886. Research Sponsor: Cancer Cures 4 Kids; N/A; Diakonos Oncology; N/A.

2015 Rapid Oral Abstract Session

Results from phase 1 study of mycophenolate mofetil with chemoradiation in newly diagnosed glioblastoma to target de-novo purine metabolism to overcome treatment resistance. First Author: Yoshie Umemura, Ivy Brain Tumor Center at Barrow Neurological Institute, Phoenix, AZ

Background: Mycophenolate mofetil (MMF) inhibits IMPDH and disrupts *de novo* purine synthesis which is preferred by glioblastoma (GBM) whilst normal brain prefers resource efficient salvage pathway. A phase 0 study demonstrated the active drug metabolite reaching both enhancing and non-enhancing GBM tissues in humans, and effective target engagement, noted by reduced GTP/IMP ratio. This phase 1 trial assessed the tolerability of MMF with chemoradiation in newly diagnosed GBM patients (NCT04477200). **Methods:** Thirty adult patients with newly diagnosed GBM were given MMF, dosed BID, 1 week prior to and concurrently with standard of care (SOC) radiotherapy (RT) of 60 Gy in 30 fractions with concomitant temozolomide (TMZ) 75mg/m2, followed by MMF 1 day before + 5 days of each SOC TMZ 150-200mg/m2 x 5/28-day cycle up 12 cycles. Optune was optional. Primary endpoint was dose limiting toxicity (DLT) and maximally tolerated dose (MTD) of MMF combined with SOC GBM chemoradiation. Time-to-event continual reassessment method was used to determine MMF dosing, with MTD defined as estimated rate of dose-limiting toxicity (DLT) closest to but not exceeding 30%. DLT periods were during and up to 4 weeks after concurrent chemoradiation (DLT1), and first two 28-day cycles of MMF with temozolomide (DLT2). Transient grade 4 neutropenia x $<$ 7 days and asymptomatic grade 4 lymphopenia were excluded from DLT. Kaplan Meier method was used to estimate overall survival (OS). **Results:** The median age was 57 (range 20-75). The majority had KPS $>$ 80 (67%) at baseline, and unmethylated MGMT (70%). During DLT1 period, 5 DLT1 was noted out of 16 subjects on 2000mg BID (grade 3 hemiparesis, cognitive disturbance, fatigue, and grade 4 thrombocytopenia x2), and none at 1500mg (N = 10) and 1000mg (N = 4). During DLT2 period, 1/6 subjects at 1500mg BID experienced DLT of grade 3 fatigue, and none at 1000mg (N = 4) and 2000mg (N = 16). All DLTs were reversible. Four patients did not receive MMF during DLT2 period due to withdrawal from the study (N = 2) and progression of disease (N = 2). The most common treatment related adverse events were fatigue (77%), leukopenia (67%), and nausea (53%). Of the dose levels studied, the MTD for DLT1 and DLT2 were both 2000mg BID (posterior probability of DLT1: 18.5%, posterior probability of DLT2: 7.5%), however, due to frequent fatigue and nausea, DLT1 period starting dose was lowered to 1500mg BID for the last 7 subjects. The recommended phase 2 dose is 1500mg BID combined with concurrent RT+TMZ followed by TMZ. Median OS was 16.8 months with 25.5 months median follow up duration (NR & 25.5 months in MGMT methylated, 14.2 & 24.9 months in MGMT unmethylated respectively). **Conclusions:** MMF can penetrate enhancing and non-enhancing GBM with evidence of successful inhibition of *de-novo* purine synthesis in humans, and is reasonably well tolerated when combined with chemoradiation newly diagnosed GBM patients. These promising results have led to a planned phase 2/3 randomized controlled trial through Alliance for Clinical Trials in Oncology. Clinical trial information: NCT04477200. Research Sponsor: Gateway for Cancer Research.

2016 **Rapid Oral Abstract Session**

Use of lucicebtide (ST101) in glioblastoma patients by antagonism of C/EBPβ-dependent mesenchymal cell transition and immunosuppressive M2 macrophage polarization. First Author: Fabio Massaiti Iwamoto, Columbia University Irving Medical Center, New York, NY

Background: C/EBPβ is a master regulator of the mesenchymal phenotype in GBM and has an essential role in the maintenance of immunosuppressive M2 tumor-associated macrophages (TAMs). Lucicebtide is a first-in-class antagonist of C/EBPβ that has shown direct anti-tumor activity in GBM as well as the ability to reprogram TAMs in the TME toward immunostimulatory M1 macrophages. In a recent recurrent GBM (rGBM) P2 study, lucicebtide was well-tolerated and resulted in disease control in 9/30 patients, including two PRs lasting > 1 year. With strong rationale for targeting C/EBPβ in GBM, additional cohorts we explored in a window-of-opportunity (WoO) study (NCT04478279). **Methods:** The WoO study enrolled 2 cohorts; 9 pts with rGBM that received 2-4 doses of lucicebtide 500mg QW prior to surgery and resumed lucicebtide after surgery to progression and 9 ndGBM pts that received 2-3 doses of lucicebtide 500mg QW prior to surgery and resumed lucicebtide + chemoradiation after surgery until progression. Endpoints include efficacy parameters of PFS and OS, safety as a single agent and in combination with chemoradiation, and pharmacodynamic analyses including spatial transcriptomics and TME characterization. **Results:** Lucicebtide was well-tolerated as a single agent and in combination with chemoradiation. Tissue analysis indicates penetration past the BBB and tumor uptake, as well as C/EBPβ target engagement. Lucicebtide + chemoradiation in ndGBM extended PFS beyond historic benchmarks, with the majority of patients remaining on study without progression (7-22+ months). As of January 25, 2025, mOS could not be evaluated, with 8/9 patients alive. In rGBM, lucicebtide improved mPFS to 3.4 months and mOS to at least 11.8 months, exceeding historical data with chemotherapy (historic mPFS ~ 2 months and mOS 5.6-9.8 months). Pathologic evidence of treatment effect, i.e. geographic necrosis, was observed in 5/6 pts including otherwise treatment naïve ndGBM patients. Spatial transcriptomics analysis revealed a significant reduction in the mesenchymal gene signature following lucicebtide, consistent with on-target antagonism of C/EBPβ. Further, immune activation in the TME, as indicated by increased M1/M2 ratio and CD8+ T cell infiltration, was associated with disease control. **Conclusions:** Lucicebtide is well-tolerated as monotherapy and in combination with SoC. Improvements in PFS and OS in GBM patients following lucicebtide exposure demonstrated penetration across the BBB and target engagement, resulting in on-target pharmacodynamic activity including a dramatic reduction in mesenchymal gene signature in tumor cells and a remodeling towards a more permissive immune TME. These data provide the mechanistic rationale for continued clinical evaluation of lucicebtide as a novel approach for patients with GBM. Clinical trial information: NCT04478279. Research Sponsor: None.

2017 **Rapid Oral Abstract Session**

Safety and tolerability of intraventricular CARv3-TEAM-E T cells following lymphodepleting chemotherapy in recurrent glioblastoma: INCIPIENT trial. First Author: Elizabeth R. Gerstner, Massachusetts General Hospital, Boston, MA

Background: CAR T therapy is a novel, promising approach in glioblastoma (GBM) but tumor heterogeneity can limit efficacy when a single antigen is targeted. We designed a second-generation CAR T molecule that targets epidermal growth factor receptor vIII (EGFRvIII) and also secretes a T-cell–engaging antibody molecule (TEAM) against wild-type EGFR. **Methods:** In a phase 1, first-in-human study (INCIPIENT, NCT05660369), patients with recurrent GBM with EGFRvIII mutation and/or EGFR amplification were eligible to receive up to 6 intraventricular doses of 10x106 CAR T cells via Ommaya catheter after lymphodepleting chemotherapy (LDC) with fludarabine and cyclophosphamide. Primary objective was safety and tolerability and secondary objective was preliminary tumor response determined by iRANO criteria. **Results:** CAR T manufacturing was successful for all patients. Seven patients (5 male) received at least 1 intraventricular infusion. Two patients received 2 infusions (1 for progressive disease (PD) and 1 without PD). One patient received 3 infusions after experiencing initial PD. No DLTs occurred. All patients experienced cytokine release syndrome (CRS) grade 1 lasting 0-9 days with only 1 patient experiencing CRS grade 2 for 1 day. One patient experienced ICANS grade 1 that lasted 2 days. All patients experienced tumor inflammation-associated neurotoxicity grade 1 with a duration of 2-9 days. Adverse events (grade 3-4) at least possibly related to CAR T were febrile neutropenia (N = 1) and neutrophil count decrease (N = 1). Toxicity was managed with supportive care without need for ICU monitoring and 3 patients received at least 1 dose of anakinra (max duration = 4 days, median = 1 day). Best response was stable disease (SD) in 5 patients with 1 patient achieving SD for 6 months after a single infusion and another experiencing a 33% decrease in tumor diameter after 2 infusions. All patients are alive 3-8 months after first infusion. From the preceding safety run-in arm of the study (without LDC), one patient survived 12 months and another is still alive > 20 months after infusion. **Conclusions:** Intraventricular CARv3-TEAM-E infusions were well tolerated, even with multiple doses, and no DLTs were noted. Toxicity was manageable in all patients with supportive care and anakinra was administered to 3 patients. Steroids were not required to manage toxicity. A subset of patients experienced SD for several months. Clinical trial information: NCT05660369. Research Sponsor: Gateway for Cancer Research; National Gene Vector Biorepository at Indiana University, which is funded under National Cancer Institute contract HSN261201500003I Task Order No. HHSN26100077; Philanthropic support to the Cellular Therapy Program at MGH.

2018 **Rapid Oral Abstract Session**

A phase 1 study of B7H3 CAR-T cells administered intracranially in recurrent glioblastoma. First Author: Gordon Li, Stanford University, Stanford, CA

Background: Glioblastoma (GBM) is an aggressive malignancy with median survival of approximately 2 years from initial diagnosis and 9 months after first progression. Effective treatments in the recurrent setting following upfront chemoradiation and adjuvant temozolomide are limited. The transmembrane glycoprotein B7H3 is over-expressed in GBM and chimeric antigen receptor T cells targeting B7H3 (B7H3-CART) have shown activity in several preclinical cancer models. Intracranial delivery of B7H3-CART may optimize targeting the immune response to the tumor microenvironment while limiting systemic toxicity. **Methods:** We conducted a single-arm phase 1 study in patients with recurrent GBM undergoing repeat resection. B7H3-CART was administered via intratumoral and intraventricular Ommaya reservoirs monthly for a planned 6 months or until confirmed disease progression. When possible per investigator discretion, the dose was divided evenly between the two reservoirs. The primary endpoints were safety and manufacturing feasibility, with secondary endpoints focused on preliminary efficacy. Dose escalation was planned according to a standard 3+3 design (dose level 1: $10x10^6$ cells; level 4 (max): $100x10^6$). Adverse events within 28 days of first dose and at least possibly related to B7H3-CART were considered dose-limiting toxicities (DLTs) if meeting additional criteria: any grade 5 toxicity, grade 4 cytokine release syndrome, neutropenia, or thrombocytopenia lasting > 14 days, or any non-hematologic grade 3 toxicity lasting > 72 hours. Neurotoxicity was considered a DLT if grade 4 for > 96 hours or new-onset grade 3 for > 28 days. Serial CSF and serum samples were collected for translational studies to determine immune cell kinetics and the mechanisms of activity and resistance. **Results:** Eleven patients were enrolled, underwent apheresis, and had B7H3-CART successfully manufactured. Nine received at least one dose of B7H3-CART and were evaluable in the dose escalation cohort. One patient in dose level 2 ($25x10^6$ cells) experienced a DLT (grade 3 hypertension). No additional DLTs were observed in this dose level after expansion to 6 patients, and the recommended phase 2 dose was established at $25x10^6$ cells. Toxicity otherwise has been primarily related to tumor inflammation-associated neurotoxicity (TIAN), observed after 29 of 36 infusions (81%), and managed acutely with anakinra and dexamethasone. The median overall survival (mOS) from date of enrollment for patients receiving at least one dose of B7H3-CART is 14.6 months (95% CI: 2.3 - 26.8 months). One patient is currently receiving B7H3-CART and 4 others are being clinically followed up to 22 months from enrollment. **Conclusions:** Intracranial administration of B7H3-CART in recurrent GBM is technically feasible and safe. TIAN was common but manageable and reversible with immunomodulators. Correlative analyses on surgical tissue, CSF, and serum are ongoing. Clinical trial information: NCT05474378. Research Sponsor: California Institute for Regenerative Medicine; CLIN2-15094.

Tirabrutinib for the treatment of relapsed or refractory primary central nervous system lymphoma: Efficacy and safety from the phase II PROSPECT study. First Author: Lakshmi Nayak, Dana-Farber Cancer Institute, Boston, MA

Background: Primary central nervous system lymphoma (PCNSL) is a rare, aggressive form of non-Hodgkin lymphoma localized to the brain, cerebrospinal fluid, or eyes. For patients with PCNSL, treatment options are limited, standard of care is not well established, and prognosis is poor, particularly in the relapsed or refractory (r/r) setting. Tirabrutinib, a highly potent selective second-generation Bruton's tyrosine kinase inhibitor, is approved in Japan, Taiwan, and South Korea based on a phase I/II study that demonstrated clinical activity in Japanese patients with r/r PCNSL. There are no currently approved drug therapies for PCNSL in the US or Europe. Here we report results from the PROSPECT study (NCT04947319) conducted in the US. **Methods:** In this open-label phase II study, patients with r/r PCNSL received oral tirabrutinib 480 mg as monotherapy once daily until disease progression or unacceptable toxicity. The primary endpoint was overall response rate (ORR) assessed by Independent Review Committee. Secondary endpoints included duration of response (DOR), time to response (TTR), best overall response (BOR), and safety. Overall survival (OS) and progression-free survival (PFS) were exploratory endpoints. **Results:** Forty-eight patients were enrolled. Median age was 65.5 y (range, 34-87). With a median follow-up of 11.2 mo as of November 1, 2024 (data cut-off), ORR was 66.7% (n = 32), with a complete response rate (CRR), confirmed (CR) + unconfirmed (CRu), of 43.8% (n = 21) and a partial response rate of 22.9% (n = 11). Median DOR was 9.3 mo (range, 0.0-23.5), and median TTR was 0.95 mo (range, 0.9-3.7). Median OS was not reached (range, 1.0-33.0); median PFS was 6.0 mo (range, 0.0-26.0). Overall incidence of any-grade treatment-emergent adverse events (TEAEs) was 97.9% (n = 47) and grade ≥3 was 56.3% (n = 27). Any-grade treatment-related adverse events (TRAEs) were experienced by 75.0% (n = 36), most frequently anemia (18.8%), fatigue (14.6%), neutrophil count decreased (14.6%), pruritus (14.6%), rash (14.6%), and maculo-papular rash (14.6%). Grade ≥3 TRAEs were experienced by 27.1% (n = 13), most frequently neutrophil count decreased (8.3%) and rash maculo-papular (4.2%). Deaths related to TEAEs occurred in 2 (4.2%) patients: 1 patient died from seizure and pneumonia, and the other from a fall; these grade 5 TEAEs were considered unrelated to study treatment. At data cutoff, 27.1% (n = 13) of patients remain on tirabrutinib treatment. Main reasons for discontinuation were disease progression (54.2%, n = 26) and death (8.3%, n = 4), and 1 (2.1%) patient discontinued due to an AE; deaths included the 2 patients with grade 5 TEAEs. **Conclusions:** With an ORR of 66.7%, CR/CRu rate of 43.8%, median DOR of 9.3 mo, and a manageable safety profile, the PROSPECT trial supports tirabrutinib monotherapy as a potentially effective treatment option for patients with r/r PCNSL. Clinical trial information: NCT04947319. Research Sponsor: ONO Pharmaceutical Co., Ltd.

2020 Rapid Oral Abstract Session

Using single-cell transcriptomics to reveal CD226 upregulation and enhancement of CD19-CAR-T function in the inhibitory CNS microenvironment of refractory CNS lymphoma. First Author: Ulrike Gerdemann, Dana-Farber/Boston Children's Cancer and Blood Disorders Center, Boston, MA

Background: Refractory CNS lymphoma (CNSL) has a poor prognosis, with 5-year survival of ~30%. We conducted a trial of axi-cel for CNSL, where we achieved a CR of 67%. To deeply interrogate the immune mediators of response, we collected daily paired CSF and peripheral blood (PB) samples post-CAR T infusion. This enabled single-cell transcriptional profiling at an unprecedented depth, identifying key drivers of CD19 CAR T responses and compartment-specific mechanisms of CAR T function. **Methods:** CNSL patients were enrolled in the 'Axi-cel in CNS Lymphoma' Trial, NCT04608487. PB and CSF samples were collected daily from Day 0–14 post-infusion, and 5'10x scRNA /TCR-Seq was performed. This analysis focused on peak CAR T expansion (Day 5-10) and included 1,224,178 T cells from 17 patients. Samples were tested for compartment (CSF vs PB) and response-specific (CR vs PD) transcriptomic differences using a mixed-effects model and GSEA. Functional assays were conducted with CD19 CAR Ts and CD19 CAR+ Jurkat-NFAT reporter cells. **Results:** Transcriptomic analysis identified distinct compartmental differences in CAR Ts, with PB CAR Ts displaying a robust proliferation signature, while CSF CAR Ts were enriched for type I interferon and T-cell dysfunction signatures, including upregulation of inhibitory genes PD-1, TIGIT, TIM3, LAG3. *In vitro*, CSF-exposed CD19-CAR Ts showed increased expression vs culture-media controls for TIGIT (up 40.1%, SEM 7.4), PD-1 (18.9%, SEM 3.8), and Tim3 (60.6%, SEM 7.5). CAR T NFAT expression was reduced from 18.4, 0.1 SEM (media) to 7.2, 0.2 SEM (CSF) relative to unstimulated controls. Differential expression analysis comparing CSF CD8+ CAR Ts from patients achieving CR (n = 11) or PD (n = 4) showed upregulation of Type I interferon signaling (IFIT1, IFIT3) in PD patients. In contrast, CR patients exhibited increased expression of counter-inhibitory genes (TCF7, CD226) in CSF CAR Ts, suggesting a functional advantage of these CAR Ts in the inhibitory CNS environment. Functional assays of CD19-CAR Ts overexpressing the costimulatory molecule CD226, demonstrated higher lymphoma-cell killing vs WT-CAR Ts (48.6%, SEM 4.1 vs 24%, SEM 2.2, p = 0.01) and greater IFNγ production (63.2%, SEM 1.6 vs 49.4%, SEM 1.7, P = 0.006). CD226 acts as a costimulatory receptor and counteracts TIGIT signaling by competing for its shared ligands, CD112 and CD155. Notably, scRNA-Seq receptor-ligand analysis identified CD112 exclusively expressed in myeloid cells, highlighting a critical myeloid-CAR T interaction that enhances CD226^{high} CAR T efficacy. **Conclusions:** ScRNA-Seq suggests tissue-specific CAR T dysfunction in the CNS microenvironment, with CR patients demonstrating upregulation of counter-inhibitory genes, including CD226. This study offers novel insights into axi-cel's mechanism of efficacy and identifies targets to improve CNSL CAR T therapy. Research Sponsor: Kite/Gilead.

2021 Poster Session

Brain metastasis: Incidence, trend analysis, and impact on survival using SEER database (2010-2020). First Author: Shaimaa Fadel, Faculty of Medicine, Suez Canal University, Ismailia, Egypt

Background: Brain metastasis has a poor prognosis in cancer patients with high morbidity and mortality rates. An updated comprehensive analysis of patients with brain metastasis across all primary cancer sites is lacking. So, the study aims to provide the literature with updated evidence about recent trends and survival analysis of brain metastasis. **Methods:** Data of 75,797 patients with brain metastasis, diagnosed in 2010-2020, were extracted using the Surveillance, Epidemiology, and End Results (SEER) software. We used a rate session to calculate the incidence, percent change (PC), and annual percentage change (APC). Rates are per 100,000 and age-adjusted to the 2000 US Std population. Confidence intervals (CI) are 95% per rate with statistical significance at $P > 0.05$. We used SPSS version 23 for data analysis and Kaplan Meier Curve and log-rank test for survival analysis. **Results:** Brain metastasis represented 1.9% of all cancer cases with a mean age of 64.4 (Sd = 11.2). The age-adjusted incidence rate of brain metastasis was 7.1 with a PC of -9.6 from 2010 to 2020 (APC = -0.60; 95% CI: -1.2-0.001, $P < 0.05$). The APC was significantly declining in Caucasians (-0.70; $P > 0.05$) and African Americans (-1.2; $P < 0.05$) with a significant decrease in males (-1, $P < 0.05$) while the Asian or Pacific islanders (API) race had PC of 11.7 and APC of 1.30 ($P < 0.05$). Lung, breast, skin melanoma, and kidneys were the most common primary sites for brain metastasis (78.5%, 3.8%, 3.7%, and 3.2%). The 5-year relative survival of patients with brain metastasis was 6.1% compared to the non-metastatic group 71.5%. The 5-year age standardized relative survival was 5.7% for the metastatic group. The 5-year relative survival of brain metastasis was higher in the API race compared to Caucasians and African Americans (10.1%, 5.9%, and 5.3%). **Conclusions:** The results of this study show a very poor survival outcome for brain metastasis. However, there was a significant decline in brain metastasis trends over the years, which highlights promising improvements in the early detection of primary cancers. Further stratifications showed disparities according to race and primary cancer site. These data may have clinical-directed variations in screening and counseling for subpopulations with cancer. 2022 Poster Session

A phase I/II study to assess safety and preliminary evidence of a therapeutic effect of azeliragon combined with stereotactic radiation therapy in patients with brain metastases (ADORATION). First Author: Rupesh Kotecha, Miami Cancer Institute, Baptist Health South Florida, Miami, FL

Background: Azeliragon is an oral, brain penetrating small molecule inhibitor of the receptor for advanced glycation end-products (RAGE), reducing neuroinflammation by inhibiting peritumoral edema/vascular leakage and overcoming radiation resistance. The primary objective of this study is to evaluate the safety and tolerability of azeliragon plus stereotactic radiosurgery (SRS) for patients with brain metastasis substituting for peri-procedural corticosteroids (loading dose [LD] and corticosteroid taper [CT]) and secondarily to assess the potential efficacy of this novel therapeutic combination. **Methods:** ADORATION (NCT05789589) is a single center, open-label, phase I/II trial. Eligible adults have a confirmed cancer diagnosis within 5 years, maximum brain metastasis diameter of $\leq$2 cm, and have discontinued corticosteroids at least 5 days prior to SRS. In phase I, participants were enrolled into sequential cohorts, starting with azeliragon + SRS + LD; depending on dose-limiting toxicities (DLTs), the next cohorts could be either azeliragon + SRS or azeliragon + SRS + LD + CT. A DLT was defined as any CNS-specific Grade $\geq$ 2 toxicity requiring corticosteroid treatment or any Grade $\geq$ 3 events not clearly due to the underlying disease or extraneous causes. **Results:** In the completed phase 1 portion, 3 patients were initially treated with azeliragon at 30 mg twice daily for 6 days followed by SRS+LD within 7 days of starting drug then a continuous dose of 20 mg daily for at least 8 weeks. As no DLTs were observed, the second cohort of 3 patients was treated with azeliragon and SRS without any corticosteroids (LD or CT). Of the 6 evaluable patients treated to 46 brain metastases, the most common primary histology was lung adenocarcinoma (n = 4). At data cutoff (1/8/2025), the median follow-up was 4.9 months (3.8-9.4 months) and no DLTs were observed. Early response rate (RR) to the combination therapy was assessed at week 8, with a per-patient RANO RR of 100% (partial response [PR] for all 100%), and a per-lesion RANO RR for all RANO-defined target lesions (n = 18) of 100% (PR 95.5%, complete response [CR] 4.5%). For all brain metastases treated (n = 46) the RR was 93.5% (PR for 69.6% and CR for 23.9%). Neurocognitive function batteries, symptom inventories, and quality of life evaluations remained stable during the 8-week early assessment period. **Conclusions:** Azeliragon was safely substituted for corticosteroids in this phase 1 study with no DLTs observed. The early response rate appears encouraging and accrual to the phase II expansion cohort (n = 40) with a primary endpoint of objective response rate is ongoing. Clinical trial information: NCT05789589. Research Sponsor: Cantex Pharmaceuticals.

2023 Poster Session

Efficacy of immune checkpoint inhibitors (ICI) in patients (pts) with central nervous system (CNS) metastases (mets) from solid tumors: A systematic review and meta-analysis. First Author: Soraia Martins, Université libre de Bruxelles (ULB), Hôpital Universitaire de Bruxelles (H.U.B), Institut Jules Bordet, Brussels, Belgium

Background: Brain metastases, a common complication of solid tumors, are associated with poor outcomes. The role of ICIs in this setting remains unclear. This meta-analysis aims to assess intracranial efficacy of ICI-based systemic treatment in pts with CNS mets from solid tumors. **Methods:** A systematic literature search of PubMed, Embase, CENTRAL, and conference proceedings (ESMO and ASCO) up to 15-Mar-24 (PROSPERO: CRD42021242755), was conducted to identify single-arm phase II or III, or randomized controlled trials of pts with CNS mets from solid tumors at baseline treated with ICI-based systemic treatment. The primary objective, CNS efficacy, was measured by pooled CNS objective response rate (CNS-ORR) and weighted median CNS progression-free survival (mCNS-PFS). Subgroup analyses evaluated the impact of disease and treatment characteristics. Overall effects were pooled using random-effects models. **Results:** Out of 1 690 records screened, a total of 1 224 pts enrolled in 32 clinical trials were included. Overall, ICI-based systemic therapy led to a CNS-ORR of 38.0% (95% confidence interval [CI] 31.8-45.5) and a mCNS-PFS of 9.1 months (mos). CNS efficacy was numerically higher in pts with non-small cell lung cancer (NSCLC, n=383, CNS-ORR 45.8% [34.4-60.9]; mCNS-PFS 9.6 mos) and melanoma (n=554, CNS-ORR 37.7% [30.6-46.5]; mCNS-PFS 11.4 mos) vs multi tumors (n=128, CNS-ORR 24.8% [7.7-80.1] and mCNS-PFS 2.8 mos). Efficacy was also greater in first-line therapy (n=553, CNS-ORR 45.2% [36.7-55.7]; mCNS-PFS 8.6 mos) vs second or later lines (n=190, CNS-ORR 14.9% [7.6-29.2]; and mCNS-PFS 2.6 mos). Dual ICI (n=279, CNS-ORR 43.9% [35.5-54.2]; mCNS-PFS 17.8 mos) and ICI plus non-ICI agents (n=432, CNS-ORR 48.7% [39.6-59.9]; mCNS-PFS 7.1 mos) were more effective than single ICI (n=419, CNS-ORR, 20.4% [11.9-34.9]; mCNS-PFS 4.8 mos). Subgroup analyses showed superior CNS outcomes in cerebral mets, treated lesions, asymptomatic pts, and low/no steroid use (table). **Conclusions:** ICI-based regimens demonstrate CNS efficacy in pts with solid tumors, particularly in pts with NSCLC and melanoma treated with first-line combination therapies. Research Sponsor: None.

Subgroup analyses by CNS characteristics	Category (*n* of pts for CNS-ORR)	CNS-ORR, % (95% CI)	mCNS-PFS, mos
Type of CNS mets	Cerebral (1063)	38.3 (31.9-45.9)	9.6
	Leptomeningeal (51)	34.6 (15.9-75.2)	2.4
CNS local therapy	Treated (197)	37.6 (26.8-52.8)	8.9
	Untreated (307)	43.1 (35.0-53.0)	5.2
Symptoms	Asymptomatic/mild (832)	40.4 (34.5-47.3)	10.3
	Symptomatic (80)	31.3 (18.3-53.4)	2.5
Concomitant steroids	No (391)	30.6 (21.6-43.4)	15.1
	Low dose (434)	40.7 (31.5-52.6)	7.6
	Any dose steroids (144)	41.6 (31.7-54.7)	3.3

Irradiated tumor volume as a predictor of local recurrence and radionecrosis in lung cancer with brain metastases treated with stereotactic radiosurgery. First Author: Andreas Koulouris, Karolinska University Hospital, Solna, Sweden

Background: Stereotactic radiosurgery (SRS) is a standard local treatment for brain metastases (BM), but it may result in local recurrence (LR) or radionecrosis (RN). This study evaluates irradiated tumor volume as a predictor of LR and RN in SRS-treated lung cancer patients with BM. **Methods:** We retrospectively analyzed 431 lung cancer patients with BM who underwent SRS at Karolinska University Hospital, Sweden, (2009-2020), encompassing all-comers from the Stockholm region. Associations among irradiated tumor volume and risks of RN, symptomatic RN, as well as LR at 6 and 12 months, were assessed using Cox regression models. Furthermore, we evaluated the diagnostic performance of Methionine PET-CT in differentiating RN from LR. **Results:** 40 patients (9.2%) developed asymptomatic RN, 37 (8.3%) symptomatic RN, and 67 (15.5%) LR. Larger tumor volumes significantly increased the risks of RN and LR. At 6 months, a tumor volume of 4.75 cm^3 was associated with an RN risk reaching the upper limit of 20%. By 12 months, substantially smaller volumes, such as 1.13 cm^3, were related to same risk levels. Symptomatic RN followed a similar trend, with a volume of 13.58 cm^3 presenting a risk of up to 20% at 6 months, while at 12 months, considerably smaller volumes, such as 3.8 cm^3, corresponded to a symptomatic RN risk as high as 40%. 20% risk of LR was observed with volumes of 5.66 cm^3 and 3.28 cm^3 at 6 and 12 months, respectively. The sensitivity and specificity of Methionine PET-CT are 0.909 and 0.600 when MRI was considered the gold standard. **Conclusions:** Larger irradiated tumor volumes were positively correlated with an increased risk of both RN and LR. At 12 months post-SRS, smaller tumor volumes were associated with higher RN and LR risks in comparison with 6 months. Methionine PET-CT, when used alongside MRI, did not demonstrate a clear advantage in differentiating LR from RN. Efficacy of systemic therapy in breast cancer with CNS metastases: "Real-world" experience. First Author: Bipin Ghimire, Henry Ford Health System, Detroit, MI

Background: The incidence of CNS metastases in breast cancer is rising. While local therapies such as surgery and radiation remain standard, data on upfront systemic therapies for active brain metastases, especially HER2-negative patients, is limited. This study examines upfront systemic therapy efficacy for CNS metastases in breast cancer patients at a single institution, including a majority African American (AA) population. **Methods:** A retrospective chart review included breast cancer patients with CNS metastases treated at Henry Ford Health (January 2014–July 2024). Eligible patients had not received concurrent local therapy; prior local therapy was permitted if unrelated to the studied lesions. CNS response was to be assessed using RANO-BM (defines measurable disease as lesions $>$ 10 mm) for parenchymal and modified RANO-LM criteria for leptomeningeal disease (LMD). **Results:** Among 35 patients (20 AA, 13 Caucasian), with a median age of 54 years, HER2-positive was the most common receptor type (49%), followed by HR-positive (37%) and triple-negative (14%); nearly half (46%) had HER2-low disease. Parenchymal metastases were predominant (86%); three had co-existing LMD, and two others had only LMD. Most metastases were multiple; 91% had lesions $<$ 10 mm. 43% had prior WBRT or SRS to unrelated lesions. HER2-positive patients had the highest CNS overall response rate (ORR, 53%) and disease control rate (DCR, 94%), followed by HR-positive (ORR 31%, DCR 69%) and triple-negative (ORR and DCR 20%). Median PFS did not significantly differ between receptor groups (p = 0.130). Trastuzumab-deruxtecan (T-Dxd) was the most common regimen (10/35) and within HER2-positive and HR-positive groups. T-Dxd achieved CNS ORR of 60%, DCR of 90%, and median PFS of 16 months. Tucatinib-based regimens showed a 100% DCR with median PFS of six months. Other therapies, including sacituzumab, abemaciclib, and trastuzumab-emtansine, showed stable disease as the best response. Among AAs, HR-positive was the most common receptor type (50%). These patients had ORR of 35% and DCR of 65%. T-Dxd maintained ORR of 60% and DCR of 80%. Of five patients with LMD, three were HER2-positive, and two were HR-positive, with an ORR of 60%, and DCR of 80%. **Conclusions:** This "real-world" experience highlights that, at our institution, most patients with breast cancer and CNS metastases considered for upfront systemic therapy lack measurable disease (91% having lesions $<$ 10 mm) typically required for clinical trials. Nonetheless, the response rate aligns with published experiences. In addition, we included patients with LMD, who are often excluded in trials. Our data also suggests impressive CNS responses with T-Dxd, both overall and in AA patients. The management of brain metastases and LMD in these patients is best approached in a multidisciplinary format. Research Sponsor: None.

2027 **Poster Session**

Whole brain radiotherapy and intrathecal injection of thiotepa, combined with systemic treatment for the primary tumor, to treat solid tumor leptomeningeal metastasis: A prospective, single center, single arm, phase II clinical study. First Author: Siyu Guo, Zhejiang University, Hangzhou, China

Background: To evaluate the efficacy and toxicity of a triple therapy regimen consisting of Hippocampal-sparing whole-brain radiotherapy (HS-WBRT), intrathecal Thiotepa (ITT), and primary lesion treatment for solid tumor leptomeningeal metastasis (LM). (NCT06376292). **Methods:** Based on the comprehensive results of MRI and cytology evidence, patients diagnosed with LM according to the diagnostic criteria in the EANO-ESMO guidelines meet the criteria. Patient began ITT twice a week, and underwent HS-WBRT as soon as possible. Before each ITT, cerebrospinal fluid (CSF) pressure is measured and CSF is collected for testing, including protein, tumor markers, IgG, albumin levels of CSF, and albumin ratio. MRI re-examination is conducted every three months, and the RANO-LM criteria is used to evaluate the response of patients after treatment. Besides,the LM-PROG SCORE we designed can be used as an indicator to evaluate the treatment effect and adjust the medication frequency or switch the treatment line of intrathecal Pemetrexed (IP). The primary endpoint is overall survival. **Results:** As of December 1, 2024, a total of 57 patients have been enrolled. 40 patients were included in the statistics. Most cases are lung cancer (27, 67.5%), in addition to breast cancer(8, 20%), gastric cancer (3, 7.5%), rectal cancer (1, 2.5%) and cervical cancer (1, 2.5%). The mOS was 7.8 months (95% CI 2.06-13.54 months). The mPFS was 5.63 months (95% CI 0.76-10.51 months). The RANO-assessed ORR to treatment was 62.5% (10/16), DCR was 87.5% (14/16), with 24 patients (60%) not reaching the follow-up time. The three longest survival among alive patients are 21.3 months, 14.9 months, and 12.7 months. The most significant effect of combination therapy is the rapid relief of symptoms. 25% of patients (10/40) had already experienced unconsciousness (RASS≠0) at the time of diagnosis. After our treatment, all patients regained consciousness (RASS = 0). The long-term therapeutic effect also significantly reduces tumor markers, protein content, albumin and IgG content, pressure drop, and albumin ratio in CSF, indicating the recovery of the blood-brain barrier. 85% of patients experience varying degrees of bone marrow suppression during treatment, but most are mild and can tolerate subsequent ITT maintenance after treatment. **Conclusions:** Under the efficacy guidance of LM-PROG SCORE we designed, our combination therapy can greatly improve patients' overall survival, progression free survival, and quality of life. And it was found that in addition to imaging, indicators such as protein content, IgG and albumin content, Albumin Ratio and tumor markers in CSF can serve as efficacy evaluation indicators. Clinical trial information: NCT06376292. Research Sponsor: None.

2028 **Poster Session**

Effect of CD4+PD-1+CXCR6+ T cells on the response of immune checkpoint inhibitor therapy in brain metastases of NSCLC. First Author: Yang-Si Li, Guangdong Lung Cancer Institute, Guangdong Provincial People's Hospital, Guangzhou, China

Background: Brain metastases (BrM) in non-small cell lung cancer (NSCLC) presented a significant challenge due to poor prognosis. While immune checkpoint inhibitors (ICIs) have been standard treatments for NSCLC, their efficacy in BrM is variable, emphasizing the urgent need for predictive biomarkers and fundamental mechanisms. **Methods:** We prospectively collected 20 cerebrospinal fluid (CSF) and 4 BrM tumors from 18 NSCLC patients with BrM undergoing ICI therapy for single-cell RNA sequencing (scRNA-seq), complemented by integrating data from multiple published datasets. Three independent cohorts (8 and 25 CSF, and 31 BrM tumors) underwent flow cytometry, proteomics, and multiplex immunohistochemistry for validation, respectively. **Results:** Our study provided a high-resolution atlas of cellular dynamics in the CSF and BrM during ICI therapy in NSCLC patients with BrM. Notably, we identified a key immune cell subset, $CD4^+PD\text{-}1^+CXCR6^+$ T cells, as a positive predictor of ICI intracranial tumor responses, which presented highly functional and transcriptomic similarities in both CSF and BrM tumor environment. Moreover, CXCR6 could serve as a specific marker for $CD4^+PD\text{-}1^+$ T cells linked to ICI response. Further, we revealed that the novel cluster of $CD4^+PD\text{-}1^+CXCR6^+$ T cells was closely associated with lymphocyte activation and aggregation in CSF and BrM of ICI responders, and cDCs of ICI responders interacted with $CD4^+PD\text{-}1^+CXCR6^+$ T cells for enhanced antigen presentation and inflammatory activation. **Conclusions:** Our findings revealed critical insights into the immune landscape of NSCLC BrM under ICI therapy, highlighting $CD4^+PD\text{-}1^+CXCR6^+$ T cells in CSF as a promising biomarker and illuminating fundamental mechanisms underlying ICI efficacy. Research Sponsor: None.

2029 Poster Session

IT-IO: Intrathecal administration of nivolumab and ipilimumab in combination with systemic combination of nivolumab and ipilimumab in patients with non-small cell lung cancer or melanoma and newly diagnosed leptomeningeal metastasis, a multicentric phase I study. First Author: Emilie Le Rhun, University Hospital Zurich, Zurich, Switzerland

Background: The optimal management of patients with leptomeningeal metastases (LM) from non-small cell lung cancer (NSCLC) or melanoma remains controversial. IT-IO (NCT05598853) is a prospective phase I, multicenter, open label, interventional clinical study aiming at determining the recommended phase 2 dose (RP2D) of intrathecal nivolumab and ipilimumab in patients with newly diagnosed LM from NSCLC or melanoma. **Methods:** The diagnosis of LM had to be confirmed or probable by EANO ESMO criteria. Planned whole brain radiotherapy (WBRT) was not allowed. Planned or prior craniospinal irradiation were not allowed. The treatment regimen consisted of intrathecal nivolumab (fixed dose 50 mg) / ipilimumab (increasing doses) in combination with systemic combined nivolumab/ipilimumab. Three dose levels of IT ipilimumab were planned: 5 mg (dose level 1), 10 mg (dose level 2), and 20 mg (dose level 3). RP2D, the primary endpoint, was determined in a 3+3 design. Secondary endpoints included compartmental efficacy and survival. **Results:** A total of 19 patients, 6 female and 13 male patients, 12 with melanoma and 7 with NSCLC, were enrolled between February 2022 and August 2024. Median KPS at study entry was 80, 12 patients had a positive CSF. The dose escalation phase (n = 12) was completed without dose-limiting toxicity until dose level 3. The RP2D is nivolumab 50 mg and ipilimumab 20 mg. Sixteen SAE were noted, all unrelated or unlikely related to intrathecal therapy. Three patients are still alive. For the whole cohort, median overall survival was 3 (range 0.6-10.3) months, for patients with a diagnosis of melanoma 2.9 (range 0.6-8.2) and for patients with NSCLC 4.5 (range 0.8-10.3) months. OS at 6 months was 20% (one patient ongoing at 5.1 months). Translational research is ongoing. **Conclusions:** No safety issue was noted. Efficacy data are preliminary and need to be confirmed in larger trials. Clinical trial information: NCT05598853. Research Sponsor: Bristol Myers Squibb.

2030 Poster Session

Evaluating the utility of DNA methylation signatures in tissue and biofluids for lung adenocarcinoma brain metastasis prediction and non-invasive detection. First Author: Jeffrey Zuccato, Oklahoma University Health Sciences Center, Oklahoma City, OK

Background: Brain metastases (BM) are common and arise in 30% of lung adenocarcinoma (LUAD) patients. Patients with LUAD that develop BM have significantly poorer outcomes, with a 10-16 month median overall survival. Unfortunately, current clinical practice for BM prediction is limited and so BM are typically detected after they develop and grow to cause neurological symptoms. Once BM are detected, currently neurosurgical tumor biopsies are performed to enable BM diagnosis via neuropathological evaluation. The aims of this study were to develop DNA methylation-based models that predict LUAD BM and non-invasively detect BM in blood to enable early diagnosis and treatment. **Methods:** DNA methylomes were acquired from 402 tumor tissue and plasma samples in a cohort of 346 LUAD and BM patients. Machine learning models were built using DNA methylation signatures that stratify BM risk in tissue and detect BM in plasma. Models were evaluated in independent validation datasets. A predictive nomogram was developed using the BM prediction model together with clinical factors to provide composite patient-specific scores reflecting BM risk. **Results:** The methylation-based BM predictor accurately stratified BM risk in a univariable Cox model using validation set data (HR = 5.65, 95%CI 1.85–17.2, p = 0.0023). Model utility was independent of the predictive value of clinical factors in a multivariable Cox model using validation set data (Table 1: HR = 8.92, 95%CI 1.97–40.5, p = 0.0046). The 5-year model accuracy was 0.81 and significantly higher than a similarly built cancer stage-based model (0.65), demonstrating utility over current practice. The combinatorial clinical-methylomic predictive nomogram had enhanced utility with an accuracy of 0.82 univariable Cox HR of 17.2 (95%CI 4.13–71.3, $p < 0.0001$), demonstrating comprehensive patient-specificity. The plasma-based model accurately classified BM from gliomas and lymphomas (AUROC=0.80), as typical clinical differential diagnoses, in validation set data. The models were validated further in additional external data. **Conclusions:** DNA methylation-based modeling of BM can accurately predict LUAD patients at risk for BM development and can non-invasively detect BM that develop. Future treatment approaches may tailor initial LUAD treatment and ongoing cancer surveillance to a patient's BM risk, allowing for the potential to prevent and treat BM early. Research Sponsor: None.

DNA methylation-based BM prediction is independent of clinical factors in a multivariable Cox proportional hazards model.

Variable		HR	95% CI	p
Methylome risk score		8.92	1.97–40.5	0.005

Effect of early integrated neuropsychological care in patients with brain metastases: A phase 2 randomized controlled trial (ATHENA trial). First Author: Haley Kopp Perlow, Department of Radiation Oncology, Seidman Cancer Center University Hospitals/Case Western Reserve University, Cleveland, OH

Background: Advancements in radiotherapy delivery through both hippocampal sparing whole brain radiotherapy (WBRT) and stereotactic radiosurgery (SRS) can better preserve QOL and reduce cognitive decline. However, even patients treated with advanced brain radiotherapy techniques have a reduction in their QOL and cognitive abilities either due to their radiation treatment, systemic therapy, or progression of disease. This Phase 2 Randomized Controlled Trial (NCT05503251) aims to evaluate the impact of a neuropsychological evaluation and intervention with a certified neuropsychologist on QOL and cognitive function for brain metastases patients treated with radiotherapy. **Methods:** Brain metastases patients were randomized 1:1 to either neuropsychology evaluation and intervention plus brain radiotherapy or brain radiotherapy alone. The intervention arm included five appointments with the neuropsychology team for testing, evaluation, and counseling over a three-month period. Patients with any number of brain metastases and an estimated survival of $\geq$ 6 months were included. Exclusion criteria included prior WBRT and pre-existing mental disability. Stratification factors for randomization were Karnofsky performance status (KPS, $>$ 70 vs. $\leq$ 70) and radiation cohort ($>$ 15 brain metastases received WBRT, $\leq$15 received SRS). All patients receiving WBRT were prescribed memantine. The primary endpoint was deterioration of QOL at 3 months as measured by Fact-Br. Repeated measures analysis of variance was used to measure QOL. Cognition was measured by Hopkins Verbal Learning Test-Revised, Controlled Oral Word Association Test, and Trail Making Test A/B, with cognitive decline defined as decline on at least one assessment using reliable change index. **Results:** Between August 2022 and June 2024, 110 patients were randomized. Baseline characteristics were balanced between arms and included a median KPS of 90 (IQR 80, 90), median age of 62.5 (IQR 54, 70), 53% female patients, 43% of patients with a primary lung cancer, and most patients (74%) with $\leq$15 brain metastases. The median overall survival or time to last follow-up was 8.5 months. The primary endpoint, deterioration of QOL at 3 months, was not different between the control and intervention arms (p = 0.93). Cognitive decline differences at 3 months were not significant between the control and intervention arms (24.1% vs. 27.3%, p = 0.33). Additionally, there were no differences at 3 months with verbal fluency, executive function, immediate recall, delayed recall, or delayed recognition between arms. **Conclusions:** This study did not meet its primary endpoint, better preserved QOL at 3 months for patients receiving early integrated neuropsychological care. Further evaluation of the delayed impact ($>$ 6 months) of neuropsychology intervention on QOL and cognitive function will be reported when data are available. Clinical trial information: NCT05503251. Research Sponsor: None.

2032 Poster Session

Intrathecal deferoxamine in patients with leptomeningeal metastases: Phase 1a analysis. First Author: Jessica Wilcox, Memorial Sloan Kettering Cancer Center, New York, NY

Background: Leptomeningeal metastases (LM), the spread of cancer to the cerebrospinal fluid (CSF), is associated with high morbidity and mortality. LM employ the iron-binding transporter and receptor system, lipocalin-2/SLC22A17, to scavenge iron from the CSF to sustain their metabolic needs. In preclinical models of LM, intrathecal administration of deferoxamine (IT-DFO), an iron chelator, resulted in reduction of LM growth and improvement of survival. We evaluated this novel treatment strategy in this first-in-human clinical trial in patients with solid tumor LM. **Methods:** This is a phase 1a, single-institution, clinical trial to determine safety and maximum tolerated dose (MTD) of IT-DFO in patients with LM. Eligibility criteria included LM from any solid tumor, age $\geq$ 18 years, Karnofsky Performance Status $\geq$ 60, life expectancy $\geq$ 8 weeks, and Ommaya reservoir. Patients were enrolled in an accelerated 3+3 dose escalation design with a primary endpoint of dose-limiting toxicity (DLT), defined as a grade 3 non-hematologic or grade 4 hematologic toxicity in the first cycle of treatment. All patients received IT-DFO twice weekly (cycle 1), once weekly (cycle 2), then once every two weeks (cycle 3+) in 28-day cycles. Patients were monitored for LM progression by neurological examination, neuraxial magnetic resonance imaging, and CSF cytology as per modified Response Assessment in Neuro-Oncology LM criteria. **Results:** A total of 8 patients received treatment with IT-DFO from May 2022 to January 2025 at the time of data cut-off. The median age at enrollment was 50 years (range, 26-69). The primary malignancy included breast (n = 4), lung (n = 2), colon (n = 1), and sarcoma (n = 1). Patients were treated with IT-DFO at doses of 10 mg (level 1, n = 4) and 30 mg (level 2, n = 4). IT-DFO was well tolerated, and the majority of adverse events (AEs) were grade 1-2. The most common any grade AEs were vomiting (50%), nausea (37.5%), chills (25%), myalgias (25%), and tremor (25%). Two patients experienced DLTs at 30 mg (grade 3 vomiting, grade 3 syncope). No grade 4-5 AEs were observed. The MTD was determined to be 10 mg. In this heterogenous heavily pretreated population, median overall survival for the evaluable cohort (n = 7) was 10.0 months (95% CI, 6.5 – NA). **Conclusions:** IT-DFO is a novel, well tolerated investigational treatment for LM. A phase 1b dose expansion study at a dose of 10 mg is currently underway to better define safety and efficacy endpoints. Clinical trial information: NCT05184816. 2033 Poster Session

Improving adherence to cancer care for socioeconomically disadvantaged patients with central nervous system tumors. First Author: Joshua Amit Budhu, Memorial Sloan Kettering Cancer Center, New York, NY

Background: Socially disadvantaged patients often face significant barriers to adhering to and completing cancer treatment. Patients with central nervous system (CNS) tumors experience cognitive, neuropsychiatric, speech, motor, sensory, and gait symptoms that exacerbate socioeconomic barriers to care. The Integrated Cancer Care Access Network (ICCAN) is a multi-institutional program developed by Memorial Sloan Kettering Cancer Center's Immigrant Health and Cancer Disparities Service (IHCD). Through ICCAN, patients are provided with patient navigation and resources to mitigate barriers to treatment adherence and completion. While ICCAN has been shown to increase treatment adherence and completion for patients with other cancers, it has not historically enrolled patients with CNS tumors. **Methods:** Under this pilot ICCAN-CNS program, 58 patients with either primary brain tumors or brain metastases were referred to the program. Of these, 45 patients enrolled, 5 patients died before contact was made, 2 patients declined participation, and 4 patients could not be reached. The patient population was evenly split between primary brain tumors (mainly glioblastomas and low-grade gliomas) and brain metastases. Patients were eligible if they were 18 years or older and receiving active treatment or were under active surveillance. If a patient was eligible, they were administered an extensive needs assessment survey that took 60 minutes to complete. The interviews consisted of basic demographic questions, Alliance Distress Screening Tool, Health Related Social Needs (HRSN) Assessment, Essential Needs Assessment, Patient Satisfaction with Cancer Care questionnaire, and an ICCAN-CNS specific questionnaire for patients with brain tumors. Caregivers were allowed to assist patients with neurocognitive or speech deficits in completing the survey questions. Patients were then provided with both patient navigation and resources depending on their needs. Follow-up assessments were conducted at the 2-, 4-, and 6-month marks. **Results:** Patients with CNS tumors completed the initial needs assessments and additional questionnaires. Trends of delayed responses and the need for questions to be repeated were observed, however, patients were still able to express socioeconomic needs. The main needs expressed among these patients were income, employment issues due to lack of ability to work from their cancer, food access, and transportation to appointments. Overall, the response to the program was positive from patients, with many patients accessing resources with the assistance of the access facilitator. **Conclusions:** This pilot demonstrates the feasibility and value of including CNS tumor patients in patient and resource navigation programs. Future plans include a randomized controlled trial using the ICCAN intervention for patients with glioblastoma. Research Sponsor: None.

2034 Poster Session

Risk of intracranial hemorrhage with DOACs vs LMWH in patients with cancer-associated thrombosis and brain metastases. First Author: Ali Mushtaq, Cleveland Clinic Foundation, Cleveland, OH

Background: Intracranial hemorrhage (ICH) is a major and often devastating complication in patients with brain metastases requiring therapeutic anticoagulation for cancer-associated thromboembolism (CAT). While direct oral anticoagulants (DOACs) provide a convenient alternative to low-molecular-weight heparin (LMWH), their safety in this population remains unclear. Comparing ICH risk between DOACs and LMWH is crucial for optimizing anticoagulation in these high-risk patients. **Methods:** This retrospective cohort study utilized TriNetX, a multi-institutional database, to analyze adults with solid tumors who developed CAT within six months of brain metastasis diagnosis. Patients receiving therapeutic-dose DOACs (apixaban, rivaroxaban, edoxaban) or LMWH within ten days of venous thromboembolism diagnosis were compared. 1:1 propensity score matching for over 50 covariates, including age, sex, and cancer type (Table 1). We assessed ICH incidence, bleeding events, ICU admissions, and all-cause mortality using Kaplan-Meier survival analysis and Cox proportional hazards models. Subgroup analyses examined ICH risk by cancer type. **Results:** After matching, 4,275 patients were included in each group. DOACs were associated with a statistically significant lower risk of ICH (HR 0.855, 95% CI 0.731-0.999, p=0.049). Additionally, significantly lower rates of ICU admission (16.7% vs. 20.3%; $p<0.001$) and all-cause mortality at 12 months (42.4% vs. 48.9%; $p<0.001$) were observed in the DOAC group. Subgroup analyses showed a trend toward lower ICH with DOACs in lung cancer (5.9% vs. 6.1%, p=0.726), melanoma (13.7% vs. 15.9%, p=0.432), and renal cell carcinoma (5.7% vs. 9.0%, p=0.103), but these differences were not statistically significant. No significant differences were found for breast (3.6% vs. 4.5%, p=0.375) or colorectal cancer (4.0% vs. 5.4%, p=0.331). **Conclusions:** DOACs were associated with significantly lower ICH, ICU admission, and mortality compared to LMWH in patients with brain metastases requiring anticoagulation, supporting their role as a viable and well-tolerated alternative. While subgroup analyses did not show significant differences in ICH risk by cancer type, the overall findings indicate a favorable profile for DOACs. These results highlight the need for individualized anticoagulation strategies and warrant further prospective validation. Research Sponsor: None.

Baseline characteristics after matching.

Characteristic	DOAC (n=4275)	LMWH (n=4275)
Age (years), mean ± SD	63.4 ± 11.9	63.5 ± 11.9
Female, n (%)	1969 (46.1%)	1958 (45.8%)

Risk factors (RF) for brain metastases (BM) in patients (pts) with metastatic breast cancer (MBC): An analysis of US electronic health records (EHRs). First Author: Jose Pablo Leone, Dana-Farber Cancer Institute, Boston, MA

Background: BM are a significant clinical challenge in pts with MBC yet risk stratification for early identification is suboptimal. We leveraged a large, contemporary, real-world database to characterize RF associated with BM to inform strategies for enriched surveillance and early detection. **Methods:** Selected pts from the nationwide Flatiron Health de-identified EHR-derived database had MBC, had initiated first-line treatment (1L tx) before March 2023 (allowing for > 1 year [yr] of potential follow-up [FU]), and were free of BM at tx initiation. Clinical characteristics were examined as potential RF for BM incidence at any time during FU, using univariate sub-distribution (sd) and cause-specific (cs) hazard ratios. Additional analyses focused on BM risk at 3 yrs from tx initiation and included longitudinal data sequential Cox models with landmarks at every 6 months of FU, and a nested case-control (NCC) design for concurrent BM detection. Analyses were conducted on complete cases, no imputation method was used for missing data, and regression methods using multivariate analyses were used to mitigate confounding. Predictive, modeling-based machine learning (LASSO Cox regression, random survival forests) was conducted using cs hazard ratios to identify potential predictors amongst 90 candidates (data-driven approach using most of the dataset). Analyses were conducted in the overall cohort and stratified by subtype: HER2-negative/hormone receptor-positive (HER2−/HR+), HER2-positive/HR-negative (HER2+/HR−), HER2+/HR+, and triple-negative breast cancer (TNBC). **Results:** The study included 21,368 female pts initiating 1L tx (n = 14,898 HER2−/HR+, 1006 HER2+/HR−, 3468 HER2+/HR+, 1996 TNBC), with 2,530 BM events. Younger age, HER2+ and TNBC subtypes, and more extensive metastasis (≥2 organ sites, particularly liver, lung, or lymph nodes) were associated with higher BM risk (Table); bone-only metastases conferred a lower risk. sd and cs hazard ratios were largely concordant. NCC analyses identified similar predictors for concurrent BM. LASSO Cox modeling yielded a C-index of 0.74 overall (HER2+ 0.70; HER2−/HR+ 0.73; TNBC 0.62). Similar C-indices were seen with random survival forests. **Conclusions:** Clinical characteristics, including metastatic distribution and tumor subtype, can help identify pts at higher BM risk within 3 yrs of initiating MBC tx. Competing risks (of BM and death) did not appear to substantially affect results, except for recurrence time and ECOG PS. Although these findings are encouraging, further refinement of predictive models is needed to improve discrimination and guide targeted neuroimaging and early intervention strategies. Memantine in radiation-induced cognitive dysfunction in brain metastases: A double-blinded, randomized, placebo-controlled trial (CTRI/2022/01/039599). First Author: Haripriya Parapparambil Surendran, Amrita Institute of Medical Sciences and Research, Kochi, India

Background: Prospective double-blinded, placebo-controlled randomized study to evaluate the role of memantine in brain metastasis (BM) in preserving cognitive function. **Methods:** Clinic-radiologically diagnosed of BM patients planned for radiation therapy (RT) (SRS or whole brain RT) were randomized to receive memantine or placebo (20 mg/day) over 24 weeks. Cognitive function assessed by Addenbrooke's Cognitive Examination (ACE). Secondary outcomes included QoL, white matter volume changes (MRI T2 FLAIR), and plasma memantine levels (by LC-MS/MS). Safety was assessed using CTCAE v5.0 criteria. **Results:** 130 BM patients were enrolled after randomization [placebo 64 & memantine (experimental arm n = 66]. In placebo and memantine arm mean age was 56.5 & 56.7; female 39 & 40; high school education status 39 (30%) & 37 (28%); SRS in 40 (30%) & 35 (27%); frontal lobe lesion 43 (33%) & 55 (42%); PS 0-1 55 (42%) & 54 (41%) respectively. In the placebo arm, ACE scores at baseline in placebo and memantine arm 83.0 ± 10.1 and 77.7 ± 12.7 (p = 0.78) respectively. At 4 months, ACE score in placebo and memantine arm 76.2 ± 14.3 and 82.2 ± 12.7 (p = 0.04). At 6 months in placebo and memantine arm were 72.9 ± 20.2 and 83.9 ± 10.8 (p = 0.005). At 24 weeks, ACE scores change was +4.0 in memantine & -9.5 in placebo arm; p = 0.001. Memantine arm had better preservation of memory (-3 vs. -2.5, $p < 0.001$), delayed recall (-1 vs. -1, $p < 0.001$), and verbal fluency (-1 vs. 0, p = 0.007). In the SRS subgroup, ACE scores in placebo and memantine at baseline, 4 and 6 month was 83.5 (± 9.5) & 79.7 (± 12.5); 76.6 (± 14.7) & 85.3 (± 10.6); 72.5 (± 23.1) & 86.4 (± 9.5) respectively. At 24 weeks, memantine arm improved ACE scores by +4 (0 to 12) compared to placebo -8 (-15.5 to -2.5) ($p < 0.001$). At 24 weeks in WBRT, memantine arm sustained cognitive improvement (ACE score +3) compared to further decline in placebo (-9.5, $p < 0.001$). At 24 weeks, percentage change in global health status in placebo & memantine arms were -5.57%. & +63.3% respectively. 21% required dose reductions due to adverse events. Loss of appetite (25.7% vs. 12.5%, p = 0.05); gastric irritation (0 vs 7.5%; p = 0.02) were higher in memantine arm. White matter volume changes in the placebo group correlated negatively with cognitive decline (r = -0.544, p = 0.055), suggesting a potential role of edema in radiation-induced cognitive dysfunction. Memantine at a 5 mg BID dose achieved a median trough concentration of 118.06 ng/mL (IQR: 68–211), within the desirable therapeutic range (70–150 ng/mL). 10 mg BID dose trough was 172 (85-290) and peak concentration 397 (258-499 ng/mL) exceeded alert threshold of 300 ng/mL. **Conclusions:** Memantine preserved cognitive function and QoL in RT for BM. Cognitive benefits were more in SRS than HA/WBRT. White matter volume change was negatively correlated to cognitive outcomes. 5 mg BID dose optimally balances efficacy with tolerability. Clinical trial information: CTRI/2022/01/039599. Research Sponsor: None.

Predictors of overall survival in patients with brain metastases from HER2+ breast cancer. First Author: Qinmei Xu, Stanford University School of Medicine, Stanford, CA

Background: Predictors of overall survival (OS) after brain metastasis (BM) in HER2-positive breast cancer (BC) are not well characterized. This study aimed to identify clinical and imaging-derived (radiomic) features that predict OS and develop a combined model for better prognostic performance. **Methods:** Our retrospective study analyzed 289 patients initially diagnosed with non-metastatic HER2-positive BC who later developed BM. We used 25 clinical characteristics and 12 treatment parameters to develop a Clinical model. We developed an Imaging model using a subset of 120 patients, who possessed evaluable pre-treatment brain MRI for delineating tumor segmentations on all brain metastatic lesions. We extracted 1078 radiomic features from each tumor segmentation using PyRadiomics, generating 8 feature sets based on 2 segmentation strategies (largest tumor per patient versus all tumors combined) and 4 tumor feature types (entire tumor, solid component, necrotic component, combined solid and necrotic features with statistical transformations). Morphological features, including lesion number, total size/volume, and necrotic-to-solid ratios, were also incorporated, along with tumor intracranial location. Cox proportional hazards regression model with Coxnet, integrating LASSO and Elastic Net regularization, was used to predict OS. For fair comparison, we randomly selected 30% (n = 31) of the smallest subset (n = 103, largest brain metastasis with both necrotic and solid components), all of which overlap with other model subsets, as validation cohort. Three model types—Clinical, Imaging and Combined—were compared using the concordance index (C-index) to assess performance based on validation cohort. **Results:** Clinical model, built on the whole cohort (286 women, 3 men; mean age 54.52 $\pm$ 12.79 years), identified 3 predictors of OS. Imaging model, built on a subset of 120 patients with brain MRI data, identified a radiomic signature (RS) consisting of 4 radiomic features most predictive of OS. Using the same subset, the Combined model (C-index: 0.728 [95% CI: 0.590–0.855]) outperformed Clinical (C-index: 0.62 [95% CI: 0.44–0.78]) and Imaging (C-index: 0.62 [95% CI: 0.46–0.77]) models in the held-out validation cohort (n = 31). Significant features associated with increased mortality risk in the Combined model included a higher RS, absence of tucatinib treatment for the primary BC prior to BM development, elevated Ki-67 expression, Black race, higher N stage, and brainstem metastases. Among these factors, RS, with the largest absolute coefficient in the Combined model (0.38), emerged as the most important predictor of OS (hazard ratio: 20.03 [95% CI: 4.92–81.48], $p < 0.005$). **Conclusions:** A distinct RS from brain MRI is the strongest predictor of OS in patients with BM from HER2-positive BC, surpassing clinical factors. RS may refine risk stratification and guide treatment or clinical trial prioritization. Research Sponsor: Susan G. Komen.

Hippocampal-avoidance whole-brain radiotherapy with dose escalation on metastases: A prospective randomized trial (HIPPORAD). First Author: Anca-Ligia Grosu, Department of Radiation Oncology, Medical Center - University of Freiburg, Faculty of Medicine, Freiburg, Germany

Background: The HIPPORAD trial aimed to evaluate a new method of whole brain radiation therapy (WBRT) with simultaneous integrated boost (SIB) to the metastases, with versus without hippocampal avoidance in patients with brain metastases. **Methods:** We conducted a prospective, multicentre, randomised, double-blind trial (DRKS00004598). Patients with 4-10 brain metastases > = 5mm were randomised at 13 centres in Germany 1:1 between WBRT+SIB with hippocampus avoidance (HA-WBRT+SIB) (arm A) and WBRT+SIB (arm B). Patients and assessors of outcome were blinded to the randomised arm. All patients received WBRT with 30 Gy and SIB with 51 Gy or 42 Gy in 12 fractions, 5x/week. The primary endpoint was the change in neurocognitive function (assessed by the Verbal Learning and Memory Test [VLMT]) 3 months after treatment. Secondary endpoints included neurocognitive changes at 9 and 18 months, development of anxiety and depression, quality of life and measures of oncological outcome. **Results:** Between August 2nd, 2016 and September 7th, 2021, 170 patients were recruited and 136 were randomised between HA-WBRT+SIB (n = 67) and WBRT+SIB (n = 69). Of these, 38 patients in arm A and 42 in arm B were known to be alive 3 months after treatment and were included in the primary endpoint analysis. The change in overall learning performance at 3 months was not significantly different between arms (p = 0.83). VLMT-scores decreased after 3 months, but improved at 9 and 18 months, with HA-WBRT+SIB showing an overall superior trend over WBRT+SIB. At 18 months, VLMT-scores improved to values above baseline in both arms. Patients treated with HA-WBRT+SIB had significantly less depression compared to patients treated with WBRT+SIB at 3 (p = 0.047) and 18 months (p = 0.048). The 12-month-tumor control for boosted metastases was 96% in Arm A and 88% in Arm B, while for the WBRT area it was 78% in both arms. Time to hippocampal tumour progression was comparable between arms (p = 0.98). After 12 months, 4% of patients in arm A and 12% in arm B had suffered neurological death. **Conclusions:** To our knowledge, this is the first prospective trial to show that hippocampal avoidance during WBRT leads to significantly lower rates of depression. The development of VLMT values after HA-WBRT+SIB and WBRT+SIB with 30 Gy in 2.5 Gy-fractions was comparable and a good recovery was observed at 18 months in both arms. The method showed a considerably higher intracerebral tumour control with lower neurological mortality rates compared to historical cohorts. Clinical trial information: DRKS00004598. Research Sponsor: German Cancer Aid.

2039 **Poster Session**

Initial report of memory avoidance whole brain radiotherapy to treat brain metastases: A prospective phase 2 trial. First Author: Joshua David Palmer, Department of Radiation Oncology, Ohio State University, Columbus, OH

Background: A common approach for patients with extensive brain metastases requiring radiation is hippocampal avoidance whole brain radiotherapy (HA-WBRT) prescribed with memantine; this was proven to be efficacious based on NRG CC001. However, a subset of patients who receive HA-WBRT with memantine still experience cognitive decline. Other brain structures with important roles in memory and cognition include the corpus callosum, fornix, amygdala, hypothalamus, and pituitary; these structures all have a low propensity for brain metastases and therefore can be safely spared in a radiotherapy plan without increasing the risk of relapse. A subset of patients enrolled on a Phase 2 Randomized Controlled Trial (NCT05503251) received an advanced "memory-avoidance WBRT (MA-WBRT) approach that spared these substructures in addition to the hippocampus, with a primary endpoint of improved cognition compared to a historical control (NRG CC001). **Methods:** All patients with > 15 brain metastases on a prospective clinical trial, which randomized patients to either neuropsychology evaluation and intervention plus brain radiotherapy or brain radiotherapy alone, received MA-WBRT. Exclusion criteria included prior WBRT, pre-existing mental disability, and metastases within the avoidance neurocognitive substructures. All patients received 30 Gy in 10 fractions of MA-WBRT and were prescribed memantine. Cognition was measured by Hopkins Verbal Learning Test-Revised, Controlled Oral Word Association Test, and Trail Making Test A/B, with cognitive decline defined as decline on at least one assessment using reliable change index (same tests and definition as NRG CC001). **Results:** Between August 2022 and May 2024, 29 patients received MA-WBRT. Baseline characteristics included a median KPS of 80 (IQR 70, 90), median age of 64 (IQR 54, 69), 62% female patients, and a plurality of patients with a primary lung cancer (48%), The median overall survival or time to last follow up was 7.9 months. The three-month decline in neurocognitive function comparing the control and intervention groups for patients receiving MA-WBRT was 15.4% and 18.8%, respectively (p = 0.39). There was one failure in the right fornix 10 months after enrollment, but this was associated with concurrent distant intracranial failure outside the memory avoidance zone. **Conclusions:** The cognitive decline rate of approximately 17% at three months for patients receiving MA-WBRT compares favorably to a 3-month cognitive decline rate of 50% seen on NRG CC001. Additionally, MA-WBRT does not appear to significantly increase the risk of intracranial failure. Further evaluation of the delayed impact (> 6 months) of MA-WBRT on cognitive function will be reported when data are available. A direct comparison of MA-WBRT plus memantine vs. HA-WBRT plus memantine is forthcoming with a randomized phase 3 trial. Clinical trial information: NCT05503251. Research Sponsor: None.

Genomic predictors of brain metastases in breast cancer. First Author: Anton Safonov, Memorial Sloan Kettering Cancer Center, New York, NY

Background: Despite therapeutic advances in metastatic breast cancer (MBC), the rising incidence of brain metastases (BM) remains a major challenge, contributing to poor prognosis and significant morbidity. Due to the absence of consensus screening strategies for BM, they are often detected only after clinical symptoms emerge. There is therefore a pressing need for predictive biomarkers to identify breast cancer patients at risk of BM. **Methods:** This study included 3908 patients who underwent sequencing of primary tumor (n = 1885) or non-brain metastasis (n = 2023) with MSK-IMPACT, a custom tumor-normal next generation sequencing assay. First, we performed penalized logistic regression on a gene level to identify alterations in extracranial metastases or primary tumors associated with development of BM. We adjusted for multiple hypothesis testing using Benjamini-Hochberg. Lastly, we developed a lasso machine-learning (ML) model, incorporating baseline genomic and clinicopathologic features, to predict onset and timing of BM from initial diagnosis (for early stage cases) or metastatic disease (for MBC). Each analysis was stratified by receptor status, and repeated to account for loss of heterozygosity (LOH) of tumor suppressor genes. **Results:** Our cohort included 528 BM events over a median follow-up of 58 mos. Pathogenic variants in several genes were associated with subsequent BM development. In the HR+/HER2- subset (n = 2624), pathogenic variants in the following genes portended the onset of BM: *RB1* (OR 2.59 [1.39 - 4.81], q = 0.011), *NF1* (OR 2.22 [1.21 - 4.06], q = 0.039), *TP53* (OR 1.91 [1.43 - 2.54], q < 0.001), *PIK3CA* (OR 1.47 [1.21-4.06], q = 0.028). Pre-existing LOH of *RB1,* in the absence of an *RB1* functional alteration, was associated with BM development (OR 1.37 [1.03 - 1.83], q = 0.090). *TP53* LoF .OR 5.14 [2.21 - 11.9], q < 0.001) was enriched in the BM group in HER2+ tumors, while amplification of *CDKN2A* (OR 11.6 [2.44 - 55.5], q = 0.01) or *EGFR* (OR 4.60 [1.54 - 13.8], q = 0.03) were enriched in TNBC. *TP53* emerged as an important feature across all receptor subtypes in our machine-learning model; *RB1* LoF was also selected as an important feature in the HR+/HER2- group. Validation of the ML model in an external cohort will be presented at the meeting. **Conclusions:** In a large cohort of genomically profiled breast cancer samples, we found several biologically plausible candidates for molecular harbingers of BM. For instance, the recurrent involvement of genes involved in cell cycle regulation (*RB1, CDKN2A, TP53)* has been implicated as candidates for BM tropism in other cancer types. Our approach also uncovers several alterations for which targeted therapies exist or are actively in development *(NF1, PIK3CA).* Our clinically actionable multimodal model of BM risk is poised to facilitate the development of early detection strategies and guide-high risk patient selection for novel clinical trials to intercept this devastating complication. Research Sponsor: None.

Characterizing functional connectivity in brain tumor patients. First Author: Alexander B. Remsik, University of Wisconsin System, Madison, WI

Background: Brain tumors (affecting 25,500 individuals in the US alone) cause unique changes to neural function and connectivity resulting in impairments in various functional domains, including cognition. **Methods:** Between 2012 and 2018, as part of their preoperative surgical planning, 91 brain tumor patients with tumors in right (R) or left (L) temporal (T), parietal (P) or frontal (F) lobes received resting-state functional magnetic resonance imaging (rs-fMRI) and the COWAT verbal fluency (VF) test. UW Hospital and Clinics uses 1.5 T (112 axial slices, 1.0 × 1.0 × 1.5 mm) and 3 T (136 axial slices, 1.0 × 1.0 × 1.2 mm) GE MRI scanners and includes high-resolution 3D BRAVO T1-weighted imaging, and rs-fMRI scans (eyes closed, 28 axial slices, 3.75×3.75×5.0mm) were also acquired during this imaging protocol. These individuals were compared to each other and to 40 age-matched non-tumor controls (Cs). **Results:** Groups were similar in age, and sex ($p>0.05$), but different in education ($p=0.028$) and VF scores ($p=0.001$). There were significant differences in post-hoc p-values when comparing VF scores between Cs and RT tumor patients ($p=0.039$). Qualitative observations indicate Cs are more integrated have greater network strength and connectivity higher transitivity, efficiency, and modularity index compared to patients. There were significant differences in VF scores between Cs, LF ($p=0.001$), RF ($p=0.012$), RT ($p=0.021$), RP ($p=0.015$). Patients show hypo-frontality of hubs and a unique cerebellar module. LF patients showed correlation to transitivity at 25% ($R=0.404$, $p=0.041$), and patients with RP tumors had significant correlations to transitivity ($R=0.654$, $p=0.029$) and global efficiency ($R=0.607$, $p=0.048$). Cs and L tumors did not show any significant correlation to VF scores, R tumors showed correlation with global efficiency at 25% sparsity ($R=0.374$, $p=0.025$). All remained significant after FDR correction. **Conclusions:** Tumor location impacts rs-fMRI-derived GT network structure and VF scores, suggesting tumors in left hemisphere and frontal areas caused the greatest impact to cognition. These methods may be used in future research and clinical care to map, track, and predict functional connectivity changes resulting from brain tumor and can help inform clinicians and care trajectories. AI-driven transcriptomic classification of glioblastoma: Associations with survival and tumor microenvironment. First Author: Juan Manuel Fernandez-Muñoz, SphereBio, Mendoza, Argentina

Background: Glioblastoma (GBM) is the most lethal primary brain tumor in adults, with a median survival of ~15 months despite current therapies (surgery, radiation, temozolomide). Advances like immune checkpoint inhibitors, anti-angiogenic agents, and tumor vaccines have shown suboptimal results. The 2021 WHO classification highlights molecular markers (e.g., IDH, MGMT) for better stratification, but these fail to fully capture tumor microenvironmental dynamics. Using an AI-driven transcriptomic approach, we identified novel prognostic subtypes in IDH-wildtype GBM, aiming to refine stratification, enhance understanding of tumor biology, and guide personalized therapeutic strategies. **Methods:** We accessed microarray data from The Cancer Genome Atlas (TCGA) (n=353 newly diagnosed, IDH-WT GBM) for a training set and RNA-seq data from the Chinese Glioma Genome Atlas (CGGA) (n=170 primary and n=106 recurrent tumors) for validation. A proprietary SphereBio machine learning–based algorithm was used to derive transcriptomic signatures with prognostic relevance. Subtypes were assessed via Kaplan–Meier analyses in the training cohort and tested in both primary and recurrent validation cohorts. Immune/stromal infiltration was quantified using a tumor deconvolution tool (DA_505), and pathway enrichment (GAGE) was performed on the validation sets. **Results:** AI-driven clustering revealed three transcriptomic subtypes with significant survival differences in both the training ($p<0.0001$) and primary validation ($p=0.0004$) cohorts. In the recurrent cohort, a similar survival trend by subtype was observed, though significance was diminished ($p=0.12$), likely due to limited sample size and therapy-related changes. Immune/stromal deconvolution showed distinct infiltration patterns: subtypes enriched for CD4+ and CD8+ T cells correlated with prolonged survival. Pathway enrichment analysis in both primary and recurrent tumors highlighted potential targets involving embryogenesis, immune modulation, cell cycle, and stress response. The persistence of a consistent survival trend and comparable microenvironment and pathway patterns suggest that these transcriptomic subtypes remain biologically relevant even after standard treatment. **Conclusions:** Our integrated transcriptomic and microenvironment-focused approach identified three prognostically distinct GBM subtypes, validated across independent cohorts. These findings underscore the utility of AI-driven transcriptomic signatures for personalized stratification, with the potential to guide targeted therapeutic strategies and inform clinical trial design in GBM. Impact of neuroradiologists' input on peer review meetings for CNS radiotherapy treatment planning. First Author: Abhishek Mahajan, The Clatterbridge Cancer Centre NHS Foundation Trust, Liverpool, Merseyside, United Kingdom

Background: Evidence shows radiologists' involvement improves planning accuracy, especially in complex anatomical areas. However, their participation remains limited. This prospective observational study evaluates the impact of neuroradiologists' input on changes to radiotherapy (RT) plans during peer review meetings. **Methods:** Data were collected from 205 patients with CNS tumours planned for radiotherapy between May 2022 and October 2023. We recorded demographics, diagnostic and RT planning scans, and therapy received. All images were reviewed by a neuroradiologist, with RT changes classified as major (affecting cure or disease control) or minor (affecting target volumes or organs at risk). Summary statistics were calculated, and Pearson chi-squared tests assessed whether changes in RT plans varied by tumour type, time since diagnosis, and neuroradiologist findings. Data were analyzed using STATA SE v.17. **Results:** Of 205 patients, 81 (40%) had gliomas, 77 (38%) had brain metastases, 23 (11%) had meningiomas, 17 (8%) had schwannomas, and 7 (3%) had pituitary tumours. The mean age was 60 years (SD 14), 56% were male, and 36% were treatment-naïve. All but one had MRI scans, 128 (62%) had CT scans, and 9 (4.4%) had PET scans. The median number of diagnostic scans per patient was 2 (IQR 2-3), and all had two planning scans. The median interval between diagnosis and RT planning scans was 35 days (IQR 21-61). Disease progression was observed in 67 (33%) patients. Major and minor changes to RT plans were reported in 35 (17%) and 78 (38%) patients, respectively. A higher proportion of RT plans changed for brain metastasis (26% & 40%) and glioma (11% & 43%). Changes were not associated with tumour type ($p = 0.07$) or time since diagnosis ($p = 0.12$), but were significantly associated with neuroradiologist findings ($p < 0.0001$). **Conclusions:** Neuroradiologists' assessments led to major and minor changes in RT plans, regardless of tumour classification or interval since diagnosis. This expertise can enhance RT plan accuracy, improving patient outcomes. Research Sponsor: None.

Changes to radiotherapy treatments as per RCR categories and by tumour type, time interval, and neuroradiologist findings.

Identification and validation of potential diagnostic plasma biomarkers for diffuse gliomas by multiplex immunoassays. First Author: Miyo K. Chatanaka, University of Toronto, Toronto, ON, Canada

Background: Diffuse gliomas are aggressive malignant tumors with poor prognosis. The current standard of care includes measurement of molecular biomarkers in biopsy samples. One unmet clinical need is to identify non-invasive biomarkers that may be used for differential diagnosis of gliomas from other brain tumors. Pre-clinical and clinical validation of such biomarkers could eliminate the need for biopsy, and support the implementation of more personalized and/or emerging treatments and the earlier enrolment of patients into clinical trials. Our objective is to use multidimensional proteomics to identify and validate potential plasma biomarkers for glioma management. **Methods:** We used the proximity extension assay from Olink Proteomics to analyze 3,000 proteins in plasma of patients with diffuse gliomas and meningiomas (as controls). By data visualization, we identified several plasma proteins that were increased or decreased in gliomas in comparison to meningiomas. Several candidate markers were selected for validation with an independent set of retrospectively collected samples by using quantitative research-use-only electrochemiluminescence assays available from Meso Scale Discovery. In the validation set, which included longitudinal data from patients, patient information included biopsy-requiring molecular tumor abnormalities such as IDH1 status, ATRX expression, MGMT promoter methylation, CDKN2A/B/p16 status, V1p 19q co-deletion and NF1 status. In the validation stage, we focused on diffuse gliomas. **Results:** In the discovery phase, associations between proteins were plotted to determine potential predictive ability for discriminating diffuse gliomas vs. meningiomas. A partitioning algorithm was fit to determine the optimal combination of GFAP (the strongest biochemical marker), age and sex, as well as with other candidate proteins. Differential expression was seen for a few other proteins such as NEFL, PROK1, FABP4, MMP3 and LMOD1. In the cross-sectional validation phase, we verified strong associations between GFAP and FABP4 plasma concentration and GBM, astrocytomas, oligodendrogliomas and meningiomas, where these markers could differentiate between the groups. Within diffuse gliomas, NEFL, GFAP, FABP4 and IL13 were significantly different. **Conclusions:** This study highlights the potential of plasma biomarkers to revolutionize glioma patient management through liquid biopsy applications. The strong associations observed between plasma protein concentrations and glioma subtypes support a diagnostic power that addresses a critical unmet need in neuro-oncology. More specifically, these biomarkers can help with patient differential diagnosis at initial presentation, with future aims to investigate the prognostic value and the possibility of acting as surrogates of molecular changes that are currently used for optimizing therapy. Association of plasma biomarkers with diagnostic molecular markers for potential diagnosis and prognosis of diffuse gliomas. First Author: Leonardo Macedo Filho, Penn State College of Medicine, Hershey, PA

Background: Diffuse gliomas were recently reclassified based on the 2021 WHO Classification criteria. Several molecular changes which carry diagnostic and prognostic power have been added to the classification parameters, including IDH1 mutation and MGMT promotor methylation. To characterize these molecular changes, however, an invasive biopsy is required. Our goal was to examine the relationship between seven plasma biomarkers for diffuse glioma and the established molecular changes and delineate if these markers can be used as surrogates of these molecular changes. **Methods:** Seven candidate markers, namely glial fibrillary acidic protein (GFAP), neurofilament light (NEFL), matrix metalloproteinase 1, 3, 9 (MMP1, MMP3, MMP9), total Tau (tTau) and fatty acid binding protein 4 (FABP4) were evaluated by quantitative research-use-only electrochemiluminescence assays available from Meso Scale Discovery by comparing the protein concentration distribution with non-parametric Wilcoxon rank sum tests and multiple testing adjustment. The molecular markers tested were IDH1, MGMT promotor and ATRX. The discovery cohort consisted of 49 IDH1 mutant (39%) and 77 IDH1 wildtype (61%) gliomas. Among this retrospective cohort were 103 primary samples (collected at diagnosis) and 23 recurrent samples (collected at time of recurrence). The retrospective validation cohort consisted of 36 IDH1 mutant (22%) and 129 IDH1 wildtype (78%), with 64 primary samples and 76 recurrent samples. **Results:** Several of the proteomic markers showed significant associations with genetic markers at an adjusted significance level of $P < 0.05$. For IDH1 status, the strongest association was with NEFL, with IDH1 wildtype samples showing higher levels of the protein. For ATRX expression, high FABP4 was correlated with ATRX retention. As expected, survival analysis based on molecular markers yielded that IDH1 status was most predictive of survival both in primary tumors and recurrent tumors. MGMT promotor methylation was predictive of survival in primary cases but not recurrent cases. When combining the genetic markers with protein concentrations, we were able to see some improvement in survival prediction. **Conclusions:** We demonstrate that some plasma biomarkers, particularly NEFL and FABP4, show significant associations with key molecular changes in diffuse gliomas, including IDH1 status and ATRX retention/loss. Future research will determine whether these proteomic markers can serve as surrogates for molecular alterations and assist in potentially improved diagnosis and monitoring of diffuse gliomas. 2046 **Poster Session**

A multicenter randomized phase III study for recurrent glioblastoma comparing bevacizumab alone with dose-dense temozolomide followed by bevacizumab: JCOG1308C. First Author: Motoo Nagane, Department of Neurosurgery, Kyorin University Faculty of Medicine, Tokyo, Japan

Background: Temozolomide (TMZ) is an alkylating agent commonly used as the standard therapy for newly diagnosed glioblastoma (GBM), with the DNA repair enzyme O^6-methylguanine-DNA methyltransferase (MGMT) serving as a key prognostic and predictive factor. Despite treatment, GBM almost always recurs with limited therapeutic options, leading to poor prognosis. Since MGMT is consumed during the repair of TMZ-induced O^6-methylguanine lesions in DNA, dose-intensified TMZ regimens are designed to deplete MGMT, thereby enhancing tumor sensitivity to TMZ. Bevacizumab (BEV), an anti-VEGF agent, has shown efficacy in recurrent GBM (re-GBM), but no effective therapies exist after BEV failure. Introducing an active agent before BEV may improve outcomes. To test this, we conducted a multicenter, phase III study comparing BEV monotherapy with dose-dense TMZ (ddTMZ) followed by BEV in re-GBM. **Methods:** Patients (pts) aged 20-75 years with KPS $\geq$60 and histologically confirmed GBM at first recurrence were enrolled from 31 Japanese hospitals. Participants were randomized to BEV monotherapy (10 mg/kg every 2 weeks; arm A) or ddTMZ (120-150 mg/m^2, 7 days on/7 days off) followed by BEV at progression (arm B). Treatment continued until progression or unacceptable toxicity. The primary endpoint was overall survival (OS). A planned sample size of 146 pts provided 70% power to detect a hazard ratio (HR) of 0.73 (median OS (mOS): 8 vs. 11 months) at a one-sided alpha of 10%. *MGMT* promoter methylation and *IDH* mutation status were analyzed. **Results:** From July 2016 to April 2022, 146 pts (73 per arm) were randomized. *MGMT* promoter methylation was observed in 78 pts, while 49 were unmethylated. *IDH1* mutations were identified in 8 of 129 pts to be tested. The mOS was 11.0 months (95% CI: 9.0-12.8) in arm A and 10.8 months (95% CI: 8.6-12.5) in arm B, with no significant difference (HR 0.922, 95% CI: 0.655-1.297, one-sided p = 0.320). No significant OS difference was observed between arms based on *MGMT* methylation status. The median progression-free survival (PFS) was 4.0 months (95% CI: 3.8-5.7) in arm A and 2.0 months (95% CI: 1.9-2.1) in arm B (HR 1.632, 95% CI: 1.168-2.281). Most pts in arm B exhibited progression at their first MRI. From the start of BEV treatment, mOS was 10.8 months (95% CI: 8.8-12.6) in arm A, and 8.0 months (95% CI: 6.1-9.1) in arm B. Grade 3-4 adverse events included hypertension (19.4%) in arm A and lymphopenia (52.1%) and leukopenia (8.2%) during ddTMZ in arm B. Grade 4 toxicities were rare. **Conclusions:** While ddTMZ was well-tolerated, this study failed to demonstrate a survival benefit for ddTMZ followed by BEV in re-GBM. BEV remains the preferred treatment at first recurrence. Further research is needed to develop effective therapies beyond the current standard for re-GBM. Clinical trial information: NCT02761070. Use of brain protein I3 (BRI3) to predict disease fate in glioblastoma. First Author: Ifeanyichukwu Ogobuiro, The University of Miami Sylvester Comprehensive Cancer Center, Miami, FL

Background: Genome-wide characterization has illuminated the molecular complexity of human gliomas. Genetic alterations help predict the clinical behavior of gliomas, but variability persists. Accordingly, there is a need to expanding molecular signatures that refine prognostication. The Brain Protein I3 (BRI3) gene, localized on chromosome 7, is associated with high-grade glioma, yielding the highest hazard ratio among all high-risk genes in an in-silico glioma model. Given GBM's known chromosome 7 gain and BRI3's chromosomal location, we hypothesized that gene dosage gains and overexpression serve as prognostic biomarkers. **Methods:** We used the Rembrandt (n = 461 patients) and TCGA low-grade glioma (LGG) and GBM (n = 1,148 patients) databases for multi-omic analyses. RNA sequencing (Illumina HiSeq) and DNA methylation profiles (Illumina 450K) were analyzed in a combined LGG and GBM cohort, with high/low expression and hyper/hypomethylation defined by median values. CNV analysis (GISTIC 2.0) classified 2 copies as gene-copy neutral and > 2 as gene dosage gain. Somatic mutation data (SNPs/INDELs) were derived from whole-exome sequencing to decipher IDH-wt and IDH-mutant gliomas. Univariate and adjusted Cox models, Kaplan-Meier estimates, and receiver operating characteristic (ROC) curve analysis were performed. **Results:** Of 461 Rembrandt patients, 47.29% were GBM, 31.89% astrocytoma, 14.53% oligodendroglioma, and 6.29% normal brain. Among 1,148 TCGA LGG/GBM patients, 551 had complete molecular and clinical data, with 28% IDH-wt status, 49% MGMT hypermethylation, and 36.66% BRI3 gene dosage gains. BRI3 expression was significantly higher in GBM, grade IV tumors, IDH-wt, and mesenchymal subtypes. Among the IDH-wt cases, 75% showed BRI3 gene dosage gains with significantly elevated mRNA expression. EGFR, co-amplified in 80% of IDH-wt cases, did not affect survival (25.27 vs. 17.90 months, p = 0.346). Conversely, BRI3 gene dosage gain correlated with worse survival (79.3 vs. 17.93 mo, p = 0.001), as did BRI3 high vs. low expression (17.90 vs. 25.27 months, p = 0.015) and MGMT hypermethylation (25.27 vs. 18.63 mo, p = 0.021). Univariate analysis linked patient age (HR: 2.858 [1.781–4.586], $p < 0.001$), MGMT hypermethylation (HR: 2.632 [1.307–5.301], p = 0.007), BRI3 high expression (HR: 1.938 [1.131–3.320], p = 0.016) and BRI3 gene dosage gain (HR: 2.504 [1.425–4.398], p = 0.001) to worse OS. Adjusted multivariate Cox regression confirmed BRI3 gene dosage gain, age, and MGMT methylation as independent OS predictors in IDH-wt cases. ROC analysis revealed stronger prognostic performance for BRI3 gene dosage gain than MGMT hypermethylation (AUC: 0.737 vs. 0.616, $p < 0.001$) in IDH-wt cases. **Conclusions:** Elevated BRI3 gene dosage and expression portend poor prognosis and could be incorporated into models predicting disease fate in GBM. Research Sponsor: None.

2048 **Poster Session**

Effect of armed oncolytic adenovirus on immunotherapy for primary and metastatic brain tumors. First Author: Jiasen He, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Oncolytic viruses have shown promise in clinical trials for solid tumors, including glioma and melanoma, but only a subset of patients benefits. We previously showed that arming the oncolytic adenovirus Delta-24-RGD with OX40L can enhance antitumor immunity. To further boost efficacy, we developed Delta-24-RGDOX-IL15, co-expressing OX40L and IL-15, and tested it in preclinical models of primary and metastatic brain tumors. **Methods:** To evaluate IL-15 and its receptor (IL15RA) expression in patients with glioma and melanoma, we conducted gene expression and survival analysis using the GEPIA web server, integrating RNA sequencing data from TCGA and GTEx. Transgene expression in Delta-24-RGDOX-IL15 was assessed via flow cytometry and ELISA, while viral potency was evaluated using replication and cell viability assays. Anti-tumor activity was tested in syngeneic intracranial models derived from mouse diffuse midline (DMG) glioma and melanoma cell lines in C57BL/6 mice, both of which expressed GD2 and luciferase. Tumor growth was monitored with bioluminescent imaging, survival with Kaplan-Meier analysis, and immune profiling of the tumor microenvironment using flow cytometry. **Results:** GEPIA analysis showed that melanoma had higher expression of IL-15 and IL-15RA compared to glioma. In melanoma patients, higher expression of IL-15RA or IL-15 was linked to better overall survival ($P < 0.005$), while no survival difference was found in patients with glioma. Delta-24-RGDOX-IL15 infected and co-expressed OX40L and IL-15 effectively in mouse glioma and melanoma cells, and induced potent oncolysis. Delta-24-RGDOX-IL15-infected tumor cells significantly enhanced the oncolysis activity of GD2 CAR T cells in culture. Intratumoral injection of the virus also resulted in better tumor reduction and improved survival in C57BL6 mice with gliomas derived from mouse DMG cells while no significant toxicity was observed. Additionally, locoregional therapy with Delta-24-RGDOX-IL15 induced a systemic inflammatory response in the tumor microenvironment, characterized by increased frequency of T cells and reduced that of myeloid cells. **Conclusions:** Higher expression of IL-15/IL-15RA is associated with better survival in patients with melanoma. Delta-24-RGDOX-IL15 demonstrates potent oncolytic activity in both glioma and melanoma cell lines. In the intracranial brain tumor mouse model, it exhibited promising anti-tumor effects with enhanced T cell stimulation and minimal toxicity. Delta-24-RGDOX-IL15 is a promising candidate for combination with cellular therapies in both primary and metastatic brain tumors. Research Sponsor: ChadTough Defeat DIPG Foundation.

2049 **Poster Session**

A phase I clinical trial on combined (neo-)adjuvant intravenous plus intracranial administration of ipilimumab and nivolumab in recurrent glioblastoma (NEO-GLITIPNI). First Author: Iris Dirven, Department of Medical Oncology, Laboratory for Medical and Molecular Oncology (LMMO), Translational Oncology Research Center (TORC), Vrije Universiteit Brussel (VUB), Universitair Ziekenhuis Brussel (UZ Brussel), Brussels, Belgium

Background: Intravenous (IV) administration of ipilimumab (IPI) and nivolumab (NIVO) has shown limited activity in recurrent glioblastoma (rGBM). Intracerebral (iCer; within the brain tissue lining the resection cavity) and intracavitary (iCav; through an Ommaya reservoir) administration (admin) of IPI and NIVO was proven to be safe and resulted in promising survival outcomes (Duerinck et al. Neuro-Oncol 2024). Adding a neoadjuvant (NEOADJ) treatment phase to iCer/iCav IPI/NIVO may further improve outcome. **Methods:** In the Neo-Glitipni trial (NCT06097975), a single center, phase I clinical trial, patients (pts) with resectable rGBM (WHO grade 4, IDH wild type) who progressed after radiotherapy and temozolomide, with a baseline ECOG performance status of 0-2 and $\leq$8 mg methylprednisolone daily, received 2 NEOADJ cycles of IV IPI 1 mg/kg + NIVO 3 mg/kg followed by maximal safe resection (MSR) in week 5 with iCer admin of IPI 5 mg + NIVO 10 mg and iCav admin of IPI 1 mg + NIVO 10 mg. The adjuvant phase consists of biweekly postoperative iCav admin of IPI 1 mg + NIVO 10 mg and IV NIVO 240 mg for 12 cycles, followed by monthly NIVO 480 mg IV maintenance for up to two years. **Results:** 5 pts (4 male, median age 57 years (44-65); 1st recurrence in 3 pts) were enrolled. All pts received the 1st and 4 pts also the 2nd NEOADJ dose of IV IPI/NIVO. Out of the 5 pts, 3 were not amenable to MSR with iCer/iCav IPI/NIVO admin according to the protocol because of disease progression during the NEOADJ treatment phase and required corticosteroids (1 pt in week 2, 2 pts in week 4). Two pts successfully underwent MSR with iCer/iCav admin of IPI/NIVO per protocol. One pt initiated adjuvant treatment with iCav IPI/NIVO and IV NIVO. There were no unexpected adverse events (AE). Two pts experienced an immune-related AE that required corticosteroids and interruption of study treatment (grade 4 hepatitis in 1 pt, onset 8 days after MSR and grade 2 colitis in 1 pt, onset 28 days after MSR). One pt developed a thyroiditis during the NEOADJ treatment phase and 2 pts experienced a grade 3 treatment related AE that was not immune-related (seizure and Ommaya reservoir infection). None of the rGBM were characterized by a high tumor mutational burden on next generation sequencing. Gene expression profiling, and pharmacokinetic analysis of NIVO and IPI in the cerebrospinal fluid and blood are ongoing. After a median follow-up of 15 weeks (9-35w) all pts are alive, one pt remains free of progression (median progression free survival: 4.3 weeks). **Conclusions:** Four weeks of NEOADJ IV IPI/NIVO (comprising 2 admin) is safe, but symptomatic disease progression was observed in 3 out of 5 rGBM pts prior to the planned MSR with iCer/iCav IPI/NIVO admin in week 5. Therefore, the trial is being amended by shortening the NEOADJ treatment phase to 2 weeks (1 admin) and planned MSR with iCer/iCav IPI/NIVO admin in week 3. Clinical trial information: NCT06097975. Research Sponsor: None.

Effect of 18F-DOPA-PET and advanced MRI on treatment response assessment in IDH1/2-mutant gliomas treated with IDH inhibitors. First Author: Diego Martín Prost, Hopital La Pitié Salpetriere, Paris, France

Background: Small-molecule inhibitors targeting IDH1/2-mutant proteins (IDHi) have shown promise as treatments for *IDH1/2*-mutant gliomas. However, accurate assessment of response using morphological magnetic resonance imaging (MRI) measurements remains difficult, and the potential of PET imaging with radiolabeled amino acids in this context is yet to be explored. Here, we investigated 3,4-Dihydroxy-6-[18F]-fluoro-L-phenylalanine PET (^{18}F-DOPA-PET) and MRI responses in *IDH1/2*-mutant glioma patients receiving IDHi. **Methods:** *IDH1/2*-mutant glioma patients receiving IDHi as part of trials or expanded access programs were included. Patients had pre- and post-treatment MRI and ^{18}F-DOPA-PET. Centralized evaluations included 2D/3D measurements on T2-weighted FLAIR images, T1-post contrast, perfusion, and diffusion imaging for MRI, and metabolic tumor volume (MTV), total lesion glycolysis (TLG), and tumor-to-background ratios (TBRs) for ^{18}F-DOPA-PET. Disease response evaluation using volumetric assessments, RANO 2.0 and PET RANO 1.0 criteria were compared and confronted to outcomes. **Results:** From 2021 to 2024, 10 patients with *IDH1/2*-mutant glioma (3 astrocytoma, 7 oligodendroglioma) receiving IDHi (4 ivosidenib, 6 vorasidenib) were analyzed. Significant reductions in ^{18}F-DOPA-PET parameters including TBRmean, TBRmax, and MTV were observed in 8/10 patients, aligning with observed changes in perfusion and diffusion imaging. Seven partial responses and one complete response were identified using ^{18}F-DOPA-PET, while both volumetric and standard 2D morphological MRI assessments indicated stable disease as best response. PET response was correlated with prolonged tumor control. **Conclusions:** This study highlights the potential of ^{18}F-DOPA-PET and advanced MRI sequences as valuable complements to standard RANO 2.0 MRI evaluations for assessing treatment response in glioma patients undergoing IDHi therapy. Research Sponsor: None.

Phase I/II study of maintenance therapy with metformin and temozolomide for newly diagnosed glioblastoma. First Author: Yoshitaka Narita, Department of Neurosurgery and Neuro-Oncology, National Cancer Center Hospital, Tokyo, Japan

Background: Glioblastoma (GBM) is an aggressive primary brain tumor with poor prognosis. A potential strategy for overcoming therapeutic resistance involves the development of novel therapies that target cancer stem/initiating cells. Our previous research demonstrated that metformin (MF), an antidiabetic drug, induces the differentiation of stem-like glioma-initiating cells and suppresses tumor formation via AMPK-FOXO3 activation (Stem Cells Transl Med, 2012). We conducted a phase I/II study to evaluate the clinical efficacy of MF combined with standard maintenance temozolomide (TMZ). Our phase I findings indicated that MF at doses of up to 2,250 mg/day combined with maintenance TMZ was well tolerated (Cancers, 2022). Here, we present the complete results of the phase I/II study. **Methods:** Patients aged 20–74 years with supratentorial GBM, Karnofsky Performance Status $\geq$ 70, and a history of initial chemoradiotherapy with TMZ were eligible. During the phase II study, patients received MF monotherapy for 14 days, followed by six cycles of TMZ combined with daily MF (2,250 mg) for 365 days. The primary endpoint was the 1-year progression-free survival (PFS) rate from the initiation of chemoradiotherapy with TMZ (target; one-sided alpha 10%, power 70%, threshold 1-year PFS, 27%; expected 1-year PFS, 50%, based on the historical EORTC/NCIC study (Stupp et al, 2005)). **Results:** From 2021–2023, 22 patients were enrolled in 5 hospitals and 21 patients received TMZ combined with daily MF. The cohort included 12 men and nine women, with a median age of 50 years (32–69 years). According to the WHO 2016 classification, the initial histology revealed 18 IDH-wild-type and 3 IDH-mutant GBMs. The 1-year PFS was 47.6 % (90% CI; 29.2–64.0), achieving the primary endpoint. The 2-year overall survival rate was 54.5%. Grade $\geq$ 3 adverse events included lymphocytopenia (19%), thrombocytopenia (4.8%), appetite loss (4.8%), body weight loss (4.8%), nausea (4.8%), and seizures (4.8%). **Conclusions:** Maintenance therapy with 2,250 mg/day of MF combined with TMZ for newly diagnosed GBM is promising. A phase III study comparing MF combined with TMZ vs. TMZ alone for the treatment of GBM is planned. Clinical trial information: jRCTs031200326. Research Sponsor: Japan Agency for Medical Research and Development; AMED 21ck0106623h0002.

Modification of the novel RANO clinical risk score for low- and middle-income countries without access to MGMT methylation testing. First Author: Imdat Eroglu, Gazi University School of Medicine, Department of Medical Oncology, Ankara, Yenimahalle, Turkey

Background: The RANO Resect Group developed a new risk score using simple variables, including age, Karnofsky performance scale (KPS), RANO resection class (RRC), and MGMT methylation (MGMTm), for patients with IDH-wildtype glioblastoma (GBM). Although this score is easy to apply and demonstrates high prognostic accuracy, routine testing for MGMTm remains inaccessible in many low- and middle-income countries. In this study, we aimed to modify the RANO risk score by excluding MGMTm. **Methods:** This is a single-center, retrospective analysis of IDH-wildtype GBM patients. We applied the same scoring system established by the RANO Resect Group, excluding MGMTm. The point (p) allocations were as follows: RRC1 = 0p, RRC2 = 1p, RRC3 = 2p, RRC4 = 5p; KPS $>$ 80 = 0p, KPS $<$ 80 = 3p; age $<$ 65 = 0p, and age $>$ 65 = 1p (age was not scored if RRC = 1p). The relationship between overall survival (OS) and the variables (age, KPS, and RRC) was evaluated using univariate and multivariate Cox regression analyses. Three risk classes were defined as numerical scores derived through ROC analysis. The primary endpoint was overall survival, and the secondary endpoint was progression-free survival (PFS). **Results:** A total of 119 patients were included in the study. Of these, 100 patients received chemoradiotherapy with temozolomide followed by adjuvant temozolomide (CRT-TMZ), while 13 received CRT only, 1 patient received temozolomide only, and 1 received radiotherapy only. Four patients were unable to undergo any treatment. RRC, age, and KPS classifications were all significantly associated with overall survival in both univariate and multivariate analyses ($p < 0.001$).Based on ROC curve analysis, three risk classes were identified: low risk (0–1 points, n:47, 39.5 %), intermediate risk (2–3 points, n:27, 22.7 %), and high risk ($\geq$4 points, n:45, 37.8 %). The median OS was 35.5 months (95% CI: 21.1–50) for the low-risk group, 16 months (95% CI: 9.9–22.1) for the intermediate-risk group, and 5 months (95% CI: 3.8–6.1) for the high-risk group ($p < 0.001$). Similarly, the median PFS was 16.3 months (95% CI: 12.3–20.2) for the low-risk group, 9.9 months (95% CI: 7.2–12.6) for the intermediate-risk group, and 4.1 months (95% CI: 3.4–4.8) for the high-risk group ($p < 0.001$). **Conclusions:** The modification of the novel RANO clinical risk score by omitting MGMTm remains highly prognostic for patients with IDH-wildtype GBM. Since it relies on very basic parameters and is easy to use, the modified RANO score can serve as a practical tool in countries where MGMTm testing is inaccessible. Research Sponsor: None.

The impact of IDH mutation and 1p/19q codeletion on immune-checkpoint inhibitor efficacy in recurrent gliomas. First Author: Shameel Shafqat, Mayo Clinic Comprehensive Cancer Center, Rochester, MN

Background: Recurrent gliomas are highly aggressive brain tumors, often resistant to conventional treatments. Immune checkpoint inhibitors (ICI) have emerged as promising therapeutic agents by targeting tumor cells through immune modulation. However, clinical trials have demonstrated limited efficacy in recurrent gliomas. This study aimed to identify potential factors influencing treatment efficacy of ICIs in recurrent gliomas. **Methods:** This retrospective study, conducted across the Mayo Clinic following IRB approval, included patients $\geq$ 18 years diagnosed with adult-type diffuse gliomas. Eligible patients received treatment with at least 2 cycles of ICI for recurrent glioma between 2014 – 2024. Patients treated with ICIs as initial therapy were excluded. Clinical, radiographic, histological, and molecular data were analyzed, with missing information excluded. Responders to ICI were defined as patients who did not meet iRANO criteria for progressive disease based on first radiographic response assessment (and confirmatory follow up imaging as needed for possible pseudo-progression). Survival outcomes [Progression-Free Survival (PFS) and Overall Survival (OS)] and potential predictive variables were analyzed using the Kaplan-Meier method and Cox-Regression Analyses. **Results:** 67 patients met eligibility criteria (mean age: 45.1 $\pm$ 15.0 years; 64.2% male; 94% white). 64 (95.5%) patients received Pembrolizumab, 2 (3%) Nivolumab, and 1(1.5%) combined Ipilimumab/Nivolumab, with a median treatment duration of 2.77 (1.39 – 19.4) months. All had prior alkylating chemotherapy. The OS (from diagnosis) for IDH wildtype (IDH-WT, n = 36), IDH mutant, 1p/19q non-co-deleted (IDH-MUT, n = 17) and IDH mutant, 1p/19q co-deleted (OLIGO, n = 14) gliomas were 3.1, 9.2, and 18.6 years, respectively. The median PFS from time of ICI was 2.23 (0.69 – 27.3) months. 24 (36.9%) patients were identified as Responders. PFS was not significantly different between patients with IDH-MUT and IDH-WT gliomas (2.30 vs 2.07 months, p = 0.593). However, patients with OLIGO gliomas had a significantly higher PFS compared to IDH-WT gliomas (5.16 vs 2.07 months, p = 0.021). The proportion of responders was greatest in OLIGO gliomas, however, did not reach statistical significance (IDH-WT, 31.4%; IDH-MUT, 29.4%; OLIGO, 61.5%, p = 0.120). Overall PFS was not impacted by patient age, sex, and extent of initial resection. When analyses were limited to Responders, the PFS for IDH-WT, IDH-MUT and OLIGO gliomas were 5.75, 7.01 and 10.8 months, respectively (p = 0.434). **Conclusions:** Patients with recurrent OLIGO gliomas may have a longer PFS with ICI therapy compared with recurrent IDH-WT and IDH-MUT gliomas. However, there is significant variability in ICI treatment efficacy between patients. Further molecular profiling is in progress to evaluate additional predictive biomarkers of response. Research Sponsor: None.

Factors influencing clinical trial enrollment in glioblastoma patients: A retrospective study at the University of Vermont Medical Center. First Author: Leena Ziane, Larner College of Medicine, Burlington, VT

Background: The standard of care for patients with glioblastoma (GBM) is a combination therapy of radiation and temozolomide. NCCN guidelines recommend clinical trials should be offered to glioblastoma patients when appropriate. This study aims to investigate the number of patients enrolled in clinical trials at the University of Vermont Medical Center (UVMMC) and/or referred to larger academic centers for trials. This study sought to identify and analyze characteristics of patients enrolled in trials at UVMMC and other outside academic centers. **Methods:** A retrospective review was undertaken of the electronic health records of ninety patients with GBM from 2021 to 2023 who were followed at UVMMC. Patient age, gender, and educational and employment status were collected. We assessed all comers who were offered a clinical trial, patients who proceeded to enroll in a clinical trial, and factors that influenced enrollment. We also assessed location where the trial was conducted (UVMMC vs Outside Center) and the trial interventions provided at the various centers. **Results:** We assessed 90 patients diagnosed with GBM at UVMMC from 2021-2023. 87% of all patients were offered the opportunity to enroll in a clinical trial. 17% of patients who were offered a trial successfully enrolled. Amongst enrolled patients, 62% completed their clinical trial at UVMMC while 38% were referred and treated at nearby academic centers in the New England Area including Mass General Hospital and Dana-Faber Cancer Institute (DFCI). Intrinsic barriers to enrollment included poor Karnofsky performance scale (KPS) scores, MGMT negative status, presence of leptomeningeal disease, and deep tumor locations precluding resection. Extrinsic factors included distance to academic centers, trial closure to accrual, and socioeconomic status. There was a correlation between socioeconomic status and trial enrollment. Of the thirty-eight patients identified with higher educational attainment (college or higher), 87% were offered a clinical trial and 18% eventually enrolled. Among the non-college educated group of thirty-six, 92% were offered a trial. However, only 14% enrolled. Further analysis on age, gender, and clinical trial intervention will be reported in future publications. **Conclusions:** Expanding access to clinical trials is critical to optimizing care for GBM patients. Our findings highlight access to academic centers is crucial to clinical trial enrollment. Further studies analyzing modifiable barriers to clinical trial accrual are needed. Research Sponsor: None.

Safety and tolerability of olaparib, temozolomide, and pembrolizumab in a phase 2 trial in patients with progressive glioblastoma. First Author: Luis Nicolas Gonzalez Castro, Dana-Farber Cancer Institute, Boston, MA

Background: Glioblastoma is the most aggressive primary brain tumor of adults, with patients obtaining limited survival benefit from standard-of-care therapies. We are conducting a phase 2, surgical window-of-opportunity study evaluating the combination of pembrolizumab (anti-PD-1 immunotherapy), olaparib (PARP inhibitor), and temozolomide (alkylating chemotherapy) in patients with progressive glioblastoma. Olaparib and temozolomide have the potential of synergistically enhancing the tumor's susceptibility to immune checkpoint immunotherapy through DNA damage and activation of immune pathways, potentially amplifying the efficacy of pembrolizumab. We provide a preliminary report on the safety and tolerability of the olaparib, temozolomide, and pembrolizumab combination. **Methods:** We enrolled patients with radiographically progressive glioblastoma, IDH-wildtype, MGMT promoter unmethylated, on 2mg daily or less of dexamethasone. Patients participating in the safety lead-in (Cohort 1) did not require surgically-resectable disease, while those enrolled in the surgical arm (Cohort 2) did. Treatment is provided in consecutive 42-day cycles with olaparib 200mg BID and temozolomide 50mg QD given on days 1-7 and 22-29, and pembrolizumab 400mg IV given on day 1. Adverse events (AEs), dose-limiting toxicities (DLTs), and high-frequency toxicities ($\geq$50% occurrence) were assessed, along with dose modifications or delays required to manage treatment-related toxicities. AEs were graded according to CTCAE v5.0 criteria, with pre-specified measures to address reversible toxicities through dose adjustments. **Results:** Six patients were enrolled in the safety lead-in (Cohort 1), which followed a 3+3 design. Grade 1–2 leukopenia, lymphopenia, and neutropenia were observed in 3 patients and resolved without intervention. Grade 4 neutropenia was observed in two patients (starting in cycle 2 for one patient, and on cycle 5 for the other). This resolved with dose delays, reduction in temozolomide dose or discontinuation of temozolomide (1 patient). In Cohort 2, which is ongoing (25 patients currently enrolled), toxicity profiles remain consistent with those observed in Cohort 1 patients. Grade 4 neutropenia has been observed in 1 (6%) of the enrolled patients, improving with dose delays and temozolomide dose reduction. **Conclusions:** The combination of olaparib, temozolomide, and pembrolizumab demonstrates a tolerable safety profile in patients with progressive glioblastoma. Observed hematologic toxicities are reversible with appropriate management, supporting the ongoing evaluation of this regimen to assess its efficacy and therapeutic potential. Clinical trial information: NCT05463848. Research Sponsor: Merck & Co.

Efficacy and safety of bevacizumab in combination with radiotherapy and temozolomide in patients with glioblastoma: A meta-analysis and meta-regression of randomized controlled trials. First Author: Ibrahim Khalil, Dhaka Medical College & Hospital, Dhaka, Bangladesh

Background: Glioblastoma (GBM), the most common primary brain tumor in adults, has a poor prognosis despite standard treatment. This meta-analysis evaluates the efficacy and safety of Bevacizumab, a VEGF inhibitor, when combined with radiotherapy and Temozolomide in terms of progression-free survival (PFS), overall survival (OS), and treatment-related adverse events. **Methods:** A systematic search of PubMed, Cochrane Library, Embase, and ClinicalTrials.gov identified randomized controlled trials (RCTs) evaluating Bevacizumab with radiotherapy and Temozolomide. Ten RCTs involving 4,425 patients (2,249 in the Bevacizumab arm and 2,176 in the control arm) met the inclusion criteria. A random-effects model calculated mean differences (MD) for continuous outcomes and risk ratios (RR) for dichotomous outcomes with 95% confidence intervals (CI). **Results:** Bevacizumab significantly improved PFS by a mean difference of 2.39 months (95% CI: 1.34 to 3.44; P = 0.0005), but no significant benefit was observed in OS (MD: 0.46 months, 95% CI: -0.53 to 1.45; P = 0.318). The therapy increased the risk of vascular adverse events (RR: 1.52, 95% CI: 1.10 to 2.11; P = 0.023). While trends towards increased hematologic adverse events (RR: 1.24, 95% CI: 0.95 to 1.60; P = 0.093) and hypertensive events (RR: 2.17, 95% CI: 0.91 to 5.16; P = 0.066) were observed, they did not reach statistical significance. Other adverse events, including serious adverse events (RR: 1.21, 95% CI: 0.84 to 1.76; P = 0.221), grade 3-4 thrombocytopenia (RR: 1.05, 95% CI: 0.44 to 2.52; P = 0.858), visceral perforation (RR: 1.92, 95% CI: 0.54 to 6.90; P = 0.202), and thromboembolic incidents (RR: 1.32, 95% CI: 0.88 to 2.00; P = 0.120), showed no significant increase. Meta-regression analysis indicated that study-level covariates, including patient age, sex distribution, and histologic differences did not significantly influence the primary outcomes. However, MGMT methylation status demonstrated borderline significance (P $<$ 0.1), suggesting potential prognostic relevance. **Conclusions:** Bevacizumab modestly improves PFS but not OS, with an increased risk of vascular toxicities. Personalized treatment strategies and further research are essential to optimize its role in glioblastoma management. Research Sponsor: None.

Adverse event outcomes associated with bevacizumab in glioblastoma patients.

Adverse Event Outcomes	RR	95%CI	P value
Any Adverse events	1.18	[0.64,2.16]	0.364
Hematologic adverse events	1.24	[0.95,1.60]	0.093
Any serious adverse events	1.21	[0.84,1.76]	0.221
Any vascular adverse events	1.52	[1.10,2.11]	0.023
Any grade 3-4 thrombocytopenia	1.05	[0.44,2.52]	0.858
Visceral perforation	1.92	[0.54,6.90]	0.202
Any arterial or venous thromboembolic incidents	1.32	[0.88,2.00]	0.120
Any hypertensive events	2.17	[0.91,5.16]	0.066

2058 **Poster Session**

Assessment of age in the clinical risk stratification of patients with IDH-mutant gliomas. First Author: Michal Nisnboym Ziv, Duke University Medical Center, Durham, NC

Background: Prognosis for mutant isocitrate dehydrogenase (mIDH) gliomas is influenced by tumor type, size, neurologic deficits, and age. Traditionally, patients over 45 are considered high-risk, prompting consideration of early chemoradiation. Recent promising results with the mIDH inhibitor vorasidenib challenge traditional age-based risk stratification, sparking debate over its role in treatment decisions. We evaluated survival relative to age and molecular data obtained from next-generation sequencing (NGS). **Methods:** Tumor specimens from 598 mIDH gliomas were analyzed using NGS and WTS at Caris Life Sciences (Phoenix, AZ). Samples were stratified by age at diagnosis into four groups: 12-26y, 27-40y, 41-60y, and $>$ 60y. Real-world overall survival (calculated from initial diagnosis to last contact) was obtained from insurance claims data and analyzed using Kaplan-Meier and Cox proportional hazards models. Covariates in the multivariate regression analysis included radiation treatment, temozolomide treatment, and mutation status of different biomarkers. **Results:** In mIDH astrocytoma group, age distribution was 12-26y, n = 74 (12.4%); 27-40y, n = 271 (45.3%); 41-60y, n = 205 (34.3%); and $>$ 60y, n = 48 (8.0%). In mIDH oligodendroglioma group, age distribution was 12-26y, n = 18 (5.5%); 27-40y, n = 76 (23.2%); 41-60y, n = 137 (41.8%); and $>$ 60y, n = 57 (17.4%). For each subtype, comparisons in survival were made between patients 27-40y vs. 41-60y given larger sample size, and patients with temozolomide treatment before biopsy were excluded (about 10%). Univariate analysis showed that 27-40y patients had shorter survival in astrocytoma (HR = 1.63, 95% CI: 1.07 – 2.50, p = 0.022). However, after adjusting for confounding factors in multivariate analysis, age was not associated with survival. In contrast, TP53 (HR = 4.0, 95% CI: 1.43-11.24, p = 0.008 – mutation rate = 95.4%) and TERT-promoter (HR = 10.36, 95% CI: 4.05-26.45, p $<$ 0.0001 – mutation rate = 9.0%) mutations were independently associated with poorer survival in astrocytoma patients. Univariate analysis showed that age was not associated with survival in oligodendroglioma (HR = 1.07, 95% CI: 0.79-3.65, p = 0.168). KRAS mutations were independently associated with poorer survival in oligodendroglioma patients (HR = 4.36, 95% CI: 1.12-16.92, p = 0.033 - mutation rate = 3%). **Conclusions:** In this enriched dataset of mIDH low grade glioma patients, which included NGS, age did not contribute to survival differences when comparing patients between 27-40 years with those aged 41-60 years. Rather, selected genetic alterations such as KRAS for oligodendroglioma and TP53 and TERT mutations for astrocytoma were associated with poorer survival. The results suggest that NGS, rather than age, may drive prognosis for mIDH glioma patients. Research Sponsor: None.

The tumoral molecular landscape of long-term survivors with isocitrate dehydrogenase wildtype glioblastoma: Lessons from ETERNITY (EORTC 1419). First Author: Michael Weller, Department of Neurology, University Hospital Zurich, and Brain Tumor Centre, University Hospital and University of Zurich, University Hospital Zurich, Zurich, Switzerland

Background: Predictors of long-term survival in patients with isocitrate dehydrogenase (IDH)-wildtype glioblastoma remain incompletely understood. ETERNITY (EORTC 1419) is the largest registry study of glioblastoma patients surviving for 5 years or more worldwide. **Methods:** Here we characterized the DNA methylation and mutational landscapes of 142 tumors from ETERNITY patients and compared the findings with different reference cohorts. **Results:** The majority of tumors of the ETERNITY cohort showed molecular profiles corresponding to established methylation subclasses of IDH-wildtype glioblastoma. ETERNITY tumors were enriched for the mesenchymal subclass, depleted of the receptor tyrosine kinase 1 subclass, and showed a high frequency of *MGMT* promoter methylation. While large chromosomal alterations were remarkably similar in all cohorts, circumscribed homozygous deletions on chromosome 10q including the *MGMT* gene were enriched in ETERNITY tumors. Gene panel sequencing showed similar types and frequencies of gene alterations as in the reference cohorts with a trend towards more frequent *RB1* mutations. Deconvolution analyses of global DNA methylation data revealed fewer monocytes in the MES methylation class in ETERNITY compared with the reference cohort. ETERNITY tumors from patients without documented relapse showed no specific molecular profile. Small subgroups of tumors corresponded to rare incompletely defined tumor entities. **Conclusions:** The present study illustrates the profound association of *MGMT* gene alterations with outcome, but also suggests as yet unidentified clinical or molecular pathways and potential host-dependent features in long-term survival with glioblastoma. Clinical trial information: NCT03770468. Research Sponsor: Brain Tumor Funders' Collaborative Consortium.

Efficacy and safety of depatuxizumab mafodotin (ABT-414) in EGFR-amplified glioblastoma: A systematic review and Bayesian network meta-analysis. First Author: Sunjida Amin Promi, Chittagong Medical College Hospital, Chittagong, Bangladesh

Background: Glioblastoma (GBM) is a highly aggressive brain tumor with a poor prognosis, typically resulting in a median survival of 12–15 months. Epidermal growth factor receptor (EGFR) alterations, present in half of GBM cases, are key therapeutic targets. Depatuxizumab mafodotin (Depatux-M, ABT-414), an EGFR-targeting antibody-drug conjugate, represents a novel therapeutic option. This Bayesian network meta-analysis assessed the efficacy and safety of Depatux-M in EGFR-amplified GBM. **Methods:** Eight randomized controlled trials (RCTs) involving 1,183 patients were analyzed. Trials evaluating Depatux-M as monotherapy or combined with temozolomide (TMZ) and/or radiotherapy (RT) were included. Outcomes included overall survival (OS), progression-free survival (PFS), and safety (grade 3/4 adverse events and keratitis). Bayesian models estimated mean differences (MDs) and relative risks (RRs) with 95% credible intervals (CrI), while SUCRA values ranked treatments. **Results:** Depatux-M plus TMZ showed modest OS improvement over TMZ alone (MD: 0.91 months; 95% CrI: -11.83 to 13.86; SUCRA: 62.09%). Depatux-M monotherapy showed minimal OS benefit (MD: 0.07 months; 95% CrI: -12.69 to 12.95; SUCRA: 51.2%), and the combination of Depatux-M, TMZ, and RT had the lowest OS benefit (MD: -2.17 months; 95% CrI: -19.83 to 15.74; SUCRA: 35.48%). For PFS, Depatux-M monotherapy performed best (MD: 1.46 months; 95% CrI: -4.92 to 7.78; SUCRA: 81.00%), while Depatux-M plus TMZ (MD: -0.45 months; 95% CrI: -6.85 to 5.89; SUCRA: 40.03%) and Depatux-M, TMZ, and RT (MD: -1.54 months; 95% CrI: -10.34 to 7.24; SUCRA: 28.32%) were less effective. Depatux-M monotherapy had a lower RR for grade 3/4 adverse events (RR: 1.38; 95% CrI: 0.23 to 8.07) and keratitis (RR: 2.62; 95% CrI: 0.43 to 15.63) compared to combination regimens, with the highest keratitis risks observed in Depatux-M, TMZ, and RT. **Conclusions:** Depatuxizumab mafodotin offers limited survival benefits in EGFR-amplified GBM, with monotherapy showing the most favorable PFS. However, significant safety concerns, particularly keratitis, warrant further research to optimize its therapeutic potential and identify more tolerable regimens. Research Sponsor: None.

Efficacy and safety outcomes of depatuxizumab mafodotin in EGFR-amplified glioblastoma.

Regimen	Overall Survival (OS)	Progression-Free Survival (PFS)	Grade 3/4 Adverse Events (RR)	Keratitis (RR)
Depatux-M + TMZ	0.91 (-11.83 to 13.86); SUCRA 62.09	-0.45 (-6.85 to 5.89); SUCRA 40.03	1.54 (0.20 to 13.53); SUCRA 41.75	4.40 (0.51 to 31.10); SUCRA 33.07
Depatux-M	0.07 (-12.69 to 12.95); SUCRA 51.20	1.46 (-4.92 to 7.78); SUCRA 81.00	1.38 (0.23 to 8.07); SUCRA 49.06	2.62 (0.43 to 15.63); SUCRA 62.34
Depatux-M + TMZ + RT	-2.17 (-19.83 to 15.74); SUCRA 35.48	-1.54 (-10.34 to 7.24); SUCRA 28.32	0.98 (0.09 to 9.65); SUCRA 68.37	6.63 (0.62 to 66.40); SUCRA 12.73

Relationship between aperiodic dynamics and transcriptomic alterations and a neural signature of glioma-induced excitation-inhibition dysregulation. First Author: Youssef Sibih, University of California, San Francisco, San Francisco, CA

Background: Diffuse gliomas disrupt neuronal dynamics, leading to excitation-inhibition (E/I) imbalance and associated functional impairments. The aperiodic component of the power spectral density (1/f slope) has emerged as a proxy for estimating E/I balance, offering a novel framework for understanding glioma-induced neural dysregulation. This study is the first to validate the relationship between 1/f slope and E/I dysregulation in glioma by integrating electrophysiological, genomic, and behavioral data. **Methods:** Resting-state intraoperative subdural electrocorticography (ECoG) data were recorded from 13 glioma patients. Power spectral analysis at a frequency of 70–150Hz (high-gamma) computed 1/f slopes, and electrodes were classified as glioma-infiltrated or normal-appearing based on preoperative MRI T2-FLAIR. Linear mixed-effects models assessed E/I balance across tissue and glioma subtypes. Single-nucleus RNA sequencing (snRNA-seq) was performed on 14 spatially annotated glioma tissue samples from regions classified as inhibitory or excitatory by 1/f slope. Behavioral analysis of language tasks examined functional correlates of E/I imbalance. **Results:** The cohort included 23.0% WHO grade 2 IDH-mutant oligodendrogliomas, 38.5% WHO grade 2-3 IDH-mutant astrocytoma, and 38.5% glioblastoma (GBM). Glioma-infiltrated electrodes (n=142) exhibited significantly lower 1/f slopes than normal-appearing electrodes (n=518;$p < 0.0001$), reflecting an excitation-dominant state. Subtype analysis revealed hierarchical E/I imbalance, with GBM showing the steepest reductions in 1/f slope compared to astrocytoma and oligodendroglioma (glioma-infiltrated: $p<0.0001$; normal-appearing: GBM vs. oligodendroglioma, p=0.012; GBM vs. astrocytoma, p=0.019). SnRNA-seq revealed elevated excitatory and reduced inhibitory signaling gene expression in glutamatergic and GABAergic neuronal populations across glioma-infiltrated (n=12; n=4 per subtype) and normal cortex (n=2) samples. Excitatory module scores were significantly higher in excitatory 1/f samples compared to inhibitory 1/f samples, validating the 1/f slope as a genomic correlate of E/I imbalance in human cortical tissue. Behavioral analysis of language tasks demonstrated error-related reductions in 1/f slope ($e > i$), emphasizing the functional impact of glioma-induced dysregulation. **Conclusions:** Diffuse gliomas are associated with a profound shift toward excitation dominance in both glioma-infiltrated and normal-appearing cortex. For the first time, the 1/f slope is validated as a robust measure of E/I imbalance through electrophysiological, genomic, and behavioral analyses. These findings position the 1/f slope as a physiologically relevant biomarker of glioma-induced neural dysregulation, offering significant potential to inform therapeutic strategies. 2063 Poster Session

Comparing ERK signaling and tumor microenvironment in BRAF-altered gliomas. First Author: Lucy Chen, Johns Hopkins School of Medicine, Baltimore, MD

Background: Many patients with BRAF-altered glioma (V600E mutations, fusions) respond to BRAF inhibitors (BRAFi), but some—particularly those with high-grade gliomas (HGG)—progress on treatment. Here, we aim to assess MAPK/ERK activation associated with various BRAF alterations in a large dataset of adult and pediatric patients with low-grade (LGG) and HGG using previously validated transcriptomic signatures. **Methods:** Samples underwent next-generation sequencing and whole transcriptome sequencing at Caris Life Sciences (Phoenix, AZ). The MAPK Pathway Activity Score (MPAS, Wagle 2018, NPJPO) and two MEK inhibitor sensitivity signatures (Dry 2019, Cancer Res & Pratilas 2009, PNAS) were calculated from RNA-seq data. Tumor immune microenvironment was assessed using immune deconvolution (quanTIseq) and the Tumor Inflammation Signature (TIS). Results were compared for HGG in two age groups (AYA: 0-39y; adult: $>$ 39y) in V600E mutation, fusions, or controls (BRAF-WT/IDH-WT/NF1-WT). For LGG 0-39y, V600E were compared to fusion, but not to BRAF-WT due to near-universal enrichment of MAPK alterations in LGG. There were insufficient LGG $>$ 39y for analysis. Mann-Whiney U tests were used at $\alpha = 0.05$. **Results:** In adult HGG (V600E: n = 35, fusions: n = 11, WT: n = 3235), both V600E and fusions showed significantly higher MAPK/ERK signatures than WT (all $p < 0.01$), with no significant difference between V600E and fusions. In AYA HGG (V600E: n = 32, fusions: n = 11, WT: n = 235), all three MAPK/ERK signatures were significantly higher in V600E compared to WT (all $p < 0.01$), while fusions fell in between BRAF V600E and WT ($p > 0.05$). In both AYA and adult HGG, B cells were higher in WT compared to V600E, while among infiltrated cells only M1 and M2 macrophages were elevated in fusions compared to WT ($p < 0.05$). Comparison of MAPK/ERK signatures in LGG (V600E: n = 28, fusions: n = 54) revealed no significant difference between V600E and fusions. TIS did not differ among BRAF alterations in any groups. Pathway analysis revealed RAS signaling and inflammation were enriched in BRAF V600E compared to WT in both HGG and LGG (NES $>$ 2; FDR $<$ 0.005), regardless of age. When comparing all V600E HGG patients (0-90y) previously treated with BRAFi (n = 21) to those who were not (n = 46), no difference in MAPK/ERK signatures were seen. Pathway analysis revealed samples with prior BRAFi had upregulated complement activation, B-cell activation, and opsonization (NES $>$ 3.5; FDR $<$ 10e-5), while treatment-naïve samples had higher BRAF/MAPK signaling (NES $>$ 2, FDR $<$ 0.03). **Conclusions:** These data confirm higher MAPK/ERK dependence signatures and RAS signaling in BRAF-altered HGG (V600E, fusion) compared to BRAF-WT controls. Differences in immune cell infiltration were observed between BRAF alteration classes. Changes in humoral immunity may be correlated with acquired resistance to BRAFi, in line with previous reports of increased B-cell infiltration in BRAFi-resistant melanomas. Research Sponsor: None.

2064 Poster Session

Phase II propensity-matched controlled trial evaluating metformin as an adjunct to neo-adjuvant, concomitant, and adjuvant temozolomide and hypofractionated-accelerated radiotherapy (M-HART) in glioblastoma patients (NCT02780024). First Author: George Shenouda, McGill University Health Centre, Montréal, QC, Canada

Background: Phase II, propensity-matched trial, to assess feasibility and toxicity of adding Metformin (MTF) to neo-adjuvant, concomitant and adjuvant Temozolomide (TMZ) and hypofractionated accelerated radiotherapy (M-HART), for patients with Glioblastoma (GBM). We compared median survival time (MST), and progression-free-survival (PFS) of M-HART versus a contemporaneous cohort of propensity-score matched controls (PSMC) who received standard of care (SOC). **Methods:** Eligible patients were $\geq$ 18 years with newly diagnosed GBM, ECOG score $\leq$ 2, with known MGMT status, gross total or partial resection, and residual surgical cavity $>$ 15 mm from brainstem, or optic apparatus. Four weeks from surgery, M-HART patients started 2 weeks of neo-adjuvant MTF/TMZ followed by concomitant MTF/TMZ + HART 60 Gy/20 daily fractions, and 6 cycles of adjuvant MTF/TMZ. The PSMC patients received Stupp's regimen. We used a nearest neighbor matching with a caliper width of 0.2 SD and compared patients' characteristics using chi-square test (Table). Propensity scores were estimated using logistic regression model, with probability of M-HART treatment as dependent variable. **Results:** From April 2015 to November 2020, 50 patients participated in the M-HART trial and matched with 50 PSMC cohort treated during the same period, with a median follow up of 24.1 (M-HART) vs 17.6 months PSMC, respectively. M-HART patients had significantly longer MST of 24.1 (95% CI, 15.2- 30.3) vs. 17.7 months for PSMC patients (95% CI, 12-20) (HR, 0.62 [95% CI, 0.40-0.93]; P = 0.02), and significantly longer PFS of 13.7 (95% CI, 11.7 to 18.8) vs. 11.0 months (95% CI, 9-12) (HR, 0.63 [95% CI, 0.42-0.95]; P = 0.02). M-HART treatment was an independent predictor of survival. M-HART patients with methylated-MGMT and gross total resection had significant longer MST of 41.9 vs. 17.8 months for PSMC (95% CI, 15.1-20.5 months) (HR 0.21 [95% CI, 0.09-0.49]; P = 0.001). **Conclusions:** M-HART protocol is novel, feasible, and well-tolerated approach with significantly longer MST and PFS as compared to propensity-matched SOC controls. These results add to growing evidence for the use of Metformin as an adjunct to HART and TMZ especially in M-MGMT GBM. Clinical trial information: NCT02780024. Research Sponsor: No funding was received.

Association of MGMT status with survival in low and high-grade IDH-mutant astrocytomas. First Author: Katherine E. Schwetye, Washington University, St. Louis, MO

Background: The role of MGMT promoter methylation status on survival for IDH-mutant astrocytomas is less known than for glioblastoma, IDH-wildtype (GBM). Further, different laboratories utilize a variety of techniques to measure methylation of the MGMT gene promoter region, including pyrosequencing, methylation-specific polymerase chain reaction (PCR), and direct Sanger sequencing; these techniques are limited by low quantitative accuracy, short read length, and low sample throughput. In the current study, we used a large database of next-generation sequencing (NGS) and whole-transcriptome sequencing (WTS) performed in a single laboratory to determine the role of MGMT status on survival in IDH-mutant astrocytomas (CNS WHO grades 2-3 and 4), as well as in GBM. **Methods:** 10,181 glioma samples were analyzed by NGS (592, NextSeq, or WES, NovaSeq) and WTS (NovaSeq) at Caris Life Sciences (Phoenix, AZ), including determination of methylation status of the MGMT promoter region by pyrosequencing. Real-world overall survival was obtained from insurance claims data and calculated from initial diagnosis to last contact, while TMZ-OS was calculated from first dose of temozolomide to last of treatment. Hazard ratios (HRs) were analyzed using Cox proportional hazards model and p values (log-rank test). Multivariate regression analysis was performed on age, gender, radiation treatment, temozolomide treatment, and mutations in different biomarkers. Fisher's exact tests was used at a significance level of 0.05. **Results:** 693 IDH-mutant astrocytomas CNS WHO grades 2 or 3 ("g2/3"), 251 IDH-mutant astrocytoma CNS WHO grade 4 ("g4"), and 4469 glioblastoma ("GBM") met inclusion criteria. Univariate and multivariate survival analysis showed that MGMT promoter methylation (mMGMT vs. unmethylated, uMGMT) was associated with improved OS only in GBM (HR = 0.62, 95% CI: 0.57 – 0.67, $p < 0.0001$), but not in astrocytoma-g2/3 and g4. Similarly, TMZ-OS was only significantly longer in mMGMT vs. uMGMT in GBM (HR = 0.53, 95% CI: 0.48 – 0.58, $p < 0.0001$). In astrocytoma-g2/3, ATRX mutation was more prevalent in mMGMT than uMGMT (73.9% vs. 62.6%, $p < 0.05$), and SETD2 was more prevalent in uMGMT than mMGMT (4% vs. 1.1%, $p < 0.05$). Tumor mutational burden (TMB)-high was more prevalent in mMGMT than uMGMT in astrocytoma-g4 (14.8% vs. 2.7%, $p < 0.05$) and in GBM (5.4% vs. 1.9%, $p < 0.0001$). In GBM, many genes had different mutational rates between mMGMT and uMGMT groups, including MSH6 (2% vs. 0.7%, $p < 0.001$), ATRX (3.1% vs. 1.6%, $p < 0.01$), and CDKN2A (4.3% vs. 2.5%, $p < 0.01$). **Conclusions:** mMGMT was not associated with better survival in IDH-mutant astrocytoma-g2/3 or g4with respect to OS or TMZ-OS, whereas mMGMT conferred improved survival in GBM. These results, derived from a large database using same platform (next-generation sequencing at a single laboratory), support similar findings from recent, smaller cohort studies. Research Sponsor: None.

2066 Poster Session

Prognostic impact of DDR mutations (mt) in IDH mutant high-grade gliomas (HGG). First Author: John L. Villano, University of Kentucky Markey Cancer Center, Lexington, KY

Background: The oncometabolite 2-hydroxyglutarate (2HG) produced by *IDH1/2* mt in HGG has profound effects on numerous pathways including DNA damage repair (DDR). We investigated the prognostic effect of DDR mt in *IDH* mutant vs. wild type (wt) tumors in a large cohort using a real-world database. **Methods:** A total of 4894 HGG tumors tested at Caris Life Sciences (Phoenix, AZ) with NextGen sequencing of DNA (592-gene panel or whole exome sequencing) were included in the study. DDR alteration was defined as a pathogenic mutation in one of $>$ 20 DDR genes. Patient survival was obtained by insurance claims data and calculated from the initiation of tissue collection (rwOS). Cox proportional hazards model was used to calculate hazard ratios (HR) and log-rank tests to calculate p values, which were adjusted for multiple comparisons. Significance was set at $p<0.05$. **Results:** In the 1121 HGG carrying either *IDH1* or 2 mutations, 100 carried a DDR mutation (8.9%) . When comparing DDR mutant (mt) vs. wild type (wt), no difference was seen in patient age (median 39 vs. 38 yrs; p = 0.8); gender (female 45% vs. 42%, p = 0.9), race or ethnicity ($p > 0.1$). The most frequent mutations were seen in *MSH6* (24% of the DDR mt), *ATM* (18%), *MLH1* (15%), *MSH2* (13%), *MSH3* (10%) and *BRCA2* (10%). When comparing the rwOS of DDR mt vs. wt, a significantly shorter survival was seen (24m vs. 51m, HR = 1.87, 95% CI [1.41-2.48], $p < 0.001$); the effect persisted in the subset of tumors collected prior to temozolomide treatment (26m vs. 64m, HR = 1.92 [1.35-2.74], $p < 0.001$). In contrast, in IDH wt tumors, patients with (N = 223) or without DDR mutation (N = 3550) showed similar survival (17.5m vs. 20.6m, p = 0.1). In the *IDH* mutant cohort, DDR mt was associated with an increased tumor mutational burden (TMB) compared to DDR wt tumors (median = 6 vs. 4 mutations/mb, by Wilcoxon). Multivariate analysis within the IDH mutant tumors indicated that both TMB and DDR status were independently associated with poorer rwOS, with TMB showing an adjusted HR of 1.01 per unit increase (p = 0.005) and DDR status with an adjusted HR of 1.59 (p = 0.028). **Conclusions:** In a large real-world database, we demonstrate IDH mt HGG with a DDR mutation exhibit significantly poorer survival compared to DDR wt. This is not seen in IDH wt, where survivals of the two groups are similar. These results stand in sharp contrast to reported prognostic effect of DDR mutation in many other solid tumors. The data suggest that DDR mutations in the context of 2HG accumulation in IDH mt HGG may be an indicator of profound genomic instability that confers severe negative impact on patient survival. Clinicians managing high-grade gliomas should consider the presence of DDR mutations in IDH mutant patients as a poor prognostic category in this overall favorable prognostic group and consider therapeutic approaches accordingly. Research Sponsor: None.

Prognostic value of inflammatory markers in glioblastoma: A meta-analysis of NLR and PLR stratified by cutoff values. First Author: Abril Carrillo, UT Southwestern Medical Center, Dallas, TX

Background: Glioblastoma (GBM) is the most aggressive primary brain tumor in adults, with an unfavorable prognosis. Identifying prognostic markers is crucial to stratify patients and tailor therapeutic approaches. The neutrophil-to-lymphocyte ratio (NLR) and platelet-to-lymphocyte ratio (PLR) are inflammatory markers that have gained attention as outcome predictors in various cancers. While numerous studies have demonstrated associations between elevated NLR, PLR, and poor GBM outcomes, consensus on standardized cutoff values remains elusive, limiting their clinical application. In this meta-analysis, we stratified the data based on preoperative NLR and PLR cutoff values, aiming to identify the most accurate cutoff thresholds to predict overall survival (OS) outcomes. **Methods:** We performed a systematic search on PubMed, Medline, OVID, Embase, and Cochrane in November 2024 to identify cohort studies reporting hazard ratios (HR) for OS associated with preoperative NLR and/or PLR in patients with histopathologically confirmed GBM. Two reviewers screened articles; discrepancies were resolved by consensus. Data analysis was conducted using a random-effects model. Pooled HRs with 95% confidence intervals (CI) were calculated and subgroup analysis were performed. **Results:** From 227 studies initially identified, 22 studies met our inclusion criteria, encompassing a total population of 3,423 patients with GBM. In our general cohort, when compared to lower PLR, a higher PLR yielded a pooled HR of 1.30 (95% CI: 1.12-1.50, $p < 0.001$). Specific cutoff subgroup analysis revealed that, the $<$ 135 cutoff group had a HR of 1.09 (95% CI: 0.62-1.93, p = 0.60), in the $>$ 135 cutoff group, the HR was 1.42 (95% CI: 1.19-1.70, p = 0.0001). Regarding the NLR analysis, cutoff subgroup analysis showed that for NLR with a cutoff of $<$ 3, the HR was 1.39 (95% CI: 0.96–2.02, p = 0.08), for NLR with a cutoff between 3 and 4.9, the HR was 1.56 (95% CI: 0.98–2.51, p = 0.06). For studies with a NLR cutoff of 4, the HR was 1.40 (95% CI: 1.23–1.58, p = 0.01). For studies with a NLR cutoff $>$ 4.9, the HR was 1.85 (95% CI: 1.37–2.50, $p < 0.0001$). The overall pooled HR for elevated NLR regardless of cutoff value was 1.40 (95% CI: 1.23–1.58, $p < 0.00001$). **Conclusions:** Elevated preoperative NLR and PLR are significant prognostic markers for worse OS in GBM patients. Stratifying data by cutoff values revealed that PLR $>$ 135 and NLR $>$ 4.9 were more consistently correlated with poor survival outcomes. These findings suggest that higher cutoff values for these markers may better predict OS, particularly for NLR where values $>$ 4.9 demonstrated a stronger association than the commonly used cutoff of 4. The results highlight the potential utility of NLR and PLR as accessible, cost-effective prognostic tools. Future prospective studies are warranted to validate these findings, refine optimal cutoff thresholds, and explore their applicability. Research Sponsor: None.

2068 Poster Session

A phase 1, first-in-human study of regorafenib plus temozolomide with or without radiotherapy in patients with newly diagnosed MGMT methylated, IDHwt glioblastoma: The REGOMA-2 trial. First Author: Marta Padovan, University of Padua, Padua, Italy

Background: Regorafenib (REG) is an oral multikinase inhibitor and in vivo studies demonstrated a synergistic antitumor effect when combined with radiotherapy (RT) and temozolomide (TMZ) against glioblastoma (GBM). We conducted a phase 1 study to evaluate the safety, dose limiting toxicity (DLT), maximum tolerated dose (MTD) of REG, pharmacokinetics (PK), preliminary activity of this combination. **Methods:** This phase 1 multicenter academic study used a "3 + 3" design to evaluate REG doses of 80mg (Level 1), 120mg (Level 2), 160mg (Level 3) in 2 different cohorts of pts with histologic diagnosis of MGMT-methylated, IDHwt GBM (WHO 2021) and ECOG PS 0-1. In cohort A, pts who completed the concurrent chemoradiotherapy (CT-RT) regimen received REG in combination with standard maintenance TMZ; cohort B received REG concurrently with standard CT-RT and continued REG with maintenance TMZ. REG was administered according to the standard schedule of 3 weeks on/1 week off. The DLT evaluation period for cohort A was during the first two maintenance cycles and for cohort B during the concurrent CT-RT phase. During the DLT period, blood and clinical assessments were performed weekly. Toxicity was assessed by CTCAE v 5.0. RANO criteria were used for neuroradiologic assessment. Pharmacokinetics (PK) was also evaluated. **Results:** In cohort A, none of the 9 pts enrolled (median age 52ys) had a DLT at any dose; 1 pt in Level 2 had REG delayed and TMZ dose reduced due to grade (G) 2 thrombocytopenia. At Level 1 and 2, 1 G3 haematological toxicity, respectively. At Level 3, 1 pt had a G3 gastrointestinal toxicity. In cohort B, 12 pts were enrolled (median age 53ys); at Level 3, 2 of 6 pts reported a DLT (n=1 G3 hypertransaminasemia with a dose reduction of REG (51%) and TMZ (50%) and n=1 G4 thrombocytopenia at the last day of RT). One case of G3 hypertension and 1 case of G3 hypertransaminasemia were also reported. REG was reduced in another pt due to G2 pain (no DLT); at Level 2 there was 1 case of G3 hyperbilirubinemia. There were no G3-4 AEs at Level 1. PK analysis of REG alone or in combination with TMZ showed a significant reduction (P=0.038) in the AUC, with a geometric mean ratio (GMR) of 80% (CI_{90} 64 – 98%) when given together with TMZ. PK analysis of TMZ showed a slight but significant reduction in the Cmax and AUC (P = 0.003 and 0.015, respectively) when given with REG, with GMR of 72% (CI_{90} 57 – 91%) and 86% (CI_{90} 79 – 92%), respectively. These results suggest a weak PK interaction between the two drugs. **Conclusions:** The MTD of REG for cohort A was 160mg, for cohort B 120mg with a weak PK interaction between the two drugs. The MTD of 120mg can be considered the recommended dose of REG in combination with standard Stupp therapy for the phase 2 study. Preliminary activity analyses are ongoing. Clinical trial information: NCT06095375. Research Sponsor: None.

2069 Poster Session

Azeliragon, a RAGE inhibitor, in combination with temozolomide and radiotherapy in patients with newly diagnosed glioblastoma: Preliminary results of phase Ib/II CAN-201 NDG trial. First Author: Juan Manuel Sepulveda, Medical Oncology Service, Hospital Universitario 12 de Octubre, Madrid, Spain

Background: Azeliragon is an orally available inhibitor of the receptor for advanced glycation end-products (RAGE). RAGE pathway promotes cell proliferation and angiogenesis, contributing to glioblastoma (GBM) progression and resistance to temozolomide (TMZ) and radiation (RT). Azeliragon has extensive clinical safety data in patients (pts) with Alzheimer's disease. Our hypothesis was that azeliragon may enhance the efficacy of Stupp regimen in newly diagnosed GBM. **Methods:** CAN-201 NDG is an open-label, single arm, phase Ib/II trial in Spain. Newly diagnosed IDH wild-type pts with GBM, MGMT methylation locally available and with tumor resection were recruited. Pts received azeliragon in combination with standard radiotherapy and TMZ followed by maintenance with azeliragon. The trial consists of an initial dose finding phase in a 6 dose escalation strategy with a subsequent expansion phase (up to 14 additional pts) at the recommended phase 2 dose (RP2D). The dose levels were: 5 mg/day (L1), 10 mg/day (L2) and 20 mg/day (L3). The primary objective is to determine the RP2D, defined as the dose for which $<$ 33% pts experience a dose limiting toxicity (DLT) within 28 days from initiation of dosing. Main secondary endpoints include progression-free survival (PFS), overall survival (OS) and changes in corticosteroid requirements. **Results:** From Oct 2023 to Jul 2024, 20 pts were included, 6 in L1, 8 in L2 and 6 in L3. The median age was 52 years (range: 40-69). Most pts were male (65%), ECOG 0-1 (95%) and MGMT unmethylated (60%). No DLTs were observed. Serious adverse events, all considered unrelated to azeliragon, were reported in 4 pts (20%), being hemiplegia, pyrexia, infectious meningoencephalitis, epilepsy and neurological decompensation. Non-serious Grade 3-4 adverse events (AE), also considered unrelated, were G3 hematological AEs in 33.3% in L1 and 37.5% in L2. G1-2 azeliragon-related AEs were reported in 33.3%, 25% and 66.7% of pts in L1, L2 and L3, respectively. Azeliragon treatment was ended due to progression in 83.3% and 62.5% of pts in L1 and L2, respectively. All pts on L3 are still on treatment. With a median follow-up time of 8.4 months, pts in L1 showed a median PFS of 5.2 months (95% CI, 4.4-Not Reached [NR]) and 9.8 months (95% CI, 6.2-NR) in L2. No progression of disease was observed in L3 with a range of follow-up of 4.9-7.0 months. Median OS in L1 was 11.1 months (95% CI, 9.4-NR). Data was not mature enough to calculate OS in L2 and L3. **Conclusions:** Azeliragon in combination with standard RT and TMZ is safe, with no dose-limiting toxicities reported so far at the initial three dose levels. To further explore the safety and efficacy profile of azeliragon, we are now expanding the study to include two additional dose levels of 30 mg/day (L4) and 50 mg/day (L5). Enrollment is currently open for level L4. Clinical trial information: NCT05635734. Research Sponsor: CANTEX Pharmaceuticals, Inc.

From retrospective analysis to real-world impact: Mismatch repair deficiency detection in gliomas by tissue and liquid ctDNA NGS in glioma management. First Author: Suman Suryanarayana Karanth, FMRI, Gurugram, India

Background: Tissue biopsy remains the gold standard for Microsatellite Instability and MMR (mismatch repair) gene alteration assessment. The regulatory approval of immune checkpoint inhibitors is for mismatch repair-deficient cancers, regardless of tumor type. Surgical resection or biopsy is challenging when the glioma is located deep in the brain or brainstem. Circulating tumor DNA (ctDNA) next-generation sequencing (NGS) offers a non-invasive alternative, garnering attention in extracranial cancers, however not so in gliomas due to the lower concentrations of tumor-derived biomarkers. While Cerebrospinal fluid (CSF) provides superior sensitivity and specificity for gliomas, it is not a standard test in gliomas with its own technical issues. **Methods:** A retrospective analysis was conducted using databases to evaluate the prevalence of pathogenic inactivating alterations in MMR genes in glioma tissue samples. Data were queried from the MSK, Clin Cancer Res 2019 database for targeted sequencing on MSK-IMPACT and FMI panels, comprising 1004 tissue samples (837 with matched normal) from 923 glioma patients through the cBioPortal platform. Frequencies of MMR gene alterations were assessed. **Results:** A total of 850 patients (out of 923) were retrospectively analyzed for MMR gene alterations, with 40.3% (343) being female and 59.6% (507) male. Primary samples constituted 79.8% (679), and recurrent samples 20.2% (172). OncoKb level alterations were categorized as Level 1 (0.5%), Level 2B (16.6%), Level 3B (13.6%), Level 4 (32.8%), and none (36.4%). MMR gene alterations were found in 35 samples (4%), with MSH2 and MSH6 each detected in 2%, MLH1 in 1%, and PMS1, PMS2, and MSH3 in less than 1% of samples. In a specific case, ctDNA NGS was performed on a 9-year-old boy diagnosed with diffuse intrinsic pontine glioma as tissue biopsy was not feasible. Survivals are 9 to 11 months despite multimodality treatment. ctDNA NGS identified a truncating MSH6 alteration at 100% Variant Allele Frequency, suggesting biallelic inactivation of MSH6. Additionally, an IDH R132C activating mutation, a TP53 splice site SNV and high tumor mutational burden (bTMB) at 132.33 Mut/Mb were detected. Post radiation resulted in no change in tumor size. Injection pembrolizumab 3 weekly was initiated. Follow up MRI revealed further reduction in size and tumor has remained stable with ongoing therapy. **Conclusions:** Identifying MMR alterations potentially broadens the therapeutic options for glioma. The compelling case of the 9-year-old boy highlights the clinical utility of ctDNA NGS in identifying actionable MMR gene alterations, leading to successful immunotherapy with pembrolizumab and continued stable disease beyond 13 months. While few studies exist on utility of ctDNA in gliomas, it is time for bigger studies in both primary and recurrent gliomas where biopsy is not feasible. Research Sponsor: None.

Immunohistochemical and gene expression profiles as predictors of survival in recurrent high-grade glioma treated with intracranial nivolumab, ipilimumab, and autologous CD1c(BDCA-1)$^+$/CD141(BDCA-3)$^+$ myeloid dendritic cells (myDC). First Author: Cleo Bertels, Universitair Ziekenhuis Brussel (UZ Brussel), Brussels, Belgium

Background: Innovative treatments are needed for recurrent high-grade glioma (rHGG) patients (pts) as current salvage therapies fail to improve overall survival (OS). Immune checkpoint inhibitors lack efficacy in rHGG when administered IV. This single center, multicohort phase I trial (Glitipni, NCT03233152) investigated intracerebral (iCer) administration of ipilimumab (IPI) +/- nivolumab (NIVO) +/- myDC after maximal safe resection (MSR), followed by adjuvant intracavitary (iCav) IPI/NIVO through an Ommaya reservoir. **Methods:** Eligible pts (ECOG $\leq$ 2, $\leq$ 8mg/day methylprednisolone) with rHGG (WHO 2021 grade 3/4, IDH-1/2 wild type (wt) or mutant) after standard postoperative radiotherapy (RT) and temozolomide (TMZ) were included. Pts underwent MSR or stereotactic biopsy (if unresectable) $<$ 24h after receiving NIVO IV (10mg), followed by iCer injection of varying doses of IPI +/- NIVO +/- myDC and Ommaya catheter placement depending on the cohort (C). NIVO was administered IV (all cohorts) +/- iCav (C3-7) biweekly up to 12 cycles. Baseline tumor microenvironment characteristics were assessed by immunohistochemical (IHC) analysis and gene expression profiling (GEP). **Results:** Between 2016 and 2023, 110 pts (68% male, median age 57, 92% ECOG 0/1) were enrolled. At primary diagnosis, the majority (85%) were glioblastoma pts (WHO grade 4, IDH-wt), treated with the standard of care (MSR + RT + TMZ) (71%). All pts received 10mg NIVO IV preoperatively. Ninety percent of the pts who underwent the neurosurgical procedure started the postoperative treatment. Early discontinuation of study treatment occurred in 76% of pts, mainly due to tumor progression (86%). Treatment-related adverse events (TRAE) were mild (CTCAE grade 1/2), no grade 5 TRAE occurred. Most frequent TRAE were fatigue, headache and fever. At database lock (Jan 1st, '25), 9 pts remained progression-free. When including durable benefit from bevacizumab at first progression (13 pts), PFS and OS were significantly higher in C5/6 (+myDC) compared to other cohorts (-myDC) of our trial with resectable rHGG, and to a historical control group treated with VEGF(R)-inhibitors (descriptive $p < 0.05$ for each pairwise comparison). Absence of B7H3 on resected tumor tissues as demonstrated by IHC (C4, 5, 7) showed longer median OS, which was consistent with GEP. PD-L1 expression and density of CD8, Granzyme B or FOXP3 positive cells/mm^2 did not correlate with survival. A proliferative gene signature on GEP was significantly correlated with shorter PFS and OS. **Conclusions:** Intracranial administration of IPI/NIVO co-administered with myDC was feasible and safe, resulting in encouraging survival in pts with resectable rHGG. Baseline B7H3 levels and a proliferative gene signature correlated with survival. Clinical trial information: NCT03233152. Research Sponsor: None.

2072 **Poster Session**

Development and validation of a droplet digital PCR (ddPCR) assay to detect MGMT promoter methylation in FFPE tumors of glioblastoma (GBM) patients. First Author: Mahrukh M Syeda, NYU Langone Medical Center, New York, NY

Background: Methylation of the MGMT gene promoter (MGMTp) is a critical biomarker to inform GBM prognosis and guide treatment decisions, including clinical trial eligibility. Rapid reporting of MGMTp methylation can help stratify patients early and facilitate clinical trial referral during the crucial post-operative period where treatment options are being considered by patients and physicians alike. **Methods:** We developed a probe-based ddPCR method to detect and quantify MGMTp methylation. Assay specificity was assessed using bisulfite-converted, unmethylated DNA. Assay linearity and Limit of Detection (LoD) were determined using MGMTp methylated cell line DNA samples of decreasing fractional abundances (35%, 5%, and 0.5%) and decreasing DNA inputs (30ng, 10ng, 3ng,1ng and 0.5ng). The limit of Blank (LoB) was calculated using 16 replicates of unmethylated bisulfite-converted PBMC DNA, and DNA from tonsil FFPE samples (n = 9). Reproducibility studies were conducted on two different days with two different operators. Accuracy and concordance were assessed using an in-house MGMTp methylation pyrosequencing assay as an orthogonal method to analyze11 melanoma and one glioblastoma cell line. Preliminary clinical validation was conducted via analysis of FFPE tumor DNA from 34 GBM patients with clinical MGMTp methylation pyrosequencing results. **Results:** The MGMTp methylation ddPCR assay demonstrated 100% specificity to detect promoter methylation. The method linearly quantified both total DNA and methylated DNA along a range of input DNAs with conserved fractional abundances. The LoB was 0.036% and 0.034% using PBMC and tonsil FFPE DNA, respectively. The LoD was 0.075%. The bisulfite conversion and assay were highly reproducible, with a coefficient of variation $<$ 20%. Among the 12 cell lines analyzed by both pyrosequencing and ddPCR the concordance was 100%. Ten of 11 GBM tumor samples identified as MGMTp methylated by the clinical pyrosequencing assay were also identified as methylated by the ddPCR assay. Five of 23 clinically unmethylated tumors were positive in the ddPCR assay with generally very low fractional abundances (0.08%, 0.12% 0.3%, 0.97% and 10.11%). **Conclusions:** We report preliminary validation of a highly sensitive and specific ddPCR assay to detect MGMTp methylation. Given the minimal sample requirements and rapid turnaround time for ddPCR assays, this test could eventually be utilized in clinical laboratories to quickly report MGMTp methylation status for GBM patient management. Combining abemaciclib, temozolomide, and radiation in DIPG PDOX models: Insights from single-cell RNA-seq on cellular subtypes and genes critical for responsiveness and resistance. First Author: Zilu Huang, Robert H. Lurie Comprehensive Cancer Center, Feinberg School of Medicine, Northwestern University, Chicago, IL

Background: Diffuse intrinsic pontine glioma (DIPG) is a highly aggressive pediatric brain tumor, with two-year survival less than 10%. Radiation therapy (XRT) offers limited survival benefits, and effective therapies are urgently needed. This study investigates the FDA-approved CDK4/6 inhibitors-Abemaciclib, XRT, and temozolomide (TMZ) as a therapeutic regimen for DIPG using organoids and patient-derived orthotopic xenograft (PDOX) models, aiming to improve survival outcomes and gain insights into the underlying cellular and molecular mechanisms of DIPG treatment responsiveness and resistance to support rapid translation into clinical trials. **Methods:** The efficacy of Abemaciclib, XRT, TMZ, and their combinations was evaluated in DIPG organoids and PDOX models (IBs-A0317DIPG and IBs-9119DIPG, H3.3K27M mutation). In vitro, PDOX organoids were treated with Abemaciclib, TMZ, with/without XRT. Synergy was assessed using the Bliss Independence model. In vivo, six treatment arms were tested: (1) control, (2) XRT (2 Gy/day $\times$ 5), (3) Abemaciclib (75 mg/kg, p.o., 14 days), (4) Abemaciclib + XRT, (5) TMZ (50 mg/kg, p.o., 5 days) + XRT, (6) Abemaciclib + TMZ + XRT. Single-cell RNA sequencing and IHC were used to assess cellular subtypes responses, gene expression changes, and resistance mechanisms. **Results:** In DIPG organoids, the combination treatment yielded Over Bliss values $>$ 0 (0.25 and 0.58 in A0317DIPG and 9119DIPG models, respectively) demonstrating synergistic activities. In PDOX models, the triple therapy showed improved median survival compared to other treatment arms and significant survival advantage over control (p = 0.0157) and Abemaciclib alone (p = 0.0461) in A0317DIPG, and control ($p < 0.0001$), XRT alone (p = 0.0032), Abemaciclib alone (p = 0.0006), Abemaciclib + XRT (p = 0.0046), and TMZ + XRT (p = 0.0001) in 9119DIPG models. Single-cell RNA sequencing revealed six tumor subtypes: AC-like, NPC-like, OPC-like, MES-like, mitotic, and radiation-resistant cells. The triple therapy increased NPC-like and mitotic cell populations while decreasing AC-like and OPC-like cells in both models. Additionally, we identified a novel radiation-resistant subpopulation that expanded after XRT treatment. Dynamic gene expression analysis in different cell types identified key target genes and cell-type specific pathways that mediate therapy responsiveness and resistance. **Conclusions:** Our study demonstrates that the combination of Abemaciclib, TMZ, and XRT offers a novel, synergistic approach for DIPG, significantly improving survival in preclinical PDOX models. Single-cell RNA sequencing reveals the roles of different cell types and molecular changes underlying resistance, highlighting potential targets for future anti-resistance strategies in DIPG management. MRI-based radiomics for prediction of isocitrate dehydrogenase subtype in glioblastoma multiforme through artificial intelligence models: A systematic review and meta analysis. First Author: Sonali Belankar, M. S. Ramaiah Medical College, Bangalore, India

Background: Gliomas are aggressive tumours with poor prognosis. Isocitrate Dehydrogenase (IDH) mutations are present in approximately 12% of all Glioma tumours and are considered biomarkers for prognosis and response to chemotherapeutic agents. IDH mutant gliomas have better prognosis in comparison to IDH wild type Gliomas. IDH mutant Gliomas exhibit features like T2-Flair mismatch sign, reduced blood flow seen on perfusion-weighted images and reduced enhancement on MRI, which aid in identification of IDH mutation. Radiomic imaging techniques extract quantitative features from medical images like MRI and CT scans with the help of advanced algorithms and the extracted data can be utilized in the development of specific artificial intelligence (AI) models like Neural Networks for the prediction of IDH mutation. Thus, MRI based Radiomics is an emerging non invasive technique in comparison to conventional biopsy, for the determination of IDH mutation. The meta-analysis conducted aims to analyse the diagnostic potential of Radiomic imaging in predicting IDH mutations in Gliomas. **Methods:** A systematic search was conducted in PubMed, Google Scholar and Scopus. PRISMA guidelines were followed. A boolean expression was constructed to retrieve and select articles from major medical databases. The R Studio package was used to evaluate the potential of the diagnostic test. The Meta, Metadata and Mada packages were utilised to evaluate Pooled accuracy, sensitivity and specificity. **Results:** A total of 35 studies and 7522 radiomic features were assessed through this meta analysis. The Pooled Sensitivity and Specificity were estimated to be 86.70% ([74.85; 87.51], 95% CI, $p< 0.0001$, I^2 = 92.7% [90.9%; 94.1%]) and 82.75% ([0.7912; 0.8587], 95% CI, $p<0.0001$, I^2 = 82.8% [77.4%; 86.9%]) utilising the random effects model. The pooled Accuracy was found to be 81.28% ([0.6037; 0.9253], 95% CI, $p>0.01$, I^2 = 0.0% [0.0%; 45.4%]). **Conclusions:** Through the compilation of previously conducted studies, MRI based Radiomics show High Pooled Sensitivity of 86.70% and High Pooled Specificity of 82.75% in the detection of Isocitrate Dehydrogenase mutations in Gliomas. Pooled Accuracy rate of 81.8% indicates steady reliability of Radiomics in the prediction of IDH mutations. MRI based Radiomics is a dependable and consistent non invasive technique in the detection of IDH mutations in GBM and can be utilized for the generation of predictive models, enhancing clinical diagnosis and tailored management based on IDH mutation. Correlative and spatial transcriptomic analysis of olaparib and durvalumab in patients with recurrent/refractory *IDH*-mutant gliomas. First Author: Xin Wang, Department of Medical Oncology, University of Toronto, Sunnybrook Health-Sciences Centre, Toronto, ON, Canada

Background: Combination of immune checkpoint and PARP inhibition has potential synergistic effects in *IDH*mt gliomas in pre-clinical models. Durvalumab and olaparib demonstrated objective responses in a subset of patients (pts) with *IDH*mt gliomas (NCT03991832). We report mutational, transcriptomic, and spatial correlative analysis of pts samples from baseline and at time of progression. **Methods:** Pts with recurrent/refractory *IDH*mt gliomas received olaparib 300 mg twice daily and durvalumab 1500 mg IV every 4 weeks until disease progression as determined by RANO 2.0 criteria. Whole exome sequencing (WES, n = 28) and total RNA sequencing (RNA-seq, n = 21) were performed on baseline archival formalin-fixed, paraffin-embedded tumor samples. Baseline tumor microenvironment was characterized with multiplex-immunohistochemistry (n = 29). Matched responders (n = 4) and non-responders (n = 6) were further profiled using 10X Visium HD for spatial transcriptomics. An unsupervised deconvolution method was applied using consensus non-negative matrix factorization for *de novo* discovery of expression programs corresponding to cell types and cell states. Associations with objective response (OR) to therapy were determined using either Fisher's exact test or rank-sum test. **Results:** In the 29 pts enrolled between January 2020–February 2023, median age was 40.5 (range 23–66) and 41% were female. The initial tumor grade was 2 (n = 9), 3 (n = 8), and 4 (n = 12). The OR rate was 14% (95% CI 3.9–32%), 1 complete response and 3 partial responses. All cases were mismatch repair proficient. The median tumor mutation burden (TMB) was 16.5, with TMB $>$ 10 in 21 pts (75%). Baseline TMB was not associated with response. The most common co-mutations were *TP53* (n = 21, 75%), *ATRX* (n = 20, 71%), *ARID1A* (n = 7, 25%), *CIC* (n = 4, 14%), and *NF1* (n = 3, 11%), none were associated with response. There were no canonical mutations in *BRCA1*, *BRCA2*, or *PALB2*. Pathway analysis on differentially expressed genes between responders and non-responders showed convergence on interferon signaling and inflammation among responders ($p <$ 0.001). Lower pre-existing M2-polarized tumor associated macrophages/microglia (high expression of CD68, PDL1, CD163) was associated with response ($p < 0.01$). These findings were supported by metaprograms in the HD spatial data, which showed higher levels of CD8+ cytotoxic T-cells at baseline in responders. Conversely, M2-polarized macrophage/microglia were enriched in non-responders. Paired progression samples will additionally be presented. **Conclusions:** Responders to olaparib and durvalumab had decreased baseline M2-polarized macrophages/microglia and increased pre-existing immunogenicity (interferon signaling). Several spatially conserved expression metaprograms targeting baseline immune infiltration were associated with response. Clinical trial information: NCT03991832. Research Sponsor: None.

The utilization of palliative care services by patients with glioblastoma: A cross-sectional study with care partners of patients with GBM recruited from Facebook support groups. First Author: Lauren Robbins, UNC Wilmington, Wilmington, NC

Background: Glioblastoma(GBM) is a terminal brain cancer that has a rapid onset and results in symptoms such as headaches, vomiting, seizures, anxiety, depression, agitation, speech impairment, memory impairment, infections, brain bleeds, mobility changes, changes in sleep patterns and cognitive changes. Palliative care helps patients diagnosed with an incurable or chronic disease manage physical, social and psychological symptoms while undergoing treatment, and has been shown to increase survival for patients with cancer. Previous data of former care partners of patients with GBM indicated only 30% of patients used palliative care during the disease trajectory, whereas 90% engaged hospice during the end of life stage. **Methods:** To better understand the reasons for underutilization of palliative care, primary caregivers of patients with GBM recruited from a Facebook support group in February 2024 completed a 38-question survey about where care was received, who was on their care team, and whether they had discussions around palliative care. Inclusion criteria: current primary care partner of a patient with GBM over the age of 18, and willing to participate (IRB exempt;H24-0393). The care partner was excluded if their patient was no longer living. **Results:** Of the 77 care partners who participated in the study, the median age of the caregivers was 56 years (98% female) and the median age of the patients with GBM was 60 years (87% female). Patients with GBM were initially diagnosed in community hospitals, major medical centers, university medical centers, brain tumor centers, and as part of incidental findings. Approximately $^{1}/_{4}$ of patients pursued second opinions. Of the 21 patients initially diagnosed in community medical centers, over half received treatment in other facilities. Medical care team members differed by facility type with a marked difference in palliative care utilization. Only 27% of care partners reported palliative care was part of the care team. Notably,when care team members discussed palliative care with patients and their care partners (n = 21), 71% of the dyads utilized palliative care. In contrast, when palliative care was not discussed (n = 56), only 7% of the care partners used these services ($p < 001$). Participants reported they would have benefited from additional supportive services provided by patient navigation and palliative care. **Conclusions:** This data highlights the value of discussions about palliative care in its utilization among GBM patients and their care partners. These conversations should take place early in the disease's progression to ensure that care partners receive the necessary education and resources in a timely manner. Research Sponsor: None.

Identification of novel electrophysiologic biomarkers of cognition in glioma-infiltrated cortex. First Author: Vardhaan Ambati, University of California, San Francisco, San Francisco, CA

Background: Diffuse gliomas, the most common primary brain cancers, often invade speech-critical areas. Maximal resection improves survival, but damage to functional cortex may cause permanent impairments. Direct cortical stimulation (DCS) differentiates functional (DCS+) from nonfunctional (DCS-) cortex by temporarily disrupting neuronal activity, yet it remains unknown how DCS+ sites elicit transient impairments. DCS is technically challenging and resource-intensive. As a result, fewer than 50% of glioma patients receive optimal surgical care. This translational study aims to identify electrophysiologic biomarkers of DCS+ cortex to 1) aid in safe resection by avoiding functional cortex and 2) to elucidate causal relations behind these transient impairments. **Methods:** Local field potentials of subdural array data from glioma infiltrated cortex was annotated as DCS+ or DCS- prospectively. We compared spectral electrophysiologic variations (mean Theta [4-8 Hz], Alpha [8-13 Hz], Beta [13-30 Hz], and Full Gamma [30-150 Hz] ranges) at resting state between DCS+ and DCS- sites using linear mixed-effects models (to account for patient-level differences). **Results:** 1421 cortical sites of language were studied in 91 patients including 21 Oligodendroglioma WHO grade 2-3, 19 Astrocytoma WHO 2-3, 3 Astrocytoma WHO 4, 48 IDHwt glioblastoma [GBM] WHO 4). 115 (8.0%) were DCS+. After alignment to ECoG electrode arrays, 512 cortical sites (49 DCS+) were assigned to electrodes. In oligodendrogliomas, DCS+ (N=16) vs DCS- (N=132) sites had higher alpha (77.7 ± 111.9 vs 38.6 ± 39.8, p=0.018), beta (23.1 ± 18.1 vs 11.9 ± 17.9, p=0.033), and full gamma (0.6 ± 0.6 vs 0.3 ± 0.3, $p<0.001$) power. Similarly, in astrocytoma, DCS+ (N=13) vs DCS- (N=147) sites had significantly higher theta (98.5 ± 94.9 vs 57.1 ± 67.2, p=0.020), alpha (83.5 ± 76.3 vs 39.9 ± 42.4, p=0.003), beta (55.9 ± 58.4 vs 16.3 ± 17.8, $p<0.001$), and gamma (0.9 ± 0.9 vs 0.4 ± 0.4, p=0.006) power. Interestingly, when comparing DCS+ (N=20) and DCS- (N=237) sites in GBM patients, no significant differences were found in any studied ranges (all $p>0.05$). **Conclusions:** This study is the first of its kind to identify unique electrophysiological biomarker differences (at resting state) for oligodendroglioma and astrocytoma speech cortex. It has two key implications. First, clinically, the identification of electrophysiologic biomarkers may improve direct cortical stimulation (DCS) mapping: It can make surgeries faster by identifying cortex critical for cognition (speech) based on these biomarkers, safer by helping neurosurgeons avoid resecting critical regions, and more accessible. Second, this research suggests that different tumor types (low-grade gliomas vs. GBM) remodel speech areas differently, prompting further investigation into tumor-specific effects on neural circuits. Research Sponsor: None.

2078 **Poster Session**

A single-institution retrospective study of multicentric gliomas stratified by *IDH* mutational status. First Author: Chuyin Yang, University of California, Los Angeles, Los Angeles, CA

Background: Multicentric glioma (MCG) is a subset of diffuse glioma that can be synchronous or metachronous and is defined as the occurrence of two or more tumor foci, with separation of FLAIR (Fluid-attenuated Inversion Recovery) hyperintensity on MRI. MCG has not been extensively studied in studies stratifying *IDH* wild-type and mutant gliomas. This large single-institution study investigates the prevalence of MCG, examines the prognostic implications of MCG, and characterizes metachronous MCG (mMCG) in a cohort that has been stratified by *IDH* mutational status. **Methods:** In this IRB approved UCLA study, we identified diffuse glioma patients with known *IDH* mutational status and adequate MRI studies. Patients with multiple lesions on the MRI study pre-surgery or up to 3 months post-surgery were considered synchronous MCG (sMCG). Patients who developed a new independent lesion at least 6 months after initial surgery were considered mMCG. To qualify as MCG, we identified additional tumors on MRI that had no overlapping FLAIR borders and met one or more of the following: pathologically confirmed with biopsy, exhibited growth and thickening over time, and developed or increased in enhancement. Difference in prevalence was compared using Student's t-test. Kaplan-Meier and Cox-multivariate analyses were used to analyze OS and time to metachronous (TtM) appearance. **Results:** We identified 911 consecutive *IDH* wild-type, high-grade diffuse glioma patients from 2013-2023 and 515 consecutive *IDH* mutant patients from 2007-2024 with pre-surgical MRI or MRI within three months of initial surgery. From the examined cohort, we found 39 *IDH* mutants with 21 sMCG and 18 mMCG and 153 *IDH* wild types with 95 sMCG and 63 mMCG. In eight *IDH* wild-type cases but no *IDH* mutant cases, mMCG arose from sMCG patients. We found that MCG had higher prevalence in *IDH* wild-types than in mutants (WT = 16%, Mut = 7%, $p < 0.0001$), and *IDH* mutant MCG showed more male predominance than *IDH* wild-type MCG (Mut = 73%, WT = 58%, $p < 0.0001$). In *IDH* mutant patients, mMCG, but not sMCG, was associated with lower OS (mMCG: HR = 2.476, p = 0.0115; sMCG: HR = 0.6437, p = 0.5027). However, in *IDH* wild types both sMCG and mMCG and were associated with lower OS (mMCG: HR = 1.589, p = 0.0025; sMCG: HR = 1.347, p = 0.0332). There was no difference in TtM between the two groups (HR = 0.5738, p = 0.5318). Amongst patients with multiple biopsied lesions, *IDH* wild types had consistent pathologies between lesions in all examined patients (29/29), but 71% of *IDH* mutants exhibited different pathologies between lesions (5/7). **Conclusions:** Our study examined a cohort of adult diffuse gliomas stratified by *IDH* mutational status and shows MCG is less common in *IDH* mutant gliomas and sMCG is not associated with worse prognosis. Further studies to identify molecular features underlying MCG will be valuable. Notes: For mMCG, FLAIR overlap might have occurred had the new lesion been observed synchronously. Research Sponsor: Bradley Zankel Foundation; NIH/NCI P50 CA211015-01A1 (UCLA SPORE in Brain Cancer).

Diagnostic accuracy of machine learning models in glioma classification: A meta-analysis. First Author: Maya Gowda, Cornell University, New York, NY

Background: Machine learning (ML) is promising in IDH-based glioma classification using magnetic resonance imaging (MRI), but variability in methods and algorithms necessitates a comprehensive evaluation. This meta-analysis assesses the pooled diagnostic performance of ML-based approaches. **Methods:** A literature search was conducted in January 2025 across PubMed, MEDLINE, and Cochrane. MICCAI, RSNA, and SNO meeting abstracts were additionally reviewed. Eligible studies evaluating ML models for IDH-based glioma classification using MRI were included. Data were pooled using a random-effects model, analyzing sensitivity, specificity, heterogeneity, and publication bias via Egger's test and funnel plots. Leave-one-out analysis was conducted. **Results:** A total of 5982 cases were analyzed. Gliomas were classified as WHO Grades II (11.5%), III (23.1%), and IV (65.4%). Histopathology-based reference standards, including genetic and molecular testing, were used in 73.1% of studies, while immunohistochemistry, pathology, biopsy-proven markers, and immunohistopathologic diagnosis were each used in 3.8–7.7%. Deep learning models, including CNNs and ResNet, were the most used classifiers (30.8%), followed by Support Vector Machines (26.9%). Ensemble methods, such as Random Forest accounted for 19.2%, regression-based approaches (LASSO, logistic regression) for 15.3%, and other techniques like multilayer perceptron and AdaBoost for 7.7%. This meta-analysis included 25 studies for sensitivity and 26 for specificity, using a random-effects model with DerSimonian-Laird estimation. Pooled sensitivity was 83.0% (95% CI: 79.5–86.5%) and specificity was 78.6% (95% CI: 73.7-83.4%), both statistically significant ($p < 0.0001$). Substantial heterogeneity was found (I^2 = 100% for both), with Cochran's Q values of 1.9e+06 for sensitivity and 4.2e+06 for specificity ($p < 0.001$). Leave-one-out analysis showed minimal variation in pooled estimates (sensitivity: 82.6–83.8%, specificity: 77.6–79.4%). Egger's test revealed significant small-study effects (p = 0.0001 for both), suggesting potential publication bias. **Conclusions:** ML models demonstrated moderate diagnostic performance in IDH-based glioma classification, achieving a sensitivity of 83.1% and specificity of 78.6%. However, substantial heterogeneity and potential biases pose significant challenges to their clinical implementation. To enhance the reliability and broader applicability of ML models in IDH-based glioma diagnosis, standardization of imaging protocols and external validation are imperative. Research Sponsor: None.

Meta-analytical findings.

Metric	Sensitivity (%)	Specificity (%)
Pooled Estimate	83.0 (79.5–86.6)	78.6 (73.7–83.4)
Z-Value	46.4	31.76
P-Value	<0.0001	<0.0001
I^2 (%)	100	100
T^2	80.0	159.0
Cochran's Q	1.9e+06 (df=24, p<0.001)	4.2e+06 (df=25, p<0.001)
Leave-One-Out Range	82.6–83.8	77.6–79.4
Egger's Test (P-value)	0.001	0.001

Identifying key molecular drivers of survival and therapeutic targets in glioblastoma through integrated transcriptomic analysis. First Author: Mohammad Kashkooli, Harvard-MIT Health Sciences and Technology, Boston, MA

Background: Glioblastoma multiforme (GBM) remains one of the most aggressive brain tumors, characterized by poor survival rates and limited therapeutic success. Advancing treatment requires identifying molecular drivers of tumor progression and therapy resistance. Integrated transcriptomic analyses offer a powerful means to uncover pathogenic pathways, therapeutic targets, and refine prognostic tools. This study aimed to explore GBM's molecular landscape to identify survival-relevant genes and actionable pathways, ultimately paving the way for precision therapies to improve outcomes. **Methods:** RNA-sequencing data from TCGA, CGGA, CPTAC, GLASS, GSE121720, and GSE147352 datasets, encompassing 783 samples, were analyzed. Only primary, untreated GBM tumors with survival data were included. Data normalization was performed using the voom function in limma, and batch effects were corrected using ComBat while preserving survival-related and gender-specific variations. Differential expression analysis (DEA) was used with thresholds of $|\log FC| > 1$ (two-fold expression change) and adjusted $p < 0.001$, accounting for age, gender, race, and IDH1 mutation. Protein–protein interaction (PPI) networks were constructed using STRING, and Cox regression identified survival-related genes. DrugBank was used to link survival-associated genes to potential therapeutics. **Results:** Of the 783 samples, 488 met inclusion criteria (473 tumor, 15 non-tumor). DEA identified 1,453 differentially expressed genes (DEGs) with significant differences between tumor and non-tumor samples. PPI analysis highlighted 270 hub genes, of which 47 were significantly associated with survival. Notably, CDK1, RRM2, and BIRC5 showed negative prognostic effects (hazard ratio [HR] > 1.7, adjusted $p < 0.05$), while RPL3L, RPL21, and RPL9 exhibited protective effects (HR < 0.5, adjusted $p < 0.001$). DrugBank analysis identified gallium nitrate (targeting RRM2) and Alsterpaullone (inhibiting CDK1) as promising therapeutic candidates. **Conclusions:** This study provides a comprehensive bioinformatics analysis of GBM, integrating multiple transcriptomic datasets to identify critical survival-related genes, including CDK1, RRM2, and BIRC5, as key therapeutic targets. Notably, it highlights the protective roles of ribosomal proteins (RPL7, RPL9, RPL21), challenging the traditional view that ribosomal upregulation solely drives tumorigenesis. These findings emphasize the dual nature of ribosomal dysfunction, which has been implicated in both oncogenic and tumor-suppressive pathways. Through rigorous data normalization, batch correction, and PPI analysis, the findings offer robust insights into GBM biology and its molecular drivers. These results lay a strong foundation for future studies to validate their clinical relevance, refine prognostic models, and advance precision therapy strategies for GBM patients. Research Sponsor: None.

Effect of ivosidenib and vorasidenib on 2-hydroxyglutarate levels in low grade glioma: An in vivo MR spectroscopy study. First Author: Max Saint-Germain, Johns Hopkins University School of Medicine, Baltimore, MD

Background: IDH-mutant gliomas are slow-growing infiltrating tumors of astrocytic (AS) or oligodendroglial (OG) origin (WHO grade 2/3). The mutations occur in genes that encode the metabolic enzyme IDH1 or, more rarely, IDH2 and lead to production of 2-hydroxyglutarate (2-HG) that can be measured with optimized in-vivo MRS. Small-molecule IDH inhibitors (IDHi) ivosidenib (inhibits mIDH1 enzyme) and vorasidenib (inhibits mIDH1 and mIDH2 enzymes) showed good tumor penetrance and ~95% 2-HG reduction measured in tumor biopsies. Both ivosidenib and vorasidenib have evidence of responses in tumor growth rate. As volume reductions are often observed, but after a delay of several months, thus an early response biomarker highly desired. The aim of this study was to explore whether MRS measurements of 2-HG can be used to non-invasively monitor response to treatment with IDHmut-inhibiting drugs and compare this response to changes in tumor volume. **Methods:** 14 patients (Age ≥18y) with a histomolecularly confirmed IDH1 mutated diffuse glioma (AS or OG) received ivosidenib (n = 12) or vorasidenib (n = 2) therapy as part of their routine clinical care. MRI was performed before treatment (*baseline*) and repeated (*follow-up*) with a median on-drug follow-up of 6 months [4, 12 IQR]. Tumors were segmented from FLAIR images in 3D Slicer and volumes were calculated in cm^3. All MRS data were processed in Osprey with the built-in LCModel fitting module. Comparisons between baseline and follow-up measured metabolite levels were conducted using paired t-tests or (in cases where the normality assumption was not met) non-parametric Wilcoxon tests. **Results:** We analyzed spectra from 11 patients with both baseline and follow-up sessions. All spectra exhibited characteristic tumor features: reduced total N-acetylaspartate (tNAA) and elevated levels of total choline (tCho), lactate (Lac), and myo-inositol (mI), along with a 2-HG peak at 2.25 ppm that is visibly smaller after treatment. The decrease in 2-HG levels was highly significant ($p < 0.001$) across all included patients undergoing ivosidenib/vorasidenib therapy, regardless of reference standard. Volumetric assessment revealed tumor growth arrest and a subtle reduction in tumor growth in some individuals. **Conclusions:** This is the first in-vivo evidence using MRS that ivosidenib/vorasidenib reduces 2-HG. We found that 2-HG levels respond specifically and rapidly to treatment, while volumetric changes manifest slowly and more gradually, consistent with previous studies. This preliminary study suggests that in vivo MRS-derived 2-HG estimates could serve as sensitive and specific biomarkers for monitoring low grade gliomas in vivo in response to small-molecule IDH inhibitor therapy after initiation of treatment. Longitudinal volumetric and radiomic analyses are underway. Research Sponsor: None.

Vault proteins as prognostic biomarkers and therapeutic targets in lower-grade gliomas. First Author: Sebawe Syaj, Division of Hematology and Oncology, Department of Medicine, University of Pittsburg Medical Center, and UPMC Hillman Cancer Center, Pittsburgh, PA

Background: Vault proteins, including MVP, VPARP, and TEP1, are components of the vault complex, and are involved in drug resistance, DNA repair, and cell survival. However, their role in low-grade gliomas (LGG) remains unclear. This study explored the expression and prognostic significance of LGG with the aim of uncovering their potential as biomarkers. **Methods:** Using the TCGA-LGG cohort, Kaplan Meier (KM) and uni/multivariate Cox proportional hazards regression (CPH) analyses were performed using R 4.3.3, and hazard ratios (HR) with 95% confidence intervals (CI) were reported. MVP, TEP1, and VPARP (PARP4) expression levels were further stratified according to the LGG subtype. Multi-gene KM plots were generated to stratify overall survival (OS), progression-free survival (PFS), and disease-specific survival (DSS) using gene set variation analysis (GSVA) scores. "ImmuCellAI" algorithm was utilized for immune infiltration analysis. The GDSC and CTRP databases were used for drug sensitivity analyses. **Results:** As indicated by KM and univariate CPH analyses, MVP (hazard ratio [HR] = 1.5, 95% CI: 1.3-1.8), TEP1 (HR = 1.7, 95% CI: 1.4-2.0), and VPARP (HR = 1.6, 95% CI: 1.3-1.9) predicted poor OS. MVP, in multivariate CPH model adjusted to tumor grade and histology, remained significant (HR = 1.37, 95% CI: 1.14-1.70). The expression of MVP, TEP1, and VPARP was the highest in astrocytomas and the lowest in oligodendrogliomas ($p < 0.05$), with oligoastrocytomas in between. 3-gene KM signature analysis revealed a negative association between higher GSVA scores and OS, PFS, and DSS (log-rank $p < 0.01$) (Table). Immune infiltration analysis indicated positive macrophage, Th1, Th2, and dendritic cell infiltration with higher GSVA (derived from MVP, TEP1, and VPARP) ($r > 0.40$, FDR < 0.05) and negative infiltration of naive CD8+ and neutrophils ($r < -0.30$, FDR < 0.05). Drug analysis revealed vincristine resistance with higher MVP expression (r = 0.44, FDR < 0.001). **Conclusions:** MVP, TEP1, and VPARP were associated with poor survival outcomes and distinct immune infiltration patterns in LGG. These findings highlight the potential of vault proteins as biomarkers and therapeutic targets for LGG. Research Sponsor: None.

Univariate Cox proportional hazards ratios for the different survival types for GSVA scores of the three major proteins of the vault (MVP, TEP1, and VPARP).

Survival type	Hazard Ratio	Cox P value	Logrank P value	Higher risk of death
OS	1.7	<0.001	24E-2.03	Higher GSVA
PFS	1.43	0.01	9.09E-03	Higher GSVA
DSS	1.75	<0.001	2.18E-03	Higher GSVA

2083 Poster Session

Accelerator-based boron neutron capture therapy, a randomized controlled trial for refractory recurrent high-grade meningiomas. First Author: Shin-Ichi Miyatake, Kansai BNCT Medical Center, Osaka Medical and Pharmaceutical University, Takatsuki, Japan

Background: High-grade meningiomas (HGMs) recurred after X-ray treatment showed pessimistic prognosis. We conducted "A phase II investigator-lead RCT using accelerator-based BNCT system for refractory recurrent high-grade meningioma". **Methods:** We prepared 2 study arms, BNCT test treatment arm (12 subjects) and control best supportive care arm (6 subjects) in RCT fashion. PFS judged by the third-party committee was primary endpoint and PFS judged by investigators themselves and OS of BNCT arm and so on were secondary endpoints. Rescue BNCT was permitted for control group patients, if they were judged as PD by investigators. First patient-in and last patient-in were August 2019 and August 2021, respectively. Last patient visit was February 2024 and final OS survey and final observation for effectiveness and safety in BNCT arm were performed in July 2024. These results were compared to EORTC's RCT of trabectedin. **Results:** Three and 2 grade 3 subjects were included in BNCT and control arm, respectively. Others were grade 2 subjects. All cases were confirmed relapse after some radiotherapy in follow-up images. One subject allocated in BNCT arms was excluded after enrollment due to protocol violation. At the end of the observation, as primary endpoint, PFS of each arm judged by committees showed statistical significance (p=0.0157, Log-rank). As one of the secondary endpoints, PFS of each arm judged by investigators also showed statistical significance (p=0.0002). Median PFS judged by committees were 14.4 (95% CI:7.9-26.4) and 1.4 (1.0-9.0) months for BNCT and control arm, respectively. Median PFS judged by investigators showed 14.7 (7.6-22.8) and 1.5 (1.0-9.0) months, respectively. Five out of 6 cases in control arm received rescue BNCT after PD assessments. Other endpoints are listed in the table. **Conclusions:** As primary endpoint, PFS judged by committee showed statistical significance between treatment and control arms. Recently, the results of RCT of "Trabectedin" for recurrent HGMs, organized by EORTC, (EORTC-1320-BTG) was reported. Unfortunately, there was no effect of Trabectedin not only in PFS but in OS. Therefore, EORTC's report seems to be natural course of recurrent refractory HGMs. Our current BNCT shows extremely excellent results in comparison with EORTC's RCT in mPFS, PFS-6 months, mOS, OS-1 year and ORR (Table). Clinical trial information: 2051190044. Research Sponsor: AMED.

Comparison of both RCT (current study and EORTC trabectedin).

	Current study (n=18)		EORTC trabectedin (n=90)	
	BNCT	Control	Trabectedin	Control
mPFS (months)	14.4	1.4	2.43	4.17
PFS-6 months (%)	100	44.4	21.1	29.1
mOS (months)	46.9	-	11.4	10.6
OS-1 year (%)	100.0	-	48.1	43.0
OS-2 year (%)	90.9	-	-	-
ORR (CR+PR) (%)	27.3	0	1.6	0

2084 Poster Session

Phase 2 study of nivolumab for patients with meningiomas refractory to surgery and radiotherapy with immune-related response criteria. First Author: Hikaru Sasaki, Tokyo Dental College Ichikawa General Hospital, Ichikawa, Japan

Background: The majority of meningiomas, which are the most common central nervous system (CNS) tumors, are benign and often cured by surgical resection alone. However, 20%–30% of meningiomas can be malignant tumors of CNS WHO grade II or III that are refractory to repetitive resection and radiotherapy. Moreover, a proportion of grade I meningiomas is associated with an aggressive clinical course reminiscent of grade II tumors. Reports of effective medical therapy for those tumors are extremely rare. **Methods:** A single-arm, open-label, phase 2 study was conducted to evaluate the efficacy and safety of nivolumab for meningiomas refractory to surgery and radiotherapy. Nivolumab (480 mg) was administered intravenously every 4 weeks and continued until tumor progression or unacceptable toxicity for up to 365 days. The primary endpoint was the objective response rate (ORR) determined by a central independent review committee. With a one-sided significance level of 5%, a power of 80%, a threshold response rate of 5%, and an expected response rate of 20%, the required sample size was calculated to be 27 patients using the exact binomial test. Considering a 10% attrition rate, the target sample size was set at 29. To avoid premature discontinuation of potentially effective immunotherapy, response was evaluated based on the iRANO (meningioma) criteria, which is based on the RANO (meningioma) criteria (Neuro Oncol 21(1):26-36, 2019) with the integration of the immune-related response criteria outlined previously (Lancet Oncol 16(15):e534-e542, 2015). Archival tumor specimens from all 29 cases were obtained for biomarker analyses. **Results:** A total of 29 patients started the study therapy. Response assessment by the central review committee was performed for 28 patients: grade I meningioma in 5, grade II in 19, and grade III in 4 by definition of the 2016 WHO criteria. The best overall response was PR in 1, SD in 13, and uPD/cPD in 14. The ORR was 3.6% and progression-free survival at 6 months was 23.9%. Biallelic inactivation of the *NF2* gene was detected in 20/27 cases (74%), whereas biallelic inactivation of the *CDKN2A* gene was identified in 7/27 cases (26%). One patient who had multiple grade I meningiomas with biopsy-proven lung metastases showed near CR following initial radiological progression. The TMB of the tumor was 8.1/MB. Next-generation sequencing found that none of the tumors had mutations of the DNA mismatch repair genes. Nivolumab was well tolerated. **Conclusions:** Although nivolumab monotherapy failed to meet the prespecified primary endpoint, our study demonstrated that a subset of patients could benefit from the therapy and that immune-related response criteria are necessary to evaluate immunotherapy for meningiomas. Clinical trial information: jRCT2031190074. Research Sponsor: Ono pharmaceuticals.

Analysis of genetic mutation profile and CNS pharmacokinetics in relapsed/refractory primary CNS lymphoma patients responding to novel emavusertib (IRAK4i) and BTKi combination. First Author: Christian Grommes, Department of Neuro-oncology, Memorial Sloan Kettering Cancer Center, New York, NY

Background: Primary Central Nervous System Lymphoma (PCNSL) is a rare and aggressive non-Hodgkin lymphoma with no approved treatments for relapsed/refractory (R/R) patients, representing a critical unmet need. MyD88 mutations in ~70% of PCNSL patients drive Interleukin-1 receptor associated kinase 4 (IRAK4) activation, promoting NF-κB signaling, inflammation, and tumor progression. Emavusertib, a potent oral IRAK4 inhibitor, crosses the blood-brain barrier and shows preclinical synergy with Bruton tyrosine kinase inhibitors (BTKi), re-sensitizing BTKi-resistant cell lines. This study evaluates the molecular and pharmacokinetic (PK) data associated with responses to emavusertib + ibrutinib combination therapy in R/R PCNSL patients. **Methods:** The safety, clinical activity, and potential biomarkers of emavusertib in R/R PCNSL are being investigated in the ongoing open-label, Phase 1/2 TakeAim Lymphoma trial (NCT03328078). Pre-dose and 1.5-hour post-dose plasma samples were collected on Cycle 3 Day 1, Cycle 5 Day 1 and Cycle 7 Day 1. Cerebrospinal fluid (CSF) samples were obtained via a lumbar puncture within 1.5 hrs of collection of the post-dose plasma PK sample on Cycle 3 Day 1. Mutation analysis was based on patients' molecular pathology reports provided by trial sites. Sequencing of archival tissues, CSF and plasma are in progress. **Results:** As of 06 December 2024, CSF concentration data were available for 7 PCNSL patients. The mean emavusertib concentration in CSF was 81.3 ng/ml (54.7-104.0) in patients receiving 100 mg emavusertib BID (n = 4). In patients receiving 200 mg emavusertib BID (n = 3), the mean emavusertib concentration in CSF was higher at 175.7 ng/ml (114.8-209.4), which is 2.2X the mean value in patients who received 100 mg emavusertib BID (p-value = 0.02). All 7 patients received 560 mg ibrutinib QD, and the ibrutinib concentrations in the CSF were consistent with findings from previously published clinical studies. MyD88 mutation status was available for 7 patients of which all had prior exposure to BTKi regimens. Among these, 6 patients had MyD88 mutation of which 4 patients had responded (3 complete responses and 1 partial response) to emavusertib + ibrutinib combination with duration of response (DOR) up to 18.9 months with data collection ongoing. **Conclusions:** Preliminary CNS pharmacokinetic data demonstrates that emavusertib concentration in CSF increases with increasing emavusertib dose. Patients with MyD88 mutations showed expected promising preliminary efficacy to emavusertib + ibrutinib combination and may overcome BTKi resistance. Enrollment in this trial is ongoing. Clinical trial information: NCT03328078. Research Sponsor: None.

Unraveling survival disparities in primary central nervous system (CNS) lymphoma: An analysis of race, socioeconomic factors, and treatment outcomes using the Surveillance, Epidemiology, and End Results program (2000–2021). First Author: Imran Khan, NYC Health and Hospitals/Woodhull, Brooklyn, NY

Background: Primary central nervous system lymphoma (PCNSL) is a rare B-cell non-Hodgkin lymphoma with survival outcomes influenced by treatment, demographic, and socioeconomic factors (Villano JL et al., Br J Cancer, 2011). This study evaluated survival disparities associated with race, socioeconomic status (SES), and treatment modalities in PCNSL patients using a large U.S. population database. **Methods:** This retrospective cohort study used the SEER-17 database to analyze data from 7,068 patients diagnosed with PCNSL between 2000 and 2021. Demographic, socioeconomic, and treatment data were collected. Kaplan-Meier analysis was used to compare survival across groups, and Cox proportional hazards models identified independent prognostic factors. **Results:** The cohort included 7,068 patients (52.3% male; mean age: 63 years, SD $\pm$ 15). Racial distribution was 63.9% Caucasians, 16.0% Hispanics, 12.2% Asian/Pacific Islanders, 7.3% African Americans, and 0.4% American Indian/Alaskan Natives. Among these, 27.3% received radiation, and 64.3% received chemotherapy. During the study period, 73.5% of patients died from PCNSL. Survival analysis revealed that Asian/Pacific Islanders had the longest median overall survival (OS) at 22 months (95% CI: 16.5–27.5), followed by Hispanics (16 months; 95% CI: 11.8–20.2), Caucasians (11 months; 95% CI: 9.8–12.2), and American Indian/Alaskan Natives with the shortest survival at 5 months (95% CI: 0–11.2) ($p<0.001$). Socioeconomic analysis showed a direct association between higher income and improved OS: patients with household incomes $\geq$75k had a median OS of 13 months (95% CI: 11.2–14.8), compared to 6 months (95% CI: 4.2–7.8) in those earning $<$50k ($p<0.001$). Multivariable Cox regression identified male sex (HR 1.21, $p<0.001$) and older age (HR 1.027, $p<0.001$) as adverse prognostic factors, while chemotherapy significantly improved survival (HR 0.43, $p<0.001$). Radiation provided a modest benefit (HR 0.913, p=0.005). **Conclusions:** This large study demonstrates that lower income levels and racial disparities are associated with reduced survival in PCNSL. Findings underscore the need for equitable healthcare access and tailored therapeutic strategies to address these inequities. Keywords: CNS lymphoma, survival disparities, socioeconomic status, race, treatment outcomes, public health oncology. Research Sponsor: None.

Predicting survival in malignant meningiomas: A machine learning approach. First Author: Mustafa Alshwayyat, Jordan University of Science and Technology, Irbid, Jordan

Background: Intracerebral meningiomas account for over 90% of all meningioma cases, with only 1–3% classified as malignant. Malignant meningiomas remain understudied compared with other brain tumors. This study is the first to apply machine learning (ML) to identify prognostic factors and improve outcomes of malignant intracerebral meningiomas. **Methods:** Data were obtained from the SEER database (2004-2021). Patients who met any of the following criteria were excluded: diagnosis not confirmed by histology; previous history of cancer or other concurrent malignancies; or unknown data. To identify prognostic variables, we conducted Cox regression analysis and constructed prognostic models using ML algorithms to predict the 5-year survival. Patient records were randomly divided into training (70%) and validation (30%) sets. A validation method incorporating the area under the curve (AUC) of the receiver operating characteristic curve was used to validate the accuracy and reliability of the ML models. We also investigated the role of multiple therapeutic options using Kaplan-Meier survival analysis. **Results:** A total of 1,363 patients were included. Most patients were White (71.8%) or female (56.7%). The median patient age was 62 years, and the median tumor size was 4.8 cm. Most of the tumors were localized (67.8%). Adjuvant radiation therapy was administered to 50.2% of the patients. Patients aged $<$ 62 years exhibited better 5-year survival rates, with an overall survival (OS) of 79.4% and cancer-specific survival (CSS) of 82%, compared to those aged $\geq$ 62 years, who had an OS of 40.9% and CSS of 50.6%. Tumors smaller than 4.5 cm were associated with higher survival rates (OS: 67.7%, CSS: 72.4%) than larger tumors (OS: 53.6%, CSS: 61.9%). The impact of adjuvant radiation therapy showed an OS of 59.9% and 64.5%, respectively, compared with those who did not receive radiation, with an OS of 59.5% and CSS of 68.7%. Multivariate Cox regression analysis identified older age (HR: 3.6, 95% CI: 3.03–4.4) and large tumor size (HR: 1.4, 95% CI: 1.22–1.7) as poor prognostic factors. The Random Forest and MLP classifiers were the most accurate models. The ML models identified age as the most significant prognostic factor. The performance metrics for all the ML algorithms are summarized in Table. **Conclusions:** This study underscores the transformative potential of ML in enhancing personalized medical approaches for malignant intracerebral meningiomas. Furthermore, whether the benefits of adjuvant radiotherapy outweigh the risks remains unclear, indicating the need for further targeted research to investigate its therapeutic impact on these rare tumors. Research Sponsor: None.

ML Model	Accuracy	Precision	Recall	F1 score	AUC
LR	63%	50.8%	61.2%	55.6%	0.696
KNN	63.3%	51.2%	45.1%	48%	0.660
RFC	69.1%	58.9%	60.2%	59.5%	0.743
GBC	66.2%	55.6%	52.6%	54.1%	0.723
MLP Classifier	67.48%	57.47%	53.76%	55.56%	0.716

TPS2088 **Poster Session**

Phase IIa study of αDC1 vaccines targeting HER2/HER3 combined with pembrolizumab in patients with asymptomatic brain metastasis from breast cancer. First Author: Shipra Gandhi, Roswell Park Comprehensive Cancer Center, Buffalo, NY

Background: Brain metastases develop in up to 50% of patients (pts) with metastatic breast cancer. Overexpression of HER3 in brain metastatic breast cancer (BMBC) is a resistance factor to HER2-targeted therapies and a driver of brain metastasis. Disease progression is associated with loss of anti-HER2 and anti-HER3 immunity. Previously, we have demonstrated that glioma-specific peptide-loaded αDC1 which produces CXCL9, CXCL10, CXCL11, and CCL5, the chemokines that attract CXCR3- and CCR5-expressing cytotoxic T-lymphocytes (CTLs) and T-helper 1 (Th1) cells, induce clinical responses and long-term disease stabilization in pts with aggressive recurrent primary brain tumors (Okada et al. JCO 2011. PMID: 21149657). We hypothesized that anti-HER2/3-loaded αDC1 combination with PD1 blockade will result in a strong Th1/CTL response against HER2/3 epitopes (Basu A et al. Cancer Immunol Res. 2022 PMID: 34785506) that will translate into anti-cancer benefit in the central nervous system (CNS) and systemically. **Methods:** This is a phase II single-arm, non-randomized multicenter study (NCT04348747). Eligibility includes pts with BMBC $\geq$18 years, ECOG PS $\leq$1, normal marrow and organ function with asymptomatic untreated brain metastases $\geq$ 5 mm. The study subjects receive αDC1 q3 weeks x 3 along with pembrolizumab every 3 weeks. Thereafter, αDC1 booster doses can be administered every 3 months until disease progression, intolerable side effects, or withdrawal from study, up to 24 months. Baseline and 9-week post-αDC1 peripheral biopsies (non-CNS) are required for six pts. The primary endpoint is CNS response rate (RR) by RANO-BM criteria. If no CNS response is observed after 12 pts, the study will be terminated. If $\geq$ 1 response is observed, then 9 more pts will be enrolled, for a total of 21 pts. If $\geq$ 3 CR are observed, the proposed therapy will be considered promising for further evaluation. Secondary endpoints include non-CNS RR per RECIST v1.1, median CNS, non-CNS and overall progression-free survival, overall survival, and safety. Exploratory endpoints include changes in intratumoral biomarkers (CTLs, PDL1, chemokines) in pre- and post-treatment peripheral tumor biopsies and immune changes in the blood. So far, 7 of the planned 21 pts have been enrolled. Clinical trial information: NCT04348747. Research Sponsor: U.S. Department of Defense.

TPS2089 **Poster Session**

A multicenter, randomized, controlled, pivotal trial of microbubble-enhanced transcranial focused ultrasound for patients with NSCLC brain metastases (LIMITLESS). First Author: Manmeet Singh Ahluwalia, Miami Cancer Institute, Baptist Health South Florida, Miami, FL

Background: The efficacy of systemic therapies for brain metastases (BM) is hindered by the blood-brain barrier (BBB) and brain-tumor barrier. Transcranial low-intensity focused ultrasound combined with IV microbubble oscillators (MB-FUS), allows for localized, controlled, non-invasive and temporary BBB opening, which has been shown to enhance tumor drug delivery of systemic therapies, as well as impro efficacy of immunotherapies. Non-small cell lung cancer (NSCLC) is the most common cause of BM, and this randomized controlled trial (RCT) aims to evaluate the safety and efficacy of MB-FUS-mediated BBB opening combined with standard of care (SOC) systemic therapy versus systemic therapy alone for patients with NSCLC BM. **Methods:** LIMITLESS is prospective, multicenter, parallel-arm, RCT, ongoing at up to 30 centers, that randomizes patients with NSCLC BM, in a 2:1 ratio to either: (i) Arm 1: MR-guided MB-FUS plus all FDA approved on-label use of immune checkpoint inhibitors (ICIs) with or without chemotherapy regimen (SOC systemic therapy), or (ii) Arm 2: SOC systemic therapy alone. Included patients are $\geq$18 years aged, with normal organ function, KPS $\geq$70, and have $\geq$0.5 cm size BM meeting measurable disease criteria as per RANO-BM. Patients on both arms receive standard-of-care therapy, while those on arm 1 also undergo MB-FUS. Patients undergo pre-treatment brain MRI, followed by IV administration of microbubbles for enhanced sonication effects. BBB opening is performed using a transcranial 220 kHz device with 1024-element phased array transducer with real-time acoustic feedback-based power control for maintaining effective microbubble activation. The primary study outcome is the overall objective response rate (ORR) at 6 months as assessed using RANO-BM criteria. Using a Bayesian design for power analysis, a superior ORR of 60% is assumed for MB-FUS arm versus 30% in the control arm for a total sample size of N = 96, 64 participants in MB-FUS and 32 in control arm, for 80% power using a two-sided chi-square test with an alpha of 0.05. For the upper-bound estimate, ORR of 45% in MB-FUS arm and 30% in the control arm, the study needs N = 369 participants: 246 in LIFU arm and 123 in control arm. The secondary outcomes are best objective response rate and median time-to-response per treatment arm. Exploratory outcomes are median progression-free survival (PFS), overall survival (OS), median intracranial PFS, median extracranial PFS, and quality of life. Patient enrollment commenced in 2022 and is ongoing (ClinicalTrials.Gov Registration: NCT05317858). Clinical trial information: NCT05317858. Research Sponsor: Insightec Inc.

TPS2090 Poster Session

Delayed or upfront brain radiotherapy in treatment-naïve lung cancer patients with asymptomatic or minimally symptomatic brain metastases and ALK rearrangements (DURABLE). First Author: Joshua David Palmer, Department of Radiation Oncology, Ohio State University, Columbus, OH

Background: Patients with non-small cell lung cancer (NSCLC) with ALK rearrangements have a high frequency of brain metastases. Alectinib was shown to be superior to crizotinib in the first-line treatment of patients with ALK-positive NSCLC in the ALEX trial, and the intracranial response rate (CNS ORR) was 85.7% with alectinib versus 71.4% with crizotinib in patients who received prior radiotherapy and 78.6% versus 40.0%, respectively, in those who had not. Alectinib has also shown benefit in earlier stages of NSCLC. Given the high intracranial efficacy rate demonstrated by alectinib, as well as the known toxicities of cranial irradiation, the role of early irradiation of CNS disease vs delaying radiation in favor of treatment with alectinib needs to be defined to inform clinical practice. **Methods:** NCT05987644 is a multi-center, multi-cohort study consisting of a Phase 1b and Phase 2 portion. The Phase 1b portion of the study is a single-arm, open label study of alectinib in patients with CNS disease. Twelve subjects will be enrolled in the Phase 1b portion of the study and treated with alectinib alone; patients with PD will come off study treatment and move on to standard of care treatment per national guidelines. The phase 2 portion will be a randomized, non-blinded, open-label study. Forty-four subjects will be enrolled and randomized 1:1 to either alectinib upfront (Arm A) or alectinib + SRS (arm B). A group sequential design will be implemented with one interim analysis for futility and, and one final analysis using the composite outcome. The primary objective of phase 1b is to determine the safety and feasibility of delayed brain radiation in patients with ALK fusion positive NSCLC and CNS metastases. The primary objective of the phase 2 study is to determine whether treatment with alectinib results in preserved neurological status and control of CNS disease at 12 months compared to alectinib plus SRS. Secondary endpoint will be intracranial progression free survival at 12 months (icPFS12), response rate and icPFS, OS, and safety and tolerability. The study is open and accruing at 4 sites. Clinical trial information: NCT05987644. Research Sponsor: Genentech.

TPS2091 Poster Session

FORTE: A phase 2 master protocol assessing plixorafenib for BRAF-altered cancers. First Author: Karisa C. Schreck, Johns Hopkins School of Medicine, Baltimore, MD

Background: Plixorafenib (FORE8394; PLX8394) is a novel, oral, small-molecule BRAF inhibitor highly selective for BRAF V600 monomers and BRAF-containing dimers. Plixorafenib binding disrupts RAF dimerization, targeting both BRAF V600 mutations and fusions, thereby preventing paradoxical activation and avoiding the need for combination with a MEK inhibitor. In a phase 1/2a study, plixorafenib demonstrated promising safety and clinical activity across a range of doses tested in tumors with BRAF V600 mutations or fusions. The most common adverse events (AEs) included predominantly low-grade liver function test changes and grade 1 fatigue, nausea, diarrhea, and vomiting. **Methods:** The FORTE Phase 2 basket study is currently enrolling patients ≥10 years of age into 4 sub-protocols. Study details are shown in theTable. Eligible patients have received prior therapy for advanced disease, have measurable disease, and have a Karnofsky (≥16 years) or Lansky (<16 years) Performance Score of ≥60 at study entry. All patients receive plixorafenib continuous dosing, in some cohorts coadministered with cobicistat, a pharmacokinetic (PK) booster. Prior MAPK inhibitor therapy is excluded unless otherwise specified below. As of January 2025, the trial is recruiting participants in 9 countries globally, with 54 sites activated. Clinical trial information: NCT05503797. Research Sponsor: Fore Biotherapeutics.

	Sub-Protocol A	Sub-Protocol B	Sub-Protocol C	Sub-Protocol D
Patient Population	Advanced solid and primary CNS tumors harboring BRAF fusions	BRAF V600-mutated recurrent primary CNS tumors	Rare[1] BRAF V600-mutated advanced solid tumors	BRAF V600-mutated melanoma[2] or thyroid cancer without anaplastic or undifferentiated components
Planned Enrollment	~100	~50	~75	~12
Design	Single-arm, open-label, Bayesian optimal phase 2 design			1:1 randomized, open-label crossover design to compare plixorafenib administered alone and with PK booster
Planned Efficacy Interim Analyses	N=25 N=50	N=25	N=25 N=50	None
Primary Endpoint	ORR[3]			Intra-patient PK
Key Secondary Endpoints	DOR, DCR, PFS, OS, PK, Safety			Safety, ORR, DOR, DCR, PFS, OS, Safety
Key Exploratory Endpoint	Longitudinal ctDNA assessments[4]			

[1]BRAF V600-mutated tumors occurring in ≤40,000 US patients annually (eg, ovarian/gynecologic cancers, cholangiocarcinoma, small intestinal/gastrointestinal cancers other than colorectal adenocarcinoma, neuroendocrine cancers).
[2]Patients with melanoma should have received and not tolerated a prior BRAF inhibitor.
[3]Response assessed by BICR using RECIST v1.1 for solid tumors or RANO HGG or LGG for primary CNS tumors. ORR for primary CNS tumors using RANO 2.0 is an exploratory endpoint. Tumors assessed at cycle 1 day 1, every 9 weeks for 48 weeks, then every 12 weeks.
[4]Plasma for all patients; plasma and CSF for patients with primary CNS tumors.

TPS2092 Poster Session

Retifanlimab with bevacizumab and hypofractionated radiotherapy to treat recurrent glioblastoma. First Author: Nishika Karbhari, Mayo Clinic, Rochester, MN

Background: Glioblastoma (GBM) is the most common primary brain malignancy in adults. GBM is universally recurrent and associated with dismal outcomes. Re-irradiation (reRT) is ideal for evaluating combination therapy for recurrent GBM (rGBM) due to its multifactorial mechanism of action, including downstream immunomodulatory activity. RT (especially multi-fraction) increases immunogenicity in preclinical models by promoting immune activation, immune migration, and antigen uptake. Additionally, a recent study demonstrated enhanced PD-L1 expression in the glioma tumor microenvironment (TME) following RT, and combining stereotactic RT with a PD-1 inhibitor improved survival in murine models. Retifanlimab is a humanized monoclonal anti-PD1 IgG4 antibody that received FDA approval for adults with metastatic or recurrent locally advanced Merkel cell carcinoma. Bevacizumab, an anti-VEGF antibody, is a treatment for radiation necrosis/cerebral edema with less immune suppression than corticosteroids. In a previous Phase 2 study, hypofractionated RT (HFRT), retifanlimab, and bevacizumab was associated with a 9-month overall survival (OS) rate of 71.4%. To demonstrate the efficacy of this regimen compared to HFRT and bevacizumab, we have designed a new randomized controlled Phase 2 trial. We hypothesize that combination reRT with retifanlimab will produce a more robust anti-tumor immune response and improve OS compared to reRT without retifanlimab. **Methods:** This is a multicenter, open-label, randomized, controlled Phase 2 study of retifanlimab, bevacizumab, and HFRT for adult patients with rGBM. Patients are randomized 1:1 to the experimental (bevacizumab + retifanlimab + HFRT) or control cohort (bevacizumab + HFRT). Key eligibility criteria include age ≥ 18 years, Karnofsky performance status ≥ 60, ≥ 4 months since administration of any prior bevacizumab, and dexamethasone dose ≤ 4 mg at the time of randomization. The primary endpoint is 9-month OS. Secondary endpoints include OS, progression-free survival, objective response rate, neurologic assessment by NANO criteria, and adverse events profile. Protocol treatment will continue up to two years, or until progression or intolerable toxicity. Survival follow up will continue every two months, up to four years. Seven of the planned 94 patients have been enrolled as of submission on 1/28/25. Clinical trial #: NCT06160206. Funding provided by Incyte. Clinical trial information: NCT06160206. Research Sponsor: Incyte Corporation.

TPS2093 Poster Session

PEAR-GLIO: Clinical evaluation of an AI-driven functional precision medicine platform for therapeutic efficacy in gliomas. First Author: Matthew Williams, Ourotech Ltd t/a Pear Bio, London, United Kingdom

Background: Gliomas and other primary brain tumors remain a leading cause of cancer-related mortality, with limited predictive biomarkers to guide therapy selection. The PEAR-GLIO trial investigates the use of Pear Bio's AI-driven ex vivo platform to assess the therapeutic sensitivity of FDA-approved and experimental treatments on patient-derived 3D immune-microtumors. This observational study seeks to validate whether this platform can provide actionable insights for patient stratification and treatment optimization in subsequent trials. The trial also incorporates patient and public involvement and engagement (PPIE) to understand perspectives and enhance study design and accessibility. **Methods:** PEAR-GLIO (NCT06038760) is a UK-based, observational study enrolling 50 patients diagnosed with operable primary brain tumors, including grades 2–4 gliomas. Inclusion criteria require histologically confirmed malignancy, the ability to provide ≥0.4g of tumor tissue and 40mL of whole blood, and consent for data and sample use. Exclusion criteria include pre-surgical chemotherapy or radiotherapy within 30 days and inoperable disease. Tumour-extracted and immune patient cells are cultured as physiologically-relevant 3D immune-microtumors and exposed to FDA-approved and experimental treatments. Phenotypic and molecular responses, including changes in tumour viability, cell death, migration, immune cell infiltration are assessed using live imaging and computer vision. The study uniquely integrates real-time confocal imaging and omics analyses to evaluate drug mechanisms of action. This includes correlation of ex vivo responses with biomarkers such as MGMT methylation, IDH mutation, and 1p/19q co-deletion, alongside exploratory analysis of experimental therapies. Recruitment began in October 2023, with 12 patients of the target 50 enrolled thus far. Data from the first cohort will inform platform optimization and scalability. All biological samples are anonymized, with outcomes tracked per RANO guidelines. Even at this early stage, PPIE has helped improve trial design. We are concurrently validating the platform in other high-unmet-need indications including early-stage breast cancer (NCT05435352), metastatic breast cancer (NCT06182306) and metastatic kidney cancer (NCT06264479) hoping to shift the paradigm in precision treatment selection. Clinical trial information: NCT06038760. Research Sponsor: Ourotech (t/a Pear Bio).

TPS2094 **Poster Session**

A multicenter, pivotal trial of microbubble-enhanced transcranial focused ultrasound (MB-FUS) for plasma-based liquid biopsy in patients with glioblastoma (LIBERATE). First Author: Manmeet Singh Ahluwalia, Miami Cancer Institute, Baptist Health South Florida, Miami, FL

Background: Liquid biopsy in glioblastoma (GBM) is hindered by a lack of requisite circulating tumor (ct) and cell-free (cf) DNA levels in blood due to the blood-brain barrier (BBB). This limits the identification of blood-based tumor biomarkers along with the development and use of biomarker-driven systemic therapies. Low intensity focused ultrasound combined with intravenously administered microbubble oscillators (MB-FUS), leads to non-invasive BBB opening. This trial aims to evaluate the utility of LIFU for bolstering blood ctDNA and cfDNA for enhance liquid biopsy in patients with GBM. **Methods:** LIBERATE is an ongoing, prospective, multi-center, self-controlled, pivotal trial evaluating safety and technical efficacy of transcranial MR-guided MB-FUS for increasing blood ctDNA and cfDNA levels in adults, aged 18-80 years with GBM. Patients with suspected GBM planned for tumor biopsy or resection at 17 centers in US and Canada are being enrolled. Patients with multifocal tumors or tumors arising from deep midline, thalamus, cerebellum, or brainstem are excluded. Patients are administered IV microbubbles for enhanced sonication, after which MR-guided BBB opening using a 220 kHz device, with 1024-element phased array transducer, is performed with real-time acoustic feedback control for effective cavitation. Pre- and post-procedure, phlebotomy and MRI brain are done. Patients are offered optional 2nd procedure during adjuvant chemotherapy phase if willing. Primary efficacy endpoint is correlation between biomarker patterns in tumor tissue collected during surgery/biopsy and blood collected following MB-FUS procedure. Confirmatory secondary efficacy endpoint is ratio between greatest yield of cfDNA in blood post-MB-FUS compared to cfDNA level in blood pre-MB-FUS. The primary study hypothesis is that agreement rate on biomarker pattern between resected/biopsied tumor tissue and blood is $>$ 70%. The secondary hypothesis is that MB-FUS BBBO leads to a $\geq$2-fold rise in blood cfDNA. Assuming the true agreement rate expected is 89%, a sample of N = 50 patients will provide 90% power to meet the primary endpoint (Exact test, Binomial Proportion, one-sided Alpha = 0.025). Exploratory endpoints include (1) sensitivity of detection of known specific somatic mutations in ctDNA from blood samples collected before and after MB-FUS, (2) estimation of ctDNA levels in samples collected at 30-minutes, 1-hour, 2-hour, and 3-hour post-MB-FUS to determine time of greatest yield, (3) correlation of MRI parameters related to grading of BBB opening and ctDNA-based biomarkers from post-MB-FUS blood samples, (4) biomarker correlation between plasma cfDNA sampled during adjuvant chemotherapy phase and tumor tissue harvested at surgery. Patient enrollment commenced in 2022 and is ongoing (NCT05383872). Clinical trial information: NCT05383872. Research Sponsor: Insightec Inc.

TPS2095 **Poster Session**

Liposomal curcumin and standard radiation and temozolomide for newly diagnosed high-grade gliomas: A phase 1/2 study. First Author: Matthias Holdhoff, Sidney Kimmel Comprehensive Cancer Center at Johns Hopkins, Baltimore, MD

Background: Curcumin, derived from turmeric (Curcuma spp.), exhibits anti-inflammatory and antitumoral activity in preclinical studies, including inducing cell cycle arrest, apoptosis, autophagy and disrupting key cancer signaling pathways (e.g., STAT-3, AKT, VEGF, NF-κB, and IDO). Despite its promise, oral curcumin has limited bioavailability. Liposomal curcumin (LC), a novel intravenous formulation, achieves plasma curcumin levels over 1000 times higher than oral administration and preferentially accumulates in tumor cells. In preclinical glioma models, LC has antitumoral efficacy, particularly when combined with cytotoxic therapies. Previous trials in healthy volunteers and cancer patients demonstrated LC's safety, pharmacokinetics, and manageable adverse effects, with doses up to 300 mg/m² being well-tolerated. However, a case of hemolytic anemia was observed in a prior study at this dose in a patient who was also taking several known hemolytic drugs, suggesting the need for further safety evaluation at this and potentially higher doses. **Methods:** This Phase I/II open-label, study evaluates LC combined with standard radiation (RT) and concomitant and adjuvant temozolomide (TMZ) in newly diagnosed HGG patients (NCT05768919). The primary endpoints are MTD, RP2D and safety. Secondary endpoints include treatment feasibility ($\geq$80% adherence to LC, RT, and $\geq$60% to TMZ), and exploratory efficacy measures (PFS, OS by RANO criteria). The study has two phases: (1) dose-escalation using the TITE-BOIN method to determine MTD, and (2) dose-extension to evaluate RP2D safety and feasibility. Up to 50 patients will be screened to enroll 30. LC is given weekly at 4 dose levels (240, 300, 350, and 400 mg/m²) alongside standard adjuvant TMZ (150–200 mg/m² x 5 days every 28 days) and RT. Treatment continues for up to 6 TMZ cycles, with LC monotherapy possible afterward until progression or toxicity. MRI is done before and 4 weeks post-chemoradiation, then every 2 cycles of TMZ, as per standard of care. DLTs are evaluated over 10 weeks to determine the MTD which will be determined by TITE-BOIN dose escalation rule and Safety Review Committee's guidance. A separate exploratory protocol is offered to patients interested in additional imaging, which uses chemical exchange saturation transfer (CEST) MRI to visualize liposome accumulation in tumor tissue non-invasively. As of 1/24/2025, 14 patients have been enrolled in the dose-escalation part of this study. Clinical trial information: NCT05768919. Research Sponsor: SignPath Pharma.

TPS2096 **Poster Session**

A global phase 3, open-label, randomized 2-arm study comparing the clinical efficacy and safety of niraparib with temozolomide in adult participants with newly-diagnosed, MGMT unmethylated glioblastoma. First Author: Nader Sanai, Ivy Brain Tumor Center at Barrow Neurological Institute, Phoenix, AZ

Background: Glioblastoma (GBM) is associated with dismal prognosis and poor quality of life. In approximately 60% of tumors, the O6-methylguanine methyltransferase (MGMT) promoter is unmethylated and the prognosis is even more dire, with a median overall survival (OS) of 12.7 months following surgical resection, temozolomide (TMZ), and fractionated radiotherapy (RT). Poly (ADP-ribose) polymerase (PARP) mediates DNA damage response in GBM and niraparib is an investigational PARP1/2-selective inhibitor. At ASCO 2024, we reported on a Phase 0/2 study of niraparib plus radiotherapy in newly-diagnosed, MGMT-unmethylated glioblastoma (GBM), demonstrating superior tumor pharmacokinetic and pharmacodynamic performance compared to other studied PARP inhibitors and a median overall survival (OS) of 21.7 months. Based on the proof-of-concept data, a global registrational Phase 3 study (Gliofocus) was initiated. **Methods:** This Phase 3, open-label, randomized 2-arm study (NCT06388733) will compare niraparib versus TMZ in 450 adult participants with newly-diagnosed, MGMT-unmethylated GBM. Participants must have a biopsied or resected GBM, per 2021 World Health Organization classification. MGMT promoter methylation status is determined locally by validated pyrosequencing or quantitative methylation-specific polymerase chain reaction assays. Other key inclusion/exclusion criteria include: (1) Karnofsky performance status of $\geq$70, (2) no prior treatment for GBM (including brachytherapy or BCNU wafers), (3) no tumor-treating field therapy, and (4) suitability for RT of 60 Gy in 30 fractions using ESTRO-EANO 'single phase' targeting approach. Following 1:1 randomization, niraparib (Arm A) or TMZ (Arm B) is administered concomitantly with RT and then adjuvantly until disease progression by Blinded Independent Central Review (BICR) or until completion of 6 cycles of TMZ. . The primary endpoints of the study are progression-free survival (PFS) (per RANO 2.0; HR = 0.612, 90% power, 1-sided alpha = 0.001) and overall survival (OS) (HR = 0.698, 90% power, 1-sided alpha = 0.0239). Secondary endpoints include overall response rate, health-related quality of life, neurocognitive function, and the safety and tolerability of niraparib compared to TMZ. The first patient was accrued in June 2024 and an interim futility analysis is planned in 2025. This study, sponsored by the Ivy Brain Tumor Center and with drug and funding provided by GSK, is expected to enroll in a minimum of 115 clinical sites across 11 countries. Clinical trial information: NCT06388733. Research Sponsor: GSK.

TPS2097 **Poster Session**

Personalized targeted glioblastoma therapies by *ex vivo* drug screening: Advanced brain tumor therapy clinical trial (ATTRACT). First Author: Anna Sophie Berghoff, Division of Oncology, Department of Medicine I, Medical University of Vienna, Vienna, Austria

Background: Targeted therapies used in a personalized treatment concept have revolutionized the management of several solid cancers. So far, various clinical trials aiming to introduce the concept of personalized targeted therapies in glioblastoma have failed, as no clinically meaningful responses were observed. Importantly, most clinical trials investigating molecular targeted therapies included all-comers and concentrated on genetic biomarkers to predict treatment response. Given the biological complexity of glioblastoma, genetic biomarkers might give only an insufficient insight into the response of a given patient, and more personalized approaches are warranted. As novel approaches to guide personalized treatment in glioblastoma are urgently needed, we designed a prospective clinical trial to investigate the novel approach of cultivated patient-derived tumor cells (PDCs) for *ex vivo* drug screening. **Methods:** In this randomized phase 2 study, we are testing the ability of PDC-based *ex vivo* drug screening to formulate a personalized recommendation for maintenance treatment in patients with newly diagnosed glioblastoma with unmethylated MGMT promoter after neurosurgical resection followed by combined radio-chemotherapy. Based on overall survival as the primary endpoint, we plan to include 240 patients (120 per group) to show with a power of 80% that we can increase the median survival from 12 to 17 months (hazard ratio 0.7). Patients are randomized 1:1 to either the standard group (no drug screening) or the intervention group (drug screening and personalized recommendation for maintenance treatment). In the intervention group, automated drug screening is performed on PDCs with 28 drugs used for treatment of solid tumors and hematological malignancies. Based on the cytotoxic/cytostatic activity of these drugs, as quantified by relative viability based on adenosine triphosphate levels, a molecular tumor board recommends a personalized treatment regimen. The first patient was enrolled in July 2024. Interim analysis of the ATTRACT study (NCT06512311) is expected in late 2027, and final results in 2030. Moreover, the clinical trial is accompanied by a comprehensive translational research program to gain insights into the biological underpinnings of treatment response in glioblastoma. Clinical trial information: NCT06512311. Research Sponsor: Ludwig Boltzmann Society.

TPS2098 **Poster Session**

Trial in progress: Feasibility of CSF and plasma ctDNA in BRAF-altered glioma during treatment with plixorafenib. First Author: Karisa C. Schreck, Sidney Kimmel Comprehensive Cancer Center at Johns Hopkins, Baltimore, MD

Background: Gliomas with BRAF alterations are often difficult to treat in the recurrent setting due to emergent resistance to FDA-approved targeted therapies. Additionally, it can be difficult to assess response to treatment given the limitations of radiographic techniques and the infeasibility of serial tissue sampling. This protocol serves as a prototype for determining the feasibility of using CSF and plasma circulating tumor DNA (ctDNA) as biomarkers for response to a novel-BRAF inhibitor, plixorafenib. Plixorafenib is a small-molecule selective inhibitor of BRAF-V600E and BRAF-fusion alterations that does not induce paradoxical reactivation of MAPK signaling. **Methods:** This study is a single institution trial of plixorafenib in patients (18+ years of age) with BRAF-V600E mutant glioma following progression on prior BRAF-targeted therapy who are recommended for a clinically-indicated diagnostic or debulking surgery. Eligible patients have recurrent BRAF-V600E mutant glioma (any grade) with measurable disease (by RANO 2.0), have a Karnofsky performance status >70, and are able to undergo surgery. Leptomeningeal disease is allowed. A total of 12 evaluable patients will be enrolled. Enrolled patients undergo clinically-indicated resection or biopsy for confirmation of disease progression and characterization of putative resistance alterations. All patients have a ventricular reservoir placed at time of surgery with CSF and plasma sampling. Patients will initiate oral plixorafenib 900mg daily with cobicistat, a CYP3A inhibitor and PK enhancer, when clinically recovered from surgery. Patients will take the drug continuously under fasting conditions. MRI, CSF, and plasma assessments will occur approximately every two months to evaluate disease status. The primary endpoint is proportion of samples with detectable tumor ctDNA baseline and after one month of treatment with plixorafenib. Secondary endpoints include the correlation of ctDNA with disease status over time and response rate to plixorafenib. The trial is IRB approved and currently open to enrollment. Clinical trial identifier NCT06610682. Clinical trial information: NCT06610682. Research Sponsor: Ivy Brain Tumor Foundation; Fore Biotherapeutics.

TPS2099 **Poster Session**

Neuro-oncology anywhere 242: Pilot study evaluating telehealth and in-person assessments in patients with glioma receiving oral chemotherapy—Clinical trial in progress. First Author: Ugur Sener, Division of Neurology, Mayo Clinic, Rochester, MN

Background: Gliomas are the most common primary central nervous system (CNS) malignancy in adults, accounting for 26.3% of all brain tumors. Care at high volume centers is associated with an overall survival benefit, but access to in-person evaluations can be challenging due to disease-related neurological disability and loss of income. Telehealth represents a convenient and efficient alternative to in-person evaluations, but acceptability and comparative safety of this care delivery modality has not been prospectively evaluated among glioma patients undergoing chemotherapy. **Methods:** This single-arm non-randomized pragmatic clinical trial evaluates patient satisfaction with, and safety of video-enabled telehealth assessments compared to in-person evaluations for patients with glioma undergoing temozolomide chemotherapy. The study includes adult patients with a diagnosis of glioma requiring adjuvant temozolomide chemotherapy. Participants act as their own controls, alternating between in-person and telehealth assessments while undergoing chemotherapy dosed per standard of care. Monitoring labs are completed locally and transmitted electronically. For participants without access to Wi-Fi or a device (e.g. mobile phone or computer), cellular-enabled tablet devices are provided to facilitate appointments and completion of electronic study components. All participants who travel to in-person appointments are reimbursed for travel expenses. The primary outcome measure is patient satisfaction with care delivered, as measured by institutional Press-Ganey survey scores obtained following telehealth and in-person assessments. A key secondary outcome measure is completion rate of planned oral chemotherapy, tracked using a digital pill diary incorporated into our institutional electronic health record. The digital diary allows real-time tracking of chemotherapy adherence and adverse events experienced by participants. Other secondary outcomes include acute care utilization days following telehealth and in-person visits (defined as emergency department evaluations and days of inpatient stay), neurologic disability as measured by the Neurologic Assessment in Neuro-Oncology (NANO) scale, and disease related quality of life measured by the EORTC QLQ-C30. All participant surveys are self-reported and completed electronically. This decentralized pragmatic clinical trial provides unprecedented, prospective real-world data on utilization of telehealth services compared to in-person visits for patients undergoing chemotherapy for glioma. We expect the data generated to inform the design and conduct of future decentralized interventional neuro-oncology trials. NCT06625047 opened for enrollment in October 2024, 16 of 30 intended participants were accrued as of January 2025. Clinical trial information: NCT06625047. Research Sponsor: Mayo Clinic.

TPS2100 **Poster Session**

Update on GBM AGILE: A global, phase 2/3 adaptive platform trial to evaluate multiple regimens in newly diagnosed and recurrent glioblastoma. First Author: Emma Maria Viktoria Hyddmark, Global Coalition for Adaptive Research, Larkspur, CA

Background: GBM AGILE (Glioblastoma Adaptive, Global, Innovative Learning Environment) is a biomarker based, multi-arm, international, seamless Phase 2/3 response adaptive randomization platform trial designed to efficiently identify investigational therapies that improve overall survival and confirm efficacious therapies and associated biomarker signatures to support drug approvals and registration. GBM AGILE is a collaboration between academic investigators, patient organizations, and industry to support new drug applications for newly diagnosed and recurrent glioblastoma. **Methods:** The primary objective of GBM AGILE is to identify therapies that improve overall survival in patients with newly diagnosed or recurrent glioblastoma. Operating under a Master Protocol, GBM AGILE allows multiple drugs from different pharmaceutical/biotech companies to be evaluated simultaneously and/or over time against a common control. New investigational therapies are added as new information about promising drugs is identified, while other therapies are removed as they complete evaluation. Bayesian response adaptive randomization is used within subtypes of the disease to assign participants to investigational arms based on their performance. GBM AGILE has screened over 2300 patients and enrollment continues to be robust. An estimated 25% of all US glioblastoma patients enrolled in clinical trials participate in GBM AGILE. The trial is open at select sites in the United States, Canada, Switzerland, France, Germany, and Australia. In addition to the efficient evaluation of investigational arms, a primary goal of GBM AGILE is to expand knowledge of glioblastoma to support advancements in treatment using the data collected within the trial (learning environment). Over 7 million data points are currently available for inclusion in the development of a longitudinal model. Such a model may be able to inform randomization by providing earlier and continuous information regarding patient and arm performance. In addition, serial magnetic resonance imaging scans and biospecimens from baseline through patient progression are being collected for further analysis. An initial 500 baseline tissue samples are being characterized using whole genome sequencing and whole transcriptome analysis. Clinical trial information: NCT03970447. Research Sponsor: None.

TPS2101 **Poster Session**

Dual targeting of VEGF and PD-1: A phase I/II trial of ivonescimab, a novel bispecific antibody, in recurrent glioblastoma. First Author: Anuj Dilip Patel, University of Texas MD Anderson Cancer Center, Houston, TX

Background: Patients with recurrent glioblastoma have limited effective treatment options due to the highly immunosuppressive microenvironment and rapid proliferation fueled by neoangiogenesis. Anti-angiogenic therapy, including targeting vascular endothelial growth factor (VEGF) with bevacizumab, and immune checkpoint inhibition with programmed cell death protein 1 (PD-1) inhibitors, have independently had limited efficacy in these tumors. Ivonescimab is a humanized tetravalent bispecific antibody against PD-1 and VEGF, which has demonstrated cooperative binding *in vitro* leading to increased binding of PD-1 in the presence of VEGF and vice-versa[1]. Ivonescimab has shown activity in multiple phase 3 trials conducted in China in non-small cell lung cancer, including one trial which demonstrated activity in patients with brain metastases, but has not yet been evaluated in patients with primary brain tumors. This trial evaluates ivonescimab in patients with recurrent glioblastoma. **Methods:** This investigator-initiated study consists of a phase I and II component; the primary objectives are safety and tolerability for phase I and determining progression-free survival for phase II. The phase I component evaluates 3 dose levels of ivonescimab (7.5, 10, and 20 mg/kg every 3 weeks), employing a Bayesian optimal interval (BOIN) design for assessing toxicity. Once the recommended phase II dose is determined, the phase II portion will follow a Bayesian optimal phase II (BOP2) design, with interim analyses at pre-specified enrollment points allowing for monitoring of efficacy as well as ongoing evaluation of toxicity. The maximum accumulative sample size at the target dose will be 30 patients. Radiographic assessment will utilize the Response Assessment in Neuro-Oncology 2.0 criteria. Key eligibility criteria include adults with recurrent glioblastoma, IDH-wildtype (by WHO CNS 2021 classification) at first or second recurrence with Karnofsky Performance Scale ≥ 60 and normal blood counts and organ function. Prior therapy with anti-angiogenic agents (including bevacizumab) or checkpoint inhibitors is excluded, as well as concurrent corticosteroids $\geq$ 2 mg/day dexamethasone or equivalent. Samples of archival tumor, blood and stool microbiome will be collected for correlative studies as an exploratory evaluation of predictive biomarkers of response or resistance to ivonescimab. The study has been approved by the institutional review board and accrual to phase I will commence in the first quarter of 2025. 1. Zhong T, Huang Z, Pang X, et al. 1194 Mechanism of action of ivonescimab (AK112/SMT112): a first-in-class tetravalent Fc-silent bispecific antibody with dual blockade of PD-1 and VEGF that promotes cooperative biological effects. Journal for ImmunoTherapy of Cancer 2023;11: doi: 10.1136/jitc-2023-SITC2023.1194. Clinical trial information: NCT06672575. Research Sponsor: Summit Therapeutics.

TPS2102 **Poster Session**

Regorafenib versus local standard of care in patients with grade 2-3 meningioma no longer eligible for loco-regional treatments: The MIRAGE trial.

First Author: Alberto Bosio, Veneto Institute of Oncology IOV, IRCCS, Padua, Italy

Background: Meningiomas are the most common intracranial tumors. Standard treatment involves surgical resection with curative intent. When gross total resection is not achievable, or in case of recurrence, RT is frequently utilized. On the other hand, the role of systemic treatments remains poorly supported by evidence.Regorafenib is an oral multi-tyrosine kinase (RTK) inhibitor. It exhibits high selectivity for VEGFR1/2/3, while also inhibiting PDGFRβ, FGFR1, and c-RAF/RAF1 and BRAF pathways, highly expressed in high-grade meningiomas. **Methods:** TheMIRAGE Trial (NCT06275919) is a multicenter, open-label, randomized phase 2 clinical trial evaluating grade 2/3 meningioma pts who have progressed following surgery and RT. A total of 94 pts are being randomized (1:1) to receive either Regorafenib (160 mg orally for 3 weeks on, 1 week off) or local standard-of-care therapies (e.g., bevacizumab, hydroxyurea, somatostatin analogues).Major inclusion criteria include histological confirmation of WHO 2021 grade 2-3 meningioma, radiologically documented progression at least 24 weeks from RT (estimated planar growth $>$ 25% in two dimensional tumor areas within the prior 12 months or development of a new lesion) with at least 1 measurable lesion (minimum 10 x 10 mm) on baseline MRI, ineligibility for further surgery and/or radiotherapy, absence of extracranial lesions and a WHO performance status of 0-1.The primary endpoint is 6-month PFS (6m-PFS). Assuming a 6m-PFS of 20% in the control arm and 40% in the regorafenib arm (corresponding to a HR = 0.57) with a = 5%, b = 85%, 104 patients are needed to assess the targeted efficacy. Response to treatment will be assessed by using RANO criteria. Secondary endpoints include OS, ORR, DCR, volumetric analysis of the target lesions, safety and health-related quality of life. Multi-omics exploratory analysis will also be performed to investigate possible prognostic and predictive biomarkers. Radiomics analysis will also be performed. MIRAGE, initiated in September 2024, is an academic trial promoted by the Istituto Oncologico Veneto, IOV-IRCCS and will recruit patients across 15 neuro-oncology Centers in Italy with an estimated study duration of 18 months. Discussion: MIRAGE is the first randomized phase 2 trial analyzing the role of a RTK inhibitor (regorafenib) in prolonging PFS in pts with grade 2-3 meningioma who are ineligible for further surgery and/or radiotherapy. Clinical trial information: NCT06275919. Research Sponsor: None.

2500 Oral Abstract Session

Assessment of efficacy of LBL-024, a novel and uniquely designed bispecific antibody against PD-L1 and 4-1BB, combined with etoposide/platinum-based chemotherapy in treatment-naive advanced extrapulmonary neuroendocrine carcinoma (EP-NEC): A multicenter phase Ib/II trial. First Author: Ming Lu, Peking University Cancer Hospital /Beijing GoBroad Hospital, Beijing, China

Background: The prognosis for patients with EP-NEC is very poor. A recognized 1L treatment for advanced disease is etoposide/platinum-based chemotherapy with no standard 2L/3L treatment. LBL-024 blocks the immunosuppressive pathway of tumor cells by targeting PD-L1 and effectively co-stimulates T cells by targeting 4-1BB, to improve the anti-tumor immune response. Here we report the safety and efficacy of LBL-024 combined with etoposide and cisplatin or carboplatin (EP/EC) as first line treatment in patients with advanced NEC. (NCT06157827). **Methods:** This is a phase Ib dose escalation and phase II dose optimization/expansion clinical trial. Phase Ib enrolled previously untreated advanced EP-NEC and SCLC patients, phase II enrolled previously untreated advanced EP-NEC patients. Three dose levels of LBL-024 (6, 10 and 15 mg/kg, i.v. Q3W) plus EP/EC in phase Ib were evaluated, 2 dose levels (6 and 15 mg/kg, i.v. Q3W) of LBL-024 plus EP/EC were evaluated in a randomized dose optimization. The primary endpoints were tolerability, safety, efficacy (RECIST 1.1) and RP2D, the secondary endpoints were PK, PD and ADA. **Results:** As of December 26, 2024, a total of 53 patients were enrolled, with 13 patients in Phase Ib and 40 patients in dose optimization stage of Phase II. Phase Ib included 2 patients with SCLC, 1 with MiNEN, and 10 with EP-NEC. All 40 patients in Phase II were EP-NEC. During the Dose escalation stage, no DLTs were observed. During the Dose optimization stage, 15 mg/kg of LBL-024 was selected as RP2D based on PK/PD, efficacy, safety and ER analysis. Out of 49 patients, the ORR across all dose levels is 77.6% and the DCR is 93.9% among which 9 patients were unconfirmed. The ORR in 21 EP-NEC patients at RP2D dose is 81.0% and DCR is 95.2% among which 3 patients were unconfirmed. Additionally, 2 patients with SCLC achieved 100% ORR. LBL-024 TRAEs of all-grade occurred in 53 patients (100%), with grade ≥3 TRAEs in 17/53 patients (32.1%). **Conclusions:** LBL-024 combined with chemotherapy was well-tolerated. The extremely improved response observed in EP-NECs is significantly higher than the historic reports (about 30%~55%). Data including ER analysis of this ongoing study will be updated by a follow-up submission to ASCO. Clinical trial information: NCT06157827. Research Sponsor: None.

Clinical benefits of first line treatment in evaluable patients bin phase Ib/II.

2501 Oral Abstract Session

First-in-human phase I/II trial evaluating BNT142, a first-in-class mRNA encoded, bispecific antibody targeting Claudin 6 (CLDN6) and CD3, in patients (pts) with CLDN6-positive advanced solid tumors. First Author: Timothy A. Yap, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: CLDN6 is an oncofetal cell surface protein silenced in normal adult tissues but aberrantly activated in testicular, ovarian, non-small cell lung (NSCLC) and other cancers. The investigational therapeutic BNT142 is a novel lipid nanoparticle (LNP)-encapsulated mRNA encoding the anti-CLDN6/CD3 bispecific antibody RiboMab02.1. After intravenous administration, BNT142 RNA-LNPs are taken up by liver cells and are translated into RiboMab02.1. The first results of the dose escalation part of the BNT142-01 trial testing 7 dose levels (DL) are presented here. **Methods:** BNT142-01 (NCT05262530) is a Phase I/II, open-label, multi-center trial to evaluate weekly BNT142 treatment with premedication (antipyretics, antihistamines, fluids) at the investigators' discretion in pts with CLDN6+ (≥10% of cells with at least weak membrane positivity) advanced solid tumors. Primary objectives include safety, tolerability and identifying the recommended Phase 2 dose (RP2D), secondary and exploratory objectives include pharmacokinetics, pharmacodynamics and preliminary efficacy (RECIST 1.1). **Results:** As of 02 Dec 2024, 65 pts (median age 57 years [range 18 – 79]; 75% female; 60% ECOG 1; 44 ovarian, 10 testicular, 5 NSCLC, 6 rare cancers) received ≥1 dose (median 7, range 1 – 38) of BNT142. Of 65 pts, 46 (71%) had ≥4 prior lines of systemic therapy. Mostly mild to moderate treatment-related adverse events (TRAEs) occurred in 41 (63%) pts, including 15 (23%) pts with ≥G3 TRAEs. Most common (≥10%) TRAEs were cytokine release syndrome (CRS) in 14 (22%) pts (1 pt [2%] ≥G3), aspartate or alanine aminotransferase (AST, ALT) increased in 12 (19%) pts (8 pts [12%] ≥G3), and pyrexia, chills or fatigue in 8 (12%) pts (0/0/2 pts [0%/0%/3%] ≥G3, respectively). TRAEs leading to dose reduction, treatment interruption or discontinuation occurred in 1 (2%), 12 (19%) or 2 pts (3%), respectively (mostly G3; most common related terms AST or ALT increased and infusion related reaction). Two (3%) pts had a dose limiting toxicity (G4 ALT increased [DL5], leading to dose reduction, and G5 CRS [DL6]). BNT142 led to transient, dose-dependent increases in inflammatory cytokines. Translated RiboMab02.1 was detected in serum in a dose-dependent manner, peaking 24 – 72 h post-dose. Across all DLs, the disease control rate (DCR) was 58% with a tendency of higher efficacy in the higher DLs. In ovarian cancer, there were 7 RECIST 1.1 partial responses (PRs) and the DCR was 75%. **Conclusions:** BNT142 demonstrated a manageable safety profile and promising anti-tumor activity at the higher DLs, with 7 RECIST 1.1 PRs in CLDN6+ ovarian cancer, a tumor usually refractory to immunotherapy. We provide the first clinical proof-of-concept for an mRNA encoded bispecific antibody. Dose optimization is ongoing. Clinical trial information: NCT05262530. Research Sponsor: BioNTech SE.

2502 Oral Abstract Session

Efficacy and safety results of a first-in-class PD-1/IL-2$^{\alpha\text{-bias}}$ bispecific antibody fusion protein IBI363 in patients (pts) with immunotherapy-treated, advanced acral and mucosal melanoma. First Author: Bin Lian, Peking University Cancer Hospital & Institute, Beijing, China

Background: Despite great success of immunotherapy (IO) in advanced melanoma, there remains an unmet clinical need for resistant tumors. Pts with acral and mucosal melanomas show limited benefit from current therapies. IBI363, a first-in-class PD-1/IL-2$^{\alpha\text{-bias}}$ bispecific antibody fusion protein that blocks PD-1 and activates α-bias IL-2 to rejuvenate exhausted tumor-specific T cells, has shown encouraging efficacy in pts with advanced melanoma. Here, we present results of IBI363 from a phase 1 study (NCT05460767) and a phase 2 study (NCT06081920) of pts with IO-treated, advanced acral and mucosal melanoma. **Methods:** Eligible pts with IO-treated advanced acral and mucosal melanoma were enrolled. IBI363 was administered intravenously at 0.1 mg/kg every week, 0.3/0.6/1 mg/kg every 2 weeks (Q2W), or 1/1.5/2/3 mg/kg every 3 weeks (Q3W). Primary endpoints for the phase 1 study were dose-limiting toxicity (DLT) and safety, and for the phase 2 study were safety and investigator-assessed objective response rate (ORR), disease control rate (DCR), duration of response (DoR) and progression-free survival (PFS) according to RECIST v1.1. **Results:** As of December 6, 2024, 91 pts were enrolled across the phase 1 (n = 76) and phase 2 (n = 15) studies (male: 47%; median age: 57 years; Asian: 100%; ECOG PS 1: 66%; stage IV: 89%); 47 pts had acral melanoma and 44 had mucosal melanoma. Median follow-up time was 8.2 months. Median treatment duration was 13.4 weeks (range: 2.0-72.4). Treatment-emergent adverse events (TEAEs) occurred in 90/91 (98.9%) pts including 27 (29.7%) pts with grade ≥3 (≥G3) TEAEs. TEAEs led to treatment discontinuation in 3 (3.3%) pts, and 1 (1.1%) pt had a TEAE leading to death which was considered to be treatment-related (sepsis). Most common TEAEs were arthralgia (59.3%, with 4.4% ≥G3), rash (42.9%, with 3.3% ≥G3), and anemia (42.9%, with 2.2% ≥G3). Among all pts with at least one post-baseline tumor assessment (n = 87), 1 pt had a complete response, 22 had partial responses, 33 had stable disease, 31 had progressive disease. ORR was 26.4% (95% CI: 17.6-37.0) with 16 responses confirmed and 2 pts still waiting for confirmation; DCR was 64.4% (95%CI: 53.4-74.4). Among pts treated at 1mg/kg and above (n = 74), the ORR was 28.4% (95%CI: 18.5-40.1) and DCR was 68.9% (95%CI: 57.1-79.2). Patients treated at 1 mg/kg Q2W (n = 30) had median DOR 14.0 months with a median follow-up of 9.1 months and 50.0% events; the median PFS was 5.7 (95% CI, 3.6-6.7) months with a median follow-up of 11.0 months and 73.3% events. **Conclusions:** IBI363 showed encouraging efficacy in pts with IO-treated advanced acral and mucosal melanoma. The safety profile was acceptable and manageable. Further global clinical development of IBI363 in melanoma is ongoing. Clinical trial information: NCT05460767 and NCT06081920. Research Sponsor: Innovent Biologics (Suzhou) Co., Ltd.

2503 Oral Abstract Session

A therapeutic vaccine for fibrolamellar hepatocellular carcinoma. First Author: Marina Baretti, Johns Hopkins Sidney Kimmel Comprehensive Cancer Center, Baltimore, MD

Background: Fibrolamellar hepatocellular carcinoma (FLC) is a rare form of liver cancer affecting children and young adults that is driven by a chimeric protein, DNAJ-PKAc. The development of molecular inhibitors of DNAJ-PKAc has been hampered by unacceptable on-target toxicity, but the chimera results in a tumor-specific antigen (neoantigen) that may be targeted immunologically. **Methods:** We conducted a phase 1 clinical trial of a therapeutic vaccine targeting DNAJ-PKAc (FLC-Vac), in combination with nivolumab and ipilimumab, in children and adults with advanced FLC. The primary objectives were safety and T cell responses, defined as 2.5-fold increase of interferon gamma (IFN-γ)-producing DNAJB1-PRKACA chimera-specific T cells in the peripheral blood after week 10 (priming phase). The study was planned with 12 evaluable patients. FLC-Vac, consisting of a peptide encoding the DNAJB1-PRACA fusion plus poly-ICLC adjuvant, was administered on weeks 0, 1, 2, 3, 6, 9 during the priming phase of the study. Nivolumab, 3 mg/kg, followed by ipilimumab, 1 mg/kg, was administered every 3 weeks for 4 doses during the priming phase. After completion of the priming phase, FLC-Vac and nivolumab were continued in maintenance. Key exclusion criteria include age < 12 years and prior treatment with immune checkpoint inhibitors. The trial incorporated a safety lead-in portion in which the first 3 patients received vaccine monotherapy for 3 weeks prior to receiving combination therapy. **Results:** Among 16 patients enrolled, 12 completed the vaccine priming phase and were evaluable for both immunological and clinical endpoints. The median age was 24 years (range: 12-47). Grade 3 treatment-related adverse events were reported by six patients (37.5%). DNAJ-PKAc-specific T cell responses were detected in 9/12 patients after treatment. In the subset of patients who completed the initial priming phase the disease control rate (DCR) was 75% (9/12), with three partial responses (25%). All 3 responding patients are without evidence of active cancer after undergoing surgical debulking of residual disease. All patients with clinical responses also had DNAJ-PKAc-specific T cell responses, from whom we identified multiple class II-restricted T cell receptors (TCRs) with specificity for DNAJ-PKAc. Correlates of response included both functional neoantigen reactivity and changes in TCR repertoire features over time. In two patients who experienced eventual progression after initial clinical response, we found evidence that the loss of efficacy was likely due to T cell exhaustion, and in one case was restored with checkpoint rechallenge. **Conclusions:** Our findings demonstrate the potential for therapeutic vaccines targeting DNAJ-PKAc in FLC and suggest a rubric for evaluating effective anti-neoantigen immunity. Clinical trial information: NCT04248569. Research Sponsor: ASCO CDA (Dr Yarchoan); Fibrolamellar Cancer Foundation; BMS; R01-CA265009.

Clinical responses to SYNC-T therapy: In situ personalized cancer vaccination with intratumoral immunotherapy in patients with metastatic castration-resistant prostate cancer (mCRPC). First Author: Charles J. Link Jr., Lankenau Institute for Medical Research, Wynnewood, PA

Background: Metastatic castration-resistant prostate cancer (mCRPC) has a poor response to immunotherapy limited by both a low ORR and high frequency of severe immune-related adverse events. SYNC-T is a novel *in situ* therapy that synchronizes the presence of tumor antigens, an immune therapy drug, and immune cells in the tumor and locoregional lymph nodes. SYNC-T Therapy combines device-induced partial cryolysis of a targeted tumor to create a personalized multi-antigen vaccine, followed immediately by intratumoral infusion of the multitarget novel drug candidate SV-102, leading to T-cell activation and an effective systemic immune response. **Methods:** 15 subjects, 13 with bone metastases, and documented failure to prior hormonal therapy (n = 10) or refused therapy (n = 5) were recruited to a single-arm study (NCT05544227). Image-guided partial cryolysis of a tumor was followed by intratumoral infusion of SV-102, comprised of fixed low dose of anti-PD-1 mAb, anti-CTLA4 mAb, CD40 agonist mAb, and TLR9 agonist CpG-ODN. All subjects received the same dose of SV-102. Subjects received SYNC-T Therapy q4 weeks for up to 12 cycles (median = 6). One site of primary prostate or soft tissue metastasis was targeted at each cycle. Primary objective was to evaluate safety and tolerability with a secondary objective to assess tumor response by PCWG3 and RECIST 1.1. **Results:** 15 subjects were treated and evaluable. Median age was 61 (48-74). Prior treatments included one or more of 1st, 2nd generation hormonal blockade, chemotherapy, immunotherapy, or radiation therapy. Within 15 evaluable subjects there were 8 radiographic CRs (53%, the two-sided 95% CI is 29.4% to 78.7%, rejecting 20% CR null hypothesis; p = 0.0085) with complete resolution of primary, bone, and soft tissue metastases and 5 PRs with an ORR of 87%. Median time to response was 3 months with a median duration of 12 months to date (range 1.2 -14.6). Among the 15 subjects, 3 have died resulting in 80% survival with 14 months median follow-up. SYNC-T Therapy was well-tolerated with 41 TEAEs in 13 subjects. The majority (95%) of TEAEs were Grade 1 or 2, most commonly fever and hematuria. There were 2 Grade 2 irAEs of hepatitis and hypothyroidism and 2 Grade 3 TEAEs of urinary retention and spinal cord compression. PSA analysis during and post SYNC-T Therapy will be presented. PK analysis revealed minimal systemic exposure to SV-102 components. PD analysis showed induction of inflammatory cytokines and the emergence of multiple, novel T-cell clones. **Conclusions:** SYNC-T Therapy was well-tolerated achieving an 87% ORR in subjects with mCRPC or who refused ADT. These encouraging clinical results have led to further study of SYNC-T SV-102 in a US, multicenter, Phase 2a trial for subjects with mCRPC. Clinical trial information: NCT05544227. Research Sponsor: Syncromune, Inc.

Phase 1 study of B440, an oral *Bifidobacterium*-engineered WT1 cancer vaccine, in patients with metastatic urothelial cancer. First Author: Toshiro Shirakawa, Kobe University, Kobe, Japan

Background: B440 is an innovative oral cancer vaccine comprised of recombinant *Bifidobacterium* engineered to express WT1 tumor-associated antigen. By delivering the WT1 protein to dendritic cells in gut-associated lymphoid tissue, B440 is designed to induce a tumor-specific cellular immunity. Preclinical data demonstrated effective WT1-specific T-cell induction and anti-tumor activity in murine models of urothelial, prostate, and renal cancers. **Methods:** This open-label, single-arm, phase 1 study evaluated the safety and preliminary efficacy of B440 in patients with metastatic urothelial cancer who had progressed after all standard therapies, including cytotoxic chemotherapy, PD-1/PD-L1 inhibitors, and antibody-drug conjugates. Twelve patients were enrolled in two dose cohorts (800 mg or 1,600 mg, *n* = 6 each), administered once daily for five consecutive days per week over four weeks (20 total doses). The primary endpoint was dose-limiting toxicity (DLT), assessed during the treatment. Secondary endpoints included safety (adverse events [AEs] graded by CTCAE v5.0), best overall response (BOR), and progression-free survival (PFS) by RECIST v1.1. WT1-specific immune responses were measured via ELISPOT assays detecting interferon-γ-producing T cells. **Results:** All 12 patients completed the treatment: (median age: 74.5 years [range: 39–81]; primary tumors in bladder [*n* = 5], renal pelvis [*n* = 4], ureter [*n* = 3]). No DLTs were observed in either dose cohort. Treatment-related AEs were generally mild (Grade 1), with the most common events being transient IL-6 elevations and cold-like symptoms (n = 3 each). The disease control rate (DCR) was 50%, as six patients achieved stable disease (SD) as their BOR. Six patients also demonstrated WT1-specific T-cell induction confirmed by ELISPOT. ELISPOT-positive patients had a significantly longer PFS compared to ELISPOT-negative patients (median PFS: 113 days vs. 57 days; *P* = 0.0033). Although not included in the study protocol, six patients subsequently underwent pembrolizumab rechallenge at the discretion of their physicians. Of these, three achieved clinical responses (one complete response [CR] and two partial responses [PR]). Spider plot analyses indicated early tumor shrinkage among ELISPOT-positive patients, with maximum reductions of −100%, −49%, and −32.7% from baseline. Notably, three of the four ELISPOT-positive patients achieved objective responses upon rechallenge. **Conclusions:** B440 exhibited a favorable safety profile and no DLTs up to 1,600 mg. The induction of WT1-specific immunity correlated with improved PFS during B440 therapy and enhanced responses upon pembrolizumab rechallenge. These data support further investigation of B440 in larger, randomized trials and potential combination with other immunotherapies in WT1-expressing malignancies. Clinical trial information: jRCT2051220143. Research Sponsor: Japan Agency for Medical Research and Development (AMED); 23ym0126081h0002; Immunorock Co., Ltd.

Effect of erythrocyte-antibody conjugates on cancers resistant to checkpoint blockade immunotherapy: A phase I trial. First Author: Xiaoqian Nie, Westlake University, Hangzhou, Zhejiang, China

Background: Despite the clinical success of immune checkpoint blockade therapy, the majority of patients do not benefit due to inadequate efficacy as well as immune-related adverse toxicities. We have previously developed WTX-212, an erythrocyte-antibody conjugate that covalently links anti-PD-1 antibodies to erythrocyte membranes. Unlike conventional antibodies, WTX-212 accumulates in the spleen, where it effectively remodels splenic immune landscape by expanding effector T cells and reducing the reservoir of immunosuppressive myeloid cells. These changes further reprogram the tumor microenvironment and suppress tumor growth in syngeneic mouse models. Based on promising preclinical results, we have investigated WTX-212 in cancer patients resistant to checkpoint blockade therapy (NCT06026605). **Methods:** This is an investigator-initiated trial designed to assess the safety, tolerability, and preliminary efficacy of autologous WTX-212 monotherapy in patients with advanced malignancies. The primary outcome measures include safety and tolerability according to NCI-CTCAE v.5.0. Secondary outcome measures preliminary efficacy based on RECIST 1.1 criteria. As of January 15, 2025, 14 heavily treated patients with 11 types of solid tumors, who had received PD-1/PD-L1 antibody-containing regimens as their last line of treatment but developed resistance, were enrolled. These patients received WTX-212 monotherapy in two dose cohorts (2×10^{11} or 3×10^{11} cells, with 6-10 mg of conjugated antibody). **Results:** Repeated WTX-212 treatment showed no DLTs or TRAEs ≥3. No patient discontinued treatment due to AEs. WTX-212 monotherapy demonstrated promising anti-tumor activity, with a DCR of 78.6% (11/14) and an ORR of 42.9% (6/14), including 1 CR and 5 PR. In the higher-dose cohort (3×10^{11} cells), DCR and ORR increased to 85.7% (6/7) and 57.1% (4/7), respectively, suggesting dose-dependent efficacy. Additionally, responders (CR+PR) exhibited higher baseline levels of circulating polymorphonuclear myeloid-derived suppressor cells (PMN-MDSCs) compared to non-responders (PD+SD), indicating that patients with elevated PMN-MDSCs may benefit more from treatment. Importantly, WTX-212 treatment rapidly reduced PMN-MDSCs in the peripheral blood of responders compared with non-responders, consistent with preclinical data. These preliminary results suggest that WTX-212 is safe, well-tolerated, and effective at low doses, supporting further investigation into WTX-212 monotherapy and combination therapies. **Conclusions:** Our study suggests that PD-1 blockade in the spleen using erythrocyte-antibody conjugates triggers systemic anti-tumor responses while maintaining a favorable safety profile. Erythrocyte-drug conjugates represent a novel approach for targeting immune cells in the spleen, with broad implications for cancer treatment and drug development. Clinical trial information: NCT06026605. Research Sponsor: None.

RETRACTED: Phase 1 clinical trial of EpCAM CAR-T cell therapy in patients with gastrointestinal cancers. First Author: Tianhang Luo, Shanghai Changhai Hospital, Shanghai, China

2508 Oral Abstract Session

Phase 1 clinical update of IMA203, an autologous TCR-T targeting PRAME in patients with PD1 refractory metastatic melanoma. First Author: Martin Wermke, University Hospital Carl Gustav Carus, Dresden, Germany

Background: Frequent recurrence and limited long-term survival in unresected or metastatic melanoma after relapse from 1L checkpoint inhibitor treatment highlight the critical need for new therapies that deliver deeper, more durable responses. ACTengine IMA203 is an autologous TCR-T targeting PRAME, an intracellular protein displayed as peptide antigen at high density on the surface of multiple solid tumors, including melanoma. **Methods:** Patients treated in this ongoing Ph1a/b trial (NCT03686124) are ≥18yo, HLA-A*02:01+, PRAME+, have recurrent and/or refractory solid tumors with no additional standard of care treatments available, measurable disease (RECIST1.1) and ECOG PS 0-1. Patients receive Cy/Flu (500 mg/m^2 & 30 mg/m^2 x4 d) lymphodepletion prior to infusion, followed by low-dose IL-2 for 10 days. **Results:** As of Aug 23, 2024: 70 heavily pretreated patients with solid tumors (median 3 prior systemic therapies) across all dose levels (median total infused dose 2.09x10^9 TCR-T cells (0.08-10.02x10^9)) were enrolled and assessed for safety. Baseline tumor burden (median sum of diameter): 11.78 cm; LDH > 1 x ULN: 64% of patients. IMA203 had an overall favorable tolerability profile. Most common TEAEs: chemotherapy-related cytopenias (100%), mild to moderate CRS (G1-2: 83%, G3: 11%), infrequent ICANS (G1: 6%, G2: 4%, G3: 4%), no G5 events. Objective responses were observed in melanoma, ovarian cancer, synovial sarcoma, and other tumor types. Successful trafficking of IMA203 cells to various organs was evidenced by their ability to shrink metastatic tumor lesions in the lung, liver, pleura, peritoneum, skin, lymph nodes, adrenal gland, bladder, kidney, spleen, and muscle. Across patients treated in dose escalation and dose expansion, higher doses of IMA203 TCR-T cells were associated with a higher rate of confirmed responses (p = 0.018), whereas tolerability profile remained favorable. Exposure data (C_{max}, AUC) demonstrated a clear dose-dependent improvement in clinical efficacy: Patients with confirmed PR had a higher concentration of IMA203 TCR-T cells in the periphery, compared to patients with unconfirmed PR, SD, and PD. In heavily pretreated patients (median 2 prior systemic therapies) with melanoma at RP2D (1-10x10^9) in Ph1b, cORR was 54% (14/26), with tumor shrinkage in 88% (23/26) of patients. Median DOR was 12.1 months with 7/14 confirmed responses ongoing (longest > 2 years). Median PFS was 6 months and median OS not reached at 8.6 months mFU. Updated data with longer follow-up will be presented. **Conclusions:** IMA203 TCR-T was well tolerated and showed durable objective responses in patients with advanced melanoma. Given its promising risk/benefit profile and high PRAME prevalence in melanoma, a registration-directed Phase 3 trial (SUPRAME; NCT06743126) is underway to further evaluate its efficacy in patients with previously treated (2L) advanced cutaneous melanoma. Clinical trial information: NCT03686124. Research Sponsor: None.

2509 Clinical Science Symposium

Phase III randomized study comparing ultra-low dose immunotherapy to standard cytotoxic chemotherapy for solid tumors in second line and beyond setting (DELII: Development of Low dose Immunotherapy in India). First Author: Vanita Noronha, Tata Memorial Hospital, Mumbai, India

Background: Although immunotherapy (IO) is approved in the second line and beyond setting for most solid tumors, cost limits its accessibility. Lower doses of IO have been shown to achieve adequate target occupancy, persisting for 3 months post administration. We hypothesized that nivolumab would retain efficacy at one-twelfth the approved dose. **Methods:** Open-label, phase III randomized superiority study in 500 patients with solid tumors, whose disease had progressed on at least one line of systemic treatment, with performance status 0-1. Patients were randomized 1:1 to ultra-low-dose nivolumab (20 mg intravenously every 2 weeks) or standard chemotherapy. Standard chemotherapy options for lung and head-and-neck cancers were docetaxel 75 mg/m^2 every 3 weeks or paclitaxel 175 mg/m^2 every 3 weeks or paclitaxel 80 mg/m^2 once-a-week; esophageal and urothelial cancers: paclitaxel 175 mg/m^2 every 3 weeks or 80 mg/m^2 once-a-week. Therapy continued until progression or intolerable toxicity. Primary endpoint was overall survival (OS). **Results:** Between Jun 2020 and Feb 2024, we enrolled 500 patients: 250 to each arm. Median age was 49.5 years (IQR, 42-58), 408 (81.6%) patients were male. Primary cancers included head and neck (259, 51.8%), lung (182, 36.4%), esophagogastric (31, 6.2%), urothelial (14, 2.8%), and microsatellite instability-high colorectal cancers (14, 2.8%). Patients had received a median of one prior line of systemic therapy (range: 1-8); 144 (28.8%) patients had received at least two prior lines of systemic therapy. PD-L1 positivity (TPS or CPS > 0) was noted in 66.2% patients. Radiologic response was 7.7% and 8.1% in IO and chemotherapy arms, respectively; P = 0.882. Disease stabilization rate was 37.7% and 39.3% in IO and chemotherapy arms, respectively; P = 0.761. Median PFS was similar between the two arms: 2.04 months (95% CI, 2.0-2.1) in IO arm, and 2.09 months (95% CI, 2.04-2.17) in chemotherapy arm (HR, 1.03; 95% CI, 0.86-1.23; P = 0.77). Median OS was 5.88 months (95% CI, 4.99-7.13) in IO arm, versus 4.70 months (95% CI, 3.91-5.65) in chemotherapy arm; P = 0.022; HR, 0.80 (95% CI, 0.66-0.97). One-yr OS in IO and chemotherapy arms was 27.28% (22.19-33.54) and 16.88% (12.75-22.34), respectively; 2-yr OS was 11.19% (7.59-16.50) and 6.55% (3.95-10.89), respectively. Grade 3 and higher treatment-related adverse events were significantly lower in IO arm (42%) than chemotherapy arm (60.3%); P < 0.001. **Conclusions:** Ultra-low dose immunotherapy dosed at one-twelfth the standard approved dose is efficacious and significantly prolongs survival in patients with solid tumors in the second line and beyond setting, as compared to standard cytotoxic chemotherapy. Low dose IO should be tested in various settings and multiple malignancies. This will substantially increase global accessibility to IO. Clinical trial information: CTRI/2020/02/023441. Research Sponsor: R G Manudhane Foundation for Excellence; Trilokchand Papriwal Trust; Tata Memorial Hospital, Mumbai, India.

2510 Clinical Science Symposium

Overall survival according to time-of-day of combined immunochemotherapy for advanced non-small cell lung cancer: A bicentric bicontinental study. First Author: Francis Albert Lévi, UPR Chronotherapie, Cancers et Transplantation, Université Paris Saclay, Hôpital Paul Brousse ID Isco 13918, Villejuif, France

Background: Circadian rhythms moderate immune cells trafficking and function over the 24 hours. This could account for the near doubling of overall survival (OS) in patients (pts) receiving immune checkpoint inhibitors (ICIs) as single agents at early times-of-day of administration (ToDA) in retrospective studies. Yet, (i) the cut-off time that differentiates ICI efficacy according to ToDA ranges from 11:30 to 16:30, and (ii) the relevance of ICI timing for OS is unknown in pts receiving immunochemotherapy (ICI-chemo). **Methods:** These issues are addressed using OS as the primary endpoint in retrospectively-included pts receiving 1st-line ICI-chemo for stage IIIc-IV non-small cell cancer (NSCLC) in France (Cohort 1) or in China (Cohort 2). The median ToDA of the initial four ICI-chemo infusions was computed for each patient. Hazard ratio (HR) functions of an earlier death or an earlier progression were computed for each cohort and for the pooled one, using ToDA cut-off times ranging from 10: 30 to 13:00, with 30-minutes increments. Median ToDA of ICI-chemo determined the allocation of patients to "Before" or "After" treatment groups. The temporal relations between HRs and ToDA as a continuous variable were further determined, using Cox models incorporating periodic restricted cubic splines. Patients were dichotomized according to the best cut off ToDA candidate, with OS and PFS being estimated using Kaplan-Meier and compared using log-rank. The association between ToDA and OS, PFS and response rates were evaluated using the Cox and logistic models controlling for main patient characteristics. **Results:** A total of 713 pts started treatment between 01/2018 and 10/2023 (Cohort 1, 165 pts; Cohort 2, 548 pts; median age, 62 y.o., male sex, 84%; pembrolizumab as ICI, 51%; pemetrexed-carboplatin/cisplatin, 49%; paclitaxel-carboplatin, 51%). HR functions in each cohort and in the pooled one, and the fitted curve using ToDA as a continuous variable identified 11:30 as a likely best cut off time. Median OS was 33.0 months (mo.) [95% CI, 27.5 - 41.0] in the 345 patients, who received 2-4 immunochemotherapy courses before 11:30) compared to 19.5 mo. [18.0 - 22.5] in those, who received 2-4 courses after 11:30 (N = 368) (p<0.0001). In the multivariable analysis, a median ToDA before 11:30 was associated with prolonged OS with an adjusted HR of 0.47 [0.37-0.60]. Statistically significant differences in ToDA effects were found for OS, PFS in each cohort, and for response rate in each cohort and in the pooled data. **Conclusions:** In this large bi-continental study, ToDA of immunochemotherapy administration before 11:30 was associated with improved OS, PFS and response rates, compared to later ToDA in pts receiving standard first line immunochemotherapy for NSCLC. Randomized trials are needed to confirm this important finding and inform recommendations for clinical practice. Research Sponsor: None.

2511 Clinical Science Symposium

Safety and efficacy of immune checkpoint inhibitors in solid organ transplant recipients: A systematic review and individual patient data meta-analysis. First Author: Muntaser Al Zyoud, University of Jordan, Amman, Jordan

Background: Immune checkpoint inhibitors (ICIs) have revolutionized cancer treatment but pose unique challenges in solid organ transplant (SOT) recipients. Transplant rejection remains the predominant safety concern. We systematically evaluated the safety (focusing on allograft rejection) and efficacy of ICIs across all organ transplant types and ICI classes, providing updated evidence-based insights for clinical decision-making. **Methods:** A systematic review of PubMed, EMBASE, and SCOPUS databases was conducted in accordance with PRISMA guidelines. Studies reporting rejection or efficacy outcomes in SOT recipients treated with any class of ICI were included. The primary endpoints were the incidence of transplant rejection and survival following ICI therapy. Secondary endpoints included objective response rate (ORR) and progression-free survival (PFS) for malignancies. Analysis was performed using SPSS (V26.0) and R (V4.3.0). **Results:** Of 2682 screened abstracts, 198 studies involving 331 SOT recipients met inclusion criteria. The transplanted organs were liver (n=175), kidney (n=136), and heart (n=15). Rejection rates were highest in Kidney at 46.3% (63/136), followed by heart (40.0%, 6/15) and liver (26.9%, 47/175). Across ICI classes, rejection rates were: Anti-CTLA4 (25%) Anti-PD1 (40.6%) and Anti-PDL1 (0%). Rejection rates were lower in patients receiving ICI pre-transplant (25.9%) compared to post-transplant (40.9%). ORR varied by ICI class: Anti-CTLA4 (25%), Anti-PD1 (41.8%), Anti-PD1 + CTLA4 (28%), and Anti-PDL1 (72.7%). Cutaneous squamous cell carcinoma (cSCC) showed the highest ORR (49.1%), followed by hepatocellular carcinoma (40.8%) and melanoma (25.3%). Post-transplant rejection risk was lower with Anti-CTLA4 (OR 0.22), 3rd-line ICI therapy (OR 0.24), and corticosteroids (OR 0.46). Pre-transplant rejection risk decreased with >60-day washout periods (OR 0.10). Multivariate analysis identified key factors influencing rejection risk (Table 1). **Conclusions:** ICI therapy in SOT recipients is high-risk yet promising. Key strategies include prolonged washout periods, Anti-CTLA4 therapy, and late-line ICI use. Prospective studies are needed to refine protocols and identify predictive markers to improve outcomes in this population. Research Sponsor: None.

Multivariate analysis results.

Factor	Total (OR)	P-Value	Pre-Transplant ICI administration (OR)	P-Value	Post-transplant ICI administration (OR)	P-Value

Durable responses in ICI-refractory or acquired resistance: Phase 2 study of NP-G2-044 combined with anti-PD-1 therapy. First Author: Anup Kasi, University of Kansas Cancer Center, Fairway, KS

Background: Although immune checkpoint inhibitors (ICIs) have transformed cancer treatment, many patients still develop primary or acquired resistance. NP-G2-044 is a first-in-class, oral fascin inhibitor that disrupts cancer cell motility, invasion, and metastasis while promoting intratumoral dendritic cell (DC) activation and CD8+ T-cell proliferation. Preclinical studies indicate NP-G2-044 synergizes with anti-PD-1 therapy to convert nonresponsive tumors into responsive ones. Early-phase clinical data support the feasibility of NP-G2-044 at pharmacologically active doses and its potential to prevent metastasis when used as monotherapy. **Methods:** In this open-label Phase 2 trial (NCT05023486), patients with advanced or metastatic solid tumors and documented primary or acquired resistance to anti-PD-(L)1 therapy received NP-G2-044 plus standard-of-care anti-PD-1. Efficacy was assessed using RECIST, with the primary endpoint being objective response rate (ORR). Secondary endpoints included progression-free survival (PFS), duration of response, disease control rate (DCR), and safety. **Results:** Forty-five patients were enrolled, with 33 evaluable for efficacy. No dose-limiting toxicities were observed. Objective responses occurred in 7/33 patients (21%) [95 % CI 9 - 38.9%], including 4 complete responses (CRs)—2 by RECIST in cervical and endometrial cancers, and 2 pathological CRs in pancreatic and gastroesophageal junction adenocarcinomas—and 3 partial responses (cutaneous squamous cell carcinoma, non-small cell lung cancer, and cholangiocarcinoma). Three patients have been cancer-free for over 7 months, and 5 have remained on therapy for more than 15 months. The DCR was 76%, and 55% of patients showed no new metastases during the study. One-year PFS is projected at 30%. The most common adverse events were diarrhea, fatigue, nausea, and transaminitis (~30%), which was transient, reversible, and preceded tumor response. Mechanistic analyses using multiplex immunofluorescence and immunophenotyping revealed enhanced intratumoral cytotoxic T-cell infiltration, proliferation, and granzyme B expression, along with an increase in activated DCs—consistent with a strong immunomodulatory effect. **Conclusions:** NP-G2-044, in combination with anti-PD-1 therapy, appears to have clinical activity across multiple cancer types, overcoming both primary and acquired ICI resistance while producing durable responses. Ongoing expansion cohorts and biomarker analyses aim to refine patient selection. These findings underscore NP-G2-044's potential to address metastatic disease and improve cancer immunotherapy outcomes, offering a promising therapeutic option for patients with limited alternatives. Clinical trial information: NCT05023486. Research Sponsor: Novita Pharmaceuticals.

Preliminary results from the dose-escalation stage of a phase I trial of an anti-CCR8 antibody in patients with relapsed/refractory cutaneous T-cell lymphoma (R/R CTCL). First Author: Zhiming Li, Sun Yat-sen University Cancer Center, Guangzhou, China

Background: Mycosis fungoides (MF) and Sézary syndrome (SS) are the most common cutaneous T-cell lymphomas (CTCL). CCR8 is expressed in the skin resident memory T cells. ICP-B05 (CM369) is a humanized monoclonal antibody against CCR8 with potent ADCC activity. Here we report safety, efficacy and PK/PD findings for ICP-B05 during the dose-escalation stage of a Phase I study. **Methods:** Patients with R/R CTCL received ICP-B05 at 150 mg, 300 mg, 450 mg and 600 mg I.V. Q2W. Patients with R/R CTCL who failed at least 1 prior standard systemic regimen. Primary objectives included safety and tolerability of ICP-B05, MTD and RP2D. Secondary Objectives included the PK/PD and objective response per investigator. **Results:** By the cutoff date of 6th Jan, 2025, a total of 13 patients with R/R CTCL were treated, with 4 patients in 150 mg, and 3 patients each in 300 mg, 450 mg and 600mg, respectively. Eleven patients had a diagnosis of MF, one had SS and one had pcALCL. The median age was 46 years, and the median prior lines of therapy were 3 (2-6). There were 10/13 (76.9%) patients had lymph nodes involvement and 1/13 (7.7%) patient with SS had above 90% Sézary cells in peripheral blood at baseline. TEAEs occurred in 12 (92.3%) patients, and ≥Grade 3 TEAEs occurred in 6(46.2%) patients. The most common≥Grade 3 TEAEs is hematological AEs, including lymphopenia (8.3%), neutropenia (8.3%) and thrombocytopenia (8.3%). Two patients (16.7%) reported serious TEAEs, including edema and cardiac failure reported by the SS patient which was assessed as not related to ICP-B05, and thrombocytopenia and anemia reported by a MF patient. There was no fatal TEAE reported. There were 12 patients received at least one skin lesion assessment followed the mSWAT. 4/12 patients (33.3%) achieved PR, and 7patients (7/12, 58.3%) were assessed as SD with reduction (medium: - 27%) in skin lesion. The 6-month PFS rate was 82.5% (95% CI: 46.1%-95.3%). At baseline, CCR8+ in skin lesions (medium: 8.38%, range: 3.22–49.6%) was assessed in 11 out of 13 patients. Among the five patients with CCR8+ levels exceeding 10%, four (80%) achieved PR. PK analysis showed that serum exposure (C_{max} and $AUC_{0\text{-}14D}$) increased with dose escalation. PD analysis demontrated significant depletion of CCR8-expressing cells in CTCL skin lesions. Significant reduction of CCR8+ malignant T cells (-80%) and CCR8+ regulatory T cells (Treg, -68%) were observed at C3D1 compared with baseline in the skin lesion. Similar PD effects were observed in the peripheral blood as well with an average decrease of 91% in CCR8+ malignant T cells and 16% in Treg at C3D1 when compared with baseline. **Conclusions:** The current study is the first and only report on the preliminary efficacy data of anti-CCR8 targeted therapy for CTCL patients. The effectiveness of ICP-B05 was supported by the PD effects in both skin lesions and peripheral blood in the depletion of CCR8+ cells. ICP-B05 is safe and well tolerated and its safety profile made it a good candidate for combo therapies for CTCL patients with lymph node and other organ involvement. Clinical trial information: NCT05690581. Research Sponsor: None.

An open-label, phase I trial of the SIRPα monoclonal antibody, BI 770371, alone and in combination with the PD-1 inhibitor ezabenlimab in patients with advanced solid tumors. First Author: Judy S. Wang, Florida Cancer Specialists & Research Institute, Sarasota, FL

Background: The signal regulatory protein alpha (SIRPα)/CD47 axis is a critical regulator of myeloid cell activation and serves as a myeloid-specific immune checkpoint, making it a potential therapeutic target. The pan-specific SIRPα monoclonal antibody, BI 770371, blocks the SIRPα/CD47 interaction, leading to reactivation of innate antitumor immune responses. This Phase I trial (NCT05327946) aimed to determine the maximum tolerated dose (MTD) and recommended dose for expansion of BI 770371 ± ezabenlimab in patients (pts) with advanced solid tumors. **Methods:** Pts with ≥1 measurable lesion and ECOG PS of 0/1 were enrolled. Pts received escalating doses ofBI 770371 alone or in combination with ezabenlimab 240 mg once every 3 weeks. Treatment continued until progressive disease, unacceptable toxicity, or pt withdrawal. BI 770731 dose escalation was guided by a Bayesian Logistic Regression Model with overdose control. Primary endpoint was dose-limiting toxicities (DLTs) in the MTD evaluation period (Days 1–21). Secondary endpoints were adverse events (AEs) and DLTs in the on-treatment period. **Results:** At data cut-off (Nov 22, 2024), 21 pts had received BI 770371 monotherapy across 6 dose levels, and 15 pts had received BI 770371 in combination with ezabenlimab (combination group) across 5 dose levels. In the monotherapy group, median age was 63 years (range: 26–77) and 95% of pts had received ≥3 prior lines of therapy. In the combination group, median age was 61 years (range: 27–78), and 80% had received ≥3 prior therapies. No DLTs were reported during the MTD evaluation period with BI 770371 monotherapy or with the combination; 1 pt in the monotherapy group had a DLT (grade 2 encephalitis, which resolved within 1 week) during the on-treatment period (likely due to prior nivolumab and ipilimumab treatment). In total, 14 (67%) and 10 (67%) pts in the monotherapy and combination groups, respectively, had a treatment-related AE (TRAE). Most common TRAEs with BI 770371 monotherapy were pruritus (24%) and fatigue (19%). Most common TRAEs with the combination were fatigue and decreased appetite (each 20%). Most TRAEs were grade 1/2, one pt in the combination group had two grade 3 TRAEs (diarrhea and fatigue); there were no grade 4/5 TRAEs. Two suspected unexpected serious adverse reactions were seen: grade 2 encephalitis (monotherapy) and grade 3 diarrhea (combination). One pt had an AE leading to discontinuation (grade 2 encephalitis). One pt in the combination group had a partial response; 13 (62%) and 8 (53%) pts in the monotherapy and combination groups, respectively, had stable disease. **Conclusions:** These preliminary data indicate that BI 770371 is well tolerated alone and in combination with ezabenlimab, with promising antitumor activity seen in heavily pretreated pts with advanced solid tumors. The MTD of BI 770371 was not reached in either group. Clinical trial information: NCT05327946. Research Sponsor: Boehringer Ingelheim.

A novel application of deep learning (DL)-based MRI with liquid biomarkers for immune effector cell-associated neurotoxicity syndrome (ICANS) after chimeric antigen receptor (CAR) T-cell therapy. First Author: Kathryn Ries Tringale, UC San Diego, La Jolla, CA

Background: ICANS is a complication of CAR T-cell therapy, yet risk factors and quantitative diagnostic criteria, particularly neuroimaging criteria, remain incompletely characterized. We implemented a novel application of a deep learning (DL)-based MRI approach alongside clinical and liquid biomarkers to better characterize neurotoxicity after CAR T-cell therapy. **Methods:** We analyzed all patients with non-Hodgkin lymphoma (NHL) or acute lymphoblastic leukemia (ALL) who underwent CAR T-cell therapy at UCSD with a commercial product from 2018-2024. ICANS was graded as per American Society for Transplantation and Cellular Therapy (gr1-4). Variables included stage, performance status, and prior receipt of high-dose methotrexate (HD MTX), intrathecal (IT) chemotherapy, central nervous system (CNS) involvement, CNS-directed radiotherapy (CNS RT), and extracranial RT. Labs obtained pre-infusion, 3 days post-infusion, and during ICANS (or 7 days post-infusion for those without ICANS) were evaluated. Available post-infusion brain MRIs were processed with a 3D U-Net convolutional neural network to quantify T2 FLAIR hyperintensity volumetrics. Linear mixed regression models accounting for zero inflation assessed longitudinal DL-derived FLAIR. Multivariable regression models assessed factors associated with ICANS. **Results:** Of 163 patients (89% NHL, 11% ALL), 52 had IT chemotherapy, 27 had HD MTX, 24 had prior CNS disease, and 22 had prior CNS RT. Most (106) received axicabtagene ciloleucel (34 tisagenlecleucel, 23 brexucabtagene autoleucel) and most had CRS (133, 82%). ICANS occurred in 73 (45%) at a median of 7 days post-infusion (39 gr1-2, 34 gr3-4). Post-infusion, 21 patients had ³1 brain MRI (93 MRIs total). Baseline factors associated with ICANS were lactate dehydrogenase (LDH; odds ratio [OR] 1.03 p = 0.002) and prior IT chemotherapy (OR 2.5 p = 0.01). There was a trend toward association of gr3-4 ICANS with HD MTX (OR 2.8 p = 0.07). Post-infusion, CRS grade was associated with ICANS (OR 2.8 $p < 0.001$). LDH (1.02 p = 0.004) and C-reactive protein (OR 1.2 $p < 0.001$) were elevated during ICANS. Patients with ICANS had significantly greater FLAIR (intercept 23.8 cm^3 $p < 0.001$) and there was increased FLAIR over time across all patients (b = 3.3 cm^3 p = 0.05). There was a trend toward association between higher ICANS grade and DL-derived FLAIR (p = 0.09). **Conclusions:** Here, we demonstrate a novel application of DL-based MRI quantification of ICANS post-CAR T-cell therapy. This metric, along with clinical features, emerged as potential quantitative biomarkers of ICANS. These findings warrant further investigation and have informed a prospective study, including standardized brain MRI pre- and post-infusion, to develop a comprehensive phenotype of neurotoxicity following CAR T-cell therapy. Research Sponsor: None.

Role of autoimmune reactivity in neurotoxicities (N-Tox) in melanoma patients treated with immune-checkpoint inhibitors (ICI). First Author: Agrima Dutt, New York University Grossman School of Medicine, New York, NY

Background: N-Tox is a grossly understudied immune-related adverse event (irAE), despite its association with mortality (e.g. encephalitis) and morbidities (e.g. peripheral neuropathy). We reported that pre-treatment sera autoantibodies (auto-Abs) are implicated in the pathogenesis of irAEs (Johannet *et al. CCR* 2022). We here examined the rate and patterns of N-Tox in melanoma patients who received ICI in the adjuvant setting and whether baseline specific serum auto-Abs are associated with N-Tox. **Methods:** We examined clinicopathological features and baseline auto-Abs of 965melanoma patients (551 male and 414 female) enrolled in two phase III clinical trials: Checkmate 238 and Checkmate 915 (797 resected stage III, 166 resected stage IV, and 2 unknown). Patients received ipilimumab (n = 423), nivolumab (n = 347), or both (n = 195). We compared pre-treatment serum auto-Ab profiles using the HuProt Human Proteome Microarray v4.0 (CDI Laboratories, Mayaguez, PR) that has 21,000+ individually purified full-length human proteins and protein isoforms in duplicate, in patients who developed at least a single incidence of N-Tox grade $\geq$2 to those who developed only other types of irAEs grade $\geq$2. We used a threshold of logFC $>$ 0.3 and false discovery rate (FDR) adjusted P value $<$ 0.05 to determine differentially expressed auto-Abs in patients with N-Tox. **Results:** 329/965 (34%) patients developed N-Tox. There were 426 total incidences of N-tox (grade 1 n = 258, grade 2 n = 132, grade 3 n = 34, grade 4 n = 2). 97/329 patients developed more than one grade of N-Tox. Patients who received ipilimumab were more likely to experience any grade N-Tox (P = 0.002) in a multivariate model. Any grade N-tox was also associated with a lower recurrence rate (P = 0.004). Gender and melanoma stage were not associated with N-Tox ($P > 0.05$). A signature of 160 auto-Abs, including those targeting mitochondrial proteins (ATP5PO, COX6C, NDUFA3, NDUFB6), calcineurin (PPP3CC, PPP3R1), cellular architecture (RAC1), and inflammation/apoptosis (TRAF2) were significantly overexpressed in the N-Tox grade $\geq$2 cohort (n = 143) compared to non-N-Tox grade $\geq$2 (n = 569). Pathway analysis revealed these auto-Abs were enriched in several pathways involved in neuroinflammation and neurodegeneration, including TNF-a signaling, B cell receptor signaling, interleukin-2 production, natural killer cell mediated cytotoxicity, and cellular senescence. **Conclusions:** Our data demonstrate that the incidence of N-Tox is higher than previously reported, possibly due to stringent assessment and follow up in clinical trial settings. The multiplicity of pathways involved, some of them directly involved in neurodegeneration and neuroinflammation, suggests a complex N-tox pathogenesis that requires further clinical and pre-clinical investigations. Natural killer cell transcriptomic expression and prediction of survival after immune checkpoint blockade across cancers. First Author: Hirotaka Miyashita, Dartmouth Cancer Center, Lebanon, NH

Background: Preclinical and clinical evidence has suggested the role of natural killer (NK) cells in tumor immunity and prognosis across various cancer types, but their significance during immune checkpoint blockade (ICB) treatment is poorly understood. This study investigated the impact of tumor-infiltrating NK cells, surrogated by the RNA expression of genes related to NK cells in the tumor microenvironment, on the outcomes of the patients who undergo ICB, using real-world, pan-cancer data. **Methods:** We analyzed RNA sequencing data of 395 immune-related genes from 514 patients with various cancers included in the Study of Personalized Cancer Therapy to Determine Response and Toxicity (NCT02478931). After excluding 25 patients ineligible for survival analysis, we defined two distinctive cohorts: patients who received ICB (ICB cohort, N = 217) and those who did not (non-ICB cohort, N = 272). Among the 395 immune-related genes, 43 were selected as NK-related genes according to the Human Protein Atlas. Patients in each cohort were clustered into two groups based on the NK-related gene expression. The associations between the clusters and the clinical outcomes, including overall survival (OS) and progression-free survival (PFS), were analyzed using univariate and multivariate analyses. In the multivariate analysis, cancer types, line of immunotherapy, positive programmed-death ligand 1 immunohistochemistry (PD-L1 IHC, $\geq$ 1%), high tumor mutational burden (TMB, $\geq$ 10/Mb), and microsatellite instability (MSI) were adjusted. **Results:** The ICB cohort (N = 217) was divided into two clusters (hot vs. cold), characterized by general abundance and paucity of NK-related gene transcripts (N = 101 and 116, respectively). The clusters were not significantly associated with histology, positive PD-L1 IHC, high TMB, or MSI. Those in the hot cluster demonstrated significantly longer overall survival (OS) after starting ICB compared to those in the cold clusters in univariate analysis (hazard ratio [HR] and 95% confidence interval [CI]: 0.65 [0.45-0.92], p = 0.015) and multivariate analysis (HR and 95% CI: 0.57 [0.34-0.87], p = 0.010). The cluster was not significantly associated with PFS. The non-ICB cohort (N = 272) was similarly divided into two clusters (hot vs. cold), with the characteristics of generally high and low NK-related gene RNA expressions. (N = 114 and 158, respectively). However, in the non-ICB cohort, patients in the hot clusters did not demonstrate significantly prolonged OS compared with those in the cold cluster either with univariate or multivariate analysis (HR and 95% CI: 0.93 [0.65-1.32], p = 0.67 and 0.97 [0.76-2.01], p = 0.90 respectively). **Conclusions:** Transcriptomic expression of NK-related genes in tumor tissue independently and significantly predicted longer survival after ICB treatment, which implies a role of tumor infiltrating NK cells in immunotherapy outcome. Research Sponsor: U.S. National Institutes of Health; CA023100.

Tumor-wide RNA splicing aberrations and their potential as therapeutic neoantigen targets. First Author: Darwin Kwok, University of California, San Francisco, San Francisco, CA

Background: Tumor heterogeneity and low mutational burden limits the availability of effective immunotherapy targets. Aberrant RNA-splicing (neojunctions) represents an underexplored yet promising source of neoantigens. To address this, we developed a neoantigen discovery platform (SNIPP) that characterizes a novel class of clonally-expressed, splicing-derived neoantigens. Furthermore, we validated the immunogenicity of these neoantigens by identifying specific TCRs that drive CD8+ T-cell-mediated tumor killing. **Methods:** SNIPP identified public neojunctions by analyzing TCGA RNA-seq data, selecting neojunctions with a positive sample rate (PSR) $>$ 10% and filtering out those found in GTEx normal tissue RNA-seq data (PSR $<$ 1%) across 12 cancer types. To characterize intratumorally conserved neojunctions, we performed maximally-distanced multi-site biopsies (n = 535) within glioma patients (n = 56) and generated RNA-seq data for each intratumoral site. Two independent algorithms were utilized to predict peptide processing likelihood and HLA-binding affinity of splicing-derived neoantigen candidates. Neoantigen-specific TCR sequences were identified via *in vitro* sensitization of PBMCs and subsequent 10x V(D)J scRNA-seq. These TCRs were transduced into CD8+ T-cells, which were tested downstream for immunogenicity and cytotoxicity against glioma cell lines. **Results:** Our pipeline identified 789 public neojunctions, including 32 neojunctions concurrently detected in transcriptomic and proteomic glioma datasets and confidently predicted to be presented by HLA-A*02:01. IVS and subsequent 10x V(D)J scRNA-seq identified TCR clonotypes reactive against neojunctions in *RPL22* (n = 7) and *GNAS* (n = 1), with the latter exhibiting high intratumoral conservation (detected in $>$ 90% of spatially-mapped biopsies across 17/56 patients (26.78%)). TCR-transduced CD8+ T-cells recognized and were immunogenically activated and demonstrated cytotoxicity against endogenously processed and presented neoantigens in GBM and melanoma lines. Additionally, IDH1-mutant oligodendrogliomas exhibited significantly higher neojunction expression compared to IDH1-mutant astrocytomas and IDH1wt subtypes. Differential gene expression analysis (DESeq2) revealed reduced expression of splicing factors in oligodendrogliomas, attributed to their specific co-deletion of chromosomes 1p and 19q. CRISPRi-mediated knockdown of these splicing factors (e.g. SF3A3, SNRPD2) in IDH1wt glioma cells resulted in significantly increased expression of corresponding neojunctions. **Conclusions:** Our study highlights a novel class of neoantigens derived from tumor-wide aberrant RNA splicing. The SNIPP platform effectively identifies public intratumorally-conserved neojunctions with strong therapeutic potential. Furthermore, elevated neojunction expression in oligodendroglioma underscores the mechanistic link between dysregulated splicing factor expression and RNA splicing abnormalities. Research Sponsor: None.

2520 Rapid Oral Abstract Session

Perturbational single-cell RNA sequencing of patient tumors in Merkel cell and small cell lung carcinomas. First Author: Curtis J. Perry, Yale School of Medicine, New Haven, CT

Background: Despite the transformational impact of immune checkpoint blockade, many cancer patients do not experience long-term survival. T cells with innate immune signatures can secrete inflammatory cytokines/chemokines and deliver potent cytotoxic signals potentially ideal for tumor immunity. The novel double-stranded RNA sensor RIG-I agonist SLR14 improved the control of murine melanoma. We tested the hypothesis that SLR14 transforms T cells to a cytotoxic state in immunologically "cold" human tumor specimens. **Methods:** We developed an approach, called PERCEPT, to directly test the response of patient tumor and immune samples to novel and established therapies *ex vivo* using perturbational single-cell RNA sequencing (Table). We obtained 9 surgical resections from primary or metastatic melanoma and Merkel Cell Carcinoma (MCC) tumors and lymph node metastases and made suspension replicates of tumor and infiltrating immune cell co-cultures. We stimulated for 42-48 hours (Table). We Flouresscently Activated Cell Sorted live cells and then barcoded for multiplexed single-cell sequencing using 10x scRNAseq. We used CINEMA-OT to identify factors associated with response and resistance to the perturbations tested. We developed and validated CRISPR-KO MCC and small cell lung cancer (SCLC) cell lines, and co-cultured with CD14+ monocytes or monocyte-derived DCs. **Results:** Stimulation with RIG-I agonist SLR14 induced expression beyond canonical IFN-stimulated genes in tumor cells, NK cells, and T cells. SLR14 stimulates tumor-infiltrating T cells into antiviral states in tumor-immune co-cultures and primes *in vitro* T-cell production of IFNγ. However, MCC immune infiltrate responsiveness to IFN or SLR14 was notably decreased compared to the melanoma samples, and perturbational computational analyses with CINEMA-OT identified the cytokine midkine (MDK) associated with nonresponse in MCC. Knockout of MDK restored response to IFN and SLR14 by MCC and SCLC tumor cell lines, as well as co-cultured CD14+ monocytes or monocyte-derived DCs. **Conclusions:** Our approach revealed that midkine, a multifunctional cytokine, suppresses innate immune sensing of IFN and SLR14 in both tumor and immune cells, disrupting the tumor immunity cycle at multiple points. We show that this effect, while comparatively infrequent in melanoma, is pronounced in MCC and SCLC. Our study thus uses a direct assessment of patient tumor and immune samples to identify a novel resistance mechanism enriched in neuroendocrine tumors MCC and SCLC. 2521 Poster Session

Phase 1/2, open-label, first-in-human study of the anti-GPC3 T-cell engager SAR444200 in patients with advanced solid tumors: Updated efficacy and biomarker analysis. First Author: Ecaterina Elena Dumbrava, Department of Investigational Cancer Therapeutics, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: SAR444200 is a novel NANOBODY T cell engager that simultaneously binds TCR$\alpha\beta$ and glypican-3 (GPC3) to co-engage T cells with GPC3+ tumor cells, resulting in T cell-dependent cellular cytotoxicity. We present updated safety, efficacy, and biomarker data from the dose escalation cohort (Part 1A) of a multicenter, first-in-human, Phase 1/2 trial (NCT05450562). **Methods:** Patients (Pts) with GPC3+ refractory solid tumors received SAR444200 intravenously (IV) weekly with lead-in doses at dose levels (DLs) 1 (3 mg), 1A (1 mg), 2A (2.5 mg), 3A (4.5 mg), 4A (18 mg), 5A (36 mg), 6A and 7A (different lead-in doses, target dose 70 mg). Pts with ECOG PS $\leq$1, and $\geq$1 measurable lesion per RECIST 1.1, were eligible. Primary objective for Part 1A was safety. Key secondary objectives included efficacy and PK/PD. Levels of interleukin-6 (IL-6) and interferon gamma (IFNγ) were evaluated with a multiplex ECL-based assay. Study imaging was performed every 9 weeks following first infusion. Circulating tumor (ct) DNA was analyzed in blood samples using a mutational profiling NGS approach. **Results:** As of October 15, 2024, 33 pts (23 pts with hepatocellular carcinoma [HCC]) were treated with SAR444200 (premedicated with dexamethasone 15 mg IV or equivalent) for a median of 23 cycles (range, 1–32). Median lines of prior therapies were 3–4. Most pts (32 [97%]) experienced $\geq$1 AE of any Grade. Grade $\geq$3 TEAEs in 16 (48.5%) pts and serious TRAEs in 8 (24.2%) pts were reported. 2 Grade 3 cytokine release syndrome events were reported as DLTs at DL6A and 1 at DL7A during the lead-in dosing. Key efficacy data are summarized in Table 1. An increase in IL-6 and IFNγ (maximum of 1326 pg and 461 pg on average per DL, respectively) was observed during lead-in-doses in pts from DL1 to DL5A, supporting CRS diagnosis. Cytokine levels declined after Cycle 1. Of 18 HCC pts with baseline alpha fetoprotein (AFP) $\geq$20%, 5 (27%) pts showed $\geq$50% AFP reduction. Median time of observing any AFP decrease was 4 weeks post-treatment. Among these, 3 pts had sustained decrease over 13 cycles. Stable disease (SD) was reported in 10 (30.3%) pts including 2 who were on study drug for 12 and 22 months. Of the 18 pts with measurable ctDNA, 4 (including 3 pts at DL5 and above) had reductions in ctDNA (18%–48%) from baseline. **Conclusions:** SAR444200 was tolerated at the investigated DLs in pts with GPC3+ advanced solid tumors. Decrease in AFP post treatment along with SD in a subset of pts is suggestive of preliminary anti-tumor activity. Clinical trial information: NCT05450562. Research Sponsor: Sanofi.

Lacutamab in patients with relapsed and refractory Sézary syndrome: Long term follow-up from the TELLOMAK phase 2 trial. First Author: Pierluigi Porcu, Sidney Kimmel Cancer Center, Thomas Jefferson University, Philadelphia, PA

Background: Sézary syndrome (SS) is a rare and aggressive cutaneous T-cell lymphoma, which commonly expresses KIR3DL2, a killer immunoglobulin-like receptor, reported in $\geq$ 85% of patients. SS is characterized by erythroderma, significant blood involvement, lymphadenopathy and poor prognosis (10-20% 5-year survival). Lacutamab is a first-in-class monoclonal antibody designed to specifically deplete KIR3DL2-expressing cells via antibody-dependent cell-cytotoxicity and phagocytosis. **Methods:** TELLOMAK is an international, Phase 2 trial with multiple cohorts (NCT03902184). We report here long term follow-up results from Cohort 1, evaluating lacutamab in patients with relapsed/refractory (R/R) SS after at least 2 prior systemic therapies including mogamulizumab. Lacutamab 750 mg is administered until progression or unacceptable toxicity. Primary endpoint was Objective Response Rate (ORR) based on the evaluation of 4 compartments: skin, blood, lymph nodes and viscera according to the International Consensus criteria Olsen 2011. Secondary endpoints included but were not limited to duration of response (DOR), progression free survival (PFS), safety, and quality of life assessments. **Results:** As of October 17, 2024, recruitment was completed with 63 SS patients enrolled. Median age was 69 years (range: 42-86), the median prior lines of systemic therapies were 5.0 (range: 2-13), 65.1% and 34.9 % patients had stage IVA1 and stage IVA2 at baseline respectively, all patients had blood involvement (B2), 63.5% had confluence of erythema covering $\geq$ 80% body surface area (T4), 34.9% had lymph node lymphoma involvement (N3). Median follow-up was 25.1 months (95% CI 21.0-29.4). Global confirmed ORR was 42.9% (CI 31.4-55.1) including 6 (9.5%) CRs who are all still in CR; with a median time to response of 2.8 months (range 1-10) and a median duration of response of 25.6 months (CI 11.0, NE). According to each compartment, ORR in skin was 52.4% (CI 40.3-64.2) including 9 (14.3%) CRs, ORR in blood was 50.8% (CI 38.8-62.7) including 21 (33.3) CRs, and ORR in lymph nodes was 28.8% (CI 18.3-42.3) including 9 (17.3) CRs. Median PFS was 8.3 months (CI 5.1-18.7). Grade $\geq$ 3 related Treatment-Emergent Adverse Events (TEAEs) were observed in 20.6% patients. Serious related TEAEs were observed in 9.5% patients and related TEAEs leading to study drug discontinuation in 6.3% patients. Data from additional key endpoints will be presented. **Conclusions:** The long term follow-up data from TELLOMAK study in a R/R SS population previously treated with 2 or more prior systemic therapies including mogamulizumab, confirm that lacutamab shows promising clinical activity with ORR 42.9% (95% CI 31.4-55.1) and median duration of response of 25.6 months (11.0, NE) and an overall favourable safety profile. These data support the further development of lacutamab in an effort to bring improved treatments to patients with SS. Clinical trial information: NCT03902184 // EU CT number: 2023-507777-18-00. Research Sponsor: Innate Pharma.

Lacutamab in patients with relapsed and/or refractory mycosis fungoides: Long-term follow-up and translational data from the TELLOMAK phase 2 trial. First Author: Pierluigi Porcu, Sidney Kimmel Cancer Center, Thomas Jefferson University, Philadelphia, PA

Background: The most common type of cutaneous T-cell lymphoma is Mycosis Fungoides (MF) accounting for 50-60% of cases. Extracutaneous involvement occurs mainly in lymph nodes or blood; 25% of patients are diagnosed at advanced stage with a 5-year survival of 15-25%. Lacutamab is a first-in-class monoclonal antibody designed to specifically deplete KIR3DL2-expressing cells via antibody-dependent cell-cytotoxicity and phagocytosis. KIR3DL2 is a killer immunoglobulin-like receptor expressed in MF patients. **Methods:** TELLOMAK is an international, multi-cohort phase 2 trial (NCT03902184). MF patients who had received at least 2 prior systemic therapies were treated with lacutamab 750 mg until disease progression or unacceptable toxicity. Primary endpoint was Objective Response Rate (ORR) by global response score based on the evaluation of 4 compartments: skin, blood, lymph nodes and viscera according to the International Consensus criteria Olsen 2011. Key secondary endpoints included duration of response (DoR), progression free survival (PFS), safety, and quality of life. Here we report long term follow-up data of MF patients. **Results:** As of October 17, 2024, recruitment was completed, with 107 MF patients enrolled. The median age was 62 years. The median number of previous systemic lines was 4 (range: 1-14). Median follow-up was 22.1 months (m) (95% CI 19.4, 23.6). Global confirmed ORR was 19.6% (CI 13.2, 28.1; Olsen 2011), and response in skin was 29.0% (CI 21.2, 38.2). Median time to response was 2.8 m (min, max 1-37) and median DoR was 13.8 m (7.4, NE), median PFS was 10.2 m (CI 8.0, 15.4). Among the KIR3DL2 $\geq$1% pts (N = 48), ORR was 20.8% (CI 11.7, 34.3; Olsen 2011), and response in skin was 33.3% (CI 21.7, 47.5), median DoR was 13.8 m (CI 4.6, NE) and median PFS 11.8 m (CI 5.6, 16.8). Among the KIR3DL2 $<$ 1% pts (N = 59), ORR was 18.6% (CI 10.7;30.4; Olsen 2011), and response in skin was 25.4 (CI 16.1, 37.8), median DoR was 15.7 m (CI 5.1, NE) and median PFS 9.5 m (CI 6.5;16.6). Grade $\geq$ 3 related Treatment-Emergent Adverse events (TEAEs) were observed in 5/107 (4.7%) patients, serious related TEAEs in 4/107 (3.7%) patients and related TEAEs leading to study drug discontinuation in 3/107 (2.8%) patients. The most common ($>$ 10%) related TEAEs were fatigue (12.1%), nausea (13.1%), asthenia (11.2%) and arthralgia (11.2%). Data from additional key endpoints and translational data will also be presented. **Conclusions:** The long-term follow-up data from the heavily pre-treated MF population enrolled to the TELLOMAK study confirms promising clinical activity of lacutamab regardless of KIR3DL2 expression, with ORR 20.8%, a median duration of response of 13.8 m, a median PFS of 10.2 m and a favorable safety and tolerability profile. These data support the further development of lacutamab in an effort to bring improved treatments to patients with MF. Clinical trial information: NCT03902184 // EU CT number: 2023-507777-18-00. Research Sponsor: INNATE PHARMA.

2524 Poster Session

Safety and efficacy of OR502, an antibody targeting leukocyte immunoglobulin-like receptor B2 (LILRB2), ± cemiplimab in patients with advanced solid tumors from a phase 1 study. First Author: Shiraj Sen, NEXT Oncology, Dallas, TX

Background: OR502 is a humanized IgG1 antibody that targets LILRB2, blocking its binding to HLA ligands A, B and G. OR502 prevents and reverses myeloid cell-mediated immune suppression and rescues T cell effector functions. Preclinical data demonstrate best-in-class properties. We report on the completed monotherapy and combination dose escalation cohorts from the ongoing, first-in-human, phase 1-2 study of this novel antibody. **Methods:** Patients had progressive, histologically confirmed, metastatic/unresectable solid tumors with ≥ 1 prior systemic standard of care treatments. Primary objectives were OR502 safety/tolerability and identifying a dose for future study supported by LILRB2 receptor occupancy (RO) and pharmacokinetics (PK). Secondary objectives included assessment of anti-tumor activity. We used a modified toxicity probability interval-2 design with a 25% dose-limiting toxicity (DLT) rate and a 20–30% equivalence interval. Patients received OR502 IV (100–1600 mg) over 30 minutes, every 3 weeks (Q3W) as monotherapy (n = 19) or with cemiplimab (350 mg) (n = 20). **Results:** In dose escalation (n = 39), there were no DLTs, treatment-related deaths, related SAEs, grade ≥ 3 treatment-related AEs or signals from vital signs, ECGs or laboratory results. One patient (monotherapy, 400 mg) discontinued due to grade 2 AEs. Infusion-related reactions (IRRs) occurred in 6 patients (3 monotherapy [1 at 800 mg and 2 at 1600 mg] and 3 combination [400, 800 and 1600 mg]). All IRRs were grade ≤ 2 and were mitigated by extending infusion duration to 60 minutes, with secondary prophylaxis if necessary (acetaminophen, diphenhydramine). All but 4 patients were evaluable for efficacy, see table. Monotherapy responses were seen at 200 and 800 mg in melanoma and non-small cell lung cancer (NSCLC), respectively. In combination, 1 patient with soft tissue sarcoma (1600 mg) had a cPR. There were 13 deaths due to progressive disease. Durable stable disease (SD) was seen in: sarcomas, cutaneous squamous cell carcinoma, thymoma, thyroid, melanoma, hepatocellular carcinoma and colorectal cancer. OR502 RO was near-complete at ≥ 200 mg and PK was roughly dose-proportional. Combination with cemiplimab did not affect RO or PK. **Conclusions:** OR502 has excellent safety and tolerability ± cemiplimab. Based on efficacy, predictable PK and near-complete RO, two mini-expansion cohorts are evaluating OR502 800 mg Q3W ± cemiplimab in patients with cutaneous melanoma or NSCLC who have failed or progressed after ≥ 12 weeks of anti-PD-(L)1. Clinical trial information: NCT06090266. Research Sponsor: OncoResponse, Inc.; The Cancer Prevention and Research Institute of Texas.

2525 Poster Session

A phase 1 study of the OX40 agonist BGB-A445, with or without tislelizumab, an anti-PD-1 monoclonal antibody, in patients with advanced NSCLC, HNSCC, or NPC. First Author: Min Hee Hong, Yonsei Cancer Center, Yonsei University College of Medicine, Seoul, South Korea

Background: BGB-A445 is a monoclonal antibody OX40 agonist that does not compete with the natural OX40 ligand, reducing the likelihood of a hook effect and distinguishing it from other OX40-targeting therapies. Here, we present results from the dose expansion portion of a ph 1, open-label, dose escalation/expansion trial of BGB-A445 in pts with advanced solid tumors (NCT04215978). Ph 1a results were previously presented (Desai *et al. J Clin Oncol.* 2023). **Methods:** Previously treated pts with NSCLC (Part A1), HNSCC (Part A2), or NSCLC with PD-L1 ≥50% (Part C) received BGB-A445 monotherapy, while pts with treatment-naïve recurrent/metastatic NPC (Part B) received BGB-A445 combined with tislelizumab and chemotherapy. Primary endpoints included ORR per investigator (RECIST v1.1); secondary endpoints were to assess PFS, DOR and DCR, safety/tolerability, PK, and host immunogenicity. **Results:** As of Sep 25, 2024, 54 pts were enrolled in Part A1, 19 in Part A2, 12 in Part B, and 7 in Part C. In the efficacy evaluable analysis set, ORR was 0% in Parts A1, A2, and C, and 70% (7/10; all confirmed PRs, one unconfirmed CR) in Part B. In Parts A1, A2, B, and C, confirmed DCR was 49.0%, 33.3%, 100.0%, and 57.1%, respectively. TEAEs occurred in the majority of pts (Table). The most common treatment-related TEAEs were pyrexia (10.0% [8/80]), chills (5.0% [4/80]), and anemia (5.0% [4/80]) in the monotherapy cohorts, and anemia (75.0% [9/12]), decreased WBC (66.7% [8/12]), decreased neutrophils, and decreased platelets (58.3% [7/12], each) in the combination cohort. Treatment-related serious TEAEs occurred in 2.5% (2/80; pyrexia and asthenia in a single pt each) of pts in the monotherapy cohorts and 8.3% (1/12; febrile neutropenia) in the combination cohort. There were no BGB-A445 or tislelizumab-related TEAEs leading to treatment discontinuation or death. The most common imAE was rash (2.5% [2/80] in the monotherapy cohort; 33.3% [4/12] in the combination cohort). No Gr ≥3 imAEs or IRRs were reported. **Conclusions:** BGB-A445 alone or in combination with tislelizumab and chemotherapy was generally well tolerated across all doses in pts with advanced NSCLC, HNSCC, and NPC, and showed preliminary antitumor activity. Clinical trial information: NCT04215978. Research Sponsor: BeOne Medicines Ltd.

2526 Poster Session

Phase 1b dose extension study of a next-generation anti-CD47 monoclonal antibody IMC-002 combined with lenvatinib in patients with advanced hepatocellular carcinoma (HCC). First Author: Jung Yong Hong, Division of Hematology-Oncology, Department of Medicine, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, South Korea

Background: IMC-002 has shown significant preclinical efficacy and safety, which are attributed to its unique binding site and distinct mechanism of action. These preclinical findings strongly support its clinical development as a cancer therapeutic. Phase 1a trial confirmed its superior safety and tolerability. Here we present initial results from the phase Ib trial, focusing on safety, efficacy, PK, and biomarker. **Methods:** Eligible pts had advanced HCC that progressed following at least 1 prior systemic therapy and ECOG PS ≤1. IMC-002 was administered at 20 mg/kg Q3W in combination with Lenvatinib, continuing until disease progression. Tumor assessments were conducted every 6 weeks using RECIST 1.1 and iRECIST. A target-mediated drug disposition (TMDD) PK model incorporating FcRn recycling was developed to predict PK values for Q3W dosing and evaluated for consistency with observed data. Immunohistochemistry (IHC) images of CD47 expression were analyzed using Lunit SCOPE uIHC, an AI-based platform capable of distinguishing staining positivity and cell types at the single cell level. **Results:** A total of 13 pts with refractory HCC received IMC-002 in combination with Lenvatinib. Most patients had received prior anti-PD-(L)1 therapy (11 pts) and had an ECOG PS of 1 (9 pts). Among the 10 pts evaluable for efficacy, the ORR was 30%, and the DCR was 70%. The median TTP was 8.3 months. AI-driven analysis of CD47 membrane specificity, using a subcellular model, revealed that samples with a high proportion of non-membrane-specific cells were associated with poor clinical outcomes (ORR 0%, DCR 33%). In contrast, samples with a low proportion demonstrated improved responses (ORR 60%, DCR 80%). We confirmed that 96.3% of the observed concentrations of IMC-002 in Phase 1b not only fell within the 90% prediction percentiles of PK model developed for Q3W dosing schedule but also demonstrated steady-state achievement (after cycle 2 of Q3W) and consistent C_{trough} exposure above the MEC (> 24 μg/mL). All TRAEs were grade 1-2 (100%), with 92% occurring during cycle 1. TRAEs reported in more than one patient included skin rash and transient vitreous floaters. Anemia was observed in only one patient, while no cases of neutropenia, thrombocytopenia, or treatment-related SAEs were reported. **Conclusions:** IMC-002, when combined with Lenvatinib at a dose of 20 mg/kg Q3W, demonstrated a promising efficacy and safety profile. AI-driven biomarker analysis identified potential predictive value, supporting the need for further investigation in larger clinical trials. Clinical trial information: NCT05276310. Research Sponsor: ImmuneOncia Therapeutics Inc.

Tumor response by CD47 non-specific cell proportion.

Cohort	Non-specific cell proportion Mean (±SD)	ORR	DCR
A	0.24 (±0.05)	0%	33%
B	0.05 (±0.05)	60%	80%
p-value	0.00	0.03	0.14

Cohort A: High proportion (≥15%) of 'non-specific' cells; Cohort B: Low proportion (<15%) of 'non-specific' cells.

Safety and efficacy of QLS31905 in patients with advanced solid tumors: Updated data from phase 1 study. First Author: Yakun Wang, Key Laboratory of Carcinogenesis and Translational Research (Ministry of Education/Beijing), Department of Gastrointestinal Oncology, Peking University Cancer Hospital and Institute, Beijing, China

Background: QLS31905 is a Claudin18.2/CD3 bispecific antibody. Here we report the updated data of a phase 1 study of QLS31905. **Methods:** This multicenter phase 1 trial (NCT05278832) recruited patients (pts) with advanced solid tumors who had progressive disease or were intolerable to or inapplicable of standard therapy. In dose-escalation stage adopting accelerated titration and interval 3+3 design, pts regardless of Claudin18.2 status were administered QLS31905 via intravenous infusion in 11 sequential single doses (0.5, 1.5, 5, 15, 45, 100, 200, 350, 500, 800, 1200 μg/kg qw or q2w) with priming dose from 350 μg/kg. In dose-expansion stage, Claudin18.2-positive (≥1% tumor cells) pts were recruited. The primary endpoint was dose limiting toxicities (DLT) and maximum tolerated dose (MTD) in dose-escalation stage, and was objective response rate (ORR) in dose-expansion stage. **Results:** As of Jul 26, 2024, 31 pts were included from 0.5 μg/kg qw to 1200 μg/kg q2w in dose-escalation stage, and 48 pts were included in five cohorts (100~200 μg/kg qw and 350~800 μg/kg q2w) in dose-expansion stage. The 1200 μg/kg q2w cohort is ongoing. There were 43 (54.4%) pts with gastric or gastro-esophageal junction (G/GEJ) cancer and 26 (32.9%) with pancreatic adenocarcinoma (PAC). Over half of (61.8%) pts had received ≥2 lines of prior treatment. No DLT occurred. MTD was not reached. Treatment-related adverse events (TRAEs) occurred in 79 (100%) pts, of whom 34 (43.04%) were ≥grade 3. The most common ≥grade 3 TRAEs (≥3%) were lymphocyte count decreased (21.5%), γ-glutamyl transferase increased (3.8%), neutrophil count decreased (3.8%), cytokine release syndrome (CRS [3.8%]), and anemia (3.8%). CRS occurred in 17 (21.52%) pts including two pts with grade 3 and one with grade 4, and all recovered. Two pts (2.53%) discontinued treatment due to TRAEs of abdominal pain and CRS, respectively. No TRAE leading to death occurred. In 33 Claudin18.2-positive pts in 350~1200 μg/kg q2w cohorts, six pts (three with G/GEJ cancer and three with PAC) had partial response. ORR was 18.18% (95% confidence interval [CI]: 6.98%, 35.46%), disease control rate (DCR) was 87.88% (95% CI: 71.80%, 96.60%), median progression-free survival (PFS) was 4.21 months (95% CI: 2.99, 5.55), and median overall survival (OS) was 9.53 months (95% CI: 7.69, not evaluable). Among the Claudin18.2-positive pts in 350~1200 μg/kg q2w cohorts, ORR, DCR, median PFS, median OS was 15.79%, 89.47%, 4.40 months, 9.20 months in 19 pts with G/GEJ cancer, and was 25.00%, 91.67%, 3.94 months, not reached in 12 pts with PAC, respectively. QLS31905 exposure was generally linear with the administered dosage. There was no tendency of accumulation after multiple administrations. **Conclusions:** QLS31905 was safe and tolerable, and showed encouraging efficacy in Claudin18.2-positive pts with gastrointestinal tumors. QLS31905 is worthy of further exploration in combined therapy in phase 2 trials. Clinical trial information: NCT05278832. Research Sponsor: None.

Epigenetic and phenotypic signatures of T-cell response to blinatumomab in pediatric relapsed and refractory B-ALL. First Author: Tyler G. Bruno, St. Jude Children's Research Hospital, Memphis, TN

Background: By forming an immunological synapse between T cells and tumor antigen, bispecific T cell engagers (BiTEs) like blinatumomab have shown great promise in treating B-cell acute lymphoblastic leukemia (B-ALL). However, many relapsed and refractory (R/R) patients fail to achieve long-term survival, with 40% not surviving past 24 months. Prolonged T cell activation with blinatumomab therapy may lead to changes in differentiation that leave the T cell population unable to elicit a sustained anti-tumor response. A deeper understanding of the dynamics of the T cell compartment in R/R B-ALL patients will lead to improved treatment strategies and optimized patient selection for blinatumomab therapy. **Methods:** To characterize T cell persistence and response in this context, we assessed memory and exhaustion phenotypes in blinatumomab-treated T cells isolated from 10 R/R pediatric B-ALL patients treated with blinatumomab. CD8+ T cells were isolated from peripheral blood and bone marrow samples and analyzed for memory and exhaustion phenotypes via flow cytometry. Absolute lymphocyte counts were measured and linked to the sample flow cytometry data to assess expansion and contraction of T cell memory subsets throughout the course of therapy. Whole genome enzymatic methyl sequencing was performed on post-treatment PD-1 High and PD-1 Low CD8 T cells to determine the multipotency of the patient T cell compartment after blinatumomab treatment. **Results:** After 7 days of continued blinatumomab infusion, patient T cells demonstrated a significant expansion of terminally differentiated and effector memory T cells. Notably, we observed that non-responders had a high tumor burden at the start of the therapy and possessed a large population of naïve CD8 T cells that failed to expand. These CD8 T cells exhibited a significant increase in expression of TIM-3 and PD-1 compared to responders after the 7-day infusion. Methylation analysis of post-treatment CD8 T cells showed decreased methylation of exhaustion regulators IKZF1 and CD300a in non-responders compared to the responders. Additionally, *in vitro* treatment of T cells with blinatumomab induced T-cell exhaustion in a target-dependent manner. **Conclusions:** Blinatumomab therapy in pediatric B-ALL patients induced variable epigenetic and phenotypic changes to the T cell compartment indicative of exhaustion, corresponding to differences in T cell expansion and persistence between patients. Our study is the first to link epigenetic changes in exhaustion regulators with response variability in blinatumomab-treated patients. Furthermore, our findings highlight a potential role of baseline T cell composition and tumor burden in determining therapeutic outcomes. These insights provide a novel framework for improving patient stratification and treatment strategies to mitigate T cell exhaustion in blinatumomab therapy. PD-1 blockade in combination with bevacizumab and nab-paclitaxel for second-line treatment in cancer of unknown primary (Fudan CUP-002): A prospective, single-arm phase II study. First Author: Zhiguo Luo, Department of Medical Oncology, Fudan University Shanghai Cancer Center, Shanghai, China

Background: Cancer of unknown primary (CUP), a heterogeneous tumor characterized by histologically confirmed metastases with undefined primary, accounts for 2-5% of all malignancies. Our previous study, Fudan CUP-001, confirmed that site-specific first-line treatment improves progression-free survival (PFS) in patients with CUP compared to empirical treatment. However, no evidence-based standard of care currently exists for second-line treatment of CUP. We conducted the Fudan CUP-002 study by Simon's two-stage design to evaluate the efficacy and safety of co-administration of F520 injection (anti-PD-1 antibody), bevacizumab, and nab-paclitaxel in patients with CUP who have progressed after first-line treatment. **Methods:** In this prospective, single-arm phase II study (ClinicalTrials.gov, NCT04848597), patients with previously treated CUP received intravenous F520 injection at a dose of 200 mg and bevacizumab 7.5 mg/kg every 3 weeks for up to 2 years, and intravenous nab-paclitaxel 125 mg/m^2 administered on day 1 and day 8 every 3 weeks for up to 8 cycles. The primary endpoint was confirmed objective response rate (ORR) by blinded independent central review (BICR) per Response Evaluation Criteria in Solid Tumors (RECIST) version 1.1. The secondary endpoints included PFS, overall survival (OS), disease control rate (DCR), and safety. **Results:** Between June 2, 2021, and January 10, 2025, a total of 48 eligible subjects were enrolled in the study. In the overall population, the median age was 60 (range: 29 to 72) years, with 31 males (64.6%) and 17 females (35.4%). At the data cutoff on January 10, 2025, the median follow-up was 27.1 months (95% CI, 20.2 to 37.2) and 3 (6.3%) cases continued treatment. The ORR was 54.2% (95% CI, 40.3 to 67.4), and the DCR was 95.8% (95% CI, 86.0 to 98.9), as assessed by BICR per RECIST version 1.1. The median PFS was 16.7 months (95% CI, 12.6 to not available (NA)), with the 12- and 24-month PFS rates at 68.6% and 38.5%, respectively. The median OS was 24.6 months (95% CI, 14.6 to 29.5), and the 12- and 24-month OS rates were 72.5% and 53.0%, respectively. The median duration of response (DoR) was 22.5 months (95% CI, 12.5 to NA), with the 12- and 24-month DoR rates at 78.9% and 47.5%, respectively. Treatment-related adverse events (TRAEs) of any grade were reported by 46 (95.8%) patients. Hematologic toxicity (43, 89.6%) and liver injury (25, 52.1%) of any grade were the most frequently reported TRAEs, and grade 3-4 TRAEs were observed in 25 (52.1%) patients. Grade 3-4 immune-related adverse events (irAEs) occurred in 8 (16.7%) participants, with pneumonitis (2, 4.2%) and endocrine disorders (2, 4.2%) being the most common. **Conclusions:** Second-line PD-1 blockade in combination with bevacizumab and nab-paclitaxel is an effective and well-tolerated treatment regimen for patients with CUP. Clinical trial information: NCT04848597. Research Sponsor: Clinical Research Plan of SHDC.

Comprehensive analysis of NSAIDs use and oncological outcomes in non-small cell lung cancer patients treated with immune checkpoint inhibitors. First Author: Yanlin Li, Second Affiliated Hospital of Xi'an Jiaotong University, Xi'an, China

Background: The effect of non-steroidal anti-inflammatory drugs (NSAIDs) on immune checkpoint inhibitors (ICIs) efficacy in non-small cell lung cancer (NSCLC) remains controversial. Although the COX-2/PGE2 pathway, a primary target of NSAIDs, has been implicated in diminished immunotherapy response, direct clinical association with NSAIDs and ICIs in real world has yet to be established. This study aims to evaluate the impact of NSAIDs use—considering types, duration, and timing—on ICI efficacy, alongside its effects on PGE2 and immune cell profiles. **Methods:** We included stage III-IV NSCLC patients receiving PD-1/PD-L1 antibodies in 5 centers. Blood and tumor samples were collected in perspective cohort. NSAIDs were categorized based on selectivity (non-selective COX inhibitors, selective COX-2 inhibitors) and chemical structure (salicylates, propionate derivatives, others). PGE2 and cytokines were measured in blood by ELISA. RNA sequencing data were obtained from databases. Tumor tissues were collected for immunohistochemical staining of immune cells. Multivariate Cox and logistic regression were used in analyses of progression-free survival (PFS) and objective response rate (ORR). **Results:** 883 patients were included, with 140 NSAIDs users and 743 non-users. 196 patients were enrolled prospectively with samples. Multivariate analysis showed that NSAIDs use was significantly associated with improved PFS (HR 0.67, 95% CI 0.51-0.88, P = 0.005) and ORR (OR 1.87, 95% CI 1.29-2.72, P = 0.001). Subgroup analyses indicated that non-selective COX inhibitors, salicylates, long-term use, and pre-ICI initiation were correlated with better outcomes. In contrast, selective COX-2 inhibitors, propionate derivatives, others, short-term use, and post-ICI initiation showed no effect on PFS or ORR. Blood analyses indicated that NSAIDs significantly lowered PGE2 levels, particularly salicylates and long-term use. Higher PGE2 was associated with worse outcomes. For immune cells, RNA sequencing revealed that COX-2 and mPGES-1 were significantly correlated with neutrophil enrichment and neutrophil-related cytokines. Single-cell RNA-seq showed high expression of COX-2 and mPGES-1 in neutrophils. Analysis of samples confirmed that NSAIDs use was associated with reduced neutrophils and neutrophil-related cytokines in blood and less neutrophil infiltration in tumor. **Conclusions:** NSAID use is an independent predictor of improved PFS and ORR in NSCLC patients receiving ICIs. Specifically, non-selective COX inhibitors, salicylates, long-term use, and pre-ICI initiation are associated with better clinical outcomes. NSAID use may enhance ICIs efficacy by reducing serum PGE2, which could serve as a predictive biomarker. Furthermore, NSAIDs decrease neutrophils in both blood and tumor, potentially contributing to the improvement in ICI efficacy. 2531 **Poster Session**

Preliminary monotherapy efficacy of novel immune checkpoint blockade GV20-0251 (anti-IGSF8) in advanced melanoma patients with primary resistance to anti-PD1. First Author: Kristopher Wentzel, The Angeles Clinic and Research Institute, A Cedars-Sinai Affiliate, Los Angeles, CA

Background: GV20-0251 is an AI-designed, first-in-class, cross-species reactive, Fc-attenuated IgG1 antibody that targets the novel cancer immune checkpoint IGSF8 which is broadly expressed across solid tumors. In syngeneic tumor models, anti-IGSF8 alone or with anti-PD1 inhibits tumor growth by increasing cytotoxicity and infiltration of natural killer cells (NK) and antigen cross-priming by dendritic cells which in turn activates T cells. **Methods:** The phase 1 portion of this first-in-human, phase I/IIa study (NCT05669430) was conducted across multiple U.S. centers. The study utilized a standard 3+3 design to evaluate the safety, pharmacokinetics (PK), pharmacodynamics, immunogenicity, and preliminary efficacy of GV20-0251, and to establish a preliminary recommended phase 2 dose (RP2D). **Results:** Forty-two patients with advanced solid tumors (median age 61 years, median 4 prior treatment lines) were enrolled across six dose levels (0.5, 1, 3, 6, 10, and 20 mg/kg) and two schedules (D1/D8 Q3W and D1 Q3W). GV20-0251 demonstrated favorable safety and tolerability across all doses and schedules with no dose-limiting toxicities, and 10 and 20 mg/kg D1 Q3W were selected as the preliminary RP2D. Treatment-related adverse events occurred in 55% of patients, predominately grade 1/2, with a single grade 3 event of pneumonitis. The most common treatment-related AEs were fatigue and rash (12% each), with no dose-dependent trends. Full target occupancy and half-life of 26 days with linear PK were observed at ≥10 mg/kg, without significant serum cytokine elevation or anti-drug antibody signals. Among 38 efficacy-evaluable patients, 17 had cutaneous melanoma, all of whom progressed on prior anti-PD1 therapy and 16 progressed on prior anti-CTLA4 therapy. Among the 9 melanoma patients with primary resistance to anti-PD1, confirmed partial response (PR) was achieved in 3 (33%) patients and tumor shrinkage was observed in an additional 3 patients. Notably, responses were observed in 2 patients with liver metastases, which are typically refractory to immunotherapy. Although no responses were seen in the melanoma patients with acquired resistance to anti-PD1 (n = 8) or in patients with other tumor types (n = 21), potentially due to the lower frequency of IGSF8 protein expression in these tumors, tumor shrinkage was observed in one non-small cell lung cancer (n = 4) and one cervical cancer (n = 1) patient. Preliminary immunohistochemistry analyses of trial patient biopsies suggest IGSF8 high tumors have low anti-PDL1 at baseline, and GV20-0251 treatment increases tumor-infiltrating NK and T cells. **Conclusions:** GV20-0251 demonstrated a favorable safety profile in heavily pretreated patients with advanced solid tumors and showed promising monotherapy efficacy in cutaneous melanoma patients with primary resistance to anti-PD1. Clinical trial information: NCT05669430. Research Sponsor: GV20 Therapeutics.

2532 Poster Session

Prophylactic infusion of allogeneic double-negative T cells as immune modulators to prevent relapse in high-risk AML patients after allo-HSCT: A phase I trial. First Author: Xiaoyu Zhu, The First Affiliated Hospital of University of Science and Technology of China, Hefei, China

Background: Our previous study demonstrated that double-negative T cells (DNTs) hold potential for treating relapsed or refractory acute myeloid leukemia (r/r AML) following allogeneic hematopoietic stem cell transplantation (allo-HSCT). In a first-in-human Phase I trial (ChiCTR-IPR-1900022795), we reported a complete response (CR) rate of 50% (5/10) with a favorable safety profile. This Phase I/II study aims to evaluate the safety and efficacy of off-the-shelf allo-DNTs in preventing relapse in AML patients following allo-HSCT. **Methods:** Six high-risk AML patients undergoing allo-HSCT were enrolled and assigned to two dosage groups: 1×10^8 DNTs/kg and 1.5×10^8 DNTs/kg. Each patient received three infusions at one-month intervals without prior lymphodepleting chemotherapy. The median time from transplantation to the first infusion was 3.1 months. Primary endpoint was the occurrence of adverse events and dose-limiting toxicities, while the secondary endpoint was cumulative incidence of relapse (CIR). GMP-grade DNTs were expanded ex vivo from healthy donor PBMCs and cryopreserved in liquid nitrogen until infusion. **Results:** As of January 20, 2025, with a median follow-up of 17.55 months post-HSCT, four of six patients (66.7%) remained in MRD-negative CR, with the longest recurrence-free survival exceeding 17 months. The two relapsed patients both carried high-risk genetic mutations (TP53 mutation) and were MRD-positive prior to transplantation. They succumbed at 11.4 and 14.2 months post-HSCT respectively. Donor-derived DNTs were detectable in peripheral blood shortly after each infusion, peaking at 1–4 days and persisting for up to 28 days. In two patients with MRD-negative CR, infused DNTs remained detectable for up to 360 days post-infusion. Elevated levels of IFN-γ, IL-6, and IL-10 post-infusion indicated immune activation. Importantly, no dose-limiting toxicities, neurotoxicity, cytokine release syndrome greater than Grade 2, or graft-versus-host disease were observed. In contrast to the two relapsed patients, MRD-negative CR patients showed expanded levels of CD4+, CD8+, and DNT cells, particularly those with the effector memory T cell phenotype. Both the infused DNTs and the recipient's CD4+ and CD8+ T cells in these patients secreted higher levels of granzymes A and K. To investigate the interaction between CD8+ T cells and allo-DNTs in MRD-negative CR patients, co-culture experiments were conducted. CD8+ T cells exhibited an increase in the secretion of granzyme B and IFN-γ within 3–4 days. Transcriptome sequencing and multi-cytokine analyses revealed strong immune activation. **Conclusions:** The dual ability of DNTs to suppress GvHD while preserving the graft-versus-leukemia effect, along with its potential for off-the-shelf availability, makes it a transformative therapy in the post-transplant setting. Targeting cancer leptomeningeal metastasis with allogeneic chimeric antigen receptor γδ T-cell therapy. First Author: Peiwen Ma, National GCP Center for Anticancer Drugs, National Cancer Center/Cancer Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College, Beijing, China

Background: Leptomeningeal metastasis (LM) occurs in 1–10% of patients with advanced solid tumors during disease progression. LM significantly worsens prognosis due to the rapid onset and progression of symptoms associated with elevated intracranial pressure. Currently, no therapies specifically targeting LM have been approved. Here, we report our clinical observations from two patients treated with intrathecal infusion of allogeneic B7H3-targeted CAR-γδT cells(QH104). **Methods:** This is an open-label, single-arm clinical study designed to evaluate the safety and efficacy of QH104 in patients with LM originating from B7H3-positive solid tumors(NCT06592092). Eligibility criteria included a diagnosis of LM from any B7H3-positive solid malignancy. QH104 was administered as a single dose of 3×10^7 cells via lumbar puncture or Ommaya reservoir infusion. Treatment-emergent adverse events were graded using CTCAE v5.0 and ASTCT criteria. Efficacy was assessed using the RANO-LM criteria. **Results:** As of January 2025, two female lung adenocarcinoma patients were enrolled. They had previously received treatments targeting LM, including intrathecal chemotherapy and oral EGFR tyrosine kinase inhibitors. No adverse events higher than grade3 were reported. One patient experienced a transient episode of absence seizures on Day 1 after cell infusion, which was considered treatment-related. At the Day 30 assessment post-infusion, both patients had stable disease, with a reduction or complete elimination of tumor cells in the CSF and improvement in clinical symptoms associated with LM. CSF component analysis demonstrated the persistence of CAR-γδ T cells for one week post-infusion. CSF cytokine analysis revealed increased levels of interleukin-5, -6, -9, -13, and -22, TNF-α and IFN-γ post-infusion compared to baseline. No significant increases in CAR-γδ T cells or cytokines were detected in peripheral blood. **Conclusions:** Our initial clinical experience with the first two patients with leptomeningeal metastasis (LM) provides preliminary evidence supporting the safety and efficacy of B7H3-targeted CAR-γδT cell immunotherapy in this patient group. A longer follow-up period and a larger patient cohort are necessary for a comprehensive evaluation of therapeutic efficacy and response durability. Clinical trial information: NCT06592092. Research Sponsor: National Natural Science Foundation of China; 82272953; The National Key Research and Development Program of China.

Patients' baseline character, administration routes and treatment evaluation.

	Diagnosis	Sex	Age	Genetic mutation	B7H3 Score	B7H3+ CAR -γδT cells infused	Administration route	Treatment response at Day 30
Patient 01	Lung adenocarcinoma with LM	F	53	EGFR 21 exon L858R mutation	70	3×10^7	Lumbar puncture	Stable disease (CSF cytology: remain positive CNS imaging: Stable Symptoms assessment score:6 to 4)
Patient 02	Lung adenocarcinoma with LM	F	58	EGFR 21 exon L858R mutation	40	3×10^7	Ommaya reservoir	Stable disease (CSF cytology: turned negative CNS imaging: Stable Symptoms assessment score:4 to 2)

Safety and efficacy of non-viral aPD1-MSLN JL-lightning–CAR-T in advanced malignant mesothelioma in a phase I trial. First Author: Yan Sun, Shanghai Cell Therapy Group Co., Ltd, Shanghai, Shanghai, China

Background: CAR-T cells face challenges in solid tumors, including weak in vivo proliferation, immunosuppressive tumor microenvironments (TME), and limited tumor infiltration. We firstly developed an innovative non-viral JL-Lightning-CAR-T fast process to enhance CAR-T stemness, in vivo expansion, and persistence. The autologous non-viral aPD1-MSLN JL-Lightning-CAR-T cells were manufactured in just 30 hours, targeting mesothelin (MSLN) and secreting anti-PD-1 antibodies to counteract the immunosuppressive TME and improve the efficacy of solid tumor treatment. Here, we report the safety and preliminary efficacy of this novel CAR-T therapy in advanced malignant pleural mesothelioma (MPM) in a first-in-human phase I pilot study (ClinicalTrials.gov: NCT06249256). **Methods:** A single-arm, open-label, dose-escalation study was designed and enrolled MPM patients who had failed standard therapies and had confirmed MSLN and PD-L1 expression on tumors by IHC. Patients received a single dose of non-viral aPD1-MSLN JL-Lightning-CAR-T cells following lymphodepletion (Flu 30 mg/m²/day, Cy 300 mg/m²/day) for 2-3 days. The dose escalation was designed as DL1 (0.5-0.6×10^6/kg) and DL2 (0.8-1.0×10^6/kg). Adverse events were evaluated using CTCAE v5.0, and clinical responses were assessed by mRECIST 1.1 or RECIST 1.1. CAR expression was analyzed by qPCR, and anti-PD-1 antibodies were detected by MSD. **Results:** Patients: Seven advanced MPM patients were enrolled and received single dose CAR-T cell infusion. Efficacy: In DL1 (0.5-0.6×10^6/kg), one patient achieved partial response (PR) with a disease control rate (DCR) of 75% (3/4). In DL2 (0.8-1.0×10^6/kg), all of three patients achieved objective response (ORR 100%, 3/3), with one patient achieving complete response (CR) at 3 months and maintaining it for over 9 months. Pharmacokinetics: Anticipated CAR-T cell expansion and anti-PD-1 antibodies increase detected in circulation. CAR-T Cmax reached up to 47,307 copies/μg, detectable for over 3 months. Anti-PD-1 antibody Cmax reached up to 376,938 pg/ml, detectable for over 6 months. Tmax for MSLN-CAR-T and anti-PD1 nanobody occurred between Day 7 and Day 14 post infusion. IFN-γ and IL-6 levels also increased during this period. Safety: In DL1, CRS was observed in 1 of 4 patients (Grade 1), with no ICANS or DLT. In DL2, CRS was observed in 2 of 3 patients (Grade 3-4), with no ICANS. Grade 3 immune-mediated pneumonia occurred in 2 of 3 patients in DL2, managed by clinical intervention strategies. All patients experienced Grade 3-4 hematologic toxicity, reversible with supportive care. **Conclusions:** Non-viral aPD1-MSLN JL-Lightning-CAR-T cells demonstrated robust proliferative capacity, manageable safety profile, and significant anti-tumor potential, offering a promising therapeutic approach for advanced MPM patients. Clinical trial information: NCT06249256. Research Sponsor: None.

2535 Poster Session

Phase I trial of personalized AI-identified TCR-transduced T cell therapy in advanced solid tumors. First Author: Shuhang Wang, Department of Clinical Trial Center, National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China

Background: TCR-T cell therapy shows promise in treating solid tumors but is limited by the need for personalized TCR identification. We developed TCR-XFinder, a deep learning model using a 3-stage transfer-learning strategy, to rapidly identify personalized tumor-reactive TCRs within 10 days after tumor tissue acquisition. This study reports the first-in-human phase I trial of KSX01, a TCR-transduced T cell therapy identified by TCR-XFinder. **Methods:** We conducted a phase I, dose-escalation study (NCT06150365) to evaluate the safety and efficacy of KSX01 in patients with advanced solid tumors. Tumor tissues were subjected to single-cell RNA sequencing and TCR sequencing to identify tumor-reactive TCRs using TCR-XFinder. These TCRs were validated and transduced into autologous T cells, which were expanded and infused back into patients. Patients received preconditioning with cyclophosphamide (500 mg/m²/day) and fludarabine (30 mg/m²/day) for 3 days, followed by intravenous infusion of KSX01 TCR-T cells at two dose levels ($5\times10^9 \pm 30\%$ and $1\times10^{10} \pm 30\%$ cells). Safety was assessed by monitoring adverse events and cytokine release syndrome (CRS). Efficacy was evaluated by RECIST v1.1 criteria. **Results:** Four patients with advanced solid tumors (alveolar soft part sarcoma, epithelioid sarcoma, colon cancer, and clear cell renal cell carcinoma) were enrolled. KSX01 TCR-T cells were well-tolerated at both dose levels, with no dose-limiting toxicities (DLTs) observed. All patients experienced Grade 3–4 pancytopenia, which was expected following lymphodepletion. One patient developed Grade 2 CRS, resolved with tocilizumab. No Grade 3 or higher AEs related to KSX01 were noted. At the first tumor assessment (Day 28), all patients showed disease control, with one patient achieving a partial response (PR) and a 46% reduction in target lesion size. Another patient achieved PR with second infusion at higher dose. qPCR analyses confirmed the infiltration and long-term anti-tumor effect of infused TCR-T cells. A transient post-infusion increase in interferon-γ (IFN-γ), interleukin-6(IL-6), IL-10, IL-4, tumor necrosis factor-α (TNF-α), and CRP levels was observed in all patients. While the C_{max} and T_{max} values varied among cytokines, the first T_{max} for 80% of cytokines and CRP occurred within the first week post-infusion. Re-biopsy of tumor lesions showed infiltration of infused TCR-T with persistent cytotoxic function and ameliorate the microenvironment for the endogenous tumor-reactive T cells. **Conclusions:** The first-in-human phase I trial of KSX01 TCR-T cell therapy demonstrated promising safety and efficacy in patients with advanced solid tumors. TCR-XFinder enabled rapid identification of personalized tumor-reactive TCRs, supporting the clinical feasibility of this approach. Further studies are warranted to explore optimal dosing and combination strategies to maximize clinical benefit. Clinical trial information: NCT06150365. Research Sponsor: National Natural Science Foundation of China; 82272953; The National Key Research and Development Program of China.

2536 **Poster Session**

Artificial intelligence (XGBoost) in predicting outcomes among CAR-T therapy patients: The impact of malnutrition and comorbidities using the National Inpatient Sample (2020-2022). First Author: Tong Ren, University of South Florida (USF) Morsani College of Medicine/HCA Florida Oak Hill Hospital, Brooksville, FL

Background: Chimeric Antigen Receptor T-cell (CAR-T) therapy has revolutionized hematologic malignancy treatment but remains costly, with limited access and complications like prolonged hospitalization, sepsis, and mortality. Malnutrition, common in cancer patients, worsens these outcomes. Despite AI's growing role in oncology, its use in risk stratification for malnourished CAR-T recipients is underexplored. This study leverages the National Inpatient Sample (NIS) 2020-2022 to develop AI-driven models predicting length of stay (LOS), mortality, and sepsis, incorporating the Charlson Comorbidity Index and other factors. **Methods:** Using the NIS database, adult CAR-T therapy patients were identified with ICD-10 codes. Key variables included demographics (age, gender, race/ethnicity, income), clinical factors (Charlson Comorbidity Index, sepsis, admission type), and hospital characteristics (size, teaching status). AI models (XGBoost, Random Forest, Neural networks) were trained on the 2020 dataset and validated on 2020-2022 data. Hyperparameter tuning via grid search was performed to optimize model performance. LOS was modeled as a continuous outcome, while mortality and sepsis were classified as binary outcomes. Data preprocessing included handling missing values, one-hot encoding of categorical variables, and standardizing continuous variables. SHapley Additive exPlanations (SHAP) were used to interpret feature importance. **Results:** The study analyzed 1,912 CAR-T hospitalizations over three years, with 11.5% identified as malnourished. AI models demonstrated strong predictive performance, with XGBoost (RMSE: 3.5 days, R^2 = 0.82) for LOS, Random Forest (AUC: 0.91) for mortality, and Neural Networks (AUC: 0.87) for sepsis. Malnutrition significantly worsened outcomes, increasing LOS by 14.2 days ($p < 0.001$) and mortality risk by 3.2-fold ($p < 0.001$). Patients with Charlson Comorbidity Index scores $\geq$3 had 9.8-day longer LOS and 2.9-fold higher mortality risk ($p < 0.001$). Racial disparities were evident, with Black patients at 25% higher risk of prolonged LOS and Hispanic patients at increased risk of sepsis ($p < 0.05$). Malnourished patients in non-teaching hospitals with high comorbidity burdens had the worst outcomes, emphasizing the need for targeted interventions in high-risk populations. **Conclusions:** AI-driven models incorporating malnutrition and Charlson Comorbidity Index accurately predict LOS, mortality, and sepsis in CAR-T patients. Early identification and management of malnutrition and comorbidities, particularly in racially diverse populations, are critical to improving outcomes. Future research should focus on prospective validation and AI integration into clinical workflows to mitigate disparities. Research Sponsor: None.

A novel cellular immunotherapy using vaccine generated neoantigen-specific effector T cells. First Author: Andrew Edward Sloan, Piedmont Healthcare and Case Western Reserve University School of Medicine, Atlanta, GA

Background: Cellular immunotherapy languished in obscurity until genetically engineered chimeric antigen receptor T cells were shown to effectively treat B lymphocyte cancers. Genetic studies also revealed that some cancer cell mutations produce neoantigens, which are consistent with historical studies demonstrating that cancer cell vaccination generates neoantigen specific immune responses in rodents and humans. Vaccination leads to an increase in neoantigen-specific T cells in lymphoid tissue that are released into the blood, which carries them to sites of disease activity, e.g., cancer tissue. TVAX Biomedical hypothesized that the natural power of the patient's immune system could be exploited using a novel neoantigen-specific cellular immunotherapy. **Methods:** Patients are vaccinated with their own attenuated cancer cells plus an immunologic adjuvant, e.g. GM-CSF, to increase the number of circulating neoantigen primed T cells. Patients are leukapheresed to collect the T cells. The collected T cells are exposed to activation and proliferation stimulating agents to generate the neoantigen-specific effector T cells that are used for treatment. TVAX is currently testing this treatment paradigm for efficacy and safety in newly diagnosed (MGMT-negative) glioblastoma patients when they have minimized immunosuppression and minimal residual disease, TVI-AST-008. **Results:** For this novel cellular immunotherapy to be effective, T cell mediated immune responses must be generated in vaccinated patients. Delayed type hypersensitivity skin testing, a method for detecting T cell mediated immunity in humans, showed reactions in patients with leukemia, brain, breast, colon, lung, kidney, melanoma, ovarian, prostate and sarcoma (data to be presented). Multiple autologous vaccinations led to detectable responses in all patients. The combination of cancer cell/immunologic adjuvant vaccination plus neoantigen-specific T cellular immunotherapy has been shown to be highly effective against a wide range of cancer types in preclinical studies and to be effective against the least immunogenic cancers. **Conclusions:** The possibility that neoantigen-specific T cells could effectively treat some human cancers has been documented through studies with tumor infiltrating lymphocytes (TILs). However, TIL efficacy is limited to a small number of (hot) cancers. Preclinical model studies demonstrated that neoantigen-specific effector T cells enter cancer tissue, initiating a cascade of T cell mediated immunologic events that ultimately leads to killing of cancer cells by cytotoxic T cells and cytokine activated accessory cells. The benefit of the vaccine enhanced neoantigen-specific effector T cell therapy (TVAX Immunotherapy) is that it expands the range of human cancers that could be safely and effectively treated. Clinical trial information: 05685004. Research Sponsor: NIH Grant, Office of Orphan Products.

Engineering iPSC-derived mesenchymal stem cells (i MSCs) to secrete IL-7/IL-15 for modulation of the tumor microenvironment in a "cold" ovarian tumor model. First Author: Sandeep Singh, University of Texas MD Anderson Cancer Center, Houston, TX

Background: We previously discovered that bone marrow derived Mesenchymal stromal cells (BM-MSCs) migrate to the stroma of numerous cancers and their metastases, forming tumor-associated fibroblasts (TAFs) and can be modified to secrete proteins within the tumor microenvironment (TME). MSCs have not been utilized extensively in cancer therapy due to their immunosuppressive properties, limited replicative capacity, and variable quality depending on the source. **Methods:** Here, we report the characterization of induced mesenchymal stromal cells (iMSCs) derived from pluripotent stem cells (iPSCs), which were uniquely generated from adult skin fibroblasts using a transient mRNA transfection technique. Notably, iMSCs demonstrated superior proliferative capacity under both normoxic and hypoxic conditions, while preserving their trilineage differentiation potential. Comprehensive molecular profiling, including RNA sequencing, single-cell mass cytometry (CyTOF), and Luminex assays, revealed strong phenotypic and functional similarities between iMSCs and BM-MSCs. Crucially, no evidence of sarcoma formation was observed in NSGS mice following intraperitoneal, subcutaneous, or intravenous administration of iMSCs, highlighting their robust safety profile. We engineered a DNA cassette into these cells to enable constitutive superphysiological expression of interleukin(IL)-7 and IL-15, expressed as either individual molecules (P2A) or a single fused molecule (FUS). Both, P2A and FUS iMSCs demonstrate the capacity to drive T cell proliferation autonomously in co-culture experiments. **Results:** IL7/IL15-modified iMSCs induced tumor cell death in a triple co-culture system comprising iMSCs, the ovarian cancer cell line ID8, and human PBMCs. In a syngeneic mouse model of ovarian cancer (ID8 cells in C57BL/6 mice), intraperitoneal administration of P2A or FUS-iMSCs resulted in reduced tumor burden and extended survival. Immunohistochemical and flow cytometric analyses revealed massive infiltration of activated T cells, macrophages, and other immune cells into the tumor microenvironment (TME) in both FUS or P2A groups, but not in unmodified iMSC controls, or in PBS injected animals. The TME in P2A- and FUS-treated mice showed enrichment in tumoricidal M1-type macrophages, with no detection of exhausted or regulatory T cells, in contrast to controls. **Conclusions:** IL7-IL15-secreting iMSCs migrate into solid tumors, induce massive immune cell infiltration into the TME and enhance antitumor immunity in a syngeneic mouse model of cancer. These cytokine-producing iMSCs represent a potentially promising anticancer immunotherapy by converting "cold" into "hot" tumor microenvironments. Research Sponsor: Eterna Therapeutics, Inc.

Universal solid tumor therapy with CD5-deleted, DSG2-directed CAR-T cells. First Author: Robert D. Carlson, Thomas Jefferson Universiy, Philadelphia, PA

Background: CAR-T cell therapy has been curative for many patients with refractory, progressive hematologic cancers, resulting in several FDA approvals. However, this therapy has not been successful for solid cancers, reflecting the need for suitable antigen targets for each disease and solutions to immunological barriers in solid tumors. Here, we have identified the desmosomal cadherin, desmoglein 2 (DSG2), as an effective CAR-T cell therapy target in epithelia-derived solid tumors. DSG2 contributes to cell proliferation, migration, and other emerging tumor-promoting pathways, resulting in its upregulation in nearly all solid cancers and correlating with poor prognosis. Moreover, we explored CRISPR-Cas9-mediated elimination of the inhibitory receptor CD5 to enhance in vivo CAR-T cell expansion and solid tumor efficacy. **Methods:** DSG2-directed CAR-T cells were generated from human T cells using a scFv derived from a murine hybridoma targeting the extracellular domain of DSG2 in a 3rd generation CAR design with CD28, 4-1BB, and CD3ζ signaling domains. CD5 elimination employed electroporation of complexed gRNA-Cas9 ribonucleoprotein (RNP). DSG2 expression was characterized in human cancers and cell lines and CAR-T cell activity was examined in vitro by cytokine production and target cell cytolysis. In vivo efficacy studies employed cancer xenografts in NSG mice treated with CAR-T cells. Safety studies employed a human DSG2 transgenic mouse treated with syngeneic murine CAR-T cells for clinical, serum biomarkers, and histopathological evaluation. **Results:** In vitro studies revealed recognition and lysis of solid cancer cell lines and effector cytokine production. Administration of DSG2-directed CAR-T cells eliminated metastatic cell-derived xenografts, patient-derived xenografts, and orthotopic tumors derived from various solid cancers, including colorectal, pancreatic, lung, prostate, breast, and liver. Moreover, elimination of CD5 enhanced the expansion of DSG2-directed CAR-T cells in vivo, resulting in curative efficacy at sub-therapeutic CAR-T cell doses. Safety studies revealed no toxicity in any human DSG2 transgenic mouse tissues. **Conclusions:** These studies reveal the robust antitumor activity of DSG2-directed CAR-T cells in solid tumors, which is enhanced by CD5 deletion, without toxicity in a human transgenic mouse model. Thus, CD5-deleted DSG2-directed CAR-T cells are a promising therapeutic approach that may be safe and effective for all solid cancers. Mayhem under the microscope: T cell cytotoxicity and serial killers captured in situ. First Author: Greg Sawyer, Moffitt Cancer Center, Tampa, FL

Background: Developing a deeper understanding of the dynamics of immune cell-mediated cytotoxicity is critical to advancing immunotherapy and cell therapy. The results from the multidisciplinary effort reported here include numerous measurements and movies of immune cell-mediated cytotoxicity with striking examples of serial killing, foraging, path-tracking, triple killing events, measurements of cytokine gradients at tumor margins, and other dynamics. Some cytotoxic events revealed peak apoptotic signatures just minutes after T Cell engagement. **Methods:** In vitro studies of immune cell killing are traditionally performed using time-lapse imaging and biochemical assays, but these methods are often limited by spatial and temporal resolution, throughput, and the ability to extract the dynamics of cellular interactions. This study integrates high-resolution and high-speed laser scanning confocal microscopy with artificial intelligence (AI), and machine learning (ML) approaches to provide a high-resolution data-driven analysis of immune cell killing dynamics in vitro. In these studies, we use human CAR T cells with an anti-cd19.28z and Burkitt Lymphoma. **Results:** We have engineered a perfusion-enabled 3D culture system integrated microscopy to assess cellular dynamics for extended periods of time. Perfusion culture maintains the interstitial flow of liquid culture media, clearing the microenvironment of toxic metabolites and reactive oxygen species. This platform uses a Liquid-Like Solids (LLS) to mimic the transport dynamics of a capillary bed. Integrated microscopy allows in situ quantification of spatiotemporal cytokine concentrations, immune cell tracking, immune cell killing dynamics, and invasion dynamics. Cytokine on and off-rates were referenced alongside measured bead fluorescence intensities and positions to fit spatiotemporal reaction-diffusion models out to a 1,600 um radius. Fast-scanning confocal microscopy facilitated in-situ observation of the evolutionary dynamics of tumor progression. In-situ cytokine measurements revealed local IL-8 concentrations reached a maximum value of 2 ng ml-1 after 10 hours. A cellular production rate was estimated at 2 molecules cell-1 s-1. **Conclusions:** T Cell cytotoxicity is shown to be incredibly heterogeneous spanning from minutes to hours. The platform developed in this study demonstrates a powerful method for real-time, high-resolution imaging of cancer-immune interactions within a controlled 3D environment. By leveraging in situ fast-scanning fluorescence microscopy, the platform enables precise quantification of spatiotemporal cytokine concentrations, T cell motility, proliferation, cytotoxic activity, and tumor invasion patterns. Impact of stromal-targeting antitumor CAR T cells in solid tumors. First Author: Abdul Khan, Roswell Park Cancer Institute, Buffalo, NY

Background: While chimeric antigen receptor (CAR) T cells have shown tremendous success in hematological malignancies, but such efficacy has not been achieved in the setting of solid tumors. One of the hurdles to CAR T cells therapy in solid tumors is the presence of physical stroma and cancer associated fibroblasts (CAFs), which inhibit the entry of activated T cells to the tumor sites. Membrane bound protein Leucine-rich repeat containing 15 (LRRC15) has been shown to be highly expressed on CAFs in many solid tumors including pancreatic cancer as well as directly expressed on tumors of mesenchymal origin including sarcomas, glioblastomas and melanomas. LRRC15 has very limited expression in normal tissues. The goal of the current study was to explore the impact of stromal targeting antitumor (STAT) in solid tumors using LRRC15-directed CAR T cells. Herein we demonstrate that CAR T cells directed to tumor stroma can eradicate solid tumor. **Methods:** LRRC15-directed CAR T cells were validated in *in vitro* assays that included specific lysis, cytokine secretion, and proliferation. STAT CAR T cells were administered intravenously into NSG mice after engrafted with osteosarcoma SaOS2 and pancreatic PANC1 tumor cell lines as well as patient derived tissues (PDXs). The efficacy of STAT CAR T cells was also assessed in syngeneic mouse model engrafted with murine OS F420 and pancreatic KPC tumor cell lines. Tumor was harvested from mice at various timepoints and analyzed for LRRC15 expression as well as for the presence of T cells. **Results:** LRRC15-directed CAR T cells specifically lysed SaOS2 cells. Upon stimulation with SaOS2 cell line, LRRC15-directed CAR T cells resulted in robust expansion and secreted cytokines including IL2, IFN-Υ, GM-CSF and TNFα. The LRRC15-directed CAR T cells were able to eliminate tumor in NSG mice xenografted with SaOS2 cell line as well as OS PDX. LRRC15-directed CAR T cells significantly increased the survival of mice. Next, we sought to test the efficacy of LRRC15-directed CAR T cells in NSG mice engrafted with LRRC15$^-$ tumor/CAFs$^+$ cell line and PDX. We showed that the NSG mice injected with the LRRC15$^-$ PANC1 cell line acquired stroma with CAFs positive for LRRC15 within 2-3 weeks. LRRC15-directed CAR T cells were able to significantly inhibit the progression of both PANC1 tumors as well as PDAC PDX in NSG mice. In syngeneic mouse model, LRRC15-directed CAR T cells resulted in tumor regression of both LRRC15$^+$ sarcoma F420 and LRRC15$^-$ pancreatic KPC tumors. **Conclusions:** To our knowledge this is the first study demonstrating targeting stroma in solid tumors using STAT CAR T cells. LRRC15-directed CAR T cells showed antitumor efficacy in mouse models engrafted with LRRC15$^+$ as well as LRRC15$^-$ tumors. Collectively, we show that targeting LRRC15$^+$ CAFs in the tumor with CAR T cells has the potential to inhibit solid tumor progression as well to circumvent the challenge of limited penetration of T cells into the tumor site by disrupting the stroma. Association of lymphopenia rescue and CA19-9 levels with overall survival following IL-15 superagonist N-803 and PD-L1 t-haNK chemo-immunotherapy for 3rd line or greater metastatic pancreatic cancer. First Author: Tara Elisabeth Seery, Chan Soon-Shiong Institute for Medicine, El Segundo, CA

Background: Lymphopenia and high CA19-9 levels are associated with poor prognosis in pancreatic cancer patients. N-803 (ANKTIVA), an IL-15 superagonist is the first FDA approved molecule with a mechanism of action of rescuing lymphopenia by proliferating lymphocytes (NK and T cells). In QUILT-88, a Phase 2 multi-center study (NCT04390399), participants with 2nd line or greater locally advanced or metastatic pancreatic cancer (mPC) received N-803 and PD-L1-targeted high-affinity natural killer (PD-L1 t-haNK) cell therapy in combination with low-dose chemotherapy as $\geq$ 3rd line therapy. The absolute lymphocyte count (ALC), CA19-9 level, and correlation with overall survival (OS) was assessed. **Methods:** Patients (n = 84) received low-dose SBRT and low-dose chemotherapy in combination with N-803 and PD-L1 t-haNK cells to orchestrate responses of the innate and adaptive immune system, a paradigm change in the treatment of mPC. The association between OS and ALC $<$ or $\geq$ median 1.045 x 10^9 cells/L and CA19-9 $<$ or $\geq$ median 4079.6 U/mL at baseline was assessed. **Results:** Median OS for 3rd line patients (n = 43) was 6.2 months (95% CI 5.0 - 7.1;) and for all patients $\geq$ 3rd to 6th line patients (n = 84) was 5.7 months (95% confidence interval [CI] 4.3 – 6.4). OS was positively associated with both higher ALC and lower baseline CA19-9 levels. OS was significantly higher for participants (median OS: 7.1 months) with ALC $\geq$ 1.045 x 10^9 cells/L and CA19-9 $<$ 4079.6 U/mL than for those participants (median OS: 3.1 months) with ALC $<$ 1.045 x 10^9 cells/L and CA19-9 $\geq$ 4079.6 U/mL (HR 3.6, p $<$ 0.001). Higher ALC count was associated with prolonged OS over the course of the study. Grade 3 or higher TEAEs occurred in 95% of patients and were largely chemotherapy-associated. **Conclusions:** The multimodal chemo-immunotherapy protocol to induce immunogenic cell death resulted in OS that exceeded 6 months for both 3rd and $\geq$ 5th line patients, exceeding OS achieved by other therapies in this setting by ~2 months. It is notable that both favorable baseline ALC/CA19-9 and on-study higher ALC was associated with prolonged survival, given N-803's ability to increase both NK and CD8+/CD4+ T cells, the first FDA approved agent that proliferates lymphocytes in the face of lymphopenia. These findings support further investigation of this novel therapeutic regimen that includes PD-L1 t-haNK, and N-803 that, as an IL-15 superagonist, may be able to overcome lymphopenia and improve prognosis. Clinical trial information: NCT04390399. Research Sponsor: ImmunityBio, Inc.

Predictors and clinical outcomes of CMV reactivation in CAR-T therapy: A systematic review. First Author: Faiza Humayun Khan, Montefiore St.Luke's Cornwall, Collaborative Opportunities for Research, Training, And Excellence in Innovation (CORTEX), Newburgh, NY

Background: Cytomegalovirus (CMV) reactivation is a common complication in immunocompromised patients, particularly those undergoing chimeric antigen receptor T-cell (CAR-T) therapy. CMV reactivation has been linked to increased morbidity and mortality due to immune dysregulation, relapses, and treatment-related toxicity. This systematic review investigates the predictors and outcomes of CMV reactivation in CAR-T recipients, focusing on survival, relapses, and non-relapse mortality (NRM). **Methods:** A systematic review was conducted following PRISMA guidelines to compare characteristics and outcomes between CMV reactivation (R) and non-reactivation (NR) groups. A comprehensive search of PUBMED, EMBASE, and CENTRAL identified 172 studies, of which only four met the inclusion criteria after screening. A descriptive statistical analysis was performed to calculate frequencies and percentages. **Results:** Among 462 patients with CAR-T therapy, 114 (24.7%) experienced CMV reactivation. The median time from CAR-T therapy to CMV reactivation was 20 days (Range: -1 to 73), with an incidence of CMV disease with end-organ damage at 1.73%. Most patients received axicabtagene ciloleucel (71%) and had lymphoma (88%). Our analysis identified a higher proportion of patients receiving BCMA-targeted CAR-T therapy (7% vs. 2.9% in NR) and a greater prevalence of prior allogeneic hematopoietic stem cell transplantation (allo-HSCT) in the R group (35% vs. 7% in NR). Severe CRS (Grade $\geq$3) was more common in the R group (11.4% vs. 8.6%), as was severe ICANS of $\geq$3 (37.7% vs. 26.7%). Immunosuppressive therapy use, including steroids (56% vs. 42.8%) and combination therapy with tocilizumab and anakinra (12% vs. 5%), was significantly higher in the R group. Outcomes varied across studies, with Lin et al. and Khawaja et al. reporting higher one-year mortality in R vs. NR groups (57% vs. 23%, P = .001; 53% vs. 38%). Khawaja et al. also noted higher NRM (48% vs. 33%). Chen et al. identified CMV reactivation (HR 2.3, 95% CI: 1.2–4.5, P = .02) as an independent mortality predictor, with relapse rates of 71.4% in R and 41.2% in NR. **Conclusions:** CMV reactivation is a significant complication in CAR-T therapy, linked to worse outcomes, including increased mortality, relapse, and NRM. Predictors include BCMA-targeted CAR-T therapy, prior allogeneic HSCT, severe CRS/ICANS, and associated treatments. Targeted CMV monitoring, prophylaxis, and immunosuppressive strategies are essential for mitigating reactivation risks and improving outcomes in CAR-T recipients. Research Sponsor: None.

Validation of an optimized tissue-agnostic genome-wide methylome enrichment assay to predict clinical outcomes in patients treated with pembrolizumab. First Author: Enrique Sanz Garcia, Princess Margaret Cancer Centre, University Health Network, University of Toronto, Toronto, ON, Canada

Background: Recent work from the INSPIRE study (PMID38393391) suggests that kinetics of cell-free DNA (cfDNA) methylation profiles reflect immunotherapy treatment response in solid tumors. Here we provide validation data of a tissue-agnostic, genome-wide methylation enrichment assay based on cell free methylated DNA immunoprecipitation and high throughput sequencing (cfMeDIP-seq) designed for clinical use, to determine response to immunotherapy. **Methods:** This study utilizes samples and clinical data from the INSPIRE study, a single-institution investigator-initiated phase II study of pembrolizumab in multiple solid tumors given every 3 weeks (NCT02644369). A prior published analysis of cfMeDIP used TCGA to develop a classifier and demonstrated an association of response to immunotherapy. In contrast, in this analysis, a novel quantitative and highly specific measurement of ctDNA was estimated using a generative machine learning model trained on differentially methylated regions identified from a large cfMeDIP methylome atlas from individuals with and without cancer. In a blinded validation analysis, Firth's logistic regressions were used to test differences in objective response (ORR) and clinical benefit rate (CBR) defined as complete or partial response or stable disease $>$ / = 6 cycles between patients with a decrease in ctDNA from baseline to cycle 3 of treatment, and those with an increase in ctDNA. Sensitivity for no objective response, specificity for objective response, and positive and negative predictive values (PPV and NPV) were summarized. Cox regressions and log-rank tests were used to evaluate differences in progression-free survival (PFS) and overall survival (OS) between the two groups. **Results:** The analysis included 64 unique patients with a median follow up of 18.43 months (a total of 128 samples), including head & neck (n = 9), triple negative breast (n = 10), ovarian (n = 11), melanoma (n = 7), and other mixed solid tumor types (n = 27). A decrease in ctDNA was associated with significantly better objective response than an increase [odds ratio (OR) 33.89 (4.07, 44426.47), p = 0.0001], 58% sensitivity, 100% specificity, 100% PPV and 35% NPV. Significantly better CBR [OR 10.17 (2.74, 55.74), p = 0.0002] was also observed. A decrease in ctDNA was associated with significantly better PFS [hazard ratios (HR) 0.28 (0.15, 0.49) p $<$ 0.0001] and OS [HR 0.42 (0.24, 0.76) p $<$ 0.003]. **Conclusions:** A clinical tissue-agnostic, genome-wide methylome enrichment approach using cfMeDIP-seq accurately predicts clinical outcomes in patients treated with pembrolizumab in multiple advanced solid tumors. This test provides relative quantification of methylated ctDNA to predict response to immmunotherapy and does not require tumor tissue. This analysis highlights potential generalizability across tumor types in response monitoring. Clinical trial information: NCT02644369. Research Sponsor: Adela, Inc; Merck.

Personalized tumor-informed circulating tumor DNA as predictor of progression risk after long-term responses to immunotherapy in advanced non-small-cell lung cancer. First Author: Fang Wu, Department of Oncology, The Second Xiangya Hospital, Central South University, Changsha, China

Background: Immune checkpoint inhibitors (ICIs) have remarkably improved survival in advanced non-small-cell lung cancer (NSCLC), with about 30% ~ 40% of patients achieving long-term responses. However, biomarkers for predicting progression remain undefined. Circulating tumor DNA (ctDNA) has demonstrated its ability to predict recurrence in resected NSCLC, but its potential to forecast progression following prolonged responses to ICIs requires investigation. **Methods:** CR1STAL study is a multicenter, prospective cohort study investigating ctDNA surveillance to monitor progression risk in advanced NSCLC treated with first-line ICIs (NCT05198154). Patients with advanced NSCLC with long-term responses, defined as a PFS of about 1 year, were enrolled. Peripheral blood samples were collected alongside radiographic evaluations. ctDNA was detected using a personalized tumor-informed assay. Somatic variants were identified using a targeting 1,021 genes, followed by the design of individualized target-capture. ctDNA-positive was defined as the detection of ctDNA at any time during surveillance. The primary endpoint was PFS, defined as the time from enrollment until progression or death. Secondary endpoints included OS and ORR. Exploratory endpoints included the association between ctDNA features and survival, and comparison to other biomarkers. **Results:** We analyzed 199 sample from 42 NSCLC patients. The median age was 60.5 years with 88.1% male, and 64.3% at stage IV. The median number of sample collections was 4, with a median follow-up time of 24.7 months. ctDNA was detected in 54.8% of patients (23/42), with 82.7% of patients (19/23) showing ctDNA-positive occurring within 2 years of ICIs treatment. A total of 23 PFS events were observed. The ctDNA-positive group showed significantly worse PFS compared to the negative group (HR: 7.65, p $<$ 0.001), with a positive predictive value of 90.0% and a specificity of 88.2%. Additionally, ctDNA-positive provided a median lead time of 6.6 months prior to radiological progression. ctDNA-positive significantly associated with poorer OS (HR: 68.42, p = 0.003) and lower ORR (60.9% vs 89.5%, p = 0.036). 18 exhibited clonal mutations. Compared to the ctDNA-negative group, the patients with clone had significantly worse PFS (HR: 9.38, p $<$ 0.001) than those with subclone (HR: 4.16, p = 0.063). The ctDNA positivity rate was 84.6% in cases of local progression, 80.0% in distant metastases with brain exhibiting lower positivity rates. Additionally, peripheral CEA showed inferior predictive value for PFS (HR: 1.76, p = 0.303) than ctDNA. **Conclusions:** ctDNA has emerged as a promising biomarker for predicting progression risk of ICIs in advanced NSCLC patients with long-term responses. ctDNA surveillance enables earlier detection of progression and supports treatment adjustments through adaptive therapy. Clinical trial information: NCT05198154. Research Sponsor: None.

2548 **Poster Session**

Novel dynamic circulating biomarkers for predicting therapeutic efficacy of PRaG regimen in advanced refractory solid tumors. First Author: Yuehong Kong, The Second Affiliated Hospital of Soochow University, Suzhou, Jiangsu, China

Background: Common biomarkers for predicting the efficacy of immune checkpoint inhibitors (ICIs), such as programmed death-ligand 1 (PD-L1) expression, face notable challenges with tumor tissue sampling and the inability to enable dynamic monitoring. Circulating T lymphocyte subset classification and cytokines offers a promising alternative, reflecting T cell functionality and predicting ICI responses. The PRaG regimen, combining PD-1 inhibitors, radiotherapy, and granulocyte-macrophage colony-stimulating factor (GM-CSF), has shown efficacy in patients with metastatic or refractory solid tumors unresponsive to standard therapies. This study seeks to develop an efficacy evaluation model by intergrating dynamic peripheral blood lymphocyte subsets and cytokines, based on comprehensive analysis of clinical data from the PRaG studies. **Methods:** Data from the PRaG 1.0 (ChiCTR1900026175), PRaG 2.0 (NCT04892498), and PRaG 3.0 (NCT05115500) studies were analyzed to evaluate the objective response rate (ORR) by RECIST 1.1. Machine learning models, including linear, sequential, attention-based, and hybrid models, were employed to predict disease progression. These models utilized dynamic peripheral blood data from thirty-five lymphocyte subsets and seven cytokines, collected across treatment cycles. Model efficacy was further validated using independent data from two additional PRaG studies (NCT05790447 and NCT06112041). **Results:** As of November 30, 2023, 132 patients were included in the study, with a median age of 63 years. Patients over 65 accounted for 41.7%, and 60.4% had more than five metastatic sites. Patients with an ECOG score of 2-3 made up 59.7% of the cohort. The ORR was 20.13%, and the disease control rate was 48.19%. Dynamic monitoring of peripheral blood features across treatment cycles facilitated the development of an LSTM-HeterGNN model, which integrates long short-term memory (LSTM) networks with heterogeneous graph neural networks (heterGNN). This model outperformed ten other models, achieving a ROC AUC of 0.818. Independent validation further demonstrated robust performance, with a ROC AUC of 0.801. **Conclusions:** This study underscores the potential of the PRaG regimen as an effective salvage therapy for advanced solid tumors after the failure of standard treatments. The LSTM-HeterGNN model, leveraging dynamic peripheral blood biomarkers, provided precise efficacy predictions, surpassing traditional models. These findings lay the groundwork for dynamic treatment monitoring and optimization. Larger sample sizes are required to further validate the model's generalizability. Research Sponsor: None.

An exploratory study to predict the efficacy and prognosis of immunotherapy for extensive-stage small cell lung cancer based on peripheral blood dynamic immune profiles. First Author: Lin Wu, Hunan Cancer Hospital, Changsha, China

Background: The high-dimensional classification information of peripheral blood mononuclear cells can provide abundant efficacy and prognosis-related data. However, in the field of immunotherapy for extensive-stage small cell lung cancer (ES-SCLC), the biomarkers that can predict the efficacy and prognosis need to be explored and clarified. **Methods:** Cytometry by Time-Of-Flight (CyTOF) was applied to the dynamic monitoring of immunotherapy using clinical resources such as dynamic peripheral blood from ES-SCLC patients. By labeling the following proteins: CD45, CD3, CD4, CD8, CD25, CD127, CD45RA, CD45RO, CCR7, TCRγδ, CD19, CD66b, CD14, CD56, CD16, CD11c, CD123, HLA-DR, CD38, CD57, CXCR3, CCR6, CCR4, CXCR5, CD95/Fas, LAG-3, Tim-3, CTLA-4, PD-L1, PD-1, CD278/ICOS, and TIGIT, this study performed high-dimensional fine-phenotyping of peripheral blood immune cells from ES-SCLC patients. We further explored the dynamic immune profile of peripheral blood that could predict the efficacy and prognosis of immunotherapy in combination with efficacy assessment and survival indicators. **Results:** 81 dynamic peripheral blood samples (baseline, after two cycles of treatment[C2], and progressive disease) were collected from ES-SCLC patients who received first-line immunotherapy combined with chemotherapy (n = 20) and chemotherapy alone (n = 7) in this study. In the immunotherapy group, a high percentage of senescent CD4+TEM/CD4+TEM at baseline (P = 0.029) was significantly associated with longer PFS. High TIGIT expression at baseline (P = 0.016) was significantly associated with shorter PFS. In addition, PD-1 (CD4+TCM, P = 0.017; Naive CD4+T, P = 0.031; pDCs, P = 0.031; NK, P = 0.007; Early NK, P = 0.007; Late NK, P = 0.02) and TIGIT (CD8+TEM, P = 0.046; NK, P = 0.038) expression levels at baseline in multiple cell subpopulations were significantly negatively correlated with OS. In contrast, the above peripheral blood immune profile was not a predictor in the chemotherapy group. In the immunotherapy group, peripheral blood dynamic monitoring showed that increased γδT cell percentage after treatment was significantly associated with longer PFS and OS (PFS, P = 0.035; OS, P = 0.032). Increased CD4+ TEM and CD4+ TCM percentage after treatment was significantly associated with shorter PFS and OS (CD4+ TEM: PFS, P = 0.021, OS, P = 0.036; CD4+ TCM: PFS, P = 0.01; OS, P = 0.014). Meanwhile, CTLA-4 and ICOS expression in total cells at progressive disease was significantly higher than C2, suggesting that it might be related to immunotherapy resistance. In the chemotherapy group, the above peripheral blood dynamic immune profile did not predict the efficacy and prognosis of chemotherapy. **Conclusions:** Dynamic peripheral blood immune profile can predict the efficacy and prognosis of immunotherapy in ES-SCLC. Research Sponsor: None.

Longitudinal tumor-informed cfDNA whole genome sequencing to capture residual disease during neoadjuvant immune checkpoint inhibition in resectable gastroesophageal cancer. First Author: Blair V. Landon, Sidney Kimmel Comprehensive Cancer Center, Johns Hopkins School of Medicine, Baltimore, MD

Background: Although circulating tumor DNA (ctDNA) detection represents a promising approach to capture minimal residual disease (MRD), the clinical performance of ctDNA MRD during neoadjuvant immune checkpoint inhibition (ICI) remains understudied. Here we employ a tumor-informed whole genome sequencing (WGS) approach to capture residual disease and link ctDNA dynamics with pathologic response and clinical outcomes. **Methods:** WGS was performed on tumor (n = 28), matched WBC (n = 28), and longitudinal plasma samples (baseline, post-ICI cycle 1, post-ICI cycle 2 and pre-op; n = 97) from 28 patients with resectable gastroesophageal cancer treated with neoadjuvant ICI and chemoradiation prior to surgical resection (NCT03044613). Tumor-specific single nucleotide variants were identified from tumor and WBC datasets, from which a high confidence candidate variant set was used to determine the presence of ctDNA through a random forest machine learning model. ctDNA status and tumor fraction (TF) were determined based on the level of signal compared to a reference population of noncancerous donor plasma samples (n = 80). Serial ctDNA TF dynamics were correlated with overall (OS) and recurrence-free survival (RFS) in comparison to a tumor-naïve targeted NGS gene panel liquid biopsy approach. **Results:** Twenty-four of the 28 patients (86%) with evaluable specimens had ctDNA detected in a least one timepoint: 22 of 25 (88%) evaluable patients had ctDNA detected at baseline, 20 of 25 (80%) evaluable patients had ctDNA detected post-ICI cycle 1, 18 of 26 (69%) evaluable patients had ctDNA detected post-ICI cycle 2, and 5 of 21 (24%) evaluable patients had ctDNA detected at the pre-op timepoint. In contrast, the tumor-naïve targeted NGS approach detected 13 of 30 (43%), 12 of 30 (40%), 11 of 30 (37%) and 5 of 25 (20%) patients at baseline, post-ICI cycle 1, post-ICI cycle 2 and pre-op respectively. A ctDNA TF peak was detected at either the post-ICI cycle 1 or cycle 2 timepoint for 50% of the patients. A 50% reduction in ctDNA TF at the post-ICI cycle 2 timepoint showed a sensitivity of 80% and specificity of 69% for prediction of complete pathologic response, which was improved compared to the tumor-naïve liquid biopsy approach and importantly showed a significantly higher evaluable rate (86% vs 62% for tumor-informed and tumor-naïve respectively). Similar trends were observed between major pathologic response and ctDNA TF. A dramatic reduction of ctDNA TF ($\geq$65%) at the pre-op timepoint predicted longer OS and RFS (log-rank p = 0.0035 and p = 0.0032 respectively). **Conclusions:** Tumor-informed cfDNA whole genome sequencing analyses showed reliable and sensitive detection and quantification of ctDNA during neoadjuvant ICI and adds to the body of evidence supporting the clinical utility of ctDNA residual disease in interpreting clinical outcomes. Plasma extracellular vesicles as biomarkers of primary versus acquired resistance to immune checkpoint inhibitors (ICI) in patients (pts) with solid tumors. First Author: Scott Strum, Princess Margaret Cancer Centre – University Health Network, University of Toronto, Toronto, ON, Canada

Background: Plasma extracellular vesicles (pEVs) have emerged as promising biomarkers in the field of oncology. They can be obtained through minimally invasive methods, and hold the potential to help differentiate the clinically relevant subgroups of primary (PR) vs acquired resistance (AR) to ICI treatments. We hypothesized that individual pEV-derived protein cargo, or combinations thereof, associate with PR vs AR to ICI. **Methods:** A cohort of patients was derived from the Immune Resistance Interrogation Study (IRIS; NCT04243720), with plasma collected at the time of progression on ICI in advanced or adjuvant settings (n = 69; n = 44 primary resistance [PR], n = 25 acquired resistance [AR]). Plasma-derived extracellular vesicles (pEVs) were isolated using serial ultracentrifugation and characterized per ISEV guidelines. All samples were analyzed using OLink Immuno-Oncology proteomics to evaluate 92 proteins. Statistical analyses included the Mann–Whitney U test, binary logistic regression, and log-rank tests. Primary and acquired resistance were defined according to trial protocol. **Results:** A total of 57 out of 69 samples (n = 37 PR, n = 20 AR) generated evaluable proteomics data. Of the 92 proteins analyzed, 11 were significantly overexpressed in AR compared to PR (ADGRG1, CD28, FGF2, IL10, IL12RB1, IL2, IL33, IL4, MCP3, PD-L2, PTN) ($p < 0.05$), with IL10 and IL33 showing the strongest associations ($p< 0.01$). When stratified by cancer type, 9/11 proteins were overexpressed in AR vs PR among melanoma pts (n = 39; ADGRG1, CD28, FGF2, IL10, IL33, IL4, MCP3, PD-L2, PTN) ($p < 0.05$), whereas only IL12RB1 ($p < 0.01$) was overexpressed in HNSCC pts (n = 16). Analysis of 5 proteins most strongly associated with AR (IL10, IL33, IL4, MCP3, CD28) yielded a sensitivity of 70% and specificity of 95% for AR vs PR, with a positive and negative predictive value of 88% and 85%, respectively; AUC 0.853 ($p < 0.001$; 95% CI 0.742-0.963). **Conclusions:** In summary, 11 pEV-derived proteins from blood samples at progression on ICI independently statistically associated with AR vs PR, and a combination of 5 of them generated a highly accurate predictive model for AR. Immunomodulatory cytokines IL10 and IL33 held the strongest associations, known to activate signaling cascades implicated in ICI resistance through the JAK-STAT and NF-Kappa-B/MAPK pathways, respectively. Differentially expressed proteins may signify distinct mechanisms of ICI escape. Despite requiring validation, our results highlight the potential of pEV-derived proteins as predictive biomarkers for ICI resistance in solid tumors. Future studies of pEV proteomics in the pre-treatment setting, as well as exploring other cargo such as RNA, may provide additional insights into the biology of resistance, and discover minimally invasive clinically relevant biomarkers. Clinical trial information: NCT04243720. Research Sponsor: BMO Chair in Precision Genomics, Dr. Lillian Siu.

Precision medicine research on chemo-immunotherapy combination treatment for locally advanced or metastatic non-small cell lung cancer based on deep plasma proteomics. First Author: Qiuchi Chen, Cancer Center, Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, China

Background: For locally advanced or metastatic non-small cell lung cancer (NSCLC) patients lacking specific genetic mutations, chemotherapy combined with anti-programmed death-1/programmed death-ligand 1 immunotherapy has become standard first-line treatment with enhanced therapeutic efficacy and prolonged survival. However, 40-50% of patients do not benefit from chemo-immunotherapy and develop resistance. Currently, there is a lack of predictive biomarkers for the efficacy of combined therapy in NSCLC, and research on the regulatory mechanisms and drug targets is insufficient, either. We leveraged an advanced proteomics platform to profile serum in NSCLC patients, aiming to identify chemo-immunotherapy biomarkers and uncover resistance mechanisms. **Methods:** This study collected pre-treatment plasma samples from 103 patients with locally advanced or advanced NSCLC receiving chemo-immunotherapy. These samples were analyzed using a deep proteomics platform that integrates antibody arrays and mass spectrometry. Patients were classified into "responders" (R, complete/partial response or stable disease $>$ 6 months) and "non-responders" (NR, progressive disease or stable disease $\leq$6 months) based on treatment efficacy. Differentially expressed serum proteins were identified between the groups, and weighted gene co-expression network analysis (WGCNA) was applied. Cox survival analysis was conducted on prognosis-related modules, leading to the identification of key proteins associated with treatment efficacy and survival. **Results:** Through our high throughput blood proteomics platform, a total of 1,397 proteins were detected. The median progression-free survival was 9 months, and the median overall survival was 32 months. A total of 175 differentially expressed proteins were identified between the R and NR groups. WGCNA identified 12 distinct modules, with ME4 associated with poor prognosis, enriched in inflammation, gene activation, and apoptosis suppression pathways, while ME8 correlated with favorable prognosis and ERK1/ERK2 cascade regulation. In the NR group, upregulated proteins associated with poor prognosis included erythropoietin receptor (HR: 1.41, $p < 0.01$), fibrinogen gamma chain (HR: 1.90, p: 0.03), Fc alpha receptor (HR: 2.63, $p < 0.01$), and prion protein (HR: 1.30, p: 0.04). In contrast, upregulated proteins in the R group linked to favorable prognosis were insulin-like growth factor-binding protein 2 (HR: 0.77, p: 0.02), keratin 19 (HR: 0.61, p: 0.02), and retinol-binding protein 4 (HR: 0.74, p: 0.03). **Conclusions:** Through in-depth proteomics analysis, this study systematically characterized the plasma proteomic landscape of patients undergoing chemo-immunotherapy, identifying potential novel biomarkers, and providing new insights to optimize clinical decision-making. T-cell exhaustion and pre-existing T-cell immunity in circulation as predictive biomarkers for immunotherapy in NSCLC patients. First Author: Anastasia Xagara, Laboratory of Oncology, School of Health Sciences, University of Thessaly, Larissa, Greece

Background: Pre-existing cancer-antigen specific T-cells describe the endogenous adaptive immunity before any treatment that may represent a valuable novel predictive biomarker for ICI. In a recent publication we have shown a positive correlation of pre-existing cancer-antigen specific $CD8^+$ T-cells with the response to ICI. Here, we analyze the major differences of exhausted T-cells between pre-existing positive ($PreI^+$) and pre-existing negative immunity ($PreI^-$) NSCLC patients as well as, between different stages of the disease. **Methods:** Blood was collected from 82 patients with NSCLC, 38 with stage III and 44 with stage IV, before ICI therapy. PBMCs were isolated with *Ficoll* density gradient centrifugation from patients and 15 healthy donors (HD). PreI was calculated by detecting endogenous IFNg expressing cells with FACS after in-vivo co-cultures of PBMCs with mixes of hTERT, MAGEA1, NY-ESO-1 και Survivin cancer-associated antigens. T-exhausted signatures were detected by multi-color flow cytometry using antibodies against CD3, CD4, CD8, PD-1 and TCF1. **Results:** 47% (18/38) of patients with stage III disease and 41% (18/44) of stage IV had peptide specific T-cells ($PreI^+$ patients). Survival analysis revealed better OS only in stage III $PreI^+$ compared to $PreI^-$ patients (Log-rank = 0.04), while for stage IV (p=0.081) there was only a trend. The percentages of CD8 T-cells that were $PD\text{-}1^+TCF1^+$(p=0.030) and $PD\text{-}1^+TCF1^-$(p=0.041) were higher in patients compared to HD, and additionally both T-cell populations harbored higher levels of PD-1 protein expression (p=0.003 and p=0.032 for stage III) as it was shown with mean fluorescence intensity (MFI). Moreover, low percentages of $PD\text{-}1^+TCF1^+$ ware associated with longer survival (p= 0.037) only in stage III patients. By subgrouping stage III patients, we observed that all patients with $PreI^+$ harboring low percentages of exhausted $PD\text{-}1^+TCF1^+$ were alive at the end of the follow up. **Conclusions:** Combinatorial analysis of Pre-existing tumor-antigen specific immunity and the status of T-cells before initiation of ICI in stage III NSCLC could serve as a good predictive factor of response. The study is ongoing. Research Sponsor: None.

Effect of fusobacterium nucleatum on NF-κB/HIF-1α/CCL20 pathway and M2 macrophages infiltration in esophageal squamous cell carcinoma. First Author: Yu Su, The Fourth Hospital of Hebei Medical University, Shijiazhuang, China

Background: Esophageal squamous cell carcinoma (ESCC) is one of the most common digestive malignant tumor with the highest mortality rate in China.Recent studies have shown that Fusobacterium nucleatum (F. nucleatum) can attenuate the efficacy of immunotherapy in ESCC patients through various mechanisms.One of them is recriuting more M2-like macrophages through tumor-derived cytokines such as CCL20. **Methods:** From January 2022 to June 2023, a total of 30 patients with ESCC from 4th Hospital of HeBei Medical University were enrolled.All of the pateints did not apply any neoadjuvant therapy before and received radical resection.Real-time reverse transcriptase - PCR(RT-PCR) were performed to examine the expressions of F. nucleatum in tumor tissues.According to the CT values,the level of the F. nucleatum infection could be seperated in two groups - positive group and negative group. Immunohistochemistry (IHC) staining were used to examine the expressions of CCL20、CD206 and HIF-1α in both groups. Immunofluorescence(IF) was characterised CD206 on $CD68^+$ macrophages.In addition,transwell assay was carried on to quantify macrophages migration ability in vitro.At last,Western blot was used to determine the expression level of CCL20, HIF-1α and p65/p-p65 on ESCC cells. **Results:** F. nucleatum DNA positivity was significantly associated with higher expression of CCL20, HIF-1α and accumulation of $CD68^+CD206^+$ macrophages.IHC showed that the expression of CCL20 and HIF-1α were higher in F. nucleatum positive tumor tissue. After coculture with F. nucleatum and Eca109 cells in vitro, CCL20 and HIF-1α production by ESCC cells were accelerated.Transwell assay showed using siCCL20, CCL20-Nab or siCCR6 could decline the macrophages invasion level caused by CCL20. Otherwise, siHIF-1α could lowered the CCL20 expression level caused by F. nucleatum.In addition,Western blot revealed NF-κB pathway was highly activated in Fn educated Eca109 cells.Using BAY11-7082 could decline both CCL20 and HIF-1α level triggered by F. nucleatum. **Conclusions:** Fusobacterium nucleatum promotes esophageal squamous cell carcinoma progression via NF-κB/HIF-1α/CCL20 pathway-mediated migration of M2-like macrophages into the tumour micro-environment and deteriorates the suppression of the local immune micro-environment within the tumor.Such bacteria may be a biomarker to predict the efficacy of immunotherapy in ESCC. Research Sponsor: None.

Monitoring PD-L1 expression in cancer-associated macrophage-like cells as predictor of clinical outcomes in metastatic cancer patients treated with PD-L1 immunotherapies. First Author: Dimpal M. Kasabwala, Creatv MicroTech, Inc., Monmouth Junction, NJ

Background: Studies have described the efficacy of immunotherapies (IMT) utilizing programmed death 1 receptor and its ligand (PD-L1) for treating solid tumors. However, many patients (pts) fail to respond to IMT, necessitating better predictive biomarkers for improved stratification. Poor IMT responses are often attributed to the dynamic nature of PD-L1 likely changing after chemotherapy or radiation, but typically quantified by static immunostaining. Recent studies have described PD-L1 upregulation in giant phagocytic stromal cells, i.e. Cancer associated macrophage-like cells (CAML), circulating macrophages that engulf tumor before entering circulation and may predict IMT responses. We conducted a pilot study to monitor the peripheral blood of n = 111 metastatic cancer pts undergoing systemic treatment with IMT in combination with other therapies, to evaluate CAML PD-L1 prior to & post IMT induction with clinical correlation at 2 years. **Methods:** In a prospective pilot study of n = 111 metastatic cancer pts, breast (n = 42), lung (n = 46), renal cell (n = 10), prostate (n = 5), esophageal (n = 5) & colon (n = 3), all starting new lines of systemic chemotherapy in combination with IMT (pembrolizumab [n = 69], nivolumab [n = 23], Durva [n = 4], or atezolizumab [n = 13]) for new recurrent metastasis (n = 45) or with previously treated progressive metastatic disease (n = 66). We isolated CAMLs from 7.5 ml baseline (T0) blood using the LifeTracDx PD-L1 test and scored PD-L1 as high or low. If possible, a follow-up sample (T1) was taken (~56 days) after IMT induction. Pts' progressive free survival (PFS) and overall survival (OS) hazard ratios (HRs) were analyzed by censored univariate analysis based on RECIST v1.1 over 2 years. **Results:** T0 PD-L1 CAML data was available for 78% (n = 86/111) of pts, with 34% (n = 29/88) having high CAML PD-L1 which was not correlated with improved PFS (HR = 0.99, p = 0.9416, CI = 0.6-1.6) or OS (HR = 1.1, p = 0.9472, CI = 0.6-1.8). T1 PD-L1 CAML data was available for 74% (n = 82/111) of pts, with 44% (n = 36/82) having high CAML PD-L1, which significantly correlated with improved PFS (HR = 3.1, p = 0.0002, CI = 1.8-5.5) & OS (HR = 6.6, $p < 0.0001$, CI = 3.4-12.7). In comparing CAML PD-L1 change post IMT, it was found that consistently low PD-L1 at T0 & T1 had the poorest responses, median PFS (mPFS) = 4.9 months & median OS (mOS) = 7.2 months. In contrast, consistently high PD-L1 at T0 & T1 had better responses, mPFS = 8.4 months & mOS = 18.3 months. Further, pts who increased in CAML PD-L1 after IMT had the best OS response rates, mPFS = 3.8 months & mOS = 20.9 months. **Conclusions:** We utilized a cancer agnostic blood-based biopsy to monitor PD-L1 changes in circulating tumor immune cells and predict clinical benefit to PD-L1 IMTs in several cancer types. While this initial pilot study appears to stratify pts with better IMT responses, larger validation studies are needed. Research Sponsor: Creatv MicroTech.

The classification of uncertain histologies based on cfDNA fragmentomic analysis in patients with uncommon cancers screened for NCI-MATCH. First Author: Chris Alan Karlovich, Molecular Characterization Laboratory, Frederick National Laboratory for Cancer Research, Frederick, MD

Background: The NCI Molecular Analysis for Therapy Choice (NCI-MATCH) was a precision medicine trial that assigned targeted treatments to patients independent of histology. We sequenced > 2500 NCI-MATCH ctDNA samples of uncommon histology (excludes colon, breast, non-small cell lung, and prostate) using the TruSight Oncology 500 (TSO500) v2 ctDNA assay. We generated a probabilistic model from ctDNA fragment sizes to assign histology to patient samples designated as "not otherwise specified (NOS)" in pathology reports. **Methods:** Fragmentomics data were computed by binning the segment-level data to each exon, followed by Shannon entropy calculation. The Least Absolute Shrinkage and Selection Operator (LASSO) algorithm was then used to build the histology classifier for each of 29 histologies (n = 1614 samples of known histology) using a 9:1 random training and validation separation for validation accuracy estimation. The 9:1 training/validation was repeated 10 times. During each training/validation step, another 10-fold cross validation within the training set was used to find the best hyperparameter. The final model was re-trained on total samples which combined 29 classifiers and final predicted histology was determined using a winner-take-all approach. Mutation data was generated by Illumina's DRAGEN TSO500 ctDNA analysis pipeline and annotated using the OncoKB knowledge base. **Results:** The fragmentomics-based classification model achieved 98.2 validation accuracy across 1614 evaluable samples. The accuracy was increased to 99.6% on a subset of samples (n = 1413) with high confidence prediction defined as prediction probability > 0.5. The model was further used to classify 232 samples with NOS histology. Although there were no ground truth cases, those where a histology was predicted with high confidence were closely aligned with their broader annotations. For example, among 37 pancreatic cancer (excluding Islets) NOS patient samples, 18/19 high-confidence predictions were adenocarcinoma of the pancreas. The model was further explored on female reproductive system cancer NOS, which includes several rare histologies with limited or no representation in the prediction model. In this analysis, 17/23 high-confidence predictions were designated as ovarian epithelial cancer (OEC) or related histologies. Interestingly, one oncogenic *BRCA2* mutation (p.T1388fs) was detected in a predicted ovarian epithelial cancer sample. **Conclusions:** The validation accuracy was high in this exploratory analysis of uncommon histologies. High-confidence prediction was achieved for adenocarcinoma of the pancreas although prediction confidence was lower in OEC or related histologies . This study may support an expanded role for large cfDNA targeted panels beyond the identification of clinically actionable mutations to the classification of tumor histologies. Research Sponsor: National Cancer Institute.

A molecular biomarker for longitudinal monitoring of therapeutic efficacy in a real-world cohort of advanced solid tumors treated with immune checkpoint inhibitors. First Author: John Guittar, Tempus AI, Chicago, IL

Background: Clinical validation studies have shown that early dynamic changes in circulating tumor DNA (ctDNA) tumor fraction (TF) can predict clinical outcomes. Yet few studies have evaluated the clinical value of longitudinal monitoring throughout the course of treatment. Here we evaluate longitudinal changes in ctDNA TF and clinical outcomes in an advanced real-world pan-cancer cohort of patients (pts) treated with immune checkpoint inhibitors (ICIs). **Methods:** The cohort included deidentified pts from the Tempus clinicogenomic database with stage IIIB or IV solid tumors who underwent ctDNA NGS and were treated with an FDA-approved ICI +/- chemotherapy (CT). Pts had a pre-treatment baseline liquid biopsy (T0) and ≥1 on-treatment sample Ti within 21-180 days of ICI. xM for treatment response monitoring estimates TF via an ensemble algorithm that incorporates variant and copy number information. Response status was determined at each on-treatment timepoint Ti relative to T0. Pts were classified as a Molecular Responder (MR) if TF < 1% at T0 and Ti or if TF decreased by ≥ 50% from T0 to Ti; otherwise, they were classified as a Molecular Non-Responder (nMR). Pts with TF < 0.09% at T0 and Ti were classified as ctDNA not detected. The longitudinal cohort included pts with ≥2 on-treatment timepoints, further classified based on the most frequent classification across each Ti as longitudinal MR, longitudinal nMR and longitudinal ctDNA not detected. If no classification was dominant, the most recent classification was used. Real-world overall survival (rwOS) was defined from T1 to death and assessed by log-rank test. **Results:** The full cohort of 84 pts with > 10 solid tumors included 34.5% (n = 29) NSCLC and 16.7% (n = 14) SCLC. The majority of pts (59.5%, n = 50) received ICI+CT, (64.0% first-line [1L]), and 40.5% (n = 34) ICI-only (35.3% 1L). rwOS was longer for 53 MRs vs. 18 nMRs (median not reached vs. 7.0 months, P < 0.005); 13 pts had no ctDNA detected. The longitudinal subcohort of 35 pts was 31.4% (n = 11) NSCLC, 20.0% (n = 7) prostate cancer, and 14.3% (n = 5) SCLC; 45.7% (n = 16) ICI+CT (56.3% 1L), 54.3% (n = 19) ICI-only (31.6% 1L). On average, pts had 3 on-treatment liquid biopsies, with a median time between on-treatment samples of 91 days. Twelve pts were longitudinal nMRs (10 MR or ctDNA not detected at T1), 18 longitudinal MRs, and 5 longitudinal no ctDNA detected. There were 6 death events in the longitudinal nMRs, 3 in the longitudinal MRs (all > 18 months after T1), and no death events in the longitudinal no ctDNA detected group. Longitudinal MRs had longer rwOS than longitudinal nMRs (median 37.4 months vs 8.7 months, P < 0.005). **Conclusions:** Longitudinal nMR was associated with worse survival compared to longitudinal MR. Longitudinal, molecular biomarker dynamics may be a useful clinical treatment decision tool for monitoring treatment response to ICI therapy. Research Sponsor: Tempus AI.

Predictive imaging of the immunotherapy and radioimmunotherapy response by immunoPET via a new target (CD103) and innovative protein formats in preclinical NSCLC. First Author: Léa Zimmermann, Université Paris-Saclay, CEA, CNRS, Inserm, BioMaps, SHFJ,, Orsay, France

Background: Immune checkpoint immunotherapies (ICI) have transformed cancer treatment, but patients have varied responses and potential risks of autoimmune disease. To improve ICI, we need to identify biomarkers to select responding patients and research new approaches. To this, resident memory T cells (TRM) LT $CD8^+$ $CD103^+$, have been identified as a promising tumor-specific biomarker for studying therapeutic efficacy involving ICI. Internal radiotherapy appears to be a promising approach. Our objective is to develop new therapeutic approaches combining radiotherapy and ICI (radioimmunotherapy) using $CD8^+CD103^+$ immunoPET imaging as a predictive biomarker of efficacy. **Methods:** After developing and characterizing a new CD103 radiotracer and validating the dual ^{18}F PET-Scan imaging for $CD8^+$ and $CD103^+$ in C57BL/6 mouse models, we implanted mice subcutaneously with MC38 and othotopically syngenetically with LLC. We evaluated the efficacy of radioimmunotherapy vs ICI and the predictive effect of TRM in this syngeneic orthotopic model. To this, we implanted two syngeneic NSCLC cell lines, either LLC for a cold tumor or CMT167 for a warmer tumor. We performed double imaging prior to treatment with [^{18}F]-CD8 mutated FcRn and [^{18}F]-CD103 minibody on 2 consecutive days. We treated our mice 3 times, 3 days apart, with the first dose of either cold Avelumab or [^{177}Lu]-Avelumab (8MBq). The second and third doses were cold Avelumab. We performed double post-treatment imaging with [^{18}F]-CD8 mutated FcRn and [^{18}F]-CD103 minibody on 2 consecutive days, as well as ex vivo analyses and a survival study. **Results:** There was a trend towards improved survival in [^{177}Lu]-Avelumab treated mice vs Avelumab treated mice but more markedly in the immunogenic model (30d vs 21d). The impact on tumor growth was assessed by comparing the two treatment groups with untreated mice. Radioimmunotherapy induced a significant decrease in overall tumor growth compared with mice treated with ICI (0.45 ccm vs 0.68 ccm, *$p < 0.05$ turkey's multiple comparison test) in the immunogenic model. In the cold tumor model, there was a significant difference in the tumor size ratio before and after treatment, for mice treated with radioimmunotherapy vs ICI (12.96 vs 26.08, ***$p < 0.001$ Uncorrected Fisher's LSD). An increase in immune infiltration was validated by PET and flow cytometry for the immunogenic model (pre-treatment: 5.00%ID/cc max, versus post-treatment 8.23%ID/cc max for CD8, *$p < 0.05$ two way-Anova). More heterogeneous results were observed in the cold tumor model. **Conclusions:** Radio-immunotherapy reduces tumour growth and stimulates the immune system by circulating LT_{CD8}. The dual ^{18}F PET-Scan imaging for $CD8^+$ and $CD103^+$ offer a promising non-invasive visualization of tumor-infiltrating $CD103^+$ TRMs. We need to correlate $LT_{CD8+/CD103+}$ infiltration with therapeutic response. Research Sponsor: None.

Ultrasensitive ctDNA profiling to identify long-term survivors in phase I immunotherapy trials. First Author: Oriol Mirallas, Vall d'Hebron University Hospital and Vall d'Hebron Institute of Oncology (VHIO), Barcelona, Spain

Background: Patients (pts) included in early clinical trials (ECT) typically show a median overall survival of 8-10 months (PMID: 18042834 and 21975023), with long-term survivors (LTS) rarely encountered. While prognostic scores have been developed to identify short-term survivors (STS) in ECT, predictors of LTS remain largely unexplored. Ultrasensitive circulating tumor DNA (uctDNA) serves as a reliable surrogate for tumor burden (Toledo R *et al*, ASCO 2024), and may provide insights into LTS. This study aims to identify key determinants of LTS. **Methods:** A case-control study was conducted on pts treated at VHIO's phase I unit between 2013 and 2023, as part of the institutional translational study RIO360. Pts with an overall survival (OS) $>$ 3 years after C1D1 were classified as LTS and compared to STS with OS $<$ 1 year, matched for age, sex, stage, prior immunotherapy (IO), and ECOG. Clinical, histopathological, uctDNA, and treatment outcomes were collected. uctDNA analysis was performed prior to C1D1 and throughout treatment (every 3 to 4 weeks) in the subset of patients treated with IO. Comparisons between LTS and STS were performed using univariate binomial generalized linear models. **Results:** Of 1282 pts, a total of 117 pts (9.1%) were classified as LTS (median OS 5.2 years) and compared with 117 matched STS pts (median OS 0.6 year). The most common tumor types among LTS were HNSCC (18%), melanoma (10%), and breast (9.1%), while in STS were colorectal (27%), breast (12%), and melanoma (11%). Treatment with 3+ prior lines was more common in STS (45%) than LTS (24%) ($p = 0.002$). Visceral metastases were present in 59% LTS and 77% STS ($p = 0.010$). Higher neutrophil count and dNLR were associated with STS ($p < 0.05$). LTS had lower mean uctDNA at baseline (7.5 vs 10.9 ppm; $p < 0.001$). Two consecutive uctDNA decreases were observed in 92% of LTS pts, while 80% of STS pts showed two consecutive uctDNA increases ($p < 0.001$). **Conclusions:** In ECT, predictors of long-term survival include the absence of visceral metastasis, less prior treatment exposure, low baseline uctDNA levels, and early decreases in uctDNA. This study further explores uctDNA dynamics during treatment, with detailed findings to be presented. Research Sponsor: BBVA.

Ultrasensitive ctDNA monitoring to reveal early predictors of immunotherapy success in advanced cancer. First Author: Daisuke Nishizaki, UC San Diego Moores Cancer Center, La Jolla, CA

Background: The potential of immune checkpoint inhibition (ICI) therapy is constrained by the inability to predict patient response. Circulating tumor DNA (ctDNA) has emerged as a promising tool for real-time response tracking and early prediction of therapeutic outcomes. However, the clinical utility of ctDNA-based liquid biopsy faces a critical challenge: reliable detection in low-shedding tumors and during dramatic therapeutic responses when ctDNA levels approach the analytical threshold. We overcome this technical limitation, achieving the precise longitudinal monitoring needed to optimize ICI therapy. **Methods:** We analyzed longitudinal plasma samples from 43 patients with treatment-refractory metastatic cancers spanning 8 distinct groups, composed primarily of GI (n = 17) and gynecological cancers (n = 6). Patients underwent a median of 1 previous line of therapy (range 0-8). Using NeXT Personal, an ultra-sensitive personalized liquid biopsy approach, we tracked up to 1,800 patient-specific somatic variants per case across 250 plasma samples. This methodology achieves exceptional analytical sensitivity, detecting circulating tumor DNA at levels as low as 1-3 parts per million (PPM). **Results:** ctDNA was detected across five orders of magnitude (2.0-239,315 PPM, median LOD: 1.76 PPM), with 31% of positive signals falling in the ultrasensitive range below 100 PPM. Early molecular response, measured by $>$ 50% ctDNA reduction or sustained ctDNA negativity from baseline to first follow-up (median 23 days), strongly predicted improved progression-free survival (PFS) (HR = 0.22, 95% CI 0.07-0.70, p = 0.006), representing a 3-fold increase in 1 year PFS rates. Achievement of durable molecular complete response (dmCR), defined as sustained ctDNA clearance $>$ 120 days, emerged as a powerful predictor of PFS, with dmCR patients maintaining 100% progression-free status at 12 months compared to 63% in non-dmCR patients (HR = 0.10, 95% CI 0.01-0.92, p = 0.017). This survival advantage persisted at 18 months with 80% PFS in dmCR patients versus 21% in non-dmCR patients. **Conclusions:** Early ctDNA kinetics predict long-term ICI outcomes across multiple advanced cancer types. The ability to detect ultra-low ctDNA levels proved critical for accurate minimal residual disease assessment, even in this heavily pretreated cohort. These results establish high-sensitivity ctDNA monitoring as an essential tool for precise, real-time evaluation of immunotherapy response to guide clinical decision-making. Clinical trial information: NCT02478931. Research Sponsor: Personalis.

Role of pelareorep in activating anti-tumor immunity in PDAC. First Author: Richard Trauger, Oncolytics Biotech, San Diego, CA

Background: Pancreatic ductal adenocarcinoma (PDAC) is highly lethal cancer with limited immunotherapeutic options. Pelareorep (pela) is an intravenously delivered unmodified reovirus containing a double stranded RNA genome that has been studied as an immunotherapeutic in multiple cancers including breast, anal, colorectal and pancreatic. We previously reported high tumor response rates in first-line metastatic PDAC patients treated with pela combined with gemcitabine, nab-paclitaxel and atezolizumab. We report here the immunologic effects of pela in a cohort of first-line metastatic PDAC subjects treated with pela plus chemotherapy and atezolizumab and the correlation of these effects with tumor response. **Methods:** To examine its effects on pancreatic cancer, a phase 1/2 Simon 2-stage platform study (GOBLET) was performed that included patients with first-line locally advanced/metastatic unresectable PDAC. Anti-reovirus T cell activity was assessed by interferon gamma secretion (ELISPOT). Changes in the expression of plasma proteins were analyzed by Olink Response panels. T cell receptor sequencing (TCR-seq; ImmunoSEQ Assay, Adaptive Biotechnologies) was performed on tissue collected prior to the start of therapy and on blood from baseline through 3 treatment cycles to identify TILs expansion. Tumor responses were scored according to the modified RECIST v1.1 criteria. **Results:** Increases in anti-reovirus T cell activation as determined by ELISPOT after cycle 3 of therapy were observed in 6/8 subjects. Three subjects with maximum responses ($>$ 300 spots) showed $>$30% decreases in tumor volume. Significant changes in plasma proteins as determined by Olink included PD-L1, CXCL9, CXCL10, CXCL11 and IFN-γ. Pre-treatment tumor tissue was used to identify the TIL clonal populations prior to therapy. Increased TIL clones in the blood pre-treatment was associated with tumor responses. Pela treatment increased the expansion of pre-existing and new TIL clones in the blood after one cycle of treatment. Sustained increases in pre-existing TIL clonal populations in the blood through cycle 3 of therapy were observed in subjects who exhibited reductions in tumor volume. **Conclusions:** These findings, while preliminary, demonstrate that pela induces not only anti-reovirus T cells but also activates innate and adaptive anti-tumor immunity in PDAC subjects treated with chemotherapy and atezolizumab. Tumor responses are associated with both the presence of TIL clones in the blood prior to treatment and the expansion of pre-existing TILs in the blood on treatment. These findings provide additional insights into the immunologic mechanisms by which pela-based therapy may provide clinical benefit in patients with metastatic PDAC. Research Sponsor: None.

ctDNA features of acquired resistance to immunotherapy in advanced NSCLC. First Author: Sofiane Taleb, Gustave Roussy Cancer Center, Villejuif, France

Background: Acquired resistance to systemic therapies, including immune checkpoint inhibitors (ICIs) and tyrosine kinase inhibitors (TKIs), is a major clinical challenge in advanced non–small cell lung cancer (NSCLC). While mechanisms of resistance to targeted therapies are well-documented, the genomic alterations associated with resistance to immunotherapy remain poorly understood. Circulating tumor DNA (ctDNA) profiling offers a non-invasive approach to identify real-time genomic changes driving resistance, providing novel insights into the underlying biology of immunotherapy failure. **Methods:** We performed a prospective ctDNA sequencing study in 57 advanced NSCLC patients from two cohorts: STING (n = 30, NCT04932525) and COPE (n = 27, NCT04258137). Plasma samples were collected before treatment initiation and at disease progression following objective response to anti–PD-1 therapy or TKIs. ctDNA analysis was conducted to detect emergent genomic alterations, evaluate tumor mutation burden (TMB), and quantify circulating tumor fraction (TF). **Results:** The study included 57 patients, with a median age of 62 years [IQR: 54.5–70], and 54.4% (31/57) were male. At disease progression, 64.9% (37/57) of patients exhibited emergent ctDNA alterations associated with secondary resistance, independent of therapy type. Among these, 70% (26/37) harbored multiple newly arising mutations. In the non–oncogene-addicted NSCLC cohort receiving anti–PD-1 therapy (n = 30), 56.6% (17/30) exhibited emergent resistance alterations, with 76.5% (13/17) harboring multiple mutations. Frequently observed aberrations included mutations in NOTCH1/3 (n = 3), KEAP1 (n = 3), KMT2B (n = 2), POLE (n = 2), SETD2 (n = 2), TYRO3 (n = 2), STK11 (n = 2), TSC2 (n = 1), TGFBR2 (n = 1), PTPN11 (n = 1), SPEN (n = 1), STAG (n = 1), CDH1 (n = 1), and CTNNB1 (n = 1). The median progression-free survival (mPFS) was 7.0 months [95% CI: 5.0–10.3]. In the anti-EGFR TKI cohort (n = 13), 84.6% (11/13) displayed emergent ctDNA alterations, including mutations in EGFR (n = 2), PIK3CA (n = 2), and MET (n = 1). The mPFS was 8.6 months [95% CI: 6.7–11.2]. TMB and circulating TF did not significantly change between baseline and progression in both cohorts. **Conclusions:** This study highlights the high prevalence of emergent genomic alterations detected by ctDNA in advanced NSCLC patients developing resistance to ICIs and TKIs. In the ICI-treated cohort, mutations in NOTCH1/3, KEAP1, and STK11 emerged as significant resistance drivers, consistent with their roles in immune evasion, oxidative stress regulation, and impaired immune cell infiltration, as supported by prior studies. Notably, this is the first study investigating features of ctDNA at acquired resistance to immunotherapy using an FDA-approved assay. These findings underscore the heterogeneous and polyclonal nature of resistance to ICIs. Research Sponsor: None.

Mutation profiling of appendiceal cancer: Distinguishing tumor grades, comprehensive mutation landscape, and ctDNA as a discovery tool. First Author: Sefali Patel, AHN Cancer Institute, Pittsburgh, PA

Background: Appendiceal cancer (AC) encompasses rare tumors with varying clinical behavior. Histologic grade is a key determinant of disease biology and prognosis. This study utilized an in-house circulating tumor DNA (ctDNA) biomarker discovery pipeline to assess genetic determinants of histologic grade in AC, analyzing both peripheral blood and tumor tissue. **Methods:** Paired peripheral blood and solid tumor samples were collected from 52 patients undergoing surgery for AC (18 low-grade and 34 intermediate/high-grade). Comprehensive genomic profiling (CGP) using the TSO500 assay was performed on ctDNA, tissue-derived DNA and buffy-coat (germline)-derived DNA. Tumor-specific and germline mutations were analyzed using OncoKB, which classifies variants as oncogenic, likely oncogenic, or actionable (Level 1 therapeutic mutations with an approved therapy). The concordance of mutations between solid tumor and plasma CGP assays was assessed, categorizing variants as detected in both tumor and ctDNA, ctDNA only, or tumor only. **Results:** ctDNA exhibited 82% concordance with tumor tissue for known actionable mutations. Among 26 patients that were identified to have Level 1 therapeutic mutations, 88% (n = 23) had matching mutations in plasma. Frequently detected mutations included *KRAS (40%), GNAS (30.8%), SMAD4 (28.8%),* and *TP53 (28.8%)*. Germline analysis revealed additional variants, including *RUNX1 (71.2%), NOTCH4 (50%),* and *BARD1* (48.1%). Tumor-specific *TP53* and SMAD4 mutations correlated with high-grade tumors; while *GNAS* was more prevalent in low-grade tumors. Germline analysis identified *NOTCH3* and *SPEN* mutations predominantly in high-grade tumors, suggesting that inherited determinants may determine tumor grade (23.5% each). Plasma samples exhibited lower variant allele frequencies, limiting sensitivity for novel biomarker discovery. Concordance analysis revealed some mutations were exclusive to solid tumors, while others were plasma-specific, highlighting the need for a multi-modal genomic assessment. **Conclusions:** Tumor *TP53, GNAS,* and *SMAD4* mutations serve as molecular classifiers for histologic grade differentiation in AC, while germline *NOTCH3, SPEN, RUNX1, NOTCH4,* and *BARD1* variants may influence histologic grade. ctDNA showed strong concordance for actionable mutations but had reduced efficacy for novel mutation discovery in the plasma samples. These findings underscore the value of integrating tumor and germline profiling for classification and treatment stratification, while refining liquid biopsy methodologies to enhance sensitivity in AC research. Research Sponsor: None.

Investigating the association of blood-to-tissue tumor mutation burden (TMB) ratio with overall survival and intratumor heterogeneity (ITH) in advanced NSCLC. First Author: Leeseul Kim, University of Chicago, Chicago, IL

Background: High tumor mutation burden (TMB) measured via tissue-based next-generation sequencing (NGS) (tTMB) has been shown to predict better survival outcomes in certain cancers treated with immune checkpoint inhibitors (ICIs). With the increasing use and sensitivity of blood-based NGS, blood-based TMB (bTMB) is frequently employed as an alternative. However, the prognostic significance of bTMB relative to tTMB and its correlation with intratumoral heterogeneity remain poorly understood. **Methods:** This study included advanced-stage NSCLC patients who underwent both pre-treatment blood-based NGS (collected between October 2020 and February 2024) and tissue-based NGS. Intratumoral heterogeneity (ITH) was assessed using the mutant-allele tumor heterogeneity (MATH) approach, with blood based NGS (bMATH). The highest allele frequency (HAF) was obtained from blood-based NGS. Survival analyses were conducted using Kaplan-Meier curves and Cox proportional hazards models, focusing on the bTMB/tTMB ratio. **Results:** A total of 102 patients met the inclusion criteria, 55 of whom had complete data for bTMB, tTMB, bMATH, and HAF. The median follow-up time was 12 months. Treatment regimens included ICI combined with chemotherapy (19 patients), ICIs alone (15), targeted therapy (16), and cytotoxic chemotherapy (5), with 33 receiving first-line treatment and 22 receiving second-line or beyond. The median interval from blood NGS to treatment initiation was 20 days (IQR 8–28), and from tissue NGS to treatment initiation was 65 days (IQR 28–255). Multivariable Cox proportional hazards analysis—adjusting for gender, smoking status, stage, ECOG, regimen type, line of therapy, and numeric values of bMATH, bTMB, tTMB, and the bTMB/tTMB ratio—revealed that a higher bTMB/tTMB ratio was independently associated with inferior overall survival (OS) (HR 1.16, 95% CI 1.03–1.30, p=0.01) but showed no significant difference in progression-free survival (PFS) (HR 1.10, 95% CI 0.94–1.29, p=0.23). The cutoff for the bTMB/tTMB ratio that best stratified OS was 0.81. Patients below this cutoff experienced significantly longer OS (median OS 10 vs. 49 months, HR 0.23, 95% CI 0.05–0.96, p=0.02). Additionally, a moderate positive correlation was observed between bMATH and the bTMB/tTMB ratio (Spearman's r=0.33, p=0.02). **Conclusions:** A higher bTMB/tTMB ratio was associated with poorer overall survival in advanced-stage NSCLC, highlighting its potential prognostic value. Moreover, the moderate correlation between bMATH and bTMB/tTMB suggests an interplay between TMB and intratumor heterogeneity. Future studies are needed to confirm these findings and to explore their potential therapeutic implications. Research Sponsor: None.

Identifying peripheral cancer-associated TCR signals for the early-detection of lung cancer. First Author: Chen Huang, China-Japan Friendship Hospital, Beijing, China

Background: Tumor-associated antigens and neoantigens play a critical role in eliciting anti-tumor immune responses, leading to a significant amplification of tumor-specific T cell clones. Consequently, the detection of tumor-associated immune signaling in peripheral blood is expected as a promising strategy for cancer screening. Notably, due to the amplification effect of the immune response, the identification of tumor-related immune signals demonstrates higher abundance compared to the direct detection of tumor-derived molecules, such as circulating tumor DNA (ctDNA). This increased abundance allows for the extension of the screening time window, underscoring its potential for early cancer detection. The present study aims to identify lung cancer-associated T cell receptor (TCR) signatures, and develops a predictive model for to recognize lung cancer based on TCR repertoire sequencing. **Methods:** Peripheral blood samples were collected from 2,699 lung cancer patients and 3,360 healthy individuals. The TCR repertoires were profiled using a multiplex-PCR-based sequencing of the TCR-β chains. The frequency of TCR clonotypes were calculated using MiXCR tools by aligning against human TCR-β gene segments. The cancer-enriched TCR sequences were identified by comprehensively considering the distribution and frequency of clonotypes in the comparison between the lung cancers and the healthy controls. We proposed an lung cancer-enriched TCR score (LCS) to evaluate the risk for lung cancer based on the CDR3 sequences alignment. A robust machine learning model was developed integrating multiple TCR repertoire characteristics and LCS. **Results:** The UMAP clustering based on TCR repertoire features revealed distinct TCR characteristics in lung cancer patients compared to healthy individuals. 3,840 TCR clones were identified to be significantly enriched in lung cancer cases. Among these, the CDR3β 'CATSRDTGGREKLFF' was identified as the most highly enriched clone specific to lung cancer patients. Furthermore, a significantly higher LCS was observed in lung cancers ($p < 0.001$). To validate the utility of LCS, we applied the LCS measurement to an independent public TCR dataset with 382 lung cancer patients, 195 healthy individuals, and 1,034 COVID-19 cases. The external validation demonstrated that lung cancers show a significantly increased LCS compared with healthy controls ($p < 0.001$), while no significant difference in LCS between COVID-19 cases and healthy controls (p = 0.25). The detection performance of model using integrated TCR features and LCS demonstrated a sensitivity of 0.96 and a specificity of 0.95. **Conclusions:** Cancer-related immune signals in peripheral blood can inform the anti-tumor responses. This study identified lung cancer-enriched TCR signatures, highlighting the potential as promising biomarkers for lung cancer detection. Clinical trial information: ChiCTR2200055761. Dietary compounds and patterns associated with immune checkpoint inhibitor (ICI) outcomes in advanced non-small cell lung cancer (NSCLC). First Author: Edmond Rafie, Research Center of the Centre Hospitalier de l'Université de Montreal, Montreal, QC, Canada

Background: The gut microbiome is a modulator of ICI activity. Diet is among the most important factors influencing the gut microbiome. We previously showed that high fiber was not associated with outcome in NSCLC, in contrast to melanoma. However, the impact of dietary patterns and specific nutrients on ICI outcomes in NSCLC is unknown. **Methods:** At the CHUM Microbiome Centre, a nutritionist prospectively collected dietary history using a validated DHQ-II survey from 147 patients (pts) with advanced NSCLC treated with ICI alone or in combination with chemotherapy. Global dietary patterns and a systematic screen of 72 macro- and micronutrients (cut-offs defined by median) were examined for their association with progression-free survival (PFS) in univariable and multivariable cox-regression analyses. Associations between diet and immune-related adverse events (irAE) were examined. In 69 pts, shotgun metagenomic sequencing (WMS) was performed on fecal samples to determine differential abundance of bacteria using linear discriminant analyses, heatmaps, and MaAsLin2. **Results:** Median age was 68, 46% were male. Median follow-up was 13 months. Total caloric intake adjusted for basal metabolic rate (Mifflin-St Jeor equation using BMI and activity level) was not associated with PFS (p = 0.3). In univariable analyses, the following nutrients were associated with improved PFS: vitamin K (HR 0.62, p = 0.03), fat (HR 0.65, p = 0.04); while the following were associated with inferior PFS: starch (HR 1.61, p = 0.03), carbohydrates (HR 1.56, p = 0.04), sucrose (HR 1.62, p = 0.03), and iron (HR 1.7, p = 0.016). In a multivariable analysis examining all macro- and micronutrients and adjusting for BMI, vitamin K intake was significantly associated with improved PFS (HR 0.60, 95% CI 0.37, 0.97, p = 0.04). Fat-based diets such as keto-like diet (high fat, low starch) was associated with improved PFS in univariable (HR, 0.47, p = 0.008) and multivariable analyses (HR 0.37, 95%CI 0.2, 0.68, p = 0.001). Compared to high starch diet, western diet (high fat, high starch) was associated with increased risk of any grade irAE (24% vs 54%, respectively, p = 0.01). WMS analyses revealed biologically relevant signals; fat-based diets were associated with enrichment of favorable commensal bacteria such as *Ruminococcus lactaris*, *Butyricimonas faecihominis*, *Lachnospiraceae* spp, with low fat associated with deleterious *Veillonella atypica*. Starch-based diets were associated with high *Prevotella* spp. Sucrose-enriched diets were enriched with *Candidatus saccharibacteria*, a known sucrose-fermenting bacteria. **Conclusions:** Our results demonstrate the importance of diet on ICI outcomes in NSCLC and WMS results suggest this is mediated by the gut microbiome. Diet is a modifiable lifestyle factor which may be targeted to improve ICI activity, meriting study in a randomized trial. The role of lipid-laden Kupffer cells in immunosuppression and immunotherapy response in MASLD-related hepatocellular carcinoma. First Author: Junzhe Jacky Zhao, Duke-NUS Medical School, Singapore, Singapore

Background: Hepatocellular carcinoma (HCC) related to metabolic dysfunction-associated steatotic liver disease (MASLD) is a rising global health burden. Despite systemic immunotherapy being the first-line treatment for advanced HCC, clinical observation shows that immune checkpoint inhibitors (ICI) offer lower benefit to patients with non-viral HCC, including MASLD-HCC. Macrophages, especially Kupffer cells (KCs), are the major PD-L1+ liver cells. With previous studies showing that more KCs are associated with poorer survival, we hypothesise that KCs in MASLD-related HCC show an immunosuppressive phenotype secondary to lipid accumulation, contributing to the poorer ICI responses in patients. **Methods:** As proof-of-concept, we characterised macrophage phenotypes and lipid accumulation in matched tumour and non-tumour tissues from HBV+ and non-viral HCC patients (n = 6 / group). We next assessed the functional consequences of lipid loading using induced pluripotent stem cell (iPSC)-derived KCs in vitro, followed by validation in KC-containing iPSC- and patient-derived HCC organoids. We evaluated lipid accumulation, paracrine signalling, transcriptomic changes, and cell-cell interactions in these organoids. **Results:** In patient samples, macrophage lipid accumulation is associated with a PD-L1 high, TREM2 high, KC-like phenotype in both non-tumour and tumour (Cohen's $d > 1.0$, power $>$ 99%). In non-viral HCC samples, lipid-laden macrophages, with an M2-KC phenotype, are enriched twofold in non-tumour (Cohen's $d > 1.0$, power = 72%) and tumour (Cohen's d = 0.3, power = 6%). Light-sheet microscopy confirmed colocalization of lipids and PD-L1+ immune cells. Exposing iPSC-KCs to free fatty acids and IL-6 suppressed antigen presentation, while enhancing phagocytosis and T-cell exhaustion ($p < 0.05$) – effects not reversed by ICI alone but alleviated when combined with tocilizumab or a CD36 inhibitor. These changes are likely independent of lipophagy or FASN-mediated fatty acid synthesis. Our HCC organoid models preserve KCs and recapitulate their immunosuppressive phenotype. scRNA-seq and CellPhoneDB analysis of HCC organoids highlighted significant KC-hepatocyte crosstalk, mediated by IL-6, SPP1, and other cytokines, corroborated by Luminex assay. **Conclusions:** These findings suggest that MASLD-associated lipid loading promotes a distinctly immunosuppressive KC phenotype, contributing to diminished ICI responsiveness in HCC. Targeting the lipid-KC axis, for instance with IL-6 blockade or CD36 inhibitors, may help restore immune competence and improve ICI-based treatment outcomes. Future studies, especially with a larger patient cohort and with our organoid platform, should determine whether lipid-laden KCs can serve as a biomarker for ICI responsiveness and further delineate the pathways driving their immunosuppressive behaviour. The economics of cancer immunotherapy: A five-year Medicare B expenditure analysis of checkpoint inhibitors. First Author: Sharanya Tripathi, Saint Vincent Hospital, Worcester, MA

Background: Immune checkpoint inhibitors (ICIs) have transformed cancer treatment, prompting a comprehensive analysis of Medicare Part B spending trends from 2018 to 2022. **Methods:** We conducted a detailed examination of Medicare Part B claims data, focusing on spending per dosage unit, total expenditure, and beneficiary utilization across multiple ICI drugs. **Results:** Our analysis revealed significant variations in ICI utilization and spending, with Keytruda (Pembrolizumab) emerging as the leading drug, totaling 4.94 billion and serving 67,022 beneficiaries in 2022. Notably, Opdivo (Nivolumab) demonstrated substantial market presence with 1.85 billion in spending and 26,957 beneficiaries. Price changes varied considerably, with Pembrolizumab experiencing a 12.9% price increase, Durvalumab rising 8.0%, and Atezolizumab increasing 10.1%. Interestingly, Libtayo showed a modest 1.5% price decrease. Other significant drugs included Tecentriq (Atezolizumab) with 777.8 million in spending and 12,812 beneficiaries, and Imfinzi (Durvalumab) with 562.7 million and 10,517 beneficiaries. **Conclusions:** Medicare Part B spending on immune checkpoint inhibitors reflects complex market dynamics, characterized by significant variations in drug pricing, beneficiary utilization, and total expenditure, highlighting the evolving landscape of cancer immunotherapy. Research Sponsor: None.

Cost trajectories and utilization patterns of eight immune checkpoint inhibitors (2018-2022).

Brand Name	Generic Name	Average Spending per Dosage Unit 2022	Annual Growth Rate in Average Spending per Dosage Unit (2018-2022)	Total Spending 2022	Total Beneficiaries 2022	Average Spending per Beneficiary 2022	Average Sales Price (ASP) 2022
Bavencio	Avelumab	$85.86	2.10%	$111,862,815	1,591	$70,310	$87.91

Phase I study of hV01, a recombinant human IL-21-expressing oncolytic vaccinia virus, as monotherapy in advanced solid tumors. First Author: Jian Zhang, Fudan University Shanghai Cancer Center, Shanghai, China

Background: Oncolytic viruses have shown an excellent safety profile and can initiate antitumour immunity through in-situ tumor lysis and systemic immune response, thereby gaining significant attention in cancer immunotherapy. Here, we conducted a phase I study of hV01, a genetically engineered oncolytic vaccinia virus expressing IL-21, in patients with advanced malignant solid tumors. **Methods:** This open-label, single-dose escalation study evaluated four dosing levels (range, 1×10^7 - 8×10^8 PFU) of intratumoral (i.t) injection of hV01, with a 28-day treatment cycle (NCT05914376). The primary aims were to determine the maximally tolerated dose (MTD), dose-limiting toxicities (DLTs) and safety. Treatment response was evaluated by RECIST v1.1 criteria on day 28 using a CT scan.Peripheral blood samples were analyzed for immune cell phenotypes with FACS and viral shedding with Q-PCR after the hV01 regimen. **Results:** Thirteen patients with advanced solid tumors were enrolled; most had failed multiple prior therapies. Twelve patients completed at least one treatment cycle, with three in each dosing cohort. Six of the twelve patients (6/12, 50%) achieved stable disease (SD), while the rest had progressive disease (PD), evaluated at the end of the first treatment cycle. Among the six patients with SD, one patient with pulmonary spindle cell carcinoma in the 1×10^7 PFU cohort had progression-free survival (PFS) for 138 days, and one patient with dedifferentiated liposarcoma in the 6.0×10^8 PFU cohort had a PFS for 206 days. One patient with nasopharynx cancer in the 8.0×10^8 PFU cohort achieved a partial response (PR) after four treatment cycles. No DLTs occurred during the observation period of this study. The most commonly treatment-related adverse events (TRAE) were fever and anemia, which were reported as grade 1-2 events in eleven patients (11/13, 84.6%) and six patients (6/13, 46.2%), respectively. The only grade 3 event was decreased lymphocyte count in one patient in the 6.0×10^8 PFU cohort. FACS analysis found a decrease in T cells and natural killer (NK) cells in the peripheral blood in all patients on the day following hV01 administration, and later, the levels of T cells and NK cells gradually rebounded. Notably, four patients had significantly higher (more than doubled or tripled) levels of NK cells compared to their baseline on day 15 after the hV01 regimen. **Conclusions:** Single-dosing of hV01 per treatment cycle was well tolerated and safe. hV01 i.t. injection demonstrated primary efficacy in patients with advanced tumors. The data support further study of multiple-dosing regimens and future trials evaluating the benefits of combining hV01 with other antitumor therapies. Clinical trial information: NCT05914376. Research Sponsor: Hangzhou ConVerd Co., Ltd.

Influence of salmonella-IL2 in combination with FOLFIRINOX on overall and progression-free survival in stage IV metastatic pancreatic cancer. First Author: Daniel Saltzman, Salspera Inc, Oakdale, MN

Background: Salmonella-IL2 is an attenuated Salmonella Typhimurium strain carrying the human gene for IL-2. When orally administered, the bacterium colonizes tumors and locally releases IL-2, triggering immunologically-mediated tumor cell killing without untoward side effects. Salmonella-IL2 was tested in a phase 2 clinical trial in which patients with stage IV metastatic pancreatic cancer were treated with standard of care chemotherapy (SOC) combined with Salmonella-IL2. **Methods:** A Health Canada and local IRB approved, non-randomized, two-arm human study evaluated the combination of Salmonella-IL2 with standard of care (SOC) chemotherapy; Arm One patients received Salmonella-IL2 plus FOLFIRINOX (FFX). Arm Two patients received Salmonella-IL2 plus Gemcitabine/nab-Paclitaxel (GEM/nabP). Overall survival (OS), progression-free survival (PFS), safety, and biomarker data in each arm were compared to corresponding values for reference patients (SOC Controls) receiving care at the study site in the four years preceding the clinical trial (2016 to 2020). Four patients with stage IV pancreatic cancer were treated via Salspera's Expanded Access Program (EAP) using the Arm One regimen. **Results:** In total, 34 patients (30 in the trial, 4 via EAP) were enrolled: 26 received Salmonella-IL2 with FOLFIRINOX (average age 58.7 years, range 32-74, 54% born female) and eight received Salmonella-IL2 with GEM/NabP (average age 68 years, range 56-82, 54% born female). SOC Control patients comprised 37 administered FOLFIRINOX (average age 58 years; range 33-75 years; 46% born female) and 31 given GEM/nabP (average age 65.1 years; range 45-84 years; 42% born female). Patients receiving more than five doses of Salmonella-IL2 with FOLFIRINOX (n = 20) had a mPFS of 15 months vs. 5.8 months in control patients who had received only FOLFIRNOX ($p < 0.0001$, 95% CI, HR 0.3, Concordance Index 0.64). For those same compared cohorts, the mOS was 20.3 months vs. 11.5 months (p = 0.07, 95% CI. HR 0.59, Concordance Index 0.59). Only eight patients were enrolled in the GEM/NabP Arm thus limiting useful conclusions. Overall, 41 serious adverse events were noted and attributed to SOC chemotherapy agents but none to Salmonella-IL2. **Conclusions:** Addition of Salmonella-IL2 to FOLFIRINOX for treating stage IV pancreatic cancer is associated with increased mPFS and mOS. A multicenter, randomized, phase III trial is warranted. Clinical trial information: NCT04589234. Research Sponsor: None.

Initial safety and efficacy results from a first-in-human, phase 1/2 study of SAR445877, an anti-PD-1/IL-15 fusion protein, for patients with advanced solid tumors. First Author: Aung Naing, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: SAR445877 is a fusion protein of an PD-1 antibody combined with a detuned IL-15, designed to selectively expand and activate CD8+ T and NK cells expressing both PD-1 and IL-2/15R$\beta\gamma$. Preclinical studies demonstrated the efficacy of SAR445877 in neoplastic models. Here, we present initial safety and efficacy observations from a first-in-human, dose escalation of SAR445877 monotherapy in patients (pts) with advanced solid tumors. **Methods:** This open-label, multicenter, Phase 1/2 study in adult pts with any type of measurable, advanced unresectable or metastatic solid tumors (NCT05584670) comprised two parts: dose escalation (Part 1) and dose expansion (Part 2). In Part 1, SAR445877 was administered intravenously at two dosing schedules (Q2W and QW). Pts with advanced solid tumors that do not typically respond or were resistant/refractory to immune checkpoint inhibitors (ICI), and with at least 1 measurable lesion per RECIST 1.1, were eligible. Tumor biopsy was performed at baseline and on treatment. The primary objective for Part 1 was safety. Secondary objectives included efficacy, pharmacokinetics, pharmacodynamics, and immunogenicity. **Results:** Thirty-two pts (Q2W) and 17 pts (QW), respectively, were enrolled. Median lines of prior therapy were 3 for both schedules. The Q2W schedule was tested at 6 dose levels (DLs) and QW schedule at 3 DLs. Median exposure to SAR445877 was around 9 weeks (Q2W range: 2–55 weeks; QW range: 1–46 weeks). All pts reported at least one treatment-emergent adverse event (TEAE). Treatment-related AEs (TRAEs) were reported in 47 pts (Grade $\geq$3: 12 pts [Q2W]; Grade $\geq$3: 5 pts [QW]). Most common TRAE was cytokine release syndrome (CRS), which was mainly Grade 1 or 2. Six pts discontinued treatment due to any TEAEs. DLTs occurred in 4 pts in the Q2W cohort (n = 1 each metabolic acidosis, pneumonia, hyperbilirubinemia, and GI hemorrhage) and in 2 pts in the QW cohort (both CRS). Serious TEAEs were reported in 23 pts (Q2W) and 7 pts (QW). All toxicities were manageable/reversible, and no TEAEs leading to death were observed. Confirmed partial response was reported in 5 pts (Q2W) and in 2 pts (QW) bearing melanoma, CRC, SCC of the scalp, penile cancer, adnexal carcinoma, urothelial carcinoma, and myxofibrosarcoma, with benefits lasting $>$ 1 year. Five of the 7 pts had progressed on prior immunotherapy. Stable disease $\geq$ 6 months was observed in 3 pts (Q2W) and 3 pts (QW). Antidrug antibodies (ADAs), detected in 23 pts (Q2W) and 13 pts (QW), did not correlate with clinical benefit or toxicity. A trend of dose dependent increase of cytokine (IFNγ, TNFα, IL-6, IL-8, IL-10) and chemokine (CCL2, CXCL10, MIP1α, MIP1ß) release were detected at both dosing schedules. **Conclusions:** SAR445877 monotherapy demonstrated a tolerable safety profile and promising antitumor activity in pts with advanced solid tumors unresponsive or resistant to ICI. Clinical trial information: NCT05584670. Research Sponsor: Sanofi.

SLAMF8 as a potential therapeutic target for modulating tumor-associated macrophages in colorectal cancer. First Author: Han Xingzhi, The Comprehensive Cancer Center of Drum Tower Hospital, The Affiliated Hospital of Nanjing University Medical School, Nanjing, China

Background: Reprogramming or repolarizing tumor-associated macrophages (TAMs) has emerged as a novel strategy in tumor immunotherapy, leveraging their remarkable plasticity. Our previous studies have demonstrated that SLAMF8, predominantly expressed in macrophages, is a promising biomarker for predicting the efficacy of immune checkpoint inhibitor (ICI) therapy in colorectal cancer (CRC). This study aims to elucidate further the regulatory role of SLAMF8 in TAMs and its influence on the tumor immune microenvironment. **Methods:** In vitro, M2 macrophage and TAM models were established to investigate the regulatory role of SLAMF8 in macrophage immunophenotypic transition and its impact on CD8+ T cell function using qRT-PCR, flow cytometry, and co-culture assays. Additionally, pathway enrichment analysis of RNA-seq data and western blotting were conducted to elucidate the underlying molecular mechanisms. In vivo, SLAMF8-specific small interfering RNA (siSLAMF8) was utilized to inhibit SLAMF8 expression in subcutaneous colorectal cancer (CRC) tumor models. Subsequent observations included tumor growth monitoring and analysis of immune cell infiltration via flow cytometry. Furthermore, two subcutaneous tumor models, one sensitive and one resistant to PD-1 therapy, were constructed to explore potential synergistic effects between SLAMF8 inhibition and anti-PD-1 treatment. **Results:** In vitro studies reveal that SLAMF8 facilitates the polarization of macrophages toward the M2 phenotype, contributing to the immunosuppressive characteristics of TAMs and dysfunction of CD8+ T cells. Inhibiting SLAMF8 in vivo significantly delayed colorectal cancer (CRC) progression. Flow cytometry analysis confirmed that the infiltration of anti-tumor TAMs (CD86+ F4/80+) and cytotoxic CD8+ T cells (IFNγ+ GZMB+ CD8+ T cells) was augmented, while the infiltration of pro-tumor TAMs (CD206+ F4/80+) and exhausted CD8+ T cells (PD1+ LAG3+ CD8+ T cells) was reduced in tumors treated with SLAMF8-specific small interfering RNA (siSLAMF8). Additionally, targeting SLAMF8 enhances the efficacy of anti-PD-1 therapy. Mechanistically, Western blotting experiments confirmed that the phosphorylation levels of key molecules in the PI3K/AKT and JAK/STAT3 signaling pathways were significantly increased in SLAMF8-overexpressing macrophages. **Conclusions:** Inhibition of SLAMF8 delays tumor growth, enhances the sensitization to ICI therapy, and reverses the immunosuppressive microenvironment by modulating TAMs via the PI3K/AKT and JAK/STAT3 pathways in CRC. These findings reveal the potential of SLAMF8 as a therapeutic target for immunotherapy focused on TAMs. Research Sponsor: National Natural Science Foundation of China; 82303970.

2574 **Poster Session**

Preclinical development of GNTbm-38, a novel class I histone deacetylase inhibitor, while combined with anti-VEGFR TKI or anti-PD-1 Ab: Assessment of immune activation and immune memory in cancer immunotherapy. First Author: Jia-Shiong Chen, New Drug Research and Development Center, Great Novel Therapeutics Biotech & Medicals Corporation (GNTbm), Taipei City, Taiwan

Background: Several clinical trials explored ICI-based combinations in MSS mCRC patients, and the promising outcomes are lacking. Histone deacetylase inhibitors (HDACis) for cancer therapy may boost antitumor immune activity, reduce immunosuppressive cells, and play a crucial role in controlling tumor progression. Therefore, rational drug combinations, containing class I HDACi or other immune-modulating drugs, may provide opportunities in immunotherapy. **Methods:** The activities of GMTbm-38 were assessed in vitro, including H3 acetylation and cancer cell growth inhibition, etc. The murine colon cancer CT-26 model was used to test antitumor efficacy in wild type and transgenic humanized PD1/PD-L1 mice. GNTbm-38 was combined with an anti-VEGFR TKI or murine/human PD1 antibody to test the antitumor synergistic effect. RNA-seq, flow cytometry, and IHC were performed to illustrate the potential mechanisms. **Results:** GNTbm-38 induced histone 3 acetylation and inhibited the cell growth of varieties of human cancer cells. By using CT-26 model, GNTbm-38 showed a superior efficacy profile in WT mice compared to immune-deficient mice. The antitumor activity related to induced immune activation and immune memory was dependent on $CD8^+$ T cell activation. Treatment with GNTbm-38 showed an increased number of intratumoral $CD8^+$ CTLs, a decreased number of MDSCs, and induced normalization of tumor vessels. GNTbm-38 substantially induced the expression of IFN-γ response genes and enhanced antigen processing and presentation signatures. GNTbm-38 acts as a TME reprogramming regulator in immunotherapy. When combined with TKI, GNTbm-38 significantly improved tumor response rate and survival rate through synergistic effect by normalizing tumor vessels, increasing tumor antigen presentation, increasing activated $CD8^+$ T cell infiltration into tumors, inducing memory T cell persistence, and inhibiting mobilization of immunosuppressive cells into tumors. Treatment with GNTbm-38 plus anti-PD-1 Ab in the CT-26 model showed greatly improved tumor response rate and survival rate with a strong synergistic effect. Furthermore, in B-hPD-1/hPD-L1 mice (humanized model) subcutaneously injected with B-hPD-L1 CT-26 cells, treatment of pembrolizumab and GNTbm-38 resulted in a 46.5% inhibition on tumor growth. Therefore, our data provided a strong rationale to explore the combination of GNTbm-38 with anti-VEGF TKI with or without ICI. **Conclusions:** Collectively, our data show that GNTbm-38 exhibits markedly superior pharmacokinetics, tolerability, and efficacy in animal models. GNTm-38 has been shown to display powerful induction of immune activation and immune memory in combination therapy with TKI/ICI against colon CT-26 cold tumor. Research Sponsor: Great Novel Therapeutics Biotech & Medicals Corporation (GNTbm).

Inhaled KB707, a novel HSV-based immunotherapy, as a monotherapy in patients with advanced solid tumor malignancies affecting the lungs: Efficacy and safety results from a phase 1/2 study. First Author: Wen Wee Ma, Cleveland Clinic Taussig Cancer Institute, Cleveland, OH

Background: The development of potent anti-tumor cytokines has been hindered by the systemic toxicity of intravenous administration. KB707 is a novel gene therapy designed to deliver high doses of cytokines to the local tumor microenvironment. The agent is a replication-defective herpes simplex virus type 1 (HSV-1)-based vector engineered to deliver human interleukin (IL)-12 and IL-2 with complementary anti-tumor effects. This replication-defective vector platform enables repeated dosing without significant toxicity or clinically relevant immunogenicity while allowing for localized, sustained IL-12 and IL-2 delivery to induce both innate and adaptive anti-tumor immunity. This study evaluates whether KB707 administered by inhalation will deliver efficacious dose to the lung while minimizing systemic exposure in advanced solid tumor patients with predominantly lung disease. **Methods:** KB707-02 is a Phase 1/2, open-label, multicenter, dose escalation (3+3 design) and expansion study of inhaled KB707 (NCT06228326). Eligible patients (pts) with at least one measurable lung lesion at screening and histological confirmation of advanced solid tumor malignancy in the lungs received nebulized KB707 once weekly for up to 3 weeks followed by treatment every 3 weeks. The primary objective is to assess safety and tolerability, with a secondary objective to evaluate preliminary efficacy per RECIST 1.1. **Results:** As of 08 Jan 2025, a total of 39 pts were enrolled and received at least one dose of inhaled KB707. Monotherapy dose escalation and expansion was completed. The doses evaluated were 10^8 and 10^9 PFU and the maximum tolerated dose (MTD) was not reached. Treatment-emergent adverse events have been consistent with known adverse event profiles of IL-2 and IL-12. The majority of treatment-related adverse events have been mild to moderate in severity and transient, with no Grade 4 or 5 adverse events observed. The 11 response-evaluable NSCLC pts were of advanced age (median 71 [54-77] years old) and heavily treated (4 median lines of prior therapies; all received at least 1 line of prior immunotherapy). The ORR was 27% (3/11) and DCR was 73% (8/11) with 7 out of 11 pts remaining on study. The response rate of the target lesions in the lungs was 36%. The median duration of response was not reached; treatment duration ranged from 10.3 to 33.3 weeks. **Conclusions:** KB707 administered by inhalation was safe and well tolerated. The MTD was not reached, and the monotherapy recommended Phase 2 dose is 10^9 PFU. Single agent anti-tumor effects were observed, including in heavily treated NSCLC patients. The study has been expanded to evaluate the combination of inhaled KB707 plus pembrolizumab, with or without chemotherapy, in advanced NSCLC pts. Enrollment in these combination expansion cohorts is ongoing. Clinical trial information: NCT06228326. Research Sponsor: Krystal Biotech Inc.

A generative model for the design of novel inhibitors targeting the PD-1/PD-L1 pathway. First Author: Juan Velasco, Yale University, New Haven, CT

Background: The programmed cell death-1/programmed cell death ligand-1 (PD-1/PD-L1) signaling pathway plays a pivotal role in tumor immunosuppression. However, the design of de novo molecules with precise pharmacological and molecular properties remains a resource-intensive and financially demanding endeavor. It is hypothesized that generative models trained on molecular graph encodings can design novel inhibitors targeting the PD-1/PD-L1 pathway. Objective: This study aims to develop a generative model capable of designing novel, orally bioavailable inhibitors of the PD-1/PD-L1 pathway. **Methods:** A large language model was pre-trained on 1 million chemical structures derived from the ChEMBL database. Each structure was represented using the Simplified Molecular Input Line Entry System (SMILES) strings, which were further tokenized into discrete atomic and functional group-level tokens. The model employs an Average-Stochastic Gradient Descent Weight-Dropped Long Short-Term Memory (AWD-LSTM) architecture. Transfer learning was applied to fine-tune the pre-trained language model on the target chemical structures, enabling domain-specific adaptation for the desired application space. **Results:** The model demonstrated robust performance in generating chemically valid, unique, and novel inhibitors targeting the PD-1/PD-L1 pathway. It achieved a validity rate of 97%, a uniqueness rate of 96%, a novelty rate of 95%, and a diversity score of 76.04%. Additionally, the generated molecules exhibited favorable physicochemical properties, including a logarithm of the partition coefficient (LogP) of 4.52, atopological polar surface area (TPSA) of 113.06 Angstrom squared, an average of 9.62 rotatable bonds, 2.77 hydrogen bond donors, and 6.79 hydrogen bond acceptors. **Conclusions:** A generative model was developed to design novel, orally bioavailable inhibitors of the PD-1/PD-L1 pathway. This approach provides an efficient and automated tool for designing de novo molecules with precise molecular and pharmacological properties, potentially accelerating drug discovery in immuno-oncology. Research Sponsor: None.

2577 **Poster Session**

Completed phase 1a dose escalation study of the first oral ENPP1 inhibitor RBS2418 immunotherapy in subjects with metastatic solid tumors. First Author: Thomas Urban Marron, Division of Hematology and Medical Oncology, Tisch Cancer Institute, Icahn School of Medicine at Mount Sinai, New York, NY

Background: ENPP1 clears cGAMP and ATP in the tumor microenvironment (TME). Its expression is associated with poor prognosis in cancer and development of metastases. ENPP1 inhibition can protect cGAMP and ATP from hydrolysis and reduce adenosine levels in the TME. These immune modulators are known to activate APCs and increase T-cell infiltration, promoting anticancer immunity. RBS2418 is a potent and selective oral first-in-class inhibitor of ENPP1. In this open-label, multi-site Phase 1a/b study, safety and efficacy of RBS2418 is being evaluated as monotherapy and in combination with pembrolizumab in advanced/metastatic solid tumors. **Methods:** The phase 1a dose escalation part comprised 100, 200, 400 and 800 mg BID dose levels of RBS2418 alone or in combination with pembrolizumab (200 mg IV q3w) in patients who have failed all approved treatments including immunotherapy using a 3+3 study design. Study objectives were to evaluate safety, pharmacokinetics (PK), pharmacodynamics (PD), and clinical outcomes. Tumor and blood samples were collected to determine PK/PD and immune profiles using LC/MS, IF, IHC, TCR and RNAseq analyses. **Results:** Dose escalation is complete, andRBS2418 was safe and well tolerated at all dose levels with no DLTs (n = 24). Treatment durations range from 1 to 15 months to date, and no treatment-related grade 3 adverse effects (TRAEs) or serious AEs (SAEs) have been observed. A total of 21 grade 1 or grade 2 TRAEs were reported in 9 (37.5%) subjects; the most common TRAE was grade 1 fatigue. Median plasma concentrations of RBS2418 increased in a dose-proportional manner. Plasma and tumor concentrations of RBS2418 were maintained above the ENPP1 inhibition EC90 level in all patients and at all dose levels tested. Of 19 patients with adequate baseline tissue, pre-treatment ENPP1 and cGAS co-expression (EG+ phenotype, n = 8) in tumors correlated with RBS2418 treatment-associated immune activation and significantly improved progression-free-survival (PFS) as compared to EG- phenotype at baseline (n = 11). A switch from “cold” tumor to “hot” tumor phenotype was consistently observed in EG+ subjects. Disease control rate (DCR) was 75% (6/8) in EG+ and 9% (1/11) in EG- subjects. **Conclusions:** The Ph1a dose escalation study with oral RBS2418 alone, and with pembrolizumab has been completed. All doses were safe and well tolerated with no grade 3 TRAEs, SAEs or DLTs. RBS2418 plasma concentrations enabling full cGAMP protection was observed in all patients at all dose levels. Immune activation and clinical benefits strongly correlated with EG+ phenotype. RBS2418 achieved Phase 1a goals of safety, PK, PD, and target engagement and showed significant treatment benefits in advanced metastatic cancer patients. The results support further development of RBS2418. Phase 1b dose expansion is in progress and the first Phase 2a study has been initiated for the treatment of mCRC. Clinical trial information: NCT05270213. Research Sponsor: None.

Deep learning—powered H&E whole-slide image analysis of endothelial cells to characterize tumor vascular environment and correlate treatment outcome to immunotherapy. First Author: Seungeun Lee, Lunit Inc., Seoul, South Korea

Background: Beyond their vascular function, endothelial cells (ECs) regulate tumor growth through recently described angiocrine signaling, influencing cancer progression and treatment outcomes. Here, we applied a deep learning model, which we validated using spatial transcriptomics data, to a pan-cancer dataset to analyze the EC distribution associated with the response to immuno-oncology (IO) treatments. **Methods:** An AI-powered H&E analyzer, Lunit SCOPE IO, quantifies tumor microenvironment EC density and tumor-infiltrating lymphocytes (TILs) density in cancer epithelium and stroma. We validated AI-powered cell type prediction by evaluating cell-specific gene expression through spatial transcriptomics (10x Xenium). 7,467 pan-carcinoma samples from The Cancer Genome Atlas (TCGA) were analyzed for EC distribution and overall survival (OS). From a previously described multi-center, multi-national pan-cancer cohort (Pan-IO, Shen et al JITC 2024), 1,654 patients were analyzed for IO treatment response. **Results:** We validated our AI prediction of cell types by demonstrating consistency with known cardinal gene expressions from spatial transcriptomic results, where 77.5% of AI-predicted endothelial cells (ECs) expressed VEGFR2 (compared to 6.9% in tumor cells (TCs)), while VEGFA expression was 2.8 times higher in TCs. Consistent with previous studies, EC density was highest in RCC and HCC, while lowest in pancreatic adenocarcinoma, melanoma, and cholangiocarcinoma. While EC and TIL density were not correlated pan-cancer ($r = 0.08$), exceptions were head and neck cancer ($r = 0.45$, $p < 0.001$) and pancreatic cancer ($r = 0.44$, $p < 0.001$). In the TCGA cohort, the high EC density was associated with prolonged OS (HR 0.84, $p < 0.001$). In contrast, within the Pan-IO cohort (HR 1.26, $p < 0.001$) and its lung cancer subgroup (HR 1.26, $p < 0.001$) high EC density was associated with shorter progression-free survival (PFS) on treatment with IO monotherapy. Moreover, the predictive impact of EC density varied by TIL status. In the Pan-IO cohort, EC density predicted PFS in both TIL-high (HR 1.40, $p < 0.001$) and TIL-low cancers (HR 1.33, $p < 0.001$). Among four groups divided by median values, the EC-low and TIL-high group showed the longest PFS (median PFS of EC/TIL high/low: 2.5m, high/high: 3.2m, low/low: 3.6m, low/high: 5.6m, $p < 0.001$). **Conclusions:** EC distribution varied among cancer types, and importantly high EC content strongly correlated with poor IO monotherapy response, including NSCLC. These findings support exploring immunotherapy combination strategies that include anti-endothelial approaches, which could encompass the emerging class of PD-1/VEGFR bispecifics, for tumors with high EC content. Early evidence was observed for this for HCC (Chon et al ASCO GI 2024), with a hazard ratio of 0.62 for high EC HCC for atezolizumab/bevacizumab. Research Sponsor: None.

2580 **Poster Session**

SECN-15: A novel treatment option for patients with checkpoint inhibitor–resistant tumors by targeting Neuropilin-1 with antisense oligonucleotides. First Author: André Maaske, Secarna Pharmaceuticals, Planegg-Martinsried, Germany

Background: SECN-15 is a high-affinity antisense oligonucleotide (ASO) targeting Neuropilin-1 (NRP1), a transmembrane protein that exerts a variety of protumorigenic functions by interacting with various receptors and ligands. NRP1 contributes to an immunosuppressive microenvironment, tumor growth, metastasis, and neoangiogenesis. The recent success of bispecific antibodies targeting PD-1/PD-L1 and VEGF such as ivonescimab has highlighted the potential of combining checkpoint inhibitors with anti-angiogenic approaches. Consequently, NRP1 represents a highly attractive target for treating patients with tumors that are resistant to or insufficiently responsive to checkpoint inhibitor therapies, such as gastric (GC) and breast cancer, where high NRP1 expression correlates with poor prognosis. **Methods:** NRP1-specific locked nucleic acid (LNA)-modified ASOs were identified using our OligoCreator platform. We assessed in vivo anti-tumor efficacy after systemic administration in various mouse tumor models as monotherapy and in combination with checkpoint inhibitors. Target downregulation was analyzed in tissues and in plasma by measuring soluble NRP1. Cell composition and transcriptome changes in tumors were analyzed using flow cytometry and RNA sequencing. Exaggerated pharmacology was investigated in a 28 non-GLP tolerability study in mice. In silico analyses of patient transcriptomics data were performed to prioritize indications for the upcoming Phase I/II clinical trial. **Results:** Systemic administration of NRP1-specific ASOs resulted in robust knockdown in tumors across various cell types, including macrophages and T cells. Soluble NRP1 levels were reduced in treated animals, serving as a target engagement biomarker. Tumor growth was delayed in the monotherapy setting, with several animals showing complete responses. Combining NRP1-specific ASOs with checkpoint inhibitors enhanced efficacy in models where checkpoint inhibitors alone had limited activity. Transcriptomic analysis showed upregulation of inflammatory genes and downregulation of extracellular matrix organization genes. No adverse effects were observed from persistent NRP1 downregulation in non-tumor-bearing mice. In silico analyses revealed that NRP1 expression is negatively associated with survival and increases in advanced GC stages. GC was selected as one of the priority indications for the upcoming Phase I/II clinical trial to investigate SECN-15's safety and efficacy as monotherapy and in combination with PD-1 blocking antibodies. **Conclusions:** Targeting NRP1 with ASOs is a promising therapeutic strategy for solid cancers. Combining NRP1 ASOs with ICIs significantly enhances anti-tumor efficacy, potentially overcoming current ICI therapy limitations. IND-enabling studies are underway to advance SECN-15 into clinical development. Research Sponsor: None.

Utilizing targeted intra-tumoral hyperthermia as an immunotherapy in immunogenically 'cold' tumor models. First Author: Carman Giacomantonio, Dalhousie University, Halifax, NS, Canada

Background: Hyperthermia is an established adjunct in multimodal cancer treatments, with mechanisms including cell death, immune modulation, and vascular changes. Traditional hyperthermia applications are resource-intensive and often associated with patient morbidity, limiting their clinical accessibility. Gold nanorods (GNRs) offer a precise, minimally invasive alternative by leveraging near-infrared (NIR) light to deliver targeted hyperthermia therapy (THT). THT induces controlled tumor heating, promoting immunogenic cell death (ICD) and modulating the tumor microenvironment (TME) to enhance immune engagement. This study explores the synergistic potential of GNR-mediated THT with immunotherapies in immunogenically 'cold' tumors to achieve durable anti-tumor immunity. **Methods:** GNRs from Sona Nanotech Inc.™ were intratumorally injected and activated using NIR light to induce mild hyperthermia (42–48°C) for 5 minutes. Tumor responses were analyzed for cell death pathways and immune modulation. The immunogenic effects of THT were assessed alone and in combination with intratumoral interleukin-2 (i.t. IL-2) or systemic PD-1 immune checkpoint blockade. Immune cell infiltration, gene expression changes, and tumor growth kinetics were evaluated. **Results:** THT reduced tumor burden through cell death mechanisms, including upregulated ICD marked by calreticulin exposure within 48 hours. By 48 hours, CD45+ immune cell levels were increased, including increased levels of immunosuppressive M2 macrophages. While THT led to innate immune cell stimulations highlighted by gene expression upregulation in the STING cGAS pathway and enhanced M1 and dendritic cell levels, tumor regrowth was observed within six days post-treatment. To enhance THT's immunogenic effects, the therapy was combined with intratumoral interleukin-2 (i.t. IL-2) or systemic PD-1 immune checkpoint blockade. Sequential administration of i.t. IL-2 post-THT induced robust CD8+ T-cell infiltration and led to sustained tumor regression in both treated and distant tumors, accompanied by the emergence of memory T cells. However, IL-2-induced immunosuppressive T-reg populations were also sustained to tumor endpoint suggesting that therapy could be further enhanced. Additionally, PD-1 expression, which was upregulated in CD8+ T cells by THT, was targeted with systemic PD-1 inhibition, further augmenting immune engagement within the TME. **Conclusions:** These combinatory treatments demonstrated synergistic effects, promoting durable anti-tumor responses and immune memory. Collectively, GNR-mediated THT effectively reduces tumor burden and remodels the TME, potentiating systemic immunity and enhancing the impact of complementary immunotherapies. Research Sponsor: None.

Employing novel pan-cancer targets for immunotherapy in leukemias and solid tumors. First Author: Ashley Varkey, Hackensack University Medical Center, Hackensack, NJ

Background: Acute myeloid leukemia (AML) and many solid tumors are difficult to treat. Tumor-associated protein targets that are the focus of cancer immunotherapy research are prone to on-target, off-tumor toxicity and antigen-negative relapse due to mutation or downregulation. Targeting cancer-specific markers less susceptible to resistance is key for safer therapies. Our research explores high mannose (Man 9) oligosaccharides and phosphatidylserine (PS) as non-protein targets. Man9 glycans are absent on healthy cells but are present in cancers like AML, breast, colon, and lung. PS, exposed during malignant transformation, is found on colon, prostate, and brain tumors. **Methods:** We have engineered trispecific T cell engagers (Man9/PS/CD3) to target Man9 and/or PS-positive cancers. We tested solid tumor cell lines (pancreatic, lung, colorectal) via flow cytometry and found that the dual affinity molecule (Man 9 x PS) had high binding to many solid tumors (Table 1). We assessed their efficacy *in vivo* and specificity using glycan microarray, and immunohistochemistry to confirm tumor specificity and predict favorable safety profiles. **Results:** Flow cytometry showed that our therapeutic molecules specifically bind to AML cells and various solid tumors while sparing healthy tissues. Glycan microarrays confirmed selective binding to abnormal glycans on cancer cells. Immunohistochemistry of FFPE tissues indicated tumor specificity and enrichment on cancer stem cells. *In vitro* studies (coculture of luciferase-transduced target cells with activated CD8+ T cells in the presence of absence of the T cell engager) demonstrated strong anti-leukemia activity against AML cell lines, with IC50 values of 5–10 pM. *In vivo* studies in human CD3 transgenic mice treated with intravenous doses of VTRU200 (Man9 x PS x CD3) showed significant therapeutic responses, based on *in vivo* bioluminescence imaging. **Conclusions:** Our data supports Man9 and PS as promising non-protein targets for pan-cancer immunotherapy. The dual targeting approach with T cell engagers reduces on-target, off-tumor toxicity and antigen-negative relapse, advancing a first-in-class Man9 x PS x CD3 trispecific T cell engager. We have also designed and validated a bispecific (Man9 x PS) chimeric antigen receptor (CAR) and research is ongoing for CAR-T therapy for pancreatic cancer. With IND-enabling studies underway, we aim to advance this breakthrough immunotherapy for AML and other cancers, targeting an IND submission within 18 months. Research Sponsor: Vitruviae; Alex's Lemonade Stand Foundation; Hyundai Hope on Wheels; National Cancer Institute.

Cell type	Man9/PS positivity (%)	Sample size
Mouse AML (cell line)	75-80	2
Human AML (cell line)	54-100	9
Human adult AML (primary)	35-98	8
Human pediatric AML (primary)	31-87	7
Human pediatric ALL (primary)	80-97	3
Human MM (cell line)	88-99.9	2
Human DLBCL (cell line)	56-93	3
Human pancreatic cancer (cell line)	46-95	3
Human colorectal cancer (cell line)	66-98	2

Prevalence of the HPV, EBV, and TTV viral RNA in the plasma of patients with solid and hematologic neoplasms and the detection of a specific immune signature. First Author: Gustavo Rivero, Tampa General Hospital, Tampa, FL

Background: Epstein—Barr virus (EBV) and human papillomavirus (HPV) are considered human oncoviruses. In contrast, the torque teno virus (TTV) is not associated with any disease but its detection in circulation is associated with the status of the immune system. In this study, we examine the prevalence of active EBV, HPV and TTV viral RNA in patients treated for solid tumors or hematologic neoplasms. In addition, we compared differential expression of selected immune and inflammatory biomarkers between Virus positive (V+) and Virus negative (V-) cases using peripheral blood cell-free RNA (cfRNA). **Methods:** cfRNA was extracted from the peripheral blood of 581patients with a diagnosis of hematologic neoplasms and 558 patients with solid tumor. cfRNA was sequenced by NGS using a targeted RNA panel of 1600 genes and the viral RNA of TTV, EBV and HPV. Two thirds of the samples were used for training and one third for testing machine learning (ML) system (Bayesian/Random Forest) and exploring the presence of specific inflammatory profiles distinguishing V+ from V- patients. **Results:** RNA testing was selected to ensure that only active and proliferating viruses were detected. We detected TTV in 52/1139 (4.6%), EBV in 251/1139 (22%), and HPV in 68/1139 (6.0%). TTV with EBV codetection was observed in 11 samples (1%), and with HPV in 4 patients (0.4%). Co-detection of EBV with HPV was observed in 13 patients (1.1%). Using 90 biomarkers in ML algorithm can reliably distinguish V+ from V- with AUC of 0.725 (CI: 0.658-0.791) in the testing set. Significantly higher levels of B-cell markers are noted in V+ patients. PD-L1 mRNA was significantly ($P < 0.001$) higher in V+ patients, which suggests that these patients may be more responsive to checkpoint immune therapy. CD70 is also detected at high level in V+ patients ($P < 0.0001$). Upon comparing between the V+ groups (TTV, EBV, and HPV), there was no statistical difference between the three groups after adjusting for multiple testing. However, some difference in cytokine levels was noted between TTV-positive patients and HPV-positive patients. CD36, IFNA2 and IL17A were higher in TTV-positive cases as compared with HPV-positive cases (P-value 0.0003, 0.005 and 0.004, respectively). **Conclusions:** Globally, detectable active viruses in plasma of patients with cancer is relatively high (29%) and this detection is associated with a specific immune/inflammatory "activation" signature characterized by transcriptomic upregulation of PD-L1 and CD70 and increase in B-cells. There is no specific signature that distinguishes between the V+ subgroups [TTV vs EBV vs HPV]. However, transcriptionally, CD36, IFNA2 and IL17A upregulation distinguished TTV+ and HPV+ cases, a phenomenon that may indicate HPV ability to initiate an immunosuppressive tumor microenvironment. Research Sponsor: None.

Phase 1 trial of HCB101, a novel Fc-based anti-SIRPα-CD47 fusion protein, in subjects with advanced cancers. First Author: Lucy Yan, Hanchor Biopharma Inc., Taipei City 114, Taiwan

Background: CD47-targeting agents face challenges, including "on-target, off-tumor" toxicities affecting red blood cells, limited efficacy, and manufacturing complexities. Clinical holds and discontinued trials highlight these difficulties. These issues have constrained their therapeutic potential and broadened the need for better solutions. HCB101 is an engineered human SIRPα fused to human IgG4 crystallizable fragment (Fc) protein developed using the proprietary FBDB platform, blocks the signal of the SIRPα-CD47 pathway, enhancing macrophage-mediated phagocytosis. Preclinical studies show HCB101's potent antitumor activity across solid tumors and hematological malignancies. HCB101's safety profile in repeat-dose cynomolgus monkey toxicity studies revealed acceptable red blood cell or platelet abnormalities, supporting its potential as a best-of-the-kind SIRPα-CD47 directed immunotherapy. **Methods:** This Phase 1, open-label, dose-escalation trial evaluates HCB101's safety, tolerability, pharmacokinetics, pharmacodynamics, and preliminary antitumor activity in advanced solid tumors or non-Hodgkin lymphoma (NHL) in the US, Taiwan, and mainland China. Eligible adults have treatment-refractory cancers, an Eastern Cooperative Oncology Group (ECOG) performance status of 0 or 1, and adequate organ function. The 3+3 dose-escalation Bayesian Optimal Interval (BOIN) design assesses dose-limiting toxicities (DLTs) in the first 28-day cycle. Secondary endpoints include objective response rate (ORR), duration of response, and progression-free survival. Exploratory endpoints include CD47 receptor occupancy (RO), correlating response, and immune cell infiltration (NCT05892718). **Results:** 32 participants (median age 61 years; 74% male) enrolled across 7 escalating cohorts (0.08-5.12 mg/kg, QW). Patients had a median of 4 prior regimens. 68% had solid tumors, and 32% had NHLs. HCB101 was well tolerated, only 1 DLT reported at 2.56 mg/kg dose level (G3 platelet decrease). The most common treatment related AEs were anemia (17%), all grade 1or 2, that did not require blood transfusion or other treatments. HCB101 systemic exposure increased in a dose-dependent manner. Preliminary efficacy showed 29% stable disease (6 patients) in 21 evaluable patients, with 2 patients have SD $>$ 16 wks, and 1 patient has SD $>$ 23 wks. Doses $\geq$1.28 mg/kg achieved $\geq$90% CD47 RO in peripheral T cells. **Conclusions:** HCB101 demonstrated an acceptable safety profile and preliminary antitumor activity in heavily pretreated advanced cancer patients. These findings support its further clinical development, including expansion cohorts to evaluate efficacy in specific tumor types or in combination with other agents. Clinical trial information: NCT05892718. Research Sponsor: None.

Role of p57 in cGAS-STING-mediated innate sensing and immunotherapy response in hepatocellular carcinoma. First Author: Shirong Zhang, The First Affiliated Hospital of Xi'an Jiaotong University, Xi'an, ShaanXi, China

Background: Hyperactivation of cell cycle programs in cancer cells suppresses the antitumor immune response. The endogenous cyclin-dependent kinase inhibitor p57 is an important tumor suppressor and a potential therapeutic target for hepatocellular carcinoma (HCC). However, the role of p57 in modulating antitumor immunity to HCC remains unclear. **Methods:** We examined p57 expression in HCC patient samples prior to treatment with immune checkpoint inhibitors (ICIs) through immunohistochemistry (IHC). Multiple mice tumor models were constructed to explore the role of p57 on the recruitment of $CD8^+$ T cells in the tumor immune microenvironment. Through performing transcriptome sequencing, we analyzed the differential genes and activation pathways induced by p57 overexpression; through Real-Time Quantitative Polymerase Chain Reaction (RT-qPCR), western blot (WB) , Enzyme-Linked Immunosorbent Assay (ELISA), IHC, immunofluorescence (IF) , Flow Cytometry (FCM) and other molecular experimental methods, we verified the molecular mechanism of increasing $CD8^+$ T infiltration and elevating PD-L1 caused by p57 overexpression; Through constructing mice model and giving different treatments, we explored the anti-tumor efficacy of p57 overexpression combining with ICIs. **Results:** We found that patients with p57 expression had a higher disease control rate, correlating with the number of tumor infiltration $CD8^+$ T cells. Using mouse models, we discovered that p57 promoted $CD8^+$ T cells infiltration and that $CD8^+$ T cells were required for p57 to function as a tumor growth suppressor. Furthermore, through RNA-sequencing analysis and the multiplex assay *in vitro* and *in vivo*, we found that p57 induced chromosomal instability and subsequently stimulates cGAS-STING-type I IFN signaling, leading to upregulation of the chemokines CCL5 and CXCL10, which promoted $CD8^+$ T cell infiltration into the tumor microenvironment. Meanwhile, p57 also elevated the expression of PD-L1 on the surface of HCC cells. Moreover, combining p57 overexpression with anti-PD-1 treatment synergistically inhibited tumor growth *in vivo*. **Conclusions:** Our studies demonstrated that p57 may serve as a new biomarker for ICIs efficacy and that increasing p57 expression is a potential therapeutic strategy for improving the efficacy of immunotherapy in HCC patients. Research Sponsor: National Natural Science Foundation of China.

2586 **Poster Session**

Phase 1 study of LB1410, a bivalent TIM-3/PD-1 bispecific antibody, in patients with advanced solid tumors or lymphoma. First Author: Jiajian Liu, L&L Biopharma Co. Ltd., Shanghai, China

Background: LB1410 is a recombinant humanized anti-PD-1/TIM-3 bispecific antibody (BsAb) developed by L&L Biopharma Co., Ltd. for patients (pts) resistant to or refractory to PD-1/PD-L1 treatments, showing superior T/DC cell activity and in vivo anti-tumor efficacy compared to a combination of TIM-3 and PD-1 antibodies in preclinical studies. Here, we report the dose escalation and dose expansion results of LB1410 as monotherapy in patients with advanced solid tumors (Keyplus-001). **Methods:** Eligible patients were $\geq$18 years old with ECOG PS 0-1 and advanced solid tumors. Dose cohorts ranged from 0.001 mg/kg to 20 mg/kg IV Q2W: 0.001 mg/kg-1 mg/kg in an accelerated titration design, and 3 mg/kg - 20 mg/kg using a traditional 3+3 design. Selected dose levels were expanded in patients with advanced clear cell renal cell carcinoma (ccRCC) and cervical cancer (CC). The primary objective was safety, including dose-limiting toxicities (DLTs). Secondary/exploratory objectives included efficacy, pharmacokinetics (PK), and immunogenicity. **Results:** As of January 15, 2025, a total of 79 patients received LB1410 at doses ranging from 0.001 mg/kg to 20 mg/kg as of January 15, 2025. The median age was 59 years, and 70% of patients were male. All enrolled patients had multiple organ metastases or multiple metastases in a single organ and were heavily pretreated with anti-tumor therapies. Of the patients, 76.9% (60/79) had solid tumors that had failed standard therapies and were resistant or refractory to anti-PD-1/PD-L1 treatments. Treatment-related adverse events (TRAEs) occurred in 63.3% of patients. The most common TRAEs ($\geq$10%) included anemia (24.1%), proteinuria (12.7%), increased alanine aminotransferase (11.4%), increased aspartate aminotransferase (11.4%), hyponatremia (10.1%), increased blood lactate dehydrogenase (10.1%), and weight loss (10.2%). Grade 3 TRAEs occurred in 7 patients, including 3 with hypokalemia, 2 with hypertension, 1 with hyponatremia, 1 with proteinuria, and 1 with pulmonary embolism. No dose-limiting toxicities (DLTs) were observed. On- treatment scan was available for 66 patients. The observed overall response rate (ORR) per RECIST 1.1 was 3/66 (4.5%), with 3 confirmed partial responses (PRs) in patients with ccRCC and CC. The disease control rate (DCR) was 45.5% (30/66). In patients with ccRCC, the ORR was 16.7% (1/6), and the DCR was 66.7% (4/6). In patients with CC, the ORR and DCR were both 66.7% (2/3). Of the 27 patients with stable disease, 3 had stable disease for nearly 12 months, and 2 of them are still receiving ongoing treatment in the study. **Conclusions:** LB1410 has a manageable safety profile and demonstrates potential efficacy at tolerable doses in heavily pretreated patients, particularly those with immune-oncology (IO)-refractory or resistant ccRCC and CC. Clinical trial information: NCT05357651. Research Sponsor: L&L Biopharma Co., Ltd., Shanghai, China.

Effect of KROS 101, a small molecule GITR ligand agonist, on T effector cells, T reg cells and intratumoral CD8 T cell cytotoxicity. First Author: John S. Yu, Cedars-Sinai Medical Center, Los Angeles, CA

Background: A small molecule was identified that stabilizes the trimerization of the glucacorticoid-induced tumor necrosis factor receptor (GITR) ligand which then leads to the trimerization of GITR and magnified signaling of GITR. GITR signaling of T cells results in T effector cell expansion and T reg reduction. An antagonist to the GITR ligand was also indentified which stabilizes the GITR ligand dimer formation preventing trimerization. **Methods:** Binding of KROS 101 to the GITR ligand was assessed and the binding region of GITR ligand to KROS was determined with targeted deletion of GITR. T cell suppression studies were performed with T cell proliferation assays and T cell cytotoxicity assays with glioblastoma target cells using patient derived PBMCs. Double humanized GITR/GITRL mice bearing B16-F10-LUC2 tumors were treated with KROS 101 or controls. Tumor-infiltrating lymphocytes were analyzed by flow cytometry and tumors assessed. **Results:** KROS 101 agonist binds to GITRL with high affinity with a K_D of 340nM by Surface Plasmon resonance. T cell suppression assay showed KROS 101 had peak proliferative induction of T effector cells at 25 uM concentration to 52% increase in proliferation, and peak proliferation induction of T effector cells with 1:1 ratio of T reg cells at 50uM concentration to 80% increase in proliferation of T effectors. KROS 101 treated T cell show enhanced effetor function and selectively target glioblastoma and cancer stem cells in vitro. KROS 101 enhances tumor immune infiltration by Increasing CD3+ T Cells, CD8+ T Cells, and M1 Macrophages While Reducing Tregs and Myeloid Cells *in vivo*. KROS 101 enhances cytotoxicity by increasing IFNγ and TNFα While Reducing TIGIT and TIM3 in CD4+ and CD8+ T Cells I*n Vivo*. **Conclusions:** KROS 101 is a GITR ligand agonist that increases T cell proliferation and increased cytotoxicity and reduces the T reg population more effectively than TRX 518 which is a therapeutic GITR antibody that was in clinical trial. Research Sponsor: None.

Machine learning–driven approaches for predicting T-cell–mediated immunity and beyond. First Author: Chongming Jiang, Terasaki Institute for Biomedical Innovation, Los Angeles, CA

Background: Recognition of peptides presented by the major histocompatibility complex (MHC) through the T cell receptor (TCR-pMHC) is crucial for T cell function, influencing disease conditions such as cancer, infections, and autoimmune disorders. Despite previous attempts, predictive models of TCR-pMHC specificity remain challenging. **Methods:** Inspired by recent breakthroughs in protein structure prediction achieved by deep neural networks, we explored structural modeling using AlphaFold 3 (AF3)-based AI-enabled computation as a potential avenue for predicting TCR epitope specificity. **Results:** We show that a specialized version of the neural network predictor AlphaFold can generate models of TCR-pMHC interactions, effectively distinguishing valid peptide epitopes from invalid ones with increasing accuracy. Strongly immunogenic epitopes could be identified and selected for vaccine development through in-silico high-throughput processes. Higher-affinity and specificity T cells could also be computationally designed to achieve improved efficacy and safety profiles for T cell therapy. An accurate TCR-pMHC prediction model is expected to significantly benefit T-cell-mediated immunotherapy and facilitate advanced drug design. **Conclusions:** Overall, precise prediction of T-cell immunogenicity holds substantial therapeutic potential, enabling the identification of peptide epitopes associated with tumors, infectious agents, and autoimmune diseases. Although much work remains before these predictions could achieve widespread practical utility, deep learning-based structural modeling represents a promising path toward the generalizable predictions of TCR-pMHC interactions and beyond. Research Sponsor: None.

Phase 1 study of DK2^{10} (EGFR), a tumor-targeted IL2 x IL10 dual immunocytokine, in advanced cancer patients: Dose escalation, immune activation, and safety results. First Author: Alexander I. Spira, NEXT Oncology Virginia, Fairfax, VA

Background: IL-2 induces anti-tumor immunity and toxicity, predominantly vascular leak syndrome (VLS), leading to edema, hypotension, organ toxicity, and therapy-inhibiting regulatory T cell (Treg) accumulation. DK2^{10} (EGFR) couples wild-type IL-2 to a high affinity variant of EBV IL-10 via an scFv that binds to epidermal growth factor receptors. The IL-10 component was designed to block IL-2 mediated cytokine release syndrome (CRS) and VLS while retaining T cell activation and proliferation and limiting Treg expansion. We report the clinical and pharmacodynamic results from the dose escalation in the DEKA-1 phase 1 (NCT05704985) study. **Methods:** Eligible patients (pts) had advanced/metastatic tumors known to express EGFR, progressive disease on $\geq$1 lines of systemic treatment, and ECOG $\leq$1. DK2^{10} (EGFR) (2-16 mg; 0.025-0.5 mg/kg for an 80 kg subject) was self-administered subcutaneously 3 times per week in 21-day cycles following a BOIN design. Adverse events (AEs) including serious (SAEs) were evaluated using CTCAE version 5.0. Cytokines and anti-drug antibodies were monitored during the first cycle and every 3 cycles thereafter. RECIST 1.1 tumor responses were evaluated every 9 weeks. **Results:** 35 pts (14 RCC, 6 NSCLC, 9 CRC, 5 PDAC, 1 SCC) were enrolled. Median age was 63 yrs (range 35-80). Treatment-related AEs (TRAEs; any grade) in $\geq$ 10% pts were injection site reactions (63%), fever (40%), fatigue (31%), nausea (23%), anemia (17%), chills (17%), eosinophilia (14%), CRS (14%), diarrhea (11%); the majority were G1-2. G3 TRAEs included fatigue (n = 4), anemia (n = 3), syncope (n = 3) and single events of acute kidney injury, cellulitis, hypoalbuminemia, and lymphopenia. No DLTs were observed. While MTD was not exceeded, a dose proportional induction of IFNγ was observed through 8 mg but not at 16 mg. Therefore, higher doses were not explored, and a 12 mg dose level was introduced for dose optimization. No appreciable increase in IL-6, TNF-a, or IL-1β was seen other than 1 subject at 4 mg with G2 CRS and elevated IL-6. IFNγ and IL-5 were concomitantly induced proportional to dose level and reached saturation between levels 3 and 4, consistent with pK exposure of DK2^{10} (EGFR). Sustained IL-5 associated eosinophilia was observed and correlated with drug concentration but did not require intervention. IL-2 and IL-10 induction led to sustained elevation of IL-2Ra and IL-18, respectively. 33% of evaluable patients had a best ORR of SD. **Conclusions:** DK210 (EGFR) demonstrates strong IL-2 activity shown by IL-5 driven eosinophilia, shed IL-2Ra, T and NK cell proliferation and expansion but not Treg accumulation. These effects have been decoupled from IL-2 driven toxicity, confirming the hypothesis of the balancing effect of IL-10. These data support further evaluation in combination with T cell engagers, T cell therapeutics, and kinase inhibitors. Clinical trial information: NCT05704985. Research Sponsor: Deka Biosciences.

PCT1:CO-STIM TCR T-cells to overcome the hostile tumor microenvironment and target triple-negative breast cancer. First Author: Dora Hammerl, Pan Cancer T, Rotterdam, Netherlands

Background: Adoptive T-cell therapy has demonstrated impressive efficacy in hematoligical cancers but the solid tumor micro-environment presents a unique challenge. However, recently TCR-T cell therapy has shown benefit in difficult-to-treat solid tumors and selection of specific tumor targets and control of the tumor micro-environment can unlock the broader potential of T cell therapy. Triple-negative breast cancer (TNBC) is a difficult-to-treat tumor as it lacks classical targets for hormone and antibody-based therapies. It harbors a highly immune-suppressive microenvironment and rarely responds to immune-checkpoint inhibitors. We sought to identify a novel target to make TNBC amenable for adoptive T-cell therapy with T-cell receptor (TCR)–engineered cells and applied a unique next-generation gene-engineering approach to make T-cells overcome the hostile microenvironment. **Methods:** (i) Discovery of TNBC-restricted target: We applied *in silico* analyses of $>$500 TNBC samples and $>$1,500 healthy tissues and validated findings with qRT-PCR and immune stainings of $>$300 TNBC samples as well as 40 healthy tissues. (ii) Discovery and selection of PCT1 TCR: We enriched ROPN1-specific TCRs from naïve repertoires and assessed specificity, sensitivity and performed preclinical safety studies. (iii) Development of TCR:CO-STIM technology to overcome immune suppression: we designed a panel of murine TCRs harboring different intracellular co-stimulatory domains, thereby providing additional stimulation to T cells aimed to overcome immune suppression in solid cancer. We tested their ability to extend anti-tumor durability in a murine melanoma model, performed comprehensive permutations to enable stable expression of fully human *TCR:CO:STIM* and applied it to multiple TCR specificities. **Results:** For TNBC, we identified that Ropporin (ROPN1), a protein expressed homogeneously in $>$90% of TNBC and persistent across disease stages but absent from healthy tissues, as an ideal target. We identified 13 clonal TCRs directed against 9 different ROPN1 epitopes. The lead TCR, termed *PCT1 TCR*, demonstrated high sensitivity and specificity towards ROPN1$^+$/HLA-A2$^+$ cell lines and patient-derived organoids in 3D. Our *TCR:CO-STIM* technology significantly improved duration of response in a murine model and improved T cell fitness. Notably, when repeatedly challenged with ROPN1$^+$/HLA-A2$^+$ TNBC cells, *PCT1:CO-STIM*, but not *PCT1* TCR T-cells, could resist up-regulation of T-cell exhaustion markers and retained tumor-killing capacity for 3-10 extra rounds of stimulation. Importantly, *PCT1:CO-STIM* did show any signs of tonic signaling nor crossreactivity nor alloreactivity towards any major HLA-I allele. **Conclusions:** *TCR:CO-STIM* technology has shown enhanced activity of a selective and specific TCR targeted at ROPN1 and we are progressing *PCT1:CO-STIM* to the clinic for the treatment of TNBC. Research Sponsor: None.

First-in-human mRNA CAR therapy: Correlative biomarker analysis from the MT-302 phase 1 study targeting TROP2 in patients with advanced epithelial tumors. First Author: Charlotte Rose Lemech, Scientia Clinical Research, Randwick, Australia

Background: Outcomes for patients with epithelial cancers, including breast, lung and gastrointestinal tumors, remain poor particularly in advanced stages. MT-302, an mRNA-based chimeric antigen receptor (CAR) therapy, seeks to address this unmet need by reprogramming myeloid cells in vivo to recognize and kill TROP2-expressing tumors, recruit immune cells into tumor and induce systemic anti-tumor responses. Its CAR construct combines an anti-TROP2 scFv with truncated CD89 and becomes functionally active only upon association with FcRγ-expressing myeloid cells, ensuring precise immune engagement. Delivered as an off-the-shelf, repeatable intravenous treatment without the need for preconditioning, MT-302 overcomes the logistical and technical challenges of traditional cell and CAR therapies. MT-302 is being evaluated in a Phase 1, multicenter, open-label dose-escalation study (NCT05969041) in adults with advanced epithelial cancers expressing TROP2. Here, we present a correlative biomarker analysis from the first-in-human MT-302 study. **Methods:** Tumor biopsies and peripheral blood samples were collected pre- and post-dose. Biomarkers were evaluated utilizing advanced technologies including immunohistochemistry (IHC), Xenium and Hyperion imaging, flow cytometry, Chromium single-cell sequencing, T cell receptor sequencing and Meso Scale Discovery (MSD). These methods assessed TROP2 expression on cancer cells, TROP2 CAR expression within immune cells, systemic pharmacodynamic effects, immune cell infiltration and tumor microenvironment changes. **Results:** Results showed robust TROP2 CAR expression in circulating myeloid cells within hours of dosing. In tumor biopsies, CAR-positive myeloid cells co-localized with TROP2-expressing cancer cells. Post-dose tumor biopsies exhibited an increase in antigen presentation markers and pro-inflammatory signaling compared to baseline. MT-302 elicited systemic interferon-driven chemokine responses and reprogrammed the tumor immune microenvironment, promoting effector T cell recruitment. T cell receptor sequencing confirmed the emergence of novel T cell clones, consistent with adaptive immunity activation. Baseline IHC confirmed high TROP2 expression in enrolled patients, correlating with pharmacodynamic activity and immune reprogramming. **Conclusions:** This Phase 1 study provides the first evidence of successful delivery of mRNA-CAR therapy in humans. These biomarker findings demonstrate that MT-302 selectively engages myeloid cells and induces robust innate and adaptive anti-tumor pharmacodynamic responses, providing support for further investigation of MT-302's potential as a transformative treatment for patients with TROP2-expressing epithelial cancers. Clinical trial information: NCT05969041. Research Sponsor: None.

AI-driven biomarker prediction in oncology: Enhancing pathological image analysis with EXAONEPath. First Author: Hyung Kyung Kim, Samsung Medical Center, Seoul, South Korea

Background: Hematoxylin and eosin (H&E)-stained whole-slide images (WSIs) are fundamental in cancer diagnosis, providing critical insights into tumor morphology and the tumor microenvironment. Traditionally, biomarker assessment has relied on manual pathological evaluations, which are prone to human error and limited in scalability. Subtle biomarker expressions that evade visual detection further challenge conventional methods. **Methods:** We developed EXAONEPath, an artificial intelligence (AI) model trained on approximately 73,000 pan-cancer H&E-stained WSIs, to predict key cancer biomarkers. The model was evaluated across three major biomarker prediction tasks: Tumor Mutation Burden (TMB) Prediction in Lung Adenocarcinoma (LUAD): Using the TCGA-LUAD cohort, the model was trained (n=373), validated (n=47), and tested (n=47). Cross-institutional validation was conducted on Samsung Medical Center (SMC) (n=341) and an in-house dataset (n=254). EGFR Mutation Prediction in LUAD: The TCGA-LUAD dataset was split into training (n=382), validation (n=48), and test (n=48) sets. Additional validation was performed on the SMC LUAD cohort (n=341). Microsatellite Instability (MSI) Prediction in Colorectal Adenocarcinoma (CRC): A combined TCGA-STAD/TCGA-READ dataset was used for training (n=432), validation (n=55), and testing (n=54). The model was further validated on the SMC CRC cohort (n=974). **Results:** EXAONEPath demonstrated a strong predictive performance: TMB in LUAD: AUROC scores of 0.77 (TCGA), 0.81 (SMC), and 0.76 (in-house). EGFR Mutation in LUAD: AUROC scores of 0.78 (TCGA) and 0.84 (SMC). MSI in CRC: AUROC scores of 0.92 (TCGA) and 0.86 (SMC). **Conclusions:** EXAONEPath advances AI-driven pathological image analysis by automating biomarker prediction with high accuracy and cross-institutional robustness. Its strong performance in predicting clinically relevant biomarkers, including TMB, EGFR mutations, and MSI, highlights its potential for integration into precision oncology workflows. Future research will focus on expanding biomarker applications and enhancing cross-institutional generalizability for broader clinical impact. Research Sponsor: None.

2593 **Poster Session**

Systemic antitumor virotherapy: Pre-clinical evaluation of tumor targeting, efficacy, and safety of lead candidate (CLD-401). First Author: Duong Hoang Nguyen, Calidi Biotherapeutics, San Diego, CA

Background: Systemic antitumor virotherapies are a promising modality of cancer immunotherapy. However, challenges include quick virus clearance from the bloodstream and potential off-target toxicity. To overcome these limitations, we have developed a novel strain called RT vaccinia virus which can be enveloped by an extracellular membrane during the manufacturing process and become resistant to human-complement. Our RTNova program, using extracellular enveloped RT (envRT) vaccinia viruses, focuses on generating potent systemic virotherapies with improved survival in circulation, tumor-specific targeting and enhanced therapeutic efficacy. **Methods:** The RT virus was genetically engineered to improve tumor selectivity and increase resistance to complement-mediated inactivation. The virus's ability to kill cancer cells was tested using the NCI-60 panel. The resistance of envRT vaccinia virus against human humoral immunity and its rapid spread were assessed ex-vivo. Targeting, biodistribution, therapeutic efficacy, and safety profile of selected envRT was evaluated in multiple animal models. **Results:** Out of several genetically modified RT Vaccinia viruses, we selected the one with three knockouts (3KO): TK (Thymidine kinase), A46R (immunomodulator), and VGF (Vaccinia virus growth factor). These genetic modifications significantly improved tumor-selective amplification and safety profile while maintaining therapeutic efficacy. The 3KO RT virus demonstrated strong oncolytic activity against more than 60 different human cancer cell lines NCI-60. Additionally, the 3KO RT virus was genetically engineered with CD55-domain fused with viral envelope A33R. This chimeric protein is designed to be expressed specifically in the extracellular envelope of the viral particle to robustly protect the envRT and viral progeny from inactivation by human complement. Targeting and biodistribution studies revealed that RT virus targeted all tumors after intravenous administration followed by significant tumor-selective amplification and spreading. In multiple immunocompetent mouse models, including metastatic lung cancer, RT virus demonstrated excellent tumor killing, and expression of selected therapeutic payload. **Conclusions:** We have developed a new scalable process to manufacture extracellular enveloped antitumor virotherapies and identified the first lead candidate from RTNova Platform, designated as CLD-401. This candidate, CLD-401, demonstrates promising therapeutic efficacy and safety in preclinical models. It effectively addresses the challenge of targeting and treating metastatic lung cancer by delivering Immunotherapeutics directly to disseminated tumors. Research Sponsor: None.

The predictive value of BRCA mutation on survival of cancer patients treated with immune checkpoint inhibitors: A systematic review and meta-analysis of phase III randomized clinical trials. First Author: Mus'ab Theeb Mustafa, The Hashemite University, Faculty of Medicine, Zarqa, Jordan

Background: Immune checkpoint inhibitors (ICIs) have significantly enhanced survival for various types of cancers; however, resistance has limited the number of patients who can benefit from these regimens. Therefore, additional biomarkers are necessary to hopefully overcome resistance. Currently, the role of BRCA Mutation in ICI therapy remains poorly understood and controversial. **Methods:** We systematically searched PubMed, Web of Science, and Cochrane for phase III randomized clinical trials (RCTs) comparing ICI with placebo or standard-of-care cancer treatment stratified by BRCA mutation status as wildtype or mutant type up to 19 November 2024 regardless of cancer type or stage. The included phase III trials must report at least one of the following: Progression-free survival (PFS) or overall survival (OS); the meta-analysis was conducted using RevMan 5.4 pooling hazard ratio (HR) with 95% confidence intervals (CI) with a p-value of < 0.05 considered significant. **Results:** We conducted a meta-analysis of six phase III RCTs involving 3,328 patients: three trials investigated ovarian cancer, two investigated prostate cancer, and one investigated breast cancer. The analysis revealed that ICIs significantly improved both OS and PFS for patients with BRCA mutation, with HR of 0.61 (95% CI, 0.46 – 0.81, p = 0.0008) and 0.64 (95% CI, 0.47 – 0.89, p = 0.008), respectively. Furthermore, for patients with wildtype BRCA, the analysis revealed that using ICIs significantly improves PFS with HR of 0.81 (95% CI, 0.72 – 0.90, p = 0.0001). However, ICIs did not significantly improve overall survival, with HR of 0.94 (95% CI, 0.84 – 1.06, p = 0.33). **Conclusions:** The use of ICIs in cancer patients with BRCA mutation is associated with significant improvement in PFS and OS; however, in patients with wildtype BRCA, the use of ICIs showed only significant improvement in PFS with no significant improvement in OS. Research Sponsor: None.

2595 **Poster Session**

Monotherapy of envafolimab in patients with high tumor mutational burden advanced solid tumors: Results from a phase II clinical trial. First Author: Jian Li, Department of Gastrointestinal Oncology, Key laboratory of Carcinogenesis and Translational Research (Ministry of Education), Peking University Cancer Hospital & Institute, Beijing, China

Background: Tumor mutational burden (TMB) has emerged as a predictive biomarker of immune checkpoint blockade response in cancers. Envafolimab, a humanized single-domain anti-PD-L1 antibody subcutaneous administration (s.c.), has been approved in China for the treatment of advanced solid tumors with MSI-H. The study is to explore the potential anti-tumor activity in patients with TMB-high (TMB-H) in China. **Methods:** The study consists of two parts. Part 1 is to explore the association of single agent envafolimab activity with tissue TMB (tTMB) measured by Onco500 assay in patients with advanced solid tumors. Part 2 will further evaluate the efficacy of envafolimab in advanced solid tumor patients base on the cutoff of TMB value identified from Part 1. Envafolimab is administrated s.c. at 400 mg every 4 weeks until disease progression, adverse events, or other reasons causing treatment discontinuation. Efficacy and safety are assessed in all patients who received at least one dose of envafolimab. tTMB is assessed by a central lab using SimcereDx Onco500 assay (Jiangsu Simcere Medical Device Co., Ltd, China). The primary endpoint was objective response rate (ORR) assessed by independent review committee per RECIST v1.1 criteria. **Results:** As of Nov 15, 2024, a total of 70 patients with advanced cancers (colorectal cancer [9,12.6%], cervical cancer and soft tissue sarcoma [8 each; 11.4%], and other 18 tumor types) have received envafolimab in Part 1. 30 (42.9%) patients had received $\geq$3 systemic therapies (median 2; range 1-19). Median follow-up time was 31.2 months (range: 0.6-36.8). 49 (70%) patients had at least one treatment-related adverse events (TRAEs), and 6 (8.6%) had grade 3 or 4 TRAEs. The most common TRAEs were anemia and alanine aminotransferase increased (9 each; 12.9%). Grade 2 decreased appetite was the only TRAE resulting in treatment discontinuation. No treatment-related death reported. TMB$\geq$13 mut/Mb with Onco500 panel was selected as the threshold of TMB-H based on the clinical data and previous comparison of platforms for determining TMB value in patients. Key efficacy outcomes are presented (Table). ORR and DOR were higher in patients with tTMB $\geq$13mut/Mb (33.3% and 20.2m) than patients with tTMB $<$ 13mut/Mb (4.3% and 3.8m). **Conclusions:** tTMB could be a useful predictive biomarker for response to envafolimab in patients with pre-treated advanced solid cancer. The Part 2 of this study is ongoing (NCT04891198). Clinical trial information: NCT04891198. Research Sponsor: None.

A phase 1 study of fixed-dose regimens of serplulimab, an anti-PD-1 antibody, in patients with advanced solid tumors. First Author: Ching-Liang Ho, Division of Hematology and Oncology, Tri-Service General Hospital, Taipei, Taiwan

Background: Serplulimab is a recombinant humanized IgG4 monoclonal antibody targeting PD-1. A two-cohort phase 1 study was conducted to evaluate the safety of serplulimab monotherapy in patients with advanced solid tumors (NCT03468751). Findings from the dose-finding cohort has been previously reported at the 2022 ASCO Annual Meeting (No. e14560). Here we present results from the dose expansion cohort, in which fixed-dose regimens were evaluated. **Methods:** This multicenter phase 1 study enrolled patients with locally advanced or metastatic solid tumors who have failed or are intolerant to standard therapy or for whom no standard therapy is available. In the dose expansion cohort, patients received intravenous serplulimab at 200 mg Q2W, 300 mg Q3W, 400 mg Q4W, or 600 mg Q6W. The primary endpoints were adverse event profile and maximum tolerated dose (MTD). Secondary endpoints included pharmacokinetic (PK), immunogenicity, pharmacodynamics (PD), and efficacy. **Results:** As of data cut-off on Jan 5, 2024, 37 patients received at least one dose of serplulimab at 200 mg Q2W (n = 9), 300 mg Q3W (n = 9), 400 mg Q4W (n = 10), or 600 mg Q6W (n = 9). All patients were Asian, 70.3% male; median age was 60.0 yrs (range 33–88). Patients had head and neck cancer (n = 10, 27.0%), esophageal cancer (n = 6, 16.2%), colorectal cancer (n = 4, 10.8%) or other types of tumor. Most patients had metastatic disease (64.9%). All patients had prior systemic cancer treatment, including 4 (10.8%) with prior immunotherapy; 51.4% had $\geq$ 3 prior lines of therapy. All 37 patients were included in safety, PK, and PD analyses; 35 response-evaluable patients were included in efficacy analysis. No dose-limiting toxicity was reported, and MTD has not been determined. Treatment-related adverse events (TRAEs) were observed in 19 patients (51.4%), including 7 (18.9%) reporting grade $\geq$ 3 TRAE. TRAE incidence was similar across regimen groups. Following multiple infusions, the geometric mean $t_{1/2}$, ss was from 341.1–751.3 h, and geometric mean CL_{ss} was 0.006–0.009 L/h. Treatment-emergent anti-drug antibody (ADA) was detected in 7 (18.9%) patients. No difference in safety or PK was noted between ADA-positive and -negative patients. Profiles of PD-1 receptor occupancy in circulating $CD3^+$ T cells and interleukin-2 stimulation ratio were similar across dose groups, suggesting dose-independent functional blockade. Six patients (300 mg Q3W, 4; 400 mg Q4W, 2) achieved partial response, resulting in an ORR of 17.1%. Among the responders, 12-month duration of response rate was 66.7% (95% CI confidence interval, 19.5–90.4). Median progression-free survival was 2.3 months (95% CI, 1.9–5.1). **Conclusions:** Fixed-dose regimens of serplulimab showed favorable safety, PK, and PD characteristics and preliminary anti-tumor activity, supporting its further investigation. Clinical trial information: NCT03468751. Research Sponsor: Shanghai Henlius Biotech, Inc.

Consolidative camrelizumab following definitive concurrent chemoradiotherapy with involved-field irradiation in locally advanced esophageal squamous cell carcinoma: A single-arm phase 2 trial. First Author: Jun Wang, Department of Radiation Oncology, the Fourth Hospital of Hebei Medical University, Shijiazhuang, China

Background: Definitive concurrent chemoradiotherapy (dCCRT) is considered the standard treatment for esophageal squamous cell carcinoma (ESCC). The PACIFIC study demonstrated that consolidation durvalumab significantly improves overall survival (OS) in patients with stage III non-small cell lung cancer (NSCLC) after dCCRT. However, the efficacy of consolidation immunotherapy in ESCC still remains unclear. We conducted a clinical trial to evaluate the efficacy of camrelizumab in patients with unresectable, locally advanced ESCC following dCCRT. **Methods:** This single-arm, phase 2 study enrolled patients with locally advanced ESCC. All participants received dCCRT with involved-field irradiation (IFI). Patients were treated with camrelizumab within 1 to 42 days after completing dCCRT. Camrelizumab was administered intravenously over 30 minutes every 2 weeks for up to 12 months. The primary endpoint was progression-free survival (PFS). Secondary endpoints included disease control rate (DCR), objective response rate (ORR), duration of response (DoR), overall survival (OS), and safety. **Results:** Thirty-five patients were enrolled between April 2020 and November 2023. Data from 32 patients were analyzed. As of December 22, 2024, the median follow-up was 25.1 months (IQR 5.5–56.8). Twelve patients experienced disease progression, and seven patients died. The DCR was 59.4%. The median PFS and OS were not reached. The 1- and 2-year PFS rates were 81.3% and 60.6%, respectively. The 1- and 2-year OS rates were 96.9% and 81.0%, respectively. The most common adverse events were grade 1-2. No grade 4 or 5 adverse events were reported. Pneumonia occurred in 31.3% of patients, all of whom experienced grade 1-2. **Conclusions:** Consolidative camrelizumab following definitive concurrent chemoradiotherapy with IFI shows promising efficacy and manageable toxicity in patients with unresectable locally advanced ESCC. Clinical trial information: NCT04286958. Research Sponsor: None.

Efficacy of low-dose nivolumab in advanced cancers: A retrospective analysis from medical oncology clinic in Eastern India. First Author: Kiran Yidagur Gangadharaiah Lokesh Sr., All India Institute of Medical Sciences, Bhubaneswar, Bhubaneswar, India

Background: Immunotherapy with PD-1/PDL1 blocking monoclonal antibodies has improved survival across several malignancies at different stages of these malignancies. But in Low- & middle-income countries, only 1-3% of cancer patients can access the standard dose of Immunotherapy. In this study, we aim to assess the response to low dose (LD) of Immunotherapy (nivolumab) across a broad range of malignancies. **Methods:** The study is a retrospective descriptive study. A total of 104 patients with advanced cancers were included in the study. Patients received a lower dose of Nivolumab (20/40 mg), ones in a 2-weekly-4weekly schedule, with treatment continued until disease progression or intolerable toxicity Their demographics, clinical profile, response to therapy, and adverse events were analyzed. **Results:** Male to female ratio was 5:1. The median age of patients was 49 years (range - 15 years to 78 years) and 70% patients were ECOG-PS 1-2 30% were ECOG-PS 3-4. Overall 56 patients were diagnosed with Squamous cell carcinoma (SCC) Head&neck, 15 had Renal cell carcinoma (RCC), 14 had Malignant melanoma, 5 had lung cancer, 4 with Hepatocellular carcinoma (HCC), 2 each of Gynecological cancer, Gall bladder cancer & CUP and 1 each of stomach cancer, Urinary bladder malignancy (HGUC), & Lymphoma. The most common metastatic sites were Lungs (46%) > Bone(27%) > Liver(15%). A total of 73 patients were included for assessment (received $\geq$2 cycles of Nivolumab). The overall response rate (ORR) was 39.7% and the Disease control rate (DCR) was 54.7%. Median PFS was 4 months (range - 1month to 26months) with Median OS being 11 months (range - 3months to 30months). Grade 3-4 adverse events were seen in 21/104(20%), the most common being dermatological (8/21) followed by anemia (7/21) and endocrinal AEs (4/21). **Conclusions:** Low-dose Nivolumab showed good response rates in advanced malignancies with manageable toxicities even in poor general condition. The cost of therapy was 1/5th to 1/10th of the standard dose of Nivolumab, highlighting its potential as a cost-effective alternative in resource-limited settings. Research Sponsor: None.

Immune related liver toxicity, management, and outcomes in ICI treated patients with advanced or metastatic cancers. First Author: Zara Izadi, Bristol Myers Squibb, Princeton, NJ

Background: The impact of hepatic immune-related adverse events (HirAEs) and their management (mgmt) on clinical outcomes in patients receiving immune checkpoint inhibitors (ICI) has not been fully examined. We aimed to evaluate the association between HirAEs, their mgmt, and overall survival (OS) in ICI-treated cancer patients. **Methods:** Data were drawn from the Flatiron Health Research Database, an EHR-based database representing 280+ U.S. community oncology practices. Adults with advanced non-small cell lung cancer (aNSCLC), advanced melanoma (aMel), or metastatic renal cell carcinoma (mRCC) who initiated ICI between 1/1/16 - 12/31/20 were included and followed from ICI initiation to death, loss to follow-up, or end of the study period (12/31/2021). CTCAE Grade 2 or higher HirAEs and mgmt actions (immunosuppression using corticosteroids or other immunosuppressants, ICI-regimen holds, ICI-regimen discontinuations) and hospitalizations were curated from unstructured data. Cox regression was used to evaluate the association between HirAEs, their mgmt (both as time-varying covariates) and OS adjusting for baseline characteristics such as line of therapy and corticosteroid use. The earliest HirAE per patient was examined in OS analysis. **Results:** The study included 529 aNSCLC, 557 aMel, and 431 mRCC patients. For aNSCLC, aMel, and mRCC, respectively, 23.4%, 41.5%, and 30.9% experienced at least one HirAE, with a median time to onset of 59, 60, and 63 days. Among all HirAEs, elevated liver enzymes were the most common (72.9% in mRCC to 76.6% in aMel), followed by hepatitis (8.3% in aNSCLC to 12.6% in aMel). Immunosuppression was used to treat HirAEs in 47.6%, 57.6%, and 38.3% of aNSCLC, aMel, and mRCC patients with HirAEs. In aNSCLC, aMel, and mRCC, respectively, median survival was 12.7, 52.2, and 25.5 months and HirAEs were associated with a higher risk of all-cause mortality than no HirAEs [HR (95%CI): 1.8 (1.3-2.2); 1.4 (1.0-1.8); 1.3 (1.0-1.8)]. In mRCC, ICI-regimen holds and discontinuations were associated with a higher risk of all-cause mortality than immunosuppression alone (HR$\geq$4.0; P$\leq$0.05). In aNSCLC, HirAEs that led to hospitalization were associated with a higher risk of all-cause mortality regardless of HirAE mgmt (HR: 6.2; $P < 0.01$). In aMel HirAE mgmt was not associated with OS. **Conclusions:** ICI-related HirAEs were associated with higher mortality in aNSCLC, aMel, and mRCC. HirAE mgmt impacted OS differently across cancer types, highlighting the need for tailored, timely, and multidisciplinary mgmt strategies in the ambulatory care setting, especially for cancers with poorer prognosis. Research Sponsor: Bristol Myers Squibb.

Baseline autoimmune diseases and characteristics of solid tumor patients on immune checkpoint inhibitor (ICI) therapy enrolled in a prospective study of immune-related adverse events (irAEs): SWOG S2013 (I-CHECKIT). First Author: Krishna Soujanya Gunturu, Hartford HealthCare Cancer Institute, Hartford, CT

Background: I-CHECKIT is a prospective observational study whose primary objective is to develop and independently validate a risk prediction model for the development of Common Terminology Criteria for Adverse Events (CTCAE) Grade 3 or higher non-hematological irAEs in patients with solid tumors during the first year of treatment with ICI. **Methods:** Any patient initiating ICI per their treating oncologist and National Comprehensive Cancer Network guidelines was eligible to participate in this study. Eligibility criteria were unrestrictive and included participants with active autoimmune disease, decreased performance status, and any stage of cancer. One important exclusion criterion was planned receipt of ICI with chemo, biological or targeted therapy. Hormonal therapy and palliative radiation were allowed. The study is close to accrual in May 2024. Here we describe baseline participant characteristics. **Results:** Of a total of 2084 enrolled participants, 62 were ineligible. Community based NCORP sites enrolled the majority (n= 1,181, 56%) of participants. Participants were also enrolled from SWOG Latin American sites and Veteran Affairs (VA). 31% (n=656) had skin cancer (melanoma 90%, squamous 5% and Merkel cell 2.9%), 29% (n=604) had lung cancer and 12% (n=256) had kidney cancer. 17% (n=346) received combination ICI. The median age was 69.9 years. 64% were male, 90% (n=1866) were white, 8% (n=165) Hispanic/Latino, 5% (110) black, and 1% (16) Asian. 12% had performance status (PS) 2 or greater. 67% of the participants were overweight or obese. 9% (n=180) of the participants had active autoimmune disease such as rheumatoid arthritis, Type I diabetes, hypothyroidism, psoriasis, Crohn's, ulcerative colitis. 3% (n=54) had a history of autoimmune disease not currently requiring treatment. **Conclusions:** The I-CHECKIT observational study enrolled participants representative of a real-world population, as most of the participants were from community practices such as NCORP. Most participants had melanoma, resulting in a higher proportion of white participants. 9% of this population had baseline active autoimmune disease, a population excluded in initial clinical trials, highlighting the broader use of ICI in daily clinical practice. Clinical trial information: NCT04871542. Research Sponsor: NIH/NCI/NCORP grant UG1CA189974.

Immune related kidney toxicity, management, and outcomes in ICI treated patients with advanced or metastatic cancers. First Author: Zara Izadi, Bristol Myers Squibb, Princeton, NJ

Background: The impact of kidney immune-related adverse events (KirAEs) and their management (mgmt) on clinical outcomes in patients receiving immune checkpoint inhibitors (ICI) has not been fully examined. We aimed to evaluate the association between KirAEs, their mgmt, and progression-free survival (PFS) and overall survival (OS) in ICI-treated cancer patients. **Methods:** Data were drawn from the Flatiron Health Research Database, an EHR-based database representing 280+ U.S. oncology practices. Adults with advanced non-small cell lung cancer (aNSCLC), advanced melanoma (aMel), or metastatic renal cell carcinoma (mRCC) who initiated ICI between 1/1/16 - 12/31/20 were included and followed from ICI initiation to death, loss to follow-up, or end of the study period (12/31/21). CTCAE Grade 2 or higher KirAEs and mgmt actions (immunosuppression using corticosteroids or other immunosuppressants, ICI-regimen holds, ICI-regimen discontinuations) and hospitalizations were curated from unstructured data. Cox regression was used to evaluate the association between KirAEs, their mgmt (both as time-varying covariates) and PFS and OS adjusting for baseline characteristics such as line of therapy and corticosteroid use. The earliest KirAE per patient was examined in survival analyses. **Results:** The study included 513 aNSCLC, 463 aMel, and 451 mRCC patients. For aNSCLC, aMel, and mRCC, respectively, 21.1%, 29.6%, and 33.9% experienced at least one KirAE, with a median time to onset of 70, 84, and 128 days. Nephritis ranged from 2.1% of KirAEs in aNSCLC to 4.6% in aMel. Elevated creatinine was the most common KirAE (23.6% in mRCC to 29.1% in aNSCLC), followed by acute kidney injury (20.5% in mRCC to 28.4% in aNSCLC). Immunosuppression was used to treat KirAEs in 67.6%, 80.3%, and 67.3% of aNSCLC, aMel, and mRCC patients with KirAEs. In aNSCLC, aMel, and mRCC, respectively, median OS was 17.1, 58.6, and 33.7 months, median PFS was 7.8, 8.9, and 9.5 months, and patients with KirAEs had longer PFS than those without KirAEs [HR (95%CI): 0.65 (0.51-0.83); 0.74 (0.57-0.97); 0.67 (0.53-0.84)]. In aNSCLC, KirAEs were associated with shorter OS [1.31 (0.98-1.74); P = 0.06]. In all cancers, KirAEs that occurred during hospitalization or led to hospitalization were associated with shorter OS (HR$\geq$2.84; P $<$ 0.02). KirAE mgmt was not associated with OS or PFS. **Conclusions:** Results suggest that while KirAEs might indicate an intensified immune response, their management and impact on survival vary across cancer types and call for cancer-specific strategies for early identification and management of KirAEs in the ambulatory care setting. Research Sponsor: Bristol Myers Squibb.

Hepatotoxic adverse events with immune checkpoint inhibitors: Real world pharmacovigilance study using FAERS database. First Author: Panah Tushar Parab, Saint Vincent Hospital, Worcester, MA

Background: Immunotherapy with immune checkpoint inhibitors (ICIs) has revolutionized cancer treatment. With their increasing use, it is important to track and manage potential adverse events (AEs) . One such AE of ICI therapy is immune-mediated liver injury (ILICI). We aim to review the real-world data on ILICI using FDA Adverse Event Reporting System (FAERS) database. **Methods:** We queried FAERS using a search-by-product strategy on 22nd January 2025 and retrieved 224889 adverse events from 2013-2024. We employed 5 ICIs in the analysis (Pembrolizumab, Nivolumab, Atezolizumab, Durvalumab, and Ipilimumab). Descriptive statistics were carried out, and disproportionality analysis was done by calculating the reportable odds ratio (ROR) with 95% confidence intervals (CI). ROR was considered significant when the lower limit of the 95% CI was $>$ 1. RORs were calculated for all hepatic events in general and Autoimmune Hepatitis (AIH), Drug-induced liver injury (DILI), Vanishing bile duct syndrome (VBDS), Primary biliary cholangitis (PBC), and Venooccluisve disease (VOD). **Results:** Total AEs from all included ICIs were 224889 and Hepatobiliary AEs constitute 9.2% of all AEs across all ICIs. ROR for any hepatic event is highest with Durvalumab i.e., 17.97 (16.08,20.08) in general as compared to the rest of the ICIs. AIH was seen highest with Ipilimumab with a ROR of 48.0 (43.1, 53.5); DILI with Pembrolizumab with a ROR of 5.8 (5.3, 6.4) (Overlapping CI); VBDS and PBC with Pembrolizumab with a ROR of 7.93 (4.9, 12.8) and 7.91 (4.46,14.03) respectively. Atezolizumab showed the highest ROR of 6.15 (3.6, 10.4) for VOD. (Table) **Conclusions:** This is the largest real-world study demonstrating specific hepatotoxic AEs with ICIs. Our results show varying patterns of hepatotoxicity with ICIs. Knowing these patterns will help us make better decisions in treating patients with ICIs. Research Sponsor: None.

Baseline characteristics, hepatic AEs and outcomes.

Baseline characteristic	Pembrolizumab (n= 67603)	Nivolumab (n=79283)	Atezolizumab (n=28521)	Durvalumab (n=13303)	Ipilimumab (n= 36179)
ROR for any hepatic event (95% CI)	8.24 (7.66,8.87)	7.46 (6.95, 8.01)	7.94 (7.08, 8.89)	17.97 (16.08, 20.08)	11.47 (10.54, 12.48)
ROR for AIH	21.34 (18.9, 24.0)	27.3 (24.8, 30.1)	22.3 (18.7, 26.5)	22.3 (18.7, 26.5)	48.0 (43.1, 53.5)
ROR for DILI	5.8 (5.3, 6.4)	3.74 (3.34, 4.19)	5.3 (4.61,6.29)	5.3 (4.61, 6.29)	5.04 (4.37, 5.82)
ROR for VBDS	7.93 (4.9, 12.8)	4.37 (2.41, 7.94)	0.5 (0.03, 8.8)	1.1 (0.15, 7.86)	2.61 (0.84, 8.1)
ROR for VOD	2.22 (1.2, 3.9)	3.79 (2.5, 5.6)	6.15 (3.6, 10.4)	0.44 (0.06, 3.12)	2.08 (0.9, 4.63)
ROR for PBC	7.91 (4.46,14.03)	3.37 (1.5, 7.5)	0.78 (0.04, 12.5)	1.51 (0.21, 11.1)	2.46 (0.6, 9.8)

Hepatic AEs included in the ROR calculation with these agents are Drug-Induced Liver Injury (DILI), Autoimmune hepatitis (AIH), Vanishing bile duct syndrome (VBDS), Veno-occlusive disease (VOD), Primary biliary cholangitis (PBC).

2603 Poster Session

Impact of body mass index on immunotherapy outcomes and complications in solid tumor patients: A real-world evidence analysis. First Author: Moath Albliwi, Cleveland Clinic Foundation, Cleveland, OH

Background: Obesity alters immune function by modifying cytokine profiles and altering immune cells. Body mass index (BMI) influences cancer outcomes, including response to therapy. Several studies have shown that patients (pts) with a higher BMI respond better to immunotherapy (IT). This study assesses the impact of BMI on IT outcomes, admission risk, and major complications in pts with solid tumors. **Methods:** We utilized TriNetX, a global data platform from 104 healthcare institutions, to analyze outcomes in cancer pts on IT. Patients were categorized into two groups: BMI $<$ 25 (n = 8,460) and BMI $\geq$ 25 (n = 13,631). Propensity Score Matching balanced groups for age, sex, race, comorbidities, smoking status, and alcohol use. Pts aged 18–65 years with solid tumors who received $\geq$1 IT dose were included with a 1-year follow-up. IT regimens included PD-L1, PD-1, or CTLA-4 antibodies. Cancers analyzed: esophagus, bladder, stomach, endometrium, melanoma, lung, kidney, head and neck, and breast. Outcomes included: ICU admissions, hospital admissions, mortality, heart failure, ischemic stroke/transient ischemic attack (TIA), venous thromboembolism (VTE), myocardial infarction, polyneuropathy, pneumonitis/pneumonia, and acute kidney injury (AKI). Risks were assessed using 1-year event-free survival and survival analysis. **Results:** After 1:1 PSM, the two groups each consisted of 8,460 pts, with balanced baseline variables. Post-matching, the mean age was ~52.5 $\pm$ 9 years, 56.0% were White, and 54.7% were female. A BMI $<$ 25 was found to be a predictor of increased risk for multiple adverse outcomes. The 1-year risk-free survival was significantly lower in pts with BMI $<$ 25 compared to those with BMI $\geq$ 25 for ischemic stroke/TIA (94.6% vs. 95.9%, log-rank P $<$ 0.01), ICU admissions (83.3% vs. 89.05%, P $<$ 0.01), hospital admissions (37.5% vs. 48.1%, P $<$ 0.01), mortality (64.01% vs. 80.62%, P $<$ 0.01), heart failure (84.3% vs. 87.6%, P $<$ 0.01), and pneumonitis/pneumonia (79.1% vs. 84.9%, P $<$ 0.01). However, there was no significant difference in the incidence of VTE, myocardial infarction, polyneuropathy, or AKI (P $>$ 0.05). We performed several sensitivity analyses using different BMI cutoff groups and compared outcomes to the BMI $<$ 25 group. In these balanced comparisons, we found similar trends except for an increased incidence of polyneuropathy in BMI $\geq$ 35 compared to BMI $<$ 25 (1-year risk-free: 89.2% vs. 91.6%, P $<$ 0.01) and in BMI $\geq$ 40 compared to BMI $<$ 25 (1-year risk-free: 89.0% vs. 91.4%, P $<$ 0.01). **Conclusions:** Our study provides real-world evidence on the types of complications experienced by pts with BMI $<$ 25 when treated with IT for different types of solid tumors. It also explains, at least partly, the improved outcomes and tolerability observed in pts with higher BMI receiving IT. Based on our findings—such as the increased risk of hospital admissions and pneumonitis—we postulate that pts with low BMI may have a stronger inflammatory reaction to IT, leading to a higher incidence of complications. Research Sponsor: None.

Final analysis of a multicenter, open-label, phase 2 study evaluating the efficacy and safety of tislelizumab (TIS) in combination with fruquintinib (F) in patients (pts) with selected solid tumors. First Author: Keun-Wook Lee, Division of Hematology and Medical Oncology, Department of Internal Medicine, Seoul National University Bundang Hospital, Seoul National University College of Medicine, Seongnam, South Korea

Background: Immunotherapy in combination with antiangiogenic agents has shown promising antitumor activity compared with either agent alone. We report efficacy and safety data from the final analysis of the phase 2 BGB-A317-Fruquintinib-201 trial evaluating the programmed cell death-1 antibody TIS combined with the selective vascular endothelial growth factor receptor (VEGFR)-1, -2, and -3 inhibitor F in pts with advanced solid tumors. **Methods:** This was an open-label, multicenter, two-part study with a safety run-in followed by dose-expansion. Eligible pts were adults with advanced or metastatic unresectable gastric cancer (GC), microsatellite stable colorectal cancer (MSS CRC), or locally advanced surgery-/radiotherapy-ineligible and programmed death ligand-1–positive (PD-L1+; defined as PD-L1 ≥1%) stage IIIB/IV non-small cell lung cancer (NSCLC). F 5 mg daily (3 weeks on, 1 week off) plus TIS (300 mg IV Q4W) was administered as second-line therapy for pts with GC, third-line therapy for pts with MSS CRC, and first-line therapy for pts with PD-L1+ NSCLC. The primary outcome measure was overall response rate (ORR) per RECIST v1.1. Secondary endpoints included other efficacy measures and safety. **Results:** The median study follow-up was 11.6 months (mo; range, 0.4-32.8). A total of 84 pts were enrolled (GC, n=31; MSS CRC, n=31; PD-L1+ NSCLC, n=22). One study treatment component-related death was reported in the GC cohort and 1 in the PD-L1+ NSCLC cohort. The recommended phase 2 dose was established at F 5 mg daily (3 weeks on, 1 week off) in combination with TIS with no observed dose-limiting toxicities. Efficacy and safety are reported in the Table. Any-grade treatment-emergent adverse events (TEAEs) occurred in 83 (98.8%) pts; proteinuria (32.1%), hypoalbuminemia (27.4%), and hypothyroidism (25.0%) were most common. 9/32 (10.7%) pts had grade ≥3 immune-mediated AEs. **Conclusions:** Despite the limited sample size, TIS+F demonstrated moderate antitumor activity in pts with advanced solid tumors, with manageable safety observed in pts with GC and MSS CRC. Further investigation of TIS+F is warranted in the GC and MSS CRC settings. Clinical trial information: NCT04716634. Research Sponsor: BeOne Ltd.

Effects of UCHL1 on tolerogenic DC maturation and promotion of mregDC-Treg crosstalk to nullify anti–PD-L1 therapy. First Author: Yu-Fei Zhao, Zhongshan Hospital Fudan University, Shanghai, Shanghai, China

Background: Immune-checkpoint blockade (ICB) therapies have revolutionized cancer treatment, but such immunotherapy regimens fail in a subset of patients. Dendritic cells (DCs) are a heterogeneous group of professional antigen-presenting innate immune cells that activate adaptive immunity and determine the efficacy of immunotherapies. While they can also be hijacked by tumour-mediated factors to contribute to immune tolerance and tumor progression. However, little is known about the molecular mechanisms that drive the tolerogenic maturation of DCs in the tumor microenvironment (TME). **Methods:** We enrolled 85 patients with advanced hepatocellular carcinoma (HCC) exhibiting varying response to immunotherapy, and profiled the tumor ecosystems using a single-cell transcriptomes sequencing (scRNA-seq) and mass cytometry by time of flight (CyTOF) for 10 patients, and plasma protein level quantification, conducted both pre-treatment and post-treatment across all patients. We integrated our in-house data and 6 additional published scRNA-seq cohorts of 83 donors to generate a comprehensive landscape of cellular dynamics underlying different responses to immunotherapy. We verified the prognostic value in our in-house tumor microarray (TMA) of 342 patients. **Results:** UCHL1 overexpression nullifies anti-PD-L1 therapy by driving conventional DC transformation into mature DC enriched in immunoregulatory molecule (mregDC) via tolerogenic maturation and promoting mregDC and regulatory T (Treg) cell crosstalk, thereby restrains $CD8^+$ T anti-tumor immunity. Mechanistically, UCHL1 enhances glycolysis and lactate accumulation in TME by stabilizing HIF-1α, which further promotes SREBP2 activation and nuclear translocation in DC. We verified the positive correlations of UCHL1 with HIF-1α/VEGFα/LAMP3/FOXP3 in 342 patients with HCC. Genetic ablation or pharmacological inhibition of UCHL1 all reduce the mregDC and Treg accumulation, restore the immuno-surveillance of tumour-infiltrating lymphocytes, and safeguard anti-tumour immunity and efficacy of anti-PD-L1 therapy in mouse models. **Conclusions:** UCHL1 hijacks tolerogenic DC maturation and promotes mregDC-Treg crosstalk to nullify anti-PD-L1 therapy. Genetic ablation or pharmacological inhibition of UCHL1 unleash the immuno-surveillance of tumour-infiltrating lymphocytes, and safeguard the anti-tumor immunity. Plasma level of UCHL1 predicts the efficacy of anti-PD-L1 therapy in patients with HCC. Clinical trial information: NCT04649489. Research Sponsor: None.

2606 Poster Session

A phase 1b/2, open-label study of selective Axl, Mer and CSF1R inhibitor adrixetinib (Q702) in combination with intravenous pembrolizumab in patients with selected advanced solid tumors: Results of a phase 1 study (QRNT-008). First Author: Hong Jae Chon, CHA Bundang Medical Center, CHA University, Gyeonggi-Do, Korea, Republic of

Background: Adrixetinib (Q702) is an orally administrated novel Axl/Mer/CSF1R tyrosine kinase inhibitor for which the primary mechanism of action of tumor regression is through immune-stimulating effects. The safety profile, pharmacokinetics (PK) and efficacy data for Q702 in combination with pembrolizumab are presented. **Methods:** QRNT-008 (NCT05438420) is an ongoing Phase 1b/2 multicenter, open-label, dose escalation and expansion study in patients with advanced esophageal, gastric/GEJ, hepatocellular, and cervical cancers who have progressed on prior anti-PD-1/PD-L1 treatment. The Part 1 dose escalation was guided by a mTPI design to determine the Part 2 dose of Q702 in combination with pembrolizumab. Patients received Q702 (week on/off dosing regimen) orally at 100 mg or 120 mg doses in combination with pembrolizumab (200 mg Q3W) intravenously in 42-day cycles. **Results:** As of the data cutoff (December 19th, 2024), 29 patients received Q702 plus pembrolizumab across 2 dose levels: 7 patients at 100 mg and 22 patients at 120 mg. The median number of prior lines of systemic therapy was 4 (range 1-7). Of the 29 patients (3 esophageal; 11 gastric; 2 GEJ; 9 hepatocellular; 4 cervical) who received Q702 across all doses, there were no treatment discontinuations due to the treatment-related AEs (TRAEs). Most common TRAEs ≥10% were AST increase (51.7%), ALT increase (41.3%), CPK increase (37.8%) and LDH increase (34.5%). One patient dosed at 120 mg experienced 1 DLT (G3 skin rash and G3 diarrhea). Adrixetinib PK analyses showed dose dependent increase of $AUC_{0\text{-last}}$ and C_{max}. Overall response assessment (RECIST 1.1) included 1 confirmed complete response (CR) in a patient with metastatic gastric cancer (GC) and 6 patients with stable disease (SD) across multiple tumor types. Among 6 SD patients, 1 GC and 1 hepatocellular cancer (HCC) patient continued treatment for ≥24 weeks. **Conclusions:** Preliminary data from QRNT-008 study showed that selective Axl/Mer/CSF1R inhibitor Q702 plus pembrolizumab has a manageable safety profile. The Part 2 dose of Adrixetinib is confirmed at 120 mg. Preliminary anti-tumor activity in patients previously treated with anti-PD-1 supports further development of the combination. Clinical trial information: NCT05438420. Research Sponsor: Qurient Co., Ltd.

Outcomes of conversion surgery after immune checkpoint inhibitor-based combination therapy in initially unresectable hepatocellular carcinoma: A retrospective cohort study. First Author: Mingjian Piao, Department of Liver Surgery, State Key Laboratory of Complex Severe and Rare Diseases, Peking Union Medical College Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China

Background: Hepatocellular carcinoma (HCC) has a high incidence rate and is often asymptomatic in its early stages. Combination therapies using immune checkpoint inhibitors (ICIs) have demonstrated survival benefits and high objective response rates, offering hope for conversion surgery in patients with initially unresectable HCC. We aimed to investigate the oncological outcomes of conversion surgery compared to those with continuing systemic treatment alone in patients who responded well to ICIs-based therapy, as well as the surgical outcomes associated with conversion surgery. **Methods:** We consecutively enrolled patients diagnosed with HCC between January 1, 2019 and April 1, 2024. These patients received treatment with ICIs combined with either anti-VEGF antibodies or tyrosine kinase inhibitors. Tumor response and resectability were assessed every 2 months. Patients who responded positively and met the criteria for conversion surgery were included. **Results:** Among 613 patients with initially unresectable HCC, 136 achieved conversion and met the surgical resection criteria during combination therapy. The median follow-up time was 26.9 and 42.5 months for the surgery and non-surgery groups, respectively. The median PFS was 29.1 months in the surgery group versus 11.2 months in the non-surgery group ($P < 0.0001$, hazard ratio [HR] = 0.40 [0.25–0.63]). The median OS was 50.8 months in the surgery group, compared to 25.8 months in the non-surgery group ($P < 0.0001$, HR = 0.27 [0.15–0.47]). The median RFS was 18.7 months in the surgery group. Multivariate Cox regression analysis indicated that conversion surgery was independently associated with improved OS and PFS ($P < 0.001$), and continuing the original treatment post-surgery significantly influenced OS and RFS. **Conclusions:** Conversion surgery after meeting the surgical criteria during immunotherapy provides significant prognostic benefits for patients with initially unresectable HCC, demonstrating high safety and R0 resection rates. For those specifically selected based on their response to immunotherapy and undergoing conversion surgery, promptly resuming the original treatment after surgery is necessary. Our results emphasize the importance of continuing immunotherapy post-conversion surgery to prevent recurrence in patients who respond to immunotherapy. Research Sponsor: None.

Phase I/II study of the EP4 antagonist vorbipiprant combined with anti-PD-1 immunotherapy: Safety and efficacy results in metastatic gastrointestinal non-colorectal cancers. First Author: Filippo Pietrantonio, Department of Medical Oncology, Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy

Background: Novel combination strategies are being explored to enhance the effectiveness of immune checkpoint inhibitors (ICIs). Prostaglandin E2, through its receptor 4 (EP4), is a major contributor to immunosuppression in the tumor microenvironment. In a dose-response phase I/II study, the EP4 antagonist vorbipiprant (CR6086) combined with PD-1 blockade was well tolerated and showed promising efficacy in refractory mismatch-repair-proficient/microsatellite stable metastatic colorectal cancer (CRC) (Pietrantonio et al, Clin Cancer Res 2024). Here we report the results from a study extension in non-colorectal gastrointestinal (GI) cancers with the vorbipiprant dose selected for further development in combination with immunotherapy. **Methods:** Twenty-seven adult patients (pts) with metastatic non-colorectal GI cancers, ECOG PS $\leq$1, and $\geq$1 prior treatment line were included in 3 cohorts (9 pts each): gastric cancer (GC) with PD-L1 Combined Positive Score (CPS) $\geq$5 (cohort A), GC with PD-L1 CPS $<$ 5 (cohort B), and GI cancers other than CRC and GC (cohort C). Pts receive oral vorbipiprant (90 mg twice daily) plus iv balstilimab (3 mg/kg every 2 weeks) until disease progression, unacceptable toxicity or death. Primary endpoints are safety and disease control rate (DCR) per RECIST 1.1. Secondary endpoints include objective response rate, progression-free and overall survival (ORR, PFS, OS). Exploratory endpoints include tissue and blood biomarkers. **Results:** At a cutoff date of November 20, 2024, enrolment is completed. In cohort C, we enrolled: 5 BTC, 2 pancreatic and 2 ampullary cancer patients. Overall, median age was 61 (interquartile range: 55-68) years, similar among cohorts; 70% were men, with a slightly higher prevalence in Cohort A; the median number of prior treatment lines was 3 (IQR: 2-4) overall and in gastric cohorts, and 2 (IQR: 2-3) in other GI cancers cohort. Prior ICIs were administered in 44%, 22% and 11% in Cohort A, B and C, respectively. No treatment-related serious or grade $>$ 3 adverse events were reported. Promising activity was observed. In cohort A, 3 pts had a partial response (PR), 2 of them still ongoing and 2 lasting more than 6 months; in addition, 1 pt had stable disease (SD). In cohort B, 4 pts had SD, 1 of them still ongoing and 2 lasting more than 6 months. In cohort C, 1 pt with pancreatic cancer had a PR, still ongoing for $>$ 6 months; in addition, 1 BTC patient had SD. Median PFS and OS were: 4,5 and 9,7 months in Cohort A, 1,8 and 6,8 months in Cohort B, 2,0 and 4,5 months in Cohort C. Responses occurred irrespective of MSI/MMR status and prior exposure to ICIs. **Conclusions:** Vorbipiprant combined with PD-1 blockade was well tolerated and showed signs of activity in non-colorectal GI cancers, thus confirming a broader spectrum of activity on top of the results in MSS CRC. Clinical trial information: NCT05205330. Research Sponsor: Rottapharm Biotech.

Bispecific innate cell engager (ICE) AFM24 in combination with atezolizumab in patients with advanced/metastatic *EGFR*-expressing non-small cell lung cancer (NSCLC) without driver mutations: Initial results from a phase 2a study. First Author: Hye Ryun Kim, Division of Medical Oncology, Yonsei Cancer Center, Yonsei University College of Medicine, Seoul, South Korea

Background: Novel treatments are needed for patients with advanced/metastatic NSCLC without actionable driver mutations who progress after prior therapies including checkpoint inhibitors (CPI) and platinum-based chemotherapy. AFM24 is a tetravalent, bispecific ICE that binds CD16A on NK cells and macrophages and EGFR on solid tumors, redirecting and enhancing the innate and possibly the adaptive immune response. The *EGFR*-wildtype (*EGFR*-WT) NSCLC expansion cohort of the Phase 1/2a study (NCT05109442) is evaluating the combination of AFM24 and atezolizumab. **Methods:** AFM24 is given weekly at 480 mg intravenously (IV) in combination with 840 mg atezolizumab IV fortnightly to patients with advanced or metastatic *EGFR*-WT NSCLC who progressed on $\geq$1 prior line of therapy, including at least a platinum doublet and a CPI. The primary endpoint is overall response rate (ORR) by RECIST v1.1 by Investigator assessment. Secondary endpoints include safety, pharmacokinetics, and immunogenicity. Treatment is given in 28-day cycles until disease progression, intolerable toxicity, investigator discretion, or patient withdrawal of consent. **Results:** As of 15 January 2025, 43 patients received AFM24 and atezolizumab for a mean (range) duration of 19.6 (1–78) weeks. Median (range) age is 67 (40–79) years; 72% male; all patients had an ECOG performance status of 0 (14%) or 1 (86%). Median (range) number of prior lines is 2 (1–7). All patients had discontinued their previous CPI treatment due to progressive disease. The combination was well tolerated with no unexpected toxicities; infusion-related reactions, the most common adverse events (AE), were reported in 54% of patients (28 Grade 1–2, 4 Grade 3). Most common $\geq$G3 treatment-related AEs were ALT/AST elevations in 2 patients, all fully resolved. The 35 response-evaluable patients showed an ORR of 23% (8 responses: 1 complete response, 7 partial responses), tumor shrinkage in 46% (16/35) and a disease control rate (DCR) of 77%. Of the 8 responders, 6 had never achieved an objective response on prior CPIs. Preliminary median progression-free survival (PFS) is 5.5 months (95% CI 2.9–7.4), with 29% of patients still on treatment. **Conclusions:** AFM24 in combination with atezolizumab shows promising clinical efficacy in patients who failed prior treatment including platinum-based chemotherapy and CPI. Patients showed a tolerable and well-managed safety profile. A considerable DCR of 77%, with some long, sustained responses was observed. Confirmed responses were achieved in patients who had not responded to prior CPI. This combination treatment approach could offer a promising chemotherapy-free alternative to patients who have exhausted the available therapeutic options and could provide a strategy to overcome resistance to prior CPI. Clinical trial information: NCT05109442. Research Sponsor: Affimed GmbH.

2610 **Poster Session**

Combination of bispecific innate cell engager (ICE) AFM24 with atezolizumab in patients with advanced/metastatic non-small cell lung cancer (NSCLC) with *EGFR* kinase domain mutations (*EGFR*mut): Initial results from a phase 2a study. First Author: Omar Saavedra, Vall d'Hebron Institute of Oncology (VHIO), Barcelona, Spain

Background: Immune checkpoint inhibitor (ICI) monotherapy has shown limited activity against advanced *EGFR*mut NSCLC. However, combinatorial approaches may enhance the clinical outcomes and are under evaluation. AFM24 is a tetravalent, bispecific ICE that binds CD16A on NK cells and macrophages and EGFR on solid tumors, redirecting and enhancing immune responses towards EGFR-expressing tumors. Atezolizumab, an anti-PD-L1 antibody, has been approved in patients with various solid tumors. The *EGFR*mut NSCLC expansion cohort of this Phase 1/2a study explores a possible synergistic effect of AFM24 in combination with atezolizumab in heavily pretreated patients with NSCLC *EGFR*mut (NCT05109442). **Methods:** AFM24 is given weekly at 480 mg intravenously (IV) in combination with 840 mg atezolizumab IV fortnightly to patients with advanced or metastatic *EGFR*mut NSCLC who progressed on $\geq$1 prior line of therapy, including $\geq$1 prior TKI. The primary endpoint is overall response rate (ORR) by RECIST v1.1 by Investigator assessment. Secondary endpoints include safety, pharmacokinetics, and immunogenicity. Treatment is given in 28-day cycles until disease progression, intolerable toxicity, investigator discretion, or patient withdrawal of consent. **Results:** As of 15 January 2025, 28 patients received AFM24 and atezolizumab for a mean (range) duration of 21.7 (2–65) weeks. Median (range) age is 65 years (32–83); 67.9% were female. All patients had received prior *EGFR*-specific TKI, 82% had received platinum-based chemotherapy and 75% 3rd gen TKIs. Patients received a median (range) of 3 (1–8) prior lines of treatment. The combination was well tolerated with no new or unexpected toxicities observed compared to each single agent. The most common treatment-related adverse events (TRAE) were infusion-related reactions in 64% of patients (19 Grade 1–2, 1 Grade 3). 9 patients had $\geq$G3 TRAEs, the most common being neutropenia/neutrophil count decrease, with no associated infections. No other immune TRAEs were reported. The 22 response-evaluable patients achieved an ORR of 23% (1 CR, 3 PRs, 1 unconfirmed PR), a DCR of 64% and tumor shrinkage in 50% of patients. Responses were deepening over time in 3 patients. With a median follow-up of 9 months, the median PFS was 5.5 months (95% CI 1.9–not-evaluable). 6 (27%) patients have received treatment for over 10 months. **Conclusions:** AFM24 combined with atezolizumab demonstrated encouraging clinical efficacy in patients with *EGFR*mut NSCLC who had exhausted prior lines of therapy. Treatment showed a well-managed safety profile. This approach potentially offers a feasible, chemotherapy-free therapeutic option for the *EGFR*mut NSCLC patients who have progressed to prior TKIs and platinum-based chemotherapy and warrants further evaluation. Clinical trial information: NCT05109442. Research Sponsor: None.
